Conclusion: This exploratory 12 week study showed that treatment of patients with inflammatory hand OA with GSK3196165 was well tolerated and while not statistically significant, resulted in reductions in pain accompanied by improvement in functional impairment. These results support findings from preclinical OA models and suggest that GM-CSF may play a role in the pain associated with inflammatory hand OA in man.

Assessment of Health-Related Quality of Life in a 52-Week, Phase 2, Randomized, Controlled Trial of a Novel, Intra-Articular, Wnt Pathway Inhibitor (SM04690) for Treatment of Knee Osteoarthritis

Vibeke Strand¹, Heli Ghandehari², Christopher Swearingen² and Jeyanesh Tambiah², ¹Stanford University School of Medicine, Palo Alto, CA, ²Samumed, LLC, San Diego, CA

Session Information

Session Date: Monday, October 22, 2018

Session Title: Osteoarthritis – Clinical Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: SM04690, a small molecule, intra-articular (IA) Wnt pathway inhibitor, is in development for knee OA treatment. A phase 2, 52-week, trial evaluated changes in Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) Pain & Function and medial joint space width (mJSW) by x-ray. Health-related quality of life (HRQoL) was measured by Short Form Survey SF-36. The objective of this study was to assess the effect of SM04690 treatment on HRQoL.

Methods: Subjects with ACR-defined knee OA, Kellgren-Lawrence grades 2-3, received 2 mL IA SM04690 (0.03, 0.07, 0.23 mg) or placebo (PBO) in the target (most painful) knee. SF-36 was assessed (Weeks 0, 4, 13, 26, 39, 52). Baseline-adjusted analysis of covariance (with multiple imputation for missing data) was conducted in the intent-to-treat (ITT) population, with improvements \geq minimum clinically important differences (MCID) noted. Two subgroups were explored: 1) unilateral symptomatic knee OA (pre-specified: UNI) and 2) unilateral symptomatic knee OA without widespread pain or comorbid symptoms (Widespread Pain Index ≤ 4 and Symptom Severity ≤ 2 , post-hoc: UNI-WP).

Results: 455 subjects (mean age 60.3 [± 8.7] years, BMI 29.9 [± 4.6] kg/m², female 58.9%, KL 3 [64.4%], with UNIOA [36.0%]) were enrolled (n=402 [88.4%] completers).

In ITT, improvements from baseline were reported in 0.03 mg (n=112), 0.07 mg (n=117), 0.23 mg (n=110) and PBO (n=116) groups, with scores \geq MCID in Physical Component Summary (PCS), Physical Functioning (PF), Role-Physical

Figure. Spidergrams of baseline (dash line) and Week 52 (solid line) in each SF-36 domain score over age- and gender-matched normative scores (yellow) within the Unilateral Symptomatic without Widespread Pain subgroup analysis.

* Baseline-adjusted ANCOVA reported analysis compared to PBO with $P < 0.05$

PF: Physical Functioning; RP: Role-Physical; BP: Bodily Pain; GH: General Health; VT: Vitality; SF: Social Functioning; RE: Role-Emotional; MH: Mental Health

(RP), and Bodily Pain (BP) domains at Weeks 13 to 52. Improvements vs PBO reported in 0.07 mg at Week 13 were significant in Mental Component Summary (MCS [P=0.024]) and Role-Emotional (RE [P=0.036]) domains.

In UNI subgroup, at Week 52, all groups reported improvements \geq MCID as in the ITT across all domains with 0.07 mg (n=35) significant vs PBO (n=39) in MCS (P=0.015), General Health (GH [P=0.028]), RE (P=0.009), and Mental Health (MH [P=0.011]) domains.

In UNI-WP subgroup at Week 52, all groups reported changes \geq MCID in PCS, PF, RP, and BP domains, and across all domains with 0.07 mg. Improvements vs PBO (n=32) with 0.03 mg (n=34) were significant in PF (P=0.025), and with 0.07mg (n=29) in MCS (P=0.002) and all domains excluding BP (PF [P=0.025], RP[P=0.027], GH [P=0.035], Vitality (VT [P=0.014]), Social Functioning (SF[P=0.028]), RE [P=0.003], MH [P=0.003]), which met or exceeded normative scores across all domains, except PF (**Figure**).

Conclusion: In this phase 2 trial, subjects receiving 0.07 mg SM04690 reported statistically significant and clinically meaningful HRQoL improvements in the ITT and subgroup analyses compared with BO. In the UNI and UNI-WP subgroups at Week 52, HRQoL improvements mirrored changes observed from analyses in WOMAC Pain and Function and mJSW (Yazici et al., *Arthritis Rheumatol* 2017) and support further investigation of SM04690 for treatment of knee OA.

Abstract Number: 1367

Efficacy of Intra-Articular Cntx-4975 for Knee OA Pain Varies with Radiographic Presence of OA in the Opposite Knee

Randall Stevens¹, James Campbell¹, Kimberly Guedes¹, Robin Burges¹, Valerie Smith² and Peter Hanson¹, ¹Centrexion Therapeutics, Boston, MA, ²Premier Research, Durham, NC

Session Information

Session Date: Monday, October 22, 2018

Session Title: Osteoarthritis – Clinical Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Nearly 60% of patients with knee OA have unilateral OA; most of those patients develop bilateral OA. CNTX-4975 is highly purified, synthetic *trans*-capsaicin that targets transient receptor potential vanilloid 1, producing analgesia via reversible desensitization of primary afferent pain fiber terminals. CNTX-4975 1.0 mg was well tolerated and effective in the phase 2b TRIUMPH study; this post hoc analysis evaluated efficacy and safety in subjects with unilateral knee pain with and without radiographic evidence of OA in the opposite knee.

Methods: Subjects aged 45–80 y with chronic knee OA and stable moderate to severe knee OA pain in 1 knee (index knee; nonindex knee, no to mild pain) who failed oral/IA therapies were randomized 2:1:2 to a single IA injection of placebo, CNTX-4975 0.5 mg, or CNTX-4975 1.0 mg. ACR criteria were met by 89% for knee OA as assessed by knee pain, radiographic findings (Kellgren-Lawrence [K-L] grade 2–4), and age >50 y; 11% had K-L grade 2–4 and were age \leq 50 years. Randomization was stratified by K-L grade (2–3 vs 4) and BMI (<30 vs \geq 30 kg/m²). Unilateral OA: K-L grade 0, 1, or missing (see **Table**) in the nonindex (untreated) knee; bilateral OA: grades 2–4 in both knees. Least squares mean differences (P values) for CNTX-4975 groups vs placebo were calculated using a mixed model for repeated measures. WOMAC question A1 (QA1; pain with walking on a flat surface), B (stiffness), and C (physical function) scores were assessed weekly through weeks 12 and 24. Statistical tests were 2-sided (alpha, 0.10). Safety assessments included treatment-emergent adverse events (TEAEs).

Results: The safety analysis comprised 175 subjects: unilateral OA, n=52 (placebo, n=17; CNTX-4975 0.5 mg, n=18; CNTX-4975 1.0 mg, n=17); bilateral OA, n=123 (placebo, n=53; 0.5 mg, n=16; 1.0 mg, n=54). Efficacy analysis included 172 subjects (3 in bilateral subgroup excluded before unblinding). Mean baseline WOMAC QA1 pain score (index knee) was 7.3 (numeric rating scale, 0–10) in each subgroup. WOMAC QA1 scores with CNTX-4975 1.0 mg were significantly improved vs placebo in the unilateral (week 12, P=0.0178; week 24, P=0.0022) and bilateral subgroups (week 12, P=0.0101). WOMAC QA1, B, and C results are in the **Table**. The incidence of TEAEs for CNTX-4975 1.0 mg was similar to placebo through week 24. All TEAEs were mild to moderate, with most unrelated to treatment.

Conclusion: A single IA injection of CNTX-4975 1.0 mg, the dose used in phase 3 trials, improved pain with walking, knee stiffness, and physical function vs placebo in the index knee and was well tolerated in subjects with moderate to severe

unilateral or bilateral knee OA. Greater absolute improvements in WOMAC QA1, B, and C were seen in unilateral versus bilateral knee OA, though the nonindex knee had no to mild baseline pain.

Table. Mean Changes From Baseline in Average WOMAC QA1, WOMAC B, and WOMAC C at Weeks 12 and 24 vs Placebo

Session Title: Osteoarthritis – Clinical Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

DiabetesMellitus is Not a Risk Factor for Knee Osteoarthritis, a Systematic Review and Meta-analysis

Background/Purpose: Obesity is a strong risk factor for both osteoarthritis(OA) and diabetes mellitus (DM). Reported associations between DM and risk of OA may be confounded by high body mass index (BMI). We conduct a systematic literature review on the risk of OA in relation to DM or hyperglycemia.

Methods: We performed PubMed and Web of Science database searches for relevant studies in the English literature published between 1966 to 22 Jan 2018. Searches focused on original research articles that gave information on the association between DM or hyperglycemia and the risk of onset or progression of osteoarthritis. Two meta-analysis model were performed for 1) risk estimate of DM comparing subjects with or without OA; and 2) risk estimate of OA, comparing people with or without DM. The risk estimates from studies that have been adjusted for BMI were utilized as far as available.

Results: From 270 publications, a total of 32 articles were reviewed, including 10 cross-sectional, 13 case-control and 9 cohort studies. The pooled population size in our systematic review was 386,516. 16 studies reported positive associations

between DM and OA, while 16 studies reported null or inverse associations. Among studies that reported positive associations between DM and OA, only 62.5% had adjusted for BMI. For studies that reported null or inverse association between DM and OA, 100% had adjusted for BMI, of which 6 studies had comparable BMI at baseline between comparison groups. In meta-analysis model 1 pooling data from 13 studies and 307, 473 subjects, there was an increased prevalence of DM comparing subjects with OA to those without OA (OR 1.385, 95% confidence intervals (CI): 1.189 –

1.614) (Figure 1). 92.3% of these studies did not adjusted for BMI. In model 2, pooling data from 21 studies and 391, 203 subjects, there was no increased risk of onset or progression of OA, comparing subjects with DM to those without (OR 1.046, 95% CI: 0.923 – 1.186, $p = 0.481$) (Figure2). 95.2% of these studies had adjusted for BMI. In sensitivity analyses, the risk of OA was not higher comparing subjects with or without DM as stratified by study design, gender, and site of OA.

Conclusion: This meta-analysis showed higher prevalence of DM among subjects with OA compared with those without. However, it does not support DM as an independent risk factor for OA. BMI was probably the most important confounding factor.

The Influence of Hand Osteoarthritis on Bone Microstructure and Biomechanical Properties of Radial Bone

David Simon, Sara Unbehend, Sara Bayat, Juergen Rech, Axel J. Hueber, Georg Schett and Arnd Kleyer, Department of Internal Medicine 3—Rheumatology and Immunology, Friedrich-Alexander-University Erlangen–Nürnberg (FAU), Universitätsklinikum Erlangen, Erlangen, Germany, Erlangen, Germany

Session Information

Session Date: Monday, October 22, 2018

Session Title: Osteoarthritis – Clinical Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Primary hand osteoarthritis (HOA) is a heterogeneous disease, with erosive and osteoproliferative changes of the finger joints. [1] Due to the lack of treatment options, HOA patients suffer from progressive functional impairment of the affected joints, which is associated with pain. Despite these severe functional changes, the impact of HOA on bone microstructure and biomechanics of the affected limb remains poorly investigated. Therefore we aimed to assess bone microstructure and biomechanical properties in HOA patients.

Methods: HOA patients fulfilled the 1990 American College of Rheumatology criteria for the classification of hand osteoarthritis [2]. For comparison, sex- and age-matched healthy controls (HC), free of present or past signs of rheumatic diseases, osteoporosis, diabetes mellitus, renal or hepatic disease were analyzed. All participants received a high-resolution peripheral quantitative computed tomography (HR-pQCT, XtremeCT 1, Scanco, Switzerland) scan of the distal radius. Volumetric bone mineral density (vBMD) parameters such as total vBMD, trabecular vBMD, cortical vBMD (in mg HA/cm³) as well as micro-finite element analysis (μFEA) parameters such as stiffness (kN/mm) and failure load (N) were determined.

Results: 105 subjects were included (76 HC/29 HOA). Mean age was 55.6±13.3 (HC) and 60.5±66.9 years respectively (HOA), while 31 HC and 6 HOA were male. HOA patients revealed significantly decreased trabecular vBMD compared to HC (139±35 vs. 159±38, $p=0.026$), while cortical vBMD was comparable between HOA and HC. Microstructural parameters such as trabecular number (1.9±0.3 vs. 2.0±0.3 1/mm, $p=0.027$) or cortical thickness (0.06±0.01 vs. 0.07±0.01 mm, $p=0.035$) were significantly reduced in HOA. Regarding biomechanical bone properties HOA patients showed a significantly lower stiffness and failure load compared with HC (stiffness: 36.2±10.2 vs. 45.3±14.7, $p=0.010$; failure load: 1770±452 vs. 2164±679, $p=0.009$).

Conclusion: This study shows that HOA affects bone microstructure and biomechanical properties of the affected limb. Impaired mobility might be an explanation for this strong reduction of biomechanical properties and trabecular bone density. These results underline the clinical importance of HOA-related functional impairment and suggest that HOA patients need to receive awareness for increased risk of fractures and anti-osteoporotic Treatment

Session Date: Monday, October 22, 2018

Session Title: Osteoarthritis – Clinical Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Although osteoarthritis (OA) has not been considered as an autoimmune disorder, there are increased evidences of the role of the immune system in OA pathogenesis. Since autoantibodies (AAbs) are produced also at asymptomatic stages, they have been proposed as potential biomarkers to identify patients without clinical symptoms. A previous work from our group demonstrated the presence of AAbs in sera from OA patients. In this study, we aimed to identify an AAbs profile associated with an increased risk for the disorder, which might be useful in the very early diagnosis of knee OA.

Methods: Nucleic-Acid Programmable Protein Array (NAPPA) platform was used to screen AAbs against 2200 human proteins in 200 sera at baseline belonging to participants enrolled in the Incidence and Non-exposed subcohorts from the Osteoarthritis Initiative (OAI). Patients from the Incidence subcohort included in the screening had developed OA at 72 months of follow-up. After a panel of 6 AAbs was established as associated to OA risk, levels of AAbs against MAT2B were validated by ELISA-based immunoassay in 136 and 113 sera from the same Incidence and Non-exposed subcohorts, respectively. In addition, 119 sera from patients belonging to the Incidence subcohort at baseline who have not developed OA at 72 months, named as Control-Incidence subcohort, were included in this validation step. The Kruskal-Wallis test was used to define significance, and a logistic regression analysis, adjusted by age, gender and BMI, was used to analyze the contribution of these AAbs levels to our prediction model of OA risk. Appropriate receiver-operating-characteristics (ROC) curves was also calculated.

Results: In the *discovery phase* of the study, the NAPPA array resulted in the identification of a panel of 6 AAbs against different human proteins significantly modulated at baseline in those patients showing specific OA risk factors. The list of proteins against which altered levels of AAbs have been found is shown in Table 1, together with the statistical metrics obtained for each AAb. MAT2B was selected to enter the *validation phase* owing to its implication in the methylation processes. MAT2B is the regulatory subunit of the enzyme in charge of the production of the main methyl group donor, S-adenosylmethionine. An increased levels of AAbs against MAT2B were detected in the Incidence subcohort compared to the Non-exposed subcohort (mean OD= 0.628 ± 0.22 vs 0.553 ± 0.21 ; $p=0.032$). The regression model of the 3 clinical variables and MAT2B AAbs levels showed a predictive power up to AUC=0.809.

Conclusion: This is the first work to screen a large number of human proteins (2200) for the detection of OA-associated AAbs. A potential panel of 6 AAbs for very early diagnosis has been defined, and MAT2B levels have been validated in individual sera from the OAI cohort. These results suggest the putative utility of a serum AAbs profile to facilitate the diagnosis of OA in a stage prior to the disease.

Table 1. Panel of 6 AAbs defined by comparing the Incidence and the Non-exposed subcohort at baseline

Session Information

Session Date: Monday, October 22, 2018

Session Title: Osteoarthritis – Clinical Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Current ACR guidelines recommend the use of IACS for short-term acute pain relief in patients (pts) with knee OA.¹ Bilateral knee OA can occur concurrently or subsequently develop in 80-90% of pts with unilateral disease.^{2,3} These pts may benefit from simultaneous IACS treatment of both knees. Triamcinolone acetonide extended-release (TA-ER; formerly FX006) is an extended-release, microsphere-based formulation of triamcinolone acetonide (TA) recently approved by the FDA for knee OA pain.⁴ In a phase 2 study, a single TA-ER injection demonstrated reduced systemic TA exposure relative to standard TA crystalline suspension (TAcS).⁵ Here, we assessed safety and systemic TA exposure following IA injection of TA-ER or TAcS into both knees in pts with bilateral knee OA.

Methods: In this phase 2, randomized, open-label study (NCT03378076), pts (≥ 40 years, BMI ≤ 40 kg/m²) meeting ACR clinical/radiographic criteria for bilateral knee OA received 2 IA injections (one in each knee) of TA-ER 32 mg (total 64 mg) or TAcS 40 mg (total 80 mg) and followed for 6 weeks. Safety was evaluated based on adverse events (AEs), physical exams, knee assessments, vital signs, and laboratory evaluations. Blood samples for plasma pharmacokinetics (PK) were collected at baseline (within 1 hour prior to injection), at Hours 1-6, 8, 10, and 12 postinjection, and on Days 2, 8, 15, 29, and 43. Plasma TA concentrations were assayed with a validated LC-MS/MS method.

Results: Twenty-four pts (TA-ER, n=12; TAcS, n=12) were randomized and included in safety and PK analyses. Baseline characteristics were well balanced. Eight of 12 and 5 of 12 pts had ≥ 1 treatment-emergent AE in the TA-ER and TAcS treatment group, respectively. AE profiles were similar, and both treatments were well tolerated. TA-ER plasma concentrations peaked at median 4.5 hours with a mean C_{max} (\pm SD) of 2577.8 (1225.22) pg/mL, whereas TAcS peaked at median 6.5 hours with a mean C_{max} (\pm SD) of 24289.4 (27123.34) pg/mL (**Figure 1** and **Table 1**).

Conclusion: In pts with bilateral knee OA, IA injection of TA-ER into both knees was generally safe and well tolerated. Peak plasma TA concentrations were substantially lower in patients treated with TA-ER, demonstrating reduced systemic exposure relative to TAcS consistent with the PK profile of a single TA-ER injection.

An Analysis of the Quality and Readability of Online Osteoarthritis Information with Historical Comparison

Session Time: 9:00AM-11:00AM

OA is the most common cause of disability in people >65 years old. : Most patients in the USA use the internet for healthcare information. The quality and readability of this is variable. Guidelines state health information for the general public should be at a 7–8th grade reading level. Health on the Net Foundation Code of Conduct (HONcode) is a well-known quality label for medical and health websites. The DISCERN instrument and JAMA Benchmark criteria are standardized validated tools to assess healthcare information quality. In 2003, online OA information was graded as “poor” by DISCERN. This study reviews the quality and readability of current online OA information.

There was a significant difference in quality between author types (ANOVA $r^2=0.24, p=0.028$). Non-doctor health professional authors scoring the highest and non-medical authors scoring the lowest. HONCode endorsed websites (n=16) were of a statistically significantly higher quality.

Readability varied by assessment tool from 8th to 12th grade level.

Conclusion: Quality of online health information for OA is “fair”, an improvement from 2003. Readability was equal to or more difficult than recommendations. HONcode certification was indicative of higher quality, but not readability.

Summary of Results:

Producer	Age (years)	HONcode certified	DISCERN Score				JAMA Benchmark Criteria				Readability		
			Readability	Treatment Choices	Quality	Total	Authorship	Attribution	Currency	Disclosure	FRES	FKGL	GFI
All	1.4	43.2%	23.1	16.6	2.6	42.3	29.7%	24.3%	59.4%	24.3%	51.4	7.8	9.0
Not-for-profit, (governmental and NGOs) (n=14)	0.9	21.4%	24.1	17.2	2.6	43.9	0%	21.4%	50%	21.4%	50.8	7.9	9.4
Professional Society (n=4)	1.3	0%	22.6	16.3	2.5	41	50%	25%	75%	25%	49.4	8.2	8.8

Predictive Probabilities Are Superior in Communicating the Clinical Relevance of Cartilage Thickness As an Imaging Biomarker of Knee Osteoarthritis Progression

C. Kent Kwok^{1,2}, Erin L. Ashbeck¹, Edward J. Bedrick³ and Felix Eckstein^{4,5}, ¹University of Arizona Arthritis Center, Tucson, AZ, ²Division of Rheumatology, Department of Medicine, The University of Arizona, Tucson, AZ, ³Department of Epidemiology and Biostatistics, University of Arizona, Tucson, AZ, ⁴Institute of Anatomy, Paracelsus Medical University, Salzburg, Austria, ⁵Chondrometrics GmbH, Ainning, Germany

Session Information

Session Date: Monday, October 22, 2018

Session Title: Osteoarthritis – Clinical Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Establishing a threshold of clinically important cartilage loss is of great interest for the design and interpretation of knee OA trials of structure-modifying treatments. Our objective was to obtain predictive probabilities of knee replacement (KR) based on the combination of femorotibial joint (FTJ) cartilage thickness (CtTh) loss over 2 years, and CtTh at baseline.

Figure 1. Predictive Probability of Knee Replacement within Five Years.

Methods: Knees with symptomatic OA, defined by definite osteophyte (OARSI atlas grade 1-3) and participant-reported frequent knee symptoms at baseline, were selected prospectively from the Osteoarthritis Initiative (Project 09B). FTJ cartilage thickness at baseline and year 2 were measured quantitatively with MRI (3T; sagittal DESS sequence) and calculated as total femorotibial cartilage volume divided by the cartilage surface area. KRs reported up to 7 years following the 2-year imaging window were self-reported and confirmed. We used a Bayesian discrete time logistic survival model with intercepts (α_k) for each year of follow-up: $\text{logit}[p_k(x)] = \alpha_k + \beta'x$. Diffuse reference prior distributions for the model parameters, $\alpha_k, \beta_j \sim N(0, 10^4)$ were specified. Posterior densities of the regression coefficients were estimated with 10,000 Markov Chain Monte Carlo samples generated with the Rpackage R2OpenBUGS. Models were compared using deviance information criteria. Sensitivity of the results to the prior specification was considered.

Results: Among 582 knees (one knee per participant), 95 underwent KR up to 7 years following the initial 2-year imaging window (median follow-up 6 years). Mean baseline CtTh was 1.85 mm (SD0.29), while mean CtTh loss over 2 years was 0.04 mm (SD 0.07). Greater CtTh at baseline (standardized) was associated with lower odds of KR (OR=0.73 [95% credible interval (CI): 0.59, 0.90]; $\Pr(\text{OR}<1 \mid \text{data}) = 0.9995$). Greater 2-year loss of CtTh (standardized) was associated with higher odds of KR (OR=1.71[95%CI: 1.41, 2.05]; $\Pr(\text{OR}>1 \mid \text{data}) = 1.0$). The figure presents three representative curves of predictive probabilities of KR as a function of 2-year CtTh loss corresponding to three baseline CtTh values. For example, a knee with baseline CtTh of 1.85 mm and 2 year loss of 0.17 mm has a probability of KR within 5 years of 0.27. A knee with less baseline CtTh, 1.56 mm (-1SD), has a probability of KR of 0.34 with the same measured loss, while a knee with greater CtTh at baseline, 2.14 mm (+1SD), has probability of KR of 0.20.

Conclusion: The same rate of 2-year FTJ cartilage thickness loss has varying predictive probability of future KR, depending on the baseline cartilage thickness, highlighting the difficulty of defining minimum clinically important differences in a tissue that eventually disappears entirely at the end-stage disease process. Predictive probabilities of clinically relevant outcomes provide a more interpretable way to communicate the clinical relevance of imaging biomarkers beyond traditionally reported odds ratios.

The Relationship between Loneliness and Osteoarthritis in US Adults from a Nationally Representative Survey

Adeela Cheema¹, Louise Hawkey², Kristen Wroblewski³ and Kichul Ko⁴, ¹Section of Geriatrics and Palliative Medicine, Department of Medicine, University of Chicago, Chicago, IL, ²NORC, University of Chicago, Chicago, IL, ³Department of Public Health Sciences, University of Chicago, Chicago, IL, ⁴Section of Rheumatology, Department of Medicine, University of Chicago, Chicago, IL

Session Information

Session Date: Monday, October 22, 2018

Session Title: Osteoarthritis – Clinical Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Loneliness in adults is a growing phenomenon across the Western world. It is associated with increased mortality, depression, coronary heart disease and stroke. Moreover, over the last 2 decades, physicians have increasingly prescribed opioids to address chronic pain from osteoarthritis (OA) resulting in increased hospital stays associated with narcotic-analgesic overuse in people aged above 85 years. Our study evaluated whether presence of OA is associated with higher loneliness and if there is a difference in loneliness score among narcotic analgesic, non-narcotic and non-analgesic groups.

Methods: Data from wave 2 (2010-2011) of National Social Life, Health and Aging Project (NSHAP) were analyzed. Data were collected via in-home face-to-face interviews as well as leave-behind respondent administered questionnaires. The study was comprised of community residing adults born between 1920 and 1947, and their co-resident partners, with an oversampling of African-Americans and Hispanics and other key subgroups. Respondents were categorized as narcotic-analgesic, non-narcotic-analgesic or non-analgesic users based on medication logs obtained by interviewers, and as having or not having osteoarthritis if they specified it as a medical problem. Physical function was assessed by self-reported ability to walk one block and gait speed measured by 3-meter timed walk. Loneliness was measured with the 3-item UCLA loneliness scale in which ratings were summed to produce a loneliness score ranging from 0 to 9, with a higher score indicating greater loneliness. Ordinal logistic regression analyses were performed; survey weights were applied.

Results: Among adults with OA (n=624 out of 2572), 70 % were female, 86 % were non-Hispanic white and the mean age was 72.7 years (± 9.06 y). 12 % of those with OA reported taking narcotic-analgesics, which was higher than the rate among those without OA (6%, $p < 0.001$). Those with OA tended to be lonelier than those without OA (mean 3.3 vs. 3.1; $p = 0.008$). Among older adults with OA, those taking non-narcotic-analgesics were lonelier than those taking no analgesics, and this association persisted when adjusting for pain and walking difficulty ($p = 0.043$). In the OA group, the pain levels were higher in the narcotic-analgesic users as 92 % of them had at least moderate pain levels compared to 65 % and 61% in non-narcotic-analgesic and non-analgesic users ($p < 0.001$). There was no difference between pain levels in non-narcotic-analgesic users and those in non-analgesic users. Pain levels did not correlate with loneliness in those with OA. Both narcotic and non-narcotic-analgesic groups reported greater difficulty walking a block compared to non-analgesic users even after the analysis was adjusted for pain, age and gender ($p = 0.004$).

Conclusion: People with OA were found to be lonelier than those without OA. In the OA group, those taking non-narcotic-analgesics were found to be lonelier. Due to higher degree of loneliness in people with OA, devising strategies to reduce loneliness is important for quality of life and wellbeing. Future research should explore associations between analgesic medication classes, physical function and loneliness in people with OA.

Abstract Number: 1375

Comparative Safety of Flavocoxid (Limbrel) Versus Nsaids Among Osteoarthritis Patients

Justin K Owensby¹, Fenglong Xie¹, Lang Chen¹ and Jeffrey R. Curtis², ¹University of Alabama at Birmingham, Birmingham, AL, ²University of Alabama, Birmingham, AL

Session Information

Session Date: Monday, October 22, 2018

Session Title: Osteoarthritis – Clinical Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Flavocoxid is a medical food formulated to assist in the management of patients with osteoarthritis (OA). Safety concerns based on case reports have been raised related to an association with acute liver injury and hypersensitivity pneumonitis (HP). However, the absolute and comparative risk of these events relative to NSAIDs is unclear. Our objectives were to determine the incidence rate (IR) of severe acute liver injury, HP and other outcomes in a cohort of OA patients who were new users of flavocoxid versus prescription NSAIDs

Methods: MarketScan claims data (2006-2016) was used to identify patients age ≥ 50 initiating flavocoxid or prescription NSAIDs with a history of OA or back pain and ≥ 6 months coverage before initiation. Patients were excluded if they had prior events or malignancy. New users defined by 6-month baseline period of non-use prior to initiation. Exposure was defined by days of supply + a 30 day extension, with a sensitivity analysis conducted with a 90 day extension. Primary outcomes included hospitalization for HP and drug-induced liver injury, based on ICD-9 codes. Secondary outcomes included hospitalized GI bleed and acute myocardial infarction (MI). Poisson regression was used to calculate crude incidence rates per 1000 person-years (PY) and 95% confidence intervals (CI). Propensity scores (PS) were used to match (1:2) flavocoxid to NSAID users based on demographics and >200 comorbidities (based on AHRQ's CCS groupings). Cox regression was used for calculating adjusted hazard ratios (aHR).

Results: A total of 4800 flavocoxid and 2,129,727 NSAID new users met eligibility criteria. Prior to PS matching, many imbalances between flavocoxid and NSAID users were observed, all of which were greatly attenuated after PS matching. Post-match mean age for flavocoxid was 57, NSAIDs was 57. Flavocoxid users had higher prevalence of comorbidities and more healthcare utilization. The IR for HP associated with flavocoxid was 1.0 (95%CI 0.3-3.2) and for hospitalized liver injury was 4.1/1000, which after adjustment, was significantly elevated (aHR for HP: 5.6, 95%CI 0.5–68.6; a HR for hospitalized liver injury: 3.9, 95%CI 1.4-10.8 referent to NSAID use). Rates and aHR for GI bleed were lower (aHR=0.5, 95%CI 0.3-0.9) and there were no significant differences for MI.

Conclusion: The absolute risk for HP and severe liver injury associated with flavocoxid is low (1-4/1000py) but higher than in NSAID users, with a rate difference $\sim 2/1000$ py). The risk-benefit profile of flavocoxid needs to be considered in light of its efficacy and overall safety profile including lower rates of hospitalized GI bleeding

Table: Incidence Rates, Adjusted Hazard Ratios

Outcome	Exposure	Event	Person Years	Incidence Rate per 1000 PY	PS-matched Adjusted HR
Hypersensitivity pneumonitis	FLAVOCOXID	3	2913.3	1.0 (0.3-3.2)	5.6 (0.5-68.6)
	NSAID	1	5506.3	0.2 (0.0-1.3)	Reference
Hospitalized drug induced liver injury	FLAVOCOXID	9	2911.9	3.1 (1.6-5.9)	3.6 (1.2-11.2)
	NSAID	5	5505.8	0.9 (0.4-2.2)	Reference
Hospitalized liver injury	FLAVOCOXID	12	2910.4	4.1 (2.3-7.3)	3.9 (1.4-10.8)

Session Information

Session Date: Monday, October 22, 2018

Session Title: Osteoarthritis – Clinical Poster II

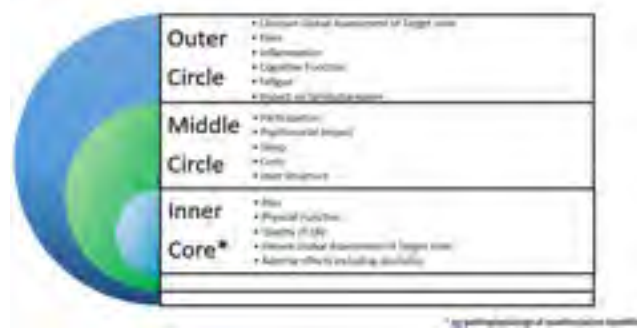

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: It has been over 20 years since the OMERACT core outcome set (COS) to measure in clinical trials with people who have hip and/or knee osteoarthritis (OA) was presented. An OMERACT-OARSI Working Group was established to update this COS using contemporary OMERACT methodologies.

Methods: A review of the COMET database of COS was undertaken to identify all domains reported in previous COS that including individuals with hip and/or knee OA. These were presented in a series of patient and public (PP) meetings involving 70 individuals across the UK, Australia and Canada to review the domain list and identify additional important domains. Based on these, a three-round international Delphi survey was undertaken recruiting patients, healthcare professionals, researchers and industry representatives to gain consensus on key domains which should be included in this core domain set. Using the Delphi results, an OMERACT 'onion' was formulated with the following rules: Inner core

Figure 1. OMERACT2018 core outcome domain set for trials of people with hip and knee OA.

inclusion (mandatory for all trials) was defined as domains reported as ‘critical’ to assess by over 70% of Delphi responses in the patient AND others stakeholder groups; Middle circle inclusion (recommended by optional in trials) was defined as domains reported as ‘critical’ to assess by over 70% of Delphi responses in the patient OR others stakeholder groups; Outer circle inclusion was defined as areas which need further research with insufficient evidence supporting middle circle placement. The findings were discussed at OMERACT2018 and a consensus vote was obtained on the core domain set.

Results: From the COMET review, four previous COS were identified including the 1997 OMERACT core outcome set. These were reviewed across the PP meetings to identify 50 potential domains which formed the Delphi survey. In total 424 (217 patients; 207 non-patients) contributed data to the Delphi exercise from 25 different countries. The OMERACT2018 delegates (129 participants) voted on those domains which met the criteria for inclusion. From this, four domains gained agreement on inner core inclusion to be mandatory in all clinical trials with people with hip and/or knee OA: ‘pain’ (100% of vote), ‘physical function’ (100%), ‘quality of life’ (90%) and ‘patient global assessment of the target joint’ (91%) in addition to the mandated core domain of ‘adverse events including mortality’. Adherence was specified as a critical contextual factor which should be assessed. The core domain set (inner core, middle and outer circle) is presented in Figure 1.

Conclusion: The updated core domain set for hip and/or knee OA has been agreed. We will now build on this work to determine which instruments should be recommended to measure each of the inner core domains based on the OMERACT Filter 2.1 guidance.

Knee Osteoarthritis Symptom Duration Is Associated with Conditioned Pain Modulation and Vibration Perception Threshold Impairment

Kharma C. Foucher¹, Samuel Chmell² and Carol Courtney³, ¹Kinesiology and Nutrition, University of Illinois at Chicago, Chicago, IL, ²Orthopedic Surgery, University of Illinois at Chicago, Chicago, IL, ³Physical Therapy, University of Illinois at Chicago, Chicago, IL

Session Information

Session Date: Monday, October 22, 2018

Session Title: Osteoarthritis – Clinical Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Impaired descending pain inhibition has been observed in people with knee OA and may be associated with development of chronic pain as well as poorer treatment outcomes. In addition, higher (worse) vibration

perception threshold (VPT) has also been observed in people with OA and linked to radiographic OA severity. It is not known how duration of symptoms may influence these neurophysiological measures. Our purpose was to evaluate the relationship between reported duration of symptoms and conditioned pain modulation (CPM), a measure of descending pain inhibition, as well as VPT. A secondary purpose was to determine whether these relationships differed in men and women.

Methods: We evaluated 18 men and 27 women with moderate to severe knee OA. All subjects satisfied ACR OA classification criteria. Subjects were asked how long they had had OA symptoms. We assessed CPM using a sub maximal-effort tourniquet test: Pressure pain threshold (PPT) at the symptomatic knee was evaluated before and after a noxious stimulus. CPM impairment was indicated by a ratio of pre-to-post stimulus PPT ≥ 1 . VPT was assessed using a biothesiometer at the medial femoral condyle. Pearson correlations were used to determine whether there were associations between symptom duration and CPM and VPT. Chi-square and t-tests were used to identify potential sex differences.

Results: 72% of men and 44% of women exhibited CPM impairment ($p = 0.062$). VPT was also similar in men (29.5 ± 7.8) and women (28.2 ± 1.6 , $p = 0.667$). Duration of symptoms (Figure 1) was associated with CPM impairment in women ($R=0.566$, $p=0.003$) but not men ($R=0.366$, $p=0.135$). Duration of symptoms was also associated with VPT in both men ($R = 0.580$, $p = 0.012$) and women ($R = 0.406$, $p = 0.039$).

Conclusion: These results suggest that longer duration of knee OA may predict more severe pain sensitization and development of hypoesthesia. In addition, important sex differences may exist in descending pain inhibition in people with chronic knee OA that may affect disease and course of treatment in male and female patients.

Figure 1. Association between duration of symptoms and CPM (L) and VPT (R). In left panel, values above dotted horizontal line indicate impaired CPM.

Session Information

Session Date: Monday, October 22, 2018

Session Title: Osteoarthritis – Clinical Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Hand Osteoarthritis (HOA) is a highly prevalent disease with important impact on the patient's daily activity performance and quality of life. Dreiser et al. developed the Functional Index for Hand Osteoarthritis (FIHOA), a questionnaire (either physician or self-patient administered) designed to assess the functional impact of HOA on daily living activities, and it is expected to change with the progression of the disease or under the effect of treatment. To translate FIHOA into Spanish and to validate the Spanish version in patients with HOA.

Methods: Prospective, analytical, cross-sectional observational study. The English version of FIHOA was translated into Spanish according to the Beaton et al. guidelines. Patients 18 years of age and older with diagnosis of HOA (ACR1990) were included. Those with secondary OA or any condition affecting upper limbs were excluded. All patients completed the questionnaire, along with other subjective measures: Pain and patient global assessment of the disease using a visual analogue scale (Pain and PtGA VAS), and Health Assessment Questionnaire (HAQ-A). For a patient subgroup, an occupational therapist performed an evaluation of hand function, using the Sequential Occupational Dexterity Assessment (SODA-A) and the Jebsen Hand Function Test (JHFT). To assess reproducibility, a subgroup of patients with similar clinical and therapeutic conditions to their first evaluation completed the questionnaire again one week later. Statistical analysis: Demographic and clinical characteristics were described. Construct validity was analyzed through the correlation of FIHOA with HAQ-A, SODA-A test and JHFT using the Spearman coefficient. Internal consistency was assessed using Cronbach's α coefficient and inter-item correlation. Reproducibility was estimated using test-retest reliability. A multiple regression model was constructed with FIHOA as the outcome variable and those variables that proved significant on bivariate analysis.

Results: Eighty-seven patients were included (93% women), mean age 67.8 years (SD 9.3). Educational mean level was 8 years (SD 3.7). Mean Pain VAS score was 4.57 (SD 2.54) and mean PtGA 4 (SD 2.63). Median TJC was 5 (IQR 3-8) and median SJC was 0 (IQR 0-1). We observed a good correlation between FIHOA and HAQ-A ($r=0.69$). FIHOA also showed a positive correlation with Pain VAS score ($r=0.57$), TJC ($r=0.70$), SODA-A ($r=0.47$) and the activities with small objects performed with the non-dominant hand in JHFT ($r=0.50$). FIHOA demonstrated good internal consistency (Cronbach's $\alpha=0.85$) and reproducibility (0.76). A multiple linear regression adjusted by age, gender and Pain VAS showed TJC as the main determinant of FIHOA. Median time to complete the test was 70 seconds (IQR 50-100). FIHOA showed good acceptance.

Conclusion: The Spanish version of the FIHOA questionnaire proved to be a valid, reliable, and reproducible assessment of functional capacity in patients with HOA, providing a valuable tool for the evaluation of our patients.

Session Information

Session Date: Monday, October 22, 2018

Session Title: Osteoarthritis – Clinical Poster – ARHP

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The SpENAT, a Spanish version of the Educational Needs Assessment Tool (ENAT), is a self-completed questionnaire that assesses educational needs (ENs) in osteoarthritis (OA) patients, with the purpose of providing tailored and patient-centered information.

Objectives: To establish the sources of information that patients use as well as to describe the educational needs of OA patients by using the SpENAT.

Methods: International multicenter, prospective cross-sectional study in patients with OA (Altman R. *et al.* 1986). Those patients with inability to read, write or understand the questionnaire were excluded. Demographic data, educational level, clinics and sources of information consulted were recorded. SpENAT Questionnaire: 39 questions grouped into 7 domains (pain, movement, feelings, OA, medical treatments, self-help and help from others); Likert scale of 0-4; score of ENs 0 to 156. Analysis of variables according to type and distribution: Fisher exact test, Student, Mann-Whitney U and X². Spearman correlation test.

Results: 1158 patients (79% women) from 8 Latin American countries were included. Mean age 65.5 years (SD +/- 11 IC95% 65-66). Mestizos 50%, whites 33%, LA / Africans 7%, and Amerindian 3%. With 79% urban residence and rural 21%. Average years of study 9 (RIC 6-12). Occupation: housewives 47%, trade 10%, administrative 2.2%, teachers 3%, professionals 4%, unemployed 6.4%, retired 14%, students 0.2%; Work disability 1.5%. BMI: low 1%, normal 22%, overweight 46%, obese 29%, and morbid obesity 2%. Average of years of evolution 3 (RIC 2-6). Comorbidities at 69%. (HTA 45%, DM 16%, Osteoporosis 6%, hypothyroidism 4%, dyslipidemias 4%, gastrointestinal 1.2%, others 6%). EVA of pain 50 mm (RIC 9-80) and activity 50 mm (RIC 10-80), EVA medical activity 40 (RIC 10-70). RAPID3 Average 16 (RIC 12-20). Treatment with NSAIDs 63%, paracetamol 58.4%, opioids 4.4%, PPI 33% and SYSADOAs 63.9% (Degree of Satisfaction: Medium 7 (RIC: 5-8) Tolerance Level: Medium 8 RIC: 7-9). Intra-articular treatment: 29% (3.6% with Hyaluronic Ac). SpENAT median 117 (RIC 102-134); median for pain domain 18 (RIC 14-20), mobility 15 (RIC 12-18), feelings 12 (RIC 10-16), OA 21 (RIC 18-25), medical treatments 21 (RIC 16-24), self-help 18 (RIC 15-21). Search for information: Rheumatologist 85%, Traumatologist 18%, Clinician 10.4%, other health professionals 9%, TV 1%, internet 16% and family and friends 12.3%.

Conclusion: The majority of patients show considerable educational needs and a greater interest in knowing about OA and its treatment. There is a low correlation between SpENAT and RAPID3. The greatest value of SpENAT was associated with resorting to the rheumatologist for better information. We consider it important to recognize both the NEs and the sources of communication with our patients and then have a starting point to develop better therapeutic strategies.

Session Title: Patient Outcomes, Preferences, and Attitudes Poster I: Patient-Reported Outcomes

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: THAs are commonly performed in patients with a history of inflammatory arthritis. These patients are likely at higher risk of complications, from both the underlying disease and immunosuppressive medications. The purpose of this study was to perform a population-based comparison of the risk of postoperative complications between patients with inflammatory arthritis and osteoarthritis.

Methods: A national private insurance database was used to select patients undergoing unilateral primary THA. Patients were categorized to the inflammatory cohort if they had an ICD diagnosis of inflammatory arthritis as well as treatment

with a DMARD, biologic, or SLE-specific medication within the year prior to surgery. Patients with no diagnosis of inflammatory arthritis were assigned to osteoarthritis. Postoperative complications were identified using Reportable CMS Complication Measures. Risk of each complication was compared between cohorts using multivariate logistic regression controlling for age, gender, length of stay, comorbidities, and steroid use within 3 months prior to THA.

Results: 68,348 patients were included; 2.12% met criteria for inflammatory arthritis as described above. Independent of age, gender, LOS, comorbidities, and recent steroid use, inflammatory patients were found to have higher risk of transfusion (OR 1.29, $p < 0.01$), mechanical complications (OR 1.35, $p = 0.01$), infection (OR 1.96, $p < 0.01$), and readmission (OR 1.35, $p < 0.01$). There were no differences in risk of VTE or medical complications.

Conclusion: Independent of other comorbidities, patients with inflammatory arthritis are at high risk of transfusion, mechanical complications, infection, and readmission following THA. Treatment of these patients is likely more costly and efforts should be made to optimize their health and treatment medications prior to THA to minimize their complication risk. Additionally, these results have important implications for evolving bundled payment models. Hospitals should receive commensurate resources to maintain access to THA for patients with inflammatory arthritis that are prone to higher resource utilization.

Q2	96 [81, 96]		96 [91, 96]	
Q3	96 [82, 96]		96 [91, 100]	
Q4	96 [86, 96]		96 [96, 100]	

Scores are summarized as median [interquartile range] and compared using the Kruskal-Wallis test.

*The median 2-year pain score for THR was 100, so the third and fourth quartiles are the same. The median 2-year pain score for TKR was 95, quartiles were as follows: 71.3, 95, 100 and 100.

**The median 2-year function score for THR was 95.6, quartiles were as follows: 86.8, 95.6, 100 and 100. The median 2-year function score for TKR was 91.2, quartiles were as follows: 77.9, 91.2, 98.4 and 98.4.

Quartiles differ for THR and TKR.

Session Information

Session Date: Monday, October 22, 2018

Session Title: Patient Outcomes, Preferences, and Attitudes Poster I: Patient-Reported Outcomes

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Up to 20% of Total Joint Replacement (TJR) patients are dissatisfied, but this is difficult to study as it is challenging to pool data due to the lack of unified core outcome measures. The OMERACT TJR Working Group has recently endorsed a core domain set for Knee and Hip TJR trials that include pain, function and patient satisfaction among others, and now seeks validation prior to development of a TJR trial core measurement set. We aim to assess the association of pain relief and improved function with patient satisfaction 2 years after TJR.

Methods: We identified all patients undergoing total hip (THR) and knee (TKR) replacement enrolled in a hospital-based registry from 2007-2011, and evaluated those with 2-year satisfaction scores. Pain and function were measured using the Knee and Hip injury and Osteoarthritis Outcome Score (KOOS, HOOS) and satisfaction was measured using 5 primary questions, each rated on a Likert scale. Each question was weighted equally and a satisfaction summary score was calculated (range 0-100, higher scores corresponding to greater satisfaction). Expectations were measured using the validated HSS Expectations survey. Correlation was analyzed with Spearman coefficients, and scores were compared by quartiles using the Kruskal-Wallis test. Rasch modeling was attempted but a unidimensional construct could not be achieved.

Results: We included 4,796 primary unilateral TKR and 4801 THR. 78% of TKR and 90.7% of THR were very satisfied with pain relief, and 6.5% of TKR and 2.5 % of THR were somewhat or very dissatisfied (**Table 1**). Satisfaction correlated moderately with pain (TKR $\rho=0.61$, THR $\rho=0.47$) and function (TKR $\rho=0.65$, THR $\rho=0.51$) at 2 years; there was no correlation with baseline expectations. When comparing satisfaction by pain, function and expectation quartiles, there were statistically significant differences (**Table 2**); those with the best scores and greatest change in pain and function were the most satisfied.

Conclusion: These findings confirm that with increasing relief of pain and functional improvement, the strength of the association of 2 core domains with satisfaction increases, further validating these core domains for use in TJR clinical trials. The range of correlation of satisfaction measure of 0.47-0.61 with pain and function, indicates that satisfaction

domain is somewhat independent of pain and function, further validating its inclusion in the core domain set. A core outcome measurement set needs to be defined for use in TJR clinical trials that includes validated measures of these domains.

Abstract Number: 1382

Evaluating Results of an Interferon- γ Release Assay in Patients with Autoimmune Skin Disease on Hydroxychloroquine

Rebecca Gaffney¹ and Victoria P. Werth², ¹Dermatology, University of Pennsylvania, Philadelphia, PA, ²Department of Dermatology, Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA

Session Information

Session Date: Monday, October 22, 2018

Session Title: Patient Outcomes, Preferences, and Attitudes Poster I: Patient-Reported Outcomes

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: QuantiFERON-TB Gold is commercial interferon- γ release assay used to screen patients for tuberculosis before starting or while on immunosuppressive therapies. Clinical studies on efficacy of QuantiFERON-TB Gold testing show higher rates of indeterminate results among immunosuppressed populations compared to the general population. An indeterminate QuantiFERON-TB Gold result may preclude patients from starting certain therapies or enrolling in clinical trials. Hydroxychloroquine (HCQ) is proposed to reduce levels of interferon- γ and therefore may affect the results of a QuantiFERON-TB Gold test, however, its relationship to QuantiFERON-TB Gold results has not been studied

Methods: The medical records of 119 patients enrolled in prospective longitudinal databases for cutaneous lupus, dermatomyositis, and autoimmune blistering disease with QFT-G testing were reviewed. Patients were sorted into groups based on the presence or absence of HCQ use within one year of QuantiFERON-TB Gold testing. We also evaluated the concomitant use of prednisone and disease modifying anti-rheumatic drugs (DMARDs).

Results: In the study population of 119 patients, 46 were in the HCQ group, while 73 did not use HCQ in the year prior to testing. There were 24 (20%) indeterminate, 92 (77%) negative, and 3 (2.5%) positive QuantiFERON-TB Gold results total. The HCQ group had significantly more indeterminate QuantiFERON-TB Gold results (37%) compared to the non-HCQ group (9.6%) ($p < 0.001$). There was no significant difference in concomitant use of prednisone or DMARDs ($p = 0.437$, and $p = 0.085$, respectively) between groups.

Conclusion: These results reveal that patients taking HCQ at the time of QuantiFERON-TB Gold testing are significantly more likely to have an indeterminate result compared to those not taking the medication, and this finding is not explained by concomitant use of prednisone or DMARDs. An indeterminate QuantiFERON-TB Gold result represents a major barrier to receiving treatment and therefore future studies are needed to evaluate the most appropriate tuberculosis screening in patients taking hydroxychloroquine.

Examining Cutaneous Disease Activity As an Outcome Measure for Clinical Trials in Dermatomyositis

Rebecca Gaffney¹, Meera Tarazi², Rui Feng³, David Pearson⁴ and Victoria P. Werth⁵, ¹Dermatology, University of Pennsylvania, Philadelphia, PA, ²Department of Dermatology, University of Pennsylvania, Philadelphia, PA, ³Biostatistics, Epidemiology and Informatics, University of Pennsylvania, Philadelphia, PA, ⁴Philadelphia Veterans Affairs Medical

Center, Philadelphia, PA, ⁵Department of Dermatology, Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA

Session Information

Session Date: Monday, October 22, 2018

Session Title: Patient Outcomes, Preferences, and Attitudes Poster I: Patient-Reported Outcomes

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The FDA encourages clearance of skin findings as a primary outcome of clinical trials for inflammatory skin conditions. However, some DM patients retain signs of inflammation and damage despite having an acceptable quality of life. The current standardized quality of life instruments, Skindex-29 and Dermatology Life Quality Index, are shown to correlate with Cutaneous Dermatomyositis Activity and Severity Index activity scores and have been validated for use in clinical trials. However, Skindex-29 and Dermatology Life Quality Index scores have not been examined in patients with mild disease (Cutaneous Dermatomyositis Activity and Severity Index activity score ≤ 14), who may have an acceptable quality of life despite their cutaneous manifestations

Methods: This is a retrospective review of 171 patients enrolled in a prospective longitudinal database for DM. We evaluated the correlation of individual Skindex-29 and Dermatology Life Quality Index scores vs. the Cutaneous Dermatomyositis Activity and Severity Index activity scores in patients with DM skin disease. A linear model was fitted to determine the “Cutaneous Dermatomyositis Activity and Severity Index cut-off value”, which is the lowest Cutaneous Dermatomyositis Activity and Severity Index activity score at which the instrument correlates well with quality of life.

Results: The Dermatology Life Quality Index had the lowest Cutaneous Dermatomyositis Activity and Severity Index cut-off value at 3, compared to the other Skindex-29 subscales (Emotions, 9; Functioning, 7; Symptoms, 6). Below these Cutaneous Dermatomyositis Activity and Severity Index values, the Skindex-29 and Dermatology Life Quality Index are not shown to directly correlate with cutaneous disease activity, and further improvement in Cutaneous Dermatomyositis Activity and Severity Index activity score does not lead to further improvement in quality of life.

Conclusion: Our findings suggest that quality of life is not directly affected by the minimal cutaneous disease activity below these Cutaneous Dermatomyositis Activity and Severity Index cut-off values and therefore total clearance of skin findings may be irrelevant as a meaningful outcome for patients. Additionally, the linear correlation of Cutaneous Dermatomyositis Activity and Severity Index with quality of life until the cut-off values suggests that changes in Cutaneous Dermatomyositis Activity and Severity Index scores are relevant over the spectrum of disease activity above these cut-offs. The results of this study should encourage design of trials that reach a meaningful endpoint in terms of quality of life for patients.

Health-Related Quality of Life in Patients with Ankylosing Spondylitis in the United States

W. Benjamin Nowell¹, Regan Reynolds¹, Kelly Gavigan¹, Shilpa Venkatachalam¹, Marie de la Cruz², Emuella Flood², Ethan Schwartz², Beverly Romero², Yujin Park³ and Alexis Ogdie⁴, ¹Global Healthy Living Foundation, Upper Nyack, NY, ²ICON, Gaithersburg, MD, ³Novartis Pharmaceuticals Corporation, East Hanover, NJ, ⁴Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA

Session Information

Session Date: Monday, October 22, 2018

Session Title: Patient Outcomes, Preferences, and Attitudes Poster I: Patient-Reported Outcomes

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Ankylosing spondylitis (AS) is a chronic, systemic, inflammatory disease that affects primarily the sacroiliac joints and spine and can cause irreversible damage. Measuring disease activity and quality of life of AS patients can be complex due to the slow progression and invisible nature of the disease. The objective of this web-based survey was to describe the impact of AS on health-related quality of life (HRQoL) from the US patient perspective.

Methods: US adults aged ≥ 18 years with a self-reported diagnosis of AS were recruited through Creaky Joints (www.CreakyJoints.org), an online patientsupport community comprising patients with arthritis and arthritis-related diseases and their caregivers, as well as through outreach on social media. Respondents completed a web-based survey that

Table. Impact of AS on Health-Related Quality of Life

	Total (N = 235)	Men (n = 61)	Women (n = 174)	P Value
RAPID3 cumulative score (5-30), mean (SD)	15.4 (5.4)	13.6 (6.0)	16.0 (5.1)	0.01
PROMIS10, mean (SD)				
Global Physical Health T-Score	35.8 (7.4)	39.2 (7.8)	34.8 (6.8)	<0.01
Global Mental Health T-Score	59.9 (8.8)	62.3 (9.2)	59.1 (8.5)	0.02
Impact on work, n (%)	N = 117	n = 33	n = 84	
Difficulty sitting or standing for long hours	94 (71.8)	25 (75.8)	59 (70.2)	0.65
Missed work	55 (47.3)	13 (39.4)	42 (50.0)	0.31
Difficulty doing physical tasks	49 (41.9)	12 (36.4)	37 (44.0)	0.53
Loss of productivity at work	48 (41.0)	10 (30.3)	38 (45.2)	0.15
Need accommodations at work	44 (37.6)	9 (27.3)	35 (41.7)	0.20
Had to switch careers/jobs	25 (21.4)	5 (15.2)	20 (23.8)	0.45
Only able to work part-time	23 (19.7)	3 (9.1)	20 (23.8)	0.12
AS has no effect on my work	5 (5.1)	3 (9.1)	2 (3.6)	0.35
Unemployment related to AS, n (%)	N = 118	n = 28	n = 90	
Yes, completely because of AS	56 (47.5)	15 (53.6)	41 (45.6)	0.51
Yes, partially related to AS	51 (43.2)	12 (42.9)	39 (43.3)	
No	11 (9.3)	1 (3.6)	10 (11.1)	
Impact on relationships, n (%)				
Difficulty spending time with my friends	147 (62.6)	37 (50.8)	110 (58.7)	0.03
Lack of understanding from family and friends about my AS	127 (54.0)	29 (37.7)	104 (59.8)	<0.01
Difficulty spending time with my family	110 (46.8)	23 (31.7)	87 (50.0)	0.10
Difficulty maintaining friendships	93 (39.5)	15 (24.5)	78 (44.3)	<0.01
Difficulty maintaining my relationship with my spouse/partner	75 (31.9)	17 (27.9)	58 (33.3)	0.52
Lack of support from my family and/or friends	68 (28.9)	9 (14.8)	59 (33.9)	0.05
I don't have any difficulties with my relationships because of AS	40 (17.0)	20 (32.8)	20 (11.5)	<0.01

AS, ankylosing spondylitis; PROMIS10, Patient-Reported Outcomes Measurement Information System Global Health Short Form.

RAPID3, Revised Assessment of Patient Index Data-3.

* Percentages could have exceeded 100% due to rounding.

was designed to collect information on sociodemographic characteristics, clinical symptoms, disease burden, and the impact of AS on work productivity and relationships. Survey questions were developed following analysis of qualitative interviews of patients with AS and clinical experts, as well as targeted literature review. Survey results were compared between men and women using 2-sample *t* tests for continuous variables and chi squared tests for categorical variables.

Results: Among 235 respondents, 174 (74.0%) were women, and the mean (SD) age was 49.8 (10.7) years. The mean (SD) and median (IQR) time since AS diagnosis was 8.5 (9.3) and 5.0 (2-12) years. Depression (62.1%), anxiety (54.5%), and fibromyalgia (35.7%) were the most commonly reported comorbidities among respondents. Women had significantly higher mean RAPID3 scores and lower PROMIS10 Global Physical and Mental Health T-Scores than men (**Table**).

Approximately 90% of respondents reported either complete or partial unemployment due to AS. Most respondents (71.8%) had difficulty sitting or standing for long hours; other common issues related to work included missed work (47.0%), difficulty doing physical tasks (41.9%), and loss of productivity (41.0%) (**Table**). Although the impact of AS on work was not significantly different between men and women, the percentage of women with negative impact of AS on work was numerically higher in most categories. The most common impacts of AS on relationships were difficulty spending time with friends (62.6%), lack of understanding from friends and family about AS (54.0%), and difficulty spending time with family (46.8%) (**Table**).

Conclusion: Whereas the study findings demonstrate a considerable impact of AS on patients' HRQoL including work productivity and relationships, these topics are often not discussed with their treating physicians, friends, and families. Encouraging patients to share their disease burden with their physicians and caregivers may help to optimize medical care and outcomes in patients with AS.

Subjective Well-Being Among Rheumatoid Arthritis Patients

Goichi Kageyama^{1,2}, Akira Onishi³, Yo Ueda³, Kengo Akashi³, Sho Sendo³, Jun Saegusa³ and Akio Morinobu²,

¹Department of Rheumatology, Hyogo Prefectural Amagasaki General Medical Center, Amagasaki, Japan, ²Department of Rheumatology and Clinical Immunology, Kobe University Graduate School of Medicine, Kobe, Japan, ³Rheumatology and Clinical Immunology, Kobe University Graduate School of Medicine, Kobe, Japan

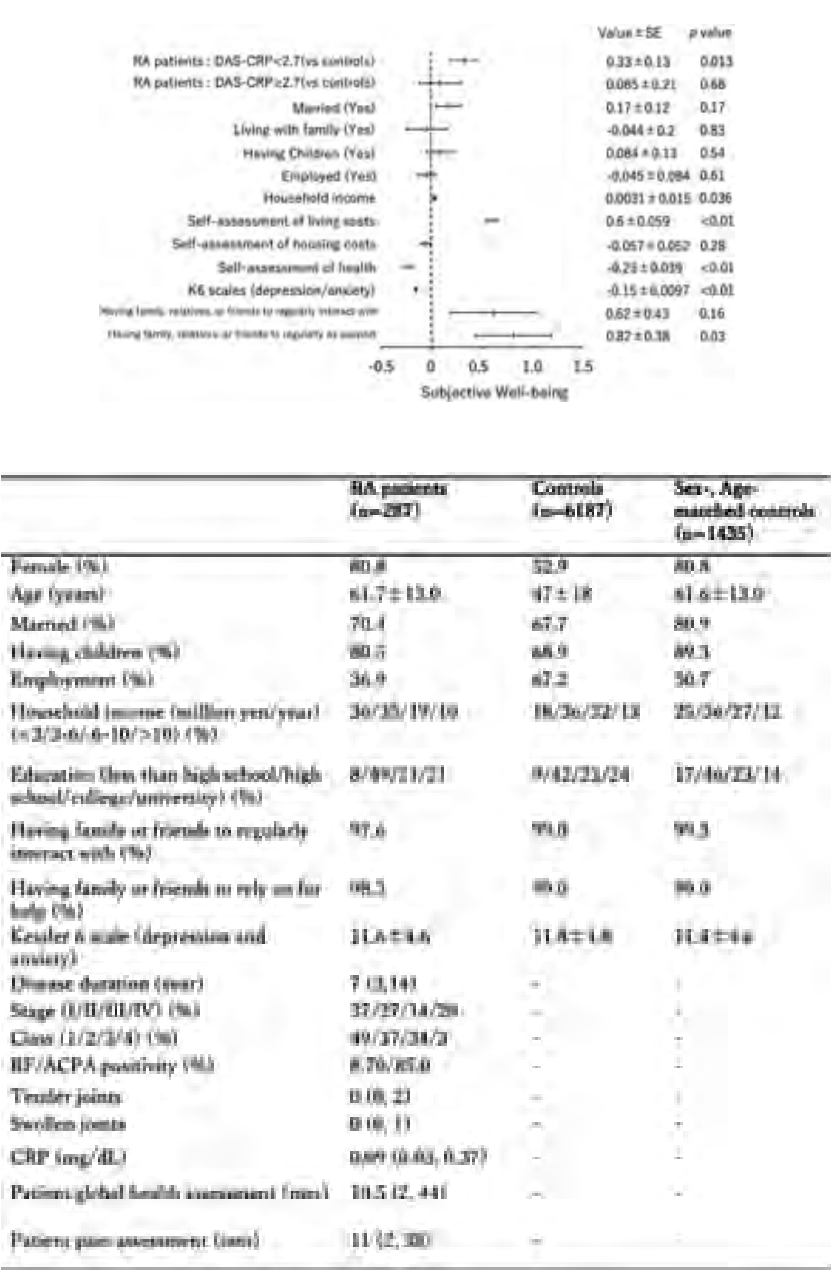

Session Information

Session Date: Monday, October 22, 2018
Session Title: Patient Outcomes, Preferences, and Attitudes Poster I: Patient-Reported Outcomes
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Subjective well-being (SWB) is a psychological construct that is synonymous with happiness. Many variables including age, sex, income, employment, and marital status are related to SWB. Health is also an important determinant of SWB that can be adversely affected in patients with chronic conditions such as rheumatoid arthritis (RA). In this study, we evaluated the SWB of RA patients and compared it with that of healthy controls.

Methods: We obtained the original dataset from the Quality of Life Survey, 2013, which was conducted by the Economic and Social Research Institute, Cabinet Office, Government of Japan. In this survey, SWB was determined by asking participants to rate their happiness on a scale from 0(very unhappy) to 10 (very happy). The survey also included a 56-point questionnaire regarding variables related to well-being. This questionnaire was administered to RA patients recruited from Kobe University Hospital. Clinical data regarding disease duration, stage, class, disease activity, health activity, complications, and treatment data were collected simultaneously.

Results: Multivariate analysis revealed that RA patients had significantly better SWB than age- and sex-matched controls (p =0.025). In addition, RA patients with high or moderate disease activity had SWBscores that were similar to those of

controls. However, the SWB scores of RA patients in remission or with low disease activity were higher than those of controls ($p=0.013$). SWB was associated with household income, financial status, psychological distress, self-assessment of health, and social connection.

Conclusion: For RA patients, achieving the therapeutic target can result in better SWB. Socioeconomic factors, financial status, psychological stress, self-assessment of health, and social network are also important for better SWB of RA patients. **Table** Summary of demographic characteristics of the study cohort

Figure.

When RA patients were stratified according to the degree of disease activity (DAS28-CRP ≥ 2.7 vs DAS28-CRP < 2.7), multivariate analysis shows that RA patients with DAS ≥ 2.7 had SWB scores similar to those of controls. However, the SWB of RA patients with DAS < 2.7 was higher than that of controls. SWB was also associated with socioeconomic factors, psychological stress, self-assessment of health and social network.

Session Information

Session Date: Monday, October 22, 2018

Session Title: Patient Outcomes, Preferences, and Attitudes Poster I: Patient-Reported Outcomes

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Golimumab has shown clinical efficacy and tolerability within its clinical trial program. No systematic outcome data regarding patient-reported outcomes and health economic parameters reflecting real-world use of golimumab in Austria are currently available.

Methods: Go Active is a prospective, non-interventional, multi-center study in Austria. The impact of golimumab therapy on work productivity and activity (WPAI) and quality of life (RAQoL for RA patients, AsQoL for axSpA patients, PsAQoL for PsA patients) is assessed by using patient-reported outcomes. Patients (target recruitment: n = 220) are followed up to 2 years. In this interim analysis (data cut-off: 03 May 2018) changes in WPAI and QoL from baseline to month 3 are analyzed after recruitment was completed

Results: At total of 234 patients were enrolled in the study and 189 patients were included in this analysis (81 patients with RA, 56 patients with axSpA, and 52 patients with PsA). Median age at registration was 52 years (patients with RA: 56 years, patients with axSpA: 40 years, and patients with PsA: 53.5 years). Almost two thirds of patients were female (81% of patients with RA, 39% patients with axSpA, and 58% of patients with PsA). Most patients were biological-naïve at study entry (78% of all patients, 75% of patients with RA, 79% of patients with axSpA, and 83% of patients with PsA). 38% of patients were not employed (54% of patients with RA, 25% of patients with axSpA and SpA); 14% due to incapacity for work (11% of patients with RA, 21% of patients with axSpA, and 15% of patients with SpA) and 55% due to age-related pension (61% of patients with RA, 21% of patients with axSpA, and 69% of patients with SpA). Most of the patients, who worked for a fee, worked full time. 179 of all patients and 92 of employed patients completed the WPAI questionnaire at baseline and after 3 months. Overall work productivity improved by 35% (40% for patients with RA, and 34% for patients with axSpA and 30% for patients with PsA) and activity impairment by 30% (40% for patients with RA and axSpA, and 20% for patients with PsA; Fig. 1). Quality of life scores improved by 7.5 for patients with RA, by 5 for patients with axSpA, and by 3 for patients with PsA. Fig. 1: WPAI questionnaire – changes from baseline after 3 months of golimumab treatment

Conclusion: This interim analysis shows that golimumab is an effective treatment for patients with RA, axSpA and PsA and leads to an improvement of work productivity and daily activities as well as of quality of life already within the first 3 months of treatment. At study entry, most patients were biological-naïve and employed.

Abstract Number: 1387

Fatigue in Patients with Rheumatoid Arthritis As Compared to Different Groups of Cancer Patients

Jens Gert Kuipers¹, Michael Koller², Ulrich Rueffer³, Florian Zeman², Karolina Mueller⁴ and Joachim Weis⁵, ¹Clinic for Internal Rheumatology, Red Cross Hospital Bremen, Bremen, Germany, ²Center of Clinical Studies, University Hospital Regensburg, Regensburg, Germany, ³German Fatigue Society, Cologne, Germany, ⁴Center for Clinical Studies, University Hospital Regensburg, Regensburg, Germany, ⁵University Clinic Centre Freiburg, Freiburg, Germany

Session Information

Session Date: Monday, October 22, 2018

Session Title: Patient Outcomes, Preferences, and Attitudes Poster I: Patient-Reported Outcomes

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Fatigue is a common symptom in patients with rheumatoid arthritis (RA) as well as patients with cancer. Fatigue considerably reduces the quality of life of patients. The present project investigated the prevalence of fatigue in RA patients as compared to cancer patients.

Methods: The RA study was based on a survey involving a representative, nationwide sample of German physicians specialized in RA and their patients [1]. The patient questionnaire included the EORTC measure of fatigue. Data of cancer patients were taken from the international psychometric validation study of the EORTC quality of life module measuring cancer related fatigue (EORTC QLQ-FA12). Thus, both studies used the same fatigue assessment, allowing for comparative analyses. The EORTC questionnaire assesses five components of fatigue: physical, emotional, cognitive, interference with daily life, and social sequelae. All scores are presented on a linear scale ranging from 0 to 100, with higher scores representing higher symptom burden.

Results: Data of 708 RA patients (Mean DAS28 2.77, SD 1.20, mean HAQ 0.75 SD 0.70) and 944 cancer patients were available for analysis. Based on clinical considerations with regard to the degree of fatigue, the cohort of cancer patients was divided into four groups: curative therapy (active treatment), palliative treatment, 3 year survivor, 5 years survivor.

N = 1652	Rheumatoid arthritis		Group A curative therapy		Group B palliative therapy		Group C 3 years survivors		Group D 5 years survivors	
	n = 708		n = 311		n = 222		n = 212		n = 199	
Age	M 59.5		M 59.5		M 61.5		M 57.6		M 58.3	
Gender	n	%	n	%	n	%	n	%	n	%
male	193	27.3	154	49.5	104	46.8	87	41.0	89	44.7
female	514	72.3	157	50.5	118	53.2	125	59.0	110	55.3
FA 1	M	95% CI	M	95% CI	M	95% CI	M	95% CI	M	95% CI
FA 2	44.4	42.3 - 46.5	34.5	31.4 - 37.6	45.9	42.5 - 49.3	33.9	30.4 - 37.4	30.7	26.9 - 34.4
FA 3	26.6	24.5 - 28.7	26.0	23.0 - 29.0	36.7	32.7 - 40.8	21.6	18.0 - 25.1	19.6	16.0 - 23.1
FA 4	11.0	9.5 - 12.4	11.5	9.3 - 13.8	17.0	14.0 - 20.1	13.9	10.8 - 17.0	12.9	9.9 - 15.9
FA 5	35.3	32.9 - 37.7	34.6	30.9 - 38.4	51.4	47.0 - 55.8	32.4	28.4 - 36.4	30.5	26.1 - 34.8
FA 5	20.2	17.9 - 22.6	9.8	7.5 - 12.1	10.8	7.6 - 13.9	15.2	11.6 - 18.7	13.5	9.8 - 17.1

FA 1 = physical Fatigue, FA 2 = emotional Fatigue, FA 3 = cognitive Fatigue, FA 4 = interference with daily life, FA 5 = social sequelae. High values in fatigue scores represent high symptom burden.

As shown in Table 1, RA patients suffered from a high level of physical fatigue (M = 44.4; CI 95% 42.3 - 46.5) that was almost identical to the value obtained in palliative care cancer patients. Furthermore, RA patients reported high burden with regard to social consequences (M = 20.2; CI 95% 17.9 - 22.6), more so than all groups of cancer patients (Ms ranging from 9.8 to 15.2). Multiple regression analyses indicated that sex and patient group were significant predictors of all five components of fatigue.

Conclusion: This study showed that RA patients suffer from a considerable level of fatigue that is comparable to cancer patients.

Characteristics and Symptom Severity in 21,101 Patients Reporting Systemic Lupus Erythematosus in the Patientslikeme Online Health Community

Elisabeth Nyman¹, Edward R. Hammond², Timothy Vaughan³, Barnabas Desta², Xia Wang², Volkan Barut⁴ and Cathy Emmas⁵, ¹Advanced Analytics Centre, AstraZeneca, Gothenburg, Sweden, ²AstraZeneca, Gaithersburg, MD, ³PatientsLikeMe, Boston, MA, ⁴Global Medical Affairs, AstraZeneca, Cambridge, United Kingdom, ⁵Patient Centricity, AstraZeneca, Cambridge, United Kingdom

Session Information

Session Date: Monday, October 22, 2018

Session Title: Patient Outcomes, Preferences, and Attitudes Poster I: Patient-Reported Outcomes

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Online health communities and research networks such as PatientsLikeMe (PLM) provide important insight into understanding chronic diseases, including systemic lupus erythematosus (SLE). We aimed to characterize PLM SLE population by their initial reported patient characteristics.

Methods: Retrospective observational study in PLM online health network. Patients were included in the study if they had registered with PLM between 2011-2017, were aged over 18 years at the time of registration, and reported both SLE and treatment with one or more SLE medications (anti-malarials, immunosuppressive, corticosteroids, calcineurin inhibitors and biologics). Information reported within 30 days of registration was used to assess eligibility and in descriptive analysis to characterize the demographic and clinical characteristics, co-morbidities, treatment of patients and the severity of symptoms they reported, both general (included in symptom panel for all PLM patients) and additional SLE symptoms.

Results: 21,101 patients met the inclusion criteria and were identified as patients with SLE. The median age at registration was 46 years (IQR 38-53), the majority were female (96.8%, N=21 050), and 94.8% (18,491) of the 19,502 patients who reported country were US residents. The 17,994 patients who recorded race were predominately Caucasian (67.8%) and African-American (22.4%). In the 6 489 patients who reported when they headfirst experienced SLE symptoms the median age of onset was 30 years (IQR 21-39) and age at first diagnosis was 36 years (IQR 27-44) (N=6 936). The most commonly

reported comorbidities were fibromyalgia 7.9%, discoid lupus 6.8%, lupus nephritis 6.3%, rheumatoid arthritis 4.8%, subacute cutaneous lupus 4.7%, Sjogren's Syndrome 3.9%, CNS lupus 3.9%, and lupus pneumonitis 3.1%. At registration patients reported having tried an average of 2.2 SLE medications, most commonly; anti-malarials 83.8%, corticosteroids 78.8%, immunosuppressive 32.3%, and biologic treatment 9.4%. Around 31% of patients (N=6,448) entered any symptom report at registration, and >80% of the patients who reported them rated the severity of fatigue, pain, and joint pain as moderate or severe (Table 1).

Table 1. Severity of symptoms in patients with SLE in PLM community

Symptoms	Severity n (%)				Total (N)
	None	Mild	Moderate	Severe	
General					
Fatigue	135 (2.1%)	832 (13.0%)	2665 (40.8%)	2815 (44.1%)	6387

Hair loss	361 (23.4%)	620 (40.2%)	403 (26.2%)	157 (10.2%)	1541
Muscle weakness	175 (11.7%)	423 (28.2%)	606 (40.5%)	294 (19.6%)	1498
Headaches	192 (19.3%)	327 (32.6%)	303 (30.2%)	181 (18.0%)	903
Raynauds	194 (47.7%)	111 (27.3%)	75 (18.4%)	27 (6.6%)	407

Conclusion: The age, gender and race of SLE patients in the PatientsLikeMe community are broadly consistent with what is known about the US SLE population. The PLM SLE population provides a unique source of real world information on the patient experience of symptoms of SLE outside the clinical environment that can be utilized to improve understanding of SLE.

Session Date: Monday, October 22, 2018

Session Title: Patient Outcomes, Preferences, and Attitudes Poster I: Patient-Reported Outcomes

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Health-related quality of life (HRQoL) is reduced in SLE. Depression is a possible contributor to reduced HRQoL. The relationship between major depression and HRQoL measured using NIH's Patient Reported Outcomes Measurement Information System (PROMIS) has not been well characterized.

Methods: Data were obtained from the California Lupus Epidemiology Study (CLUES), a cohort of adult patients in San Francisco County with physician-confirmed SLE. Subjects attended a research clinic encounter with a physician and completed a structured interview with a research assistant. The primary outcomes were T-scores on 13 PROMIS short forms (Table 1), scaled to a population mean of 50 and SD of 10. The primary predictor variable was major depression, defined as a score of 10 or greater on the Patient Health Questionnaire (PHQ-8) depression scale. Mean T-scores in depressed and non-depressed patients were compared using linear regression models with and without adjustment for age, sex, race/ethnicity, disease activity measured by the SLEDAI, BMI, and education less than high school graduate.

Table 1		Unadjusted Mean PROMIS T-Score			Adjusted* Mean PROMIS T-Score		
PROMIS Domain	N	No Depression [PHQ<10]	Depression [PHQ≥10]	p	No Depression [PHQ<10]	Depression [PHQ≥10]	p
Physical Health							
Physical Function	326	50.3	41.3	<0.001	49.8	42.6	<0.001
Pain Interference	323	58.4	60.0	<0.001	59.7	59.2	<0.001
Fatigue	323	48.4	63.6	<0.001	48.6	63.1	<0.001
Sleep Disturbance	323	50.1	59.2	<0.001	50.8	58.6	<0.001
Sleep Impairment	301	48.5	63.7	<0.001	49.7	63.1	<0.001
Mental Health							
Applied Cognitive Abilities	195	50.8	43.8	<0.001	50.1	43.4	<0.001
Applied Cognitive Concerns	119	54.7	46.2	<0.001	54.8	46.0	<0.001
Psychosocial Illness: Impact - Negative	169	49.8	60.1	<0.001	49.9	59.9	<0.001
Psychosocial Illness: Impact - Positive	267	50.4	41.3	<0.001	50.3	41.9	<0.001
Social Health							
Ability to Participate in Social Roles - Activities	186	53.3	43.8	<0.001	53.0	43.8	<0.001
Satisfaction, Discretionary Social Activities	301	55.9	43.6	<0.001	55.6	44.5	<0.001
Satisfaction, Social Roles	289	54.2	41.6	<0.001	53.8	42.6	<0.001
Social Isolation	296	43.7	54.3	<0.001	43.9	53.7	<0.001
SF-36[†] scores							
SF-36 Physical Component Score	324	45.4	34.6	<0.001	44.9	36.2	<0.001
SF-36 Mental Component Score	324	52.1	35.1	<0.001	52.2	37.9	<0.001

*PHQ = Patient Health Questionnaire

†SF-36 = Medical Outcomes Study Short Form

*Adjusted for age, sex, race/ethnicity, SLEDAI, SLICC, BMD, high school graduate

Results: 296 of 326 study participants met at least 4 of 11 ACR criteria for SLE, 20 met 3 ACR criteria and had SLE confirmed by a rheumatologist, and 10 had a diagnosis of lupus nephritis. Approximately 89% were female, 29% white, 23% Hispanic, 10% black, and 36% Asian. A quarter had a PHQ-8 score consistent with major depression. Depression was independently associated with worse mean T-scores on all 13 PROMIS short form domains tested ($p < 0.001$, Table 1). In multivariable analyses, depressed subjects scored more than 10 points (1 SD) worse on Fatigue, Sleep Impairment, Negative Psychosocial Impact of Illness, Applied Cognitive Concerns, Satisfaction in Discretionary Social Activities, and Satisfaction in Social Roles. Depressed patients also had worse scores on the Medical Outcomes Study Short Form (SF-36) Physical Component Summary and Mental Component Summary ($p < 0.001$).

Conclusion: Major depression was independently associated with substantially worse patient-reported outcomes on every tested PROMIS domain of physical, mental, and social health, as well as on SF-36 mental and physical subcomponents, even after adjusting for disease activity and sociodemographic characteristics. Assessment of comorbid major depression may be an important part of interpreting and targeting HRQoL in SLE patients when using PROMIS.

Session Date: Monday, October 22, 2018

Session Title: Patient Outcomes, Preferences, and Attitudes Poster I: Patient-Reported Outcomes

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Psoriatic arthritis (PsA) is a complex disease with high impact on quality of life (QoL). The PsA core domain set¹ includes pain, patient (pt) global assessment, physical function, QoL and fatigue. To evaluate the impact of PsA on health domains, a global survey was developed; we report results in the context of the PsA Impact of Disease (PsAID) questionnaire due to its high content validity for pts.²

Methods: A pt-based survey was conducted online from Nov 2 2017 to Mar 12 2018. Eligible pts (≥18 yrs) had PsA for >1 yr, had visited a rheumatologist/dermatologist in the past 12 months and reported using ≥1 synthetic/biologic DMARD for PsA. Pts reported current symptoms and impact of PsA on daily life. Post-survey, responses were aligned with PsAID health domains. Analyses included descriptive statistics and binomial tests.

Results: 1286 pts were surveyed across 8 countries; mean age 41 yrs, 52% female, 84% reported moderate/severe PsA. Pt-perceived PsA social and work impacts were reported by 1075 (84%) and 1035 (81%) pts; 56% stopped participating in certain sports/recreational activities and 42% reported decreased work productivity. The most commonly reported major/moderate impacts of PsA were on physical activity (78%), ability to perform activities (76%), and emotional/mental well-

	Global total ^a (n=1286)	Australia (n=152)	Brazil (n=152)	Canada (n=155)	France (n=124)	Spain (n=135)	Taiwan (n=109)	UK (n=159)	USA (n=101)

^aRaw data were not weighted at the individual country level. For the global total, a post-weight was applied to adjust for the relative size of each country's adult population within the total adult population across all countries surveyed. The unweighted sample sizes reflect the total number of pts who completed the survey, while all reported percentages are calculated based on the weighted global total.

^bHave you done any of the following as a result of PsA? Please select all that apply. Data shown here reflect a positive response to either the Social or Work impacts of PsA. Social impacts included emotional distress, stopping doing or participating in certain sports/recreational/social activities, experienced social shame or disapproval. Work impacts included sick days, decreased productivity at work, medical leave, quit or been let go from work, went on permanent disability, lost job.

^cHow much of a negative impact, if any, has PsA had on each of the following aspects of your life (slight/moderate/major)? Data represent sum of moderate/major impact.

^dSignificant difference (p<0.05) between countries indicated using log₁₀ odds ratio (Australia, b-Brazil, c-Canada, d-France, e-Spain, f-Taiwan, g-UK, h-USA).

being (69%). A greater proportion of pts in Brazil, France, Spain and UK reported negative impact on emotional well-being compared with Australia, Canada and Taiwan ($p < 0.05$; Table). Social impacts included emotional distress (58%), social shame or disapproval (32%), and ceased participation in social activities (45%). Most respondents (62%) reported a major/moderate impact on work productivity. A greater proportion of pts in Brazil, France and USA reported negative impact on work productivity compared with Canada, Spain and Taiwan ($p < 0.05$). Overall, 97% of pts reported musculoskeletal symptoms in the past year, most commonly joint pain, tenderness, swelling, stiffness or inflammatory back pain (IBP) (79%, 60%, 60%, 57%, 53%, respectively). Of these, joint pain and IBP were considered most bothersome (32%, 12% respectively), and 53% pts currently taking prescription medication reported joint pain. Skin/nail symptoms occurred in 80% of pts (skin patches/plaques, 58%; skin discomfort, 55%; nail changes, 34%) and unusual fatigue in 52% of pts.

Conclusion: All health domains that pts reported on were impacted by PsA in this survey aligning with life impact domains of the pt-derived PsAID questionnaire. Most pts reported an impact of PsA on social, work, and physical life aspects. These results highlight the impact of PsA on multiple health domains from a pt perspective that should be considered during shared decision-making processes between physicians and pts.

Session Information

Session Date: Monday, October 22, 2018

Session Title: Patient Outcomes, Preferences, and Attitudes Poster I: Patient-Reported Outcomes

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Treatment goals in psoriatic arthritis (PsA) are remission or low disease activity. We know little about whether these objectives correlate well with a patient-acceptable symptom state (PASS). To analyze the frequency of PASS in routine clinical practice, we used the Psoriatic Arthritis Impact of Diseases (PsAID) questionnaire proposed by EULAR.

Methods: Cross-sectional multicenter study including patients with PsA according to CASPAR criteria. Patients with at least one year of disease evolution and under treatment with synthetic (s) and / or biological DMARDs were included. The MDA, VLDA, DAPSA remission and clinical (c) DAPSA remission (without CRP) were measured as treatment targets. A PsAID value < 4 was defined as PASS. Factors associated with PASS were analyzed by uni and multivariate models.

Results: This study included 227 patients, 123 men and 104 women, with a mean age of 53.2 ± 12.4 years. The average duration of PsA was 9.6 ± 7.7 years. One hundred and thirty three (58.6%), 26 (11.5%), 52 (30.6%), 65 (36.9%) and 125 (55%) patients were in MDA, VLDA, DAPSA remission, cDAPSA remission, and PASS, respectively. Mean PsAID was significantly lower in patients reaching any of the treatment targets ($p < 0.0001$). Unadjusted associations with PASS ($p < 0.25$) were: age, BMI, level of education, work situation, smoking, debut pattern, DIP disease, family history of PsA, ischemic heart disease, obesity, CRP, NSAID use, corticoids use, structural damage in hands, and sindesmophytes. Involvement of DIP joints (OR 0.40, 95%CI: 0.20-0.79, $p = 0.009$), PsA family history (OR 0.25, 95%CI: 0.09-0.72, $p = 0.010$) and higher CRP values (0.92, 95% CI: 0.85-0.99), $p = 0.036$, decreased the odds of PASS in the multivariate model.

Conclusion: More than half of patients treated with systemic therapies under routine clinical practice reach a PASS status according to the PsAID. The involvement of DIP joints, higher CRP levels and PsA family history are associated with lower odds of achieving that status.

Decreased Injection Site Pain Associated with New Etanercept Formulation in Patients with Rheumatoid Arthritis or Psoriatic Arthritis

Stanley Cohen¹, Ahmed Samad², Elaine Karis², Bradley S. Stolshek², Mona Trivedi², Hao Zhang², Girish A. Aras², Greg Kricorian² and James Chung², ¹Metroplex Clinical Research Center, Dallas, TX, ²Amgen Inc., Thousand Oaks, CA

Session Information

Session Date: Monday, October 22, 2018

Session Title: Patient Outcomes, Preferences, and Attitudes Poster I: Patient-Reported Outcomes

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Injectionsite pain (ISP) is a component of the patient experience with injectable drugs. A new formulation of etanercept was developed to reduce ISP. In this work, we assessed ISP associated with a new formulation of etanercept compared to the prior formulation in patients with rheumatoid arthritis (RA) or psoriaticarthritis (PsA).

Methods: This phase 3b, randomized, double-blind, 2-period, 2-sequence crossover study (NCT02986139) enrolled etanercept-naïve patients with RA or PsA (inclusion based on the Classification criteria for Psoriatic Arthritis [CASPAR criteria]). The 2-week treatment period was followed by a 30-day safety follow-up. Patients were randomized 1:1 to prior formulation first followed by new formulation or new formulation first followed by prior formulation; administered 1 week apart, consistent with labeled dosing (50mg weekly). ISP was assessed within 30 seconds after administration and was measured using a validated ISP scale based on a visual analog scale ranging from 0 mm (no pain at all) to 100 mm (worst pain imaginable).

Results: Of 111 patients enrolled (56 prior 77.5%/new sequence; 55 new/prior sequence), 77.5% had RA, 22.5% had PsA. Of these, 104 patients received both doses. Overall, the mean change (least squares mean; 95% confidence interval [CI]) in ISP between prior and new formulations was 4.0 mm (0.03, 7.98) (Table). Patients with higher ISP scores from the prior formulation (by quartile cut points) had greater ISP improvements with the new formulation (Table, Figure). The reduction in ISP(95% CI) for those with prior formulation ISP scores above the arithmetic mean(23.6 mm) was 12.2 mm (3.1, 21.3) and for those below the mean was -0.9 mm(-3.9, 2.1). Injection site reactions were few in number and similar between formulations.

Conclusion: The new formulation of etanercept was associated with lower mean ISP compared to the prior formulation. Patients with higher levels of pain with the prior formulation showed greater pain reduction with the new formulation.

	n	Prior Formulation Mean ISP (mm)	New Formulation Mean ISP (mm)	Reduction in ISP Mean (95% CI) [%]	P-value
All patients	104	23.1	19.1	4.0 (0.03, 7.98) [17.3%]	0.048
Cut point analyses based on: Prior formulation ISP quartiles					
≥ 6 mm	79	30.8	24.5	6.2 (1.1, 11.3) [20.2%]	0.017
≥ 17.5 mm	52	43.4	33.9	9.5 (2.3, 16.8) [22.0%]	0.011
≥ 35 mm	27	58.0	40.8	17.2 (6.6, 27.8) [29.6%]	0.003
Prior formulation ISP mean					
≥ 23.6 mm	39	52.3	40.1	12.2 (3.1, 21.3) [23.3%]	0.01
< 23.6 mm	65	9.1	10.1	-0.9 (-3.9, 2.1) [-10.2%]	0.539

Session Information

Session Date: Monday, October 22, 2018

Session Title: Patient Outcomes, Preferences, and Attitudes Poster I: Patient-Reported Outcomes

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Fatigue is prevalent and important to people with psoriatic arthritis (PsA)¹. Women with PsA have worse symptom and life impact scores than men, including fatigue², and men are more likely to reach PsA remission³. We aimed to identify how patients experience fatigue in an international qualitative study conducted to identify PsA domains for clinical trials⁴. Prior research suggested possible differences in how men and women experience fatigue.

Methods: We conducted and audio-recorded focus groups (FG) in six countries (Australia, Brazil, France, Netherlands, Singapore, US) and in-depth interviews in the US with participants with PsA. Two bilingual moderators (native and English languages) facilitated each FG in the native language using broad areas of inquiry: experience of, and life changes since, diagnosis; disease activity; key PsA features; and medical care. Recordings were transcribed verbatim, translated into English, checked for accuracy, and imported into Atlas.ti qualitative software. Two qualitative researchers coded each transcript independently using an iterative comparative process. Codes were reconciled and organized into themes. In analyzing fatigue, we considered variability by participant category (men/women).

Results: There were 16 FG with 2-9 participants each and 90 participants in total; and 25 in-depth interviews (Table1). We identified the following themes that describe the experience of fatigue for patients with PsA: 1) intersection of PsA disease activity and fatigue, 2) fatigue meaning and explanatory theories, 3) attitudes and communication about fatigue, 4) strategies people use when living with fatigue, and 5) feelings associated with fatigue. We found differences between men and women especially for attitudes and communication, and feelings/emotional impact associated with fatigue. Women

were more likely to discuss sharing their fatigue experience and relying on close relationships for support. Men were more likely to describe seeking control and not communicating their fatigue. Both men and women reported associating fatigue with negative attitudes (Table2).

Conclusion: The experience of fatigue in PsA is diverse and there are variations between men and women. Fatigue impacts what people do, how they communicate and how they feel. This has implications for fatigue assessment and treatment in PsA. Patients may benefit from provider validation of their fatigue and from individualized treatment strategies.

Table 2. Illustrative quotes for each theme from participants with psoriatic arthritis

Themes	Representative quotes
1. Intersection of PsA disease activity and fatigue	<i>I am still wondering whether fatigue, which already played a role for a long time in my life, has anything to do with it. Maybe that is linked to [PsA] while I also have linked it to the way I cope with stress. (M2.3, Netherlands)</i> <i>Fatigue, in the morning, when I was suffering the most, it would take me a long time even to think about getting out of bed, and it is not just the stiffness, it is just absolute tiredness. It is not about strength, it is about just feeling really, really, tired, physically unable to roll out of bed. (W1.1, Singapore)</i> <i>I think it was just a real fatigue syndrome, because I got stiff, I got sore, I stopped pretty much all physical activity, I was just going through the motion of getting through all that I had to do in a day. But there was nothing, there was no recreational joy or release. I was just miserable. (W22, US)</i>
2. Fatigue meaning and explanatory theories	<i>For me, it is the illness that is wearing me out. (W1.3, France)</i> <i>When I first fell ill, my medication indeed made me extremely tired. Nowadays this is not so much the case anymore. (M1.3, France)</i> <i>Not really pain but I do not have much energy, I feel a bit weak. If I did not take my medicine. Pain for me is not so much. (M2.1, Singapore)</i>
3. Attitudes and communication about fatigue	<i>You cannot show your fatigue to others, you need to support your family. (W2.2, France)</i> <i>None of my co-workers are aware of my illness. [...] Chances are that the people around you will think that they cannot rely on you. [...] I do not want them to judge me as an unable-bodied person. When the fatigue kicks in, I take a short leave of absence. (M1.1, France)</i> <i>I do not allow myself to be tired. I have pain, not always, especially in the hands. That restricts me somehow. (M2.1 Netherlands)</i> <i>I am functional, and I do not want to admit that I have fatigue with anybody, but sometimes I get tired, I just want to take a nap. (M1.1 US)</i>
4. Strategies people use when living with fatigue	<i>If you have a dinner party, you are going to have 3 days to recover. Therefore, you just cannot be bothered. (W1.2, Australia)</i> <i>When I am very tired then I just go and lie in bed for an hour. Then I can do something again. I just need to go flat for a moment and then I take another pain reliever and then, everything just must go on. That seems to be going well. (M2.2, Netherlands)</i> <i>I don't feel like going out at all, my wife, let's go out for lunch or meal, I said I'm sorry, I'm not joining you all, but somehow, I am able to go to church in the morning. After that, when I come back home, I will not go out again. (M1.1, Singapore)</i>
5. Feelings associated with fatigue	<i>At times I cry because I want to do things, I am used to doing my housework. I do it, but it is not like it was before, it wears me out a lot, I get tired. (W2.1, Brazil)</i> <i>I had to stop completely all my sports activities to ensure saving my energy level for my job. [...] You develop a feeling as if... you feel incapacitated. You try to hang on to your essential daily routines. You really have to fight for it. (W2.2, France)</i> <i>I also think that you become frustrated, stressed out because of your fatigue. (W1.2, Netherlands)</i> <i>For me it is the fatigue and the pain that make me depressed. (W1.1, Singapore)</i>

Development and Pilot of a Patient Satisfaction Scale in Rheumatology

Antonia Valenzuela¹, Khushboo Sheth², Stanford Shoor², Philip L. Ritter² and Kate Lorig³, ¹Immunology and Rheumatology, Stanford University, Palo Alto, CA, ²Immunology & Rheumatology, Stanford University, Palo Alto, CA, ³Stanford University, Palo Alto, CA

Session Information

Session Date: Monday, October 22, 2018

Session Title: Patient Outcomes, Preferences, and Attitudes Poster I: Patient-Reported Outcomes

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Patient satisfaction has been studied as a performance improvement measure in clinical practice among patients with a variety of diseases, but to date there are no validated scales that evaluates it in rheumatic diseases. As part of the Patient Centered Care project in the Rheumatology Division, we developed and piloted a simple questionnaire to study patient satisfaction with the care they receive for their arthritis.

Methods: We developed a 12-item scale, and tested it on 70 patients in the Rheumatology clinic at Stanford University Hospital and Clinics. Based on these responses, we subsequently tested a revised 10-item scale (5 items targeting helpfulness of rheumatology team, and 5 items targeting satisfaction) on a national self-selected sample of 130 arthritis patients. Demographic data were collected including age, gender, race and ethnicity, country of origin, years of education, and perception on rheumatology team members. Following psychometric analysis of this larger sample, we developed a shorter and reliable six-item patient satisfaction scale.

Results: Our sample (N=130) characteristics included 94% female, 88.4% self-identified as Caucasian, 3.9% Asian, 6.2% Black/African-American and 8.7% Hispanic/Latino ethnicity. Majority of patients (44.6%) were 60-69 years old, and 41.5% had a College degree. 37.7% identified a rheumatologist as part of their rheumatology team, whereas 39.2% mentioned other (e.g. PCP), 13.1% were not sure of the composition of their team, and only 10% mentioned their medical assistant. In addition, 82.9% identified themselves as part of their rheumatology team. 38.5% were seeing a rheumatologist. For the final scale development, we included only items with correlations below 0.9 to reduce redundancy in items. The final scale included 6 items (Table 1). Reliability of the final scale was very high; coefficient Alpha was 0.94 (raw) and 0.95 (standardized). Based on the results of this survey, mean patients satisfaction factor was 6.1 ± 2.7 . Item scale correlations ranged from 0.60 to 0.87. The only demographic variable found to be correlated with satisfaction was identifying a rheumatologist as part of the rheumatology team (correlation 0.37 ± 0.5 , p -value $< .0001$).

Conclusion: A simple and practical questionnaire to measure patient satisfaction with their rheumatology care was developed and piloted on 130 patients. This is a condition-specific scale, which may be useful in determining satisfaction with specific practices and possibly physicians.

Table 1. Items included in final rheumatology patient satisfaction scale

On a scale from 1 to 10, how satisfied are you with how your arthritis team works with you to:

1. Know more about your arthritis
2. Get to see your team when you feel you need to see them
3. Solve problems related to my arthritis
4. Set goals for the treatment of my arthritis
5. Manage your emotions related to arthritis
6. Decide when I need to make an office visit for my arthritis

Could the Shortening of the Electronic Osteoarthritis Knee and Hip Quality of Life (OAKHQOL) Questionnaire Improve Its Metric Properties?

Maud Wiecezorek¹, Christine Rotonda¹, Jonathan Epstein^{1,2}, Francis Guillemin^{1,2} and Anne-Christine Rat^{1,3}, ¹Université de Lorraine, EA4360, APEMAC, Nancy, France, ²Inserm, CIC-1433 Epidémiologie Clinique, Vandoeuvre-lès-Nancy, France, ³Rheumatology Department, CHRU Nancy, Vandoeuvre-lès-Nancy, France

Session Information

Session Date: Monday, October 22, 2018

Session Title: Patient Outcomes, Preferences, and Attitudes Poster I: Patient-Reported Outcomes

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The aim of this study was to assess the validity of a short version of the electronic OAKHQOL questionnaire in a combined analysis with classical test theory (CTT) and a Rasch measurement model for item response theory.

Methods: Patients with knee osteoarthritis (ACR criteria) were consecutively recruited by their general practitioners. They responded to the electronic version of the OAKHQOL questionnaire, called e-OAKHQOL¹. It contains 43 items and describes health-related quality of life (HRQoL) in 5 dimensions: physical activity, mental health, pain, social functioning and social support. Each total score is normalized to a score from 0 (worst HRQoL) to 100 (best HRQoL). A shortened version of the OAKHQOL has been developed, the mini-OAKHQOL. It retains 20 items of the original instrument and maintains the same structure with five dimensions. The scoring method was kept as the original, for items and dimensions. For the present study, only items of the e-OAKHQOL retained in the mini-OAKHQOL were included in the statistical analysis. Metric properties were assessed by the CTT approach and a Rasch measurement model (partial credit model).

Results: The confirmatory factor analysis showed that the five-factor model best fitted the data (RMSEA= 0.067 (90% confidence interval: 0.059-0.075), CFI=0.94, TLI=0.93). Cronbach's alpha coefficients were good to excellent for four of the five subscales. As expected, discrimination was good for the physical activity and the pain dimensions. In Rasch analysis, one item ("Staying for a long time in the same position") showed underfit (item not discriminative enough). A lack of fit to the model was observed for the social support and the social functioning dimensions (significant item-trait interaction). Internal consistency was excellent for the physical activity (Person Separation Index (PSI) = 0.92) and pain (PSI = 0.84) dimensions but were less than 0.80 for the other dimensions. Examination of person-item threshold distribution map demonstrated good targeting between persons and items in the physical activity and the pain dimensions while it was fairly good in the three other dimensions. No statistical differential item functioning was detected for all 5 dimensions by gender, age, educational level, low-back pain or body mass index.

Conclusion: Analysis with CTT and Rasch measurement of the mini e-OAKHQOL questionnaire revealed the good measurement properties of the 5 dimensions of the questionnaire. The shortening of the e-OAKHQOL has considerably improved its structural properties. However, some shortcomings remain such as item-trait interaction. Further research is needed to confirm or refute these findings in an independent sample.

Session Information

Session Date: Monday, October 22, 2018

Session Title: Patient Outcomes, Preferences, and Attitudes Poster I: Patient-Reported Outcomes

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: To analyze variables associated with evolution of disease-specific health related quality of life (HRQoL) in systemic lupus erythematosus (SLE) patients.

Methods: We conducted a prospective longitudinal multicenter French cohort of SLE patients followed over 2 years. All patients fulfilled ACR 1997 SLE criteria. Disease-specific HRQoL was evaluated using Lupus Quality of Life (LupusQoL) and Systemic Lupus Erythematosus Quality of Life (SLEQOL) every 3 months. Domain scores were rescaled from 0 to 100 (best HRQOL). Disease Activity (DA) and flare were recorded every six months utilizing SELENA-SLEDAI, SELENA-SLEDAI Flare Index (SFI) and revised SELENA-SLEDAI Flare Index (SFI-R). Each SLEQOL and LupusQoL domains' scores evolution were explained by fitting a multivariate linear mixed model. For each independent variable, interaction with time was tested to see if was linked with a greater decline in HRQOL. Social deprivation is defined it as an unstable state concerning one or more basic securities (a job, health, family status) that prevented people from enjoying fundamental rights and that could lead to poverty. It was identified as having an EPICES score greater than 30.

Results: Between December 2011 and July 2015, 336 patients were included (89.9% female). Mean (SD) SELENA-SLEDAI was 3.9(4.3). Twenty-two percent were taking immunosuppressive drugs. Each HRQoL domain was significantly impaired in patients with a poor social deprivation status (mean difference in HRQoL score ranging from -9 to -15, $p<0.01$ in all domains). Social deprivation was also associated with a greater decline in HRQOL scores across visits in two domains: LupusQoL Physical Health (p for interaction with time $p=0.03$) and fatigue (p for interaction with time: $p=0.02$). SFI flares were significantly associated with a decrease in the following domains of LupusQoL Pain, Planning, Emotional Health and Burden to Others) and SLEQOL (Physical Functioning, Symptoms and Mood; $p<0.05$) SFI-R musculo-skeletal flares resulted in a significant decrease in all domains of the SLEQOL and LupusQoL (mean difference ranging from -5 to -15 points difference with $p<0.01$), interaction with time being significant in the LupusQoL Pain (-0.5 every 3 months, $p=0.03$) and SLEQOL Social Activities domain scores (-0.6 every 3 months, $p<0.01$). Corticosteroids daily dosage >10 mg was associated with significant decrease of the Body Image LupusQoL score: -6 ($p<0.05$) without time interaction.

Conclusion: Variation in disease activity, according to SFI and SFI-R, is associated with specific HRQoL evolution, independently of patient's other characteristics. musculoskeletal flares negatively impacted both disease specific HRQoL tools in SLE. Socio-economic status is a major risk factor of HRQoL decline for SLE patients and thereby should be recorded to allow a correct interpretation of HRQoL, and to identify those at risk, so that appropriate interventions can be targeted to those at risk.

Session Information

Session Date: Monday, October 22, 2018

Session Title: Patient Outcomes, Preferences, and Attitudes Poster I: Patient-Reported Outcomes

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: To explore, at an item-level, the effect of disease activity (DA) on disease specific health related quality of life (HRQoL) factors in systemic lupus erythematosus (SLE) patients using an item response theory (IRT) longitudinal model.

Methods: This prospective longitudinal multicenter French cohort followed SLE patients over 2 years. All patients fulfilled ACR 1997 SLE criteria. Disease specific HRQoL according to LupusQoL and SLEQOL was collected every 3 months. DA according to SELENA-SLEDAI, and flare assessment according to SELENA-SLEDAI Flare Index (SFI) and organ-based revised ELENA-SLEDAI Flare Index (SFI-R) was evaluated every 6 months. Response to SLEQOL and LupusQoL items were compared between remitting and non-flaring patients, in the 18 months following a flare, using an IRT approach fitting a linear logistic model with relaxed assumptions for each dimension of the questionnaires. Parameters estimations for an item are interpreted as a difference in improvement measured by a given item according to QoL in given domain resulting in being remitting from a flare compared to patients with no flare. A parameter is considered statistically significant when different from 0 according to its 95% confidence interval.

Results: Between December 2011 and July 2015, 336 patients were included (89.9% female). Mean (SD) SELENA-SLEDAI score was 3.9(4.3). twenty-two percent were taking immunosuppressive drugs. Among patients remitting from an SFI-R musculoskeletal flare (image 1), remission led to significant improvement in HRQoL among items of LupusQoL in the physical health and pain domains (going to the market, pain interference with the quality of sleep), and SLEQOL physical functioning, symptoms and treatment domains (walking 3 km, joint pain, fear of needles, inconvenience of clinic visits). SFI-R Cutaneous flares impacted items related to self-image issues and intimate relationships (anxiousness, attractiveness linked to skin rashes, being less interested in sex or sexual relationship). Patients HRQoL remained adversely impacted up to 18 months after a flare. LupusQoL Item "weight gain due to treatment" was negatively impacted after an osteoarticular flare.

Conclusion: IRT analyses pinpoint HRQoL items most important to patients in specific situations. LupusQoL and SLEQOL items related to physical HRQoL (physical health, physical functioning and pain domains) were most influenced by musculoskeletal or cutaneous flares.

Image 1 : summary of significant HRQoL changes in remitting patients compared with non-flaring patients for one item with both modeling features (a model estimating variations between time points - baseline to 6, then to 12 and to 18 months - and a model considering a constant amount of change between time points).

LupusQoL Domain	Impacted item	Flare involved	HRQoL changes of remitting patients regarding non-flaring ones
Physical health	2 - need help to do moderate physical jobs	Renal	↑
	3 - need help to do light physical jobs	Constitutional symptoms	↑
	7 - going to the market	Orthopaedic	↑
Pain	9 - prevented from performing activities like I would due to pain	Cutaneous	↑
	10 - the pain I experience interferes with the quality of my sleep	Orthopaedic Cutaneous	↑
	11 - the pain due to my lupus is so severe that it limits my mobility	Cutaneous	↑
Planning	14 - commitment issues	Constitutional symptoms	↑
Intimate relationship	15 - less interested in sexual relationship due to pain	Cutaneous	↑
	16 - not interested in sex because of my lupus	Cutaneous	↑
Burden to others	17 - concern that my lupus is stressful for those closer to me	Constitutional symptoms	↑
Emotional health	23 - my lupus make me anxious	Cutaneous	↑
Body image	27 - my appearance makes me avoid social situations	Neurological or psychiatric	↓
	28 - lupus related skin rashes make me feel less attractive	Cutaneous	↑
	29 - The hair loss I have experienced makes me feel less attractive	Renal	↑
	30 - weight gain due to my treatment makes me feel less attractive	SFI Orthopaedic	↓
Fatigue	33 - I need to have early nights	Neurological or psychiatric	↑
STARQoL domain			
Physical functioning	1 - walking outdoors on level ground	Cutaneous	↑
	2 - Shopping	SFI	↑
	4 - Going to the market	SFI	↑
	6 - walking 3 km	Orthopaedic Cutaneous	↑
Activities	9 - missed work or school	Renal	↑
	11 - sports	SFI	↓
	12 - sex	Constitutional symptoms	↑
	13 - difficult social activities	Renal	↑
Symptoms	17 - loss of appetite	Renal	↑
	22 - sore skin	Cutaneous	↑
	23 - joint pain	Orthopaedic Cutaneous	↑
Treatment	24 - fear of needles	Orthopaedic	↑
	27 - inconvenience of clinic visits	Orthopaedic	↑
Mood	29 - feeling low	Neurological or psychiatric	↑
	30 - depression	Neurological or psychiatric	↑
	31 - anxiety	Neurological or psychiatric	↑
Self-image	37 - trouble because of concern medicines don't	SFI	↑
	40 - consuming more alcohol or tobacco	Cutaneous	↑

Legend for image 1

- ↑ Significant HRQoL improvement of remission patients compared to non-flaring patients present with both IJRA modelling features (following estimator' variations between time points (baseline to 6, then to 12 and to 18 months) and model considering a constant amount of change between time points)
- ↓ Significant HRQoL deterioration of remission patients compared to non-flaring patients present with both IJRA modelling features

Session Information

Session Date: Monday, October 22, 2018

Session Title: Patient Outcomes, Preferences, and Attitudes Poster I: Patient-Reported Outcomes

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: There is suboptimal reporting of adverse events (AE) in trials. The OMERACT Safety Working Group is developing a patient-centered AE collection and reporting approach to complement existing methods. Our initial goal was to hear from inflammatory arthritis (IA) patients about their perspectives on the benefit-harm balance of DMARDs.

Methods: Using an interview schedule, experienced interviewers conducted focus groups with IA patients in the US (n=14), Canada (n=10), and Australia (n=15) that were recorded, transcribed, and analyzed using a pragmatic thematic analysis approach based in grounded theory.

Results: Almost all patients reported AE ranging from mild to severe. The majority learn to live with AE, but some lives were completely changed.

"It was like I was domiciled on the toilet. . . I couldn't go anywhere because you never knew when you needed a toilet." (M 60s, CA)

"I'm on MTX and I'm finally friends with it. It took 2 years. . . I feel normal. . . except med day. . . But I'm happy to give up half a day. . . to have my life." (F 20s, USA)

Many patients reported making adjustments to diet, sleep, and lifestyle to address AEs. Patients used different complementary and alternative approaches to self-manage their AEs but continued to live with ongoing disruption of function, self-confidence, work, and social roles due to AE.

"I feel like I can't think anymore, and that really affects my work. And that's my biggest problem. I can push through the pain and. . . fatigue, but I can't think clearly. I just can't do my job." (F 30s USA)

The cumulative burden of AEs often led to patient-initiated discontinuation.

"I would open the fridge and look at the little brown envelope that the syringes were in. The nausea would start just looking at the envelope. . . I took it for a few more years, but I just couldn't stand it anymore. It's just like, get me off of this stuff." (M 70s CA)

Underreporting was common due to embarrassment and uncertainty whether and how to discuss AEs. Providers were often perceived to react with disinterest, minimization, or irritation. Long-term safety was less concerning to patients with longer IA duration who had more symptoms and decreased function but greater treatment benefits despite repeated drug failures and serious AE.

Conclusion: The prevalence and importance of AEs, especially "nuisance AEs" is viewed differently by patients and clinicians. AEs negatively impacted function, participation, and QOL. Acceptability, tolerability and self-management of SEs varied among patients, by drug type and life stage, and in response to disrupted social and work roles. Patients learned to underreport SE when they perceived disinterest/minimization by clinicians.

Assessing a Conceptual Framework of Quality of Life in a Cutaneous Lupus Erythematosus Population

Motolani E. Ogunsanya¹, Andrew Hudson², Rebecca Vasquez³ and Benjamin F. Chong³, ¹College of Pharmacy, University of Oklahoma Health Sciences Center, Oklahoma City, OK, ²Texas Tech University Health Sciences Center, Lubbock, TX, ³Dermatology, University of Texas Southwestern Medical Center, Dallas, TX

Session Information

Session Date: Monday, October 22, 2018

Session Title: Patient Outcomes, Preferences, and Attitudes Poster I: Patient-Reported Outcomes

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: In order to better discern medication efficacy for CLE, a better understanding of CLE's impact on quality of life (QoL) in individuals with CLE is required. Further, the use of a theoretical framework allows for the development, validation, and eventual use of patient-reported outcome measures that identify empirical factors significantly impacting QoL of patients with CLE. Thus, the purpose of this study was to examine multiple factors associated with CLE that affect QoL, using the Revised Wilson and Cleary's Model (WCM) for QoL. The WCM is a disease-based, physiological framework that links biological and physiological factors, symptoms status, functioning, general health perceptions, individual and environmental characteristics, and overall QoL.

Methods: A cross-sectional, correlational study was conducted in 101 CLE patients recruited from an outpatient university-based dermatology clinic in Dallas, Texas. Demographic, clinical characteristics, and QoL data were collected from patients. Descriptive statistics were calculated, and multiple regression was employed to determine significant ($p < 0.05$) predictors of overall QoL. Data were analyzed using SPSS v24.

Results: The overall QoL - CLEQoL regression model was significantly different from zero, $F=24.96$; $df=14, 76$; $p < 0.001$. Approximately 85 percent of the variation in overall QoL ($R^2=0.85$) was accounted for by predictor variables within the WCM model, where the adjusted R^2 was 82 percent ($R^2=0.82$). Disease activity ($\beta=0.13$, $p=0.027$), fatigue ($\beta=0.24$, $p=0.002$), and body image ($\beta=0.62$, $p < 0.001$) were significant, positive predictors of overall QoL while controlling for other predictor variables ($\beta=0.19$, $p=0.03$). Pain ($\beta=-0.23$, $p=0.019$) and side-effects ($\beta=-0.13$, $p=0.041$) were negative predictors of overall QoL. Patients who experienced higher levels of disease activity, higher fatigue severity, and greater degree of body dissatisfaction had significantly poorer QoL. Lower pain intensity and fewer side effects experienced from CLE medications were significantly associated with higher QoL.

Conclusion: Hence, in addition to performing thorough skin exams, asking patients about symptoms, body perception, and medication toxicities can aid providers in better understanding CLE's impact on patients' QoL. Using a theoretical framework, patient-centered and clinical outcomes were integrated to facilitate a fuller understanding of the several factors impacting QoL in CLE patients. As such, future studies aimed at understanding QoL in CLE patients can consider using a theoretical framework as healthcare becomes more patient-centered.

Session Date: Monday, October 22, 2018

Session Title: Patient Outcomes, Preferences, and Attitudes Poster I: Patient-Reported Outcomes

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: To investigate the effects of cSLE on education, vocation and employment in a large cohort of adults with cSLE.

Methods: Patients were seen by the CHILL-NL (CHILdhood Lupus in the NetherLands) study team for a single study visit containing a structured history and physical examination. Medical records were retrieved to supplement the information obtained during the study visit. Education and employment status were assessed by structured and/or validated questionnaires. Health-related quality of life (HRQOL) was measured with the SF36.

Results: 106 cSLE patients (93% female, 73% white) were included with median disease duration of 20 years. Almost all patents stated that the disease had influenced their education but level of completed education was higher than the general Dutch population. Half of patients had adjusted their vocational choice due to the disease but still 44% of patients who had finished education did not have a paid job. Of the employed patients, the majority (61%) worked part-time. Disease damage was more prevalent in the patients without paid employment. A high percentage of patients (51%) were declared work disabled and this was related to damage, specifically neuropsychiatric damage. Not having paid employment and work disability were closely related and both had a clear negative influence on HRQOL.

Conclusion: The effect of cSLE on academic achievements and employment is substantial, despite adjusting educational and vocational choices to the disease. Ongoing support, not only to help patients find suitable education and vocation, but also to offer guidance regarding potential adjustments during their career, is necessary to optimise participation in the community.

Session Date: Monday, October 22, 2018

Session Title: Patient Outcomes, Preferences, and Attitudes Poster I: Patient-Reported Outcomes

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Pain and fatigue are common symptoms for patients with rheumatoid arthritis (RA). JAK inhibitors (JAKi) already proved similar efficacy on disease activity as bDMARD (anti-TNF, anti-IL6, abatacept and rituximab). Moreover, some trials suggest that JAKi may have a supplementary interest on the patient's reported outcomes (PRO). Based on a systematic review of the literature, our goal was to determine the impact of each treatment on the pain and fatigue.

Figure 1. Improvement of pain with bDMARDs (1a) and with JAKi (1b)

Figure 2. Improvement of fatigue (FACIT) with bDMARDs (2a) and JAKi (2b).

Methods: We screened the literature for clinical trial comparing biological DMARDs or one of the JAKi to placebo for pain and/or fatigue, using PubMed , Cochrane Library, Embase. For JAKi, we restricted our investigation to baricitinib and tofacitinib that are registered by the FDA and the EMA in RA treatment. Among 1488 articles initially identified, 33 randomized controlled trials evaluated pain VAS and 17 investigated fatigue using the FACIT-F score were selected. Data was extracted independently by two authors. For each study, we calculated the change of VAS pain and FACIT between baseline and study endpoint for the DMARDs and the placebo. Meta-analyses were performed to estimate pooled mean difference (MD) with their 95% confidence interval using the inverse variance approach. Heterogeneity was assessed (Cochran's Q-test and I^2).

Results: The result of pain improvement with all bDMARDs versus Placebo is MD:-12,94 (IC95% (-15,32; -10,57); $I^2=79\%$). In subgroup analysis, for antiTNFs MD: -13.97 (IC95% (-15,92; -12,02); $I^2=30\%$), for anti-IL6 MD:-8,81(IC95% (-14,54;-3,08); $I^2=86\%$), for AbataceptMD: -12,27 (IC95% (-18,90; -5,63); $I^2=83\%$) and for Rituximab MD:-17,87 (IC95% (-23,85; -11,9); $I^2=82\%$). For the JAKi, improvement of pain is MD: -13,81 (IC95% (-16,46 ; -11,16); $I^2=70\%$)(figure 1).

Fatigue improvement with bDMARDs versus Placebo is MD: 3,92 (IC95% (3,27; 4,57); $I^2=63\%$). In subgroup analysis, for antiTNFs MD: 3,73 (IC95% (2,80;4,66); $I^2=26\%$), for anti-IL6MD: 3,4 (IC95% (3,33; 3,47); $I^2=0\%$), and for Rituximab MD: 6,01(IC95% (0,96; 11,05) $I^2=94\%$). For the JAKi, MD: 4,13 (IC95% (3,37; 4,88); $I^2=48\%$) (figure 2).

Conclusion: Our results indicate that the impact of JAKi on pain and fatigue is not significantly different than biologic DMARDs, at least during the short and middle term corresponding to the duration of clinical trials.

Session Information

Session Date: Monday, October 22, 2018

Session Title: Patient Outcomes, Preferences, and Attitudes Poster I: Patient-Reported Outcomes

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Juvenile Myositis (JM) is an autoimmune disease that negatively impacts quality of life (QoL) outcomes via muscle weakness and vasculopathic rashes. The relative contribution of pain, fatigue, and emotional distress to QoL in JM is incompletely understood. In this cross-sectional study, we assessed the relationships of pain, fatigue and emotional distress to QoL in JM.

Methods: JM patient-parent dyads (5-17 yo) were enrolled at routine visits. Descriptive statistics were calculated for demographic and clinical variables. Generic QoL was measured by PedsQL Generic Core Scales (PedsQL-GC) self-report (8-17yo) and parent-proxy report(5-17yo), while Patient-Reported Outcomes Measurement Information System (PROMIS) patient (8-17yo) and parent-proxy (5-17yo) fixed short forms were used to assess depressive symptoms, anxiety, fatigue, and pain interference. Since PedsQL-GC were not normally distributed, multivariable quantile regression was performed with PROMIS domains on the median PedsQL-GC measures.

Results: Seventy-five JM patient-parent dyads were enrolled, with typical demographic features (n =71 [94.7%] with dermatomyositis, n = 59 [78.7%]female, n = 59 [78.7%] white, median age = 11.7 yo [IQR:8.1-14.3]). Descriptive statistics for clinical/patient-reported outcome variables are shown in Table 1. Patient PROMIS Fatigue was significantly associated with PedsQL-GC Physical and Psychological scores across most quartiles. Parent-proxy PROMIS Fatigue was significantly associated with PedsQL-GC Physical scores across all quartiles, but this relationship was not as consistent for PedsQL-GC Psychological scores. While patient/parent-proxy PROMIS Depressive Symptoms, Anxiety, and Pain Interference were significantly associated with most PedsQL-GC Physical and Psychological score quartiles in univariable models (not shown), these relationships did not persist in multivariable models. Table 2 displays statistically significant multivariable quantile regression results.

Conclusion: Our findings demonstrate a uniquely strong relationship between fatigue and physical QoL as measured by both patients and parents. Patient and parent perceptions differed with regards to the relationship of fatigue to psychological QoL, reinforcing the need for both respondents to be engaged. The relationship between disease activity, treatments, fatigue, and QoL warrants further study, as fatigue may be an important target for interventions to improve QoL.

Estimates of Minimally Important Differences and Patient Acceptable Symptom State in Five Patient-Reported Outcomes Measurement Information System Short-Forms Among Individuals with SLE

Patricia Katz^{1,2}, Evo Alemao³, Jayanti Mukherjee³ and Kaleb Michaud^{2,4}, ¹Forward/National Data Bank for Rheumatic Diseases, Wichita, KS, ²University of California San Francisco, San Francisco, CA, ³Bristol-Myers Squibb, Princeton, NJ, ⁴Rheumatology, University of Nebraska Medical Center, Omaha, NE

Session Information

Session Date: Monday, October 22, 2018

Session Title: Patient Outcomes, Preferences, and Attitudes Poster I: Patient-Reported Outcomes

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: As the NIH PROMIS (Patient-Reported Outcomes Measurement Information System) measures are used more widely, information is needed to enhance interpretation. Minimally important differences (MIDs; estimate of clinical significance of change; “feeling better/worse”) and patient acceptable symptom state (PASS; state at which patients consider symptoms to be acceptable; “feeling good”) are important components in interpretation. We estimated MIDs and PASS for five PROMIS domains in SLE.

Methods: Data were from the Forward/National Data Bank for Rheumatic Diseases. Participants complete questionnaires every 6 months. In July 2015 to July 2017 (five administrations), 4-item short-forms for 5 PROMIS domains were added: Physical Function, Fatigue, Sleep Disturbance, Pain Interference and Satisfaction with Social Roles. PROMIS scales were scored to derive T-scores scaled to population means of 50 and SD of 10. Changes were calculated for consecutive administrations, yielding 4 change periods. MID estimates were calculated using both anchor- and distribution-based methods.¹ Anchors were comparisons of each domain and overall health to 6 months before (rated as much better, somewhat better, neither better nor worse, somewhat worse, much worse).² Domain-specific comparisons (e.g., “compared to 6 months ago, is your fatigue now...?”) were asked only once; overall health comparisons were asked in all questionnaires. PASS was estimated as the 75th percentile positive score of those who stated their current health was acceptable.³

Results: The number of respondents ranged from 389 – 462 in the 5 administrations. Table 1 shows characteristics of respondents from one administration. Tables 2 and 3 show MID and PASS estimates, respectively.

Conclusion: MIDs for PROMIS scales in SLE appear to be similar to those reported elsewhere (± 2 points).⁴ PASS estimates have not been examined previously for PROMIS. PASS estimates for PROMIS T-scores are 0.5 to 1 standard deviation better than the population mean of 50. Such information will improve interpretation of PROMIS scores and changes in those scores.

Responsiveness of Promis (Patient Reported Outcomes Measurement Information System) Measures in a Multi-Racial, Multi-Ethnic Systemic Lupus Erythematosus (SLE) Cohort

Patricia Katz¹, Stephanie Rush², Jinoos Yazdany³, Laura Trupin¹, Louise Murphy⁴, Cristina Lanata¹, Lindsey A. Criswell¹ and Maria Dall’Era³, ¹University of California San Francisco, San Francisco, CA, ²Medicine/Rheumatology, University of California San Francisco, San Francisco, CA, ³University of California, San Francisco, San Francisco, CA, ⁴Arthritis Program, Centers for Disease Control and Prevention, Atlanta, GA

Session Information

Session Date: Monday, October 22, 2018

Session Title: Patient Outcomes, Preferences, and Attitudes Poster I: Patient-Reported Outcomes

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Recent studies have demonstrated the reliability and validity of the NIH PROMIS (Patient-Reported Outcomes Measurement Information System) measures in SLE. Analyses of their responsiveness to changes in SLE disease and health status have not yet been reported.

Methods: Data were from the California Lupus Epidemiology Study (CLUES), a population-based, multi-ethnic cohort with physician-confirmed SLE. Subjects participated in structured interviews in English, Spanish, Mandarin, or Cantonese. Follow-up (FU) interviews were conducted an average of 12.8 months after baseline. Eight PROMIS short-forms (Tables) were administered and scored to derive T-scores scaled to population means of 50 and SD of 10. Race and ethnicity were self-reported. To determine the PROMIS measures' responsiveness to change, we examined whether PROMIS score changes occurred in the appropriate direction and magnitude for individuals classified as improved or worse for two anchor items: self-rated health (SRH; 5 categories: excellent, very good, good, fair, poor) and self-reported lupus disease activity (Systemic Lupus Activity Questionnaire, SLAQ, score range 0–44). Improvement/worsening in SRH was defined as a 2-category change from baseline to FU (e.g., “good” to “poor”). Improvement/worsening in SLAQ scores was defined as a 4-point change in score (0.5 SD of baseline score). Changes in PROMIS scales from baseline to FU were calculated. Mean PROMIS change scores and standardized response means (SRM; mean change / SD of change) were calculated for the better and worse groups for each anchor item. SRMs were defined as small (0.20), medium (0.50), or large (0.80). Analyses were repeated within each of 4 racial/ethnic groups (white, Hispanic, black, Asian).

Results: 432 individuals completed baseline interviews; 337 have completed FUs to date (83% of eligible). 92% met 4/11 ACR criteria for SLE; the rest either had a diagnosis of lupus nephritis, or met 3 ACR criteria and were diagnosed by a rheumatologist. Mean age was 46 years, mean disease duration was 18 years. 89% were female, 97 (29%) white, 83 (25%) Hispanic, 37 (11%) black, and 120 (36%) Asian. Mean PROMIS changes and SRMs for better/worse groups (all race/ethnicities combined) are shown in the table. SRMs were medium to large for improvement and worsening for all scales except for Sleep Disturbance and Cognitive Ability (improvement). No substantive differences in responsiveness were noted by racial/ethnic group.

Conclusion: PROMIS scales appeared to be responsive to positive and negative changes in general health status and lupus disease activity, including within racial/ethnic groups, with the exception of the Sleep Disturbance and Cognitive Ability scales. Qualitative studies may be needed to determine reasons for lower responsiveness of these two scales. Overall, however, results add to the evidence supporting the use of PROMIS scales in lupus.

Table. Changes in PROMIS scores and Standardized responses means by change in self-rated health and disease activity (SLAQ)

	Change in self-rated health			
	Better (n=42; 12.6%)		Worse (n=64; 19.2%)	
PROMIS scale	Mean change	SRM	Mean change	SRM
Physical Function*	9.4	0.82	-10.8	-0.88

Assessment of the Psychometric Properties of Patient-Reported Outcomes of Depression in SLE

Andrew Kwan¹, Sherief Marzouk², Helia Ghanian², Michelle Vitti³, Kishwar Ali³, Dennisse Bonilla³, Nicole Anderson³, Jiandong Su³ and Zahi Touma³, ¹Faculty of Medicine, Queen's University, Kingston, ON, Canada, ²Psychiatry, University

Session Information

Session Date: Monday, October 22, 2018

Session Title: Patient Outcomes, Preferences, and Attitudes Poster I: Patient-Reported Outcomes

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Mood disorders, including depression, are amongst the most common manifestations of neuro-psychiatric SLE. Currently, the screening and diagnosis for depression in ambulatory settings are delayed and often missed due to the lack of standardized valid questionnaires for assessing depression in patients with SLE. This study aims to: 1) Determine the prevalence of depression in SLE patients using the Center for Epidemiological Studies-Depression Scale [CES-D] and Hospital Anxiety and Depression Scale [HADS] questionnaires. 2) Study the criterion validity and interpretability of CES-D and HADS, and 3) evaluate their diagnostic accuracy when compared to the assessment of an independent psychiatric assessment using the Mini-International Neuropsychiatric Interview (MINI), based on the DSMV, as the gold standard.

Methods: A cross-sectional study of consecutive consenting SLE patients (n=227), aged 18-65 and attending the Toronto Lupus Clinic between June 2017–September 2017, was performed. Participants were screened for depression using the CES-D and HADS, and underwent the MINI on the same date of their clinic visit. Conventional cut-off scores were used to indicate the prevalence of depression: CES-D ≥ 16 and HADS-D ≥ 8 . Sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV) were evaluated against the MINI. Receiver operator characteristic (ROC) curves and the Youden Index were utilized to determine the optimal cut-off scores for CES-D and HADS-D.

Table 1: Cut-offs to predict depression by Youden Index

Cutoffs	Sensitivity	Specificity	PPV	NPV
CES-D				
26*	0.80	0.82	0.43	0.96
24	0.80	0.77	0.37	0.96
21 [†]	0.85	0.71	0.34	0.97
16 [†]	0.95	0.55	0.27	0.98
HADS-D				
8* [†]	0.80	0.79	0.40	0.96
7	0.85	0.72	0.35	0.97
6	0.95	0.62	0.30	0.99

*Optimal cutoff as determined by the Youden Index

[†]Conventional cutoffs found in literature

Results: Among 227 patients, the prevalence of depression ranged from 27.8% (HADS-D) to 46.3% (CES-D). ROC curves showed that the CES-D (AUC 0.86, 95% CI: 0.78-0.95) slightly outperformed HADS-D (AUC 0.84, 95% CI: 0.75-

0.93) when compared to the MINI. The sensitivity, specificity, PPV, and NPV for CES-D at the optimal cut-off of 26 was 80%, 82%, 43%, and 96%, respectively. The Youden index exhibited optimal cut-offs for CES-D at 26 and HADS-D at 8 that optimized their sensitivity and specificity as screening metrics for depression in SLE patients. The performance of the CES-D and HADS-D at various cut-offs are displayed in Table 1 below.

Conclusion: This study assessed the criterion validity and interpretability of patient-reported outcome tools HADS, and CES-D for depression screening in SLE patients. Compared to the gold standard, CES-D outperformed HADS-D. These results suggest that SLE-specific cut-offs may improve the diagnostic accuracy of current screening metrics in lupus.

Background/Purpose: The Psoriatic Arthritis Impact of Disease (PsAID) questionnaire is a patient reported measure of disease impact. The 12-item questionnaire has many advantages including demonstrated validity, reliability, responsiveness and discrimination. However, few studies have examined the use of individual items as surrogates for important patient reported outcomes. For example, we were interested in whether the single PsAID fatigue item could be used in place of the 13 item FACIT-F instrument. Likewise, the pain, function, depression, and anxiety items could be used in place of additional questionnaires if the items correlated well with validated instruments both in cross-sectional and longitudinal settings. The objective of this study was to examine the longitudinal construct validity of the individual PSAID items for pain, fatigue, function, depression and anxiety.

Methods: Patients with PsA were enrolled in the Psoriatic Arthritis Research Consortium (PARC) between 2015-2017. PARC is a longitudinal observational cohort at four institutions: University of Pennsylvania, Cleveland Clinic, New York University, and University of Utah. Two of these institutions (Utah and Penn) administered the PSAID. Patient characteristics at the first/baseline visit were descriptively reported. The correlations were calculated among individual PSAID items with similar constructs (e.g., “tired” item with FACIT-F, BASDAI tired item, etc.) at baseline using Spearman’s correlation coefficients. The change scores (e.g., score at visit 1 – score at visit 0) and the correlation among change scores between the individual items and related constructs were also calculated.

Results: PSAID data were available from 862 visits; 302 patients completed at least one PSAID and 208 patients completed PSAIDs at ≥ 2 visits. Most patients were in low disease activity (mean 66/68 swollen and tender joint counts were 2.6 and 5.3, respectively). At baseline, the mean PsAID9 and PsAID12 scores were 3.39 (SD2.45) and 3.22 (2.40) respectively. The individual PsAID items were moderately correlated ($\rho = 0.5-0.8$) with similar constructs at baseline. However, aside from the moderate to strong correlation between the PsAID pain question with the RAPID3 pain question ($\rho = 0.71$), change scores were only slightly correlated with like instruments ($\rho = 0.2-0.45$, Table).

Conclusion: The individual PsAID items did not correlate well with change in similar constructs over time. This may be due to the attribution of each symptom to PsA in the PSAID questionnaire. The assessed PsAID items cannot be used as close substitutes for the validated questionnaires with which they were compared.

Session Date: Monday, October 22, 2018

Session Title: Patient Outcomes, Preferences, and Attitudes Poster I: Patient-Reported Outcomes

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Most studies evaluating patient-reported outcomes such as the PROMIS Physical Function Short Form 10a (PF10a) in rheumatoid arthritis (RA) have been performed in white and English-speaking populations. We assessed the measurement properties of the PF10a in a racially/ethnically diverse population with RA. We determined the effect of on-English language proficiency, insurance status and race/ethnicity, on the validity and responsiveness of the PF10a.

Methods: Data were derived from electronic health records for all RA patients seen in a university rheumatology clinic between February 2013 and October 2017. We evaluated the PF10a’s floor and ceiling effects across categories of language preference, insurance and race/ethnicity. To assess convergent and discriminant validity, we examined Spearman’s correlation coefficients (r) between the PF10a and other patient-reported outcomes (patient global assessment and pain), clinical outcomes (tender and swollen joint counts) and inflammatory markers (ESR and CRP) across population

Table: Construct validity analysis, showing Spearman's correlation coefficients between PROMIS PF10a scores and patient reported outcomes, physician assessed outcomes, and inflammatory markers among different subgroups

	Spearman's correlation coefficients with PF10a (r)					
	Patient reported outcomes		Physician assessed outcomes		Inflammatory markers

≥0.6: Strong correlation; ≥0.3: Moderate correlation; <0.3: Weak correlation

subgroups. We used linear mixed effects models to evaluate the responsiveness of the PF10a to longitudinal changes in the Clinical Disease Activity Index(CDAI) across population subgroups.

Results: We included 595 patients with complete data in across-sectional analysis of validity and 341 patients in longitudinal analyses of responsiveness. The group was racially/ethnically diverse (50% non-white)and 14% preferred a language other than English. Most patients had Medicare(47%) or private (40%) insurance. Mean (SD) PF10a score was 40 (11), nearly a standard deviation lower than the overall US population mean. PF10a had acceptable floor (≤7.5%) and ceiling (≤11%) effects across population subgroups. As expected, we observed strong correlations($r \geq 0.6$) with patient-reported outcomes, and moderate correlations($r \geq 0.3$) with clinical outcomes among whites, English speakers and privately insured patients (Table). However, constructs evaluated by the PF10a were less correlated with clinical outcomes among Chinese speakers and Hispanics ($r < 0.3$ and statistically non-significant), and less sensitive to clinical improvements among Medicaid patients ($p=0.005$) and Spanish speakers($p=0.029$) (Figure).

Conclusion: Consistent with published research, the PF10a had good measurement properties among whites, English speakers and privately insured patients. However, we also found important differences across racial/ethnic groups and those with limited English proficiency that warrant further investigation.

differences (MCID) are patient derived scores that reflect changes in clinical care that are meaningful for the patient. Little is known about MCID in many immune mediated diseases. Since small differences in PROs may be statistically significant yet clinically unimportant, it is important to study across disease states. We evaluated the MCID of PROMIS Global Health (GH) and RAPID3 in multiple immune mediated diseases at point of care.

Methods: Data from patients with diagnosis codes of rheumatoid arthritis(RA), psoriatic arthritis (PsA), lupus and granulomatosis with polyangiitis(GPA) who had completed PROMIS GH and RAPID3 via My Rheum using computerized adaptive testing (CAT) at two separate visits, six months apart, were included. Paired t-tests were performed to assess the change in PROMIS and RAPID3. PROMIS MCID change of 5 and RAPID3-weighted score of 1.2 (improvement or worsening) was used to identify important differences.

Results: The analyses included more than 7,463 patients (age 58.3 ± 14 , female 76.8%, white 86.2%). The complete dataset included 4,845 patients for PROMIS and 6,837 patients for RAPID3. The differences in PROMIS and RAPID3 scores by diagnosis are displayed in Table 1. The change in PROMIS score was statistically significant overall ($p < 0.001$) as well as for those with a diagnosis of either GPA ($p = 0.030$) or RA ($p < 0.001$), even though the mean change in PROMIS was less than 1 point for all groups. Approximately 15-20% of patients showed an improvement or worsening of MCID by 6 months. 60-70% had no change between visits. The change in RAPID3 score (table b) from the first to second visit was significant ($p < 0.001$), as was the change for lupus ($p = 0.048$) and RA ($p < 0.001$). Thresholds for clinically meaningful change in PROMIS GH were most significant in GPA and RA compared to PsA and lupus and in RAPID3 were most significant in lupus and RA compared to PsA and GPA.

Conclusion: This study supports the feasibility of collecting PROMIS GH and RAPID3 scores at point of care in patients with immune mediated diseases and using CAT with significantly reduced patient question burden. There was improvement on average for PROMIS and RAPID3 scores among all immune mediated diseases after 2 visits. This study highlights that it is unlikely to have a single MCID value applicable across all chronic diseases. The variability in MCID observed in the My Rheum cohort implies that some patients improve, while others worsen, and this study provides an opportunity to better understand patient characteristics and therapies that may explain these changes in the future.

Session Information

Session Date: Monday, October 22, 2018

Session Title: Patient Outcomes, Preferences, and Attitudes Poster I: Patient-Reported Outcomes

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The World Health Organization describes empowerment in health promotion work as a process in which the person receives more control over decisions and actions that affect their own life and health (1998). Empowerment (E) is an important concept in rheumatoid arthritis(RA), where it has been associated to favorable outcomes. Currently, there is no validated E instrument for use with Spanish speaking RA patients. Objective of the study were to adapt the Spanish version of the Health Empowerment Scale(S-HES) (1) for RA (S-ERA) and to perform its psychometric validation.

Methods: The S-ERA instrument was adapted from the already existing S-HES (1). Adaption was performed by 3 researchers who at first, substitute the word “health” with “rheumatoid arthritis” in each item from the S-HES. A first proposal of the S-ERA included 2 alternative sentences per item. Then, an external Committee integrated by 6

rheumatologists and 2 psychiatrists rated each sentence according to 3 categories: Unnecessary, important but not necessary or essential. One sentence per item was retained when $\geq 80\%$ of the validators agree that the sentence/item was essential. A first version was obtained and it was pilot tested in a convenience sample of 50 RA outpatients (Cronbach's $\alpha=0.84$). After that, minor modifications were adopted and a final version of the S-ERA integrated by 8 items scored on a 5 point Likert scale, was applied to 109 additional consecutive RA patients from the outpatient Clinic of a tertiary care level Center (Table 1). Test-retest exercise was performed in a sample of 50 patients. All the patients gave written informed consent.

Results: The 109 RA outpatients were primarily females (89%) and 99 (91%) had low-medium socioeconomic status; their (mean \pm SD) age was 50.6 \pm 13.3 years and their formal education was 9.7 \pm 3 years. Ninety-four (86.2%) patients had rheumatoid factor and 56 (51.4%) were in remission according to their attending rheumatologist, meanwhile 27 patients (25%) had a major comorbidity.

The (mean \pm SD) score of the S-ERA was 34.4 \pm 3.8(8-40, where 40 indicates the strongest level of RA related E). S-ERA instrument had a good internal consistency (Cronbach's $\alpha=0.82$); construct validity was examined by factor analysis that showed a single factor explaining 46.2% of the variance. The intra-class coefficient correlation in the test-retest was 0.79, $p\leq 0.0001$. Table 2 summarizes additional psychometric properties.

Conclusion: The S-ERA instrument is easy to apply and had adequate validity and reliability to evaluate E in Hispanic RA patients.

Table 1. Empowerment properties and items included in the final version of the S-ERA

Instrument			
No. of item	Dimensions	Properties	Items
1	Psychosocial-coping/ Self-support Support Motivation	Stress management	I can deal positively with the stress that RA causes me.
2		Request support	I can find support to take care of my RA.
3		Self-motivation	I recognize what helps me to be motivated to take care of my RA.
4	Decision-making	Making cost/benefit decisions about making behavior changes	I know myself enough to choose what is best for me to take care of my RA.
5	Self-control	Satisfaction and dissatisfaction related to health	I know well what aspects of my RA-care I am dissatisfied with.
6	Self-efficacy	Identification and achievement of personally meaningful goals	I am capable to reach the goals that I have set for my RA through concrete actions.
7	Problem solving	Application of a systematic problem solving process	I can do different things to overcome obstacles and achieve the goals I have set for my RA.
8	Psychosocial-coping	Coping with the emotional aspects of living with health	I can find ways to feel good by having RA.

Table 2. Statistics of the S-ERA instrument

# Item / Dimension	Mean	Standard deviation	Cronbach's α if item deleted	Confirmative Factor Loading*
1 / Psychosocial-coping/Self-support	3.99	0.811	.816	0.605
2 / Support	4.33	0.708	0.807	0.652

Felson^{3,4} and Julie Keyser⁵, ¹Biostatistics, Boston University School of Public Health, Boston, MA, ²The Emmes Corporation, Rockville, MD, ³ARC Epidemiology Unit, University of Manchester, Manchester, MA, ⁴Clinical Epidemiology Research and Training Unit, Boston University School of Medicine, Boston, MA, ⁵Physical Therapy, MGH Institute of Health Professions, Boston, MA

Session Information

Session Date: Monday, October 22, 2018

Session Title: Patient Outcomes, Preferences, and Attitudes Poster I – ARHP

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Methods for causal analysis in randomized clinical trials (RCT) where functional outcomes may be *truncated* by death of participants have been developed but are not widely used in arthritis. To demonstrate one of these methods, based on a composite score, we applied it to WORK-IT, a parallel-arm RCT of a work disability prevention intervention for persons with musculoskeletal conditions (ClinicalTrials.gov NCT01387100.). In WORK-IT the primary outcome was the 2-year (104-week) value of the Output Job Demand subscale (OJD) of the Work Limitations Questionnaire. The OJD measures the percentage of time an employee has job output limited by health, (0% best -100% worst). Unemployment at 104-weeks *truncated* the OJD for some participants and made these values missing. The rate of unemployment was significantly lower in the intervention arm (11/11744 vs. 25/12535 in controls [Events/Person-Week], $p=0.03$ Logrank test), however the OJD was not different by arm (Intervention: 25.9 ± 1.8 , Control: 28.0 ± 1.9 [Mean \pm SE], $p=0.44$ t-test).

Methods: We derived a composite score (CS) defined as $CS = \#(\text{Follow-up weeks employed}) + (100 - \text{OJD})$. A participant employed at 104 weeks with no OJD limitation would have the highest $CS=204$; and participants unemployed at 104 weeks would have $CS < 104$, depending on when they became unemployed. An intent-to-treat (ITT) analysis with multiple imputation was used to obtain OJD values for participants who withdrew or provided incomplete responses. A complete case analysis excluding these subjects was also performed. The CS combines different outcomes, so a Wilcoxon test-based estimate of the probability that an intervention subject had a better outcome than a control subject $P(I > C)$ quantified the difference between treatments, with values above 0.5 indicating intervention subjects had better outcomes. The difference between arms was significant if a 95% bootstrap confidence interval (CI) for $P(I > C)$ excluded 0.5.

Results: We studied 143 intervention and 144 control participants, 36 were unemployed at 24 months and unable to provide OJD, but used in CS. The median CS value of 179 for the intervention group (see table) indicates that at least half the intervention subjects were employed at follow-up with no more than 25% time of limited output. In both analyses $P(I > C)$ is above 0.5 indicating that intervention subjects have higher probability of a better outcome than control subjects, and since the lower bounds on the 95% CI exclude 0.5, both the complete case and ITT analysis find a statistically significant difference between the arms.

Conclusion: Use of composite scores allow consistent estimation of treatment effects in clinical trials where outcomes are truncated by a related event. This approach could be extended to other longitudinal studies where a measured outcome is truncated, such as knee pain evaluation in osteoarthritis being truncated by knee replacement.

Composite Score (CS) Results for the WORK-IT Study

	Complete Case		Intent-to-Treat (Multiple Imputation)	
	Intervention	Control	Intervention	Control
Subjects	119	132	143	144
Median CS [0-204]	179	172	179	173
Interquartile Range CS [0-204]	160 – 192	151 – 192	160 – 192	154 – 192
$P(I > C)^*$ (95% CI)	0.571 (0.519, 0.625)		0.558 (0.505, 0.610)	

* Probability that an intervention subject has a better outcome than a control subject on the composite score, based on Wilcoxon test statistic.

Session Information

Session Date: Monday, October 22, 2018

Session Title: Pediatric Rheumatology – Clinical Poster II: Autoinflammatory Disorders, Scleroderma, and Miscellaneous

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Canakinumab (CAN), a human anti-interleukin-1 monoclonal antibody, has shown to be efficacious and safe in the treatment of all phenotypes of cryopyrin-associated periodic syndrome (CAPS).¹ However, no real-life data are available on the effect of different doses of CAN in CAPS patients (pts) of different age groups. Here, we analyze the safety of different doses of CAN (<2, 2–<4 and 4–<8 mg/kg) in pts of different age groups (<4–≥65 years; yrs) with CAPS and other auto inflammatory syndromes from a real-life study (β-CONFIDENT Registry; NCT01213641).

Methods: The β-CONFIDENT Registry was a multicenter, long-term, prospective, observational study conducted at 38 sites across 13 countries. Pts with CAPS and those with other auto inflammatory diseases receiving CAN at physician's discretion were enrolled in the registry. Cumulative safety data were reported as exposure-adjusted incidence rate per 100 pt-yrs (IR/pyr) from enrollment of the first pt (November 2009) until the end of study (December 2015). Pts were followed up for at least 1 yr. The protocol did not mandate any visits or procedures. All observed and reported adverse events (AEs) and serious AEs (SAEs) were recorded for the following age groups: <4, 4–<12, 12–<18, 18–<65, and ≥65 yrs.

Results: Of the 285 pts enrolled, 21% (n=60) discontinued the study mainly due to loss to follow-up (35%, n=21), followed by AEs (10%, n=6), poor efficacy (8%, n=5), and pt preference (3%, n=2). In total, 1114 AEs and 155 SAEs were reported in 223 pts (110.7 IR/100 pyr) and 83 pts (15.4 IR/100 pyr), respectively. Incidence rates of AEs (IR/100 pyr) among pts in the <4 and 4–<12 yrs age group were lowest in pts who received <2 mg/kg (130.3 and 59.7, respectively) compared with pts who received 2–<4 mg/kg (450.8 and 169.6, respectively) and 4–<8 mg/kg (121.5 and 90.0, respectively) CAN. In pts aged 12–<18 yrs, IR/100 pyr were lowest in pts who received 2–<4 mg/kg doses (118.2) compared with pts who received <2 mg/kg (169.6) and 4–<8 mg/kg (139.4) CAN. Similarly, in the 18–<65 yrs age group, IR/100 pyr were lowest in pts who received <2 mg/kg (93.1) compared with pts who received 2–<4 mg/kg (100.7) and 4–<8 mg/kg (154.4) CAN. In the ≥65 yrs age group, IR/100 pyr decreased with increasing dose (<2 mg/kg: 26, 2–<4 mg/kg: 17). Overall, 5, 13, 19, 84, and 7 SAEs were reported in the <4, 4–<12, 12–<18, 18–<65, and ≥65 yrs age groups, respectively. One death (metastatic rectal adenocarcinoma in a 76-yr-old Muckle-Wells syndrome pt) was reported.

Conclusion: These results from the β-Confident Registry demonstrated that in general the incidence of adverse events in each dose group of canakinumab increased with age (<4–<65 years). However, an increase in canakinumab dose from 2–<4 mg/kg to 4–<8 mg/kg in each age group was not associated with an increased rate of AEs, which corroborate the need of treat-to-target strategies for different age groups. Canakinumab demonstrated a safety profile consistent with previous reports^{2,3}, and is well tolerated in CAPS patients aged <4–≥65 years.

Session Information

Session Date: Monday, October 22, 2018

Session Title: Pediatric Rheumatology – Clinical Poster II: Autoinflammatory Disorders, Scleroderma, and Miscellaneous

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Hyperimmunoglobulinemia D syndrome (HIDS), also known as mevalonate kinase deficiency (MKD), and TNF receptor-associated periodic syndrome (TRAPS) are rare auto-inflammatory diseases grouped as periodic fever syndromes. There is limited evidence on treatment outcomes for these syndromes. We assessed the efficacy/effectiveness and safety of current treatments used for HIDS and TRAPS.

Methods: A systematic literature review was conducted using Embase®, MEDLINE®, MEDLINE®-In Process and Cochrane library to identify randomized controlled trials (RCTs) and real-world (prospective and retrospective) studies of HIDS/TRAPS patients (pts) published in English language as full-text articles (2000 to September 2017) or conference abstracts (2014 to September 2017). Studies with <5 pts were excluded.

Results: Of the 3342 retrieved publications, 27 studies were included (11 HIDS, 9 TRAPS, and 7 had both cohorts). The majority of studies were full-text (20), published after 2010 (21), and retrospective (13). Studies included two RCTs [one for canakinumab (CAN) vs placebo (PBO); one for simvastatin (SIM) vs PBO]. HIDS pts were most often treated with anakinra (ANA; 9), CAN (7), and corticosteroids (CST; 5); and TRAPS pts with etanercept (ETA; 10), CAN (6), ANA (6), and CST (5).

In the CAN RCT, at 16 weeks (wks), a significantly higher proportion of CAN treated pts vs PBO achieved clinical response (i.e., resolution of the index flare at Day 15 and no new disease flare over 16 wks) in both cohorts (HIDS: 35% vs 6%; TRAPS: 45% vs 8%). The clinical response was higher with CAN vs PBO up to 40 wks. A crossover RCT of SIM in HIDS pts showed a decrease in urine mevalonic acid levels in 100% of pts at 24 wks and reduced the number of febrile days in 83% of pts.

In real-world studies, complete (CR) or partial response (PR) was often assessed, and their definitions and follow-ups (FUP) varied (Table 1; Figure 1). At mid-term FUP, in HIDS pts, CR was 50% [for tocilizumab (TOC)] and 11%-30% (ANA); in TRAPS pts, CR was 100% (CAN) and 33% (ANA). At long-term FUP, in HIDS pts, CR was 100% (ANA),

Figure 1. Response in real-world studies of HIDS and TRAPS at mid- and long-term follow-up

ST 52... denotes studies the details of which are provided in Table 1. N is the number of patients.

In studies where the response does not add up to 100%, the missing information was not reported in that study.

ADA, atakinumab; ANA, anakinra; CAN, canakinumab; COL, colchicine; CR, complete response; CST, corticosteroid; ETA, etanercept; mos, months; NR, no response; PR, partial response; PRD, prednisone; TOC, tocilizumab; wks, weeks; yr, year.

Table 1. Definitions of complete, partial and no response used in HIDS and TRAPS real-world studies with follow-up details reported				
Study (S)/Design	Patients	Definition of response		
		Complete	Partial	No
Storck, 2015 (S1)/Prospective	HIDS	Doing very well and not had an inflammatory attack in last 3 months	Milder but recurrent inflammatory symptoms despite normalization of acute phase response	Had very active disease despite continuous treatment
Roasi-Semerano, 2015 (S2)/Retrospective	HIDS, TRAPS	CR or remission was defined when signs of active disease were absent and inflammatory markers had normalized	PR was defined when CR was not achieved but clinical improvement was evident as per treating physician	Not reported
Gileotti, 2012 (S3)/Retrospective	HIDS	Not reported	Partial clinical remission was defined by a decline of both the symptoms and the frequency of attacks	Not reported
Bodar, 2011 (S4)/Prospective	HIDS	Complete cessation of fever attacks	Febrie episode recur occasionally and CRP was intermittently elevated	No response
Hernández-Rodríguez, 2015 (S5)/Retrospective	HIDS, TRAPS	Good response	Partial response	No response
Cervinski, 2014 (S6)/Retrospective	HIDS, TRAPS	Not reported	Partial response	No response
Chandrasekar, 2014 (S7)/Retrospective	HIDS, TRAPS	Good response	Partial response	Poor response
S1, S2, ... were used to simplify the name of study to use in Figure 1 CR, complete response; CRP, C-reactive protein; PGA, Physician Global Assessment of the disease; PR, partial response; SAA, serum amyloid A.				

100% [colchicine (COL) + prednisone (PRD)] and 50% (CAN); in TRAPS pts, CR was 100% (CAN), 100% (COL + PRD), 50% (ETA) and 33% (ANA). CAN, TOC, SIM, ETA and ANA were generally well-tolerated by HIDS and TRAPS pts; but for ETA and ANA, local injections site reactions were commonly reported.

Conclusion: CAN was efficacious in controlling and preventing flares in HIDS and TRAPS pts in the studies assessed. Although response criteria and treatments were not directly comparable, the available evidence suggested higher effectiveness of CAN in the real-world setting.

Session Information

Session Date: Monday, October 22, 2018

Session Title: Pediatric Rheumatology – Clinical Poster II: Autoinflammatory Disorders, Scleroderma, and Miscellaneous

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The US Food and Drug Administration approved intravenous (IV) tocilizumab (TCZ) for patients (pts) ≥ 2 years of age with systemic JIA (sJIA) in 2011 based on the phase 3 TENDER study.¹ Approval was associated with a post marketing requirement to investigate TCZ in pts with sJIA < 2 years of age (study NP25737; ClinicalTrials.gov, NCT01455701). Results from the 12-week main evaluation period (MEP) have been reported.² Safety results following completion of the optional extension period (OEP) of NP25737 (until 52 weeks from baseline or 2 years of age was reached) are now reported.

Methods: NP25737 was a multicenter, open-label, single-arm study to evaluate pharmacokinetics and safety of IV TCZ 12 mg/kg every 2 weeks for 12 weeks in pts aged < 2 years with active sJIA for ≥ 1 month whose treatment with glucocorticoids and nonsteroidal anti-inflammatory drugs failed and who were receiving stable background therapy. After the MEP, pts could continue TCZ treatment (no requirement for stable background therapy) in the OEP to evaluate long-term safety. Cumulative adverse events (AEs) over the entire study period are reported.

Results: Of 11 pts enrolled in the MEP, 7 entered the OEP and received ≥ 1 dose of TCZ. For the entire study period (n = 11), the median number of TCZ doses was 11.0 (range, 2-26), and median duration of TCZ exposure was 22.1 weeks (range, 4.1-58.1). Most pts (10/11; 90.9%) had ≥ 1 AE; most were mild or moderate and unrelated to TCZ. The most common AEs were upper respiratory tract infection (6/11 pts; 54.5%) and hypersensitivity, neutropenia, rash, viral upper respiratory tract infection, and vomiting (each 3/11 pts; 27.3%). Seven serious AEs occurred in 5/11 pts (45.5%): 2 during the OEP (transaminases increased, histiocytosis hematophagic), 3 during the MEP (3 hypersensitivity events), and 2 during safety follow-up of the MEP (sJIA flare, hand-foot-and-mouth disease). AEs leading to dose modification occurred in 5/11 pts (1 in the MEP, 4 in the OEP) mostly because of infections, neutropenia, and elevated liver enzymes, all mild or moderate in intensity. AEs leading to withdrawal occurred in 5/11 pts (45.5%): during the OEP, 1 pt withdrew because of a serious AE of increased transaminases; during the MEP, 3 pts withdrew because of serious hypersensitivity reactions to TCZ and 1 because of thrombocytopenia. No deaths were reported. AE rates are shown in Table 1.

Table 1. Rates of AEs

	TCZ 12 mg/kg IV Every 2 Weeks		
	MEP n = 11	OEP n = 7	Entire Study n = 11
Total PY at risk	2.3	5.1	7.4
No. of events (AE rate per 100 PY at risk)			
Any AE	32 (1396.4)	47 (926.5)	79 (1072.7)
Serious AE	5 (218.2)	2 (39.4)	7 (95.1)
AE with fatal outcome	0	0	0
AE leading to withdrawal	4 (174.6)	1 (19.7)	5 (67.9)
AE leading to dose interruption	1 (43.6)	12 (236.5)	13 (176.5)

AE, adverse event; IV, intravenously; MEP, main evaluation period; OEP, optional extension period; PY, patient-years.

Conclusion: During the OEP, long-term treatment with TCZ was well tolerated in sJIA pts aged < 2 years. No additional safety signals were reported in the OEP beyond those reported in the MEP or observed previously for pts with sJIA aged > 2 years. **References:** 1. Session Information

Session Date: Monday, October 22, 2018

Session Title: Pediatric Rheumatology – Clinical Poster II: Autoinflammatory Disorders, Scleroderma, and Miscellaneous

Background/Purpose: Long-term surveillance of biologic drugs is particularly important in pediatric patients(pts). Since 2001, the German Biologics JIA Registry (BIKER) is allowing to follow up of an unlimited number of patients in routine clinical care. Safety with regard to adverse events of special interest was assessed.

Methods: The BIKER database was used to identify systemic JIA pts exposed to biologics. Safety assessments were based on adverse events (AE) reports for 25 predefined AEs of special interest (AESI). Events per 100 patient-years (PY) of exposure were calculated using AEs reported after first dose through 70 days after last dose. Rates were compared by Wald test. Only 5 pts receiving abatacept and 2 with infliximab were excluded from the Analysis.

Results: 278 pts received 388 biologics courses with a total exposure time of 765 PY. 152 pts received Etanercept (ETA,366 PY), 95 Tocilizumab (TOC,171 PY), 73 Anakinra (ANA,121 PY), 49 Canakinumab (CAN,69 PY) and 19 Adalimumab (ADA,38 PY). Differences in pts characteristics and concomitant treatment between these cohorts were noted. A total of 456 AE (rate 59.5/100 years), 94 SAE (12.3) and 95 AESI (12.4) were reported. The most common AESI were serious or medically important infections (30), cytopenias (21), macrophage activation syndrome (MAS,13), anaphylaxis (11), hepatic events (10), malignancies (4) and others occurring only once (other autoimmuneopathies, chronic inflammatory bowel disease, depression, demyelination, thrombotic disorder, uveitis). There were marked differences in the rate of AESI between the cohorts with different biologics (table). Risk Ratios for serious and medically important infections were significantly higher with TOC and lower with ETA. Risk ratios for cytopenias were significantly higher with CAN and TOC. MAS occurred significantly more frequently with TOC and CAN and less frequently with ETA. Risk ratios for hepatic events were significantly higher in the TOC cohort and lower with ETA. Risk ratio for cytopenias was significantly higher with TOC. Risk ratios for anaphylaxis were significantly higher with TOC probably due to the intravenous route of application. There was no death, no cardiovascular event, no bleeding, no intestinal perforation, pregnancy or opportunistic infection in this cohort

Biologic	ADA	ANA	CAN	ETA	TOC
Pat/exposure years	19/37.6	73/120.9	49/69.0	152/366.2	95/171.7

* Data outlined as n(rate/100 years), RR=Risk ratio[95% CI], p-value.

Conclusion: These data provide support for the long-term and comparative safety of biologics in JIA pts. Overall, tolerance is acceptable. Surveillance of pharmacotherapy as provided by BIKER is an import approach especially in the case of long-term treatment of children. Differences between several biologics were noted and should be considered in daily patient care. Interpretation of these data requires caution.

BiKeR is sponsored by unrestricted grants from Abbvie, Chugai, MSD, Novartis, Pfizer, Roche.

Session Date: Monday, October 22, 2018

Session Title: Pediatric Rheumatology – Clinical Poster II: Autoinflammatory Disorders, Scleroderma, and Miscellaneous

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Interferon gamma (IFN γ) plays a pathogenic role in primary and secondary HLH. An ongoing phase 2/3 trial with emapalumab in primary HLH provides encouraging preliminary data and a pilot trial in MAS in the context of sJIA has just been initiated. Gain-of-function mutations in NLRC4 are associated with a distinct auto inflammatory syndrome, with recurrent HLH.

Methods: We report safety and efficacy of emapalumab treatment in 2 patients carrying de novo missense mutations in NLRC4, with severe early onset HLH. Cytokine levels were measured by multiplex assay and by specific ELISAs and expression of IFN γ in freshly isolated PBMCs by cytometry.

Results: Pt 1. Caucasian male, presented, at age 20 days, fever and rash and progressively developed clinical and laboratory features of HLH leading to multi-organ failure. A de novo missense mutation in NLRC4 (T337N) was found. High-dose glucocorticoids and cyclosporine-A (CyA) led only to partial improvement. A sepsis triggered HLH reactivation. Emapalumab was started on background of dexamethasone (13.6mg/m2) and CyA. After 3 months, the child was discharged in excellent conditions. Infections resolved during treatment with emapalumab. After 7 months of emapalumab treatment, all therapies, including emapalumab, were discontinued, without signs of HLH reactivation. Pt 2. This is 16 months old Caucasian boy with recurrent HLH and vasculitic skin lesions, since 1 month of life, secondary to a de novo missense mutation in NLRC4 (I343N). His disease was not controlled despite treatment with repeated methylprednisolone pulses and chronic daily glucocorticoid therapy, CyA and anakinra (ranging from 5 to 25 mg/kg/day). When anakinra was withdrawn prior to start emapalumab he immediately developed high-grade fever, skin rash with vasculitic lesions and diarrhea with laboratory features of HLH. Emapalumab was started on background of methylprednisolone and CyA with rapid resolution of fever and improvement in biochemical parameters. During emapalumab treatment the patient resolved his initial HLH flare and presented two HLH episodes of mild intensity controlled with moderate intensification of glucocorticoid therapy. These episodes were triggered by systemic infections caused by pathogens translocated from the gut. His diarrhea persisted with low grade inflammation; emapalumab was eventually withdrawn after 3 months. His subsequent course was characterized by additional mild episodes of HLH. In both patients increased production of IFN γ was demonstrated by high levels of CXCL9 (pt.1: 5670 pg/ml, pt.2: 3310 pg/ml), a chemokine induced specifically by IFN γ , by increased IFN γ expression in NK cells and CD8T cells, and by presence of high levels of total IFN γ bound to circulating emapalumab.

Conclusion: In both patients, treatment with emapalumab was well tolerated, no safety concerns emerged, normalization of all HLH clinical and laboratory abnormalities was achieved. Pt. 1 showed no disease reactivation even in the absence of treatments. In pt. 2 IFN γ neutralization has provided control of HLH, while his underlying disease and, in particular, gut inflammation and gut colonization by MDR pathogens remained unchanged.

Risk Score of Macrophage Activation Syndrome in Patients with Systemic Juvenile Idiopathic Arthritis

Simone Carbogno¹, Denise Pires Marafon², Giulia Marucci³, Manuela Pardeo³, Antonella Insalaco³, Virginia Messina³, Rebecca Nicolai³, Fabrizio De Benedetti⁴ and **Claudia Bracaglia**³, ¹University of Milan, Milan, Italy, ²Pediatric Unit, Fondazione IRCCS Ca' Grande Ospedale Maggiore Policlinico, Milan, Italy, ³Division of Rheumatology, IRCCS Ospedale Pediatrico Bambino Gesù, Rome, Italy, ⁴IRCCS Ospedale Pediatrico Bambino Gesù, Roma, Italy

Session Information

Session Date: Monday, October 22, 2018

Session Title: Pediatric Rheumatology – Clinical Poster II: Autoinflammatory Disorders, Scleroderma, and Miscellaneous

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Macrophage Activation Syndrome (MAS) is a severe, life-threatening, complication of rheumatic diseases in childhood, particularly of systemic Juvenile Idiopathic Arthritis (sJIA), occurring in approximately 25% of the patients with sJIA. The mortality rate of MAS is still significantly high. A score that identify sJIA patients who are at high risk to develop MAS would be useful in clinical practice. There are no parameters available to identify from onset sJIA patients with high risk to develop MAS in their disease course. We evaluated whether routine laboratory parameters at disease onset may predict the development of MAS in patients with active sJIA. To define a risk score of MAS for sJIA patients using these parameters.

Methods: Laboratory parameters of disease activity and severity (WBC, N, PLT, Hb, ferritin, AST, ALT, gGT, LDH, TGL, fibrinogen, D-dimer and CRP), were retrospectively evaluated in 56 sJIA patients referred to our Division of Rheumatology from 1998 to 2016 with at least one year of follow-up. Laboratory parameters were evaluated during active sJIA, without MAS, at time of hospitalization (T1) and before treatment for sJIA was started (T2). Patients were divided in two groups: group 1 (patients without history of MAS), group 2 (patients with at least one MAS episode during disease course). In order to calculate a MAS risk score, laboratory parameters, collected at T2, with a statistical significant difference between the two groups of patients were selected.

Results: Fourteen patients, that fulfilled the 2016 classification criteria for MAS [1] at time of sampling, were excluded from the analysis. Therefore, we analyzed laboratory parameters of 42 patients with sJIA, 27 of whom without history of MAS (group 1) and 15 who developed at least one episode of MAS during disease course (group 2). Levels of ferritin, AST, LDH, gGT and TGL, collected at T2, were statistically significant higher in patients with a history of MAS compared to those without a history of MAS. For each of these parameters an arbitrary cut-off was defined. In order to define the final score an arbitrary rate was attributed to each parameter. Sensitivity (Se), specificity (Sp), positive predictive value (PPV) and negative predictive value (NPV) were calculated to define the best scoring system. The scoring system with the best sensitivity was chosen (Table 1). A MAS risk score >3 identified 14 out of 15 sJIA patients with a history of MAS and 3 out of 27 sJIA patients without history of MAS.

Table 1. Laboratory parameters and cut-off used to create the MAS risk score in sJIA patients.

Laboratory parameters	Cut-off	Rate
Ferritin (ng/ml)	>900	1
AST (UI/L)	>35	1
LDH (UI/l)	>550	1
gammaGT (UI/L)	>30	2
Triglycerides (mg/dl)	>150	2
Sensitivity (Se)	0.933	CI95% 0.680-0.998
Specificity (Sp)	0.889	CI95% 0.708-0.977
Positive predictive value (PPV)	0.824	CI95% 0.566-0.962
Negative predictive value (NPV)	0.96	CI95% 0.797-0.999

* Patients with score >3 were identified to have high risk for MAS

Conclusion: We developed an MAS risk score based on routine laboratory parameters that are available worldwide, that can help clinicians to identify these patients early in the disease course. Our results are preliminary and a validation in a larger population is ongoing.

Hemophagocytic Lymphohistiocytosis (HLH) Mimickers: CXCL9 As a Potential Biomarker Distinguishing HLH from Other Hyperferritinemic Syndromes

Giulia Marucci¹, Ivan Caiello², Manuela Pardeo¹, Virginia Messina¹, Giusi Prencipe¹, Antonia Pascarella¹, Fabrizio De Benedetti³ and **Claudia Bracaglia**¹, ¹Division of Rheumatology, IRCCS Ospedale Pediatrico Bambino Gesù, Rome, Italy, ²Division of Rheumatology, IRCCS Ospedale Pediatrico Bambino Gesù, Roma, Italy, ³IRCCS Ospedale Pediatrico Bambino Gesù, Roma, Italy

Session Information

Session Date: Monday, October 22, 2018

Session Title: Pediatric Rheumatology – Clinical Poster II: Autoinflammatory Disorders, Scleroderma, and Miscellaneous

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Increased ferritin is considered biomarker highly suggestive of primary and secondary HLH and it is one of the HLH-2004 diagnostic and MAS guidelines (1,2), nevertheless it could also be elevated in other inflammatory conditions. Interferon-gamma (IFN γ) and IFN γ -induced chemokines, particularly CXCL9, have been demonstrated to be markedly elevated in patients with primary and secondary HLH.

Methods: We describe eight patients with hyperferritinemia who fully or partially met the HLH-2004 diagnostic guideline, but in which the subsequent clinical course and further investigations led to different diagnosis that required different therapies and to investigate the CXCL9 levels in identify diseases that may mimic HLH. To be noted that soluble CD25 was not measured in these patients. Serum CXCL9 levels were analyzed by DuoSet ELISA KIT DY392 (R&D Systems, Minneapolis, Minn). Normal values of CXCL9 are lower than 700 pg/ml.

Results: We identified 8 patients with laboratory features suggestive of HLH, included high ferritin levels (>500 ng/ml). Three of these patients met five of the HLH-2004 criteria, two of them met four criteria and the others two met three criteria. One patient presented only high serum ferritin level and cytopenia. CXCL9 levels were <300 pg/ml in seven of them and approximately 600 pg/ml in one patient. The clinical disease course and the other investigations ruled out the diagnosis of HLH and every patient received a different diagnosis. None of them received treatment for HLH (Table 1).

Table 1. Patients' features.

Pt	Gender	Months at onset	HLH-2004 Criteria	Ferritin ng/ml	CXCL9 pg/ml	Final diagnosis
1	M	1	5	9.849	<300	Osteopetrosis
2	M	6	5	800	<300	Vitamin B12 deficiency
3	M	1	5	543	<300	Chronic granulomatous disease
4	M	1	4	15.629	<600	Short bowel syndrome
5	M	3	4	4.378	<300	Cobalamin deficiency
6	F	2	3	37.232	656	Shaken baby syndrome
7	M	165	3	1.400	<300	Ghosal hematodiaphyseal dysplasia
8	M	172	2	1.184	<300	Primitive myelofibrosis

Conclusion: Since HLH is a life-threatening condition, early recognition and promptly therapy are essential to modify the disease course. One of the most typical feature of primary and secondary HLH is high ferritin level. Due to the severity of the disease, sometimes patients need to be treated before all criteria are fulfilled. The eight patients reported had features highly suggestive of HLH and met the HLH-2004 criteria, or part of them. However they all received a different final diagnosis. Despite all presented with high ferritin levels, CXCL9 was low in all. CXCL9 is a chemokine specifically induced by IFN γ , and has been demonstrated to be markedly elevated in patients with primary and secondary HLH due to the activation of the IFN γ pathway. In these cases CXCL9 was able to differentiate diseases with high ferritin that mimics HLH. High CXCL9 levels appear to be a potential specific biomarker for HLH diagnosis. Early dosage of CXCL9 levels in patients with hyperferritinemia and with clinical suspicion of HLH may be helpful for a timely differential diagnosis.

Session Title: Pediatric Rheumatology – Clinical Poster II: Autoinflammatory Disorders, Scleroderma, and Miscellaneous

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: AIDAI is an ovel and unique, validated patient (pt)-reported assessment tool to evaluate disease activity in familial Mediterranean fever (FMF), hyper-IgD syndrome/mevalonate kinase deficiency (HIDS/MKD) and TNF receptor-associated periodic syndrome (TRAPS).¹ Here we performed an external validation of AIDAI by calculating scores over 40 weeks (wks) of canakinumab (CAN) treatment in pts enrolled into the CLUSTER trial (NCT02059291) and assessed correlation between AIDAI and disease/response characteristics.

Methods: CLUSTER consisted of one cohort per disease (crFMF, HIDS/MKD and TRAPS).² AIDAI was calculated as the sum of 12 items (Yes=1; No=0)¹ for 30 consecutive days. AIDAI score was calculated if the first score was recorded before ≥ 29 days. Missing items beyond last evaluable measurement were imputed by last observation carried forward (LOCF). Inactive disease (ID) was defined as AIDAI score < 9 . Correlation analysis of AIDAI with Sheehan disability score (SDS), child health questionnaire–psychological/physical (CHQ–PSC/PCS), physician global assessment (PGA), short form 12–physical/mental component summaries (SF12–PCS/MCS), C-reactive protein (CRP), and serum amyloid A (SAA) were performed. Significance was set at $p < 0.05$.

Figure 1. Median AIDAI scores over 40 weeks

Table 1. Correlation between AIDAI and disease activity variables at Week 40								
	Correlation coefficient (95% CI)							
	SDS	CHQ-PSC	CHQ-PCS	PGA	SF12-PSC	SF12-MCS	SAA	CRP
crFMF (n=59)	20	12	12	42	11	18	39	42
	0.54* (0.22; 0.78)	-0.43* (-0.66; -0.19)	-0.38* (-0.60; -0.16)	0.34 (-0.08; 0.61)	-0.47* (-0.72; -0.21)	-0.43* (-0.70; -0.05)	-0.39 (-0.58; -0.20)	-0.37 (-0.58; -0.24)
HIDS/MKD (n=60)	23	20	20	54	9	0	32	33
	0.39* (0.05; 0.65)	-0.47* (-0.70; -0.23)	-0.32 (-0.57; 0.14)	0.24 (-0.03; 0.47)	-0.06 (-0.71; 0.61)	-0.19 (-0.76; 0.54)	0.06 (-0.22; 0.32)	0.28 (-0.19; 0.54)
TRAPS (n=42)	20	12	12	32	14	14	20	31
	0.41* (0.02; 0.69)	-0.57 (-0.82; 0.53)	-0.32 (-0.59; 0.56)	0.37* (0.02; 0.63)	-0.40* (-0.66; -0.11)	-0.13 (-0.62; 0.43)	-0.17 (-0.50; 0.20)	-0.18 (-0.51; 0.16)

* $p < 0.05$; N, total number of patients in the cohort; n, number of evaluable patients.

Results: Overall, 167 (crFMF: N=59; HIDS/MKD: N=66; TRAPS: N=42) pts were randomized to CAN 150 mg or placebo every 4 wks. Median AIDAI scores in all 3 cohorts decreased from baseline (BL) to Wk 16 (crFMF: 22.5 to 5.0; HIDS/MKD: 41.5 to 12.0; TRAPS: 89.0 to 13.0) and through Wk 40 (crFMF: 1.0; HIDS/MKD: 5.0; TRAPS: 20.5; Fig 1). In all cohorts, the proportion of pts with ID (AIDAI score <9) was higher at Wk 40 versus BL (crFMF: 69.5% vs 5.1%; HIDS/MKD: 56.1% vs 6.1%; TRAPS: 42.9% vs 2.4%). AIDAI at Wk 40 correlated significantly with: SDS in all 3 cohorts; CHQ-PsCS in crFMF and HIDS/MKD; CHQ-PCS in crFMF; PGA in TRAPS; SF12-PCS in crFMF and TRAPS. SF12-MCS, CRP, and SAA did not correlate with AIDAI (Table1).

Conclusion: AIDAI scores decreased markedly over 40 weeks of treatment with canakinumab in crFMF, HIDS/MKD and TRAPS, with a relevant percentage of patients having inactive disease score. AIDAI improvements at Week 40 correlated with patient- and physician-driven evaluations. AIDAI is a validated patient-reported tool to assess disease activity and appears to have good sensitivity to change to be used in comparative trials. Patient's experience on disease activity does not strictly correlate with CRP and SAA, as these reflect more closely biological inflammation than clinical symptoms.

Session Information

Session Date: Monday, October 22, 2018

Session Title: Pediatric Rheumatology – Clinical Poster II: Autoinflammatory Disorders, Scleroderma, and Miscellaneous

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Linear Scleroderma (LS) is the most common subtype of localized Scleroderma in children and the one most frequently associated with tissue damage and functional disability. During the last decade, methotrexate (MTX) has been used as first choice agent for LS but, to date, available data on long-term outcome are partial and incomplete. Aim of this study was to assess the disease recurrence and the long-term outcome of children with LS treated with MTX since diagnosis.

Methods: We conducted a retrospective and cross-sectional study including children with LS followed at our Paediatric Rheumatology Centre between 2000 and 2016. Patients treated with MTX for at least one year, then followed for at least 2 years were included. Disease course was evaluated by retrospective analysis of clinical features, treatment and number of flares. Outcome at the last visit was assessed by evaluation of disease activity and severity of tissue damage and/or functional impairment by Localized Scleroderma Cutaneous Assessment Tool (LoSCAT) and thermography. Clinical remission (CR) was defined in presence of inactive disease off treatment for more than two years; clinical remission on medication (CRM) in presence of inactive disease while on treatment.

Results: 50 patients, 24 with LS of the trunk/limbs and 26 with LS of the face, entered the study. MTX treatment duration was 3.1 years (median 2.9, range 1.8-8.5 years). Only 16% patients did not respond to the first therapy with MTX, 16% had at least one flare of the disease, on average 30 months after starting MTX and 10% presented recurrent relapses. The mean follow-up was 7.8 years (median 6.8, range 2.1-16.3). Within 5 year follow-up, 81.8% of patients achieved CRM and by 10 year follow-up, 80.0% obtained CR. In the group of 16 patients with >10 years, CR was reported in 87.5%. At the last evaluation, tissue damage was very mild in 42% of patients, moderate in 32% and severe in 26%. Various degree of functional limitation was reported in 41.7% of patients with LS of the limbs. Severity of tissue damage was not related to the part of the body involved or to the disease duration, while functional disability was more frequent in LS of the limbs (p=0.039). LS body site and severity of tissue damage were not associated with disease recurrence or remission, while the length of therapy was related to number of disease relapses (p=0.040) and severity of tissue damage (p=0.003).

Conclusion: Most patients with LS treated with MTX achieve complete remission without flares and only a minority present repeated relapses or active disease after more than 10 years. The long-term monitoring of the patients, even after stopping MTX treatment is crucial to promptly identify possible flares and treat them properly. Overall aesthetic and functional sequelae are moderate and develop early in the disease course as their severity is not related to the disease duration.

Session Information

Session Date: Monday, October 22, 2018

Session Title: Pediatric Rheumatology – Clinical Poster II: Autoinflammatory Disorders, Scleroderma, and Miscellaneous

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Currently, the techniques used for the monitoring of Localized Scleroderma of the face (LSF) have significant limitations. We prospectively evaluated the reliability of the Cone Beam Computed Tomography (CBCT), a non-invasive, reproducible technique with a radiation dose lower than a conventional CT, to quantify changes of facial asymmetry over time as compared with the clinical and instrumental methods currently in use.

Methods: Consecutive patients with LSF, followed from January 2009 to December 2017 at our Pediatric Rheumatology Center, entered the study. CBCT was carried out following the same method previously described¹. Measurements of total thickness, soft tissue and bone thickness were taken in both affected and unaffected sides of the case. These data allowed us to calculate the Absolute Rate of Change (ARC) of the lesion over time and the comparison with the ARC obtained from the healthy side, allowed us to calculate the Relative Rate of Change (RRC). The judgment of stability or worsening of the lesion was compared with the one derived from the physician global assessment (PGA), infrared teletermography (IT) and sequential clinical photographs (SCP). The Sensitivity-to-change of CBCT was assessed by Standardized Response Mean (SRM) and Effect Size (ES).

Results: 26 subjects with LSF, 15 females and 11 males, mean age 7.6 years (range 1.2-17.8) entered the study. 18 patients presented Parry Romberg syndrome (PRS), 5 En coup de sabre (ECDS) and 3 facial hemiatrophy (FH). The disease duration at the first CBCT was 3.7 years (range 0-28). During the study period, 69 CBCTs have been performed. On average, each patient underwent 2.7 CBCTs, 15 patients underwent two CBCTs, 8 patients three, and one patient 4, 5 or 6 CBCTs each, respectively. In all, the total thickness of the affected and unaffected side were evaluated. A worsening of CBCT with RRC > 5%, was found in 10 out of 40 evaluations (25%). The agreement between the CBCT and SCP was found in 20 out of 37 evaluations (54%). The comparison of the four clinical-instrumental methods performed in 40 evaluations, revealed an overall agreement of 66.7%. CBCT results were consistent with the PGA in 67.6% evaluations, with IT in 62.2%. The sensitivity to change of CBCT over time was very good at the mandibular condyle level (SRM values ranging from 0.53 to 0.77, ES 0.40-0.50) on the healthy side. The affected side reported SMR and ES values <0.5.

Conclusion: CBCT is an innovative technique that allows to assess the changes of the affected side, usually the *non-growth*, of LSF in comparison with the healthy side, during the developmental phase of pediatric patients. CBCT represents a reliable and objective tool for monitoring LSF over time in association with the other clinical-instrumental methods currently in use. Its practical benefit lies in its potential of correctly addressing therapeutic changes including the timing of start the reconstructive surgical process.

Evaluating the Validity of SIX-Minute Walk Test in Juvenile Systemic Sclerosis

Oya Koker¹, Amra Adrovic², Sezgin Sahin², Kenan Barut², Rukiye Omeroglu³ and **Ozgun Kasapcopur⁴**, ¹Istanbul University, Istanbul Medical School, Department of Pediatric Rheumatology, Istanbul, Turkey, ²Pediatric Rheumatology, Istanbul University, Cerrahpasa Medical School, Department of Pediatric Rheumatology, Istanbul, Turkey, ³Pediatric Rheumatology, Istanbul University, Istanbul Medical School, Department of Pediatric Rheumatology, Istanbul, Turkey, ⁴Istanbul University, Cerrahpasa Medical School, Department of Pediatric Rheumatology, Istanbul, Turkey

Session Information

Session Date: Monday, October 22, 2018

Session Title: Pediatric Rheumatology – Clinical Poster II: Autoinflammatory Disorders, Scleroderma, and Miscellaneous

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Pulmonary vascular disease and interstitial lung fibrosis are the leading causes of morbidity and mortality in Juvenile Systemic Sclerosis (JSSc). Six-minute walk test (6MWT) is a self-paced sub maximal exercise test used for evaluating functional exercise capacity, prognosis and response to therapy in patients with cardiopulmonary diseases. While the results of studies on the availability of the test in adults are contradictory, there are limited data concerning the usefulness of 6MWT in children with JSSc. We aimed to evaluate the walking distance and oxygen desaturation during the 6MWT in JSSc, and to establish correlations between the 6MWT results and other clinical findings in children with JSSc.

Methods: 25 JSSc, 27 Juvenile Systemic Lupus Erythematosus (JSLE) and 30 healthy controls were included. The test is conducted according to the guidelines recommended by the American Thoracic Society (ATS), standardized in 2002. The Borg Scale which is a well-validated scoring system on a 0-10 point scale was used to determine the patient self reported fatigue and dyspnea levels.

Results: Demographic data are shown in Table 1. Mean walking distance was 480,18 ± 47,22 m in JSSc; 513,66 ± 51,70 m in JSLE and 553,21 ± 41,65 m in healthy controls. JSSc patients walked significantly less distance comparing to controls (p <0.001). The mean oxygen saturation in JSSc was 98.0 ± 0.9% before the test and 97.5 ± 1.6% after the test (p = 0,01). JSSc patients with lung involvement walked less than those without lung involvement (476.08 ± 47.13 m vs .483.96 ± 48.89 m), but without statistically significant difference (p = 0.68). JSSc patients with carbon monoxide diffusion capacity (DLco) ≤ 60% walked less than those with DLco ≥ 60% (466.92 ± 45.74 m vs. 485,33 ± 48,05 m). However, no statistically significant correlation was detected. (p = 0.39). No significant difference was found when patients walking distances were compared to activity scores (Juvenile Systemic Sclerosis Severity Score (J4S)) (p = 0.26). Lower extremity pain during and after the test was more statistically significant in JSSc patients (p = 0.001). Patients with myalgia were found to walk less than those without myalgia (498.61 ± 46.94 m vs. 460.20 ± 40.29 m) (p = 0.038).

Total	Juvenile Systemic Sclerosis N=25	Juvenile Systemic Lupus Erythematosus N=27	Healthy children N=30	p-value
Gender , Female, n(%)	22 (88%)	21 (77.8%)	16 (53.3%)	p=0,04
Age mean±SD (years)	16,44±3,19 years	16,74±3,59 years	15,57±1,50 years	p=0,27
Body mass index, mean±SD	18,75±2,99 kg/m ²	20,43±3,05 kg/m ²	19,94±1,69 kg/m ²	p=0,06

Conclusion: The findings of our study showed that patients with JSSc have limited walking distances. The pulmonary involvement and associatively high disease activity score are unable to determine the results of the 6MWT in JSSc patients. However, the musculoskeletal involvement may influence the walk distance and complicate interpretation of the 6MWT in JSSc patients. Since there are a limited number of studies regarding the role of 6MWT in the evaluation of JSSc, we believe that the results of our study will enlighten the future studies.

Session Information

Session Date: Monday, October 22, 2018

Session Title: Pediatric Rheumatology – Clinical Poster II: Autoinflammatory Disorders, Scleroderma, and Miscellaneous

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Juvenile localized scleroderma (jLS) is a chronic autoimmune disease, with cutaneous and extra-cutaneous manifestations (ECM) requiring long-term immunosuppressive therapy. Few studies have evaluated the effect of jLS on health-related quality of life (HRQoL). We describe parental HRQoL findings in a multi-center prospective jLS study.

Methods: A prospective, pilot study of 50 jLS subjects beginning immunosuppressive therapy and followed for 1 year was conducted in 10 Childhood Arthritis and Rheumatology Research Alliance centers. Clinical assessments, treatment effects, and HRQoL measures (including Peds QLTM Family Impact (PedsQLTM FI) reports and ACR functional class) were collected at study visits. Domains of Peds QLTM FI include effect of child's disease on parental Physical, Emotional, Social and Cognitive Functioning, the family's Daily Activities, and Family Relationships. The Worry module relates to parental worry about treatment and disease related issues affecting the child and family. Peds QLTM FI scores were analyzed for association with patient characteristics, with change in domain scores over time analyzed by mixed effects models. Dunnett post-hoc tests were used to compare follow-up scores against baseline.

Results: Twenty-five subjects completed parental Family Impact QOL data at 0, 6, and 12 month visits. Most were female (68%), Caucasian (88%), had linear subtype (60%), and ECM (84%), and experienced at least one treatment-related adverse effect (72%). Seventeen percent of subjects had ACR global functional > class 1. At all visits, the lowest scores were found in the Peds QLTM FI domains of Worry and Emotional Functioning (Table). Overall, scores for Emotional Functioning, Daily Activities, and Family Relationships improved from 0 to 12 months (p = 0.015- 0.035, Table). Parents of female subjects were more likely to report higher Physical Functioning and lower (worse) Worry scores over time (p <0.0001, 0.0264, respectively). Parents of subjects with ACR class 2 or higher reported lower Daily Activities scores, with improvement in scores over time (p<0.0001).

Conclusion: Our study supports the hypothesis that jLS impacts HRQoL. Parents of female subjects were found to worry more about disease issues and treatment, while poorer subject global function impacted family daily activities. Over time, scores improved for parental Emotional Functioning, family Daily Activities, and Family Relationships, possibly related to treatment. Head involvement and ECM were not specifically associated with poorer parental HRQoL scores. Future studies should evaluate the potential impact of jLS on parental and family HRQoL, and how these relate to patient HRQoL to improve long-term management of this disease.

Table. Summary of PedsQLTM Family Impact Scores at Three Study Timepoints

	0 months (study entry)		6 months		12 months		
DOMAINS*	Mean	SD	Mean	SD	Mean	SD	p-value
Physical Functioning	72.0	24.3	81.2	17.7	86.7	14.9	0.08
Emotional Functioning	64.4	26.8	76.0	18.4	80.9	20.3	0.04
Worry	54.6	22.0	61.1	20.1	65.4	17.6	0.10
Daily Activities	83.7	26.0	88.4	15.8	95.7	9.4	0.02
Family Relationships	84.6	17.6	87.6	14.1	95.2	8.9	0.02

* Scores range from 100 (no issues) to 0 (almost always has issues). P-values refer to change over time.

SSB	-	-	-	-	5	7%	Tight skin, hypopigmented

deep), generalized plaque morphea, and mixed subtype. It has become increasingly recognized that LS effects more than the skin; greater than 50% of patients are affected by extra-cutaneous manifestations (ECMs), such as musculoskeletal and neurologic involvement. In systemic sclerosis (SSc), a related but typically more serious type of scleroderma, distinctive clinical subsets and specific patterns of organ involvement can be anticipated by autoantibody serological findings, which aid in the treatment and preventive care for these patients. The role of autoantibodies (autoAbs) in LS as a disease risk stratifier or ECM associations has only been partially evaluated with select antibodies. We suggest a wide array of SSc-associated autoAbs to investigate patterns with clinical associations in LS.

Methods: Plasma from 69 pediatric LS patients and 46 pediatric healthy controls were tested for anti-nuclear antibody (ANA) and various SSc-specific and SSc-associated auto Abs including those to extractable nuclear antigens (ENE) in the FIDIS™ Connective Profile, and to those contained in a SSc line immunoassay (LIA) (Euroimmun, Germany) and a MagPix® (Luminex™) addressable laser bead immunoassay (ALBIA), for a total of 29 distinct autoAbs. Normal cutoffs were determined from the healthy pediatric samples (2 SD above the mean) and then applied to the LS samples to determine positivity. Chi-square analysis was used to determine relationships with clinical variables.

Results: ANA positivity ($\geq 1:80$ titer) was present in 70% of the LS patients, half of them with a speckled pattern, followed by cytoplasmic (17%), homogenous (12%), nucleolar (10%) and centrosome (9%) pattern. Fifteen of the 28 specific antibodies tested were seen in $> 5\%$ of the LS patients and are summarized in Table, along with their significant clinical associations.

Conclusion: Certain 'classic' SSc-associated auto-antibodies, such as Scl-70, centromere (CENP A) and RNA Pol III (RP11) were found in a frequency ranging from 6 – 14%, and these 3 auto-antibodies were associated with deep tissue involvement, signified by joint contractures, nerve entrapment and muscle involvement. Interestingly, none of the 15 auto Ab associated with LS subtype designation. Although internal organ involvement is uncommon in LS, when it was present, it did associate with an autoantibody. Therefore, supporting the use of these SSc-associated antibodies as potential classifiers or predictors of disease involvement in LS, though may be different manifestations from SSc. Further analyses of the details of ECMs, and associations of autoAbs with traditional labs (WBC, ESR, CPK), other autoAbs, and cytokines are underway.

Session Date: Monday, October 22, 2018

Session Title: Pediatric Rheumatology – Clinical Poster II: Autoinflammatory Disorders, Scleroderma, and Miscellaneous

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Juvenile systemic sclerosis (jSSc) is an orphan disease with a prevalence 3 in a 1 000 000 children(1). Published data is limited regarding the course of jSSc with standardized assessment of patients. We report our data from the juvenile sclerosis inception cohort over the first 24 months after enrollment.

Methods: The juvenile sclerosis inception cohort is a prospective multicenter registry of patients with jSSc, who fulfill the adult classification criteria, are less than 16 years old at onset, and are less than 18 years at the time of inclusion in the cohort. We evaluated the clinical characteristics of those followed at least 24 months in the registry.

Results: Forty jSSc patients met this criteria. The majority were female (80%) with diffuse cutaneous subtype (77.5%) and 20% had overlap features. Mean disease duration at time of inclusion was 3.2 years. Mean age of onset of Raynauds was 8.2 years and the first non-Raynauds 8.7 years. Those on DMARDs increased from 73% at the time of inclusion and to 95% after 24 months. 85% of the patients were ANA positive, approximately 25% anti-Scl70 positive and 3% antitopoisomerase positive. The mean modified skin score decreased from 14.4 to 12.9. The frequency of Raynaud's stayed around 87.5%. The frequency of the nail fold capillary changes increased from 55% to 62%, but the frequency of active ulcerations decreased from 23% to 20%. The number of patients with FVC <80 % decreased from 42% to 39% (p=0.8). The number of patients with DLCO < 80% decreased from 54 to 44% (p=0.58). The number of patients with pulmonary hypertension assessed by ultrasound increased from 5% to 10% (p=0.396). No patient developed hypertension or renal crisis. Gastrointestinal involvement decreased from 32.5% to 22.5% (p=0.317). Number of swollen joints decreased from 23% to 17.5% (p=0.53). Total muscle weakness decreased from 5 % to 0% (p=0.224) and elevated CK decreased from 17% to 11% (p=0.54). Several patient related outcomes improved significantly. Patient global disease activity (VAS 0-100) from 49.2 to 29.4(p=0.001), patient global disease damage (VAS 0-100) from 43.9 to 29.8 (p=0.013) and patient Raynaud activity VAS 0-100) from 26.7 to 14.2 (p=0.045) as physician global disease activity (VAS 0-100) from 48.3 to 33.2 (p=0.021).

Conclusion: Over the 24 months observation period patient related outcomes improved significantly and fortunately most other clinical parameters did not reveal any significant deterioration. It seems, that the current treatment can reach improvement judged by the patients and stabilization of the disease outcomes.

Session Information

Session Date: Monday, October 22, 2018

Session Title: Pediatric Rheumatology – Clinical Poster II: Autoinflammatory Disorders, Scleroderma, and Miscellaneous

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Juvenile systemic scleroderma (jSSc) is an orphan disease with a prevalence of 3 in 1 000 000 children(1). There is limited data published regarding the clinical presentation of jSSc. The juvenile systemic scleroderma inception cohort is a multinational cohort with a prospective standardized assessment of the patients. We present the clinical characteristics of the patients at time of the inclusion in the cohort.

Methods: The juvenile scleroderma inception cohort is a prospective multicenter registry of patients with jSSc, who fulfill the adult classification criteria, are less than 16 years old at disease onset, and are less than 18 years of age at the time of inclusion in the cohort. We evaluated the patient’s characteristics at time of inclusion in the cohort.

Results: One hundred and nine jSSc patients were enrolled and analyzed as of April 15th, 2018. The majority are female (79%) and Caucasian (90%). Diffuse cutaneous subtype was the most common (80%), with 15% having overlap features. The mean age of onset of Raynauds was 9.7 years in the diffuse subtype (djSSc) and 10.5 years in the limited subtype (ljSSc) (p=0.62). The mean age of non-Raynauds was 10.2 in the djSSc and 11.2 in the ljSSc (p=0.52). Mean disease duration at time of inclusion was 3.4 in the djSSc and 2.5 in the ljSSc group. Approximately 80% of all jSSc patients received DMARDs. ANA positivity was around 86% in both groups. Anti-Scl70 was 32% in djSSc and 39% in the ljSSc group. Anticentromere positivity was 4% in the djSSc and 11% in the ljSSc group(p=0.28). Mean Modified Rodnan skin score was 18.2 in the djSSc and 7.7 in the ljSSc (p=0.001). Gottron papulae were significantly more common the djSSc with 27% compared to 7% in the ljSSc group. History of ulceration was significantly more common in the djSSc with 57% compared to 29% in the ljSSc group (p=0.010). FVC<80% occurred in 34% in the djSSc and 21% in the ljSSc group (p=0.295). DLCO <80% occurred 44% in the djSSc and 43% in the ljSSc group. Pulmonary hypertension assessed by ultrasound occurred 7% in both groups. No hypertension or renal crisis was reported or observed. Gastrointestinal involvement occurred 35% in the djSSc and 24% in the ljSSc (p=0.28). Number of swollen joints were observed around 20% in both groups. Muscle weakness with joint contractures were present in 12% in the djSSc and 28% in the ljSSc group. Tendon friction rub was present in 4 % in djSSc and 7% in the ljSSc group. djSSc patients had significantly worse scores for physician global disease activity (VAS 0-100), 41.6 compared to 30.7 (p=0.041) and for physician global disease damage (VAS 0-100) 38.2 compared to 18.9 (p=0.023).

Conclusion: In this large cohort of jSSc patients there are surprisingly not many significant differences between djSSc and ljSSc. According to the physician global, the djSSc patients have significantly more severe disease.

The Utilization of S100 Proteins Testing in Pediatric Rheumatology Patients in a Tertiary Care Institution and Implications for Care

Najla Aljaberi¹, Angela Merritt², Alexei Grom¹, Grant Schulert³, Jennifer L. Huggins⁴, Michael Henrickson⁵ and Hermine I. Brunner¹, ¹Pediatric Rheumatology, Cincinnati Children's Hospital Medical Center, Cincinnati, OH, ²Pediatric Rheumatology, Division of Rheumatology, Cincinnati Children's Hospital Medical Center, Cincinnati, OH, ³Rheumatology, Divisions of Rheumatology, Cincinnati Children's Hospital Medical Center, Cincinnati, OH, ⁴Cincinnati Children's Hospital Medical Center, Cincinnati, OH, ⁵Cincinnati Children's Medical Center, Cincinnati, OH

Session Information

Session Date: Monday, October 22, 2018

Session Title: Pediatric Rheumatology – Clinical Poster II: Autoinflammatory Disorders, Scleroderma, and Miscellaneous

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: S100 proteins are calcium-binding proteins of increasing value as biomarkers in various inflammatory conditions (e.g. auto inflammatory diseases, vasculitides, inflammatory bowel disease). The two highly studied members in this family; S100A12 and S100A8/9 complex have been proven useful as diagnostic markers. Our study evaluated the utilization of S100 proteins in the clinical setting. We studied the correlation between those markers and other widely used inflammatory markers, disease activity, medication use in our JIA population.

Methods: Subjects were patients seen at the hospital's specialty clinics (mainly rheumatology) who had S100 proteins tested at some point during their care. The lab reports S100 proteins results as a numeric value above zero. Obtaining S100 proteins is considered part of clinical practice in our institution in the investigation of certain inflammatory conditions. This is a relatively recent addition to practice, and therefore, there are no standard guidelines on specific indications and

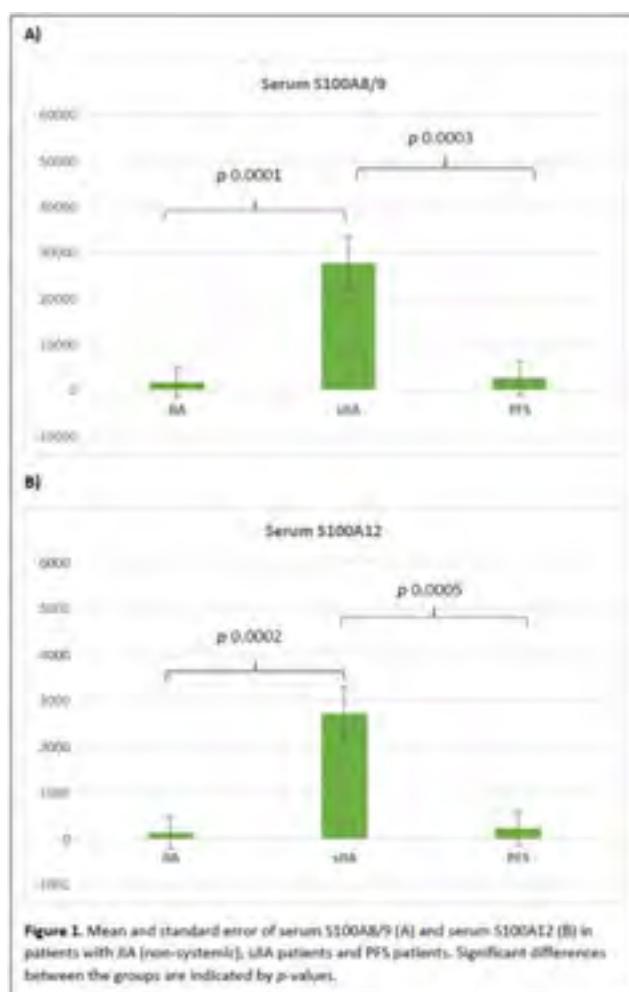

Table 2. Correlation between serum S100 protein levels and clinical and laboratory variable in JIA patients.

S100 level	Diagnosis							
	JIA				sJIA			
	CRP	ESR	AJC	LROM	CRP	ESR	AJC	LROM
A8/9	0.53***	0.35	-0.21	0.00	0.97***	0.82*	0.30	0.46
A12	0.25	0.26	-0.17	-0.09	0.98***	0.81*	0.53*	0.79*

* p<0.05 ** p<0.01 ***p<0.001
CRP (C-reactive protein), ESR (erythrocyte sedimentation rate), AJC (active joint count), LROM (limited range of motion).

follow-up tests. A retrospective chart review was performed to collect data on serum S100 protein levels, other inflammatory markers and disease activity. Descriptive statistics were calculated for all variables. SAS software was used to perform all analyses. For continuous variables, mean and standard errors are reported, and comparisons were calculated using two-sample t-tests. For categorical variables, frequency and percentage are reported. Correlation was studied using Pearson Correlation Coefficient.

Results: A total of 118 patient charts with S100 protein levels were reviewed. most patients have a diagnosis of JIA. Patients with systemic JIA (sJIA) had higher levels of S100A8/9 and S100A12 compared to patients with non-sJIA and periodic fever syndrome (PFS) (Figure 1).Correlation analysis revealed strong correlation between CRP and S100A8/9 as well as S100A12 in sJIA patients. S100A12 was found to have moderate to strong correlation with disease activity in sJIA patients. However, other variables including disease activity showed weak to moderate correlation (Table 2).

Conclusion: S100A8/9 and S100A12 were found to be particularly elevated in sJIA patients with a strong correlation with concomitant CRP values. Elevated S100A12 was linked to disease activity in sJIA patients. More data points are needed to delineate correlation between disease activity over time and S100 proteins. S100 proteins can serve as markers to aiding the diagnostic work-up of fever and sJIA and potentially disease activity monitoring in JIA.

Session Information

Session Date: Monday, October 22, 2018

Session Title: Pediatric Rheumatology – Clinical Poster II: Autoinflammatory Disorders, Scleroderma, and Miscellaneous

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Twenty-five pediatric rheumatologists (PR) service a population of 14 million Ontarians. To facilitate care to patients living in distance communities we proposed a new model of care using a local Advanced Clinician Practitioners in Arthritis Care (ACPAC) to engage with PRs via tele medicine. The first phase of this project reported our needs assessment of patients seen in London and Toronto. Of a total of 265 patient/caregiver respondents, 80% of patients travelled > 50 km with 13% travelling > 200 km with an associated cost >\$50 in 37% and ≥1 missed day of work in 56% to attend PR visits. We present preliminary results from the second phase of this project: a survey of patient/parent satisfaction in attending an ACPAC-PR tele health clinic visit.

Methods: Twenty-five ACPACs interested in additional pediatric rheumatology training attended a two-day training program occurred in September 2016. Of the four ACPAC therapists participating in the pilot clinic phase, 3 had extensive

pediatric experience and fourth received on-site training. Patient/caregiver perception of visit burden and satisfaction of the ACPAC-PR telehealth visit were surveyed. Quantitative data were summarized using descriptive statistics and qualitative data were analyzed using grounded theory.

Results: Four telehealth clinics in both Windsor ACPAC-London PR (28 visits, 20 unique patients) and Thunder Bay ACPAC-Toronto PR (18 unique patient visits) have occurred to date. 19/23 surveys were returned from the Windsor-London clinic and 12/18 distributed at the Thunder Bay-Toronto site. 26/31 (84%) travelled < 25 km to the clinic. 21/31 (68%) spent <\$ 25 on travel with 32% spending nothing. 12/45 (27%) of parents/guardians missed 1/2 to 1 full day of work with no one missing more than 1 day. >90% of respondents strongly agreed/agreed that they were satisfied with the telemedicine process and interaction with the ACPAC and PRs. 30/31 (96%) indicated that “the care I received today was equal to the care I receive in person” and that the wait time to see the PR was adequate (versus too short or too long) compared with an in person visit (87%).

Conclusion: A model of care integrating ACPACs, telemedicine and PRs improves local access to pediatric rheumatology care while reducing the burden of travel and cost to families. Barriers to the full implementation of this model include the lack of funding for ACPACs to provide these outreach clinics as well as lack of (pediatric) ACPACs in distant communities to sustainably provide this valuable service.

Session Information

Session Date: Monday, October 22, 2018

Session Title: Pediatric Rheumatology – Clinical Poster II: Autoinflammatory Disorders, Scleroderma, and Miscellaneous

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: A NIH focus group study found that adolescents and young adults (AYA) with active disease relied heavily on their parents for disease management. It was reported that increased parental involvement demonstrated less AYA control and responsibility. It was further recommended to reduce the role of the parent in order to enable the AYA to manage the disease into adulthood (Huang, JS et al. Transition to Adult Care: Systematic Assessment of Adolescents with Chronic Illnesses and their Medical Teams, J Ped, 159;6, Dec 2011). This study examines parental involvement and AYA self-management of healthcare responsibilities and decision-making in pediatric rheumatology.

Methods: A cross sectional study of 42 adolescent/young adult patients ages 14-25 yrs with a childhood onset rheumatic disease and 32 of their parents were prospectively recruited from consecutive ambulatory visits at single center urban academic institution. Both groups were asked to complete separate surveys that assessed transition readiness perception, parental involvement, and AYA management skills. Healthcare providers were asked to complete a questionnaire assessing age appropriate parental involvement at each encounter. Patient and parent demographics were obtained.

Results: There were 23 AYAs between ages 13-17 (16 yrs, SD 0.93) and 17 AYAs between 18-25 (20 yrs, SD 1.98). AYA self-reported ethnicity showed 38% (16) were white, 21% (9) were Hispanic, and 7% (3) were Hispanic. Diagnosis composed of 55%(23) JIA, followed by 19% (8) SLE. Of the parents, 64% (27) were mothers and 48% (20) were white. Table 1 demonstrates that parents agreed that AYA self-management was somewhat/very important. Both groups of parents reported to be somewhat/very involved in the patient's health and consistently performed most tasks for the AYA. (Figure 1a). Yet 53% of all parents answered that AYA should self-manage between ages 16-18. Both adolescents (87%) and young adults (84%) also agreed that self-management was somewhat/very important. There was a discrepancy between young adult involvement (89%) and the tasks performed by the AYA (Figure 1b).

Table 1. Descriptive Statistics-Primary Variable. Figure 1. Survey Results

Physicians perceived a progression in decision-making from the adolescent to young adults, but reported that only a minority of young adults(41%) demonstrated independent healthcare responsibility again. AYAs and parents perceived increased parental and less AYA decision-making from adolescent to young adult (Figure 1c).

Conclusion: In this cohort of childhood onset rheumatic diseases there was a failure to demonstrate progress towards independence from the adolescent to the YA cohorts. The majority of patients over age 18 were nonindependent in making health care decisions and one third of young adults took over health related specific tasks from their parents. Further prospective longitudinal study is needed to determine the optimal goals and methods to successfully achieve health care independence.

Session Information

Session Date: Monday, October 22, 2018

Session Title: Pediatric Rheumatology – Clinical Poster II: Autoinflammatory Disorders, Scleroderma, and Miscellaneous

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Transfer from pediatric- to adult-oriented health care is challenging for patients with childhood-onset rheumatologic disease, and may be associated with treatment on-adherence, disease flares and urgent healthcare utilization. This study aimed to measure transition outcomes among young adults transferring from pediatric to adult care at a single US academic medical center, before and after implementation of transition process improvements.

Methods: Transition process improvements implemented by the pediatric rheumatology practice between 2012 and 2017 included the creation of a transition policy, systematic identification of transition-age patients, and quarterly transition planning rounds. Electronic health record (EHR) query was used to identify patients who transferred from pediatric to adult rheumatology care within the institution during 2012-2017. Primary endpoints were transfer time (time from last pediatric to first adult appointment) and successful transfer. Successful transfer was defined as 1) transfer time from pediatric to adult care <6 months and 2) completion of >2 visits with an adult provider within a 12-month period. Secondary endpoints were pre- and post- transfer disease activity as measured by physician global assessment or SLEDAI score (active v. inactive), and insurance type (public, private, both). We compared outcomes to those of patients who transferred during 1995-2005, prior to the implementation of transition support processes. Bivariate statistics were used to compare differences between groups.

Results: 87 patients transferred from pediatric to adult rheumatology care during 2012-2017, and 31 patients transferred during 1995-2005 (Table 1). Diagnoses were similar in both groups. During 2012-2017, median transfer time was significantly shorter (3.5 vs. 7.1 months, $p=0.03$), and 52% of patients transitioned successfully. Transitioning patients were more likely to have active disease in 1995-2005, both pre-transfer (61% vs 29%, $p=0.001$) and post-transfer (61% vs 26%, $p=0.001$). More patients were publicly insured pre-transfer during 1995-2005 (74% public and 26% private vs. 42% public, 55% private and 2% both, $p=0.009$), but there were no differences in insurance type post-transfer.

Conclusion: During the implementation of transition initiatives, median transfer time from pediatric to adult rheumatology significantly decreased, and over half of patients transferred successfully. Disease activity at the time of transfer also improved, which may reflect improvements in disease management or differences in disease severity. Although direct causal associations between transition support interventions and transfer success cannot be made, this study suggests that implementation of structured transition processes may positively impact the transfer to adult care.

Research Priorities for Addressing Mental Health Needs of Pediatric Patients with Rheumatologic Disease

Tamar Rubinstein¹, Lindsay Waqar², Jennifer Woo³, **Ekemini Ogbu**⁴, W. Blaine Lapin⁵, Lawrence Ng⁶, Erin Treemarcki⁷ and Andrea M. Knight⁸, ¹Pediatric Rheumatology, Albert Einstein College of Medicine, Children's Hospital at Montefiore, Bronx, NY, ²Children's Hospital of Philadelphia, Philadelphia, PA, ³University of California Los Angeles, Los Angeles, CA, ⁴Pediatrics, Emory University, Atlanta, GA, ⁵Baylor College of Medicine, Houston, TX, ⁶The Hospital for Sick Children, Toronto, ON, Canada, ⁷Hospital for Special Surgery Weill Cornell Medical College, New York, NY, ⁸Center for Pediatric Clinical Effectiveness & PolicyLab, Children's Hospital of Philadelphia, Philadelphia, PA

Session Information

Session Date: Monday, October 22, 2018

Session Title: Pediatric Rheumatology – Clinical Poster II: Autoinflammatory Disorders, Scleroderma, and Miscellaneous

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Mental health problems are prevalent in pediatric rheumatology patients. Gaps in knowledge exist regarding the detection, effective treatment, and the impact of mental illness on patients with rheumatologic disease. To address these gaps and direct research efforts to improve mental health for children and adolescents with rheumatologic diseases, the Childhood Arthritis and Rheumatology Research Alliance (CARRA) Mental Health Workgroup developed and prioritized an agenda of research topics.

Methods: A systematic review of the literature on mental health in pediatric rheumatology was completed and published. From the review, 5 major research domains in further need of study were identified: (A) mental health burden and relationship to pediatric rheumatologic disease, (B) impact of mental health disorders on outcomes, (C) mental health awareness and education, (D) mental health screening, and (E) mental health treatment. Research topics within these areas were developed and presented at the CARRA Mental Health Workgroup Annual Meeting in April 2018, where they were discussed and refined. An online survey was created to prioritize the 33 refined topics. The survey was emailed to 132 people who expressed interest in the workgroup, including pediatric rheumatologists, patients/parents, research coordinators, psychologists, social workers, and members of industry. Participants were asked to: i) grade each research topic on a 5-point Likert scale on how important, feasible, and actionable they were, and ii) provide an overall ranking of the research topics within each research area.

Results: Fifty-six (42%) responded to the survey, and 45 of the respondents completed the survey (80%). Topics related to the impact of mental health on clinical outcomes were rated most important, and those related to mental health screening

Figure 1. Highest Ranking Research Topics for Mental Health Research in Pediatric Rheumatology by Research Area:

Ranking of 33 mental health research topics by domain from the results of a survey of CARRA Mental Health Workgroup. Number of topics per domain was as follows: domain A had 5 topics, domain B 6 topics, domain C, 5 topics, domain D 9 topics, and domain E 8 topics.

were rated most feasible and actionable (Table 1). Overall rankings revealed additional topics of high priority within each research domain (Figure 1).

Conclusion: Addressing gaps in knowledge about how mental health affects youth with rheumatologic disease and how best to address mental health for these patients is an important step in improving care. We have identified high priority research topics regarding mental health of pediatric rheumatology patients in need of further investigation, that are feasible to study and believed to lead to actionable results in patient care.

Table 1. Highest Scored Research Topics for Mental Health Research in Pediatric Rheumatology by Importance, Feasibility, and Actionability.

Research Topic:	Mean Score (\pm SD) (1=Low, 5=High):
Most Important:	
(B1) Investigate the impact of mental health on clinical outcomes, such as disease activity.	4.7 (\pm 0.5)
(A1) Determine the prevalence and incidence of mental health disorders in pediatric patients with rheumatologic disease, as well as socio-demographic and disease-specific risk factors.	4.7 (\pm 0.5)
(B2) Investigate the impact of mental health on long-term clinical outcomes, such as disease damage and mortality.	4.6 (\pm 0.6)
Most Feasible:	
(D4) Determine barriers and facilitators to mental health screening for pediatric patients with rheumatologic disease.	4.2 (\pm 0.9)
(D2) Determine the accuracy of mental health screening tools for identifying mental health conditions in specific pediatric rheumatology disease populations (i.e. validation of tools for disease-specific diagnostic cut-points).	4.1 (\pm 0.7)
(A1) Determine the prevalence and incidence of mental health disorders in pediatric patients with rheumatologic disease, as well as socio-demographic and disease-specific risk factors.	4.1 (\pm 0.8)
Most Actionable:	
(D1) Determine which mental health conditions are most important to screen for in pediatric patients with rheumatologic disease.	4 (\pm 0.8)
(D2) Determine the accuracy of mental health screening tools for identifying mental health conditions in specific pediatric rheumatology disease populations (i.e. validation of tools for disease-specific diagnostic cut-points).	3.9 (\pm 0.7)
(D5) Determine acceptability of mental health screening in pediatric rheumatology clinics for patients, caregivers, and clinicians, and identify strategies to improve acceptability.	3.9 (\pm 0.8)

Means and standard deviations presented of the highest ranking research topics from 33 developed research topics addressing mental health in pediatric rheumatology around importance (relevance of the topic to advancing clinical care and research, considering existing knowledge), feasibility (ease with which research related to the topic can be conducted and completed), and actionability (ability to apply the results of research on the topic towards advancing clinical care and pediatric rheumatology research). Likert scale responses were 1 = Low, 2 = Somewhat Low, 3 = Neutral, 4 = Somewhat High, 5 = High.

Kikuchi-Fujimoto Disease: A Retrospective Analysis of 23 Pediatric Cases from a US Center

Ekemini Ogbu^{1,2}, Shanmuganathan Chandrakasan^{1,2}, Sunita Park^{1,2} and Sampath Prahalad^{1,2}, ¹Pediatrics, Emory University, Atlanta, GA, ²Children's Healthcare of Atlanta, Atlanta, GA

Session Information

Session Date: Monday, October 22, 2018

Session Title: Pediatric Rheumatology – Clinical Poster II: Autoinflammatory Disorders, Scleroderma, and Miscellaneous

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Kikuchi-Fujimoto Disease (KFD) is often described as a benign self-limited disease. However, there is a risk of recurrence. It is most common in adult Asian females but has been reported in other races and in children. Prior studies have noted differences between pediatric and adult cases and suggest that male children are more affected than female children. However, these were mostly Asian studies raising the question of racial and sex differences of this disease in other populations. In particular, studies from North America is lacking. As we have one of the largest, diverse centers in the US, our objective was to describe our cohort of pediatric patients with KFD and to examine racial and gender differences in clinical and laboratory parameters.

Methods: We conducted a retrospective study of patients diagnosed at our center from January 1, 2007 to January 1, 2017. Using natural language selection, patients with biopsy-proven KFD were identified from our institutional pathology database and included in our study. We extracted corresponding clinical and laboratory data from our electronic medical records. We excluded patients older than 18 years at the time of diagnoses and patients with a concurrent or pre-existing

diagnosis of systemic lupus erythematosus. IRB approval of the study protocol with waiver of informed consent was obtained from our institution.

Results: We identified 23 patients with KFD who met our inclusion and exclusion criteria as shown in table 1 with racial and sex comparisons in table 2. The majority of our patients were Black (74%). Female to male ratio was 1.3:1. Mean age for males was significantly lower than for females. Bilateral cervical lymphadenopathy, fever, fatigue and elevated lactose dehydrogenase were common. There were more males with severe KFD, consisting of fever and weight loss, than females. The odds of having severe KFD in males was 12.831 times the odds in females (95% CI 1.694, 97.172 p-value 0.0135). Median follow-up period was 4 months. Four patients (17%) had a recurrence of disease during their follow-up. We found no significant difference in clinical or laboratory data in Black patients compared to other races.

Conclusion: To the best of our knowledge, this is the largest pediatric study of KFD in the US. Our findings show a slight female predominance and higher recurrence rate relative to prior pediatric reports. This strengthens the need for longitudinal studies on patients with KFD to determine risk factors for recurrence.

Session Information

Session Date: Monday, October 22, 2018

Background/Purpose: Mental health conditions are common in youth with rheumatologic disease, yet intervention strategies are under studied. We used a patient-engaged approach to investigate the mental health needs of youth with rheumatologic disease.

Methods: An anonymous online survey examined beliefs and experiences with mental health for youth with rheumatologic disease. Eligible youth ages 14-24 years had a diagnosis of juvenile arthritis, juvenile dermatomyositis, or systemic lupus erythematosus, and reported specific treatment for the condition. Parents of youth 8-24 years meeting the above criteria were also eligible to participate. The survey was developed in collaboration with patient and parent advisors, the Childhood Arthritis & Rheumatology Research Alliance (CARRA), and the Patients, Advocates, and Rheumatology Teams Network for Research and Service (PARTNERS). Participants were recruited through the Arthritis Foundation, Lupus Foundation of America, and Cure JM Foundation. We compared youth and parent responses using regression models (adjusted for demographic and disease covariates) to examine: 1) reported prevalence of mental health problems, categorized into mutually exclusive clinician-diagnosed disorders and self-reported symptoms, 2) mean Likert ratings (0=low, 4=high) forth impact of disease aspects on mental health, and 3) comfort level with potential mental health providers.

Results: 485 respondents included 140 patients(29%) and 345 (71%) parents. Clinician-diagnosed anxiety was reported by 39% of youth, depression by 29%, and adjustment disorders by 19% (Figure 1); another 22%, 15% and 11% had self-reported symptoms of these disorders, respectively. Mean Likert ratings by youth indicated that disease aspects most impacting mental health were physical limitation at 2.7 (SD 1.1), taking medications at 2.6(1.2), and dealing with disease flares at 2.5 (1.2). Adjusted models showed no difference between youth and parents for reported mental health problems or impacting factors. Youth were significantly less comfortable interacting with potential mental health providers than

parents, particularly social workers and school counselors (Figure 2); both groups felt most comfortable with rheumatologists and primary care providers.

Conclusion: Youth with rheumatologic disease have high rates of diagnosed and undiagnosed mental health problems, which are impacted by their disease. Mental health intervention in primary care and subspecialty care settings may improve mental health education, screening and treatment for these youth.

Session Information

Session Date: Monday, October 22, 2018

Session Title: Pediatric Rheumatology – Clinical Poster II: Autoinflammatory Disorders, Scleroderma, and Miscellaneous

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Resilience is a dynamic process of positive adaptation in the context of significant adversity. While higher levels of resilience have been associated with improved physical function and reduced depression and pain in adults

Table. Clinical Characteristics and Resilience Levels Among Children with AMPS and Their Caregivers

	Patients (n=20)	Parents (n=20)
Demographics		
Female, n (%)	19.0 (95.0)	15.0 (75.0)
Age (years), median (IQR)	15.0 (13.0, 15.5)	48.0 (45.0, 51.0)
Caucasian, n (%)	14.0 (70.0)	19.0 (95.0)
Non-Hispanic, n (%)	16.0 (80.0)	17.0 (85.0)
Clinical Variables, median (IQR)		
Pain visual analog scale (0-100)	63.0 (30.5, 79.5)	27.0 (7.5, 62.0)
Energy level (0-100)	55.0 (41.8, 72.5)	80.0 (62.5, 90.0)
Functional Disability Inventory (FDI) (0-60)	23.5 (17.5, 39.0)	28.0 (18.5, 33.5)
Widespread Pain Index (WPI)* (0-19)	5.0 (2.5, 11.0)	—
Symptom Severity Score (SSS)* (0-12)	6.0 (5.0, 7.5)	—
Resilience Measures, mean (SD)		
RS-14	74.1 (12.9)	79.4 (11.7)
CD-RISC-10	26.5 (7.0)	28.8 (6.5)
The 7 Cs Tool	3.1 (1.7)	—

AMPS = amplified musculoskeletal pain syndrome; IQR = interquartile range; SD = standard deviation; FDI scores range from 0-60 with greater scores indicating more functional disability; RS-14 (14-item Resilience Scale) scores range from 14-98, with greater scores indicating greater resilience. Scores are categorized into very low (14-56), low (57-64), on the low end (65-73), moderate (74-81), moderately high (82-90) and high (91-98). The Connor-Davidson Resilience Scale 10-item scores range from 0-40 with higher scores indicating greater resilience. The mean CD-RISC-10 level of patient resilience in this study is lower than that previously reported in adolescents with cancer, type 1 diabetes and inflammatory bowel disease, which all range from 27.3-30.4 (Rosenberg et al 2015; Carlson et al 2017). The 7 Cs Tool is validated for an adolescent population only (≥ 13 years). Scores range from 0-14 with higher scores indicating lower resilience and a cut off of ≥ 3 considered low resilience (Garg et al 2017). *WPI and SSS defined according to the 2010 American College of Rheumatology Criteria for Fibromyalgia Syndrome

with chronic musculoskeletal pain, our knowledge regarding the role of resilience in children with amplified musculoskeletal pain syndrome (AMPS) is limited. We aimed to 1) measure the level of resilience among patients with amplified musculoskeletal pain syndrome and one of their caregivers and 2) determine factors associated with patient resilience.

Methods: This was a prospective inception cohort study of children ages 13-17 years diagnosed with AMPS and one of their caregivers. Eligible subjects were seen for an initial consultation in the pediatric rheumatology pain clinic from March 2018 – May 2018. Subject-caregiver pairs completed online questionnaires including demographic surveys and two measures of resilience: The 14-Item Resilience Scale (RS-14) and the Connor-Davidson Resilience Scale 10-item (CD-RISC-10). Children completed another resilience measure, the 7 Cs Tool. Clinical and demographic variables were abstracted from electronic medical records. We performed multivariate linear regression analyses, using stepwise forward selection with $p < 0.2$, to explore the relationship between patient resilience (using CD-RISC-10) and variables of interest including parental resilience.

Results: 20 patient-proxy pairs were included. The majority of patients were female (75%) and Caucasian (70%). Parents were predominantly mothers (95%) and Caucasian (95%). Table 1 shows other demographic variables. 95% of children had ≥ 1 adverse childhood experience (ACEs) with parental separation being the most common (20%). According to the RS-14, both children and parents had moderate resilience (Table). On the CD-RISC-10, children had a mean score of 26.5 (SD 7.0) and parents had a mean score 28.9 (SD 6.5). This compares to a mean level of resilience of 30.1 (SD 5.3) among a normative student sample (Hartley MT, 2012). According to the 7 Cs Tool, the mean level of patient resilience was low (total score ≥ 3), with a mean of 3.05 (SD 1.7). All measures of resilience were statistically significantly correlated with one another ($p < 0.05$). From the final regression model, higher patient resilience was found to be associated with lower pain scores ($\beta = -0.17$), less depression ($\beta = -4.9$), more ACEs ($\beta = 1.93$), older age ($\beta = 1.92$), and a lower symptom severity score ($\beta = -0.63$) (all $p < 0.02$). Parental resilience did not contribute significantly to the model ($p > 0.2$).

Conclusion: Children with AMPS and their parents had low to moderate levels of resilience. Higher patient resilience was associated with lower disease burden among children with AMPS. Resilience-training interventions serve as potential treatment modalities for this patient population.

Abstract Number: 1434

Patient-Proxy Agreement on Health-Related Quality of Life in Juvenile Fibromyalgia Syndrome

Sabrina Gmuca, Audrey Urquhart and David D. Sherry, Pediatric Rheumatology, Children's Hospital of Philadelphia, Philadelphia, PA

Session Information

Session Date: Monday, October 22, 2018

Session Title: Pediatric Rheumatology – Clinical Poster II: Autoinflammatory Disorders, Scleroderma, and Miscellaneous

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The administration of proxy-reported health-related quality of life (HRQoL) measures in the assessment of juvenile fibromyalgia syndrome (JFMS) is common but its added clinical value to patient-reported measures is unclear. The aim of this study was to examine the level of agreement between patient- and proxy-reports of the Pediatric Quality of Life Inventory Short Form 15 (PedsQL SF-15) among children with JFMS and to examine potential factors influencing patient-proxy agreement. Given the strong parent-child pain relationship, we hypothesized good agreement.

Methods: This was a cross-sectional cohort study of children 8-17 years old presenting for initial evaluation to a pediatric rheumatology pain clinic from April 2017 – April 2018. Included subjects met the 2010 American College of Rheumatology criteria for fibromyalgia syndrome. All patients and proxies completed electronic questionnaires, including the PedsQLSF-15, as part of routine clinical care. Additional information collected included age, sex, race, ethnicity, verbal pain score (0-10), and pain duration (months). Descriptive statistics were performed to assess patient characteristics. Intra-class correlation (ICC) estimates and their 95% confidence intervals were calculated based on a mean-rating, absolute-agreement, 2-way mixed-effects model to examine patient-proxy agreement on the PedsQL SF-15. We performed multiple regression analyses to explore the relationship between different independent variables and patient-proxy agreement.

Results: Over the study interval, 54 patient-proxy pairs met criteria and completed the HRQoL measures. The majority of patients were non-Hispanic (94%), Caucasian (79%), and female (83%). The median age at time of presentation was 15

Table 1.

PedsQL SF-15 Scores and Level of Patient-Proxy Agreement (ICC's)

PedsQL Domain	Patient-report (N=54) median (IQR)	Proxy-report (N=54) median (IQR)	Patient-proxy ICC (95% CI)
Physical Functioning	35.0 (25.0, 60.0)	35.0 (20.0, 55.0)	0.83 (0.71, 0.90)
Emotional Functioning	56.3 (43.8, 75.0)	50 (38.0, 56.3)	0.73 (0.52, 0.84)
Social Functioning	91.7 (66.7, 100)	83.3 (66.7, 100)	0.85 (0.73, 0.91)
School Functioning	50.0 (33.3, 66.7)	58.3 (41.7, 75.0)	0.72 (0.52, 0.84)
Physical Health Summary Score	35.0 (25.0, 60.0)	35.0 (20.0, 50.0)	0.83 (0.71, 0.90)
Psychosocial Health Summary Score	65.0 (52.5, 77.5)	60.0 (52.5, 70.0)	0.84 (0.72, 0.91)
Total Summary Score	59.2 (48.3, 68.3)	53.3 (43.3, 61.7)	0.85 (0.74, 0.91)

Legend: PedsQL SF-15 = pediatric quality of life inventory short form 15 item. HRQoL = health-related quality of life. PedsQL SF-15 scores range from 0-100 with higher scores indicating better HRQoL. Intra-class correlations (ICC's) were rated as 0-0.40: poor agreement; 0.41-0.60: moderate agreement; 0.61-0.80: good agreement; and 0.81-1.00: excellent agreement. The Psychosocial Health Summary Score is the sum of the items over the number of items answered in the Emotional, Social, and School Functioning Scales. The Physical Health Summary score is equal to the Physical Functioning Scale Score. The Total Summary Score is the sum of all items over the number of items answered on all of the scales.

years (IQR: 14, 16). The median verbal pain score was 5 (IQR: 4, 7). Median duration of pain was 24 months (IQR: 12-36). Cronbach's alpha coefficient for the PedsQL SF-15 exceeded 0.70. All domains demonstrated good to excellent agreement between patients and proxies (Table 1). Multiple regression analyses, adjusting for patient sex, Caucasian race, age, current pain level and pain duration showed that the greater the child's pain, the greater the patient-proxy agreement on the Total Scale ($\beta = -1.20$, $p < 0.05$) and the Emotional Functioning Scale ($\beta = -2.03$; $p < 0.05$).

Conclusion: The high levels of patient-proxy agreement in this study suggest that children with JFMS and their parents communicate their feelings and opinions well to one another and this agreement is associated with greater pain severity in the child. These findings reflect the enmeshed relational and communication styles between children with JFMS and their parents. In order to facilitate adolescents becoming partners in their own healthcare and to decrease the burden of multiple questionnaires, we propose focusing on children's own perceptions of HRQoL.

Hormonal Contraception Use and Capacity to Self-Screen for Contraindications Among Adolescents in a Pediatric Rheumatology Clinic

Stacey Tarvin¹, Tracey Wilkinson², Tom Vielott², Ashley Meredith³, Carolyn Meagher² and Mary Ott⁴, ¹Pediatric Rheumatology, Riley Hospital for Children, Indiana University School of Medicine, Indianapolis, IN, ²Riley Hospital for Children, Indiana University School of Medicine, Indianapolis, IN, ³Purdue University, West Lafayette, IN, ⁴Adolescent Medicine, Riley Hospital for Children, Indiana University School of Medicine, Indianapolis, IN

Session Information

Session Date: Monday, October 22, 2018

Session Title: Pediatric Rheumatology – Clinical Poster II: Autoinflammatory Disorders, Scleroderma, and Miscellaneous

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Many states allow pharmacists to prescribe combined hormonal contraception (HC), eliminating the barrier of a provider visit. For adolescent rheumatology patients, however, a clinician visit can be an opportunity to discuss specific hormonal contraindications. We examine adolescent rheumatology patients' HC experience, ability to self-screen for HC contraindications, and acceptability of pharmacist prescribing HC.

Methods: After IRB approval, females ages 14-21 were recruited from pediatric rheumatology (RC), primary care (PC), and other subspecialty (OS) clinics. Participants completed a demographic and behavioral survey, including Child with Special Health Care Needs (CSHCN) screener, perceived severity of pregnancy (1 item, range 1-5) and acceptability of pharmacist prescribing HC (2 items). Adolescents and physicians separately completed checklists for potential contraindications to HC per the CDC Medical Eligibility Criteria (MEC). The checklist was a screener, capturing broad categories rather than specific high-risk diagnoses (e.g. lupus in general, vs. + antiphospholipid antibodies). Discordance was any difference between adolescent and physician for a potential level 3/4 MEC contraindications. Unsafe discordance was Adol No/Physician Yes for a level 3/4 MEC contraindication (under-report) while safe discordance was Adol Yes/Physician No (over-report). We used Chi Square, ANOVA and logistic regression.

Results: We recruited 47 (16%) RC adolescent/physician pairs, 175 (58%) PC pairs, and 77 (26%) OS pairs. In RC, 71% identified as white, 11% African American, 2% Latino, and 16% multiracial or other. PC were more likely to be African American or Latino, and OS White. The mean age for RC was 16.3 +/- 1.3 years, similar to PC and OS (p=NS). 94% of RC were CSHCN, compared to PC 45% and OS 88% (p<.001). 19% of RC were sexually active, compared to 45% PC and 13% OS (p<.001).

In RC, 13 (28%) had ever used HC (combined pills, injection, ring, patch), and 2 (4%) LARC (implant, IUD), lower than PC (45% HC, 9% LARC) or OS (35% HC, 6.5% LARC) (p=.05 for HC). Thirty-two (68%) of RC patients had at least 1 potential MEC level 3/4 contraindication, higher than PC (14%) or OS (26%) (p<.001). The most common for RC were lupus, migraines, and hypertension. RC reported a higher perceived severity of pregnancy (RC 4.1 +/- 1.1 vs PC 3.2 +/- 1.6 and OS 3.6 +/- 1.4, p<.05). Although the rate of overall discordance between adolescent and providers for RC was high (RC 36% vs. PC 17% and OS 25%, p<.05), the rate of unsafe discordance was low (RC 11%, PC 6%, OS 9%, P=NS). Adolescents in RC were equally interested in pharmacist prescribing HC (RC 45%, PC 43% and OS 51%). Logistic regression among RC patients, controlling for age, only sexual experience was associated with (lower) unsafe discord.

Conclusion: Despite adolescent rheumatology patients' high rates of potential contraindications and low rates of HC use, they are interested in pharmacist access. When discordant, they are more likely to over-report (safe) rather than under-report (unsafe) potential contraindications. Clinicians caring for these adolescents should proactively address HC and associated risks.

Pregnancy Outcomes in Partners of DMARD Exposed Men with Juvenile Idiopathic Arthritis – an Observational Study

Paula Drenches¹, Jens Klotsche², Martina Niewerth², Gerd Horneff³ and **Kirsten Minden**⁴, ¹Epidemiology, German Rheumatism Research Center, Berlin, Germany, ²Program Area Epidemiology, German Rheumatism Research Center, Berlin, Germany, ³Asklepios Clinic Sankt Augustin, and University Hospital of Cologne, Cologne, Germany, ⁴Epidemiology unit, German Rheumatism Research Center and Charité University Medicine Berlin, Berlin, Germany

Session Information

Session Date: Monday, October 22, 2018

Session Title: Pediatric Rheumatology – Clinical Poster II: Autoinflammatory Disorders, Scleroderma, and Miscellaneous

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Males account for about one third of all cases of juvenile idiopathic arthritis (JIA). During the course of the disease and often into adulthood, they are exposed to various disease-modifying antirheumatic drugs (DMARDs). If men with JIA wish to have a child, they have to weigh the risk of disease flare on drug withdrawal against a not yet clearly defined impact of drugs on offspring.

The study objective was to investigate the outcomes of pregnancies in partners of male JIA patients who were exposed to DMARDs.

Methods: In the JIA biologic registry JuMBO (Juvenile arthritis MTX/Biologics long-term Observation), male patients with pregnancies in partners were identified. Standardized patient interviews were conducted and the outcome of pregnancies inquired. In addition, prospectively collected physician-reported data on treatment and disease activity of JIA patients were considered in the analysis.

Results: Out of the 1,397 patients enrolled in JuMBO, a total of 243 pregnancies in 125 women and in partners of 26 men with JIA were reported. Until February 2018, detailed information was available for 39 pregnancies of partners of 21 men

with JIA. Most male patients (43%) had polyarticular JIA, 24% enthesitis-related arthritis, 10% psoriatic arthritis. At first pregnancy, the mean paternal age was 23.2 ± 4.2 years, the mean disease duration was 13.3 ± 6.0 years and the mean disease activity according to cJADAS-10 4.8 ± 4.5 .

All men had been exposed to 2.5 ± 1.0 DMARDs for a mean of 7.1 ± 3.1 years until 1st pregnancy, 90.5% had received biological DMARDs. Of the 39 pregnancies, there were 26 (66.7%) with paternal DMARD exposure during time of conception. Exposures included etanercept in 12, adalimumab in 3, infliximab in 3, certolizumab in 2, anakinra in 1, methotrexate in 9 and leflunomide in 2 pregnancies. Pregnancy outcomes with paternal exposure (n=26) and without (n=13) were as follows: 22 and 10 live births, 1 and 1 elective pregnancy termination, 2 and 2 spontaneous abortions, 1 and 0 stillbirth, respectively. Of the 9 pregnancies with paternal MTX exposure, 6 (66.7%) resulted in a live birth, one (11.1%) was terminated electively and 2 (22.2%) resulted in an early miscarriage.

In the 32 pregnancies with live births, pregnancy complications were reported in 22% of the cases (in exposed pregnancies in 18%, in unexposed pregnancies in 30%). Adverse neonatal outcomes like preterm delivery and neonatal hospitalizations were reported in 3 (13.6%) and 3 (30.0%) and 5 (22.7%) and 3 (30.0%) cases, respectively. No children were born small for gestational age or with low APGAR score at 5 minutes, no child died in the neonatal period. Two children were born with major congenital anomalies (club foot, agenesis of the corpus callosum) according to the EUROCAT classification, both fathers were exposed (leflunomide, corticosteroids, NSAIDs, and MTX, certolizumab, corticosteroids, NSAIDs, respectively).

Conclusion: Men with JIA who are still undergoing treatment in young adulthood often procreate children under medication, why more information on the effect of medication on male reproduction is needed. For this, more patient data must be carefully evaluated.

Abstract Number: 1437

Use, Safety and Efficacy of Thalidomide from a Tertiary Level Pediatric Rheumatology Centre in India

Manjari Agarwal¹ and Sujata Sawhney², ¹Institute of Child Health, Attending Consultant, New Delhi, India, ²Paediatric rheumatology, Senior Consultant, New Delhi, India

Session Information

Session Date: Monday, October 22, 2018

Session Title: Pediatric Rheumatology – Clinical Poster II: Autoinflammatory Disorders, Scleroderma, and Miscellaneous

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Thalidomide is an effective agent for several pediatric rheumatic diseases: SOJIA, Behcet's disease and recalcitrant skin disease in cSLE to name a few.

Systemic onset Juvenile idiopathic arthritis is a common subtype of JIA seen in India. Patients with SOJIA are often steroid dependent and relapse on dose reduction. Tocilizumab though available is prohibitively expensive. Thalidomide also has a role to play for the therapy of recalcitrant oral aphthae in Behcet's disease and is also used for the calcinosis of Juvenile dermatomyositis. This study was undertaken to study the usage, safety & efficacy of thalidomide in children with pediatric rheumatic diseases.

Methods: This study was a retrospective chart review of all children with pediatric rheumatic diseases who had been prescribed Thalidomide from 01/06/2009 to 15/05/2018.

The safety & side effects were studied for all patients (71/71). Efficacy was studied for patients with SOJIA (65/71) due to small sample size of other diseases.

Results: Use: Thalidomide was taken by 71 children. SOJIA:65, SLE:1, Behcet's disease:3, Juvenile dermatomyositis with calcinosis universalis:1, Muckle wells syndrome:1

Safety and Side effects: Thalidomide was safe in all patients at a maximum daily dose of 5.7mg/kg/day. No NCV screening was done in children prior to starting thalidomide.

11/71 children (15.5%) reported minor side effects, 2 had constipation that necessitated dose reduction, 9 had increased somnolence. No neurological adverse events were noted. Thalidomide was used as a single bedtime dose to decrease somnolence. Maximum dose used was 200mg/day.

Efficacy in SOJIA patients: Thalidomide taken by 65/208(31%)patients with SOJIA followed at our unit. 23 girls and 42 boys.

Demographic Details		range
Median age at disease onset	4.5 years	0.7-16 years
Median age at disease diagnosis	5.4 years	1-16.16 years
Median delay to diagnosis	4 months	1-48 months
Median age at thalidomide commencement	7 years	1.7-18.08 years
Median duration of therapy with thalidomide	16 months	1-110 months
Median dose of thalidomide	3.1 mg/kg	1-5.7 mg/kg
Median dose of oral steroids prior to thalidomide	0.4 mg/kg	0-3.5 mg/kg
Median dose of oral steroids 6 months after thalidomide	0.01 mg/kg	0-1.18 mg/kg (P<0.001)
Steroids stopped after 6 months of Thalidomide	28/65	43%
Response in systemic features	60/65	92%
Response in articular features	37/65	57%
No response to Thalidomide(systemic features/articular features)	5/65	7.6%
Median time taken for response in systemic features	1 month	0.5-18 months
Median time taken to response for articular ds.	4 months	1-16 months
Longitudinal follow up		
No flare ever		30/65=46%
Only articular flare		13
Both articular and systemic flare		17
Thalidomide stopped		37/65=57%
No response/step up to Tocilizumab		5/37=13.5%
Disease remission		17/37=46%
Persistent articular disease not responding to Thalidomide after 6 months		15/37=40.5%

Conclusion: 1.Thalidomide is a safe drug with no neurological side effects noted in 71 children with a maximum daily dose of 5.7mg/kg/day over the maximum follow up period of 110 months.

2. It was used in 1/3 of total SOJIA patients

3. It was effective in 92% for systemic and in 57% for articular disease.

Treatment and Response of Down Syndrome Arthropathy

Jordan T. Jones¹, Nasreen Talib², Daniel J Lovell³ and Mara L Becker⁴, ¹Rheumatology Division, Children's Mercy Kansas City, Kansas City, MO, ²General Pediatrics, Children's Mercy Kansas City, Kansas City, MO, ³Pediatrics, Cincinnati Children's Hospital Medical Center, Cincinnati, OH, ⁴Rheumatology, Children's Mercy Kansas City, Kansas City, MO

Session Information

Session Date: Monday, October 22, 2018

Session Title: Pediatric Rheumatology – Clinical Poster II: Autoinflammatory Disorders, Scleroderma, and Miscellaneous

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Of the very few studiesdescribing Down syndrome arthropathy (DA), crude prevalence estimates indicate DA maybe as common as juvenile idiopathic arthritis (JIA), however, DA is still largely under recognized at onset. Previous studies indicate the majority of DA present with greater than 5 affected joints and bony changes at diagnosis. Additionally, treatment is complex and most require a second-line therapy after Methotrexate (MTX) due an increased methotrexate toxicity. Further, gaps in literature exist around optimal treatment approach, escalation and response. The objective of this study was to investigate treatment and response of DA.

Methods: In a retrospective chart review that took place at two tertiary care hospitals, potential DA patients were identified through electronic medical record system (EMR) from January 1, 1995 to December 31, 2015. ICD-9-CM codes were used to identify patients (less than 18 years of age) with both Down Syndrome (DS; 758.0) and JIA (714.3, 714.31, 714.32,714.33). Individual charts were then manually reviewed to confirm diagnosis of DS and JIA. Chart review included analysis of all documents included in EMR, including demographic data, clinical visits, imaging studies and laboratory results.

Results: Forty-three patients met inclusion criteria with a mean follow-up period of 6 years (SD 4.4). Patients had a mean 7.4 year (SD 3.9) age at onset of musculoskeletal symptoms with a mean 19 months(SD 17) to JIA diagnosis. Patients were mostly female (58%). At JIA diagnosis 63% had a polyarticular, RF negative presentation, 70% reported morning stiffness with an average of 15 active joints (SD 13), 14 limited joints (SD 13), and mean physician global of disease activity 4.5

(SD 2.2). Most patients (93%) were started on nonsteroidal anti-inflammatory drugs (NSAIDs) at diagnosis with 28% simultaneously starting a disease modifying antirheumatic drug (DMARD), and 5% a Biologic. Over the course of disease 74% used a DMARD (94% MTX) and 47% used a biologic (83% Enbrel). Eight patients (25%) had at least one change in DMARD and nine patients (39%) had at least one change in biologic therapy (Table 1). At the last visit there were significantly ($p < 0.001$) less active (3 [SD 5]) and limited joints (5 [SD 9]), and the mean physician global of disease activity was 1.3 (SD 1.5). Of those on DMARD therapy 60% were discontinued due to side effects and 39% had inadequate response to first-line biologic therapy.

Conclusion: Down syndrome arthropathy remains under recognized, but does have a significant reduction in active and limited joints when treated with NSAIDs, DMARDs, and biologics, however, treatment approach, optimal therapy and escalation is unclear. Other barriers that inhibit optimal treatment and response are DMARD toxicity and anti-TNF effectiveness. More research is currently needed to determine optimal therapy approach.

juvenile ARD patients. Therefore, the aim of this study was to evaluate the short-term safety of immunization with fractional YFV in juvenile ARD.

Methods: Thirty pediatric patients with inactive rheumatic diseases treated with low dose immunosuppression (sulfasalazine, prednisone<0.5mg/Kg/day or 20mg/day, MTX<0.4mg/Kg/week or 20mg/week, leflunomide) and living in high risk area [16 juvenile idiopathic arthritis, 6 Henoch-Schönlein purpura, 4 juvenile systemic lupus erythematosus, 3 juvenile dermatomyositis and 1 juvenile systemic sclerosis] and 30 healthy controls with comparable ages were vaccinated with a fractional dose of the 17 DD YF vaccine [one fifth (0.1 ml) of the standard dose]. All participants were evaluated pre-vaccination (D0) and after 5 days (D5), 10 days (D10) and 30 days (D30) for clinical and laboratory parameters (AST, ALT, complete blood count, CRP). Disease activity was evaluated according to specific tools for each juvenile ARD at D0 and D30. A rigorous follow-up of adverse events was performed during the first 30 days after vaccination. Serious adverse events were defined as those resulting in hospitalization or death.

Results: Patients and controls had comparable median age [12.4(6.3-18.2) vs. 12(6.9-18.7) years, P= 0.25]. Disease activity parameters of ARD patients (JADAS-71, SLEDAI-2K, CMAS, DAS, MMT, ESR and CRP) remained stable 30 days after YFV (P>0.05). Patients and controls reported only mild symptoms during follow-up, with comparable frequencies of fever, muscle pain, abdominal pain, nausea and diarrhea (P>0.05). Both groups presented similar median white blood cells counts kinetics with transient decreases in leukocytes and neutrophils levels in D10, followed by full recovery to baseline levels in D30 (P<0.05) (Table1). For lymphocytes the decrease occurred at D5, with complete recovery in D30 (P<0.05). Of note, new onset leukopenia (<4,000mm³), neutropenia (<1,500mm³) and lymphopenia (<1,500mm³) were rarely observed in these patients after vaccine (Table1). Liver enzymes alterations and acute kidney injury were not observed in patients and healthy controls, and none of the patients and controls had serious adverse events.

Conclusion: Fractional dose of 17DD YFV was safe and well tolerated in juvenile ARD. We further demonstrated that this vaccine did not trigger disease flare. Therefore, this study may contribute to future recommendation for YF vaccine in pediatric patients, under low immuno suppression, living or travelling in endemic areas. (ClinicalTrials.gov, NCT03430388)

Systemic Sclerosis in Pediatric Patients: An Epidemiological Study in a Large Insured Population in the US

Alexander Michel¹, Marcela Rivera², Tatsiana Vaitiakovich², Simon Teal² and **Janethe Pena³**, ¹Epidemiology, Bayer Basel, Basel, Switzerland, ²Real World Evidence, Bayer AG, Berlin, Germany, ³Clinical Development, Bayer US LLC, Whippany, NJ

Session Information

Session Date: Monday, October 22, 2018

Session Title: Pediatric Rheumatology – Clinical Poster I – ARHP

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic sclerosis (SSc) is a very rare autoimmune disorder and only very few population-based epidemiological studies described its incidence and prevalence in children. In a nationwide, prospective hospital-based case-series from Finland, the incidence of SSc was 0.05 per 100,000 person-years in children aged 0–15 years based on 2 cases (Pelkonen et al. 1994). A field study in the UK by Herrick et al. (2010) that collected SSc cases from all secondary care physicians to whom childhood systemic sclerosis could be referred, reported an estimate of 0.027 cases per 100,000 person-years, based on 7 pediatric SSc cases. For North America, we could not identify any previous study on pediatric SSc epidemiology.

Methods: We conducted a retrospective cohort study in the Market Scan Commercial Claims and Encounters Database of IBM Watson Health, a large US-based claims database containing data from over 50 million patients from over 150 large employers geographically distributed throughout the US that covers employees and their dependent family members. The database is frequently used for studies in the area of descriptive disease epidemiology. Study period was 01. Jan 2010 until 31. Dec 2015. Following manual review of electronic patient profiles from a sample of patients with SSc claims in Market Scan, cases of SSc were defined using the following minimal-criteria:

- Raynauds Syndrome diagnosis and two SSc outpatient diagnosis (at least 30 days apart) **or**
- Raynauds Syndrome diagnosis and one SSc inpatient diagnosis **or**
- Three SSc outpatient diagnoses (two of these diagnosis should be at least 30 days apart) **or**
- One SSc inpatient diagnosis plus one SSc outpatient diagnosis (on different dates)

Yearly incidence and prevalence estimates and 95% confidence intervals were calculated for each calendar year from 2010 until 2015. Incident cases were required to have no recorded claim of SSc any time before the entry date.

Results: In the overall pediatric population (<18 years of age), yearly incidence estimates ranged from 0.29 (95% CI: 0.11–0.47) to 0.69 (95% CI: 0.43–0.95) cases per 100 000 person-years, based on 10-27 incident pediatric cases per year. Overall female to male ratio was 2.34 (75/32). Rates were highest in the 12-17 year age group (table 1).

Yearly prevalence ranged from 0.95 (95% CI: 0.78–1.16) to 1.20 (95% CI: 0.95–1.51) per 100 000 children, based on 77-165 prevalent cases per year.

Age (years)	Incidence rates per 100,000 person-years (95% CI)					
	2010	2011	2012	2013	2014	2015
<2	0.00 (–)	0.00 (–)	0.00 (–)	0.00 (–)	0.00 (–)	0.00 (–)
2–11	0.45 (0.17 – 0.72)	0.23 (0.05 – 0.41)	0.03 (0.00 – 0.10)	0.17 (0.00 – 0.34)	0.08 (0.00 – 0.20)	0.05 (0.00 – 0.15)
12–17	1.03 (0.54 – 1.52)	0.73 (0.35 – 1.11)	0.83 (0.45 – 1.22)	0.86 (0.43 – 1.30)	0.56 (0.21 – 0.91)	0.61 (0.21 – 1.00)

Conclusion: Pediatric SSc is a very rare disorder. Our study based on a large pediatric population in the Market Scan claims-database in the US yielded higher incidence estimates than those observed previously in smaller studies conducted in Europe. The female/male disproportionality of SSc may be less pronounced in children than known from the adult population.

Abstract Number: 1441

Diagnostic Performances of Antibodies Against Carbamylated Proteins in US Based Populations with Rheumatoid Arthritis and Other Autoimmune Rheumatic Diseases

Jing Shi¹, Jay Milo², Kelley Bradey¹, Chelsea Bentow², John Conklin¹, Tyler O'Malley¹, Armida Sace¹, Rowena Lafon¹, Duncan Poling¹, Claudia Ibarra¹, Michael Mahler² and Thierry Dervieux¹, ¹Exagen Diagnostics, Inc., Vista, CA, ²Research and Development, Inova Diagnostics, San Diego, CA

Session Information

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster II: Diagnosis and Prognosis

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Recently, antibodies directed against carbamylated antigens (anti-CarP antibodies) were identified in rheumatoid arthritis (RA). Studies have established the predictive and prognostic value of this antibody system. As most of the previous reports described the performance characteristics of anti-CarP assay in European populations using a two-step research assay, we analyzed the performances characteristics of a single step anti-CarP assay in US based population of RA subjects and control groups.

Methods: Anti-CarP antibodies were measured using fetal calf serum based single step assay (research use only, Inova Diagnostics, San Diego, USA). The analytical and diagnostic performances of the anti-CarP assay were established using a biobank of specimens collected from consented subjects (640 RA subjects fulfilling the 1987 or 2010 criteria, 197 normal healthy volunteers and 636 other disease subjects). The median age of RA subjects at diagnosis was 60 years and it ranged from 41 to 55 years in control groups. Mean disease duration in RA was 12 years, versus 3 to 12 years in control groups. Anti-citrullinated protein antibodies (ACPA) and rheumatoid factor IgM (RF-IgM) status were tested using EliA CCP and RF IgM assays, respectively (ThermoFisher, Upsala, Sweden). Diagnostic performances in distinguishing RA from other control groups were analyzed using sensitivity, specificity, likelihood ratio (LR) and diagnostic odds ratio (DOR).

Results: The intra-assay and inter-assay variations of the anti-CarP ELISA were 7.0% and 11%, respectively. Anti-CarP antibodies, anti-CCP antibodies and RF-IgM were present in 34%, 66% and 67% of RA subjects, respectively. The overall specificity of anti-CarP antibodies was 78%. When stratified by anti-CCP status, the prevalence of anti-CarP antibodies was 42% and 16% among anti-CCP positive and negative RA subjects, respectively, a finding consistent with previous studies. The prevalence of anti-CarP antibodies in various control groups ranged from 5.9% to 30% (Table 1), thereby yielding specificities ranging from 70% (systemic lupus erythematosus, SLE) to 94% (primary fibromyalgia). Diagnostic odds ratios (DOR) for RA versus the different control groups ranged from 1.2 to 8.2.

Conclusion: These data replicate previous studies and support the notion that anti-CarP antibodies are helpful in the setting of ACPA negative RA subjects. However, clinicians should be aware of the low specificity of this marker in certain autoimmune rheumatic diseases, particularly SLE.

Table 1: Diagnostic performances of anti-CarP antibodies in RA versus other control groups

Control groups	Anti-CCP+	RF-IgM+	Anti-CarP+	Specificity	LR+	LR-	DOR
	%	%	%	%	[95% CI]	[95% CI]	[95% CI]
Systemic lupus erythematosus	4.1%	13%	30%	70%	1.1 [0.94,1.4]	0.94 [0.87,1.0]	1.2 [0.91,1.6]
Sjogren's syndrome	4.7%	41%	27%	73%	1.3 [0.83,1.9]	0.90 [0.77,1.1]	1.4 [0.79,2.3]
Autoimmune thyroid/hepatitis	2.4%	7.1%	26%	74%	1.3 [0.77,2.2]	0.90 [0.74,1.1]	1.4 [0.71,2.9]
Idiopathic inflammatory myopathies	3.5%	6.9%	21%	79%	1.6 [0.79,3.4]	0.84 [0.69,1.0]	2.0 [0.78,4.9]
Systemic sclerosis	6.1%	27%	15%	85%	2.2 [0.99,5.0]	0.78 [0.67,0.91]	2.9 [1.1,7.5]
Other autoimmune diseases	0%	14%	14%	86%	2.4 [0.65,8.6]	0.77 [0.62,0.96]	3.1 [0.68,14]
Primary fibromyalgia	1.2%	1.2%	5.9%	94%	5.7 [2.4,14]	0.70 [0.65,0.76]	8.2 [3.3,20]
Normal Healthy Individuals	0.50%	6.2%	14%	86%	2.4 [1.7,3.4]	0.77 [0.71,0.84]	3.1 [2.0,4.7]

The sensitivities of anti-CarP antibodies, anti-CCP antibodies and RF-IgM in RA subjects were 34%, 66% and 67%, respectively.

Differential Chemical Isotope Labeling Liquid Chromatography Mass Spectrometry and a Universal Metabolome Standard Reveals a Metabolome Profile with Consistent Accuracy for Rheumatoid Arthritis

Walter P. Maksymowych¹, Xiaohang Wang², Joel Paschke¹, Rana Dadashova¹, Edna Hutchings¹ and Liang Li², ¹CaRE Arthritis, Edmonton, AB, Canada, ²Chemistry, University of Alberta, Edmonton, AB, Canada

Session Information

Session Date: Monday, October 22, 2018

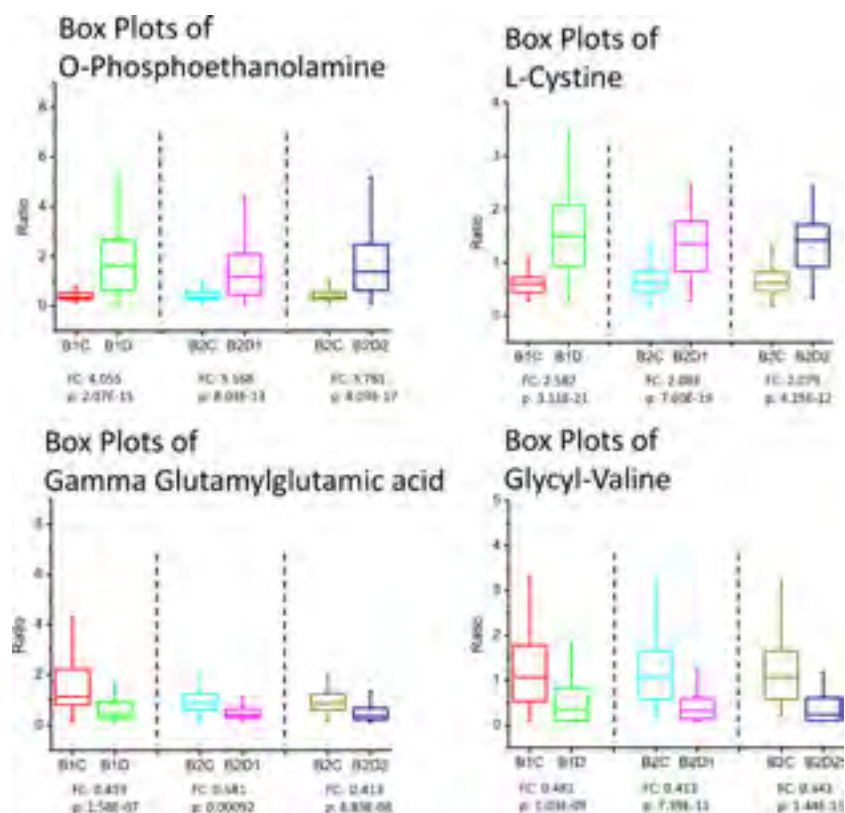

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster II: Diagnosis and Prognosis

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Early diagnosis of rheumatoid arthritis(RA) is hampered by suboptimal accuracy of currently available serological biomarkers. Recent advancements in metabolomic profiling include dansylation liquid chromatography mass spectrometry (LC-MS),resulting in 1000-fold increase in detection sensitivity of amine/phenol-containing metabolites, and universal metabolome-standard (UMS)methodology in conjunction with differential chemical isotope labeling (CILLC-MS), to provide long-term analytical reproducibility and facilitate metabolome comparisons among different data sets. CIL LC-MS uses different labeling reagents to target chemical group-based sub metabolomes to provide in-depth metabolomic analysis. We aimed to identify a metabolite signature with consistently high accuracy for RA.

Methods: 12C-dansylation and acid labeling of individual serological samples and 13C-dansylation and acid labeling of pooled samples from 2 RA cohorts was undertaken. Cohort A samples were from 50 RA patients, 39 female (mean age 49.9), 11 male (mean age 47.8), symptom duration <3 years, DAS >3.7, naïve to b-DMARD, and 50 age and sex-matched healthy controls. Cohort B samples were from 50 RA patients, 40 female (mean age 53.4), 10 male(mean age 57.2),

symptom duration <5 years, samples from both pre- and post-(3 months) treatment with TNFi and a second set of 50 age and sex-matched healthy controls.

Results: A total of 3415 amine/phenol metabolites were commonly detected in 80% of the samples, of which 116 metabolites were positively identified using dansyl standard library search. Orthogonal partial least squares discriminant analysis showed a clear separation of the groups for each cohort ($R^2=0.98/Q^2=0.92$ for cohort A and $R^2=0.93/Q^2=0.79$ for separation of controls, pre- and post-treatment cohort B). 18 positively identified metabolites from cohort A and 23 from cohort B were identified as potential RA biomarkers with ROC AUC(95%CI) of 0.99(0.96-0.99) and 0.98(0.93-0.99) for the top 10 metabolites, respectively. L-Cystine, O-Phosphoethanolamine, Gamma Glutamylglutamic acid, Glycyl-Valine, and 3 unidentified metabolites were significant in both cohorts, with the combination ROC AUC(95%CI) of 1.0(1.0-1.0) and 1.0(0.99-1.0) for cohorts A and B, respectively. For the 4 positively identified metabolites, sensitivity/specificity plus AUC (95%CI) were 89%/88% plus 0.95(0.87-0.99) and 91%/91% plus 0.97(0.92-1.0) for cohorts A and B, respectively. None of these biomarkers correlated with age, gender, or symptom duration.

Conclusion: 7 metabolites, 4 of which are positively identified, have consistently high discriminatory capacity for RA.

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster II: Diagnosis and Prognosis

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is the most prevalent chronic inflammatory joint disease (1,2) responsible for structural damage. Radiography (RX) is considered as the gold standard for visualizing and quantifying bone lesions in RA (3). Musculoskeletal ultrasound (US) is booming in clinical practice for the diagnosis of RA. US can detect more erosions than RX at the joint level, especially at an early stage of the disease.(4) The objectives are to determine thresholds for the diagnosis of erosive RA by US in RA and OA patients and to compare these US thresholds with RX ACR/EULAR 2013 criteria for erosive RA.

Methods: Patients fulfilling ACR 1987 and/or ACR/EULAR 2010 criteria for RA or hand OA criteria were prospectively included. A modified Sharp erosion score was assessed by two blinded readers and one adjudicator for discordant cases (number of eroded joints \leq three). Erosions in US were scored on six bilateral joints (MCP2-3, 5; MTP2-3, 5) with a four-grade scale to calculate total US score for erosions (USSe).

Results: A total of 168 patients were included: 122 RA (32 early RA <2 years; 90 late RA \geq 2 years); 46 OA patients. On RX: 42 RA patients (6 early; 36 late) and 5 OA patients were eroded according to ACR/EULAR 2013 criteria with sensitivity at 34.4% and specificity at 89.1%. On US, 95 RA patients (21 early; 78 late) and 12 OA patients were eroded. Considering at least two joint facets eroded or at least one joint facet eroded at grade 2 on US, sensitivities were good (68-72.1%) and specificities excellent (89.1-100%). Agreement between RX and US was excellent (90-92%). US diagnosed two times more patients than RX as erosive disease in both early and late RA patients.

Conclusion: USSe can differentiate RA from OA in erosive disease and detect two times more patients with erosive RA than RX with excellent specificity and agreement, according to two different criteria (number of facets eroded and severity of erosion at the joint facet level).

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster II: Diagnosis and Prognosis

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is the most prevalent chronic inflammatory joint disease (1,2) responsible for structural damage. Radiography (RX) is considered as the gold standard for visualizing and quantifying bone lesions in RA (3). Musculoskeletal ultrasound (US) is booming in clinical practice for the diagnosis of RA. US can detect more erosions than RX at the joint level, especially at an early stage of the disease. (4) The Objectives are to determine thresholds and better scenarios for the diagnosis of erosive RA by US in RA and osteoarthritic (OA) patients.

Methods: Patients fulfilling ACR 1987 and/or ACR/EULAR 2010 criteria for RA or hand OA criteria were prospectively included. A modified Sharp erosion score was assessed by two blinded readers and one adjudicator for discordant cases (number of eroded joints \leq three). Erosions in US were scored on six bilateral joints (MCP2-3, 5; MTP2-3, 5) with a four-grade scale.

Results: A total of 168 patients were included: 122 RA (32 early RA <2 years; 90 late RA ≥ 2 years); 46 OA patients. On RX: 42 RA patients (6 early; 36 late) and 5 OA patients were eroded according to ACR/EULAR 2013 criteria (sensitivity: 34.4%, specificity: 89.1%). On US, 95 RA patients (21 early; 78 late) and 12 OA patients were eroded. Considering at least two joint facets eroded (threshold 1) or at least one joint facet eroded at grade 2 (threshold 2), sensitivities were good (68-72.1%) and specificities excellent (89.1-100%). With only six targeted joint facets examined, 73 and 74 patients were classified as erosive RA with threshold 1 and 2 with good sensitivities (59.8-60.0%) and excellent specificities (95.6-100%) respectively. For all scenarios, agreement between RX and US for the diagnosis of erosive RA was excellent (88.1% to 92.8%).

Conclusion: US erosion assessment of six targeted joint facets permitted to detect 1.7 times more erosive RA patients than RX in late and early RA.

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster II: Diagnosis and Prognosis

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) has a preclinical phase without symptoms that progress to symptomatic phases. Clinically suspect arthralgia (CSA) refers to patients with symptoms without clinically apparent synovitis. The presence of erosions of grade 2 or greater by MRI was reported to be specific to the diagnosis of RA. We do not know the frequency of RA specific erosions, defined by RAMRIS in CSA patients.

Methods: Cross-sectional and observational study with 60 patients older than 18 years, divided into two groups: CSA group: n = 23 (38%) RA first-degree relatives with hand arthralgia without clinical inflammation, and RA group: n = 37 (%) patients who met 2010 ACR/EULAR criteria. MRI images were evaluated looking for synovitis, bone erosion, and bone marrow edema (BME). The bone erosions were scored on a scale of 0 to 10 based on the proportion of eroded.

Results: Baseline and clinical characteristics are depicted in table 1. No difference was found in the frequency of patients without any bone erosion in MCP between CSA versus RA, 7/22(31.8%) and 12/38(31.6%), respectively. However, 18/60 (30%) patients had ≥ 2 bone erosions, 6/22(27.3%) in CSA patients and 12/38(31.6%) in established RA patients (p=0.72).

Conclusion: There were a similar number of patients with bone erosions Grade ≥ 2 in both groups. The presence of the combination of the MCP joints of bone erosions with bone edema and synovitis is more frequent in patients with RA compared to patients with CSA.

Table 1: Baseline characteristics of CSA patients and RA patients

Session Information

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster II: Diagnosis and Prognosis

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The recently introduced composite OMERACT-EULAR power Doppler (PD)/grey scale (GS) ultrasound (PDUS) scoring system for RA with a proposed 18 joint set was developed without reference to modern psychometric analysis. We aimed to assess the scoring system and joint selection using the Rasch measurement model, which sets out criteria for measurement of an underlying 'latent' quantity, and to propose a refined tool.

Methods: We included biologic-naïve patients with ACR 1987 RA diagnosis, disease duration <6 months who received abatacept and methotrexate for 24 weeks in a clinical trial[1]. US was performed at weeks 0, 1, 2, 4, 6, 8, 12, 16, 20 & 24. Bilateral MCPs 1–5, PIPs 1–5, wrist, elbow, shoulder (glenohumeral), knee, ankle (tibiotalar), hind foot (talonavicular and calcaneocuboidal) and metatarsophalangeal joints (MTPs) 1–5 (44 total) were scored 0-3 for GS, PD & PDUS. The scoring system and joint set were assessed for fit to the Rasch model and acceptable reliability (person separation index (PSI) >=0.7). Standardised response mean at 24 weeks was calculated.

Results: We included 96 patients (mean age 56.5, disease duration <=2 years 43%, 2-10+ years 57%; 83% female). Analysis of the composite score showed that the probability of a joint being assigned a higher score did not consistently

increase with the underlying latent quantity i.e. level of inflammation, indicating that assessors were not completely able to distinguish the categories. Shifting the point of transition between a score of 1 and 2, and reserving 3 for GS=3 PD=3 resulted in ordered thresholds. We also found residual correlation between some joints within the proposed 18 joint set, indicating that their scores were not independent. Joints that were only likely to score >0 at high levels of inflammation, beyond the observed range, were prioritised for exclusion. Using revised scoring in a set of 15 joints (bilateral MCPs 1-5, right side wrist, PIPs 2&5, MTPs 2&5) yielded fit to the Rasch model (item-trait interaction Chi-square $p=0.647$) and acceptable reliability (PSI=0.77; Cronbach's $\alpha=0.81$). Using linear-scaled (transformed) estimates from the Rasch model for the revised scoring in the 15 joint set showed significantly greater sensitivity to change than using original scoring in either the 44 joint set (mean difference (bootstrapped 95% CI)= -0.33 (-0.59, -0.06), $p=0.016$) or 18 joint set (-0.42 (-0.71, -0.13), $p=0.004$) in 74 patients with 24 week data available (Table 1).

Conclusion: Refining both the scoring system and the joint set using the Rasch model resulted in enhanced sensitivity to change. Future work will validate these findings in external data in order to confirm that the proposed changes further improve the sensitivity and reliability of US in clinical trials.

Session Information

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster II: Diagnosis and Prognosis

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Near infrared (NIR) imaging studies of subdermalindocyanine green (ICG) in murine models of inflammatory arthritis established abnormally lymphatic vessel (LV) function during arthritic progression. Quantitatively, this LV dysfunction is primarily assessed by ICG clearance from the injection site via longitudinal (days) NIR imaging. As the role of LV function in rheumatoid arthritis (RA) pathogenesis is unknown, we tested the hypothesis that ICG clearance from the hands of RA patients experiencing flare is significantly decreased from that of normal healthy volunteers.

Methods: The web spaces of both hands of 8 healthy controls (Ctl) and 4 subjects in RA flare were injected with 0.1ml of 100µM ICG on 2-4 separate occasions and the NIR fluorescence of the dorsal aspect of the hands were imaged. To measure clearance of ICG from the web spaces, a subset of 3 Ctl and 3 RA subjects returned to the clinic 8-15 days after the first injections and any remaining NIR fluorescence in each hand was measured via region of interest analysis (n=6 per group, Wilcoxon Signed-RankTest). Controlling for the number of days between subjects, the change in intensity between the initial and second visit was divided by the number of days between visits. To assess the branching structure of the vessels, two independent graders quantified the total number of bifurcations of the LVs. Median values for each hand across all visits and graders were used to test for differences (n=13 Ctl, n=8 RA, Wilcoxon on Rank-Sum Test).

Results: Representative NIR images of Ctl and RA hands at baseline and at the second visit are presented in **Fig 1A-D**, demonstrating the dramatic retention of ICG at the injection sites (WhiteArrows) in RA subjects. Statistical analysis revealed a decrease in ICG clearance in the RA subjects compared to Ctls (**Fig 1E**, $*p<0.05$). When controlling for days between the initial visit and second visit the relationship holds (**Fig 1F**, $**p<0.01$). Interestingly, no differences were observed in bifurcation counts between RA and Ctl ($p=0.11$).

Conclusion: Imaging outcome measures of LV function in mice demonstrated diminished clearance of lymph from the inflamed joint during arthritic progression and we recently described functional and anatomic differences in the hands of RA subjects in joint flare compared to controls. Herein, we expand upon these findings by demonstrating a significant reduction in ICG clearance in RA patients during flare. Surprisingly, there was no difference in the bifurcations of LVs, however, this is likely due to relatively small sample size or differences in clinical characteristic in our cohort. The accumulation and retention of inflammatory cells and molecules in rheumatoid joints as are result of diminished lymphatic clearance likely triggers synovitis. This clinical pilot demonstrates the feasibility of quantifying LV function, and warrants formal investigation in clinical trials

Session Information**Session Date:** Monday, October 22, 2018**Session Title:** Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster II: Diagnosis and Prognosis**Session Type:** ACR Poster Session B**Session Time:** 9:00AM-11:00AM

Background/Purpose: It is well established in the literature that musculoskeletal ultrasound (MSUS) is more sensitive than clinical examination in the detection of synovitis. MSUS can help rheumatologists with the diagnosis and follow-up of uncertain cases. The main objective of this study is to validate the added value of MSUS in the diagnosis and follow-up of patients presenting with arthritis in the rheumatology department of the CHUS.

Methods: We reviewed retrospectively the medical records of patients with an uncertain initial diagnosis of arthritis (Group 1: n=58) and patients with clinically uncertain disease activity on follow-up (Group 2: n=103). We examined the contribution of MSUS in the diagnosis of arthritis and its impact on treatment decision making.

Results: In group 1, 56.9% of patients were confirmed with polyarthritis after MSUS (n=33). 54.5% of them were diagnosed with rheumatoid arthritis (n=18). There were no statistically significant predictors for a positive MSUS. In the follow-up group, 27.2% had a positive MSUS (n=28). 67.9% had their treatment optimised (n=19). 44.4% of patients with positive ultrasound but without treatment modification had articular infiltrations following the MSUS (n=4). Within patients with negative ultrasound (n=75), 10% had a decrease in their medication (n=8) while 71% had no change in their treatment (n=53). The result of the ultrasound had a statistically significant impact on the treatment decision making ($p < 0.0001$).

Conclusion: Our results support the added value of MSUS in the diagnosis and management of polyarthritis, mainly in patients with a doubtful clinical picture. Similar results can be found in the current literature. We did not succeed to identify predictive factors of a positive ultrasound.

Microwave Radiometry As a Novel Additional Method for Rheumatoid Arthritis Disease Activity Assessment: A Prospective Single-Center Study

Katerina Laskari¹, George Pentazos¹, George Konstantonis¹, Maria Tektonidou¹, Elias Siores² and Petros Sfikakis¹,
¹Rheumatology Unit, 1st Dept. of Propaedeutic Internal Medicine, Joint Academic Rheumatology Program, Athens University Medical School, Athens, Greece, ²Institute of Materials Research and Innovation, University of Bolton, Bolton, United Kingdom

Session Information**Session Date:** Monday, October 22, 2018**Session Title:** Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster II: Diagnosis and Prognosis**Session Type:** ACR Poster Session B**Session Time:** 9:00AM-11:00AM

Background/Purpose: Microwave Radiometry (MR) is an easy-to perform, rapid, non-invasive method detecting in-depth tissue temperature that may be useful for joint inflammation assessment in RA (1,2). We tested the hypothesis that MR can diagnose and grade (teno)synovitis in small and large joints in RA; thus, may be used for the development of an MR-derived combined joint-temperature score to measure RA disease activity.

Methods: Eighty-two RA patients and 23 age- and sex-matched healthy individuals, underwent MR, clinical and laboratory assessments and joint ultrasound, as described (2); 21 patients were re-examined 2 months after treatment initiation. The temperature of each joint was expressed by Δt (difference between MR-derived temperature of pre-defined joint points resulting in lower Δt values in warmer joints). A thermo-score was created by summing the Δt of 7 small joints according to the US7 ultrasound score (wrist, 2nd-3rd MCP, 2nd-3rd PIP, 2nd and 5th MTP), as well as of elbow, knee and lower leg of the clinically dominant upper/lower extremity. This thermo-score was reproducible among healthy individuals (Intraclass Correlation Coefficient 0.714).

Results: At the joint level, MR performed better than clinical examination in the knees to predict ultrasound confirmed joint effusion [area under the curve (AUC) 0.815 vs. 0.688, respectively], or power Doppler (AUC 0.901 vs. 0.791, respectively), whereas a $\Delta t \leq 0.2$ had 80% sensitivity and 82% specificity for power Doppler. Also, 85% of knee joints with

subclinical inflammation could be diagnosed by MR. In all other joints MR performed similarly to clinical examination and its diagnostic performance was moderate. At individual patient level, the thermo-score strongly correlated to DAS28 score, tender and swollen joint counts, patient's and physician's visual analogue scale, CRP and ESR levels (all $p < 0.001$), as well as to the US7 ultrasound scores ($p < 0.026$). Moreover, the thermo-score could discriminate patients in high/moderate disease activity ($\text{mean} \pm \text{SD} = 4.6 \pm 3.0$), low disease activity/remission (8.0 ± 2.9) ($p < 0.001$), or healthy subjects (8.8 ± 1.9) ($p < 0.001$). A thermo-score ≤ 7.4 could distinguish highly/moderately active patients from healthy controls with a sensitivity and specificity of 81% and 83%, respectively (AUC 0.866), whereas a cut-off of 8.1 could distinguish highly/moderately active from patients in low activity/remission with both a sensitivity and specificity of 71% (AUC 0.802). Finally, individual changes from baseline to follow-up mirrored the corresponding DAS28 changes in 17/21 patients ($p = 0.001$).

Conclusion: Increased in-depth joint temperature detected by MR performed well for the detection of knee joint inflammation in RA. The MR-derived score of 10 selected joints correlated to clinical, laboratory and ultrasound measures of RA disease activity, could discriminate disease activity stages, as well as mirrored treatment-induced disease activity changes. Multicenter studies are needed to confirm these novel findings.

Clinical Radiology Reports Are Unreliable for Assessment of Radiographic Structural Progression in US Veterans with Rheumatoid Arthritis Initiating Tumor Necrosis Factor Inhibitor Therapy

Kevin R. Lammert¹, Alan R. Erickson², Brian C. Sauer¹ and Grant W. Cannon¹, ¹Salt Lake City VA Medical Center and University of Utah, Salt Lake City, UT, ²Omaha VA Medical Center and University of Nebraska Medical Center, Omaha, NE

Session Information

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster II: Diagnosis and Prognosis

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatologists rely on hand radiograph findings including bone erosions (BE) and joint space narrowing (JSN) to make treatment decisions for patients with rheumatoid arthritis (RA). Radiographic progression (RP) on serial hand radiographs may prompt changes in therapy. We assessed whether radiology reports reliably identify BE, JSN, and RP in a cohort of Veterans Affairs (VA) patients initiating tumor necrosis factor inhibitor (TNFi) therapy.

Methods: Subjects were US veterans with RA initiating TNFi therapy who had two sets of bilateral hand radiographs: baseline obtained between 6 months prior to and 1 month after TNFi initiation and follow-up obtained 10-18 months after TNFi initiation. An expert reader, blinded to radiograph sequence, quantified BE, JSN, and RP at baseline and follow-up by modified Sharp Score (mSS). An independent chart abstractor reviewed the corresponding radiology reports in the electronic medical record. BE and JSN were coded "present" or "absent" if the report specifically stated they were present or absent and were coded "not specified" if the report did not comment on their presence. RP was coded "present" or "absent" if the follow-up report specifically stated it was present or absent and was coded "not compared" if it did not include comparison to baseline. BE, JSN, and RP from radiology reports were then compared to BE, JSN, and RP as quantified by the expert reader. Sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV), and accuracy ($\text{true positive} + \text{true negative} \div \text{total cases}$) were calculated for baseline reports that reported BE and JSN, and for follow-up reports that reported RP.

Results: 249 patients from 84 VA sites were included. Baseline demographics: age 58 ± 11 years, 81% male, 68% positive rheumatoid factor, 65% positive anti-cyclic citrullinated peptide antibody. Baseline mSS: 19.5 ± 33.2 (median 8, range 0-214). Mean change in mSS: 0.5 ± 4.6 (median 0, range -19-45). BE or JSN not reported in 65 (26%) and 83 (33%) baseline cases respectively. In 70 (35%) of cases with comparison radiographs at the same site, the follow-up radiology report did not include comparison of baseline and follow-up radiographs.

Conclusion: Many clinical radiology reports may be of limited value and reliability for assessing RP in patients with RA during TNFi therapy because reports often fail to include important data, do not include comparisons, and disagree with findings reported by an expert reader. Reports of radiologist assessments of BE and JSN are also of limited utility—while

Bone Erosions on Baseline Radiographs

		Expert Reader				
		Present	Absent	Total		
Clinical Radiologist	Present	71	10	81	Sensitivity	55.5%
	Absent	57	46	103	Specificity	82.1%
	Total	128	56	184*	PPV	87.7%
					NPV	44.7%
					Accuracy	63.6%

*249 reports reviewed. 65 did not specify presence/absence of BE and were excluded.

Joint Space Narrowing on Baseline Radiographs

		Expert Reader				
		Present	Absent	Total		
Clinical Radiologist	Present	106	12	118	Sensitivity	79.1%
	Absent	28	20	48	Specificity	62.5%
	Total	134	32	166*	PPV	89.8%
					NPV	41.7%
					Accuracy	75.9%

*249 reports reviewed. 83 did not specify presence/absence of JSN and were excluded.

Radiographic Progression on Follow-Up Radiographs

		Expert Reader				
		Present	Absent	Total		
Clinical Radiologist	Present	14	14	28	Sensitivity	30.4%
	Absent	32	70	102	Specificity	83.3%
	Total	46	84	130*	PPV	50.0%
					NPV	68.6%
					Accuracy	64.6%

*249 reports reviewed. 49 with baseline and follow-up at different sites were excluded. Of the remaining 200, 70 did not specify presence/absence of progression and were excluded.

a report positive for BE or JSN appears to be accurate, a negative report does not reliably exclude these findings. Rheumatologists should be aware of the limitations of radiology reports when using these assessments to make changes in RA management. Standardization of radiologist reporting and terminology may be of clinical utility.

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster II: Diagnosis and Prognosis

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Targeting MRI remission in rheumatoid arthritis (RA) patients in clinical remission may improve clinical outcome and halt joint damage progression.

The purpose of the trial was to determine whether a treat-to-target (T2T) strategy based on structured MRI assessments targeting absence of osteitis/bone marrow edema (BME) would lead to improved clinical and radiographic outcomes, compared with a conventional T2T strategy in RA patients in clinical remission.

Methods: The IMAGINE-RA study was a 2-year investigator-initiated, randomized, open-label multicentre study. Two hundred RA patients in clinical remission (defined as: DAS28-CRP<3.2 and no swollen joints) receiving conventional synthetic disease-modifying antirheumatic drugs (csDMARDs) were randomly assigned 1:1 to a conventional DAS28-CRP guided T2T strategy, targeting DAS28-CRP<3.2 and no swollen joints or an MRI guided T2T strategy based on the same clinical T2T strategy and MRI targeting absence of BME. Patients were followed every 4 months over a 2-year follow-up period. In the MRI T2T arm contrast-enhanced MRI of the dominant hand 2nd-5th metacarpophalangeal joints and wrist was performed ahead of the clinical visit and evaluated for presence/absence of BME. Treatment was escalated according to a predefined treatment algorithm if target was not reached, starting with increments in csDMARD mono/combination therapy and then adding biologic DMARDs. The co-primary endpoints were 1) proportion of patients achieving DAS28-CRP remission (DAS28-CRP<2.6) and 2) proportion of patients with no radiographic progression (change in total Sharp/vdHeijde score≤0) 24 months from baseline. Secondary outcomes included various clinical, functional, radiographic and MRI variables. Pearson's chi-square statistics and repeated-measures logistic regression models were used to assess primary and secondary outcomes.

Results: Primary and secondary clinical and radiographic outcomes at 24 months are presented in the table. 76 patients in the MRI T2T arm and 95 patients in conventional T2T arm completed the study. Of them 64 patients (85%) in the MRI T2T arm and 83 patients (88%) in the conventional T2T arm reached the primary clinical endpoint (chi-square=0.324, p=0.569) and 49 patients (66%) in the MRI T2T arm and 58 (62%) in the conventional T2T arm reached the primary radiographic endpoint (chi-square=0.265, p=0.606). ACR/EULAR remission rates, swollen joint count, patient VAS global and HAQ favoured the MRI T2T arm (p<0.038).

	MRI T2T	Conventional T2T	Difference between groups (95% CI)	P value*
Primary endpoints				
Radiographic:

95% CI, 95% confidence interval; ACR=American College of Rheumatology; CDAI=Clinical Disease Activity Index; CRP=C-reactive protein; DAS28-CRP=Disease activity score in 28 joints based on four variables, including CRP; EQ-5D=EuroQol-5 dimensions; EULAR=European League Against Rheumatism; HAQ=Health Assessment Questionnaire; MCS= Mental Component Summary score; MRI=Magnetic Resonance Imaging; PCS=Physical Component Summary score; RAMRIS=RA magnetic resonance imaging scoring system; SDAI=Simplified Disease Activity Index; SF-36=Short Form 36 item questionnaire; T2T=treat-to-target; TSS=Total Sharp/van der Heijde score; VAS=Visual Analogue Scale. Data are presented as least square means (SE) unless otherwise stated. Analyses are based on full analysis set (patients having a baseline visit and at least one follow-up visit) with no data imputation to replace missing data.*P values are based on repeated-measures logistic regression models. For some of the variables, fewer patients were included in the analyses due to missing data, with the minimum being 86 patients in the MRI T2T arm (range 86-98) and 91 (range 91-99) in the conventional T2T arm.

Conclusion: Targeting absence of MRI BME in addition to a conventional T2T strategy in RA patients in clinical remission had no effect on the probability of achieving DAS28-CRP remission or halt radiographic progression. However, more patients achieved ACR/EULAR remission and positive effect on physical function was seen when MRI was used for treatment guidance.

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster II: Diagnosis and Prognosis

Session Type: ACR Poster Session B

Session Time: 9:00 AM-11:00 AM

Background/Purpose: We conducted this retrospective study to determine objective and comprehensive diagnostic criteria for early rheumatoid arthritis (RA) that are based on ultrasound (US) and serologic findings.

Methods: From August 2014 to May 2016, we recruited 216 consecutive patients at Hospital 1 and 223 consecutive patients at Hospital 2 who were suspected to have RA and underwent US of bilateral hands. The duration from the appearance of the patient's symptoms to his or her entry into the study was ≤6 months. In the US of bilateral hands from

22 sites, the findings obtained by grayscale (GS) and power Doppler (PD) assessments were graded on a semi-quantitative scale from 0 to 3. We also examined the assessment of the novel Outcome Measures in Rheumatology (OMERACT)-European League Against Rheumatism (EULAR) combined power Doppler ultrasound (PDUS) score (i.e., thecPD score) and the Global OMERACT-EULAR Synovitis Score (GLOESS). The diagnostic performance of the patients was evaluated using US findings and the combination of US and serologic findings.

Results: Seventy patients (32.4%) at Hospital 1 and 59 patients (26.5%) at Hospital 2 were diagnosed as having RA. The best-balanced diagnostic performance at each hospital was achieved using a combination, such as (1) the presence of PD grade ≥ 2 articular synovitis or (2) the presence of PD grade ≥ 1 articular synovitis and serologic positivity, as well as (1) the presence of cPD grade = 3 or (2) a cPD grade ≥ 2 and serologic positivity (Table 1 and 2).

Conclusion: The combination of a PD assessment or the cPD score with the measurement of autoantibodies of rheumatoid factor and/or anti-cyclic citrullinated peptide antibodies can accurately identify the patients with early RA.

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster II: Diagnosis and Prognosis

Session Type: ACR Poster Session B

Session Time: 9:00 AM-11:00 AM

Background/Purpose: In this study, we aimed to investigate the concordance of ultrasonographic remission with other remission criteria and to show the influence of non-inflammatory patient-induced factors such as depression, anxiety, fibromyalgia and fatigue on both clinical and ultrasonographic remission.

Methods: Fifty consecutive patients with clinical remission (DAS-28-ESR <2.6) who were diagnosed according to the 2010 ACR / EULAR criteria were recruited to this study.

Patients were also assessed whether they met the Boolean and SDAI remission criteria. 28 joint gray scale (GS) and power Doppler (PD) ultrasonography were performed. Patients' depression and anxiety were assessed by The Hospital Anxiety and Depression Scale (HADS), and their fatigue was assessed by multidimensional Assessment of Fatigue (MAF) scores and patients' fibromyalgia was assessed by widespread pain index (WPI) and symptom severity score (SS).

Results: Patients were divided into 4 groups according to different remission definitions by ultrasonography. (Group1: PD=0 and GS=0, Group2: PD=0 and GS≥0, Group3: PD=1 or 0 and GS=1 or 0, Group4: PD=1 or 0 and GS≥0). Although it is not statistically significant, the highest agreement with all the clinical remission criteria was found in the USG remission group 4 (table).

Patients with ultrasonographic remissions at their first visit in 2011 were reevaluated with clinical remission criteria at the end of 5 years. The highest remission rates were found in patients with USG remission group 3 (DAS28 58%, Boolean 29%, SDAI 47%). There was no significant difference between fatigue, fibromyalgia, depression and anxiety measures between remission and non-remission in all USG remission groups. In contrast, depression (p <0.05) and anxiety (p <0.03) were significantly higher in patients without SDAI remission. Depression (p <0.008) and anxiety (p <0.014) were also significantly higher in patients without Boolean remission.

Conclusion: Clinical and ultrasonographic remission was found to be compatible in half of the patients.

The compliance of the USG remission in Group 4 with the clinical remission definitions was good, and clinical remission continuity was higher in the group meeting the definition of group 3. In contrast the ultrasound remission, the high levels of depression and anxiety in patients without SDAI and Boolean remission suggest that non-inflammatory patient-derived measures have less influence on the ultrasound remission.

Table. The concordance between Ultrasound remission and other remission criteria

		Das28 (n=50)	SDAI (n=23)	Boolean (n=22)
Group 1: PD=0 GS=0	n (%)	13 (% 26)	8(%34,7)	5 (%22,7)
Group 2: PD=0 GS≥0	n (%)	22 (% 44)	10 (%43,4)	8(%36,3)
Group 3: PD=1 or 0 and GS=1 or 0	n (%)	17 (%34)	8 (%34,7)	7 (%31,8)
Group 4: PD=1 or 0 and GS≥0	n (%)	28 (%56)	13(%56,5)	11 (%50)

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster II: Diagnosis and Prognosis

Session Type: ACR Poster Session B

Session Time: 9:00 AM-11:00 AM

Background/Purpose: Our objective is to examine the additional contribution of 14-3-3 η levels to known predictors of radiographic progression in inflammatory polyarthritis, both over several years and over the following year.

Methods: All variables were measured at initial and annual visits up to 4 years in patients with recent onset polyarthritis treated to remission. HIGH 14-3-3 η was ≥ 0.50 ng/ml; elevated CRP ≥ 8 mg/L; rapid radiographic progression (RRP) was ≥ 5 Units per year in Sharp van der Heijde (Sharp) Erosion score. General linear models (Glimmix) combining baseline predictors and treatments over time were performed with random effect for repetitions over time to assess the independent effect of 14-3-3 η on radiographic progression; Model 1: Positive anti-CCP2; Model 2: Positive Rheumatoid Factor (RF); Model 3: Positive anti-CCP2 and RF plus elevated CRP; Model 4: Age, Gender, Symptom Duration, Smoking, DAS28-CRP, Sharp, HAQ and Treatments, Model 5: All variables in Models 3 and 4. Generalized Estimated Equations (GEE) assessed the association with RRP of anti-CCP2, elevated CRP, and HIGH 14-3-3 η , alone and in combination.

Results: Mean age was 58.5 years, 60.2% women; median duration at inclusion 3.4 months. Out of 1529 complete evaluations (including baseline) in 533 patients, 511 (33.4%) were HIGH 14-3-3 η , 590 (38.6%) positive anti-CCP2, 554 (36.2%) positive RF, 476 (31.1%) elevated CRP; 157 (10.3%) RRP episodes. In univariate analyses, baseline 14-3-3 η levels (as did positive anti-CCP2, positive RF and elevated CRP) predicted erosion scores at 42 months (median (IQR): 5.0 (1.0-10.0) vs 2.0 (0.0-7.0), $p < 0.001$) and radiographic progression (mean \pm SD: 5.7 ± 10.2 vs 3.3 ± 8.5 , $p < 0.001$). HIGH 14-3-3 η , positive anti-CCP2 and elevated CRP were each associated with increased Relative Risks (RR) of RRP: 1.82 (1.36-2.43) $p < 0.001$; 2.33 (1.65-3.30) $p < 0.001$; 2.21 (1.65-2.95), $p < 0.001$, respectively. In multivariate Glimmix models, continuous 14-3-3 η remained a highly significant independent predictor of Erosion progression in all Models, including the 5 described above (all $p < 0.001$). In GEE, relative to being negative for all three, being positive for all of HIGH 14-3-3 η , anti-CCP2, and CRP was associated with a RR of 6.19 (3.82-10.05), $p < 0.001$; RRP occurred following 34.1% of visits when all three were positive. Being positive for only 2 variables identified subsets of patients at intermediate RR (1.84 to 4.42) of RRP. The contribution of HIGH 14-3-3 η to predict RRP was highest in patients with positive anti-CCP2 and/or elevated CRP; sensitivity was then 46.2%, specificity 84.0% and negative predictive value 93.3%.

Conclusion: In patients treated to remission, baseline 14-3-3 η levels were predictive of erosion scores and erosion progression, but not of narrowing, over the following 4 years, even when combined with multiple baseline predictors of erosive progression and taking into account treatments received from baseline. The presence of HIGH 14-3-3 η amplified the risk (up to 34%) for RRP conferred by anti-CCP2 and/or CRP. Adding 14-3-3 η measurement to anti-CCP2 and clinical measures over the course of RA may inform therapeutic strategies tailored to halt rapid joint damage progression in the most susceptible patients.

Session Information

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster II: Diagnosis and Prognosis

Session Type: ACR Poster Session B

Session Time: 9:00 AM-11:00 AM

Background/Purpose: Rheumatoid arthritis (RA) is a chronic inflammatory disease associated with increased mortality and disability. Although different factors have been associated with prognosis, it is still difficult to predict the evolution of a specific patient. Therefore, our objective was to train and validate a predictive model of disease severity using radiological damage as a surrogate marker, based on Artificial Intelligence techniques, and using clinical and genetic data as predictors.

Methods: Four independent cohorts were included (959 patients with 1902 hand X-rays). Radiological damage was measured using the hands and wrists Sharp / van-der-Heijde score (SvdH). The variables to be predicted [total value of SvdH, erosion component (ES) and joint narrowing (NS)] were logarithmically transformed before analysis. As clinical predictors, age at onset of symptoms, sex, duration of the disease at the time of each radiograph, year of onset of symptoms and presence of rheumatoid factor were used. As genetic variables, the single nucleotide polymorphism data obtained from the Immunochip genotyping platform (Illumina) were used. In addition to an additive effect of the genetic variants, an interaction between each polymorphism and the duration of the disease was introduced in the analysis. Three cohorts were used for the selection of variables, generation of predictive models and internal validation. The fourth cohort was used to perform the external validation of the models. Regression trees with random effects (RTRE) were generated using the R package “REEMtree”. The goodness of fit of the models was measured using the root mean squared error (RMSE) and the intraclass correlation coefficient (ICC).

Results: After the variable selection step, for the prediction of total SvdH, ES and NSLS, the RTRE selected 253, 235, and 192 unique sets of variables composed of a median (interquartile) 31 (26-38), 21 (17-26), and 34 (28-38) elements, respectively. Regarding interval validation, the lowest RMSEs were 3.16, 1.25 and 2.43 units of the Sharp / van-der-Heijde score, for total SvdH, ES and NSLS, respectively. The highest ICCs were 0.91, 0.88 and 0.92, respectively. Regarding external validation, the lowest RMSEs were 5.79, 3.34 and 4.09 units of the Sharp / van-der-Heijde score, respectively. The highest ICCs were 0.90, 0.77 and 0.89, respectively. We selected those sets of variables located in the lowest deciles of the RMSE for both the internal and the external validation cohorts: 4 data sets were selected for Total SvdH, 16 for ES, and 14 for NSLS, with 88 polymorphisms in combination.

Conclusion: It is possible to generate predictive models of radiological damage of great precision using Artificial Intelligence techniques. This could allow early stratification of patients according to prognosis. It is necessary to validate these models in other populations.

Neutrophil Activation Is Associated with Disease Activity and Predicts Development of Erosive Disease and Extra Articular Manifestations in Rheumatoid Arthritis

Mary Bach^{1,2}, Tiffany Pan³, J. Lee Nelson^{3,4} and Christian Lood⁵, ¹VA Puget Sound Health Care System, Seattle, WA, ²Division of Rheumatology, University of Washington, Seattle, WA, ³Fred Hutchinson Cancer Research Center, Seattle, WA, ⁴Division of Rheumatology, University of Washington, SEATTLE, WA, ⁵Department of Medicine, Division of Rheumatology, University of Washington, Seattle, WA

Session Information

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster II: Diagnosis and Prognosis

Session Type: ACR Poster Session B

Session Time: 9:00 AM-11:00 AM

Background/Purpose: Neutrophil activation is associated with inflammation and autoimmunity, including rheumatoid arthritis (RA), where neutrophil infiltration into joints participates in tissue destruction and development of arthritis. In RA, neutrophils may undergo a programmed form of necrosis, NETosis, upon which neutrophil extracellular traps (NETs) are extruded. Due to their inflammatory capacity *in vitro*, as well as containing key autoantigens such as citrullinated histones and vimentin, NETs have been suggested to be an important contributor in the pathogenesis of RA. However, the clinical utility, and in particular the prognostic capacity, of neutrophil biomarkers has not been carefully addressed.

Methods: Markers of neutrophil activation (S100A8/A9) and NETosis were analyzed by ELISA in healthy controls (HC, n=24, and n=100) and RA patients from two independent cross-sectional cohorts (n=101 and n=93), as well as one longitudinal inception RA cohort (n=250) followed for a median of 8.3 years (4.4-19.8 years). The first cohort focused on disease activity measures, whereas the other cohorts were designed to study outcome measures.

Results: Levels of S100A8/A9 and NETs were markedly elevated in all three RA cohorts as compared to healthy individuals (p<0.0001). Both markers, particularly S100A8/A9, were associated with clinical markers of disease activity, including CDAI (r=0.52, p<0.0001) and the presence of swollen joints (r=0.50, p<0.0001). Patients who met the 1958 criteria for probable or definite RA but did not fulfill the 1987 ACR criteria (n=32), had significantly lower levels of circulating NETs as compared to individuals fulfilling the 1987 ACR criteria for RA (n=250, p<0.0001), and were indistinguishable from healthy individuals (p=0.16). Levels of NETs showed high specificity for patients fulfilling the 1987 ACR criteria for RA, as compared to healthy individuals (90%), as well as compared to symptomatic individuals not fulfilling the 1987 ACR criteria (94%), indicating a potential diagnostic utility of the test. Using the inception cohort, levels of NETs and S100A8/A9 were able to predict future development of extra articular nodules (OR=2.8, p<0.05, and OR=3.4, p<0.01, respectively). Furthermore, S100A8/A9 levels could predict future joint space narrowing (OR=4.4, p<0.0001) and erosive disease (OR=5.5, p<0.0001). A small number (12.5%) of newly diagnosed RA patients had noticeable erosive changes when recruited. Excluding these individuals from the analysis further strengthened the results with S100A8/A9 predicting joint space narrowing (OR=8.8, p=0.003) and the development of erosive disease (OR=5.7, p<0.0001).

Conclusion: Our results demonstrate a clear contribution of neutrophils in RA pathogenesis. Neutrophil-derived biomarkers may be able to monitor and predict disease activity and severity in RA patients. Thus, therapies targeting exaggerated neutrophil activation are anticipated to be beneficial in RA. Finally, monitoring of neutrophil biomarkers may allow for early preventive treatment avoiding long-term disabling disease in RA, including extra articular manifestations and erosive changes.

Session Information

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster II: Diagnosis and Prognosis

Session Type: ACR Poster Session B

Session Time: 9:00 AM-11:00 AM

Background/Purpose: Recent studies suggested a disconnect between disease activity and radiographic damage in rheumatoid arthritis (RA) patients treated with more aggressive treatment (1). Therefore, the aim of this retrospective study was to examine the longitudinal association between disease activity and radiographic damage in a real world cohort of consecutive patients with early RA treated according to treat-to-target (T2T) of remission step-up therapy.

Methods: Baseline to 3-year follow-up data were used from patients with early RA (79% fulfilling ACR 1987 criteria) included in the DREAM remission induction cohort (2). Patients were treated according to protocolized T2T, aimed at 28-joint disease activity score-erythrocyte sedimentation rate (DAS28-ESR) <2.6. Disease activity assessments were performed every 3 months; X-rays of the hand and feet were assessed at baseline and after 0.5, 1, 2 and 3 years of treatment and scored using modified Sharp/van derHeijde scoring (SHS). Between and within-person relations between time-integrated disease activity scores (DAS28-ESR and CRP) and radiographic change scores overtime were examined using Pearson correlations.

Results: 229 patients (63.3% female, mean age 57.5 years, baseline median symptom duration 13 weeks) with at least two radiographic assessments in the first 3 years were available for analysis. At the between-patient level, time-integrated DAS28-ESR scores were not significantly correlated with progression at the 6 month ($r=0.06$) and 2-year follow-up ($r=0.11$) and only weakly at the 1-year ($r=0.17$, $P<0.05$) and 3-year follow-up ($r=0.21$, $P<0.05$). Within individual patients, however, a different but fairly linear relationship between disease activity and progression existed over time (Figure). Individual slopes of the relationship between disease activity and progression were significantly correlated at each time point (Table) and the slope of the first 6 months was moderately significantly associated with this slope at later time points. Analyses using CRP showed similar results.

	6 months	1 year	2 year	3 year
6 months	–			
1 year	0.394***	–		
2 year	0.527***	0.172*	–	
3 year	0.592***	0.252**	0.478***	–

* $P < 0.05$; ** $P < 0.01$; *** $P < 0.001$.

Conclusion: In early RA patients treated according to T2T, radiographic progression appears to be an individually determined disease process, driven by factors other than consistent high disease activity. Within individual patients, the association between disease activity and radiographic damage during the first 6 months in individuals seems to be a good indicator for the progression and its association with disease activity in later years.

Session Information

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster II: Diagnosis and Prognosis

Session Type: ACR Poster Session B

Session Time: 9:00 AM-11:00 AM

Background/Purpose: Despite efforts to predict treatment response, treatment of rheumatoid arthritis (RA) patients remains mostly a case of trial and error. Previous research, mostly in clinical trials, focused mainly on radiological outcomes after treatment with methotrexate and identified baseline presence of erosions and ACPA as risk factors. We investigated in newly diagnosed RA patients if erosions and/or ACPA at baseline are associated with functional outcomes in the first year of treatment in daily practice.

Methods: Newly diagnosed patients with a clinical diagnosis of RA, ≥ 3 months follow-up and available data on ACPA, erosions and medication use were identified in the international, observational METEOR registry (n patients=4623). Timing and frequency of follow-up visits were non-protocolled and according to daily practice. We focussed at results after a maximum follow-up duration of 6 months or of 1 year from baseline. Associations between the presence of erosions and/or ACPA (4 groups) with the change of DAS and HAQ over time were assessed using linear mixed models. Missing data were imputed using multiple chained equations (40 cycles) and models were adjusted for the potential confounders age, gender, smoking, symptom duration, BMI, initial medication and country. In case of statistically significant effect modification ($p < 0.20$) by country, medication group (csDMARD monotherapy, csDMARD combination therapy, csDMARD + glucocorticoid and other) or symptom duration group (< 1 year, 1-2 years, 2-5 years and > 5 years), results were stratified.

Results: Baseline characteristics and follow-up duration of each ACPA/erosions group are shown in table 1. Baseline DAS and HAQ were slightly higher in erosions+ patients. Follow-up was similar between the 4 groups. We found statistically significant differences in DAS and HAQ change over time between the 4 groups, both after maximum follow-up durations of 6 months and 1 year (table 1). The adjusted change in DAS over time was slightly larger in the erosions+ groups and the adjusted change in HAQ over time was slightly smaller in the erosions-/ACPA+ group, but differences were small and not clinically relevant. No effect modification was found by country, medication or symptom duration.

Conclusion: In this analysis of worldwide real life data, we found statistically significant, but no clinically relevant differences in treatment response to initial DMARD therapies as measured by DAS and HAQ in ACPA-/erosions-, ACPA-/erosions+, ACPA+/erosions- and ACPA+/erosions+ RA patients. Instead, all groups had a similar response to initial treatment.

Table 1. Baseline characteristics and follow-up duration of each ACPA/erosions group.

		ACPA negative		ACPA positive

^aResults stem from multivariable linear mixed models analyses with random intercept and slope and exchangeable covariance matrix, adjusted for age, gender, smoking, symptom duration, BMI, initial medication and country. Regression coefficients represent the units of change in the outcome per unit of time, in this case, per month. Missing data were imputed using multiple chained equations (40 cycles).

^aP-values are only shown for the interaction between erosions/ACPA and time in months. In the presence of a statistically significant interaction, results are stratified by gender and the evolution of DAS and HAQ over time is shown for the erosions/ACPA groups separately.

Bone Erosion Volume Changes Measured By HR-pQCT at 3-Months after Initiation of Anti-TNF Treatment Predicted Erosion Volume Changes at 1-Year in RA

Tomohiro Shimizu¹, Kenji Mamoto¹, Matthew Tanaka¹, Andrew J Burghardt², Thomas Link¹, Jonathan Graf³, John B. Imboden Jr³ and Xiaojuan Li¹, ¹Radiology and Biomedical Imaging, Musculoskeletal Quantitative Imaging Research, University of California, San Francisco, San Francisco, CA, ²Department of Radiology & Biomedical Imaging, Musculoskeletal Quantitative Imaging Research, University of California, San Francisco, San Francisco, CA, ³Medicine, University of California, San Francisco, San Francisco, CA

Session Information

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster II: Diagnosis and Prognosis

Session Type: ACR Poster Session B

Session Time: 9:00 AM-11:00 AM

Background/Purpose: Bone erosions and joint space narrowing (JSN) are significant aspects of structural damage in rheumatoid arthritis. High resolution peripheral quantitative computed tomography (HR-pQCT) allows detailed analysis of bone erosion, joint space and bone microstructure. We previously reported bone erosion and microarchitecture evaluation using HR-pQCT within the first three months after the initiation of anti-tumor necrosis factor (TNF α) treatment. However, no study has yet reported if early bone changes such as three months would predict the future changes of bone destruction. Hence, the goal of this study was to quantify erosion volume, bone microarchitecture, joint space volume and width from prior to anti-TNF α therapy to one year after initiation using HR-pQCT, and to investigate if development of erosions at 3-months can predict progression of erosions after 1 year.

Methods: Twenty-one RA patients receiving MTX treatment were recruited and divided into two groups according to disease activity scores (low (DAS28 \leq 3.2) (N=9) and high (DAS28>3.2) (N=12) DAS group). Patients in the high DAS group were treated with anti-TNF α and MTX immediately after the baseline MRI (BL). All patients underwent HR-pQCT scans of the MCP at BL, 3-months (3M) and 1-year (1Y). HR-pQCT-derived erosion volume, joint space volume and width and bone microarchitecture at the MCP2 and MCP3 were measured using in-house developed software with previously reported excellent in-vivo reproducibility.

Results: 37 bone erosions were detected at BL. In the high DAS group, one erosion was full repaired, while two new erosions were observed at 1-year. Although there were no significant changes of mean bone erosion volume in the high DAS group from BL to 1Y, the low DAS group showed increases in mean bone erosion volume from BL to 1Y regardless of lower disease activity (P=0.006). Changes of bone erosion volume from BL to 3M were significantly correlated with changes of bone erosion volume from 3M to 1Y (P=0.001). On the other hand, both groups showed significant joint space narrowing at 1Y compared to BL (P=0.008).

Conclusion: Our findings suggest that early changes in bone erosion volume can predict future disease progression. Therefore, additional treatment may be necessary for patients whose bone erosion volume increases during the early period despite good response for DAS28. HR-pQCT provides sensitive technique to measure erosion progression even within 3-months after treatment.

Plasma Mir-146a-5p Associates with Beneficial Body Composition and Plasma Metabolic Profiles in Rheumatoid Arthritis

Brian J. Andonian¹, Ching-Heng Chou², Virginia B. Kraus², William E. Kraus³ and Kim M. Huffman⁴, ¹Department of Medicine, Division of Rheumatology and Immunology, Duke University, Durham, NC, ²Duke Molecular Physiology Institute, Duke University, Durham, NC, ³Medicine, Duke University, Durham, NC, ⁴School of Medicine, Division of Rheumatology, Immunology and Molecular Physiology and Durham VA Medical Center, Duke University, Durham, NC

Session Information

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster II: Diagnosis and Prognosis

Session Type: ACR Poster Session B

Session Time: 9:00 AM-11:00 AM

Background/Purpose: In rheumatoid arthritis (RA), sarcopenic obesity is associated with significant cardio metabolic disease and mortality. Biomarkers of disease activity in RA and obesity are complicated by inflammation associated with both conditions. The microRNA miR-146a is implicated as a biomarker in both RA pathogenesis and adiposity. However, it is unclear whether systemic miR-146a is impacted primarily by autoimmunity or obesity in RA. Here, we investigated relationships of miR-146a with RA disease activity, body composition and metabolic intermediates associated with obesity.

Methods: All RA patients in this study satisfied 1987 ACR criteria. Plasma miR-146a-5p expression was measured via PCR as delta cycle threshold (Δ Ct) using a reference microRNA sequence in 48 persons with RA and 23 age-, sex- and BMI-matched healthy controls. Plasma acylcarnitine and amino acid measurements were made via flow injection tandem mass spectrometry. Body composition was assessed using CT scan analyses to determine central and muscle adipose and thigh muscle tissue size and tissue density. Disease activity in RA was assessed by DAS-28-ESR. Plasma miR-146a-5p was compared in RA versus control subjects using the Wilcoxon signed rank test. Correlations were evaluated using Spearman ρ . Strengths of associations for the two groups were compared with Fisherr-to-z transformations.

Results: There was no significant difference in plasma miR-146a-5p expression between RA (-0.158 ± 0.98 (SD) Δ Ct) versus controls (-0.086 ± 1.53 Δ Ct; $p=0.69$). miR-146a-5p was not correlated with RA disease activity ($r=-0.03$, $p=0.84$). In RA, greater expression of miR-146a-5p was associated with younger age, lower BMI, smaller waist circumference, less adiposity, and greater thigh muscle density (Table 1). Body composition correlations were not significantly different between groups (Fisher r-to-z $p>0.05$ for all). In RA, greater miR-146a-5p was also associated with lower concentrations of adiposity-related (Newgard et al. Cell Metabolism (2009); 9: 311–326) metabolic intermediates, acylcarnitines and branched chain amino acids (Table 2).

Conclusion: Greater plasma miR-146a-5p was associated with multiple indicators of reduced adiposity: smaller central and thigh fat areas, less intra-muscular adiposity, and less circulating adiposity-related metabolic intermediates. Plasma miR-

146a-5p expression in RA was similar to controls and not associated with DAS-28 scores. These findings suggest that rather than disease activity, in established RA, plasma miR-146a-5p inversely reflects adiposity.

Peptidylarginine Deiminase-4 Antibodies Are Not Associated with Worse RA Activity, Symptoms or Impacts

Dana DiRenzo¹, Erika Darrah², Susan J. Bartlett^{3,4}, Clifton O. Bingham III⁴ and Laura C. Cappelli¹, ¹Division of Rheumatology, Johns Hopkins University School of Medicine, Baltimore, MD, ²Department of Medicine/Division of Rheumatology, Johns Hopkins University School of Medicine, Baltimore, MD, ³Department of Medicine, Division of ClinEpi, Rheumatology, Respiriology, McGill University, Montreal, QC, Canada, ⁴Rheumatology, Johns Hopkins University School of Medicine, Baltimore, MD

Session Information

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster II: Diagnosis and Prognosis

Session Type: ACR Poster Session B

Session Time: 9:00 AM-11:00 AM

Background/Purpose: Antibodies to peptidylarginine deiminase (PAD) enzymes have been implicated in the pathogenesis of RA. Previous studies have shown that patients with PAD4 antibodies have more erosive joint disease compared to patients who do not. We hypothesized that patients with PAD4 antibodies would have more severe disease and report higher levels of RA symptoms and functional impacts than those without antibodies.

Methods: Adults with MD-diagnosed RA enrolled in a longitudinal cohort study with serum available from the visit were included; almost all (96%) met 2010ACR/EULAR RA criteria. Anti-PAD4 antibodies were detected by immunoprecipitation. Independent t-tests and chi-square were used to compare patient and RA characteristics and selected patient reported outcomes (PROs: PROMIS™ pain intensity, physical function, fatigue, ability to participate in social roles and activities, anxiety, depression, and sleep disturbance) by antibody status.

Results: Patients (n=151) had a mean age of 55 +/-13, were mostly female (80%), and white (85%). Most had longstanding RA (11 +/-10 years) with 35% in CDAI remission and 34% with low disease activity. Nearly half (47%) were on a

biologic, and 68% were on MTX. Anti-PAD antibodies and PROs were available on 135 patients (89%); baseline characteristics did not differ between those with and without completed PROs. A total of 38 (28%) patients were anti-PAD4+. No significant differences were evident between groups in mean CDAI, SJC, PGA, EGA, stiffness severity, ESR, or CRP (Table 1). Although a higher proportion of anti-PAD4+ patients had erosions, there was no statistically significant difference between groups (Table 1). Mean PROMIS scores (pain intensity, physical function, fatigue, ability to participate in social roles and activities, anxiety, and depression) were in the normal range (i.e., 55-65) except pain intensity and physical function which were lower in both groups (Table 2); however, PRO scores were similar between groups.

Conclusion: In this well characterized cohort of RA patients, anti-PAD4+ patients had longer disease duration and a slightly lower TJC compared to patients without PAD antibodies. Anti-PAD4+ patients had a trend toward more erosive disease; but PROs were similar between groups. Contrary to expectations, anti-PAD4+ patients did not have clinical evidence of worse symptoms or functional impacts. The lack of congruency between bony damage and disease activity may suggest a difference in pathogenesis between these processes

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster II: Diagnosis and Prognosis

Session Type: ACR Poster Session B

Session Time: 9:00 AM-11:00 AM

Background/Purpose: Stiffness is a hallmark of RA, but little is known about the etiology. We investigated stiffness association with RA disease activity and determined whether synovial histologic features are associated with stiffness severity or stiffness duration.

Methods: 194 patients with RA meeting ACR criteria undergoing arthroplasty were included (Table 1). Morning stiffness duration was determined using the RADAI question, “Were your joints stiff when you woke up today? If yes, how long did the stiffness last?”; “no stiffness, <30 min, 30-60 mins, 1-2 hrs, 2-4 hrs, >4 hrs, all day”. Stiffness severity was measured by the OMERACT Flare question, “How severe was your stiffness over the past week” on a 10 point Likert scale. Histopathology of synovium was scored for 10 features: synovial lining hyperplasia, lymphocytes, plasma cells, Russell

bodies, binucleate plasma cells, fibrin, synovial giant cells detritus, neutrophils and mucin. Severity was modeled as a continuous outcome and duration was modeled as a binary outcome using < 30 mins vs ≥ 30 mins. Simple regression models were performed to examine the association between DAS28-ESR and RAPID3, with severity and duration. Multivariable regression models were performed with (either DAS28-ESR or RAPID3) and the following clinical variables: age, gender, BMI, duration of diagnosis, anti-CCP, and RF. Chi-squared or Fisher's exact test was used to test the association between 10 histology features and morning stiffness outcomes. FDR-adjusted p-values were reported to correct for multiple comparisons.

Results: Morning stiffness duration of greater than 30 minutes was significantly associated with both DAS28-ESR (OR: 1.79 [1.26, 2.55], p value = 0.001) and RAPID3 (OR: 1.17 [1.06, 1.29], p value = 0.002) and remained significantly associated after incorporating age, gender, BMI, duration of diagnosis, anti-CCP and RF. Stiffness severity was also significantly associated with both DAS28 (β = 0.51, p value = 0.006) and RAPID3 (β = 0.29, p value < 0.0001) and remained significantly

associated after incorporating age, gender, BMI, duration of diagnosis, anti-CCP, and RF into the model. After adjusting for multiple comparisons, neutrophils (P_{adj}=0.005) and fibrin (P_{adj}=0.005) were significantly associated with greater than 30 minutes of morning stiffness. None of the 10 synovial features examined were significantly associated with stiffness severity.

Conclusion: Both stiffness severity over the past week and duration of morning stiffness were significantly associated with the disease activity measurement instruments, DAS28 and RAPID3. Fibrin deposition and neutrophil infiltration are associated with the duration of morning stiffness in RA, suggesting acute synovial inflammation and relatively recent or ongoing neutrophil recruitment may play a role in the pathogenesis of this symptom.

Session Information

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster II: Diagnosis and Prognosis

Session Type: ACR Poster Session B

Session Time: 9:00 AM-11:00 AM

Background/Purpose: Secondary Sjögren's syndrome (sSS) is considered an extra-articular manifestation of RA and is an autoantibody-mediated condition similar to RA. Thus, patients (pts) with sSS could be anti-citrullinated protein antibodies (ACPA) and anti-Ro/Sjögren's-syndrome-related antigen A (SSA) autoantibody double positive (double+). There are limited data on the impact of double positivity on RA disease burden. The objective of this analysis was to compare pts with sSS with and without double positivity.

Methods: Data from adult pts with RA enrolled in a longitudinal sequential RA registry were analyzed. Pts in the registry were evaluated annually by a rheumatologist for disease activity and treatment, and semi-annually on multiple clinical patient-reported outcomes (PROs) and resource utilization parameters. Pts with sSS were identified with a clinician's diagnosis or based on meeting the 2016 ACR/EULAR classification of primary Sjögren's syndrome. Pts with sSS were divided into two mutually exclusive groups: pts with and without double positivity (the latter including single positive or double negative pts). The two cohorts were compared using descriptive statistics to summarize baseline differences in demographics, disease activity measures, sero status and treatments. A Kruskal–Wallis test for continuous variables and a chi-square test for categorical variables were performed with a significance level of 0.05. Mean changes from baseline to 12 months in disease activity measures and PROs were assessed for pts with available data at baseline and follow-up.

Results: A total of 415 pts were identified as having sSS associated with RA, with 80 (19.3%) and 86 (20.7%) pts in the cohorts with and without double positivity, respectively. The double+ pts with sSS were diagnosed with RA at a younger age, had longer duration since onset of RA symptoms and a higher number of swollen joints compared with pts with sSS without double positivity (Table 1). In addition, the mean changes in disease activity were lower in pts with versus without double positivity, though these were not statistically significant, potentially due to the limited sample size (Table 2).

Conclusion: Pts with sSS with versus without double positivity for ACPA and SSA had greater RA disease burden at baseline and 12-month follow-up. Further analysis with a larger sample size is warranted.

Newer Generation Cyclic Citrullinated Peptide (CCP) 3.1 Assay in the Diagnosis of Rheumatoid Arthritis

James Son¹, Lindsay J. Forbess² and Mariko Ishimori³, ¹Internal Medicine, Cedars-Sinai Medical Center, Los Angeles, CA, ²Division of Rheumatology, Cedars-Sinai Medical Center, Los Angeles, CA, ³Medicine, Division of Rheumatology, Cedars-Sinai Medical Center, Los Angeles, CA

Session Information

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster II: Diagnosis and Prognosis

Session Type: ACR Poster Session B

Session Time: 9:00 AM-11:00 AM

Background/Purpose: Rheumatoid factor (RF) and anti-cyclic citrullinated peptide antibody (CCP) are important serum markers used in clinical diagnosis of rheumatoid arthritis (RA). Multiple studies have investigated previous generations of CCP assays, and several have shown CCP to be a highly specific and predictive marker for the diagnosis of RA. There are differences in sensitivity, specificity, and predictive value between the various generations of the CCP test. Previous studies of the CCP3.1 assay indicate that it may have a similar degree of specificity with a greater sensitivity than prior generations. However, these studies examined CCP levels in patients with already established RA. Our aim was to investigate the predictive value of the new CCP3.1 assay in identifying RA versus other conditions.

Methods: We performed a retrospective systematic chart review of patients with a positive CCP level (≥ 20) from July 2016 to June 2017 at Cedars-Sinai Medical Center (CSMC) ordered by physicians from all specialties for any indication. Among those with a positive CCP, we investigated the different associated underlying diagnoses present at least 6 months after testing was performed, including RA and other autoimmune and non-autoimmune diagnoses. RA diagnoses were confirmed by a rheumatologist according to the 1987/2010 ACR criteria. The data was further stratified into low (≥ 20 and < 40) and high (≥ 40) CCP levels and analyzed. Anti-CCP3.1 antibody levels were assessed using QUANTA Lite CCP 3.1 IgA/IgG ELISA (Inova Diagnostics, Inc., San Diego, CA). The tests were performed by ETI-Max 3000 analyzer with manual dilution of the specimens.

Results: Of the 2027 CCP tests performed at CSMC, 307 positive CCP tests were reported among 281 unique patients. Among 281 patients, 48% (135/281) had a final diagnosis of RA, 46.3% (130/281) had a non-RA diagnosis, and 5.7% (16/281) did not have any diagnosis. 105 patients (37.4%) had a low CCP level, and 176 (62.6%) had a high CCP level. The positive predictive value of RA in patients with a high CCP (109/176, 61.9%) was 2.5-fold higher than those with a low CCP (26/105, 24.7%). Among the 130 non-RA diagnoses, the other most common autoimmune diseases included systemic lupus erythematosus (15.4%), primary Sjogren's syndrome (8.5%) and polymyalgia rheumatica (3.8%). The most common non-autoimmune diagnoses were osteoarthritis (13.8%), interstitial lung disease (7.7%), malignancy (7.7%) and fibromyalgia (3.8%).

Conclusion: Of the 281 patients with a positive CCP, nearly half were found to have a diagnosis other than RA. There seems to be a higher likelihood of RA with higher CCP levels. Overall, there were similar rates of autoimmune and non-immune mediated diseases between low and high CCP levels. Interestingly, certain autoimmune conditions, such as lupus, Sjogren's and psoriatic arthritis were more likely to have a low CCP titer than a high one. Further research needs to be conducted to investigate the utility of this CCP3.1 assay.

Session Information

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster II: Diagnosis and Prognosis

Session Type: ACR Poster Session B

Session Time: 9:00 AM-11:00 AM

Background/Purpose: Rheumatoid arthritis (RA) is a progressive immune-mediated disease involving the synovitis that can culminate in joint destruction and early mortality. IL-17-producing T (Th17) cells and regulatory T (Treg) cells have been showed to play critical roles in the pathogenesis of RA. Osteopontin (OPN) is a matricellular protein that mediates diverse biological functions. OPN mediates cell migration, adhesion, and survival in many cell types. OPN also functions as a Th1 cytokine, promotes cell-mediated immune responses, and plays a role in chronic inflammatory and autoimmune diseases. Recently, studies revealed that OPN produced in RA SF was responsible for markedly increased Th17 and Both Treg-intrinsic and Treg-extrinsic factors maintaining Bcl6 are important for controlling Treg cell stability. Recently, our studies have found that absolute number of CD4⁺CD25⁺Foxp3⁺ regulatory T cells (CD4⁺Tregs) was significantly decreased in peripheral blood from patients with RA as compared to that from normal controls. The purpose is to investigate the absolute number of Th17, CD4⁺CD25⁺Foxp3⁺Treg cells as well as OPN content in peripheral blood of patients with RA and the correlation between OPN content with Th17 and Treg cells, to find a possible pathogenesis related to RA and new therapy for the RA treatment.

Methods: A total 67 of new-onset diagnosed patients with RA fulfilled the 2010 ACR/EULAR Classification Criteria of Rheumatoid Arthritis were enrolled and 93 healthy donors were used as control. The absolute number of peripheral CD4⁺Tregs cell was detected by multicolor flow cytometry. ELISA was used to detect OPN. Meanwhile, Test parameters were anti-cyclic citrullinated peptide antibody (Anti-CCP), erythrocyte sedimentation rate (ESR), C reactive protein (CRP), rheumatoid factor (RF). At the same time, the DAS28 score of RA group was calculated.

Results: The levels of OPN in RA patients were increased significantly [(14.84±8.64) vs (10.59±3.40), P<0.001] and significantly positively correlated to ESR, DAS28 score, and RF (r=0.284, P=0.02; r=0.290, P=0.039; r=0.376, P=0.007). The absolute number of Treg cells was significantly decreased in RA patients as compared with the controls [(23.63±2.80) vs (33.67±26.83) ng/μl, P<0.001]. However, the absolute number of Treg cells was negatively to OPN levels, and the difference was statistically significant (r=-0.459, P=0.000). The absolute number of Th17 cells tends to reduce and there was no statistical significance [(7.64±6.44) vs (6.64±4.26) ng/μl, P=0.0129]. There is no significant correlation between OPN and Th17 (r=0.006, P=0.963).

Conclusion: The levels of OPN in peripheral blood plasma in RA were significantly higher than in healthy group, OPN was positively correlated with the laboratory parameters of disease activity. There was a negative correlation between Treg cells and OPN in RA group, which suggested that the reduction of Treg cell levels may be associated with OPN concentration. The correlation of decreased CD4⁺Tregs and OPN may be involved in the pathogenesis of RA. Whether OPN lays a role in the reduction of Treg cells need to study further

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster II: Diagnosis and Prognosis

Session Type: ACR Poster Session B

Session Time: 9:00 AM-11:00 AM

Background/Purpose: Anti-citrullinated protein antibodies (ACPA) are detectable long before the manifestation of rheumatoid arthritis (RA). EULAR provided a clinical definition of individuals with arthralgia suspicious for progression

to RA (clinically suspect arthralgia, CSA). The alteration of monocyte subpopulations in patients with established RA has been described. We aimed to evaluate possible predictive value of the monocyte and lymphocyte subpopulations in individuals in the preclinical phase of RA.

Methods: Thirty-four individuals with arthralgia (mean age 45.11 ± 12.6 years; 91% females) and 80 age and gender matched healthy controls (HC) were included. Leukocytes from peripheral blood were analysed by flow cytometry. Lymphocyte subpopulations were defined as CD19+CD3-, CD3+CD4+, CD3+CD8+ and CD16/56+CD3- (NK) cells, monocytes were segregated into classical (CD14+CD16-), intermediate (CD14+CD16+/++) and non-classical (CD14-/dimCD16++) subsets. Data were analysed using t-test and Spearman's correlation and are expressed as median and interquartile range (IQR).

Results: Out of 34 patients with arthralgia, 27 were ACPA+ and 17 met CSA definition (10 of them were ACPA+), with symptoms duration 36 months (IQR: 77.5), CRP 2.27 mg/L (IQR 3.35), DAS28 2.13 (IQR 1.32). As per definition, there was no clinical synovitis at baseline. Five individuals developed RA within 3-9 months of follow up. Patients with arthralgia had higher %CD3+ ($p=0.002$) and %CD3+CD8+ ($p=0.034$) T cells and lower %NK ($p=0.003$) and absolute count of NK cells ($p=0.002$) compared to HC. This was confirmed in a subgroup of ACPA+ patients. The count of tender joints correlated positively with %CD3 ($p=0.009$; $r=0.491$) and %CD3CD8 ($p=0.034$; $r=0.410$) T cells and negatively with %NK cells ($p=0.019$; $r=0.045$). Moreover, individuals who developed RA during follow up, had higher baseline %CD3+ cells ($p=0.046$) with the trend for lower %NK cells ($p=0.065$). No differences were seen between patients meeting CSA definition and non-CSA individuals. Expansion of intermediate ($p=0.012$) and non-classical ($p=0.007$) monocytes with reduction of classical monocytes ($p=0.001$) were demonstrated in all patients with arthralgia compared to HC. Importantly, ACPA+ patients had higher non-classical ($p=0.041$) and lower classical monocytes ($p=0.022$) than ACPA- patients. Similarly, ACPA+ patients had higher intermediate ($p=0.006$) or non-classical ($p=0.012$) and lower classical ($p=0.004$) monocytes compared to HC, while no differences were seen between ACPA- patients and HC.

Conclusion: We demonstrate lower NK cells, expansion of intermediate and non-classical monocyte subpopulation in patients in the preclinical phase of RA, especially in ACPA+ individuals. Since this pattern has been described so far in patients with established RA, our data suggest their role even in early phases of RA development. These leukocyte subpopulations could be considered as prognostic biomarkers for further development of RA.

Session Information

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster II: Diagnosis and Prognosis

Session Type: ACR Poster Session B

Session Time: 9:00 AM-11:00 AM

Background/Purpose: Rheumatoid arthritis (RA) is a long-lasting inflammatory autoimmune disorder that ultimately leads to the destruction of joint architecture. The activity of this disease is measured by the assessment of clinical symptoms. The aim of this study was to apply a proteomic strategy to find plasma biomarkers able to discriminate patients with different RA activities.

Methods: 80 plasma samples from the IMID (Immune-Mediated Inflammatory Diseases) Consortium, classified according to the DAS28 score into low (40 samples with DAS28: 2,6-3,2) and high (40 samples with DAS28>5,1) activity were randomly selected to be analyzed by mass spectrometry (MS). This study was conducted in two stages: a panel of proteins were firstly selected based on the regulation of the RA activity in an initial discovery phase, followed by the verification and absolute quantitation of this set of proteins on the 80 independent RA samples, using targeted MS.

A shotgun MS strategy was performed in the discovery phase. For this aim, four independent pools of each condition were firstly albumin-depleted, digested and differentially labelled with iTraQ 8-plex reagents. Subsequently, the 8 labelled pools were combined, cleaned using StageTips-C18, fractionated by HPLC and analyzed by nanoLC-MS/MS using three different MS equipments. Afterwards, the verification phase was performed by a targeted Multiple Reaction Monitoring (MRM) strategy on a QTRAP 5500 on the 80 independent samples, using 26 synthetic heavy-labelled peptides as internal standards for absolute protein quantitation. The results were analyzed using the proteomic software Skyline and statistical tools from SPSS and PRISM.

Results: In the discovery stage, 186 proteins were identified by shotgun MS. The abundance of 11 of these proteins was found to be significantly different ($p<0.05$) between patients with high and low RA activities. To verify these results, a method for the absolute quantitation of this 11-protein panel, based on targeted MS and the use of labelled internal standards, was developed and applied on the 80 RA plasma samples. The data obtained in this verification step showed a significant increase in four of these proteins, in accordance with that observed in the discovery phase: Haptoglobin, Serum Amyloid A1, Alpha-1-antichymotrypsin and Alpha-1-acid Glycoprotein 1. The increased abundance of these four proteins in plasma was significantly associated ($p<0.05$) with a high disease activity in RA patients. These proteins are related with the RA process and its effects (inflammation and immune disorder in joints), giving significance to the results obtained. This protein panel is being validated in a larger cohort of samples of similar characteristics (including healthy and disease controls) to qualify them for clinical applications.

Conclusion: A two-step proteomic approach (including both discovery and verification phases) has been followed for the identification of protein biomarkers associated with disease activity in RA patients. A panel of four proteins has been verified as increased in the plasma of patients with high activity, and could be useful for the molecular monitoring of the disease.

Session Information

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster II: Diagnosis and Prognosis

Session Type: ACR Poster Session B

Session Time: 9:00 AM-11:00 AM

Background/Purpose: Secondary Sjögren's Syndrome (sSS) is a common extraarticular manifestation in patients with Rheumatoid Arthritis (RA). According to the 2002 European American criteria (EA 2002) classification for Sjögren's Syndrome (SS), the secondary term is used for all cases present concomitantly with another connective tissue disease. There is little evidence regarding the difference between patients with SS associated with RA with minor salivary gland biopsy with and without focal lymphocytic sialadenitis (FLS).

Objective: Determine whether FLS is associated with clinical and serological differences in a group of patients diagnosed with RA and sSS.

Methods: Patients with RA diagnosis were included according to ACR 1987 and / or ACR-EULAR 2010 criteria, and who also met criteria EA 2002 for sSS. Ocular tests, sialometry and minor salivary gland biopsy were performed. Clinical, serological and treatment characteristics were compared between patients with positive FLS and negative FLS. For continuous variables, t-test or Mann Whitney test was used, and for the categorical variables Chi square or Fisher's exact

test was used. A multivariate logistic regression analysis was performed taking the presence of FLS as a dependent variable.

Results: We included 88 patients with SS associated with RA. 92% were women, with a mean age of 53 years (SD \pm 11.3) and 12.5 years of RA evolution (IQR 6-17). 63.6% had FLS vs. 36.4% that did not. In the univariate analysis, patients who presented FLS had higher current HAQ (1.12 IQR 0.5-1.62 vs 0.55 IQR 0.06-1.37, p 0.04); parotid swelling frequency (23% vs 0%, p 0.003); interstitial lung disease (25% vs 6.25%, p 0.04); autoimmune liver disease (14.3% vs 0%, p 0.047); hypergammaglobulinemia (51.8% vs 3%, p <0.001); anemia (35.7% vs 15.6%, p 0.04); hypocomplementemia (51.9% vs 16%, p 0.001); double seropositivity for RF and ACPA (87.5% vs. 68.7%, p 0.03); Positive ANA (94.6% vs 71.8%, p 0.007) and extra-joint and extraglandular manifestations (66% vs 21.9%, p <0.001). No differences were found regarding the positivity of RO and / or LA, in the positivity of ACPA (92.8% vs 81.3%), nor in treatments and total number of immunosuppressants received. The variables that were found to be independently associated with the presence of FLS were the presence of extra-joint and extraglandular manifestations (OR 5.67 CI95% 1.6-20), positive ANA (OR 11.7 CI95% 1.6-83) and hypergammaglobulinemia (OR 21 CI95% 2.46-179).

Conclusion: Patients with RA and sSS who have FLS in the minor salivary gland present greater frequency of extra-articular and extraglandular manifestations, as well as serological differences with respect to patients without FLS.

Measurement of Anti-Amyloid β Autoantibodies in Patients with Rheumatoid Arthritis

Masao Sato¹, Masao Takemura², Tomohisa Tani³ and Toshiro Ohashi³, ¹R, Ohashi-Tani Orthopaedic, Gifu, Japan, ²Advanced Diagnostic System Research Laboratory, Fujita Health University, Toyoake, Japan, ³Ohashi-Tani Orthopaedic, Gifu, Japan

Session Information

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster II: Diagnosis and Prognosis

Session Type: ACR Poster Session B

Session Time: 9:00 AM-11:00 AM

Background/Purpose: Amyloid β (A β) accumulation in the brain is a risk factor for Alzheimer's disease (AD). The incidence of AD increases with age. Rheumatoid arthritis (RA) patients have been reported to be at a lower risk of AD, and the non-steroidal anti-inflammatory drugs (NSAIDs) used to treat RA have also been shown to have an effect against AD. In this study, we measured the concentration of anti-A β autoantibodies (anti-A β AAB) in the serum of treatment-naive RA patients who had not previously undergone drug therapy.

Methods: The study subjects were 174 patients with no treatment history, who presented for initial outpatient examination, complaining of joint pain between the years 2010 and 2014. They comprised of 106 patients (mean age 55.5 ± 17.2 years) diagnosed with RA based on the 2010 American College of Rheumatology/European League Against Rheumatism Classification Criteria for Rheumatoid Arthritis, and 68 (mean age: 59.1 ± 12.8 years) with unclassified arthritis (UA) who were not classifiable as having RA. Serum was collected at initial examination and stored frozen at -80°C , with all samples measured at the same time. Anti-A β AAB was measured by an ELISA assay developed in our department. We investigated the association among anti-A β AAB titers, age, and laboratory test results (C-reactive protein, rheumatic factor, anti-CCP antibodies [CCP], IgG, IgA, and IgM). Similar measurements were also made in 50 healthy individuals (mean age: 54.6 ± 14.3 years) as control.

Results: Anti-A β AAB titer values were 17.0 ± 2.3 units in the RA group, 11.2 ± 0.95 units in the UA group, and 8.3 ± 0.87 units in the control group, being significantly higher in the RA group than in the UA ($p < 0.02$) or control ($p < 0.002$) group. An investigation of the association between anti-A β AAB titer and laboratory test results identified a weak positive correlation with age in the control and UA groups ($r = 0.240$, $r = 0.234$), and a negative correlation with age in the RA group ($r = -0.418$). An investigation of the association between anti-A β AAB titer and CCP classified RA patients into the following three groups: in half ($n = 57$) both anti-A β AAB titer and CCP were low (anti-A β AAB < 20 units, CCP < 200 IU/ml), in one quarter ($n = 25$) anti-A β AAB titer was high and CCP was low, and in the other quarter ($n = 24$) anti-A β AAB titer was low and CCP was high.

Conclusion: The anti-A β AAB titer was significantly higher in treatment-naïve RA patients. In the RA group, the anti-A β AAB titer negatively correlated with age. RA patients with high anti-A β AAB titer tended to have low levels of CCP, and those with high CCP tended to have low levels of anti-A β AAB. Studies involving larger numbers of patients to investigate changes in anti-A β AAB titer during treatment are required, but our results suggest that CCP levels may be implicated in the relationship between RA and AD.

Session Type: ACR Poster Session B

Session Time: 9:00 AM-11:00 AM

RussellBodies and Serological Status in Rheumatoid Arthritis

Background/Purpose: Russell bodies (RBs) are globular aggregates of immunoglobulin produced by plasma cells and identified both within the plasma cells (PCs) and free in inflamed tissues. ¹It has been suggested that RBs form when antibody production surpasses protein transportation mechanisms in the cell, possibly indicating heightened production of the antibodies. Rheumatoid factor (RF) and anti-cyclicitrullinated peptide (aCCP) are antibodies commonly identified in serum of patients with rheumatoid arthritis (RA). In some patients with RA undergoing arthroplasty, synovial tissue is highly inflamed and the histologic features include the presence of plasma cells with and without RBs. The molecular features and clinical significance of RBs are unknown. Here we test the hypothesis that RBs associate with the degree of positive serology in RA.

Methods: Tissue samples from 191 RA patients undergoing total hip, knee, shoulder, or elbow arthroplasty were scored for the proportion of PCs, the presence of binucleate plasma cells (bnPC), and RBs. Serological test results for RF and aCCP were collected. Logistic regression was used to calculate an odds ratio for positive serological results with the presence of RBs seen histologically. The concordance of bnPCs and RBs was evaluated.

Results: Of the 191 RA patients, 170 (89%) cases had suitable synovium for histologic characterization. Of the 170 synovial samples assessed, 37 (22%) contained RBs. Demographics (age, sex, joint replaced) of RB positive cases were similar to RB negative cases. Clinical measures (tender and swollen joint counts, patient global, and MD global) were similar between groups. Erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP) levels were significantly elevated in the RB-positive cohort ($p < 0.001$). Significantly more RB-negative patients were in DAS28-ESR remission ($p = 0.024$). RF and a CCP status were both significantly different between groups ($p < 0.001$ and $p = 0.024$, respectively) as well as the proportion of patients with both RF and aCCP positive results ($p < 0.001$). The unadjusted odds ratio of having a positive serological test (RF or CCP) when RBs are found on histology is 3.94 (1.13-13.72, $p = 0.031$). There was good concordance between bnPCs and RBs (kappa coefficient [95% CI], 0.62 [0.48 - 0.75]).

Conclusion: The presence of RBs in synovial histology is not specifically incorporated into most synovial pathology scoring schemes. This study suggests that the presence of RBs is a significant histological finding that parallels serological status in RA, perhaps in patients with undiagnosed or untreated disease. Additionally, the association of RBs and bnPC may suggest a mechanistic connection that stands to be further explored.

Session Information

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster II: Diagnosis and Prognosis

Session Type: ACR Poster Session B

Session Time: 9:00 AM-11:00 AM

Background/Purpose: Anti-citrullinated protein/peptide autoantibodies (ACPAs) define a major subset of rheumatoid arthritis (RA) patients. Cyclic citrullinated peptides (CCP) are commonly used as the antigen for assessing ACPAs. However, these synthetic peptides may not represent the citrullinated proteins found *in vivo*. We have utilized ECV304, a human cell line containing high protein arginine deiminase (PAD) levels, to generate a naturally derived citrullinome. Next, we assessed by proteomics the ECV304 antigens recognized by antibodies present in RA sera. Finally, we compared the performance of an *in house* ECV304-based ELISA with that of a commercial anti-CCP2-ELISA for RA diagnosis.

Methods: Citrullination was assessed in ECV 304 and other human cell lines (n=7) by Western blot and the amount of citrulline generated was quantified by a colorimetric assay. PAD isotypes present in ECV304 were determined by PCR. ECV304 citrullinated proteins/peptides were immunoprecipitated by autoantibodies present in RA sera, and characterized by mass spectrometry. The ECV304-based ELISA contained a citrullinated ECV304 cell extract and myelin basic protein (MBP, an arginine-rich potential citrullinated -epitope carrier). The performance of this assay was tested in sera from 1) 74 patients with a clinical diagnosis of RA (55 CCP positive, 50 rheumatoid factor [RF] positive; 8 CCP and RF negative), 2) 51 patients with non-RA rheumatic diseases (non-RA controls), and 3) 25 healthy controls.

Results: Among 7 human cell lines tested, ECV304 was the only one that abundantly citrullinated self-proteins and exogenous MBP. ECV304 expressed PAD2 and PAD3 iso-enzymes, and the ECV304 citrullinated proteins/peptides were detected by autoantibodies present in RA sera. Proteomic analysis confirmed the presence of known citrullinated RA antigens (i.e., calreticulin, profilin 1 and vinculin), as well as novel targets such as: 14-3-3 protein beta/alpha, 14-3-3 protein zeta/delta, mitochondrial peroxiredoxin-5, and transketolase in the ECV304 extracts. The net binding to ECV304 citrullinated proteins (compared to non-citrullinated proteins) was the ELISA readout, and the cut-off of the test was defined to optimize specificity. The sensitivity, specificity, positive and negative predictive values of the ECV304-based ELISA were 39%, 98%, 97% and 63%, respectively.

Conclusion: The human cell line ECV304 possesses all the molecular machinery to citrullinate self-proteins that are recognized by ACPA-positive RA sera. Due to its high specificity, and low cost, the ECV304-based ELISA could represent an alternative to ACPA tests for the diagnosis of RA in resource-limited settings.

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster II: Diagnosis and Prognosis

Session Type: ACR Poster Session B

Session Time: 9:00 AM-11:00 AM

Background/Purpose: We have observed in previous analyzes in our early arthritis (EA) cohort that patients with a higher body mass index (BMI) are, more frequently, ACPA negative and these patients carry, with a lower frequency, HLA-DRB1 alleles that encode for the shared epitope. The **objective** of this study is identifying SNPs (Single Nucleotide Polymorphisms) of immune system genes related to BMI in EA patients.

Methods: The 257 patients of the PEARL (Princess Early Arthritis Register Longitudinal) cohort in whom high density genotyping was available (using the ImmunoChip array of Illumina Inc) were included. As a previous step, those SNPs that did not meet the requirements of a genotyping call rate lower than 98%, being out of Hardy-Weinberg equilibrium ($p < 10^{-4}$) and minor allele frequency lower than 1% were excluded. IMPUTE v.2 was used for the genotype imputation of the SNPs that failed in the immunoChip, using as reference the data of phase III of the 1000G project. The association analysis of the remaining SNPs was made by linear regression adjusted by sex, age and study level with PLINK v1.9. Of the 1384 SNPs associated with BMI with a value of $p < 0.01$, 250 SNPs were selected according to the lowest values of the division of p divided by the absolute value of its β coefficient. After analyzing and excluding the SNPs that were in linkage disequilibrium, the importance of the 186 resulting SNPs was quantified with the “Random Forest” and “Boosted Regression Tree” techniques using %IncMSE (Mean Decrease Accuracy).

Results: Table 1 shows the selection of the 15 SNPs that were more important in both “machine learning” techniques according to BMI. Although most of these SNPs are located in non-coding regions (intergenic or intronic), some of the genes where the SNPs belong or the neighboring genes have shown association in some GWAS (Genome-Wide Association) with a minor (BMP7) or a greater (RSPO3) BMI; and some of them have shown to have a regulatory role in the immune system in patients with RA (WDFY4, BMP7).

Table 1. SNPs related to BMI in our early arthritis registry.

SNP	Gene	β Coef. [CI 95%]	p

rs1638020	PTPRN2	-1.329 [-2.1,-0.558]	8.409x10 ⁻⁴
rs11019575	MULTIPLE GENES: 399942, 100131364	3.356 [1.309,4.307]	2.939x10 ⁻⁴
rs72917213	MEX3C / LOC729051	2.319 [1.172,3.466]	9.677x10 ⁻⁵
rs6014959	BMP7	-1.942 [-3.122,-0.762]	1.434x10 ⁻³
rs2870662	DOK5 / CBLN4	1.455 [0.615,2.295]	7.993x10 ⁻⁴
rs10776644	WDFY4	-2.159 [-3.49,-0.828]	1.661x10 ⁻³
rs7800039	STEAP4 / ZNF804B	1.564 [0.76,2.368]	1.725x10 ⁻⁴
rs12517451	ANKRD34B / DHFR	1.629 [0.695,2.562]	7.351x10 ⁻⁴
rs12722531	IL2RA	-3.544 [-5.713,-1.376]	1.535x10 ⁻³

Conclusion: Our preliminary approach allowed us to select 15 SNPs that may have more relevance related to BMI in patients with early arthritis. However, this is a preliminary study and it is necessary to validate these results in other populations to ensure their involvement in the relationship between the BMI and EA.

Session Information

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster II: Diagnosis and Prognosis

Session Type: ACR Poster Session B

Session Time: 9:00 AM-11:00 AM

Background/Purpose: Cytokines and chemokines (CK) are central to RA pathogenesis, a fact underscored by the emergence of multiplex immunoassays for quantifying CK values in both research and clinical endeavors. Intrinsic factors to RA, namely rheumatoid factor (RF), may interfere with assay outcomes by non specifically binding detection analytes. Thus, we evaluated the performance of a commercially available multiplex platform using banked serum samples and assessed the impact of RF depletion on these measurements.

Methods: Forty-five CK analytes were tested in a central laboratory using the Meso Scale Discovery V-PLEXTM immunoassays and serum from 40 RA and 40 OA patients. True serum duplicates were tested for 20 RA and OA samples, while 20 additional samples from seropositive RA patients were depleted of RF using a commercial binder and compared to duplicates spiked with equal volumes of saline. Intra-assay coefficients of variation (CV) and intraclass correlation coefficients (ICC) were calculated for each analyte measured using true duplicates. The percent change in analyte concentrations were determined. Finally, rank sum tests were used to compare CK concentrations between RA and OA. Analytes were determined to be “high performers” if the CV was <10% and there was <15% change following RF depletion. Conversely, “low performers” were defined as those with a CV >20% or if RF depletion altered values >30%.

Results: CVs and ICCs generated using true serum duplicates for the 45 analytes tested are shown in Table 1. Of the 45 analytes, 22 yielded CVs <10%; all but two were “high performers”. ICCs universally exceeded 0.85 with the exception of 7 analytes (6 were “low performers”). RF depletion altered CK values by <15% for 35 analytes with larger changes (>30%) seen only for IL-2 and TNF- α (Figure1). IL6,IL8, IL10, TNF α , and TNF β concentrations were increased in RA vs. OA (p<0.05); IL16 was decreased(p<0.05).

Conclusion: In this study, a commercially available multiplex assay performed well in the context of RA. For most analytes, results were highly reproducible with minimal interference from RF. Additional testing will be needed to identify the source of variability observed for the analytes with higher CVs.

Circulating Transfer RNA-Derived Small RNAs Are Altered in Patients with Rheumatoid Arthritis

Qiong Wu, Quanhu Sheng, Joseph F. Solus, Kasey Vickers, Ryan Allen, Shilin Zhao, Yan Guo, Fei Ye, C Michael Stein and Michelle J. Ormseth, Vanderbilt University Medical Center, Nashville, TN

Session Information

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster II: Diagnosis and Prognosis

Session Type: ACR Poster Session B

Session Time: 9:00 AM-11:00 AM

Background/Purpose: Small RNAs (sRNAs) are important gene regulators and markers of disease. Transfer RNA (tRNA)-derived sRNAs (tDRs), including tRNA fragments (tRFs) and halves (tRHs), are novel regulatory sRNAs, which are often upregulated in the setting of cellular stress to downregulate metabolic processes. Rheumatoid arthritis (RA), a common autoimmune disease, is associated with excessive cellular stress due to immune activation. We hypothesized that circulating tDRs are altered in patients with RA and serve as novel markers for RA and RA disease activity.

Methods: Plasma sRNA sequencing was performed on archived samples from 167 RA patients, and 91 matched controls using Illumina NextSeq500. tDRs were quantified by TIGER pipeline, permitting one mismatch. Total tDRs, individual tDRs and tDRs based on amino acid of the parent tRNA normalized to total reads were compared between RA and control subjects by DESeq2 with adjustment for age, race, sex, and batch with 5% false discovery rate and multiple test correction.

Results: RA patients had 1.16-fold higher proportion of plasma tDRs compared to controls ($P=0.04$). Among RA patients a higher proportion of total plasma tDR reads was associated with higher disease activity by DAS28 score ($\rho=0.17$, $p=0.03$), erythrocyte sedimentation rate ($\rho=0.21$, $p=0.007$) and swollen joint count ($\rho=0.18$, $p=0.02$). Several individual tDR sequences were increased (3.7-fold to 1.5-fold), while one individual tDR sequence was decreased 2.2-fold among RA patients. tDRs aligning to a suppressor tRNA were increased 1.7-fold, while tDRs aligning to tRNAs encoding for asparagine, isoleucine, and aspartic acid were decreased (1.8-fold to 1.5-fold) among RA patients.

Conclusion: RA patients have a greater proportion of plasma tDRs compared to controls, and total tDRs were correlated with disease activity. Several individual tDRs and tDRs aligning to a suppressor tRNA and several other amino acid encoding tRNAs were altered in RA patients. Circulating tDRs may be novel markers of RA diagnosis and disease activity.

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster II: Diagnosis and Prognosis

Session Type: ACR Poster Session B

Session Time: 9:00 AM-11:00 AM

Background/Purpose: Elderly-onset RA, EORA, which is defined as rheumatoid arthritis (RA) starting at >60 years of age, has received less attention than young-onset RA. Polymyalgia rheumatica (PMR) is also a common rheumatic disease in the elderly. Eicosanoids are biological lipids that serve as specific role as either activators or suppressors of systemic inflammation and have been involved in the development and progression of arthritis. We hypothesized that eicosanoid-related perturbations are related to arthritic symptoms in the elderly, and by defining the eicosanoid profile we might be able to define elements of inflammation pathobiology in this population.

Methods: ARTIEL (Arthritis in the Elderly) is a recent collection cohort with newly diagnosed arthritis in patients older than 60 years, with blood samples collected at baseline (pre-treatment), 1, 3 and 12 months after treatment, along with physician and patient outcome measures through 12 months. They are compared with randomly control individuals of the same age and gender. A thorough clinical examination was conducted. Patients completed a health assessment questionnaire (HAQ). Disease activity score (DAS)28CRP was calculated. Serum eicosanoids were determined by mass spectrometry at baseline and after 3 months of treatment and were classified in groups according to their eicosanoid precursor: eicosapentaenoic acid (EPA), docosahexaenoic acid (DHA) or arachidonic acid (AA). Data processing and statistical analysis were performed in R.

Results: 64 patients (average: 75.15, standard deviation (SD) 6.80) and 18 controls (average: 75.39, SD, 6.04) were analyzed. Of these, 44 were diagnosed with RA and 20 with PMR. At the start of the study, patients had a mean DAS28CRP of 5.72 (SD, 1.05), mean HAQ was 1.64 (SD, 0.73). In addition, 84% of the patients reported scapular pain,

Precursor	Eicosanoid	Control	0 Months	3 months

* = significant when compared to control				
# = significant when compared to 0 months				

and 56% of the patients reported pelvic pain at baseline. After three months of treatment, patients had a DAS28CRP of 2.38 (SD, 1.23), and a HAQ of 0.36 (SD, 0.41). As shown in table 1, several eicosanoids, especially anti-inflammatory species derived from EPA and DHA were significantly downregulated in patients at the start of the study as compared to normal controls. Moreover, similar anti-inflammatory species were even further downregulated in patients with DAS >5.1 compared to patients with DAS <5.1. Three months after treatment, the levels of anti-inflammatory species derived from EPA and DHA went back to normal in responders (DAS28CRP <3.2). However, new proinflammatory species from AA were significantly elevated in non-responder patients (table 1).

Conclusion: These results suggest that certain eicosanoids may be key effectors in arthritis in the elderly and that the disbalance between pro and anti-inflammatory eicosanoids before and after treatment might be related to clinical and therapeutic outcomes in this population.

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster II: Diagnosis and Prognosis

Session Type: ACR Poster Session B

Session Time: 9:00 AM-11:00 AM

Background/Purpose: The chemokine molecule CXCL5 (C-X-C motif chemokine ligand 5, also known as epithelial neutrophil activating peptide 78 -ENA78-) constitutes a link between obesity, inflammation and insulin resistance (IR) in the general population. CXCL5 has also been found to play a role in rheumatoid arthritis (RA) pathogenesis. Since chronic inflammation promotes IR and impairs pancreatic beta cell function in RA patients, we assessed the role of CXCL5 in the development of IR in RA.

Methods: Cross-sectional study that encompassed 141 non-diabetic patients with RA. IR assessed by homeostatic model assessment (HOMA2), insulin and C-peptide serum levels and lipid profile, and CXCL5 serum levels were studied. Regression analysis was performed to evaluate how CXCL5 was related to IR, disease activity, and disease characteristics in RA patients.

Results: HOMA2-IR indexes showed high values for both IR and beta cell production (%B), and low insulin sensitivity (%S) in patients with RA. C reactive protein (beta coef. 0.2 [95%CI -1.5-1.9], p=0.80) and disease activity through DAS28 (beta coef. 13 [95% CI -14-41], p=0.34) revealed no relation with CXCL5. Other disease characteristics, such as disease duration, serological status, or use of methotrexate or anti-TNF alpha therapies, were not associated with CXCL5 serum levels. While glucocorticoids were related to insulin, C-peptide serum levels, and HOMA2-IR and HOMA2-%B-C peptides, the use of prednisone was not associated with CXCL5 serum levels. Insulin and C peptide serum levels and IR indexes showed strong correlations among each other, but not with CXCL5 (insulin r²=0.034, p=0.69; C peptide r²=0.050, p=0.56).

Conclusion: CXCL5 is not related to IR in RA patients. Therefore, the mechanisms leading to IR in patients with RA may be different from those in the general population.

³Duke School of Medicine, Division of Rheumatology and Immunology, Durham, NC, USA

Background/Purpose: Rheumatoid arthritis (RA) diagnosis requires a combination of clinical, laboratory, and imaging investigations. In clinical practice, testing for both Rheumatoid Factor (RF) and cyclic citrullinated peptides (CCP) is considered beneficial; however, when interpreting laboratory test results together, the clinician advertently decides whether test sensitivity or specificity is preferable. The individual patient characteristics with the presence of appropriate signs and symptoms help the health care practitioner assign diagnostic value to:

A) a singular “positive result or positivity to at least one test” increases overall sensitivity by minimizing the number of False Negative (FN) results at the expense of specificity, or

B) “positivity of all the tests” increases overall specificity by minimizing the number of False Positives (FPs), but overall sensitivity is lower than that of any single test.

FP results can lead to incorrectly managed individuals, who undergo further investigations, and bring about extra costs until a correct diagnosis is made.

The first aim of the present study was to evaluate the diagnostic performance of RF IgA, RF IgM and CCP, used alone or in multi-analyte combinations, in distinguishing a true positive diagnosis from a FP RA diagnosis. The secondary goal focused on the economic consequences brought about by FP serology results in the USA.

Methods: Single-/multi-analyte testing diagnostic performance was assessed in 190 established RA patients and 197 controls. A 12-month Markov model simulated 10,000 RA-suspected individuals tested with mono-/multi-analyte testing. Costs came from the published literature [1].

Results: Multi-analyte testing increased diagnostic accuracy, reduced the number of FP results, and allowed for important cost savings due to a reduction of clinical procedures and resource utilization (Table 1).

Conclusion: Simultaneous multi-analyte testing can improve the diagnostic accuracy over testing for the individual RF IgA, RF IgM and CCP tests by helping to maximize sensitivity (when disease is defined as “positivity to at least one test”) as well as maximizing specificity (if “positivity to all tests” occurs). Double- and triple-positive serology combinations minimize the number of FPs, thus reducing avoidable costs. Simultaneous multi-analyte testing demonstrates superior value from the patient and payer perspective.

N=10,000 RA-suspected individuals	Sensitivity [95% CI]	Sensitivity [95% CI]	Number of FP (80% from PC, 20% from SC)	Total Costs of FPs (\$) [1]

Scott^{1,2}, Julie Mount³, Jane Barry³ and **Bruce Kirkham**⁴, ¹Research Institute for Primary Care & Health Sciences, Primary Care Sciences, Keele University, Keele, United Kingdom, ²Department for Rheumatology, Haywood Hospital, Stoke on Trent, United Kingdom, ³Eli Lilly and Company, Basingstoke, United Kingdom, ⁴Rheumatology, Guy's & St Thomas' NHS Foundation Trust, London, United Kingdom

Session Information

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster II: Diagnosis and Prognosis

Session Type: ACR Poster Session B

Session Time: 9:00 AM-11:00 AM

Background/Purpose: A treat-to target (T2T) strategy is recommended for the management of rheumatoid arthritis (RA), with the target being remission or at least low disease activity. Many do not reach these targets (45% at our centre), some remaining in moderate disease activity with DAS28 between 3.2 and 5.1 (MDAS). We recently reported that baseline disability predicted persistent poor function and health-related quality of life (HRQOL) at 12-months in biologic-naïve patients in persistent MDAS(1). In patients receiving biologic DMARDs (bDMARDs) the outcomes of those in persistent MDAS are less certain. We therefore studied factors that predicted function and HRQOL in patients taking/previously receiving bDMARDs.

Methods: We analysed data from the RA Centre, which has aimed for DAS28 remission in all patients since 2006, in a Health Research Authority-approved study, studying outcomes over 12-months. Persistent MDAS was defined as patients with two consecutive MDAS scores, with the second score taken as “baseline”. Linear regression models tested relationships between baseline variables and a) 12-month Health Assessment Questionnaire-Disability Index (HAQ-DI) scores, b) rank-transformed EQ-5D-3L index scores, and c) 12-month changes in HAQ-DI and EQ-5D-3L index scores. Factors with associations achieving $p < 0.1$ in univariate analysis, were included in multivariate models.

Results: 188 patients currently/previously taking biologics with persistent MDAS were identified (Table). Most were female, seropositive, and had established disease. In multivariate analysis, only HAQ-DI associated with 12-month HAQ-DI scores ($P < 0.001$); the β -value of 0.76 suggested that per unit increase in baseline HAQ-DI, end-point HAQ-DI scores were 0.76 units higher. In multivariate analysis, HAQ-DI ($\beta = -0.21$; $P < 0.001$) and tender joint counts ($\beta = -0.03$, $P = 0.006$) associated with 12-month changes in HAQ-DI, indicating that higher baseline HAQ-DI scores associated with larger 12-month reductions in HAQ-DI. In multivariate analysis, baseline HAQ-DI ($\beta = -0.35$; $P = 0.003$) and EQ-5D ($\beta = 1.23$, $P = 0.014$) associated with 12-month EQ-5D scores, and baseline EQ-5D scores associated with 12-month changes in EQ-5D scores ($\beta = -0.40$, $P = 0.003$).

Conclusion: These data show that many patients with persistent MDAS have ongoing disability despite intensive treatment. Also of note, 96% patients score moderate to severe pain on EQ-5D pain scale. Baseline HAQ-DI was a key predictor of end-point disability and HRQOL, with higher baseline HAQ-DI scores associating with higher and lower 12-month HAQ-DI and EQ-5D scores, respectively. Despite this, in routine practice, the HAQ-DI is rarely measured. These findings highlight the importance of measuring and focussing on patient-reported outcome measures like the HAQ-DI, in managing patients with RA. The Predictive Utility of Anti-Cyclic Citrullinated Peptide Antibodies to Diagnose Rheumatoid Arthritis in Patients with Hepatitis C and Polyarthralgias

Divya Jayakumar^{1,2}, Xinliang Huang^{1,2}, Seth Eisen^{1,2}, Prabha Ranganathan^{1,2} and Amy Joseph^{2,3}, ¹Rheumatology, VA St. Louis Health Care System, St Louis, MO, ²Rheumatology, Washington University School of Medicine, St Louis, MO, ³Rheumatology, VA St. Louis Health Care System, St. Louis, MO

Session Information

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster II: Diagnosis and Prognosis

Session Type: ACR Poster Session B

Session Time: 9:00 AM-11:00 AM

Background/Purpose: Joint pain is a common extra-hepatic manifestation of chronic hepatitis C (HCV) infection. HCV infection is often associated with the presence of autoantibodies such as rheumatoid factor (RF), seen in approximately 50% of patients, and anti-nuclear antibodies (ANA). Consequently, it can be difficult to distinguish HCV arthralgias from rheumatoid arthritis (RA), especially in early RA when erosions or joint space narrowing are often lacking. Recent studies suggest that antibodies to cyclic citrullinated peptides (anti-CCP antibodies) are highly specific for RA and are absent in patients with HCV arthralgias. In this study, we determined the sensitivity, specificity, and positive and negative predictive values of RF and anti-CCP antibodies for RA in patients with HCV arthralgias.

Methods: We enrolled 97 patients with HCV and arthralgias (defined as pain in >3 joints) in this St. Louis VA Medical Center-based cross-sectional study. Patients were classified as HCV with RA (RA+) or HCV without RA (RA-) based on the presence of HCV antibodies, HCV RNA, or consistent liver biopsy, and meeting 1987 ACR criteria for the diagnosis of RA. Demographic, clinical and serologic information was collected on all patients during a standardized in-person medical evaluation. Patients were excluded if they had other major autoimmune extrahepatic manifestations of HCV (vasculitis, glomerulonephritis, monoclonal gammopathy, lymphoma or multiple myeloma) or were on current anti-viral treatment for HCV infection. Categorical and continuous variables were analyzed using Fisher's exact test and t-tests respectively. A two-sided p-value <0.05 demonstrated statistical significance.

Results: Of the 97 patients with HCV and polyarthralgias, 17 met ACR criteria for RA (HCV RA+) and 80 had arthralgias from non-RA causes (HCV RA-): HCV arthralgia (31), osteoarthritis (28), crystalline arthropathy (9), spondyloarthropathy (7), fibromyalgia (3), polymyalgia rheumatica (2). Both groups were predominantly male (94.1% and 88.8%) and mainly consisted of African Americans in the HCV RA+ group (64.7%) and Caucasians in the HCV RA- group (50%). In the HCV RA+ group, 94.1% had synovitis, while only 6.9% of HCV RA- patients did. RF was the most sensitive (100%) serology, while anti-CCP was highly specific (98.8%). Anti-CCP antibodies exhibited high positive and negative predictive values, 94.1% and 98.8% respectively. Synovitis had a high negative predictive value of 98.6%.

Conclusion: The presence of anti-CCP antibodies and synovitis is highly specific for the diagnosis of RA in patients with HCV arthralgias.

Table 1: Demographic and clinical characteristics of 97 patients with HCV arthralgias with and without RA

Characteristics	HCV arthralgia with RA (n=17)	HCV arthralgia without RA (n=80)	P value
Age	57.2	55.2	0.26
Female	1 (5.9%)	9 (11.3%)	1.00

Prognosis of Pneumonia in Rheumatoid Arthritis Patient: An Analysis of Using a Nationwide Administrative Database

Eishi Uechi^{1,2} and Kiyohide Fushimi², ¹Division of Rheumatology, Tomishiro Central Hospital, Okinawa, Japan,

²Department of Health Policy and Informatics, Tokyo Medical and Dental University Graduate School, Tokyo, Japan

Session Information

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster II: Diagnosis and Prognosis

Session Type: ACR Poster Session B

Session Time: 9:00 AM-11:00 AM

Background/Purpose: Pneumonia is the leading cause of mortality in RA patients. No research has been conducted on the prognosis of pneumonia in RA patients. This study aimed to investigate the prognostic factors for RA patients hospitalized due to pneumonia.

Methods: This study used data from the Diagnosis Procedure Combination database, a nationwide inpatient database in Japan. We reviewed the abstract data and medical actions between 2014 and 2016, and identified RA patients with pneumonia who received RA treatment (conventional synthesis DMARD [cs-DMARD] or biological and targeted synthetic DMARD [b/ts-DMARD]) before admission within 8 weeks. We examined the predictor of in-hospital mortality and worsening of activities of daily living (ADL) from before admission and readmission to after discharge. The covariate included the patients' background data (age, sex, body mass index (BMI), etc.), RA treatment (cs-DMARD alone, b/ts-DMARD, or corticosteroids), assessment of ADL (Barthel index), comorbidities (diabetes mellitus, chronic obstructive pulmonary disease, chronic heart failure, coronary heart disease, cancer, hypertension, and chronic renal disease), a history

of hospitalization for pneumonia within a year, and pneumonia severity at admission. Predictors were identified using a multiple logistic regression analysis.

Results: For this study, 2951 patients from 194 hospitals were eligible. Of these patients, 560 (19%) received b/ts-DMARD. The multivariate analysis revealed that severe ADL impairment at admission (odds ratio [OR], 95% confidence interval [CI]: 9.12, 2.26–33.2), severe pneumonia severity (3.13, 1.92–5.11), and male sex (1.98, 1.12–3.51) were independent risk factors of in-hospital mortality. Use of b/ts-DMARD (OR, 95% CI: 0.93, 0.56–2.27) and corticosteroids (1.45, 0.66–3.02) just before admission was not associated with increased risk of in-hospital mortality as compared with cs-DMARD alone after adjustment for covariates. The risk of ADL worsening at discharge was slight to moderate ADL impairment at admission (OR, 95% CI: 2.81, 0.49–4.54). Use of b/tsDMARD was the factor that reduced the risk of ADL impairment at discharge (OR, 95% CI: 0.44, 0.22–0.80). The risk of readmission was male sex (OR, 95% CI: 2.55, 1.21–5.35), severe ADL impairment at admission (2.32, 1.01–5.11), and corticosteroid use (2.02, 1.04–3.84).

Conclusion: The prognosis of pneumonia in RA patients was mainly associated with patient status on admission, patient sex, ADL, pneumonia severity, and BMI. The use of b/ts-DMARD immediately before admission was not attributed to increase in-hospital mortality and length of hospital stay and decreased risk of ADL impairment at discharge as compared with cs-DMARD alone.

Are ACPA Associated with More Bone Loss over Time in Patients with RA?

Emma de Moel¹, Josephine Amkreutz¹, Lotte Heimans², Cornelia F. Allaart³, Tom W.J. Huizinga⁴ and Diane van der Woude⁴, ¹Rheumatology, Leiden University Medical Center, Leiden, Netherlands, ²Internal Medicine, Leiden University Medical Center, Leiden, Netherlands, ³Department of Rheumatology, LUMC, Leiden, Netherlands, ⁴Department of Rheumatology, Leiden University Medical Center, Leiden, Netherlands

Session Information

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster II: Diagnosis and Prognosis

Session Type: ACR Poster Session B

Session Time: 9:00 AM-11:00 AM

Background/Purpose: Anti-citrullinated protein antibodies (ACPA) are one of the most important serological markers for rheumatoid arthritis (RA) and have been suggested to play a pathophysiologic role in osteopenia, a common RA comorbidity, by directly binding to osteoclasts. However, the effect of ACPA on systemic bone mineral density and in particular their effect on changes in bone mineral density over time is currently unknown. Therefore, we determined whether ACPA associate with changes in bone mineral density over time in patients with rheumatoid arthritis.

Methods: Yearly dual X-ray absorptiometry scores were performed during 5 years of follow-up in 412 patients with recent-onset RA participating in the IMPROVED study¹, a clinical trial in which patients were treated according to a remission- (disease activity score<1.6) steered strategy. The effect of the presence of ACPA on 1) Z-scores of lumbar spine and hip over time, and 2) prevalence of osteopenia/osteoporosis (defined as a T-score ≤ -1) over time was analysed using generalized estimating equations. Analyses were adjusted for age, gender, BMI, and symptom duration (determined at baseline), as well as smoking status, disease activity, prednisone intake, bisphosphonate use, calcium intake, and serum 25-OH vitamin D levels (determined longitudinally).

Results: ACPA-positive patients had a significantly lower lumbar spine ($p=0.04$) and hip ($p=0.01$) Z-score at baseline. There was no difference in prevalence of osteoporosis/osteopenia at baseline between ACPA-positive and ACPA-negative patients (OR (95% CI) 1.02 (0.55 to 1.19)). We hypothesised that ACPA-positive patients would have more bone loss over time compared to ACPA-negative patients. However, ACPA positivity did not associate with a stronger decline in Z-score over time at lumbar ($p=0.43$) or femoral sites ($p=0.66$). Additionally, no effect of anti-citrullinated protein antibody positivity was found on the development of osteoporosis/osteopenia over time ($p=0.23$).

Conclusion: ACPA-positive patients have a significantly lower bone mineral density at baseline compared to ACPA-negative patients. Surprisingly, in this cohort of patients treated according to a tight control strategy, ACPA do not associate with a decrease in bone mineral density over time. These results indicate that in the absence of inflammation/disease activity, ACPA do not contribute to increased bone loss after disease onset.

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster II: Diagnosis and Prognosis

Session Type: ACR Poster Session B

Session Time: 9:00 AM-11:00 AM

Background/Purpose: Optimal management of rheumatoid arthritis (RA) requires early diagnosis and therefore sensitive methods for early identification of RA to prevent joint damage and disability. 14.3.3 η is a novel protein biomarker involved in the upregulation of inflammatory and joint damage factors. The serum/plasma concentration of 14.3.3 η has been shown to differentiate patients with established RA from healthy controls¹ and may therefore have predictive value in early arthritis.

The purpose of the study was to investigate if the serum 14.3.3 η concentrations can predict development of RA in patients with early undifferentiated arthritis.

Methods: In this study, 117 patients with early undifferentiated arthritis, i.e. without a specific rheumatological diagnosis, but with ≥ 2 tender and/or 2 swollen joints among the metacarpophalangeal, proximal interphalangeal, wrist, or metatarsophalangeal joints for >6 weeks but <24 months, were included². Clinical examination, imaging and blood samples were obtained at baseline with follow-up after 1-2 years.

Baseline serum samples were analysed with 14.3.3 η ELISA kits (JOINTstatTM, Augurex, Canada). Previously established cut-offs for 14.3.3 η were applied, as follows: negative (-): <0.19 ng/ml, mildly-moderately positive (+): $0.19-0.79$ ng/ml, strongly positive (++) : ≥ 0.80 ng/ml.

Twenty-one healthy controls were also examined. Descriptive statistics were used to describe baseline characteristics, and Fisher's exact test and univariate logistic regression analysis were used to assess the ability of 14.3.3 η to predict development of RA according to the American College of Rheumatology (ACR) 1987 criteria within the follow-up period of 1-2 years (Table 2).

Results: Baseline data are shown in Table 1. Significantly more patients with baseline positive (+ and ++) 14.3.3 η values developed RA compared to patients with negative (-) 14.3.3 η (Fisher's exact test $p=0.003$, Table 2). The sensitivity and specificity of a 14.3.3 η cutoff at <0.19 ng/ml vs ≥ 0.19 ng/ml were 0.36 and 0.90, respectively. The negative predictive value of a 14.3.3 η <0.19 ng/ml was 0.82. If the 14.3.3 η cut-off was set at 14.3.3 η ≥ 0.80 ng/ml (++) , the sensitivity decreased to 0.21 while the specificity increased to 0.94.

Univariate logistic regression analysis confirmed a relation between baseline 14.3.3 η and development of RA($p=0.003-0.02$ depending on the selected cut-off, Table 2).

Conclusion: Serum 14.3.3 η predicted development of RA in patients with early undifferentiated arthritis.

Comparison of Clinical Features of Seronegative and Seropositive Early Rheumatoid Arthritis: Blinded Data from the Ongoing Phase IIb Trial with the EP4 Receptor Antagonist CR6086 in DMARD-Naïve Patients

Giampaolo Giacobelli, Beatrice Barbetta, Cristina Vitalini, Nadia Brambilla, Massimo D'Amato, Federica Girolami and **Lucio C. Rovati**, Clinical Research Department, Rottapharm Biotech, Monza, Italy

Session Information

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster II: Diagnosis and Prognosis

Session Type: ACR Poster Session B

Session Time: 9:00 AM-11:00 AM

Background/Purpose: Rheumatoid arthritis patients positive for rheumatoid factor (RF) or anti-cyclic citrullinated peptide antibody (ACPA) are considered to manifest an aggressive disease course compared with seronegative RA patients. On the other hand, the relationship between seropositivity and measures of disease severity other than radiologic outcome is disputed. Recently, the comparison of disease characteristics of seropositive versus seronegative DMARD-naïve patients showed that seronegative patients had higher levels of inflammation as assessed clinically and by ultrasound [1], and manifested more active disease at baseline [2]. We aimed to compare the clinical features of seronegative and seropositive patients screened to participate in the ongoing Phase IIb trial of CR6086 in DMARD-naïve patients with early RA.

Methods: We used blinded data from the ongoing trial with the EP4 receptor antagonist CR6086 in early rheumatoid arthritis, DMARD-naïve patients (the CREATIVE study). This is a randomized, placebo-controlled, double-blind, dose response, Phase IIb, multicentre trial of CR6086 administered for 12 weeks in combination with methotrexate (NCT03163966). All DMARDs-naïve patients with early RA (disease duration < 1 year) who fulfilled the 2010 ACR/EULAR classification criteria were included in the analysis, regardless of whether they were actually randomized in the trial. Demographic and disease characteristics at enrolment were compared between seropositive (RF+ and/or ACPA+) and seronegative patients (RF- and ACPA-) using independent samples t test or Chi-square test, as applicable.

Results: A total of 257 patients could be included in the analysis, and 44 patients (17%) were seronegative. Age, gender distribution and disease duration were similar between groups (overall mean age 52.4 years, 77% females and mean disease duration 7 months). Joint counts at enrolment were significantly higher in the seronegative patients compared to seropositive patients (68-tender joint count: 29±16 vs. 20±11 P=0.002; 66-swollen joint count: 18±12 vs. 13±7 P=0.009), whereas DAS28, CRP, ESR, patient's arthritis pain, patient's and physician's global assessment of arthritis did not differ significantly between the two subsets of patients.

Conclusion: Among the newly diagnosed RA patients screened to participate in the ongoing Phase IIb trial with CR6086, seronegative patients have higher disease activity compared to seropositive patients, as assessed by tender and swollen joint counts. These results are in line with recent literature and may be influenced by the role of serology within the 2010 ACR/EULAR classification criteria, in that more involved joints are required for seronegative patients to fulfil the criteria.

Value of Anti-RA33 Isotypes in an European Rheumatoid Arthritis Patient Cohort

Maresa Grundhuber¹, Daniela Sieghart², Günter Steiner², Maryam Poorafshar³ and Sascha Swiniarski¹, ¹Thermo Fisher Scientific, Freiburg, Germany, Freiburg, Germany, ²Division of Rheumatology, Department of Internal Medicine III, Medical University Vienna, Austria, Vienna, Austria, ³Thermo Fisher Scientific, Uppsala, Sweden, Uppsala, Sweden

Session Information

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster II: Diagnosis and Prognosis

Session Type: ACR Poster Session B

Session Time: 9:00 AM-11:00 AM

Background/Purpose: Early diagnosis of rheumatoid arthritis (RA) leading to effective treatment is essential to improve prognosis and to prevent disease progression. Anti-cyclic citrullinated peptide (CCP) antibodies (ACPA) offers similar sensitivity, but higher specificity for RA than rheumatoid factor (RF) in early RA. In single analyte-testing scenarios, ACPA can detect approx. 70% of RA patients but fewer during early RA (~ 60%). As a biomarker for RA, anti-RA33 IgG antibodies are known to be specific, especially in the early stage of the disease. Recent studies show an emerging role of all three anti-RA33 isotypes in diagnosis and prognosis of RA¹.

The aim of this study was to evaluate anti-RA33 isotypes IgM, IgA, and IgG for the diagnosis of early RA and to examine the added value compared to anti-CCP antibodies and RF within two independent European RA cohorts.

Methods: The first cohort provided by Medical University of Vienna, Austria, includes in total 654 patient samples, 257 RA patient samples and 357 control samples; various autoimmune (n=128), non-autoimmune diseases (n=130) and healthy individuals (n=99). To validate the data, a second patient cohort (MATURA, United Kingdom) consisting of 295 patient samples, 100 RA patient samples, 75 autoimmune, 70 non-autoimmune diseases and 50 healthy subjects was measured. Serum samples of both cohorts were analyzed for the presence of anti-RA33, anti-CCP and RF (each IgM, IgA, IgG) using the EliATM instrument platform (Phadia AB, Uppsala, Sweden).

Results: Analyzing both cohorts, one third of RA patients were positive for at least one of the anti-RA33 isotypes, whereas anti-RA33 IgM showed the highest sensitivity (23%) followed by IgA (12%) and IgG (9%). Both cohorts revealed a specific pattern of all three anti-RA33 isotypes with a diverse distribution among RA patients and little overlap between the immunoglobulin classes. The combination of all three anti-RA33 isotypes detects 26% of the seronegative RA patients and the specificity of each isotype is $\geq 90\%$.

Conclusion: Anti-RA33 isotype distribution shows remarkably little overlap of IgM, IgA and IgG in European RA patient cohort. Therefore, the combination of all three anti-RA33 isotypes provides a considerable added value for the diagnosis of RA in the anti-CCP- and RF-negative group. To fully evaluate the importance of the different anti-RA33 immunoglobulin classes within the pathogenesis of RA, further investigations are required.

Surviving Measurements Improve Prediction of Rheumatoid Arthritis Among Patients with Unexplained Arthralgia

Malin C Erlandsson^{1,2}, Minna Turkki³, Rille Pullerits^{2,3,4} and Maria I Bokarewa^{2,3}, ¹Department of rheumatology and inflammation research, University of Gothenburg, Gothenburg, Sweden, ²Rheumatology Clinic, Sahlgrenska University Hospital, Gothenburg, Sweden, ³Department of Rheumatology, Institute of Medicine, Sahlgrenska Academy, Gothenburg University, Gothenburg, Sweden, ⁴Department of Clinical immunology and transfusion medicine, Sahlgrenska University Hospital, Gothenburg, Sweden

Session Information

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster II: Diagnosis and Prognosis

Session Type: ACR Poster Session B

Session Time: 9:00 AM-11:00 AM

Background/Purpose: Early recognition of rheumatoid arthritis (RA) is believed to be the key to successful treatment of this disease. Symptoms of arthralgia often predate development of RA. A set of clinical features assisting recognition of patients during their transition from arthralgia to RA, has been recently proposed. We therefore designed a study, in which we followed patients with unexplained arthralgia prospectively aiming to find new cases of RA and to explore a combination of clinical features and serological markers predicting transition from arthralgia to RA. The aim of the present study was to improve recognition of imminent RA among patients with arthralgia (ALG) using a combination of clinical symptoms with RA-specific antibodies RF and anti-CCP and survivin, serological markers predating transition from ALG to RA.

Methods: All new cases of RA, undifferentiated arthritis (UA) and unexplained ALG were identified among the total of 1743 first-visit patients attending the rheumatology ward in Gothenburg during 12 consecutive months. The ALG patients were prospectively followed for 48 months and development of additional RA cases was recorded. The set of 13 joint symptoms was applied to the first-visit records aiming to distinguish patients with arthritis from ALG and from the new RA cases. The symptoms with odds ratio >2.0 between ALG and pre-RA and information about RF/aCCP and survivin dichotomised were included in predictive models. Receiver operating characteristic (ROC) curves and Kaplan-Meiers curves were constructed.

Results: Among the first-visit patients, 63 were classified as RA, 73 had undifferentiated arthritis and 180 had ALG. Additional 32 new RA cases developed during 48 months of follow-up and comprised pre-RA group. The analysis of joint symptoms at the first visit distinguished ALG from RA/UA (both, $p < 0.001$). A combination of symptoms in several small joint areas, increasing number of joints with symptoms, and patient's experience of swelling in small hand joints at the first visit discriminated pre-RA from ALG with 93% sensitivity ($p = 0.005$, $AUC = 0.660$). Presence of survivin in serum strongly associated with 7 of 13, and RF/aCCP with 1 of 13 joint symptoms. Grouping those symptoms with age >50y, gender, survivin and RF/aCCP in the final algorithm allowed reaching 50% sensitivity for transition from ALG to RA ($AUC = 0.767$, $p < 0.001$).

Conclusion: Clinical and serological parameters in combination aid recognition of imminent RA among ALG patients with appropriate sensitivity.

Session Information

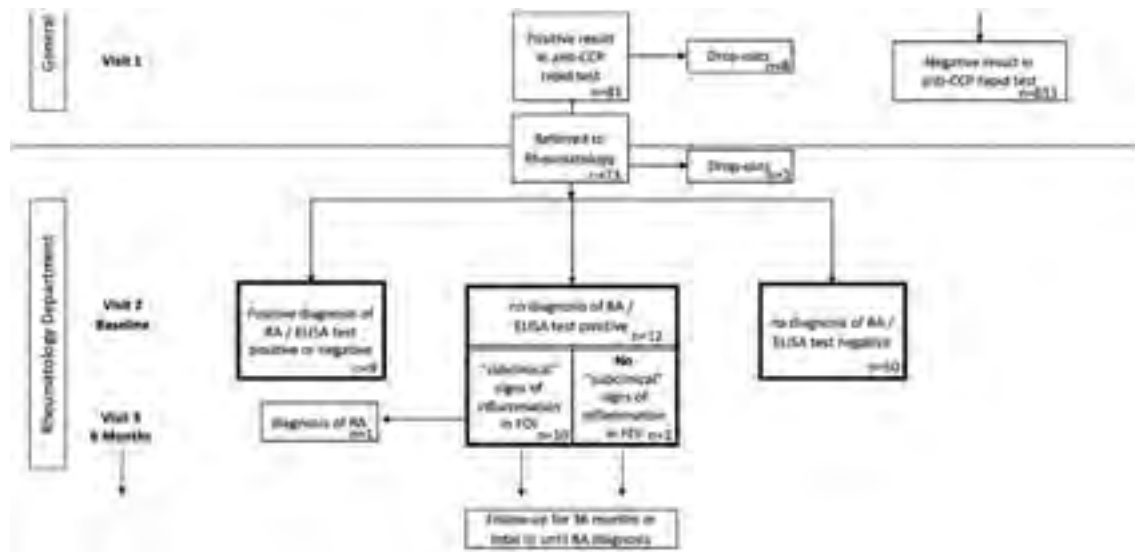

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster II: Diagnosis and Prognosis

Session Type: ACR Poster Session B

Session Time: 9:00 AM-11:00 AM

Background/Purpose: Rheumatoid Arthritis (RA) is a chronic inflammatory joint disease affecting approx. 1% of the adult population of Northern Europe and North America. Strategies for its early diagnosis are of high importance as prompt treatment improves clinical and structural outcome significantly. Formation of autoantibodies against cyclic citrullinated proteins (anti-CCP) are identified to be associated to RA-development. Non-specific musculoskeletal (nsMSK) pain often precedes RA-development. Fluorescence-optical imaging (FOI) technique is a new ICG-tailored technique to display changes in microvascularisation which might be useful for early detection of joint inflammation in high-risk populations.

Methods: In this prospective study (PANORA), patients presenting with new onset of nsMSK pain at General Practitioners (GP) and with evidence for anti-CCP positivity (rapid-test, CCPoint®) were included to be referred to Rheumatology Department for rheumatologic assessment and RA-evaluation. At Rheumatology Department, validation of anti-CCP testing (using ELISA) and a rheumatological examination including ultrasound was performed. Subclinical signs of inflammation defined as increase of microvascularisation were monitored by FOI. In case of ELISA positivity but missing evidence of clinical RA, patients were monitored for RA-development every 6 months for a total follow-up of 36 months or until RA-diagnosis.

Results: For this interim analysis, data from the first 692 patients was analyzed. 12% of the patients showed a positive anti-CCP rapid-test at GP, of which 40% were confirmed positive by ELISA. 10 patients were diagnosed with RA (1 in the ELISA negative group), thereof one case of a newly detected RA at month 6 of the follow-up period. In the three groups at baseline (figure 1), age was well balanced, the proportion of female patients was highest in the RA-diagnosis cohort (77.8%) and the proportion of patient with current or past smoking-status was prominent in the ELISA negative group (52.9%). Signs of unspecific subclinical inflammation defined as increased microvascularisation were detected by FOI in 83% of the ELISA positive patients compared to 39% in the ELISA negative cohort. Moreover, descriptive characteristics in FOI signals clear differ in both groups. After the first follow-up at month 6 (data from 40% available), 2 patients exhibited changes in the FOI from baseline towards "RA-suspicious" imaging patterns but without evidence of clinical RA.

Conclusion: The combination of serological biomarkers and imaging using FOI might represent a strategy for sensitive detection of early stages in RA-development in an at-risk population for improvement of a timely initiation of appropriate treatment options to prevent aggressive diseases courses. The continuation of PANORA will give more insights in specific characteristics of the RA-risk population at early stages of the disease.

Fig.2: Correlation Matrix for ACPA- patients; ACPA-nw below the diagonal, ACPA-ow above the diagonal

Session Information

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster II: Diagnosis and Prognosis

Session Type: ACR Poster Session B

Session Time: 9:00 AM-11:00 AM

Background/Purpose: Multiple cytokines are assumed to be involved in RA pathogenesis. It has been hypothesized that ACPA-negative RA with wrist affection constitutes a separate entity. Differences in cytokine profile between ACPA positive and negative RA are not known. A Multi-Biomarker Disease Activity (MBDA) assessment is commercially available. Intraarticular inflammatory activity can be measured using power-Doppler (PD) sonography. This study examines whether PD activity is correlated with different cytokines in ACPA positive (ACPA+) and ACPA negative (ACPA-) RA, and whether such differences are BMI dependent.

Methods: 120 visits by 89 patients from a single centre were evaluated retrospectively. All patients fulfilled the 2010 ACR criteria, and were treated with FDA-approved DMARDs. All ACPA- patients had PDS positive wrist arthritis. Patients were divided according to BMI: normal weight (NW, BMI 18.5-25) or overweight (OW, BMI >25), as well as ACPA status (+/-), yielding four groups. Bilateral sonography of MCP 2 and 3, ECU, wrist, and MTP 2 and 5 was performed by a single

technician, activity was graded semiquantitatively (0-3), and a total PD score (PDT) was calculated. An MBDA was performed in all patients. Correlations between cytokines and BMI/PDT were calculated using Spearman's r. The means between groups were compared using the Wilcoxon-Mann-Whitney test. A multiple linear regression was performed for each group using a conditional inference trees approach.

Results: Overall treatment did not differ between the groups. PDT and MBDA total scores did not differ significantly between groups. Leptin correlated significantly with BMI in ACPA+ both normal and overweight, but neither in ACPA-normal nor overweight. In the linear regression, the following variables best predicted PDT: ACPA+nw: log(IL-6) (p=0.1, n.s); ACPA-nw: Log(IL-6)(p=0.04); ACPA+ow: Log(CRP)(p=0.03); ACPA-ow:Log(MMP-3)(p=0.01). Further cytokine associations were also different indifferent groups (Fig. 1 and 2).

Conclusion: Different cytokines are associated with PD activity in ACPA+ and ACPA- RA. This finding supports the theory that the etiology of the two forms is different. The differences appear to be BMI dependent. Further research into cytokines in RA should take BMI into account.

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster II: Diagnosis and Prognosis

Session Type: ACR Poster Session B

Session Time: 9:00 AM-11:00 AM

Background/Purpose: Patients (pts) with early RA often present with multiple and different areas of joint involvement. While the ACR and EULAR guidelines specify high disease activity, erosions, seropositivity and other factors for a poor prognostic RA, limited data exist to identify which specific joints or joint locations may be indicative of disease severity and poorer prognosis.¹ This analysis investigated the distribution of affected joints at baseline (BL) as well as the correlation between BL swollen joint status and disease characteristics and prognostic factors in early RA pts.

Methods: Data from AGREE (NCT00122382), a double-blind Phase III study of abatacept (ABA) plus methotrexate (MTX) (n=256) vs MTX (n=253) in MTX-naïve pts who were seropositive for RF and/or ACPA with early (≤2 years [yrs]) erosive RA, were analyzed post hoc by baseline swollen joint status (present, absent) for 8 different joint locations: hands,

Table 1. BL Disease Characteristics for BL swollen versus non-swollen knee, jaw, elbow or wrist joints

	Knee		Jaw		Elbow		Wrist

***p < 0.001, **p < 0.01, *p < 0.05, vs No SJC.

Table 2. Pairwise association of BL swollen joint status (Chi-Square test)

	Elbow	Foot	Jaw	Knee	Shoulder	Wrist
Ankle	0.0022 *	0.0016 *	0.0046 *	<0.0001 **	0.0712	0.0028 *
Elbow		0.0825	0.0004 **	<0.0001 **	<0.0001 **	0.1227
Foot			0.0083 *	0.0815	<0.0001 **	0.4777
Jaw				0.0019 *	<0.0001 **	0.8295
Knee					<0.0001 **	0.0016 *
Shoulder						0.8933

**p < 0.001, *p < 0.05, †p < 0.01

wrists, elbows, shoulders, jaw, knees, ankles and feet. Pairwise associations of BL swollen joint status were evaluated for all evaluable joint locations. Overall characteristics and study results were previously reported.

Results: In this early RA cohort with poor prognostic factors, (n=509), BL swelling was most frequently observed in the hands (99%), followed by the wrist (92%), ankle (79%), knee (69%), foot (66%), elbow (48%), shoulder (34%) and jaw (9%). Pts with a BL swollen knee, jaw, elbow or wrist have a poorer prognosis and more aggressive RA. When these joints were involved in this MTX-naïve, seropositive, early erosive cohort, these pts had more tender and swollen joints, higher DAS28 (CRP), SDAI and CDAI than those without swelling (Table 1). Higher HAQ-DI was seen in pts with a swollen knee versus those without knee swelling (1.8 [0.6] vs 1.5 [0.7], respectively (p < 0.001)). Swollen shoulder status was significantly associated with swelling status of almost all other joint locations (elbow, foot, jaw and knee: p < 0.001), whereas swelling status of the foot and wrist were the least associated with swelling status of other joints (Table 2). Presence of BL synovitis was not associated with greater BL ACPA or RF positivity, probably due to the inclusion of mainly seropositive pts.

Conclusion: In this cohort of early, seropositive erosive RA, swelling in the knee, jaw, wrist or elbow suggests that large joint locations are associated with the poorest prognosis. Pts with such a presentation might be considered for more intensive treatment.

“Continuous Reduction” in Serum RF Titers Predicts Low Disease Activity and Good Therapeutic Response in RA Patients Treated with TNF Inhibitors, but Does Not Relate to Clinical Outcomes during ABT Treatment

Takayoshi Owada¹, Kazuhiro Kurasawa¹, Yuta Takamura¹, Tomoyuki Miyao¹, Ayae Tanaka¹, Ryutaro Yamazaki², Satoko Arai¹, Reika Maezawa¹ and Masafumi Arima³, ¹Rheumatology, Dokkyo Medical University, Mibu, Tochigi, Japan, ²Rheumatology, Dokkyo Medical University, Mibu, tochigi, Japan, ³Rheumatology, Dokkyo Medical University, mibu-gun, Tochigi, Japan

Session Information

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster II: Diagnosis and Prognosis

Session Type: ACR Poster Session B

Session Time: 9:00 AM-11:00 AM

Background/Purpose: Relative change of serum RF titer has been reported to correlate with those of RA disease activity. However, it is debatable whether serum RF decrease was associated with clinical improvements in RA. Therefore, to clarify whether “Continuous Reduction” in serum RF during biologics therapy was associated with better clinical outcomes, we examined serum RF titers and disease activity in RA patients treated with TNF inhibitors (TNFIs) or abatacept (ABT) as 1st-biologics.

Methods: Subjects were RA patients who filled RA criteria 2010, were biologics-naïve, were treated with TNFIs (adalimumab and golimumab) or ABT, and had active diseases (DAS28-CRP ≥ 2.7) and high titer in serum RF (≥ 45 IU/ml). Their medical records were reviewed retrospectively. RF titers were measured at 0, 4 and 12 month (mo.) after

starting biologics. More than 10% decline in RF titer was considered as significant decrease, and “Continuous Reduction” was defined as significant decreases during both 0-4 and 4-12 months. DAS28-CRP was calculated for each patients, and RA disease activity and therapeutic efficacy was assessed by achievement of clinical remission or low disease activity (CR+LDA, DAS28-CRP<2.7) and “Good Response” of EULAR response criteria.

Results: Subjects were 66 RA patients with 25 male and 41 female, 67.9 years (median) of age, 2.1 years (median) of disease duration and 8 mg/week (median) of MTX dosage. TNFIs and ABT were administered in 36 and 30 patients, and improved DAS28-CRP (median) from 4.16 at 0 mo. to 2.00 at 12 mo. and from 3.87 to 2.07, respectively. Serum RF titers (median) were decreased during 0-4 months in TNFI-treated patients (RF titer; 104 at 0 mo., 58 at 4 mo. and 43.5 IU/ml at 12 mo.), whereas RF among ABT-treated cases was increased during 4-12 months after decline during 0-4 months (RF; 188 at 0 mo., 75 at 4 mo. and 94 IU/ml at 12 mo.). “Continuous RF reduction” was found in 19 (52.8%) of 36 TNFI-treated patients and in 8 (26.7%) of 30 ABT-treated ones, and was significantly fewer in cases receiving ABT. Among TNFI-treated patients, CR+LDA at 12 mo. was found in 17 (89.5%) of 19 “Continuous RF Reduction” and in 9 (52.9%) of 17 patients without “Continuous RF Reduction”, and proportion of CR+LDA was significantly higher in “Continuous RF Reduction” ($p=0.0248$). Additionally, percentage of “Good Response” at 12 mo. was significantly higher in “Continuous RF reduction” (84.2% ($n=16$) vs 35.3% ($n=6$), $p=0.0054$). Among ABT-treated patients, CR+LDA at 12 mo. was found in 7 (89.5%) of 8 “Continuous RF Reduction” and in 13 (59.1%) of 22 patients without “Continuous RF Reduction”, and proportion of CR+LDA was not different in these patients. Similarly, ratio of “Good Response” at 12 mo. was not higher in “Continuous RF reduction” (75.0% ($n=6$) vs 50.0% ($n=11$), $p=0.4069$).

Conclusion: “Continuous RF reduction” was associated with lower disease activity and better therapeutic response only in RA patients treated with TNFIs, not ABT. Therefore, “Continuous reduction” in serum RF titers reflects low RA disease activity and predicts good therapeutic response during TNFI therapy, but does not relate to clinical outcomes during ABT treatment.

Effects of Biologic Drugs on Prognosis of Rheumatoid Arthritis Among Patients with Poor Glycated Hemoglobic A1c (HbA1c) Control

Yusuke Miwa¹ and Tsuyoshi Kasama², ¹Division of Rheumatology, Department of Medicine, Showa University School of Medicine, Shinagawa-ku Tokyo, Japan, ²Div of Rheumatology, Showa University School of Med, Shinagawa-ku Tokyo, Japan

Session Information

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster II: Diagnosis and Prognosis

Session Type: ACR Poster Session B

Session Time: 9:00 AM-11:00 AM

Background/Purpose: Poor control of glycated hemoglobic A1c (HbA1c) worsens prognosis for diabetes mellitus and various complicated diseases. Corticosteroids exacerbate poor HbA1c control. This study, investigated the effects of biological disease-modifying antirheumatic drugs (bDMARDs) on HbA1c control among patients with RA, as it has not been examined before.

Methods: In total, 632 patients with RA from the All Showa University of RA database (ASHURA) were used for our study. The following background factors were investigated: age; gender; type of bDMARD; dosage of methotrexate and prednisolone (PSL); usage of conventional synthetic DMARD and nonsteroidal anti-inflammatory drugs; body mass index; smoking history; HbA1c; presence or absence of hypertension and dyslipidemia; and levels of serum creatinine, C reactive protein, and matrix metalloproteinase-3. We also used the simplified disease activity index (SDAI) and health assessment questionnaire (HAQ) to evaluate RA disease activity and activities of daily living, respectively. Poor HbA1c control was defined as HbA1c ≥ 6.0 ; accordingly, we divided the patients into good and poor HbA1c control groups. Primary and secondary failures, adverse drug events, missing data, and patients who moved or had care withdrawn were excluded. SDAI and PSL dosage were the primary and secondary endpoints, respectively. Repeated measures analysis of variance (ANOVA) evaluated the HAQ scores before treatment and 1 year later.

Results: Of 632 patients, 296 patients enrolled in this study. The SDAI was from 27.7 ± 15.6 to 7.1 ± 8.0 in the poor HbA1c control group ($n = 83$) and from 22.9 ± 14.0 to 6.3 ± 7.6 in the good HbA1c control group ($n = 213$). There was no interaction between the groups. Repeated measures ANOVA showed a significant difference between the groups ($p =$

0.011) and during the treatment period ($p = 0.001$). PSL dosage was from 3.5 ± 3.6 (mg/day) to 2.2 ± 3.0 in the poor HbA1c control group and from 2.3 ± 3.0 to 1.6 ± 3.6 in the good HbA1c control group. A significant difference was observed between the groups ($p = 0.007$) and during the treatment period ($p = 0.001$). Notably, there was no significant difference in HAQ. No patient reported HbA1c increasing by 1.0 or more during 1 year.

Conclusion: Results showed that bDMARD therapy reduced RA disease activity and PSL dosage in both groups. Therefore, we recommend bDMARD treatment for RA regardless of good or poor HbA1c control

Oestrogen Levels and the Outcome of Leflunomide Treatment in Rheumatoid Arthritis

Alaa A A Mohamed¹, Manal Hassanien¹ and Esraa A Ahmed², ¹Rheumatology and Rehabilitation, Faculty of Medicine, Assiut University Hospitals, Assiut, Egypt, ²Pharmacology, Faculty of Medicine, Assiut University, Assiut, Egypt

Session Information

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster II: Diagnosis and Prognosis

Session Type: ACR Poster Session B

Session Time: 9:00 AM-11:00 AM

Background/Purpose: Rheumatoid arthritis (RA) is an autoimmune and inflammatory polyarthritis involving mainly the synovial joints, and causing destruction of the articular cartilage and disabilities. Leflunomide is one of the anti-proliferative drugs proved to be effective in controlling the disease by suppressing the inflammatory cytokines and inducing apoptotic genes in synovial macrophages. However, regulation of the disease seems to be complex where the sex hormone, oestrogen, is incriminated in counteracting the effect of leflunomide in vitro. Moreover, detected oestrogen receptors polymorphisms were supposed to play a role in disease resistance. We aimed in this study to unravel the relationship between oestrogen levels and leflunomide outcome in RA.

Methods: RA patients fulfilling the ACR/EULAR 2010 RA criteria and receiving only leflunomide (20 mg daily) and hydroxychloroquine were gathered from the outpatient clinics after being consented. Disease activity of the patients was evaluated by the disease activity score (DAS)-28 and the clinical disease activity index (CDAI). Serum oestrogen levels were detected by enzyme-linked immunosorbent assay (ELISA). Descriptive and correlation studies were used as appropriated.

Results: RA patients (n=50) were recruited. 98% were females and mean age was 47.2 ± 10.3 years. Median (IQR) levels of oestrogen were 8.6 (7.4- 50.5) IU/mL. Minimal and maximal levels of oestrogen were 6 IU/mL and 185.5 IU/mL respectively. Values of DAS-28 and CDAI did not correlate with oestrogen levels. Neither the patient's global assessment using 100 mm visual analogue scale nor the erythrocyte sedimentation rate correlated with oestrogen levels. Contrarily, swollen joint count (SJC) and tender joint count (TJC) correlated positively with oestrogen levels ($\rho = .433$, $p = .006$ and $\rho = .33$, $p = .04$ respectively) as shown in Fig 1.

Conclusion: The changes in oestrogen levels among RA patients could be responsible for the different outcome of leflunomide therapy in these patients. Further studies on bigger cohorts and longitudinal observations are required.

Fig.1 Correlations between oestrogen levels and the number of swollen or tender joints

Methotrexate Response in Early Rheumatoid Arthritis Predicted Using a Somamer Proteomic Assay

Carol Hitchon¹, Victor Spicer¹, Nathalie Carrier², Ang Gao¹, Hani El-Gabalawy¹, John Wilkins¹ and Gilles Boire³,
¹University of Manitoba, Winnipeg, MB, Canada, ²Centre intégré universitaire de santé et de services sociaux de l'Estrie - Centre Hospitalier Universitaire de Sherbrooke, Sherbrooke, QC, Canada, ³Rheumatology Division, Centre intégré universitaire de santé et de services sociaux de l'Estrie - Centre Hospitalier Universitaire de Sherbrooke and Université de Sherbrooke, Sherbrooke, QC, Canada

Session Information

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster II: Diagnosis and Prognosis

Session Type: ACR Poster Session B

Session Time: 9:00 AM-11:00 AM

Background/Purpose: Available clinical tools do not adequately identify treatment non-responders in early rheumatoid arthritis (RA) leading to delayed disease control. Tools informed by molecular phenotype may aid treatment decisions. Using an aptamer based assay that measures the relative quantity of 1310 proteins, (SOMAscan), we sought to identify predictors of Methotrexate (MTX) response in Disease Modifying Anti-rheumatic Drug (DMARD) naïve patients with less than 1 year of RA (ERA).

Methods: Sera from 36 DMARD naïve seropositive ERA (female 67%, rheumatoid factor (RF) positive 47%, baseline symptom duration 4 (1.9) months, baseline DAS28CRP 5.1 (SD 1.2) were assayed for SOMAmer protein expression. All patients met ACR/EULAR 2010 criteria for RA and all received MTX monotherapy. At one year, clinical response was defined by change in DAS28CRP (dDAS) and radiographic outcome by the presence of erosions on hand and feet radiographs and Sharp score. Pre-treatment protein expression levels were log2 transformed and correlated with their corresponding log2 transformed dDAS using a Pearson's R-squared (RSQ) applied across the cohort. A constant offset was included to account for negative dDAS values. The proteins with RSQ over a threshold had their expression values weighted into a linear combination SCORE. The value of the threshold was manually, iteratively tuned to yield an optimal correlation of SCORE against dDAS using the smallest number of proteins. Biological processes of included proteins were identified using an in-house enrichment tool. The SCORE was included in logistical regression models to predict radiographic outcome.

Results: The mean dDAS at one year was -1.9(SD1.6), 47% achieved remission ($\text{DAS} < 2.6$) and 19(53%) had erosions at one year (median Sharp score 3 (range 0-18)). A panel of 9 proteins each with $\text{RSQ} > 0.18$ correlated with dDAS (overall $\text{RSQ} 0.58$). Three proteins enriched to processes regulating cell proliferation (BIRC7, MMP7, CXCL9). SCORE did not correlate with one year radiographic Sharp scores and were similar between patients with or without erosions. In multivariable models including RF, age and sex, SCORE predicted remission (OR 0.01; 95% confidence interval 0.001-0.2) but did not predict the presence of erosions at one year. The dynamic range of protein expression values suggests this assay could be transferable to more clinically accessible protein quantification technologies.

Conclusion: High content proteomic approaches based on aptamers can assist the development of biologically based prediction tools. While further validation in cohorts with expanded disease activity and broader treatment is needed, this pilot study suggests a panel of proteins reflecting cellular proliferation predicts treatment response to MTX monotherapy in ERA however, different biomarkers are needed to predict erosions.

Abstract Number: 1493

Clinical Predictor Factors Associated with Sustained Disease Activity Among Patients with Early Rheumatoid Arthritis

Gabriela Gonzalez and Juan Molina Rheumatology, La Paz University Hospital, Madrid, Spain

Session Information

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster II: Diagnosis and Prognosis

Session Type: ACR Poster Session B

Session Time: 9:00 AM-11:00 AM

Background/Purpose: In rheumatoid arthritis (RA) patients the disease outcome has an unpredictable course and may differ even with an early diagnosis and treatment. Low disease activity is associated with favourable outcome and a normal level of functionality. It is desirable to identify patients with a high probability of sustained disease activity in an early stage. The purpose is to identify clinical baseline predictor factors associated with sustained disease activity after 12 months of follow up in patients with early RA.

Methods: Demographic, clinical, laboratory and treatment data of patients with an established diagnosis of RA (according to physician diagnosis) were recruited from an early arthritis clinic at baseline and after 12 months of follow-up. Sustained disease activity at 12 months was defined as DAS28 >3.2 and SDAI >11. Univariate and multivariate logistic regression of DAS28 and SDAI disease activity were performed at baseline and after 12 months

Results: 566 patients diagnosed of RA were included. 75.8% (429) were women with a predominance of Caucasian (74.7%; 423) an age average of 54 +/- 17 years old at the baseline visit and a mean of 16+/- 15 weeks since symptoms onset. 440 (77.7%) had positive rheumatoid factor and 373 (65.9%) had positive ACPA. 508 (89.8%) patients received Methotrexate as first line treatment and 459 (81.1%) received glucocorticoids. At baseline 88.8% (487) had moderate-high disease activity with DAS28 and 77.6% (439) with SDAI. After one year of follow-up, 34% (170) had moderate-high activity with DAS28 and 30.9% (175) with SDAI. Univariate logistic regression analysis results are shown in Table 1. On multivariate analysis we found that a higher DAS 28 score at baseline visit (OR 1.34; p=0.02) was associated with sustained disease activity after 12 months. Higher tittle of rheumatoid factor (OR 2.6; p=0,019), higher HAQ (OR 1.06; p=0.005) and high doses of glucocorticoids at baseline visit (OR 2.1; p=0.025) were associated with sustained disease activity after 12 months with SDAI score.

Table 1. Univariate logistic regression analysis results (baseline visit)

	DAS28		SDAI	
	OR	P value	OR	P Value
Age	1.00	0.6	0.03	1.02
Sex (women)	1.64	0.06	0.599	1.14
Tabaco	0.66	0.1	1.12	0.690
Nonsmokers (ref)	0.58	0.05	1.08	0.804
Past smokers				
Smokers				
RF (+)	1.61	0.09	0.444	0.007
ACPA (+)	0.685	0.1	0.691	0.14
DAS28	1.5	<0.001		
SDAI			1.00	0.008
HAQ	1.05	0.001	1.07	<0.001
ESR	1.01	0.001	1.01	<0.001
PCR	1	0.804	1.0	0.91
Pain	1.02	<0.001	1.01	<0.001
Patients Global Assessment	1.01	<0.01	1.01	0.002
Evaluator Global Assessment	1.02	<0.001	1.02	<0.001
Swollen Joint count 28	1.07	<0.001	1.07	<0.001
Tender Joint Count 28	1.07	<0.01	1.06	<0.001
Methotrexate use	8,2	<0.05	2,4	0,2
Glucocortoids use	1.8	<0,05	2,7	<0.001

Conclusion: 34% of RA patients had moderate-high activity with DAS28 and 30.9% with SDAI after 12 months of follow up even with an early diagnosis and intensive treatment. With the DAS28 score, high clinical activity at baseline can predict a sustained disease activity after one year; however with the SDAI score a high rheumatoid factor tittle, an

impaired functionality and the need of higher doses of glucocorticoids at baseline can predict a sustained disease activity after one year, showing a poor correlation between both indexes

Session Information

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster II: Diagnosis and Prognosis

Session Type: ACR Poster Session B

Session Time: 9:00 AM-11:00 AM

Background/Purpose: As a step towards personalized medicine, we seek to identify patients with new-onset RA who are likely to remain well on MTX monotherapy. Patients unlikely to persistently respond could potentially avoid adverse effects such as pain, functional impairment, structural damage, reduced work ability, or co-morbidities if offered alternative treatments already at diagnosis.

This project aims at assessing the performance, and marginal gains, of different statistical approaches to modelling predictions of persistence to methotrexate DMARD monotherapy at 1 year after RA diagnosis in patients with new-onset RA. Here, we report first results.

Methods: A cohort of incident RA diagnosed 2006-2014, starting treatment with MTX and DMARD monotherapy, and with clinical and treatment data available from diagnosis, was identified through the Swedish Rheumatology Quality (SRQ) register. Through linkages to nationwide population health and demographics registers, information on age, gender, educational level, income, hospital admissions and outpatient visits (coded using ICD10-codes), and prescribed drugs (coded using ATC codes) was collected. With regards to previous medical conditions and drug use, we compiled three sets of covariates, with increasing complexity: A) including 20 a priori defined co-morbid conditions only, B) including all ICD and ATC codes irrespective of time before RA, and C) including all ICD and ATC codes but with each ICD codes assessed in three different time periods before RA (<1 year, 1-4.9, and 5-10 years before RA). For B) and C), the ICD and ATC codes were further included at four levels of resolution (1 to 5-digit covariates). The outcome was defined as remaining on MTX as DMARD monotherapy, without any other type of DMARDS added or switched to, after 12 months.

We first assessed the association between all variables in covariate set C and the outcome in a univariate logistic regression. We then computed a logistic regression model for only gender and age as a baseline predictor, followed by L1-regularized logistic regression (“Lasso”) models based on the full covariate sets A, B, and C, respectively. Predictive capacity is estimated as average ROC AUC under 10-fold nested cross-validation

Results: A total of 6225 patients with new-onset RA starting MTX as DMARD monotherapy were included. After 1 year, 4497 (72%) remained on MTX DMARD monotherapy. In the association analysis, 254 of the 1449 covariates had a p-value < 0.05. The logistic regression model with age and sex as the only covariates had an average ROC AUC of 0.596. The Lasso models showed mean ROC AUC values of 0.634 for set A, 0.650 for set B and 0.646 for set C.

Conclusion: Prediction of persistence to MTX treatment is difficult and advanced analytical methods based on diagnostic codes and co-medication can potentially increase ROC AUC as compared to a baseline model. We are currently decomposing the main outcome into different subcomponents, e.g. early stopping due to side effects, to understand predictive potential more granularly and are exploring several machine learning methods such as random forest and deep learning to improve predictive performance.

Session Information

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster II: Diagnosis and Prognosis

Session Type: ACR Poster Session B

Session Time: 9:00 AM-11:00 AM

Background/Purpose: Tofacitinib is an oral Janus kinase inhibitor for the treatment of RA. ORAL Strategy (NCT02187055) was a Phase 3b/4, 1-year, double-blind, triple-dummy, active comparator-controlled trial in patients (pts) with moderate to severe RA who were inadequate responders (IR) to MTX.¹ In ORAL Strategy, tofacitinib + MTX showed non-inferiority to adalimumab + MTX, clinically important improvement was seen with tofacitinib monotherapy, although non-inferiority vs tofacitinib + MTX oradalimumab + MTX was not demonstrated. The current investigation was a post hoc analysis of baseline (BL) characteristics in patients from the tofacitinib 5 mg BID monotherapy group in ORAL Strategy.

Methods: The (binary) efficacy outcome measure was achievement of low disease activity (LDA) at Month (M)6. LDA was defined using three different response variables separately: Simplified Disease Activity Index (SDAI) ≤ 11, Clinical DAI (CDAI) ≤ 10, or Disease Activity Score in 28 joints, erythrocyte sedimentation rate (DAS28-4[ESR]) < 3.2.² BL characteristics by response/no response at M6 were summarized; BL covariates were evaluated for association with each efficacy outcome

Table 1. Descriptive statistics of select baseline characteristics in patients receiving tofacitinib 5 mg BID monotherapy in ORAL Strategy, by SDAI LDA status at Month 6

Parameter	Responders, SDAI ≤11 (N=167)	Non-responders, SDAI >11 (N=199)
Female, n (%)	131 (78.4)	168 (83.4)
Age, mean age (SD)	49.2 (12.4)	51.6 (12.0)

RF+/ACPA+	102 (61.1)	123 (61.8)
RF+/ACPA-	9 (5.4)	8 (4.0)
RF-/ACPA+	22 (13.2)	27 (13.6)
RF-/ACPA-	34 (20.4)	33 (16.6)

ACPA, anti-citrullinated protein antibody; BID, twice daily; CDAI, Clinical Disease Activity Index; CRP, C-reactive protein; DAS28-4[ESR], Disease Activity Score in 28 joints, erythrocyte sedimentation rate; HAQ-DI, Health Assessment Questionnaire-Disability Index; LDA, low disease activity; PCS, physical component summary; RF, rheumatoid factor; SD, standard deviation; SDAI, Simplified Disease Activity Index; SF-36, Short Form-36 Health Survey; SJC, swollen joint count; TJC, tender joint count

using univariate logistic regression analysis without adjustment for other covariates. Category cut-offs of BL variables were defined by existing publications, clinical practice, or expert opinion provided to the study sponsor.

Results: Overall, 357 pts were included in the analysis for SDAI; Table 1 shows selected BL characteristics by SDAI LDA status at M6. From univariate analysis, more BL covariates showed significant association with M6 SDAI LDA (Table 2) than CDAI or DAS28-4(ESR) LDA. M6 CDAI LDA univariate results showed similar trends to SDAI LDA, but with fewer factors showing associations. The BL covariates significantly associated with any of the three LDA measures at M6 included age, gender, disease severity (eg, tender joint count [TJC], DAS28-4[ESR], SDAI, and rheumatoid factor/anti-citrullinated protein antibody status) and Short Form-36 Health Survey physical component summary (SF-36 PCS; Table 2).

Conclusion: This post hoc analysis suggests that for MTX-IR pts who use to facitinib monotherapy, age, gender, and BL disease severity (e.g. by TJC) and SF-36 PCS score may be associated with achieving LDA at M6. Multivariable analysis will be performed to further explore the associations; additional prospective research is warranted to confirm the findings.

Crescenz VA Medical Center, Philadelphia, PA, ²Center for Rheumatology and Spine Diseases, Rigshospitalet Glostrup Copenhagen Center for Arthritis Research, Copenhagen, Denmark, ³Rheumatology, University of Pennsylvania, Philadelphia, PA, ⁴Division of Rheumatology, University of Pennsylvania, Philadelphia, PA, ⁵Johnson & Johnson, Spring House, PA, ⁶University of Leeds, Leeds, UK, Leeds, United Kingdom

Session Information

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster II: Diagnosis and Prognosis

Session Type: ACR Poster Session B

Session Time: 9:00 AM-11:00 AM

Background/Purpose: Several prior studies have demonstrated poor clinical responses and reduced likelihood of achievement of remission among women with rheumatoid arthritis (RA). We aimed to determine if this observation represents a biologic effect versus a bias in the performance of clinical disease activity measures and their components. Specifically, we compared rates of treatment response in men and women based on different clinical composite and component scores as well as by MRI definitions of low activity in two large clinical trials.

Methods: This is an ancillary study of patients who completed the 52-week MRI sub-studies of two large clinical trials of golimumab. MRI of the dominant hand was performed and RAMRIS synovitis scores were determined at baseline, and at week 52. Standard clinical assessments and patient-reported measures were recorded at all time-points and composite scores were determined including the DAS28 (ESR), DAS28 (CRP), and CDAI. Remission was defined according to standard thresholds and using Boolean criteria for individual components. A low synovitis score on MRI was defined according to prior published thresholds (≤ 3). Multivariable logistic regression models assessed relationships between sex and achievement of remission or MRI low inflammatory activity by 52 weeks adjusting for age, race, study and treatment group.

Results: Men (N=58) and women (N=295) had similar DAS28 (CRP) and CDAI at baseline, but women had higher DAS28 (ESR) and higher patient global and tender joint counts (Table 1). Women were less likely to achieve remission by 52 weeks when remission was defined by the DAS28 (ESR) or CDAI (Table 2). However, there was not a significant difference in the achievement of remission between men and women for DAS28 (CRP). Among component scores, women were less likely to reach a low patient global score and a low ESR (<30 mm/hr) and tended to be less likely to reach a low tender joint count ($p=0.056$). Men and women were equally likely to achieve low CRP, a low swollen joint count, and a low evaluator global score. Men and women also achieved low MRI synovitis scores with similar frequency.

Table 2. Partial data from univariate logistic regression analyses of baseline characteristics by SDAI-LDA at 56 (≤11.0)

Baseline characteristic	Overall p value	Association with SDAI-LDA (reference level/unit)*	OR (95% CI)	P value
Gender	0.0119	Male (vs female)	2.10 (1.18, 3.74)	0.0119
Age category	0.9871	<65 (years) (vs ≥65 years)	1.01 (0.54, 1.88)	0.9871
Age	0.0282	Lower age (unit=1 year [†])	0.98 (0.96, 1.00)	0.0282
TJC count	<0.0001	4–8 (vs >12)	2.94 (1.00, 8.41)	0.0005
		9–12 (vs >12)	2.82 (1.70, 4.69)	<0.0001
TJC	<0.0001	Lower count (unit=1 [†])	0.92 (0.89, 0.96)	<0.0001
SF-36 PCS	0.0006	Higher score (unit=1 [†])	1.05 (1.02, 1.08)	0.0006

*Associated with higher proportion of responders.

[†]In Unit(s), 'x' is the increment/unit in the continuous variable corresponding to which the change in odds is observed.

Results for other parameters not shown: the following parameters were also assessed and will be provided in the final presentation: BMI, CRP, DAS28-4(ESR), geographic region, glucocorticoid dose, HAQ-DI, pain VAS, SF-36 MCS, smoking status, RA duration, race, weight, CDAI, SDAI, SJC, and RF/ACPA status.

ACPA, anti-citrullinated protein antibody; BMI, body-mass index; CDAI, Clinical Disease Activity Index; CI, confidence interval; CRP, C-reactive protein; DAS28-4(ESR), Disease Activity Score in 28 joints, erythrocyte sedimentation rate; HAQ-DI, Health Assessment Questionnaire-Disability Index; LDA, low disease activity; MCS, mental component summary; OR, odds ratio; PCS, physical component summary; RA, rheumatoid arthritis; RF, rheumatoid factor; SDAI, Simplified Disease Activity Index; SE, standard error; SF-36, Short Form-36 Health Survey; SJC, swollen joint count; TJC, tender joint count; VAS, visual analogue scale.

Conclusion: Although women were less likely to achieve DAS28 (ESR) and CDAI remission, they were equally likely to achieve a low CRP, swollen joint count, and low MRI synovitis. These findings suggest that there is not a biologic difference in treatment response in men and women, but that differences in the performance of subjective clinical measures of disease activity and expected sex differences in ESR may explain differences in observed response rates. Table 1: Baseline characteristics of the combined study populations from the combined population from GO-BEFORE, and GO-FORWARD studies.

PRISM-RA: A Personalized Medicine Test That Accurately Predicts Rheumatoid Arthritis Patients Who Will Not Respond Adequately to Tumor Necrosis Factor Inhibitors

Keith Johnson, Nancy Schoenbrunner and Dina Ghiassian, Scipher Medicine Inc, Waltham, MA

Session Information

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster II: Diagnosis and Prognosis

Session Type: ACR Poster Session B

Session Time: 9:00 AM-11:00 AM

Background/Purpose: Rheumatoid arthritis (RA) is a complex disease affecting about 1.3 M adults in the US. The patient population is very heterogeneous; no single drug mechanism achieves treatment targets in the majority of patients. Tumor necrosis factor inhibitors (anti-TNFs) are the first line therapy in >90% of biologic naïve patients, although less than half of patients achieve treatment targets on them. This is despite the fact that in the past decade therapies with alternative mechanisms have been approved. The case for a test to predict which therapy a patient will respond to is overwhelming because of the disease heterogeneity, and because the approved therapies for RA are molecularly targeted. Scipher is developing PRISM-RA to accurately predict from a baseline blood sample, using a gene expression profile, which patients will not reach their treatment target on anti-TNFs. Identified non-responders will be offered alternative approved therapies much earlier in their treatment course than currently in clinical practice. This will lead to better patient outcomes and significant savings of healthcare costs.

Methods: The test user requirements were developed based on in depth discussions with payers and rheumatologists. The overwhelming consensus is that PRISM-RA must identify non-responders (NRs) with >90% accuracy and with sufficient specificity to identify the majority of NRs. Response is defined as achieving ACR-defined treatment targets, equating to a minimum of ACR50 improvement in disease activity after 3 months of therapy. Independent patient cohorts treated with anti-TNFs with associated baseline gene expression data were analyzed to train a classifier to predict response.

Results: In a 50 subject training cohort PRISM-RA achieved >90% accuracy (NPV) with the required specificity. PRISM-RA passed proof of concept (POC) by exceeding the pre-specified user requirements in a blinded fashion across an independent cohort of 39 subjects. Scipher is validating PRISM-RA in an ongoing observational study of >150 patients; the results of this confirmatory study will be presented in the near future. Thereafter, Scipher will conduct an appropriately powered, double-blinded prospective interventional trial to confirm both clinical performance and utility of PRISM-RA. PRISM-RA will be offered commercially as CLIA certified laboratory developed test (LDT). During the prospective trial, data will be collected to train classifiers to predict responders across all classes of approved targeted therapies for RA

Conclusion: PRISM-RA has achieved POC and will provide rheumatologists with a scientific rationale for selecting therapies based on a biologic naïve patient's molecular data before initiating treatment, meaning that more patients will achieve their treatment targets than is the case today. By de-selecting non-responders the overall rate of achieving treatment targets on anti-TNFs will increase significantly. Ultimately, PRISM-RA will provide response predictions for all approved targeted therapies for RA, providing rheumatologists with a validated scientific rationale for the selection of the right therapeutic agent for an individual patient.

Serum MMP-3 More Than 155ng/ML at Baseline Predicts One-Year Radiographic Progression in Patients with Rheumatoid Arthritis

Jian-Da Ma¹, Jun-Wei Wang², Yan-Hui Xu², Kui-Min Yang², Le-Feng Chen², Jian-Zi Lin² and Lie Dai², ¹Department of Rheumatology, Sun Yat-Sen Memorial Hospital, Sun Yat-Sen University, Guangdong, China, ²Department of Rheumatology, Sun Yat-Sen Memorial Hospital, Sun Yat-Sen University, Guangzhou, China

Session Information

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster II: Diagnosis and Prognosis

Session Type: ACR Poster Session B

Session Time: 9:00 AM-11:00 AM

Background/Purpose: Core disease activity indicators of rheumatoid arthritis (RA) have been found to be limited in predicting joint destruction progression. We previously reported that continuously elevated serum matrix metalloproteinase (MMP)-3 predicted one-year radiographic progression (RP) in RA patients. Here we aimed to develop a cutoff value of serum MMP-3 for clinical practice.

Methods: Consecutive patients with active RA (DAS28-CRP more than 2.6) were retrospectively recruited and divided into study cohort (naïve patients without previous DMARDs and corticosteroids treatment, $n=102$) and confirmatory cohort (others, $n=140$). Clinical data were collected at baseline and visits at month 1, 3, 6, and 12, and a change in modified total Sharp score more than 0.5 from the 12th month to baseline was defined as RP.

Results: RA patients in study cohort had shorter disease duration but higher disease activity and HAQ-DI at baseline than that of patients in confirmatory cohort. However, there were significantly higher rate of remission and lower rate of RP in study cohort than that in confirmatory cohort (Table 1). In study cohort, patients in progressive group had higher serum MMP-3 at baseline than that in non-progressive group ($P=0.014$), whereas there was no different of CRP, ESR, RF, ACPA and DAS28-CRP between these two group (all P more than 0.05). ROC curve analysis showed that the area under the curve (AUC) of serum MMP-3 in predicting one-year RP was 0.671 with the cutoff value of 155 ng/ml according to Youden index, whereas there was no significance of CRP, ESR, RF and ACPA (AUC: 0.491~0.570, all P more than 0.05). Univariate and multivariate logistic regression showed that baseline serum MMP-3 (more than 155 ng/ml) was a significant predictor of one-year RP after adjusted for sex, age, disease duration, baseline DAS28-CRP and HAQ-DI (Table 2). This cutoff value of serumMMP-3 was validated by the confirmatory cohort (Table 2).

Table 1 Baseline characteristics and outcome of RA patients in study and confirmatory cohorts

Characteristics	Study cohort ($n=102$)	Confirmatory cohort ($n=140$)	P
Baseline			
Age, years	50 (40-60)	49 (36-58)	0.125

MMP-3 (2)	>155ng/ml	32%	97%	17.182 (1.203–183.985)* 14.726 (1.863–116.437) [‡]	0.007* 0.011 [‡]	49%	81%	4.200 (1.875–9.407) [‡]	<0.001 [‡]

△ The cutoff values of CRP, ESR, RF, ACPA and MMP-3 (1) were determined according to the upper limit of normal range. The cutoff value of MMP-3 (2) was determined according to the Youden index in ROC curve analysis. *OR of predictors was determined by univariate logistic regression according to the cutoff value, # OR of MMP-3 was determined by multivariate logistic regression adjusted for sex, age, disease duration, baseline DAS28-CRP and HAQ-DI.

Conclusion:

Elevated serum MMP-3 with a cutoff value of 155 ng/ml is an applicable predictor for one-year RP in RA. : Fundings: This work was supported by National Natural Science Foundation of China (81471597,81671612), Guangdong Natural Science Foundation (2017A030313576,2017A030310236), Guangdong Medical Scientific Research Foundation (A2017109).

Elevated Serum MMP-3 in Remission Predicts Relapse in Patients with Rheumatoid Arthritis

Le-Feng Chen¹, Jian-Da Ma², Jun-Wei Wang¹, Yan-Hui Xu¹, Kui-Min Yang¹, Jian-Zi Lin¹ and Lie Dai¹, ¹Department of Rheumatology, Sun Yat-Sen Memorial Hospital, Sun Yat-Sen University, Guangzhou, China, ²Department of Rheumatology, Sun Yat-Sen Memorial Hospital, Sun Yat-Sen University, Guangdong, China

Session Information

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster II: Diagnosis and Prognosis

Session Type: ACR Poster Session B

Session Time: 9:00 AM-11:00 AM

Background/Purpose: Our previous study showed continuously elevated serum matrix metalloproteinase (MMP)-3 predicted one-year radiographic progression (RP) in RA and the cutoff value at 6th month was 161 ng/ml (*ArthritisRes Ther.* 2015). Here we aimed to explore whether elevated serum MMP-3 predicted relapsed in RA.

Methods: RA patients with moderate to high disease activity (DAS28-CRP>3.2) were recruited. Clinical data were collected and serum MMP-3 was detected by ELISA at baseline and each visit (1st, 3rd, 6th and 12th months). The cutoff value of MMP-3 at 6th month was 161 ng/ml. RP was defined as modified total Sharp score (mTSS) changed more than 0.5 from baseline to the 12th month.

Results: There were 214 RA patients finished one-year follow-up and 64 (29.9%) showed RP (Table 1). There were 59 (27.6%), 102 (47.7%), 112 (52.3%) and 106 (49.5%) patients reached remission at each visit, respectively. Among 112 patients reached remission at 6th month, there were 30% relapsed at 12th month. Among 102 active patients at 6th month, there were 27% achieved remission at 12th month. Patients who relapsed from 6th to 12th month had significant higher one-year RP than those sustained remission (15.4 %vs. 35.3%, $P=0.018$), accompanied with higher HAQ-DI, PtGA, PrGA and pain VAS at 12th month (all $P<0.05$). Patients who relapsed from 6th to 12th month had significantly higher CRP [3.1 (3.0–7.0)mg/L vs.3.0 (3.0–3.1)mg/L], DAS28 [2.0 (1.6–2.3) vs. 1.6 (1.5–2.0)] and the ratio of elevated MMP-3 [19 (55.9%) vs. 26 (33.3%); all $P<0.05$] at 6th month than those sustained remission. Univariate and multivariate logistic regression

showed that elevated serum MMP-3 was a significant predictor of one-year RP after adjustment of sex, age and disease duration (adjusted OR 2.599, 95% CI 1.087~6.216, $P=0.032$).

Conclusion:

Elevated serum MMP-3 at 6th month in remission RA patients may be a useful predictor for relapsed at one-year. :

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster II: Diagnosis and Prognosis

Session Type: ACR Poster Session B

Session Time: 9:00 AM-11:00 AM

Background/Purpose: A multi-biomarker disease activity (MBDA) score was developed to objectively measure disease activity for patients with rheumatoid arthritis (RA).¹ The MBDA score is calculated by an algorithm using concentrations of 12 serum biomarkers and has been shown to track response to treatment with several DMARDs.²⁻⁴ We aimed to assess the ability of the MBDA score to track response to rituximab treatment in RA patients.

Methods: Data were used from 3 cohorts (1 in the United Kingdom, 2 in the Netherlands) of RA patients treated with rituximab 1000 mg and methylprednisolone 100 mg at days 1 and 15. The MBDA score was assessed in serum samples at baseline (BL, n=57) and at 6 months (n=46). Wilcoxon signed-rank test was used to statistically compare the medians at BL and 6 months. Spearman's rank correlation (r) was used to analyse relationships between BL and 6 month values and change (Δ) from BL to 6 months for MBDA score vs. the following endpoints: DAS28-ESR, DAS28-hsCRP, ESR, hsCRP and Health Assessment Questionnaire (HAQ). Logistic regression analysis with adjustment for age, sex, smoking, ACPA and RF was used to assess the association between Δ MBDA score and non-response, using EULAR response categories at 6 months. $p < 0.05$ was considered statistically significant.

Results: At baseline the median MBDA score and DAS28-ESR were 56.0 (range 16.0-84.0) and 6.2 (range 2.5-8.4), respectively. The improvement in both scores after 6 months was statistically significant (both $p < 0.01$). MBDA score correlated with DAS28-ESR, DAS28-hsCRP, ESR and hsCRP at BL and 6 months, respectively (Table 1). Δ MBDA score from BL to 6 months correlated with changes in these measures. Spearman's correlation for Δ MBDA score vs. Δ DAS28-ESR was $r=0.60$, $p < 0.01$ (Table 1). Δ MBDA score also correlated with EULAR non-response (n=38), with adjusted

Table 1: Correlations between the MBDA score and disease activity measures

Measure	Timepoint or period for comparison with MBDA score	Number of available patients	Spearman's ρ	p-value
DAS28-ESR	BL	46	0.52	<0.01*
	6M	42	0.49	<0.01*
	Δ	38	0.60	<0.01*
ESR	BL	44	0.75	<0.01*
	6M	42	0.66	<0.01*
	Δ	41	0.48	<0.01*
DAS28-hsCRP ^(b)	BL	25	0.40	0.05*
	6M	24	0.46	0.03*
	Δ	23	0.46	0.02*
hsCRP ^(b)	BL	25	0.60	<0.01*
	6M	24	0.60	<0.01*
	Δ	23	0.71	<0.01*
HAQ	BL	39	0.02	0.91
	6M	41	-0.03	0.86
	Δ	34	0.19	0.28

MBDA: multi-biomarker disease activity; DAS28: disease activity score using 28 joints; ESR: erythrocyte sedimentation rate; hsCRP: high-sensitivity C-reactive protein; HAQ: Health Assessment Questionnaire; BL: MBDA score and measure at baseline; 6M: MBDA score and measure at 6 months; Δ : changes in MBDA score and measure; BL: from baseline at 6 months; (b) United Kingdom cohort only
* Statistically significant, $p < 0.05$

OR=0.91 (95% CI=0.84-0.99, p=0.02), which corresponds to an OR of 0.39 for every 10-unit decrease in MBDA score. Correlations were not observed between MBDA scores or Δ MBDA score and the corresponding HAQ measurements (Table 1).

Conclusion: We have shown, for the first time, that the MBDA score tracked disease activity in RA patients treated with rituximab and that change in MBDA score reflected the degree of treatment response.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster II: Diagnosis and Prognosis

Session Type: ACR Poster Session B

Session Time: 9:00 AM-11:00 AM

Background/Purpose: The Multi-Biomarker Disease Activity (MBDA) score was developed to provide an objective measure of rheumatoid arthritis (RA) disease activity. Demonstrating moderate correlations with conventional measures of RA disease activity, the capacity of the MBDA to predict treatment response may vary among available disease-modifying agents. The performance of the MBDA in patients initiating methotrexate (MTX), a cornerstone therapy in RA, has not been evaluated to date.

Methods: We conducted a secondary analysis of a 16-week, open-label study of RA patients initiating MTX (15mg/wk) with dose escalation to 20mg/wk for those failing to achieve disease remission (DAS28 <2.6) at 8 weeks. The primary study outcome was the proportion achieving ACR50 response at week 16. MBDA scores were measured using banked serum collected at baseline (N=130) and week 16 (N=95). The association of baseline MBDA with treatment response was assessed using multivariable regression models adjusting for age, sex, race, smoking status, and rheumatoid factor (RF) concentration. Convergent validity and responsiveness were determined by calculating correlations of the MBDA with DAS28-ESR, ESR, patient global assessment (PtGA), Health Assessment Questionnaire (HAQ), as well as correlations of MBDA change with changes in alternative disease activity measures and through the calculation of standardized response means (SRM).

Results: Patients had a mean age of 54 yrs and were predominantly female (75%), seropositive (73% for RF, 75% for anti-CCP), and had high baseline disease activity (DAS28-ESR of 5.3, SD 1.2). Mean baseline MBDA score was 48.3 (SD 17.2) with 12%, 28%, and 61% categorized as low, moderate, and high disease activity by MBDA. After 16 weeks, the MBDA improved by a mean of 9.4 (SD 14.5) and DAS28-ESR improved by a mean of 1.9 (SD 1.5). Patients achieving an ACR50 response demonstrated greater reductions in MBDA than those failing to achieve an ACR50 response ($p=0.01$). However, baseline MBDA scores (OR 1.01, 95% CI 0.99, 1.04) and categories (moderate: OR 1.55, 95% CI 0.45-14.20; high: OR 2.55, 95% CI 0.50-12.98) were not predictive of response. Higher baseline MBDA scores were associated with greater improvement in DAS28-ESR ($p=0.01$), as were baseline DAS28-ESR values ($p<0.001$). The MBDA demonstrated moderate correlations with DAS28-ESR and ESR, but weaker correlations with the HAQ and PtGA (Table 1). Treatment responsiveness was greater for DAS28-ESR (SRM -1.32) than MBDA (SRM -0.65).

Conclusion: In this 16-week open-label study of MTX in RA patients, baseline MBDA was associated with greater reductions in DAS28-ESR but was not a robust predictor of ACR50 response. Although demonstrating moderate convergent validity with standard disease activity assessments, the MBDA yielded lower responsiveness than the DAS28-ESR in the context of MTX treatment.

Table 1 Correlation (r) of the MBDA Score with disease activity measures and functional status in RA patients initiating MTX

	DAS28-ESR		ESR		PtGA		HAQ	
	r	p-value	r	p-value	r	p-value	r	p-value
MBDA	0.44	<0.001	0.59	<0.001	0.23	0.008	0.34	<0.001
Baseline	0.30	0.004	0.51	<0.001	0.19	0.07	0.23	0.03
Week 16								
Δ MBDA	Δ DAS28-ESR	<0.001	Δ ESR	<0.001	Δ PtGA	0.02	Δ HAQ	0.02
	0.42		0.46		0.23		0.25

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster II: Diagnosis and Prognosis

Session Type: ACR Poster Session B

Session Time: 9:00 AM-11:00 AM

Background/Purpose: We previously identified higher disease activity score assessing 28 joints (DAS28) at baseline, current smoking and no alcohol consumption as clinical predictors for inadequate response (IR) to a methotrexate (MTX) strategy.¹ In addition, we showed the potential of protein biomarkers to improve the prediction of clinical response in patients likely to show IR to MTX.² In this analysis, we aimed to validate predictive protein biomarkers with additive value to the clinical predictors mentioned above in predicting IR to MTX.

Methods: Data was used from patients initiating MTX therapy in the U-Act-Early trial for developing the prediction model.³ If remission (DAS28) <2.6 with ≤4 swollen joints for ≥24 weeks) was not achieved, hydroxychloroquine was added and thereafter replaced by tocilizumab if remission still was not achieved. Serum was collected at baseline and analyzed using multi-analyte (n=85) profiling; relevant proteins were identified using partial least square discriminant analyses. Data of patients treated with MTX plus glucocorticoid (GC) in the Rotterdam Early Arthritis Cohort trial were used for validation.⁴ These patients switched to MTX plus etanercept, if remission (DAS44 <2.4) was not achieved. IR to MTX was defined for both studies as the need of adding abiological DMARD within the first year to MTX, including additional conventional synthetic disease modifying anti-rheumatic drug (csDMARD) or GC therapy (here designated as 'MTX+').

Results: None of the potentially relevant proteins (n=7) in the development sample were found to be significant (IR vs. no IR) in the validation sample. Although not statistically significant, the best performing biomarker was vascular cell adhesion protein 1 (VCAM-1, odds ratio (OR) 1.36, 95%-confidence interval (CI), 0.84-2.32; p=0.19), and was further investigated. In the development sample, the area under the receiver operator characteristics curve (AUROC) of the combined model (*i.e.* clinical predictors plus VCAM-1) was 0.80 (95%-CI 0.71-0.88); no significantly improved discriminative ability compared to clinical model (AUROC 0.75, 95%-CI 0.65-0.84; p=0.051). When applying the linear predictor to the validation sample, an AUROC of 0.67 (95%-CI 0.55-0.80) was found for the combined model: neither significantly different from clinical model (AUROC 0.68, 95%-CI 0.55-0.80).

Fig. 1: ROC curves of predicting IR to MTX therapy in the development (left) and validation (right). The clinical model contains baseline DAS28, current smoking and alcohol consumption as predictors; the combined model contains the predictors of the clinical model plus VCAM-1. AUROC = area under the receiver operator characteristics curve, CI = confidence interval, DAS28 = disease activity score assessing 28 joints, IR = inadequate response, MTX = methotrexate, ROC = receiver operator characteristics, VCAM-1 = vascular cell adhesion protein 1.

Conclusion: No protein biomarkers with additive value to clinical predictors for predicting IR to 'MTX+' in new-onset RA could be externally validated. The relatively easily obtainable clinical predictors still remain the most accurate factors to predict the need for adding a biologic DMARD to the initial MTX-based treatment strategy.

Rheumatoid Factor Positivity Is Related with Higher Discontinuation Rate of Tumor Necrosis Factor Inhibitor Therapy Due to Adverse Event and Insufficient Response in Rheumatoid Arthritis: A Multiple Imputation Method for COX Proportional Hazard Model

Yoshikazu Ogawa¹, Nobunori Takahashi², Toshihisa Kojima² and Naoki Ishiguro², ¹Nakatsugawa Municipal General Hospital, Nakatsugawa, Japan, ²Orthopaedic Surgery, Nagoya University Graduate School of Medicine, Nagoya, Japan

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster II: Diagnosis and Prognosis

Session Type: ACR Poster Session B

Session Time: 9:00 AM-11:00 AM

Background/Purpose: Discontinuation of tumor necrosis factor inhibitor (TNFi) therapy in rheumatoid arthritis (RA) is attributable to various reasons. Above all, adverse event (AE) and insufficient response (IR) are principal and crucial. In this study, we investigate association between covariates including rheumatoid factor (RF) positivity and discontinuation of TNFi therapy due to AE and IR using COX proportional hazard analysis. Additionally, multiple imputation analysis for COX proportional hazard regression was performed. This approach is becoming increasingly popular for handling missing data. Excluding participants who have one or more missing values, a so-called complete case analysis can introduce selection bias as participants who have complete data may be different to those with missing data.

Methods: This study included patients enrolled in the Tsurumi Biologic Communication Registry which comprises Nagoya University and 18 affiliated institutions in Japan. We assessed relationships between individual characteristic components and patient outcomes using multiple imputation method for COX proportional hazard model. All analyses were conducted in R version 3.5.0.

Results: There was a higher crude discontinuation rate in RF positive patients than in RF negative patients using Kaplan-Meier survival curve and log-rank test ($P < 0.05$; Figure). The difference was significant in COX proportional hazard analysis adjusting for baseline characteristics including age, sex, stage, das28 using erythrocyte sedimentation rate at baseline, methotrexate use, and prednisolone use ($n = 643$, HR = 1.47, $P < 0.05$; Table 1), and multiple imputation method for COX proportional hazard model ($n = 2352$, HR = 1.31, $P < 0.05$; Table 2).

Conclusion: Using multiple imputation method for COX proportional hazard regression, we demonstrated that RF positivity is related with higher discontinuation rate of TNFi therapy due to AE and IR on bio-naïve RA patients.

Table 1 Complete-case analysis ($n = 643$)

	Hazard ratio	Lower 95%CI	Upper 95%CI	p-value
RF positivity	1.47	1.05	2.04	$p < 0.05$
Age	1	0.99	1.01	0.92

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster II: Diagnosis and Prognosis

Session Type: ACR Poster Session B

Session Time: 9:00 AM-11:00 AM

Background/Purpose: Anti-citrullinated peptide antibody (ACPA) and rheumatoid factor (RF) define “seropositive” rheumatoid arthritis (RA). Both predict disease course, development of extra-articular features and treatment outcomes. ACPA is more specific than RF for the diagnosis of RA. There is little evidence to determine if repeat testing of ACPA and RF is required. We investigated the incidence of seroconversion to ACPA after commencement of treat-to-target therapy in patients with early RA.

Methods: DMARD-naïve patients presenting between September 1998 - July 2017 with RA according to the 1987 ACR criteria, with a disease duration of <12 months were enrolled. All patients received combination triple DMARD therapy (methotrexate, sulfasalazine and hydroxychloroquine) according to a treat-to-target strategy. Adjustments to treatment by predefined protocol were contingent on failing to reach a target DAS28-ESR score of <2.6. ACPA and RF were recorded at baseline and at least 6 monthly. Before 2011, ACPA was analysed using ELISA and then by immunoassay. Before 2011, RF was measured by latex nephelometry and then by turbidimetry with excellent correlation between methods. Normal ranges were defined for ACPA as <6 units/mL and for RF <14 IU/mL. Differences between seroconverters and non-seroconverters were assessed via Mann Whitney test (for continuous variables) and Fisher Exact Test (for categorical variables).

Results: 368 patients had a total of 2889 ACPA and 4170 RF measurements. Median follow up was 272 (IQR 53-467) weeks. Median disease duration at diagnosis was 20.4 weeks (IQR 11-26). At 1 year, 44% of patients were in DAS28 remission and 10% progressed to require a biologic DMARD during study follow up. At baseline, 154 (41.8%) patients were seronegative for ACPA, 10 (6.5%) of whom seroconverted at some time during follow up. Four (2.6%) patients had persistent seroconversion. Of the 10 ACPA seroconverters, 9 patients were RF positive at baseline. Baseline RF titre predicted seroconversion to ACPA (mean 10IU/ml vs 55IU/ml in non-converters, $p < 0.001$). Of the 107 patients who were RF negative and ACPA negative at baseline, ACPA became positive at 10 IU/ml in a single patient who subsequently reverted to negative. Median time to seroconversion for ACPA was 29 months (range 3-192). No patient seroconverted from negative to positive for both RF and ACPA.

Conclusion: Persistent seroconversion of ACPA from negative to positive after diagnosis in patients with RA is uncommon. ACPA and RF double negative patients are highly unlikely to ever develop ACPA positivity with a risk of < 1%. It is therefore unlikely to be helpful or cost effective to perform serial ACPA measurements in patients with seronegative RA.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster II: Diagnosis and Prognosis

Session Type: ACR Poster Session B

Session Time: 9:00 AM-11:00 AM

Background/Purpose: Anti-cyclic citrullinated peptide (CCP) antibody test is a very important test for the diagnosis of rheumatoid arthritis (RA), but one of the disadvantages of the existing enzyme-linked immunosorbent assay (ELISA) is that its method is labor-intensive and time-consuming. The aim of this study was to assess the measurement characteristics of a rapid point-of-care (POC) anti-CCP test compared to the conventional anti-CCP test.

Methods: We used the POC ichroma anti-CCP test of Boditech Med and two anti-CCP assays (Elecys[®] Anti-CCP by Roche Diagnostics and the FCCP600 of Axis-Shield Diagnostics) and rheumatoid factor (RF) by latex agglutination test (LAT) respectively.

Results: A total of 430 subjects (199 RA patients, 112 non-RA patients and 119 healthy controls) were enrolled in this study. For the RA patients, the anti-CCP test were positive for 136 (68.3%), 155 (77.8%), and 158 patients (79.3%) with the ichroma anti-CCP, the Elecys anti-CCP, and FCCP600, respectively. For the non-RA patients, the anti-CCP test were positive for 5 (4.5%), 7 (6.3%), and 5 patients (4.5%) with the ichroma anti-CCP, the Elecys anti-CCP, and FCCP600, respectively. The overall agreement between the ichroma system and other tests was 91.6% (Elecys) and 88.8% (FCCP) and 76.7% for RF. The difference between three areas under the ROC curves, including the POCT test, was not statistically significant (ichroma, 0.903(0.874-0.933); Elecys, 0.909 (0.877-0.941); and FCCP600, 0.892 (0.858-0.926)). There was, however, a significant difference from RF (0.770 (CI 0.721-0.819)).

Fig. Scatter plots of anti-CCP level according to the concentrations of anti-CCP antibodies and rheumatoid factor for different groups of patients

Conclusion: The POC ichroma anti-CCP test is not only a quick and convenient test, but also provides a comparable and reliable diagnostic performance of conventional methods.

Table. Diagnostic performance of the three anti-CCP assays and one rheumatoid factor test for diagnosis of RA

	Ichröma	Elecys	FCCP600	RF
Manufacturer's cut-off	50 U/mL	17 U/mL	5 U/mL	13 U/mL

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster II: Diagnosis and Prognosis

Session Type: ACR Poster Session B

Session Time: 9:00 AM-11:00 AM

Background/Purpose: The development of ultrasound (US) guided synovial biopsy will enable synovial tissue collection from small joints and will facilitate histopathological studies, thus improving the understanding of early rheumatoid arthritis (ERA). The CAP48 cohort is an original multicentre prospective observational study of ERA patients (pts) up to 50 years old supported by a charity program of the Belgian French speaking radio-television (RTBF). The objectives of this cohort are to observe if a tight control favours remission at 6 months and to define synovial markers for disease severity and response to therapy.

Methods: ERA pts fulfilling the ACR/EULAR 2010 criteria and naive to DMARDs therapy were recruited. Synovial biopsies before treatment were obtained using an US guided needle biopsy (US-NB) of the small joints or mini arthroscopy of the knee and used for blinded tissue pathology description. ERA disease activity measures including DAS28CRP were evaluated every 3 months and treatment was adapted by the treating physician. Tissues were assessed for quality. Pts were classified according 3 types of synovial histopathology findings: pts whose synovial tissue showing mostly lymphoid (CD3+ and CD20+) infiltrates, myeloid (CD68+) infiltrates and a group with low inflammation, combined or not with a fibroid aspect of the stroma, clustered, respectively in Lymphoid, Myeloid and Pauci-Immune groups.

Results: A synovial biopsy was performed in 37 pts. Baseline characteristics of the cohort and different histologic pattern groups are summarized in Table.

	All patients n=37	'Lymphoid' group n=18	'Myeloid' group n=6	'Pauci-Immune' group n=13
Age mean (SD)	34.6 (± 11.6)	31.2 (± 10.9)	38.4 (± 11.7)	37.7 (± 11.9)
Gender	30F/7M	14F/4M	5F/1M	11F/2M
ACPA %	37.8% (n= 14)	22.2% (n=4)	0% (n=6)	76.9% (n=10)
RF %	48.6% (n=18)	38.9% (n=7)	16.7% (n=1)	76.9% (n=10)
Erosion %	32.4% (n=12)	27.8% (n=5)	33.3% (n=2)	38.4% (n=5)
Baseline DAS28CRP	4.60 (± 1.37)	4.46 (± 1.42)	5.24 (± 1.52)	4.50 (± 1.26)
6 Month DAS28CRP	2.68 (± 1.13)	2.19 (± 0.89)*	2.83 (± 1.44)	3.15 (± 1.13) * p=0.023

ACPA negative pts were classified in the Myeloid (100%) or in Lymphoid (77.8%) groups compared to a majority of the ACPA positive pts (76.9%) in the Pauci-Immune group. Since the myeloid pattern can be associated with a lymphoid infiltration, it raised a question on the relevance to maintain a distinct subgroup. The Pauci-Immune RA group showed lower DAS28-CRP response than the other groups.

Conclusion: Synovial tissue analysis could provide a step change towards personalized medicine in daily clinical practice for disease stratification and treatment selection of ERA. In the CAP48 cohort, a high number of these young and ERA pts achieved remission at 6 months but a lower response was observed in the Pauci-Immune group. Further analyses are ongoing to define individual synovial markers of severity and response.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster II: Diagnosis and Prognosis

Session Type: ACR Poster Session B

Session Time: 9:00 AM-11:00 AM

Background/Purpose: Fatigue is a multifactorial and persistent symptom reported by patients with rheumatoid arthritis (RA). It is considered as frequent as pain. It would be of value to identify potential predictive factors of fatigue that could influence on its evolution.

Methods: *The Etude et Suivi des polyarthrites Indifférenciées Récentes (ESPOIR)* is a multicenter French cohort of patients with early arthritis. We selected patients fulfilling the 2010 ACR/EULAR criteria for RA during the first year of follow-up. We recorded fatigue (SF vitality score ≤ 40), persistent fatigue (SF vitality score ≤ 40 at the end of the study and at least in 50% of visits in the 5 years follow up) and disease variables at baseline and every 6 months up to 5 years. The association between fatigue/persistent fatigue and disease characteristics were evaluated by bivariate logistic regression models / tests. A multivariate logistic regression model was used to determine independent predictors of fatigue at baseline and persistent fatigue at 5 years of follow-up. Moreover, to analyse the association between the course of fatigue and disease characteristics over the time, baseline variables associated with fatigue at the multivariate analysis were analysed by a repeated measures logistic regression model at various time points (M12, M24, M36, M48 and M60).

Results: We included 677 patients (73.4% women, mean \pm SD age 48.6 ± 12 years); 46.5%, 28% and 22% of patients presented fatigue at baseline, 6 months and 5 years of follow up respectively. At baseline, fatigue was independently and significantly associated with single patients (OR = 2.5 95% CI [1.42-3.33] $p < 0.001$), abnormal BMI (OR = 1.1 95% CI [1.01 – 1.10] $p = 0.007$), higher DAS28 (OR = 1.3 95% CI [1.08-1.60] $p = 0.006$), higher severity of morning stiffness (scored 0-10) (OR = 1.0 95% CI [1.00-1.01] $p = 0.012$), higher HAQ (OR = 2.4 95% CI [1.70-3.44] $p < 0.001$), negativity of FR (OR = 1.5 95% CI [1.09-2.29] $p = 0.016$) and history of depression or anxiety (OR = 6.1 95% CI [3.90-9.83] $p < 0.001$).

The most important predictors of fatigue over 5 years were disability ($p < 0.001$) and depression/anxiety ($p < 0.001$).

A 14.9% of patients presented persistent fatigue. Its independent predictors at 5 years of follow-up were HAQ (OR = 0.5 95% CI [1.66-3.73] $p < 0.001$), history of depression/anxiety (OR = 3.6 95% CI [1.48-8.82] $p = 0.005$), >3 comorbidity (OR = 2.1 95% CI [1.18- 3.66] $p = 0.010$), dry syndrome (OR = 2.3 95% CI [1.39- 4.17] $p = 0.002$), and anti CCP negativity (OR = 1.96 95% CI [1.1-3.44] $p = 0.021$).

Conclusion: Fatigue was a frequent symptom in this cohort of early RA patient; its presence decreased at 6 months and remained stable over time. Baseline fatigue and persistent fatigue were both predicted by functional impairment and history of depression or anxiety. Disease activity measured by DAS28 was strongly associated to fatigue at baseline but it was not a predictor of persistent fatigue.

Relationship between BMI and Lower Limb Dysfunction in Japanese Female Patients with Rheumatoid Arthritis (the data from NinJa registry)

Toshihiro Matsui¹, Atsushi Hashimoto¹, Kimio Masuda² and Shigeto Tohma³, ¹Rheumatology, National Hospital Organization Sagamihara Hospital, Sagamihara, Japan, ²Department of Rehabilitation Medicine, National Hospital Organization Sagamihara Hospital, Sagamihara, Japan, ³National Hospital Organization Tokyo Hospital, Sagamihara, Japan

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestions, and Outcomes Poster – ARHP

Session Type: ACR Poster Session B

Session Time: 9:00 AM-11:00 AM

Background/Purpose: To clarify the relationship between Body Mass Index (BMI) and lower limb dysfunction in patients with rheumatoid arthritis (RA).

Methods: The data of 8,332 Japanese female patients with RA registered in the nation-wide observational cohort of RA in Japan (National database of rheumatic diseases in Japan: NinJa) in 2015 were used in this study. According to the BMI category, they were divided into 4 groups; Underweight (n=1,275), Normal weight (n=5,538), Overweight (n=1287), and Obese (n=232). “Lower limbs dysfunction” was defined here as the values (≥ 2) of questionnaire related to the lower limbs function in health assessment questionnaire (HAQ). Operation related to the lower limbs included replacement of hip, knee, or ankle joint. We examined the relationship between BMI and lower limbs dysfunction and/or operation. This study was reviewed and approved by Research Ethics Committees in each facilities. Informed consent was obtained from all study participants. This study was conducted in accordance with the principles expressed in the Declaration of Helsinki.

Results: Rates of lower limbs dysfunction were significantly higher not only in Overweight (16.9%) and Obese (23.7%) but also in Underweight (17.3%) than in Normal weight (12.6%) ($p < 0.0001$). Operation rate of lower limbs was also significantly higher in Overweight (17.6%), Obese (20.3%) and Underweight (15.6%) than those in Normal weight (12.9%). Patients with operation showed significantly elder and longer disease duration than those without operation in all groups. Lower limbs dysfunction by disease duration was smallest in Normal weight except early onset patients. Compared with Normal weight, other groups showed higher values of DAS28-CRP and HAQ-DI.

Conclusion: This study indicated that both higher and lower BMI correlated with lower limbs dysfunction in female patients with RA. It is difficult to interpret whether this relationship is the cause or the result, but total care considering nutritional guidance and weight management is important as well as medication in RA patients.

Associations between Perceived Stress and Joint Signs in an Anti-Cyclic Citrullinated Peptide Antibody Positive at-Risk Population

Kristen J. Polinski¹, Elizabeth A. Bemis¹, M. Kristen Demoruelle², Marie L. Feser², LauraKay Moss², Jennifer Seifert², V. Michael Holers³, Kevin D. Deane² and Jill M. Norris¹, ¹Epidemiology, Colorado School of Public Health, Aurora, CO, ²Division of Rheumatology, University of Colorado Denver, Aurora, CO, ³Division of Rheumatology, University of Colorado School of Medicine, Aurora, CO

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestions, and Outcomes Poster – ARHP

Session Type: ACR Poster Session B

Session Time: 9:00 AM-11:00 AM

Background/Purpose: Psychosocial factors have been associated with rheumatoid arthritis (RA) outcomes, but have not been well characterized in the early development of RA. We examined the associations of perceived stress, measured by the Perceived Stress Scale-14 (PSS), with joint signs in an anti-cyclic citrullinated peptide (CCP) antibody positive population.

Methods: At community health fairs from 2014-2018, 56 subjects without previously diagnosed RA were found CCP positive through the CCP3 test (Inova). Subjects were recruited into a prospective cohort, and at their immediate post-health fair research visit (baseline) 14 had at least 1 tender joint, 7 had at least 1 swollen joint based on a rheumatologist exam, and 2 were classified as RA by 2010 ACR/EULAR Criteria only. The PSS responses were summed to obtain a total score, in which a higher score indicates greater perceived stress. Additionally, responses on the PSS underwent an explanatory factor analysis which suggested two meaningful factors: 1) perception of control, named ‘helplessness’ and 2) ability to cope with stress, named ‘self-efficacy.’ These factors align with other studies suggesting a two-factor structure for the PSS. T-tests and multivariable logistic regression assessed the associations of PSS-related scores with joint signs.

Results: Individuals with at least 1 tender joint compared to those without a tender joint have a higher total PSS score, higher helplessness or poor self-efficacy sub-scores (Table). A one point increase in the total PSS score was associated with a 12% increase in the odds of having a tender joint. Similarly, increases in the helplessness and self-efficacy sub-scores

were associated with a 16% and 21% increase in the odds of tender joints, respectively. A sensitivity analysis removing the two individuals with newly classified RA at their baseline visit found that the absolute differences in the mean total PSS and self-efficacy scores remained, while ORs were slightly attenuated and not significant.

Conclusion: In a cohort of untreated CCP positive individuals, we found a significant association between higher perceived stress and joint tenderness. The ability to cope or control stressors may be an important component of the evolution from CCP positivity to joint signs that could indicate early inflammatory arthritis even if a swollen joint consistent with clear inflammatory arthritis is not seen. Further longitudinal study is needed to better understand the direction of the relationships between these factors, underlying immune dysregulation and transitions to classified RA. This is important because a relationship between perceived stress and clinical signs of disease in individuals at-risk for developing RA may support the incorporation of stress-targeted therapy management and other global health improvement activities, with the potential for increased quality of life.

Table 1 Associations between PSS-related scores and Joint Signs

	At least 1 Tender Joint Sign (N=14)	No Tender Joint Signs (N=42)	Odds Ratio (95% CI)
Total PSS score, mean (SD)*	25.8 (6.8)	19.1 (9.2)	1.12 (1.02, 1.23)
PSS Helplessness score, mean (SD)*	14.1 (5.6)	10.1 (5.7)	1.16 (1.02, 1.32)
PSS Self-efficacy score, mean (SD)*	10.0 (3.7)	6.7 (4.6)	1.21 (1.01, 1.45)
	At least 1 Swollen Joint Sign (N=7)	At least 1 Swollen Joint Sign (N=49)	Odds Ratio (95% CI)
Total PSS score, mean (SD)	27.1 (7.8)	19.8 (9.0)	1.11 (0.95, 1.32)
PSS Helplessness score, mean (SD)	14.1 (5.6)	10.1 (5.7)	1.11 (0.98, 1.25)
PSS Self-efficacy score, mean (SD)*	11.3 (3.7)	7.0 (4.5)	1.28 (0.99, 1.67)

* indicates T-test p-value of <0.05 for comparison of mean PSS-related scores

Abbreviations: standard deviation (SD); odds ratio (OR); confidence interval (CI).

Odds ratios obtained from logistic regression models adjusted for age, race, and ever smoking status. The joints assessed on the examination include the elbow, wrist, metacarpophalangeal, proximal interphalangeal, and metatarsophalangeal.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestions, and Outcomes Poster – ARHP

Session Type: ACR Poster Session B

Session Time: 9:00 AM-11:00 AM

Background/Purpose: Depression is one of the most frequent comorbidity in RA patients. It's presence is associated with higher healthcare costs, mortality rate and reduced odds of achieving a good treatment response. The aim of our study was to determine the prevalence of depression in Argentinean patients with RA and to establish its relationship with different sociodemographic and clinical factors.

Methods: Consecutive patients ≥18 years old, with a diagnosis of RA according to ACR-EULAR2010 criteria were included. Sociodemographic data (sex, age, work and marital status, physical activity), comorbidities, RA characteristics (disease duration,

RF and anti-CCP, presence of erosions), disease activity (joint count (28), composite indexes, pain, patient's and physician's global assessment-NVS-, morning stiffness), CRP, ESR and current treatment were registered. Questionnaires were administered to assess quality of life by EQ-5D-3L and QOL-RA, functional capacity by HAQ-A and depression by PHQ-9. Major depression was defined as a PHQ-9 score ≥ 10 . PHQ-9 scores of 5-9, 10-14, 15-19, ≥ 20 represented mild, moderate, moderate/severe and severe depression, respectively. Patients with difficulties in answering the questionnaires (illiterate, blind) and with decompensated comorbidities were excluded. *Statistical analysis:* Student's T, ANOVA and χ^2 tests. Multiple logistic regression.

Results: 258 patients were included. 85.7% were females, with a median (*m*) age of 54 years (IQR 45-62) and *m* disease duration of 9 years (IQR 3.6-16.7). Disease activity by DAS28-ESR was *m* 3.5 (IQR 2.5-4.5). The *m* PHQ-9 score was 6 (IQR 2-12.3). The prevalence of mayor depression was 33.7%. 66 (25.6%), 42 (16.3%), 27 (10.5%) and 18 (7%) patients presented mild, moderate, moderate/severe and severe depression, respectively. Patients with mayor depression had worst functional capacity (HAQ mean 1.56 ± 0.78 vs 0.69 ± 0.65 , p 0.0001), poorer quality of life (QOL-RA mean 5.38 ± 1.78 vs 7.31 ± 1.61 , p 0.0001), more pain (NVS mean 56.15 ± 27.48 mm vs 33.42 ± 25.72 mm, p 0.0001) and higher disease activity (DAS28-ERS mean 4.33 ± 1.39 vs 3.3 ± 1.28 , p 0.0001). Unemployment, presence of comorbidities, and less physical activity were more frequent in this group. No differences between early arthritis patients (≤ 2 years) and established rheumatoid arthritis (> 2 years) were seen. In the multivariate analysis, worst functional capacity and quality of life were independently associated to the presence of mayor depression. Patients with moderate and severe depression had worse functional capacity, independently of disease activity. (Fig.1)

Conclusion: The prevalence of mayor depression measured by PHQ-9 score in this Argentinean cohort of rheumatoid arthritis patients was 33.7%. Patients with depression had a significant impact on functional capacity and quality of life regardless of disease activity.

The Relationship between Lipid Profile Changes and Inflammation across the Phase 3 Sarilumab Rheumatoid Arthritis (RA) Developmental Program

Christina Charles-Schoeman¹, Gregory St. John², Henry Leher², Toshio Kimura², Hubert van Hoogstraten³, Michael T. Nurmohamed⁴, Miguel Angel González-Gay⁵ and Edward C. Keystone⁶, ¹Rheumatology, UCLA David Geffen School of Medicine, Los Angeles, CA, ²Regeneron Pharmaceuticals, Inc., Tarrytown, NY, ³Sanofi Genzyme, Bridgewater, NJ, ⁴VU University Medical Center, Amsterdam, Netherlands, ⁵University Hospital Marques de Valdecilla, Santander, Spain, ⁶University of Toronto and Mount Sinai Hospital, Toronto, ON, Canada

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster II: PROs, Safety and Comorbidity

Session Type: ACR Poster Session B

Session Time: 9:00 AM-11:00 AM

Background/Purpose: Sarilumab showed superiority to placebo and adalimumab in Phase 3 trials. Serum lipids may be reduced in the setting of chronic inflammation associated with active RA and may increase following effective response to RA therapy. In this post hoc analysis we investigated the relationship between lipid levels and markers of inflammation.

Methods: Fasting total, HDL and LDL cholesterol, triglycerides, lipoprotein(a) (Lp(a)), and apolipoproteins (Apo) A and B were evaluated in two placebo-controlled studies of sarilumab (150 mg and 200 mg q2w) +csDMARDs inpatients with

inadequate response to MTX (MOBILITY; NCT01061736) or intolerance or inadequate response to TNF inhibitors (TARGET; NCT01709578) and a monotherapy study of sarilumab vs adalimumab (MONARCH; NCT02332590). Spearman and Pearson correlations compared relationships between lipid levels and inflammatory markers (CRP and SAA [MOBILITY only]).

Results: Safety has been previously reported with no evidence of increased risk of major adverse cardiac events with sarilumab.¹⁻³ In 52-wk MOBILITY (Figure) and 24-wk TARGET, both sarilumab doses led to increases in total cholesterol, HDL-C, LDL-C, and triglyceride levels vs placebo (as early as Wk 2), which were maintained throughout the studies. In MONARCH, sarilumab treatment led to a greater mg/dL increase from baseline in total cholesterol (16.3 vs 1.4), HDL-C (1.4 vs -0.2), LDL-C (10.5 vs 0.5), and triglycerides (26.6 vs 5.7) and a greater decrease in Lp(a) (-41% vs -2.8%).⁴ Changes from baseline in total cholesterol/HDL-C ratio for sarilumab 200 mg q2w vs placebo were 0.41 vs 0.01 (MOBILITY Wk 52), 0.32 vs -0.06 (TARGET Wk 24) and vs adalimumab were 0.22 vs 0.02 (Wk 24). Sarilumab reduced CRP and SAA (MOBILITY) vs placebo and adalimumab.⁴ Negative Spearman correlations ($P < 0.001$ or $P < 0.0001$) between decreases from baseline in CRP and increases in lipid levels were seen with sarilumab 200 mg q2w for total cholesterol (-0.26 [MOBILITY Wk 52] and -0.33 [TARGET Wk 24]), HDL-C (-0.26 TARGET Wk 24), LDL-C (-0.21 [MOBILITY Wk 24] and -0.25 [TARGET Wk 24]), and triglycerides (-0.21 [MOBILITY Wk 52]) and with adalimumab (data not shown).

Conclusion: Sarilumab, an IL-6R blocker recently approved for the treatment of RA, showed an increase in various lipid parameters vs placebo or adalimumab and reduction in Lp(a). This was seen relatively quickly and stabilized after 4 weeks. Lipid elevation was associated with a reduction in inflammatory markers and was consistent with IL-6 blockade.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster II: PROs, Safety and Comorbidity

Session Type: ACR Poster Session B

Session Time: 9:00 AM-11:00 AM

Background/Purpose: Musculoskeletal ultrasound (MSUS) can detect synovitis by Power doppler (PDUS) and can predict erosive progression on xrays in rheumatoid arthritis (RA) patients. We previously reported an association of active RA with impairment in HDL function, changes in HDL-associated protein levels, and suppression of paraoxonase-1 (PON1) activity, a novel risk factor for cardiovascular disease (CVD), which has been associated with carotid plaque in RA patients. In the current work, we evaluated an association of tocilizumab treatment with PDUS changes and the “protective profile” of HDL including HDL’s ability to inhibit low density lipoprotein (LDL) oxidation, PON1 activity, HDL-associated apoA-I (HDL-apoA-I) and haptoglobin (HDL-Hp) in patients with RA.

Methods: Assessment of PDUS was performed on 46 RA patients in a 6 month (mos) open-label study of IV tocilizumab initiated at 4mg/kg and dose escalated to 8mg/kg if DAS28 >3.2 at 12wks. 34 joints were scanned by MSUS (bilateral wrists, MCP1-5, PIP1-5, knees, and MTP2-5). PDUS was scored semiquantitatively according to published consensus definitions (*J Rheum.* 2005; 32:2485-7). HDL’s anti-oxidant function was measured by a cell free assay as described previously (*A&R* 2009; 60(10): 2870-9). PON1 activity was measured by previously published assays and HDL-associated apoA-I and Hp were measured by sandwich ELISA.

Results: Treatment with tocilizumab for 6 mos was associated with increases in traditional cholesterol levels including significant increases in HDL-C (baseline: 59± 23mg/dL; 6 mos: 71 ± 26 mg/dL, p<0.05), and improvements in HDL’s overall antioxidant function (baseline: 2347± 1710 FU; 6 mos: 1570 ± 1050 FU, p<0.05), increases in PON1 activity (baseline: 10.2± 3.8; 6 mos: 11.9 ± 4.4 , p<0.05), and trends for increases in HDL-apoA-I levels and decreases in HDL-Hp (p values >0.05). Greater decreases in PDUS scores over 6 mos were significantly associated with greater improvements in the HDL particle profile including increases in HDL-C (r= -0.32, p<0.05), PON1 activity (r= -0.30, p<0.05), HDL-apoA-I (r= -0.31, p<0.05), HDL’s anti-oxidant capacity (r= 0.38, p= 0.009) and trends for decreases in HDL-Hp (r= 0.24, p= 0.11). Associations between other disease assessments (DAS28 and CDAI) and HDL function/structure were noted, but were generally of lesser magnitude and consistency across the HDL profile. Increases in total and HDL-C levels with tocilizumab treatment were strongly correlated with improvement in HDL function (r= -0.41, p= 0.005, r= -0.60, p < 0.0001) and PON1 activity (r= 0.73, p< 0.0001, r= 0.43, p = 0.003).

Conclusion: Improvements in PDUS scores with tocilizumab treatment were significantly associated with improvements in the protective profile of HDL including increased HDL’s anti-oxidant capacity, PON1 activity, and HDL-apoA-I levels. This data supports previous work suggesting a direct association of joint inflammation with abnormal HDL function, and suggests that further evaluation of PDUS as a non-invasive CV risk assessment tool in RA may be warranted.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster II: PROs, Safety and Comorbidity

Session Type: ACR Poster Session B

Session Time: 9:00 AM-11:00 AM

Background/Purpose: In patients with RA treated with TNF- α inhibitors, a higher BMI has been associated with lower odds of achieving disease remission. We evaluated the effect of BMI on response to etanercept (ETN) treatment in women and men with RA, (a) during open-label treatment and (b) following dose reduction or dosing off in patients who achieved low disease activity (LDA) or remission.

Methods: In this post hoc analysis, data were collected from three randomized trials (PRESERVE, N=834; PRIZE, N=306; T2T, N=489) in which patients with RA were assigned to an open-label treatment with ETN (50 mg) and MTX for 24-52 weeks, followed by randomized double-blind treatment with ETN (25 mg or 50 mg) + MTX, placebo + MTX, or placebo for 28-52 weeks in those who achieved LDA or remission. Observed cases data were analyzed by BMI (<25 kg/m², \geq 25 and <30 kg/m², or \geq 30 kg/m²) for women and men separately, using a one-way analysis of covariance model for continuous variables and a logistic regression model for categorical variables. The outcomes included changes from baseline in Clinical Disease Activity Index (CDAI), 28-joint DAS with CRP level (DAS28 CRP) or ESR (DAS28 ESR), and HAQ –Disability Index (HAQ-DI), as well as the percentages of patients who achieved CDAI remission (CDAI \leq 2.8) or LDA (CDAI >2.8 and \leq 10). The analysis was sponsored by Pfizer Inc. Medical writing assistance was provided by Vojislav Pejović of Engage Scientific Services.

Results: In the open label periods of all three studies, there was no significant BMI effect on treatment response to ETN in male patients, except for CDAI remission at a single visit in PRIZE (Figure). In open-label periods of the PRIZE and T2T trials, a significantly smaller decrease in DAS28 CRP and DAS28 ESR in women with BMI \geq 30 kg/m², compared with the other two BMI categories, was observed at most visits. In addition, in PRIZE trial (but not in PRESERVE or T2T), women, but not men, with BMI \geq 30 kg/m² had a significantly smaller decrease in CDAI and HAQ-DI scores and lower rates of CDAI LDA at most visits, compared with their counterparts with BMI <30 kg/m². For CDA remission, there was evidence of the effect of BMI \geq 30 kg/m² in women in both PRIZE and PRESERVE (Figure). Overall, these nominally significant differences between women with BMI \geq 30 kg/m² and <30 kg/m² were transient: most of them diminished or were no longer significant toward the end of the open-label periods. In randomized, double-blind periods, there were no discernible trends attributable to BMI category in either women or men.

Conclusion: Results of this post hoc analysis suggest that, in men with RA, there was no impact of BMI on ETN efficacy. In women, there was evidence of a transient negative impact of BMI \geq 30 kg/m² on ETN efficacy in open-label periods, but it diminished by the end of the induction period and was not consistent across trials. There was no evidence of BMI effect in men or women during the double-blind periods.

Impact of Comorbidity Burden and Obesity on the Effectiveness of Tocilizumab in Patients with Rheumatoid Arthritis

Dimitrios A. Pappas¹, Carol J. Etzel², Margaux Crabtree³, Jennie H. Best⁴, Steve Zlotnick⁴ and Joel Kremer⁵, ¹Columbia University, New York, NY, ²Corrona LLC, Waltham, MA, ³Corrona, LLC, Waltham, MA, ⁴Genentech, Inc., South San Francisco, CA, ⁵Albany Medical College and The Center for Rheumatology, Albany, NY

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster II: PROs, Safety and Comorbidity

Session Type: ACR Poster Session B

Session Time: 9:00 AM-11:00 AM

Background/Purpose: Few real-world studies have evaluated the impact of comorbidity burden or obesity on the effectiveness of tocilizumab (TCZ) for the improvement of rheumatoid arthritis (RA) disease activity. This study compared the effectiveness of TCZ in treating RA in patients with high vs low comorbidity burden and in obese vs non obese patients in US clinical practice.

Methods: Patients in the Corrona RA registry who initiated TCZ and had follow-up visits at 6 and 12 months after initiation were included. To assess the impact of comorbidity burden on TCZ effectiveness, outcomes were stratified by patients with low Charlson Comorbidity Index (CCI = 1) vs high (CCI \geq 2). To assess the impact of obesity, outcomes were stratified by patients with BMI < 30 (non obese) vs \geq 30 (obese). The primary outcome was mean change in CDAI at 6 and 12 months. Secondary outcomes were mean change in HAQ, the proportions of patients with change \geq the minimum clinically important difference (MCID) in CDAI and HAQ and the proportion who achieved low disease activity (LDA);

CDAI ≤10). Baseline demographics, clinical characteristics, disease activity and treatment history in the comorbidity and BMI cohorts were compared separately using standardized differences; characteristics with |standardized difference| >0.1 were identified as covariates for inclusion in adjusted comparisons. Outcomes were compared between cohorts using two-sample *t*-tests or χ^2 tests in unadjusted analyses and linear or logistic regression models to adjust for covariates.

Table. Study Outcomes at 6 and 12 Months in Patients With RA Who Initiated TCZ, Stratified by Comorbidity Burden and Obesity Status

	Comorbidity Burden				Obesity			
	Low* (CCI† = 1) [n = 575]	High (CCI† ≥ 2) [n = 195]	Unadjusted Difference	Adjusted Difference‡	Nonobese* (BMI < 30) [n = 449]	Obese (BMI ≥ 30) [n = 356]	Unadjusted Difference	Adjusted Difference§
Outcomes at 6 Months¶

BMI, body mass index; CCI, Charlson Comorbidity Index; CDAI, Clinical Disease Activity Index; csDMARD, conventional synthetic disease-modifying antirheumatic drug; HAQ, Health Assessment Questionnaire; LDA, low disease activity; MCID, minimum clinically important difference; OR, odds ratio.

* Reference group.

† The CCI used for this analysis is a modified CCI and is the sum of prior reported comorbid conditions that are captured in Corrona at the time of drug initiation, including myocardial infarction, congestive heart failure, peripheral vascular disease, cerebrovascular disease, chronic obstructive pulmonary disease, peptic ulcer disease, diabetes mellitus, leukemia, lymphoma, solid tumor cancer (excluding nonmelanoma of the skin) and liver disease. The CCI also includes connective tissue disease, which was coded as 1 to account for rheumatoid arthritis.

‡ Adjusted for age, duration of RA, race, college educated, smoking status, alcohol consumption, BMI, work status, insurance type, number of prior csDMARDs, current csDMARD use, number of prior biologics used, current prednisone use, CDAI at initiation, HAQ at initiation, patient-reported fatigue at initiation and length of morning stiffness at initiation.

§ Adjusted for age, duration of RA, race, college educated, smoking status, work status, insurance type, comorbidity burden category at initiation, number of prior csDMARDs, current csDMARD use, number of prior biologics used, CDAI at initiation, HAQ at initiation, patient-reported fatigue at initiation and patient-reported pain at initiation.

¶ The 6-month visit occurred in a window of 4 to 8 months; the 12-month visit occurred in a window of 10 to 14 months.

¶ CDAI ≤ 10 at baseline, MCID = 2; CDAI > 10 to ≤ 22 at baseline, MCID = 6; CDAI > 22 at baseline, MCID = 11.

** MCID = 0.22.

** LDA, CDAI ≤ 10.

Results: Of 770 patients who initiated TCZ and had CCI data available at baseline (93.8% treated with intravenous [IV] TCZ and 6.2% with subcutaneous [SC] TCZ), 575 (74.7%) had a low CCI and 195 (25.3%) a high CCI. Patients with a high CCI were older (mean [SD] age, 61.5 [12.3] vs 56.9 [13.1] years), were more likely to be obese (52.8% vs 41.7%), had a longer disease duration (mean [SD], 12.8 [9.9] vs 11.6 [8.9] years) and had higher mean (SD) baseline CDAI (25.7 [13.4] vs 23.9 [13.9]) and HAQ (0.71 [0.57] vs 0.57 [0.51]) scores than those with a low CCI.

Of the 805 TCZ initiators with BMI data available at baseline (93.9% treated with IV TCZ and 6.1% with SC TCZ), 449 (55.8%) were not obese and 356 (44.2%) were obese. Obese patients were younger (56.7 [12.0] vs 59.0 [13.7] years), had shorter disease duration (11.4 [8.6] vs 12.6 [9.7] years) and had higher baseline CDAI (25.4 [14.3] vs 23.6 [13.4]) and HAQ (0.65 [0.53] vs 0.57 [0.53]) scores than non obese patients.

Patients in all cohorts had improvement from baseline in CDAI at 6 and 12 months, with no significant differences between those with a low vs high CCI or between obese vs non obese patients (Table). Secondary outcomes yielded similar results (Table).

Conclusion: In this real-world analysis, the effectiveness of TCZ for the improvement of RA disease activity was comparable among patients regardless of comorbidity burden or obesity.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Figure. (A) Interval and (B) Cumulative exposure estimates and IRs for Malignancies over 36 months

CI, confidence interval; IR, incidence rate; PY, patient-years

Session Title: Rheumatoid Arthritis – Treatments Poster II: PROs, Safety and Comorbidity

Session Type: ACR Poster Session B

Session Time: 9:00 AM-11:00 AM

Background/Purpose: Tofacitinib is an oral Janus kinase inhibitor for the treatment of RA. The efficacy and safety of tofacitinib have been demonstrated in patients (pts) with RA in global Phase (P)2, P3, and long-term extension (LTE) studies, and also in two P2 and one LTE study in Japanese pts. In this interim analysis (IA) of post-marketing surveillance (PMS) data, we report rates of serious adverse events (SAEs), malignancies, and deaths in Japanese pts with RA receiving tofacitinib.

Methods: All Japanese pts with RA receiving tofacitinib were prospectively registered in an ongoing three-year PMS study, and a 6-month IA of safety data was conducted (November 5, 2017 data-cut). All AEs were collected during tofacitinib treatment, and were coded using MedDRA ver.20.1. Follow-up surveillance after discontinuation of tofacitinib was conducted for serious infections, malignancy and death (up to 36 months). Incidences of malignancy or death were determined for the 6-month period. All-period (36-month) data were used to calculate cumulative incidence rates (IRs; pts with events/100 pt-years [PY]) over time for malignancies.

Results: Overall, 3929 pts received tofacitinib (1704.1 PY of exposure at six months). Mean age (standard deviation [SD]) was 62.7 (12.6) years, 80.5% of pts were female, and mean duration of RA was 11.8 years. A total of 3037 pts (77.3%) completed six months of treatment; 892 pts (22.7%) discontinued treatment, mainly due to AEs (351 pts; 8.9%), or lack of efficacy (335 pts; 8.5%). At least one AE (all causality) was observed in 1313 pts (33.4%). The most frequent AE by system organ class was Infections and Infestations (12.5%), and SAEs (all causality) occurred in 287 pts (7.3%). Over the six-month period, malignancy (all causality) was reported in 25 pts (0.6%); 12 cases were reported to be related to treatment. There were 21 deaths (0.5%) during the six-month period. The most common cause of death (including pts with multiple causes listed) was infection (six cases); malignancy was the second most common cause of death (five cases). From all-period (36-month) data, malignancies occurred in 61 pts (1.6%); gastric cancer occurred in eight pts (0.2%), lung neoplasm malignant in six pts (0.2%), breast cancer in five pts (0.1%), and diffuse large B-cell lymphoma, ovarian cancer, uterine cancer, colon cancer, and pancreatic carcinoma in four pts each (0.1%). Over 36 months, the IR of malignancy was 1.25 (61 pts; 4874 PY). The IR of malignancy did not increase in the time intervals representative of longer tofacitinib treatment, suggesting no cumulative toxicity related to malignancy, though exposure time for intervals were limited (Figure).

Conclusion: In this IA of tofacitinib PMS in Japanese pts with RA, rates of malignancies and death were comparable with those in the tofacitinib RA clinical program; no new or unexpected safety risks were identified.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster II: PROs, Safety and Comorbidity

Session Type: ACR Poster Session B

Session Time: 9:00 AM-11:00 AM

Background/Purpose: Tofacitinib is an oral Janus kinase inhibitor for the treatment of RA. Previously, the efficacy and safety of tofacitinib were demonstrated in patients (pts) with RA in global Phase (P)2, P3, and long-term extension (LTE) studies, and in Japanese pts with RA in two P2 studies and one LTE study. Safety is being evaluated in Japanese pts with RA in an ongoing three-year post-marketing surveillance (PMS) study. Here, we report incidence of serious infection events (SIEs), *Pneumocystis jirovecii* pneumonia (PCP), tuberculosis (TB), and herpes zoster (HZ) among Japanese pts with RA treated with tofacitinib, using interim PMS data.

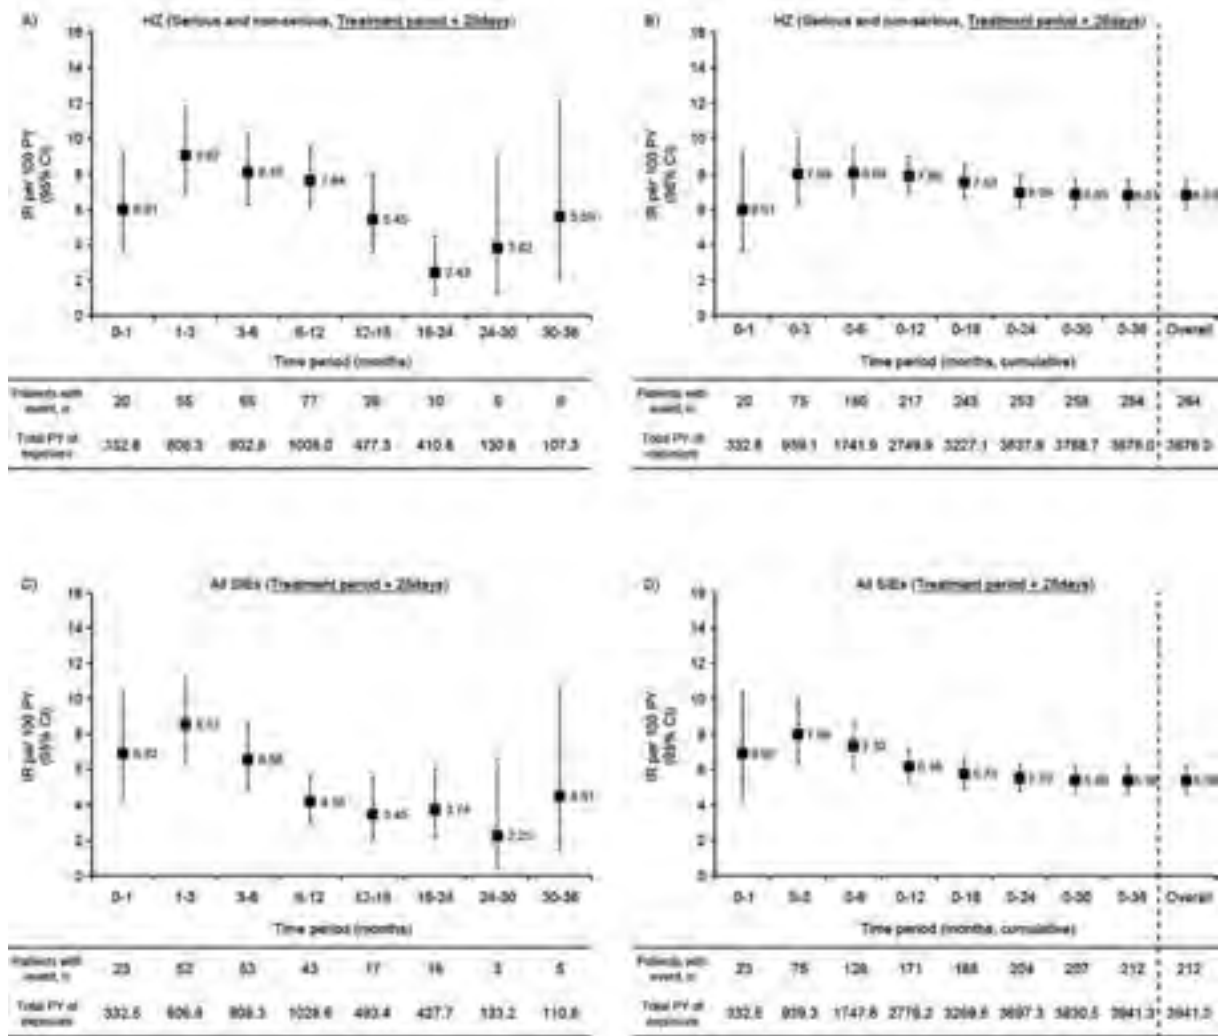

Methods: All pts treated with tofacitinib in Japan were consecutively registered in this PMS study. Adverse events (AEs) in pts with RA receiving tofacitinib were collected throughout the PMS study (36 months; data-cut: November 5, 2017), and were coded using MedDRA ver.20.1. For SIEs, follow-up surveillance after discontinuation of tofacitinib was conducted up to Month 12, and the frequency and types of SIEs, PCP, TB, and HZ are reported for the PMS first six-month observation period. All-period data (up to 36 months) were used to calculate cumulative incidence rates (IRs: pts with events/100 pt-years [PY]) over time for HZ and SIEs during treatment +28 days.

Results: In total, 3929 pts received tofacitinib (3956.4 PY of exposure at 36 months). At baseline, 80.5% of pts were female; mean age (standard deviation [SD]) was 62.7 (12.6) years; 32.6% of pts were ≥ 70 years. In the six-month observation period, 2041 AEs (all causality) were reported in 1313 (33.4%) pts. The most frequently reported AE by system organ class was Infections and Infestations (n=493; 12.5%) and the most frequently reported AE by preferred term was HZ (n=145; 3.7%), including one HZ meningoencephalitis (serious) and two disseminated HZ (one serious; one non-serious). PCP was reported in 16 (0.4%) pts (15 serious; one non-serious). There were three TB cases (including one serious bone tuberculosis); no pts with TB had received chemoprophylaxis with isoniazid before starting tofacitinib. At Month six, 130 (3.3%) pts had SIEs; most common by preferred term were HZ (n=24; 0.6%), pneumonia (n=23; 0.6%), PCP (n=15; 0.4%), and pneumonia bacterial (n=10; 0.3%). The IRs of HZ and SIE were highest at Months 1-3 and stabilized after Month 12 (all-period data; overall IR was 6.81 [n=264; 3876.0PY] and 5.38 [n=212; 3941.3 PY] for HZ and SIEs, respectively [Figure]).

Conclusion: This interim analysis of PMS data from Japan did not reveal any new or unexpected safety risks vs tofacitinib RA clinical trials, although exposure time was short. HZ IR was similar to that reported in P2, P3, and LTE trials in Japanese pts with RA; SIE IR was within the range of IRs in prior PMS studies of RA biologic treatment.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster II: PROs, Safety and Comorbidity

Session Type: ACR Poster Session B

Session Time: 9:00 AM-11:00 AM

Background/Purpose: The GO-FURTHER, GO-VIBRANT, and GO-ALIVE randomized controlled trials evaluated the efficacy and safety of intravenous (IV) golimumab (GLM) in patients (pts) with active rheumatoid arthritis (RA), psoriatic

arthritis (PsA), and ankylosing spondylitis (AS), respectively. This integrated analysis assessed safety events across indications in pts who received IV GLM.

Methods: Integrated safety data from 3 Phase 3, double-blind, placebo (PBO)-controlled trials were analyzed up to week (WK) 112 in RA pts and up to WK 60 in PsA and AS pts. Pts received either IV PBO or IV GLM (2 mg/kg) at 0, 4, 12, and 20 WKS. PBO pts crossed over to IV GLM at WK 24, except RA pts randomized to PBO who met early escape criteria crossed over at WK 16 and AS pts randomized to PBO who crossed over at WK 16. Cumulative adverse events (AEs) were reported by indication and pooled by treatment. Anti-drug antibodies (ADAs) were evaluated.

Results: Overall, 1248 pts were treated with IV GLM across indications. A numerically greater proportion (%) of IV GLM pts with RA reported safety events than pts with PsA or AS (Table 1): SAEs (18.2 vs 5.2 vs 3.4), infections (49.1 vs 22.8 vs 32.8), serious infections (6.2 vs 2.2 vs 1.5), and infusion reactions (4.6 vs 0.9 vs 1.5). Incidence (per 100 pt-years) of opportunistic infections, malignancy, active tuberculosis, and death with IV GLM was low (≤ 0.5) across indications (Table 2). Infections were the most commonly reported type of SAE among pooled IV GLM pts; the most frequent was pneumonia (10 [0.8%]). Incidence (per 100 pt-years) of serious infections was similar among IV GLM pts with and without corticosteroid use (3.35 vs 3.37, respectively). Overall, 1 IV GLM pt (PsA) experienced a demyelination event. A numerically greater proportion of IV GLM pts discontinued due to an AE than PBO pts (5.0% vs 0.9%, respectively). In IV GLM pts with baseline alanineaminotransferase (ALT) \leq upper limit of normal (ULN), 1.2% had post-baseline ALT elevations $\geq 5X$ ULN. The proportion of IV GLM and PBO pts with post-baseline ALT elevations $\geq 5X$ ULN was 2.1% vs 0% with methotrexate and 0.7% vs 1.4% without methotrexate use at baseline, respectively. Using a drug-tolerant enzyme immunoassay, the incidence of ADAs was 22% through WK 52 across indications, which primarily consisted of low titer ADAs.

Conclusion: IV GLM demonstrated a consistent safety profile across indications in the PBO-controlled (up to WK 24) and uncontrolled study periods. Similar to WK 24, more safety events occurred in RA pts, who represented the largest study population with older pts, longer disease duration, and more concomitant medication use.

Table 1 Summary of Adverse Events During the Placebo-controlled and Uncontrolled Study Periods

Variables	RAa IV GLM	PsAb IV GLM	ASb IV GLM	All IV GLM
Treated patients, n	584	460	204	1248
Average duration of follow up, wks	95.9	47.2	51.8	70.7
Patients who discontinued due to an AE	41 (7.0)	17 (3.7)	4 (2.0)	62 (5.0)
Patients with ≥ 1 AE	462 (79.1)	234 (50.9)	113 (55.4)	809 (64.8)
Patients with ≥ 1 SAE	106 (18.2)	24 (5.2)	7 (3.4)	137 (11.0)
Patients with ≥ 1 infection	287 (49.1)	105 (22.8)	67 (32.8)	459 (36.8)
Patients with ≥ 1 serious infection	36 (6.2)	10 (2.2)	3 (1.5)	49 (3.9)
Patients with ≥ 1 infusion reaction	27 (4.6)	4 (0.9)	3 (1.5)	34 (2.7)

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster II: PROs, Safety and Comorbidity

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The influence of obesity on treatment response of tumor necrosis factor inhibitors in patients with rheumatoid arthritis (RA) is described in literature, but data on Janus kinase inhibitors (JAKi) are scarce. We investigated the impact of obesity on the achievement of low disease activity (LDA = DAS28-ESR<3.2) in RA patients treated with JAKi.

Methods: In the German prospective longitudinal observational cohort RABBIT (Rheumatoid Arthritis: Observation of biologic therapy) RA patients are enrolled when they start a therapy with biologics, biosimilars, JAKi or new csDMARDs. We used RABBIT data reported between March 2017 and April 2018 of patients who started either baricitinib or tofacitinib. The time of JAKi treatment start was considered as baseline. Patients were stratified according to their BMI into normal weight (<25 mg/m²), overweight (25 - <30 mg/m²) and obese (≥30 mg/m²). Treatment response of patients with a baseline DAS28 ≥3.2 and available follow-up information within the first 6 months was investigated. Adjusted logistic regression models were applied to analyze the impact of BMI categories on LDA achievement (vs. non-response or stopping JAKi treatment).

Results: A total of N=539 patients started a treatment with JAKi; n=355 (66%) received baricitinib and n=184 (34%) tofacitinib. Baseline characteristics stratified by BMI category are given in table 1. Obese patients were not considerably older, but less often female compared to normal weight patients. Despite lower frequency of seropositivity, obese patients presented with higher values for DAS28 and fatigue, and had a worse physical function at baseline. Most of the patients received JAKi in recommended standard dosages.

Out of n=217 patients with available information, LDA was reached within the first 6 months of treatment by 42% of patients with normal weight and 41% with overweight, but only by 19% obese patients. Remission rates (DAS28<2.6) were 20%, 24% and 11% in the respective groups.

The regression model revealed a high negative impact of obesity on the achievement of LDA compared to normal weight (table 2). A better physical function at baseline and no prior biologic treatment increased the chance for LDA. We did not find an impact of JAKi dosage or mono-/ combination therapy on the response to treatment (data not shown).

Conclusion: Obesity but not overweight had a negative impact on the achievement of LDA in RA patients treated with JAKi. Further studies are needed to investigate factors that affect treatment response in obese patients.

Table 1 Baseline characteristics of patients starting JAKi stratified by BMI categories

	Normal weight N=204 (37.8%)	Overweight N=157 (29.1%)	Obesity N=158 (29.3%)
Age in years	57.9 ± 13.6	60.5 ± 11.3	59.6 ± 10.3
Female gender	169 (83.8%)	127 (72.8%)	109 (69.0%)

Session Title: Rheumatoid Arthritis – Treatments Poster II: PROs, Safety and Comorbidity

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Tofacitinib is an oral Janus kinase inhibitor for the treatment of RA. We explored characteristics of patients (pts) who discontinued (d/c) open-label, long-term extension (LTE) studies.

Methods: Data were pooled from 2 LTE studies (NCT00413699 [ORAL Sequel LTE main study database locked at time of analysis: March 2017] and NCT00661661) in pts with RA who participated in qualifying Phase 1/2/3 index studies. Pts (N=4967) received tofacitinib 5 or 10 mg BID as monotherapy or with conventional synthetic DMARDs. We analyzed pts who d/c within: ≤1 yr, >1–≤3yrs, and >3 yrs, and study completers (Table 1). BL was that of the index study if pts began LTE treatment within 14 days of completing index study. Otherwise, LTE BL values were used. Demographics, reasons for

discontinuation, disease activity (DAS28-4[ESR]), physical function (HAQ-DI), serology (CRP, RF, anti-cyclic citrullinated peptide [CCP]), concomitant medications, and treatment-emergent adverse events (TEAEs) were analyzed descriptively for all tofacitinib-treated pts.

Table 1. Baseline demographics and disease characteristics at baseline and adverse event summary for all tofacitinib-treated patients

	Discontinued ^a			Completed ^b

^aDiscontinued subgroups are defined based on the time of discontinuation during the active treatment period relative to baseline for the long-term extension study; values are from the last available visit before discontinuation.

^bCompleted subgroups are defined based on the time between enrollment and study completion for patients (completers) who remained in the study until the study was closed in their respective country, or who completed the study due to their respective country's regulatory authority's requirements.

^cN, the number of patients with non-missing data for a given analysis.

ΔCRP, change from baseline in C-reactive protein level; ΔDAS, change from baseline in disease activity score; ESR, erythrocyte sedimentation rate; ΔHAQ-DI, change from baseline in Health Assessment Questionnaire-Disability Index; SE, standard error; yrs, years.

Results: Of 4934 pts in this analysis, 2518 (51.0%) d/c (702 within<1 yr; 984 >1–≤3 yrs; 832 >3 yrs), predominantly due to AEs (n=1231; 48.9%), and 2416 (49.0%) pts were completers (Table 1); 33 pts ongoing in the LTE at database lock were not included. At BL, pts who d/c had numerically longer disease duration and more pts were from USA/Canada, current or ex-smokers, or used glucocorticoids than completers. Pts who d/c >1 yr had numerically lower values and a greater change from BL in CRP, DAS28-4(ESR), and HAQ-DI than pts who d/c ≤1yr, and had higher values and a lower change from BL than completers for all parameters (Table 2). TEAEs were reported by 91.4% of evaluable completers and 80.6%, 92.0%, and 97.0% of evaluable pts who d/c within ≤1, >1–≤3, and >3yrs, respectively. Of pts with TEAEs, 62.4%, 55.2%, and 46.8% d/c due to TEAEs within ≤1, >1–≤3, and >3 yrs, respectively. Among the most common TEAEs experienced by all groups were nasopharyngitis, upper respiratory tract infection, urinary tract infection, herpes zoster, and bronchitis. Pneumonia was more frequently observed in pts who d/c (5.7% [≤1 yr], 7.1% [>1–≤3 yrs], and 6.9% [>3 yrs]) than in completers (2.9%).

Conclusion: Pts who d/c had a longer disease duration at BL, and were more likely to use glucocorticoids, be smokers/ex-smokers, and be from USA/Canada than completers. Pts who d/c ≤1 year had higher disease activity than those who d/c >1 year; pts who d/c >1 year had higher disease activity than completers, supporting close monitoring of pts. Of pts with TEAEs, discontinuation due to TEAEs was more frequently observed in pts who d/c ≤1 yr.

DMARD Hepatotoxicity in Rheumatoid Arthritis and Its Association with the Surrogates of Metabolic Syndrome

Abhishek Nandan¹, Huzaifah Syed¹, Josna Haritha², David Maniscalco¹, Rabia Gill¹, Puneet Puri¹ and Vivana Rodriguez¹,
¹Virginia Commonwealth University Health System, Richmond, VA, ²University of Chicago Medicine, Chicago, IL

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster II: PROs, Safety and Comorbidity

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Hepatotoxicity is a common reason why DMARDs are abandoned or changed in RA. We hypothesize that features of metabolic syndrome (such as obesity, dyslipidemia, and diabetes) are risk factors for DMARD hepatotoxicity in RA.

Methods: We conducted a retrospective chart review of 361 patients with RA listed as the primary diagnosis code for ≥ 3 consecutive visits. Demographic information, BMI, lipid panel, prior alcohol use, smoking status, viral hepatitis serologies,

Figure 1: Adjusted Odds Ratios [OR] for DMARD Hepatotoxicity

Characteristic	Percentage
Gender	
Female	82.3
Male	17.7
Race	
African American	47.1
Asian	1.9
Caucasian	47.6
Other	3.3
BMI ^a	7.6
<25	31.2
25 - 35	53.6
≥35	15.1
Smoking status ^b	
Yes, current	24.4
Former	22.8
Never	52.8
Alcohol use ^c	
Active alcohol abuse	1.3
Previous alcohol abuse	3.5
Current use	42.2
No alcohol use	53.0
CCP +	50.7
RF +	51.9
Current statin	21.1
Reported diabetes mellitus II	17.8
DMARD started: methotrexate	57.3
DMARD started: leflunomide	6.4
DMARD started: hydroxychloroquine	40.7
DMARD changed / decreased due to hepatotoxicity	5.5

Table 1: Baseline Characteristics

statin use, seropositive status, and type of DMARD used were recorded at the initial visit. Patients with active hepatitis B and C were excluded from analysis. DMARD hepatotoxicity was defined as change of DMARD or dose decrease of DMARD with corresponding provider documentation of concern for hepatotoxicity. Using exact logistic regression, odds ratios for the risk factors of DMARD hepatotoxicity were calculated.

Results: Out of the 361 patients reviewed: 15.1% had BMI > 35 and 17.8% had a diagnosis of diabetes mellitus II. Table 1 has additional baseline information. 20 of 361 patients (5.5 %) had DMARD hepatotoxicity. Methotrexate (OR 3.07) and leflunomide (OR 6.11) were significantly associated with risk of DMARD hepatotoxicity. Figure 1 demonstrates the adjusted odds ratios for BMI, diabetes, and alcohol abuse as risk factors for DMARD hepatotoxicity. HDL ≤ 40 had an unadjusted OR of 2.98 (0.74 – 12; p 0.119) toward being a risk factor for DMARD hepatotoxicity. RF or anti-CCP seropositivity, statin-use, age, and sex did not demonstrate a correlation value to suggest they are risk factors.

Conclusion: Our study does suggest that several surrogates of metabolic syndrome such as BMI and diabetes mellitus are likely risk factors for development DMARD hepatotoxicity, especially with methotrexate and leflunomide. Though the study was underpowered for the statistical significance on some of these variables, clinicians should consider features of metabolic syndrome as potential risk factors for hepatotoxicity with DMARD use. Further studies need to be performed examining this relationship.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster II: PROs, Safety and Comorbidity

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Leptin is an adipokine that plays an important role in the regulation of body weight and also participates in immune homeostasis and inflammatory processes^{1,2}. Chronic systemic inflammation is of major importance in the development of atherosclerosis in rheumatoid arthritis (RA)³. IL-6 blocker yields a rapid improvement of endothelial function⁴. Therefore, the aim of this study was to determine whether the infusion of IL-6 blockade improves the endothelial function by altering circulating leptin concentrations in patients with RA.

Methods: 50 Spanish patients on treatment with anti-IL-6 monoclonal antibody-Tocilizumab who fulfilled the 2010 classification criteria for RA⁵ were recruited. Patients with diabetes mellitus or plasma glucose >110 mg/dl were excluded. Leptin serum levels were determined immediately prior to (time 0) and after (time 60 minutes) Tocilizumab infusion by ELISA.

Results: A significant reduction in leptin concentration was observed following Tocilizumab infusion (mean \pm standard deviation (SD): 9.24 ± 7.98 ng/ml versus 7.91 ± 7.36 ng/ml, $p < 0.0011$). In addition, a significant positive correlation between leptin concentration and insulin resistance (HOMA at the time of the study) was found ($r=0.40$; $p=0.0046$). Furthermore, a significant negative correlation between leptin levels and insulin sensitivity (QUICKI) was disclosed ($r = -0.46$; $p=0.0009$).

Conclusion: Our study confirms that circulating leptin concentrations are modulated by anti-IL-6 treatment. In addition, leptin concentration correlates with insulin resistance and sensitivity. The beneficial effect of anti-IL-6 blockage on cardiovascular mortality in RA may be mediated by reduction in serum levels of leptin.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster II: PROs, Safety and Comorbidity

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Biologic disease-modifying anti-rheumatic drugs (bDMARDs) are commonly used in the treatment of rheumatoid arthritis (RA). But the use of bDMARDs in patients with RA and cancer is controversial.

Methods: We performed a retrospective cohort study of patients with prevalent RA and cancer seen at MD Anderson Cancer Center between 2002 and 2014. Cancer patients were identified from the institutional tumor registry and RA patients were identified through ICD-9 codes and verified by chart review. Patients were followed until 2016 to assess overall survival (OS). We built Cox Proportional Hazard regression models using bDMARD therapy as a time-varying covariate.

Results: We identified 431 patients with RA of which 111 received bDMARDs at various times after a cancer diagnosis. Of these 111 patients, 60 received bDMARDs prior to the cancer diagnosis and remained on bDMARDs following the cancer diagnosis. In a multivariable model stratified by tumor type and stage and after adjusting for age at diagnosis, OS in patients that received tumor necrosis factor (TNF) inhibitors was compared to patients who never received bDMARDs with a hazard ratio (HR) of 0.67 (95% confidence interval (CI), 0.31, 1.44). Patients who received non-TNF bDMARDs had a HR of 1.10 (95% CI, 0.26, 4.60) compared to those without treatment. These differences were not statistically significant (overall effect $p=0.58$). We evaluated the effects of bDMARDs in a subgroup of 175 breast cancer patients (the largest subgroup, to remove the confounding effect of tumor type on OS) with RA. Of these patients 25% ($n=44$) received bDMARDs, 35 received TNF inhibitors and 9 received non-TNF bDMARDs. Fifty-two percent of these patients were on bDMARDs prior to cancer and continued after a cancer diagnosis. Another 16% were started on bDMARDs within the first 5 years after cancer diagnosis and the remaining 32% received the first dose > 5 years after cancer diagnosis. Only two patients with distant stage received bDMARDs. In a multivariable model, after adjusting for age at diagnosis and tumor stage, compared to the patients who never received bDMARDs, the patients who received TNF inhibitors (HR, 1.21; 95% CI, 0.38, 3.87) or non-TNF bDMARDs (HR, 1.86; 95% CI, 0.34, 10.3) had inferior OS. However, these differences were not statistically significant (overall effect $p=0.75$).

Conclusion: We did not observe any statistically significant differences in OS between those that received bDMARDs and those that did not in patients with RA and cancer. More research is necessary to evaluate the effects of bDMARDs in a larger sample of cancer patients, especially with respect to individual tumors, and also in those with early or advanced cancer.

Pain Is Improved in Around 50% of Patients and Fatigue in 40% of Patients with Rheumatoid Arthritis Treated with Sarilumab in the Target, Mobility and Monarch Trials

Laure Gossec^{1,2}, Susan Boklage³, Gregory St. John³, Hubert van Hoogstraten⁴ and Toshio Kimura³, ¹Sorbonne Universités, Paris, France, ²Stanford University, Palo Alto, CA, ³Regeneron Pharmaceuticals, Inc., Tarrytown, NY, ⁴Sanofi Genzyme, Bridgewater, NJ

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster II: PROs, Safety and Comorbidity

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Pain and fatigue are common symptoms of rheumatoid arthritis (RA) and can severely impact patients' quality of life. With multiple biologic disease-modifying antirheumatic drugs (bDMARDs) available for RA, symptoms such as pain and fatigue may play an increasing role in shared decision-making. Sarilumab is a human monoclonal antibody that blocks interleukin-6 (IL-6) from binding to both membrane-bound and soluble IL-6 receptor- α ; it is indicated for the treatment of moderate-to-severely active RA in adult patients who have had an inadequate response to ≥ 1 DMARDs. The objective of this study was to explore the effect of sarilumab on pain and fatigue in patients with moderate-to-severely active RA.

Methods: *Post hoc* statistical analyses were performed using data from sarilumab randomized controlled trials: TARGET (NCT01709578) and MOBILITY (NCT01061736) (sarilumab 150 or 200 mg every 2 weeks [q2w] vs placebo, combined with conventional synthetic DMARDs), and MONARCH (NCT02332590), (sarilumab 200 mg q2w vs adalimumab 40 mg q2w). At each study visit, pain was assessed using a 0–100 mm visual analog scale (VAS); fatigue was assessed using the Functional Assessment of Chronic Illness Therapy-Fatigue (FACIT-F) scale. The proportion of patients achieving $\geq 30\%$ / $\geq 50\%$ / $\geq 70\%$ pain VAS and FACIT-F improvement, and median time to first pain VAS and FACIT-F $\geq 50\%$ improvement was assessed at Week 24 in TARGET and MONARCH, and Weeks 24 and 52 in MOBILITY (not pooled). Median time to first pain VAS and FACIT-F $\geq 50\%$ improvement was analyzed by Kaplan–Meier. *P*-values were considered nominal.

Table. Pain and fatigue 30%/50%/70% improvement in TARGET, MOBILITY, and MONARCH

	30% improvement			50% improvement			70% improvement

Sarilumab 150 mg + MTX (Week 52)	35.9	1.84 (1.31, 2.61)	0.0001	27.3	2.19 (1.43, 3.38)	<0.0001	17.3	1.87 (1.24, 2.81)	0.0027
Sarilumab 200 mg + MTX (Week 52)	35.8	1.87 (1.37, 2.55)	<0.0001	27.3	2.11 (1.46, 3.03)	<0.0001	21.3	2.59 (1.58, 4.38)	<0.0001
MOBILITY²									
Adalimumab 40 mg	44.3			32.4			50.2		
Sarilumab 200 mg	51.7	1.50 (1.07, 2.08)	0.0190	48.2	1.85 (1.03, 3.31)	0.0330	28.8	1.52 (0.88, 2.63)	0.2032

cDMARDs: conventional synthetic disease-modifying antirheumatic drugs; MTX: methotrexate; OR, odds ratio.
Data reported at Week 24 (Week 52/Week 52).
¹Values placebo; ²Values sarilumab 150 mg/sarilumab 200 mg.

Results: 546 patients from TARGET, 1197 from MOBILITY, and 369 from MONARCH were included. In TARGET and MOBILITY, more patients receiving sarilumab 150 or 200 mg achieved $\geq 30\%$ / $\geq 50\%$ / $\geq 70\%$ improvements in pain and fatigue than placebo. In MONARCH, more patients receiving sarilumab 200 mg achieved $\geq 30\%$ / $\geq 50\%$ / $\geq 70\%$ improvements in pain and fatigue than adalimumab. (**Table**). Overall, pain was improved by at least 30% in around 50% of patients and fatigue in 40% of patients (**Table**). Median time to first pain $\geq 50\%$ improvement was shorter for patients receiving sarilumab 200 mg than both placebo (12 vs 24 weeks) in TARGET and MOBILITY or adalimumab (12 vs 16 weeks) in MONARCH. Median time to first fatigue $\geq 50\%$ improvement was shorter for patients receiving sarilumab 200 mg vs placebo (TARGET: 12 vs 24 weeks, MOBILITY 52 weeks vs not reached) with no significant advantage vs adalimumab. In these clinical studies, sarilumab had a safety profile consistent with IL-6 inhibition.

Conclusion: In this study of patients with moderate-to-severely active RA, sarilumab demonstrated faster and greater pain improvement vs placebo or adalimumab. In addition, sarilumab demonstrated faster and greater fatigue improvement vs placebo but not adalimumab. These results are important to consider in RA treatment decision-making.

Session Title: Rheumatoid Arthritis – Treatments Poster II: PROs, Safety and Comorbidity

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Two JAK inhibitors are currently approved by different agencies worldwide for their use in patients with rheumatoid arthritis. The safety profile of these agents has been of interest since the approval of the first JAK inhibitor, particularly the risk of developing malignancies or serious infections. Therefore, we conducted a systematic review and meta-analysis of phase 2 and phase 3 trials to evaluate these two outcomes in patients receiving JAK inhibitors for rheumatoid arthritis.

Methods: We performed a search in 5 electronic databases and also searched <http://clinicaltrials.gov/>, Food and Drug Administration, and European Medicines Agency. In addition, the bibliography list of included studies was also screened to search for further citations not retrieved from other sources. We included controlled trials evaluating the efficacy of a JAK inhibitor (i.e., tofacitinib, baricitinib, filgotinib, peficitinib, ABT-494, or decenotinib). Two reviewers independently screened studies, evaluated their risk of bias, and extracted data. Primary outcome data included number and type of malignancies and infections and time point of occurrence when available. The reported publications were considered the primary source of data for all trials. Serious infections were defined as those meeting the criteria for a serious adverse event such as a fatal, life threatening, or leading to hospitalization.

Results: Thirty-six trials were analyzed, reporting data on 15,602 patients. Follow-up of the included trials ranged between 4 and 52 weeks with a median of 24 weeks. The risk of attrition bias was judged low for most studies. The reported rates of malignancies and serious infections across studies ranged from 0% to 1.7% and 0% to 5.5%, respectively. Most commonly reported malignancies were lung cancer, melanoma, non melanoma skin cancer, basal cell and squamous cell carcinoma. Patients receiving the combination of JAK inhibitor plus methotrexate or JAK inhibitor monotherapy had higher rates of malignancies, compared with methotrexate between 12 and 24 weeks before the rescue treatment was

implemented, but the difference did not reach statistical significance (odds ratio (OR) 1.92, 95% confidence interval (CI) 0.78 to 4.76 and 1.40, 95% CI 0.26 to 7.59, respectively). Regarding serious infections, the JAK inhibitor groups had similar rates to those observed in the control groups (OR 1.07, 95%CI, 0.68 to 1.67, and 0.95, 95% CI, 0.46 to 1.98, respectively). However, there was a dose-response effect with higher rates of serious infections observed in those patients receiving higher doses of JAK inhibitors.

Conclusion: Although not reaching statistical significance, in the currently available RCTs, the rates of malignancy were higher in the JAK inhibitors groups compared to their controls. The rates of serious infections were similar between JAK inhibitor groups and their controls, but were dose-dependent. Future studies should aim to indirectly compare each JAK inhibitor to evaluate if these safety signals are also drug dependent and to assess risk per type of malignancy or infection.

Effect of JAK-Inhibitor Versus Bdmards on Quality of Life in Rheumatoid Arthritis : A Meta Analysis of Randomized Controlled Trials

Mamadaly Boudhabhay¹, Thomas Barnetche² and Pascale Vergne-Salle³, ¹CHU de Limoges, Limoges, France, ²Rheumatology Department, FHU ACRONIM, Bordeaux University Hospital, Bordeaux, France, ³Rheumatology, CHU de Limoges, Limoges, France

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster II: PROs, Safety and Comorbidity

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Recent studies comparing JAK-inhibitors (Jak-i) and adalimumab seem to show a better efficacy of JAK-i on patient-reported outcomes in rheumatoid arthritis (RA). As there is no study comparing directly the JAK-i with other biologic DMARDs (bDMARDs), we performed a meta-analysis and compared the effect size of JAK-i and bDMARD versus synthetic DMARDs (sDMARDs) on quality of life

Methods: We performed a systematic review of the literature until May 2018 using database including : MEDLINE (via PUBMED), EMBASE and abstracts from the ACR and EULAR congresses 2015-2017. We selected all randomized controlled trials (RCT) comparing quality of life (evaluated by SF36) in patient with rheumatoid arthritis treated with bDMARD or JAK-i versus sDMARDs. We performed meta-analysis comparing the effect size of JAK-i (versus sDMARDs) and bDMARD (versus sDMARDs) on PCS SF36 and MCS SF36 at 12 weeks. Statistical analysis determined in each study effect size. Pooled ES were computed by meta-analysis. Data were analyzed using the inverse variance approach.

Results: The literature search identified 240 articles plus one found by manuel search and no congress abstract. Finally, 44 articles met the inclusion criteria.

JAK-i and bDMARD showed higher level of quality of life than sDMARDs. The results concerning the meta-analysis comparing the effect size are:

- For the SF36 PCS at 12 weeks: JAK-i: +4,82 IC95% [3,88, 5,77] and bDMARDs : +3,99 IC95% [2,81, 5,18]
- For the SF36 MCS a 12 weeks: JAK-i: +3,42 IC95% [2,24, 4,60] and bDMARD: 2,99 IC95% [2,02, 3,96]

The range of the confidence intervals seems similar between JAK-I and bDMARDs.

SF36 PCS at 12 weeks:

-Results for JAK-i:

Conclusion: In this meta-analysis, JAK-inhibitor and bDMARD showed better SF36 PCS and MCS at 12 weeks in comparison with sDMARDs.

The range of the confidence intervals seems similar between JAK-I and bDMARDs, suggesting a similar efficiency on the components of the SF36.

More head-to-head studies are needed to draw definitive conclusions on potential efficacy differences between JAK-inhibitor and bDMARDs in RA.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster II: PROs, Safety and Comorbidity

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Tofacitinib is an oral Janus kinase inhibitor for the treatment of RA. The purpose of this study is to describe the profile of patients (pts) with RA and clinically significant anemia, and the impact of tofacitinib on those with anemia.

Methods: In this post hoc analysis, data were pooled from Phase (P)2, P3, and P3b/4 studies across the tofacitinib clinical program. Pts received tofacitinib 5 or 10 mg BID with/without background csDMARDs, or placebo (PBO). Pts with grade ≥ 2 anemia (G2A; Hgb < 10 g/dL) at baseline (BL) were compared to pts without G2A (Hgb ≥ 10 g/dL) at BL. Demographic and BL characteristics, Hgb levels and efficacy (DAS28-4[ESR]) at Month (M)6, and treatment-emergent adverse events (TEAEs) were summarized descriptively.

Results: The proportion of pts with G2A at BL was similar for tofacitinib (3.2%, 152 of 4736 pts) and PBO (2.4%, 27 of 1125 pts) groups. Presence of G2A at BL was higher in those with female gender, Asian ethnicity, never smoker status, lower age and BMI, and higher CRP and ESR, compared to pts without G2A; RA duration was generally similar across groups (Table). Tofacitinib seemed to improve anemia more rapidly than PBO: among pts with G2A at BL, a lower proportion of those receiving tofacitinib had G2A at M1 and M3 compared with those receiving PBO (48.8 vs 75.0% and 36.1 vs 57.1%), while the proportions were similar at M6 (28.9 vs 30.6%). Among pts receiving tofacitinib, mean Hgb levels gradually increased from BL to M6 in those with G2A at BL (1.25 g/dL change), but not in those without G2A at BL (0.15 g/dL change). In pts receiving tofacitinib with and without G2A at BL, DAS28-4(ESR) scores decreased from BL to M6 by -2.40 and -2.42, respectively. DAS28-4(ESR) low disease activity rate at M6 was lower in tofacitinib-treated pts with G2A at BL than in those without G2A at BL (18.3 vs 28.4%). Among pts receiving tofacitinib, those with BL G2A had a higher incidence of TEAEs than those without BL G2A in the following MedDRA system organ classes (with incidence $> 20\%$ in pts with and without BL G2A): gastrointestinal disorders (30.9% vs 22.5%) and infections and infestations (44.1% vs 39.0%).

Conclusion: In these studies, female gender, Asian ethnicity, never smoker status, low BMI and elevated ESR/CRP seemed to be associated with G2A at BL. G2A resolved within 6 months in most pts with RA receiving tofacitinib, while inflammation and disease activity (assessed by DAS28-4[ESR] scores) decreased. G2A appeared to resolve more rapidly in pts receiving tofacitinib than in those receiving PBO. These data suggest that tofacitinib can be a treatment option for pts with active RA and anemia. In pts with Hgb < 8 g/dL or a decrease in Hgb > 2 g/dL, however, it is recommended that tofacitinib dosing is interrupted until Hgb levels have normalized.¹

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster II: PROs, Safety and Comorbidity

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatologists need to develop primary and secondary prevention strategies for cardiovascular disease (CVD) in rheumatoid arthritis (RA) patients. We reported tofacitinib (Tofa) (with or without methotrexate) improved left ventricular mass index (LVMI) in patients with rheumatoid arthritis^{1,2}. We have experienced RA patient with chronic heart failure (CHF). We couldn't use some TNF blockers in RA patients with CHF³. There is no evidence that Tofa effects on left ventricular (LV) morphology and function in RA patients with CHF. To study the effect of Tofa on LV morphology and function in conventional synthetic (cs) DMARDs resistant active RA patients with CHF, in a cohort study design.

Methods: RA patients with CHF were eligible if they had active disease despite treatment with cs DMARDs. Consecutive 42 patients with moderate to severe active RA patients (DAS28>3.2) despite cs DMARDs were received Tofa plus cs DMARDs. LV morphology and function was assessed with cardio-MRI at baseline and 24 weeks follow-up. Cardiovascular risk factors and clinical data were collected at regular visits.

Results: 37 patients completed 24 weeks. New York heart association functional classification (NYHA) class 1 is 24 cases, class 2 is 9 cases, and class 3 is 4 cases respectively. Left ventricular mass index (LVMI) was attenuated significantly by Tofa (week 0-week24, -9.45 ± 7.8 g/m²; $p=0.02$). Cardiac output (CO) was attenuated significantly by Tofa (week 0-week24, 0.4234 ± 1.1 l/min). DAS28 and CRP improved significantly by Tofa (week 0-week 24; DAS28: -1.96 ± 0.88 ; CRP: -2.11 ± 5.7 mg/l) ($p<0.05$). Surprisingly, the change of disease activity (DAS 28 and CRP) is no correlation with the change of LVMI or CO in this study. Observationally, 3 cases significantly improved right ventricular mass as well as left ventricular mass (10 % improved right ventricular mass index from baseline).

Conclusion: Tofa improved LVMI and CO in active RA despite cs DMARDs with CHF. Tofa might be improving LVMI and CO independently of its effects on disease activity. Tofa might be improved right ventricular mass. JAK-STAT pathway might be an important role of LV hypertrophy. Tofa, JAK-STAT pathway blocking, may prevent cardiovascular morbidity and mortality in RA with CHF.

SESSION INFORMATION

Session Date: Monday, October 22, 2018
Session Title: Rheumatoid Arthritis – Treatments Poster II: PROs, Safety and Comorbidity
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Anemia (WHO criteria: Hemoglobin [Hb] levels <12.0 g/dL [females] or <13.0 g/dL [males]) is a common finding associated with increased joint inflammation in patients with RA and changes in Hb levels are associated with changes in disease activity; therefore, the influence of sarilumab on Hb is of clinical interest. This post hoc analysis assessed potential relationships between Hb, disease activity, and physical function in the adalimumab-controlled MONARCH study (NCT02332590).

Methods: In the MONARCH study, adult patients intolerant of, inappropriate for, or inadequate responders to methotrexate were randomized to SC sarilumab 200 mg q2w or adalimumab 40 mg q2w monotherapy for 24 wks. The primary endpoint was change from baseline in DAS28-ESR at Wk 24. Post hoc analyses were conducted on changes in Hb using a mixed-effects model for repeated measures assuming an unstructured covariance structure: Model = baseline, treatment, region, visit, and treatment-by-visit interaction. Missing data were not imputed. Proportion of anemic patients was summarized by visit. Relationships between Hb and efficacy measures were explored.

Results: At baseline, mean Hb levels were 13.0 g/dL in sarilumab(n=184) and adalimumab (n=185) groups and 25% of patients had anemia (WHO criteria). For the primary endpoint of change from baseline in DAS28-ESR, sarilumab was superior to adalimumab (−3.28 vs −2.20; $P<0.0001$). Compared with adalimumab, at Wks 12 and 24, sarilumab resulted in larger increases in Hb (Wk 24 least squares mean change from baseline 0.591 vs 0.075 g/dL; least squares mean difference 0.516 [95% CI: 0.319, 0.713]; nominal $P<0.001$ [Figure]). By Wk 24, 16.2% of adalimumab-treated and 10.9% of sarilumab-treated patients were classified with anemia. In the adalimumab group, at Wk 24, correlations between increases in Hb and decreases in markers of disease activity and physical disability were noted (Figure). In the sarilumab group, increases in Hb and decreases in disease activity and physical disability were not correlated. Most common adverse events were neutropenia and injection-site reactions (sarilumab) and headache and worsening RA (adalimumab). There were three adverse event reports of anemia (none were serious or led to treatment discontinuation): 1 report of microcytic anemia (adalimumab) and 2 of worsening of anemia (sarilumab). Decreases from baseline in hepcidin and ferritin were similar for sarilumab and adalimumab at Wk 2, but not measured thereafter.

Conclusion: Sarilumab treatment was associated with larger increases in Hb and reductions in patients with anemia than adalimumab, unrelated to its better control of RA disease activity. Sarilumab appears to be a good treatment choice in patients with RA and anemia.

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster II: PROs, Safety and Comorbidity

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The incidence of adverse events (AE) among rheumatology medication users has not been well documented in real-world disease registry datasets in the US. We quantified the incidence of AEs of interest among rheumatoid arthritis (RA) patients treated with adalimumab in the Corrona RA registry.

Methods: Adult RA patients from the US Corrona RAregistry who initiated treatment with adalimumab between 1/1/2008 and 6/1/2017 and had at least one follow-up visit were included. AE of interest included serious infections, malignancy (excluding non-melanoma skin cancer), hospitalized congestive heart failure (CHF) and all-cause mortality. The incidence of patients experiencing at least one new event of that type was calculated. Person-time at risk was estimated from time of drug initiation to either the occurrence of first event or 90 days after discontinuation of adalimumab (serious infections and hospitalized CHF) or last Corrona visit (censored). All time post adalimumab initiation regardless of discontinuation was considered for both malignancy and mortality. Incidence rates (IR) per 100 person-years were calculated with 95% confidence intervals assuming a Poisson distribution.

Results: There were 2798 adalimumab initiators available for analysis with mean age of 54.5 years, 77% were female, and mean duration of disease was 8.3 years. Nearly half (48%) were biologic naïve at the time of adalimumab initiation. Prednisone use of ≥ 10 mg occurred in 9% of patients at the time of adalimumab initiation and the majority of the patients (74%) used adalimumab for 3 years or less.

The IR per 100 person years for serious infections, CHF requiring hospitalization, malignancy excluding non-melanoma skin cancers, and all-cause mortality were 1.86 (1.50, 2.31), 0.15 (0.07, 0.31), 0.64 (0.50, 0.84), 0.33(0.24, 0.48), respectively. The incidence of events by duration of adalimumab exposure categories (≤ 1 year, >1 -3 years, >3 -5 years, > 5 years) are provided in the Table. Serious infection was higher in the first year of therapy (3.44 [95% CI 2.45-4.84) and other AEs did not vary by duration of exposure.

Conclusion: The IR of serious infection, CHF, malignancy and mortality in this prospective real-world registry are reassuring as they appear consistent with adalimumab RA clinical trial data and other observational registry data.¹⁻⁴

Table. Incidence of events by subgroups of overall exposure to adalimumab

	Adalimumab initiators	
	# Events	Unadjusted Rate (95% CI) Events/100 PYs
Serious Infections*		
≤1 year	33	3.44 (2.45-4.84)
>1-3 years	30	2.03 (1.42-2.90)
>3-5 years	15	1.40 (0.84-2.32)
>5 years	5	0.53 (0.22-1.28)
Congestive heart failure requiring hospitalization		
≤1 year	2	0.20 (0.05-0.80)
>1-3 years	3	0.19 (0.06-0.59)
>3-5 years	1	0.09 (0.01-0.62)
>5 years	1	0.10 (0.01-0.71)
Malignancy**		
≤1 year	29	0.73 (0.51-1.05)
>1-3 years	17	0.69 (0.43-1.12)
>3-5 years	8	0.63 (0.32-1.26)
>5 years	2	0.20 (0.05-0.80)
Mortality		
≤1 year	15	0.35(0.21-0.58)
>1-3 years	11	0.42 (0.23-0.76)
>3-5 years	4	0.29 (0.11-0.79)
>5 years	1	0.10 (0.01-0.68)

* Serious Infections included infections that led to hospitalization or IV antibiotics. **Malignancy excluded NMSC.

CRP Changes during Bacterial Infections in Baricitinib-Treated Patients with RA

Oliver Hendricks¹, Stavros Chrysidis², Jens Gerwien³, Chadi Saifan³, Francesco de Leonardis³, Pedro Lopez-Romero³, Jinglin Zhong⁴, Kevin Winthrop⁵ and Josef S. Smolen⁶, ¹King Chr.Xs Rheumatology Hospital, Graasten, Denmark, ²Rheumatology Department Sydvestjysk Sygehus, Esbjerg, Denmark, ³Eli Lilly and Company, Indianapolis, IN, ⁴Quintiles, Rockville, MD, ⁵Oregon Health Sciences University, Portland, OR, ⁶Division of Rheumatology, Department of Medicine 3, Medical University of Vienna, Vienna, Austria

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster II: PROs, Safety and Comorbidity

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Baricitinib (BARI) is a selective inhibitor of Janus kinase 1/2, modulating responses to inflammatory cytokines, e.g. IL-6 or IFNs¹. During acute inflammation, including those caused by bacterial infections (BI), IL-6 induces hepatic CRP synthesis; elevated CRP levels often represent a non specific, yet clinically useful marker of infections². IL-6 blockers can lead to blunting of CRP signals^{3,4}. This analysis evaluated CRP levels during BI in RA patients treated with BARI or placebo (PBO).

Methods: Using a high sensitivity (hs) assay, CRP values were obtained from patients with moderate to severe active RA pooled from the BEAM, BUILD and BEACON studies who were treated with BARI 4-mg or PBO for 24 weeks and had BI TEAEs (Tab.1). Patient inclusion was based on the experience of ≥1 BI before rescue and availability of a CRP measure within ± 3 days of the start of the BI. Multiple CRP measures per patient were aggregated into the median resulting in 2 observations per patient corresponding to the infection and infection-free period (Fig.1). Paired comparisons

Fig.1. Distribution of the CRP (mg/L) Values per Patient within Treatment and Infection Status

Footnote to Fig.1: CRP values during bacterial infection period (measured \pm 3 days around the start of infectious TEAE) and during infection-free period (measured \pm 2 weeks of bacterial infectious TEAE) are shown. During the infection period, only 3 patients (2 BARI, 1 PBO-treated) had 2 CRP measures; all others had 1 CRP. During the infection-free period, all patients had multiple CRP measures. Multiple CRP measures per patient were aggregated into the median, resulting in 2 observations per patient corresponding to the infection and infection-free period, shown as blue dots in Fig.1. For each treatment, the p-values correspond to the comparisons of CRP within patients between infection and infection-free period from Wilcoxon Signed-Rank test.

Tab.1: Preferred terms* for bacterial infectious events

<p>Acute tonsillitis, Arthritis infective, Atypical pneumonia, Bacterial infection, Bronchitis bacterial, Brochococciuria, Campylobacter gastroenteritis, Cellulitis, Cystitis, Ear infection, Escherichia urinary tract infection, Eye infection, Folliculitis, Gingivitis, Infected skin ulcer, Lobar pneumonia, Lung infection, Mycobacterial infection, Periodontitis, Pharyngitis bacterial, Pneumonia, Pulmonary tuberculosis, Sinusitis bacterial, Staphylococcal infection, Tonsillitis bacterial, Tuberculosis, Upper respiratory tract infection bacterial, Urinary tract infection, Urinary tract infection bacterial, Vaginitis bacterial, Wound infection, Wound infection staphylococcal, *as defined in the MedDRA version 18.0</p>
--

between CRP at infection and infection-free states were done within the same patients for each treatment group and p-values for the two differences were obtained from a Wilcoxon Signed-Rank test.

Results: Overall, 36 and 30 patients treated with BARI and PBO (Tab.2) had CRP values during BI TEAEs, of which 60% were urinary tract infections. For BARI, the median CRP were 6.2 and 3.0 mg/L in the infection and infection-free period, ($p < 0.001$; Fig.1) and the maximum values were 99.2 and 25.4 mg/L, respectively. For PBO, the median CRP were 10.1 and 13.7 mg/L for the infection and infection-free period ($p = 0.896$); and the maximum values were 110.8 and 71.4 mg/L.

Conclusion: CRP remains a useful monitoring tool for BI in BARI-treated patients. CRP elevations were observed in BARI-treated patients during BI, with no apparent blunting of response. In the PBO patients, elevations of CRP also were observed in infection-free periods, in line with the presence of active RA, and these values may be comparable to the CRP values observed on those patients during BI.

Tofacitinib Show Similar Retention When Used with and without Methotrexate. Analysis from the Rhumadata® Clinical Database and Registry

Denis Choquette¹, Louis Bessette², Jacques Brown², Boulos Haraoui¹, Frédéric Massicotte¹, Jean-Pierre Pelletier¹, Jean-Pierre Raynauld¹, Marie-Anaïs Rémillard¹, Diane Sauvageau¹, Angèle Turcotte², Édith Villeneuve¹ and Louis Coupal¹, ¹Rheumatology, Institut de Recherche en Rhumatologie de Montréal (IRRM), Montréal, QC, Canada, ²Rheumatology, Centre de l'Ostéoporose et de Rhumatologie de Québec (CORQ), Québec, QC, Canada

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster II: PROs, Safety and Comorbidity

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Tofacitinib (TOFA), a targeted synthetic DMARD has recently appeared on the Canadian market. It is an oral agent, targeting the JAK 1 and JAK 3 subunits of the Janus Kinase pathway, indicated in the treatment of rheumatoid arthritis (RA). We describe here the experience that we have accumulated in the last four years on 131 patients.

Methods: The data of all patients with RA exposed to TOFA at the *Institut de Recherche en Rhumatologie de Montréal* and the *Centre de l'Ostéoporose et de Rhumatologie de Québec* either in monotherapy or in combination with other conventional

synthetic DMARDs (csDMARDs) was extracted from the database. All patients' data were obtained from the Rhumadata® clinical database and registry. Descriptive statistics include age, gender, diagnosis, previous and actual exposure to other csDMARDs and biologic agents, CDAI at the initiation of TOFA, duration of treatment, response to treatment, and the reason for ceasing therapy.

Results: The 131 patients exposed to TOFA since its launch were mostly female (82%), with a mean age and disease duration at treatment initiation of respectively 58.1 (11.8) and 11.5 (10.3) years. Most patients were rheumatoid factor positive (73%) and 47% ACPA positive. At the time of the analysis, 63% remained on treatment. Reasons for stopping are inefficacy (66%), adverse events (21%), infections (4%) and other/unknown (11%). Of all patients, 31% had previously been treated with csDMARDs only. Prior biologic agent exposure ranges from 1 to 9, and 62% had been exposed to less than five biologic agents. The 6, 12, 24 and 36 months' retention rates of patients treated with tofacitinib were respectively 75.0 (SE=4.0), 65.4 (4.5), 54.7(5.2), and 52.3 (47.7) percent. Subjects treated with and without methotrexate (MTX) had similar retention curves (see figure). Baseline CDAI for this sub population is 22.1 (SD=13.1) with improvements (decreases in CDAI) of 3.3 (SD=10.8) and 10.7 (SD=15.2) units from baseline for patients stopping and remaining on therapy respectively. At their last evaluation, 14.8%, of patients were in remission, and 3.3%, 55.7% and 26.3% had low, moderate and high disease activity.

Conclusion: Patients treated with TOFA often had severe long-standing disease and had been exposed to numerous prior treatments, the majority being biologic agents. These patients show improvement in their disease activity score compared to baseline and the addition of MTX did not provide better sustainability over time.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster II: PROs, Safety and Comorbidity

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: SB4, SB2, and SB5 are biosimilars of reference etanercept, infliximab, and adalimumab, respectively. The phase III randomized, double-blind clinical studies comparing the efficacy and safety of each biosimilar with its reference product had similar study designs, patient demographics, and the same primary end point of the ACR20 response rate. In this study, the immunogenicity of three TNFi and the potential impact of anti-drug antibodies (ADABs) on efficacy and injection site reactions (ISR) or infusion related reactions (IRR) were assessed by a pooled analysis of three biosimilar studies.^{1,2,3}

Methods: In each study immunogenicity was measured using a validated ECL assay tagged with the biosimilar and patients who had immunogenicity results from each phase III study were pooled. Data to the time of the primary endpoint for each study (week 24 for etanercept and adalimumab studies and week 30 for infliximab study) are included. Efficacy (ACR responses, clinical response [defined as good or moderate EULAR response], change in disease activity [DAS28, SDAI, CDAI]) and ISR/IRR were evaluated in relation to the presence of ADAB (at least one ADAB positive result up to when the primary endpoint was measured).

Results: The analysis included 1710 patients and the incidence of ADAb by treatment group is presented in the Table. Across treatment groups, efficacy was greater in patients without ADAb compared to those with ADAb. In all treatments combined, the ACR20 response rate was lower in the presence of ADAb (OR 2.01, 95% CI: 1.60-2.53, $p<0.0001$) (Figure) and the mean improvement in DAS28 was significantly greater in patients without ADAb (estimated difference: 0.33, 95% CI: 0.19-0.48, $p<0.0001$). The ADAb effect on reducing efficacy parameters was similarly observed in other treatment combinations.

In all treatments combined, the presence of ADAb was associated with increased ISR/IRR (OR 1.78, 95% CI: 1.05-3.02, $p=0.033$), predominantly with the infliximab combined (OR 2.67, 95% CI: 1.04-6.89, $p=0.041$) rather than the etanercept combined (OR 1.72, 95% CI: 0.38-7.77, $p=0.478$) and adalimumab combined (OR 1.14, 95% CI: 0.41-3.13, $p=0.804$).

Conclusion: In a pooled analysis, the development of ADABs to TNFi is associated with reduced clinical efficacy and increased incidence of ISR/IRR in patients with RA.

Simulating Population Disability Outcomes for Alternative Treatment Pathways in Patients with Active Rheumatoid Arthritis

Josephine Mauskopf¹, Mahdi Gharaibeh², David Wamble¹, David H. Collier², Bradley S. Stolshek² and Eric L. Matteson³,
¹RTI Health Solutions, Research Triangle Park, NC, ²Amgen Inc., Thousand Oaks, CA, ³Division of Rheumatology, Mayo Clinic College of Medicine and Science, Rochester, MN

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster II: PROs, Safety and Comorbidity

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is a chronic, systemic inflammatory disorder that causes joint pain and swelling, bone erosions, and deformity. This debilitating disease can severely impact patients' quality of life, employment opportunities, daily activities, and life expectancy. Over time, RA can cause the joints to become permanently deformed, which may lead to disability. Because of advances in treatment options such as biologic disease-modifying antirheumatic drugs (bDMARDs), many patients with RA are now able to continue to work and lead full lives, whereas decades ago this was not possible. The goal of this study was to assess the impact of introducing bDMARDs as a treatment option for patients with RA.

Methods: A population simulation model was developed to assess the impact of different treatment pathways on disability based on clinical trial data and real-world evidence. The model included patients diagnosed with RA with symptoms <2 years (median 6 months) who were DMARD-naïve. The following treatment pathways were evaluated: 1) non biologics (including nonsteroidal anti-inflammatory drugs, glucocorticoids, and synthetic DMARDs) for remaining lifetime, 2) bDMARDs for remaining lifetime, 3) bDMARDs until age 65 years then either 100% or 80% of patients switch to non biologics while the remaining patients continue on bDMARDs. A cohort of 1,000 patients newly diagnosed with RA, aged 56 years, with mean HAQ score of 1.2 were added every year. We assumed a decrease in mean HAQ of ~0.2 for non biologics and ~0.6 for biologics for the first year. For subsequent years, we assumed an annual change in HAQ of +0.002 at ages <65 years and +0.027 at ages ≥65 years for non biologics and of -0.009 at ages <65 years and +0.016 at ages ≥65 years for bDMARDs. The primary model outcomes were: expected population distribution of disability defined by HAQ score (score <0.5 to <1.1 = mild; score 1.1 to < 2.1 = moderate; score 2.1 to 3.0 = severe disability), and patient life expectancy. The impact of introducing bDMARDs on societal cost will be evaluated in the final analysis.

Results: For each simulated treatment pathway, the figure presents an expected distribution of disability in an RA population at steady state. Individual cohort life expectancy ranged from 22.11 years (non biologics) to 24.11 years (bDMARDs). Results were sensitive to starting age and disease severity. Greater benefits (ie, greater reduction in severe disability) associated with bDMARDs compared to non biologics can be seen in patients with higher mean HAQ scores entering the simulation model.

Conclusion: The simulation model estimates show that biologics will reduce the RA population disability burden and increase the life span of RA patients. The model can be used to estimate additional population outcomes including costs and healthcare resource use.

Comparative Risk of Diabetes Mellitus in Rheumatoid Arthritis Patients Treated with Different Biologics- a Cohort Study

Rishi J. Desai¹, Sara Dejene², Yinzhu Jin², Jun Liu³ and Seoyoung C. Kim², ¹Division of Pharmacoepidemiology and Pharmacoeconomics, Brigham and Women's Hospital, Harvard Medical School, Boston, MA, ²Brigham and Women's Hospital, Boston, MA, ³Division of Pharmacoepidemiology and Pharmacoeconomics, Brigham and Women's Hospital, Boston, MA

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster II: PROs, Safety and Comorbidity

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with rheumatoid arthritis (RA) often develop diabetes mellitus (DM), potentially due to aggravated systemic inflammation. Reducing inflammation with disease-modifying antirheumatic drugs (DMARD) may alter the risk of DM in RA. To date, few head-to-head comparisons of individual biologic or targeted synthetic DMARDs on the risk of DM in patients with RA are available.

Methods: We conducted a cohort study to compare DM risk in RA patients treated with different biologics or tofacitinib, using claims data from Truven Market scan (2005-2015). RA patients free from DM at baseline were selected into one of eight exposure groups based on treatment initiation: abatacept, infliximab, adalimumab, golimumab, certolizumab, etanercept, tocilizumab, or tofacitinib. From the treatment initiation date (i.e. index date), patients were followed for the outcome of

incident DM, defined as a combination of a diagnosis code and initiation of antidiabetic treatment, in an as-treated approach. To account for 60 baseline covariates including demographics, co-morbid conditions, and co-medications, we used a stabilized inverse probability (IP) weighted Cox-proportional hazard model to estimate hazard ratios (HR) of different treatments versus abatacept. All analyses were conducted separately in the following two groups: 1) new biologic initiators, who did not use any biologic DMARD in 365 days pre-index and 2) biologic switchers, who used one TNF inhibitor in 365 days pre-index and switched to a different biologic DMARD. HR estimates were then combined using inverse variance pooling.

Results: A total of 56,014 new biologic initiators and 27,152 biologic switchers with an average age of 50 years in both groups were included, of which 75% and 78% were females, respectively. Infliximab, adalimumab, and etanercept represented a large majority in both groups (86% initiators and 62% switchers), while abatacept was the most frequently used non-TNF biologic (6% initiators and 16% switchers). We observed 335 DM events in the new initiator group and 155 events in the switcher group, corresponding to incidence rates/1,000 person-years (95% CI) of 6.7 (6.0-7.5) and 7.3 (6.2-8.5), respectively. After IP weighting, a higher risk was observed among infliximab and etanercept initiators compared to abatacept initiators (**Table 1**). The risk was similar with all other drugs compared to abatacept.

Conclusion: In this large cohort study, we found a greater risk of incident DM in patients initiating infliximab or etanercept compared to abatacept initiators. The risk of DM was similar between other biologic or tofacitinib and abatacept initiators. Our findings corroborate observations from earlier smaller studies, which showed potentially improved insulin sensitivity and glycemic profile with abatacept.

Table 1 Inverse probability weighted hazard ratios (95% confidence intervals) for the risk of diabetes mellitus in patients with rheumatoid arthritis treated with different biologics

	New biologic initiators	Biologic-switchers	Pooled
Abatacept	Reference	Reference	Reference
Adalimumab	2.08 (1.07-4.08)	0.54 (0.31-0.94)	0.94 (0.61-1.44)
Certolizumab	1.03 (0.27-3.86)	0.45 (0.17-1.18)	0.60 (0.27-1.31)
Etanercept	2.28 (1.17-4.45)	1.30 (0.76-2.21)	1.62 (1.07-2.45)

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster II: PROs, Safety and Comorbidity

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Guidelines for the treatment of rheumatoid arthritis (RA) underscore the importance of an early and targeted approach to control inflammation. However, patients are often reluctant to agree to aggressive therapy when they believe their symptoms are tolerable, despite high disease activity scores. This study is based on the premise that educating patients about treatment risks and benefits requires a two-pronged approach: (1) Simplifying written materials to reduce user burden and (2) Teaching patients the skills needed to process complex information. Drug Facts Boxes® are designed to address the former; Gist Reasoning (GIST) Training is designed to address the latter.

Methods: The study is a randomized controlled trial in which participants with doctor-diagnosed RA are randomized to one of four groups: (1) Medication Guide without GIST Training, (2) Medication Guide with GIST Training, (3) Drug Facts Box® without GIST Training, and (4) Drug Facts Box® with GIST Training. Data are collected at baseline (prior to

intervention implementation) and at 6 weeks, 3 months, and 6 month follow-up. The primary outcome is informed decision making regarding the use of disease-modifying anti-rheumatic drugs (DMARDs). Patients using a DMARD are classified as having made an informed decision if they have adequate knowledge (≥ 85 on a 100 point scale) and values that favor aggressive treatment of RA. Patients not using a DMARD are classified as having made an informed decision if they have adequate knowledge and have values that do not favor aggressive treatment. Knowledge is a secondary outcome variable. Data were analyzed using logistic and linear regression.

Results: Data collection is ongoing. To date, 297 participants have completed baseline data collection and 135 have completed the 6-month follow-up. Controlling for baseline knowledge, participants assigned to GIST Training exhibited greater knowledge at the 6-month follow-up, compared to those not assigned to training (Means: 86.1 vs 83.4, $p = .06$). In a logistic regression predicting informed decision making at the 6-month follow-up, there was a significant interaction between (1) whether the participant met the criteria for informed decision making at baseline and (2) assignment to GIST Training ($p = .003$). Among those classified as not meeting the criteria for informed decision making at baseline, 56.7% ($n = 17$) of those assigned to GIST Training met the criteria at the 6-month follow-up, compared to 25% ($n = 11$) of those not assigned to training ($p = .007$). However, among those classified as meeting the criteria at baseline, 35.0% ($n = 7$) of those assigned to GIST Training did not meet the criteria at the 6-month follow-up, compared to 14.7% ($n = 5$) of those not assigned to training ($p = .09$). No differences were observed between those randomized to Medication Guides versus Drug Facts Box®.

Conclusion: These findings provide preliminary support for the effectiveness of GIST Training in helping patients develop the skills needed to process complex information about medication risks/benefits. RA Treatment benefits appear to be limited to those who do not meet the criteria for informed decision making prior to the initiation of training.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster II: PROs, Safety and Comorbidity

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Transient increases in circulating platelets were observed in patients with RA treated with baricitinib, an oral selective Janus kinase 1/2 inhibitor, approved for the treatment of RA in over 40 countries. We assessed mean platelet volume (MPV) in relation to platelet count to determine whether treatment-associated patterns of platelet change are indicative of altered platelet synthesis, release, and/or clearance.

Methods: MPV and platelet count were measured in a subset of patients with RA treated for up to 16 weeks ($N = 629$), enrolled in the phase 3 RA-BEAM trial (NCT01710358), a 52-week, randomized, double-blind, placebo- and active-controlled study of moderately-to-severely active methotrexate-inadequate responders. Adalimumab (40-mg every other week), a monoclonal antibody against TNF-alpha, was included as an active comparator to baricitinib (4-mg once daily).

Results: There was a significant increase in platelet count at Week 2 with baricitinib treatment, which then returned toward baseline and remained stable (though slightly above baseline) thereafter for the 16-week time-period (Figure). In contrast, adalimumab treatment resulted in a decrease in platelet count starting at 2 weeks that persisted over 16 weeks. The corresponding MPV changes with baricitinib treatment demonstrated a decrease in MPV at 2 weeks, which then returned to baseline, mirroring the platelet count change over time (Figure). By contrast, adalimumab treatment resulted in an increase in MPV at Week 2 and remained elevated through Week 16. Platelet count and MPV changes in the placebo arm were not significant throughout the 16-week time-period.

Conclusion: These analyses indicate that the increase in platelet count observed with baricitinib treatment at 2 weeks maybe caused by a transient increase in circulating older, smaller platelets, accounting for the MPV decline; this finding is most consistent with a period of decreased platelet clearance rather than an increase in platelet production. By contrast,

Figure. Changes from Baseline in Platelet Count and Mean Platelet Volume with 95% Confidence Intervals

Baricitinib 4-mg-treated patients with individual N shown for each time point. The mean baseline platelet count was 8.8×10^9 /L and the mean baseline mean platelet volume was 302.7×10^9 cells/L for baricitinib 4-mg-treated patients. Bari=baricitinib, CI=confidence interval. * $p \leq 0.05$ compared with baseline.

the prolonged platelet changes with adalimumab are consistent with increased platelet clearance and resultant increased platelet production. The association of changes in MPV with platelet function should be explored in future studies.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster II: PROs, Safety and Comorbidity

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Tolerability remains ill-defined in clinical trials and most commonly refers to non-serious adverse events (AEs) that may impact patient (pt) satisfaction and adherence to treatment. Tofacitinib is an oral Januskinase inhibitor for the treatment of RA. This update to a previously reported post hoc analysis¹ describes the frequency and duration of the most commonly reported non-serious AEs related to tolerability in pts with RA treated with tofacitinib 5 mg twice daily (BID) as monotherapy or in combination with conventional synthetic (cs)DMARDs in Phase (P)3 and P3b/4 studies.

Methods: Data were pooled from the following studies of tofacitinib in pts with moderate to severe RA: ORAL Step (NCT00960440); ORAL Solo (NCT00814307); ORAL Scan (NCT00847613); ORAL Sync (NCT00856544); ORAL Standard (NCT00853385); and ORAL Strategy (NCT02187055). This analysis included data from pts receiving tofacitinib 5 mg BID monotherapy (ORAL Solo, ORAL Strategy), placebo (PBO; ORALSolo), or tofacitinib 5 mg BID or PBO in combination with csDMARDs (all studies except ORAL Solo). Non-serious AEs with an incidence rate (IR, pts with events per 100 pt-years [PY]) ≥ 5 were evaluated up to Month 3. Non-serious AEs were defined as AEs affecting pts' day-to-day experience and ability to tolerate treatment. Infections, laboratory test abnormalities, general disorders, or events not reported directly by pts, and musculoskeletal events likely to be due to underlying RA, were excluded, to focus on AEs which could impact treatment adherence.

Results: In total, 2657 pts were included in the analysis; 1976 received tofacitinib 5 mg BID (monotherapy: N=627; combination therapy: N=1349); 681 received PBO (monotherapy: N=122; combination therapy: N=559). Up to Month 3, the most frequently reported non-serious AEs which met the search criteria for either tofacitinib or PBO groups were headache, diarrhea, nausea, vomiting, dyspepsia, and abdominal pain upper; an IR of ≥ 10 was observed for headache and diarrhea in pts receiving tofacitinib 5 mg BID, and for nausea in pts receiving PBO (Table). Duration of AEs was ≤ 4 weeks for the majority of pts experiencing headache, diarrhea, or gastric discomfort (defined as any gastrointestinal pain,

Table. Non-serious, non-infectious treatment-emergent AEs* in Phase 3 studies up to Month 3

*Defined as AEs with an IR ≥ 5 per 100 PY in at least one treatment group under monotherapy, combination therapy or overall therapy. IRs listed (95% CI) are IRs per 100 PY (95% CI). IR < 5 per 100 PY is not listed. †Includes pts receiving PBO without background csDMARDs in ORAL Solo study; otherwise, background medications were allowed. ‡Includes pts receiving PBO with background csDMARDs in Phase 3b studies.

AE, adverse event; BID, twice daily; CI, confidence interval; csDMARDs, conventional synthetic disease-modifying antirheumatic drugs; IR, incidence rate; PBO, placebo; PY, pt-year.

dyspepsia, epigastric discomfort, or abdominal discomfort or pain). Overall, in pts receiving tofacitinib 5 mg BID and PBO, respectively, 43.2% and 64.7% experienced headache; 66.1% and 81.3% experienced diarrhea; and 36.2% and 58.6% experienced gastric discomfort, for ≤ 2 weeks. The majority of AEs were mild or moderate.

Conclusion: Overall, non-serious, non-infectious AEs were mild or moderate and self-limiting. The frequency of non-serious AEs was comparable for pts receiving tofacitinib as monotherapy, or in combination with csDMARDs, and was generally similar for pts receiving tofacitinib compared with pts receiving PBO.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster II: PROs, Safety and Comorbidity

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: In rheumatology, we are aware of the possibility to develop adverse drug reactions (ADR) to the widely used Disease Modifying Drugs (DMARD). We are certain of the efficacy of the DMARD in the treatment of rheumatoid arthritis (RA) and we know their safety profile in clinical trials. However, it is necessary to increase our knowledge of their ADR, especially those that lead to discontinuation, in real life conditions. **Purpose:** to describe the incidence and characteristics of moderate ADR (MADR) to DMARD in patients with incident RA as well as the factors related to their development.

Methods: Observational longitudinal study. **Patients:** all recent on set RA diagnosed between April 15th 2007 and December 31st 2014 followed in outpatient clinic at Hospital Clínico San Carlos until December 31st 2016, which used any DMARD (synthetic and biologic). **Primary outcome:** development of a MADR (discontinuation of the DMARD due to the ADR). Incidence rates of discontinuation (IR) per 100 patient-years were estimated using survival techniques with their respective 95% confidence interval [CI]. Comparisons between associated factors were run by Cox bivariate and multivariate regression models. Results were expressed by hazard ratio (HR) and [CI].

Results: We included 2388 courses of DMARD treatment in 814 patients (3706.14 patient-years). 77.52% were women with a mean age at diagnosis of 57.53±15.50 years. From the courses of DMARD, 13.74% were biologicals (72.04% anti-TNF) and 60% were used in monotherapy. There were 591 ADR in 335 patients, 90.52% of them moderate. Gastrointestinal was the most frequent cause of MADR (31.96%), followed by hepatic (10.15%). IR are shown in table 1. We performed a multivariate analysis (table 2) adjusted by ESR at the beginning of each drug. We repeated the model changing the reference category of DMARD: Golimumab (HR: 2.21, p=0.010), Leflunomide (HR: 1.84, p=0.000), Sulfasalazine (HR: 1.47, p=0.012), Chloroquine (HR: 1.37, p=0.004) and Hidroxicloroquine (HR: 0.77, p=0.030); the rest of DMARD did not achieve statistical significance in the models performed.

Conclusion: The IR of MADR estimated was 14.4%, being gastrointestinal the main cause. We found differences in discontinuation rates among DMARD due to MADR, with Golimumab, Leflunomide, Sulfasalazine and Chloroquine being the drugs with the highest risk. Methotrexate and Hidroxicloroquine are a protective factor for the development of MADR. Caution should be taken in patients of female gender, with positive rheumatoid factor, receiving combined therapy, higher dose of corticoids and with certain comorbidities.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster II: PROs, Safety and Comorbidity

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Best treatment of Rheumatoid Arthritis (RA) requires to begin early, with a tight control, including nonsteroidal anti-inflammatory drugs (NSAIDs), steroids, disease-modifying antirheumatic drugs (DMARDs) and biologic therapies (BT).

High cost limits use of BT, especially in the low-middle income countries. In this setting, a common therapeutic strategy is the use of combination therapy (CT) with methotrexate (MTX) plus leflunomide (LEF). There is not too much information about the efficacy of this CT, and there are some concerns about its safety. Our purpose was to assess the safety of CT in our RA patients.

Methods: An observational, retrospective study in adult RA patients controlled in our center was conducted. Patients with prescription of MTX plus LEF by June 2016 in pharmacy records were included. We found 253 cases, and randomly 127 were selected for review of clinical records. Five patients with incomplete information were excluded. Demographic, underlying diseases, time and dose in RA medications, adverse events (AE) and clinical activity data were collected.

Results: In 121 patients included, 95.9% were females. The mean age was 60.6 (31-86) years. Only 5 of them (4.1%) had pre-existing liver disease, all with fatty liver disease. None of the patients reports alcohol use. Active smoking was reported in 28 cases (23.1%). Continuous use of NSAIDs was documented in 11 patients (9.1%). Average dose of MTX was 18.6 (7.5-25) mg/wk, with oral route being the most frequent (77.7%). Average dose of LEF was 19.75 (10-20) mg/d, initial loading dose was not used.

In 101 (83.5%) patients CT was retained, with a mean duration therapy of 70.0 (17-162) months. In 20 patients (16.5%) CT was discontinued, with mean time to discontinuation of 49.9 (2-180) months. Kaplan-Meier analysis of survival in CT showed more than 85% of patients still on CT after 5 years.

AE were reported in 31 patients (25.6%), with estimated rate of 4.37 x 100 person-year. Most of them (62.1%) were mild and resolved by reducing doses of one CT drug. AE presented in nine patients lead to a suspension of CT, one of these was considered as serious adverse event (SAE): pulmonary tuberculosis. We didn't find association between dose of MTX and the risk of adverse effects ($p = 0.6$).

In the beginning of CT, 90.9% of patients used prednisone, with an average dose of 7.1 mg/d. With CT use, the average dose was significantly reduced to 4.9 mg/d ($p < 0.0001$).

In 7 cases (5.8%) a BT was initiated because of the persistent high clinical activity RA. All of them suspended CT, continuing with only MTX or LEF.

In 60 of 101 patients remaining on CT, clinical activity of RA was registered by DAS 28 during follow-up. In 50% of them remission or low activity was achieved.

Conclusion: In this group of Chilean RA patients, the MTX plus LEF CT show to be safe, with a good survival rate.

AE were observed in the 25% of the patients on CT, and most of them resolved with the reduction of the dose of MTX or LEF. Frequency of SAE was very low.

A half of the patients who remained on CT, and evaluated with DAS 28 during follow up achieved remission or low RA activity, with a significant steroid-sparing effect.

CT is a reasonable therapeutic alternative when there is a limited access to the BT.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster II: PROs, Safety and Comorbidity

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: MTX is the cornerstone of treatment of RA. A relatively rare side effect is liver fibrosis and cirrhosis, the incidence in patients on long-term therapy is thought to be less than 3%. Neither dose nor duration of MTX are associated with liver fibrosis, and abnormal liver enzymes in RA patients do not accurately detect liver fibrosis, making screening problematic. The gold standard for diagnosing liver fibrosis is by biopsy. Routine biopsy is invasive and associated with risks. Other screening tests include hepascor, aminoaspartate transaminase (AST) to platelet ratio index (APRI) and transient elastography (fibroscan) – which have been validated in patients with liver disease but have not been validated in patients with RA.

Methods: Patients were recruited from Fiona Stanley Hospital (FSH) outpatient general rheumatology and inflammatory arthritis clinics from July 2017, and is ongoing. A DAS-28 (ESR) was completed, BMI, alcohol intake and dose and duration of MTX noted. FBC, UEC, LFT, ESR, CRP, AST, coagulation profile and hepascor were performed at FSH Path West. Fibroscan was performed on the same day.

An APRI score of >0.7 , hepascor of >0.45 and fibroscan of >7 kPa (=F2 metavir score) were used as cut-offs for significant fibrosis.

Statistical analysis was performed using SPSS with non-parametric statistics for non-normally distributed data and parametric for normally distributed data. Comparison between outcome tools was made using Spearman rank correlation (Rs).

Results: To the end of February 2018, 17 patients have been recruited, with unexpectedly low recruitment due to exclusions mainly from high BMI and treatment with leflunomide. The age range of patients is 53-74 years old, with 41% female, 59% male and duration of methotrexate ranging from 3-240 months. 1 patient was found to have significant fibrosis based on fibroscan and hepascor, however liver biopsy reported no significant fibrosis. 1 patient was found to have cirrhosis based on fibroscan,

hepascare and APRI, awaiting liver biopsy. 6 patients had raised hepascare indicative of significant fibrosis in the absence of correlated fibroscan or APRI scores. Duration of methotrexate ranged from 12-240 months, and was not statistically significant. 4 of 8 patients with raised hepascare had raised inflammatory markers. CRP was shown to be associated with fibrotic hepascare values (Rs 0.557, $p=0.028$), but not ESR (Rs 0.149, $p=0.574$) or DAS-28 (Rs -0.136, $p=0.645$). Fibrosis detected by APRI was highly correlated with fibrosis detected by fibroscan (Rs 0.683, $p=0.04$), but not hepascare (Rs 0.258, $p=0.334$). Hepascare detection of fibrosis did not correlate.

Conclusion: Results suggest that screening for liver fibrosis in RA patients may be indicated. Fibroscan and APRI correlate and are useful in detecting significant fibrosis in RA patients on methotrexate, however fibroscan may have limited utility in obese patients. Hepascare may be useful in detecting significant fibrosis though may also be falsely elevated in those with raised CRP, therefore limiting its utility in RA patients.

Session Title: Rheumatoid Arthritis – Treatments Poster II: PROs, Safety and Comorbidity

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

The retention rate and safety profile of igaratimod in real clinical practice: Analysis of 456 patients with Rheumatoid arthritis.

Background/Purpose: Igaratimod is one of the disease modifying anti-rheumatic drugs (DMARDs) with anti-inflammatory and immunomodulatory actions. Previous RCTs shows the efficacy, but tolerance in daily practice is unknown. The aim of our study is to show the tolerability of igaratimod in real clinical practice.

Methods: We retrospectively collected data of all the 456 RA patients treated with igaratimod from the electrical chart of St Luke's International Hospital, Tokyo, Japan. We extracted following parameters during the period between April 2012 and March 2018; patients baseline characteristics, duration of using igaratimod, and reasons of discontinuation. To assess the safety of in igaratimod in patients with various complications, we further evaluated whether concomitant conditions such as, malignancy, tuberculosis, and interstitial lung disease, affect retention rate or not. Drug retention rates were calculated using the Kaplan-Meier method, which were analyzed using SPSS software version 21.

Results: During the study period, 74(16.2%) patients discontinued igaratimod. The reasons are 19(4.1%) renal injury, 15 (3.2%) liver function abnormality, 13(2.9%) GI symptoms, 9(2.0%) skin, 3(0.6%) interstitial lung disease, 1 edema, 1 IgG depletion. All the adverse events recovered after discontinuation. The number of the patients who have malignancy, tuberculosis, and interstitial lung disease is 35(7.7%), 39(8.6%), and 38(8.3%), respectively. The retention rates show no significant difference between the groups with concomitant conditions and without them.

Conclusion: Igaratimod shows considerable retention rate in real clinical practice. Although adverse events of renal injury and liver function abnormality are common, all of them recovered after discontinuation. In addition, igaratimod is well tolerated even in patients with complications such as malignancy, tuberculosis, and interstitial lung disease.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster II: PROs, Safety and Comorbidity

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Tofacitinib is an oral Janus kinase inhibitor for the treatment of RA. A prospective observational 5-year study, embedded within the US Corrona RA registry, was initiated to evaluate the safety of tofacitinib after US Food and Drug Administration approval on November 6, 2012. The study has now completed 5 years of data collection. The objective of the study was to assess the rates of adverse events (AEs) in patients initiating tofacitinib vs biologic DMARDs (bDMARDs) and conventional synthetic DMARDs (csDMARDs). This analysis describes the age- and sex-standardized rates of AEs for the completed 5-year study period.

Methods: AEs were evaluated in three patient populations: 1) initiators of tofacitinib; 2) initiators of a bDMARD (with no prior/current tofacitinib exposure); and 3) initiators of a csDMARD (with no prior/current tofacitinib or bDMARD exposure). AE data were captured from prescribing physicians during follow-up. Patients who had at least one visit or AE at any time after initiation were included in the analysis. Standardized incidence rates and 95% confidence intervals were estimated across the 5-year period (November 6, 2012–December 31, 2017) using the age and gender distribution of tofacitinib initiators as the reference population.

Table. Baseline characteristics of patients with RA newly exposed to tofacitinib or comparator bDMARD/csDMARD in the Corrona study

	Tofacitinib initiators, N=1482		bDMARD initiators, N=6881		csDMARD initiators, N=2115	
	N	%	N	%	N	%
Gender (female), %	1482	80.6	6881	80.9	2115	74.6
	N	Mean (SD)	N	Mean (SD)	N	Mean (SD)
Age, years	1482	59.3 (12.1)	6881	58.2 (11.0)	2115	60.3 (13.4)
Time since diagnosis, years	1471	13.7 (10.2)	6828	10.5 (10.0)	2097	4.6 (7.5)
Tender joint count	1461	6.6 (7.2)	6874	6.7 (7.2)	2113	6.8 (8.9)
Swollen joint count	1460	8.8 (5.0)	6873	8.8 (4.1)	2113	8.9 (5.1)
PGA score	1479	47.4 (26.8)	6853	45.3 (27.0)	2110	37.1 (26.8)
Number of prior bDMARDs	1482	2.7 (1.8)	6881	1.5 (1.4)	2115	0.0 (0)
Number of prior TNF inhibitors	1482	1.8 (1.1)	6881	1.1 (1.0)	2115	0.0 (0)

bDMARD, biologic disease-modifying antirheumatic drug; csDMARD, conventional synthetic disease-modifying antirheumatic drug; N, number of patients evaluated; PGA, patient global assessment; RA, rheumatoid arthritis; SD, standard deviation; TNF, tumor necrosis factor.

Results: Age- and gender-standardized incidence rates of safety events per 100 patient-years [PY] were calculated for 1482 tofacitinib, 6881 bDMARD, and 2115 csDMARD initiators with 1925.34 PY, 8566.82 PY, and 2274.51 PY of follow-up, respectively. Patient characteristics are shown in the Table. Disease duration was longer, and both the number of prior bDMARDs and number of prior TNF inhibitors were higher, in tofacitinib initiators compared with bDMARD and csDMARD initiators. Standardized incidence rates for serious infections, cardiovascular events, malignancies, and gastrointestinal perforation were generally similar for the three groups (Figure). Non-serious herpes zoster incidence rates were higher for tofacitinib compared to bDMARDs and csDMARDs, consistent with the known safety profile.

Conclusion In this analysis, despite patients in the tofacitinib group having longer disease duration and more prior biologic treatments, patients initiating tofacitinib, bDMARDs, and csDMARDs for the treatment of RA experienced comparable age- and gender-adjusted rates of serious infections, cardiovascular events, and malignancies. Tofacitinib initiators had a higher rate of non-serious herpes zoster than bDMARD and csDMARD initiators. A formal, propensity-matched analytic comparison of these data is planned.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster II: PROs, Safety and Comorbidity

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Elderly patients with rheumatoid arthritis (RA) have declined physical performances and increased various complications. We are concerned about decrease of efficacy and increase of adverse events in elderly RA patients treated with biologic disease-modifying anti rheumatic drugs (bDMARDs) under conditions of insufficient dose of MTX or increased risk of infections. The purpose of this study is to examine the efficacy, safety and adherence of bDMARDs including infliximab (IFX), tocilizumab (TCZ) and abatacept (ABT) in elderly patients with RA.

Methods: RA patients (n=253) who received IFX (n=73), TCZ (n=104) or ABT (n=76) in Saitama Medical University Hospital between 2008 and 2016 were divided into 2 groups. The younger group consists of patients with younger than 64 years old (n=158) and the elderly one over 65 years old (n=95). In these 2 groups, we analyzed retrospectively the patients' background, disease activity, physical performance, safety and continuation rate of those bDMARDs.

Results: The patients' background (younger/elderly, p value) was as follows; mean age of onset (44/61 year-old, p<0.001), rate of female (75.3/81.1%), naïve rate of bDMARDs (54.4/46.3%), mean disease duration (6.9/10.5 years, p=0.001), rate of MTX use (82.9/46.3% p<0.001), rate of PSL use (55.7/75.8% p=0.001), mean dose of MTX (7.3/3.7 mg/week p<0.001), mean dose of PSL (3.3/3.9 mg/day), CDAI (22.3/20.9), DAS28-ESR4 (5.37/5.49), HAQ-DI (1.03/1.56 p<0.001), positive rate of RF (79.3/87.9%) and positive rate of anti-CCP antibody (83.9/93%). In efficacy, CDAI and HAQ significantly decreased in both groups during one year after bDMARDs exposure (P<0.001). There was no significant difference in the prevalence of patients who achieved remission by CDAI between the groups (younger vs. elderly: 30.5% vs. 22.2%). The continuation rate of bDMARDs in elderly patients did not inferior to that in younger patients (82% vs 79%). Moreover, we could not find significant difference in continuation rate of each 3 bDMARDs between the 2 groups (younger vs. elderly: IFX 75% vs. 77%, TCZ 83% vs. 84%, ABT 89% vs. 75%). The reasons for bDMARDs discontinuation within one year (younger/elderly) were adverse events (8.2/14.7%), ineffective (10.1/5.3%) and remission (0.0/1.1%).

Conclusion: The efficacy, safety and adherence of bDMARDs in elderly patients were not inferior to those in younger patients. These results suggest that the utility of bDMARDs would not be affected by age.

Session Title: Rheumatoid Arthritis – Treatments Poster II: PROs, Safety and Comorbidity

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Tofacitinib is an oral Janus kinase inhibitor for the treatment of RA. This post hoc analysis assessed tofacitinib safety and efficacy in the Central and Eastern European (CEE) subpopulation of the tofacitinib clinical program vs the rest of the world (ROW; not including CEE countries).

Methods: Data for safety analyses were pooled from two Phase (P)1, ten P2, six P3, one P3b/4, and two long-term extension (LTE; ORAL Sequel LTE main study database locked at time of analysis: March 2, 2017) studies in patients with RA. Safety comparisons evaluated were adverse events (AEs), serious AEs (SAEs), and AEs of special interest for combined tofacitinib doses. Pooled data from five pivotal P3 studies (DMARD-IR pts) were assessed for efficacy of tofacitinib 5 and 10 mg twice daily and placebo at Month 3; endpoints are listed in the table. CEE countries in the efficacy analyses from five P3 studies included: Bosnia and Herzegovina, Bulgaria, Croatia, Czech Republic, Poland, Russian Federation, Slovakia, and Ukraine; safety analyses based on the 21 above studies included these countries plus Hungary, Romania, and Turkey.

A, change from baseline; ACR, American College of Rheumatology; AE, adverse event; BID, twice daily; CEE, Central and Eastern Europe; CI, confidence interval; CRP, C-reactive protein; DAS28-4(ESR), Disease Activity Score in 28 joints, erythrocyte sedimentation rate; DMARD, disease-modifying antirheumatic drug; ESR, erythrocyte sedimentation rate; HAQ-DI, Health Assessment Questionnaire-Disability Index; IR, incidence rate; LTE, long-term extension; MACI, major adverse cardiovascular safety events; NMSC, non-melanoma skin cancer; pt, patient; ROW, rest of world; SAE, serious adverse event; SOC, swollen joint count; TB, tuberculosis

Results: 1765 patients (pts) from CEE and 5296 from ROW were included in the safety analyses. Demographics and baseline characteristics were generally similar between CEE and ROW aside from race (99.9% vs 53.1% white), prior TNF inhibitor use (2.2% vs 20.8%) and non-TNF inhibitor biologic DMARD use (1.0% vs 6.4%); mean duration of RA was 7.6 years (range 0–65) in CEE and 8.2 years (range 0–55) in ROW. Safety results based on 21 studies and efficacy results based on five P3 studies are summarized in the table. Efficacy outcomes improved with tofacitinib vs placebo in CEE and ROW pts at Month 3. Improvements in composite measures (ie, ACR response rates and Disease Activity Score in 28 joints using erythrocyte sedimentation rate [DAS28-4(ESR)] ≤2.6) and Health Assessment Questionnaire-Disability Index (HAQ-DI) were numerically greater for ROW vs CEE pts; changes in objective measures (ie, swollen joint count and inflammatory markers) were more similar.

Conclusion: Tofacitinib showed substantial improvements in efficacy vs placebo in CEE and ROW. Results were generally consistent between CEE and ROW subpopulations. Following tofacitinib treatment, incidence rates of serious and

opportunistic infections were lower for CEE vs ROW, which may reflect the marginally lower RA duration beforehand; the lower prior biologic DMARD use in CEE may also have impacted efficacy and safety. Major limitations include the post hoc nature of this analysis and the small CEE population vs ROW, therefore results should be interpreted with caution. Previous analyses have revealed consistent safety and efficacy with tofacitinib in US and Western European subpopulations vs ROW.^{1,2}

Exploring the Effects of Depressive Symptoms on the Efficacy of Sarilumab and Improvements in Health-Related Quality of Life

Vibeke Strand¹, Erin Mangan², Owen Hagino³, Jonathan Sadeh⁴, Susan Boklage² and Toshio Kimura², ¹Division of Immunology/Rheumatology, Stanford University, Palo Alto, CA, ²Regeneron Pharmaceuticals, Inc., Tarrytown, NY, ³Sanofi Genzyme, Bridgewater, NJ, ⁴Sanofi, Bridgewater, NJ

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster II: PROs, Safety and Comorbidity

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The pro-inflammatory cytokine IL-6 has been found to play a critical role in mood disorders, with symptoms such as anxiety and depression having implications for RA disease activity. Studies have shown poorer disease outcomes in RA patients with depression.¹ This study evaluated the effect of baseline depressive symptoms on the efficacy of sarilumab and improvements in health-related quality of life (HRQOL).

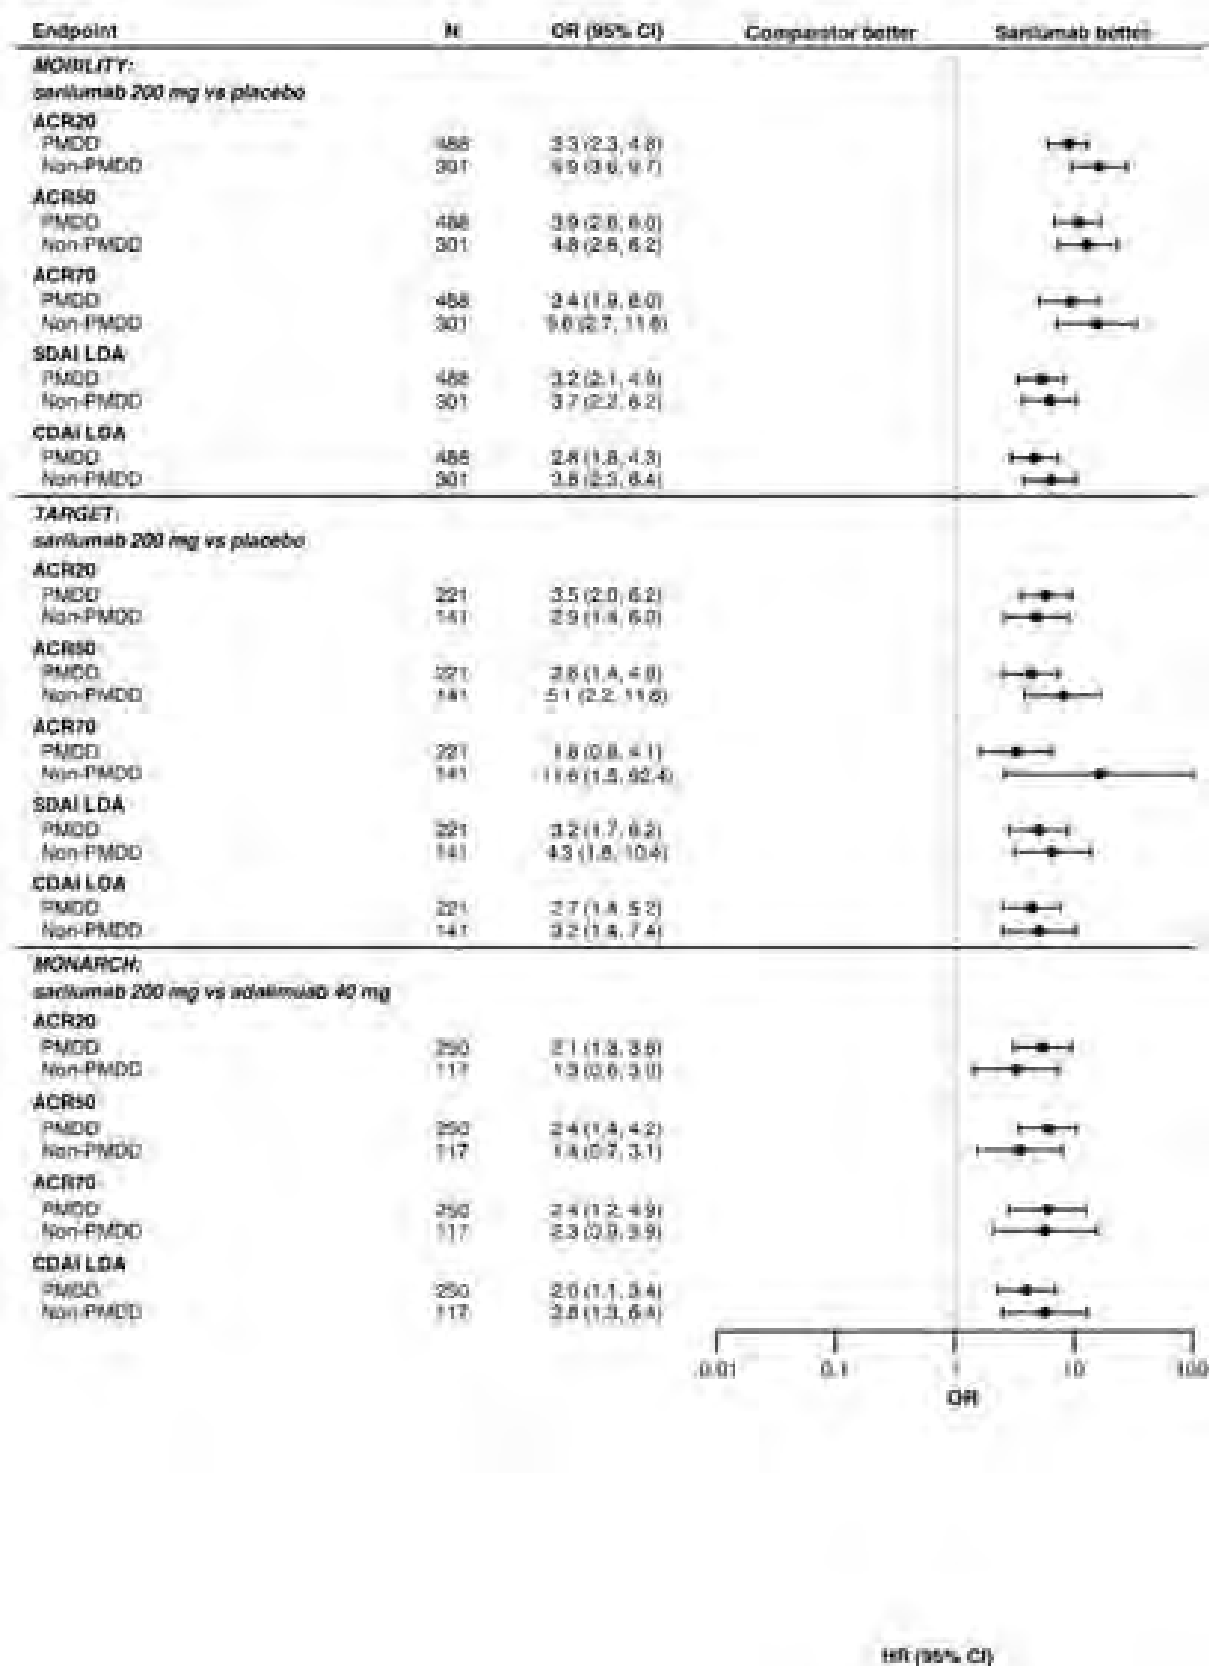

Methods: Post hoc statistical analyses of clinical and patient-reported outcomes (baseline; Week 24) were conducted in patients with moderately-to-severely active RA from 3 Phase 3 randomized controlled trials (RCTs) comparing the efficacy and safety of subcutaneous (SC) sarilumab 200 mg every 2 weeks (q2w) plus methotrexate (MTX) in MOBILITY [NCT01061736], plus csDMARDs in TARGET [NCT01709578] and as monotherapy versus adalimumab SC 40 mg q2w in MONARCH [NCT02332590]. Patients were categorized with probable Major Depressive Disorder (PMDD)² at baseline defined by a Mental Health (MH) domain score ≤ 56 on the Medical Outcomes Study 36-item short form (SF-36) questionnaire.

Results: Of 1197, 546 and 369 patients in MOBILITY, TARGET and MONARCH, respectively, 60.2%, 59.5% and 67.8%, were classified as PMDD. Disease duration, baseline DAS-28 CRP, tender and swollen joint counts and SF-36 MH scores were similar between sarilumab 200 mg plus MTX in MOBILITY and sarilumab 200 mg plus csDMARDs in TARGET versus placebo, and versus adalimumab in MONARCH in the PMDD subgroups. Interaction between PMDD and non-PMDD subgroups was non-significant for all endpoints except change from baseline in Patient Global Assessment of disease activity in MOBILITY (nominal $P < 0.05$). Odds ratios for responses by ACR20/50/70, SDAI ≤ 11 and CDAI ≤ 10 at Week 24 were nominally higher with sarilumab 200 mg versus placebo in both PMDD and non-PMDD subgroups in MOBILITY (nominal $P < 0.0001$), TARGET (nominal $P < 0.01$), and in PMDD by ACR20/50/70 in MONARCH (nominal $P < 0.05$) (Figure 1). MH scores for PMDD subgroups were nominally higher ($P < 0.05$) in ACR20 responders with sarilumab 200 mg versus placebo at Week 24 in MOBILITY (Figure 2). Sarilumab safety was consistent with IL-6R blockade.

Conclusion: These post-hoc analyses suggest that sarilumab treatment is equally efficacious irrespective of baseline PMDD status.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster II: PROs, Safety and Comorbidity

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Corticosteroids are effective in rheumatoid arthritis (RA) patients but their adverse events limit their use. The aim of this study was to: 1) To systematically and critically review the evidence on the characteristics, efficacy and safety of corticosteroids in RA; 2) To generate practical recommendations on its use.

Methods: We performed sensitive systematic literature searches in Medline and Cochrane (up to September 2017), screened EULAR and American College of Rheumatology meeting-abstracts. An expert librarian designed the strategies that included Mesh and text word terms. The search was limited to human RA, adults and the English and Spanish language. The inclusion criteria were as follow: 1) RA patients on corticosteroids; 2) Placebo and an active comparator were accepted as comparators; 3) Articles including typical efficacy and safety variables such as pain, DAS-28, radiographic progression or the infections rate; 4) Only meta-analyses, systematic reviews and clinical trials were selected. Two reviewers screened the titles and abstracts of the retrieved articles independently. They also collected the data from the studies included by using ad hoc standard forms. All collection was double by article and independent. Subsequently, a secondary manual search of the bibliography of the articles that were finally included was performed. Evidence tables were produced. The quality was evaluated with Jadad scale. In a nominal group meeting, based on their results, a panel of experts discusses this evidence and generated practical recommendations. The level of evidence and grade of recommendation was assessed according to the Center for Evidence Based Medicine de Oxford.

Results: A total of 47 articles were included. Corticosteroids in combination with DMARDs help control disease activity and radiographic progression, especially in the short-medium term and in early RA. Corticosteroids can also improve function and pain. Different types and routes of administration are effective, but there is not a standardized scheme (initial dose, de-escalation and duration of treatment with corticosteroids) superior to others. Adverse events when using corticosteroids are very frequent, dose-dependent although most are mild. Seven recommendations were generated on the use and risk management of corticosteroids (see table).

Conclusion: These recommendations aim to resolve some common clinical questions and facilitate decision-making with the use of corticosteroids in RA.

#	Recommendations
1	In patients with early RA, treatment with corticosteroids in combination with synthetic DMARDs is recommended (NE 1b; GR A)
2	In established RAs it is recommended to individualize the use of corticosteroids as a symptomatic treatment (NE 5; GR D)
3	Corticosteroids are recommended as bridging therapy in early RA, using low doses (≤ 7.5 mg/day of prednisone or equivalent), or medium doses (30 mg/day) following a rapid tapering scheme (NE 1b; GR A)
4	In patients with RA it is recommended to use the lowest effective dose of corticosteroids and to stop them as soon is possible (NE 1b; GR B)
5	When using corticosteroids in patients with RA, it is recommended to rule out comorbidities and risk of infection before their prescription (NE 5; GR D)
6	If corticosteroids are prescribed in the medium to long term, in patients with RA, close monitoring of cardiovascular risk factors and bone mineral density is recommended (NE 5; GR D)
7	If corticoids are prescribed in the medium to long term, in patients with RA, the prophylaxis of osteoporosis induced by corticosteroids is recommended (according to the recommendations of the international guidelines) (NE 5; GR D)

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster II: PROs, Safety and Comorbidity

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Several previous reports suggest that obesity impairs the effectiveness and drug survival of anti-TNF- α agents in rheumatoid arthritis (RA). The aim of the study was to analyze the impact of obesity on drug survival of tofacitinib inpatient with RA, based on their baseline body mass index (BMI).

Methods: Data on patient characteristics, demographics, diagnosis, disease duration, treatment and outcomes have been collected since 2011 in Turkish Biologic (TURKBIO) Registry. By the end of May 2018, 140 RA patients received tofacitinib and were included. Demographic and clinical data including age, sex, disease type, disease duration and previous or current treatment with DMARDs and biological drug durations are stored in the database. Kaplan-Meier survival analysis was performed to estimate the drug survival.

Results: All patients received tofacitinib 5 mg BID. Patients were grouped according to BMI. Forty-eight were obese (BMI >30), 92 were non-obese patients. Obese patients were found to be older, had more DM and HT compared to non-obese patients as expected (Table 1). Gender distribution, disease duration, serologic positivity, previous or current treatment with DMARDs, previous TNF inhibitor or non-TNF biological drug use, concomitant prednisolone use and mean clinical and laboratory parameters through the observation period did not differ between groups. Tofacitinib treatment was ongoing in 59.8% in non-obese and 70.8% in obese patients. Median drug survival duration was 10 months in non-obese patients and 24 months in obese ones ($p=0.1$). Estimated drug survival rates for tofacitinib were not statistically significantly different between groups (Figure 1).

Conclusion: Real life experience from this nationwide TURKBIO registry suggests obesity does not adversely affect drug survival of tofacitinib in patients with RA. Further studies are needed to study impact of obesity on its clinical efficacy.

Abstract Number: 1548

Favorable Effect of Hydroxychloroquine in Patients with Rheumatoid Arthritis and Diabetes or Impaired Glucose Control

Farhana Polara, Mohmed Imran Gora and Shante Hinson, Internal Medicine, Lincoln Medical and Mental hospital, Bronx, NY

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster II: PROs, Safety and Comorbidity

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Hydroxychloroquine (HCQ) is widely prescribed for patients with Rheumatoid Arthritis (RA) and Systemic Lupus Erythematosus (SLE). It is fairly well tolerated with multiple well studied side effects, including those on insulin homeostasis and glucose metabolism. In this study, we review the long term effects of HCQ on blood glucose control in patients with RA and Impaired Glucose tolerance (Pre-DM) or Diabetes (DM).

Methods: 155 patients with RA who were prescribed HCQ from Jan, 2014 to Jan, 2017 were identified. These patients were grouped into patients HgbA1c ranging from 5.7 to 6.4 as Pre-DM and those with HgbA1c >6.4 as DM. HgbA1c levels 6 months prior to initiation of therapy was identified and compared to HgbA1c levels 6 months and 1 year after the initiation of HCQ. We also compared LDL levels of these patients 1 year prior to and 1 year after the initiation of HCQ.

Results:

- 19 patients were identified as DM. 17 (89%) patients had a repeat HgbA1c at 6 months of which 12 (70%) had improvement and 5 (30%) had worsening. The average improvement in HbA1c in all these patients was 1.46% at 6 months. 17 patients had HgbA1c at 1 year. Of them, 11 (64%) had improvement, 5 (22%) had worsened and 1 (6%) had no change. The average improvement in HbA1c in all these patients was 2.62% at 1 year. These patients were on different combination of diabetes medications.

- 25 patients were identified as Pre DM prior to start of therapy. Of these, 11 patients (44%) had a HgbA1c at 6 months, 9 (81%) of them showed improvement and 3 (19%) showed worsening. The average improvement in HbA1c in all these patients at 6 months was 0.33%. 9 patients had followed up HgbA1c at 1 year after their HCQ therapy. Of them, 7 (77%) showed improvement while 2 (12%) had similar and 2 (11%) patient had worsening of their HgbA1c. The average improvement in HbA1c at 1 year was 0.29%. None of these patients were on any form of glucose control medication.
- We also reviewed 58 patients with LDL levels approximately 6 months prior to and 1 year after treatment with HCQ. 30 (51%) patients showed a decrease and 28 (49%) showed an increase in their LDL level.

Conclusion: HCQ has been shown to reduce the risk of development of DM in patients with RA. Studies have also shown reduction of HgbA1c in patients with RA and DM on treatment. HCQ also improves glucose control in patients with DM without any rheumatologic disease. This has been postulated to be from its effect on increased insulin secretion and decreased degradation leading to insulin accumulation at cellular level increasing their insulin sensitivity and this is independent of its anti-inflammatory activity. Our study suggests the positive effect of HCQ on average blood glucose levels represented by the drop in HgbA1c by 2.62% in DM patient and a drop of 0.29% in the PreDM group of patients. This favorable effect of HCQ on glucose control could makes it a preferred anti-inflammatory in those patients that have RA along with PreDM or DM.

Disclosure: F. Polara, None; M. I. Gora, None; S. Hinson, None.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster II: PROs, Safety and Comorbidity

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: According to clinical practice guidelines for patients with rheumatoid arthritis (RA), after failure to a c-DMARD (conventional disease modifying antirheumatic drug) can be chosen either by the combination with another c-DMARD, or by the addition of b-DMARD (biological) or ts-DMARD (target synthetic). The most frequent c-DMARD combination therapy in our country is methotrexate (MTX) plus lefunomide (LEF).

The objective is to compare the survival and safety of treatment between two cohorts of patients with RA who have failed to c-DMARD monotherapy: one with combination of MTX + LEF (cohort A) and the other with the first b-DMARD (cohort B).

Methods: Patients ≥ 18 years old with RA (ACR 1987 or ACR/EULAR 2010 criteria), who received treatment with MTX plus LEF or with the first b-DMARD therapy after failing c-DMARD monotherapy were included. Sociodemographic, clinical and therapeutic variables were recorded. Disease activity was assessed by DAS28. The adverse events (AE) that occurred during the treatment, the severity of them, as well as, the interruptions of the treatment were consigned. The causes of discontinuation and survival of both types of treatment were evaluated. *Statistical analysis:* Descriptive statistics. Chi ² test, Student's T test and/or Mann Whitney test. Multiple logistic regression analysis. Kaplan Meier curves and Log Rank test for survival analysis.

Results: 202 patients were included, median age was 58 years old (IQR 50.7-65), 86.6% were female and the median disease duration was 15 years (IQR 9-22). 69.8% had associated comorbidities. 100 patients (49.5%) were in cohort A and 102 (50.5%) were in cohort B. No baseline differences were found related to the clinical characteristics, except for the prevalence of previous tuberculosis (Cohort A 5.2% vs cohort B 0%, $p = 0.02$) and heart failure (Cohort A 7.4% vs cohort B 1%, $p = 0.03$). We did not observe differences in treatment survival between both cohorts [Cohort A: mean 121.2 months (95%CI: 100.3-142) and cohort B: mean 77.1 months (95%CI 63.3-91), $p = 0.2$]. 47.6% of cohort A permanently or temporarily suspended therapy vs 52.4% of cohort B ($p = 0.67$), being the most frequent causes of discontinuation: for cohort A inefficacy (31.1%) and AE for cohort B (55.8%). 56.9% suffered at least one AE and 60% of them were receiving concomitant corticosteroids. The infections were more frequent in cohort B 39.7% vs cohort A 19.6% ($p = 0.02$). In multivariate analysis, adjusting for age and disease duration, corticosteroid treatment was associated with the presence of AE (OR: 19.8, 95% CI: 6.23-57.6, $p < 0.001$) regardless of the type of treatment, and the use of biological therapy was associated with higher risk of infections (OR 2.7, 95%CI: 1.15-6.34, $p = 0.02$) regardless of the use of concomitant corticosteroids.

Conclusion: Treatment survival in both cohorts was comparable. The frequency of infections was higher in cohort with b-DMARD. Concomitant treatment with steroids increased the risk of AE, regardless of the type of treatment.

Session Title: Rheumatoid Arthritis – Treatments Poster II: PROs, Safety and Comorbidity

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Interleukin 6 (IL-6) and C-reactive protein (CRP) are independent risk factors for type 2 diabetes mellitus [1], and IL-6 plays a role in insulin resistance [2]. Ogata et al. demonstrated a tocilizumab (TCZ) induced a reduction of HbA1c in patients with diabetes and rheumatoid arthritis (RA) [3]. The present analysis of the non-interventional study ICHIBAN (final dataset) investigated whether there is a difference in the effectiveness and safety of TCZ in RA patients with and without diabetes.

Table 1: Comparison of effectiveness and safety of TCZ between diabetic and nondiabetic patients.

Infections (TESAEs) ^c	3.9	7.2	3.5

Table 1: Comparison of effectiveness and safety of TCZ between diabetic and nondiabetic patients.

BL: Baseline; LV: last visit under TCZ; Q1, Q3 = lower, upper quartile; SD: standard deviation; TCZ: tocilizumab; TEAE: treatment-emergent adverse events; TESAE: treatment-emergent serious adverse events; VAS: visual analog scale; CHD: coronary heart disease.

^a For 6 patients (0.2% of Total) the diabetes status was not documented.

^b Analysis based on 31 patients with HbA1c values available at BL and Week 104 (10 diabetic and 21 nondiabetic patients).

^c Two patients with a HbA1c >7.5% were classified as diabetic.

^d Infections: all AEs/SAEs with MedDRA preferred term indicating any kind of infection.

Methods: The ICHIBAN study (NCT 01194401) observed patients with RA during treatment with TCZ iv (max. 2 years) between 2010 and 2017. All 3164 patients who had received at least 1 dose TCZ were included in the analysis (Total). Classification of diabetes mellitus was based on the data provided by the investigators at baseline (BL).

Results: At BL, 9.9% (N=314) of the patients were diabetic and 89.9% (N=2844) were nondiabetic.

Diabetic patients were markedly older compared to nondiabetic patients (mean age: 63.0 vs 54.7 years), had a higher BMI (mean: 29.6 vs 26.6 kg/m²), a higher disease activity (mean DAS28: 5.5 vs 5.2), a more severe functional impairment at BL (mean HAQ: 1.6 vs 1.3%), and a higher comorbidity rate, particularly regarding coronary heart disease (11.5% vs 3.7%), osteoporosis (25.2% vs 16.3%) and depression (11.5% vs 7.0%).

Both subgroups had a comparable response regarding all investigated variables, despite the differences in BL characteristics. DAS28-ESR improved by 2.2 vs 2.1 points in patients with and without diabetes; HAQ improved by 0.2% in both subgroups. HbA1c was markedly decreased (-0.73%) after 104 weeks of TCZ treatment in diabetic patients, whereas there was no change in nondiabetic patients (Tab. 1).

The rates of serious adverse events (20.7% vs 14.3%) and of serious infections (5.4% vs 3.4%) were higher in patients with diabetes than in those without; there was no difference regarding non-serious adverse events.

Conclusion: The proportion of diabetic patients was slightly higher in the ICHIBAN study (9.9%) compared to the general population (~8%) [4]. An effective clinical response was observed during TCZ iv therapy. Despite a higher disease activity and comorbidity rate at BL, patients with diabetes benefitted to the same extend as nondiabetic patients with regard to all investigated efficacy variables. The safety data underscore the higher risk for infection in diabetic patients. HbA1c decreased from 7.46% to 6.73% in diabetic patients. Further research is necessary to clarify the underlying mechanisms.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster II: PROs, Safety and Comorbidity

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Anti-drug antibodies (ADAb) to biological drugs predispose patients (pts) to low drug levels and lack of treatment response. For certolizumab pegol (CP) knowledge about the frequency and clinical relevance of ADAb is limited in pts with inflammatory joint diseases (IJD).

Objectives: To assess the frequency and clinical relevance of early ADAb development in pts with inflammatory joint diseases treated with CP.

Methods: Pts from the NOR-DMARD study (n=310) with a clinical diagnosis of RA (91), PsA (61), axSpA (116) and other IJD (42) starting treatment with CP, who had available biobank sample at 3 months follow-up, were included. Serum samples are non-trough samples collected at 3 months. Drug concentrations were analysed using an in-house immunofluorometric assay automated on the AutoDELFLIA immunoassay platform. ADAb was detected by a principal assay measuring neutralising ADAb and two confirmational tests (antigen-bridging test and a 3-step immuno fluorometric assay). Pts with RA, PsA and axSpA were included in response analyses. Treatment response was defined by EULAR good/moderate response in RA, DAS28 improvement ≥ 0.6 in PsA, and ASDAS clinically important improvement (CII) in axSpA.

Results: After 3 months of treatment, 19 of 310 (6.1%) patients were ADAb positive (5 RA, 4 PsA, 6 axSpA and 4 other IJD). ADAb positive pts had significantly lower CP levels than ADAb negative pts, median 1.0 (IQR 0.2-6.8) vs 34.4 (IQR 21.2-44.7) mg/L ($P < 0.001$).

Response data were available for 245 pts. Of these, only 1/11 (9%) ADAb-positive pts was classified as a responder, while 10/11 (91%) were non-responders. Among ADAb-negative pts with response data, 129/234 (55%) were responders, while 105/234 (45%) were non-responders.

Conclusion: ADAb against CP were detected in 6.1% of patients after 3 months of treatment and were associated with low drug levels and reduced treatment response. These results suggest that drug levels and ADAb may be important for the monitoring efficacy of treatment with TNF inhibitors, but the clinical significance needs to be examined in randomised clinical strategy trials.

No effect of concomitant glucocorticoid therapy on efficacy and safety of tocilizumab monotherapy in rheumatoid arthritis clinical trials

M. Safy¹, J.W.G. Jacobs¹, M. Edwardes², M.J.H. de Hair¹, X.M. Teitsma¹, P.M.J. Welsing¹, M.E.A. Borm³, Y. Luder⁴, J.M. van Laar¹, A. Pethö-Schramm⁴, J.W.J. Bijlsma¹

¹Dept. of Rheumatology & Clinical Immunology, University Medical Center Utrecht, Utrecht University, Utrecht, the Netherlands, ² Everest Clinical Research, Canada, ³ Roche Nederland BV, Woerden, the Netherlands, ⁴ F Hoffmann-La Roche, Basel, Switzerland

Background/Purpose: Among RA patients in clinical trials, background treatment with glucocorticoids (GCs) is common. The potential impact of GCs on safety of the DMARD tested in these trials has rarely been evaluated. Our aims were to establish whether a stable concomitant GC treatment influenced: 1) efficacy and safety of tocilizumab (TCZ) monotherapy initiated in RA patients in TCZRCTs and 2) efficacy and safety in the comparator arms of these trials, in which adalimumab (ADA) or methotrexate (MTX) was initiated.

Methods: Data were used from 4 RCTs including AMBITION, ACT-RAY, ADACTA and FUNCTION with TCZ monotherapy arms. Patients had discontinued bDMARDs or were bDMARD naïve and MTX-naïve, MTX-intolerant or MTX inadequate responders. Stable GC dose at baseline was allowed. Differences in change from baseline up to week 24 in CDAI and DAS28 between GC-users and non-GC-users were analysed using ANCOVA. Difference in radiographic progression up to week 104 between GC-users and non-GC-users was analysed. Incidence rates of SAEs were assessed by GC use.

Results: Baseline characteristics were comparable between GC users and non-GC users within RCTs. No significant differences were found in DAS28 change or CDAI change from baseline to 24 weeks, nor in CDAI remission percentages and ACR50 response at 24 weeks, between GC users and non-GC users in TCZ, ADA, or MTX arms (Figure). In the MTX arm a significant difference in radiographic progression was found, in favour of GC use. SAE rates were numerically higher for GC users vs non-GC users in MTX and ADA arms (Table), however this difference was not tested statistically.

Conclusion: In 4 RA TCZ clinical trials, no effect of stable concomitant GC treatment at baseline and continued during the trial was found on efficacy of MTX or TCZ or ADA monotherapy. The SAE rate was numerically higher in GC users compared to non-GC users in the MTX and ADA monotherapy arms.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster II: PROs, Safety and Comorbidity

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Both rheumatoid arthritis (RA) and older age are associated with a higher risk of comorbidities, and the appropriate treatment approach for older patients is unclear. We evaluated real-world data (RWD) to determine whether there is an association between etanercept (ETN) and select adverse events (AEs) in patients with RA, stratified by age. We hypothesized that there is no difference in risk of AEs between younger (aged ≤65 yr) and older (aged >65 yr) patients.

Methods: Data from 2013 to 2018 were analyzed from the IBM Watson Health Markets can Database which contains information on 104.5 million distinct patients, including 531,996 with RA. Patients were required to be rolled ≥1 yr prior to RA diagnosis; the first exposure to ETN was after RA diagnosis and before the AE of interest: congestive heart failure (CHF), serious infection (SI), non-melanoma skin cancer (NMSC), or interstitial lung disease (ILD). Proportion of patients experiencing each AE was determined for patients ≤65 yr and >65 yr receiving and not receiving ETN. Differences were evaluated using Fisher's Exact test. Logistic regression models assessed the interaction between ETN and age group.

Propensity matching was performed, and logistic regression was applied using the propensity-score-matched cohort. Patients receiving and not receiving ETN were matched by age, age >65 yr, gender, and geographical region.

Results: Average age of patients with RA was 56.1 ± 14.9 yr; 73.5% were female. Risk of experiencing CHF did not differ significantly for patients receiving vs not receiving ETN: odds ratio (OR) = 0.883, 95% CI: 0.770-1.009; $p=0.072$. However, the risks of SI, NMSC, and ILD were significantly higher in the patients receiving ETN (SI: OR=1.14, 95% CI: 1.07-1.21, $p<0.001$; NMSC: OR=1.20, 95% CI: 1.05-1.37, $p=0.008$; and ILD: OR=1.89, 95% CI: 1.56-2.29, $p<0.001$). In patients >65 yr, the occurrence of CHF was lower for patients receiving vs not receiving ETN (8.7% vs 10.7%, $p=0.025$) (Figure); the occurrence of SI and NMSC did not differ significantly; SI: 21.8% vs 20.4% for ETN vs no ETN, respectively, $p=0.186$; NMSC: 6.3% vs 5.2%, $p=0.952$. The occurrence of ILD was higher for patients receiving ETN: 3.4% vs 1.4%, $p<0.001$. The difference in AE occurrence between patients ≤65 yr and >65 yr did not differ significantly for patients receiving vs not receiving ETN for any of the AEs (Figure).

Conclusion: In this analysis of RWD of patients with RA, the risk of CHF, SI, NMSC, and ILD between younger and older patients was not modified by ETN usage. This analysis suggests an overall acceptable safety profile of ETN; however, clinicians should use caution when treating older patients.

Figure. Occurrence of AEs according to age group and ETN treatment status

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster II: PROs, Safety and Comorbidity

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Smoking is one of the described risk factors for rheumatoid arthritis (RA) since smoking may induce citrullination of peptide antigens and thus the trigger anti-citrulline immunity. Moreover, smoking increases the disease activity and radiological progression in RA. Current smoking is associated with poor responses to therapy with anti-rheumatic drugs including methotrexate and anti-TNF agents in RA. The aim of our study was to investigate whether cigarette smoking influences the response to tofacitinib treatment in patients with RA.

Methods: Data on patient characteristics patients receiving targeted treatments have been collected since 2011 in Turkish Biologic (TURKBIO) Registry. By the end of May 2018, 115 RA patients received tofacitinib from the TURKBIO registry, were included in the analysis. Patients were divided into subgroups as current smokers and non-smokers (never+ex-smokers). Demographic and clinical data including age, sex, disease type, disease duration, and previous or current treatment with disease-modifying anti-rheumatic drugs and tofacitinib usage durations are compared. Kaplan-Meier survival analysis was performed to estimate the drug survival of tofacitinib.

Results: There were no significant differences in gender, seropositivity, tender and swollen joint counts at baseline in the study groups, although current smokers were significantly younger ($p<0.001$). Almost all baseline parameters were similar in the current smokers and non-smokers. 71.6% and 65.1% of current smokers and 68.2% and 48.6% of non-smokers were going on the treatment at 6th and 12th months, respectively ($p=0.378$). There was no significant difference between groups in terms of drug survival rates for tofacitinib.

Table 1 Clinical and laboratory characteristics

	Current Smokers (n=27)	Non-Smokers (n=88)	p
Age, year	44.5 (35.8-53)	56.5 (47.6-63)	<0.001
Gender (Females), n (%)	20 (74.1)	77 (87.5)	0.128
Disease duration, years	10 (4-16)	10.5 (5-16.5)	0.835
Tofacitinib is 1 st choice biologic or targeted DMARD, %	48.1	56.8	0.509
Concomitant glucocorticoid usage, %	41.1	51.1	0.346
Glucocorticoid dosage, mg/day	4 (4-5)	5 (4-6)	0.173
RF positivity, n (%)	77.8	65.6	0.328
CCP positivity, n (%)	25.1	28.8	0.763
Baseline swollen joint count, n	2 (0-4)	3 (0-5)	0.521
Baseline tender joint count, n	3.5 (2-7)	5 (2-9)	0.371
Baseline ESR, mm/h	24 (19-38)	36 (17-55)	0.099
12 th month ESR, mm/h	16 (12-31)	28 (21-52)	0.063
Baseline CRP, mg/dl	4 (3-8)	5.4 (3.33-15.45)	0.232
12 th month CRP, mg/dl	3 (1-6)	8 (3.02-11)	0.139
Baseline DAS28-CRP	4 (3-4.8)	4.4 (3.5-4.9)	0.279
12 th month DAS28-CRP	1.7 (1.3-3)	2.1 (1.9-3.1)	0.233
Baseline HAQ	1 (0.625-1.5)	1 (0.75-1.5)	0.849
12 th month HAQ	0 (0-0.25)	0.75 (0.25-1.375)	0.020

DMARD; disease modifying anti-rheumatic drug, RF; rheumatoid arthritis, CCP; cyclic citrullinated peptide, ESR; erythrocyte sedimentation rate, CRP; C-reactive protein, DAS; disease activity score, HAQ; Health Assessment Questionnaire.

Conclusion: Current smoking does not affect the response and drug survival for tofacitinib in RA. However, it is obvious that smoking is related with high morbidity and mortality in RA, since it increases pulmonary disabilities and the risks of atherosclerosis and malignancies. Moreover, it is known to increase the risk for RA, and the clinical and radiological progression of RA. Therefore, the cessation of tobacco use should be still advised to all smoker RA patients.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster II – ARHP

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Major advances in the management of rheumatoid arthritis (RA) have been recorded over the last decade thanks to the introduction of biologics. However, medical needs concerning functioning and quality of life of patients are not completely fulfilled⁽¹⁾. In France, the quality of life of RA patients treated with long-term biotherapy in real life has never been the subject of a specific study.

Methods: In partnership with two patients' associations, a cross-sectional observational survey of RA patients treated with biologics since at least one year, with the aim of assessing their functioning (using the HAQ-DI⁽²⁾ questionnaire) and quality of life (EQ-5D⁽³⁾ questionnaire) on a daily basis was carried out. Treatment satisfaction and expectations have been also evaluated.

Results: A total of 504 RA patients have been included in the study (mean age = 62.4 years; 18% male and 82% female). The average RA duration was 19.2 years and the mean treatment period with biologics was 8 years. About 40% of patients received first-line biologic treatment and 30% received 2nd- or 3rd-line biologic treatment. When RA was poorly controlled with first-line treatment, patients changed their treatment every 3 years on average. Reasons for switching biologics included poor efficacy (60% of patients) and tolerance problems (31%). Hospitalization due to RA progression during the last 12 months were reported by 22% of patients in 1st line-treatment and by 32% of patients in 2nd line and more. Functional disability, particularly affecting manual activities of daily living, also increased with the number of treatment lines. In addition, more than 50% of the patients in professional activity had to adapt or change their activity because of their state of health. Regarding health perception, only 14% of patients were satisfied with their symptom improvement (scored 80 to 100 on a scale from 0 to 100). The average score was 63.5 (quite satisfying). In addition, whether on symptoms or well-being, only a third of patients were satisfied with their condition. If patients recognize the major contribution of biologics (average satisfaction score was 7.5/10), they are more than 80% to expect the arrival of new biologics to improve their quality of life.

Conclusion: Despite the major therapeutic progress achieved with biologics for the management of rheumatoid arthritis, the results of this survey conducted with patient associations demonstrate a persistent functional disability in patients with RA as well as a reduced quality of life. The level of expectation of these patients remains high concerning future therapeutic alternatives.

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Small fibre neuropathy (SFN) is a peripheral neuropathy characterized by neuropathic pain associated with normal routine nerve conduction study but rarefaction of intraepidermal nerve fibres (IEFN). Primary Sjögren Syndrome (pSS) is one of the many aetiology of SFN. To compare phenotype of SFN in pSS, transthyretin (TTR) familial amyloidosis and idiopathic SFN. To describe evolution of SFN in pSS.

Methods: All patients referred since 2012 with a skin biopsy-proven SFN associated with either pSS (ACR/EULAR 2016 criteria), TTR amyloidosis or idiopathic were included in this monocentric retrospective study. Diagnosis of SFN was confirmed by normal nerve conduction study and abnormal lower limb skin biopsies. All patients undergo standardized diagnosis procedures during an outpatient day-clinic, pSS patients were further followed and undergo a second evaluation. Characteristics of SFN were compared between 3 groups: pSS, TTR-amyloidosis and idiopathic. Outcome of pSS associated SFN was analysed.

Results: We included 15 patients with pSS (13 (86.7 %) women, median age: 55 years [IQR:47.5-66.5], 7 (46.7%) anti-SSA positive, 12 (80%) focus score ≥ 1), 17 with TTR-amyloidosis (7 (41.2%) women, median age: 47 years [35-56]) and 11 with idiopathic SFN (7 (63.6%) women, median age: 47 years [36-56.5]). Patients with pSS had a median ESSDAI of 5 [5-8]. One had monoclonal gammopathy (6.7%), 5/13 (38.5%) rheumatoid factor, 2/13 (15.4%) hypergammaglobulinemia and none had cryoglobulin. Time to diagnosis SFN was significantly higher for pSS (21 months [9-54]) and idiopathic group (35 months [11.5-65]) than for TTR group (6 months [0-15]). Clinical presentation was length dependent in 2 (13.3%) pSS patients compared to 10 (58.8%) in TTR amyloidosis ($p=0.01$) and 2 (18.2%) in idiopathic group ($p=1$). A "patchy" presentation (defined as asymmetrical and/or proximal symptoms involving limb, trunk and/or face), was significantly more frequent in pSS than in TTR amyloidosis (7 (46.7%) vs. 1 (5.9%); $p=0.01$). This more frequent non-length dependent course was confirmed by skin biopsies (IEFN at proximal site $<$ IEFN at distal site) in 7/14 (50%) pSS patients compared to 1 (9.1%) in idiopathic ($p=0.04$) and 2/15 (13.3%) in TTR groups ($p=0.05$). Lauria score was significantly higher in pSS than in TTR, (5 [4-7.5] vs. 2 [2-5], $p=0.007$), mainly due to items of sicca symptoms ($n=14/15$) and peripheral limb pain ($n=13/15$). Ten patients with pSS have been reassessed with a median follow up of 37 months [20.5-56.3]. At reassessment, the Lauria score did not significantly differ (6.5 [5.3-7.8], $p=0.48$) from baseline, patchy presentation was still predominant (50%). Patients did not evolve through large fibre neuropathy, except one patient who had received a neurotoxic chemotherapy by platin for ovarian cancer, between the 2 evaluations.

Conclusion: Compared to other causes of SFN, in pSS SNF was characterized by a more frequent non-length dependent and patchy presentation and a higher Lauria score. After a median follow-up of >3 years, SFN in pSS did not evolve through large fibre neuropathy, which supports the hypothesis that it is related to a specific mechanism and does not represent the beginning of an axonal neuropathy like it is for TTR amyloidosis.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Sjögren's Syndrome – Basic and Clinical Science Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Sjögren's syndrome (SS)-associated neuropathy manifests as various forms of neuropathy, including sensory ataxic neuropathy (SAN). Dorsal root ganglionitis, pathologically defined as the lymphocytic infiltration of the

dorsal root ganglion (DRG),causes SAN. This study aimed to determine whether 3-Tesla magnetic resonanceneurography (3T-MRN) is useful for detecting abnormalities of DRGs, and making diagnoses in patients with SS-SAN.

Methods: We conducted a retrospective chart review from 2015 to 2017 and enrolled 3 patients with SS-SAN fulfilling American–European Consensus Group classification criteria. We evaluated with a3T MRI scanner and used the coronal short-tau inversion recovery (STIR) technique because of its advantages in depicting a symmetric normal hyperintensityof DRGs and nerves. On measuring a pair of DRGs, regions of interest (ROI) were manually drawn by using ImageJ (<http://rsb.info.nih.gov/ij/>). The area, medianSI, and transverse diameter of each DRGs were measured and compared with those of the corresponding proximal nerve roots. The SI ratio (SI within a DRG/SIwithin a proximal nerve root) and diameter ratio (transverse diameter of aDRG/width at the middle point of a proximal nerve root) were subsequently calculated. For each nerve root level, data from SS patients were compared with those of age- and sex-matched non-neuropathy controls (20 DRGs from 10 cases). All statistical analyses were performed with EZR, a graphical user interface for R(The R Foundation for Statistical Computing, Vienna, Austria). The Mann–WhitneyU test was applied for the statistical analysis.

Table 1. Clinical and Laboratory Findings, and Treatment Responses.

Patient Age/sex	Onset duration	Clinical presentation	Laboratory findings	Genetic findings	PTB findings	Immunological findings	Immunohistochemical findings	Treatment and responses
1/73/Female	3 years	Sensory ataxia, Romberg's test (+)	DRG: 4-6 MUSC: 4-6 Normal Cytology	Positive	PTB: 2-4 MUSC: 4-6	Normal (CBC, complement, and IgG)	Normal (CD3, CD4, CD8, CD20, CD45, and IgG)	Normal (CD3, CD4, CD8, CD20, CD45, and IgG)
2/67/Female	4 months	Sensory ataxia, Romberg's test (+)	DRG: 4-6 MUSC: 4-6 Normal Cytology	Positive	PTB: 2-4 MUSC: 4-6	Normal (CBC, complement, and IgG)	Normal (CD3, CD4, CD8, CD20, CD45, and IgG)	Normal (CD3, CD4, CD8, CD20, CD45, and IgG)
3/58/Female	2 years	Sensory ataxia, Romberg's test (+), parosmia, and parosmia	DRG: 4-6 MUSC: 4-6 Normal Cytology	Positive	PTB: 2-4 MUSC: 4-6	Normal (CBC, complement, and IgG)	Normal (CD3, CD4, CD8, CD20, CD45, and IgG)	Normal (CD3, CD4, CD8, CD20, CD45, and IgG)

Abbreviations: ATR: Achilles tendon reflex; CBC: complete blood count; DTRs: deep tendon reflexes; IVIG: intravenous immunoglobulin; MUSC: minor salivary gland biopsy; PTB: posterior tibial nerve; SEP: somatosensory evoked potential; Area (mm ²)	42.46	37.04	58.90	47.66	52.71	0.9
Diameter ratio	0.94	1.60	1.63	1.39	1.81	0.16
SI ratio	0.76	1.21	1.08	1.04	1.32	0.28

Results: Table 1 summarizes the clinical data of the 3 patients. These SS-SAN patients presented with sensory ataxia with positive Romberg's test and also had various painful symptoms. All 3 patients showed normal motor strength. Compared with the control data, all DRGs in SS patients were numerically smaller and had a lower SI through the L2-S1 level. Moreover, the area, diameter ratio, and SI ratio were significantly reduced in L3-L4 DRGs (Table 2).

Conclusion: We revealed that the DRGs in patients with SS-SAN were atrophic and showed a decreased SI than those in the controls. We suggest the visualization of DRGs by 3T-MRN as a potentially useful imaging biomarker for the clinical diagnosis, as well as the assessment of pathophysiological mechanisms. DRG atrophy and decreased signal intensity may reflect the sensory neuronal loss caused by chronic lymphocytic inflammation in DRGs.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Sjögren's Syndrome – Basic and Clinical Science Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: To analyze the efficacy and tolerance of intravenous immunoglobulin (IVIG) therapy in 11 patients with primary Sjögren's syndrome (pSS)-associated small-fiber neuropathy (SFN).

Methods: Retrospective, single-center study of the efficacy and safety of IVIG therapy for 6 months (0.4 g/kg/day monthly for 5 days) in 11 consecutive pSS-SFN patients. The primary endpoint was a decrease in pain intensity (scored on a 0-10 Numeric Rating Scale, NRS) $\geq 30\%$ between the onset (M0) and the end of treatment (M6). The impact of treatment on quality of life (SF-36 scale) and small fiber neurophysiological tests was also evaluated.

Results: The median (95%CI) age at treatment onset was 52 (48-63) years with a median duration of SFN symptoms until treatment of 6.5 (3-11) years. Between M0 and M6, the median NRS score decreased from 7 (5.5-8) to 3 (1.8-5) ($P < 0.00001$). The primary endpoint was achieved in 8 patients (72%). The median SF-36 physical component subscore also significantly improved from 23/100 to 48/100 ($P = 0.003$). Regarding neurophysiological tests, only the warm detection threshold improved from 5.5°C to 4.6°C ($P = 0.01$), others remaining stable. The most common side effect was transient headache during infusion (73%), while no major side effect was reported.

Conclusion: IVIG treatment appears to be effective and well tolerated in pSS-associated SFN, leading to a significant pain relief and improvement of quality of life and thermal sensory testing. These encouraging results need to be interpreted with caution and have to be confirmed in a randomized double-blinded placebo-controlled trial.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Sjögren's Syndrome – Basic and Clinical Science Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Non-Hodgkin lymphoma (NHL) is one of the most feared complications of primary Sjögren's syndrome (pSS). The most frequent is MALT type lymphoma, with localization in the parotid glands being usual. There

are no multicentric data in the Argentine population regarding the frequency of appearance of this type of cancer in patients with pSS and the possible predictors for this outcome.

The aim of this study was to describe the prevalence and incidence rate of lymphoma in patients with pSS in nine centers in Argentina. To determine the frequency of commitment of the domains of the baseline clinical ESSDAI in the patients who developed lymphoma in the course of their follow-up and compare it with the rest of the sample.

Methods: To respond to the primary objective, the design will be observational, descriptive and retrospective. To evaluate the predictors of lymphoma development, the design will be observational, analytical, retrospective cohort. We included patients older than 18 years with a diagnosis of pSS according to ACR / EULAR 2002 criteria, included in a multi-center Argentine database. Patients diagnosed with another associated autoimmune rheumatic disease were excluded.

Results: We included 708 patients, 95% female, with a mean age of 54.44 years (SD +/- 13.67), mean age at diagnosis of 49.72 years (SD +/- 13.32) and mean age of onset of symptoms 47.19 (SD +/- 13.03). Fifteen patients presented lymphoma (prevalence: 2.12%). Six hundred thirty-six patients provided information for the survival analysis. The average follow-up time was 5 years (SD +/- 6.5). The incidence rate of lymphoma was 0.47 per 100 patient-years. The median time from the diagnosis of pSS to the development of lymphoma was 4 years (ric: 1-6). The most frequently lymphoma type was MALT. The main predictor of lymphoma development was recurrent parotidomegaly (H.R: 4.17, 95% CI: 1.42-12.22). Table 1 reports the results regarding the clinical ESSDAI.

Conclusion: The prevalence of lymphoma was 2.12% and the incidence rate of 0.47 lymphomas per 100 patients per year. Patients who developed lymphoma had a higher frequency of involvement of most of the domains of the baseline clinical ESSDAI compared to patients who did not present this complication. We found recurrent parotidomegaly as the main predictor of the development of this cancer.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Sjögren's Syndrome – Basic and Clinical Science Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: primary Sjögren's syndrome (SS) is the autoimmune disease having the highest risk of lymphoma. The differential diagnosis between benign and malignant lymphoproliferation is sometimes difficult. Among imaging procedures, 18F-FDG PET could be useful for that purpose.

The purpose was to compare 18F-FDG PET results between patients with and without lymphoma to identify PET pattern associated with lymphomas in primary SS.

Methods: Retrospective study conducted in 2 centers including primary SS patients (according to ACR/EULAR 2016 criteria) who undergo 18F-FDG PET. We compared PET abnormalities in patients with and without lymphoma, the PET having been done before any chemotherapy. Two independent readers analyzed PET blind to lymphoma diagnosis. PET score previously described by Cohen *et al.* was calculated.

Results: 45 patients were included; 15 had lymphoma: MALT (n=12), nodal marginal zone with plasmacytic differentiation (n=2), diffuse large B-cell (n=1). Patients with lymphoma had more frequently parotid gland swelling (67% vs 20 %,

p=0.003) and higher ESSDAI score (24 [13.5-29] vs 9 [5-20], p=0.03), even after exclusion of lymphoma item (19 [11-27] VS 9 [5-20], p=0.03).

Compared to non-lymphoma patients, mean size (45.5 [38-56] mm vs. 40 [37-41] mm; p = 0.048) and maximum standardized uptake value (SUVmax) of the parotid glands (5.6 [5-6.9] vs 3.8 [3.2-4.4]; p = 0.001) were higher in lymphoma patients. 53.3% of patients with lymphoma and 43.3% without lymphoma had lymph node FDG uptake, but neither their number nor their repartition or mean SUV differ between them.

Pulmonary uptake was observed in 6 (40%) patients with lymphoma and 6 (20%) without lymphoma (p=0.17). But in lymphoma patients, this uptake was focal in 5 (33.3%) patients (nodules or condensation) and in only one (3.3%) patient without lymphoma (p=0.01). Remaining patients had interstitial FDG uptake. Mean PET score (4 [2-4] vs. 2 [1-3] p=0.04) and SUVmax at any site (6.3 [5.6-7.3] vs. 4.2 [3.7-5.9] p =0.02) were significantly higher in lymphoma group.

The best combination retained for identifying patients with a currently evolving lymphoma was the highest SUVmax at parotid gland ≥ 4.7 and the pulmonary focal condensation or nodular lesions as being sensitive (sensitivity=80.0%) and specific (specificity=83.3%) .

20 patients had PET guided biopsy of a hypermetabolic lesion that conducted to lymphoma diagnosis in 7 cases (46.6%). After chemotherapy for lymphoma, PET was available for 10 patients: complete regression of hypermetabolic lesions was observed in 6 patients (60%), and decreased uptake intensity in the 4 remaining patients. After a median follow-up of 19 months [13.5-30.3] months , one patient with diffuse large B-cell lymphoma relapsed.

Conclusion: some of the systemic manifestation of primary SS (lung, lymph nodes and salivary glands) can be assessed by 18F-FDG PET. Lymph nodes hypermetabolism is frequent and not associated with lymphoma. The best 18F-FDG PET abnormalities associated with lymphoma diagnosis are the highest SUVmax at parotid gland ≥ 4.7 , and/or the pulmonary focal condensation or nodular lesions. Finally, PET can be helpful to guide biopsy toward the most hypermetabolic structure for diagnosing lymphoma

B Lymphocyte Depletion Therapy with Rituximab in Primary Sjögren's Syndrome: Indications , Effectiveness and Ultrasonographic Response

Francesco Ferro, Nicoletta Luciano, Elena Elefante, Maurizio Mazzantini, Marta Mosca and Chiara Baldini, Rheumatology Unit, University of Pisa, Pisa, Italy

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Sjögren's Syndrome – Basic and Clinical Science Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Aim of this study was to assess indications, effectiveness, clinical and ultrasonographic response to rituximab (RTX) therapy in primary Sjögren's syndrome (pSS), focusing in particular on the safety of multiple courses of B-cell depletion therapy .

Methods: Out of a single centre cohort of 378 pSS patients (AECG 2002) we retrieved the clinical charts of patients treated with RTX, focusing particularly on those that received multiple courses. In addition to patients' demographics, clinical and serological features, we analyzed the following data: indications for RTX therapy, changes in the ESSDAI, lab parameters and in salivary gland ultrasonography (SGUS), number of RTX courses, regimens, time to re-treatment and adverse events.

Results: We included in the study 34 patients (M/F = 3/31) who received RTX during their disease course for the following indications: lymphoproliferative disease (16/34), cryoglobulinemic vasculitis (7/34), systemically active disease $5 \leq$ ESSDAI<13 with at least 1 extraglandular domain moderate (7/34), and highly active disease in the haematological (2/34), articular (1/34) or pulmonary (1/34) ESSDAI domains. B-depletion therapy resulted in a significant reduction of disease activity (p <0.05) producing a partial response only for lung involvement. SGUS was performed in 7 patients, showing a significant improvement of the score in one case and stable findings in the others. Six female received at least a second infusion of RTX: in 3/6 only a second cycle was administered "on demand" (after 1, 3 and 4 years, respectively), in the other 3 cases multiple maintenance courses were administered (6, 6 and 11, respectively). Each course of re-treatment consisted in 1 or 2 g bi-weekly infusion; median interval between courses was 9 months (IQR 6-31.5). Multiple courses of RTX resulted in significant improvement of ESSDAI (median ESSDAI before RTX re-treatment =13.5 (IQR 11.25-25.25) vs median ESSDAI post-retreatment =3.5 (IQR 2-5), p=0.008). Re-treatment with RTX was well-tolerated in five cases;

one patient developed allergic drug reaction. Infectious events included: recurrent urinary tract infection (2/6), skin infection and Herpes Zoster reactivation (1/6). One patient who received multiple courses of RTX (in association with plasma-exchange therapy) developed a severe hypogammaglobulinemia complicated with recurrent infections that required Ig replacement therapy.

Conclusion: Single or multiple courses of B-depletive therapy with RTX seem to be effective, relatively safe and tolerated in pSS. Allergic reactions and infections remain still an issue. Further studies are needed to optimize repeated depletion therapy with RTX for pSS remission maintenance.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Sjögren's Syndrome – Basic and Clinical Science Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Large granular lymphocyte (LGL) proliferations can be observed in some auto-immune disorders, especially rheumatoid arthritis. However, reports of LGL proliferations in primary Sjogren's syndrome (pSS) are extremely rare. We here described the main characteristics and outcome of 9 patients presenting LGL proliferation in the context of pSS.

Methods: All patients from the reference centre for systemic autoimmune diseases (in particular for pSS) diagnosed with pSS (ACR/EULAR 2016 criteria) and having a LGL proliferation were included. LGL proliferations were characterized by blood lymphocyte immunophenotyping and their TCR clonality by PCR. Clinical data and outcome were analyzed for all patients.

Results: Nine pSS patients (8 women; median age of 67 [range 52 to 87] years) were diagnosed with LGL proliferation. All but one had active disease at the time of LGL diagnosis (median ESSDAI 11 [range 6 to 35]). Two patients had a history of lymphoma, one developed LGL proliferation under chemotherapy and the other in the context of an indolent and untreated lymphoma. In 8/9 patients, LGL proliferations were T-CD8 (T-LGL), and only one was of NK-type (NK-LGL). LGL proliferation was monoclonal in 4/9 and oligoclonal in 4/9 (data missing for patient with NK-LGL proliferation). A STAT3 mutation was searched in 2 patients and was negative in both. Neutropenia was the main reason for searching for a LGL proliferation ; neutrophil count was < 1500/mm³ in 7/9 and < 500/mm³ in 3/9 patients. At diagnosis, median lymphocyte cell count was 1120/mm³ (range 480 to 7250) and median LGL cell count was 440/mm³ (range 150 to 6000) representing 23% (range 13 to 64%) of the total lymphocyte count. Interestingly, 6 patients had received Rituximab (for lymphoma in 2, for pSS systemic manifestations or cryoglobulinemia in 4). The median time between LGL proliferation diagnosis and first Rituximab injection was 7 months (range 15 days to 13 months). Neutropenia occurred in 5/6 patients having received RTX. One patient with neutropenia, was retreated with Rituximab for a cryoglobulinemia relapse. Neutropenia occurred after the first injection (1200/mm³) and even worsened after the second (700/mm³). In 2 patients, severe neutropenia required treatment by G-CSF which only led to transient efficacy between the injections. Methotrexate was added in these 2 patients and allowed normalization in one case whereas neutrophil count partly improved in the other case. Spontaneous remission occurred in 1/7 patients and non-severe neutropenia persisted in 4/7 others at last evaluation.

Conclusion: This is one of the largest study analyzing LGL proliferation in pSS. As in other auto-immune diseases, LGL were mainly T-LGL, their main feature is neutropenia and they were observed in patients with high activity. Interestingly, the majority occurred in patients treated by Rituximab and could have a link with this treatment. This study suggest that neutropenia occurring after Rituximab treatment in patients with lymphoma or systemic auto-immune disease (but rarely

in patients with rheumatoid arthritis) could be the consequence of a minimal LGL proliferation that should be searched in this context.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Sjögren's Syndrome – Basic and Clinical Science Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: A significant association has been found between primary Sjögren syndrome (pSS) and non-hodgkin's lymphoma (NHL), but few studies have been conducted to explore the association of pSS with the risk of overall malignancies. We conducted the study to investigate the association between pSS and the risks of malignancy including overall and site-specific malignancies.

Methods: Using the Korean nationwide claims database, a retrospective cohort of prevalent pSS patients between January 2012 and December 2014 was constructed. After exclusion of patients who had a previous history of malignancy, each patient was observed up to the development of any malignancy, or December 2015. The crude incidence rate (IR) of overall and site-specific malignancies in patients with pSS over 19 years old was estimated. To assess excess occurrence of overall malignancies in patients over 50 years of age, we calculated standardized incidence ratios (SIR) by dividing the observed number of malignancies of pSS patients by the expected number of malignancies calculated from the accumulated person-years and the age-, sex-, calendar period-specific malignancy incidence rates of knee OA patients.

Results: A total of 9,826 patients with pSS over 19 years of age were enrolled in this study. During 30,082 person-years (PYs) of observation, 424 cases of solid malignancies (IR 140.6/10,000 PYs) and 62 cases of hematologic malignancies (IR 20.2/10,000 PYs) occurred in adult pSS patients. For patients with pSS aged over 50 (n=6,359), 314 cases of solid malignancy (IR 160.8/10,000 PYs) and 42 cases of hematologic malignancies (IR 21.0/10,000 PYs) were diagnosed during 19,474 PYs of follow-up. For the patients over 50 years of age, the SIRs of overall (1.29, 95% CI 1.16-1.43), solid (1.21, 95% CI 1.07-1.34), and hematologic malignancies (4.54, 95% CI 3.17-5.92), in patients with pSS increased compared to those of OA patients (n=5,476,302). Patients with pSS were at a significantly increased risk of non-hodgkin's lymphoma (SIR 5.75, 95% CI 3.58-7.92), multiple myeloma (SIR 4.88, 95% CI 2.00-7.76), lung cancer (SIR 1.59, 95% CI 1.08-2.09), and lip and oropharyngeal cancer (SIR 4.16, 95% CI 1.90-6.42).

Conclusion: Our study indicates that pSS is significantly associated with increased risks of overall malignancy, NHL, multiple myeloma, lung cancer, and lip and oropharyngeal cancer.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Sjögren’s Syndrome – Basic and Clinical Science Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: To analyse the clinical features and outcomes of patients presenting with life-threatening systemic disease in a large cohort of Spanish patients with primary Sjogren syndrome (SjS).

Methods: The GEAS-SS multicenter registry was formed in 2005 with the aim of collecting a large series of Spanish patients with primary SS, and included more than 20 Spanish reference centers with substantial experience in the management of SS patients. By January 2018, the database included 1580 consecutive patients fulfilling the 2002 classification criteria for primary SS. Severe, life-threatening systemic disease was defined as an activity level scored as “High” in at least one ESSDAI domain.

Results: Among 1580 patients, 208 (13%) were classified as presenting a severe, potentially life-threatening systemic disease: 193 presented one ESSDAI domain classified as high, 14 presented two high scored domains and only one presented three high activity domains. The ESSDAI domains involved consisted of lymphadenopathy in 78 (37%) cases, CNS in 28 (13%), PNS in 25 (12%), pulmonary in 25 (12%), renal in 21 (10%), cutaneous in 19 (9%), articular in 18 (9%), hematological in 7 (3%) and muscular in 4 (2%). Patients with severe systemic disease were more frequently men ($p=0.001$) and had a higher frequency of anemia ($p<0.001$), lymphopenia ($p<0.001$), rheumatoid factor ($p=0.021$), low C3 levels ($p=0.015$), low C4 levels ($p<0.001$) and cryoglobulins ($p<0.001$). From a therapeutic point of view, systemic patients received more frequently glucocorticoids ($p<0.001$), immunosuppressants ($p<0.001$), intravenous immunoglobulins ($p=0.008$) and rituximab ($p<0.001$). We found an overall mortality rate of 20% in severe systemic patients, a rate that reach to 33% in patients presenting two or more high systemic involvements; these patients had a higher frequency of low C4 levels ($p=0.012$) and cryoglobulins ($p=0.001$) in comparison with those with a single severe organ involved.

Conclusion: A 13% of patients with primary SjS develop a potentially life-threatening systemic disease (mainly lymphoma, but also severe internal organ involvements including nervous system, the lungs and the kidneys). This subset of patients requires intensive therapeutic management with a mortality rate of nearly 20% of cases.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Sjögren's Syndrome – Basic and Clinical Science Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Primary Sjögren's syndrome (pSS) is a complex disorder that may affect any organ and system. In this new era of personalized medicine, a growing interest has arisen for a more tailored patient care designed on individual's specific features and comorbidities. However, to date a limited number of studies have analysed the prevalence of chronic comorbidities in pSS, especially during the long-term evolution of the disease. Aims of the study were therefore: 1) to describe the prevalence of comorbidities in a cohort of patients with pSS and a minimum follow-up of 10 years from the time of the diagnosis; 2) to explore any association between comorbidities and pSS clinical phenotypes, disease activity and treatments.

Methods: Out of a single-centre cohort of 542 pSS patients we identified 112 subjects who had a minimum follow-up of 10 years from the time of the diagnosis. Information on patients' demographics, clinico-serological features and treatments were retrieved. Conventional statistics and autocontractive map analysis were used to define pSS clinical phenotypes. An adapted version of the Charlson Comorbidity Index (CCI) was used to score the comorbidity burden.

Results: We included 112 (109 F: 3 M) pSS patients, median age 65 years (IQR 53-73), and median follow-up of 14 years (min 10-max 34 yrs). The comorbidities most frequently observed included: osteoporosis (53/112, 47.3%), autoimmune thyroiditis (35/112, 31.3%), arterial hypertension (27/112, 24.1%) depression and anxiety (23/112, 20.5%), dislipidemia (19/112, 17%), diabetes (9/112, 8%), cerebrovascular disease (8/112, 7.1%) and myocardial infarction (4/112, 3.6%). To explore the association between comorbidities and pSS features, patients were stratified by conventional and autocontractive map analysis in three subsets: "glandular" (30/112, 26.8%), "systemic vasculitic" (16/112, 14.3%) and "systemic not-vasculitic" (66/112, 58.9%). The "vasculitic" subset presented the highest ESSDAI scores ($p < 0.001$), the highest glucocorticoid ($p = 0.001$) and DMARDs ($p = 0.001$) use and the highest comorbidity burden ($p < 0.001$). The mean (SD) CCI of the "vasculitic" subset was significantly higher with respect to the CCI of the other pSS subgroups (2.9(2.3) vs 1.0(1.2) vs 1.2(1.1), $p < 0.001$), particularly regarding cerebrovascular diseases. CCI correlated significantly with the use of glucocorticoids ($r = 0.298$, $p = 0.001$), DMARDs ($r = 0.290$, $p = 0.002$) and with the age of the patients ($R = 0.426$, $p < 0.001$).

Conclusion: Long term comorbidities are common in pSS and are related to both the disease and its treatment. The data suggest that it would be advisable to reduce glucocorticoid use, especially in older pSS patients.

Prevalence and Prognosis of Interstitial Lung Disease in a Large Cohort of Chinese Primary Sjögren's Syndrome Patients

Hui Gao^{1,2}, Xuewu Zhang¹, Jing He³, Jing Zhang⁴, Ye Sun⁵ and Zhan-Guo Li¹, ¹Department of Rheumatology and Immunology, Peking University People's Hospital, Beijing, China, ²Department of Rheumatology and Immunology, Peking University International Hospital, Beijing, China, ³Rheumatology, Peking University People's Hospital, Beijing, China, ⁴Peking University International Hospital, Beijing, China, ⁵Department of Radiology, Peking University People's Hospital, Beijing, China

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Sjögren's Syndrome – Basic and Clinical Science Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: To determine the prevalence and identify the prognosis associated with pulmonary involvement in pSS patients.

Methods: A total of 1341 hospitalized patients (853 with pSS and 488 with secondary Sjögren's syndrome [sSS]) were recruited.

Results: Pulmonary involvement rates were 19.34% (165/853) and 25.82% (126/488) for pSS and sSS patients, respectively. Of the 165 pSS-ILD patients, 69 patients underwent HRCT in this hospital. Non-specific interstitial pneumonia (NSIP) was the predominant HRCT pattern (n = 27, 39.1%). Chest HRCT findings revealed a lymphocytic interstitial pneumonia (LIP) pattern in 12 patients (17.4%), a NSIP+LIP pattern in 4 (5.8%), and a usual interstitial pneumonia (UIP) pattern in 11 (15.9%). The rest of the findings were as follows: 1 (1.4%) cryptogenic organizing pneumonia (COP), 1 (1.4%) respiratory bronchiolitis-interstitial lung disease (RBILD), and 13 indeterminates. The total HRCT score was 9.71 ± 4.77 . Impairment in diffusion capacity was the most common manifestation of pulmonary involvement (74.3%) and the most severe complication. The 5-year survival rate for pSS-ILD patients was 88.5%. Thirty-five (21.2%) of 165 patients died during the follow-up period. Causes of death were as follows: respiratory failure (n = 27), progression of malignant disease (n = 5), gastrointestinal bleeding (n = 1), viral meningoencephalitis (n = 1), and cerebral hemorrhage (n = 1). Multivariate analysis showed that age, disease duration, smoke, HRCT scores, and TLC, TLco/VA, FEV1 were independent risk factors for mortality for pSS-ILD patients.

Conclusion: Lung involvement is a common complication of pSS and the outcome is not favorable.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Sjögren's Syndrome – Basic and Clinical Science Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The present study aimed to investigate the risk factors and prognosis of primary Sjogren's syndrome-associated interstitial lung disease (pSS-ILD).

Methods: Data were retrospectively collected from 28 hospitals in China during August 2008 and May 2018. ILD was confirmed by chest high resolution CT (HRCT). Baseline demographic data, clinical manifestations, laboratory tests, pulmonary function, radiology patterns, and treatment regimens were analyzed. Patients were followed up every 6 to 12 months. The primary end point was all-cause death.

Results: Of the 184 patients enrolled, 90.2% were female, with a mean age of 59.8 ± 10.7 years at baseline. The median disease duration of pSS was 39 (0-324) months, while the median disease duration of ILD was 13 (0-236) months. In 50.5% patients, ILD was the initial clinical manifestation of pSS. Presenting ILD manifestations were: dry cough (19%), productive cough (23.4%), dyspnea on exertion (41.8%), and asymptomatic patients exhibiting abnormalities consistent with ILD on HRCT and/or pulmonary function test (47.8%). NSIP was the most common HRCT pattern, including f-NSIP (23.9%) and c-NSIP (15.9%). Pulmonary function presented restrictive ventilation impairment as well as reduced diffuse function, with FVC 68.8 ± 33.5 % of predicted and DLCO 48.8 ± 28.3 % of predicted. Steroid was administered in 123 (66.8%) patients. Intensive immunosuppressive treatment included cyclophosphamide (32.6%), mycophenolate mofetil (9.2%), and azathioprine (3.3%). Nine patients died in this cohort. Predictive risk factors of ILD in pSS was older age (OR 1.222, 95%CI 1.076-1.169, p <0.001), late onset of pSS (OR 1.041, 95%CI 1.006-1.080, p = 0.024), elevated ESR (OR

2.011, 95%CI 1.107-3.653, $p = 0.022$), and positive anti-Ro52 antibody (OR 3.658, 95%CI 1.780-7.514, $p < 0.001$). Predictive factors of death in pSS-ILD were older age ($p < 0.001$), history of smoking ($p = 0.002$), and honeycomb lung pattern on HRCT ($p = 0.026$).

Conclusion: ILD can be the initial manifestation of pSS. The results provide strong evidence that patients with older age, late onset of pSS, and positive anti-Ro52 antibody were more likely to complicate ILD. We also suggest that patients with older age, history of smoking, and honeycomb pattern in HRCT may need a closer follow-up.

Table 1. Comparing the demographic and clinical data in pSS patients with and without ILD

	pSS-ILD	pSS-non-ILD	p-value

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Sjögren's Syndrome – Basic and Clinical Science Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Interstitial lung disease (ILD) is a common extraglandular manifestation of Sjögren's syndrome (SS). There is a paucity of literature on the management of SS-ILD. The aim of this retrospective cohort study is to assess the efficacy of immunosuppressive therapy in the treatment of adult patients with SS-ILD.

Methods: A retrospective electronic health record search using codes for ILD and SS was performed for patients seen between 2000-2017 at an academic medical center. Records were reviewed to include adults meeting the 2016 American College of Rheumatology/European League Against Rheumatism classification criteria for SS and to exclude those with other connective tissue diseases. ILD was confirmed by characteristic CT pattern or histopathology findings. Sociodemographic, clinical, and pulmonary function test (PFT) data were abstracted for patients with and without azathioprine, mycophenolate, and rituximab treatment and followed longitudinally from the date of ILD diagnosis. PFT values were anchored (T_0) on time of treatment start. Linear mixed-effects modeling and paired t-tests were used to analyze changes in diffusion capacity for carbon monoxide (DLCO) and forced vital capacity (FVC) before and after treatment initiation.

Results: We identified 19 subjects who had SS-ILD, of whom 89% were female, with ages ranging from 37-84 years at the time of ILD diagnosis. Seven patients were treated with azathioprine, seven patients were treated with mycophenolate, and six patients were treated with rituximab. Five patients were not treated with immunosuppressive therapy and five patients were treated with more than one agent. Within the azathioprine group, paired t-test showed a significant improvement in FVC% after treatment was initiated ($p=0.01$) with mixed model effect similarly showing improvement although with a non-significant change in slope ($p=0.22$) (Figure 1). A trend toward improvement in slope was also seen in DLCO% after treatment with azathioprine ($p=0.16$). Similarly, among those treated with mycophenolate, there was a trend toward improvement in slopes of both FVC% and DLCO% (FVC% $p=0.4$, DLCO% $p=0.45$), although these did not reach statistical significance (Figure 2). Among those patients treated with rituximab, there was a post-treatment decline in FVC% and DLCO%, although only three patients had PFTs measured before and after treatment.

Conclusion: Azathioprine appears to improve PFTs of SS-ILD patients and a similar non-significant trend is seen after mycophenolate treatment. Further prospective studies are needed to further evaluate these findings.

Session Date: Monday, October 22, 2018

Session Title: Sjögren's Syndrome – Basic and Clinical Science Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Labial salivary gland biopsy (LSGB) is a safe and minimally invasive procedure used in the diagnostic evaluation of Sjögren's Syndrome (SS). The objectives of this study are: to describe the demographic, clinical and histological characteristics of patients submitted for LSGB; to examine the usefulness of this procedure as a diagnostic tool for SS; to assess the association between histological findings and antibodies.

Methods: An observational, analytical, cross-sectional study was performed between June 1996 and July 2017. Patients with SS were classified according the AECG-2002 and ACR-2012 criteria. Grades III and IV biopsy of the Chisholm and Mason's classification/focus score ≥ 1 were considered positive. Data was analyzed using the statistical package SPSS 21.

Results: 1101 patients were included, 91 % females. The mean age was $52 \pm$ years(range18–86). SS was diagnosed in 413 (37.5%) patients. 34% of the biopsies were positive. Table 1 shows the clinical characteristics and complementary studies in patients with nonspecific dryness syndrome (No-SS) and SS. In bivariate analysis there was an association between antiRo, ANA and RF antibodies and LSGB. In multivariate analysis the significance for anti-Ro (OR: 6.33; 95% CI 3.22 to 12.15), ANA (OR: 3.26; 95% CI 2.15 to 4.94) and RF (OR: 3.05; 95% CI 2.04 to 4.56) was maintained.

Table 1

Parameters	SS n (%)	No-SS n (%)	p	OR
Female	380/413 (92)	619/688 (90%)	0.284	1.284 (0.832-1.981)

Xerophthalmia	368/409 (90)	559/679 (82.3)	0.001	1.93 (1.32-2.81)
Parotidomegaly	90/404 (22.3)	58/673 (8.6)	<0.001	3.04 (2.13-4.34)
Abnormal ophtalmic test	260/277 (93.9)	237/355 (66.9)	<0.001	7.62 (4.45-13.04)
Abnormal salivary test	66/76 (86.8)	84/115 (73)	0.03	2.44 (1.11-5.33)
antiRo/SS-A	120/366 (32.8)	18/558 (3.2)	<0.001	14.63 (8.72-24.56)
antiLa/SS-B	49/366 (13.4)	3/557 (0.5)	<0.001	28.55 (8.83-92.33)
ANA	194/387 (50.1)	82/606 (13.5)	<0.001	6.42 (4.73-8.73)
RF	176/394 (44.7)	115/618 (18.6)	<0.001	3.53 (2.66-4.69)
LSGB G III	143/413 (34.6)	0/687 (0)	<0.001	3.54 (3.2-3.9)
LSGB G IV	227/413 (55)	0/687 (0)	<0.001	4.69 (4.13-5.33)

Parameters	Sensitivity	Specificity	PPV	NPV	LR
Ro/SS-A*	32.8	96.8	86.9	68.7	8
La/SS-B*	13.4	99.5	94.2	63.6	13
ANA*	50.1	86.5	70.2	73.1	3.57
RF*	44.7	81.4	60.4	69.7	2.3

Conclusion: LSGB is a simple, safe, and useful tool for the diagnosis of Sjögren's syndrome. It exhibits an adequate balance between sensitivity, specificity, positive and negative predictive value. Antibodies showed a significant association with a positive LSGB with low sensitivity for SS screening but high specificity. LSGB has a great value in “seronegatives patients”.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Sjögren's Syndrome – Basic and Clinical Science Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: To determine whether the repetition of minor salivary gland biopsy (MSGB) has a clinical diagnostic utility in patients with suspicion of primary Sjögren's syndrome (pSS).

Methods: We studied retrospectively patients with suspected pSS who had routinely benefited from two MSGB at our institution between January 1, 1990 and January 14, 2015. We collected for each of these patients the clinical and biological features and the results of the two MSGB, as well as the diagnoses performed by the evaluating physician after each biopsy. We compared the characteristics of patients with and without a clinical diagnosis of pSS after the first MSGB, and analysed the changes between the two MSGB.

Results: We included 93 patients, 18 pSS and 75 npSS (clinical diagnosis after the first MSGB). pSS patients were significantly older and more often had renal or pulmonary involvement, and, as expected, had more often rheumatoid factor, anti-SSA and anti-SSB antibodies and positive biopsy with focus score ≥ 1 or Chisholm score > 2 . The mean time between the 2 MSGB was 5.7 \pm 4.3 years. The concordance between the results of the 2 biopsies was low ($k=0.345$). Diagnosis changed after the second MSGB in 23 cases, but in only 13 patients the second biopsy was considered clinically useful to revise the initial diagnosis.

Conclusion: There was a low concordance between two MSGB in patients with suspected pSS in our study. Despite this variability, performing a second MSGB changed the initial diagnosis in a minority of the patients.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Sjögren's Syndrome – Basic and Clinical Science Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Primary Sjögren's syndrome (pSS) is a chronic autoimmune disorder characterized by lymphocytic infiltrates and destruction of the salivary glands. Several lines of evidence support the hypothesis that salivary gland

epithelial cells (SGECs) are not only the target of autoimmunity in pSS patients but may also play a role for its initiation and maintenance.

The objective of this study was to establish a transcriptomic map of differentially expressed genes in SGEC from pSS patients compared to controls using RNASeq analysis.

Methods: Patients had pSS according to 2016 EULAR/ACR criteria and controls had sicca symptoms without any antibodies and with normal lip biopsy. SGEC, B, T CD4 and CD8 lymphocytes were sorted from salivary gland biopsies from 9 pSS patients and 4 controls, using a FACS ARIA. Total RNASeq profiling was performed using MiSeq (Illumina). For SGEC subset, 4 samples were excluded due to a contamination by B lymphocytes, thus analysis was performed on 5 pSS and 4 controls. We identified transcriptional differences between pSS and controls SGEC using R software. Functional enrichment analysis was performed with Ingenuity Pathway Analysis software.

Results: In SGEC, 495 genes were differentially expressed between pSS and controls. 280 genes were up-regulated, and 215 genes were down-regulated. Enrichment analysis (**Table 1**) highlighted IL-7 signaling pathways (including IL-7, STAT5A, STAT1 genes) and interferon signaling (including OAS1, IFIT3, IFI6, TAP1 genes). Other genes potentially involved in immune responses and interactions between SGEC and lymphocytes were significantly up-regulated, including bone marrow stromal cell antigen 2, HLA-DRA, BAFF-R and IL-23 A (**Table2**). These results need to be confirmed by RT qPCR. However, consistent results have already been obtained in our laboratory, showing that IL-7 serum level is increased in pSS patients compared to controls and that SGECs secrete IL-7 after interferon stimulation. The analysis of the other sorted cells subtypes is ongoing.

Conclusion: Immune interactions between SGEC and B or T lymphocytes could represent a key in the understanding of the initiation and/or maintenance of autoimmunity in pSS. Our study highlights the key role of epithelial cells in activation of immune cells. In vitro experiments are needed to confirm these results and elucidate the molecular mechanisms.

Table 1 Pathways identified as statistically over-represented with Ingenuity Pathways Analysis in epithelial cells from pSS compared to controls.

Pathway	-log p-value
Primary Immunodeficiency Signaling	4,08
Interferon Signaling	3,52
B Cell Development	2,89
Role of JAK2 in Hormone-like Cytokine Signaling	2,73
IL-7 Signaling Pathway	2,51

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Sjögren's Syndrome – Basic and Clinical Science Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Ultrasonography (USG) of major salivary glands (SG-USG) as a non-invasive method is widely used to evaluate salivary gland involvement in Sjögren's syndrome (SjS). Since decreases in salivary flow rates (SFRs) due to chronic inflammation and destruction of the salivary glands limit the functional and protective capacities of saliva in the oral environment, poor oral health related quality of life (OHRQoL) is commonly seen in patients with SjS. The aim of the study was to assess the relationships between SFRs, OHRQoL and USG changes of major salivary glands in patients with primary SjS.

Methods: Sixty-seven SjS patients (F/M:66/1) with the mean age of 51.1 ± 11.8 years. The duration of follow-up period of 60 ± 49 months fulfilling ACR-EULAR classification criteria (2002) were included. Major salivary glands (bilateral parotis and submandibular glands) were scored according to two different scoring systems which are Hocevar A. (0-48) and Milic VD. (0-12). Unstimulated saliva were collected in patients between 9 a.m. and 10 a.m. in the morning. Then, salivary flow rate (SFR) were calculated as millilitres per minute (ml/min) in laboratory conditions (FTO). Oral health related quality of life (OHRQoL) as a patient reported outcome measure (PROM) was evaluated by using Oral health impact profile (OHIP-14). High scores indicated poor OHRQoL status. Oral health (GM) and USG images (NI) were evaluated by two authors as double-blind in the same visit.

Results: Unstimulated SFR was 0.9 ± 0.8 ml/min and xerostomia (SFR ≤ 0.1 ml/minute) was seen 31,3% (n=21) of the group. Scores of Hocevar, Milic and OHIP-14 were found to be poor in patients with dry mouth compared to those of others (p<0.05). Scores of homogeneity and hypoechogenic areas in Parotid glands were also higher in patients with xerostomia than the others (p<0.05) (Table 1).

Conclusion: Unstimulated SFRs were associated with the structural changes of Parotid glands. Poor OHRQoL as a PROM was shown in patients due to reduced salivary outputs. In clinical practice, USG images of salivary glands could give insight to physicians about SFR and OHRQoL in patients with SjS.

Tablo-1: Salivary Flow Rates, OHIP-14 and Parotid Glands-USG Scores of SjS Patients

	Salivary Flow Rates (SFR)		p
	$\leq 0,1$ ml/minute (n=21)	$>0,1$ ml/minute (n=46)	
Parotid R-homogeneity	$1,7 \pm 0,7$	$1,02 \pm 0,7$	0.001
Parotid R-hypoechogenic areas	$1,3 \pm 1,1$	$0,4 \pm 0,7$	0.001
Parotid L-homogeneity	$1,6 \pm 0,9$	$1,1 \pm 0,7$	0.007
Parotid L-hypoechogenic areas	$1,2 \pm 0,9$	$0,5 \pm 0,8$	0.001
Hocevar-total score	$24,6 \pm 9,1$	$15,4 \pm 8,7$	0.001
Milic-total score	$7,4 \pm 2,2$	$4,8 \pm 2,4$	0.000
OHIP-14 score	$27,4 \pm 20,4$	$8,04 \pm 13,9$	0.000

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Sjögren's Syndrome – Basic and Clinical Science Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Neonatal lupus is linked to the presence of circulating anti-Ro antibodies in the mother. These antibodies are present in asymptomatic individuals, who in a subset years later progress to develop overt autoimmune disease. This study was initiated to investigate whether an environmental trigger such as oral colonization by autoreactivity-inducing commensals may contribute to pathogenesis. This goal was approached by leveraging agnostic profiling of the salivary microbiome to identify pathobionts associated with disease outcome in high titer anti-Ro positive women of children with neonatal lupus.

Methods: The study included 24 anti-Ro⁺ women from the Research Registry for Neonatal Lupus (RRNL) with nine being asymptomatic or having insufficient criteria for Sjögren's Syndrome (SS) and/or ACR/SLICC SLE (incomplete diagnoses) and 9 SS, 2 SLE, and 4 SS/SLE (established diagnoses). The rheumatologic diagnoses of the RRNL women were independently determined by two rheumatologists via questionnaire, telephone interview, and/or in-person history/physical exam, and review of medical records. An additional 7 healthy women served as controls. After extraction of host and non-host genomic DNA from saliva (without use of artificial saliva or stimulants), the microbiome was assessed by 16S rRNA gene library analysis using standard protocols (mean of 20k reads per sample). Operational taxonomic units (OTUs) were identified by closed-reference OTU-picking using Green Genes as reference. Shannon's index, a mathematical measure of species diversity (H') and relative abundance, was tested for differences using the Kruskal-Wallis tests.

Results: H' was different for virtually all taxa. At the phylum level, H' was significantly lower in RRNL vs controls (1.33 vs 1.53 respectively, $p=0.018$). Significance was retained down to the family level (2.46 vs 2.82 respectively, $p=0.007$). Contrasting RRNL with controls identified six phyla and 19 families having significant differences in relative abundance ($p<0.05$). For example, at the family level, *Porphyromonadaceae*, *Fusobacteriaceae*, *Pasteurellaceae*, and *Flavobacteriaceae* were less abundant in RRNL compared to controls ($p=0.003$, $p=0.004$, $p=0.030$, $p=0.038$, respectively). In contrast, *Peptostreptococcaceae*, *Weeksellaceae*, *Coriobacteriaceae* and *Prevotellaceae* were significantly more abundant ($p=0.001$, $p=0.003$, $p=0.0081$, $p=0.0421$, respectively) in the RRNL. Using a model with comparisons to healthy controls and with RRNL divided into the two subgroups (i.e., incomplete and complete, as described in the methods), the three-group test retained this pattern of significance and differential relative abundance down to the family phylogenetic level, except for *Flavobacteriaceae* which still showed a similar trend ($p=0.08$).

Conclusion: These data support a decrease in the diversity of the oral microbiota in anti-Ro positive women, especially in those with established autoimmune diseases such as SS. Our evidence of concurrent increases in relative abundance of organisms, such as inflammatory-provoking *Prevotellaceae*, may provide insight into disease evolution in a predisposed host.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Sjögren's Syndrome – Basic and Clinical Science Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: There is evidence for B cell involvement in the pathogenesis of Sjögren's syndrome by the presence of autoantigen-specific B cells. Autoantibodies toward Ro/SSA and La/SSB are classification criteria. Autoantibodies are produced by plasmablasts within the salivary glands, but whether the serum autoantibodies originate from these cells is

unknown. We hypothesized that if serum autoantibodies originate from the antibody secreting cells in the glands, they may be present in the saliva prior to their detectable levels in the plasma. As a first step to explore this, we tested the saliva autoantibody profiles in a group of SS patients and sicca controls and compared them to their respective IgG serum autoantibody profiles.

Methods: 27 subjects, symptomatic for dry eyes and mouth, were evaluated for American/European Consensus Group (AECG) primary SS inclusion/exclusion criteria. 14 subjects met the AECG primary SS criteria, and 1 also met the ACR criteria for SLE. 13 subjects did not meet the SS classification criteria and served as non-Sjogren's sicca controls. Serum and stimulated parotid saliva samples were obtained from all subjects. Enzyme-linked immunosorbent assays (ELISAs) were performed by applying saliva (1:20, in duplicate) to antigen-coated (Ro/SSA, La/SSB, Sm, and Sm-RNP) plates and detected using anti-human IgA-, or IgG-alkaline phosphatase and substrate. 4 control subjects negative for all SS inclusion criteria and all other measures were used to establish positive thresholds for each ELISA (mean+5SD). To confirm stringency of this measure, we determined that the $Q3+1.5*IQR$ threshold was similar. mAbs produced from salivary gland plasmablasts from 4 SS and 5 sicca control patients were tested for antigen reactivity. Each subject's saliva specificities were compared to their mAb and serum specificities measured by DID, ELISA, INNO-LIA, and Bioplex 2200.

Results: In the glands from 14 patients, 12 had focal lymphocytic sialadenitis (FLS) and 2 had non-specific chronic inflammation (NSCI). Of the 13 sicca controls, 12 had NSCI, one had FLS, and one was histologically normal. Two sicca controls were seropositive for Ro and seronegative for all other antigens. The SS patients had a wide range of serum specificities for Ro/SSA, La/SSB, Sm, and nRNP. In both the SS patients and sicca controls there were saliva reactivities not detectable in the serum; in SS patients, 5/14 were Ro+, 4/14 La+, 4/14 Sm+ and 3/14 smRNP+, and in sicca controls, 8/13 were Ro+, 6/13 La+, 3/13 Sm+ and 3/13 smRNP+. The mAb specificities from SS patients correlated well with the serum specificities, however the monoclonal antibodies from the sicca controls had specificities for all four antigens not detected in the serum.

Conclusion: These findings suggest that the salivary gland may be a source of SS serum autoantibodies. Future studies will evaluate saliva positive, seronegative subjects longitudinally for development of serum autoantibodies. If this does occur, it would be likely that certain sicca controls would then fulfill the criteria for primary SS classification, suggesting that testing of saliva for autoantibodies may be indicated for prediction of progression to systemic disease.

The Association between Salivary Gland Ultrasonography and Clinical Manifestation in Patients with Early Primary Sjögren's Syndrome

Yen-Fu Chen¹ and Yao-Fan Fang², ¹Division of Rheumatology, Allergy and Immunology, Chang Gung Memorial Hospital, Taoyuan, Taiwan, ²Chang-Gung Memorial Hospital, Taoyuan city, Taiwan

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Sjögren's Syndrome – Basic and Clinical Science Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: To investigate the clinical manifestations in patients with early primary Sjögren's syndrome based on different severity score under salivary gland ultrasonography.

Methods: We enrolled 44 newly diagnosed patients with early primary Sjögren's syndrome at Chang Gung Memorial Hospital in Taiwan (Figure 1). We divided patients into two groups according to baseline salivary gland ultrasonography grade scores. Severe group was defined score 2-3 and mild group was score 0-1. Student's t-test was used to compare the two groups.

Results: The mean age of patients were 50.02 years old. The mean duration of sicca symptoms were 0.86 years. The mean score of ESSPRI and ESSDAI were 16.98 and 3.35, respectively. Higher rheumatoid factor titer was statistically significant in severe group ($p=0.04$). Higher titer of autoantibodies such as anti-SSA/SSB, anti-dsDNA and IgG were found in severe group but not reached significant. However, ESSDAI and ESSPRI was not associated with sonography severity score.

Conclusion: Only higherrheumatoid factor titer is associated with higher salivary glandultrasonography grade score. However, severe ultrasonography grade score was not related to clinical disease activity such as ESSDAI. Previous study showedsalivary gland ultrasonography as a good diagnostic tool of Sjögren's syndromeand as a predictor of clinical activity in Sjogren's syndrome, but the diseasemean duration is around 7.5 years. Our study enrolled patients with earlyprimary Sjögren's syndrome with mean disease duration less than one year. Theclinical manifestations are not associated with salivary ultrasonographyseverity score in early primary Sjögren's syndrome.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Sjögren's Syndrome – Basic and Clinical Science Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Sjögren's syndrome (SS) is an autoimmune disease characterized by lymphocytic infiltration in exocrine organs with dry mouth and dry eyes. Semaphorin 4D (SEMA4D) / CD100 was reported to be highly expressed in salivary gland. Its abnormal expression in immune cells has been reported to be associated with autoimmunity. Membrane-bound SEMA4D could be proteolytically cleaved to soluble SEMA4D (sSEMA4D). This study was aimed to evaluate the sSEMA4D from saliva in patients with SS.

Methods: Total 47 SS patients, 34 sicca patients with non-SS and 28 healthy controls were examined. Saliva samples were collected on ice, centrifuged, and stored at -80°C with treatment of protease inhibitors. Salivary sSEMA4D was measured by ELISA kit. Area under the ROC curve (AUC) was analyzed to assess the sSEMA4D as a diagnostic marker of SS. Levels of sSEMA4D were presented as median (interquartile ranges [IQR]).

Results: The levels of salivary sSEMA4D were increased in patients with SS compared to healthy controls (median [IQR], 290.8 [188.3-478.0] vs. 170.0 [95.6-265.6] ng/mL, $p = 0.002$). The sSEMA4D from sicca patients with non-SS (220.0 [135.8-330.5] ng/mL, $p = 0.123$) was similar to that of HC. Salivary sSEMA4D was not correlated with ESR (Spearman's rho = 0.196, $p = 0.274$) or CRP (Spearman's rho = -0.225, $p = 0.280$) in SS. In analysis of ROC curve, the levels of salivary sSEMA4D showed acceptable accuracy to distinguish the SS patients from healthy controls (AUC = 0.710, 95% confidence interval : 0.594-0.827, $p = 0.002$), and optimal cut off value for diagnosis of SS is 235.5 ng/mL, with a sensitivity of 63.8% and a specificity of 71.4% (chi-square test $p = 0.003$).

Conclusion: Salivary sSEMA4D was increased in patients with SS and may be useful as a potential marker to diagnose SS by non-invasive method.

Soluble Siglec-5 Is a Novel Salivary Biomarker for Primary Sjogren's Syndrome

Jennifer Lee¹, Hong-Ki Min², Ji-Won Kim³, Seung-Ki Kwok⁴ and Sung-Hwan Park⁵, ¹Rheumatology, Seoul St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Seoul, Korea, Republic of South, ²Division of Rheumatology, Department of Internal Medicine, College of Medicine, The Catholic University of Korea, Seoul, Korea, Republic of South, ³Medicine, Division of Rheumatology, Department of Internal Medicine, Seoul St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Seoul, Korea, Republic of South, ⁴Seoul St. Mary's Hospital, The Catholic University of Korea, Seoul, Korea, Republic of South, ⁵Division of Rheumatology, Department of Internal Medicine, Seoul St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Seoul, Korea, Republic of South

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Sjögren's Syndrome – Basic and Clinical Science Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Despite advances in the understanding of the pathogenesis, disease-specific biomarkers have not been included in the classification criteria for Primary Sjogren's syndrome (pSS). Based on the microarray of peripheral blood mononuclear cell (PBMC) of pSS patients, we aimed to investigate whether sialic acid-binding immunoglobulin-like lectin (siglec)-5 might serve as a biomarker for pSS.

Methods: Microarray of PBMCs obtained from 26 pSS patients and 10 healthy control (HC)s was performed to screen potential biomarkers for pSS. The concentration of siglec-5/14 in saliva and sera was determined by ELISA. Clinical parameters related with pSS were obtained from pSS registry and correlation with salivary siglec-5/14 level was evaluated. Receiver operating curve (ROC) analysis was performed to determine cut off value. A separate validation cohort consisted of subjects with suspicious pSS was evaluated to determine the performance.

Results: The level of salivary siglec-5/14 was significantly higher in pSS patients compared with HCs or sicca patients (1346.8 [202.8-4280.0] pg/mL, 6.08 [0-134.0] pg/mL, and 0 [0-385.3] pg/mL, median [interquartile range], $P < 0.001$), meanwhile the serum level was not different between the groups. Clinical parameters were available in 170 patients in pSS registry. Salivary siglec-5/14 level negatively correlated with salivary flow rate (spearman's rho: -0.420, $P < 0.001$), and positively correlated with ocular surface score (rho: 0.331, $P < 0.001$) and serum immunoglobulin G level (rho = 0.202, $P = 0.008$). However, the level of salivary siglec-5/14 was not correlated with ESSDAI or focus score. On ROC analysis, area under the curve was 0.835(0.782-0.888). With cut off value 200pg/mL, sensitivity and specificity was 0.75 and 0.75 respectively. In validation cohort where patients without sicca symptom but have 1 or more positive items in ESSDAI were included, sensitivity and specificity of siglec-5/14 was 68.2% and 71.7%, respectively.

Conclusion: The level of soluble siglec-5/14 is significantly increased in the saliva of pSS patients and reflects the severity of hyposalivation and ocular surface damage. Although the mechanism of the contribution to gland dysfunction is unclear yet, this easily obtainable salivary biomarker may add benefits on the diagnosis of pSS.

Exercise Increases Aerobic Capacity in Primary Sjögren's Syndrome: A Randomized Controlled Trial

Ana Beatriz Andreo Garcia, MD¹, Virginia Fernandes Moca Trevisani², Luciana Dardin³ and Paulo Alexandre Minali⁴, ¹Evidence-based Health, UNIFESP, São Paulo, Brazil, São Paulo, Brazil, ²UNIFESP, Sao Paulo, Brazil, San Paulo, Brazil, ³Emergency Medicine and Evidence-Based Medicine Department, UNIFESP, São Paulo Brazil, SÃO PAULO, Brazil, ⁴UNIFESP, São Paulo, Brazil, São Paulo, Brazil

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Sjögren's Syndrome – Basic and Clinical Science Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Recent studies have shown increased cardiovascular risk in patients with primary Sjögren's syndrome (pSS). As physical exercise is one of the pillars in primary and secondary prophylaxis of cardiovascular events, we evaluated whether the combination of resistance and aerobic exercises is able to increase aerobic capacity and quality of life and to improve echocardiographic parameters and the metabolic profile of patients with this rheumatic disease.

Methods: 60 women with pSS (age 18-90 years) were evaluated from the SF-36 Short-Form Health Survey (SF-36) and EULAR Sjögren's Syndrome Disease Activity Index (ESSDAI) questionnaires. The participants performed ergospirometry in an electromagnetic braking cycle ergometer (Lode Excalibur Sport, Groningen, The Netherlands), coupled to a computerized gas analyzer (Quark CPET, Cosmed, Italy) and echocardiography on the Philips IE33 device; blood samples were collected to evaluate the metabolic profile (glycemia, glycated hemoglobin, total cholesterol and fractions) by the central laboratory of the Hospital São Paulo - UNIFESP. Patients were divided into 2 groups: a training group (30 patients) that participated in the supervised training program and a control group (30 patients) that did not participate in the program. All variables were analyzed at baseline and after 28 weeks for both groups. The training program was divided into two phases according to the nature of the exercise. The first stage consisted of 16 weeks of resistance exercises, in the form of a 45 minute circuit, and each muscle group was exercised in 3 sets of 12 repetitions each. From the seventeenth week, the exercise became aerobic, performed on an electromagnetic braking cycle ergometer (Lode Excalibur Sport, Groningen, The Netherlands), the same instrument used to perform the ergospirometric test. The intensity and duration of the training increased progressively, until the last 3 weeks with sessions of 50 minutes and intensity of 60 to 84% of the VO_2max . Statistical analysis included Wilcoxon's rank sum test, chi-square test, and ANOVA test. P values <0.05 were considered to be statistically significant.

Results: The 2 groups were homogeneous and comparable at baseline. The training group showed a significant improvement in aerobic capacity measured by oxygen maximum volume (VO_2max) (19.64 ± 3.47 vs 22.95 ± 4.01 , $p < 0.001$) and by anaerobic threshold VO_2 (16.86 ± 2.86 vs 19.56 ± 3.18 , $p < 0.001$). Comparison of the training group and control group after 28 weeks showed a significant difference relating to VO_2max [$F(1; 58) = 31.43$; $p < 0.001$] and in the anaerobic threshold VO_2 [$F(1; 58) = 5.41$; $p < 0.001$]. After cardiovascular training, we found a small but significant decrease in glycated hemoglobin (5.88 ± 0.73 vs 5.75 ± 0.66 , $p = 0.006$). We did not find statistically significant difference in echocardiographic parameters, lipemic profile, quality of life (SF-36) and disease activity (ESSDAI).

Conclusion: This study showed significant improvement in aerobic capacity and glycated hemoglobin after a supervised training program in patients with pSS with safety.

Sjögren's Syndrome Is Associated with Reduced Sex Hormone Exposure: A Case-Control Study

Sara S. McCoy¹, Emmanuel Sampene² and Alan N. Baer³, ¹Department of Medicine, Rheumatology Division, University of Wisconsin School of Medicine and Public Health, Madison, WI, ²Biostatistics, University of Wisconsin School of Medicine and Public Health, Madison, WI, ³Division of Rheumatology, Johns Hopkins University School of Medicine, Baltimore, MD

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Sjögren's Syndrome – Basic and Clinical Science Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Sjögren's Syndrome (SS) is an autoimmune disease with female predominance and frequent perimenopausal onset, indicating a potential pathogenic role for sex hormones. The goal of this study was to evaluate if cumulative sex hormone exposure impacts the risk of development of SS.

Methods: We performed a case-control study of 2860 women from the Sjögren's International Collaborative Clinical Alliance registry, including 1320 SS participants, 1106 participants with sicca symptoms but no key objective phenotypic features of SS ("sicca controls"), 371 participants with no sicca symptoms or phenotypic features of SS ("non-sicca controls"), and 63 participants with positive SSA antibody but not meeting criteria for SS (participants were not included in analysis due to low number). Individual reproductive and menstrual factors were used to create composite scores. Composite estrogen score (CES) was calculated by point assignment for early menarche (≤ 10 years), high parity,

hysterectomy, use of hormone therapy, and late menopause (≥ 53 years). Cumulative menstrual cycling (CMC) years for premenopausal registrants was calculated as the age of the registrant minus years since first sicca onset, menarche age, and time pregnant. Covariates included age, referral source, race, education level, employment status, smoking status, and recruitment site. Multivariable logistic regression was used for outcomes against the predictors of interest and all results are interpreted in terms of odds ratios (ORs).

Association between CES and CMC and SS

SS: Sjögren's Syndrome; CES: Composite Estrogen Score; CMC: Cumulative menstrual cycling; Q: Quintile

Results: Using a regression model adjusting for age, recruitment site, ethnicity, education, employment status, and smoking, we observed a progressive inverse trend between SS and both CES and CMC. For each stratum of greater cumulative estrogen exposure (CES1-3), there was a progressive and significant decrease in SS risk relative to sicca controls. The ORs and 95% confidence interval(95% CI) were as follows for the sicca control group:CES1, OR 0.84 [95% CI, 0.7-1.0]; CES 2, OR 0.7 [95% CI, 0.5-0.9]; CES 3, OR0. 43 [95% CI, 0.25-0.75]. Similar trends were seen in the non-sicca control group(Table). The higher stratum of CES were not significant, but numbers of registrants were small, leading to wide confidence intervals. This finding was corroborated by analysis of the CMC. At the highest level of CMC within the non-sicca control and sicca control postmenopausal groups there was a 45% and 25% reduction in cumulative sex hormone exposure among SS registrants relative to controls, after adjusting for covariates.

Conclusion: Women with SS have lower estrogen exposure and cumulative menstrual cycling compared to non-autoimmune sicca and non-sicca control groups. As estrogen exposure and cumulative menstrual cycling increased, there was a trend toward decreased risk of SS. Further longitudinal studies of sex hormone exposure in SS are needed to confirm these findings.

Persistent Serological Activity in Primary Sjögren's Syndrome

Jorge Lopez-Morales, Daniel Cortes-Muñoz and Gabriela Hernandez-Molina, Immunology and Rheumatology, Instituto Nacional de Ciencias Médicas y Nutrición SZ, Mexico City, Mexico

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Sjögren's Syndrome – Basic and Clinical Science Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: To assess presence of persistent serological activity and its association with clinical outcomes in a cohort of patients with primary Sjögren's syndrome (pSS).

Methods: We retrospectively reviewed the clinical charts of 275 patients with pSS according to the AECG criteria, attending a tertiary referral center. We defined persistent serological activity as increase IgG \geq 1.6 g or globulins $>$ 3.7 gr or diminished C3 $<$ 52 mg/dL or C4 $<$ 12 mg/dL at least during two consecutive visits during a year period (index period). We selected whenever possible, the closest period to the diagnosis of SS. We defined clinical activity, as the presence of at least 1 point in the clinESSDAI at the index period. We also scored the cumulative clinESSDAI as well as the SSDDI at the last medical appointment. We excluded patients with incomplete serological data or with $<$ 1 year of follow-up after the

index period. We registered demographics, glandular and extraglandular features, anti-Ro/SSA, anti-La/SSB and RF determinations. We used descriptive statistics and used regression logistic analysis.

Results: We excluded 115 patients due to incomplete data. Thus we included 160 patients with available serological data and follow-up: most females (95%), 94% with ocular symptoms, 91.2% oral symptoms, 46.9% parotid enlargement, 90% anti-Ro/SSA and 58% anti-La/SSB antibodies and median disease duration of 10.2 years. We identified persistent activity in 85 patients (53.1%): 57 due to hyperglobulinemia, 5 due to low C3 or C4, and 23 patients due to both. In only 13 patients, the serological status changed during the follow-up from active to inactive.

At the moment of the assessment (index period) we identified 58 patients with both clinical and serological activity, 49 with only clinical activity, 27 with only serological activity and 27 without clinical or serological activity. When we compared patients with (n=85) vs. without serological activity (n=74), the first group had a higher prevalence of impaired whole non-stimulated salivary flow (94% vs. 79.2%, p=0.01), anti-La/SSB antibody (70.6% vs. 44.6%, p=0.001) and RF (84.5% vs. 51%, p=0.0001). In addition, the persistent active serological group had a higher cumulative clinESSDAI at the last medical appointment (11 vs. 6 points 0.0001), being the main affected domains the constitutional (30.6% vs. 13.5%, p=0.02), glandular (52.9% vs. 32%, p=0.01), cutaneous (21.2% vs. 5.4%, p=0.005), renal (17.6% vs. 2.75, p=0.002) and hematological (42.4% vs. 17.6%, p=0.001). The SSDDI score was similar among groups (3 vs. 2 points, p=0.18), however the active serological group had more damage at the oral (92.5% vs 80%, p=0.03) and renal domain (12.6% vs. 2.7%, p=0.02). At the logistic regression analysis, the variables that remained associated were renal involvement (OR 12.8, 95% CI 1.7-92, p=0.01), hematological involvement (OR 4.7, 95% CI 1.6-13.4, p=0.004) and RF (OR 6.4, 95% CI 1.8-22, p=0.003).

Conclusion: Half of the patients with pSS had persistent serological activity, being this status constant during the follow-up. Persistent serological activity was associated with renal and hematological features, as well as with the presence of RF.

Lack of Specificity in Testing for Murine Tissue Specific Autoantibodies for the Diagnosis of Sjogren's Syndrome

Frederick B Vivino¹, Michael D. George², Chadwick Johr³, Nora Sandorfi⁴, Vatinnee Bunya⁵, Giacomina Massaro-Giordano⁵, Andrew Diederich⁶, Brandon Eilberg⁶, Lakshmanan Suresh⁷ and Long Shen⁷, ¹Rheumatology Division, Department of Medicine, University of Pennsylvania, Philadelphia, PA, ²Division of Rheumatology, University of Pennsylvania, Philadelphia, PA, ³University of Pennsylvania, Philadelphia, PA, ⁴Rheumatology, University of Pennsylvania, Philadelphia, PA, ⁵Ophthalmology, University of Pennsylvania, Philadelphia, PA, ⁶Orthopedic Surgery, University of Pennsylvania, Philadelphia, PA, ⁷Trinity Biotech, Inc., Buffalo, NY

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Sjögren's Syndrome – Basic and Clinical Science Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: A group of murine parotid tissue specific autoantibodies (TSAs) which includes anti-SP1 (salivary protein 1), anti-PSP (parotid secretory protein) and anti-CA6 (carbonic anhydrase) are markers for early disease in the IL-14 α transgenic mouse model of Sjogren's (SS). These TSAs are also found in NOD mice, patients (pts) classified with SSA+ or - Sjogren's according to the American European Consensus Group criteria and in pts with idiopathic dry eyes.

Methods: We tested serum for TSAs from 6 patient groups followed in a rheumatology clinic for > 1 year at a university medical center including: 1) SS who met published classification criteria (n=152), 2) non-autoimmune controls (n=36), 3) SLE (n=22), 4) RA (n=17), 5) scleroderma (n=7) and 6) chronic nonspecific sialadenitis (n=16). Saliva samples were also obtained from groups 1,2 & 6. Electronic medical records were reviewed to verify diagnoses & all pts were questioned re: the presence & duration of dry eyes/mouth & medical history. Volunteers with history of dry eyes/mouth, any autoimmune diseases or family history of autoimmune disease were excluded as controls. Serum samples were anonymously coded & assayed by a modified ELISA (Trinity Biotech, Inc., Buffalo, NY). All laboratory personnel were blinded to pts diagnoses. Analyses was performed to determine the sensitivity, specificity & discriminative ability of the presence of ≥ 1 TSAs to differentiate SS from other groups.

Results: Of the 152 SS pts, 9% had disease duration ≤ 3 years. TSAs were detected in both the serum and saliva of pts with SS. The most frequently detected TSA in SS was anti-PSP IgG (13%) (**Table 1**). The presence of ≥ 1 TSA was similar in SS (40%), controls (44%), chronic sialadenitis (50%), and patients with other CTD (35%). No particular TSA or

isotype was specific for SS. Results suggested a sensitivity and specificity of 40% and 56% respectively for the presence of ≥ 1 TSAs in SS. Prevalence of + ANAs/ RF IgM in each group were as follows: SS (57%/ 44%), controls (14%/ 39%), chronic sialadenitis (31%/ 31%) and other connective tissue diseases (65%/ 47%) (**Table 2**). Prevalence of ≥ 1 TSAs did not significantly vary between ANA+ vs. ANA- or between SSA+ vs. SSA- individuals.

Conclusion: The presence of ≥ 1 TSAs in the serum does not distinguish between established SS and other patient groups. The value of the serum assay, as presently performed, for confirmation of early or undiagnosed SS (≤ 3 years) in humans is doubtful given the lack of assay specificity. Assay of TSAs in saliva or calculation of a saliva/serum TSA ratio may prove to be a more valuable diagnostic test.

Table 1 Frequency of Positive Murine Parotid Tissue Specific Autoantibodies in Different Patient Groups

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Sjögren's Syndrome – Basic and Clinical Science Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Genome-wide association studies of multiple autoimmune diseases, including primary Sjögren's syndrome (pSS), systemic lupus erythematosus (SLE) and rheumatoid arthritis (RA) have revealed an association with the chromosome 8 locus *FAM167A-BLK*. The disease-associated genotypes of SNPs in the locus have been linked to a significantly increased expression of FAM167A in B cells. While BLK (B lymphocyte kinase) has a well-established role in

B cells, little is known about FAM167A (family with sequence similarity 167 member A). We recently cloned and investigated the gene product of FAM167A, identifying an encoded protein with high content of intrinsic disorder which we denoted Disordered Autoimmunity 1 (DIORA-1). In the present study we investigated the expression of DIORA-1 in human immune cells and in salivary glands of patients with pSS, as well as assessed DIORA-1 expression in relation to pSS clinical manifestations to begin understanding the role of DIORA-1 in rheumatic disease pathogenesis.

Methods: Primary cells were purified from peripheral blood or buffy coats by MACS beads, and cell lines representing discrete differentiation stages of B cells were cultured under standard conditions. DIORA-1 mRNA expression was assessed by qPCR. Immunohistochemistry was performed to identify DIORA-1 expressing cells in salivary gland biopsies, and characterization of the cells and DIORA-1 localization performed by immunofluorescence using double staining. Characterization of DIORA-1 expressing cells was performed by immunofluorescence. In all, 55 patients with pSS, 20 sicca patient controls and 29 healthy donors were included in the study.

Results: We observed expression of DIORA-1 in CD19+ B cells from peripheral blood, while CD3+ T cells and CD14+ monocytes expressed little or no DIORA-1. To further define the expression pattern of DIORA-1 in B cells, we analyzed cell lines representing discrete differentiation stages of B cells. Interestingly, we observed a graded expression of DIORA-1 in these various cell lines, with the highest expression found in the two plasma cell myeloma lines and intermediate expression in other B cell lines, whereas little or no expression was observed in T cells and other investigated cell lines. CD138+ plasma cells expressing DIORA-1 intracellularly were observed within the salivary glands of pSS patients. Spatially, DIORA-1+ cells were detected within the focal infiltrates and interstitially in salivary gland biopsies. Notably, expression of DIORA-1 correlated to salivary gland focus score, as well as serum IgG levels and the presence of Ro/SSA autoantibodies.

Conclusion: These findings indicate a role for DIORA-1 in select B cell subsets, and moreover suggest that DIORA-1 potentially contribute to the inflammatory process and disease pathogenesis in pSS through B cell involvement.

Low-Dose IL-2 Promotes the Proliferation of Peripheral Regulatory T Cells in Primary Sjögren's Syndrome to Restore Its Balances with Pro-Inflammatory Lymphocytes

Miao Miao¹, Zhenye Hao¹, Yingying Guo¹, Xiaoying Zhang¹, Sheng-Xiao Zhang¹, Jing Luo², Jinfang Zhao³, Chong Gao⁴ and Xiao-Feng Li⁵, ¹The Second Hospital of Shanxi Medical University, Taiyuan, China, ²the Second Hospital of Shanxi Medical University, Taiyuan, China, ³The Shanxi Medical University, Taiyuan, China, ⁴Department of Pathology, Brigham and Women's Hospital, Harvard Medical School, Boston, MA, Cambridge, MA, ⁵Rheumatology, the Second Hospital of Shanxi Medical University, Taiyuan, China

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Sjögren's Syndrome – Basic and Clinical Science Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: To investigate the effect of low-dose IL-2 on the balance of Treg with Teff and other pro-inflammatory lymphocytes in peripheral blood of pSS patients.

Methods: A total of 190 pSS patients and 30 healthy controls were included in the study. The absolute numbers of total CD4+ T, CD8+ T, B, and NK cells in peripheral blood were determined using flow cytometry and BD Trucount™ tubes, while the percentage of each cell subpopulation and CD4+ cell subsets was measured, and then calculated their absolute numbers. Of the 190 patients, 88 were given subcutaneous injections of small doses of recombinant human IL-2 (rhIL-2, 50*10⁶ IU/day for 5 days) in combination with standard therapy, including glucocorticoids, immunosuppressants, Treatment of biologics or their combinations, while other patients received only standard therapies.

Results: (1) The absolute number of peripheral Treg cells of pSS patients was significantly lower than that of normal controls. (2) The absolute number of Th17 and CD8+ T cells before treatment was not different from that of normal controls, whereas the ratios of Th17/Treg and CD8+T/Treg were higher than normal, indicating that the imbalance of them was caused by insufficient number of Treg cells. Although Th17 and CD8+ T cells increased, Treg cells increased

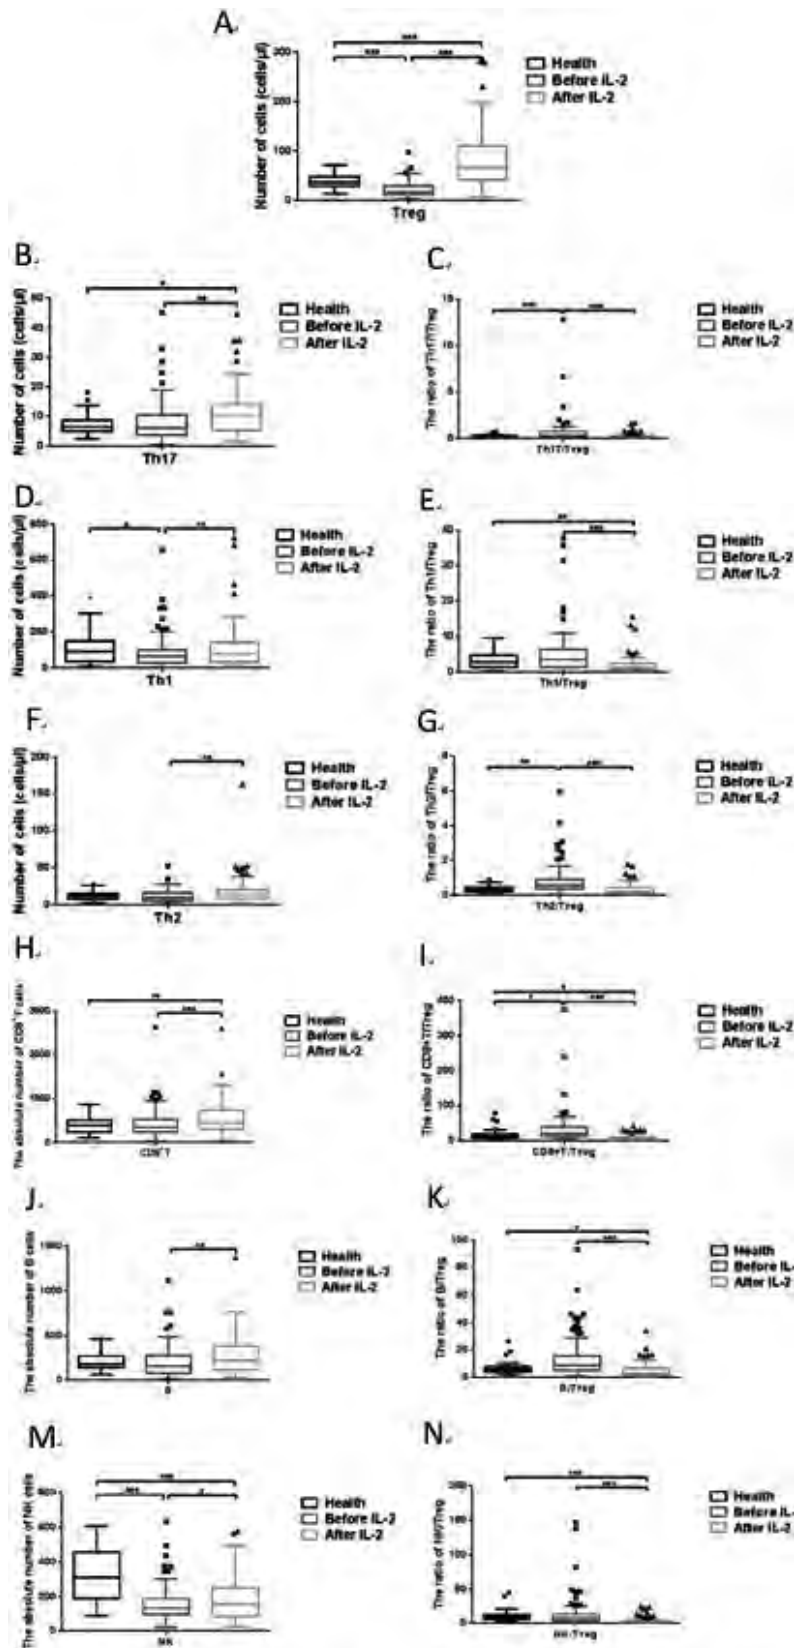

Figure legends. Changes in the absolute number of cells (A, B, D, F, H, J, M) and ratios of individual cells to Treg cells after short-dose, low-dose IL-2 treatment (C, E, G, I, K, N). The data is represented by the median (Q1, Q3). Statistical analysis uses the two-way analysis of variance of the relevant sample Friedman. Compared with healthy controls, * $P < 0.05$, ** $P < 0.01$, *** $P < 0.001$. Shows asymptotic significance (two-tailed test). The significance level was $p < 0.05$.

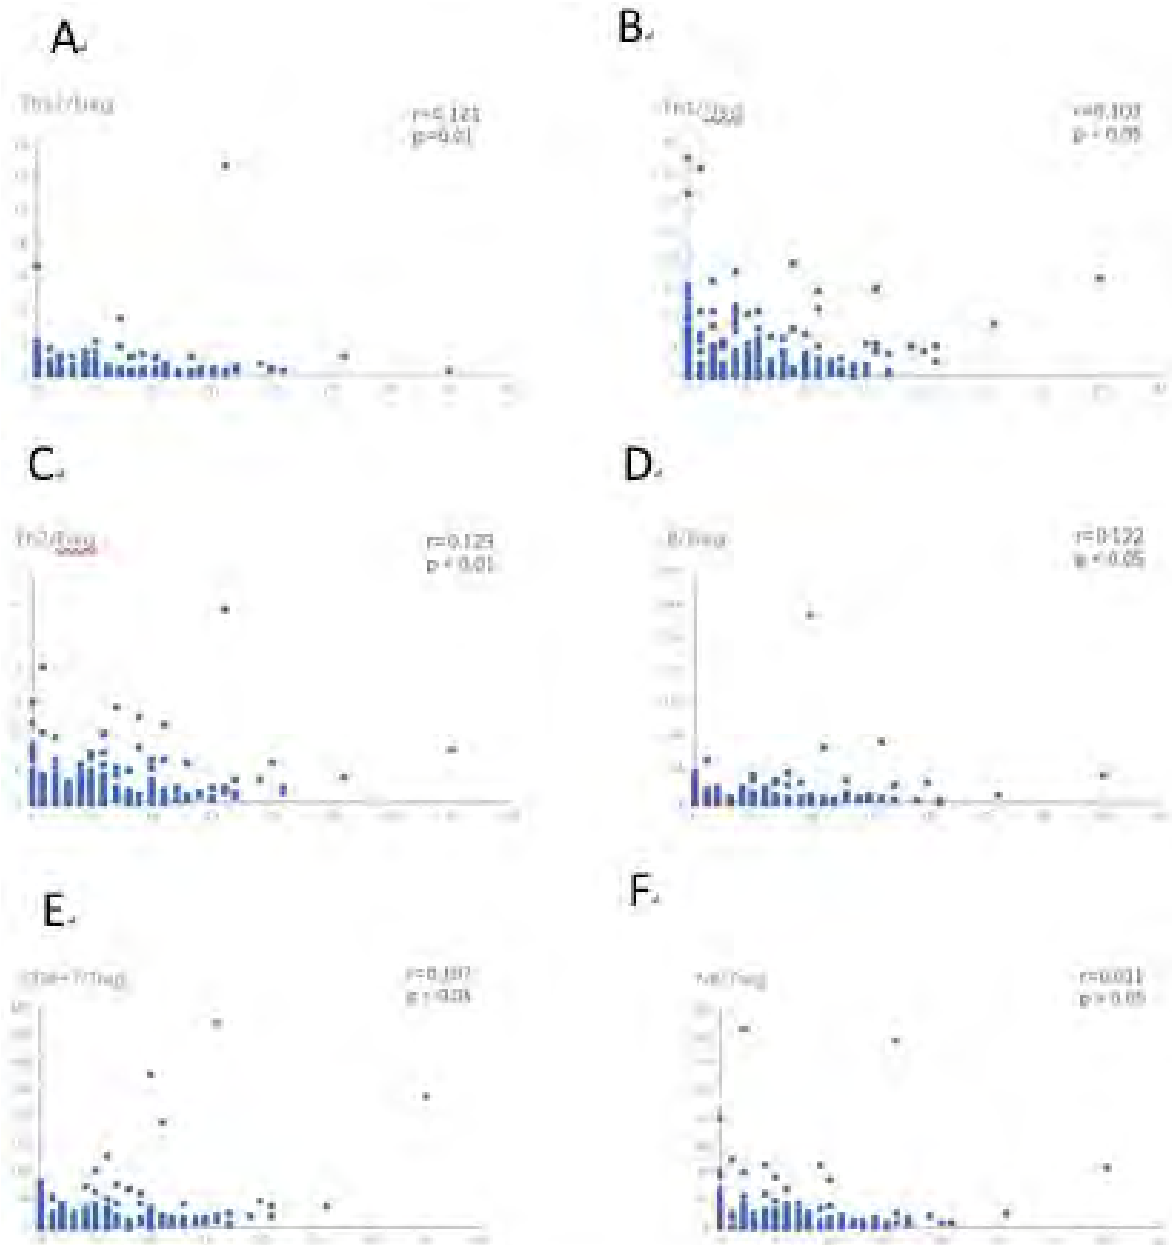

Figure 2 legends: There were positive correlations between ESSDAI value and the ratios of Th17/Treg ($r=0.121$, $P=0.01$), Th1/Treg ($r=0.103$, $P<0.05$), Th2/Treg ($r=0.123$, $P<0.01$), B/Treg ($r=0.122$, $P<0.05$), CD8+T/Treg ($r=0.107$, $P<0.05$).

There was no correlation between ESSDAI value and the ratio of NK/Treg ($r=0.011$, $P>0.05$). Statistical analysis used Spearman's rank correlation. The significance level was $p < 0.05$.

more dramatically, so the ratio returned to normal. Similarly, Th1, Th2, NK, and B cells had similar changes, as shown in Figure 2. (3) Compared with the standard treatment group, low-dose IL-2 increased the proportion of the patients with balanced Th17/Treg, who had a more pronounced improvement in symptoms, and less usage of glucocorticoid and HCQ. (4) There were positive correlations between ESSDAI value and the ratios of Th17/Treg ($r=0.121$, $P=0.01$), Th1/Treg ($\rho=0.103$, $P<0.05$), Th2/Treg ($\rho=0.123$, $P<0.01$), B/Treg ($\rho=0.122$, $P<0.05$), CD8+T/Treg ($\rho=0.107$, $P<0.05$), but no correlation between ESSDAI value and the ratio of NK/Treg ($\rho=0.011$, $P>0.05$).

Conclusion: Low-dose rhIL-2 treatment can promote the proliferation of various cell subsets, but mainly Treg cells, indicating that this treatment can restore the overall balances of Treg/Teff, B/Treg, and NK/Treg. Thus, due to improvement of ESSDAI, the overall balances between Treg and pro-inflammation cells are more important than the change in the single cell subset.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Sjögren's Syndrome – Basic and Clinical Science Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Primary Sjögren`s Syndrome (pSS) is a multisystemic, autoimmunity disease, characterized mainly by the hypofunction of the salivary and lacrimal glands, however the clinical spectrum of this disease extends from SICCA symptoms to the presence of extra-glandular manifestations being able to compromise multiple systems. The recent 2016 ACR-EULAR classification criteria were designed to be applied not only in patients with dryness symptoms, but also in those with clinical manifestations included in the ESSDAI domains (EULAR primary Sjögren's syndrome disease activity) which would allow to classify those patients who debuted with extra-glandular manifestations.

Objetives: To evaluate the performance of the 2016 ACR-EULAR classification criteria for pSS in adult population of different centers in Argentina.

Methods: A multi-center study of 5 national centers was carried out. We included patients older than 18 years of age, who presented clinical and/or analytical manifestations suggestive of pSS. To discriminate between cases and controls, the opinion of experts from different centers, blind to the previous diagnosis of the patients, (with a degree of agreement $\geq 70\%$) was used as gold standard. The exclusion criteria were similar to those present in the 2002 American-European and the 2012 ACR classification criteria. Sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV) and positive likelihood ratio (LR +) were evaluated.

Results: A total of 226 patients were included, 97.3% were women, with an average age of 55 years (SD ± 12), and a mean duration of symptoms of 7.9 years (SD ± 6.8). 178 patients (78.7%) had a diagnosis of pSS according to expert opinion, of which 171/178 (96.1%) had xerophthalmia, 172/178 (96.6%) xerostomia, 162/178 (91%) positivity at least one domain of the ESSDAI and 3/178 (1.7%) did not present xerostomia or xerophthalmia at the time of diagnosis. A

sensitivity of 94.9% (95% IC: 92.1 - 97.8%), a specificity of 95.8% (95% IC: 93.2 - 98.4%), a PPV of 98.8% (95% IC: 97.4 - 100%), a NPV of 83.6% (95% IC: 78.8 - 88.4%) and an LR + of 22.7 (95% IC: 13.6 - 62.7) was obtained.

Conclusion: The recent classificatory criteria showed a performance comparable to the precedents 2002 American-European and 2012 ACR classification criteria, with the advantage that the new ones allow to classify those patients who debuted with extra-glandular manifestations.

Primary Sjögren's Syndrome Stratification Based on the Severity of Patient-Reported Fatigue

Saviana Gandolfo, Elena Doriguzzi Breatta, Cinzia Fabro and Salvatore De Vita, Rheumatology Clinic, Academic Hospital S. M. della Misericordia, Medical Area Department, University of Udine, Italy, Udine, Italy

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Sjögren's Syndrome – Basic and Clinical Science Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Fatigue is one of the most common symptoms reported by patients affected by primary Sjögren's syndrome (pSS), and a major contributor to impaired quality of life. The purpose of this study was to analyze the clinical, serological and histological features of pSS patients stratified according to the severity of their self-reported fatigue.

Methods: Among pSS patients undergoing clinical evaluation in our Sjögren's Clinic in a six-months period (January-June 2017), 86 consecutive unselected patients, fulfilling the latest ACR/EULAR pSS classification criteria, accepted to report their degree of fatigue on a 10-cm VAS (range 0-100) and to complete the ESSPRI questionnaire. Four subgroups of fatigue severity were defined, as previously published (1): no fatigue (VAS=0); low fatigue (VAS=1-24); moderate fatigue (VAS=25-74); high fatigue (VAS=75-100). For each subgroup demographic, serological, histological features and the ESSDAI score were collected, as well as the prevalence of pSS-related lymphoma, fibromyalgia (FM), autoimmune thyroiditis, and anemia.

Results: Fatigue was reported by the 87.2% (n=75) of pSS patients, distributed in subgroups as following: 25.3% (n=19) with low fatigue, 58.7% (n=44) with moderate fatigue and 16% (n=12) with high fatigue. Lymphoma was significantly (p=0.0133) more frequent in the pSS subgroup with high fatigue (33.4%, by considering active lymphoma cases; 50%, by considering also the cases with lymphoma in remission). FM patients were a minority (4.7%; n=4), and never complained of high fatigue, all of them reporting moderate fatigue. A significant correlation was finally found between fatigue severity and ESSPRI (p<0.0001), but not with ESSDAI (p=0.31). No significant age or sex difference was observed between subgroups. Also, autoimmune thyroiditis, anemia, anti-SSA and/or anti-SSB positivity, rheumatoid factor positivity, and cryoglobulinemia showed no significant different frequency between subgroups.

Conclusion: When fatigue is better stratified in pSS, it appears that it is usually moderate or severe, rather than mild. Furthermore, it is unrelated to FM. Overall, fatigue appears as a consequence of pSS itself. Of note, severe fatigue was related in this study with the most important complication influencing patient survival in pSS, i.e., lymphoma. Further studies are needed to disclose the pathogenetic events leading to fatigue in pSS, and investigation of lymphoma in pSS might be also helpful to this end.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Sjögren's Syndrome – Basic and Clinical Science Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Sjögren's syndrome (SS) is an autoimmune epitheliitis that mainly affects the salivary and lacrimal glands. The glandular hypofunction has been associated to loss of epithelium by apoptosis. However, several lines of evidence indicate the existence of survival mechanisms that counteract the apoptosis, one of them being the autophagy. This mechanism is involved in decreasing inflammation by selectively removing proteins related to Toll-like receptors and inflammasomes, among other pathways. A previous study on SS showed increased autophagy in T lymphocytes of salivary glands, but the glandular epithelium was not evaluated. Interestingly, IL-6 implicated in SS pathogenesis mediates its response activating the JAK-STAT signaling pathway. In macrophages and other cellular types, activation of the JAK-STAT pathway inhibits autophagy. Studies in SS have shown increased expression of STATs, however, expression of JAK proteins has not been evaluated. The aim of this study was to evaluate the expression of JAKs proteins and autophagy markers in labial salivary glands from SS-patients.

Methods: In labial salivary glands of 11 SS patients and 10 control subjects, mRNA levels of JAK1, JAK2, mTOR and ATG5 were measured by qPCR.

Results: A significant decrease of JAK1 mRNA levels ($p=0.0068$), as well as decreased mRNA levels of genes that participate in autophagy such as mTOR and ATG5 ($p=0.0074$ and $p=0.02$, respectively) were observed in labial salivary glands of SS-patients.

Conclusion: Low JAK1 mRNA levels in SS-patients suggest a downregulation mechanism in response to previously reported hyperactivation of JAK-STAT signaling pathway in SS patients. On the other hand, decreased mRNA levels of autophagy markers, such as ATG5 and mTOR, could indicate an attenuation of this pro-inflammatory mechanism in SS.

Pathogenic Role of Interleukin 27 in the Nonobese Diabetic Mouse Model of Sjögren Syndrome

Scott Lieberman¹, Jennifer Barr², Xiaofang Wang² and Yi-Guang Chen³, ¹Division of Rheumatology, Stead Family Department of Pediatrics, Carver College of Medicine, University of Iowa, Iowa City, IA, ²Stead Family Department of Pediatrics, Carver College of Medicine, University of Iowa, Iowa City, IA, ³Pediatrics, Medical College of Wisconsin, Milwaukee, WI

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Sjögren's Syndrome – Basic and Clinical Science Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Sjögren syndrome is an immunologically complex autoimmune disease characteristically targeting the lacrimal and salivary glands leading to progressively worsening oral and ocular health and poor quality of life. No effective treatments for reversing the exocrine gland inflammation have been identified owing in part to a lack of understanding the

early immunological events responsible for initiation of lacrimal and salivary gland inflammation. Interleukin 27 (IL27) is a heterodimeric cytokine that was elevated in serum of Sjögren syndrome patients. IL27 may have immunostimulatory or immunomodulatory properties depending on the context, so this elevation in Sjögren syndrome may represent a pathologic process or a compensatory anti-inflammatory process. Similar to Sjögren syndrome in humans, nonobese diabetic (NOD) mice develop spontaneous autoimmune dacryoadenitis and sialadenitis and represent a well-characterized model of Sjögren syndrome. Our objective here was to evaluate the role of IL27 in the development of dacryoadenitis and sialadenitis in the NOD mouse model of Sjögren syndrome.

Methods: NOD mice with deletion mutations disrupting expression of genes encoding the p28 component of IL27 (*Il27*) or the alpha chain of the IL27 receptor (*Il27ra*) were developed through Zn-finger nuclease or CRISPR/Cas9 mediated gene editing, respectively. Development of dacryoadenitis and sialadenitis were determined by histological analyses, and T cell phenotypes were characterized by flow cytometry. *In vivo* regulatory T cell (Treg) depletion with anti-CD25 monoclonal antibody (PC61) and adoptive transfers were performed to determine the effects of disrupted IL27 signaling on development of dacryoadenitis. Studies were approved by the Institutional Animal Care and Use Committee of the University of Iowa.

Results: NOD mice lacking IL27 or IL27Ra failed to develop spontaneous autoimmune dacryoadenitis or sialadenitis. Phenotypically, T cells from IL27-deficient or IL27Ra-deficient NOD mice showed no evidence of defective T cell activation based on expression of T cell activation markers analyzed by flow cytometry *ex vivo*. Depletion of Treg cells in IL27-deficient NOD mice failed to drive dacryoadenitis in these mice. In our adoptive transfer model, wild-type T cells transferred dacryoadenitis to NOD-SCID recipient mice, but IL27Ra-deficient T cells failed to transfer dacryoadenitis. When co-transferred with wild-type cells, IL27Ra-deficient CD8 and CD4 effector T cells each demonstrated a significant competitive disadvantage in their ability to infiltrate lacrimal glands.

Conclusion: IL27 is required for development of dacryoadenitis and sialadenitis in NOD mice. T cell-intrinsic IL27 signaling is required to transfer disease. Defective infiltration of lacrimal glands by IL27Ra-deficient effector T cells suggests IL27 signaling may drive upregulation of homing receptors required for lacrimal gland inflammation. More extensive gene expression and flow cytometric analyses to determine the effects of IL27 signaling on pathogenic immune cell populations in NOD mice are currently underway.

Risk of Cancer in Patients with Psoriasis/Psoriatic Arthritis: A Population-Based Study in the Province of British Columbia

Julia Tan¹, J. Antonio Avina-Zubieta², Alyssa Dominique³, Hamid Tavakoli⁴ and Teresa A Simon³, ¹Medicine, University of British Columbia, Vancouver, BC, Canada, ²Division of Rheumatology, Department of Medicine, University of British Columbia, Vancouver, BC, Canada, ³Bristol-Myers Squibb, Princeton, NJ, ⁴Arthritis Research Canada, Vancouver, BC, Canada

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Clinical/Epidemiology Studies

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Psoriasis (PsO) is a relapsing chronic autoimmune disease of the skin. Up to one-third of patients (pts) also develop inflammatory arthritis, known as psoriatic arthritis (PsA). PsO/PsA, like other forms of chronic inflammatory arthritis, are often associated with complications such as cardiovascular disease and infections. However, data on the risk of cancer in pts with PsO/PsA at population level are limited.

Methods: We created a population-based matched retrospective cohort of PsO/PsA pts diagnosed between 1 January 1997 and 31 December 2012 using administrative health data from British Columbia, Canada. We identified all incident cases of PsO/PsA and an equal number of controls matched on sex, age and calendar year. PsO/PsA cases met ≥ 1 of the following: 1 diagnostic code for PsO/PsA by a rheumatologist/dermatologist; ≥ 2 diagnostic codes for PsO/PsA, ≥ 2 months apart in a 2-year period by a non-rheumatologist/dermatologist; or ≥ 1 hospitalization with diagnostic code for PsO/PsA. We evaluated incident cancers during follow-up from the Cancer Registry in both cohorts. Adjusted risk of cancers was estimated using a generalized estimating equation extension of multivariate Poisson regression models.

Results: We identified 81,568 incident cases of PsO/PsA (mean age 48.5 years [SD=17.8], 51.5% female). Individuals with PsO/PsA were at significantly higher risk of being diagnosed with 8/41 types of cancer examined, including eye and orbit (4

fold), female genital (3 fold), non-melanoma skin (2 fold), prostate (males; 1.1 fold) (Table). Incidence of rectum and colon cancer was lower among PsO/PsA pts relative to the non-PsO/PsA cohort (Table)

Conclusion: This general population-based study demonstrates that pts with PsO/PsA have an increased risk of several types of cancer, and a decreased risk of rectum and colon cancer. This association highlights the need to further explore potential risk factors and pathways that contribute to these complications.

Outcome	PsO/PsA events	Non-PsO/PsA events	PsO/PsA follow-up (PY)	Non-PsO/PsA follow-up (PY)	PsO/PsA IR (per 100,000 PY)	Non-PsO/PsA IR (per 100,000 PY)	IRR (95% CI)

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Clinical/Epidemiology Studies

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Laboratory biomarkers indicative of cardiac ischemia or dysfunction improve cardiovascular(CV) risk stratification in the general population. Their utility in patients with psoriatic disease (PsD) is unknown. Our objective was to evaluate the levels of cardiac biomarkers in patients with PsD vs. non-psoriatic controls and to assess their association with the burden of carotid atherosclerosis and plaque progression.

Methods: Patients with psoriasis only (PsC) or psoriatic arthritis (PsA) from a longitudinal PsD cohort were enrolled. Non-psoriatic controls were recruited through advertisements and from hospital personnel. Baseline evaluation included clinical assessment of CV risk factors, joint and skin disease activity and medication use. Ultrasound assessment of the carotid arteries was performed only in patients with PsD. Total Plaque Area (TPA) was measured at baseline and after 2-3 years. The average annual progression rate of atherosclerosis was calculated by subtracting the baseline from the follow-up TPA divided by the number of years between the visits. Concentrations of high sensitivity Troponin I (TNT-I) and N-terminal pro-brain natriuretic peptide (NT-proBNP) were measured using automated clinical assays. The association between cardiac biomarkers and carotid atherosclerosis was assessed by multivariable regression analysis after adjusting for age, sex, diabetes, hypertension, smoking, BMI, lipid lowering therapy, LDL-c, HDL-c and creatinine.

Results: A total of 391 patients with PsD (71% PsA, 29% PsC) and 88 controls were included. Their mean age was 54.1±11.7 years (53.4% men). Unadjusted levels of TNT-I were higher in patients with PsD compared to controls (Odd Ratio (OR) 1.41, 95% Confidence Interval (CI) 1.11, 1.81),however, after controlling for age, sex and creatinine levels, no

significant differences were found. The unadjusted and adjusted levels of NT-pro BNP were similar in patients with PsD and controls. Higher levels of NT-Pro-BNP were associated with PsA vs. PsC (adjusted OR 1.35, 95% CI 1.09, 1.68). Higher levels of TNT-I were associated with the burden of carotid atherosclerosis at baseline in unadjusted models (β 0.66, 95% CI 0.46, 0.87; Table 1) and after controlling for CV risk factors (adjusted β 0.27, 95% CI 0.08, 0.46; Table 1). However, baseline TNT-I levels did not predict carotid atherosclerosis progression ($p=0.47$). No significant association was found between baseline levels of NT-pro BNP and carotid atherosclerosis at baseline (adjusted $P=0.15$) or the rate of atherosclerosis progression (adjusted $p=0.64$). No interaction was found between each of the biomarkers and sex.

Conclusion: Higher TNT-I is associated with more pronounced atherosclerosis in patients with PsD independently of usual CVD risk factors. The utility of hsTnI in improving CV risk stratification in these PsD patients warrants assessment.

Table 1 The Association between Troponin I levels and Total Plaque Area* at Baseline by Linear Regression Model in Patients with Psoriatic Disease (N=391)

Variable	Adjusted β	95% Confidence Interval	P value
High-Sensitivity Troponin I* (ng/L)	0.27	0.08, 0.46	0.006
Age (10 year increase)	0.06	0.05, 0.07	<0.001
Sex: Female	-0.18	-0.49, 0.12	0.25
BMI (kg/m ²)	0.01	-0.01, 0.04	0.32
Hypertension (y/n)	0.22	-0.11, 0.56	0.18
Diabetes (y/n)	0.24	-0.30, 0.78	0.38
Smoking (Current vs. No)	0.46	0.04, 0.88	0.03
LDL-c (mmol/L)	0.27	0.12, 0.42	<0.001
HDL-c (mmol/L)	0.002	-0.37, 0.38	0.99
Use of lipid lowering drugs (y/n)	0.68	0.36, 1.01	<0.001
Creatinine (μ mol/L)	0.21	-0.62, 1.05	0.61

Session Date: Monday, October 22, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Clinical/Epidemiology Studies

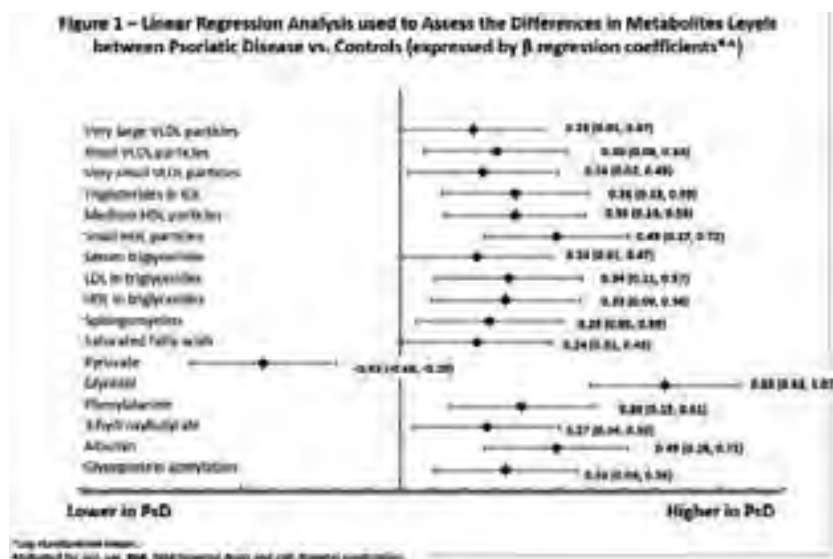

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Metabolomic profiling of patients with psoriatic disease (PsD) offers unparalleled opportunity to unravel the molecular and clinical interactions linking PsD with cardiovascular (CV) risk. Our objective was to evaluate the metabolomics profile in patients with PsD vs. non-psoriatic controls and to assess its association with carotid atherosclerosis progression.

Methods: Patients with psoriasis only or psoriatic arthritis from a longitudinal PsD cohort were enrolled. Non-psoriatic controls were recruited through advertisements and from hospital personnel. Baseline evaluation included clinical assessment of CV risk factors, joint and skin disease activity and medication use. Ultrasound assessment of the carotid arteries was performed only in patients with PsD. Total plaque area was measured at baseline and after 2-3 years. The average annual progression rate (APR) of atherosclerosis was calculated by subtracting the baseline from the follow-up TPA divided by the number of years between the visits. Atherosclerosis progression was defined as being in the top quartile of APR. A high-throughput serum nuclear magnetic resonance metabolomics platform was used to quantify the baseline levels of 58 lipoprotein subclasses, fatty acid composition, amino acids glycolysis precursors and ketone bodies. Multivariable logistic regression analysis was performed to assess the association between metabolite levels and the following outcomes: 1) disease status (PsD vs. controls); 2) carotid atherosclerosis progression.

Results: A total of 392 patients with PsD and 88 controls were included in the analysis. Their mean age was 54.1 ± 11.7 years (53.4% men). 19 metabolite measures were found to be significantly associated with PsD compared to controls after adjusting for age, sex, BMI and medication use (Figure 1). The metabolites included lipoprotein subclasses, fatty acids, amino acids and intermediates of glycolysis. We then evaluated the incremental value of adding circulating metabolites to established CV risk factors for prediction of atherosclerosis progression using regression analysis. 13 metabolites, primarily atherogenic lipid particles, predicted atherosclerosis progression after adjusting for CV risk factors (Table 1).

Conclusion: Substantial differences were found in the metabolomic profile between patients with PsD and non-psoriatic controls. Atherogenic lipoprotein particles across the non-HDL-c spectrum predicted atherosclerosis progression in PsD independently of conventional CV risk factors.

Is Enthesitis a Marker of Disease Severity in Early Psoriatic Arthritis?

Lihi Eder¹, Chandra Farrer² and Dana Jerome³, ¹Women's College Research Institute, University of Toronto, Women's College Hospital, Toronto, ON, Canada, ²Rheumatology, Women's College Hospital, Toronto, ON, Canada, ³University of Toronto, Women's College Hospital, Toronto, ON, Canada

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Clinical/Epidemiology Studies

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Enthesitis is a key feature in psoriatic arthritis (PsA) affecting approximately a third of the patients. Ultrasound improves the detection of enthesitis compared to clinical examination. However, there is little information about the construct validity of sonographic enthesitis scores in PsA. We aimed to evaluate the correlation between the severity of sonographic enthesitis and measures of disease activity in patients with early PsA.

Methods: Sixty-four patients with early PsA (duration <5 years) who were naïve to biologic medications, were enrolled. PsA disease activity was assessed in each of the key domains using validated measures of disease activity, laboratory markers of inflammation and patient reported outcomes. The severity of sonographic enthesitis was assessed in 14 enthesal sites using a modification of the Madrid Enthesitis Scoring Index (MASEI) with power Doppler scored on a scale of 0 to 3. We considered the total score of modified MASEI(mod-MASEI) and the total Doppler scores (mod-MASEI-Dop) as the outcomes of interest. Pearson correlation coefficients were calculated between sonographic enthesitis scores and measure of disease activity. Since sonographic enthesitis confounded by aging and mechanical stress we used

Table 1 - The Association between Metabolemic Biomarkers* and Atherosclerosis Progression by Logistic Regression Model		
Each model is adjusted for: Age, sex, systolic blood pressure, anti hypertensive therapy, lipid lowering therapy, BMI, smoking, diabetes and disease status (PsA vs psoriasis)		
Biomarker	Odds Ratio (95% Confidence Interval)	P value
Very small VLDL particles	1.43 (1.09, 1.88)	0.009
IDL particles	1.51 (1.14, 1.99)	0.004
Phospholipids in IDL	1.52 (1.16, 2.01)	0.003
Total cholesterol in IDL	1.42 (1.09, 1.85)	0.009
Triglycerides in IDL	1.30 (1.00, 1.72)	0.05
Large LDL particles	1.51 (1.14, 1.99)	0.004
Medium LDL particles	1.47 (1.12, 1.93)	0.006
Small LDL particles	1.40 (1.07, 1.84)	0.01
Large HDL particles	0.73 (0.54, 0.98)	0.03
Remnant cholesterol	1.35 (1.03, 1.75)	0.03
Total cholesterol in LDL	1.42 (1.09, 1.84)	0.009
Apo-B	1.29 (1.00, 1.68)	0.05
Creatinine	0.75 (0.57, 0.99)	0.04
*log standardized values		

regression analysis to evaluate the association between diseases related measures and sonographic enthesitis after adjusting for age, sex and BMI.

Results: The mean age was 46.6 ± 13.7 (53.1% males) and mean disease duration was 1 ± 1.3 years. Clinical enthesitis was found in 51.6% (≥ 1 tender enthesial site) and active sonographic enthesitis was found in 57.8% of the patients. A mild to moderate correlation was found between sonographic enthesitis and tender and swollen joint counts, damaged joint count, clinical enthesitis count, physician global assessment and health assessment questionnaire (HAQ)(Table 1). In multivariable analysis the following variable were associated with higher sonographic enthesitis score (Table 2): nail pitting (β 9.3, 95% confidence interval (CI) 1.7, 16.8), physician global assessment (β 1.9, 95% CI 0.3, 3.5), HAQ (β 9.7, 95% CI 3.9, 15.5), swollen joint count (β 1.3, 95% CI 0.6, 1.8) and tender joint count (β 1.2, 95% CI 0.6, 1.8).

Conclusion: The severity of sonographic enthesitis correlates with measures of disease activity, joint damage and patient function in early PsA. These findings suggest that sonographic enthesitis has construct validity and may be considered as a marker of severity in early PsA.

Table 1- The correlation sonographic enthesitis and measures of PsA disease activity

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Clinical/Epidemiology Studies

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Uveitis is the most frequent extra-articular manifestation (EAM) of spondyloarthritis (SpA). Its prevalence is approximately 30% and increases with the duration of the SpA. The characteristic pattern is anterior, acute, recurrent and unilateral uveitis. However, the frequency and characteristics of uveitis in SpA treated with biological therapy (BT) are unknown. The main target is to describe the frequency and characteristics of uveitis in SpA with BT in a single center.

Methods: Descriptive and retrospective study (January 2003-December 2017) of SpA that develops uveitis in a reference hospital. The epidemiological variables, type of SpA, presence of uveitis and its characteristics, presence of BT at the time of onset and treatment received are collected. For the analysis, frequencies and percentages were used in qualitative variables, and mean and standard deviation (SD) for quantitative variables. Statistical analysis was performed with IBM SPSS v.23.

Results: We studied 246 patients with SpA. The subtypes of SpA were: ankylosing spondylitis (AS) (n=125, 50.8%), psoriatic arthritis (PsA) (n=101, 41.1%), undifferentiated SpA(n=13, 5.3%), non-radiographic axial SpA (n=3, 1.2%), enteropathic arthropathy (n=3, 1.2%) and reactive arthritis (n=1,0.4%). Uveitis was observed in 41 patients (16.7%) after an average time of development of 109.47 (73.9) months of the SpA. The incidence rate was 5.5 cases of uveitis/100 patients-year of follow-up. Men were 70.7% of the patients and the mean age(SD) was 47.4(12.06) years. The HLA B27 was positive in 87.8% of the cases and 41.5% had family history of SpA. Uveitis was observed in 33 patients (80.5%) with AS, in 6 (14.6%) with PsA, in 1(2.4%) with non-Rx axial SpA and in 1 (2.4%) with undifferentiated SpA. (TABLE) The uveitis pattern was anterior (100%), acute (92.7%), unilateral (87.8%) and in 12.2% bilateral (80% in PsA). At the time of onset of uveitis, the mean ESR was 30.11 mm1sth, CRP 3.56 mg/dL, DAS 28 3.66 and BASDAI 3.21. Regarding the diagnosis of SpA, uveitis was after (85.4%), before (12.2%) and simultaneous (2.4%). At the time of the onset of uveitis, 14 patients (34.1%) were with BT (35.7% etanercept, 28.6% infliximab, 21.4% adalimumab, 7.1% golimumab and 7.1% certolizumab). BT was modified in 3 of the cases. The treatment of uveitis was topical (78%), corticoids in oral regimen (57.5%), conventional DMARDs (12.5%), with methotrexate predominating in 60% of cases and BT (15%). The most used biologics were adalimumab (60%) and infliximab (40%).

Conclusion: In our series, uveitis was observed in 16.7% of patients with SpA of which 80.5% were AS and 14.6% PsA. The most frequent uveitis was anterior, unilateral, acute and recurrent. In PsA, the association with HLA B27 was less frequent and was more bilateral. In most cases, the diagnosis was later than the SpA.

TABLE. CHARACTERISTICS OF THE UVEITIS IN SpA SUBTYPES

	AS (n=125)	PsA (n=101)	undifferentiated SpA (n=13)	non-radiographic axial SpA (n=3)	enteropathic arthropathy (n=3)	reactive arthritis (n=1)
Age (mean)	47.4	47.4	47.4	47.4	47.4	47.4
Sex (M/F)	88/37	70/31	8/5	2/1	2/1	1/0
HLA B27	110/15	14/87	1/12	1/2	1/2	1/0
Family history of SpA	52/73	41/60	6/7	1/2	1/2	1/0
Time of onset of uveitis (months)	109.47	109.47	109.47	109.47	109.47	109.47
Pattern of uveitis	Anterior	Anterior	Anterior	Anterior	Anterior	Anterior

Extra-Articular Manifestations, Neoplasms and Cardiovascular Events in a Series of Spondyloarthritis from a Single Center

Itziar Calvo Zorrilla¹, Edurne Guerrero Basterretxea¹, Oihane Ibarguengoitia¹, David Montero¹, Maria Luz Garcia Vivar¹, Esther Ruíz Lucea², Ignacio Torre Salaberri², Olaia Begoña Fernandez Berrizbeitia², Juan Maria Blanco Madrigal², Ana Rosa Inchaurre Pellejero¹, Clara Eugenia Perez Velasquez², Natalia Rivera-García³, Maria Jesus Allande Lopez Linares³, Inigo Gorostiza-Hormaetxe⁴ and Eva Galíndez Agirregoikoa², ¹Rheumatology, Rheumatology Department; Basurto University Hospital, Bilbao, Spain, ²Rheumatology Department; Basurto University Hospital, Bilbao, Spain, ³Rheumatology, University Hospital of Basurto, Bilbao, Spain, ⁴Research Department, Basurto University Hospital, Bilbao, Spain

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Clinical/Epidemiology Studies

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Spondyloarthritis(SpA) is characterized by axial, peripheral and extra-articular manifestation(EAMs). Its frequency depends on the series, being the psoriasis(Ps), uveitis and inflammatory bowel disease(IBD) the most frequent. Neoplasms and cardiovascular events(CVE) are the comorbidities which have the highest mortality. The main target is to describe the prevalence of EAMs, neoplasms and CVE in a series of patients with SpA of a reference hospital.

Methods: Descriptive and retrospective study (January 2003-December 2017) of patients with SpA with biological therapy (BT). For the analysis, frequencies and percentages were used for qualitative variables, and mean and standard deviation (SD) for quantitative. Statistical analysis was performed with IBM SPSS.

Results: We studied 246 patients (74.4% males) with a mean age(SD) of 52.9(13.3) years. The types of SpA were: ankylosing spondylitis (AS) (50.8%), psoriatic arthritis (PsA) (41.1%), undifferentiated SpA (5.3%), non-radiographic axial SpA (1.2%), enteropathic arthritis (1.2%) and reactive arthritis (0.4%) (TABLE). In the diagnosis of SpA, age was 39.7(12) years, ESR 37.4mm1sth, CRP 3.15mg/dL, DAS28 3.01 and BASDAI 4.9. Entesitis was present in 28.9% and 23.2% presented dactylitis. At the final study visit, the average duration of the SpA was 158(106.7) months. In 130 patients (59.8%) one EAM was observed, and two in 17 patients (6.9%).

Ps was observed in 102 patients (41.5%) after a mean development of the SpA of 241.4(163) months. In 20 cases, Ps was paradoxical (55% with adalimumab and 15% infliximab). The most frequent form was plaques (75.5%) and palmoplantar localization (29.7%). Uveitis was observed in 41 patients (16.7%) after a mean development of the SpA of 109.5(73) months. The most frequent associations of uveitis were with AS (80.5%), men (70.7%) and HLAB27+ (87.8%). The pattern was anterior (100%), unilateral (87.8%) and acute (92.7%). 14 patients (34.1%) were with BT (35.7% etanercept, 28.6% infliximab, 21.4% adalimumab). The incidence rate was 5.5 cases of uveitis/100 person-years of follow-up. We found IBD in 21 patients (8.5%) after a mean development of the SpA of 165(118.1) months. Three of the 21 presented it with BT (2 etanercept and 1 infliximab). Other MEAs were observed in 25.6%: osteoporosis (20.6%), cardiac arrhythmias (15.7%) and nephropathy (16%). A CVE was observed after a mean period of SpA of 133(115) months in 6.9% of the patients with an average CRP of 1.64 mg/dL. Neoplasms were observed in 7.3% of the patients (66.7% were solid tumors (58.3% urothelial and 25% breast) and 27.8% lymphoproliferative).

Conclusion: The AS and the PsA were the most frequent SpA in our series. The appearance of at least one EAM was observed in 60% of the patients, being a significant proportion (46.3%) before the diagnosis of SpA. The frequency of CVE and neoplasm seems similar to the population.

TABLE. SUBTYPES OF SpA AND ASSOCIATION WITH MEAs

Liver Enzyme Elevation in Patients with Ankylosing Spondylitis Treated with TNF Inhibitor: A Single-Center Historical Cohort Study

Su Jin Choi, Ji Seon Oh, Seokchan Hong, Yong-Gil Kim, Chang Keun Lee and Bin Yoo, Division of Rheumatology, Department of Internal Medicine, University of Ulsan College of Medicine, Asan Medical Center, Seoul, Korea, Republic of (South)

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Clinical/Epidemiology Studies

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: TNF inhibitors have been known to cause liver enzyme elevation in rheumatologic disease. However, liver enzyme elevation could be affected easily by other causes including concomitant medications and underlying liver disease. In ankylosing spondylitis (AS), there has been little analysis related to the study of liver enzyme elevation. The use of disease-modifying anti-rheumatic drugs (DMARDs) for treating AS has become less common after the introduction of TNF inhibitor treatment. Therefore, we identified the incidence and risk factors of liver enzyme elevation after TNF inhibitor exposure in patients with AS.

Methods: Retrospectively, we collected 363 AS patients who had normal liver enzyme levels before treatment with TNF inhibitor in a tertiary hospital from Jan. 2003 to Dec. 2017. Patients did not have evidence of viral or alcoholic liver disease before treatment with TNF inhibitor. TNF inhibitor medications included adalimumab, etanercept, infliximab, and golimumab. Clinical, laboratory and medication data were collected from the electronic medical records. Liver enzyme elevation was defined as aspartate aminotransferase (AST) and/or alanine aminotransferase (ALT) levels $>1\times$ upper limit of normal (ULN) and consecutively elevated for two or more visits without evidence of new exposure to hepatotoxic drugs. The Cox proportional hazards model was used to evaluate hazard ratio (HR) with 95% confidence interval (CI) for liver enzyme elevation.

Results: The incidence of liver enzyme elevation was 23.7% (86/363). AST and/or ALT elevation $>2\times$ ULN occurred in 37.2% (32/86) of patients with liver enzyme elevation. The median duration of TNF inhibitor exposure before liver enzyme elevation was 3.72 months (IQR 1.77-12.51). There was no difference in the occurrence of liver enzyme elevation in the DMARDs and TNF inhibitor users compared with TNF inhibitor alone users (24.5% vs 22.9%, $p=0.718$). In multivariable analysis, the HRs for liver enzyme elevation were 3.41 (95% CI 1.44-8.06) for males, 3.02 (95% CI 1.68-5.43) for fatty liver disease, and 2.54 (95% CI 1.54-4.19) for hyperlipidemia. Among TNF inhibitors, infliximab was weakly associated with liver enzyme elevation compared with adalimumab, etanercept, and golimumab (HR=0.75, 95% CI 0.59-0.96). Among patients with liver enzyme elevation, 13 patients switched to another TNF inhibitor during the follow-up period. The normalization of the liver enzyme levels after switching was observed in four patients.

Conclusion: Liver enzyme elevation was observed in approximately a quarter of AS patients after treatment with TNF inhibitors. Male gender, fatty liver disease, and hyperlipidemia were independent risk factors for liver enzyme elevation. Switching to another TNF inhibitor had limited effect on normalization of the liver enzyme levels.

Session Date: Monday, October 22, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Clinical/Epidemiology Studies

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: There are conflicting data between studies of psoriasis and psoriatic arthritis (PsA), and there have been recent concerns about the potential of anti-TNF agents to facilitate malignancy. We aimed to estimate the prevalence and incidence of malignancy and its types in PsA and psoriasis without arthritis (PsC) patients, in comparison to the general population, and to identify the predictive factors for developing cancer in psoriatic disease (PsD).

Methods: Patients with PsA have attended the PsA Clinic and have been followed prospectively since 1978. Patients with PsC have been assessed by a rheumatologist to confirm the absence of PsA and have been followed since 2006. Patients have been evaluated at 6-12 month intervals according to a standard protocol which includes demographics, lifestyle habits, medical history, co-morbidities, and disease-related outcomes. Malignancies are recorded prospectively. In addition, a linkage with Cancer Care Ontario and the Death Registry was carried out to confirm the identification of malignancy and the type of malignancy to the end of December 2016. Non- melanoma skin cancers were not included. Descriptive statistics are provided. Standardized incidence ratios (SIR) were calculated for overall cancers and by sex. Multistate analysis was performed.

Results: 2124 patients (PsA and PsC) were included in the study of whom, 235 developed cancer (11%). 168 patients developed cancer after first clinic visit and are included in this report. Overall malignancy SIR is 0.89 (0.74, 1.07), SIR for females is 1.13 (0.87, 1.45), and for males 0.72 (0.55, 0.94). The most common malignancies were skin, breast, and male reproductive system. No predictor for malignancy was identified for PsD overall nor for PsA or PsC individually.

Conclusion: In this long-term prospective follow up of patients with PsA and PsC the malignancy risk is not increased. No predictors for malignancy could be identified. In particular there was no increased risk associated with biologics use.

Atherosclerotic Cardiovascular Disease in Psoriatic Arthritis: Evaluation of Risk Factor Management and Use of Aspirin and Statin for Prevention in a Primary Care Setting

Linh Truong¹, Nicole Ridolfi¹ and Maida Wong^{2,3}, ¹Internal Medicine, University of California, Irvine, Orange, CA, ²Department of Medicine, University of California, Irvine, orange, CA, ³Division of Rheumatology, Tibor Rubin Veterans Affairs Medical Center Long Beach, Long Beach, CA

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Clinical/Epidemiology Studies

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: There is accumulating evidence that shows an increased prevalence of atherosclerotic cardiovascular disease (ASCVD) risk factors among the psoriatic arthritis (PsA) population. The aim of this study is to assess the ASCVD morbidity in PsA and the management of this group's ASCVD risk according to national guidelines in the primary care setting.

Methods: A retrospective study at a Veterans Affairs Hospital involving PsA patients (n=99) and controls (n=99) without autoimmune diseases was performed. The groups were matched on age, sex, race, BMI and ASCVD risk factors (hypertension, diabetes, and hyperlipidemia). Their ASCVD risk was evaluated using the American College of Cardiology/American Heart Association's (ACC/AHA) ASCVD risk score. The odds ratio (OR) for myocardial infarctions (MI), congestive heart failure (CHF), and cerebral vascular accidents (CVA) were calculated. The yearly ASCVD management outcomes in a primary care setting, averaged over five years, were evaluated according to the frequency of primary care provider (PCP) visits, laboratory checks for Hgb A1c and lipid profile, non-pharmacological ancillary referrals, and use of cardio-protective supplements like niacin and fish oil. The appropriate statin intensity prescribed, and the use of aspirin (ASA) and statin for primary and secondary ASCVD prevention according to the US Preventative Services Task Force (USPSTF) and ACC/AHA guidelines were also evaluated.

Results: PsA and controls have an ASCVD risk score of 23.8% and 17.1% (p=0.003). PsA patients have twice the risk for developing ASCVD events (OR 2.18; 95% CI 1.19 to 3.98). CHF (OR 4.17; 95% CI 1.48 to 11.75) was the most likely event to develop when compared to CVA (OR 2.03; 95% CI 0.82 to 5.03) or MI (OR 1.72; 95% CI 0.89 to 3.29). PsA patients had similar, if not worse, average yearly PCP visits (1.0 vs 1.4), A1c checks (2.3 vs 1.2), and lipid panel checks (1.2 vs 1.2). Fewer PsA patients received non-pharmacological ancillary referrals (6% vs 69%) and cardio-protective supplements (7% vs 11%). In PsA patients, ASA was underutilized for primary (0% vs. 26%; p=0.018) and secondary prevention (52% vs. 60%; p=0.25). Similarly, statin therapy was underutilized (37% vs. 60%; p=0.006) (40% vs. 86%; p=0.009) and the statin intensity prescribed was often inappropriate (28% vs 63%; p=0.0001).

Conclusion: PsA patients have an increased risk for developing ASCVD and yet, receive worse risk factor management by PCPs. The use of ASA and statin is underutilized in PsA, and the statin intensity prescribed to this group is inadequate according to current national guidelines. Additional studies are warranted to elucidate whether shifting the responsibility of managing ASCVD risk from PCPs to rheumatologists, or providing greater education to PCP on this topic could improve ASCVD outcomes in the PsA population.

Bone Mineral Density and Serum Biomarkers of Bone Turnover in Ankylosing Spondylitis Patients Treated with Secukinumab: 2-Year Data from the Pivotal Phase 3 Study

Jürgen Braun¹, Bjoern Buehring¹, Xenofon Baraliakos¹, Lianne S. Gensler², Brian Porter³, Abhijit Shete⁴, Erhard Quebe-Fehling⁵ and Sibylle Haemmerle⁵, ¹Ruhr-University Bochum, Herne, Germany, ²University of California, San Francisco, CA, ³Novartis Pharmaceuticals Corporation, East Hanover, NJ, USA, East Hanover, NJ, ⁴Novartis Pharma AG, Basel, Switzerland, Basel, Switzerland, ⁵Novartis Pharma AG, Basel, Switzerland

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Clinical/Epidemiology Studies

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Low bone mass is common in ankylosing spondylitis (AS) and patients (pts) with AS have an increased risk of bone fracture.¹⁻³ Treatment of AS pts with TNF inhibitors has resulted in bone mineral density (BMD) increases;^{4,5} however, this has not been studied for IL-17A inhibitors yet. This is a *post hoc* analysis of the pivotal MEASURE 1 study⁶ with secukinumab 150 mg (approved dose for AS), in which changes in BMD and bone turnover biomarkers from baseline were assessed over 2 years.

Methods: A total of 104 pts originally randomized to the secukinumab 150 mg group with baseline BMD and at least one post-baseline lumbar spine BMD value at Week 52 or 104 were included in the analysis. BMD was assessed by dual-energy X-ray absorptiometry of the lumbar spine, total hip, and femoral neck at baseline, with the change from baseline in group mean calculated for the 150 mg group at Weeks 52 and 104. Additionally, to account for the variability in baseline BMD, the mean of individual percent changes in BMD at the lumbar spine, total hip, and femoral neck at Weeks 52 and 104 was also calculated. Bone turnover biomarkers (osteocalcin, procollagen type 1 N-terminal propeptide, procollagen-1 carboxy-terminal peptide, bone specific alkaline phosphatase, osteoprotegerin, sclerostin, and type I collagen C-telopeptides) were assessed at baseline, Weeks 52 and 104. Descriptive statistics were used to examine changes over time.

Results: At baseline, 66% were male pts and 34% female, with a mean age of 40.3 ± 12.3 years. Change from baseline in mean values for the 150 mg group at Weeks 52 and 104 for BMD (lumbar spine, total hip, and femoral neck) and bone turnover biomarkers are shown in the **Table**. The mean of individual BMD percent changes at Week 52 were 2.6% for lumbar spine, 0.9% for total hip, and 0.8% for femoral neck. Corresponding changes at Week 104 were 4.7% for lumbar spine, 0.5% for total hip, and 0.2% for femoral neck.

Conclusion: BMD increased over 2 years in AS patients treated with secukinumab 150 mg, with more pronounced increases observed in the lumbar spine. No consistent pattern was observed in the changes in bone turnover biomarkers through 2 years of treatment, although levels of the bone resorption biomarker Type I collagen C-telopeptides remained stable. Depression and Anxiety Reduce Probability of Achieving a State of Minimal Disease Activity in Patients with Psoriatic Arthritis

Antonio Wong Lam¹, Justine Y. Ye², Dafna D Gladman¹ and Vinod Chandran², ¹University of Toronto, Toronto Western Hospital, Toronto, ON, Canada, ²Rheumatology, University of Toronto, Toronto Western Hospital, Toronto, ON, Canada

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Clinical/Epidemiology Studies

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Depression and/or anxiety are comorbidities associated with psoriatic arthritis (PsA) that may affect treatment response. We aimed to determine whether the presence of depression/anxiety is associated with lower probability of achieving minimal disease activity (MDA) in patients with PsA.

Methods: Patients with PsA from a large cohort evaluated at 6-12-month intervals according to a standard protocol were studied. Those with a minimum number of 2 visits between 2008 and 2017 were eligible for this study. Given the lack of a formal psychiatric assessment, patients were classified as having depression/anxiety based on 3 definitions: 1) if they scored ≤ 38 on the Mental Component Summary of the SF-36 questionnaire (Definition 1); 2) if they scored ≤ 56 on the Mental Health subscale (Definition 2); and 3) if the physician reported a diagnosis of depression/anxiety in the PsA clinic protocol (Definition 3). The primary outcome was the achievement of sustained MDA, defined as meeting 5 of the 7 following: tender joint count ≤ 1 , swollen joint count ≤ 1 , tender enthesal points ≤ 1 , Psoriasis Activity and Severity Index ≤ 1 or Body Surface Area $\leq 3\%$, patient pain visual analogue scale (VAS) ≤ 20 , patient global disease activity VAS ≤ 20 ; Health Assessment Questionnaire ≤ 0.5 , for at least two consecutive visits. Univariable and multivariable proportional odds discrete time to event analyses were conducted to identify predictors for sustained MDA.

Results: 743 patients were included in the study (Table 1). The total number of patients identified as having depression/anxiety according to the 3 definitions was: Definition 1- 331 (44.54%), Definition 2- 364 (48.99%), and Definition 3- 211 (28.39%). A total of 337 patients (45.35%) failed to achieve sustained MDA during follow-up. The presence of depression/anxiety was associated with reduced probability of achieving sustained MDA in the multivariable regression analysis (reduced model), (OR 0.29 $p < 0.0001$ [Definition 1], OR 0.33 $p < 0.0001$ [Definition 2] and OR 0.44 [Definition 3] $p < 0.0001$). Male sex and daily alcohol intake was associated with a higher probability of achieving sustained MDA, whereas Charlson Comorbidity index reduced the probability. Similar results were observed when using the definitions 2 and 3 for anxiety/depression.

Conclusion: The presence of anxiety/depression reduces the probability of achieving sustained MDA in PsA. Comprehensive management of PsA thus should include measures for addressing these comorbidities.

Rodrigues^{1,5}, Nélia Gouveia^{1,5}, Mónica Eusébio⁵, Helena Canhão^{5,6} and Jaime Cunha Branco^{1,5}, ¹CEDOC, NOVA Medical School, Lisbon, Portugal, ²Rheumatology, Leiden University Medical Center, Leiden, Netherlands, ³Hospital Ortopédico de Sant 'Ana, Cascais, Portugal, ⁴University College London - MRC Centre for Neuromuscular Diseases, London, United Kingdom, ⁵EpiReumaPt Study Group, Lisbon, Portugal, ⁶EPIDOC, Nova Medical School, Faculdade Ciências Médicas, Lisboa, Portugal

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Clinical/Epidemiology Studies

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Several strategies have been proposed to promote early referral of patients with SpA, but consensus on the 'best' strategy is yet to be achieved. Moreover, few studies compared referral strategies (RS) head-to-head and none has neither evaluated these in a 'nationwide' setting (external validity) nor assessed the entire spectrum of SpA (i.e. ax SpA and peripheral SpA). We aimed to evaluate the performance of the screening strategy for SpA of a nationwide epidemiological study(EpiReumaPt), as compared to previously proposed RS.

Methods: EpiReumaPt was a three-stage national health survey (2011-2013) where, in the first phase, 10,661 adult participants were randomly selected and interviewed using a structured face-to-face questionnaire that included screening for rheumatic diseases (RD),such as SpA. In the second phase, positive screenings for ≥1 rheumatic complaint plus 20% negative screenings were invited for an assessment by the rheumatologist. Finally, 3 rheumatologists revised all the information and defined the final diagnosis by consensus. All participants of the second phase were included (N=3,877). Each RS (table) was tested against the SpA revised diagnosis using the following metrics: sensitivity, specificity, positive predictive value (PPV), and post-test probability of disease given a negative test (1-negative predictive value). RS with an imaging(e.g. MRI) or laboratory component (e.g. CRP, HLA-B27) were modified (by excluding these components) given limited data obtained in the survey (table). A weighting factor was used to take the survey design into account.

Table. Performance of the referral strategies against the rheumatologist clinical diagnosis (N=3,877; pre-test probability: 1.6% = weighted national SpA prevalence)

	Sensitivity (%)	Specificity (%)	PPV (%)	1-NPV (%)
ASAS	85.4	38.8	2.2	0.6
EpiReumaPt	72.1	67.6	3.5	0.7
CafaSpA one	56.3	69.7	2.9	1.0
Brandt I	49.2	79.3	3.7	1.0
Braun I/II	47.5	78.7	3.5	1.1
MASTER	36.7	87.7	4.6	1.2
Brandt II	27.7	92.4	5.6	1.3
Herrmann	22.4	93.2	5.1	1.3
CafaSpA two	15.2	95.2	4.9	1.4
Braun 2 step	15.1	95.7	5.3	1.4
Brandt III	7.9	98.4	7.6	1.5

ASAS (21/54): IIP (ASAS definition), good response to NSAIDs, family history of SpA, peripheral manifestations (arthritis, enthesitis and/or dactylitis), extra-articular manifestations (uveitis, psoriasis and/or IBD); EpiReumaPt (21/54): previous SpA/PSA diagnosis, IIP ($\geq 3/8$ features), CRP (≥ 3 months) starting <45 years and $\geq 1/6$ SpA features, dactylitis, enthesitis; CafaSpA one (21/34): IIP (ASAS definition), good response to NSAIDs, family history of SpA; CafaSpA two (22/34): see CafaSpA one; Brandt I ($\geq 1/3$): IIP (morning stiffness ≥ 30 min, pain at night/early morning, improvement by exercise; 21/31); Brandt II ($\geq 1/1$): 22/3 IIP features (see Brandt I); Brandt III ($\geq 1/1$): 21/3 IIP features (see Brandt I); Braun I/II ($\geq 2/5$): start IIP ≥ 35 years, waking second half of the night, alternating buttock pain, improvement by movement, not rest; MASTER ($\geq 2/3$): IIP (morning stiffness ≥ 30 min, improvement exercise, not rest, swimming in the night because of IIP), good response to NSAIDs, family history of AS; Herrmann (21/31): IIP (Gellin's criteria); Braun 2 step ($\geq 2/3$): psoriasis, alternating buttock pain, improvement BP by exercise; HEA-827 excluded from ASAS, Brandt I-III and Braun 2 step; elevated CRP/ESR excluded from ASAS.

Results: From the total 3,877 participants, 92 received a SpA diagnosis [weighted prevalence:1.6% (95%CI: 1.2; 2.1)], 3,107 other RD diagnosis [e.g. knee osteoarthritis(31%)] and 678 no RD diagnosis. The ASAS RS was the most sensitive (85%) followed by the EpiReumaPt strategy (72%) (Table). The ASAS and EpiReumaPt RS had the lowest post-test probabilities of SpA in the presence of negative screening(0.6% and 0.7% respectively), thus, yielding a marked decrease in the probability of disease if negative [(1.6-0.6)/1.6*100=63%; (1.6-0.7)/1.6*100=56% respectively). On the other hand, the likelihood of SpA increased by 38% (2.2-1.6)/1.6*100) and 119% (3.5-1.6)/1.6*100) in case of a positive ASAS and EpiReumaPt RS, respectively. Brandt III was the least sensitive strategy in this study and not contributive to excluding SpA (1-NPV: 1.5%; pre-test probability: 1.6%), but expectedly increased the likelihood of SpA by 3.8 times if positive. The performance of the remaining RS is described in the table.

Conclusion: For the first time, a wide range of SpA RS were tested in a population-based setting where the ASAS and EpiReumaPt RS were shown to be the most sensitive. Our data suggest that these strategies can be effectively used as screening tools for SpA especially when laboratory and imaging data are not available.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Clinical/Epidemiology Studies

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The Assessment of SpA international Society Health Index (ASAS HI) was developed to assess function, disability, and health in patients (pts) with SpA. This is the first time that the ASAS HI has been included in a Phase 3 clinical study. Psychometric properties of the ASASHI in pts with active radiographic axial SpA (r-ax SpA) in a Phase 3 study of ixekizumab, an IL-17A monoclonal antibody (COAST-V [NCT02696785]) are presented.

Methods: The ASAS HI questionnaire consists of 17 items, total score ranging from 0 (good health) to 17 (poor health). The psychometric properties of the questionnaire, including test-retest reliability, convergent and discriminant validity, as well as responsiveness, were evaluated using pooled data from 4 treatment groups (placebo, adalimumab 40 mg every 2 weeks, and ixekizumab 80 mg every 2 or 4 weeks). COAST-V enrolled biologic DMARD-naïve adults with active r-ax SpA per ASAS criteria (sacroiliitis defined centrally by modified New York Criteria and ≥ 1 SpA feature), BASDAI ≥ 4 , back pain ≥ 4 , and inadequate response or intolerance to NSAID therapy.

Figure. Construct validity.

Magnitude of correlation is presented regardless of direction. Thresholds for moderate (>0.3) and high (>0.5) correlations are based on Cohen (1988).^{*} Abbreviations: MCS = mental component score; PatGA = patient's global assessment of disease activity; PCS = physical component score; SF-36 = 36-item short-form health survey ^{*} Cohen, J. (1988). Statistical power analysis for the behavioral sciences (2nd ed.). New Jersey: Lawrence Erlbaum.

Results: A total of 341 pts were randomized at Week 0. Mean (SD) ASAS HI score at baseline in the pooled group was 8.05 (3.6). Test-retest reliability of ASAS HI between screening and baseline was evidenced by intraclass correlation (0.76). Construct validity analyses demonstrated that the ASAS HI score is moderately correlated with Spinal Pain, Short-Form 36 physical and mental component scores, EQ-5D 5-Level UK Population-based Index, Patient's Global Assessment, BASDAI, and BASFI at baseline ($|r| > 0.30$, Figure [circles]) and strongly correlated at Week 16 ($|r| > 0.50$; Figure [crosses]). Known-group validity of ASAS HI was demonstrated by significant difference among ASDAS categories at baseline and Week 16 ($p < .001$ for all comparisons). Greater improvements in disease activity were associated with greater improvements in ASAS HI scores at Week 16 (Table). Changes in ASAS HI from baseline at Week 16 were highly correlated with ASDAS, BASDAI, and BASFI changes (all correlations $> .50$).

Conclusion: The ASAS HI demonstrated reliability, construct validity, and responsiveness in adults with r-ax SpA, supporting measurement properties of this instrument in an external study. Based on its content validity, the data suggest that the ASAS HI provides additional information beyond core disease activity and response criteria traditionally used in randomized clinical studies. This includes a balanced characterization of treatment effects from the patient perspective.

Table. Association between ASAS HI Change from Baseline and Disease Activity at Week 16 (Pooled Treatment Groups)

	ASAS20 Nonresponder	Patient Achieving ASAS20, But Not ASAS40	ASAS40 Responder
N	143	67	130
ASAS HI (LSM [SE])	-0.7 (0.2)	-1.6 (0.3)*	-4.2 (0.2)***,§
N	171	101	68
ASAS HI (LSM [SE])	-0.9 (0.2)	-2.5 (0.2)***	-4.9 (0.3)***,§
N	226	114	
ASAS HI (LSM [SE])	-1.2 (0.2)	-4.3 (0.2)***	

ASAS HI = Assessment of SpA International Society Health Index; ASDAS = AS Disease Activity Score; CII = clinically important improvement; LSM = least-squares mean; MI = major improvement.

* $p < .05$; ** $p < .001$ versus lowest response group.

§ $p < .001$ versus middle response group.

Note: An analysis of covariance model with change in ASAS HI score as dependent variable and clinical outcome (ASAS, ASDAS, or BASDAI50) response and baseline ASAS HI as independent variables was applied. Post hoc comparison was conducted with Scheffe's correction.

*P-value from two sample t-test: Rheumatologist vs Dermatologist.

^aAll data are presented as mean (SD) unless otherwise specified.

^bn=40; ^cn=8; ^dn=67; ^en=13; ^fn=361; ^gn=144; ^hn=321; ⁱn=314; ^jn=145; ^kn=365; ^ln=138; ^mn=341; ⁿn=65; ^on=361.

BSA = body surface area with psoriasis; DAS28 (CRP) = 28-joint disease activity score based on C-reactive protein; DAS28 (ESR) = DAS28 based on erythrocyte sedimentation rate; Derm = dermatologist; DLQI = Dermatology life quality index; HAQ-DI = health assessment questionnaire – disability index; LEI = Leeds enthesitis index; MCS = mental component score; PASI = psoriasis area and severity index; PCS = physical component score; PGA = physician global assessment; PsA = psoriatic arthritis; PtGA = patient's global assessment of disease; Rheum = rheumatologist; SF12v2 = Short form 12-item health survey version 2.0; SD = standard deviation; SJC66 = swollen joint count, 66 joints; TJC68 = tender joint count, 68 joints.

Background/Purpose: Inpatients (pts) with psoriatic arthritis (PsA), early diagnosis and effective treatment has been shown to decrease functional disability and structural progression (Gladman DD, et al., *Ann Rheum Dis*, 2011; 70:2152-4). However, factors influencing treatment management decisions are poorly understood. The objective of this LOOP study was to evaluate the impact of clinical specialty setting and geographic regions on the management of pts with PsA in the United States (US).

Table 2. Current Disease Activity and Disease Burden by Geographical Regions in US Patients with PsA from LOOP Study

Measure ^a	East (n=348)	Central (n=94)	West (n=71)	P-value [*]

^qn=298; ^rn=57; ^sn=51; ^tn=347; ^un=90.

ANOVA = analysis of variance; BSA = body surface area with psoriasis; DAS28 (CRP) = 28-joint disease activity score based on C-reactive protein; DAS28 (ESR) = DAS28 based on erythrocyte sedimentation rate; Derm = dermatologist; DLQI = Dermatology life quality index; HAQ-DI = health assessment questionnaire – disability index; LEI = Leeds enthesitis index; MCS = mental component score; PASI = psoriasis area and severity index; PCS = physical component score; PGA = physician global assessment; PsA = psoriatic arthritis; PtGA = patient's global assessment of disease; Rheum = rheumatologist; SF12v2 = Short form 12-item health survey version 2.0; SD = standard deviation; SJC66 = swollen joint count, 66 joints; TJC68 = tender joint count, 68 joints.

Methods: LOOP was a multi-center, cross-sectional, observational study conducted across 44 sites in the US. Adult pts with a suspected or an established diagnosis of PsA who were routinely visiting a rheumatologist (rheum) or a dermatologist (derm) were eligible to participate in this study. Each enrolled pt was assessed by both rheum and derm. The association between enrolling or diagnosing clinical specialty setting or geographic regions (East, Central, and West) and time from symptom onset to PsA diagnosis and to different disease management steps were examined.

Results: Of 681 pts enrolled, 513 pts with a confirmed diagnosis of PsA were included in this analysis. Pt demographics and disease characteristics were comparable between PsA pts enrolled by rheum and derm settings. Current disease activity and disease burden were also mostly similar between rheum and derm settings (Table 1), although pts enrolled in derm setting had higher scores on skin measures and enthesitis. Interestingly, skin-related disease activity measures were similar among pts in East, Central, and West regions of the US, but there were significant differences in most other disease activity measures (Table 2). The median (95% CI) time from symptom onset to PsA diagnosis was 1.0 (0.5, 1.1) and 2.6

(1.7, 4.1) years (y) in pts enrolled in rheum and dermatology settings, respectively ($P < .001$). After PsA diagnosis, the median times to first csDMARD and to first bDMARD were 1.0 and 2.4 y, respectively. The median time from symptom onset to PsA diagnosis and from PsA diagnosis to first csDMARD and bDMARD did not differ significantly based on geographic regions.

Conclusion: The duration from symptom onset to PsA diagnosis was shorter in pts enrolled by rheumatologists compared with dermatologists. The median time was longer for treatment with first bDMARD compared with first csDMARD. There were differences in current disease activity and burden among pts based on enrolling specialty and geographic regions. Current disease activity and disease burden highlight the delay in PsA diagnosis and the need for appropriate management of PsA pts, irrespective of clinical specialty setting or geographic region.

McLean², Peter Hur⁴ and Alexis Ogdie⁵, ¹Swedish Medical Center and University of Washington, Seattle, WA, ²Corrona, LLC, Waltham, MA, ³Corrona, LLC, Southborough, MA, ⁴Novartis Pharmaceuticals Corporation, East Hanover, New Jersey, USA, East Hanover, NJ, ⁵Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Clinical/Epidemiology Studies

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Prior studies showed psoriatic arthritis (PsA) patients with enthesitis had greater disease burden than patients without enthesitis, yet it is unknown whether the impact of enthesitis differs by its location. This study compared patients with PsA who had enthesitis in different locations vs patients without enthesitis.

Methods: This study included adult patients with PsA enrolled in the Corrona PsA/SpA Registry between March 2013 and March 2018. Enthesitis at enrollment was assessed via the Spondyloarthritis Research Consortium of Canada (SPARCC) Enthesitis Index. Those with enthesitis were further classified by affected site locations as upper extremities only, lower extremities only, or both upper and lower. Enrollment demographics, clinical characteristics, treatment profile, disease activity, quality of life, and work productivity in each of the 3 enthesitis groups were compared to PsA patients without enthesitis using t tests or χ^2 tests.

Results: Of 2003 patients with PsA, 391 (19.5%) had enthesitis, among whom 80 (20.5%) had upper sites only, 137 (35.0%) had lower sites only, and 174 (44.5%) had both upper and lower sites. In patients with enthesitis, 61.5% were treated with biologics and 21.7% with csDMARD monotherapy, and there was a higher prevalence of fibromyalgia vs those without enthesitis (10.7% vs 3.4%; $P < 0.05$). Patients with lower sites only had increased prevalence of depression, and patients with upper sites only and both upper and lower sites had increased nail psoriasis compared to patients without enthesitis (**Table 1**). Regardless of enthesitis site location, patients with enthesitis had worse disease activity (modified MDA, tender and swollen joint counts, CDAI scores, DAPSA and cDAPSA scores, modified DAS28 scores, and physician global assessment) and quality of life (pain, fatigue, patient global assessment, HAQ scores, EQ VAS scores, and percentage impairment while working and overall activity impairment) than patients without enthesitis (**Table 2**). Patients with both upper and lower site involvement tended to have worse disease activity and quality of life than those with either location alone, and patients with lower sites only tended to have worse patient-reported outcomes vs patients with upper sites only (**Table 2**).

Conclusion: These results confirm the previously observed relation between presence of enthesitis and higher disease activity and worse quality of life; however, this study suggests that some aspects of disease burden may differ according to site location. Further analyses are needed to determine whether lower, upper, or specific sites have greater impact on disease burden.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Clinical/Epidemiology Studies

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Growing evidence suggests gender-specific differences in the phenotypes of ankylosing spondylitis (AS). However, a literature search failed to reveal evidence of such differences in Chinese AS patients. We aimed to assess the gender-specific associations with disease patterns of Chinese AS patients.

Methods: This study included 223/60 male/female AS patients, and 98.6% were of Han descent. All AS patients fulfilled the modified New York criteria. Structural damage of sacroiliac (SI) joints, hip joints and spine were evaluated by computed tomography (CT) scans, lumbar and cervical X-ray, respectively. Structural damage of AS was assessed by

mSASS, BASRI-SI, BASRI-spine and BASRI-hip (modified) by a trained rheumatologist and musculoskeletal radiologist with high test inter-rater reliability (average κ :87.3%). The association of gender with BASRI-spine category, expressed as odds ratio (OR) and 95% confidence interval (95% CI), was calculated using ordinal logistic regression.

Table 1. Baseline characteristics of study participants

Characteristic	Female AS Patients (n=68)	Male AS Patients (n=221)	p Value
Age (years)	57.99 (10.54)	52.79 (10.66)	0.000

Abbreviations: AS, ankylosing spondylitis; HLA-B27, human leukocyte antigen B27; ESR, erythrocyte sedimentation rate; CRP, C-reactive protein; ASDAS-CRP, ankylosing spondylitis disease activity score; BASFI, bath ankylosing spondylitis functional index; BASDAI, bath ankylosing spondylitis disease activity index; VAS, visual analog scale; BASRI, Bath Ankylosing Spondylitis Radiology Index; BASRI-hip (modified) (0: normal, 1: suspicious/mild/moderate, 2: severe, 3: complete joint fusion, 4: joint replacement); BASMI, Bath Ankylosing Spondylitis Mennings Index; mSASS, modified sickle ankylosing spondylitis spine score; IBD, inflammatory bowel disease; CA, celiac disease; Occupation was categorized as without occupation (described as 0), manual occupation (described as 1) and physical occupation (described as 2). Data are expressed as either mean (standard deviation) or median (interquartile range) or count (per cent). The p value was calculated by t test or Wilcoxon rank-sum (Mann-Whitney) test or Chi-squared test, where appropriate.

Table 2. Associations of male gender with Bath Ankylosing Spondylitis Radiographic Index Spine score category, with adjustments for age or duration of ankylosing spondylitis and multivariate modeling*

Independent variable	Age-adjusted OR (95% CI)	p Value	Duration adjusted OR (95% CI)	p Value
Male	2.04 (1.15 to 3.62)	0.016	1.21 (0.70 to 2.10)	0.500
Multivariable analysis*				
Male	1.91 (0.99 to 3.69)	0.054	1.46 (0.77 to 2.75)	0.247

Abbreviations: OR, odds ratio; 95% CI, 95% confidence interval. *Additional adjustment for HLA-B27, age of AS onset, family history, occupation, smoking (ever and current), smoking duration, cigarettes per day, ESR, CRP and BASDAI. OR represents the likelihood that men were more likely than women to be in a higher BASRI-spine category than in the same or in a lower category.

Results: Female AS patients were older than males ($p=0.0003$), and they also had older age of AS onset ($p<0.0001$), a lower frequency of HLA-B27 ($p=0.018$), a higher family history of reported AS in first-degree relatives ($p=0.0025$) than male patients. Both genders had similar disease duration. Mean levels of CRP ($p<0.0001$) and ASDAS-CRP ($p=0.0284$) were significantly higher in male patients than in female patients (Table 1). As previously reported, male AS patients from

non-Chinese cohorts had more radiographic damage, more hip impact, worse function and higher diagnostic delays than female patients [PMID:20357993, 17127685, 26385369]. However, in Chinese AS patients, no gender-associated diagnostic delays or functional impairment were observed. Structural damage severity was worse among male AS patients only at the SI joint, but not at lumbar or cervical spine and hip. After adjusting for age or disease duration and other risk factors (Table 2), no gender-specific association with categorized BASRI-spine was noted (OR=1.91 or 1.46, 95% CI: 0.99 to 3.69 or 0.77 to 2.75, $p=0.054$ or 0.247).

Conclusion: In a Chinese cohort, female AS patients were observed to have later age of disease onset, but similar severe spine and hip joint structure damage and limited function as male patients. Compared with other racial groups, Chinese female AS patients may have more severe disease and worse outcome.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Clinical/Epidemiology Studies

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: From previous cross-sectional research we know that minimal disease activity (MDA) is associated with better health-related quality of life (HRQoL) in psoriatic arthritis (PsA). Whether being in MDA early is related to better outcomes is unknown. We aimed to evaluate the impact of time to MDA on HRQoL at one year follow up in patients newly diagnosed with PsA.

Methods: Data collected in the Dutch southwest early PsA cohort (DEPAR) study was used. PsA patients with a new diagnosis of PsA and not yet treated for PsA with disease-modifying antirheumatic drugs are eligible to participate. MDA status was determined every three months in the first year by trained research nurses. Short Form 36 (SF36) Physical Component Scores (SF36-PCS) and Mental Component Scores (SF36-MCS) were used to assess HRQoL.

Results: In July 2017, 296 patients had had their 1-year visit (mean age 51 years, 53% male). Of those, 96 (32%) were in MDA within three months (early MDA), 78 (26%) between 3 and 12 months (late MDA), 98 (33%) were not in MDA at any time during the first year (no MDA) and 24 (8%) patients could not be assigned to either group due to missing data. 43 early MDA patients (46%) had sustained MDA and 46 (60%) of the late MDA patients. Late MDA patients and no MDA patients had significantly higher baseline tender joint counts, enthesitis scores, and VA S scores than early MDA patients. Methotrexate was also prescribed more frequently in no MDA (81%) and late MDA (79%) groups than early MDA (62%). At baseline SF36-PCS scores were significantly lower in the late and no MDA groups, but after one year only the scores of the no MDA group were significantly lower (Figure 1).

Conclusion: HRQoL of early MDA patients and late MDA patients did not differ significantly at twelve months, but patients not in MDA in their first year after diagnosis had significantly worse HRQoL than patients that are in MDA. A quarter of patients was in MDA within three months and in total 58% within the first year.

Research support for this analysis was funded by Pfizer. The company had no role in the study design, collection of data, analysis or interpretation of data, nor in the preparation or approval of the abstract and the decision to submit the abstract

Figure 1. SF36-PCS scores in MDA groups over first year follow up

SF36-PCS: Short-Form 36 Physical Component Summary; MDA: Minimal Disease activity; Early MDA: MDA within three months; Late MDA: MDA within three to twelve months; No MDA: no MDA in first year. Data shown as mean with 95% Confidence Intervals.

Prevalence of Anterior Uveitis in Patients with Spondyloarthropathy in a Single US Academic Center: A Retrospective Study from Routine Care

Ofelya Gevorgyan¹, Rebecca D. Saran², Pauline T. Merrill², Joel A. Block³ and Isabel Castrejon¹, ¹Rheumatology, Rush University Medical Center, Chicago, IL, ²Ophthalmology, Rush University Medical Center, Chicago, IL, ³Division of Rheumatology, Rush University Medical Center, Chicago, IL

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Clinical/Epidemiology Studies

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Acute anterior uveitis (AAU) is the most common extra-articular feature of spondyloarthropathies (SpA) over the course of the disease. Around 33% of patients with SpA present with AAU¹. To better characterize patients with SpA and AAU we aimed to determine the prevalence of AAU in patients with SpA seen in our clinic, and to compare demographic, clinical characteristics and treatment in patients with and without uveitis.

Methods: We conducted a retrospective study of all patients with SpA with and without uveitis seen at our rheumatology clinic between January 2016 and June 2017. Patients were identified from our rheumatology repository using ICD-10 codes (M45, M46.1, M46.8, M46.9, H20.00-02, H20.04, H20.1, H20.9, H22) and administrative claim codes for the same period of time. Charts were reviewed to confirm the diagnoses. Extracted data included patient demographics, laboratory investigations, HLA-B27 typing, current and previous treatments with nonsteroidal anti-inflammatory drugs (NSAIDs), non-biologic and biologic disease-modifying antirheumatic drugs (DMARDs). To assess disease activity, we calculated RAPID3 scores based on a Multidimensional Health Assessment Questionnaire (MDHAQ) routinely completed by our patients. RAPID3 has been previously shown to be useful in this population². Comparison between patients with and without uveitis was performed using Student's t-test for differences between means and chi² for proportions.

Results: A total of 190 patients with SpA were identified: 48% with ankylosing spondylitis (AS), 26% with psoriatic arthritis (PsA), 22% with undifferentiated SpA and 4% with SpA associated with inflammatory bowel disease (IBD). Prevalence of uveitis differed by etiology: 17% in SpA in this series, 25% in AS, 4% in PsA-associated SpA, 9.5% in undifferentiated SpA, and 57% in IBD-associated SpA (p=0.001, Table). Overall, 39.5% of patients were HLA-B27 positive, the antigen was more frequently detected in patients with uveitis than without uveitis, 69.7% and 33.1%, respectively (p<0.001), and interestingly, those with AAU had less pain (p=0.03). Delay to SpA diagnosis tended to be longer in patients with uveitis, 12.3 (11.2) versus 7.9 (9.5) years but did not reach statistical significance. There were no significant differences in age, gender, clinical, laboratory characteristics and treatment between the two groups (Table).

Conclusion: In our SpA population the prevalence of uveitis was lower than expected, and there were significant differences by underlying disease. There was a delay to diagnosis of SpA of about 8 years, which tended to be longer in patients with uveitis. New screening strategies in collaboration with ophthalmology may lead to earlier diagnosis, treatment and better patient outcomes.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Clinical/Epidemiology Studies

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Psoriatic arthritis (PsA) core domain set to be measured in randomized controlled trials (RCT) and longitudinal observational studies (LOS) was developed by Group for Research and Assessment of Psoriasis and PsA (GRAPPA) and endorsed by Outcome Measures in Rheumatology (OMERACT) in 2016. Joint counts are central to the measurement of musculoskeletal (MSK) disease activity, one of the key domains. Having reviewed the 28 as well as 76/78 joint counts, the 66/68-swollen and tender joint count (SJC66/TJC68) was identified as the target instrument for peripheral joint assessment. We assessed the domain match, feasibility, construct validity, reliability, responsiveness, discrimination and thresholds of meaning of SJC66/TJC68 in PsA to secure endorsement of this instrument for inclusion in the PsA Core Outcome Measurement Set at OMERACT.

Table. Summary of measurement properties of the SJC66/TJC68

Overall Rating for Instrument across properties	Green: Working Group is Recommending Endorsement							

*The color indicates the good methods checklist/recommendation; the +/- sign indicates the adequacy of the data in support of the instrument.

*For test-retest reliability, we have provided primary [unpublished] data for test-retest reliability in PsA (1 study) but also additional evidence to support the intra-rater reliability of the joint count in RA (2 studies).

Methods: A multi-prong protocol was designed to assess the properties of the joint counts. A provider and methodologist focus group at GRAPPA, an international web-based working group survey, and patient research partner survey and web-based focus groups were conducted to assess domain match and feasibility. To address reliability, construct validity, responsiveness and discrimination, we conducted a systematic literature review and analyzed data from one LOS and 8PsA RCTs using a standardized protocol. These results were summarized in a “Summary of Measurement Properties Table,” (developed by OMERACT), and presented and discussed at OMERACT2018. OMERACT participants voted on endorsement of the SJC66/TJC68 as an instrument for the PsA Core Outcome Measurement Set.

Results: Participants in the preconference work and within our working group agreed that the SJC66/TJC68 joint count matched the domain “MSK disease activity: peripheral arthritis” and is feasible for use in RCT and LOS. Construct validity was demonstrated in four published studies and within our primary data analyses. Test-retest reliability was only examined in one cohort of 14 patients with PsA but was found to be excellent (0.8-0.9). Inter-rater reliability has been previously shown to be low for the SJC66 (intraclass correlation [ICC], 0.24) but good for the TJC68 (ICC, 0.78). The SJC66/TJC68 was responsive and able to discriminate between patients receiving placebo and active treatment. Finally, the minimally important difference was found to be 2.5 joints for both SJC66 and TJC68 in a new analysis of an LOS. Overall, 17 (100%) of patient research partners and 96/113 (85%) of other stakeholders (eg, clinicians, methodologists) voted for full endorsement of the SJC66/TJC68.

Conclusion: SJC66/TJC68 is a feasible, valid and reliable instrument for the measurement of peripheral joint activity in RCT/LOS and is recommended over the 76/78 and 28 joint counts. The SJC66/TJC68 is the first fully endorsed instrument within the PsA Core Outcome Measurement Set.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Clinical/Epidemiology Studies

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Therapeutic targets for psoriatic arthritis (PsA) include the achievement of remission (REM) or low disease activity (LDA), measured by the Clinical Disease Activity Index for Psoriatic Arthritis (cDAPSA), a composite of swollen and tender joints counts (SJC and TJC), Patient's Assessment of Pain (PAP), and Patient's Global Assessment of Disease Activity (PtGA). We examined the trajectories for improvement in cDAPSA and PsA manifestations not measured by cDAPSA among subjects achieving cDAPSA LDA or REM at Week 52.

Methods: Pooled analyses of 3 phase III studies (PALACE 1-3) were performed for subjects assigned to receive apremilast 30 mg BID (APR) at baseline (BL). Subjects with cDAPSA components available to calculate responses at Week 52 were included and grouped according to the cDAPSA categories reached at Week 52 (REM: ≤ 4 ; low: >4 to ≤ 13 ; moderate: >13 to ≤ 27 ; high: >27 disease activity). We then traced their mean cDAPSA trajectory from BL to Week 52. Mean disease activity in core PsA domains were also reported longitudinally by cDAPSA category reported at Week 52, including SJC (0-76), TJC (0-78), PAP (visual analog scale [VAS] 0-100 mm), PtGA (VAS 0-100mm), Physician's Global Assessment of Disease Activity (PhGA; VAS 0-100 mm), Psoriasis Area and Severity Index (PASI; 0-72), enthesitis (Maastricht Ankylosing Spondylitis Enthesitis Score [MASES]; 0-13), dactylitis count (0-20), and HAQ-DI (0-3).

Results: A total of 375 APR subjects were included in the analyses. Achievement of LDA or REM at Week 52 was associated with lower mean cDAPSA at BL, and these subjects had continuous improvements in disease activity from BL to Week 52 (Figure). Among subjects who achieved LDA at Week 52, most were classified as having moderate (mean cDAPSA: 16.6) or low (mean cDAPSA: 8.5) disease activity at Week 16. At Week 24, these subjects had mean cDAPSA scores of 13.1 (moderate disease activity) and 6.2 (LDA). Furthermore, subjects who achieved REM at Week 52 had already shown early improvement to either no or mild articular and extra-articular disease activity by Week 16. Patients in REM and LDA showed parallel improvements in extra-articular disease activity at Week 52 with APR (Table).

Conclusion: In the subgroup who achieved cDAPSA REM or LDA, early improvement was seen in disease activity by Week 16 and sustained to Week 52 with continued treatment. Patients achieving control of peripheral arthritis (classified as REM or LDA by Week 52) with APR also exhibited REM or LDA in other manifestations of PsA, including enthesitis, dactylitis, function, and skin psoriasis.

Articular and Extra-Articular Disease Activity in Subjects With LDA or REM at Week 52								
Mean	Subjects With REM at Week 52 n=25				Subjects With LDA at Week 52 n=106

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Clinical/Epidemiology Studies

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with psoriatic disease (PsD) are at a high risk of developing cardiovascular events (CVE). The performance of clinical algorithms for cardiovascular risk stratification, such as the Framingham Risk Score (FRS), is sub-optimal in this patient population. The study aims were: 1) to assess whether subclinical atherosclerosis, as evaluated by carotid ultrasound, could predict future CVE in patients with PsD and 2) to determine whether incorporation of imaging data could improve the prediction of CVE beyond clinical cardiovascular algorithms.

Methods: Patients with PsD from a large longitudinal cohort underwent ultrasound assessment of the carotid artery at baseline. The extent of atherosclerosis was assessed using mean carotid intima media thickness (cIMT in μm) and total plaque area (TPA in cm^2). Patients were followed according to a standardized protocol at 6-12 month intervals. Incident CVE that occurred following the ultrasound assessment were identified from the cohort database and through linkage with national hospitalization and death registries. A cardiologist reviewed the medical records related to each CVE and classified them to major CVE (myocardial infarction, stroke, revascularization or cardiovascular death) and minor CVE (angina, TIA, CHF exacerbation). The association between measures of carotid atherosclerosis and the risk of developing future CVE was evaluated using Cox proportional hazard models after adjusting for FRS categories.

Results: Overall, 607 patients with PsD (66.7% with PsA) were assessed and 37 patients developed incident CVE confirmed by the cardiologist (28 major CVE). Their mean age was 57.1 (SD 11.7) and 57.7% were males. 26% and 34.8% had unilateral and bilateral carotid plaques, respectively. The incidence rate of CVE was higher in patients with bilateral carotid plaques compared with unilateral/no plaques (3.96 vs. 0.54 events per 100 person years; $p < 0.001$, Figure 1). In multivariable regression models, TPA (Hazard Ratio (HR) 2.20, 95% Confidence Interval (CI) 1.51, 3.22; $p < 0.001$), mean cIMT (HR 1.21, 95% CI 1.08, 1.34; $p < 0.001$) and bilateral carotid plaques (HR 2.89, 95% CI 1.07, 7.77, $p = 0.03$) predicted incident CVE after controlling for FRS. The results were similar after restricting the analysis to patients with major CVE and after excluding patients with a history of CVE at baseline.

Conclusion: Patients with PsD with subclinical carotid atherosclerosis are more likely to develop future CVE. Carotid ultrasound could potentially improve the identification of patients with PsD who are at high cardiovascular risk.

The Incidence Rate of Spondyloarthritis in Slovenia

Natasa Potocnik Pucelj¹, Alojzija Hočevar¹, Rok Jese¹, Ziga Rotar² and Matija Tomšič³, ¹Department of Rheumatology, University Medical Centre Ljubljana, Ljubljana, Slovenia, ²BioRx.si, Ljubljana, Slovenia, Ljubljana, Slovenia, ³Faculty of Medicine, University of Ljubljana, Ljubljana, Slovenia

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Clinical/Epidemiology Studies

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Spondyloarthritis (SpA) are heterogeneous group of inflammatory diseases, affecting both, axial and peripheral skeleton. Incidence studies in SpA are sparse. There is no data for peripheral SpA as an entity. In axial SpA, recent incidence study reported a decrease of the incidence over decades (1). As data for our country are lacking, we aimed to determine the incidence of SpA in a well defined country region.

Methods: The study was conducted at rheumatology department of an integrated secondary/tertiary teaching hospital, which provides services to region of around 704,000 adult residents. A retrospective chart review of adult patients diagnosed with SpA for the first time between January 2014 and December 2016 was performed. Potential cases were ascertained by searching the electronic medical records for ICD-10 codes M02*, M07*, M13*, M45*, K50*, K51* and L40*. SpA cases were further stratified into axial and peripheral subgroup. The annual incidence rate of SpA was calculated.

Results: During the three year period we identified 294 new SpA cases (55.1% males, median (IQR) age 46.7 (35.0-57.7) years). We diagnosed ankylosing spondylitis, psoriatic arthritis, reactive arthritis, enteropathic arthritis and undifferentiated SpA in 22.4%, 39.8%, 7.1%, 3.7%, and 26.9% cases, respectively. We classified 98 patients (33.3%) with axial SpA and the rests with peripheral SpA. Characteristics of SpA cohort and both subgroups are presented in Table 1. The estimated annual incidence rate of SpA in our region was 13.9 cases per 100,000 adults per year (95% CI 12.4-15.6), in axial SpA 4.6 per 100,000 adults (95% CI 3.8-5.6), and in peripheral SpA 9.3 per 100,000 adults (95% CI 8.0-10.6). Gender specific incidence rates are presented in Table 1.

Table 1: Characteristics of Spodyloarthritis

Characteristics	All SpA	Peripheral SpA	Axial SpA
No. (%) of cases	294 (100%)	196 (66.7%)	98 (33.3%)
Male gender (%)	162 (55.1%)	95 (48.5%)	67 (67.4%)
Age (years) [#]	46.7 (35.0-57.7)	49.9 (36.4-58.6)	39.9 (33.7-55.8)
Symptom duration (months) [#]	7.1 (1.9-24.7)	3.5 (1.0-12.1)	31.7 (10.8-73.2)
HLA B27 positivity (%)	158/261 (60.5%)	81/166 (48.8%)	77/95 (81.1%)
Incidence rate ^{&}	13.9 (12.4-15.6)	9.3 (8.0-10.6)	4.6 (3.8-5.6)
Incidence in females ^{&}	12.2 (10.2-14.4)	9.3 (7.6-11.3)	2.9 (2.0-4.0)
Incidence in males ^{&}	15.8 (13.5-18.3)	9.2 (7.5-11.3)	6.5 (5.1-8.2)

Legend: SpA spondyloarthritis; # median (IQR); & incidence per 100,000 adults per year and 95% confidence interval.

Conclusion: The incidence rate of SpA is similar to the incidence of rheumatoid arthritis in our country (2). Peripheral SpA is two times more frequent than axial SpA.

EQ-5D VAS, mean (SD)	-0.7 (23.6) N=351	9.7 (18.4) [†] N=107	16.7 (20.5) ^{†‡} N=89	26.0 (20.7) ^{†‡} N=107
SF-36 PCS, mean (SD)	0.8 (6.9) N=351	3.5 (6.0) [†] N=107	10.0 (8.1) ^{†‡} N=89	14.7 (8.5) ^{†‡} N=107
SF-36 physical functioning domain, mean (SD)	2.7 (17.9) N=351	8.4 (16.4) [†] N=107	21.7 (19.3) ^{†‡} N=89	33.8 (24.6) ^{†‡} N=107

*p<.05 vs. <PASI 75

[†]p<.05 vs. PASI 75 but not PASI 90

[‡]p<.05 vs. PASI 90 but not PASI 100

*p<.01 vs. <ACR20

[†]p<.01 vs. ACR20 but not ACR50

[‡]p<.01 vs. ACR50 but not ACR70

*Missing PASI, ACR, and DLQI data were imputed using NRI and missing health outcomes were imputed using LOCF. PASI data are based on patients with baseline psoriasis ≥3% BSA and ACR data are based on all ITT patients. ACR20/50/70=20%, 50%, 70% improvement in American College of Rheumatology response criteria; BSA=body surface area; DLQI=Dermatology Quality of Life Index; ITT=intent-to-treat; LOCF=last observation carried forward; MCS=Mental Component Score; N=number of patients in each category after imputation; NRI=non-responder imputation; PASI 75/90/100=75%, 90%, 100% improvement in Psoriasis Area and Severity Index; PCS=Physical Component Score; SD=standard deviation; SF-36=36-Item Short Form Health Survey; VAS=visual analog scale

Methods: Data from the 24-week(wk), randomized, double-blind, placebo-controlled periods of 2 Phase 3 clinical trials (SPIRIT-P1, NCT01695239; SPIRIT-P2, NCT02349295) were combined to assess pts with active PsA who were biologic-naïve (N=316) or were intolerant to TNF inhibitors (N=363) and received sc placebo or 80 mg ixekizumab every 2 or 4 wks, after a 160 mg starting dose.^{1,2} All pts met the Classification Criteria for PsA. QoL outcomes were assessed in categories of pts based on Psoriasis Area and Severity Index (PASI) or ACR responses at Wk 24. ACR response categories included pts not achieving ACR20, pts achieving ACR20 and <ACR50, ACR50 and <ACR70, and ACR70. PASI response categories included pts with baseline (BL) psoriasis ≥3% body surface area not achieving PASI 75, pts achieving PASI 75

and <PASI 90, PASI 90 and <PASI 100, and PASI 100. The percentage of pts achieving Dermatology Quality of Life Index (DLQI) score 0-1 or 0, indicating no impact on QoL, and mean change in EQ-5D visual analog scale (VAS) and 36-Item Short Form Health Survey (SF-36) Mental Component Score (MCS) was evaluated across PASI categories at Wk 24. Mean change in EQ-5D VAS, SF-36 Physical Component Score (PCS), and SF-36 physical functioning was evaluated across ACR categories at Wk 24. Missing data were imputed using non-responder imputation for categorical data and last observation carried forward for continuous data. Response categories were compared using logistic model for categorical outcomes; analysis of covariance was used for continuous outcomes, with BL health outcome score as a covariate.

Results: At Wk 24, the greatest improvements in QoL as assessed by EQ-5D were associated with achieving PASI 100 or ACR 70. Also, the proportion of pts achieving DLQI score 0-1 or 0 and the mean change in SF-36 MCS increased with PASI improvement, with the greatest QoL improvements in pts achieving PASI 100. Similarly, from BL-Wk 24, SF-36 PCS and SF-36 physical functioning improved with ACR response, with the greatest improvements alongside ACR50 and ACR70 responses.

Conclusion: Incremental QoL benefits were observed across PASI and ACR response categories. Clear skin (PASI100) was associated with the greatest improvements in skin-specific QoL, mental aspects, and general QoL. Pts achieving ACR50 and ACR70 achieved the greatest improvements in physical aspects and general QoL. These data provide more evidence that optimal QoL improvements are associated with greater improvements in joint and skin-related PsA symptoms.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Clinical/Epidemiology Studies

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Increased risk of infections has been recognized in patients with psoriatic arthritis (PsA) compared to those without PsA. Immunomodulatory effects of PsA, immunosuppressive therapies and associated comorbidities might all play a role. However, the rate of hospitalizations with serious infections in patients with PsA is largely unknown. We used the National Inpatient Sample (NIS) to compare hospitalizations for serious infections in patients with and without PsA in the US from 2000-2014.

Methods: Using NIS data from 2000-2014, we identified patients ≥ 18 years with PsA at any secondary diagnosis positions based on ICD-9 code 696.0. For each patient with PsA, a matched control of the same age (± 1 year), sex, race/ethnicity and NIS stratum (based on hospital's census region or division, ownership/control, location/teaching, and bed size) was randomly selected. We evaluated 8 different infections as primary diagnoses: sepsis/bacteremia, pneumonia, urinary tract infection, skin and soft tissue infections, septic arthritis, osteomyelitis, brain/spinal cord infections and opportunistic infections. We compared the hospitalization rates for each infection among all hospitalizations with and without a secondary diagnosis of PsA. Hospitalized infection rates were estimated as the number of hospitalizations with primary discharge diagnosis of infection divided by the total number of hospitalization in the groups. Analyses were weighted to account for the sampling design of the NIS.

Results: NIS database from 2000-2014 contained 53,788 (weighted count, N=265,842) hospitalizations in the PsA and (weighted count, N=266,082) in the matched non-PsA cohort. Mean age at hospitalization for patients with PsA was 60 years (SD: 14.3) and 56% were female. Overall, there were an estimated 25,681 PsA and 15,014 non-PsA hospitalizations with a primary discharge diagnosis of infection, which corresponded to rates of 9.6 and 5.6 per 100 hospitalizations observed in the PsA and non-PsA cohorts, respectively (Rate ratio: 1.79, 95% CI: 1.71 - 1.88). While highest number of hospitalizations was observed for skin/soft tissue infections, sepsis/bacteremia and pneumonia in both groups, the highest differences in the rate ratio among the two groups were observed for septic arthritis, brain/spinal cord infections and opportunistic infections (Table).

Conclusion: Our study shows that patients with PsA have a higher proportion of hospitalizations for serious infections compared with non-PsA patients. Whether this difference is secondary to the immunosuppressive agents used in PsA or due to the immunologic disturbance associated with PsA itself would require careful evaluation in dedicated PsA studies. Future work will estimate rates of serious infections among all patients with PsA in the US and will also examine yearly trends in the rates of serious infections for patients with PsA.

Infection type	Estimated number of hospitalized infections (rate per 100 hospitalizations)		Rate ratio (95% CI)
	PsA	Non-PsA	
Total	25681 (9.65)	15014 (5.65)	1.79 (1.71, 1.88)
Pneumonia	9878 (3.71)	8242 (3.10)	1.21 (1.13, 1.30)
Sepsis/bacteremia	10017 (3.76)	7702 (2.90)	1.31 (1.22, 1.40)
Urinary tract	1216 (0.46)	811 (0.30)	1.49 (1.22, 1.81)
Skin and soft tissue	11253 (4.23)	5285 (1.99)	2.20 (2.04, 2.37)
Septic Arthritis	1011 (0.38)	276 (0.10)	3.76 (2.77, 5.09)
Osteomyelitis	1000 (0.38)	458 (0.17)	2.24 (1.75, 2.86)
Brain/spinal cord	254 (0.10)	84 (0.03)	3.06 (1.76, 5.31)
Opportunistic	928 (0.35)	399 (0.15)	2.31 (1.78, 2.99)

Myocardial Infarctions Among Ankylosing Spondylitis Patients in a Large US Insurance Database

Maureen Dubreuil¹, Christine Peloquin², David T. Felson³ and Tuhina Neogi³, ¹Clinical Epidemiology and Rheumatology, Boston University School of Medicine, Boston, MA, ²Clinical Epidemiology Unit, Boston University School of Medicine, Boston, MA, ³Clinical Epidemiology Research and Training Unit, Boston University School of Medicine, Boston, MA

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Clinical/Epidemiology Studies

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Risk of myocardial infarction (MI) is estimated to be increased up to 60% in ankylosing spondylitis (AS). Studies in patients with rheumatoid arthritis, psoriatic arthritis and psoriasis have demonstrated reduced risk of MI in users of TNF inhibitors relative to users of other treatments. We sought to evaluate risk of MI in AS patients with use of TNFi, either alone, or in combination with other therapies, in a large US health insurance claims database.

Methods: We conducted a nested case-control study using 1994-2017 data from the OptumLabs® Data Warehouse which includes de-identified claims data and demographic information on enrollees. We included adults aged 18-89 with an AS diagnosis after at least 6 months of claims data prior to their AS diagnosis. Incident MI cases were defined by diagnostic codes. Four controls without MI were matched to each case based on sex, age (+/- 2 years) and year of AS diagnosis (+/- 2 years). AS treatment was assessed within the year prior to MI or the matched date in controls. Treatment was categorized as: NSAID only, symptom-modifying anti-rheumatic drugs (SMARD) only, TNFi only, combinations these categories, hormone. Odds of MI was assessed in each exposure category, relative to NSAID use alone, with adjustment for potential confounders (smoking, obesity, diabetes, chronic kidney disease stage 2 or greater, hypertension and ischemic heart disease at any time prior to AS diagnosis date) using conditional logistic regression. Additionally, a sensitivity analysis was performed assessing for exposure within the 6 months prior to index date.

Results: Among 23249 adults with AS meeting inclusion criteria, we identified 629 MI cases and 2385 matched controls. The mean age of included subjects was 59.1 (SD 11.9) years, and 48.9% were female. Relative to NSAID use, the RR for

MI among TNFi only users was 1.03 (95% CI 0.59-1.78), and for SMARD only users 0.95 (95% CI 0.68-1.32). No combinations of NSAID, SMARD and TNFi use resulted in a significantly increased or decreased OR after adjustment for potential confounders. Results were not materially changed with an assessment period of 6 months prior to index date.

Conclusion: In this large health insurance claims database, use of TNFi among AS patients, either alone or in combination with NSAIDs or SMARDs was not associated with a reduced risk of MI. While this study is limited a small study sample, and there is the potential for bias related to confounding by disease severity, these findings suggest that TNFi are not cardio protective in AS.

Table 1. Odds of Myocardial Infarction among ankylosing spondylitis patients within each drug treatment category

	Cases, N	Controls, N	Crude Odds Ratio (95% CI)	Adjusted+ Odds Ratio (95% CI)
NSAID only	284	998	1.0 (ref)	1.0 (ref)
SMARD only	60	211	0.97 (0.71-1.34)	0.95 (0.68-1.32)
TNFi only	<20*	69	0.95 (0.56-1.64)	1.03 (0.59-1.78)
NSAID and SMARD	79	227	1.23 (0.92-1.65)	1.27 (0.94-1.70)
NSAID and TNFi	<20*	78	0.72 (0.41-1.27)	0.76 (0.42-1.35)
TNFi and SMARD	<20*	56	0.43 (0.19-0.97)	0.42 (0.18-0.96)
NSAID, SMARD and TNFi	23	60	1.37 (0.83-2.26)	1.42 (0.85-2.38)
None of the above	141	686	0.65 (0.52-0.83)	0.64 (0.50-0.81)

* Small cells are suppressed to prevent the possibility of patient identification

NSAID: Non-steroidal anti-inflammatory drug. SMARD: Symptom-modifying anti-rheumatic drugs, including sulfasalazine, azathioprine, methotrexate, leflunomide, tofacitinib and apremilast. TNFi: tumor-necrosis alpha inhibitors; etanercept, adalimumab, golimumab, certolizumab and infliximab.

+ Adjusted for sex, and baseline age, smoking, obesity, diabetes, hypertension, chronic kidney disease stage 2 or greater, and ischemic heart disease

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Clinical/Epidemiology Studies

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Dactylitis is a particular feature shared across the several phenotypical forms of spondyloarthritis (SpA), part of the classification criteria. There are only few data available about impact of dactylitis in early stage of SpA, and factors associated with the presence/history of dactylitis.

Aim: To study, at baseline of the DESIR cohort the presence/history of dactylitis in an attempt to evaluate frequency of dactylitis in SpA and to look at the factors associated with presence of dactylitis.

Methods: DESIR is a prospective observational cohort of patients with recent onset (less than 3 years) inflammatory back pain, beginning before 50 years, suggestive of axial SpA. All available factors in the database (clinical, biological, imaging and medico economic) were compared between patients with and without past or present dactylitis at baseline (for categorical variables : odds-ratio +/- 95% CI and chi-square/Fisher tests, for continuous variables : unpaired t-tests / Mann-Whitney) , by uni and then multivariate analysis(logistic regression). Significance: p less than 0.05.

Results: At baseline, 708 patients were analyzed. 97 had a past history or a concomitant dactylitis [prevalence 13.7% (CI 95% : 11.6 – 16.2)]. Dactylitis occurred before axial symptoms in 41.3 % and before any other symptom in 14.1 % of the cases. By univariate analysis, dactylitis was significantly associated with history of arthritis, enthesitis, psoriasis, with elevated CRP and ESR, enthesitic and arthritis scores, BASDAI, ASDAS,BASFI, SF-36, HAQ, ASQoL, shorter disease duration, systemic and local steroids use, and with lower structural damage (sacro iliac, spine)

Table shows the result of the multivariate analysis.

item	OR	CI 95%
Arthritis history or presence	2.9	[11.2 – 30.9]
csDMARD use during the past 6 months	5.2	[2.9 – 9.1]
Calcaneal enthesitis history or presence	6.7	[3.0 – 14.7]
BASDAI > median	1.08	[1.05 – 1.11]
BASFI > median	1.04	[1.02 – 1.06]
SF36 phys <median	0.92	[0.87 – 0.97]
Systemic steroids during the past 6 months	5.49	[2.93 – 10.28]
Sacro iliac erosion (MRI central reading)	0.02	[0.004 – 0.13]
mSASSS (central reading)	0.37	[0.21 – 0.66]

Conclusion: In the DESIR cohort of patients suspected for early SpA, history of dactylitis is present in 13.7 % of the cases at baseline. It is an early feature associated with peripheral involvement, and associated with more burden of the disease, more frequent use of DMARDs and steroids, but with less structural damage.

Prevalence of Sonographic Enthesitis in Patients with Psoriasis without Arthritis and Its Association Risk Factors of Psoriatic Arthritis

Anwar Albasri¹, Justine Y. Ye², Cheryl F. Rosen³, Vinod Chandran², Dafna D Gladman⁴ and Lihi Eder⁵, ¹Rheumatology, University of Toronto, Toronto, ON, Canada, ²Rheumatology, University of Toronto, Toronto Western Hospital, Toronto, ON, Canada, ³University of Toronto, Toronto Western Hospital, Toronto, ON, Canada, ⁴Department of Medicine, Toronto Psoriatic Arthritis Research Program, University of Toronto, Toronto Western Hospital, Toronto, ON, Canada, ⁵Women's College Research Institute, University of Toronto, Women's College Hospital, Toronto, ON, Canada

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Clinical/Epidemiology Studies

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Enthesitis is one of the hallmarks of psoriatic arthritis (PsA) and may be the initial site of musculoskeletal inflammation. Enthesitis affects up to 50 % of patients with PsA and is a marker of more severe disease. However, clinical evaluation of enthesitis may be difficult. Ultrasound (US) is more sensitive than physical examination in detecting enthesitis. In patients with psoriasis alone (PsC) US can detect subclinical enthesitis which may predict future development of PsA. The aim of this study was to assess the association between the severity of sonographic enthesitis and risk factors for developing PsA. These risk factors include included obesity, severity of psoriasis, nail psoriasis in addition to physically demanding occupation and the presence musculoskeletal symptoms.

Methods: A cross-sectional study was conducted in patients with a dermatologist confirmed diagnosis of psoriasis. Each patient was assessed by a rheumatologist to exclude the presence of PsA. Information was collected about lifestyle habits, medical history, musculoskeletal symptoms and the skin activity using validated measures. The Madrid Sonography Enthesitis Index (MASEI) was used to quantify the severity of enthesitis in 12 enthesal sites. The sonographer was blinded to the clinical data. MASEI score³20 was considered as high score based on a previously validated cut-off in spondyloarthritis. Logistic regression analysis was used to assess the association between PsA-related risk factors and high MASEI score after adjusting for age, sex and BMI. The results were expressed as odds ratio (OR) and their 95 confident interval (CI).

Results: A total of 180 patients were studied. Of those, 52% were male with a mean age of 51.1±13.6 yrs. Majority of the patients (97%) did not have tender enthesal site on the examination. The mean total MASEI score was 9.3±8.3 and high MASEI (≥20) was found in 17 (9.4%) of the patients. The results of the regression analysis are shown in Table 1. Univariate regression analyses found an association between high MASEI score and Health Assessment Questionnaire (HAQ) (OR 14.8; *P* 0.006), the presence of morning stiffness (OR = 4.7; *P* 0.009) physically demanding occupation (OR = 5.5; *P* 0.01). The multivariable analysis showed that the presence of inflammatory back pain (OR 22.9, 95% CI 1.3, 401.8), morning stiffness (OR 5, 95% CI 1.03, 24.3), physically demanding occupation (OR 5.1, 1.01, 25.8) and HAQ (OR 13.9, 95% CI 1.02, 190.5) were associated with high MASEI.

Conclusion: In PsC patients, the severity of subclinical enthesitis was associated with occupational related physical stress and with inflammatory musculoskeletal complaints. Enthesitis might be playing a role in explaining the patients MSK complains in the absence of clinical features of PsA.

Table 1 D The association between high MASEI score (≥ 20) and PsA-related risk factors in patients with PsC by logistic regression multivariable analysis

Variable	Odds Ratio	95% Confidence Interval	P value
Age (years)	1.12	1.04, 1.21	0.002

Comparative Risk of Atrial Fibrillation and Cardiovascular Events between TNF-Inhibitors and Ustekinumab in Patients with Psoriasis and Psoriatic Arthritis: A Population-Based Multi-Database Study

Moa Lee¹, Rishi J. Desai², Yinzhu Jin³, Gregory Brill¹, Alexis Ogdie⁴ and Seoyoung C. Kim¹, ¹Brigham and Women's Hospital, Harvard Medical School, Boston, MA, ²Division of Pharmacoepidemiology and Pharmacoeconomics, Brigham and Women's Hospital, Harvard Medical School, Boston, MA, ³Division of Pharmacoepidemiology and Pharmacoeconomics, Brigham and Women's Hospital, Harvard Medical School, Boston, MA, ⁴Medicine/Rheumatology and Epidemiology, University of Pennsylvania, Philadelphia, PA

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Clinical/Epidemiology Studies

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Cardiovascular disease is a major comorbidity in patients with psoriasis (PsO) and psoriatic arthritis (PsA). Increasing evidence suggests a potential reduction in the risk of cardiovascular (CV) events with biological disease-modifying antirheumatic drugs (bDMARDs) treatment, mainly including tumor necrosis factor inhibitors (TNFi) with the more recent focus on atrial fibrillation (AF). However, the comparative CV risk with different bDMARDs has not been adequately studied in this patient population.

Methods: Using two large US commercial insurance databases, Optum Clinformatics and MarketScan, we identified patients with PsO or PsA diagnosis initiating ustekinumab or TNFi (i.e., adalimumab, etanercept, infliximab, certolizumab, and golimumab) from September 25, 2009 to September 30, 2015. The primary outcome was incident AF and the secondary outcome was a composite CV event including myocardial infarction, stroke, and coronary revascularization. Patients were followed until the first occurrence of the following events: 1) outcomes, 2) death, 3) plan disenrollment, 4) switching or 5) discontinuing treatment. To account for potential confounding, we estimated propensity score (PS) as the predicted probability of receiving ustekinumab conditioning on 62 covariates including demographic and clinical factors in each database. We used weighting based on PS fine stratification with 50 strata to control for confounding. The adjusted hazard ratio (HR) of each outcome was estimated using a weighted Cox proportional hazards regression model. We performed all the analyses separately in each of the databases and then combined the HR by a random-effects meta-analysis.

Results: We identified 60,028 (15,470 in Optum and 44,558 in MarketScan) adult patients with PsO or PsA and no prior AF. The mean age of the cohort was 47.2 ± 12.7 , and 51% were female. 81% had diagnosis for PsO while 46% had PsA, and 27% had both PsO and PsA. After PS stratification, covariates were well balanced between the two groups. As presented in **Table 1**, 60 incident AF occurred in 9,071 ustekinumab initiators while 323 incident AF did in 50,957 TNF inhibitor initiators (IR=4.7 and 5.0 cases per 1,000 person-year, respectively). MACE occurred in 74 patients among ustekinumab initiators, and 421 of patients initiated TNF inhibitors (IR=6.2 and 6.1 cases per 1,000 person-year,

respectively). The combined HR for AF among the ustekinumab initiators compared to those initiated TNFi was 1.15 (95% CI 0.70-1.89), and for MACE, the HR was 1.14 (95% CI 0.89-1.46).

Table 1. Comparison of phenotypic characteristics of Akpa patients

Conclusion: In this large cohort study of 60,028 patients with PsO or PsA, we found no substantially different risk of AF or CVD after initiation of ustekinumab or TNFi. However, a possible small effect cannot be ruled out warranting further studies with a longer follow-up.

Table 1. Risk of atrial fibrillation and composite CVD (ustekinumab vs. TNFi) adjusted through PS weighting

Region-Specific Differences in Clinical Presentation of Patients with Axial Spondyloarthritis – Results from a Large Multinational Cohort Study

Denis Poddubnyy¹, Robert D Inman², Joachim Sieper¹, Fabiana Ganz³ and Maja Hojnik⁴, ¹Charité Universitätsmedizin Berlin, Berlin, Germany, ²Department of Medicine, University of Toronto, Toronto, ON, Canada, ³AbbVie, Baar, Switzerland, ⁴AbbVie, Ljubljana, Slovenia

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Clinical/Epidemiology Studies

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: There is limited evidence on the phenotypic characteristics of axial spondyloarthritis (axSpA) patients (pts) in various geographic regions around the world. This analysis aimed to compare demographic and disease-related characteristics in axSpA pts included in PROOF study in different regions.

Methods: PROOF is an ongoing 5-year prospective observational study inputs with recently (≤ 1 year prior to study enrollment) diagnosed axSpA and fulfilling the ASAS classification criteria. Baseline data of pts with centrally confirmed sub-classification as non-radiographic (nr)-axSpA or radiographic (r)-axSpA, based on the absence or presence of definite radiographic sacroiliitis (\geq grade 2 bilaterally or \geq grade 3 unilaterally), were considered in the current analyses. Twenty-nine participating countries were divided into 4 geographic regions: 1. Europe and Canada (EC), 2. Middle East and South Africa (MEA), 3. Asia (China only), and 4. Latin America (LA).

Results: A total of 1583 axSpA pts were centrally sub-classified as nr-axSpA (n=544) or r-axSpA (n=1039). The proportion of patients with r-axSpA was highest in China (81%), followed by MEA (64%), EC (61%) and LA (54%) (Table). Gender distributions were similar across the regions in nr-axSpA (M:49% vs. F:51%), while in r-axSpA the proportions of men differed, with the highest in China (79%) and lowest in MEA (58%). In both nr-axSpA and r-axSpA, Chinese patients were the youngest, reported the shortest time since chronic back pain onset and had the highest HLA-B27 prevalence. The frequency of peripheral manifestations did not differ between nr-axSpA and r-axSpA within the regions, however, significant differences were observed in the frequency between the regions: peripheral arthritis was most common in LA ($>50\%$ pts); enthesitis in LA and MEA regions ($\approx 50\%$), while dactylitis was not frequent with the highest prevalence again in LA ($\approx 12\%$). Similarly, the prevalence of Extra-articular manifestations (EAMs) also did not differ between nr-axSpA and r-axSpA patients within the regions. Uveitis was significantly more frequent in r-axSpA pts in LA (19%) and EC ($\approx 12\%$) vs China (6%). Psoriasis was almost absent in China, and had the highest frequency in EC and LA ($\approx 10\%$). There were no IBD cases reported in China, while the highest IBD prevalence was reported in EC (3 and 6% for r-axSpA and nr-axSpA, respectively). Use of NSAIDs did not differ between regions, but there were differences in the frequency of therapy with conventional DMARDs, glucocorticoids and TNF inhibitors.

Conclusion: The results showed differences between axSpA phenotypes between the geographic regions: peripheral manifestations were more prevalent in LA and MEA. EAMs were least frequent in Asian (Chinese) pts who were also the youngest, had the lowest disease activity and impairment in physical function.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Clinical/Epidemiology Studies

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: It is generally assumed that patients with chronic arthritis conditions tend to exercise less than what is currently recommended. Although several evidences support this contention in rheumatoid arthritis patients, there is little data on the level of daily physical activity (PA) in psoriatic arthritis (PsA) patients vs. healthy controls, using objective procedures, such as accelerometry. Moreover, there is currently no evidence that decisively answers an important question concerning PA vis-à-vis PsA: Does disease activity influence PA in PsA patients?

The purposes of this study were to compare PA in a group of PsA patients versus healthy controls through both objective (triaxial accelerometry) and subjective (International Physical Activity Questionnaire- IPAQ) methods, and to explore the impact of disease levels on PA in these patients. We also sought to determine the potential role of PA assessment as a measure of PsA disease activity.

Methods: A group of 53 PsA patients and 36 age- and sex-matched healthy controls were included in this cross-sectional study. PA was assessed by accelerometry and with IPAQ in both groups. We performed multiple regression analysis not only to compare PA between groups, but also to explore the relationship between PsA features, including disease activity (assessed by DAS28-ESR, DAS28-PCR and DAPSA) and PA. In a randomized group of 36 PsA patients a test/re-test study was carried out 6 month after the first evaluation in order to determine the correlation between variation in disease activity and PA.

Results: The number of minutes of moderate and vigorous activity (MVPA)/day, as evaluated by accelerometry and adjusted for sex, age work activity was similar in PsA patients and in healthy controls (40 ± 29 vs 33 ± 15 min/day, $p=0.2$). In PsA patients, accelerometry and IPAQ demonstrated concordance to a moderate degree. When PA between the two visits of PsA patients was compared, a significant differences in minutes of MVPA was found (40 ± 29 vs 30 ± 22 min/day, $p=0.035$). Interestingly, variations in PA, as measured by accelerometry, inversely correlated with RA disease activity by DAS28-PCR ($r=-0.37$, $p=0.04$) and DAPSA ($r=-0.43$, $P=0.01$). When this analysis was done assessing disease activity by DAS28-ESR, a similar, but not significant tendency was observed ($r=-0.34$, $p=0.07$).

Conclusion: In PsA patients, accelerometry is a reliable technique to evaluate PA. This study not only showed that PsA patients spend similar time doing MVPA than healthy controls, but also PA, as assessed by accelerometry, was sensitive to any changes in disease activity.

Adipose Tissue Inflammation in Psoriatic Arthritis: Overexpression of a Wide Array of Inflammatory Mediators and Associations with Disease and Treatment Characteristics

Jae Hee Yun¹, Robert Winchester², Hui-Zhu Zhang², Christopher Dependler¹ and Jon T. Giles¹, ¹Medicine/Rheumatology, Columbia University, College of Physicians & Surgeons, New York, NY, ²Rheumatology, Columbia University, College of Physicians & Surgeons, New York, NY

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Clinical/Epidemiology Studies

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Obesity is associated with PsA risk, severity, and lack of response to DMARDs. However, no studies have explored adipose tissue inflammation at the molecular level and its associations with PsA features.

Methods: Periumbilical subcutaneous adipose tissue was obtained from 26 PsA patients without diabetes and compared with individuals with RA (n=42) and controls without rheumatic disease (n=21). Using real time polymerase chain reaction (RT-PCR), gene expression profiles for selected inflammatory cytokines, chemokines, macrophage and T cell markers, adipokines, and mediators of glucose and lipid metabolism were assessed and their correlations with PsA disease characteristics were compared between groups. Multivariable linear and logistic regression were used to adjust for relevant confounders.

Results: The PsA group [54% female, mean age 56 years, mean BMI 31.1 kg/m², median Composite Psoriatic Disease Activity Index (CPDAI)=4 units] did not differ significantly on age distribution compared with the RA or control groups. However, the PsA group was more frequently male and mean BMI was higher by 3.0-3.3 kg/m². In general, adipose expression of inflammatory and metabolism genes was many fold higher in the PsA group compared with the RA and control groups, with 17 genes meeting the Bonferroni corrected threshold of $p < 0.002$ [adiponectin, C3, MCP-1, CD4, HIF1a, IL-17R, IL-1, IL-4, IL-8, insulin receptor, leptin, NFkB, PPAR-gamma, PAI-1, osteopontin, STAT1, and TLR4], ranging from 4 to >450-fold higher in PsA vs. non-rheumatic controls, with little change after adjustment for sex and BMI. For each, higher expression was observed across all strata of BMI (Fig A depicted for MCP-1 as a representative example). Adipose MCP-1 expression was significantly associated with CPDAI (Spearman's $\rho = 0.402$; $p = 0.042$). CPDAI was also inversely associated with adipose GLUT4 expression, a key glucose transporter and indicator of insulin sensitivity (Spearman's $\rho = -0.434$; $p = 0.030$). The PsA feature with the strongest association with adipose MCP-1 expression was dactylitis (Fig B). Somewhat unexpectedly, those treated with biologics [$n = 18$; TNF inhibitors ($n = 16$), IL-17 inhibitors ($n = 2$)] had more extensive adipose expression of inflammatory genes, even with adjusting for CPDAI, BMI, and demographics. Those using biologics had an average of 7.2 adipose inflammatory genes expressed at high level (i.e. >75th percentile) vs. an average of 1.6 genes among those not treated with biologics ($p = 0.014$; Fig C).

Conclusion: PsA adipose tissue is a potent producer of inflammatory mediators that may contribute to disease phenotype. The potential for an off-target detrimental effect of biologics on adipose inflammation warrants additional study, particularly in light of reports of weight gain with TNF inhibitor use and a blunted effect of biologics among obese PsA patients.

Session Date: Monday, October 22, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Clinical/Epidemiology Studies

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Ankylosing Spondylitis Disease Activity Score (ASDAS) was adopted to evaluate the degree of disease activity and the inflammatory response in AS patients. ASDAS score ≤ 1.3 represents inactive disease (ID) status and achievement of T2T. Hospital anxiety and depression scale (HADS) is commonly used to evaluate the mental health of chronic disease patients.

The purpose of this study is to evaluate pattern shifts and outcome trends of treat-to-target (T2T) under standard of care in ankylosing spondylitis (AS) patients and potential correlation between disease activity and mental health with interactive Smart System of Disease Management (SSDM).

Methods: SSDM is a set of disease management tool based on mobile internet. The patients were trained to master SSDM by health care professionals and conducted their ASDAS and HADS self-evaluations, then were required for repeated self-evaluation after leaving the hospital. After data entry, patients can synchronize data to the mobile terminal of their authorized rheumatologist.

Results: From Jan 2015 to May 2018, 8,175 AS patients from 373 hospitals registered on SSDM, with mean age of 34.17 ± 11.22 years and mean disease duration of 45.01 ± 56.42 months. Among them, 5,480 patients performed ASDAS evaluation at least once, totally 9,601 times; 1,368 (male 906, female 462) patients carried out repeated evaluation for 4,121 times and 551 patients performed HADS for 970 times during >6 months follow-up. Among patients repeated evaluate ASDAS, the final T2T rate was significantly increased to 38% from the baseline rate of 23% ($\chi^2 = 468.253$, $p < 0.001$) after median evaluation of 3 (2-29) times per patient. The mean score of ASDAS decreased from 2.22 ± 1.08 to 1.83 ± 1.07 (mean improvement -0.39 ± 0.58 , $p < 0.001$). Among T2T patients in baseline (318/1,368, 23%), 214/318 (67%) remained T2T and 104/318 (33%) relapsed at the end of follow-up. Among patients failed to T2T at baseline (1,050/1,368, 77%), 300/1,050 (29%) patients achieved T2T and 750/1,050 (71%) patients remain failure of T2T. The mean evaluation interval of the T2T achievers was significantly shorter than that of the failures (25 days vs. 42 days and 27 days vs. 40 days, $p < 0.05$). Analysis of the correlation between ASDAS and HADS showed that patients who achieved T2T had lower depress morbidity compared with the group which didn't achieve T2T (13% vs 27%, $p < 0.05$), but there was no difference of anxiety morbidity between the two subgroups (17% vs 21%, $p > 0.05$).

Conclusion: Significant improvement is observed under applying SSDM through empowering patients. The depress morbidity is higher in AS patients doesn't achieve T2T but anxiety stay same. Regularly performing self-management with SSDM associates with the achievements of maintaining T2T pattern and converting the patterns from failure of T2T to T2T. SSDM warrant a further evaluation and clinical application.

Session Date: Monday, October 22, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Clinical/Epidemiology Studies

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The severe consequences of osteoporosis in the general population are well outlined. In axial spondyloarthritis (axSpA), osteoproliferation of the spine means posterioranterior (PA) dual-energy x-ray absorptiometry (DXA) can't discriminate between new bone formation and vertebral body, potentially overestimating BMD. To understand the impact of low BMD in axSpA, we need an accurate and reproducible method of assessment. Lateral DXA of the spine avoids spinal osteoproliferation and is an attractive option. The aim of this study was to compare lateral DXA of the lumbar spine with PA DXA, and determine patient variables that render conventional DXA unreliable.

Methods: Patients fulfilling modified New York (mNY) or Assessment of Spondyloarthritis International Society (ASAS) criteria were consecutively recruited from rheumatology clinics in this twin-centre cross-sectional study. A detailed assessment of patients included demographics, clinical exam, laboratory assessment and validated measures of disease severity (BASDAI, ASDAS-CRP, BASMI, mSASSS). BMD of the spine was assessed using DXA in the lateral and PA projections. BMD of the hip was assessed in the conventional manner. R software was used for statistical analysis.

Results: One hundred and ten patients were assessed, 100 of whom had paired AP and lateral DXAs: 76% (n=84) male, 92% Caucasian, 81% mNY criteria. Median(IQR) age was 52 (17) years, disease duration 23.5 (20) years, delay to diagnosis 7 (12) years, body mass index (BMI) $27.6 (6.3)$ kg/m², BASDAI 3.9 (2.1-5.6), BASMI 4.1 (2.8-5.8), ASDAS-CRP 2.2 (1.5-3), mSASSS 8.5(2-36).

Lateral spine BMD is significantly lower than PA BMD (see figure 1), with a mean difference between AP and lateral lumbar spine DXA of 0.337 g/cm² (95% CI 0.3-0.37), and detects more cases of both osteopenia (27% versus 17%) and osteoporosis (16% versus 2%) at the spine ($p < 0.01$). The prevalence of osteopenia at the hip is 25% and osteoporosis is

1%. When combined with hip DXA to assess for low BMD at any site, using lateral DXA characterises 52% of the cohort as having low BMD, in comparison to 36% when AP DXA is used ($p<0.01$).

The following variables correlate with a larger difference between the measurement of AP and lateral DXA: BASMI ($r=0.54$), disease duration($r=0.37$), BMI ($r=0.32$), mSASSS ($r=0.52$).

In multiple regression analysis, a model with disease duration, BMI, BASMI and shorter time to diagnosis predicts a greater difference between AP and lateral BMD ($p<0.05$).

Figure1: Plot of difference between AP and lateral BMD. The dashed line indicates equal BMD for both scanning methods.

Conclusion: Lateral DXA detects more cases of low BMD than PA DXA, particularly in patients with higher BASMI and BMI and longer disease duration. Continuing to rely on AP DXA will miss a significant number of axSpA patients with low BMD. Lateral DXA is a practical and feasible tool suitable for use in clinical practice and should be considered as an alternative to PA when measuring BMD in the lumbar spine.

Higher Serum Uric Acid Levels Protect Against Osteoporosis in Patients with Axial Spondyloarthritis

Gillian Fitzgerald^{1,2}, Tochukwu Anachebe³, Ronan Mullan⁴, David Kane⁵, Kevin McCarroll⁶ and Finbar O' Shea², ¹School of Medicine, Trinity College Dublin, Dublin 2, Ireland, ²Rheumatology, St. James's Hospital, Dublin 8, Ireland, ³Department of Rheumatology, St. James's Hospital, Dublin 8, Ireland, ⁴Department of Rheumatology,, Tallaght Hospital, Dublin, Ireland, ⁵Department of Rheumatology, Tallaght Hospital, Dublin 24, Ireland, ⁶Department of Medicine for the Elderly, St. James's Hospital, Dublin 8, Ireland

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Clinical/Epidemiology Studies

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: High serum urate (SUA) is a risk factor for metabolic disease, including hypertension and coronary artery disease. However, SUA has an antioxidant effect and can play a role in protecting against diseases characterised by high oxidative stress, such as neurodegenerative disease. Osteoporosis, a condition defined by bone loss and fragility fractures, is also characterised by high oxidative stress levels, mediated through increased osteoclastic activity. Therefore,

antioxidants are of considerable interest due to theoretical protective properties against bone loss. Existing literature examining SUA and its impact on bone mineral density (BMD), particularly in axial spondyloarthritis (axSpA), is limited. The aim of this study is to examine the relationship between SUA and BMD in a well-characterised axSpA cohort.

Methods: Patients fulfilling modified New York (mNY) or Assessment of SpondyloArthritis International Society (ASAS) criteria were consecutively recruited from 2 centres in this cross-sectional study. Patients underwent a detailed assessment: demographics, disease-related variables (validated measures of disease activity included BASDAI, ASDAS-CRP, BASMI), clinical examination, laboratory parameters (routine bloods, SUA, CRP, vitamin D). BMD was assessed using dual-energy x-ray absorptiometry of the lumbar spine and hip (total hip and femoral neck). SUA >360 µmol/L (>6 mg/dL) was considered high. Analysis was performed using SPSS.

Results: A total of 107 patients were included: 76% male, 81% fulfilling mNY criteria, median (IQR) age 51.5 (17.8) years, disease duration 23.5 (20.4) years. Median BMI was 27.6 (6.5) kg/m², with 31% of the cohort obese. The median (interquartile range [IQR]) BASDAI was 3.9 (3.6), ASDAS-CRP 2.1 (1.5) and BASMI 4.1 (3.2). Low BMD was present in 38.5% of the cohort and 44% had a previous fracture.

Median (IQR) SUA in the cohort was 312 (119) µmol/L, with a SUA >360 µmol/L present in 34% (n=36). More men than women had high SUA (94% v 5.6%, p<0.01). BMI was significantly higher in those patients with SUA above 360 µmol/L than patients with normal levels (mean difference 4.2 kg/m², 95% CI 2.1-6.3). Age, disease duration, axSpA disease severity, psoriasis prevalence, vitamin D and CRP were equal in patients with high and normal levels of SUA.

SUA correlated positively (p<0.01) with BMD at the spine (r=0.3) and total hip (r=0.3). The cohort was subsequently examined in 3 groups of SUA: <300 µmol/L (43% of cohort), 300-360 µmol/L (23%) and >360 µmol/L (34%); mean BMD increased at the spine and total hip across the 3 groups (p<0.05), but not at the femoral neck.

Patients with a high SUA had significantly less osteopenia or osteoporosis (19%) than patients with a normal SUA (46%) (OR 3.5, 95% CI 1.4-9.3).

In univariate logistic regression analysis, low SUA and low BMI were associated with low BMD. After correcting for obesity, patients with high SUA remained independently associated with normal BMD compared to those patients with a normal SUA (OR 3.4, 95% CI 1.2-9.6).

Conclusion: This study demonstrates that high SUA levels are independently associated with normal BMD, suggesting a protective effect of SUA against osteoporosis in axSpA patients.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Clinical/Epidemiology Studies

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: In the last three decades, major advances in the spondyloarthritis (SpA) field have been achieved leading to new terminology. Whilst this terminology is well established in English, there is concern about the disparity of translated words and acronyms in Spanish, which is used by more than 437 million people in 21 countries. Our aim was to develop a consensus to standardize the use of Spanish terms, abbreviations and acronyms in the field of Spondyloarthritis (SpA).

Methods: An international task force comprising all ASAS Spanish-speaking members, the executive committee of GRESSER, two methodologists, two linguists from Real Academia Nacional de la Medicina Española (RANM) and two patients from CEADE was established. A literature review was performed to identify the conflicting terms/abbreviations/acronyms in SpA. This review examined written sources in Spanish including manuscripts, ICF and ICD, guidelines, recommendations and consensus. A nominal group meeting and three-round Delphi was followed. There were commendations from the RANM based on the Pan-hispanic dictionary were followed throughout the process.

Results: Consensus was reached for 46 terms, abbreviations or acronyms related to the field of SpA. A Spanish translation was accepted for 6 terms and 6 abbreviations to name or classify the disease, and for 6 terms and 4 abbreviations related to SpA (Table 1). In addition, it was agreed not to translate into Spanish 15 acronyms because these are very well established. However, when mentioning these, it was decided to recommend following this structure: type of acronym in Spanish and acronym and expanded form in English (Table 2). With regards to 7 terms or abbreviations attached to acronyms, it was agreed to translate only the expanded form and a translation was also selected for all of them.

Conclusion: Through this standardisation, it is expected to establish a common use of the Spanish nomenclature for SpA. The implementation of this consensus across the community will be of substantial benefit, avoiding misunderstandings and time-consuming procedures.

Table 1. Terms and abbreviations recommended by the group of experts.

#	English term (abbreviation)	Spanish term	Spanish abbreviation
1	Spondyloarthritis (SpA)	Espondiloartritis	EspA
2	Axial spondyloarthritis (axSpA)	Espondiloartritis axial	EspAax
3	Ankylosing spondylitis (AS), radiographic spondyloarthritis (r-SpA)	Espondilitis Anquilosante	EA
4	Non radiographic axial spondyloarthritis (nr-axSpA)	Espondiloartritis axial no radiografica	EspAax-nr
5	Peripheral spondyloarthritis (pSpA)	Espondiloartritis periferica	EspAp
6	Psoriatic arthritis (PsA)	Artritis psoriasica	APs
7	Inflammatory back pain (IBP)	Dolor lumbar inflamatorio	DLI
8	Magnetic resonance imaging of the sacroiliac joints (MRI-SI)	Resonancia Magnética de articulaciones sacroilíacas	RM-SI
9	Bone marrow edema (BME)	Edema de médula ósea	EMO
10	Modified New York criteria (mNY)	Criterios de Nueva York modificados	NYm

SESSION INFORMATION

Session Date: Monday, October 22, 2018

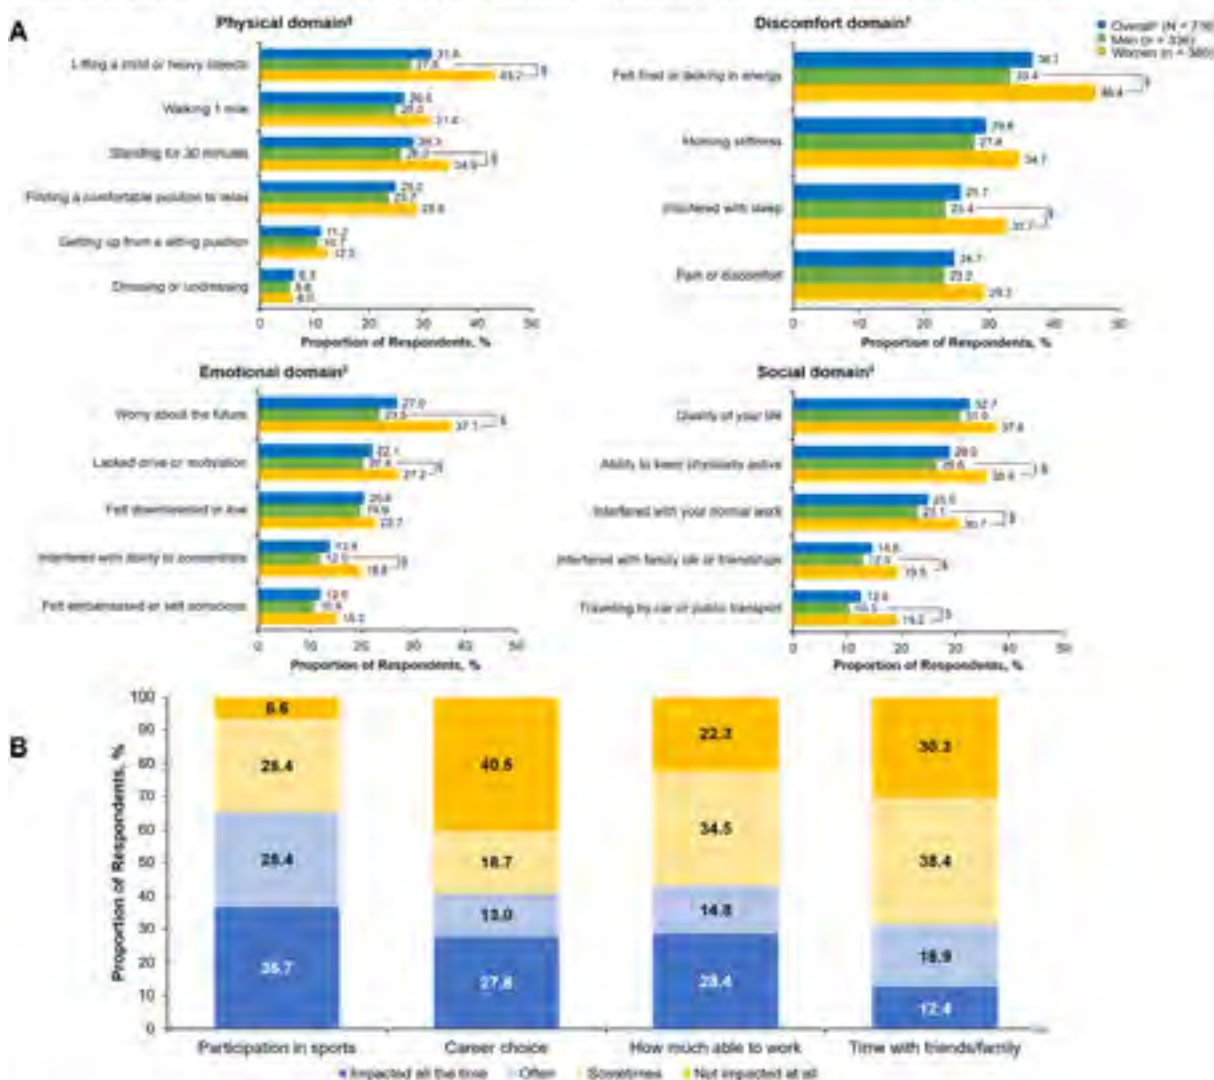

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Clinical/Epidemiology Studies

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: While severe pain and stiffness are common hallmarks of ankylosing spondylitis(AS), disease progression is slow and not always visible; however, the quality of life (QoL) of patients with AS is still significantly impacted. We aimed to assess patient-reported impact of AS on QoL in the physical, discomfort, social, and emotional domains among US patients with AS in a real-world setting.

Figure 1. (A) Proportion of respondents with AS reporting the top two levels of impairment by their disease across 4 domains of disease stratified by sex,* and **(B)** respondent-reported impact of AS on lifestyle characteristics†

AS, ankylosing spondylitis; QoL, quality of life.

* Respondents were "very limited" or "totally limited/unable to do" each activity as a result of their AS.

† Weighted 3:1 (male to female).

‡ For activities related to the physical domain, respondents were queried on the impact of AS on their QoL on the day of survey participation.

§ P < 0.05, male vs female.

¶ For activities related to the discomfort, emotional, and social domains, respondents were queried on the impact of AS on their QoL during the previous week.

Methods: Descriptive data on demographics and QoL were collected from a random sample of patients associated with the Spondylitis Association of America (SAA). QoL measures were based on the Evaluation of Ankylosing Spondylitis Quality of Life (EASi-QoL) questionnaire (scale, 0-80, with higher score indicating more severe impact). Between July 7 and December 31, 2017, 820 interviews were conducted with SAA contacts via web survey or follow-up over the phone. Of 820 participants who completed the survey, 716 self-reported receiving a diagnosis of AS from their doctor and were included in this study. Participants were queried on the impact of AS on their QoL within the day of survey participation with regard to the physical domain, and within the past week prior to participation with regard to the discomfort, social, and emotional domains. A 3:1 (male to female) weighting was performed to reflect the reported prevalence of spondyloarthritis in US adults.

Results: The mean age of the 716 respondents was 55.5 years; 46.9% were male. The most common locations of pain reported were the lumbar spine (86.8%), neck (84.1%), and hip joint (80.2%). The mean total EASi-QoL score was 28.9; overall, 33.7%, 31.7%, and 34.7% of respondents, respectively, reported low (EASi-QoL score 0-17), medium (18-35), and high (≥ 36) impact of AS on QoL (weighted). Physical aspects of the disease contributed the most impact, with 41.9% of respondents (weighted) reporting high impact of AS on the physical domain (EASi-QoL score ≥ 10). The proportion of respondents reporting high impact of AS (ie, the top 2 levels of impairment for each question) in the 4 QoL domains is shown in **Figure 1A**. Women were significantly more likely than men to report high impact of AS in several aspects in all QoL domains, such as lifting a child or heavy objects (43.2% vs 27.8%), worrying about the future (37.3% vs 23.5%), feeling tired or lacking in energy (46.4% vs 33.4%), sleep interference (32.7% vs 23.4%), trouble keeping physically active (35.9% vs 26.6%), standing for 30 minutes (34.9% vs 26.0%), and traveling by car or public transport (19.2% vs 10.5%). AS also impacted their lifestyle, as shown in **Figure 1B**.

Conclusion: Negative impacts in all QoL domains were reported, with a mean overall EASi-QoL score of 28.9. Sex differences were also pronounced in several aspects, including lifting a child or heavy objects, and worrying about the future. Incorporating subjective measures of disease via patient-reported outcomes should be considered with evaluation of disease progression.

Real-World Insight into the Disease Burden and Treatment of Spondyloarthritis from a US-Based Life Impact Survey

James T. Rosenbaum¹, Lisa Pisen², Yujin Park³ and Richard Howard⁴, ¹Ophthalmology, Oregon Health & Science University and Legacy Devers Eye Institute, Portland, OR, ²UCB, Inc., Smyrna, GA, ³Novartis Pharmaceuticals Corporation, East Hanover, NJ, ⁴Spondylitis Association of America, Van Nuys, CA

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Clinical/Epidemiology Studies

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Spondyloarthritis (SpA) is a group of chronic, inflammatory diseases associated with severe pain in the joints and entheses. There is limited evidence on real-world disease burden and treatment patterns in the overall SpA population, as well as individual SpA conditions. This study surveyed self-reported burden of disease and medication use in US patients with SpA in a real-world setting.

Methods: Descriptive data on demographics, disease definition and history, and medication were collected from a random sample of patients with SpA associated with the Spondylitis Association of America (SAA). Between July 7 and August 31, 2017, 820 interviews were conducted with SAA contacts, including 720 completed via Websurvey (from 7750 emails) and 100 via follow-up over the phone (from 10,784 phone calls made to 5000 unique numbers). All 820 participants self-reported receiving a diagnosis of SpA from their doctor and were included in this study.

Results: The mean age of the 820 respondents was 55.1 years, and 44.3% were male. The most common self-reported SpA disease was ankylosing spondylitis (AS; 87.3%), followed by uveitis/iritis (28.3%). The most frequently reported comorbidities were high blood pressure (34.8%), high cholesterol (26.5%), and depression (23.4%). Compared with women, men were more impacted by high blood pressure (42.7% vs 28.5%) and heart disease (14.0% vs 4.0%), and less impacted by fibromyalgia (4.2% vs 22.1%). Acid reflux (50.7%) and eye inflammation (45.2%) were also common issues experienced among respondents. On average, respondents with AS first noticed disease symptoms 26.6 years ago, and

Slightly satisfied		73 (8.9)	
Not satisfied		59 (7.2)	
Unsure/not available		64 (7.8)	

NSAIDs, nonsteroidal anti-inflammatory drugs; PDE, phosphodiesterase; SAARDs, slow-acting anti-rheumatic drugs; SpA, spondyloarthritis.

received an AS diagnosis \approx 8.2 years later. Respondents saw an average of 2.2 doctors about their back pain, joint pain, or inflammatory problems within the last 2 years, including 20.7% of respondents who saw \geq 4 doctors. Regarding treatment, 76.7% of respondents with AS received care from rheumatologists, 8.7% from primary care physicians, and 3.8% from orthopedic surgeons; 57.5% of respondents with AS discussed medication options with their doctor and jointly participated in treatment decisions. Prior and current medications are shown in **Table 1**. More than one-half of respondents (54.4%) were at least mostly satisfied with their current treatment. Many respondents also applied non-medicinal treatment to their lifestyle, including stretching and strengthening exercises (66.2%); biking, running, or walking (57.4%); practicing proper posture techniques (56.5%); and special diets (39.4%).

Conclusion: In this real-world survey, most respondents reported substantial delays in diagnosis of AS, received care from rheumatologists, and participated in making treatment decisions. Many respondents indicated making lifestyle modifications in addition to using pharmacologic treatment. These data provide valuable insight into patient-reported disease burden and treatment profile of US patients with SpA.

Association of HLA-B Type and Sacroiliitis in Patients with Psoriatic Arthritis

Daniel Kuo¹, Isela Valera², Mihaela Taylor¹, Roy Altman¹, Veena K. Ranganath¹, Thanda Aung¹, James Louie¹ and Suzanne Kafaja¹, ¹Rheumatology, UCLA David Geffen School of Medicine, Los Angeles, CA, ²Autoimmunity and Tolerance Laboratory, Division of Rheumatology, Department of Medicine, UCLA David Geffen School of Medicine, Los Angeles, CA

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Clinical/Epidemiology Studies

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Psoriatic arthritis (PsA) is a heterogeneous disease with strong genetic heritability. Class I major histocompatibility complex (MHC) genes have been associated with PsA phenotype (1), though data is limited. The goal of this study was to establish the frequency of human leukocyte antigen (HLA)-B alleles in patients with PsA at our center and evaluate associations of allele frequency with radiographic sacroiliitis and other clinical features of PsA.

Methods: This was a retrospective observational study of patients with PsA at a tertiary academic medical center where patients were identified by ICD code and confirmed to have PsA by an experienced treating rheumatologist. Patients with HLA-B locus testing by reverse sequence specific oligonucleotide (SSO) hybridization were included in the study. Background demographics including age, sex, and ethnicity as well as available radiographs of the sacroiliac joints and MRI exams of the pelvis were collected. Clinical features of psoriatic skin disease, dactylitis, enthesitis, uveitis, and nail disease were also noted. Frequencies of HLA-B alleles were calculated for PsA patients with and without sacroiliitis, then compared to estimates from the general population based on ethnic mix (2). Associations between HLA-B alleles and sacroiliitis on imaging were evaluated with Fisher's exact test

Results: We identified 234 patients using ICD coding for psoriatic arthritis from outpatient visits with the treating rheumatologist. Of those, 89 patients did not have HLA-B locus testing and were excluded. 146 PsA patients were included in the study with mean age 48.6 ± 13.5 years, 56.8% female, 76.7% Caucasian, 8.2% Asian, 7.5% Hispanic, and 1.4% African American. The most common HLA-B alleles amongst PsA patients were HLA-B*35, B*44, B*8, B*7, B*27, and B*38 (Figure 1). X-rays of the sacroiliac joints were available in 86 patients, with 11 cases of radiographic sacroiliitis (12.8%). MRI of the pelvis was available in 25 patients, with 8 cases of sacroiliitis found (six previously noted on x-ray, and two pre-radiographic). Among patients with imaging-proven sacroiliitis, HLA-B*35, B*8, and B*38 were the most common alleles and significantly associated with sacroiliitis ($p = 0.03$).

Conclusion: In patients with psoriatic arthritis, HLA-B alleles B*35, B*8, and B*38 may be associated with sacroiliitis. Further larger studies would be helpful in determining the role of HLA-B gene subtypes as predictors of disease features in psoriatic arthritis.

The Disease Expression in Familial and Sporadic Axial Spondyloarthritis Patients

Dilek Solmaz¹, Onay Gercik², Gökhan Kabaday¹ and Servet Akar³, ¹Rheumatology, Izmir Katip Celebi University, Faculty of Medicine, Izmir, Turkey, ²Rheumatology, Izmir Katip Celebi University School of Medicine, Izmir, Turkey, ³Faculty of Medicine, Department of Rheumatology, Izmir Katip Celebi University, Izmir, Turkey

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Clinical/Epidemiology Studies

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Familial aggregation of the SpA in particular AS has long been known and up to 40% of AS patients have a positive family history of SpA. However differences in disease expression in familial and sporadic cases were evaluated in a few studies and there are some discrepancies among those reports. Therefore our aim was to explore the frequency of familial cases in our axial SpA (axSpA) patients and to evaluate the effects of family history of SpA according to the ASAS recommendations on disease phenotype.

Methods: In total 526 patients with axSpA (325 [62%] male; mean age 42.3 ± 11.9 years) followed up in one center were included in the analysis. The study group was consisting 358 (68%) AS and 168 (32%) non radiographic-axSpA patients. Family history of SpA is determined as in ASAS classification criteria and defined as the presence of any of the followings in the first or second-degree relatives; AS, acute anterior uveitis (AAU), ReA, psoriasis, or IBD. Demographic data and disease related characteristics including disease activity, function, quality of life and spinal mobility were collected with a structured method. Structural damage was evaluated by using modified Stoke Ankylosing Spondylitis Spine Score (mSASSS).

Results: 134 (25.5%) of our patients had family history of SpA. AS (102/134; 76.1%) and psoriasis (46; 34.3%) were most frequently found diseases in family history. 89 patients (66%) had affected FDR and 40 (29.8%) had more than one affected family member. Female sex, psoriasis and HLA-B27 positivity were more frequent in familial cases in comparison with sporadic ones. They also had longer symptom duration (Table). However other disease related characteristics including disease activity, spinal mobility and structural damage at the time of assessment were similar between familial and sporadic axSpA patients. Among patients with positive family history, men had higher mSASSS scores (19.0 ± 26.1 vs 3.4 ± 12.4 $p < 0.001$) than women. However in sporadic cases this was not statistically significant (19.0 ± 26.1 vs 14.6 ± 22.8 $p: 0.481$).

Conclusion: In our study group familial axSpA had longer disease duration and more frequent HLA-B27 positivity. However disease expression including functional limitation and structural damage did not differ between familial and sporadic cases.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Clinical/Epidemiology Studies

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Axial spondyloarthritis (axSpA) is a chronic inflammatory disease that mainly affects axial skeleton. Although some differences like sex and objective signs of inflammation were described between ankylosing spondylitis and non-radiographic (nr-) axSpA patients, overall disease burden was found to be similar in these subgroups of axSpA. The association of chronic inflammation with cardiac dysfunction was well documented in many inflammatory rheumatic diseases. However it was not assessed in the subgroups of axSpA. Advanced two-dimensional (2D) speckle tracking echocardiographic analysis is more sensitive and accurate method of early detection of myocardial dysfunction than the conventional 2D transthoracic echocardiography (TTE). Therefore the aim of this study was to evaluate the left ventricular function by using speckle tracking echocardiography in patients with both r- and nr-axSpA.

Methods: In total 72 patients with ankylosing spondylitis (72% male) and age- and sex-matched 38 patients with nr-axSpA (58% male) and 56 healthy control subjects (54% male) were included in the analysis. Patients with hypertension, diabetes and known cardiac disease were excluded. All patients underwent detailed echocardiographic examination including M-mode, pulsed-wave Doppler imaging, pulsed-wave tissue Doppler imaging and 2D speckle tracking.

Results: Age and sex distribution were not different between groups. Some demographic and disease related characteristics were shown in the table. BASDAI, BASFI, global assessment of disease activity and ASAS-HI scores were found to be similar between r- and nr-axSpA patient groups. Although ejection fraction (EF) (P=0.449) and the other echocardiographic variables were similar between groups, global longitudinal strain (GLS) (P=0.004) was found to be different among groups (table) in ANOVA analysis. Post-hoc tests showed that GLS was similar between nr-axSpA and

control groups however GLS was significantly low in r-axSpA patients. In univariate analysis GLS was correlated with age (P=0.032) and peripheral arthritis (P=0.035). However in regression analysis peripheral arthritis (P=0.009) was found as the only independent predictor of GLS.

Conclusion: The results of the present study showed that left ventricular function had impaired in ankylosing spondylitis patients and impaired ventricular function might also be the other differentiating factor between radiographic and nr-axSpA patients.

Table. The demographic and disease related characteristics of study groups.

	Ankylosing Spondylitis (n=72)	Non-radiographic axSpA patients (n=38)	Control subjects (n=56)	p

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Clinical/Epidemiology Studies

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Spondyloarthritis include two major phenotypes: ankylosing spondylitis (AS) and psoriatic arthritis (PsA). 10% of AS patients have concomitant psoriasis, while 25% - 70% of PsA patients have axial disease. The question arises whether AS with concomitant psoriasis and axial PsA are essentially the same disease?

The aim of this study was to compare the demographic, genetic, clinical and radiographic characteristics of patients with AS, with and without psoriasis, to axial PsA patients.

Methods: A retrospective analysis of prospective observational cohorts was performed. Four cohorts of patients were recruited from AS and PsA clinics at one center: 1. AS without psoriasis, 2. AS patients with psoriasis (ASPs), 3. Axial PsA patients (radiographic sacroiliitis: \geq bilateral grade 2 or unilateral grade 3), 4. Peripheral PsA patients. All patients were 18 years old and were followed prospectively according to the same protocol. The four groups were compared using ANOVA and Pearson chi-square tests. Axial PsA was subsequently compared specifically to the ASP group using the appropriate tests. Adjusted means (AM) were used for variables that change over time. They were calculated by plotting the values of the variables over time and calculating the area under the curve. AM more accurately account for the varying time intervals between visits that are common in the usual clinic setting. A logistic regression was performed to assess the differences in clinical and radiographic features between ASP vs. axial PsA adjusting for demographic and genetic variables and follow-up duration. When $p < 0.05$ the results were considered statistically significant.

Results: Table number 1: Four group comparison

Variable	Ankylosing spondylitis		Psoriatic arthritis		P Value
	Without psoriasis (N=675)	With psoriasis (N=91)	Axial (N=477)	Peripheral (N=826)	
Age at diagnosis	30.4 (12.0)	28.7 (11.0)	35.6 (13.3)	39.3 (13.7)	z0.001
Male gender n (%)	489 (72%)		303 (64%)	414 (50%)	<0.001
HLA-B*27 n (%)	509 (75%)	75 (82%)	91 (19%)	77 (9%)	<0.001

Biologic treatment n (%) at baseline	145 (21%)	26 (29%)	34 (7%)	56 (7%)	<0.001
Sacroiliitis grade 3,4 (unilateral or bilateral) at baseline	576 (79%)	82 (87%)	282 (51%)	—	<0.001

ASDAS=ankylosing spondylitis disease activity score; BASDAI=Bath ankylosing spondylitis disease activity index; BASMI=Bath ankylosing spondylitis metrology index.

Table number 2: The Comparison of ASPs and axial PsA

Variable	ASPs (N=91)	Axial PsA (N=477)	P Value
Age of diagnosis	28.7 (11.0)	35.6 (13.3)	<.001
Male, n (%)	69 (76%)	303 (64%)	0.024
HLA B27, n (%)	75 (82%)	91 (19%)	<.001
Adjusted mean active arthritis (tender and swollen joints)	1.5 (3.5)	5.2 (6.5)	<.001
Presence of back pain at presentation, n (%)	82 (90%)	100 (21%)	<.001
Adjusted mean ASDAS ESR	2.3 (0.9)	2.2 (1.0)	0.47
Adjusted mean BASDAI	4.1 (2.0)	3.5 (2.2)	0.028
Adjusted mean BASMI	2.9 (2.2)	1.8 (1.4)	<.001
Adjusted mean physician global assessment	2.4 (0.9)	2.1 (0.6)	<.001
Adjusted mean patient global assessment	4.3 (2.2)	4.0 (2.3)	0.27
Biologic treatment at baseline, n (%)	26 (29%)	70 (15%)	0.001

ASDAS=ankylosing spondylitis disease activity score; BASDAI=Bath ankylosing spondylitis disease activity index; BASMI=Bath ankylosing spondylitis metrology index

Table number 3: Logistic regression, outcome: ankylosing spondylitis with psoriasis compared to axial PsA (axial PsA reference group)

Variable	Univariate			Multivariate		
	OR	95% CI	P value	OR	95% CI	P value
Adjusted mean active arthritis (tender and swollen joints)	0.68	0.61 - 0.76	<.0001	0.75	0.64- 0.86	<.0001
Adjusted mean ASDAS – ESR	1.1	0.83- 1.45	0.51			
Adjusted mean BASMI	1.41	1.21- 1.63	<.0001	1.44	1.02- 2.03	0.04
Sacroiliitis (grade 3,4) at diagnosis	7.58	3.68- 15.59	<.0001	3.24	1.10- 9.49	0.03

Adjusted variables: follow-up duration, age of diagnosis, sex, HLA-B*27, biologic/NSAIDS treatment.

ASDAS-ESR=ankylosing spondylitis disease activity score; BASMI=Bath ankylosing spondylitis metrology index; NSAIDS=non-steroidal anti-inflammatory drugs

Conclusion: AS patients, with or without psoriasis, are different demographically, genetically, clinically and radiographically to axial PsA patients. AS patients are younger, male predominant with higher HLA-B*27 rates. They have worse axial disease, while axial PsA have worse peripheral arthritis.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Clinical/Epidemiology Studies

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Cardiovascular disease (CVD) is one of the main cause of mortality and morbidity in patients with spondyloarthritis (SpA), partially explained by traditional CV risk factors (CVRF). Other non-conventional CVRF, probably related to chronic systemic inflammation, may be involved. In this sense, lipoprotein (a) [Lp (a)], an non-conventional risk factor with proatherogenic and thrombogenic properties, could be involved, since it seems to act as an acute-phase reactant, however, there are few data on this aspect in these patients. The purpose of this study is to evaluate the prevalence of hyperlipoproteinemia (a) in patients with SpA and analyze the possible related factors.

Methods: Analysis of the baseline visit of patients with ankylosing spondylitis (AS) and psoriatic arthritis (PsA) of the CARMA project (CARDiovascular in Reumatology), a prospective cohort study of 10 years of follow-up, to evaluate the cardiovascular risk in chronic rheumatic inflammatory diseases, including rheumatoid arthritis, AS and PsA, followed in 67 Spanish rheumatology centers. A multivariate logistic regression model was performed, in which the dependent variable was hyperlipoproteinemia (a), defined as the plasma concentration of lipoprotein (a) [Lp (a)] > 50 mg/dl. Sociodemographic factors and those related to the disease itself, classic CVRF, lipid profile and apolipoproteins, and treatments have been included as independent variables.

Results: 1459 patients were analyzed, 738 with AS and 721 with PsA, and 677 controls. Plasma concentrations of Lp(a) were available in 57.7% of the patients with AS and in 57.1% of the patients with PsA, and in 58% of the controls. A 19.2% (95% CI: 16.80-22.05) of the patients with SpA, 20.7% (95% CI: 16.91-24.82) of AS and 17.7% (95% CI: 14.15-21.75) of PsA, respectively, and a 16.7% (95% CI: 13.23-20.86; p=0.326) of the control group, had hyperlipoproteinemia (a), without statistically significant differences between groups. After adjusting for age and sex, SpA patients were more likely to have hyperlipoproteinemia (a) than control group (OR : 1.43, CI :1.00-2.04; p=0.05), especially in patients with AS (OR: 1.81, 95% CI: 1.18-2.77; p=0.007). In the model adjusted for possible confounding factors, high values of apolipoprotein B in all patients, non-steroidal antiinflammatories in AS, and sex (women) in PsA, were associated with a higher probability of presenting hyperlipoproteinemia (a).

Conclusion: Patients with SpA show a moderately increased risk of hyperlipoproteinemia (a) compared to the control group, especially in those with AS. No specific factors of the disease have been identified that are associated with hyperlipoproteinemia (a) in each of the analyzed groups. The determination of Lp (a) may be of potential interest to improve the assessment of CV risk in patients with SpA, especially in those with a moderate / high CV risk according to the algorithms of the risk tables.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Clinical/Epidemiology Studies

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Psychological disturbances, frequently observed in inflammatory rheumatic diseases, seem to negatively influence patient's clinical status and treatment response. The aim of this study was to examine the longitudinal impact of depression (D)/anxiety (A) in treatment response, disease activity, physical disability and quality of life in patients with Ankylosing Spondylitis (AS).

Table 1. Difference-in-differences estimation results. (p-value<0.05).

Difference-in-differences		Baseline Mean difference (p-value)	3 Months Mean difference (p-value)	Global Mean difference (p-value)
Anxiety symptoms (HADS ₂₁)	ASDAS-CRP	0.27 (0.308)	0.30 (0.317)	0.03 (0.317)
	BASDAI	1.63 (0.009†)	1.08 (0.106)	-0.55 (0.541)
	BASFI	2.04 (0.006†)	1.62 (0.044†)	-0.42 (0.693)
	ASQoL	7.32 (<0.001†)	4.53 (0.005†)	-2.79 (0.199)
	ESR	-7.24 (0.208)	-2.99 (0.644)	4.26 (0.622)
	CRP	-10.05 (0.017†)	-0.503 (0.914)	9.54 (0.128)
	Patient's VAS	21.43 (0.003†)	21.52 (0.006†)	0.09 (0.993)
	Physician's VAS	-0.70 (0.909)	-0.54 (0.931)	0.16 (0.986)
	Fatigue	1.90 (0.014†)	1.05 (0.204)	-0.84 (0.452)
Depression symptoms (HADS ₂₁)	ASDAS-CRP	0.35 (0.339)	0.19 (0.665)	-0.17 (0.789)
	BASDAI	0.93 (0.293)	0.56 (0.587)	-0.37 (0.784)
	BASFI	2.94 (0.003†)	1.88 (0.100)	-1.06 (0.476)
	ASQoL	5.84 (0.004†)	5.26 (0.022†)	-0.58 (0.846)
	ESR	9.85 (0.168)	-1.48 (0.859)	-11.33 (0.301)
	CRP	-4.44 (0.450)	1.36 (0.843)	5.80 (0.522)
	Patient's VAS	15.25 (0.121)	1.70 (0.881)	-13.55 (0.366)
	Physician's VAS	25.76 (0.005†)	-3.16 (0.721)	-28.92 (0.023†)
	Fatigue	0.69 (0.509)	0.271 (0.825)	-0.424 (0.793)

Methods: Data from patients who fulfilled the modified New York criteria for AS were collected at baseline, weeks 2 and 14 post-treatment with Adalimumab. The Hospital Anxiety and Depression Scale (HADS) was used to evaluate D/A symptoms severity. The primary outcomes were AS disease activity score - C reactive protein (ASDAS-CRP), Bath AS Disease Activity Index (BASDAI), Bath AS Functional Index (BASFI) and AS Quality of Life (ASQoL) Scale. Secondary outcomes were patient and physician global assessment by Visual Analogue Scale (VAS), erythrocyte sedimentation rate (ESR), CRP and BASDAI question 1 (fatigue). Difference-in-differences estimation took into account the covariates gender, age at baseline and disease duration.

Results: Data from 54 patients were included (Table 1). At baseline, D/A symptoms significantly influenced the mean value of BASFI ($p=0.006$; $p=0.003$) and ASQoL ($p<0.001$; $p=0.004$). On the other hand, BASDAI ($p=0.009$), CRP ($p=0.017$), patients' VAS ($p=0.003$) and fatigue ($p=0.015$) were only influenced in the individuals with A symptoms, while the physician's VAS ($p=0.005$) was only influenced in patients with D symptoms. After 14 weeks of treatment, significant differences in ASQoL mean values were found in patients with both D/A symptoms at baseline ($p=0.005$; $p=0.022$) and in BASFI ($p=0.044$) and patient VAS ($p=0.006$) for the population showing only A symptoms at the baseline. Apart from the physician's VAS ($p=0.023$), D/A baseline symptoms did not affect the treatment response.

Conclusion: Psychological status does not seem to affect response to treatment with Adalimumab, even if the overall characteristics of the population are different at baseline between patients with/without D/A symptoms.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Clinical/Epidemiology Studies

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Uveitis is a common extra-articular manifestation in Spondyloarthritis (SpA). The purpose of this study was to analyze incidence of uveitis in SpA patients during the last decade and to evaluate the impact of the biologic therapies on this incidence.

Methods: This study is an ancillary analysis of the ASAS-COMOSPA study and included patients fulfilling ASAS SpA criteria from 22 countries. We calculated overall cumulative incidence of uveitis and evaluated difference across continents and clinical phenotypes. Patients were stratified according to date of disease onset [before 2000 and after 2000 (Biologics Era)]. We performed univariate and logistic multivariate models looking for risk factors associated with uveitis. A p-value of 0.05 was considered statistically significant.

Results: We included 3984 patients. 65% were male with a mean disease duration was 15 ± 12 years and mean age at disease onset of 28 ± 13 years. HLA-B27 were positive in 72%. 805 patients developed uveitis, with a cumulative incidence of 0.20 in 32137 patient-years from disease onset. Median time to develop uveitis was 9 ($p_{25-p75}=3-16$) years and it was present at disease onset in 5% of patients. Inflammatory bowel disease (IBD) showed the higher frequency of uveitis (33%), enthesitis (24%), axial involvement (22%), peripheral arthritis (20%), dactylitis (19%) and psoriasis (13%). 94% of patients with IBD and 89% of patients with enthesitis, also presented axial involvement. 88% of patient with uveitis were HLA-B27 positive and 17% had first/second degree relatives with uveitis. Patients who meet ASAS Peripheral Criteria

showed less frequency of uveitis than those who meet ASAS Axial Criteria (11% vs 23%, $p<0.01$). Europe show a significantly higher cumulative incidence of uveitis (0.23) than Asia (0.20), Latin-America (0.17), North-America 0.15 and Africa 0.18. Patients with disease diagnosis after 2000 showed a lower cumulative incidence of uveitis than those with disease diagnosis before 2000 year (14% vs 27%, $p<0.01$). Risk factors associated with uveitis were HLA-B27 positive, family history of uveitis, enthesopathy and/or IBD. (table 1).

Conclusion: One fifth of patient with SpA developed uveitis. HLA-B27 positive and family history of uveitis were associated with higher risk of uveitis. Patients from Europe showed the highest frequency. Patients with disease onset after biologics development had a lower cumulative incidence of uveitis, but after adjust for multiple confounders, did not reach statistical significance.

Table 1. logistic multivariate analysis using uveitis as dependent variable.

Dependent variable=Uveitis	Adjusted Odd Ratios	
	OR (CI ⁹⁵)	p
Female	1.06 (0.85-1.31)	>0.20
Disease duration (years)	1.03 (1.02-1.05)	<0.01
HLA-B27 positive	3.25 (2.41-4.39)	<0.01
Family history of uveitis	4.33 (3.07-6.12)	<0.01
Peripheral arthritis	1.00 (0.80-1.24)	>0.20
Peripheral enthesitis	1.27 (1.03-1.57)	0.03
Dactylitis	1.08 (0.78-1.48)	>0.20
Axial involvement	0.83 (0.50-1.40)	>0.20
Psoriasis	0.68 (0.50-0.93)	0.02
IBD	2.20 (1.51-3.21)	<0.01
Continent (Africa=0)		
Asia	0.85 (0.51-1.40)	>0.20
Europe	0.76 (0.46-1.24)	>0.20
Latin-America	0.83 (0.47-1.47)	>0.20
North-America	1.13 (0.57-2.27)	>0.20
ASAS peripheral criteria	0.89 (0.60-1.33)	>0.20
Disease onset >=2000 year (Biologics Era)	0.79 (0.58-1.08)	0.14

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Clinical/Epidemiology Studies

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Enteropathic arthritis (EA) belongs to the spondyloarthritis (SpA) spectrum of diseases and occurs in patients affected by inflammatory bowel diseases (IBD). Several works demonstrated that ultrasonography (US) is feasible, reliable and easily accessible means of detecting chronic and active enthesal abnormalities even in a subclinical context (1,2) in SpA patients. Aim of our study was to evaluate the prevalence of US enthesal involvement in patients with EA at the level of the distal insertion of patellar ligament.

Methods: Twenty-two consecutive AE patients (12 with Crohn's disease and 10 with ulcerative colitis; 8 females and 14 males; mean age 44.7 years, range 18-72 years; mean AE duration 10.1 years range 4-21 years) and 18 healthy age- and gender-matched controls (8 females and 10 males; mean age 48 years, range 24-68 years) underwent an US examination (ESAOTE MyLAB 70 6-18 MHz linear array transducer) according with the validated Madrid Sonographic Enthesis Index (MASEI). Clinical and clinimetric variables were assessed in both groups according with daily clinical practice.

Results: Focusing on the 44 distal patellar entheses we identified a higher prevalence of all the elementary lesion analysed. In 34 entheses we identify a dishomogeneous echostructure (77.3% vs 33.3%; $p=0.0001$), in 38 structural thickness (86.4% vs 66.7%; $p=0.03$), in 16 power Doppler positivity (36.3% vs 16.7%; $p=0.04$), in 17 presence of calcifications (38.6% vs 16.7%; $p=0.03$) and in 8 entheses the presence of erosions (18.8% vs 0%; $p=0.007$). A simultaneous presence in the same entheses of dishomogeneous echostructure, structural thickness and power Doppler positivity suggestive for US active enthesitis was found in the 45% of the examined patients.

Conclusion: US detectable signs of enthesopathy and enthesitis are very frequent in EA patients even when we analyse only the distal entheses of the patellar ligament. Further studies involving a larger number of patients are needed to confirm these preliminary data.

Fragility Fractures in Psoriatic Arthritis Patients: A Matched-Control Study

Luciano Fernando Lo Giudice¹, Marina Scolnik², Florencia Pierini³, Nicolas Martin Marin Zucaro¹, John Fredy Jaramillo Gallego¹ and Enrique R Soriano², ¹Rheumatology Unit, Internal Medicine Service, Hospital Italiano de Buenos Aires, Capital Federal, Argentina, ²Rheumatology Unit, Internal Medicine Service, Hospital Italiano Buenos Aires, Argentina, Buenos Aires, Argentina, ³Rheumatology Unit, Internal Medicine Service, Hospital Italiano de Buenos Aires, CABA, Argentina

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Clinical/Epidemiology Studies

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with Psoriatic Arthritis (PsA) in spite of having bone production as one of their characteristic features, very often have osteoporosis, but scarce data is available on fracture risk. Our objective was to compare incidence of osteoporotic fractures in PsA patients diagnosed after year 2000 with matched controls from a university hospital-based health management organization (HMO).

Methods: Consecutive PsA patients diagnosed after year 2000, from the HMO, were matched (age and sex) with controls (1:2). The follow-up period began at the first medical claim at the HMO. Subjects were then followed until they voluntarily left the HMO, a fracture occurred, the end of study (May 1st 2018), or death. Electronic medical records were reviewed and demographic, clinical and treatment data were collected. Incidence rates per 1000 persons-years (PY) of distinct types of fractures after index dates were calculated and compared between groups. A multivariate cox regression analysis was performed to investigate determinants of fractures.

Results: 92 PsA patients were included. Patients characteristics are shown in table 1. 92 PsA patients contributed with 788.2 PY of follow up, and 184 controls contributed 1718.4 PY. Media age at psoriasis and PsA diagnosis was 34.5 years (SD 19.3) and 49.1 years (SD 17.7) respectively. 8.7 % (95% CI 4.4-16.5) of PsA patients had axial involvement. 84.6 % (95% CI 75.5-90.8) of PsA patients were treated with conventional DMARDs and 29.7% (95% CI 21.1-40.0) received biologic treatment. Topical corticosteroids were used by 60.9% (95% CI 50.5-70.4) of PsA patients and 22.8% (95% CI 15.3-32.6) received oral corticosteroids. No difference was found in the overall fracture incidence rate per 1000 PY between PsA and controls (10.2, 95% CI 5.1-19.3, vs 8.7, 95% CI 5.2-13.9, $p=0.36$). Vertebral fractures were more frequent in PsA patients with an incidence rate of 10.2 per 1000 persons-years (95% CI 5.1-19.3) versus 4.6 per 1000 persons-years in the control group (95% CI 2.4-9.2), but it did not reach statistical significance ($p=0.06$). In the Cox regression analysis, after adjusting for bisphosphonate use, only age (HR 1.10, 1.05-1.16, $p<0.001$) and a female sex (HR 3.94, 1.11-13.91, $p=0.03$) were associated with fractures while PsA diagnosis and use of corticosteroids were not.

Conclusion: In this cohort of PsA patients diagnosed after year 2000, no overall increased risk of fractures was found in comparison with matched controls. This may be due to a rational use of corticosteroids.

	PsA patients (n=92)	Controls (n=184)	p

Session Date: Monday, October 22, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Clinical/Epidemiology Studies

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Functional status gets worse with comorbidities regardless of disease activity in patients with rheumatoid arthritis (RA). However, the impact of comorbidities on physical function in ankylosing spondylitis (AS) and psoriatic arthritis (PsA) is less known.

The aim of this study is to assess the impact of comorbidities on physical function in patients with AS and PsA.

Methods: Analysis of the baseline visit from the ongoing multicentric, observational, prospective, CARdiovascular in rheuMATology (CARMA) study. For this study, data from patients with AS and PsA were analyzed. Two different multivariate models were performed, where physical function was the dependent variable (using BASFI in AS and HAQ in PsA) and the following independent variables: comorbidities, a proxy for the Charlson index (CCIp) (minimum 0; maximum 27), sociodemographic (age, sex and educational level), disease activity (ESR, CRP and BASDAI in AS; while SJC, TJC, CRP, ESR, DAS, dactylitis count and PASI in PsA), disease duration, radiographic damage (defined as “spinal radiographic changes” in AS and “presence of erosions” for PsA), and treatments (for the rheumatic disease and comorbidities); adjusted for disease activity, radiographic damage and sociodemographic variables. Results are presented as β coefficients and p-values.

Results: 38 patients with AS and 721 with PsA included (mean age at inclusion 48.1 ± 11.7 and 51.8 ± 12 years, respectively, $p < 0.001$). Patients with AS: median BASFI 3.1 [interquartile range (IQR): 1.3-5.2], BASDAI 3.5 [IQR: 1.7-5.3], mean CCIp 1.32 ± 0.73 . PsA patients: HAQ 0.4 [IQR: 0.0-0.9], DAS 28 2.9 [IQR 2.0-3.8], mean CCIp 1.30 ± 0.66 . A CCIp > 1 was found in 21% of the patients. Patients with PsA have higher BMI and more hypercholesterolemia; on the other hand, we found more smokers among patients with AS (all $p < 0.001$). No differences between the two groups were found regarding the different comorbidities, except for a higher prevalence of chronic pulmonary disease in patients with AS. Patients with PsA with higher CCIp showed worse adjusted physical function (β : 0.09; $p = 0.005$). In patients with AS, the CCIp was not independently associated with physical function, but thyroid disease (β : 1.18, $p = 0.002$), disease activity (BASDAI; β : 0.81, $p < 0.001$) and spinal radiographic damage (β : 0.61, $p < 0.001$) were independently associated. In patients with PsA, obesity (β : 0.09; $p = 0.04$), disease duration (β : 0.01; $p = 0.009$), disease activity (DAS-28, β : 0.19; $p < 0.001$) and NSAIDs (β : 0.1; $p = 0.014$), corticosteroids (β : 0.12; $p = 0.02$) and biologic DMARD use (β : 0.15; $p < 0.001$) were associated with worse physical function. In contrast, a higher educational level was associated with less disability (β : -0.27; $p = 0.004$).

Conclusion: The presence of comorbidities in patients with PsA is independently associated with worse physical function, similar to what happens in RA. Early detection and control may yield an integral management of the disease and better final outcomes.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Clinical/Epidemiology Studies

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The Patient-Reported Outcomes Measurement Information System (PROMIS) developed by the US National Institutes of Health is a patient-reported outcomes system designed to measure disease burden across a wide array of chronic diseases and the general population¹. We sought to evaluate the validity of selected PROMIS measures in Ankylosing Spondylitis (AS) patients across self-reported Assessment in Spondyloarthritis International Society core set and patient-identified domains.

Methods: Patients at the Houston, Texas site of the Prospective Study of Outcomes in Ankylosing Spondylitis, a longitudinal, prospective, AS cohort from Sept 2017-May 2018 were enrolled in a sub-study in which they completed PROMIS short forms (SFs) assessing global health, depression, fatigue, pain and physical function in addition to the other legacy measures collected in the cohort study. PROMIS SFs ranged from 3-12 questions. We assessed internal

consistency using Cronbach's alpha. Content validity was assessed by asking patients if the PROMIS SF questions related to their disease. We assessed construct validity through examination of score distributions, floor effects and through examination of the Spearman's correlation coefficients between PROMIS measures and existing legacy AS measures (e.g. BASDAI, BASFI, Global Numeric Rating Scale (NRS), Pain NRS and CES-D) of similar domains. We hypothesized that there would be moderate to strong correlation (e.g., 0.6-1) between the PROMIS measures and the target legacy measures.

Figure 1. Distribution of select PROMIS and legacy scores in Ankylosing Spondylitis patient sample (N=82). Representative histograms (Physical Function, Global, and Fatigue) show legacy measures floor effects not observed in PROMIS measures. Similar results seen on all domains analyzed

Table 1. PROMIS and legacy measure scores in AS patients

	N	Mean	Median	Std. Deviation	Range	Minimum	Maximum	Cronbach's alpha (95% CI)	Correlation Coefficients ^a

Bath Ankylosing Spondylitis Functional Index	82	2.8549	2.2000	2.62279	9.40	0.00	40	—	—

a. Spearman's correlation coefficient between legacy and PROMIS measure in each domain.

** Correlation is significant at the 0.01 level (2-tailed). * Correlation is significant at the 0.05 level (2-tailed)

Results: Participants (n=82) were mostly male (75%), white (84%), college educated (82%) with a mean age of 53 years. All patients felt the PROMIS SFs addressed AS disease aspects. Legacy measures demonstrated a floor effect that was not present in the PROMIS SFs (Figure 1). Strong internal consistency was noted in the PROMIS SFs ranging from .843-.973. PROMIS Global, Depression, Fatigue, Pain, Physical Function correlated moderately-strongly (rho .684-.865) with the appropriate legacy measures (Table 1). Patients reported time to complete the entire PROMIS SFs packet was <10 minutes overall.

Conclusion: This study demonstrates the content and construct validity of PROMIS SFs to assess AS symptoms from a single-center sample of AS patients. Further research is needed to assess discrimination (the ability of PROMIS SF to distinguish disease activity groups), responsiveness, feasibility/resource burden, and translations for AS patients.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Clinical/Epidemiology Studies

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: A broad spectrum of MRI lesions has been described in the sacroiliac joint (SIJ) of patients with axial spondyloarthritis and a recent consensus from the ASAS MRI group has culminated in updated lesion definitions (ASAS_MRI_defⁿ). There has been no detailed evaluation of MRI scans from the ASAS Classification Cohort (ASAS-CC)¹ to determine the spectrum of MRI lesions in the SIJ in this cohort according to these definitions. We conducted a multi-reader exercise of ASAS-CC MRI scans comprising 7 experts from the ASAS-MRI group to compare the frequencies and specificity of different lesion types according to diagnostic category.

Methods: ASAS_MRI_defⁿ were recorded in an eCRF that comprises global assessment (lesion present/absent), links to reference images, and detailed scoring (SPARCC SIJ inflammation, SPARCC SIJ structural). MRI images were available from 278 of the 495 cases that had MRI performed in the ASAS-CC and were available in a variety of formats (DICOM (n =175), JPEG (n =71), DICOM film (n =32)) and sequences, axial and semicoronal orientations. Image quality was considered sufficient for global assessment in all cases by all readers. Detailed SPARCC scoring data was based only on assessment of images in DICOM format (n =175). Comparison of active and structural lesion frequencies was assessed according to individual and majority agreement ($\geq 4/7$ readers) data. MRI lesions were compared between axial SpA and non-axial SpA back pain patients according to diagnostic ascertainment by local rheumatologists.

Results: Active and structural lesions discriminated equally well between axSpA and non-axSpA patients, and the frequency of active and structural lesions in each subgroup of patients was comparable. SPARCC BME, erosion, and fatty lesion scores were significantly higher in those with axSpA (Table). 8.6% and 11.4% of axSpA and non-axSpA, respectively, had subchondral BME which was not deemed typical of axSpA. Inflammation in the erosion cavity and enthesitis were only reported in axSpA. Erosion was the most frequently observed structural lesion (36.6%) followed by fatty lesion (25.2%) in patients with axSpA with <5% of non-axSpA having these lesions.

Conclusion: In this first central reader analysis of MRI images from the ASAS-CC we demonstrate similar frequencies of active and structural lesions typical of axSpA. Erosions and fatty lesions are common structural lesions in axSpA. Some degree of subchondral inflammation, which was not considered typical of axSpA, was also detected, both in axSpA and non-axSpA.

Serious Infections Among Psoriatic Arthritis Patients Taking TNF Inhibitors Versus Non-TNF Biologics: A Systematic Review and Network Meta-Analysis

Saad Ullah Malik¹, Kinza Muzaffar², Jawad Bilal³, Warda Faridi⁴ and Salman Muddassir⁵, ¹University of Arizona, Tucson, AZ, ²Internal medicine, Oak Hill Hospital, affiliated with USF, spring hill, FL, ³Internal Medicine, University of Arizona, Tucson, AZ, ⁴Department of Hematology/Oncology, University of Arizona, Tucson, AZ, ⁵Oakhill Hospital, Brooksville, FL

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Clinical/Epidemiology Studies

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Psoriatic arthritis (PsA) is an inflammatory condition of peripheral joints. If left untreated, it can lead to significant pain and joint deformity. Its treatment has undergone a revolution with the advent of TNF inhibitors and non-TNF biologics. Generally, these agents are well tolerated but due to their immunosuppressive properties there has been concerns for the increased risk of infections. The aim of this study was to estimate the risk of serious infections among patients with active PsA who are receiving either TNF inhibitors or non-TNF biologics.

Methods: We conducted a systematic review and random-effects network meta-analysis of randomized clinical trials in STATA 15.1 assessing the occurrence of serious infections with the use of TNF inhibitors (etanercept, adalimumab, infliximab, certolizumab pegol, golimumab) and non-TNF biologics (apremilast, secukinumab, ixekizumab, brodalumab, ustekinumab, abatacept, tofacitinib, guselkumab, rituximab, tildrakizumab) in adult patients with PsA. We used random effects model to estimate the pooled odds ratios (ORs) and 95% confidence interval (CI). Serious infections in included trials were defined as those requiring hospitalization or discontinuation of therapy. Studies from five databases: PubMed, EMBASE, Cochrane, Web of Science and Clinicaltrials.gov databases were included from date of inception to June 4, 2018. The risk of bias of each study was evaluated using Grading of Recommendations Assessment, Development and Evaluation (GRADE) tool for clinical trials.

Results: 2,052 citations were identified and on reviewing full-text papers 16 randomized clinical trials (n=4705) met our inclusion criteria. Based on 12 to 24-week placebo-controlled follow-up data, we identified seven trials using TNF inhibitors (infliximab, adalimumab, certolizumab and golimumab) and 9 trials using non-TNF biologics (apremilast, secukinumab, ixekizumab, bimekizumab, ustekinumab, abatacept, tofacitinib). There was no statistically significant difference in odds ratio of serious infection between TNF inhibitors and non-TNF biologics. Overall, ustekinumab had lowest odds of serious infections (0.17, 95% CI: 0.01-4.1) followed by golimumab (0.23 95% CI: 0.06-0.92) and apremilast (0.50, 95% CI: 0.07-3.50). Highest rate of serious infection was observed with infliximab (OR 2.95, 95% CI: 0.30-28.16).

Conclusion: TNF inhibitors were not found to confer a higher risk of serious infection than non-TNF biologics. These results provide a better understanding of the risk of serious infection from psoriatic arthritis pharmacotherapy in patients.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Clinical/Epidemiology Studies

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Extra-articular manifestations (EAMs) in rheumatic diseases have been previously found to negatively impact health outcomes including quality of life and work capacity. Even though EAMs may be directly associated with worse response to treatment, differences in patient-reported outcomes (PROs) based on the presence of EAMs could be an important contributory variable. The objective of this study was to assess the impact of EAMs on PROs among patients with active AS or PsA followed in Canadian routine clinical care.

Methods: Patients eligible for the COMPLETE studies are anti-TNF α naïve adults, with active AS or PsA per the judgment of the treating physician, who require change in their treatment regimen. In the current analysis, patients enrolled between July 2011 and June 2017 were included. The EAMs were defined as the presence of the following at baseline: enthesitis, uveitis, IBD or psoriasis (EAM_{AS1} for AS); enthesitis, uveitis, or IBD (EAM_{AS2} for AS); enthesitis or dactylitis (EAM_{PsA} for PsA). The PROs included the Short Form Health Survey (SF-12), Work Limitations Questionnaire (WLQ), and Beck's Depression Inventory (BDI). The PROs were compared between patients with and without EAMs using the independent samples t-test. The independent association between presence of EAMs and PROs at baseline was assessed with multivariate generalized linear models adjusting for disease state (high/very high vs. inactive/low/moderate disease based on the BASDAI for AS and the DAS28 for PsA), disease type, and ever smoking.

Results: A total of 609 AS and 406 PsA patients were included with a mean (SD) age of 43.1 (13.4) and 51.3 (12.3) years, respectively. The EAM_{AS1} and EAM_{AS2} prevalence among AS patients was 33.9% and 25%, respectively, while among PsA patients EAM_{PsA} prevalence was 45.4%.

In univariate analysis, presence of EAMs in AS was associated with significantly higher disease activity, BDI total score, WLQ mental interpersonal demands (only for EAM_{AS1}), WLQ physical demands, WLQ time demands, SF-12 physical function, SF-12 role physical, SF-12 bodily pain, SF-12 vitality, SF-12 mental health (only for EAM_{AS1}), and the SF-12 physical component summary score (PCS). Among PsA patients, patients with EAM_{PsA} had higher disease activity but no significant association was observed between EAM_{PsA} and PROs.

Upon adjusting for disease state, disease type, and ever smoking, presence of EAM_{AS1}/EAM_{PsA} for AS/PsA patients was associated with significantly higher BDI total score (14.0 vs. 12.6, $p=0.046$) and lower SF-12 physical function (38.4 vs. 44.8, $p=0.047$). When evaluating the impact of EAM_{AS2}/EAM_{PsA} for AS/PsA patients no significant differences were observed in PROs; however, BDI was notably higher among patients with EAMs (14.1 vs. 12.7, $p=0.056$).

Conclusion: In a Canadian routine clinical care setting, a substantial proportion of AS and PsA patients requiring a change in treatment report EAMs. Presence of EAMs, particularly psoriasis for AS patients, was found to be a significant independent predictor of depressive symptoms and reduced quality of life due to worse physical functioning.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Clinical/Epidemiology Studies

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The objectives of this study were: a) to assess the prevalence of uveitis in patients with Spondyloarthritis(SpA) in the Spanish registry REGISPONSER; b) to describe the moment of appearance of the uveitis regarding other SpA symptoms and the date of SpA diagnosis; c) to evaluate the impact of the moment of appearance of uveitis on the use of bDMARDS.

Methods: Data from the Spanish registry REGISPONSER were analysed. The prevalence of uveitis was assessed regarding the time of occurrence of other SpA symptoms (before/ at the same time/ after) and the date of SpA diagnosis. Among patients who had suffered uveitis before SpA diagnosis, we evaluated whether this group presented other SpA features, in order to determine potential diagnostic delay of SpA. Finally, we compared the use of bDMARDS regarding the time of appearance of uveitis through Chi-square test.

Results: From the 2367 patients included in REGISPONSER, 410 (17.5%) patients reported uveitis at anytime of the course of disease. Among these, the date of first uveitis episode was available in 321 patients. Among patients with uveitis, a total of 9.0%, 11.2% and 79.8% had suffered the first episode of uveitis before, at the same time and after other SpA symptoms, respectively (Figure 1). Among patients who had suffered the first episode of uveitis before other SpA symptoms (i.e., uveitis as first SpA manifestation), the median time passed between this episode and the appearance of a second SpA manifestation was 3.0 years. However, considering the date of SpA diagnosis, a total of 36.8%, 13.3% and 49.8% of patients had suffered the first episode of uveitis before, at the same time and after SpA diagnosis, respectively (Figure 2). Among patients who had suffered the first episode of uveitis before SpA diagnosis, the median time passed between this episode and the date of SpA diagnosis was 5.0 years and, among these, 80.2% were HLA-B27 positive. We did not find statistically significant differences ($p=0.827$) in the use of bDMARDs regarding the moment of appearance of uveitis (17.4% vs. 16.7% vs. 19.1% for patients with uveitis before, at the same time and after SpA diagnosis).

Conclusion: Among patients with history of uveitis from REGISPONSER, 36.6% suffered a gap time between the first episode of uveitis and the date of SpA diagnosis (around 5 years) and, among these, 80% were HLA-B27 positive, suggesting a diagnostic delay in these patients. However, this diagnostic delay did not have an impact on the use of bDMARDs.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Clinical/Epidemiology Studies

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Psoriatic Arthritis (PsA) is an inflammatory disease with an important impact on the quality of life and work productivity. Although the activity of the disease is better controlled by the new treatments, work disability remains a frequent problem. Our objectives were to identify associated factors with work disability and fatigue in Psoriatic Arthritis and to compare Work disability and productivity loss in patients with psoriatic arthritis and rheumatoid arthritis.

Methods: A cross-sectional and observational study was conducted. Consecutive patients older than 18 years old, with diagnosis of PsA (CASPAR criteria) and RA (ACR / EULAR 2010 criteria) from 3 centers of Argentina between June 2015 and May 2016 were included.

Variables: Demographic, socio-economics, clinimetric and treatment variables were measured.

Productivity loss was evaluated with Work productivity and Activity Impairment (WPAI) questionnaire and fatigue with the first question of BASDAI. All patients with disability certificate and / or disability benefit were considered "disabled".

Results: 7 patients (37 PsA and 60 RA) were included. PsA PATIENTS: Mean age 46 ± 7.6 years, 67% females. Mean disease duration at diagnosis 62.7 ± 26.2 months and mean age at diagnosis of 40.3 ± 3.3 years. The mean fatigue value was 6.7 ± 2.4 . Seventy percent were unemployed (26/37) and 11 patients were working; 62% (23) of the patients had disability certificates and 38% disability benefits (14). The mean HAQ was significantly higher in the non-working group (1.4 vs 0.6 , $p = 0.002$). In working patients group, the mean productivity loss was 46% and mean daily life activities (DLA) commitment was 58%. BASDAI correlated significantly with greater productivity loss and greater fatigue ($R = 0.64$ and $R = 0.86$ respectively). There was no correlation between productivity loss and DAS28.

RA PATIENTS: Mean age 48.4 ± 3.7 years, 85% females. Mean disease duration at diagnosis 15.4 ± 9.6 months and mean age at diagnosis of 37.7 ± 5.3 years; 80% (48/60) of the patients were unemployed, 71.6% (43) had a disability certificate and 53.3% (32) were receiving disability benefits. There were no differences in HAQ and DAS 28 among working and unemployed patients. The percentage of productivity loss was 29% and the commitment of DLA was 60%. Higher value of EQ5D correlated with lower productivity loss ($r = -0.7$). Age, HAQ, DAS 28, educational level and

socioeconomic status were similar in RA and PsA groups. Mean disease duration at diagnosis was higher for APs (89.7 vs 33.8 months, $p = 0.02$). The frequency of patients with certificate of disability, unemployed and commitment of DLA were similar in both groups.

Conclusion: In PsA patients, disease activity correlated with higher productivity loss and greater fatigue. Work disability and productivity loss were similar between Rheumatoid Arthritis and Psoriasis Arthritis patients.

Spa-Net: A Disease-Specific Integrated Ehealth System and Quality Registry for Spondyloarthritis in Daily Practice in the Netherlands

Casper Webers^{1,2}, Esther Beckers^{1,2}, Yvonne van Eijk-Hustings^{1,2}, Harald Vonkeman³, Mart van de Laar³, Piet van Riel⁴, Monique Efde⁵, Annelies Boonen^{1,2} and Astrid van Tubergen^{1,2}, ¹Department of Medicine, Division of Rheumatology, Maastricht University Medical Center, Maastricht, Netherlands, ²Care and Public Health Research Institute (CAPHRI), Maastricht University, Maastricht, Netherlands, ³Department of Rheumatology, Medisch Spectrum Twente, Enschede, Netherlands, ⁴Department of Rheumatology, Bernhoven, Uden, Netherlands, ⁵Department of Rheumatology, VieCuri Medical Center, Venlo, Netherlands

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Clinical/Epidemiology Studies

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Regular and personalised monitoring of disease activity, functioning, medication use and side effects is essential to improve and maintain patients' health-related quality of life in spondyloarthritis (SpA). Transparency on outcomes and efficiency of care are increasingly demanded, and patient-centeredness is considered essential for quality of care. An integrated eHealth system including an electronic patient medical record (EMR) and real-time quality management system could support these aspects of care. The aim of the current study was to develop and test the usability and acceptability of a disease-specific integrated eHealth system and quality registry for SpA in the Netherlands ('SpA-Net').

Methods: The eHealth system was developed in four phases. First, content and design were discussed with experts in the field of SpA and patients. Second, the database, EMR and quality management system were developed. Third, multiple

rounds of internal and external testing were performed in collaboration with IT specialists, care providers and patients. Fourth, the eHealth system was implemented in practice, usability and acceptability were tested among patients (semi-structured focus interviews) and care providers (feedback meetings).

Figure. Example of graph in SpA-Net reporting the evolution of ASDAS in relation to medication use over time

Results: SpA-Net was designed and developed in 2015 and implemented in May 2016. All patients entered into SpA-Net have a clinical diagnosis of SpA. Information prospectively collected at routine outpatient consultations on diagnosis, demographics, specific SpA manifestations, patient reported outcome measures, clinical outcomes, comorbidities, medication use and safety, supplemented with data from the hospital information system, is directly stored in a database and readily available to care providers. Patients can access an excerpt of these data and complete online questionnaires prior to their visit. The information is presented in graphs wherever possible (Figure). As of May 2018, 1215 patients participated in SpA-Net (mean [SD] age 54.3[14.5] years, 48.4% females). Focus interviews and feedback meetings were held with 16 patients, 9 rheumatologists, and 5 nurses. Patients considered SpA-Net as an accessible and intuitive system that was beneficial to patient-physician communication and had additional value to current care. Points of improvement were the login process and providing more details about the care provider's notes. Care providers appreciated the additional information for (preparing) consultations. Barriers against use were the initial time required to adopt the EMR and the quantity of data entry.

Conclusion: SpA-Net enables (tele-)monitoring of patients with SpA and optimizes knowledge and communication among patients and care providers. Both patients and care providers considered SpA-Net acceptable and a valuable addition to current care for SpA.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Clinical/Epidemiology Studies

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Specific recommendations for the detection/prevention of comorbidities have been proposed for patients with SpA. However, we know that often a gap exists between recommendation and their implementation in daily practice. The objective was to evaluate the impact of a program of systematic screening of comorbidities and its management (detection/prevention).

Methods: Prospective, randomized controlled open, 12-month trial (COMEDSPA, NCT02374749). Patients: Axial SpA (according to rheumatologist). Study treatment: Collection of data by the nurse during a specific out-patient visit for the 5 studied SpA comorbidities (i.e. cardiovascular disease (CVD), osteoporosis, cancer, infection and peptic ulcer) according to the recommendations of the French Society of Rheumatology. In the event of non-agreement with the recommendation the patient was informed. A report summarizing the results of this program prepared by the nurse was sent to the patient's attending physician and rheumatologist. Treatment allocation: After written informed consent, the study treatment was allocated randomly. Outcome variables: the main outcome was the change after one year of a comorbidity score. This weighted composite comorbidity score ranged from 0 to 100, where 0= optimal management of the 5 studied comorbidities and its weights were derived from the percentage of attributed mortality in SpA to each comorbidity in the literature, i.e. 40 points for CV disease, 20 points for cancer and infection, 10 points for osteoporosis and 10 points for peptic ulcer. The number of patients with actions undertaken against comorbidities according to the recommendations during the 12 months following this program were defined as secondary variables

Results: There were no differences in the baseline characteristics of the 502 recruited patients (252 and 250 in the active and control groups, respectively): Age: 46.7±12.2 years, male gender: 62.7%, disease duration: 13.7±11.0y, Xray sacroiliitis 62.8%, MRI sacroiliitis 65.7%, current biologic treatment: 78.3%, ASDAS-CRP: 1.9 ± 0.8, BASFI: 25.6±22.3. During the 1 year follow-up period, the comorbidity score decreased more in the active group, but this difference was not significant (-3,20 vs. -1.85). The number of actions per patient was statistically higher in the group comorbidities : 4.54 ± 2.08 vs 2.65 ± 1.57 (p< 0.001); the number of patients with actions performed to be in agreement with recommendations during the 12-months follow-up was higher in the active group for infections (flu vaccination : 28.6% vs. 9.9%, p<0.01; pneumococcal vaccination: 40.0% vs. 21.1%, p=0.04), skin cancer screening (36.3% vs. 17.2%; p=0.04), and osteoporosis (BMD performed: 22.6% vs. 8.7%, p<0.01; Vitamin D supplementation initiation: 51.9% vs. 9.4%, p<0.01).

Conclusion: This study highly suggests the short-term benefit of program on the systematic screening of comorbidities for its management in agreement with recommendations, even if this young age population of axSpA patients.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Clinical/Epidemiology Studies

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: We examined clinical correlations between disease activity, as measured with the Clinical Disease Activity for PsA (cDAPSA) components and PsA life impact/health-related quality of life (HRQoL) assessed with the PsA Impact of Disease Questionnaire (PsAID12). We hypothesized that PsAID12 scores will be statistically different among the disease activity categories and there will be moderate correlation between PsAID12 and cDAPSA.

Methods: LAPIS-PsA is a multicenter, prospective, non-interventional study assessing long-term apremilast (APR) treatment in adult patients with active PsA in routine clinical practice in Germany. Analyses were performed in patients treated with APR 30 mg BID who had cDAPSA and PsAID12 scores at baseline (BL). We also report data from Visits 1 to 3 (V1: ≥ 1 month; V2: ≥ 4 months; V3: ≥ 7 months). Mean PsAID12 scores and proportions of patients meeting the PsAID12 Patient-Acceptable Symptom State (PASS), defined as PsAID12 of 4, were assessed among each cDAPSA category at BL. PsAID12 scores were compared among the cDAPSA categories at BL and each visit using the ANOVA method. Pearson correlations were calculated between cDAPSA and PsAID12 at BL, V1, V2, and V3.

Clinical Characteristics and Disease Assessments at Visits

	BL (Baseline) N=328*		V1 (21 Month) N=259*		V2 (24 Months) N=251*		V3 (27 Months) N=168*	
	n†	Mean (SD)	n†	Mean (SD)	n†	Mean (SD)	n†	Mean (SD)
SJC (0-66)	251	5.6 (4.5)	148	4.2 (3.9)	150	3.9 (4.3)	48	2.4 (1.9)
TJC (0-66)	296	11.4 (11.1)	205	6.3 (10.6)	198	8.9 (9.6)	97	5.7 (10.4)
Pain (VAS 0-100 mm)	326	52.9 (22.4)	256	46.1 (23.2)	251	39.8 (25.5)	164	36.1 (26.3)
PGA (VAS 0-100 mm)	324	56.1 (22.5)	248	44.8 (23.9)	248	37.7 (26.6)	165	35.7 (26.5)
cDAPSA (0-154)	235	28.6 (14.2)	130	22.5 (13.3)	90	18.7 (11.7)	40	17.7 (9.5)
PsAID (0-12)	318	5.4 (2.0)	263	4.7 (2.1)	234	3.9 (2.2)	160	3.6 (2.3)

Data as observed. *Number of patients included at each visit. †Number of patients with data for the given assessment at both baseline and post-baseline (V1, V2, and V3).
SJC=swollen joint count; TJC=tender joint count; VAS=visual analog score; PGA=patient's Global Assessment of Disease Activity; cDAPSA=Clinical Disease Activity Index for Psoriasis; PsAID=Psoriasis Affecting Impact of Disease.

PsAID PASS by cDAPSA Categories at Baseline and Visits (APR)

Data as observed. Includes patients with both PsAID12 and cDAPSA scores at the specific visit. PsAID12=PsA Impact of Disease Questionnaire; PASS=Patient-Acceptable Symptom State; cDAPSA=Clinical Disease Activity for PsA; REM=remission (cDAPSA ≤ 4); Low=low disease activity (cDAPSA > 4 to ≤ 13); Mod=moderate disease activity (cDAPSA > 13 to ≤ 27); High=high disease activity (cDAPSA > 27).

Results: A total of 330 patients were included in the analysis population. At BL, patients had a mean PsAID12 of 5.4 and a mean cDAPSA of 28.6. Mean PsAID12 and cDAPSA scores are reported at all visits (Table). Patients reported incrementally reduced mean cDAPSA and consistent improvements in PsAID12 scores from BL to V3. Patients with low disease activity (cDAPSA > 4 – ≤ 13) at BL had a mean(SD) PsAID12 score of 3.2 (1.5) with 74% in PsAID12 PASS

(Figure). Those with moderate (cDAPSA >13–≤27) and high (cDAPSA >27) disease activity had mean (SD) PsAID12 scores of 5.0 (2.0) and 6.1 (1.7), with 33% and 11% showing PsAID12 PASS, respectively. Consequently, proportions of patients achieving PsAID12 PASS decreased with higher disease activity (Figure). At BL and V1-3, PsAID12 scores were significantly different among the cDAPSA categories ($P<0.001$). Additionally, significant moderate to high correlations were observed between cDAPSA and PsAID12 at V1 (Pearson's coefficient $r=0.41$; $P<0.0001$), V2 ($r=0.64$; $P<0.0001$), and V3 ($r=0.70$; $P<0.0001$).

Conclusion: Results from this observational PsA study of APR demonstrate a significant correlation between disease activity, as assessed by cDAPSA, and PsA-specific life impact/HRQoL, as measured by PsAID12. More patients met the PsAID12 PASS cutoff at lower disease activity levels, suggesting that improvements in PsA disease activity lead to decreased impact of disease.

Improvement in Morning Stiffness in Subjects with PsA Is Associated with Improvements in Pain, Physical Function, and Patient Global Response to Treatment

Ana-Maria Orbai¹, Jessica Walsh², Peter Nash³, Lichen Teng⁴, Benoit Guerette⁴ and Rieke Alten⁵, ¹Johns Hopkins University School of Medicine, Baltimore, MD, ²University of Utah School of Medicine, Salt Lake City, UT, USA, Salt Lake City, UT, ³University of Queensland, Brisbane, Australia, ⁴Celgene Corporation, Summit, NJ, ⁵Schlosspark-Klinik University Medicine, Berlin, Germany

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Clinical/Epidemiology Studies

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Stiffness is an important component of inflammatory arthritis and plays a role in PsA flare. Patients with inflammatory arthritis report difficulty with activities, “slowing down” due to stiffness, and reduced quality of life. Stiffness is hard to quantify because it cannot be measured directly. We examined morning stiffness in PsA patients treated with apremilast (APR) for 16 weeks in the ACTIVE study and explored the relationship between improvements in morning stiffness and pain, physical function, and Patient's Global Assessment of Disease Activity (PtGA).

Methods: Subjects who met CASPAR criteria for PsA, were biologic-naïve, and had prior exposure to ≤1 conventional disease-modifying anti-rheumatic drug (DMARD) were randomized (1:1) to APR 30 mg BID or placebo (PBO) for 24 weeks; thereafter, all subjects received active treatment with APR. In the post-hoc analysis, changes in morning stiffness severity and effect on pain, physical function, and PtGA from baseline (BL) to Week 16 were compared between treatment arms. Duration of morning stiffness and severity, assessed by subjects' reported categories of stiffness (none, mild, moderate, moderately severe, severe), were reported. An ANCOVA model adjusting the BL value was used in the analysis, where missing values were imputed using the last-observation-carried-forward approach.

Results: A total of 219 subjects were randomized (APR: n=110; PBO: n=109), and 192 remained in the study through Week 16. Most subjects (84%) reported moderate to severe morning stiffness at BL (Table 1). As early as Week 2, a significantly greater proportion of APR vs. PBO subjects experienced morning stiffness severity improvements (≥1 category improvement) (43% vs. 21%; $P=0.0007$). Significant improvements in morning stiffness severity were sustained through Week 16 in APR vs. PBO subjects (46% vs. 26%; $P=0.0015$). Subjects with improvements in morning stiffness severity in the APR and PBO groups showed consistent improvements at the group level in pain, physical function, and PtGA at Week 16 (Table 2). In patients with unchanged stiffness severity, greater improvements were observed across outcome measures in the APR vs. PBO group, although to a lesser extent compared with the improved stiffness group. Worsened morning stiffness was associated with lack of improvement in other patient-reported outcome measures.

Conclusion: In biologic-naïve subjects with PsA treated with APR for 16 weeks, improvement in morning stiffness severity was evident as early as Week 2 and associated with improvements in pain, physical function, and PtGA response.

Table 1. Baseline Subject Demographic and Clinical Characteristics

Characteristic	APR n=110	PBO n=109
Tender joint count, mean (SD)	17 (13)	18 (14)
Swollen joint count, mean (SD)	9 (5)	10 (6)
Duration of morning stiffness, minutes Mean (SD) Median	48 (49) 30	72 (127) 30
Severity of morning stiffness, n (%)		
None	7 (6.4)	8 (7.3)
Mild	6 (5.5)	14 (12.8)
Moderate	43 (39.1)	39 (35.8)
Moderately severe	44 (40.0)	40 (36.7)
Severe	9 (8.2)	8 (7.3)
Missing	1 (0.9)	0 (0)
PGA, mean (SD) [†]	5.9 (2.1)	6.1 (2.0)
Subject's Assessment of Pain, mean (SD) [‡]	6.1 (1.9)	5.8 (2.2)
HAQ-DI score, mean (SD) [§]	1.3 (0.6)	1.2 (0.6)
SF-36v2 PCS, mean (SD)	32.4 (9.2)	33.9 (8.3)
SF-36v2 PF, mean (SD)	33.2 (11.2)	34.2 (10.1)
Previous use of DMARD, n (%)		
Yes	74 (67)	76 (72)
No	36 (33)	31 (28)
Previous use of methotrexate, n (%)		
Yes	81 (55)	86 (81)
No	49 (45)	43 (39)
Oral corticosteroid use, n (%)		
Yes	13 (12)	14 (13)

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Clinical/Epidemiology Studies

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Diagnosis of axial spondyloarthritis (axSpA) often relies on a positive MRI of the SI joints. However, pitfalls in interpretation of MRI images were recently acknowledged (1). Thus reader's expertise might be a source of heterogeneity in patient populations diagnosed with non-radiographic axSpA. Therefore we compared clinical characteristics between axSpA patients diagnosed in general (secondary) hospitals (MRI evaluation by local experts) versus a university-affiliated (tertiary) hospital (MRI central reading by trained radiologists and rheumatologists). In all centers, patients were free to visit a rheumatologist of their choice without necessity for referral by a general practitioner.

Methods: Patients originate from the Be-Giant cohort, a nationwide observational registry of axSpA patients diagnosed by expert opinion. Included patients fulfill the Assessment of SpondyloArthritis international Society (ASAS) classification criteria for axSpA (2) and are anti-TNF- α naïve prior to inclusion. Patient enrollment started in 2010 and 2012 at the outpatient clinic of 1 tertiary and 7 secondary centers respectively. An extensive patient description was performed at baseline, followed by a 6-monthly follow-up.

Results: By June 2018, 223 axSpA patients were included. Demographic and clinical features are presented according to the diagnostic echelon (Table 1). The HLA B27 positivity rate was 52,9% and 74,6% in secondary versus tertiary centers ($p = 0,013$). The patient fraction fulfilling the imaging arm of the ASAS classification criteria was similar in both (89,9% vs. 85,3%, $p = 0,418$), but significantly more patients both fulfilled the imaging and the clinical arm in the tertiary versus secondary centers (64,5% vs. 38,2%, $p = 0,004$).

Conclusion: Patients diagnosed with axSpA in secondary versus a tertiary hospital generally show similar demographic and clinical characteristics. For axSpA patients diagnosed in a tertiary center, fulfillment of both ASAS classification arms and HLA B27 positivity rate was significantly higher, indicating that rheumatologists in secondary hospitals seem to assign more value to MRI findings compared to HLA B27 status in the diagnostic process.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Clinical/Epidemiology Studies

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Anterior uveitis (AU) is a common extraarticular manifestation in spondyloarthritis (SpA). The disease can precede the typical axial and peripheral features. Additionally, some studies had described the imaging signs of sacroiliac involvement in patients with AU lacking chronic back pain. The aim of this study was to examine patients with AU, to determine whether the patients already fulfil criteria for axial and/or peripheral SpA and to stratify risk factors for SpA development.

Methods: We recruited 41 patients without prior rheumatologic diagnosis who developed at least one episode of AU. The clinical data were collected and rheumatology examinations were performed by trained rheumatologists. Magnetic resonance imaging (MRI) of sacroiliac joints (SIJ) was read by trained rheumatologist who was blinded to the patient data. Patients were further divided into SpA subsets (axial: imaging and clinical arm and peripheral SpA) fulfilling The Assessment of SpondyloArthritis international Society (ASAS) classification criteria¹ and non-SpA subset. The ASAS modified Berlin algorithm for diagnosis of axial SpA² (axSpA) was also applied.

Results: Altogether, 22.0% (n=9) patients referred inflammatory back pain, 48.8% (n=20) referred non-inflammatory back pain and 29.3% (n=12) did not refer back pain. Bone marrow edema (BME) was found in 48.8% (n=20) of all patients with AU, however 31.7% (n=13) had highly suggestive BME³ corresponding to typical findings in sacroiliitis. The diagnosis of SpA was confirmed in 41.5% (n=17) of all patients with AU, 26.8% (n=11) patients fulfil the imaging arm and 12.2% (n=5) fulfil the clinical arm of ASAS classification criteria for axSpA, 4.9% (n=2) patients fulfil ASAS classification criteria for peripheral SpA (one patient fulfil both axial and peripheral criteria). Two patients lacking back pain developed highly suggestive BME on SIJ. The diagnosis of axSpA according to the Ankylosing Spondylitis Disease Activity Score (ASDAS) modified berlin algorithm was confirmed in 41.5% (n=17) patients. Analysis of clinical characteristics showed significant difference between ASDAS in SpA vs. non-SpA (1.6 ± 0.7 vs 0.8 ± 0.6 , $p < 0.001$, respectively), and remained significant in axSpA and also in those fulfilling only imaging arm of axial SpA (i-axSpA) ($p = 0.002$, $p = 0.016$, respectively). The levels of CRP were significantly higher in SpA and axSpA compared to non-SpA subsets (9.5 ± 10.3 , 8.7 ± 10.1 vs. 2.2 ± 2.2 mg/L,

p=0.005, p=0.009, respectively). Presence of back pain and inflammatory back pain were more often in SpA compared to non-SpA subsets (94.1% and 47.1% vs. 54.2% and 4.2%, p=0.006 and p=0.002 respectively).

Conclusion: More than one third of patients with anterior uveitis fulfilled the criteria for axial or peripheral SpA. Furthermore, these patients had significantly higher presence of back pain, increased ASDAS and serum CRP levels. Inflammatory back pain was significantly more often in patients classified as axSpA.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Clinical/Epidemiology Studies

Session Type: ACR Poster Session B:

Session Time: 9:00AM-11:00AM:

Background/Purpose: Acute Anterior Uveitis (AAU) is the most frequent extra-articular manifestation in axial Spondyloarthritis (axSpA), with an overall prevalence of 32.7%. It is a manifestation of great socioeconomic impact, since it generates considerable disability. The objective of this study was to determine the prevalence of AAU in a cohort of patients with axSpA and to describe their clinical characteristics, frequency of episodes, response to treatment and long-term prognosis, as well as, their association with general disease characteristics.

Methods: A cross-sectional study was carried out. We included patients diagnosed with axSpA (ASAS 2009 criteria) from ESPAXIA cohort. Sociodemographic data, type of axSpA, extra-articular manifestations, comorbidities, disease duration and treatments received, numbers of episodes of uveitis, incidence date, and its characteristics, treatment and complications were consigned. Morning stiffness, night pain, global pain and patient's and physician's global assessment (NVS), number of swollen joints (44), axial mobility (BASMI), enthesitis (MASES), ESR, CRP and *HLA-B27* were registered. BASDAI, BASFI and ASQoL self-questionnaires were administered. *Statistical analysis:* Descriptive statistics. Student's T-test, Chi² test and multiple logistic regression analysis. Kaplan Meier curves. A p value <0.05 was considered significant.

Results: Two hundred and thirty one patients with axSpA were included, 174 male (75.3%) with a median age of 46 years (IQR 36-57) and median disease duration of 20.5 years (IQR 10.5-30.5). Sixty patients (26%) had at least one episode of uveitis, being the first manifestation of the disease in 22 of them (37.9%). Acute anterior uveitis was the most frequent form, and it was observed in 59 patients (98.3%). The mean number of episodes was 4.78 (SD 5.64). Recurrences were unilateral in 48.8% of cases. The treatment received was local in 42 (79.2%) of the patients. Twenty patients (33.33%) where in treatment with Tumor Necrosis Factor α inhibitors (TNF α -i) by the time of the data collection: 17 patients with monoclonal antibodies and 3 with Etanercept (ETN). Patients with axSpA and UAA received monoclonal agents more frequently (85% vs 15%, p=0.018). The presence of UAA was associated with a lower survival of biological medication, with a median of 91.42 months (SD 19.74) vs 109.44 months (SD 12.34). Twelve patients (22.2%) presented a complication after the first episode, being the decrease in visual acuity and cataracts, the most frequent ones (16.7% and 5.6%, respectively). The presence of uveitis was significantly associated with longer disease duration (24.9 years vs 20.7 years, p=0.038) and with the presence of *HLA-B27*, (69% vs 47.4%, p=0.006) and these associations were maintained in the multivariate analysis, after adjusting for other variables.

Conclusion: The prevalence of uveitis in our cohort was 26%, and it was significantly more frequent in patients *HLA-B27* (+) and with longer disease duration.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Clinical/Epidemiology Studies

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The BIOmarkers of COMorbidities (BIOCOM) in psoriasis study is a longitudinal study which aims to identify clinical, genetic or protein biomarker features associated with the development of co-morbidities, notably Psoriatic Arthritis (PsA), in patients with psoriasis.

There is a well-established association between smoking and psoriasis, and between smoking and PsA, in the general population. Paradoxically, smoking has been shown to be negatively associated with the development of PsA in patients with established psoriasis. Herein we describe the prevalence of smoking in this BIOCOM cohort.

Methods: Patients with psoriasis were recruited from the dermatology clinics at St. Vincent's University Hospital, Dublin. Inclusion criteria included disease duration of less than 10 years and an age of 18 years or older. Patients with another serious active medical illness, a previous diagnosis of inflammatory arthritis or those who were receiving systemic immunosuppressant therapy for psoriasis were excluded.

Patients with PsA were recruited from the rheumatology clinics at St. Vincent's University Hospital. Patients had to meet CASPAR (CLASSification criteria for Psoriatic Arthritis) criteria for inclusion in the study.

Results: To date 190 patients with psoriasis have been recruited. Of those, 9 were excluded due to a diagnosis of psoriasis > 10 years previously. One was excluded due to a previous diagnosis of JIA. This left 180 patients with psoriasis who were brought in for an initial assessment. After the initial assessment 7 patients were diagnosed with PsA, meeting CASPAR criteria. This left 173 patients for inclusion in the analysis.

100 patients with established PsA were recruited and were included in the study.: Table 1 describes demographic and clinical characteristics of the study population at baseline assessment.

	Psoriasis	PsA
Age, mean +/- SD years	41.3 +/- 14.9	52.4 +/- 10.5
Male Sex, number (percentage)	105 (60.7)	55 (55.0)
Duration of Psoriasis, mean +/- SD years	6.2 +/- 2.9	26.1 +/- 13.1
Duration of PsA, Mean +/- SD years		17.9 +/- 10.0
PASI score, mean +/- SD	7.3 +/- 3.9	3.6 +/- 3.2
Type 1 Psoriasis, number (percentage)	107 (61.9)	86 (86.0)

The proportion of smokers (current and past) was lower in the PsA group compared to the psoriasis group: 52.0 versus 63.6. Table 2 shows smoking characteristics of patients with PsA and psoriasis.

Smoking Status	Psoriasis	PsA	p Value
Never Smoked, number (percentage)	63 (36.4)	48 (48.0)	0.06
Current, number (percentage)	49 (28.3)	10 (10.0)	<0.001
Past, number (percentage)	61 (35.3)	42 (42.0)	0.268

Conclusion: Analysis of patients recruited to date for the BIOCOM-Pso study shows a higher percentage of smokers (current and past) in the psoriasis group compared to the PsA group. The proportion of smokers (current and past) in the PsA group was comparable to the general Irish population.

These findings are consistent with previous studies that showed a negative association between smoking and the development of PsA in patients with psoriasis. However, prospective follow-up of patients with psoriasis, which is ongoing in this BIOCOT cohort, is required to further elucidate the role of smoking in the development of PsA.

Cohort Identification of Axial Spondyloarthritis in a Large Healthcare Dataset: Current and Future Methods

Gopi Penmetsha¹ and Jessica Walsh², ¹University of Utah, Salt Lake City, UT, ²University of Utah School of Medicine, Salt Lake City, UT, USA, Salt Lake City, UT

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Clinical/Epidemiology Studies

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Big data research is important for studying uncommon diseases in real-world settings. Most big data studies in axial spondyloarthritis (axSpA) have been limited to populations identified with billing codes for ankylosing spondylitis (AS). axSpA is a more inclusive concept, and reliance on AS codes does not produce a comprehensive axSpA study population. The first objective was to describe our process for establishing an appropriate sample of patients with and without axSpA for developing novel axSpA identification methods. The second objective was to determine the classification performance of AS billing codes against the chart-reviewed reference standard.

Methods: Veteran Health Affairs data, between January 2005 and June 2015, were used to randomly select patients with phenotypes determined by expert opinion to represent high, moderate, and low likelihoods of an axSpA diagnosis. A risk stratified sampling approach was applied to balance chart review feasibility(enrichment with high risk patients) with generalizability (inclusion of low risk patients). With chart review, the sampled patients were classified as Yes, No, or Uncertain axSpA status. These classification assignments were used as the reference standard for determining the positive predictive value (PPV) and sensitivity of AS ICD-9 codes for axSpA

Results: A higher percentage of patients were included from the high risk stratum than the moderate and low risk strata (0.83%, 0.25%, 0.01%, respectively) (Table 1). Six hundred patients were classified as Yes axSpA (26.8%), No axSpA (68.3%), and Uncertain axSpA (4.8%) (Table 2). The PPV of an AS ICD-9 code for axSpA was 83.3% and the sensitivity was 57.3% (Figure 1).

Conclusion: Standard methods of identifying axSpA patients with AS diagnosis codes lacked sensitivity. An appropriate sample of patients with and without axSpA was established for developing novel axSpA identification methods that are anticipated to enable previously impractical big data research

Table 1. Selection of patients sampled for the chart review population

Subgroups	Subgroup Criteria (ICD-9 or laboratory data)	No. of Veterans	No. of Veterans selected to chart review population	% from each risk stratum selected to the chart review population
High risk for AxSpA

Subclinical Atheromatosis and Estimation of Cardiovascular Risk in Patients with Axial Spondyloarthritis

Tomas Cazenave¹, Maria Celeste Orozco², Gustavo Citera³, Emilce E Schneeberger¹ and Marcos G. Rosemffet², ¹Instituto de Rehabilitación Psicofísica, Buenos Aires, Argentina, ²Rheumatology, Instituto de Rehabilitación Psicofísica, Buenos Aires, Argentina, ³Rheumatology Section, Instituto de Rehabilitación Psicofísica, CABA, Argentina

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Clinical/Epidemiology Studies

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: There is evidence that shows an increased cardiovascular risk in patients with Axial Spondyloarthritis (axSpA). Ultrasonography (US) is a simple imaging tool used to assess cardiovascular risk by the detection of atherosclerotic lesions. **Objectives:** To evaluate the association between the cardiovascular (CV) risk estimated by a traditional score and the prevalence of subclinical atheromatosis detected by carotid US in patients with axSpA

Methods: A cross-sectional study was designed including consecutive patients with a diagnosis of axSpA (ASAS 2009 Criteria) without previous history of CV events. Patient's demographic and disease characteristics were recorded. The presence and history of traditional CV risk factors were evaluated. The cardiovascular risk was stratified according to the Framingham score [percentage of risk of presenting a 10-year cardiovascular event]. All patients underwent bilateral US carotid artery examination (common and internal carotid) to assess subclinical atherosclerosis. The presence of intima-media thickness (IMT) >0.9 mm and/or carotid plaques was used to define carotid atherosclerosis (US Carotid Atherosclerosis=USCA) as a marker of high cardiovascular risk. The association between clinical characteristics and US findings was assessed by univariate and multivariate analysis. ROC curves were developed to estimate cut-off values.

Results: Fifty-one patients with axSpA were included. The mean age was 43 ± 13 years, and 75% were men. The median disease duration was 12 years (IQR: 6-23), and the mean BASFI and BASDAI were 3.8 ± 2.9 and 3.9 ± 2.6 , respectively. Sixty-five percent were receiving NSAIDs and 51% biological treatment. Eleven patients (22%) had hypertension, 13 (25%) dyslipidemia, and 9 (18%) were smokers. The mean score of the Framingham index was 8.6 ± 1.3 . The patients

were stratified in: low risk: 34 (67%), moderate risk: 12 (23%) and high risk: 5 (10%). The US evaluation detected the presence of USCA (plaque and / or IMT > 0.90 mm) in 21 (41%) patients, presence of plaques in 19 (37%), and IMT > 0.9 mm in 13 (25%). The frequency of USCA found in patients stratified by the different Framingham categories were: low risk: 6/34 (18%); moderate risk: 10/12 (83%); high risk: 5/5 (100%). In the univariate analysis the presence of USCA was more frequent in older patients ($p < 0.0001$), longer disease duration ($p = 0.008$), hypertension ($p = 0.001$), dyslipidemia ($p = 0.008$) and higher BMI ($p = 0.02$). After adjusting for multiple confounding factors, age was the only variable associated with the presence of USCA. In the ROC analysis, the optimal cut-off value for age to predict the presence of USCA was 42.5 years, with a sensitivity and specificity of 85% and 82%, respectively (AUC: 0.90). The USCA prevalence was 82% ($n = 18$) in patients with age ≥ 42.5 years, compared to only 10% ($n = 3$) in those with age < 42.5 years.

Conclusion: Subclinical atherosclerosis detected by US was found in a significant proportion (35%) of patients classified in low to moderate risk by the Framingham score. The majority of patients over 42.5 years of age presented high risk US lesions, and may require intensive CV risk management.

De Vera^{1,2,3}, ¹Collaboration for Outcomes Research and Evaluation (CORE), Vancouver, BC, Canada, ²Arthritis Research Canada, Richmond, BC, Canada, ³Faculty of Pharmaceutical Sciences, University of British Columbia, Vancouver, BC, Canada, ⁴Department of Dermatology and Skin Science, University of British Columbia, Vancouver, BC, Canada

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Clinical/Epidemiology Studies

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Shared inflammatory processes underscore a substantial burden and risk of psychiatric complications—namely depression and anxiety—in patients with psoriatic arthritis (PsA), yet to our knowledge there is no synthesis of the evidence to date. We conducted a systematic review and meta-analysis with the following aims: 1) determine the prevalence and incidence of depression and/or anxiety; 2) assess the impact of depression and/or anxiety on patient outcomes; and 3) describe treatment of depression and/or anxiety among patients with PsA.

Methods: We conducted a systematic literature review of Medline, Embase, Cochrane Database of Systematic Reviews, CINAHL and PsycINFO. We included full-length studies that: 1) utilized an observational design; 2) involved a sample of patients with PsA, with/without a comparator group; 3) reported depression and/or anxiety as an outcome, comorbidity, or predictor of a health outcome; and 4) reported relevant estimates (e.g. prevalence proportion, odds ratio, hazard ratio) or sufficient data to allow calculation. We extracted information on study setting and design, sample size, methods of assessing depression and anxiety and reported prevalence and incidence of depression and/or anxiety. When relevant data was provided, we pooled estimates using random effects models.

Results: Of 683 titles identified in our search 10 studies met inclusion criteria. Several methods were used to assess depression and anxiety including the Hospital Anxiety and Depression Scale (HADS), Patient Health Questionnaire (PHQ-9) and International Classification of Diseases 9th Revision Codes (ICD-9). The majority of included studies assessed the prevalence of psychiatric complications; the pooled prevalence proportion of depression based on 6 studies and a total of 22,163 PsA patients was 20% (95% confidence interval (CI), 15% to 25%) and the pooled prevalence proportion of anxiety based on 4 studies and 15,878 PsA patients was 27% (95% CI, 12% to 43%) (Figure 1). The incidence of depression in PsA patients as compared to the general population was reported in 3 studies and meta-analysis yielded a pooled incidence rate ratio (IRR) of 1.34 (95% CI, 1.20 to 1.49). Depression and anxiety were reported to be associated with increased inflamed joint count, pain, disability and fatigue. Treatment for depression in PsA patients included antidepressant/anxiolytic medications and/or psychotherapy. In studies reporting antidepressants use, only a small minority of patients take antidepressants.

Conclusion: We found a high prevalence of depression and anxiety in patients with PsA, and 30% higher risk of incident depression as compared to the general population. A clinical approach that includes screening and early treatment of psychiatric complications by health care professionals may impact mental health in patients with PsA.

Figure 1. Pooled prevalence estimates (ES) of depression (a) and anxiety (b) in psoriatic arthritis.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Clinical/Epidemiology Studies

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Musculoskeletal symptoms are frequently reported by patients with inflammatory bowel diseases (IBD). Those symptoms may vary from arthralgia to arthritis, involving peripheral or axial joints, with a prevalence ranging from 17% to 62% when considering any SpA manifestation (with a similar range for axial or peripheral involvement from 5 to 30%) and a definite SpA diagnosis up to 46%. To date, a more comprehensive approach is needed, also because the use of DMARDs or biologics could improve both gastrointestinal and musculoskeletal symptoms. The purpose of the study is to evaluate the rate of MSK involvement in a mono centric cohort of IBD patients.

Methods: A questionnaire based on the features of SpA was used in the IBD out-patient clinic from January 1st to December 31st 2017. When there was a positivity for any feature, the patients were evaluated by a rheumatologist (with more than 18 years of experience in SpA). All the visits were performed in 2-3 weeks from the moment the questionnaire was performed (varying according to the seasonal time for holidays). When there were some doubts about the diagnosis, further examinations were requested.

Results: A total of 403 patients were visited in the out-patient clinic (220 affected by CD, 172 affected by UC and 11 with a not defined IBD). Fifty-nine patients were sent to the rheumatologist (33 CD, 24 UC and 2 not defined IBD). Eleven patients had 2 or more rheumatologic visits (to follow-up the disease and check the results of the exams requested). To allow a diagnosis, 4 sacroiliac joints MRI and 1 ultrasound assessment of the feet were requested. A diagnosis of peripheral SpA was given in 9 patients while axial SpA was diagnosed in 7 subjects. The diagnosis was fibromyalgia, osteoarthritis and arthralgia in 1, 2 and 40 patients, respectively. Therapy was modified in 16/59 patients after the rheumatologic assessment (DMARDs were prescribed in 12 subjects while anti-TNFα in 4 of them). In 1 patient (with absolute contraindication for biologic therapy), two courses of SI joint injection were performed, improving local pain.

Conclusion: The results of our study confirm the already published prevalence of musculoskeletal involvement in IBD patients (15% of our IBD population complained musculoskeletal pain and 27% of the patients sent to the rheumatologist

were given an enteropathic arthritis diagnosis). As for the already existing literature, we did not notice any evident difference in the prevalence of axial and peripheral involvement. An established collaboration between gastroenterologists and rheumatologists is necessary to provide an integrated and more comprehensive management of IBD, improving the quality of life of the patients.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Clinical/Epidemiology Studies

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: To assess the association between sociodemographic characteristics, disease activity, and psychological distress in patients with axSpA.

Methods: Between July 2017 and February 2018, 2,846 axSpA patients participated in the patient survey of the European Map of Axial Spondyloarthritis (EMAS) across 13 countries. The General Health Questionnaire (GHQ-12), ranging from 0 to 12, using a score of ≥ 3 as a threshold for risk of psychological distress, was employed. Sociodemographic characteristics (age, gender, relationship status, educational level, job status), disease assessments (BASDAI, spinal stiffness ranging from 3-12, functional restriction in 18 daily activities), and diagnosis of depression and/or anxiety were collected. The chi-square independence test and Mann-Whitney tests were applied, and a level of significance of 5% was adopted, to compare those at risk of distress (GHQ-12 ≥ 3) and those not at risk of distress (GHQ-12 < 3). Rank-based test was applied to stiffness index, BASDAI and age to determine if their distributions were different based on level of distress. In addition, correlation between age, spinal stiffness and BASDAI scores with GHQ-12 scores were assessed using Pearson correlation coefficient. To assess the degree to which these factors explain the variance in distress scores, a stepwise forward regression was conducted.

Results: All variables, except educational level, showed significant univariate correlation with distress (Table 1). Total GHQ score showed a significant inverse correlation with age indicating that younger participants had greater distress scores ($r = -0.154$). Higher GHQ scores also showed significant positive correlation with spinal stiffness and BASDAI scores, implying that higher BASDAI scores and stiffness are associated with more distress ($r = 0.405$ and 0.201 respectively). From the regression analysis, explanatory variables were indicated as significant in the following order from higher to lower explanatory power: BASDAI scores, anxiety, gender, job status, age and relationship status (Table 2).

Conclusion: In axSpA, clinical characteristics such as degree of disease activity and spinal stiffness are good predictors of psychological distress. Therefore, in patients with greater disease activity and more physical restriction, psychological evaluation and intervention should be considered as part of a holistic medical treatment.

Table 1. Sample characteristics according to the risk of distress GHQ-12 (N=2,846, unless other specified).

	No Risk of Distress (GHQ-12 < 3) (mean \pm SD or %)	Risk of Distress (GHQ-12 ≥ 3) (mean \pm SD or %)	P
Age, mean \pm SD	46.39 \pm 12.84	42.1 \pm 11.48	<0.001

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Clinical/Epidemiology Studies

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Clinical expression and pathophysiology of dry eye disease (DED) have recently changed and pro-inflammatory cytokines, such as TNF- α , may play a role in the multifactorial mechanism of DED. Few studies evaluated the effect of TNF blockage in DED and there are no data regarding this complication in ankylosing spondylitis (AS). The aim of the study is to analyze the ocular surface (OS) in AS patients according to the DED severity grade and conjunctival impression cytology (IC) and the effect of anti-TNF therapy in a subgroup of patients with a one-year follow-up.

Methods: Thirty-six AS patients and 39 controls with strict exclusion criteria for DED were enrolled at study entry, and 14 were followed prospectively post-anti-TNF therapy at 3months (3M), and 12 months (12M). AS disease parameters were performed for all patients. Ocular evaluation included OS Index Disease questionnaire, Schirmer I test, break-up time, vital staining, and conjunctival IC. DED severity grade was also applied.

Results: AS patients presented higher frequency of DED (80.5% vs. 43.6%, p=0.01), a worse score of severity [1(0-3) vs. 0 (0-1), p=0.001], and a higher frequency of altered IC (55.5% vs. 12.8%, p=0.007) when compared to controls. The 14 patients under anti-TNF therapy presented an improvement in all clinical AS disease activity parameters throughout the one-year treatment (p<0.05). A concomitant increase in the Schirmer test was also observed [BL:10(2-35) mm, 3M:17.5(4-35) mm and 12M:20(4-30) mm, respectively, p=0.04] as well as a significant amelioration in the altered IC to a normal IC was noticed (p=0.006).

Conclusion: DED is a frequent and under-diagnosed ocular disease in AS patients. The long-term parallel improvement of disease activity and OS parameters in AS patients receiving anti-TNF therapy suggests that the OS is an additional target of systemic inflammation in AS.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Clinical/Epidemiology Studies

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: In inflammatory arthritis such as RA, early initiation of highly effective targeted treatments is a successful strategy to aim for sustained remission.¹ Here we aimed to assess if a similar strategy is effective in psoriatic arthritis (PsA) by assessing the efficacy and safety of golimumab + methotrexate (MTX) vs. MTX alone in PsA patients with early, active disease.

Methods: This investigator-initiated, multicenter, double blind, randomized, placebo-controlled trial included MTX and bDMARD-naïve patients with PsA fulfilling the CASPAR criteria and with active disease at baseline (≥ 3 SJC/TJC). Patients were randomized to either golimumab (50mg SC monthly) + MTX (n=26) (TNFi arm) or matched placebo + MTX (n=24) (MTX arm). MTX was started 15mg/week orally and increased to 25mg/week over 8 weeks. Primary efficacy endpoint was % of patients achieving DAS remission (<1.6) at week 22. Key secondary endpoints included changes in DAS CRP, VAS global, VAS pain, VAS physician, SJC (66) and TJC (68) and achievement of MDA. Safety was assessed throughout the study.

Results: The baseline demographics and disease characteristics were similar between both groups. The median disease duration at inclusion was 0.5 (0.5-2) (yrs), disease activity at baseline was: DAS CRP 2.25 (1.86-2.78) swollen joint count (66) 5 (4-8.25); tender joint count (68) 10 (5-15.3), PASI 1.75 (0.35-4.48). The median MTX dosage used was 19.2 (4.5) mg/week in the TNFi arm and 21.2 (2.4) in the MTX arm. There were 6 early drop-outs due to withdrawal of informed consent: 1 in the TNFi arm (wk14), 1 in the MTX arm (wk14); due to AE: 1 in the TNFi treatment arm (wk14) and 3 in the MTX arm (wk14). The study met the primary efficacy endpoint with DAS remission at week 22 achieved by 81% of the subjects in the TNFi arm versus 42% in the MTX arm ($p=0.004$). This difference in DAS remission was already observed at week 8 (73% vs. 42%, $p=0.025$). MDA was achieved by 81% vs. 29% at week 22 ($p<0.001$) and in 58% vs. 21% at week 8 ($p=0.008$). A

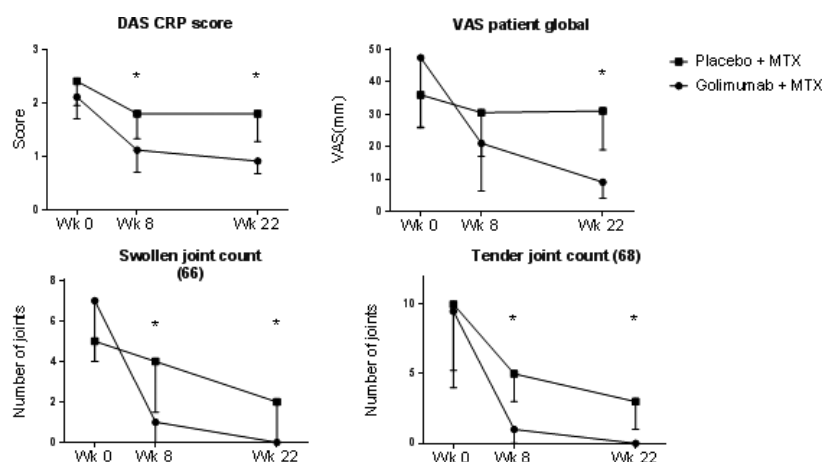

Figure 1 - Changes in clinical disease activity parameters during treatment with golimumab + MTX and placebo + MTX from baseline to week 22. The panels represent the DAS CRP score, VASpt global on a 100mm visual analogue scale, swollen joint count and tender joint count. Data are presented as median and interquartile range. * statistically significant

significant difference in favor of the TNFi arm at week 22 was also observed for several key secondary endpoints, most secondary parameters were already significantly different in favor of the TNFi arm at week 8 (Figure 1). As to safety, one SAE occurred in a patient in the MTX arm (cervical spine stenosis), which was considered not to be study related and did not result in early withdrawal. 43/50 patients experienced ≥ 1 AE (range 1-7), all of which were graded mild to moderate. The occurrence rates of AE and TEAE were similar in both arms.

Conclusion: DAS remission at week 22 was achieved by almost double the number of patients with early PsA treated with golimumab + MTX versus placebo +MTX. This double-blind, randomized, placebo-controlled study supports the concept that early initiation of TNFi in patients with active PsA favors rapid and sustained remission.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Clinical/Epidemiology Studies

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: A positive family history (PFH) of spondyloarthritis (SpA), in particular aPFH of ankylosing spondylitis (AS) or acute anterior uveitis (AAU), can be used to identify HLA-B27 carrier ship in chronic back pain patients¹. It is unknown if a PFH contributes to diagnosing axial spondyloarthritis (axSpA) once HLA-B27 status is known.

Methods: Baseline data of patients suspected of axSpA in the ASAS, DESIR, and SPACE cohorts were analysed. Logistic regression analyses were performed with HLA-B27 status and PFH according to the ASAS definition (ASAS-PFH) as determinants and clinical axSpA diagnosis as the outcome. Analyses were repeated with a PFH of AS or AAU.

Table 2 Logistic regression analysis between a PFH of AS, HLA-B27, and clinical axSpA diagnosis in the ASAS, DESIR, and SPACE cohort

Statistically significant associations are printed in bold. AS, Ankylosing Spondylitis; ASAS, Assessment of SpondyloArthritis International Society; (ax)SpA, (axial) spondyloarthritis; CI, confidence interval; HLA-B27, human leucocyte antigen B27; OR, odds ratio; PFH, positive family history.

Results: In total, 1,964 patients suspected of axSpA were analysed (ASAS n=594, DESIR n=647, and SPACE n=577). Patients from the ASAS, DESIR, and SPACE cohorts, respectively had a mean (SD) symptom duration of 85.7 (108.4), 18.2 (10.5), and 13.3 (7.1) months; 46%, 47%, and 38% were male; 23%, 39%, and 38% had an ASAS PFH, 52%, 58%, and 43% were HLA-B27 positive, and 62%, 47%, and 54% were diagnosed with axSpA. In the univariable analysis, HLA-B27 status was significantly associated with an axSpA diagnosis in all three cohorts (Table 1). An ASAS-PFH and a PFH of AAU were univariately associated with an axSpA diagnosis in the SPACE cohort, but not in the ASAS and DESIR

cohorts. A PFH of AS was associated with an axSpA diagnosis in the ASAS cohort, but not in the DESIR and SPACE cohorts. In the multivariable models, HLA-B27 was independently and positively associated with an axSpA diagnosis in each cohort but such an independent positive association was not found for an ASAS-PFH in any cohort (Table 1). Similarly, a PFH of AS did not have an independent positive association with an axSpA diagnosis in any cohort (Table 2). Similar results were found for PFH of AAU (ASAS cohort: HLA-B27 OR:6.9 (95%CI:4.7-10.1), ASAS PFH OR:0.4 (95%CI:0.08-1.8);DESIR cohort: HLA-B27 OR:2.1 (95%CI:1.5-2.9), ASAS PFH OR:1.1 (95%CI:0.5-2.3);SPACE cohort: HLA-B27 OR:10.7 (95%CI:7.0-16.3), ASAS PFH OR:0.8 (95%CI:0.3-1.8)).

Conclusion: A PFH did not contribute independently of HLA-B27 to a diagnosis of axSpA in axSpA suspected patients.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Clinical/Epidemiology Studies

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: In a Phase 2 study, Guselkumab (GUS) was shown to be safe & effective in pts w/active PsA w/ meaningful improvements in enthesitis. To evaluate the effect of GUS on enthesitis in a subset of pts w/enthesitis at baseline (BL) from the Phase 2 PsA study of GUS.

Methods: Pts w/active PsA & $\geq 3\%$ BSA of plaque PsO, despite current or previous treatment, were randomized 2:1 to 100mg SC GUS or PBO at wks 0,4, \rightarrow q8w during a 24-wk double-blind treatment period. At wk16, pts w/ $<5\%$ improvement in swollen & tender joint counts(SJC&TJC) early escaped(EE) to open-label ustekinumab. At wk24, the PBO group crossed over to GUS at wks24,28 \rightarrow q8w(PBO \rightarrow GUS) & the GUS group continued receiving GUS(GUS \rightarrow GUS) through wk44. Enthesitis was assessed using the Leeds enthesitis index(LEI). Enthesitis scores during the 24wk double-blind treatment was analyzed using LOCF imputation for missing data & EE. Enthesitis after wk24 was analyzed using observed data.

Results: Of 149 total pts w active PsA,107(72%) presented w/enthesitis at BL(PBO N=31,mean[SD] LEI=2.6[1.48], median [range]=2.0[1, 6]; GUS N=76,mean(SD) LEI=2.7[1.54], median[range]=2.0[1, 6])& 85 continued at Wk24(PBO \rightarrow GUS N=18;GUS \rightarrow GUS N=67). Except for higher TJC/SJC & CRP, BL characteristics of enthesitis subset was similar to overall population. GUS significantly reduced the LEI by wk8(mean[SD]] change from BL, PBO:-0.4[1.59]; GUS:-1.2[1.65]; p=0.037),& through wk24(mean[SD] change from BL, PBO:-0.7[1.53]; GUS:-1.5[1.81];p=0.045). GUS also significantly increased the % of pts w/enthesitis resolution(Figure). After wk24, PBO \rightarrow GUS group achieved rapid, sustained resolution (wk56: mean[SD] change from BL=-2.1[1.65];62.5% of pts w/resolution), similar to GUS \rightarrow GUS group(wk56:mean[SD] change from BL=-1.9[1.59],70.8% of pts w/resolution). Improvement in enthesitis was observed at each enthesitis site assessed, & was greater in ACR20(Table) responders vs non-responders in GUS-treated pts & was correlated w/ improvement in TJC (R=0.37, p=0.001) & SJC (R=0.27,p=0.020), physician's(R=0.47,p<0.0001) & pts global assessment of disease activity(R=0.32,p=0.005), & SF36 PCS(R=0.27,p=0.02) & MCS(R=0.35,p=0.002).

Conclusion: GUS treatment produces rapid & sustained improvement of enthesitis in pts w/active PsA, which correlates w/ improvement in joint symptoms & pt-reported outcomes.

Figure. Proportion of Patients with Enthesitis Resolution over Time

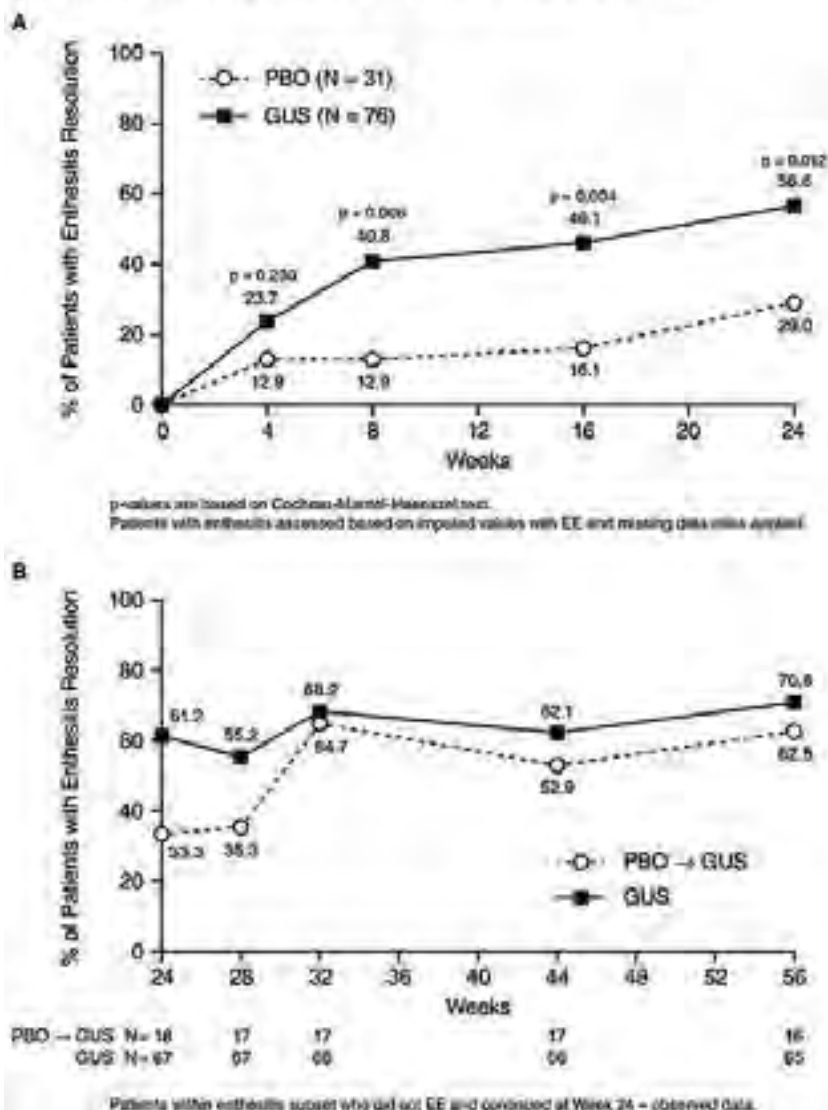

Table. Change in LEI in ACR20/50 and PASI75 Responders and Non-responders

Which Factors Influence the Diagnostic Delay in Patients with Axial Spondyloarthritis?

Imke Redeker¹, Johanna Callhoff¹, Falk Hoffmann², Hildrun Haibel³, Joachim Sieper⁴, Angela Zink⁵ and Denis Poddubnyy⁴, ¹Epidemiology Unit, German Rheumatism Research Centre, Berlin, Germany, ²Department of Health Services Research, Carl von Ossietzky University, Oldenburg, Germany, ³Charité Universitätsmedizin Berlin, Berlin,

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Clinical/Epidemiology Studies

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The interval from symptom onset till diagnosis in axial spondyloarthritis (axSpA) was reported a decade ago to be between five and ten years. The objective of this study was to explore if the diagnostic delay has improved over the past years and to analyse factors associated with the delay.

Methods: A sample of persons with axSpA (ICD-10 M45) stratified by age and sex was drawn from claims data of a large nationwide statutory health insurance fund in Germany. Each person in the sample received in 2015 a questionnaire gathering information on demographic, disease-related and socioeconomic characteristics. Disease-related parameters comprised the date of first symptoms, the date of diagnosis, the HLA-B27 status as well as the presence of extra-articular manifestations (uveitis, psoriasis, chronic-inflammatory bowel disease). Multivariable linear regression analysis was used to analyse factors associated with the diagnostic delay.

Results: A total of 1,677 persons with axSpA were included in the analysis. The mean age was 56 years and 46% were female. The mean (95% confidence interval [CI]) diagnostic delay in the whole group was 5.7 (5.4 – 6.0) years and the median was 2.3 years (Fig. 1). Overall, 407 persons were diagnosed between 1996 and 2005 and 484 persons between 2006 and 2015. The diagnostic delay was not substantially different in both periods: For patients diagnosed between 1996 and 2005 the mean (95% CI) diagnostic delay was 6.3 (5.6 – 7.0) years and the median was 2.6 years. For patients diagnosed between 2006 and 2015 the mean (95% CI) diagnostic delay was 7.4 (6.6 – 8.1) years and the median was 2.7 years. Persons with a long diagnostic delay were more often female and had less often a positive HLA-B27 status compared to persons with a short diagnostic delay (Tab. 1). Multivariable linear regression revealed that female sex, negative HLA-B27 status, prevalence of psoriasis and younger age at symptom onset are factors associated with a longer diagnostic delay (Tab. 2).

Conclusion: The mean diagnostic delay of about 7 years represents currently one of the major challenges in field of SpA. Female sex, negative HLA-B27 status, presence of psoriasis and younger age at symptom onset had a negative impact on the diagnostic delay.

Table 1 Main demographic, disease-related, lifestyle and socioeconomic characteristics of patients with axSpA stratified by the delay to diagnosis.

Sustained Improvements in Physical Function, Quality of Life, and Work Productivity after Ixekizumab Therapy in Patients with Active Psoriatic Arthritis: 3-Year Results

Roy Fleischmann¹, Vinod Chandran², Eric Lespessailles³, Julie Birt⁴, Olivier Benichou⁴, Janelle Erickson⁴ and Catherine Shuler⁴, ¹University of Texas Southwestern Medical Center, Dallas, TX, ²Krembil Research Institute and University of Toronto, Toronto, ON, Canada, ³University of Orléans, Orléans, France, ⁴Eli Lilly and Company, Indianapolis, IN

SESSION INFORMATION

Session Date: Monday, October 22, 2018
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Clinical/Epidemiology Studies
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Ixekizumab (IXE), a high-affinity mAb that selectively targets IL-17A, has shown improvements compared to placebo not only in disease activity but also in various patient-reported outcomes (PROs) assessing physical function, fatigue, quality of life, and work productivity in PsA patients treated for 24weeks.¹ Herein, we report the effects of treatment with IXE on these PROs after up to 3 years of treatment.

Methods: InSPIRIT-P1¹ (NCT01695239), a Phase 3 trial, 417 biologic-DMARD-naïve patients with active PsA were randomized to IXE 80 mg every 4 weeks (IXE Q4W; N=107) or every 2 weeks (IXE Q2W; N=103), adalimumab 40 mg every 2 weeks (ADA; N=101), or placebo (PBO; N=106) in the double-blind treatment period (Weeks 0-24). Both IXE regimens had a starting dose of 160 mg. Results are reported from a subset of the intent-to-treat population defined as patients randomized to IXE at baseline (Week 0). The following PROs were assessed in the study (during Weeks 0-156):HAQ-DI (minimally clinically

Table: Overview of Patient-Reported Outcomes at Week 156 of the Intent-to-Treat Population: Patients Randomized to IXE at Baseline				
	Baseline		At Week 156

Abbreviations: EQ-5D= European Quality of Life 5 Dimension Questionnaire; HAQ-DI=Health Assessment Questionnaire-Disability Index; IXE=ixekizumab; mBOCF=modified baseline observation carried forward; MCTD= minimal clinically important difference; MCS= Mental Component Summary; mNRI=modified nonresponder imputation; n=number of patients with nonmissing data; N=number of patients in the analysis population; PCS=Physical Component Summary; Q4W/Q2W=80 mg ixekizumab once every 4 or 2 weeks; SD=standard deviation; SI-36=Short Form (36 items) Health Survey; VAS=visual analog scale; WPAI=Work Productivity and Activity Impairment Questionnaire.				
*Data presented as mean (SD) for mBOCF analysis.				
*Patients with baseline HAQ-DI score ≥0.35.				
MCTD defined as patients achieving improvement (decrease in score) ≥0.33.				

important difference [MCID]: improvement ≥ 0.35 from baseline), medical outcomes survey Short Form-36 (SF-36) Physical and Mental Component Summary (PCS and MCS), European Quality of Life 5 Dimensions Visual Analog Scale (EQ-5D VAS; 0-100 scale), fatigue Numeric Rating Scale (NRS; 0 [no fatigue] to 10 [as bad as you can imagine] scale), and Work Productivity and Activity Impairment Questionnaire-Specific Health Problem (WPAI-SHP; absenteeism, presenteeism, work productivity, and activity impairment). Missing values were imputed by modified nonresponder imputation (mNRI) for categorical data and by modified baseline observation carried forward (mBOCF) for continuous data.

Results: Mean baseline (Week 0) scores for HAQ-DI, SF-36 (PCS and MCS), fatigue NRS, WPAI-SHP, and EQ-5D VAS (Table) indicated impaired physical function and quality of life. Patients receiving IXE up to 3 years reported improvements in SF-36 (PCS and MCS), EQ-5D VAS, fatigue NRS, and WPAI-SHP (presenteeism, work productivity, and activity impairment) (Table). The percentage of IXE patients achieving MCID for HAQ-DI (improvement >0.35) was sustained at 3 years.

Conclusion: In bDMARD-naïve patients with active PsA, improvements with IXE in all the measured PROs, including physical and mental function, quality of life, fatigue, and work productivity are maintained up to 3 years.

Depression Has a Greater Impact on Psoriatic Arthritis Than Rheumatoid Arthritis

Surjeet Dheer¹, Vivekanand Tiwari², Ammarah Hussain¹, Kakageldi Hommadov¹, Ana Maheshwari¹ and Martin J. Bergman³, ¹Mercy Catholic Medical Center, Philadelphia, PA, ²St John's Hospital, Springfield, IL, ³Drexel University College of Medicine, Philadelphia, PA

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Clinical/Epidemiology Studies

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Depression has been shown to be more common in patients with psoriatic arthritis (PsA) and rheumatoid arthritis (RA), than in the general population. The extent of this disease has not been studied in comparison between patients with PsA and those with RA. We studied the prevalence of depression in patients with PsA in comparison to those with RA.

Methods: A retrospective observational study was done using data collected from a community-based rheumatology clinic. All patients with data on depression were included for analysis. Baseline demographics, tender joint count (TJC), swollen joint count (SJC), Physician Global Assessment (PhGA), Pain Scale, Patient Global Assessment (PtGA), Function, Routine Assessment of Patient Index Data 3 (RAPID3) (a composite score of patient pain, PtGA, and Function), and Clinical Disease Activity Index (CDAI) (a composite score of TJC, SJC, PtGA, and PhGA) were collected. A validated depression scale was used to assess depressed mood. Data from random visits were chosen and analyzed using an ordered logistical regression. Both a univariate analysis and an analysis controlling for potential confounding variables were performed, using either CDAI or RAPID3 as the marker for disease activity.

Results: The study population consisted of 146 patients who had PsA and 366 who had RA. On a 0-3 scale for depressed mood, patients with PsA reported a mean of 0.55 ± 0.73 , whereas patients with RA reported a mean of 0.40 ± 0.64 (Table 1). When assessing the data using an ordered logistical regression, patients with PsA were 57% ($p=0.02$) more likely to report a higher level of depression than those with RA. When adjusted for disease activity using the CDAI and the RAPID3, the likelihood of PsA having a higher level of depression was 78% ($p=0.01$) and 58% ($p=0.04$) compared to RA, respectively. Lastly, a T-test was performed revealing a statistically significant difference between the PsA and RA groups ($p<0.02$).

Table 1 Data comparison of patients with PsA vs patients with RA

	PsA	RA
Number of Patients	146	366
Age (years)	55.21 ± 12.77	63.27 ± 14.89
Sex (% male)	36.99	28.49
Disease Duration (years)	7.49 ± 7.72	9.40 ± 11.06
Depression Problems (0-3)	0.55 ± 0.73	0.40 ± 0.64
Pain (0-10)	4.80 ± 2.88	4.23 ± 3.01
Global Severity (0-10)	4.33 ± 2.63	4.31 ± 2.91
Function (0-10)	2.15 ± 1.89	2.15 ± 2.05
Tender Joint Count (0-28)	1.65 ± 3.64	2.31 ± 4.94
Swollen Joint Count (0-28)	2.87 ± 4.00	4.60 ± 5.09
Physician Global (0-10)	2.42 ± 2.21	2.26 ± 2.22
RAPID3 (0-30)	11.35 ± 6.74	10.68 ± 7.29
CDAI (0-76)	11.21 ± 9.16	13.47 ± 11.25
Patients on Any Biologic Agents (%)	32.88	24.32

Conclusion: In this cohort, patients with PsA were more likely to report higher levels of depression than those with RA. Furthermore, this occurred independently from levels of disease activity as measured by either the CDAI or the RAPID3. Although causality is yet to be determined, this study enforces the importance of depression screening in rheumatology practice, and early treatment.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Clinical/Epidemiology Studies

Background/Purpose: It is known that uveitis is present in the extra-articular findings of spondyloarthritis (SPA) patients. Sufficient information is available in the literature on the frequency and characteristics of uveitis in SpA patients. The factors associated with uveitis in SPA patients are not clear. In this study, uveitis-related factors were analyzed in SPA patients in a large cohort.

Methods: In patients with and without uveitis, age, gender, duration of illness, delayed onset, body mass index, educational status, smoking habit, SPA subgroup, SPA clinical findings as well as co-morbid diseases, HLA B27 and acute phase responses, VAS pain, VAS patient global, VAS fatigue, BASDAI and BASFI values, swollen and painful joint counts, and direct X-ray findings were evaluated retrospectively. The history of uveitis was accepted only if diagnosed by ophthalmologists.

Results: As of May 2018, there are 2359 registered SPA patients. Among the total number of patients, 2096 patients had axial spondyloarthropathy (axSPA) (1249 ankylosing spondylitis, 100 non-radiographic axSPA), 179 psoriatic arthritis, 50 peripheral SPA and 51 enteropathic arthritis. Overall, 269 (11.4%) patients had experienced one or more episodes of uveitis. Median (Q1-Q3) uveitis beginning age was 36 (27-43) years. Duration between SpA symptom beginning age and first uveitis attack were 6.8 (2.6-12.8) years. Median (Q1-Q3) uveitis attacks number was 2 (1-4). Uveitis was usually unilateral (78.9%). 19/184 (10.3%) patients had permanent damage in the eye. Patients with permanent eye damage had more frequent uveitis attack (4 (2-10) vs 2 (1-3), $p=0.018$), and had tendency of bilateral uveitis attack (37.5% vs 16.6%, $p=0.082$). Demographic and clinical feature of patients were given in table 1. In multivariate analysis, only disease duration was related with uveitis OR 1.069 (1.05-1.09).

Conclusion: In our cohort, genetic background, radiographic severity, enthesitis, and particularly disease duration may be related with uveitis. Although uveitis is usually self-limited, however almost 10% of SpA patients may have permanent eye damage.

Table 1: Comparison of demographic, clinical and laboratory findings of patients with and without uveitis

	Uveitis (-) n=2359	Uveitis (+) n=269	p
Gender (Male/Female, %)	56.4/43.6	60.2/39.8	0,233*
Age	41 (34-49)	44 (37-52)	0,001*

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Clinical/Epidemiology Studies

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: 1) To evaluate the association of inflammation, adipokines and endothelial dysfunction with the cardiovascular risk profile and the metabolic comorbidities associated with psoriatic arthritis (PsA). 2) To explore the effects of the inflammation on the glucose and lipid metabolism in the PsA context. 3) To analyze the effect of apremilast in the adipo/cytokine pattern, metabolic components and endothelial dysfunction in patients with PsA and metabolic syndrome (MetSyn).

Methods: Human study: 60 PsA patients and 30 age and gender-matched healthy donors (HD) were analyzed. An extensive clinical analysis was performed. Endothelial function was measured through post occlusive hyperemia using Laser-Doppler. Twelve PsA patients having metabolic syndrome were given apremilast 30 mg twice daily for 6 months. The levels of cytokines, endothelial dysfunction markers and adipokines were analyzed on serum and leukocytes by ELISA and RT-PCR, respectively. **Treatment of adipocytes with serum from PsA patients:** 3T3L1 adipocytes were treated with serum 10% of PsA patients and HD for 24h. The expression of genes and proteins involved in inflammation, lipid metabolism and insulin signalling was analysed.

Results: MetSyn, obesity and insulin resistance (IR) were increased in PsA. PsA patients had impaired endothelial function. Levels of cytokines, adipokines and endothelial function markers were altered in PsA serum and leukocytes. Increased levels of HOMA-IR correlated with DAS28, clinical and serological inflammatory markers, and diverse adipokines. In addition, PsA serum induced inflammation and modified lipid and glucose metabolism in adipocytes, suggesting a link between the degree of systemic inflammation and the development of IR in these patients. After 6 months of treatment, Apremilast reduced BMI, insulin resistance, inflammation, and levels of ApoB. Adipokines profile was reversed and levels of Apo A increased. Endothelial dysfunction was significantly restored shown by an increase of the peak flow and hyperaemia area and decreased adhesion molecules in serum.

Conclusion: 1) PsA is associated with an increase of inflammatory cytokines and adipokines, alongside with an endothelial dysfunction. These alterations are related to the disease activity and the presence of metabolic comorbidities such as insulin resistance or obesity, contributing to the burden of cardiovascular disease risk. 2) The inflammatory components are directly involved in the development of IR in PsA. 3) Apremilast might reduce IR, inflammation and endothelial dysfunction, parameters strongly involved in cardiovascular disease.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster – ARHP

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Several studies demonstrate efficacy of biologics on disease activity measured by the Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) in patients with axial spondyloarthritis (AxSpA). The Bath Ankylosing Spondylitis Metrology Index (BASMI) is a measure of spinal and hip mobility using 5 domains. To our knowledge no studies have specifically looked at the impact of biologics on BASMI. The aim of our study was to assess if biologics appear to have an effect on BASMI.

Methods: We retrospectively collected the data from a cohort of patients with AxSpA reviewed within a designated clinic in the North West of England who were treated for at least 12 months with a biologic . BASMI scores were recorded at pre biologic, 3 month and 12 month follow up.

Results: Data from 68 patients were analysed (57 AS, 7 PsA, 4 enteropathic arthritis). 58 (85.3%) were male; median age was 52 years (IQR 43,61) Overall 63/68 patients (92.6%) were treated with TNF-inhibitors - including etanercept n=25 (originator or biosimilar), adalimumab n=31, golimumab n=5, infliximab n=2 , 5/68 patients (7.4%) were treated with secukinumab. Median BASMI at baseline was 4.55 (IQR 2.7,6.05). Improvements of BASMI scores were demonstrated with a reduction to a median BASMI of 3.6 (IQR 2,5) at 3 months and 3 (IQR 1.7, 5.2) at 12 months. Improvement appeared to be independent of age. There was no difference identified in improvement between TNF and IL-17 drugs.

Conclusion: Biologics drugs appeared to improve BASMI scores in our cohort through a 12 month period. Due to the small cohort we were unable to highlight any differences between patients treated with aTNF and IL-17 inhibitor medication. Multiple factors can be associated with BASMI changes including motivation, disease duration and progression, use or non use of NSAIDs, exercise behaviours, gender (women may be more flexible in the lumbar spine than men due to less radiographic changes in the hips, lumbar spine and sacroiliac joints (3 BASMI domains) but may have more progression in the neck and upper thoracic spine (2 BASMI domains). We know there is variance in exercise behaviours in that when some feel better they don't perceive the need to physiotherapy exercise so much and therefore don't, but may be more likely to participate in a more active lifestyle and others who are more motivated to do their exercise therapies. We also know that other factors such as anxiety and depression also have a bearing on exercise behaviours and are likely to be related to how they would rate on BASMI and Bath Ankylosing Spondylitis Functional Index (BASFI) scoring. Unfortunately some of the above aspects are difficult to measure but we are planning to further analyse our data inclusive of disease duration prior to commencement of biologics and correlation between BASDAI and BASMI and radiological progressions.

Fatigue Measurements in Systemic Lupus Erythematosus

Ariane Barbacki¹, Michelle Petri², J. Antonio Avina-Zubieta³, Graciela S. Alarcón⁴ and Sasha Bernatsky⁵, ¹McGill University, Montreal, QC, Canada, ²Medicine (Rheumatology), Johns Hopkins University School of Medicine, Baltimore, MD, ³Division of Rheumatology, Department of Medicine, University of British Columbia, Vancouver, BC, Canada, ⁴University of Alabama at Birmingham, Birmingham, AL, ⁵Divisions of Rheumatology and Clinical Epidemiology, McGill University Health Centre, Montreal, QC, Canada

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster II: Biomarkers and Outcomes

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Fatigue is one of the most frequent and disabling issues in systemic lupus erythematosus (SLE). It is, however, difficult to quantify. The Ad Hoc Committee on SLE Response Criteria for Fatigue in 2007 recommended use of the Krupp Fatigue Severity Scale (FSS). Since then, the Functional Assessment of Chronic Illness Therapy (FACIT)-Fatigue score has also been validated in SLE. We performed a review of instruments used to measure fatigue in adult SLE patients from 2007 onward.

Methods: We used Medline and EMBase from 2008 to Oct. 2017 search terms to identify clinical trials and observational studies in adult SLE, where fatigue was an outcome. All English and French studies were reviewed to determine the fatigue measures used, and study results.

Results: 22 studies met our inclusion criteria. Eight fatigue scales were used. The most frequently used instruments were the Visual Analogue Scale (VAS) for fatigue (used in 32%), the FSS (32%) and the FACIT-Fatigue scale (14%). The FSS was used in the majority of clinical trials (5 of 12; 42%) with the remaining evenly divided between the two other scales. The VAS was used by the majority of observational studies (5 of 10; 50%), followed by the FSS (2 of 10; 20%). Fourteen of the 22 studies demonstrated a difference in fatigue levels in terms of statistical and clinically meaningfulness. Of the 8 studies which did not, 3 used the FFS, 3 used the VAS and 2 used other scales (MFI and BFI). All 3 studies using FACIT detected clinically and statistically significant differences.

Conclusion: The VAS, FSS and FACIT Fatigue scale were the most frequently used instruments to measure fatigue in adult SLE studies from 2008-2017. Several studies detected clinical important changes in fatigue with these instruments. If

fatigue is considered a core data element of observational studies in SLE, this review may help inform choice of instruments.

Table 1: Fatigue scales used in studies of adults with systemic lupus (SLE)

Measure	Description	Psychometrically Validated in SLE(38)	Minimal Clinically Important Difference (MCID) in SLE (39)
Visual Analogue Scale (VAS) (40)	Single 100mm line to measure fatigue	No*	Δ 10%
Krupp Fatigue Severity Scale (FSS) (33)	9-item questionnaire on impact of fatigue on specific types of functioning	Yes	Δ 9.7%
Functional Assessment of Chronic Illness Therapy (FACIT)- Fatigue Scale (5)	13-item questionnaire on aspects of physical and mental fatigue and its impact on daily living over the past 7 days.	Yes	Δ 11.5%
Multidimensional Assessment of Fatigue (MAF) (33)	16 item scale that measures fatigue over the past week according to four dimensions: severity, distress, timing and its impact on daily living.	No	Δ 11.5%
Multidimensional Fatigue Inventory (MFI) (41)	20-item self-reported instrument that covers general, physical and mental fatigue as well as reduced motivation and activity.	No	Δ 14.3%
Fatigue Assessment Scale (FAS) (42)	Self-administered 10 item fatigue measure	No	N/A**
Brief Fatigue Index/Inventory (BFI) (43)	Multidimensional self-assessment tool which assesses severity of pain and fatigue in patients with chronic conditions	Yes	N/A**
Vanderbilt Fatigue Severity VFS) (4)	Consists of a fatigue subscale originally developed in Rheumatoid arthritis patients	No	N/A**

* Validated in other populations, including chronic fatigue syndrome, and stroke.

** N/A= not available

Table 2: Summary of Clinical Trials with Fatigue as an Outcome in SLE

Authors	Data collection/ publication	Scale	Intervention	N	Findings	Country

Session Date: Monday, October 22, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster II: Biomarkers and Outcomes

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The highly heterogeneous clinical presentation of lupus is characterized by the unpredictable appearance of flares of disease activity and important organ damage. Attempts to stratify lupus patients have been limited to clinical information, leading to unsuccessful clinical trials and controversial research results. Our aim was to develop and validate a robust method to stratify patients with lupus according to longitudinal disease activity and whole-genome gene expression data in order to establish subgroups of patients who share disease progression mechanisms.

Methods: We applied a clustering-based approach to stratify SLE patients based on the correlation between disease activity scores and longitudinal gene expression information. Clustering robustness was evaluated by bootstrapping and the clusters were characterized in terms of clinical and functional features.

Results: Using two independent sets of patients, one pediatric and another adult, our results show a clear partition into three different disease clusters not influenced by treatment, race or other source of bias. Two of the clusters differentiate into a neutrophil correlated disease group and a lymphocyte correlated disease group, while the third that correlated to a lesser extent with neutrophils, was functionally more heterogeneous. The neutrophil-driven clusters were associated with increased development towards proliferative nephritis.

Conclusion: We found three subgroups of patients that show different mechanisms of disease progression and are clinically differentiated. Our results have important implications for treatment options, the design of clinical trials, the etiology of the disease, and the prediction of severe glomerulonephritis.

The Use of Patient-Reported Outcome Measures to Assess Clinical Features of Fibromyalgia in SLE

Jennifer Rogers¹, Amanda M. Eudy², Lisa Criscione-Schreiber², David Pisetsky³, Kai Sun⁴, Jay Doss⁴ and Megan E. B. Clowse², ¹Medicine, Division of Rheumatology, Duke University, Durham, NC, ²Department of Medicine, Division of Rheumatology and Immunology, Duke University, Durham, NC, ³Department of Medicine, Duke University, Durham, NC, ⁴Division of Rheumatology & Immunology, Duke University, Durham, NC

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster II: Biomarkers and Outcomes

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Patient-reported outcome measures (PROs) in SLE can capture patient specific information and the patient perspective, but clinical use can be challenging due to confounding conditions like fibromyalgia (FM). We employed three PROs to evaluate clinical features and patient assessment of disease activity in SLE patients with and without FM.

Methods: This was across sectional study of SLE patients (ACR 1997 or SLICC 2012 criteria) in a university lupus clinic from January to May 2018. All patients completed these PROs: Systemic Lupus Activity Questionnaire (SLAQ), Patient Health Questionnaire-9 (PHQ9), and 2011 ACR FM criteria. Active SLE was defined as SLEDAI ≥ 6 , clinical SLEDAI ≥ 4 , or active lupus nephritis. We identified 4 groups based on SLE activity and FM criteria: active SLE without FM, active SLE with FM, inactive SLE with FM, and inactive SLE without FM. Clinical variables assessed included self-reported lupus symptoms, flare, disease activity level, hospital/ER admission, medication adherence, SLEDAI, and PGA. Relationships between variables in different groups were analyzed by Fisher's exact test and ANOVA. A step-wise linear regression analysis analyzed predictors of treatment for FM.

Results: 212 patients completed PROs (92% female, mean age 45 years). In our cohort, 31% had active SLE without FM, 13% active SLE with FM, 8% inactive SLE with FM, and 48% inactive SLE without FM. Regardless of SLE disease activity, patients with FM (21% of respondents), reported more muscle weakness, muscle pain, fatigue, sicca, oral/nasal ulcers, dyspnea, chest pain, forgetfulness, headache, numbness, abdominal pain, cognitive dysfunction and waking unrefreshed. There was no difference in reported ER/hospitalization rates (24%) or self-reported medication compliance (86.4%) between the 4 groups in the preceding 3 months. Active and inactive SLE patients with FM self-reported higher disease activity, rates of lupus flare, and had higher SLAQ scores, compared to inactive or active SLE without FM. FM symptoms were addressed (education or intervention) at 38% of visits. In regression models, FM counseling increased with increasing PHQ9 score (OR: 1.21; 95% CI: 1.11, 1.33) and for patients who self-reported a lupus flare (OR: 3.05; 95% CI: 1.16, 8.03). In contrast, FM counseling decreased with increasing PGA score (OR: 0.17; 95% CI: 0.07, 0.44). Without FM, there was moderate correlation between patient and physician disease activity measures in active SLE, but there was discordance between patient and physician assessments as measured by the SLEDAI, PGA, SLAQ and patient reported lupus activity in SLE patients with FM.

Conclusion: FM is common in SLE patients and is associated with a unique set of self-reported symptoms. FM in SLE results in discordance between patient reported lupus activity and physician assessment as patients with FM report higher levels of disease activity.

Session Date: Monday, October 22, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster II: Biomarkers and Outcomes

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Approximately 38% of adults living with Systemic Lupus Erythematosus (SLE) experience cognitive impairment (CI) that can detrimentally affect employment, disease self-management, and quality of life. Identifying those with SLE related CI is critical, but is difficult to do in busy and resource-limited clinics. The patient-reported 20-item Perceived Deficits Questionnaire (PDQ-20), used to screen for SLE related CI, could be less time and cost-burdensome than other objective instruments. However, there is a dearth of published measurement property evidence for using the PDQ-20 with SLE patients. In adults with Multiple Sclerosis the PDQ-20 is purported to have four factors (subscales): attention/concentration, retrospective memory, prospective memory, and planning/organization. This structure has not been examined in adults with SLE. The purpose of this study is to examine the factor structure and the internal consistency of the PDQ-20 in an SLE cohort.

Methods: Consecutive SLE patients aged 18-65 years were recruited from a single rheumatology center between July 2016 and March 2018. Patients completed the PDQ-20. Analyses included socio-demographic descriptive analyses and confirmatory factor analyses (CFA) of the purported PDQ-20 four-factor structure. Sample size calculations indicated that a cohort of $n=177$ was sufficient to perform the CFA (power=0.99). Analysis was completed on returned baseline PDQ-20 data using SAS[®] software.

Results: Patient demographics are presented in Table 1. There was no missing PDQ-20 data. CFA model fitting was adequate (standardized root mean square residual=0.05; root mean square error of approximation=0.10; Bentler comparative fit index=0.90). All factor loadings were statistically significant (factor loading range 0.55-0.88; all t -value >9.82). All factors highly correlated with each other (correlation range: 0.87-0.97; all $p<0.01$). Lagrange Multiplier (LM) tests indicated that multiple alternate item-factor pathways could improve the four-factor model (ten largest significant LM statistics range from 7.92-20.78; new possible pathways for 7 items to other factors). Item 19 (forget to take medication) had low reliability to its purported factor (prospective memory; $R^2=0.30$). The internal consistency (Cronbach's alpha) for the four factors ranged from 0.82 to 0.91.

Conclusion: The CFA analyses indicate that while the fit of the four-factor model for the PDQ fits, the model could be improved. Particularly concerning is the different factor-pathways for seven items, the current low item-factor reliability for item 19, and the increased correlations between factors. In adult SLE patients, researchers and clinicians should be cautious in interpreting PDQ-20 results using the current four factors (subscales). Further validity analyses, including exploratory factor analyses, are needed.

Table 1 Socio-demographic information of recruited patients ($n=208$) who returned and did not return PDQ-20

	PDQ-20 returned ($n=177$)	PDQ-20 not returned ($n=31$)
Sex (% female)	89.8%	83.9%
Age at study visit (mean \pm SD years)	42.75 \pm 12.12	41.97 \pm 12.75
Age at SLE diagnosis (mean \pm SD years)	28.16 \pm 10.48	28.57 \pm 10.19
Highest education level obtained at study visit (% of sample*)	High-school or less 25.1% College/University 74.9%	High-school or less 16.1% College/University 83.9%

Table . (Cont'd)

	PDQ-20 returned (n=177)	PDQ-20 not returned (n=31)
Employment status at study visit (% of sample#)	Employed 51.7% Retired 2.9% Homemaker 6.9% Student 5.2% Disability/sick leave 27.6% Looking for work 4.0% Other 1.7%	Employed 73.3% Retired 0.0% Homemaker 3.3% Student 6.7% Disability/sick leave 16.7% Looking for work 0.0% Other 0.0%

Note: All demographic variables not statistically significantly different between groups ($p > 0.05$); all data from baseline visits of longitudinal study.

* n=170 (7 patients missing data) for returned group; n=31 for not returned

n=174 (3 patient missing data) for returned; n=30 (1 missing) for not returned

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster II: Biomarkers and Outcomes

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Clinical outcomes in SLE are challenging to predict. In non-SLE populations, susceptibility to adverse outcomes has been measured using a frailty index (FI), which quantifies vulnerability via the accumulation of health deficits. Using data from the Systemic Lupus International Collaborating Clinics (SLICC) inception cohort, we constructed and validated a frailty index for patients with SLE.

Methods: Patients fulfilling ≥ 4 ACR classification criteria for SLE were recruited within 15 months of diagnosis and were assessed annually for medication use, comorbidities, disease activity (SLEDAI-2K), organ damage [SLICC/ACR Damage Index (SDI)], health-related quality of life [Short-Form 36 (SF-36)] and other measures.

For our analysis, the baseline visit was defined as the first at which both SDI and SF-36 data were available. From this baseline dataset, health deficits were identified for inclusion in the SLICC frailty index (SLICC-FI). Using standard criteria, a health deficit was defined as any symptom, disease process, functional impairment, or laboratory abnormality that is: (i) acquired, (ii) associated with increasing age, (iii) associated with adverse outcomes, (iv) present in $\geq 1\%$ and $\leq 80\%$ of patients, and (v) missing values for $< 5\%$ of patients. Once selected, the health deficits were used to calculate a baseline SLICC-FI score for each patient.

To assess validity, we estimated correlations of the SLICC-FI with existing SLE instruments, including the SDI and the SLEDAI-2K. Multivariable Cox regression was used to estimate associations between baseline SLICC-FI values and mortality risk, adjusting for relevant demographic and clinical variables.

Results: 1682 SLE patients (92.1% of the cohort) were eligible for inclusion and were predominantly female (89%) with mean (SD) age 35.7 (13.4) years and mean (SD) disease duration 18.8 (15.7) months at baseline. Of 222 candidate variables, 48 met the required criteria for inclusion as health deficits in the SLICC-FI. These included items related to organ damage, disease activity, comorbidities, and functional status. The mean (SD) baseline SLICC-FI score was 0.17 (0.08) with a range from 0 to 0.51. At baseline, SLICC-FI values were weakly correlated with both SDI ($r=0.262$; $p<0.0001$) and SLEDAI-2K ($r=0.227$; $p<0.0001$) scores. These correlations persisted after removing overlapping SDI and SLEDAI-2K items from the SLICC-FI.

Sixty-six deaths occurred during a mean (SD) follow-up of 6.7 (4.0) years. Higher baseline SLICC-FI values (per 0.05 increase) were associated with increased mortality risk (Hazard Ratio [HR] 1.59; 95% CI 1.35-1.87), after adjusting for age, sex, baseline steroid use, race/ethnicity, geographic region, and baseline SDI scores. The association between baseline SLICC-FI scores and mortality risk persisted when damage items were omitted from the SLICC-FI (HR 1.37; 95% CI 1.22-1.53) and when a subgroup of patients without baseline organ damage (SDI=0) was analyzed (HR 1.47; 95% CI 1.18-1.83).

Conclusion: The SLICC-FI is a relevant health measure in SLE. It predicts future mortality risk independent of the SDI and is a potentially valuable tool for identifying SLE patients who are most vulnerable to adverse outcomes.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster II: Biomarkers and Outcomes

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM iC3b/C3 Ratios More Strongly Correlate with SLE Disease Activity in African-Americans Compared with Whites

Background/Purpose: Complement activation is a hallmark of systemic lupus erythematosus (SLE) pathophysiology. iC3b is a complement split product of C3b formed during complement activation. We have previously found that iC3b/C3 ratios associated with both active disease and clinically meaningful changes in SLE disease activity. Since SLE is more severe in nonwhite populations, we hypothesized that iC3b/C3 ratios would be a more sensitive marker of disease activity and examined this relationship in African-American (AA) and white subjects with SLE.

Methods: 159 adult SLE (92 AA and 67 white) patients were enrolled. C3 and C4 were measured by nephelometry; iC3b by a lateral flow assay. SLE disease activity was measured using the SLEDAI 2K Responder Index-50 (S2K RI-50). Statistical analyses were performed using SAS v9.4. Multilevel regression models examined associations with SLE disease activity. Ordinal logistic regression models with generalized estimating equation (GEE) modeling examined associations with clinically meaningful changes since the outcome variable is ordinal. Odds ratios (OR) and 95% confidence intervals (CI) were estimated using Proc GLIMMIX and Proc GENMOD.

Figure 1. Univariate regression analysis of the association of biochemical variables with active SLE. Red (AA) and pink (whites) whiskers represent statistically significant variables, while grey (white) and black (AA) represent non-significant variables.

Figure 2. Univariate regression analysis of the association of biochemical variables with clinically meaningful changes in disease activity. Red (AA) and pink (whites) whiskers represent statistically significant variables, while grey (white) and black (AA) represent non-significant variables.

Results: Both iC3b/C3 ratios and C3 associated with active disease in AA and whites in univariate regression analysis, although association of the iC3b/C3 ratio was stronger in AA (Figure 1). In AA, active disease also associated with C4, ESR, and dsDNA levels, whereas it was CRP in whites. Association of iC3b/C3 ratios was independent of other variables in multiple regression analysis (AA: OR=1.48, 95% CI=1.21-1.82; whites: OR=1.17, 95% CI=1.02-1.34).

We next examined whether there were differences in clinical meaningful changes in disease activity and iC3b/C3 ratios with race. In univariate regression analysis, iC3b/C3 ratios were associated with clinically meaningful changes in disease activity in AAs; less so in whites. (Figure 2). In multiple regression analysis, an association was demonstrated in both races; stronger in AA (AA: OR=0.89, 95% CI=0.83-0.96; whites: OR=0.92, 95% CI=0.88-0.97).

Conclusion: iC3b/C3 ratios were more strongly associated with active SLE and clinically meaningful changes in disease activity in AA compared with whites. This likely reflects either racial differences in complement activation or disease phenotypes. Our data suggest that the iC3b/C3 ratio is a valuable biomarker in AA SLE patients.

Disease Course Patterns in Systemic Lupus Erythematosus: Impact on Long-Term Outcomes

Konstantinos Tselios, Dafna D Gladman, Zahi Touma, Jiandong Su, Nicole Anderson and Murray Urowitz, University of Toronto, Toronto Western Hospital, Toronto, ON, Canada

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster II: Biomarkers and Outcomes

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Previous studies have described three patterns of disease activity over time in systemic lupus erythematosus (SLE), namely long quiescence, relapsing remitting, and persistently active. However, they all enrolled prevalent patients, many of whom in the late stages of the disease. As such, the patterns of disease course since diagnosis are not known. The aim of the present study was to assess the impact of these patterns on damage accrual, flare and mortality in an inception cohort.

Methods: Inception patients of our long-term longitudinal cohort (enrolled within 18 months of diagnosis), with at least 10 years of follow-up and no time interval >18 months between consecutive visits, were investigated. Prolonged remission (PR) was defined as a clinical SLEDAI-2K=0 [serology (anti-dsDNA antibodies and C3/C4 levels) excluded], achieved within five years since enrolment and maintained for ≥10 years after that. Relapsing-remitting (RR) pattern was defined based on ≥2 remission periods (one remission period equals two consecutive visits with a clinical SLEDAI-2K=0), while patients with no remission were categorized as persistently active (PA). Patients with only one remission period (“hybrids”) were re-allocated to the RR and PA groups according to the lower quartile of the time spent in remission for the RR patients (3.5 years). Multivariable analysis was performed using baseline demographic, clinical, immunological and therapeutic variables as well as disease-related variables at two years to identify predictors for disease course. Descriptive and regression analyses were used to compare groups regarding cumulative damage at 10 years, mortality and flare rate beyond 10 years (median follow-up 17.5 years).

Results: Of 267 patients who fulfilled the inclusion criteria, 27 (10.1%) achieved prolonged remission, 180 (67.4%) RR and 25 (9.4%) PA disease. Thirty-five patients (13.1%) had only one remission period (“hybrids”). At enrollment, there were no significant differences in demographic, clinical, immunological and therapeutic characteristics among the PR, RR and PA groups. Multinomial regression analysis for the identification of predictors for group membership showed Black race [OR=2.78, 95%CI=1.05-7.31, $p=0.039$] and higher adjusted mean SLEDAI-2K over the first two years [OR=1.21, 95%CI=1.11-1.32, $p<0.0001$] to be associated with a more severe disease course. Outcomes at 10 years and beyond are given in Table 1.

Table 1 Outcomes at 10 years after enrolment and beyond for all groups

	PR (n=27)	RR (n=180)	PA (n=25)	<i>p</i>
Outcomes at 10 years				
SLICC/Damage Index (mean±SD)	0.93±1.07	1.22±1.33	2.36±1.60	<0.001
Outcomes at the last visit				
Flare incidence (/100 patient-years)	1.0±1.8	4.9±7.0	5.0±4.0	<0.001
All-cause mortality (%; n)	11.1% (3)	13.3% (24)	24.0% (6)	0.22
Time to death (since diagnosis, years±SD)	24.0±4.1	20.1±7.2	18.4±4.4	0.11

P value from Cochran-Armitage trend test for all groups

Re-allocation of the hybrids into the RR and PA groups (17 and 18 patients respectively) provided similar results.

Conclusion: Black race and more severe disease over the first two years were associated with a worse disease course over time. Disease course was, in turn, associated with a gradual increase in damage accrual (from PR to RR to PA) as well as flare rate. Differences in mortality did not reach statistical significance.

Laboratory Investigation Results Influence Physician's Global Assessment of Disease Activity in Systemic Lupus Erythematosus

Cynthia Aranow¹, Anca Askanase², Molla Huq³, Shereen Oon⁴, Alicia Calderone⁴, Eric Morand⁵ and Mandana Nikpour⁶,
¹Feinstein Institute for Medical Research, Mahasset, NY, ²Columbia University, College of Physicians & Surgeons, New York, NY, ³The University of Melbourne at St Vincent's Hospital, Melbourne, Australia, ⁴The University of Melbourne at St. Vincent's Hospital, Melbourne, Australia, ⁵Monash University, Melbourne, Australia, ⁶The University of Melbourne, Melbourne, Australia, Melbourne, Australia

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster II: Biomarkers and Outcomes

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The Physician Global Assessment (PGA) is a frequently-used outcome measure in Systemic Lupus Erythematosus (SLE). The PGA is intended to encapsulate the physician's judgement of overall disease *activity*. Consensus on whether the PGA should be performed prior to, or after the receipt of laboratory values is lacking. A single-clinician pilot study in a US-outpatient clinic suggested that there are significant differences between the PGA score determined pre and post knowledge of labs¹. The primary objective of the current study was to determine, in a diverse international group of lupus experts, whether there is a difference in PGA scores with and without awareness of laboratory test results.

Methods: Fifty clinical vignettes based on real-life cases, spanning the spectrum of SLE manifestations and severity (SLEDAI-2K ranging from 0 to 28), were presented via an online survey to 194 international SLE experts. Respondents were asked to rate the PGA pre and post inclusion of laboratory test results for each case, with only forward progression through the survey allowed. Scoring of the PGA was done on an anchored scale of 0-3 with 0=none, 1=mild, 2=moderate and 3=the most active disease imaginable. Measures of central tendency and spread were used to describe responses, and Pearson's correlation coefficient (CC) was used to evaluate the relationship between pre- and post-lab PGA for each case. Inter-rater reliability of PGA responses was assessed using the Intraclass Correlation Coefficient (ICC), and the correlation between PGA and SLEDAI-2K was also determined.

Results: There were 60 complete surveys (North America n=24, South America n=5, Europe n=15, Asia n=10, Australia n=6), comprising a data set of 3000 unique paired responses. The inter-rater reliability for PGAs was excellent (pre-lab ICC 0.98; post-lab ICC 0.99). Post-lab PGA were higher than pre-lab PGA: median (IQR) pre-lab PGA 0.5(1.05), post-lab PGA 1(1.3) ($p<0.001$), and the median (IQR) difference in post- and pre-lab PGA (delta-PGA) for all case pairs was 0.2(0.45). The correlation between pre and post-lab PGA was moderately strong (Pearson CC 0.79, 95% CI: 0.67-0.88, $p<0.001$). In 20 cases the CC was ≥ 0.8 and in 14 cases the CC was 0.6-0.79. In the 16 cases where the CC was ≤ 0.59 , delta-PGA was median (IQR) 0.58 (0.68); these were mostly cases where lab data revealed lupus nephritis and/or hematologic manifestations. In general, all abnormal labs, including elevated anti-dsDNA and low complement level, impacted the PGA assessments. The correlation between SLEDAI-2K and PGA was higher for post-lab than pre-lab PGA (CC 0.79 and 0.67, respectively).

Conclusion: Although the PGA is known to be a subjective measure, we found excellent inter-rater reliability in a group of international lupus experts from six continents. Post-lab PGA scores had stronger correlation with SLEDAI-2K, and were generally higher than pre-lab PGA scores, with abnormalities on urinalysis and cytopenias having the greatest impact. Overall, our findings indicate that the PGA should be performed with knowledge of the pertinent laboratory values.

Poor Sleep Quality Predicts Worsening SLE Disease Activity

Philip Chu¹, Alicia M. Hinze², Noor Al-Hammadi³, Lacey Feigl⁴, Nancy Mathis⁴, Deepali Sen⁵, Seth Eisen⁴, Yo-El Ju⁶ and Alfred Kim⁷, ¹Internal Medicine, Washington University School of Medicine, Saint Louis, MO, ²Rheumatology, Johns Hopkins University, Baltimore, MD, ³Division of Biostatistics, Washington University School of Medicine, Saint Louis, MO, ⁴Rheumatology, Washington University School of Medicine, Saint Louis, MO, ⁵Rheumatology, Washington University

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster II: Biomarkers and Outcomes

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Poor sleep quality is commonly observed in patients with SLE. We hypothesize that poor sleep contributes to worsening SLE. The aims of this study are to evaluate the relationship between subjective sleep measures and SLE activity over time.

Methods: A prospective, longitudinal, observational study evaluated the relationship between sleep and SLE disease activity. 151 patients were enrolled. Pittsburgh Sleep Quality Index (PSQI), Epworth Sleepiness Scale (ESS), Patient Reported Outcomes Measurement Instrument System (PROMIS)-Sleep Related Impairment (SRI), and PROMIS-Sleep Disturbance (SD) survey instruments measured patient reported sleep quality. The population mean for the PROMIS instruments is 50. The SLEDAI-2000 Responder Index-50 (S2KRI-50) was used to define active SLE as S2KRI-50 >4 and worsening SLE at subsequent visits as an increase in S2KRI-50 ≥ 4 . Baseline comparisons were calculated using non-parametric tests. Kaplan-Meier and Cox proportional hazards methods examined the relationship between poor sleep and worsening SLE activity over time.

Results: At baseline, the median age was 42, 90.7% were female, 54.3% were African American, 24.5% were on prednisone doses >7.5mg/day, and 36.4% had active SLE. Patients with active SLE had significantly higher SRI scores (median 64.3) vs inactive SLE (median 56.6) as well as significantly higher SD scores (median 58.3 vs 52.2), whereas PSQI and ESS were not significantly different.

Data from 109 patients with ≥ 2 visits were used for longitudinal studies. Kaplan-Meier analysis, stratified by SRI T-score of >60 vs ≤ 60 demonstrated that worse sleep (SRI >60) at the previous visit predicted worsening SLE activity at the next visit (Figure 1). Over a 12 month period, the probability of SLE activity worsening was 21.4% overall, 34.2% for SRI >60, and 15.0% for SRI ≤ 60 ($p=0.024$). Cox proportional hazards regression analysis showed that SRI >60 (hazard ratio (HR) 3.06), male sex (HR 4.66), and prednisone use (>7.5mg/day) (HR 3.59), but not age (HR 0.97), were significantly associated with worsening SLE.

Figure 1. Poor sleep at prior visit predicts worsening SLE

Conclusion: Our study reinforces that patients with SLE report worse subjective sleep compared to the general population, and patients with active SLE have worse sleep than patients with inactive SLE. Our longitudinal data demonstrate that poor sleep predicts worsening SLE disease activity. Thus, variation in subjective sleep may have an important role in SLE flares.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster II: Biomarkers and Outcomes

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Disease activity in Systemic Lupus Erythematosus (SLE) leads to damage, comorbidities and increased overall mortality. Frequent assessment is needed to adapt patients' management. The Systemic Lupus Activity Questionnaire (SLAQ) is a patient self-reported instrument to screen for disease activity outside the clinical setting. Our aim was to validate the SLAQ in Spanish and evaluate its association with other validated disease activity scores.

Methods: The SLAQ questionnaire was translated and adapted in Spanish. For its validation, we included consecutive SLE patients (fulfilling the 1997 ACR classification criteria) from 3 Rheumatology centers in Argentina who responded the questionnaire. A rheumatologist blinded to S-SLAQ results examined each patient and completed a SLEDAI and Physician's Global Assessment (PGA). Internal consistency (Cronbach's alpha), test-retest reliability (intraclass correlation coefficient), and construct validity (Spearman's correlation coefficient) were examined. We further evaluated the questionnaire in a larger cohort of consecutive patients from 8 Rheumatology centers. Correlations with SLAM, SLAM-no lab, SLEDAI and Patient's Global Assessment (PGA2) were assessed (Pearson's correlation coefficient). Sensitivity, specificity, and positive and negative predictive values for clinically significant disease activity (SLEDAI ≥ 6) of different S-SLAQ cut-off points (ranging 0-35) were evaluated.

Results: In the first part of the validation, we included 40 patients [97% female, mean age 40 SD13], with a median disease duration of 116 months (IQR 49-112). The median time of answering was 2.65 minutes (IQR 1.46-4.83). The internal consistency was good to excellent (Cronbach's alpha=0.84, $p<0.001$) and the intraclass correlation coefficient was 0.95 ($p<0.001$). Correlation with other scores was weak (SLEDAI $r=0.1$, PGA $r=0.2$). In the larger cohort where we continued to evaluate construct validity, we included 97 consecutive patients ([93% female, mean age: 40 years (SD14.7)]. 42% were “Mestizos”, 33% Amerindians and 25% Caucasians. Mean score of S-SLAQ was 8.24 (SD 7.31); mean SLAM-no lab was 2.06 (SD 2.38); mean SLAM was 3.68 (SD 3.17), mean SLEDAI-2K was 2.75 (SD 3.96) and mean PGA2 was 0.52 (SD 0.79). No differences in SLAQ score were detected when comparing different gender, ethnic, educational and socioeconomic groups. Correlation of S-SLAQ with PGA2 was moderate ($r=0.63$ $p<0.001$); and weak with SLAM-no lab ($r=0.42$, $p<0.001$) and SLAM-R ($r=0.38$, $p<0.0001$). It was very weak with SLEDAI-2K ($r=0.15$, $p=0.1394$). Using the S-SLAQ cut-off of five points the sensitivity was 72.2 % and specificity 37.9 %, for clinically significant disease activity (SLEDAI 2K ≥ 6).

Conclusion: The S-SLAQ showed good validity and reliability. A good correlation was observed with patient's global disease activity. No correlation was found between S-SLAQ and standard disease activity measures like SLEDAI 2K and SLAM. The S-SLAQ cut-off point of 5 showed a good sensitivity to identify the active SLE population and therefore could be an appropriate screening instrument for disease activity in clinical and epidemiological studies.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster II: Biomarkers and Outcomes

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Lupus Impact Tracker (LIT) is a ten item unidimensional patient reported outcome tool developed from and for patients with systemic lupus erythematosus (SLE). It has been widely validated and shown to have good psychometric properties and responsiveness, to patient reported changes in health, physician based disease activity and composite response Index. Herein we report functioning of LIT in the largest European SLE registry cohort.

Methods: Multi-center data collected prospectively, two years apart, from 1,364 adult patients SLE meeting 1997 ACR criteria were obtained. This included demographics, patient reported tools (LIT, EuroQoL- EQ5D) and SLE (activity-SLEDAI & SLAQ; damage-SDI). We evaluated LIT for reliability (Internal consistency), validity (construct (convergent and factor analysis), and criterion). Cronbach alpha was obtained for internal consistency reliability. Spearman correlation coefficient (r) of LIT against EQ5D and factor analysis were obtained for Construct validity. Correlation of LIT with

SLEDAI, SLAQ and SDI were made for Criterion Validity. Responsiveness of LIT to changes in SLEDAI (cutoff 5) and SLAQ (cutoff 5) from baseline and year 1 data were obtained using mixed model analysis.

Results: 1232/1364 (90%) were women, and 95% were Caucasian. Mean (SD) SLEDAI, NRS-SLAQ and SDI were 2.6 (3.5), 3.1 (2.5) and 0.7 (1.1) respectively. Mean (SD) LIT and EQ5D VAS were 29.2 (23.2) and 67.3 (21.4). Internal consistency reliability of LIT was good (Cronbach α 0.92). Construct-convergent validity with EQ5D domains and VAS were as follows: Mobility (r 0.46, $p < 0.001$), Self-Care (r 0.38, $p < 0.001$), Usual Activities (r 0.62, $p < 0.001$), Pain/Discomfort (r 0.63, $p < 0.001$), Anxiety/Depression (r 0.60, $p < 0.001$), and EQ5D-VAS (r -0.62, $p < 0.001$). Single factor explained 58% of variance in LIT (Eigenvalue 5.8), confirming its uni-dimensionality and construct validity. LIT scores were correlated with SLEDAI (r 0.12, $p < 0.001$), NRS-SLAQ (0.71, $p < 0.001$ & 0.67, $p < 0.001$) and SDI (0.16, $p < 0.001$) supporting criterion validity. EQ5D VAS also correlated with SLEDAI, SLAQ and SDI. Mean decline in LIT in response to improvement in SLEDAI and SLAQ were -2.9 (SRM -0.17, ES 0.08, P 0.04) and -13.1 (SRM -0.74, ES -0.30, $p < 0.001$); while mean increase in LIT in response to worsening in SLEDAI and SLAQ were 0.91 (SRM 0.04, ES 0.03, p 0.06) and 12.6 (SRM 0.65, ES 0.43, $p < 0.001$) respectively.

Conclusion: Lupus Impact Tracker documented good measurement properties among Spanish SLE patients enrolled in this observational largest European SLE registry.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster II: Biomarkers and Outcomes

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Remission & Low Disease activity state (LDAS) are the two new health outcome measures developed with “treat to target” strategy in mind for Systemic Lupus Erythematosus (SLE). Lupus Impact Tracker (LIT), a ten item unidimensional patient reported tool has good psychometric properties and responsiveness to patient reported changes in health, physician based disease activity (DA) & composite response Index (SRI). Herein we report responsiveness of LIT to changes in LDAS & remission status among SLE patients from the largest European SLE registry- cohort.

Methods: One year longitudinal, observational, multi-center data from 1,364 adult patients with SLE meeting 1997 ACR criteria were obtained from baseline (B) and year 1 visit (Y1). This included demographics, patient reported tools (LIT), SLE (activity-SLEDAI) and medications. Remission off therapy was defined as SLEDAI=0 without prednisone or Immunosuppressive/s. Remission on-therapy was SLEDAI=0 & a prednisone dose ≤5mg/day and/or Immunosuppressive/s (maintenance dose). LDAS (modified) was defined as SLEDAI ≤4, prednisone dose ≤9mg/day and/or maintenance immunosuppressive/s. Non-optimal (NO) disease status was SLEDAI >4 and/or prednisone dose >9mg/day and/or immunosuppressive/s in induction dose. Use of hydroxychloroquine was permitted in all groups. LIT values were compared between groups with various disease activity using mixed models & both visits data. Due to relatively less number of observations in remission on and off therapy groups, both were combined into one remission group for responsiveness analysis. Latter was calculated by standard response means (SRM) in groups with a change of DA (NO was referent category). Due to relatively less number of observations in remission on and off therapy groups, both were combined into one remission group for responsiveness to change analysis.

Results: 1232/1364 (90%) were women, and 95% were Caucasian. Mean (SD) SLEDAI and SDI were 2.6 (3.5) and 0.7 (1.1) respectively. Distribution for each group is shown in Table 1 a. LIT scores were significantly lower among those in combined Remission (lower by average 9.4, SE 1.4, p<0.001) and LDAS (lower by average 6.2, SE 1.2, p <0.001) when compared with “non-optimal” activity group (Mean 34.0, SE 1.0).

LIT showed significant small to moderate responsiveness in the appropriate direction with improvement and worsening in disease activity status over time (Table 1 b). Mean changes to and from “LDAS” to “non-optimal” activity state ranged from 2-3.5, while they ranged from 5-8 for to and from “Remission” to “non-optimal” activity state.

Conclusion: Lupus Impact Tracker is able to differentiate between remission off and on treatment, LDAS and non-optimal disease activity state. LIT shows responsiveness to change in disease activity state over time, in the appropriate direction among Spanish SLE patients enrolled in the largest observational, European SLE registry.

Table 1a LIT scores by Disease Activity State

	n	Mean	SE P value	
Remission Off treatment	1359	24.63	1.38	<0.001
Low Disease Activity State	1359	27.8	1.05	<0.001
Remission On Treatment	1359	31.9	1.04	0.13
Non Optimal Activity State	1359	34.0	1.03	Reference
Table 1b: Responsiveness of Lit				
Disease Status Change	n	Mean Δ LIT	Std Dev	SRM
Non optimal activity to remission	33	-7.83333	17.940675	-0.44
Non optimal activity to LDAS	94	-2.16667	18.00588	-0.012
Non optimal to non-optimal Activity	75	-0.07142857	16.397148	-0.04
LDAS to non-optimal activity	86	3.3783784	21.331662	-0.16
Remission to non-optimal Activity	28	5.208333	17.413086	0.30

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster II: Biomarkers and Outcomes

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is a chronic disease affecting the physical, social, and psychological well-being of patients. Health related quality of life (HRQoL) measures add a new dimension to treatment response. However, their longitudinal correlation with clinical indicators such as disease activity and organ damage are not known. We aimed to determine HRQoL over time in a multi-ethnic Asian SLE cohort and to study its relationship with disease activity and damage.

Methods: Adult patients with SLE (ACR or SLICC criteria fulfilled) attending rheumatology clinics at our institution are recruited in a longitudinal observational study since 2013. Demographic and clinical data including SLEDAI-2K are collected at enrollment and every three months while organ damage (SLICC-ACR damage index [SDI]) is assessed annually. HRQoL is measured using SF-36 survey at enrollment and annually. Patients with 4 or more HRQoL measures from enrollment to December 2016 were included in the current analyses. Linear mixed effect model was used to compare the subsequent SF-36 scores with baseline, and among different races. Moreover, linear mixed effect model was used to evaluate the effect of disease activity (SLEDAI-2K) and damage (SDI) on the SF-36 scores, after adjustment for baseline scores, ethnicity, and time.

Results: A total of 196 patients were studied; mean \pm SD age at enrollment was 47.05 ± 12.54 years, 180 (90.9%) were women. 140 (70.7%), were Chinese; 28 (14.1%) Malays, 17 (8.6%) Indians, and 13 (6.6%) were other races. Majority were non-smokers (91.9%) and 10.1% had a family history of SLE.

Baseline mean \pm SD score of physical component summary (PCS) was 47.8 ± 8.2 , while mental component summary (MCS) score was 48.5 ± 9.8 (Table 1). The mean PCS improved significantly in second ($p < 0.008$) and third year ($p < 0.001$) as compared to baseline scores while no significant change was noted in MCS scores in second ($p < 0.76$) or third year ($p < 0.25$).

Significant association was noted between PCS and SLEDAI 2K scores ($p < 0.006$). For every unit increase in the SLEDAI-2K, the mean PCS would reduce by 0.808 (95% CI 0.236 – 1.381). SDI was negatively associated with MCS ($p < 0.035$); for every unit increase in SDI, the mean MCS would reduce by 0.363 (95% CI 0.026 – 0.701). Indian ethnicity was associated with worse MCS scores ($p < 0.008$).

Conclusion: This study demonstrated that HRQoL improves over time in SLE patients with proper management. Disease activity affects physical health while organ damage dictates psychosocial aspect of life in these patients. Therefore, HRQoL should be considered as an essential outcome measure in management of SLE patients.

Table 1. Yearly scores for PCS, MCS, and subscales (Mean and Standard Deviation)

Domains	Baseline	Y1	Y2	Y3
PCS	47.887 \pm 8.26	49.001 \pm 8.037	49.531 \pm 8.377	50.232 \pm 7.618

Evaluation of Erythrocyte Sedimentation Rate As a Marker of Disease Activity in Patients with Systemic Lupus Erythematosus

Bobby Kwanghoon Han¹, Elizabeth Rathwell¹, Bernard Ng¹ and Mark Wener², ¹Division of rheumatology, University of Washington, Seattle, WA, ²Division of Rheumatology, Department of Laboratory Medicine, University of Washington, Seattle, WA

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster II: Biomarkers and Outcomes

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: SLEDAI is a global disease activity index for SLE and includes anti-DNA and complement levels. However, elevated anti-DNA or low C3 & C4 levels may not be normalized in certain patients when SLE disease activity improve with treatment. In previous studies, ESR was associated with disease activity in SLE. In this study, we evaluated if ESR was a better marker for SLE disease activity compared with anti-DNA and complement.

Methods: We examined the data of patients with SLE who were enrolled in University of Washington Lupus Repository from 2014 through 2018. We included SLE patients who presented with arthritis, mucocutaneous symptoms, serositis or nephritis and excluded those with active CNS lupus, interstitial lung disease, myositis or hemolytic anemia. Additionally, we excluded patients with concomitant diagnosis of other rheumatic diseases including RA, SSs, chronic infection including HBV, HCV, HIV, any significant comorbidities including chronic kidney disease or malignancy, and recent infection, thrombosis or surgery within 4 weeks of the visit. We selected the most recent visit from each patient and examined the relationship between disease activity measured by clinical SLEDAI scores vs. ESR, anti-DNA, C3 and C4. Clinical SLEDAI was defined as SLEDAI without anti-DNA and complement levels in this study. Next, we selected patients who had a minimum of two visits with different clinical SLEDAI scores over the study period and examined whether there were differences in ESR, anti-DNA, C3 and C4 between the two visits in individual patients.

Results: Eighty-three patients met the eligibility criteria. There was a significant correlation between ESR and clinical SLEDAI ($r = 0.3$, $p = 0.007$), which remained significant after adjusting for hemoglobin or hematocrit. Anti-DNA, C3 and C4 did not correlate with clinical SLEDAI. ESR was significantly higher in patients with moderate to severe activity (clinical SLEDAI ≥ 3) than in patients with no activity (clinical SLEDAI = 0) ($p = 0.009$). No differences in anti-DNA, C3 or C4 were found between the two groups. Twenty patients had a minimum of two visits with different clinical SLEDAI and mean difference in clinical SLEDAI between two visits in these patients were 4.5 ± 3.4 . ESR and anti-DNA were significantly different between the two visits and C3 and C4 were not different (Fig 1).

Conclusion: ESR correlated with clinical SLEDAI in SLE patients and was higher in patients with moderate to severe activity compared to those with no activity. Anti-DNA, C3 or C4 did not correlate with clinical SLEDAI and were not different between active and inactive patients. ESR and anti-DNA were different between two visits with different clinical SLEDAI scores in individual patients while there were no differences in C3 and C4. These results suggest that ESR may be a better test than anti-DNA, C3 or C4 in assessing SLE disease activity.

How Consistently Do Publications Define SLE? a Systematic Review

Linjia Jia¹, Ecem Sevim², Medha Barbhaya² and Michael Lockshin³, ¹Hospital for Special Surgery, Weill Cornell Medicine, New York, NY, ²Rheumatology, Hospital for Special Surgery, New York, NY, ³Barbara Volcker Center, Hospital for Special Surgery, New York, NY

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster II: Biomarkers and Outcomes

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is clinically heterogeneous. ACR and/or SLICC classification criteria provide homogeneous populations for research purposes, but studies differ in selection and exclusion criteria and in definitions of SLE. We examine recent publications to determine how consistently they characterize SLE patients.

Methods: We reviewed English-language studies, using “systemic lupus erythematosus” as the search term, and filtering for full text availability, publication dates 4/2//2013-4/2/2018, and human. We excluded reviews, letters, and papers from <2 impact factor journals and/or irrelevant to the question and classified papers as translational if they examined pathophysiology or biological factors that lead to treatment interventions or clinical/epidemiological if patients or populations were studied. We evaluated these papers for inclusion and exclusion criteria, disease activity, overlap syndrome (SLE coexisting with another rheumatic illness), disease stability (defined as no change in treatment regimen for a specified duration), diagnostic antibody status (including antinuclear (ANA), anti-double stranded DNA (anti-dsDNA) and/or anti-Smith (anti-Sm) antibodies), and disease duration.

Results: 402 of 732 papers were suitable for analysis, of which 80 were translational and 322 clinical/epidemiological. 71% of translational studies and 66% of clinical/epidemiological studies used only ACR and/or SLICC classification criteria to define SLE, of which only 9% of translational and 7% of clinical/epidemiological studies specified requirement for both ACR and/or SLICC criteria and diagnostic antibodies. 30% of clinical/epidemiological and only 16% of translational studies specified exclusion criteria. Of the 402 studies overall, only 6% specified exclusion of patients with overlap syndrome, 14% specified disease activity using either SLEDAI score or BILAG index, and 8% specified disease stability. 2% of clinical/epidemiological studies, but no translational studies, specified disease duration.

Conclusion: Although translational and clinical/epidemiological studies all use the term SLE, only 67% specify use of ACR and/or SLICC criteria, 27% specify exclusion criteria; ≤15% of both types of studies exclude patients with overlap syndromes, specify SLE-specific autoantibodies, disease activity, or duration. Improved consistency in the use of these study characteristics might better standardize current literature on SLE.

Table. Characteristics of SLE studies published between 2013-2018 by study type

Study Characteristics	Study Type (n)		
	Translational (80) %	Clinical/Epidemiological (322) %	All (402) %
ACR and/or SLICC SLE Classification Criteria	71	66	67
ACR Criteria + ANA or anti-dsDNA/anti-Smith	9	7	7
Anti-dsDNA or anti-Smith	8	7	7
Exclusion criteria	16	30	27
Exclusion of overlap syndrome	5	7	6
Activity by SLEDAI or BILAG	15	14	14
Disease duration	-	2	1
Disease stability*	6	8	8

ACR and/or SLICC, American College of Rheumatology and/or Systemic Lupus International Collaborating Clinics; ANA, antinuclear antibody; anti-double stranded DNA antibodies (anti-dsDNA), anti-Smith (anti-Sm) antibodies; SLEDAI, systemic lupus erythematosus disease activity index; BILAG, British Isles Lupus Assessment Group.

* defined as no change in treatment regimen for a specified duration

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster II: Biomarkers and Outcomes

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Cardiac block in neonatal lupus is associated with placental transfer of anti-Ro antibodies. The effect of these antibodies on cardiac conduction disorders in adult patients is controversial. Association between anti-Ro antibodies and heart rhythm disorders have been described in isolated cases. However, there are just a few studies that analyse the relationship between autoimmune diseases and electrocardiographic disturbances. Our aim is to determine if there are differences in cardiac conduction of SLE patients in presence of anti-Ro antibodies.

Methods: All patients included fulfilled the SLE criteria (SLICC 2012) and were followed up in a single centre. Patients taking drugs that alter cardiac conduction (except antimalarial drugs) and those who had heart or thyroid disease were discarded. All patients were assessed blindly by a cardiologist who performed an interrogation and physical examination, an electrocardiogram, an echocardiogram and a 24-hour Holter study. Besides, a rheumatologist performed a clinical and analytical assessment including a qualitative analysis by immunoblotting of anti-Ro Ab and a quantification by chemiluminescence of the anti-Ro52 and Ro60 Ab. The presence of other SLE specific Ab (ANA, DNA, antiphospholipid) was also analysed by immunoblot, indirect immunofluorescence and ELISA. Clinical, analytical activity and damage indexes were collected (SLEDAI and SLICC).

Results: 145 patients were included: 92% women, mean age 45 ± 2 , average disease duration 11 years. Patients were undergoing the following treatments: antimalarial 91%, mycophenolate 20%, azathioprine 12%, biological treatment 5% and glucocorticoids 70%. The clinical characteristics are summarized in table 1.

There were no significant differences between positive and negative anti-Ro Ab in terms of gender, age, clinical characteristics or cardiovascular risk factors. None of the patients was affected by an atrio-ventricular block and the rest of the electrocardiographic alterations had no clinical significance and did not predominate in the positive Ro Ab group. Additionally, no differences in heart rate, ventricular extrasystoles or PR, QT or QRS intervals were detected between both groups. The echocardiogram's findings were not relevant and there were no differences between groups. Since the majority of patients with SLE are double positive differences between two subspecificities of Ro (52 and 60) could not be analysed. On the other hand, no differences were found in cardiac conduction regarding the treatments received, the activity or damage indexes, or the analytical or clinical characteristics of the patients.

Conclusion: The study results show that there are no differences in cardiac conduction according to the presence of anti-Ro antibodies in SLE patients. Thus, the cardiac screening in SLE patients with anti-Ro positive antibodies seems not helpful in clinical practice.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster II: Biomarkers and Outcomes

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Clinical manifestations of systemic lupus erythematosus (SLE) and infections sometimes are difficult to distinguish. In clinical practice low complement and anti(ds)DNA levels are used to assess lupus activity but its determination usually requires some days. Leukocyte count, CRP and ESR cannot discriminate SLE from infectious processes. Calprotectin could be a good biomarker to assess lupus activity since it is more specific than CRP and ESR and faster to analyse than anti(ds)DNA. Our aim is to determine serum calprotectin levels in patients with SLE, and its correlation with analytical and clinical manifestations, especially with disease activity.

Methods: A total of 148 patients were included. All patients included fulfilled the SLE criteria (SLICC 2012). A quantitative ELISA analysis was performed to assess levels of serum calprotectin (CALPRO AS, Norway). Other biomarkers of lupus disease activity were also assessed (levels of anti(ds)DNA, hypocomplementemia, ESR and CRP). Clinical variables and activity/damage index (SLEDAI/SLICC) were also evaluated. The study was approved by the Clinical Research Ethics Committee of the hospital and all patients signed an informed consent. The results were compared with a healthy control group of similar age and sex (n=20).

Results: 134 patients (92%) were women with a mean age of 46±12 years and an average SLE evolution of 12±7 years. Mean SLEDAI was 2±2 (105 inactive [<3], 43 mild [4-12], 0 severe [>13]). Mean SLICC was 0.31±0.70. No significant differences were observed in serum calprotectin levels between patients with SLE and healthy controls (2.93±2.35 vs 2.17±1.49 µg/mL, p=0.160). Calprotectin was positively correlated with CRP (r=0.447, p=<0.001) and leukocyte count (r=0.462, p=<0.001). Additionally, patients with higher anti(ds)DNA levels (>100UI/mL) had higher calprotectin compared to patients with lower anti(ds)DNA (3.20±2.63 vs 2.42±1.57 µg/mL; p=0.027), however this pattern was not observed with hypocomplementemia. Contrary to what we expected, we did not observe significant differences on calprotectin levels depending on SLEDAI index classification (cutoff at 4 and 12). Moreover, no differences were observed on calprotectin levels between those patients with/without clinical manifestations such as serositis, arthritis or glomerulonephritis. Patients with antiphospholipid antibodies had higher calprotectin levels (3.75±2.04 vs 2.77±2.38 µg/mL; p=0.045).

Conclusion: Serum calprotectin levels were positively correlated with CRP levels and leukocyte count. Patients with higher anti(ds)DNA levels had higher calprotectin levels, however we did not observe significant differences depending on SLEDAI index or the presence of arthritis, serositis neither glomerulonephritis. Even that calprotectin determination is faster than anti(ds)DNA levels and could be helpful in assessing inflammatory activity. There is an interesting relation between antiphospholipid antibodies and calprotectin. This study should be continued in a larger sample of active SLE patients to assess its utility in clinical practice as a discriminating biomarker for flares and even infections.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster II: Biomarkers and Outcomes

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: A new classification criteria for SLE was proposed at the ACR/ARHP 2017 annual meet. The aim of this study was to compare the performance of the proposed ACR/EULAR'17 criteria against the 2012 SLICC (SLICC'12) and ACR 1997 (ACR'97) classification criteria for SLE in the adult (A-SLE) and juvenile SLE (J-SLE) cohort from India.

Methods: Patient records were chosen from the disease registry collected over the past 8 years for A-SLE, J-SLE, MCTD, Primary SS and primary APS from a tertiary care center in South India. The records were screened to include only ANA associated rheumatic diseases (AARD). Patients who were diagnosed as SLE at their first visit by trained rheumatologists were designated as cases and the other rheumatic diseases as controls. The performance of ACR 97, SLICC'12 and ACR/EULAR'17 criteria at the first visit was analysed. Sensitivity of the three criteria were analysed by sub classifying the patients based on the duration of illness as <18, 19-36, 37-54 and >54 months.

Results: We analysed 273 j-SLE and 884 a-SLE patients as cases and 435 other AARDs (MCTD-119, UCTD-69, SS-217, APS-30) as controls. The demography, clinical and immunological profile of the cases and controls are shown in table 1. The sensitivity, specificity, positive and negative predictive values of each of these criteria are depicted in table 2. The subgroup of adult patients with <54 months disease had the largest difference in sensitivity between the ACR'97 and the other two criteria; whereas the difference was seen in the j-SLE patients presenting within 18 months of disease onset (table 3). False positivity was seen in 41, 71 and 66 patients in ACR'97, SLICC'12 and ACR/EULAR'17 criteria respectively. A score of +4 for low serum c3 and c4 led to the false diagnosis of 15 controls by the ACR/EULAR'17 who were not diagnosed by ACR'97 criteria.

Conclusion: The proposed ACR/EULAR '17 criteria has higher sensitivity and lower specificity than the ACR'97 criteria but is similar to the SLICC'12 criteria among J-SLE and A-SLE. A score of +4 for low c3 and c4 was the probable cause for lower specificity and needs consideration. Assigning an appropriate negative or positive score in case of negative or positive antibodies to either of anti-nucleosome, anti-ribosomal p or anti-histone in all the anti-dsDNA and anti-Smith negative patients may overcome this shortcoming.

Table 1 Demography, Clinical and immunological profile of patients with juvenile SLE, Adult SLE and other ANA associated rheumatic diseases.

	Juvenile SLE (N=273)	Adult SLE (N=884)	Controls (N= 435)
Age (Mean \pm SD, In Years)	18.45 \pm 7.48	31.46 \pm 9.29	38.23 \pm 12.55

Correlation between SLE Specific and Generic Health Related Quality of Life Surveys, and Their Association with Patient Global Rating of Change and Lupus Low Disease Activity State: A Longitudinal Study

Worawit Louthrenoo¹, Nuntana Kasitanon¹, Eric Morand² and Rangi Kandane-Rathnayake³, ¹Division of Rheumatology, Faculty of Medicine, Chiang Mai University, Chiang Mai, Thailand, ²Medicine, School of Clinical Sciences at Monash Health, Monash University, Melbourne, Australia, ³School of Clinical Sciences at Monash Health, Monash University, Melbourne, Australia

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster II: Biomarkers and Outcomes

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: To determine the correlation between SLE-specific and generic patient reported outcomes measures (PROs), and to examine their associations with patients' global rating of change (GRC) in their health-related quality of life (HRQoL), and Lupus Low Disease Activity State (LLDAS).

Methods: SLE patients who full-filled either the 1997 ACR or the 2012 SLICC classification criteria, and attended a rheumatology clinic in Thailand between 2013 and 2017, were recruited for this study. They completed the SLEQoL-TH and SF36-TH surveys (Thai versions), and rated their GRC compared to their previous visit using a 7-point Likert scale (GRC -7 to +7) on the same day of clinic visits. Based on GRC scores, patients were categorised as 'no change' (-1 to +1), 'deterioration' (-2 to -7) or 'improvement' (+2, to +7) in HRQoL. SLE disease activity was determined by the SLEDAI-2K. Physician global assessment (PGA) of disease activity was rated 0-3. LLDAS was defined as described (*Franklyn K. Ann Rheum Dis* 2016). Correlation between SLEQoL-TH and SF36-TH was examined using Person's correlation coefficients. Associations of GRC and LLDAS with SLEQoL-TH/SF36-TH surveys were examined using generalised estimating equations.

Results: 337 patients (2,062 visits) were included. Median [inter-quartile range (IQR)] values of patients' age at enrolment, disease duration, and study duration was 37 [28, 48] years, 7 [3, 13] years, and 3.18 [1.55, 3.46] years, respectively. 56% of patients experienced at least one flare. Median [IQR] time adjusted mean (TAM) -SLEDAI and TAM-PGA scores were 3.5 [2.0, 5.6] and 0.4 [0.3, 0.7], respectively. During the study, 81% of patients achieved LLDAS at least once, and were in LLDAS in approximately 50%. TAM SLEQoL-TH score, and SF36-TH physical component summary (PCS) and mental component summary (MCS), were 89.8 [81.7, 94.9], 46.8 [42.0, 52.1] and 49.4 [42.9, 55.0], respectively. SLEQoL-TH total scores correlated significantly with both SF36-TH PCS and MCS scores ($r = 0.55$ and 0.60 , respectively, $p < 0.01$). Patients who were in LLDAS had statistically significantly higher scores in both SLEQoL-TH and SF36-TH surveys when compared to patients who were not in LLDAS. Patients reported improvement in 58%, deterioration in 15% and no change in HRQoL in 27% of all visits. Compared to the 'no change' control group, patients who reported deterioration in HRQoL were significantly less likely to be in LLDAS (OR 0.53, 95% CI: 0.39-0.72, $p < 0.001$), but HRQoL improvement was not associated with significant increased likelihood of LLDAS. The PGA showed a weak association with the GRC ($r = -0.14$).

Conclusion: The SLE specific PRO, SLEQoL-TH, correlated significantly with the generic PRO, SF36-TH. LLDAS was associated with better HRQoL, and improving HRQoL was predictive for LLDAS attainment.

Variation in HEp-2 Antinuclear Antibody (ANA) Titer Is Strongly Associated with the ANA Kit Manufacturer

Mark Wener¹ and Mark H. Wener², ¹Division of Rheumatology, Department of Laboratory Medicine, University of Washington, Seattle, WA, ²Rheumatology, University of Washington, Seattle, WA

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster II: Biomarkers and Outcomes

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Titers of HEp-2 ANAs vary between laboratories, with many contributing factors. We sought to systematically determine the contribution of different ANA kit manufacturers to ANA variation.

Methods: Proficiency surveys involve sending aliquots of the same specimen to performing laboratories, allowing labs to compare results. Positive HEp-2 ANA titers reported by over 500 participant labs in ANA proficiency surveys by the College of American Pathologists between 2008 and 2017 were analyzed according to the kit manufacturer used by labs. The mean positive ANA titers reported for each specimen were ranked by kit manufacturer, relative to other manufacturers reporting on the same specimen. A total of 79 positive ANA specimens and up to 10 manufacturers were available for analysis, totaling 733 specimen-manufacturer combinations, with a median 46 laboratories reporting results for each combination.

Results: ANA titers of individual specimens differed by up to 5 2-fold dilutions (e.g. ANA 1:40 and 1:1280 reported by one or more laboratories testing the same specimen). The geometric mean titers for different methods differed from the overall mean titer by as much as 2-fold, and the difference between the geometric means of the highest method and the lowest method testing a given specimen over 3 2-fold dilution titers. ANA titer results were strongly influenced by the HEp-2 manufacture used by the labs ($p < 0.0001$ by analysis of variance). Each manufacturer tended to have a fairly consistent rank, relative to the other manufacturers, (figure 1, median rank is indentation, diamond is mean for each manufacturer). Over the 10 years studied, the rank order of the ANA titer for each method was remarkably consistent (figure 2; each line tracks a manufacturer's mean rank by year). The ANA patterns did not significantly affect these results.

Conclusion: The variability in ANA titers is strongly influenced by the manufacturer of the HEp2 kit used in the assays and the differences between kits are generally consistent. Since much of the variability is systematic and associated with the kit manufacturer, harmonizing manufacturers' kits could improve consistency of ANA reporting.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster II: Biomarkers and Outcomes

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Achieving remission and low lupus disease activity state (LDAS) in systemic lupus erythematosus (SLE) patients improves their prognosis in terms of damage accrual. But, the impact of these states on health-related quality of life (HRQoL) has only been sparsely assessed (1,2). The aim of these analyses is to evaluate the association between the duration of remission and LDAS and HRQoL, after adjustment for possible confounders.

Methods: Patients from a single center cohort started in 2012 and who had at least two visits were included in this study. Visits were performed every six months. Socioeconomic and clinical data were recorded at every visit. Disease activity was ascertained with the Systemic Lupus Erythematosus Disease Activity Index 2000 (SLEDAI-2K), disease damage with the SLICC/ACR Damage Index (SDI) and HRQoL with the Spanish version of the Lupus QoL. Remission was defined as a SLEDAI-2K=0, prednisone≤5mg/d, immunosuppressants on maintenance dose, LDAS was defined as not on remission and a SLEDAI-2K≤4, prednisone≤7.5mg/d, immunosuppressants on maintenance dose. Disease activity states were recorded in each visit. The outcomes were each of the Lupus QoL's domains at the last visit. Univariable and multivariable linear regression models, adjusted by age at diagnosis, disease duration, socioeconomic status, antimalarial use, damage, comorbidities and baseline value of the same domain were performed. Duration of remission/LDAS was categorized as ≤25%; >25 but ≤50%; >50 but ≤75%; and >75. Due to the relatively small number of patients on remission, remission and LDAS were examined together.

Results: Two hundred and thirty-five patients were included, 217 (92.3%) were female, mean (SD) age at diagnosis was 35.42 (13.30) years. Disease duration at baseline was 7.32 (6.69) years. The mean follow-up was 3.29 (1.27) years, and they had 4.93 (1.99) visits. Mean percentages of visits on each state during the follow up were 24.23 (31.38) for remission 32.16 (32.63) for LDAS and 43.60 (38.71) for active. The association between the percentage of follow-up on remission/LDAS is depicted in Table 1.

Conclusion: A longer duration on remission/LDAS is associated with a better HRQoL (Physical Health, Pain, Fatigue and Burden to Others) independently of possible confounders.

Table 1: Duration of follow-up on remission/LDAS and HRQoL

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster II: Biomarkers and Outcomes

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is an autoimmune disease characterized by deregulation of cytokine production. IL2 is an anti-inflammatory cytokine in SLE, but its loss leads to the Th2 system activation and in consequence, Th2 proinflammatory cytokines as IL10 are produced. The aim is to analyze the association between IL2 serum levels and clinical activity in SLE. The secondary objective is to characterize the correlation between IL2 and IL10 serum levels.

Methods: A cross-sectional, observational study of 142 patients diagnosed of SLE (according to SLICC 2012 criteria), and 35 healthy controls, was performed. A complete blood-test and an interview were carried out to collect their clinical data. We analyzed IL2 and IL10 serum levels by colorimetric methods. SLE patients were dichotomized as high and low levels for IL2 based on the 5% and 95% percentile values in healthy controls. Biostatistical analysis with R was performed.

Results: 142 SLE patients were evaluated; 94.4% of them were female. Mean values were as follow: age at diagnosis 33.29±13.53 years, disease duration 15.82±10.56 years, SLEDAI 5.91±5.06, IL2 levels 4.34 ±12.2 ng/mL and IL10 levels 12.29 ± 32.82 ng/mL.

We observed lower values of IL2 in SLE patients than in healthy controls (P=0.002), and higher values of IL10 in SLE patients than in healthy controls (P<0.001). Statistical analysis indicates that decreased levels of IL2 is associated with anti-DNA positivity (P=0.045). We did not observe a statistically significant association between IL2 serum levels and SLEDAI scores or complement consumption.

Due to this finding, we categorized SLE patients by low IL2 levels (n=37), normal IL2 levels (n=98) and high IL2 levels (n=7).

	IL2 high levels (n = 7) Mean (SD)	IL2 normal levels (n = 98) Mean (SD)	IL2 low levels (n = 37) Mean (SD)
IL2 levels (ng/mL)	40.05 (41.08)	3.37 (3.52)	0.16 (0.08)
Anti-dsDNA (ng/mL)	12.63 (15.49)	27.49 (57.84)	35.31 (63.12)
C3 (ng/mL)	103.71 (40.13)	107.46 (28.77)	107.89 (24.27)
C4 (ng/mL)	15.86 (6.72)	18 (9.05)	18.35 (8.1)
SLEDAI	7.29 (5.68)	5.63 (5.12)	6.38 (4.82)

The statistical analysis did not yield differences in the clinical activity, anti-DNA or C3-C4 serum levels among patients with lower, normal and higher IL2 levels. Despite the fact that no specific IL2 profile associated with clinical activity was observed, those patients with low IL2 profile had increased anti-DNA levels.

Conclusion: In our series, we observed a decrease in IL2 levels and an increase of IL10 levels, according to the production of the Th2 proinflammatory cytokines in IL2 low levels context. We noted a statically significant association between low IL2 levels and anti-DNA high levels. We have found no statistical evidences on the relationship of IL2 levels and clinical activity in our series of patients.

Kho³ and Rosalind Ramsey-Goldman⁵, ¹Center for Health Information Partnerships, Northwestern University, Chicago, IL, ²Department of Medicine, Division of General Internal Medicine and Geriatrics, Northwestern University, Chicago, IL, ³Northwestern University, Chicago, IL, ⁴Rheumatology, Northwestern University, Chicago, IL, ⁵FSM, Northwestern University, Chicago, IL

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster II: Biomarkers and Outcomes

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic Lupus Erythematosus(SLE) is an autoimmune disease that can affect many parts of the body including skin, lungs, brain, heart, kidneys, joints, and blood vessels. How lupus looks in one patient is different than in another patient. Because of this, it is hard to diagnose a patient as having SLE. EHRs are widely used in healthcare settings and are a rich source of information about patients that can be mined for earlier diagnosis identification.

Methods: We identified 513 patients we knew had SLE from the Chicago Lupus Database (CLD) in the Northwestern Medicine Electronic Data Warehouse (NMEDW). We built an algorithm of SLICC classification criteria using ICD9/10 and labs to see if we are finding the same SLICC classification criteria that are in the CLD. According to SLICC classification rules, to have definite lupus you need at least 1 clinical criteria, at least 1 immunologic criteria, and a total of 4 or more criteria.

Results: As shown in Table 1, of 513 patients with SLE in the CLD, we detected the following SLICC classification criteria correctly in the NMEDW: clinical- chronic cutaneous 97%; acute cutaneous 98%;renal 65%; serositis 52%; arthritis 34%; neuro 29%; ulcers 16%; alopecia 3%;and labs - thrombocytopenia 99%; dsDNA 89%; hemolytic anemia 80%; complement 74%; leukopenia/ lymphopenia 73%; Anti-Sm Antibody 72%; Antiphospholipid Antibodies 64%; Antinuclear Antibody 60%; Coombs 17%; Of the 513 patients with SLE in the CLD, all had at least 1 clinical criteria, 469 had at least 1 immunologic criteria, and 498 had 4 or more criteria. Using EHR data from the NMEDW and rules for the SLICC classification criteria, we categorized 467/513(91%) patients as having definite lupus correctly.

Conclusion: Based the results, we are able to capture over 90% of patients in the NMEDW correctly. Future work includes implementing NLP on criteria like alopecia, oral ulcer, arthritis, and renal biopsy to improve identification of individual criteria in EHR data that ICD9/10 and labs missed. Once we develop an algorithm that is able to capture the same criteria in the NMEDW that are in the CLD, we can use that algorithm to identify patients that might have a missed diagnosis of lupus. If we are able to find patients who have lupus earlier in their disease progression, we can improve their quality of care and treat earlier with the goal of minimizing disease damage.

Table 1. SLICC Classification Criteria Identified in CLD and NMEDW

SLICC Criteria	Identified in CLD (N)	Identified in NMEDW (N)	Identified in CLD and NMEDW (%)
Clinical			
acute cutaneous	435	425	98%
Chronic cutaneous	146	141	97%

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster II: Biomarkers and Outcomes

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Evaluation of lupus flares is inconsistent using glossary-based definitions for grading (1). BILAG 2004 rates flares by new/worse organ scores. The SELENA-SLEDAI flare index (SFI) combines treatment change, new/worse features, and a weighted physician's global assessment (SFI-PGA) visual analogue scale (VAS). A modified SFI (mSFI) improves accuracy by excluding medication criteria while clinicians differentiate mild from moderate flare (2). The Rapid Evaluation of Activity in Lupus (LFA-REALTM) expands the SFI-PGA and other earlier systems (3) for comprehensive VAS-based evaluation of individual symptoms, organs, or global disease. We compared mSFI and BILAG flares during a clinical trial, using SFI-PGA and LFA-REALTM to clarify their differences.

Methods: Disease activity (SLEDAI, BILAG 2004, mSFI, SFI-PGA, and LFA-REALTM) was rated monthly in a clinical trial. Severity of mSFI and BILAG flares was compared to SFI-PGA and LFA-REALTM changes by receiver operating characteristic (ROC) curve analysis.

Results: 50 SLE patients were examined at 430 monthly visit pairs. The mSFI defined 108 flares (73 mild, 34 moderate, 1 severe); BILAG only 77 (63 mild, 8 moderate, 6 severe) (Table 1). The mSFI rated 36 mild BILAG flares as mild and 26 as moderate. These were effectively discriminated by SFI-PGA or LFA-REALTM ($p < 0.001$). There were 34 moderate mSFI flares vs only 8 by BILAG (new/worse B in ≥ 2 organ domains). Also, mSFI flare was scored in 32 of 353 visit pairs with no BILAG flare (27 with mild flare in < 3 BILAG domains). Both SFI-PGA and LFA-REALTM captured flares by mSFI or BILAG (ROC analysis, $p < 0.0001$ for all). Mild vs moderate/severe mSFI flares were distinguished by SFI-PGA or LFA-REALTM. Only LFA-REALTM reflected mild vs moderate/severe flares by BILAG (Table 2).

Table 1. Flares by mSFI and BILAG 2004.

		mSFI flares				
		none	mild	moderate	severe	total
BILAG flares	none	321	32	0	0	353
	mild	1	36	26	0	63
	moderate	0	5	3	0	8
	severe	0	0	5	1	6
	total	322	73	34	1	430

Table 2 ROC analysis of changes in SFI-PGA and LFA-REAL™ in differentiating mild from moderate/severe flares by mSFI and BILAG 2004.

		mSFI	BILAG
Δ LFA-REAL™	AUC	0.7714	0.7466
	p value	<0.0001	0.0041
Δ SFI-PGA	AUC	0.8348	0.6587
	p value	<0.0001	0.0645

Conclusion: BILAG and mSFI flares are captured by changes in SFI-PGA or LFA-REAL™. BILAG flare thresholds are higher (mild flares require increase in 3 organs; moderate flares in a single organ default to mild). SFI compresses these into “mild-moderate”, which hinders clinically significant distinctions. The mSFI clinician’s discrimination of mild vs moderate/severe flare is supported by SFI-PGA or LFA-REAL™ changes. LFA-REAL™ can also distinguish mild vs moderate/severe BILAG flares, likely due to its expanded multisystem scale.

Changes in Heart Rate Variability Reflect Clinical Improvement and Flare in Systemic Lupus Erythematosus

Aikaterini Thanou¹, Stavros Stavrakis², Stan Kamp³, Paul Kamp³, Teresa Aberle³, Cristina Arriens³, Eliza Chakravarty³, Judith A. James⁴ and Joan T. Merrill³, ¹Arthritis and Clinical Immunology Research Program, Oklahoma Medical Research Foundation, Oklahoma City, OK, ²University of Oklahoma Health Sciences Center, Ok, OK, ³Arthritis and Clinical Immunology, Oklahoma Medical Research Foundation, Oklahoma City, OK, ⁴Arthritis & Clinical Immunology, Oklahoma Medical Research Foundation, Oklahoma City, OK

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster II: Biomarkers and Outcomes

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Decreased heart rate variability (HRV) reflects autonomic dysfunction and inflammatory dysregulation and has been observed in SLE. We examined associations of HRV with clinical improvement and flare in patients with SLE participating in a clinical trial.

Methods: HRV was evaluated by a 5 minute electrocardiogram in SLE patients completing ≥2 visits in an ongoing investigator-initiated clinical trial of a targeted biologic. HRV parameters were calculated in the time (RMSSD, SDNN, pNN50) and frequency domains [high frequency (HF), low frequency (LF) and the LF/HF ratio]. Mixed effects linear models (adjusted for baseline HRV) with generalized estimating equations were used to compare changes in HRV between paired visits.

Results: Fifty-eight patients (age 46±11, 55 female) were followed in 505 consecutive visit pairs with complete data on HRV and disease activity available. Categorical improvement (≥1 letter grade improvement in BILAG A/B scores and no new BILAG A/B) occurred in 96 (19%) visit pairs and no improvement or worsening in 409 (81%). RMSSD, pNN50 and HF increased in improving vs. non-improving visit pairs [group differences: 26.1±13.3 (p=0.05), 3.9±1.8 (p=0.038) and 16.9±4.2 (p<0.0001), respectively] and the LF/HF ratio decreased (group difference: -2.1±1.0, p=0.032), suggesting a favorable change in sympathovagal balance (Table 1). There were 82 mild and 43 moderate/severe flares, assessed by a modification of the SELENA-SLEDAI flare index (mSFI) that excludes medication criteria and differentiates mild from moderate flares by physician’s global opinion (1). RMSSD, SDNN, pNN50 and HF decreased [group differences: -37.8±2.5 (p<0.0001), -63.4±31.8 (p=0.04), -10.8±2.1 (p<0.0001) and -69.1±1.8 (p<0.0001), respectively] and LH and LF/HF increased [group differences: 17.6±6.5 (p=0.007) and 5.3±1.9 (p=0.008)] in flaring compared to non-flaring visit pairs (Table 2). Moreover, SDNN, HF and LF/HF deteriorated [group differences: -23.8±5.1 (p<0.0001), -58.9±6.1 (p<0.0001) and 2.8±0.9, (p=0.002), respectively] in moderate/severe compared to mild mSFI flares.

Table 1. Average per visit changes in HRV in improving vs non-improving visit pairs.

Variable	Improving (n=96)	Non-improving (n=409)	P value
RMSSD	26.7±14.5	0.6±4.7	0.05
SDNN	21.6±14.7	0.4±3.4	0.09
pNN50	4.0±1.5	0.1±1.2	0.038
HF	18.8±3.8	1.9±1.7	<0.0001
LH	-0.4±2.6	1.3±1.9	0.72
LF/HF	-2.2±1.0	-0.1±0.2	0.032

Table 2. Average per visit changes in HRV in flaring vs non-flaring visit pairs.

Variable	Flare (n=125)	No Flare (n=380)	P value
RMSSD	1.9±3.5	39.7±4.7	<0.0001
SDNN	1.1±2.6	64.5±31.7	0.04
pNN50	0.1±1.2	10.9±1.7	<0.0001
HF	2.5±1.8	71.6±1.9	<0.0001
LF	0.6±1.9	-17.0±6.2	0.007
LF/HF	0.1±0.1	-5.2±1.9	0.008

Conclusion: Changes in HRV reflecting improved autonomic function correlate with clinical improvement and absence of flare in SLE. These data suggest that HRV may be a simple non-invasive tool to gauge transitions of SLE disease activity. The role of HRV parameters as targets for SLE therapy warrants further investigation.

Abstract Number: 1689

Explaining the Discrepancy between Physician and Patient-Reported Measures of Disease Activity in Systemic Lupus Erythematosus

Nathaniel J. Harris¹, Amanda M. Eudy² and Megan E. B. Clowse², ¹Department of Medicine, Duke University, Durham, NC, ²Department of Medicine, Division of Rheumatology and Immunology, Duke University, Durham, NC

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster II: Biomarkers and Outcomes

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM Explaining the Discrepancy between Physician and Patient-Reported Measures of Disease Activity in Systemic Lupus Erythematosus

Background/Purpose: Patient-reported measures of disease activity provide useful adjuncts to physician-reported measures in identifying patients and pregnancies at greater risk for adverse outcomes. Comparatively little is known about the utility of these measures in SLE patients, and it is unclear how well these measures correspond to physician measures of disease, why they may differ, and if they work for the myriad presentations of SLE.

Methods: Data on patient-reported disease activity during pregnancy were collected on 178 patients with SLE enrolled in a prospective registry at a single academic center from 2008-2018. Physician assessment of disease activity was measured by physician global assessment (PGA) and compared to patient-reported measures in patients with SLE. The patient-reported measures used include domains of the SF-36, as well as visual analog scales assessing pain and general health. We used univariate and multivariable regression models to assess the strength of the relationship between patient and physician-reported measures of disease activity.

Results: Among 178 women with SLE, the mean age was 30 and 49% were black. There was a weak but significant correlation between measures of general health and PGA (R^2 SF-36=0.11; visual analog scale=0.09). However, this relationship was not consistent across all severity levels of SLE. In particular, in women with internal organ disease (PGA 2-3) there was no relationship between patient assessment of general health and PGA (R^2 =0.0). In contrast, those with less severe disease showed a stronger correlation between patient-reported measures and PGA (R^2 SF36=0.18, VAS=0.13). Pain was the most important variable correlating with patient-reported disease (R^2 = 0.5).

Conclusion: Patient-reported measures of disease activity such as general health appear to correlate with physician measures; however, this relationship only holds for those with lower levels of disease activity. For women with internal organ disease, patient self-assessment of health had no relationship with the physician assessment. In addition, our findings suggest that pain is one of the primary symptoms driving patients' health assessments. Our findings continue to show the need for the development of patient-reported measures that more accurately reflect lupus disease activity, particularly among those with the most dangerous manifestations of the disease.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster II: Biomarkers and Outcomes

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: SLE diagnosis can be challenging especially at the early stages, and existing classification criteria are biased towards classifying patients with long-standing disease. A joined ACR/EULAR initiative has introduced a new set of criteria (herein referred to as 2017 criteria), using positive ANA test as an entry criterion coupled with variably-weighted clinical and immunological criteria (Tedeschi et al., 2018). We compared the sensitivity of the 2017 criteria against the SLICC 2012 and ACR 1997 criteria in an early SLE cohort.

Methods: Consecutively registered patients aged ≥ 15 years diagnosed with SLE during 01/2012-12/2016 by an expert physician and followed-up for ≥ 6 months in the University Hospitals of Heraklion and "Attikon" (Athens). All sets of

criteria (ACR 1997, SLICC 2012, 2017) were applied at the time (\pm 3 months) of physician-based diagnosis and also at last follow-up. Cases were assessed for disease severity (according to the BILAG definitions and the use of lupus treatments) and the SLICC/ACR organ damage index.

Results: 341 patients were included [91.5% women, 98.8% Caucasian, mean (SD) age at diagnosis 42.1 (15.3) years] with mean disease duration 32.3 (SD 18.2) months. At the time of diagnosis, more patients were classified with the 2017 criteria (79.5%), followed by the SLICC (75.4%) and the ACR (67.2%) criteria. A total 39 patients (11.4%) met only the 2017 criteria and 25 patients (7.3%) met only the SLICC criteria. The former had increased frequency of fever, synovitis, anti-dsDNA or anti-Smith autoantibodies. In contrast, SLICC-only classified patients had increased rates of chronic cutaneous lupus, alopecia, mouth ulcers, haematological disease, anti-phospholipid antibodies and hypocomplementemia (**Table 1**). At last follow-up, the sensitivity of the 2017, SLICC and ACR criteria were 84.5%, 89.4% and 78.6%, respectively. Among 25 patients (7.3%) who were ANA negative, thus failing to meet the entry criterion, 23 scored above the threshold of ≥ 10 points in the 2017 criteria. Patients classified according to the 2017 criteria did not differ from SLICC-classified patients regarding disease severity (mild/moderate/severe: 46.5%/33.7%/19.8% vs. 46.2%/33.8%/20.0%, respectively) and organ damage.

Conclusion: Both the 2017 and the 2012 SLICC criteria are more sensitive than the ACR criteria in classifying early SLE. The new criteria enable the classification of more patients with synovitis and positive autoantibodies whereas the SLICC criteria have increased sensitivity for hematologic disease, suggesting that they may need to be combined to assure maximum capture of patients for clinical trials. The majority of ANA-negative patients scored above the 2017 classification threshold, suggesting that inclusion of ANA as an additional item (instead of entry criterion) could further enhance the sensitivity of the new SLE criteria at early stages.

Table 1 Prevalence of each manifestation included in the SLICC 2012 criteria and the 2017 criteria, in patients who fulfil only the SLICC or the 2017 criteria at the time of SLE diagnosis.

	Time of SLE diagnosis according to physician	
	Fulfilling only SLICC 2012 (%)	Fulfilling only 2017 criteria (%)

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster II: Biomarkers and Outcomes

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic Lupus Erythematosus (SLE) is characterized by a fluctuating course. To achieve sustained remission is the ultimate goal of maintenance treatment. However the definition of remission is difficult in SLE. In 2014, an international Task Force named DORIS proposed four definitions of remission. The aim of this study was to evaluate the performance of the DORIS algorithm, to identify the frequency of remission as determined by DORIS for each clinical disease pattern, and to evaluate the impact of remission on damage accrual.

Methods: Monocentric retrospective study. Among all SLE patients followed at the Lupus Clinic between 2014 and 2017, we enrolled patients fulfilling the SLICC 2012 criteria who were visited at least once in 2017 and who had at least 5 biannual medical examinations in the previous 2 years. Definitions of remission according to DORIS and disease patterns are reported in Table 1. Damage accrual was measured by the SDI score¹.

Results: 101 SLE patients were enrolled for this study (94% female, mean age 45 years). 505 time-points were evaluated: 211 (42%) were defined as “remission” according to DORIS and in particular 181 (85.5%) were “remission on treatment”. 17.8% of patients were in remission in all the 5 time-points, vice versa 29.7% of patients never got into remission. 17.8% of patients have been in remission for 24 months, while 21.8% of patients less than 6 months. Mean duration of DORIS remission was 7.96 months. The most frequent disease patterns were RR (41,6%) and CQ (41,6%), while CA pattern was present in 16,8% of patients. DORIS remission was most frequently achieved in CQ pattern (65.2% of visits), less frequently in CA (5.9%). At the end of follow-up 50% of patients had a SDI \geq 1, and cumulative dosage of steroids was significantly associated to damage accrual (p:0.04 OR: 1.04 CI: 1.001-1.088). Moreover patients with at least one time-point in remission according to DORIS had a significantly lower damage accrual (p: 0.01) when compared to patients who never got into remission.

Conclusion: The DORIS algorithm is easy to be employed in clinical practice. In this cohort 30% of patients never achieved remission. Since damage accrual was associated with both cumulative dosage of steroids and unremitted disease, the goal in SLE management should be sustained remission with the lowest dose of steroids.

Using ICD-10-CM Codes to Identify Patients with Systemic Lupus Erythematosus in the Electronic Health Record

April Barnado¹, Robert Carroll², Joshua C. Denny² and Leslie Crofford¹, ¹Division of Rheumatology and Immunology, Vanderbilt University Medical Center, Nashville, TN, ²Biomedical Informatics, Vanderbilt University Medical Center, Nashville, TN

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster II: Biomarkers and Outcomes

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The electronic health record (EHR) serves as a powerful tool to enable researchers to collect a large cohort of patients across the healthcare system. To assemble these patients, algorithms are needed to identify these patients accurately. We have previously validated and published algorithms to identify systemic lupus erythematosus (SLE) subjects in the EHR using ICD-9 billing codes, labs, and keywords. Currently, there are no published algorithms using ICD-10-CM codes. We aimed to develop algorithms using ICD-10-CM codes and clinical data to identify SLE patients accurately in the EHR. **Methods:** We analyzed data from a de-identified version of Vanderbilt’s EHR that contains over 2.8 million subjects with longitudinal data. We identified 7399 potential SLE subjects with at least one count of the SLE ICD-9 (710.0) or ICD-10-CM (M32.1*,M32.8, or M32.9) codes. Of these subjects, we randomly selected 200 as a training set for chart review to identify true case status. A subject was defined as a case if diagnosed with SLE by a Vanderbilt or external rheumatologist, nephrologist, or dermatologist (specialist). We selected the following algorithm components based on clinical knowledge and available data: SLE ICD-10-CM codes, positive anti-nuclear antibody (ANA)(titer ≥ 1:160), and ever use of antimalarials. Positive predictive values (PPVs) and sensitivities were calculated for ICD-10-CM codes and combinations of the above algorithm components. Of the 200 subjects, 88 had ICD-10-CM codes with 13 missing clinic notes and excluded from the analysis. Ten subjects had unsure or “probable” SLE diagnoses by a specialist and were not counted as cases. **Results:** Table 1 provides the PPVs and sensitivities of the algorithms. PPVs were higher for algorithms using ICD-10-CM codes compared to those using the ICD-9 code. Algorithms that used only ICD-10-CM codes without clinical data had PPVs from 71 to 92%. When adding a positive ANA, PPVs slightly increased and ranged from 69 to 100%. PPVs also slightly increased with adding ever antimalarial use with PPVs from 76 to 95%. The algorithms with the highest PPVs of 100% were 1) ≥ 4 counts of the ICD-10-CM codes and ANA positive and 2) ≥ 4 counts of the ICD-10-CM codes and ANA positive or ever antimalarial use. **Conclusion:** Overall, the PPVs for algorithms using ICD-10-CM codes were higher compared to PPVs for ICD-9 codes. Adding clinical data to ICD-10-CM codes slightly improved the algorithms’ PPVs but may not be required. Since “probable” cases were treated as not cases, PPVs could be underestimated. ICD-10-CM codes can identify SLE cases accurately in the EHR. Studies are underway to investigate the performance of algorithms that combine both ICD-9 and ICD-10-CM codes with clinical data.

Table 1.

Algorithm	Positive Predictive Value	Sensitivity
ICD-9 codes only		
≥ 1 count of the ICD-9 code (710.0)	58%	100%
≥ 2 counts	69%	78%
≥ 3 counts	77%	67%
≥ 4 counts	79%	60%
ICD-10-CM codes only^a		
≥ 1 count of the ICD-10-CM codes	71%	76%
≥ 2 counts	85%	63%
≥ 3 counts	83%	54%
≥ 4 counts	92%	50%
ICD-10-CM codes AND ANA positive^b		
≥ 1 count of the ICD-10-CM codes AND ANA positive	69%	62%
≥ 2 counts	87%	55%
≥ 3 counts	89%	45%

Session Title: Systemic Lupus Erythematosus – Clinical Poster II: Biomarkers and Outcomes

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is a complex autoimmune disease marked by immune dysregulation. A comprehensive but cost-effective tool to track relevant mediators of altered disease activity would help improve disease management and prevent organ damage. The goal of this study was to identify critical components of a practical biometric to distinguish active from low lupus disease activity

Methods: SLE-linked immune mediators and autoantibodies were evaluated in 311 plasma samples from 198 patients with classified SLE procured on dates of low clinical disease (SLEDAI < 4, range 0-3, n=132) or more active disease (SLEDAI ≥ 4, range 4-30, n=179) as well as healthy controls (HC) matched for race, sex, and age (n=48). Thirty two soluble mediators and SLE-associated autoantibody specificities, including dsDNA, chromatin, Ro/SSA, La/SSB, Sm, SmRNP, and RNP, were assessed by multiplex bead-based assay or sandwich ELISA (BLyS, APRIL, and TGF-β). Soluble mediator levels were compared across clinical disease activity levels in conjunction with the presence of autoantibodies.

Results: Patients with low or active disease were similar in age, ethnicity, and sex. After adjusting for multiple comparisons (Bonferroni corrected $p < 0.0018$), IL-6, IL-1α, IP-10, and IL-8 were significantly correlated with SLEDAI scores (Spearman $r = 0.179-0.253$), yet 22/32 soluble mediators significantly correlated with the number of SLE-associated

autoantibodies accrued, including those listed above, as well as SCF, IFN- α , IFN- γ , IL-17A, IL-10, MIG, MIP-1 β , TNFR1I, and BLyS ($r=0.318$ [IL-17A]-0.468 [IP-10]). The regulatory mediator IL-10 was highest in samples ($p<0.05$) from patients with low disease activity, while inflammatory mediators were highest in active disease samples with accrued autoantibody specificities ($p<0.001$). We integrated these findings to build a Lupus Disease Activity Immune Index (LDAII), calculated utilizing normalized (case vs. control) soluble mediator levels ($n=32$) weighted by the number of SLE-associated autoantibodies in each individual. The LDAII distinguished patients with clinically active (CA) vs. quiescent (CQ) disease who were either serologically (dsDNA binding and low complement) active (SA) or quiescent (SQ) ($p<0.0001$), whereby the number of accumulated autoantibodies ($p<0.0001$) as well as IL-6, IL-8, and IP-10 levels ($p\leq0.0006$) were most significantly altered. In addition, the LDAII was able to differentiate clinically and serologically quiescent (CQSQ) SLE patients vs. HC ($p=0.019$). Finally, the LDAII significantly correlated with SLEDAI scores in patients ($p<0.0001$) and identified patients with renal organ involvement ($p=0.002$), in whom SCF, TNFR1I, and MCP-1 were also most significantly altered ($p\leq0.005$).

Conclusion: Clinically meaningful components of immunological profiles may help illuminate disease pathogenesis, guide therapy, improve clinical trial design, and detect serious autoimmune disease with subtle presentation.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster II: Biomarkers and Outcomes

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The Lupus Severity Index (LSI)* was recently proposed to stratify patients by disease severity for clinical research. The LSI ranges from 0-10, is calculated using ACR classification criteria (ACRc) and demonstrated high predictive accuracy for severity anchored to major immunosuppressive drug use. We investigated the performance and characteristics of the LSI in a large multiethnic lupus cohort.

Methods: Patients from a single academic center were followed from 1990-2016 using a custom database. Records of all SLE patients were abstracted. Variables included birthdate, diagnosis date, self-reported ethnicity, ACRc, SLICC Damage Index (SDI), treatment and date of death. Ethnicity was categorized into White (WHI), Asian (ASN), Indigenous (IND), and Other. The LSI was calculated from ACRc, and compared between ethnic groups and demographic variables known to be associated with severe SLE using t-tests, ANOVA, Pearson correlation coefficient and logistic regression.

Results: Eight hundred thirty-two SLE patients were identified: 497 (60%) WHI; 220 (26%) IND; 91 (11%) ASN; 24(3%) Other. Mean age was 49 ± 16 years, mean disease duration 15 ± 11 years, 90% female, mean age at diagnosis 35 ± 15 ; 163 (20%) of patients had died. The mean LSI was 6.9 ± 1.7 , range 3.2-9.7. The distribution of the LSI was similar to that in the original dataset (Fig 1A) and the area under the ROC curve, measured against prescription of major immunosuppressive drugs, was 0.69 (95% CI 0.65-0.73). LSI was higher in males compared to females (7.3 ± 1.6 vs.

Figure 1. Distribution of Lupus Severity Index in all patients and in different ethnic groups.

6.9±1.7; p<0.019), and was negatively associated with onset age (Onset< 18 yrs LSI=7.8±1.3; 18-50 yrs LSI= 6.8±1.7; >50 yrs LSI=6.6±1.6; p<0.001). LSI correlated with SDI (Pearson 0.28, p<0.001), and was a predictor of accruing any damage (SDI>1) (OR 1.2 95% CI 1.1-1.3). LSI was higher in non-whites compared to whites: WHI LSI=6.6±1.7; IND LSI=7.2±1.6; Other LSI=7.3±1.3; ASN LSI 8.1±1.1; p<0.001). LSI was a predictor of early mortality (Death at age<50, or disease duration<10 years): OR 1.2; 95% CI 1.0-1.3). The distribution of the LSI varied by ethnic group with more uniformly severe disease in ASN patients (Figure 1 B,C) compared to WHI and IND.

Conclusion: Similar to the original publication, a higher LSI correlated with male sex, younger onset age, and non-white ethnicity; all groups shown to have more severe SLE. LSI was also a predictor of damage and early mortality. In addition we also found the distribution of LSI to differ between ethnicities. These findings confirm the utility of the LSI in stratifying patients by severity, and supports further exploration of the LSI to investigate contributors to severe SLE.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster II: Biomarkers and Outcomes

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Approximately 20% of patients with Systemic Lupus Erythematosus (SLE) begin their illness in childhood or adolescence. These patients are described with a phenotype of greater severity. The aim of this study was to evaluate the prevalence of early onset SLE and the clinical and laboratory manifestations of these patients.

Methods: A total of 659 consecutive patients were included in one year. All met at least four diagnostic criteria from the American College of Rheumatology (ACR 82/97). Early-onset SLE was defined as disease diagnosed before 18 years of age and late onset or adult when age at diagnosis was ≥ 18 years. Criteria for diagnosis and damage were measured by

cumulative Systemic Lupus Collaborating Clinical Damage Index (SLICC-SDI). Disease activity was measured by the Systemic Lupus Erythematosus Disease Activity Index (SLEDAI) at the time of entry into the study. SLEDAI ≥ 12 was considered as severe activity. Manifestations were compared between early and late-onset SLE patients. Statistical analysis for categorical variables was performed with chi-square test or Fisher exact test as appropriate and for continuous variables with Student t-test. Strength of association were obtained by odds ratio and 95% confidence interval (CI). Multivariate analysis was performed using early-onset Lupus as outcome variable.

Results: 82/659 (12.44 %) met criteria for early-onset SLE, 90% of these patients were women vs. 87% late onset ($p = 0.408$, OR: 1.38, 95% CI: 0.63-3.45). Mean age at diagnosis was 15 ± 2 (7-17) vs. 32 ± 11 years (18-76), with a median time of 134 ± 86 vs. 96 ± 92 months ($p = 0.00034$) at diagnosis. Mean number of classification criteria was 7 vs. 6 ($p = 0.016$), and for SLEDAI score was 2 (0-36) vs. 2 (0-73), $p = 0.955$. At the time of their inclusion in the study, they had severe activity: 18% vs. 8.5% ($p = 0.005$, OR: 2.41, 95% CI: 1.19-4.6). Mean SLICC score was 1.14 (0-8) vs. 1.02 (0-9), $p = 0.57$. Univariate analysis also showed that Malar erythema ($p: 0.014$), nephritis ($p: 0.010$), glomerulonephritis Class IV ($p: 0.0001$), CNS ($p: 0.019$), cataracts ($p: 0.019$) were statistically significant. In the multivariate analysis, there was a significant association with early onset-SLE mestizo ethnicity: OR: 1.65, 95% CI: 1.01-2.69, $p = 0.041$; Malar erythema: OR: 1.81, 95% CI: 1.009- 3.25, $p = 0.046$ and renal disease: OR: 1.86, 95% CI: 1.15-3.006, $p = 0.01$.

Conclusion: In this cohort of SLE patients, 12.4% were classified as early onset, with a mean age at diagnosis of 15 years (7-17). Multivariate analysis persisted as independent variables associated with early-onset Lupus, mestizo ethnicity, cutaneous involvement with malar erythema and nephropathy. Association with damage index was not significant.

Impact of Hurricane Maria on a Cohort of Systemic Lupus Erythematosus Patients from Puerto Rico

Luis M. Vilá¹, Yaritza Berríos-López¹, Carla Santiago-Burgos¹, Lorena González-Sepúlveda², Ileana Vázquez-Otero¹ and Elizabeth Brown³, ¹Department of Medicine, Division of Rheumatology, University of Puerto Rico Medical Sciences Campus, San Juan, Puerto Rico, ²Puerto Rico Clinical and Translational Research Consortium, University of Puerto Rico Medical Sciences Campus, San Juan, Puerto Rico, ³Department of Pathology, University of Alabama at Birmingham, Birmingham, AL

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster II: Biomarkers and Outcomes

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: On September 20, 2017, Puerto Rico was devastated by Hurricane Maria causing severe damage to the Island infrastructure and essential services such as electricity, water supply, communications, and access to health care. Catastrophic natural disasters can have negative effects on the health and outcome of patients with chronic diseases. Thus, we sought to determine the impact on disease activity and patient-reported outcomes of health in a group of Puerto Ricans with SLE.

Methods: Hispanics from Puerto Rico participating in PROFILE, a longitudinal multiethnic cohort, were studied. Disease activity (per Systemic Lupus Erythematosus Activity Index [SLEDAI]) and patient-reported outcomes of health (per Short Form-36 [SF-36]) were examined before and after Hurricane Maria. SF-36 scores were transformed into a 0-100 scale in which higher scores represent better health. Patients seen between October 2017 and April 2018 were included in the analysis. SLEDAI and SF-36 scores were compared before and after Hurricane Maria using paired t test and Wilcoxon signed rank test, as appropriate.

Results: A total of 127 patients had their scheduled annual visits during the study period; 90 patients were seen, 15 missed their scheduled visit, 15 migrated to continental United States, 6 were unable to reach, and 1 died. Among patients seen at their study visits, 81 (90%) were women and the mean age was 45.3 ± 11.7 years. Forty-four percent had private healthcare

insurance, 39% had public insurance, 14% had Medicare, and 2% had no insurance coverage. No significant changes were seen for disease activity or overall SF-36 scores before and after Hurricane Maria. However, differences were observed for some mental and physical health components of the SF-36. Significantly lower scores were seen after Hurricane Maria in the mental health (60.2 ± 24.9 vs. 65.2 ± 22.6 , $p=0.011$) and bodily pain (43.6 ± 31.1 vs. 50.8 ± 30.8 , $p=0.011$) components when compared to the visit prior to the hurricane. Similarly, a tendency was observed for lower scores in the social functioning (59.4 ± 31.9 vs. 65.0 ± 29.0 , $p=0.051$) and role emotional (67.7 ± 29.3 vs. 73.1 ± 26.7 , $p=0.096$) components.

Conclusion: In this cohort of SLE patients from Puerto Rico, 71% were seen at their scheduled study visits after Hurricane Maria. Among these patients, worse patient-reported outcomes of health were seen for some mental and physical components of the SF-36. No differences were observed for disease activity. Nonetheless, longer follow up is needed to determine the long-term impact of Hurricane Maria on this cohort of SLE patients.

Refractory Lupus Patients: How Frequent Do We See Them in the 21st Century?

Valeria Scaglioni¹, Marina Scolnik¹, Enrique R Soriano¹ and Guillermo J. Pons-Estel², ¹Rheumatology Unit, Internal Medicine Service. Hospital Italiano Buenos Aires. Argentina, Buenos Aires, Argentina, ²Centro Regional de Enfermedades Autoinmunes y Reumáticas (GO-CREAR), Rosario. Argentina, Rosario, Argentina

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster II: Biomarkers and Outcomes

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: management of systemic lupus erythematosus (SLE) patients is challenging because of the heterogeneity of the disease. While treatment of renal nephritis is more standardized, treatment of non-renal refractory lupus remains controversial. Our objective was to identify non-renal non-neurologic refractory SLE patients in our cohort and described therapeutic behaviors in these patients.

Methods: All SLE patients (ACR and/or SLICC criteria) seen at a university based hospital between 2000 and 2017 were included and electronic medical records manually reviewed. Patients' characteristics, clinical manifestations and treatment patterns were recorded. Refractory lupus was defined as a patient with a SLEDAI score ≥ 6 (excluding renal and CNS manifestations) despite being on a stable treatment regimen for ≥ 30 days. Stable treatment could include prednisone alone (7.5 to 40 mg/d) or combined (0 to 40 mg/d) with antimalarial drugs and immunosuppressant therapies.

Results: A total of 257 lupus patients were included, 230 females (89.5%, 95% CI 85.1-92.7), mean age at diagnosis 29.9 years (SD 16.4). 211 patients (82.1%) fulfilled ACR criteria and 255 (99.2%) SLICC criteria. Type of clinical manifestations and treatments received during first year of disease, and cumulative are shown in table 1. After a median follow-up of 5.7 years (IQR 2.4-10.2), 16 patients (6.2%, 95% CI 3.8-9.9) met the refractory lupus criteria, with a median disease duration of 9.6 years (IQR 3.9-19.1). At that time, 87.5% of patients (95% CI 56.9-97.4) had low complement and 81.3 % (95% CI 51.4-94.7) had positive antiDNA antibodies. Main reasons for being refractory were mucocutaneous disease (50%, 95% CI 24.9-75.0) and arthritis (37.5%, 95% CI 16.1-65.2). Treatments received after being refractory were: corticosteroids > 20 mg/d of prednisone in 8 patients, mycophenolate in 1, rituximab in 5 and belimumab in 7, with optimal response in all of them (table 2). In a multivariate logistic regression analysis, only a younger age was associated with refractory disease (OR 0.93, 95% CI 0.87-0.99, $p=0.03$).

Conclusion: Despite receiving intensive treatments during follow-up (prednisone >20 mg/d in 73.5% of patients, antimalarial in 94.9% and immunosuppressant in 67.5%), 6.2% of patients met refractory criteria.

Table 1. SLE patients' clinical manifestations and treatments at first year and cumulative

	At first year of SLE(n=257)	Cumulative(n=257)
Acute cutaneous lupus (SLICC definition), n (% , 95% CI)	140 (54.7, 48.5-60.7)	160 (62.3, 56.1-68.1)
Chronic cutaneous lupus, n (% , 95% CI)	11 (4.3, 2.4-7.6)	15 (5.8, 3.5-9.5)

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster II: Biomarkers and Outcomes

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Periodontitis is common disease. Recently, it is pointed out that periodontitis was associated with systemic disease. There were a few studies of assessing the relationship between periodontitis and the disease activity of systemic lupus erythematosus(SLE). However, it was unclear that there was evidence to support the relationship. Our hypothesis is that periodontitis is associated with the disease activity of SLE. This study aimed to assess the association between periodontitis and the disease activity of SLE.

Methods:

Design: A cross-sectional study.

Participants: SLE patients (according to the criteria revised in 1997 by the American College of Rheumatology) who diagnosed at Showa University Hospital, who were under 65-years-old and were collected from June 2016 to December 2016.

Exposure: Our main exposure was periodontitis assessed with pocket of depth, attachment loss by dentists. We divided a grade of periodontitis into four categories (Non-periodontitis, Mild periodontitis, Moderate periodontitis, Severe periodontitis) by Centers for Disease Control and Prevention – The American Academy of Periodontology (CDC-APP) definition.

Outcome measures: Main outcome was Systemic Lupus Erythematosus Disease Activity Index-2000 (SLEDAI-2000). Secondary outcome were anti-dsDNA antibody level, and complement level.

Statistical Analysis: In the main analysis, a multiple regression analysis using the score of SLEDAI-2000 as outcome was conducted to assess the association between periodontitis and the disease activity of SLE with adjustment for age, sex, current smoking status, current prednisolone(PSL) dose, the maximum dose of past PSL treatment and current immunosuppressant therapy. In the secondary analysis, a multiple regression analysis was conducted to analyze the association between periodontitis and the anti-dsDNA antibody level, complement level under the same conditions as above. In multivariable analysis, missing variables were replaced by multiple imputation.

Results: Among 119 SLE patients, mean age was 40.0 years, and 88.2% was female. The prevalence of periodontitis was 69% (1.7% in mild periodontitis, 58.8% in moderate periodontitis, 8.4% in severe periodontitis). Compared with non-periodontitis, the regression coefficients [95% Confident Interval] for SLEDAI of mild periodontitis, moderate periodontitis and severe periodontitis were -4.74 [-11.23 to 1.76], -1.07 [-2.99 to 0.83] and 0.54 [-4.08 to 3.01], respectively. In the secondary analysis, compared with non-periodontitis, the regression coefficients [95%CI] for SLEDAI of severe periodontitis for anti-dsDNA antibody titer was statistically significant (44.6 [7.3-81.9]).

Conclusion: This study demonstrated for the first time in Japan that the prevalence of periodontitis in SLE patients was remarkably high. Our data raise the important possibility that physicians pay attention to periodontitis in SLE practice. Our result did not provide a clear association between periodontitis and the disease activity of SLE. Further studies are needed to test our hypothesis in a longitudinal study in the future.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster II: Biomarkers and Outcomes

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: M-phase phosphoprotein (MPP-1), also termed kinesin interacting protein (KIF20B), is a 210 kDa protein that is highly expressed during cell division. Autoantibodies to MPP-1 were first described in approximately 25% of patients with idiopathic ataxia, but recent studies have indicated that they are also found in systemic lupus erythematosus (SLE). The goals of this study were to determine the frequency of anti-MPP-1 in a local SLE cohort and then identify demographic, clinical, and serologic correlations.

Methods: Patients fulfilling the American College of Rheumatology (ACR) or Systemic Lupus International Collaborating Clinics (SLICC) Classification Criteria for SLE were enrolled in a local cohort. Demographic, clinical information (disease activity – SLEDAI-2K; damage – SLICC/ACR DI), and sera were collected at time of enrollment. Antibodies to MPP-1 were determined by an addressable laser bead immunoassay (ALBIA) utilizing an *in vitro* expressed MPP-1 cDNA construct inserted into a GFP vector (Clontech Laboratories Inc., Saint-Germain-en-Laye, France). ALBIA results were expressed as median fluorescence units (MFU) and a dilution of greater than or equal to 1:500 MFU was considered highly positive. Univariable and multivariable analysis were performed to determine associations between the prevalence of high positive anti-MPP-1 and demographic (age, sex, race/ethnicity), clinical features (SLEDAI-2K and SLICC/ACR DI total scores and subscales and neurological subscale of the ACR and SLICC Classification Criteria), medications, and other autoantibodies (anti-dsDNA, extractable nuclear antigens, and anti-phospholipid antibodies).

Results: One hundred and fifty-six SLE patients were included; 89.8% were female with a mean age of 47.5 years (SD 15.8) and disease duration of 13.6 years (SD 11.8). The prevalence of high titre anti-MPP-1 was 14.1% (22/156). Univariable analysis demonstrated that high anti-MPP-1 positivity was associated with a higher total SLEDAI-2K score (Odds Ratio (OR), 1.1 [95% CI 1.0, 1.3]), particularly with the serositis (OR 2.7, [95% CI 1.3, 5.6]) and immunological SLEDAI-2K subscales (OR 1.9, [95% CI 1.3, 2.7]). High anti-MPP-1 positivity was also associated with anti-dsDNA (OR 4.7 [95% CI 1.7, 13.4]) and anti-phosphatidylserine/prothrombin complex (aPS/PT)-IgG (OR 3.2 [95% CI 1.1, 9.9]). In the multivariable analysis, only the serositis (OR 2.5, [95% CI 1.1, 5.7]) and immunological SLEDAI-2K subscales (OR 1.9, [95% CI 1.3, 2.7]) were independently associated with anti-MPP-1 positivity.

Conclusion: High titer anti-MPP-1 antibodies were relatively common in this SLE cohort (14.1%) and may be associated with greater clinical and serologic SLE disease activity. A larger study is currently underway to more clearly delineate its role as a biomarker in SLE.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster II: Biomarkers and Outcomes

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Although the survival rate of patients with Systemic Lupus Erythematosus (SLE) has improved over the years, patients are frequently hospitalized or evaluated in the Emergency Room; these events account for most of the direct cost of these patients' care. The objective of this study was to determine whether remission and low disease activity state (LDAS) are protective of hospitalizations and Emergency Room visits in our SLE patients.

Methods: All hospitalizations and Emergency Room visits of Peruvian SLE patients members of a single center cohort were identified during the two-years following their baseline visit. We used the baseline data (at cohort entry) to determine which factors were associated with hospitalizations and Emergency Room visits in these patients. Remission was defined as a SLEDAI-2K=0, prednisone ≤ 5 mg/d and immunosuppressants on maintenance dose, LDAS was defined as not on remission and a SLEDAI-2K ≤ 4 , prednisone ≤ 7.5 mg/d and immunosuppressants on maintenance dose; antimalarials were allowed in both groups(1). Univariable and multivariable Poisson regression models were used to determine the impact of being on remission or LDAS on the risk of hospitalization and Emergency Room visits, adjusting for gender, age at diagnosis, socioeconomic status, disease duration, damage, comorbidities, time of exposure to prednisone and antimalarial use.

Results: Of the 314 cohort patients, 92.7% (n = 291) were female, the median age of the patients was 40.7 (32.9-51.1) years, with a disease duration of 5.5 (2.6-10.3) years. Fifty-nine of the patients included were hospitalized, a total of 165 times (range 2.8 per patient). In the multivariable analysis we found that remission [RR 0.036 (0.005-0.259), p=0.001] and LDAS [RR 0.289 (0.182-0.457), <p=0.001] at baseline decrease the risk of hospitalization in SLE patients. Similarly, remission [RR: 0.019 (CI95%: 0.107-0.815), p=0.019] and LDAS [RR=0.383 (CI95%: 0.222-0.661), p=0.001] decrease the risk of Emergency Room visits. One hundred- thirty-five of the 165 hospitalizations presented a defined cause, being disease activity the most common cause of hospitalization with 73 admissions (54.1%); within them, renal disease was the leading cause, with 37 admissions (50.7%).

Conclusion: Remission and LDAS decrease the risk of hospitalizations and Emergency Room visits in SLE patients. Disease activity was the most frequent cause of hospitalization and within them, renal disease. These findings have economic implications for the health care system.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster II: Biomarkers and Outcomes

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic Lupus Erythematosus (SLE) is a heterogeneous disease that can cause multisystem inflammation and damage. There are currently no widely agreed upon targets for determining adequate disease control. Lupus Low Disease Activity State (LLDAS) is a new clinical evaluation tool that assesses low disease activity state in lupus patients (Franklyn, et al. *Ann Rheum Dis.* 2016; 75: 1615-1621). Our study examines the relationship between the percentage of time patients spend in LLDAS and organ damage accrual, cardiovascular events, and death.

Methods: We studied a prospective longitudinal cohort of 246 patients with SLE during a 5-year follow-up period. Disease activity was measured using the SLE Disease Activity Index 2000 (SLEDAI-2K) and SELENA-SLEDAI physician global

assessment (PGA). Cumulative organ damage was assessed at 1-year, 3-year, and 5-year intervals using the Systemic Lupus International Collaborating Clinics/American College of Rheumatology Damage Index (SDI). The determination of LLDAS $\geq 50\%$ of the time (LLDAS-50) was done retrospectively through clinical chart review. The following criteria for LLDAS included: (SLEDAI)-2K ≤ 4 without major organ activity, no new disease activity, PGA ≤ 1 (scale 0–3), ≤ 7.5 mg/day and stable dose of maintenance treatments. The longitudinal presence of carotid plaque and intima-media thickness (IMT) was measured at baseline and follow-up three years later. We determined the relationships between LLDAS, SDI, IMT, carotid plaque, and PREDICTS profile using multivariate regression analysis. T-tests were used for analysis of continuous variables and chi-squared for parametric variables.

Results: The average age was 42.8 years for patients in LLDAS-50 and 39.5 years for those not in LLDAS-50 ($p = 0.048$). Patients in LLDAS-50 or higher during the year after cohort entry had a mean SDI score of 1.5 (± 1.8) at 1 year, a mean SDI of 1.6 (± 1.9) at 3 years, and 1.9 (± 2.1) at 5 years after cohort entry. On average, patients who were in LLDAS-50 during the first year after cohort entry had lower SDI scores at 3 years and 5 years than patients who were not, reaching near significance ($p = 0.06$) for both.

There was no significant difference in measured IMT or plaque at baseline or at 3- or 5-year follow-up between patients in LLDAS-50 and those not in LLDAS-50 for the first year after baseline. However, patients in LLDAS-50 were significantly less likely to have major cardiac events (major stroke, myocardial infarction, positive stress test, angioplasty or percutaneous coronary intervention) or death compared with patients who were not in LLDAS-50, 20.7% and 38.2%, respectively ($p = 0.02$).

Conclusion: We assessed SLE patients in LLDAS from our cohort of 246 patients. With regard to damage progression, there was near significantly less damage among those in LLDAS 50% of the time during the first year after cohort entry. Interestingly, although there were no differences between IMT, presence of carotid plaque, or plaque progression at any of the three time points, there was a statistically significant difference in number of cardiovascular events or death in the LLDAS-50 group. This supports LLDAS as a valid predictor of lower overall and cardiovascular damage in SLE patients.

Utility of the Avise Connective Tissue Disease Test in Predicting Lupus Diagnosis and Progression of Disease

Emily Liang¹, Mihaela Taylor² and Maureen A. McMahon³, ¹UCLA David Geffen School of Medicine, Los Angeles, CA, ²Rheumatology, UCLA David Geffen School of Medicine, Los Angeles, CA, ³Division of Rheumatology, UCLA David Geffen School of Medicine, Los Angeles, CA

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster II: Biomarkers and Outcomes

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The AVISE Connective Tissue Disease test is a newly approved, commercially available test that combines autoantibody and biomarker levels to help diagnose systemic lupus erythematosus (SLE) and other connective tissue diseases. However, few studies have examined whether AVISE can predict future clinical diagnosis and outcomes in a real-world cohort. We evaluated the utility of AVISE in predicting SLE diagnosis and damage progression.

Methods: This longitudinal observational study enrolled patients of a single adult rheumatologist who underwent AVISE testing between April 1, 2014 and April 30, 2016. A \odot positive \odot AVISE test for SLE was defined as positive or moderate-positive scores. \odot Non-positive \odot tests were defined as negative, moderate negative, equivocal, or indeterminate scores. SLE diagnosis was confirmed using SLICC/ACR classification criteria. Damage was evaluated using SLICC/ACR damage index (SDI) at baseline ($t=0$) and two years ($t=2$) after AVISE testing. Statistical analyses were performed using SPSS.

Results: The cohort consisted of 77 women and 6 men; 7 patients had long-established SLE at $t=0$. Among the remaining 76 patients, the most common confirmed diagnoses in those with a positive test was SLE, followed by UCTD and RA, at both $t=0$ and $t=2$ (Table 1). Among those without established SLE at $t=0$, 53% of patients with a positive test vs. 25% in those with a negative test ($p=0.04$) had an SLE diagnosis at $t=2$.

There was a significant difference in the number of SLICC clinical and immunologic diagnostic criteria fulfilled at t=0 and t=2 by patients with a positive vs. a non-positive AVISE test (Table 2). There was also a significant difference in SDI between positive and non-positive patients, with positive patients having higher SDI at t=2 (Table 2). Among the individual AVISE result biomarkers, BC4d levels significantly correlated with the number of clinical SLE classification criteria at t=0 ($r=0.24$, $p=0.02$) and the SDI at t=0 ($r=.28$, $p=0.01$) and t=2 ($r=0.34$, $p=0.002$), yet EC4d and dsDNA levels did not.

Conclusion: AVISE CTD test results are predictive of eventual rheumatologic diagnosis, and BC4d levels are predictive of both SLICC/ACR classification criteria fulfillment and SDI in SLE patients. These data suggest that AVISE may be useful in standard rheumatologic care for establishing a SLE diagnosis and identifying patients at higher risk for adverse clinical outcomes.

Table 1 Suspected diagnoses at t=0 and t=2 in those without an established SLE diagnosis at baseline.

	AVISE Neg (n=63)		AVISE Pos (n=13)	
	t=0	t=2 years	t=0	t=2 years
SLE	0%	9.5%	0%	53.8%
RA	15.9%	23.8%	7.7%	15.3%
UCTD	31.7%	30.1%	38.4%	15.3%
Other autoimmune	27%	23.8%	15.3%	7.7%
Non-inflammatory (OA)	7.9%	4.8%	15.3%	7.7%
Fibromyalgia without connective tissue disease	9.5%	6.3%	7.7%	0%
Discoid lupus without SLE	1.6%	1.6%	0	0%
Unclear Dx	6.3%	0	15.3%	0%

Table 2 Differences in mean SDI and number of SLICC lupus classification criteria met at t=0 and t=2 years between AVISE result groups

AVISE test results	Negative, equivocal, or indeterminate (n=66)	Positive or moderately positive (n=17)	p= (Student's t-test)
SLICC/ACR criteria met t=0	2.0 ± 1.4	3.6 ± 1.9	0.004
SLICC/ACR criteria met t=2	2.3 ± 1.4	3.7 ± 1.9	0.01

Fragmented Qrs in Patients with Systemic Lupus Erythematosus: Relation to the Disease Activity: A Cross-Sectional Study

Masahiro Hosonuma, Nobuyuki Yajimam, Ryo Yanai and Ryo Takahashi, Division of Rheumatology, Department of Medicine, Showa University School of Medicine, Tokyo, Japan

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster II: Biomarkers and Outcomes

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Cardiovascular disease is an important contributor to mortality in Systemic Lupus Erythematosus (SLE). It has been reported that disease activity at diagnosis was associated with the occurrence of myocarditis and coronary artery disease (CAD) in SLE. Fragmented QRS (fQRS) is a convenient marker of myocardial scar by electrocardiogram (ECG) defined as additional spikes within the QRS complex. FQRS is useful for identification of myocardial scars such as CAD and cardiac sarcoidosis, and for identifying high-risk patients of various cardiac diseases. It has reported that the prevalence of fQRS in a patient with SLE appears to be higher than that in controls. However, no clinical studies have investigated the prevalence at the time of diagnosis. In addition, there is no report that examined the association of disease activity of SLE and fQRS. In this study, we aimed to assess the relationship between disease activity of SLE and fQRS in SLE patients at the time of diagnosis. We hypothesized that the frequency of fQRS on ECGs would be higher in SLE patients with high disease activity.

Methods: The study design was a cross-sectional study. The participants were SLE patients who diagnosed at Showa University Hospital and Showa University Koto Toyosu Hospital from January 2010 to December 2017. The participants who satisfied American College of Rheumatology criteria were included. The patients with cardiac disease, other

rheumatic diseases, and already treatment at the time of an ECG measurement were excluded. The exposure was the appearance of fQRS. All ECGs were evaluated by two experienced cardiologist blinded for patient characteristics. The primary outcome was Systemic Lupus Erythematosus Disease Activity Index 2000 (SLEDAI-2K). The secondary outcomes were the complement level and the anti-dsDNA antibody level. In the main analysis, a multiple regression analysis was conducted to assess the association between fQRS and SLE activity adjusted for age, sex and period from the estimated date of onset to the date of diagnosis. In the secondary analysis, a multiple regression analysis was conducted to analysis the association between fQRS and the serological activity of SLE (the complement level, the anti-dsDNA antibody level) under the same conditions as above. Interobserver variabilities were assessed using Cohen's kappa coefficient.

Results: In total, 45 participants were enrolled. The mean age was 42.3 years, and 37 (82%) were female. The median SLEDAI-2K was 14 [IQR, 10 to 20]. The median period from the estimated date of onset to the date of diagnosis was 3 months [IQR, 2 to 14.5]. 25 patients (56%) had fQRS. In the main analysis, the regression coefficients [95%CI] of fQRS for SLEDAI were 2.99 [1.15 to 4.84, $p=0.002$] with reference to non-fQRS. In the secondary analysis, there were no significant associations between fQRS and the blood test. There was a good agreement between two blinded experienced cardiologists reading of fQRS. There was a 91.1% consensus ($\kappa=0.81$, 95% CI 0.63 to 0.98, $p<0.001$).

Conclusion: Our results demonstrated that fQRS positive SLE patients tended to have high disease activity. It was suggested that fQRS could be expressed by myocardial scar in SLE cases with high disease activity.

Session Date: Monday, October 22, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster II: Biomarkers and Outcomes

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Drug development in systemic lupus erythematosus (SLE) has been challenging. One of the reasons can be traced in the choice of outcome measures. In the clinical trials of belimumab, the primary endpoint was the SLE responder index (SRI) at week 52. In the present analysis, we investigated the frequency of the Lupus Low Disease Activity State (LLDAS) and a clinical SLE disease activity index 2000 (clinSLEDAI-2K) score of zero in relation to SRI.

Methods: A total of 1684 patients with SLE from the BLISS-52 (n=865) and BLISS-76 (n=819) trials were analysed. Data were accessed through a data sharing agreement with GSK. The clinician-based evaluation was defined as a Physician Global Assessment (PGA) score <0.5 in a 3-point scale, one of the conditions in the recently developed Definitions of Remission in SLE (DORIS), and was used for comparative purposes. For correlations, we used the Pearson correlation coefficient. For comparisons, we used the chi-square test.

Results: At week 52, the LLDAS definition was met in 8.6% of the patients (n=1332), and 34.5% had aclinSLEDAI-2K score of zero (n=1332). According to data from the initial studies, 45.1% were SRI responders at week 52 (n=1684). Among the three measures, clinSLEDAI-2K zero showed the strongest correlation with PGA <0.5 (r=0.36, P<0.001), whereas the correlations with SRI (r=0.25, P<0.001) and LLDAS (r=0.21, P<0.001) were more moderate. Comparing the placebo and 10mg/kg belimumab treatment arms, SRI performed best at revealing the superiority of belimumab to placebo (P<0.001), followed by clinSLEDAI-2K zero (P=0.003), PGA <0.5 (P=0.004), and LLDAS (P=0.033) (Figure).

Conclusion: LLDAS appears to be a stringent outcome measure, being met by only 8.6% of the patients. AclinSLEDAI-2K score of zero showed the best correlation with the clinician-based evaluation. Since it is only based on one index (SLEDAI-2K), clinSLEDAI zero may be considered a more pragmatic outcome measure compared to SRI and LLDAS for use in SLE studies and clinical trials.

Session Date: Monday, October 22, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster II: Biomarkers and Outcomes

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: For patients with SLE, disease status, physical functioning, and participation in daily activities affect health-related quality of life. This study aims to: 1) describe physical functioning and disease activity trajectories over time; 2) determine latent classes of different physical functioning and disease activity trajectory combinations; 3) identify membership predictors of these latent classes.

Methods: This retrospective longitudinal study used single centre inception adult patient data. Physical functioning was measured using patient-reported annual Medical Outcomes Study Short Form 36 (SF-36). Only the physical component summary (PCS) scale was used. Patients with ≥ 2 SF-36 questionnaires, within the first 2 years of diagnosis, were studied. Disease activity was measured by adjusted mean SLEDAI-2K (AMS) for the year, measured annually. Latent class trajectory modelling was used to combine PCS and AMS trajectories. Models with 2-6 classes were examined. The best model was determined by a combination of clinical and statistical interpretability. The nature of the different classes was explored by examining for annual distribution of clinical features, damage (SDI), cumulative glucocorticoid (GC) dose, and fibromyalgia presence.

Results: Out of 826 inception patients, 222 were analyzed. Data up to 10 years after diagnosis was examined. Mean age at SLE diagnosis was 35.5 ± 13.2 years. 5 latent classes was the best fit (Figure 1). The 5 classes are: 1) low PCS, very low disease activity (18.9%); 2) high PCS, very low disease activity (17.1%); 3) very low PCS, moderate disease activity (25.3%); 4) high PCS, moderate disease activity (29.7%); and 5) low PCS, high disease activity (9%). More patients in classes 1 and 3 (low to very low PCS) had fibromyalgia than other classes, suggesting this affected their PCS rather than disease activity. Although less class 5 patients had fibromyalgia, more still had this compared to those in classes 2 and 4 patients. Class 1 had more activity in CNS and skin systems, more damage, and higher cumulative GC dose (30.2 ± 8.2 vs 20.7 ± 8.7 grams) compared to class 2. Class 3 had more activity in skin and musculoskeletal systems, more damage, and more GCs

(38.0 ± 17.9 vs 29.2 ± 11.5 grams) compared to class 4. Class 5 had significant vasculitis and renal involvement, damage, and the highest cumulative dose of GCs.

Conclusion: There are 5 distinct classes of combined physical component summary scale and disease activity. PCS trajectories seemed more related to the presence of fibromyalgia, except in those with the most severe disease (vasculitis and renal). Identification of comorbid fibromyalgia and targeted supportive measures may help improve the physical component summary scale of 44% (class 1+ 3) of SLE adults.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster II: Biomarkers and Outcomes

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The Lupus Foundation of America is in Year 3 of a 5-year cooperative agreement with the Centers for Disease Control and Prevention to develop an online self-management program for individuals newly diagnosed with lupus. This presentation will summarize 1) formative research to identify the key self-management behaviors that will be the focus of the program, and 2) initial steps in the application of the Transtheoretical Model of Change (TTM) to those key behaviors. Meeting the needs of individuals with lupus requires an intervention designed to promote behavior change for those who are not ready, getting ready, and ready to manage their condition. The TTM provides an evidence-based framework for matching interventions to stage of change--Precontemplation, Contemplation, Preparation, Action and Maintenance.

Methods: Two literature reviews and a landscape analysis were completed with the goal of identifying and classifying: 1) the top needs of individuals with lupus (particularly those of minorities); and 2) key self-management strategies that best meet those needs. Next, based on findings from the literature review and landscape analysis, draft operational definitions of those key behaviors were developed. In a series of interviews, the definitions were reviewed and refined by four cultural experts—three of whom had expertise on lupus--and three lupus subject matter experts. Upcoming activities will include nine interviews with individuals with lupus. The first step in applying the TTM to those behaviors is to develop and validate measures of stage of change for each behavior. Stage measures begin with an operational definition of the target

behavior, and then ask questions about current behavior and intentions, using simple decision rules to assign individuals to stages. This summer, an online survey will be administered to 150 individuals with lupus to validate the stage of change measures. Analyses will examine the degree to which stage of change for each behavior is related, as predicted, to measures of lupus self-management and well-being.

Results: Four key self-management behaviors have been identified: 1) communicating with one's health care team; 2) managing medications; 3) managing symptoms of lupus; and 4) managing stress and distress related to lupus. Operational definitions for each are being finalized. The online survey described above will examine the degree to which stage of change measures for each behavior relate to well-being and other indicators of effective lupus self-management.

Conclusion: Meeting the needs of individuals with lupus requires an intervention matched to readiness to engage in key behaviors for lupus self-management. This is particularly important given the waxing and waning of lupus symptoms, and the heterogeneity of the disease in terms of severity and manifestations. The relationships between stage of change and the program's behavior change constructs provide an evidence-based framework for developing and delivering tailored feedback that may be more likely to be considered relevant, credible and memorable and to lead behavior change among people with lupus.

Prolactin and Dehydroepiandrosterone Sulfate in Women with Active Systemic Lupus Erythematosus of Recent Onset Versus Chronic Inactive Patients

Olga Vera-Lastra¹, Cristopher Vázquez², María Pilar Cruz-Dominguez³ and Luis J. Jara-Quezada⁴, ¹Internal Medicine, Hospital de Especialidades Centro Médico nacional La Raza, Instituto Mexicano del Seguro Social, Mexico City, Mexico, ²Internal medicine Department, Hospital de Especialidades Centro Médico La Raza, IMSS, Mexico City, Mexico, ³Hospital de Especialidades "Dr. Antonio Fraga Mouret", Centro Médico Nacional "La Raza", Mexico City, Mexico, ⁴Departamento de Inmunología, Escuela Nacional de Ciencias Biológicas, Instituto Politécnico Nacional,, Mexico, Mexico

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster II: Biomarkers and Outcomes

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Prolactin has a role in pathogenesis of Systemic Lupus Erythematosus (SLE); high levels have been associated with activity. In contrast, a decrease in dehydroepiandrosterone sulfate (DHEAS) has been observed with low disease activity.

Objective: To evaluate serum PRL levels and DHEAS levels in patients with active SLE of recent onset vs patients with inactive chronic and healthy controls and their correlation with activity and chronicity scores.

Methods: Serum PRL levels and DHEAS levels were studied, as well as their correlation with SLEDAI and SLICC scores. Group 1: 15 patients with SLE of recent onset (active SLEDAI >3) Group 2: 20 patients with inactive chronic SLE (SLEDAI<3) and Group 3: 20 healthy controls. SLEDAI and SLICC were calculated in group 1 and group 2 respectively. PRL and DHEAS was measurement by radioimmunoassay in all groups. Statistical analysis: U-Mann Whitney and Spearman correlation.

Results: Group 1: serum PRL levels were 27.82±9.96 ng/dl vs group 2: 20±5.02 ng/dl (p= 0.004) and group 3:19.58±4.57 ng/dl (p=0.004). Group 1: serum DHEAS levels were 14.58±9.26 µg/dl, group 2: 19.36±7.21 µg/dl (p=0.04) and group 3: 154.43±50.88 µg/dl (p =0.001). The average DHEAS was lower in patients with chronic SLE vs controls (p = 0.001). A positive linear correlation was found between serum PRL levels and SLEDAI score (Rho 0.92, p=0.001). No correlation was found between PRL and SLICC score. A negative linear correlation was shown between DHEAS concentration and SLICC score (Rho-0.46, p =0.03).

Conclusion: PRL levels were higher in active SLE patients VS. chronic inactive SLE and healthy controls. In contrast, serum DHAS levels were lower in patients with active SLE vs. inactive chronic SLE. We found a positive correlation between SLEDAI score and PRL serum concentrations and an inverse correlation between SLICC score and DHAS serum levels.

Abstract Number: 1708

Serum Complement Regulatory Proteins and Disease Activity of Systemic Lupus Erythematosus

Min-Hua Tseng¹ and Jing-Long Huang², ¹Pediatrics, Chang Gung Memorial Hospital, Taoyuan, Taiwan, ²Medicine, Chang-Gung University, Taoyuan city, Taiwan

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster II: Biomarkers and Outcomes

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Although aberrant complement activation is involved in the pathogenesis of systemic lupus erythematosus (SLE), the role of complement regulatory proteins in disease activity of SLE remains limited.

Methods: We enrolled the pediatric-onset SLE patients from our cohort study over 10 years. The clinical and laboratory data including SLEDAI disease activity score, and serum complement factor H (CFH), CFI, CD46, C5a, and C5b-9 in the active and remission phases were determined. Glomerular C5b-9 deposition as a complement activity marker was also examined.

Results: Forty patients (35 female and 5 male, aged 13.9 ± 3.8 years) met the criteria of investigation and were assessed. Fever and kidney were the most common symptom and organ involved, respectively. Mean SLEDAI in the active and remission phases were 12.6 vs 1.7, respectively. All patients exhibited lower serum C3, C4, CFH and CFI and higher serum anti-dsDNA and CD46 in the active phase. There was a significant difference in serum CFH, CFI and CD46 between active and remission phases. Serum CFI but not CFH and CD46 level was negatively correlated with SLEDAI score in active phase. Compared to classical activity markers, serum CFI was superior to C4 and anti-dsDNA in reflecting disease activity and also significantly correlated with white blood count and hemoglobin. Glomerular C5b-9 depositions were detected in patients with nephritis during active phase but not in disease controls.

Conclusion: Serum CFI level may not only be a promising biomarker for disease activity of SLE, but also reflects the hematological features of SLE.

Utilization of Complementary and Integrative Medicine Among Lupus Patients: a Patient Centered Analysis of Perceived Effectiveness and Preference

Lindsey Warner and Shazia Beg, University of Central Florida College of Medicine, Orlando, FL

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster II: Biomarkers and Outcomes

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Lupus is an autoimmune disease with multitude of symptoms that are often not fully controlled by standard biomedical treatments. This study was designed to gauge current patient use and perspective on Complementary

and Integrative Medicine (CIM) therapies. To our knowledge the last poll of CIM use in this patient population was that of the tri-nation study in 1997.

Methods: 85 participants were recruited from an academic rheumatology practice, lupus support groups, lupus foundation listservs and lupus walks. Of the 85 participants, 77 completed the Qualtrics survey and were used in the data analysis. The survey was organized into five sections correlating with 5 major branches of CIM therapies: manipulative and body based, mind body, biologically based, alternative medical systems and energy healing. The participant was then asked to answer five questions regarding each of the 20 modalities included. These questions ask the following: (1) whether they have used the therapy, (2) how often, (3) what motivates them to utilize the therapy, (4) what symptoms are they trying to address, and (5) how effective do they perceive the therapy to be.

Results: The three most commonly used modalities among patients with lupus were non-herbal natural products 44 (57%), aromatherapy/ essential oils 32 (41.5%) and meditation 31 (40.2%). Non-herbal natural products include chondroitin, coenzyme Q 10, fish oil, omega 3 and DHA, glucosamine, lutein, melatonin, Methylsulfonylmethane (MSM), and sesame oil. The most commonly utilized were natural fats 40 (90.9%) (fish oil, omega 3, and DHA). This was followed by melatonin 13 (29.5), and glucosamine 11 (25 %). Despite their high rate of utilization, over a third of participants [17 (38.6%)] felt that they were not effective or only somewhat effective. 21 (67.7%) of the meditation users found their therapy to be effective, very effective, or extremely effective. The majority of respondents in all three groups indicated that their motivation for utilizing these therapies was because “they believed it worked” and when asked about their desired benefit indicated “general wellness.” This was a common theme for and was reported as the motivation and benefit for 10 of the 19 therapies. The most striking deviation from this theme however was herbal medicine, with (22; 84.6%) reporting motivation was relief of a lupus related symptom. 91.7% of the 26 respondents that utilized herbs did so specifically to alleviate lupus-related symptoms rather than general wellness, with 20 (76.9%) reporting benefit. Of the 20 herbs listed, turmeric (7; 26.9%), marijuana (6; 23.1%), and green tea (2; 7.6%) were reported to be most beneficial for lupus-related symptoms.

Conclusion: The rate of CIM utilization reported by our lupus patient sample was 87.6%, which is approximately three times higher than the 2012 National Health Statistic Reports estimated 33.2% for the general U.S. population. Like the general public, our respondents gravitated towards the supplement industry. Modalities that had highest perceived effectiveness included massage, herbal medicines, and meditation and may provide therapeutic benefit. Future research should be done to explore efficacy of these therapies in larger lupus population.

Polypharmacy in Older Adults with Systemic Lupus Erythematosus

Dale Seguin¹, Christine A. Peschken², Ruby Grymonpre³, Phil St. John⁴ and Annaliese Tisseverasinghe⁵, ¹Internal Medicine, University of Manitoba, Winnipeg, MB, Canada, ²RR 149G, University of Manitoba, Winnipeg, MB, Canada, ³College of Pharmacology, University of Manitoba, Manitoba, MB, Canada, ⁴Geriatrics, University of Manitoba, Winnipeg, MB, Canada, ⁵Rheumatology, University of Manitoba, Winnipeg, MB, Canada

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster II: Biomarkers and Outcomes

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Polypharmacy is a strong risk factor for drug toxicity and adverse clinical outcomes, including delirium, falls, hospitalizations, and death. Polypharmacy is correlated with the prescribing of potentially inappropriate medications (PIMs) and of combining medications with adverse drug-drug interactions. Systemic lupus erythematosus (SLE) is an inflammatory disease associated with significant comorbidity and medication toxicities. While long-term treatment reduces flares and mortality, SLE patients have high rates of medication non-adherence due at least in part to polypharmacy. However, the extent of polypharmacy in this vulnerable population is not known. We aim to gauge the following in older adults with SLE: 1. Prevalence of use of >5 and >10 prescription medications, 2. Prevalence of use of benzodiazepines and non-benzodiazepine sedative-hypnotics (Z-drugs), opioids, and antipsychotics, 3. Prevalence of concurrent use of opioids and benzodiazepines/Z-drugs, and 4. Compare patients ≥ 75 to <75 years of age with respect to polypharmacy and PIM use.

Methods: Adults ≥ 67 years old, meeting the ACR/SLICC classification for SLE seen at least once at the Health Sciences Centre (HSC) Rheumatology Clinic in the 2 years preceding chart review were included. Patients lacking data on prescriptions in the Manitoba Drug Program Information Network (DPIN), such as those from Ontario, were excluded.

For each patient meeting study criteria, the DPIN was reviewed in April 2018 to document all unique medications dispensed in the preceding 4 months. Medication were categorized using the Anatomical Therapeutic Chemical (ATC) codes. Number of medications per patient, as well as the number of patients with prescriptions for one or more opioids, benzodiazepines, Z-drugs, and antipsychotics were calculated. The χ^2 tests, or Fisher's Exact Tests, where appropriate, were used to assess differences between groups, with statistical "significance" (α) predefined at the 5% level.

Results: The charts of 66 patients were reviewed, of whom 54 (48 female, 6 male; 24 ≥ 75 years old) met our study criteria. Of the 12 excluded, 6 were deceased, 4 were from outside Manitoba, and 2 did not meet ACR/SLICC classification for SLE. Almost 2/3 of the patients were dispensed ≥ 5 medications; of those ≥ 75 years old, close to 75% met this definition of polypharmacy. About 1/5 of all patients were dispensed benzodiazepines or Z-drugs. More than 5% were dispensed a combination of opioids and sedative-hypnotic medications. The prevalence of polypharmacy, using either definition, and opioid use, was higher in the older age group and in females, but the differences were not statistically significant ($p > 0.1$). Those on ≥ 5 medications (or ≥ 10 medications) were more likely to be on one or more PIM compared to those on < 5 medications.

Conclusion: This is the first study to assess and document the prevalence of polypharmacy and use of PIMs in older SLE patients. The rates of polypharmacy in our SLE cohort are just slightly higher than the 2012 rates reported for Canadian seniors on public drug programs.

Utility of the Lupus Low Disease Activity State (LLDAS) in Discriminating Responders in the BLISS-52 and BLISS-76 Phase 3 Trials of Intravenous Belimumab in Systemic Lupus Erythematosus

Shereen Oon¹, Molla Huq², Vera Golder³, Emily Ong⁴, Eric Morand⁵ and Mandana Nikpour⁶, ¹The University of Melbourne at St Vincent's Hospital, Fitzroy, Australia, ²The University of Melbourne at St Vincent's Hospital, Melbourne, Australia, ³School of Clinical Sciences at Monash Health, School of Clinical Sciences at Monash Health, Monash University, Melbourne, Australia, ⁴School of Clinical Sciences at Monash Health, Monash University, Melbourne, Australia, ⁵Medicine, School of Clinical Sciences at Monash Health, Monash University, Melbourne, Australia, ⁶The University of Melbourne, Melbourne, Australia, Melbourne, Australia

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster II: Biomarkers and Outcomes

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Measurement of treatment response in SLE clinical trials has been based on measurement of change from baseline; however a treat-to-target analysis has seldom been applied. The Lupus Low Disease Activity State (LLDAS), a potential response indicator for lupus clinical trials, has been found to correlate with reduced damage accrual in SLE¹, indicating it may be a useful treatment target in the clinic. In a trial setting, LLDAS correlated with key outcome measures and discriminated responders from non-responders in a *post-hoc* analysis of the phase IIb MUSE trial of anifrolumab².

We evaluated the utility of LLDAS in this *post-hoc* analysis of the BLISS-52³ and BLISS-76⁴ trials of intravenous belimumab in patients with moderate-severe SLE.

Methods: LLDAS attainment was assessed at baseline and week 52. LLDAS is defined as having all of the following: a) SLEDAI-2K ≤ 4 without major organ activity; b) no new disease activity; c) physician global assessment of activity score (PGA, 0-3) ≤ 1 ; d) prednisolone dose ≤ 7.5 mg/day; and e) standard immunosuppressants allowed. Attainment of LLDAS, association with the primary trial endpoint (SRI-4), discrimination between belimumab and placebo-treated patients, and predictors of LLDAS attainment, were evaluated using descriptive statistics and the Chi-square test, using R (v3.4.3).

Results: Few patients were in LLDAS at study entry (0-2.2%). At week 52, in both studies, fewer patients attained LLDAS compared to the SRI-4 (Table 1). At week 52, for belimumab 10mg/kg, 17.0% of patients in BLISS-52 and 19.3% of patients in BLISS-76 who achieved an SRI-4 also attained LLDAS. In BLISS-52, significantly more patients attained LLDAS at week 52 on belimumab 10mg/kg compared to placebo (12.5% vs 5.8%, $p=0.02$), with a near significant difference at the same time-point in BLISS-76 (14.4% belimumab 10mg/kg vs placebo 7.8%, $p=0.06$). Numerically more patients were in LLDAS at week 52 for both studies for the belimumab 1mg/kg group compared to placebo. In subgroup analysis, LLDAS attainment at week 52 was more likely on belimumab 10mg/kg than placebo in patients with high anti-

dsDNA antibody levels ≥ 30 IU/ml (both studies), low C3 (<90 mg/dl)/C4 (<16 mg/dl) (both studies), high anti-dsDNA antibody levels or low complement levels (both studies), SLEDAI-2K ≥ 10 (BLISS-52), or prednisone dose ≥ 7.5 mg/d (BLISS-52) at study entry.

Conclusion: In BLISS-52, LLDAS was able to discriminate responders from non-responders in the belimumab 10mg/kg group. Fewer patients met LLDAS criteria at week 52 compared to the SRI-4, suggesting that LLDAS is a more stringent measure of treatment response than the SRI-4. Our findings support the discriminant validity of LLDAS as a useful outcome measure in SLE RCTs.

Validation of Proposed EULAR/Acr SLE Classification Criteria Versus SLICC SLE Classification Criteria

Michelle Petri¹, Daniel Goldman¹ and Laurence S Magder², ¹Medicine (Rheumatology), Johns Hopkins University School of Medicine, Baltimore, MD, ²Epidemiology and Public health, University of Maryland School of Medicine, Baltimore, MD

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster II: Biomarkers and Outcomes

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The SLICC 2012 SLE classification criteria and the revised ACR-11 criteria count each SLE manifestation equally. We validated the recently proposed EULAR/ACR classification rule that uses a weighted approach against these criteria and also against a weighted version of the SLICC classification criteria.

Methods: The physician-rated patient scenarios used to develop the 2012 SLICC classification criteria were re-employed to devise a weighted SLICC classification rule. A multiple linear regression model was constructed with the 2012 SLICC criteria variables as predictors and the binary outcome (physician classification of SLE) as the outcome. To generate the weights for each criteria, we then multiplied each criteria's coefficient by 100 and rounded to the nearest integer. The 'Direct Coombs' criteria (coefficient <1) was deleted for simplicity. The weights for the remaining manifestations were: acute cutaneous (26), chronic cutaneous (12), oral ulcers (16), arthritis (9), serositis (16), renal without biopsy (9), neurologic (9), hemolytic anemia (1), leukopenia or lymphopenia (14), thrombocytopenia (15), alopecia (9), ANA (17), anti-dsDNA (19), anti-Sm (16), antiphospholipid antibodies (8), low complement (11). A cutoff for classification was chosen as the score that maximized overall agreement (i.e., the sum of sensitivity and specificity) of the new weighted criteria with physician diagnosis. Patients with lupus nephritis or the new weighted classification rule of 56 or more with at least one clinical component and one immunologic component were classified as SLE. We evaluated the performance of this revised SLICC criteria, on an independent set of patient scenarios, and compared this to the performance of the older revised ACR criteria, the previous SLICC 2012 criteria, and the newly proposed EULAR/ACR criteria.

Results: Table 1 shows the performance of the four classification rules. There was no statistically significant difference (at the .05-level) between any pair of rules with respect to overall agreement with the physician diagnosis.

Table 1: Sensitivity and specificity of four different SLE classification rules based on physician diagnoses of patient scenarios

Classification Rule	Sensitivity (n=349)	Specificity (n=341)	Overall Agreement (n=690)
Proposed EULAR/ACR	317 (89%)	302 (90%)	619 (90%)
Revised ACR-11	290 (83%)	326 (96%)	616 (89%)
SLICC 2012	340 (97%)	288 (84%)	628 (91%)
Weighted SLICC 2012 criteria	310 (88%)	304 (89%)	614 (89%)

Conclusion: We validated the new EULAR/ACR criteria against both ACR-11 and SLICC classification criteria. Weighted SLICC criteria were a trade-off with less sensitivity but better specificity. The two newly derived weighted classification rules did not perform better than the existing list-based rules in terms of over-all agreement. Given that the list-based rules are easy to calculate, they may be preferred in most clinical settings.

Session Date: Monday, October 22, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster II: Biomarkers and Outcomes

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Low disease activity (LDA) and remission are important goals in the treatment of patients (pts) with SLE.^{1,2} Lupus Low Disease Activity State (LLDAS) is associated with reduced damage accrual,² and has been shown to be a feasible clinical trial endpoint.³ In pts with high disease activity (HDA; SLEDAI-2K \geq 10) enrolled in the ADDRESS II study, atacicept improved SRI-6 response rates and flare prevention at Week 24 vs placebo (PBO).⁴ Atacicept was also shown to have an acceptable safety profile. We present a post-hoc analysis of data from ADDRESS II and its long-term extension describing 48-week LDA and remission rates in pts with HDA at Screening.

Figure 1. Endpoint stringency of LDA, LLDAS and remission attainment versus SRI-6 response in all patients with high disease activity at Week 24 (A) and Week 48 (B)

A. Week 24 (ADDRESS II; n=158)

B. Week 48 (Long-term extension; n=158*)

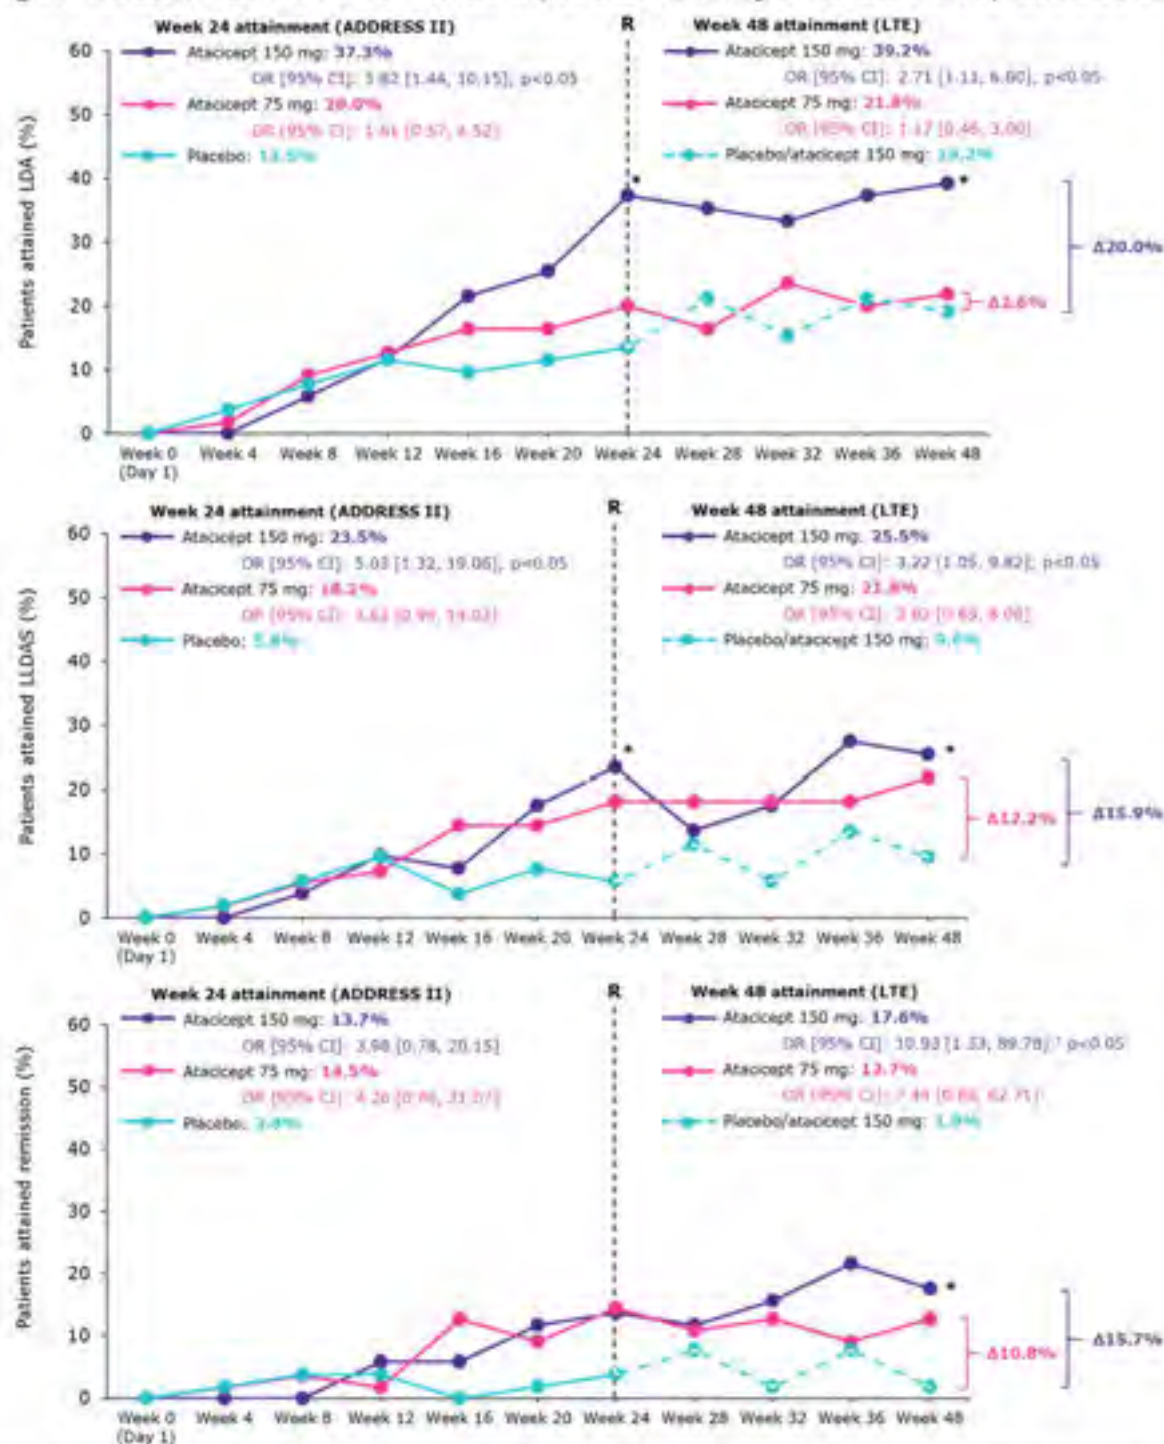

*26 patients who had HDA at Screening and who did not enter the LTE following ADDRESS II were considered non-responders for this analysis.
LDA, Low disease activity; LLDAS, Lupus Low Disease Activity State; SRI, SLE responder index

Methods: In ADDRESS II, pts were randomized (1:1:1) to weekly subcutaneous PBO or atacicept 75 or 150 mg for 24 weeks. Atacicept completers continued at the same dose in the extension study; PBO pts were switched to atacicept 150 mg (PBO/atacicept 150 mg). This post-hoc analysis assesses: LDA (SLEDAI-2K \leq 2), LLDAS (SLEDAI-2K \leq 4 without major organ activity, no new disease activity vs previous visit, Physician's Global Assessment [PGA] \leq 1, prednisone-equivalent \leq 7.5mg/day, and stable immunosuppressants),² and remission (clinical SLEDAI-2K=0, PGA \leq 0.5, prednisone \leq 5 mg/day), as proposed by the task force on definitions of remission in SLE (DORIS).¹

Results: A total of 158/306(52%) ADDRESS II pts had HDA at study entry. At Week 24, 42.4% achieved SRI-6, 23.4% attained LDA, 15.8% LLDAS and 10.8% remission (Figure 1A). At Week 48, 52.5% achieved SRI-6, 26.6% attained LDA, 19.0% LLDAS and 10.8% remission (Figure 1B). Among 83 SRI-6 responders with HDA at Screening, 49.4% (n=41)

Figure 2. LDA, LLDAS and remission in patients with high disease activity at Screening

*p<0.05 versus placebo (24 weeks) or placebo/atacicept 150 mg (48 weeks); †Results should be interpreted with caution due to the wide CI; CI, Confidence interval; LDA, Low disease activity; LLDAS, Lupus Low Disease Activity State; LTE, Long-term extension; OR, Odds ratio

attained LDA, 34.9% (n=29) LLDAS and 20.5% (n=17) remission at Week 48. At 48 weeks, LDA, LLDAS and remission rates were higher in pts treated with atacicept 150 mg vs PBO/atacicept 150 mg and vs atacicept 75 mg (Figure 2).

Conclusion: ADDRESS II pts with HDA at Screening receiving atacicept 150 mg were more likely to attain LDA, LLDAS and remission at Week 48 than those treated with atacicept 75 mg or PBO/atacicept 150 mg. These endpoints were more stringent and discriminatory than SRI-6, confirming LLDAS, LDA, and remission to be robust and meaningful endpoints for SLE trials. In addition, these data further support future studies of atacicept in SLE.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster – ARHP

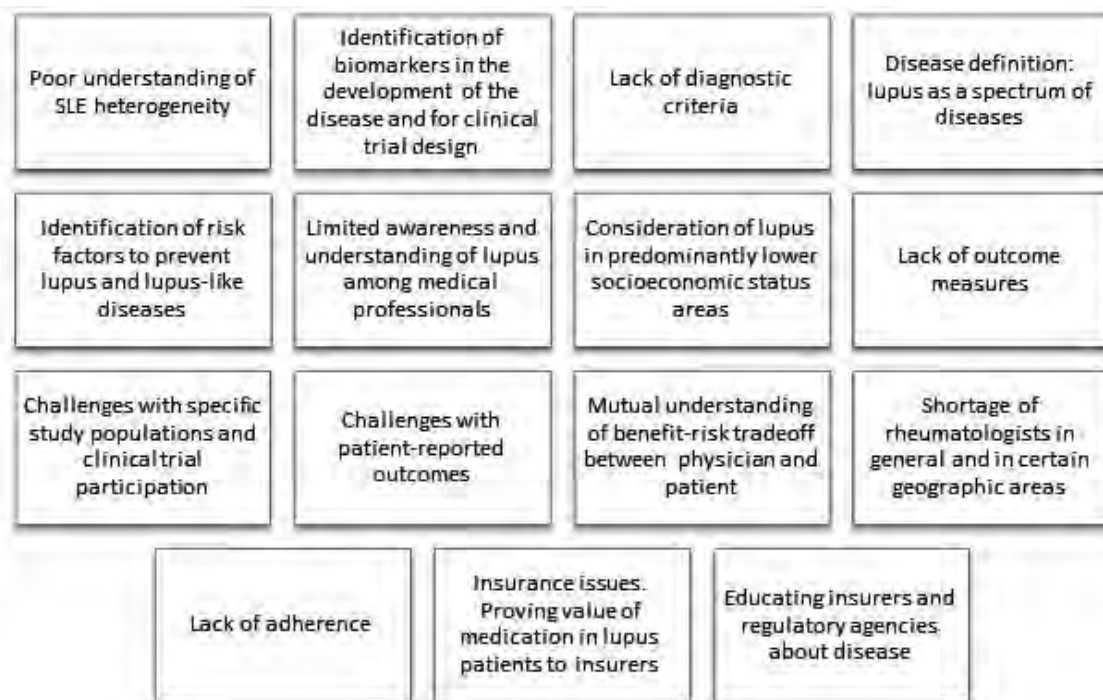

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The Addressing Lupus Pillars for Health Advancement (ALPHA) Project is a global consensus initiative seeking to identify and prioritize top barriers in lupus impacting diagnosis, care, treatment and research, with the goal of improving rates of accurate and timely diagnosis, increasing access to care, and improving short and long-term patient outcomes. This abstract presents Phase I consensus building and prioritization process methodology, and findings of initial project activities.

Methods: The Lupus Foundation of America and its research partner, Tufts Center for the Study of Drug Development, assembled a Global Advisory Committee (GAC) of 13 lupus experts across 5 countries to provide input and support throughout the effort. A mixed methods approach is being used to elicit concepts seen as major barriers in lupus diagnosis, care, treatment and research, then consolidate and confirm those selected as most urgent. First, a brief web survey was distributed to each GAC member to begin concept elicitation. Identified items were then ranked during a GAC meeting, and will be presented through an in-depth semi-structured interview among 22 stakeholders representing industry, academia, regulatory bodies, patient/advocacy groups, clinicians, and researchers. Finally, an online survey among 200-500 individuals will further validate and demonstrate consensus around top barriers in a broader audience for this Phase I initiative.

Results: GAC member response rate was 85% for the concept elicitation exercise. Findings are shown in Figure 1. 15 main concepts were identified, with substantial discussion on lupus heterogeneity, lupus as a spectrum of diseases, and the

importance of biomarkers in trial design and understanding of the disease. Categorization and prioritization of these concepts is seen in Figure 2. Notably, all GAC members cited issues surrounding disease definition and diagnosis as the most significant burden in lupus. Half also cited clinical trial design and availability and side effects of current medications as significant burdens.

Conclusion: The ALPHA Project is a collective, iterative research effort among lupus key opinion leaders and diverse stakeholder groups to build consensus and create actionable steps to advance the field. Findings from the GAC meeting showed initial consensus on key priority issues, such as lupus heterogeneity, disease definition, and clinical trial design. Figure 1. SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Sclerosis and Related Disorders – Clinical Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Lenabasumis a synthetic, non-immunosuppressive, selective cannabinoid receptor type 2 agonist that activates resolution of innate immune responses. Lenabasum had acceptable safety and tolerability, and improved multiple efficacy outcomes in the double-blinded, randomized, placebo-controlled Part A of Phase 2 trial JBT101-SSc-001 (NCT02465437) in diffuse cutaneous SSc (dcSSc) subjects.

Objective: To provide long-term open-label safety and efficacy data in dcSSc subjects in study JBT101-SSc-001.

Methods: Subjects who completed Part A were eligible to receive oral lenabasum 20 mg BID in an open-label extension (OLE) that assessed safety and efficacy at 4 weeks, then every 8 weeks.

Results: 36/38(95%) eligible subjects enrolled in the OLE, with mean interval of 134 (range 33-392) days or 19.1 weeks from end of dosing in Part A to start of OLE when subjects received only standard-of care drugs. 34/36 (94%) subjects were on stable doses of immunosuppressive drugs. At the time of data cut-off, 5/36 (13.9%) subjects had discontinued the OLE for reasons all unrelated to lenabasum: difficulty coming for study visits (n = 2), fatigue, inflamed tendons, and high dose steroid-induced scleroderma renal crisis. Of the remaining 31 subjects, 27(87.1%) had already completed ≥ 1 year of dosing in OLE. Adverse events(AEs, n = 180) occurred in 33/36 (91.7%) subjects, with 7/36 (19.4%) subjects having ≥ 1 AE related to lenabasum. No subject had a serious or severe AE related to lenabasum. Three serious AEs occurred: renal crisis, thumb fracture, and digital ulcer. AEs that occurred in $\geq 10\%$ of subjects (n, % of subjects) were: upper respiratory tract infection (8, 22.2%), skin ulcer, arthralgias, urinary tract infection (5, 13.9% each), and diarrhea (4, 11.1%). Mild dizziness occurred in 3 (8.3%) subjects.

Improvement was seen in multiple physician- and patient-reported efficacy outcomes compared to study start and start of OLE (examples in Figure 1), including Combined Response Index in diffuse cutaneous Systemic Sclerosis (CRISS), mRSS, HAQ-DI, Physician Global Assessment, skin symptoms, itch, and multiple PROMIS-29 domains. FVC % predicted was relatively stable. Compared to baseline at study start, the CRISS median score was 92% (23%, 100% IQR) at Week 52 and mRSS declined by mean (SD) = 9.4 (8.43) and 41.3% (32.7%) from baseline, with 35% of subjects newly achieving a low mRSS ≤ 10 .

Conclusion: In OLE of Phase 2 trial JBT101-SSc-001, lenabasum continues to have acceptable safety and tolerability in dcSSc with no severe or serious AEs or study discontinuations related to lenabasum. Only about 1 in 5 subjects had an AE related to lenabasum over 1-year OLE dosing. ACR CRISS score, mRSS, Physician Global Assessment, and multiple patient-reported outcomes show continued improvement, although background therapy, potential for spontaneous improvement, and open-label dosing limit what can be definitely attributed to lenabasum.

Abstract Number: 1716

Evaluation of American College of Rheumatology Provisional Composite Response Index in Systemic Sclerosis in a Phase II Trial of Abatacept Vs. Placebo

Dinesh Khanna¹ and Cathie Spino², ¹Division of Rheumatology, Department of Internal Medicine, University of Michigan Scleroderma Program, University of Michigan, Ann Arbor, MI, ²Biostatistics, University of Michigan, Ann Arbor, MI

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Sclerosis and Related Disorders – Clinical Poster II

Background/Purpose: Treatment with CTLA4Ig, abatacept (ABA), in early diffuse cutaneous systemic sclerosis (dcSSc; the Phase 2 ASSETtrial) showed evidence of improvements in modified Rodnan skin score (mRSS) and secondary outcome measures at month 12 (2018 ACR abstract submitted); however, statistical significance was not always shown vs. placebo. The CRISS index, a composite outcome measure for trials in SSc¹, is a 2-step process that assigns a probability of improvement for each subject ranging from 0 [no improvement] to 1 [marked improvement]. Step 1 assesses clinically meaningful decline in cardio-pulmonary-renal involvement with a probability of 0. For remaining subjects, probability of improvement is based on 5 variables: changes from baseline to month 12 in FVC%, mRSS, patient (PTGA) and physician global assessments (MDGA), and HAQ-DI. We assessed the performance of CRISS, a secondary outcome measure, in ASSET at month12.

Methods: ASSET was an investigator-initiated, multicenter double-blind, randomized placebo-controlled trial. Eligible subjects were randomized in a 1:1 ratio to either 12 months 125 mg SC ABA or matching placebo, stratified by duration of dcSSc (≤ 18 vs >18 to ≤ 36 months). Investigators reported SSc end organ involvement (Step 1 for CRISS) prospectively using a case report form. These and all AEs and SAEs were reviewed for cardio-pulmonary and renal involvement by the study PI. Step 2 calculated the CRISS index as previously defined. Treatment differences, adjusted for duration of dcSSc, in the CRISS score were assessed by the non-parametric Van Elteren test and by ANCOVA for individual CRISS components. We calculated Spearman's correlation coefficients to assess the relationship between the CRISS score and its individual components. Multiple imputation was used for analysis, creating 25 complete datasets with estimates, standard errors and p-values pooled over each imputed dataset.

Results: 88 subjects (44 ABA, 44 PBO) were randomized; 63 (72%) had complete data for all relevant outcomes at month 12. 5 PBO and 5 ABA subjects met the pre-defined definition of worsening cardio-pulmonary-renal involvement(Step 1) and were given a score of 0. There is evidence of improved CRISS scores on ABA compared to the PBO at month 12 and the difference was statistically significant ($p=0.03$; Table). For individual variables, MDGA and HAQ-DI were statistically significant ($p=0.004$ and $p=0.05$) favoring ABA. Most variables, except HAQ-DI and PTGA, had statistically significant correlations with the CRISS (Table).

Conclusion: Although the degree of correlation is high between the mRSS and CRISS, there is evidence that CRISS may be more sensitive to clinically meaningful treatment changes than the standard skin score endpoint. This suggests further validation of CRISS as an independent primary endpoint for scleroderma clinical trials.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Sclerosis and Related Disorders – Clinical Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic sclerosis (SSc), or scleroderma, is a rare, autoimmune, multisystem connective tissue disorder characterized by vascular damage, autoimmunity, and fibrosis of the skin and other internal organs ¹⁻³. Pulmonary manifestations account for 60% of SSc-related deaths, and interstitial lung disease (ILD) is identified more often in SSc than in any other connective tissue disease (CTD), with the prevalence of ILD in SSc patients ranging from 75% to 90% ^{1,4}. There are many gaps in our understanding of the methodology for screening and the management of SSc-ILD. Hence, the objective of the current Delphi study was to solicit the opinions of rheumatologists and pulmonologists with expertise in the management of patients with SSc-ILD in order to develop consensus on screening and treatment criteria, and to evaluate the potential role of anti-fibrotics in a treatment paradigm for SSc-ILD.

Methods: A three-stage Delphi method was designed to query rheumatologists and pulmonologists with expertise in SSc-ILD on identifying the criteria for screening, treatment, and management of patients with SSc-ILD. The potential role of anti-fibrotics in the treatment paradigm for patients with SSc-ILD was also explored. Here preliminary data at the completion of the second survey by 9 panelists are presented. Survey two had panelists rate their agreement on a Likert scale from -5 (complete disagreement) to +5 (complete agreement). Consensus was defined as a score of 2.5 or more with standard deviation not crossing zero.

Results: Preliminary data, based on two rounds of Delphi, show high agreement regarding how to screen, how to identify the patient population to treat, treatment paradigms, and how to monitor progression and eventually successfully manage patients with SSc-ILD (Table 1: Mean \pm SD).

Conclusion: Preliminary data suggest consensus on screening and treatment with initial immunosuppressive therapy in SSc-ILD. The group was amenable to concomitant use of anti-fibrotics with CYC/MMF in SSc-ILD patients. Further guidance should be available in the near future with ongoing and recently completed trials.

Table 1:

How do you screen?

Screening for the general scleroderma population for ILD should include Spirometry with DLCO (4.78 \pm 0.44) Full PFT (4.89 \pm 0.33) HRCT (3.67 \pm 1.94) Autoantibody testing (4.22 \pm 0.97) Echocardiogram and (3.89 \pm 1.69) Chest auscultation (4.44 \pm 1.33)

Who do you screen?

In determining which patients to screen for ILD, I would consider Patients with symptoms (4.56 \pm 1.01) High risk patients (ex: diffuse cutaneous SSc (dcSSc), positive Scl-70 antibodies, African American ethnicity, and/or a high modified Rodnan Skin Score (4.78 \pm 0.67)

Who do you treat?

When deciding whether to treat patients for ILD I consider Extent of ILD or fibrosis on HRCT (4.44 \pm 0.88) Clinically meaningful change in PFT value (4.89 \pm 0.33)

Based on high resolution computed tomography (HRCT), I treat patients that have Worsening HRCT with symptoms or declining PFTs (5.00 \pm 0.00) >20% involvement on HRCT with abnormal PFTs (4.78 \pm 0.44)

Based on forced vital capacity (FVC) and symptom status (assume all patients have ILD on HRCT), I treat patients that have FVC >80% with ILD on HRCT in a high-risk patient (early diffuse disease, Topo+) (3.89 \pm 0.60) Decline in FVC by >10% in one year (4.78 \pm 0.44)

To determine the phenotype of patients that are likely to respond to treatment, I would likely employ Findings or changes on HRCT (3.56 \pm 1.33) Findings or changes on PFTs (3.89 \pm 1.45)

Additional tests that can help make the decision PFTs (Spirometry with DLCO) (1.00 \pm 0.0) HRCT (2.0 \pm 0.0) Autoantibodies (3.6 \pm 0.89)

How do you treat?

Once I have decided to treat SSc-ILD, the initial therapy I use is Mycophenolate Mofetil (CellCept) (4.78 ± 0.44) The typical/target dose for mycophenolate (MMF) I recommend is 3,000 mg daily (4.78 ± 0.44)

With regard to anti-fibrotics...

I see anti-fibrotics (nintedanib [OFEV] and pirfenidone [Esbriet]) fitting into the management of SSc-ILD as first line therapy (0.44 ± 2.83) I see anti-fibrotics (nintedanib [OFEV] and pirfenidone [Esbriet]) fitting into the management of SSc-ILD **after CYC/MMF** (2.22 ± 3.11) I see anti-fibrotics (nintedanib [OFEV] and pirfenidone [Esbriet]) fitting into the management of SSc-ILD **concomitant with CYC/MMF**: (3.44 ± 1.88) I **do not** see anti-fibrotics fitting into the management of SSc-ILD (-2.56 ± 3.28)

How long do you treat?

I typically treat patients with SSc-ILD for 5 years (3.89 ± 1.17)

What is progression to you, and how do you monitor it?

I monitor progression as follows: Changes in PFTs over time (FVC or DLCO) (4.67 ± 0.71) Features on HRCT (ILD pattern or extent of fibrosis) (3.56 ± 1.33) Changes in HRCT over time (4.11 ± 1.05) Changes in symptoms over time (2.78 ± 3.15)

What is success to you?

I consider the following elements in defining success in SSc-ILD: FVC improvement (4.33 ± 0.71) DLCO improvement (4.11 ± 0.93) HRCT improvement (4.22 ± 0.97) Symptom stabilization / improvement (3.89 ± 0.93)

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Sclerosis and Related Disorders – Clinical Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic sclerosis (SSc) causes varying degrees of skin fibrosis with varying trajectory. Extent of skin involvement is measured by the modified Rodnan skin score(mRSS), a semi-quantitative clinical method of pinching the skin to determine fibrosis. Previously, a 415-gene signature in skin was identified whose change between baseline and 12 months predicted mRSS at 24 months. We identified a skin gene expression signature at a single time point that predicts mRSS 6 or 12 months later.

Methods: Gene expression profiles were obtained from 260 skin biopsies from 45 SSc patients treated with mycophenolate mofetil (MMF) and 22 healthy controls. Participants were classified into progressing, stable, or regressing groups based on the mRSS change between the baseline skin biopsy and the subsequent time point 6 or 12 months later. A multinomial generalized linear model determined the probability of skin trajectory from gene expression profiles and clinical information.

Results: The mRSS regressing group compared to the mRSS progressing and stable groups combined demonstrated 762 differentially expressed genes (823 probes). A multinomial generalized linear model that included genomic and clinical data was developed to predict skin trajectory with 58.8% total accuracy compared to 40% using a random permutation null model. Up-regulated genes in improvers were enriched for extracellular matrix (ECM) metabolism, transforming growth factor-pathway expression, and angiogenesis.

Conclusion: We demonstrate proof-of-principle that significant prognostic information may be obtained from analysis of skin gene expression at a single time point. Further investigation is warranted to determine the generalizability of the model. Future directions include incorporating additional information such as serum protein data and histologic data to increase the predictive accuracy of the model.

Figure 1. Error matrix comparing the performance of the experimental model to a null model. The null model permutes 1000 times yielding a mean prediction accurate to 0.1. The experimental model more accurately predicts patients whose mRSS improves or remains stable compared to the null model.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Sclerosis and Related Disorders – Clinical Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The lack of a reproducible and quantitative method to accurately assess histological skin fibrosis in patients with systemic sclerosis (SSc) has long plagued clinical studies. Deep neural network(DNN) analysis, a computer vision technique, has the potential to radically augment histopathological analyses for myriad diseases including SSc. DNN analysis is a computational tool that extracts and quantifies complex image patterns. To test the hypothesis that DNN analysis applied to SSc skin biopsies is a useful method for dermal fibrosis quantification, the association between DNN outputs and skin score was determined.

Methods: One rheumatologist performed modified Rodnan skin score (mRSS) assessments followed by four mm dermal, punch biopsies of the non-dominant volar forearm, in patients with SSc. Biopsies were repeated at 6-, 12- 24-, and 36-months. Trichrome-stained sections were photomicrographed and transformed into quantitative features using AlexNet in the Matlab Neural Network Toolbox. Principal component analysis was used to identify the combination of quantitative features that captured the most quantitative feature variance. The correlation between the first principal component, mRSS, and local arm skin score was assessed.

Results: Twenty-six photomicrographs were analyzed. DNN analysis identified 4096 unique quantitative features. The first principal component of these 4096 quantitative features strongly correlated with local skin score ($R = 0.52$) and mRSS ($R = 0.71$).

Conclusion: This investigation demonstrates that DNN-derived quantitative features of SSc biopsies are sensitive to both local skin score and mRSS. Future directions include testing for generalizability in a larger sample and evaluating whether DNN are sensitive to biochemical measures of fibrosis. If validated, this suggests that DNN analysis can dramatically expand the quantifiable SSc phenome to permit inclusion of histological information into SSc trajectory models.

Figure 1: A) 100 *image patches* (red square) were randomly sampled from the dermis and input to AlexNet. B) For each image patch, AlexNet identified 4096 *quantitative features*, resulting in a 2600 x 4096-dimensional matrix. The rows and columns of the quantitative feature matrix have been sorted by the first principal component (PC). C) Histograms of the principal component scores for image patches from the patients with the highest(35) and lowest (4) mRSS show little overlap. Across all 2600 image patches grouped by biopsy, the biopsy accounted for 30% of the total variance in the principal component scores ($p < 10^{-100}$, one-way ANOVA). Therefore, biopsies were summarized into *biopsy scores* by taking the mean of the 100 patches. D) Biopsy score significantly correlated with mRSS (Pearson's $R = 0.71$, $p = 5 \times 10^{-5}$). E) Biopsy score significantly correlated to local skin score (Pearson's $R = 0.53$, $p = 0.0049$).

Higher Neutrophil Count Predicts More Severe Skin/Lung Disease and Increased Mortality in Early Systemic Sclerosis

Rana Taherian¹, Vishnu Mohan¹, Jun Ying², Samuel Theodore¹, Julio Charles¹, Hau Pham¹, Minghua Wu³, Maureen D. Mayes³ and Shervin Assassi³, ¹University of Texas Health Science Center at Houston, Houston, TX, ²Department of Internal Medicine - Rheumatology, University of Texas Health Science Center at Houston, Houston, TX, ³Rheumatology, University of Texas Health Science Center at Houston, Houston, TX

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Sclerosis and Related Disorders – Clinical Poster II

Background/Purpose: Our recent global blood transcript studies show that systemic sclerosis (SSc) patients have a prominent neutrophil signature. Mechanistic studies with neutrophils are hampered by their short half-life in-vitro, and the fact that neutrophils are not the predominant leukocyte in mice, underscoring the importance of direct human data for their relevance. Herein, we investigated whether higher neutrophil counts were associated/predictive of more severe disease and worse mortality in SSc.

Methods: Neutrophil counts were prospectively obtained as part of complete blood count examination in the GENISOS cohort. All patients had a disease duration < 5 years. Mixed effect linear regression analysis was used to examine the relationship between neutrophil count and longitudinal FVC% / modified Rodnan Skin Score (mRSS) measurements.

Results: At the time of analysis, 444 patients with SSc were enrolled from whom 392 had a baseline neutrophil count available (88.2%). The mean disease duration (SD) was 2.4 (1.5) years, 59.6% of patients had diffuse SSc. For the longitudinal analysis of serially obtained neutrophil counts, the number of concomitantly obtained mRSS and FVCs were 1676 and 1030, respectively.

At the baseline visit, higher neutrophil count was associated with male gender ($p<0.001$), diffuse disease type ($p<0.001$), higher mRSS ($p<0.001$), lower FVC% ($p=0.013$), and anti-topoisomerase positivity ($p=0.015$). There were no significant associations with age, disease duration, race, and RNA polymerase positivity.

Higher longitudinal neutrophil counts were associated with higher serially obtained mRSS and lower FVC% (s ($p<0.001$ for both).

Next, the neutrophil count was dichotomized based on the top quartile value at the baseline study visit (6100 cells/ul). Patients with a positive neutrophil count at the baseline visit had on average 6.4 points higher serially obtained mRSS ($p<0.001$) and had on average 6.9% lower longitudinal FVC% (s ($p=0.007$). Moreover, positive neutrophil count was predictive of higher mortality in the univariable model ($p<0.001$ - Figure), as well as after adjustment for age, gender, topoisomerase status, diffuse disease type and prednisone use (Table). Specifically, patients with a positive neutrophil count had 1.9 times higher mortality during the follow-up time.

Conclusion: We show for the first time higher neutrophil count is predictive of more extensive skin/lung involvement and higher mortality in SSc. Neutrophils might play a role in SSc pathogenesis and their baseline counts can serve as an easily obtainable prognostic biomarker for disease severity.

	Hazard Ratio	95% CI	p-value*
Positive neutrophil count	1.93	1.25, 2.99	0.003
Age at enrollment	1.03	1.02, 1.05	<0.001
Female gender	0.74	0.45, 1.22	0.24
Prednisone use (>5mg per day)	1.51	0.93, 2.45	0.096
Positive topoisomerase I	1.54	0.97, 2.44	0.066
Diffuse disease type	1.05	0.7, 1.56	0.815

* p-value based on multivariable Cox regression analysis for all-cause mortality

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Sclerosis and Related Disorders – Clinical Poster II

Figure. Kaplan-Meier curves with 95% CI of the first non-RP feature after RP onset according to racial group.

Patients who experienced their first non-RP feature of the disease before the onset of RP were included with a simultaneous onset.

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Genetic and environmental factors play a significant role in SSc. African Americans are known for a higher SSc incidence, an earlier age of onset, and a greater prevalence of interstitial lung disease and pulmonary hypertension (PH) compared to white patients. Data on blacks mostly stem from African Americans and studies on Asians are mostly from outside Asia and lack direct comparison with other racial groups.

We aimed to further evaluate differences of SSc presentations between white, Asian and black patients.

Methods: Characteristics of self-reported white, Asians or black SSc patients from the EUSTAR cohort were compared across racial groups; cox/logistic regression analyses were adjusted for age, sex, disease duration and antibody status.

Results: 9161 white, 341 Asian (208 patients from within, 133 from 34 centres outside Asia) and 198 black patients (82 patients from within, 116 from 35 centres outside sub-Saharan Africa [SSA]) were included.

Asian and black patients were on average 10 years younger than white patients ($p<0.001$). Black patients developed the first non-Raynaud's phenomenon (RP) SSc feature faster than Asian and white patients (all $p<0.01$; Figure) also after adjustment (HR [blacks] 1.4, $p<0.001$; HR [Asians] 1.1, $p=0.009$ vs whites). Asian patients treated within Asia (China) developed the first non-RP comparably to Asian patients treated outside Asia (HR [within Asia] 1.09, $p=0.48$). Black patients treated within SSA (South Africa) had a slightly faster disease onset than those treated outside SSA (HR [within SSA] 1.16, $p=0.37$).

Among ANA specificities, ACA predominated in white patients (whites: 42%, Asians: 16%, blacks: 10%; $p<0.001$) and anti-Scl-70 in Asian patients (whites: 35%, Asians: 47%, blacks: 34%; $p<0.001$). The prevalence of diffuse skin involvement was similar in Asian (28%) and white patients (26%), but more common in black patients univariately (56%; $p<0.001$) and multivariably (OR [Asians] 0.7, $p=0.06$; OR [blacks] 2.7, $p<0.001$ vs whites).

The prevalence of PH (defined as PAPsys >40 mmHg as estimated by echocardiography) was lower in white patients (whites 12%, Asians 18%, blacks 17%; $p=0.004$; OR [Asians] 2.6, $p=0.001$, OR [blacks] 2.8, $p=0.020$ vs whites). Asians had a higher prevalence of an impaired diffusing capacity for carbon monoxide ($<80\%$ of predicted; 84%) than black (74%) or white patients (70%, $p<0.001$) also in multivariable analysis (OR [Asians] 2.4, $p<0.001$; OR [blacks] 1.2, $p=0.55$ vs whites). Both, Asians (44%) and black patients (50%), had a higher prevalence of a reduced forced vital capacity ($<80\%$ of predicted) compared to white patients (23%, $p<0.001$) univariably and multivariably (OR [Asians] 2.5, $p<0.001$; OR [blacks] 2.4, $p=0.002$ vs whites).

Conclusion: Our analysis replicates the known clinical and serological differences between black and white patients and suggests that Asian have high prevalences of anti-Scl-70, PH and lung involvement.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Sclerosis and Related Disorders – Clinical Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Repeat hospitalizations in patients with pulmonary hypertension from all causes are associated with worse survival. However, predictors of systemic sclerosis associated pulmonary hypertension (SSc-PH) readmissions are unknown. The objective of this study is to identify patient-level factors associated with readmission among SSc-PH patients.

Methods: This retrospective study used clinical data from the prospective observational Pulmonary Hypertension Assessment and Recognition of Outcomes in Scleroderma (PHAROS) registry. All patients met the 2013 ACR/EULAR classification criteria for SSc. PH was defined as a mean pulmonary artery pressure ≥ 25 mmHg on right heart

catheterization. The PHAROS investigators collected data for each hospitalization's primary reason and admission date. Readmission was defined as a subsequent hospitalization for any reason within 12 months. We compared patient-level characteristics of individuals with vs. without readmission using Fisher's exact test and the Wilcoxon rank-sum test. Logistic regression models were used to estimate associations between clinical variables and likelihood of readmission. Odds ratios (OR) and 95% confidence intervals (CI) were calculated for all estimates. Survival comparisons were made using the log-rank test.

Results: Of 335 SSc-PH patients, 169 (50%) had at least 1 hospitalization. Of these, 48 (28%) had are admission. Patients with vs. without readmission more commonly had diffuse disease ($p=0.02$), positive Scl-70 autoantibody status ($p=0.03$), World Health Organization (WHO) Group 2 PH ($p=0.01$), higher modified Rodnan Skin Score($p=0.01$), and did not require home oxygen ($p=0.01$) (Table 1). Patients with diffuse vs. limited disease were significantly more likely to have a readmission (OR 2.49; 95% CI 1.23-5.06). Readmission was less likely in individuals who required vs. did not require home supplemental oxygen (OR 0.28; 95% CI 0.09-0.88) and in those with vs. without desaturation during a 6 minute walk test (0.11; 95% CI 0.01-0.90). Fifty-four patients died. Mortality rates were higher in patients with ≥ 2 vs. 0-1 readmission (66%

WHO=World Health Organization; MRSS=modified Rodnan Skin Score, ANA=antinuclear antibody.
Note: * denotes p-values <0.05 . **At Risk = high-risk for PH SSc patients with (1) carbon monoxide diffusing capacity (DLCO) $<55\%$ predicted, (2) forced vital capacity to DLCO ratio ≥ 1.6 , or (3) estimated right ventricular systolic pressure >35 mmHg on echocardiography, but without right heart catheterization mean pulmonary artery pressure ≥ 25 mmHg.

vs. 30.6%, $p=0.009$) and similar in patients with 0 vs. 1 readmission (30.6% vs. 31%, $p=0.561$). Race, age, sex, SSc disease duration, and patient reported outcomes were not significantly associated with readmission.

Conclusion: Readmission was more common among SSc-PH patients with diffuse disease, WHO Group 2 PH, and positive Scl-70 autoantibody status. These patients may benefit from closer post-hospitalization follow-up. Home oxygen use was associated with lower likelihood of readmission and can be routinely assessed at the time of discharge in SSc-PH patients. Future studies should determine if universal testing for the need for home supplemental oxygen at the time of discharge reduces readmission among SSc-PH patients.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Sclerosis and Related Disorders – Clinical Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic sclerosis (SSc) is a connective tissue autoimmune disease with systemic involvement and a serious medical condition with a high rate of mortality, especially due to interstitial lung disease (ILD). The exact pathophysiology is still unclear, but B cells seem to play a crucial role in the initiation and the progression of the disorder. Therefore, the use of Rituximab (RTX) might have a rational in the treatment of SSc.

Methods: We retrospectively collected data from SSc patients resistant or intolerant to previous therapies, treated with intensified B-depletion therapy, between 2013 and 2016. Therapeutic protocol comprehends: RTX 375 mg/sm on days 1, 8, 15, 22, and two more doses after one and two months, associated with two intravenous administrations of 10mg/kg of cyclophosphamide and three methylprednisolone pulses (15 mg/kg) followed by oral prednisone (0.8mg/kg/day, rapidly tapered to 5mg/day by the end of the 3rd month after RTX).

Results: The study included 20 SSc patients (18 females and 2 males; mean age 66.7 ± 11.0 years). Patients presented with severe multi organ involvement: ILD (19/20, 95%), pulmonary hypertension (12/20, 60%), and skin thickening (17/20, 85%). After a follow-up of 24 months, we observed a decrease in the levels of NT-proBNP (mean baseline: 385.4 ± 517 , mean at 24 months: 283 ± 648 , $p < 0.05$), and in the Modified Rodnan Skin Score (mRSS) (mean mRSS baseline: 14.4 ± 10.5 , mean after 24 months of follow-up: 12.9 ± 10 , $p < 0.05$). Four out of 19 (21%) patients experienced a significant improvement of ILD, as assessed by high-resolution computed tomography, while in 12/19 (63%) patients the intensified B-cell depletion therapy was associated with a stabilization of the imaging features with no sign of progression. Three out of 19 (16%) patients showed a deterioration of the ILD.

Patients showed no significant decrease in forced vital capacity (FVC) (mean baseline FVC: 93.6 ± 19.3 , mean after 24 months of follow-up: 92.2 ± 23.3), no significant decrease in forced expiratory volume in one second (FEV1) (mean baseline FEV1: 89.5 ± 15.6 , mean FEV1 at 24 months: 87 ± 21.2), no significant decrease in diffusing capacity (DLCO) (mean baseline DLCO values: 58.8 ± 8.6 , mean at 24 months: 60.3 ± 14), no significant change in the ejection fraction (EF)

(mean baseline EF values: 62.8 ± 6.4 , mean EF values at 24 months: 58.6 ± 7.1) and in pulmonary artery pressure (PAP) (mean baseline PAP: 30.2 ± 10.5 , mean at 24 months: 31.1 ± 11.05).

Conclusion: Our data suggest that the intensified B-depletion therapy protocol might represent a promising tool for the management of SSc in terms of controlling the progression of the disease, especially when considering pulmonary and skin manifestations.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Sclerosis and Related Disorders – Clinical Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: To analyze the effectiveness and safety of rituximab (RTX) for the treatment of refractory systemic sclerosis (SSc)–associated calcinosis.

Methods: We undertook an observational study of patients with this complication treated with 1 or more cycles of RTX (1 g x 2 weeks) and evaluated for at least 12 months after RTX treatment in a single center. The end point of patient follow-up was the date of the last clinic visit. All patients had baseline pre-rituximab (RTX) and follow-up X-rays every 12 months. The primary outcome measures of the study were the improvement of calcinosis symptoms (pain, signs of local inflammation, and new episodes of skin ulceration) and the radiologic evolution of the calcification(s). Clinical response was defined as a sustained improvement in the VAS of $\geq 50\%$ and no new episodes of local inflammation or skin ulceration. Radiologic response was defined as the complete resolution of the calcification(s) on the X-ray or as a significant reduction in calcification size ($\geq 20\%$ using the measurement functionality of the DICOM viewer), without appearance of new lesions.

Results: Thus far, we have treated 8 SSc patients with calcinosis with RTX (off-label use).

The mean number of previous treatments tested for calcinosis was 3. Of the 8 patients, 4 (50%) presented limited cutaneous scleroderma, and 4 (50%) had diffuse cutaneous involvement. The main indications for RTX were complicated calcinosis unresponsive to previous therapies with concomitant arthritis in 2 patients and refractory arthritis or interstitial lung fibrosing disease in the remaining 6 patients.

The mean number of RTX cycles administered was 3.12 ± 2.1 (range, 1-7), the median duration of RTX treatment was 9 months (interquartile range [IQR], 7.5-36 months), and the median follow-up after the first infusion of RTX dose was 19 months (IQR, 15-45 months).

Four patients (50%) had a significant improvement in clinical symptoms (sustained improvement in the visual analog scale for pain of at least 50% and no new episodes of local inflammation or skin ulceration). Two of these patients (25%) also had a complete resolution or significant reduction in the size of the calcification(s) on X-ray. None of them had drainage or surgical removal of these deposits that could explain the improvement of symptoms.

In the remaining 4 patients (50%), RTX did not provide any significant clinical or radiological benefit for calcinosis. In one of these patients, RTX was discontinued due to inefficacy; in the other three, treatment was maintained due to its beneficial effect in arthritis and interstitial lung disease.

No clinical predictor of response could be identified.: The frequency of adverse effects was low, occurring in only 1 patient (12.5%), who developed upper-respiratory tract infections not requiring hospitalization.

Conclusion: There is no definitely effective treatment for SSc-associated calcinosis to date. Our results and those previously reported suggest that RTX may be helpful in some patients with SSc-related calcinosis. These positive data remain preliminary and need to be viewed with caution, restricting for the moment its off-label use as a rescue therapy in selected cases of severe and refractory SSc-related calcinosis.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Sclerosis and Related Disorders – Clinical Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Upto 90% of patients with systemic sclerosis (SSc) have symptoms from the gastrointestinal (GI) tract. Earlier studies have shown a distinct alteration of the intestinal microbiome in SSc patients, compared to healthy adults. We therefore postulated that a normalization of the GI microbiota could improve some of the GI symptoms in this patient group. We aimed to determine the safety and efficacy of gut microbiota transplantation (GMT) in SSc patients and assess the effect on GI-symptoms and the general disease activity.

Methods: In this double-blind, placebo controlled pilot trial patients were randomized to the patented single-donor Anaerobically Cultivated Human Intestinal Microbiome (ACHIM) developed by ACHIM AB or placebo (culture media) (clinicaltrials.gov: NCT03444220). All participants had objective GI-involvement, were female >18 years old with limited cutaneous SSc and fulfilled the 2013 SSc classification criteria. Treatment was installed during upper gastroscopy twice with two weeks apart (week 0 and 2). Patients were followed for 16 weeks with six visits (week 0, 2, 4, 8, 12 and 16). GI-symptoms were reported using the ULCA-GIT score questionnaire. Primary end-point was defined as the minimally clinically important difference - the smallest change in score that patients perceive as beneficial. Disease activity was assessed by the validated SSc Disease Activity Index (DAI). Adverse events/safety were registered at each visit.

Baseline characteristics

Characteristics	
Number patients	10
Age, yrs (SD)	61.5 (5.5)
Time from disease onset, yrs (SD)	12.6 (10.1)
Sex, n (%)	10 (100)
lcSSc, n (%)	10 (100)
AC/A ₂ , n (%)	8 (80)
mRSS	4.1 (2.1-6.1)
DLI ₁ , n (%)	0 (0)
FVC, % (SD)	97.7 (88.9-106.5)
DLCO, % (SD)	74.4 (63.5-85.4)
UCLA GIT score	0.72 (0.13-1.62)
Bristol stool index (IQR)	4 (0.5)
Hb	13.1 (12.5-13.7)
CRP	5.1 (0.1-10.3)
ESR	13.4 (8.1-18.7)

Results: Ten patients were enrolled and randomly assigned to GMT or placebo. One patient was excluded due to laryngospasms during the first gastroscopy. GMT was safe, mostly mild and short-term side effects were reported like abdominal bloating (n=4), intermittent diarrhea (n=4), nausea (n=1) and constipation (n=1). One patient suffered a severe side effect during biopsy with duodenal perforation, requiring intravenous antibiotics. Baseline and prospective changes in UCLA-GIT score are demonstrated in figure 1, showing clinical improvement in total UCLA GIT-score and diarrhea. Five patients reported fecal incontinence at visit 1; three received GMT and reported restoration of continence. DAI-score in the GMT group was 2.4 (SD 1.4) at week 0 and 2.1 (SD 1.9) at week 16. In the placebo group mean DAI at week 1 was 2.5 (SD 1.5) and 1.8 (SD 1.5) at week 16.

Conclusion: The first double-blind, randomized clinical trial on GMT in SSc patients shows promising effects on GI symptoms. There was a clinically meaningful improvement in diarrhea and fecal incontinence after treatment with GMT. Larger trials are needed to confirm the results of this pilot study.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Sclerosis and Related Disorders – Clinical Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic sclerosis (SSc) is a chronic autoimmune disease leading to various physical and psychological impairments including sexual dysfunction. The aim of this study was to assess sexual functions/quality of life and pelvic floor function in female SSc patients compared to age-/sex-matched healthy controls (HC), and to analyze the potential impact of disease activity, fatigue, physical activity and depression.

Methods: In total, 41 women with SSc (mean age: 50.9, disease duration: 5.8 years, lcSSc/dcSSc: 18/23, mRSS: 13.6, ESSG activity index: 2.5), who fulfilled the ACR/EULAR 2013 criteria, and 41 healthy controls (mean age: 50.9) without rheumatic diseases filled in 12 well-established and validated questionnaires assessing sexual function/quality of life, pelvic floor function, fatigue, physical activity and depression. Full names of questionnaires are listed in the table. Data are presented as mean±SEM.

Results: Compared to HC, patients with SSc had significantly higher prevalence and greater severity of sexual dysfunction (FSFI, BISF-W: in all subscales as well as total scores), dysfunction of pelvic floor (PISQ-12, PFIQ7), and worse sexual quality of life (SQol-F) (table). Worse scores in SSc patients were associated with higher disease activity [ESSG activity index: SQol-F ($r=-0.364$, $p=0.0443$), PFIQ7-gynaecological subscale ($r=0.492$, $p=0.0036$)], greater fatigue [all three questionnaires FSS/FIS/MAF correlated negatively with FSFI, BISF-W], more severe depression [BDI-II: FSFI ($r=-0.553$, $p=0.0002$), BISF-W ($r=-0.514$, $p=0.0007$), PFIQ7 ($r=0.495$, $p=0.0010$)], deteriorated quality of life [SHAQ: FSFI ($r=-0.536$, $p=0.0003$), BISF-W ($r=-0.563$, $p=0.0001$), SQol-F ($r=-0.338$, $p=0.0382$), PISQ-12 ($r=0.563$, $p=0.0051$), PFIQ7 ($r=0.380$, $p=0.0142$)], and worse ability to perform physical activities [HAP: FSFI ($r=0.407$, $p=0.0082$), BISF-W ($r=0.409$, $p=0.0078$)].

Conclusion: Women with SSc reported significantly impaired sexual function, sexual quality of life and pelvic floor function than age-matched healthy controls. Worse scores in SSc were associated with disease activity, physical activity, fatigue, depression and quality of life.

Questionnaire: score range	Systemic sclerosis (n=41)	Healthy controls (n=41)	p-value
FSFI: Female Sexual Function Index: 2(worst)-36(best)	15.2±1.7	25.0±1.7	p<0.0001

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Sclerosis and Related Disorders – Clinical Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Long-term use of proton pump inhibitors (PPI) have been linked to safety concerns. In a previous retrospective analysis, a potential association between PPI use and calcinosis in systemic sclerosis (SSc) was identified. We explored this in a prospective study.

Methods: Data from prospectively recruited patients were collected by patient survey, clinical review and medical records. Calcinosis was graded; size (+= <1cm, ++= ≥1≤3cm, +++= >3cm) and number of sites involved (NSI) (I = 1 body site, II = 2-3, III = >3). A total daily PPI equivalent dose (TDED) was calculated for each patient. We computed PPI exposure score (PPE) by multiplying the total duration of use in years (y) by TDED. For analysis, PPE was categorised into four groups; 0 = no exposure, 1 = up to 5y, 2 = 6-10y, 3 = >10y. Fishers exact test assessed categorical variables. Logistic regression assessed association between calcinosis and independent variables.

Results: 216 patients were recruited. Table 1 outlines patient and disease characteristics, including calcinosis and PPI use. Gastroesophageal reflux symptoms occurred in 83.3% of patients. Eleven (73.3%) of patients with large volume calcinosis (>3cm) had a PPE for > 10 years and all with calcinosis > 3cm had exposure to PPI. Of patients with only one body site involved 7/16 (43.75%) had PPE category 3 (>10 y). While of those patients with > 1 body site involved 36/49 (73.5%) had a PPE cat >10 years. The most frequent sites for calcinosis were finger (70.8%), elbow (35.4%) and knee (18.5%). Univariable analysis found associations between calcinosis at any time (CAT) and; disease duration (CAT OR 1.07, CI 1.04-1.11, p <0.001), PPE (CAT OR 1.03, CI 1.01-1.05, p =0.003) and increasing age (CAT OR 1.02, CI 1.00-1.04, p = 0.043). ATA and ANA positivity was associated with a risk reduction of CAT (ATA OR 0.27, CI 0.12-0.58, p = 0.001, ANA+ OR 0.25, CI 0.09-0.70, p =0.009). Greater than 10 years of exposure to PPI increased the odds of calcinosis by 4 times (CAT OR 4.07, CI 1.68-9.85, p = 0.002) compared to no exposure. Multivariable logistic regression results are shown in Table 2. Although the effect of PPI on calcinosis was attenuated after adjusting for disease duration and antibodies, higher exposure to PPI remained a significant predictor of calcinosis, with PPE category 3 (>10) increasing risk of CAT (OR 3.34, CI 1.16-9.17, p = 0.025).

Conclusion: We confirm a significant association between PPI exposure with calcinosis in SSc. Given the clinical impact of calcinosis, a potentially modifiable risk factor of PPI exposure warrants further study.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Sclerosis and Related Disorders – Clinical Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The pharmacokinetics (PK) of cyclophosphamide (CP) and its primary active metabolite, 4-hydroxycyclophosphamide (4-OH-CP) have not been adequately studied in scleroderma. The hypothesis of this sub-study of the Scleroderma: Cyclophosphamide or Transplantation (SCOT) trial (Sullivan, KM et al., N Engl J Med 2018;378:35-47) was that response to CP, defined as event-free survival (EFS) at 54 months, will correlate with exposure (C_xT) to the active metabolite 4-OH-CP. Secondary objectives were to determine whether the initial CP exposure enhances activation of a second dose (auto-activation) and to evaluate the effect of CP on myelosuppression.

Methods: CP was infused over 1 to 2 hours in both study arms. Subjects in the transplant arm received a conditioning regimen of 120 mg/kg (mean 2099 mg/m²). Subjects in the CP arm received an initial infusion of 500 mg/m², then twelve doses of 750 mg/m²; PK analyses were only done after the first two doses. For transplant, 3 ml blood samples were drawn pre-dose and at 2, 4, 6, 8, 10, and 23 hours after infusion. For the CP arm, samples were collected at pre-dose, 0.5, 1, 2, and 24 hours. All samples were immediately derivatized with O-(2,3,4,5,6-pentafluorobenzyl) hydroxylamine and the 4-OH-CP oxime product analyzed by gas or liquid chromatography-mass spectroscopy. Separate blood draws (5 ml) were collected at ~24 and 48 hours following CP infusion in the transplant arm to determine white blood cell count (wbc). The single-dose PK parameters for CP and 4-OH-CP were computed from the drug C-T data using non-compartmental methods within WinNonLin Phoenix Version 6.2. Metabolic ratio was computed as the ratio of the AUC over 24h for 4-OH-CP to that for CP.

Results: Of the 12 subjects in the transplant arm and 9 in the CP arm, 75-89% were Caucasian women of median age 44 and 49, respectively. While the metabolic ratio varied 14-fold (0.6 – 8.3), the CxT profiles for both treatment arms were similar with a single elimination phase for both CP and 4-OH-CP. In the CP arm, CxT profiles for both parent drug and active metabolite were very similar in both cycles 1 and 2. When normalized for dose, the median AUC for 4-OH-CP in cycles 1 and 2 were 173 and 171 µg-h/ml, hence there was no auto-activation. There was a significant Pearson product-moment correlation between decrease in wbc and metabolic ratio at 48 h (p = 0.026) in the transplant arm. Odds ratios via logistic regression among PK parameters and EFS were not statistically significant. Odds Ratios - Likelihood of not meeting Event-Free Survival Endpoint¹

Arm	Parameter	Odds Ratio	Lower 95% CI	Upper 95% CI	P value
Cyclophosphamide	CP AUC242	1.0	1.0	1.0	0.94
Cyclophosphamide	CP Cmax	1.1	0.8	1.7	0.51

Cyclophosphamide	4-OH-PC AUC24	1.1	0.7	1.8	0.70
Cyclophosphamide	4-OH-CP Cmax	3.3	0.1	126.3	0.53
Transplant	CP AUC24	1.0	1.0	1.0	0.20
Transplant	CP Cmax	0.8	0.5	1.1	0.15
Transplant	Metabolic Ratio	1.8	0.5	6.7	0.36
Transplant	4-OH-CP AUC24	1.0	0.7	1.6	0.89
Transplant	4-OH-CP Cmax	1.2	0.1	12.5	0.91

1 Event-free survival is survival without respiratory, renal or cardiac failure as defined in Sullivan, KM et al., N Engl J Med 2018;378:35-47.

2 AUC24, area under the concentration-time curve at 24 hrs.

3 Ratio of AUC24 for 4-OH-CP to that for CP.

Conclusion: This pilot study, the first of its kind, revealed variable metabolism of CP in scleroderma subjects and drug-induced myelosuppression in the transplant setting. However, in this small cohort of patients, CP exposure did not correlate with EFS in either treatment arm.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Sclerosis and Related Disorders – Clinical Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic Sclerosis (SSc) is a complex, heterogenous autoimmune disease characterized by microvascular injury and widespread fibrosis of the skin and internal organs, particularly lungs and heart. The heart is one of the major organs affected in SSc, although the recognition of cardiac abnormalities is probably underestimated due to the occult nature and variable reports of prevalence. Clinically evident cardiac involvement is associated with a poor

prognosis, with up to 70% mortality at 5 years. In this population-based cohort study, we aimed to examine the occurrence of moderate/severe valvular heart disease (VHD) in patients with SSc relative to comparators.

Methods: Medical records of patients with a diagnosis or suspicion of SSc in a geographically well-defined area from Jan 1, 1980 to Dec 31, 2016 were reviewed to identify incident cases of SSc (defined by physician diagnosis). Fulfillment of the 1980 and 2013 SSc classification criteria was ascertained. A 2:1 cohort of age- and sex-matched non-SSc subjects from the same population base was randomly selected for comparison. Data on SSc characteristics, cardiovascular risk factors including smoking status, obesity, hypertension, dyslipidemia, diabetes mellitus, use of aspirin, known coronary heart disease, peripheral artery disease, abdominal aneurysm, atrial fibrillation, and heart failure were collected by manual record review. Echocardiogram reports were reviewed for occurrence of moderate/severe VHD including aortic, pulmonary, mitral or tricuspid valve stenosis or regurgitation. Cumulative incidence of VHD adjusting for the competing risk of death was estimated. Cox models were used to examine potential associations between baseline factors of interest and the development of VHD.

Results: The study included a total of 79 incident SSc cases and 158 non-SSc comparators [mean age 55.8 years (SD 15.7), 90% female for both cohorts]. There was a nearly 4 fold increase in the prevalence of moderate/severe VHD prior to SSc diagnosis compared to non-SSc subjects (11% vs 3%; $p=0.011$). During a median of 9.0 years of follow-up in patients with SSc and 10.5 years of follow-up in non-SSc comparators, 15 SSc and 15 non-SSc patients developed VHD. The cumulative incidence of VHD at 10 years after SSc incidence/index was 23.6% (95% confidence interval [CI]: 14.5-38.4%) in patients with SSc compared with 7.4% (95% CI: 4.0-13.5) in non-SSc subjects (Hazard Ratio: 2.86; 95% CI: 1.38- 5.91, $p=0.004$). No significant risk factors for VHD were found.

Conclusion: SSc patients have a 3 fold increased risk of developing moderate/severe valvular dysfunction after diagnosis of SSc compared to Non-SSc subjects. They also have a 4 fold increased prevalence of moderate-severe VHD at diagnosis compared to non-SSc patients. Underlying mechanisms for this association require further elucidation.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Sclerosis and Related Disorders – Clinical Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Small vessel arteriopathy precedes the development of organ damage and tissue fibrosis in systemic sclerosis (SSc) and related disorders. It is currently considered that providing early vascular protection might result in a slower and milder progression of the disease. However, there is still no standard of care for this poorly understood process, besides symptomatic measures and treatment of complications. A major reason could be the lack of available tools for the routine assessment of the microcirculation at the clinic. In order to overcome this hurdle, we have launched a study addressing the utility of ultrasonography (US) in identifying robust outcome measures in patients with relevant SSc-like vasculopathy. Our first objective was to look for associations between US-based hemodynamic measures and features of vascular injury in a cohort of patients with Raynaud's Phenomenon (RP).

Methods: 26 real-life patients have been enrolled, 10 of which had primary RP (PRP) and 16 secondary RP (SRP), with 11p diagnosed with SSc. 5 of the patients with SRP had a past history of complications, and 10 had macroscopic alterations at the time of the study. All patients had a recent nailfold videocapillaroscopy (NVC) recording which had been pathologic in 15p. Of these, 10p had an SSc typical NVC pattern of lesions. Patients underwent a Duplex US evaluation of 6 arterial regions (cubital, radial, 1st, 2nd, and 3rd digital branches and the superficial palmar arch) at the non-dominant hand. Systolic peak (PS), end diastolic velocity (ED), maximum speed, resistance index and the PS to ED ratio (PS/ED)

were registered. Global and specific health questionnaires were recorded as independent variables, and their association with the US data was established with non-parametric tests. An alpha value of 5% was considered significant.

Results: Globally, no single US parameter discriminated between PRP and SRP. However, patients with anti CENP-B antibodies, history of RP-associated complications, concurrent macroscopic alterations and/or an SSc-type of NVC pattern of lesions showed significantly lower PS and/or ED, at least at one region, in particular at the cubital artery and the 2nd digital branch, while a decreased PS/ED at the palmar arch was associated to CENP-B antibodies and to a past history of complications. Interestingly, the SF36 domain of global health was lower in the SRP subgroup (p 0.035) and associated to a lower PS/ED at the cubital artery (p 0.019). Also associated to this hemodynamic parameter were SF36 social performance (p 0.037) and mental health (p 0.04) domains, while both the RP severity scale and number of episodes were negatively associated with the cubital artery PS values (p 0.002, p 0.019, respectively).

Conclusion: In this initial approach we have observed that Duplex US is able to distinguish patients with SSc-associated vasculopathy from those with milder RP. Our results point to reduced PS and PS/ED in the ulnar territory as potential outcome measures for further research.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Sclerosis and Related Disorders – Clinical Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Osteoporosis screening is not systematic in sclerodermic patients but some studies demonstrated a similar risk between rheumatoid arthritis and systemic scleroderma [1,2,3]. Thoracic and/or TAP (thoraco-abdomino-pelvic) CT (Computed Tomography) scans are classically performed in the follow-up of scleroderma, mainly to evaluate lung involvement.

Objectives: To study vertebral fracture (VF) prevalence and the scanographic bone attenuation coefficient of the first lumbar vertebra (SBAC-L1) on CT scans in systemic scleroderma patients. Secondary objectives are to study specific risk factors of SBAC-L1 \leq 145 Hounsfield Units (HU) and to evaluate SBAC-L1 measurements reliability.

Methods: This monocentric retrospective study included patients followed from 2000 to 2014 and fulfilling ACR/EULAR 2013 criteria for systemic scleroderma and who underwent a thoracic or TAP CT scan. Osteoporotic risk factors, Dual Energy X-ray Absorptiometry (DXA) measurements and clinical characteristics were collected. For CT scan, the VFs were determined according to Genant's classification on sagittal sections. The SBAC-L1 was measured in Hounsfield Units (HU) on axial section of L1 in a Region of Interest drawn in trabecular bone. Intra- and inter-reader reliabilities for SBAC-L1 were calculated. An SBAC L1 \leq 145 HU (fracture threshold) was used to define patients at risk of VF [4]. Predictive factors for VF or SBAC-L1 \leq 145 HU were studied.

Results: A total of 70 patients were included (mean age: 62.3 (\pm 15.6) years, women 88.5%, diffuse scleroderma 22.9% (n=16)) in the study. Sixty patients (85.7%) presented with at least one clinical risk factor for osteoporosis. Eighteen patients (25.7%) received vitaminocalcic supplementation and 10 (14.3%) received antiresorptive therapy. DXA was only performed on 30 patients (42.8%), and 5 (16.7%) of them presented a T-score \leq -2.5 DS. 3 VFs were detected in 3 patients (4.3%). The mean SBAC-L1 was 157.26 HU (\pm 52.1), and 35 patients (50%) presented a SBAC-L1 \leq 145 HU. SBAC-L1 measurements were highly reliable (Kappa $>$ 0.9 for both intra- and inter-reader reliability). For the univariate analysis, a SBAC-L1 \leq 145 HU was significantly associated with age (OR=1.09, CI 95%: 1.04-1.13), calcinosis (OR=6.3, CI

95%: 1.61-24.75) and periarticular calcifications (OR=3.22, CI 95%: 1.06-9.77). For the multivariate analysis, age (especially patients older than 63 years), calcinosis and acro-osteolysis were independently associated with a SBAC-L1 \leq 145 HU.

Conclusion: On a large sample of sclerodermic patients with clinical risks of osteoporosis, only 42.8% were screened for DXA and 16.7% of them were osteoporotic. The VF prevalence on CT scan was 4.3% and the SBAC-L1 measurement identified 50% of the population at the fracture threshold. The presence of calcinosis, periarticular calcifications or acro-osteolysis should lead to an osteoporosis screening, especially for patients under 63 years old.

Session Title: Systemic Sclerosis and Related Disorders – Clinical Poster II:

Session Type: ACR Poster Session B:

Session Time: 9:00AM-11:00AM:

Background/Purpose: Fibrosis of the skin and visceral organs, especially digestive tract, and musculoskeletal involvement in systemic sclerosis (SSc) can have a negative impact on body composition and physical activity. The aim was to assess body composition and physical activity of SSc patients and healthy controls (HC) and the association with selected inflammatory cytokines in SSc.

Methods: 59 SSc patients (50 females; mean age 52.5; disease duration 6.7 years; lcSSc:34/dcSSc:25) and 59 age-/sex-matched HC (50 females, mean age 52.5) without rheumatic or tumour diseases were included. SSc patients fulfilled ACR/EULAR 2013 criteria. We assessed body composition (densitometry: iDXA Lunar, bioelectric impedance: BIA-2000-M), physical activity (Human Activity Profile, HAP questionnaire), disease activity (ESSG activity index) and serum levels of 27 cytokines (commercial multiplex ELISA kit, Bio-Rad Laboratories). Data are presented as mean \pm SD.

Results: Compared to HC, SSc patients had significantly lower body mass index (BMI), body fat % (BF%) and visceral fat weight (VF), and also significantly decreased lean body mass (LBM), and bone mineral density (BMD). Compared to HC, SSc patients had increased extracellular mass/body cell mass (ECM/BCM) ratio, reflecting deteriorated nutritional status and worse muscle predispositions for physical activity (Table 1). Increased ECM/BCM in SSc positively correlated with disease activity (ESSG), skin score (mRSS) and inflammation (CRP, ESR), and was associated with worse quality of life (HAQ, SHAQ), fatigue (FSS), and decreased physical activity (HAP). ESSG negatively correlated with BF%. HAP positively correlated with BMD (Table 2). Increased serum levels of several inflammatory cytokines were associated with alterations of body composition (Table 3).

Table 1			
Correlated parameters	SSc (n=59)	JRC (n=59)	p-value
BMI (Body Mass Index) (kg/m ²)	22.4±4.3	27.4±8.3	<0.001

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Sclerosis and Related Disorders – Clinical Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Prevalence of pulmonary arterial hypertension (PAH) in systemic sclerosis (SSc) is 8-12%, and 3-year survival rate is 47-56%. Rest echocardiogram is used to screen for this pathology; recent studies suggest that systolic pulmonary artery pressure (sPAP) increase >18 mmHg with exercise may be a marker for early PAH diagnosis in SSc patients. However, left diastolic dysfunction, comorbidities, and sarcopenia may impair exercise echocardiogram interpretation. We explored its use as a screening tool for early PAH detection in SSc patients.

Methods: Cross-sectional, observational study that included SSc patients (ACR/EULAR 2013 criteria) NYHA classes I-II, and peak tricuspid regurgitant jet velocity at rest echocardiogram <3m/s. We excluded patients with established PAH, interstitial lung disease (ILD) >20% of extent, cardiac disease, renal failure, diabetes mellitus, lipid disorders, systemic arterial hypertension, untreated thyroid disease, pulmonary embolism, tobacco use (>2 pkg/year), use of vasodilators, pregnancy or contraindication to perform the tests (echocardiogram with cycloergometer, starting at 10W and increasing 5W every min, maximum 60W; cardiopulmonary exercise test (CPET) with modified Bruce protocol on a computer-controlled cycle ergometer, and body mass composition). All the patients read and signed an informed consent form. The study was approved by the local IRB and was performed according to the Declaration of Helsinki contents.

Results: We included 19 patients. Fourteen (73.7%) with limited cutaneous (lc) SSc and 5 (26.3%) with diffuse cutaneous (dc) SSc; 17 were female. Mean age was 50.8 (\pm 8.6 SD) years and mean duration of the disease was 78.2 (\pm 53.7 SD) months. Mean modified Rodnan Skin Score (mRSS) was 3.6 (\pm 3.1 SD) in lcSSc and 13.4 (\pm 6.1 SD) in dcSSc patients. Twelve patients had NYHA I (63.2%). Mean BNP was 47.8 (\pm 48.1 SD). Mean forced vital capacity (FVC) was 87.4%. Cardiovascular evaluation: Mean rest sPAP was 28 mmHg (\pm 6.4 SD), sPAP at maximum effort was 52 mmHg (\pm 8.4 SD), with mean delta sPAP of 24 mmHg (\pm 6.4 SD). A sPAP increase of >18mmHg was observed in 15 (78.9%) of our patients. Pulmonary Vascular Reserve (PVR) was elevated (mean 3.4 ± 0.8 mmHg/ml/m² SD), suggesting pulmonary vasculopathy, while E/E' ratio was normal (8.3 ± 1.9 SD), suggesting normal left diastolic function. At CPET, mean peak oxygen uptake was normal (80.6%), suggesting early, non-severe, pulmonary vasculopathy. The normal relative skeletal muscle mass index (RSMI) (6.5 ± 0.95 kg/m² SD) ruled out sarcopenia as a cause of low exercise performance.

Conclusion: Seventy nine percent of SSc patients without cardiovascular risk factors and with normal mPAP at rest echocardiogram, showed changes suggestive of pulmonary vasculopathy in exercise echocardiogram. This finding was not related to diastolic dysfunction or muscular impairment, and may reflect vascular changes that may lead to overt PAH. Standardized exercise echocardiogram may be useful to screen SSc patients for PAH.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Sclerosis and Related Disorders – Clinical Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Interstitial lung disease (ILD) is one of the leading causes of morbidity and mortality in patients with SSc. However, the impact of changes in pulmonary function on clinical outcomes in SSc-ILD patients is not well understood. We assessed the association of changes in clinical and physiologic variables with survival in SSc-ILD patients.

Methods: Adult patients from the EUSTAR (European Scleroderma Trial and Research) database enrolled since January 2009, fulfilling 1980 ACR or 2013 ACR/EULAR criteria for SSc, with signs of lung fibrosis on X-ray and/or HRCT and/or an available date of ILD diagnosis, with ≥ 1 follow-up visit within 12 months after the first visit with ILD diagnosis (index visit) were eligible for the study. 12-month absolute changes in lung function including predicted forced vital capacity (FVC% pred) and predicted diffusing capacity of carbon monoxide (DLco%pred), changes in the modified Rodnan skin score (mRSS) and occurrence of digital ulcer (DU) were assessed for associations with overall survival. 2 disease progression definitions were analysed for association with survival: (A) lung and skin progression defined as 'absolute decline in $>10\%$ FVC pred or mRSS $>25\%$ & >5 points' (FVC/mRSS) and (B) 'absolute decline in $\geq 10\%$ FVCpred or $\geq 5\%$ FVCpred. & DLco $\geq 15\%$ pred' (FVC/DLco). Survival time was defined as the duration between the visit where change was determined and the last visit with survival status, censored after 5 years of observation. Kaplan–Meier (KM) survival was analysed by Breslow test, and Cox's proportional hazards models (Cox-PH) adjusted for age, gender, pulmonary hypertension, smoking and treatment status.

Results: Of 7752 patients enrolled in the EUSTAR database between 2009 and April, 2018, 857 fulfilled the inclusion criteria. In the KM analysis, a deterioration of $\geq 10\%$ FVC pred within 12 months since index date as well as both FVC/mRSS and FVC/DLco progression definitions were associated with significantly lower survival (Fig.1). No associations with survival were found for changes in DLco%pred, mRSS, or occurrence of DU. Cox-PH multivariate models confirmed lower survival in patients with FVC decline $\geq 10\%$ pred (OR=3.1 [1.6;6.0]), with FVC/DLco decline (OR=2.7 [1.5;4.9]), or with FVC/mRSS deterioration (OR=1.9 [1.1;3.4]).

Conclusion: Our study showed that a decline in FVC of $\geq 10\%$ pred within 12 months follow up is associated with lower survival in SSc-ILD patients. Also both disease progression definitions showed an association with reduced survival. Short term changes in clinical and physiological variables over 12 months should be considered for prognostic stratification of SSc-ILD patients in addition to baseline values.

Figure 1: KM survival analysis:(L-R) Change in FVC% pred; FVC/DLco; FVC/mRSS

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Sclerosis and Related Disorders – Clinical Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Vasculopathy is a major feature of systemic sclerosis (SSc). It leads to intimal proliferation and adventitial fibrosis of small and large arterial blood vessels. Videocapillaroscopy (VC) for nailfold-capillaries and MR-angiography (MRA) for arteries are established methods to assess pathologies. However, little is known about the correlation between VC and MRA and about the evolution of changes in response to therapy over time.

Methods: We included consecutive patients of our tertiary center who had a MRA between 1.1.2008 - 30.04.2018. We present an intermediate analysis performed in 03/2015: twenty-one patients with SSc (mean age 55.2 ± 15.6 ; 13 females, 8 males; 4 diffuse SSc, 17 limited SSc) and 22 patients with other inflammatory rheumatic diseases (OD; mean age 50.1 ± 18.8 ; 15 females, 7 males) had a total of 71 MRA acquired by a 3T MR scanner. We analyzed digital arteries and calculated a semiquantitative vascular score. We compared the MRA with the VC in correlation with clinical and laboratory data. We further analyzed a subgroup of 8 patients who had both a MRA and VC twice or more. We used SPSS version 23 program, Pearson's Chi-Test, Fisher's test for statistics.

Results: ANA were significantly more frequent in SSc- (85%) than in OD-patients (50%) ($p < 0.001$), ACA in 38% and 10% ($p = 0.02$), Scl70 in 38% and 4% ($p < 0.001$) respectively. Raynaud was present in 95% of SSc patients and 61% in OD, DU in 71.4% and 73.5% respectively. Duration of Raynaud was significantly longer ($p = 0.005$) in limited vs diffuse form (72.2 vs 30 months). However, prevalence of DU was similar in both limited and diffuse SSc.

The subgroup analysis of patients with 2 or more pairs of VC/MRA are showed in table 1.

In 7 out of 11 cases, the clinical changes correlated with MRA changes, in 2 cases they didn't; 2 cases cannot be analyzed because of missing data. VC only correlated with the clinical course in 2 cases, while 5 cases had missing or unclear data. VC status did not improve, even if the clinical status did. Two patients with OD and 2 of 6 with SSc showed clinical improvement.

In case of DU, there was a good correlation with vessel damage, but damaged vessels did not necessarily result in DU of the corresponding finger.

Table 1: Course of VC, MRA and clinical status in a subgroup of 8 patients. \leftrightarrow stable status; \uparrow better status; \downarrow worse status; * the patient 8 had 5 pairs of VC/MRA; each letter depicts the course between two such pairs; x the patient had the medication mentioned above. NA not available; ? status could not be interpreted

Conclusion: MRA assesses reliably and accurately the vasculopathy of the hand in SSc. It may unveil important subclinical vessel damage and bears the potential to guide preventive drug treatment. Unlike VC, MRA appears to correlate with the clinical course.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Sclerosis and Related Disorders – Clinical Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: In patients with systemic sclerosis (SSc), peripheral vasculopathy can promote critical ischemia and gangrene that are very severe complications with potential life-threatening consequences. Recently the DUO registry suggested a 18% prevalence of gangrene in SSc patients with digital ulcers (DUs), with smoking and a high number of DUs being predictive factors. However, little is known about gangrene in unselected SSc patients. The aim of this study was to investigate the prevalence, incidence and risk factors for gangrene in the EUSTAR cohort.

Methods: We included patients from the EUSTAR database fulfilling the ACR 1980 or the ACR/EULAR 2013 classification criteria for SSc, with at least one visit recording data on gangrene. We extracted from this database data regarding the reporting of DUs, DU history and gangrene. Centers were asked for supplementary data on traditional cardiovascular (CV) risk factors. We analyzed by uni- and multivariable logistic regression the cross-sectional relationship between gangrene and its potential risk factors such as history of DUs, cutaneous subset, disease duration, autoantibodies, classical cardio-vascular risk factors. Longitudinal data were analyzed by Cox proportional hazards regression.

Results: 1757 patients matched the inclusion criteria (age at inclusion 55.9 ± 14.5 years, disease duration since first non-Raynaud's symptom 7.9 ± 10.3 years, male sex 16.7%, 24.6% diffuse cutaneous subset (DcSSc)). At inclusion, 8.9% of patients had either current or previous digital gangrene, 15.7% had current DUs and 42.7% have had DUs ever. Among the potential risk factors, older age, a history of DUs and the DcSSc subset were statistically significant risk factors in the cross-sectional multivariable model (Table).

For the longitudinal part, during the entire follow-up (median [Q1,Q3] 13.1 [9.6, 19.3] months), 16/771 patients had incident gangrene (0.9%), accounting for an incidence of 1.94/100 patient-years. All 16 patients who developed incident gangrene had previously had DUs and gangrene. Further risk factors for incident gangrene were the DcSSc subset and longer disease duration.

Table. Factors associated with gangrene in patients with SSc from the EUSTAR cohort: univariable and multivariable logistic regression on cross-sectional data from the first visit mentioning data on gangrene.

	Univariable logistic regression		Multivariable logistic regression	
	OR (CI 95%)	p	OR (CI 95%)	p
Age	1.009 (0.997-1.021)	0.131	1.024 (1.001-1.049)	0.044
Male sex	1.206 (0.793-1.834)	0.382	1.208 (0.555-2.628)	0.634
Disease duration	1.039 (1.023-1.055)	0.000	1.010 (0.981-1.040)	0.505
Digital ulcers ever	26.171 (13.24-51.73)	0.000	38.37 (9.16-160.73)	0.000
DcSSc	2.262 (1.609-3.179)	0.000	2.498 (1.226-5.093)	0.012

Table . (Cont'd)

	Univariable logistic regression		Multivariable logistic regression	
	OR (CI 95%)	p	OR (CI 95%)	p
Anti-centromere+	0.709 (0.499-1.008)	0.055	0.998 (0.446-2.186)	0.976
Anti-topoisomerase+	1.727 (1.229-2.427)	0.002	0.720 (0.331-1.568)	0.408
Cigarette smoking ever	1.246 (0.745-2.083)	0.402	1.243 (0.641-2.411)	0.519
Dyslipidemia	1.155 (0.788-1.693)	0.459	0.998 (0.464-2.147)	0.997
Diabetes mellitus	2.097 (1.103-3.989)	0.024	0.519 (0.099-2.711)	0.437
Arterial hypertension	1.008 (0.687-1.479)	0.967	0.829 (0.389-1.765)	0.627
History of CV events	2.829 (1.747-4.580)	0.000	2.468 (0.956-6.371)	0.062

Conclusion: In unselected SSc patients, gangrene still occurs in 9% of SSc patients. A history of DUs and, to a lesser extent, the DcSSc subset are strongly and independently associated with gangrene, while traditional CV risk factors were not identified as risk factors. Our results confirm that gangrene is still a concern in SSc. They emphasize on the importance of microvascular SSc-associated disease in the pathogenesis of gangrene and suggest that the DcSSc subset should be prioritized for risk-stratification of the patients.

Multiplexed Autoantibody Profiles in a Systemic Sclerosis Clinical Trial Comparing Autologous Hematopoietic Stem Cell Transplantation and Cyclophosphamide

Paul J. Utz¹ and Burcu Ayoglu², ¹Medicine, Stanford University School of Medicine, Stanford, CA, ²Medicine, Stanford University, STANFORD, CA

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Sclerosis and Related Disorders – Clinical Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: In a randomized, open-label, phase II clinical trial (SCOT, Scleroderma: Cyclophosphamide or Transplantation)¹, subjects were randomly assigned to treatment with myeloablative CD34⁺ selected autologous hematopoietic stem-cell transplantation (HSCT) or high-dose monthly cyclophosphamide (CYC). Global rank composite scores at 54 months post-randomization revealed significant benefits of HSCT vs CYC. We used multiplexed antigen arrays to profile serum IgG autoantibodies in all subjects at all available time points.

Methods: We fabricated a 288-plex, bead-based array containing 223 protein antigens, including 113 autoantigens, 87 soluble proteins such as cytokines, chemokines, and growth factors, and 23 control or viral proteins. A total of 193 serum samples from 63 SCOT subjects, and 20 samples from healthy controls, were profiled for the presence of serum IgG autoantibodies. We compared autoantibody profiles from subjects at month 26 (n=23 HSCT, n=22 CYC) using Significance Analysis of Microarrays (SAM) to identify differences in mean fluorescence intensity values between groups (q value ≤5%; abs(log2 fold change) ≥0.5).

Results: No significant baseline differences were found in autoantibody profiles between the CYC and HSCT groups. Control subjects had significantly less or no reactivity to any of the 223 arrayed proteins. At 26 months, SAM identified antibodies against 17 antigens that were significantly different between treatment groups (11 increased in CYC, 6 increased in HSCT, Fig 1, panel A). Using Principal Component Analysis (PCA), PC1 and PC2 explained 43% of the variance (Fig 1, panel B). Wilcoxon rank sum scores generated using the 17 antigens were significantly different between groups (p=1.8e-06, Fig 1, panel C). Antibodies to Epstein Barr Virus (EBV) antigens were higher in the CYC group. Anti-Hepatitis B surface antigen levels were higher in the HSCT group, consistent with vaccination in the HSCT but not CYC group. Levels of antibodies against the chemokine CCL3 and two different commercial sources of the neutrophil protein bactericidal

permeability increasing protein (BPI) were higher in the HSCT group. The top loadings in PC2 included CCL3 and BPI, as well as Scf70, EBV p18, and thyroperoxidase (TPO).

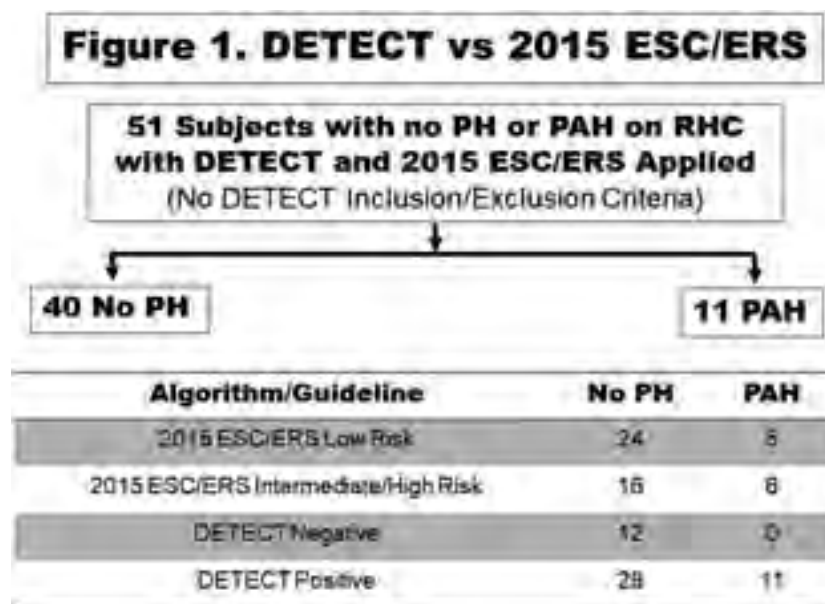

Conclusion: Antibodies to traditional autoantigens, infectious agents and secreted factors differed between HSCT and CYC groups post-treatment. Ongoing analyses include comparison of responder status, and assessment of time-dependent trends in antibody levels in individual subjects that could serve as actionable biomarkers.

1. Sullivan K.M. *et al.* *NEJM* 2018;378:35-47.

had PAH. DETECT had 100% sensitivity and NPV whereas 2015 ESC/ERS had 54.5% sensitivity and 82.8% NPV as 5 subjects with PAH were missed(Figure 1). DETECT was able to detect PAH even in those with DLCO \geq 60% (N=3).

Conclusion: Evidence based screening algorithms using composite measures and not just echocardiography alone improve screening for SSc-PAH. Although use of DLCO < 60% enriches the probability for SSc-PAH, subjects with SSc-PAH can have higher DLCO values. Although our sample size is small, it appears that DETECT performs well in those with DLCO \geq 60%.

Frech⁶, ¹School of Medicine, University of Utah, Salt Lake City, UT, ²Bioinformatics, University of Utah, Salt Lake City, UT, ³University of Utah, Salt Lake City, UT, ⁴The University of Melbourne, Melbourne, Australia, Melbourne, Australia, ⁵Department of Medicine, McGill University, Montreal, QC, Canada, ⁶Division of Rheumatology, University of Utah, Salt Lake City, UT

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Sclerosis and Related Disorders – Clinical Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The implementation of patient reported outcome measures (PROMs) is increasingly recognized as a critical aspect of clinical practice. The use of gastrointestinal (GI) PROMs is particularly important in systemic sclerosis (SSc), especially for the identification of small intestinal bacterial overgrowth (SIBO), where hydrogen breath testing for definitive diagnosis is difficult to perform. In this report, we examine the clinical correlates of two validated GI PROM scores in SSc to inform the design of a pragmatic trial in SSc SIBO.

Methods: Patients seen at a single center SSc Clinic, who met the 2013 ACR/EULAR Criteria and were enrolled in the INSYNC registry received an electronic link to a personal health assessment questionnaire that included the Scleroderma

Clinical Trials Consortium University of California Los Angeles Gastrointestinal Tract (GIT2.0) and gastrointestinal global symptom score (GSS), which have previously been validated in the SSc population. The GIT 2.0 (34 questions) provides a total score of GIT severity, and is calculated by an average of all scales (questions 1-8 reflux, 9-12 distention/boating, 13 soilage, 14-15 diarrhea, 16-21 social function, 22-30 emotional well-being, 31-34 constipation), except constipation. The scores range from mild (0-0.49) to severe-to very-severe (1.01-3). The GSS assesses nausea, vomiting, abdominal pain/discomfort, bloating, diarrhea, constipation, abdominal tenderness, dysuria, tenesmus, fever and general illness/malaise, with each symptom scored from 0 (absent) to 3 (severe). It has previously been reported in the SSc population that a GSS ≥ 5 is predictive of SIBO. We compared the GIT 2.0 scores in those with GSS <5 and ≥ 5 , using the t-test, with significance set at 5%.

Results: From January to May 2018, 43 SSc patients completed both the SCTC GIT 2.0 and GSS (59 % completion rate). These patients were 95% female, 67% limited cutaneous subtype, 73% scleroderma-specific autoantibodies (40.5% centomere, 13.5% SCL70, 18.9% RNA pol3), with an average disease duration of 13.5 years. The subscales of GIT 2.0 according to GSS are shown in Table 1. As expected the potential SIBO patients with a GSS ≥ 5 had significantly more distention/bloating ($p=0.001$), but unexpectedly more constipation ($p=0.04$) on the GIT 2.0.

Conclusion: Gastrointestinal complaints are common in SSc and PROM questionnaires are an essential aspect of care, but the optimal number of questions and mode of questionnaire delivery are important as evidenced by our completion rate. If a GSS ≥ 5 represents SIBO, then this study suggests that subscales of the GIT 2.0 may be able to effectively capture this disease entity. The social functioning and emotional well-being domains of GIT 2.0 warrant further study in SIBO patients.

Table 1: Subscales of the GIT 2.0 according to GSS(with ≥ 5 possibly identifying SIBO)

GIT 2.0 Subscales	GSS ≥ 5 (n=24)	GSS < 5 (n=19)	p-value
Reflux	0.83	0.46	0.051
Distention/Bloating	1.28	0.57	0.001
Diarrhea	0.65	0.34	0.093
Social	0.56	0.13	0.002
Emotional	0.65	0.15	0.001
Constipation	0.67	0.29	0.043
Soilage	0.33	0.11	0.171

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Sclerosis and Related Disorders – Clinical Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: To evaluate the efficacy and safety of TCZ as a rescue therapy in patients with refractory scleroderma-associated interstitial lung disease (SSc-ILD).

Methods: We undertook an open observational study of patients with progressive SSc-ILD despite treatment with immunosuppressants and rituximab (RTX), treated with TCZ for at least 6 months. The main efficacy variables evaluated at the end of the follow-up period were the evolution of the respiratory functional tests, distance traveled during the 6-minute walk test (6MWT), and changes in high-resolution chest computed tomography scan (HRCT).

Results: Thus far, we have treated 9 patients with TCZ (off-label use). All of them were women, with a mean (\pm SD) age at TCZ onset of 57 ± 7 years (range, 40-64 yrs). Of the 9 patients, 5 (55%) presented limited cutaneous scleroderma, and 4 (45%) had diffuse cutaneous involvement. The median durations of SSc and ILD were 8 years (range, 2-15 yrs) and 7 yrs (range, 2-12 yrs), respectively. All cases corresponded to fibrosant nonspecific interstitial pneumonia (NSIP). Regarding their autoantibody profile, 67% (6/9) of the patients tested positive for anti-Scl-70 antibodies, whereas ACA antibodies were positive in 33% (3/9); anti-Ro 52 antibodies were tested in 5 patients, being positive only in 1 case.

Previous or ongoing therapies for SSc-ILD included mycophenolate (100%), cyclophosphamide (67%), azathioprine (11%), and rituximab (100%). The mean number of RTX cycles previously administered was 2.6 ± 1.9 (range, 1-6); in three patients (33%) RTX was discontinued due to adverse effects (mainly respiratory or urinary infections and transient neutropenia).

The median follow-up after the first dose of TCZ dose was 12 months (interquartile range [IQR], 25th-75th: 6-33 months). The outcome of the main efficacy variables evaluated during the follow-up period is detailed in these tables.

	Pre-TCZ (mean \pm SD)	Post-TCZ (mean \pm SD)	Delta (mean)	p
FVC % predicted	74.2 \pm 24.7	76.1 \pm 29.1	1.2	0.627
TLC% predicted	88 \pm 7	75.6 \pm 10.1	-11.5	0.034
DLCO% predicted	50.4 \pm 18.9	47.3 \pm 17.4	-1.8	0.492
Mean distance covered in 6MWT	398.3 \pm 13.7	357.2 \pm 47.3	-41.3	0.949

	FVC	DLCO	HRCT (performed only in 5 patients)
No change / Stabilization	5	4	2
Improvement	1	0	0
Worsening	3	5	3

Considering the total sample, at the end of the follow-up period, only 4 patients (45%) were still in treatment. In the other 5 (55%) TCZ was discontinued due to inefficacy. One (9%) of these 5 patients died due to progression of ILD. The frequency of adverse effects was low, occurring in only 1 patient (11%), who developed several infections (upper respiratory tract infection not requiring hospitalization, herpes zoster, and osteomyelitis complicating one scleroderma digital ulcer).

Conclusion: According to this preliminary real-life experience, the effectiveness of TCZ as a rescue treatment in patients with refractory SSc-ILD seems modest but not negligible, achieving a stabilization of pulmonary function in 45% of patients.

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Although severity of skin involvement and change in skin thickness over time vary substantially between patients with diffuse cutaneous systemic sclerosis (dcSSc), for the majority of patients, skin tends to improve over time. We were interested in determining the effect of autoantibodies on the patterns of change in skin thickness over time in patients with dcSSc.

Methods: Subjects with confirmed diagnosis of dcSSc and at least one modified Rodnan skin score assessment were included. Linear mixed models were used to assess association between changes in mRss over time and autoantibody specificities.

Results: In total, 572 dcSSc patients were included. Of those, 127(22.2%) were male and mean \pm SD age at disease onset was 44.5 \pm 13.7 years. The most common scleroderma-specific antibodies were anti-topoisomerase I (ATA), present in 174 (30.4%) and anti-RNA polymerase (ARA) in 153 (26.8%) of the subjects. Anti-U3RNP was found in 39 (6.8%), anti-PmScl in 28 (4.9%) and ACA in 17 (3%). A substantial proportion of the cohort was ANA+, but ENA- (n=99,17.3%). Other antibody specificities included anti-nRNP, SL, Ku, Jo1, Ro, PL7, hnRNP and Sm. In 24 subjects (4.2%) ANA was negative. Three or more mRss assessments were available for 72.2% (n=413). For 66.4% of the patients (n=380), first mRss assessment was made within 3 years from disease onset.

For the cohort as a whole, the average mRss at 12 months from disease onset was estimated to be 23.5 (SD 9.4; 95% CI 22.6, 24.5) and this gradually declined following a non-linear trajectory ($mRss = 23.5 - 2.3 * \text{years} + 0.1 * \text{years}^2 - 0.002 * \text{years}^3$, $p < 0.001$ for all parameters). Thus skin improvement was greater in earlier disease (average drop in mRss was 2.2 between years 1 and 2, compared to 1.58 between years 4 and 5, and 0.8 between years 9 and 10, for example). There was a moderately strong, negative association between mRss at 1 year and drop in mRss over time (correlation coefficient = -0.62), suggesting that higher initial skin scores are associated with greater subsequent improvement. Focusing on the first 10 years of disease, autoantibodies showed significant association with both baseline mRss and changes in mRss overtime (Figure 1). At 1 year from disease onset, highest average mRss (27.0) was observed in ANA+ ENA- patients. Compared to those, mRss in ARA+ patients was 24.9, $p = 0.166$; in ATA+ 23.8, $p = 0.043$; in anti-U3RNP+ 20.3, $p = 0.008$ and in anti-PmScl+19, $p = 0.009$. Over subsequent years, the greatest improvement was observed in ANA+ ENA- and ARA+ patients with respective drop in mRss of 4.2 and 3.3 between year 1 and 2, compared to 2 in ATA+ patients ($p < 0.005$) and 1.4 in anti-U3RNP+ ($p < 0.020$).

Conclusion: Skin score change is significantly associated with autoantibody specificity and disease duration. While mRss can be much higher in ARA+ and ANA+ENA- patients compared to other antibodies, those patients experience the greatest improvement over time.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Sclerosis and Related Disorders – Clinical Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Pulmonary fibrosis (PF) is a leading cause of disease-related death in SSc patients. Some studies suggest that the timing of PF development differs between patients with different autoantibodies. We set out to assess a large single-center SSc cohort, focusing on the timing of clinically significant PF (csPF), and to compare this within

subgroups with different disease-specific autoantibodies, in particular ACA, anti-Scl-70 and anti-RNA polymerase antibody (ARA).

Methods: Patients with confirmed SSc and information on autoantibodies were included. PF was confirmed on high-resolution CT and defined as clinically significant based on at least one of the following: FVC<70%; a drop in FVC>15%; DLCO<70% with no pulmonary hypertension (PH) present; or a drop in DLCO>15% with no PH. Only subjects who had first available lung function test result within the first 3 years from onset were included. 1-Kaplan-Meier (1-KM) estimation was used to calculate cumulative incidence of csPF. To assess the timing of highest rates of csPF development, hazard rates were calculated within intervals of 12 months over the follow-up.

Results: A total of 450 subjects, 75 (16.7%) male, mean age of onset 47.4 years, were included in the study. Of those 225 (50%) had dcSSc, 105 (23.3%) carried ACA, 113 (25.1%) Scl-70 and 72 (16%) ARA. Mean follow-up was 12 years, interquartile range 8-16 years. Over the entire follow-up period, 196 (43.6%) of the subjects developed csPF. Using 1-KM estimation, for the whole cohort, over the first 20 years of disease, approximately half of the patients developed csPF. Three quarters of those had reached this endpoint by 5 years (38.2%) with much lower incidence thereafter (at year 10, 15 and 20 - 43%, 47% and 49.6%, respectively). Subgroup analysis showed that ACA was associated with a very low risk of csPF development (cumulative incidence of 5.9%, 8.1%, 9.8% at 5, 10 and 15 years from SSc onset). On the other hand, Scl-70+ patients had a remarkably high risk of csPF development, which ultimately occurred in the majority of cases, with cumulative incidence of 77.6% at 5 years, 82.7% at 10 years and 87.1% at 15 years. Rates of csPF development among ARA+ patients were higher than those in ACA+, but still much lower than ATA+, and even after 20 years of follow-up, the cumulative incidence of csPF among them was less than a half of that among ATA+ patients (23.7%, 33% and 41% at years 5, 10 and 15). The hazard of csPF among ACA+ patients was highest in the second year from SSc onset (3%) and in the subsequent years varied between 0 and 1.8%. On the other hand, among Scl-70+ patients hazard of csPF was 28.3% in year 1, 44.9% in year 2, peaked at 52.5% in year 3 and went down sharply thereafter. Although hazard was much lower among ARA+ patients, this still peaked at year 3 (2.8%, 6.1% and 12.1% at year 1, 2 and 3 respectively) and declined after.

Conclusion: Our analysis demonstrates that overall risk of csPF differs by antibodies but csPF tends to develop early in the disease course, regardless of antibody specificity. The overall risk is highest at around 3 years from disease onset and goes down thereafter. These findings can inform clinical monitoring and trials recruitment.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Sclerosis and Related Disorders – Clinical Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Pulmonary arterial hypertension (PAH) is a feared complication in systemic sclerosis (SSc). Detection of PAH at a preclinical stage is important as early diagnosis seems to improve outcome. Serum markers of PAH are in demand as detection of PAH to date relies on echocardiography and right heart catheterization (RHC), which are both time- and cost consuming. Also, identifying mechanistic pathways may aid the development of novel treatment strategies for PAH. Several serum markers are to date proposed to be altered in PAH patients, but studies are often conflicting, stressing the necessity for validation studies.

Methods: All SSc patients referred to the Oslo University Hospital are included in the prospective SSc cohort. Serum samples are collected at first visit. RHC is performed on patients suspected of pulmonary hypertension (PH) based on echocardiography, DETECT calculator or clinical suspicion. We defined PAH as precapillary PH (mean pulmonary arterial pressure, mPAP ≥25 mmHg) in the absence of significant interstitial lung disease (ILD), based on high resolution

computed tomography and lung function tests. Patients with group II or III PH were excluded from analyses on PAH, as well as patients with combined high tricuspid regurgitant velocity (TRV) on echocardiography and normal or absent RHC. Serum markers previously shown to be associated with immunologic diseases and/or cardiopulmonary organ involvement were quantified by ELISA (Table 1). Observation period was defined as time from serum sampling to death or study end (May 2018).

Results: The cohort included 297 SSc patients of whom 37 were excluded due to PH group II/III, while 11 were excluded due to conflicting TRV and RHC. Patients were compared to 99 healthy controls. RHC was performed in 132 patients and PAH was diagnosed in 43 patients (15% of total) during the observation period. PAH-patients presented with higher age (64 vs 53 years, $p<0.001$), more frequent limited disease (93% vs 73%, $p<0.001$) and anti-centromere antibodies (84% vs 48%, $p<0.001$) than patients without PH. Besides previously shown associations of CCL21 and endostatin, patients with PAH presented higher values of osteoprotegerin, osteopontin, and activin-A compared to other SSc patients (Table 1). Activin-A (OR 1.15, 95%CI 1.03-1.29, $p=0.013$) and osteopontin (OR 1.01, 95% CI 1.01-1.01, $p=0.018$) also showed association with PAH-status in multivariable logistic regression adjusted for age and sex.

Conclusion: In this study we show associations between higher levels of osteoprotegerin, osteopontin and activin-A with SSc-PAH.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Sclerosis and Related Disorders – Clinical Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: In SSc, cardiac dysfunction is associated with poor prognosis. Right ventricular involvement is frequently secondary to PAH. Echocardiography is the routine imaging tool to detect cardiac involvement and pulmonary hemodynamic. Our aim was to evaluate right ventricular function and non-invasive hemodynamic by standard trans-thoracic Doppler echocardiography in SSc patients without known cardiac involvement and PAH, compared to healthy controls.

Methods: 343 SSc patients (mean age, 54.2±14.8 years) and 340 healthy age-matched controls (mean age 52.0±16.9 years, p=ns) prospectively underwent a comprehensive trans-thoracic 2D and Doppler echocardiography, including tissue Doppler imaging analysis (TDI) of both the right and left heart. Patients with known cardiac involvement and/or a diagnosis of PAH were excluded. Patients were followed-up and cardiac events were recorded as new onset of heart failure (HF), development of PAH, significant ventricular or supra-ventricular arrhythmias requiring therapy or implantable cardioverter-defibrillator (ICD).

Results: Compared to controls, SSc patients did not show differences in systolic left ventricular function, while a worse diastolic left ventricular function, as well as worse right ventricular function and pulmonary circulation parameters were found (table). Mean follow-up was 32 ± 28 months. During the follow-up a total of 52 events occurred. Echocardiographic predictors of cardiac events at univariate analysis were E/e' (e' as mean of TDI lateral and septal values), right ventricular (RV) end-diastolic diameter, pulmonary artery systolic pressure (PASP), and presence of even trivial pericardial effusion. At multivariate analysis, only PASP was an independent predictor (hazard ratio 1.05, C.I. 1.01-1.10, p<0.0001).

Conclusion: SSc patients without overt cardiac dysfunction and no PAH show worse parameters of right ventricular function and pulmonary hemodynamic compared to controls, although still within normal values. These indexes of subclinical right heart involvement provide prognostic information and are independent predictors of further cardiac events, even in patients without PAH.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Vasculitis – ANCA-Associated Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Eosinophilic granulomatosis with polyangiitis (EGPA) (Churg–Strauss) is a small-vessel necrotizing vasculitis characterized by blood and tissue eosinophilia and asthma. Glucocorticoids (GCs) represent the cornerstone of treatment. So far, EGPA management has been based on conventional immunosuppressants, but relapses and/or GC-dependence are frequent. More recently, biotherapies targeting B cells and interleukin-5 have been used, but data on large cohorts are lacking. This study aimed to describe therapeutic management and efficacy of conventional immunosuppressants and targeted biotherapies in EGPA patients.

Methods: We started a multicenter European collaborative initiative that included 376 EGPA patients from tertiary referral centers. Remission was defined as the absence of vasculitis manifestations (BVAS=0), asthma and ENT manifestations with a GC dose <7.5 mg/d. Treatment failure was defined as no improvement or worsening and the inability to taper GCs.

Results: After median follow-up of 58.5 (IQR 26.7–101) months, 175 (46.5%) patients were in prolonged remission, 141 (37.5%) had GC-dependent asthma and/or ENT manifestations and 108 (28.7%) had had [≥]1 vasculitis relapse(s). For remission induction, cyclophosphamide was the most frequently used immunosuppressant (54%), mainly because of cardiac, renal and/or nervous system involvement. Induction conventional immunosuppressants (cyclophosphamide, azathioprine or methotrexate), prescribed based on disease severity, achieved remission rates similar to GCs alone, in terms of overall survival, relapse-free survival and evolution towards 4 different identified profiles. At the first vasculitis relapse, having GC-dependent asthma and/or ENT manifestations and a high GC-dependency threshold were associated with a higher risk of treatment failure (57% vs. 32%, P=0.008). As for induction, conventional immunosuppressants seemed to be similar to GCs alone to achieve remission and lower the relapse risk. Rituximab was prescribed as first-line therapy for 5 patients and for 6 relapsing patients, and achieved remissions in 82%. During follow-up, GC-dependent asthma and/or ENT manifestations were treated with azathioprine (48%), methotrexate (35%), mycophenolate mofetil (16%), cyclophosphamide (10%), cyclosporine (6%) or rituximab (6%), achieving GC-tapering to <7.5 mg/d for 27%, 41%, 42%, 15%, 71% and 29%, respectively. Mepolizumab

Conclusion: Despite their beneficial impact on overall survival of EGPA patients, the efficacies of conventional immunosuppressants proved disappointing, as achieving remissions, preventing vasculitis relapses and controlling GC-dependent asthma and/or ENT manifestations were not improved. Notwithstanding a small number of treated patients, eosinophil-targeted therapies seemed to be promising but their efficacies against vasculitis, asthma and/or ENT manifestations require further investigation.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Vasculitis – ANCA-Associated Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: ANCA-associated vasculitis including microscopic polyangiitis (MPA) involves multiple organs including lungs. Clinical characteristics and impact on long-term survival in MPA patients with interstitial lung disease (ILD) have not been well characterized. The aim of this study is to clarify clinical characteristics and long-term survival in MPA patients with and without ILD.

Methods: All our patients suspected to have MPA are admitted to our hospital for evaluations. We retrospectively investigated consecutive 76 Japanese patients, classified as MPA with algorithm by Watts, with (n = 44) or without ILD (n = 32) from 2006 through 2014. We compared between-group differences. All patients underwent chest CT.

Results: The 76 patients (female, 88%) had mean follow-up period (SD) of 66 (42) months. Mean age (SD) was 71 (8) and 67 (15) in patients with and without ILD, respectively (NS). The frequency of nephritis was lower in patients with ILD (57%) than in those without ILD (84%) (P = 0.01). Eight (18%) and 4 (13%) patients with and without ILD had mononeuritis multiplex, respectively. Treatment in patients with / without ILD included prednisolone alone (with / without ILD, 30% / 41%) or combination with immunosuppressants such as cyclophosphamide (43% / 41%), rituximab (5% / 0%), or azathioprine (23% / 16%). Patients with ILD tended to have low survival compared with those without ILD (P = 0.056). The survival of both groups was similar at the first 4 years. Notably, death in patients with ILD was continuously observed even after 4 years, which was in contrast to those without ILD (figure). Seventeen (39%) and 5

(16%) of patients with and without ILD died during the follow-up, respectively ($p = 0.04$). Death in 14 patients with ILD (82%) was associated with MPA ($n = 8$) including deterioration of ILD ($n = 5$), heart failure ($n = 2$), and alveolar hemorrhage ($n = 1$) or with infection ($n = 6$) including sepsis ($n = 3$), bacterial pneumonia ($n = 2$), and pneumocystis pneumonia ($n = 1$). Among 12 patients with ILD who died after 4 years, death in 9 (75%) patients was associated with lung disease such as deterioration of ILD ($n = 6$) or infectious pneumonia ($n = 3$), whereas only one without ILD died from late-stage renal failure. Hazard ratios (HR) for ILD and renal disease were 2.56 (95% CI 0.94-6.97) and 0.89 (95% CI 0.36-2.20), respectively. Patients over age 70 and ILD had independent risk for death (HR 2.61, 95% CI 1.12-6.10).

Conclusion: Death associated with MPA and infections were seen at any period in patients with ILD, which affected the survival. Establishment of more efficient maintenance as well as induction therapy with less side effects is needed in MPA patients with ILD.

Disclosure: H. Matsushita, None; Y. Yamasaki, None; Y. Takakuwa, None; H. Yamada, None; K. Kawahata, None.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Vasculitis – ANCA-Associated Poster I

Background/Purpose: At month 24 (M24), CHUSPAN2-trial patients with nonsevere eosinophilic granulomatosis with polyangiitis (EGPA), who received 1 yr of azathioprine (AZA) and glucocorticoids (GC) as remission-induction therapy, did not have lower remission failure, vasculitis relapse-risk or asthma/rhinosinus-exacerbation (ARE) rates, or steroid-sparing (1). These EGPA patients' long-term outcomes were analyzed to determine whether vasculitis-relapse or isolated ARE rates differed thereafter.

Methods: After M24, treating physicians chose treatments. Long-term outcomes were analyzed according to randomization group (AZA vs placebo). Flares and reasons for GC escalation or immunosuppressant use were reviewed to distinguish vasculitis relapses from isolated AREs according to EGPA Task Force recommendations. Trial entry parameters were evaluated as potential prognostic factors for vasculitis relapse or isolated ARE during follow-up.

Results: The 50 EGPA patients (25 men, mean age 53.4 yr, mean eosinophilia 5,900/ μ L) were followed for a median [IQR] of 6.3 [5.4–7.6] yr. Two (4%) patients (1 after remission-induction failed) died 11 months postinclusion. At M24, 21/48 (43.8%) patients had vasculitis relapse and 14/50 (28%) had isolated AREs. Among the 48 follow-up patients analyzed, 1 died 4.8 yr postinclusion (probable infection); 19.6% (9/46) had subsequent vasculitis relapses of whom 3 had their 1st relapse after M24; 25/45 (55.6%) patients had later isolated AREs, the 1st for 17 only after M24. From M24 to last update, conventional immunosuppressants were prescribed for 22/48 (45.8%) patients to control flares (17 AZA, 5 MTX, 4 cyclophosphamide, 1 leflunomide) and, after immunosuppressants failed, rituximab for 7; 4 received mepolizumab and 3 omalizumab, mostly for AREs. At 5 yr, respective vasculitis relapse and isolated ARE rates were 48.3% (95% CI: 34.0–62.6) and 56.2% (95% CI: 41.7–70.8), with no long-term between-arm differences ($P=0.16$ and $P=0.06$). For the AZA and placebo arms, respective 5-yr overall survival (OS) rates were 100% and 91.3% (95% CI: 79.7–100; $P=0.15$). At last update, 78.7% of patients still required GC (median dose: 5 [3.0–8.0] mg/d) to control AREs and/or as vasculitis maintenance therapy. Damage resulted from asthma ($n=42$), followed by peripheral nerve involvement ($n=28$) and chronic sinusitis/nasal obstruction ($n=27$); Vasculitis Damage Indexes (mean \pm SD) were comparable for AZA (2.8 ± 1.5) and placebo (2.2 ± 0.9) groups ($P=0.42$). Among the 18 (36%) patients MPO-ANCA+ at entry, 13 had ANCA ELISA results at M24: 6 became ANCA– (none relapsed later) and 7 were ANCA+, after having been transiently ANCA– for 3, (2/7 subsequently relapsed). Analyses retained no entry clinical or biological parameter, including blood eosinophil count and ANCA status, as significantly associated with vasculitis relapse or ARE during follow-up.

Conclusion: These results confirmed that 1 yr of AZA and GC obtained good OS but had no long-term benefit for EGPA patients. Extrapulmonary vasculitis relapses, occurring mostly during the first 2 yr, and isolated AREs, predominating thereafter, remain worrisome and require further studies to prevent them.

Interstitial Lung Disease in ANCA-Positive Vasculitis Patients

Andy Abril¹, Minkyung Kwon², Isabel Mira-Avendano³, Carlos Rojas⁴ and Andras Khoor⁵, ¹Rheumatology, Mayo Clinic Florida, Jacksonville, FL, ²Pulmonary and Critical Care, Mayo Clinic, Jacksonville, FL, ³Pulmonary and Critical Care, Mayo Clinic Florida, Jacksonville, FL, ⁴Radiology, Mayo Clinic, Jacksonville, FL, ⁵Pathology, Mayo Clinic, Jacksonville, FL

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Vasculitis – ANCA-Associated Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Rarely, ANCA-positive vasculitis patients are found to have interstitial lung disease (ILD). Clinical characteristics and prognosis are not well known in these patients. The largest report to date is from Japan, describing microscopic polyangiitis (MPA) as the most common type of ANCA vasculitis associated to ILD.

Methods: We retrospectively reviewed 26 patients at Mayo Clinic Florida for the past 10 years diagnosed with both ANCA-positive vasculitis and ILD(AAV-ILD). We compared the clinical characteristics of AAV-ILD to idiopathic pulmonary fibrosis (IPF) and idiopathic pneumonia with autoimmune features(IPAF) patients

Results: There were 24 AAV patients. 11 were male and 13 were female. 14 patients had microscopic polyangitis (MPA), 8 patients had granulomatosis polyangitis (GPA), and 2 patients had eosinophilic granulomatosis polyangitis (EGPA). Usual interstitial pneumonia (UIP) pattern was found in 11 patients and other patterns were inconsistent with UIP. P-ANCA and anti-MPO were positive in most MPA patients and c-ANCA and anti-proteinase-3 were positive in most GPA patients. Cyclophosphamide and corticosteroids were the mainstay of therapy, and rituximab was used in 13 patients. A total of 5 patients died. Death was directly related to the progression of ILD in 4 patients.

Conclusion: We were able to identify the characteristics of ILD in ANCA-positive vasculitis patients. We observed that a fair number of PR3-positive/GPA patients do have ILD, comparable to MPA. This is to our knowledge the largest case series of clinically confirmed ANCA vasculitis with ILD reported in North America.

Long-Term Renal Outcome in Pulmonary-Limited Microscopic Polyangiitis

Hironari Hanaoka, Harunobu Iida, Tomofumi Kiyokawa, Yukiko Takakuwa and Kimito Kawahata, Division of Rheumatology and Allergology, Department of Internal Medicine, St. Marianna University School of Medicine, Kawasaki, Japan

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Vasculitis – ANCA-Associated Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with pulmonary-renal or renal-limited microscopic polyangiitis (MPA) frequently manifested with rapidly progressive glomerular nephritis resulting in chronic renal failure if clinical response to the remission

induction treatment was not successfully obtained. In contrast, pulmonary-limited MPA lacks renal involvement at diagnosis and its long-term renal outcome after remission induction treatment has been poorly investigated. Here, we compared long-term renal outcome of pulmonary-limited MPA with that of pulmonary-renal and renal-limited MPA.

Methods: We retrospectively examined the patients who met the MPA diagnostic criteria and received induction therapy. We divided them into 3 groups, pulmonary-renal, renal-limited and pulmonary-limited MPA and evaluated estimated glomerular filtration rate (eGFR) for 5 years. We further investigated the pathological features of kidney on available sample.

Results: Twenty-five patients with pulmonary-renal, 28 with renal-limited, and 19 with pulmonary-limited type were enrolled. At baseline, significantly higher eGFR, lower incidence of active sediment, lower BVAS, and lower titer of MPO-ANCA were observed in pulmonary-limited type comparing with other types ($p<0.01$, $p<0.01$, $p<0.01$, $p=0.02$, respectively). Initial treatment regimens including glucocorticoid dose, %cyclophosphamide use, and %rituximab use were not significantly different among the groups. The eGFR of patients with pulmonary-renal and renal-limited types was significantly improved ($p=0.01$, $p=0.03$) whereas that of pulmonary-limited was deteriorated ($p=0.05$), resulting in no difference of eGFR at year 5 in all types comparison (Figure 1). By multivariate analysis, eGFR at baseline was

Table 1. Independent factor associating with deterioration of renal function*

Parameters	Univariate		Multivariate	
	OR (95% CI)	P	OR (95% CI)	P
Pulmonary-limited	23.03 (6.47-101.9)	<0.01	1.97 (0.16-21.1)	0.57
Renal-limited	0.13 (0.03-0.47)	<0.01	0.19 (0.01-1.61)	0.13
Pulmonary-renal	0.36 (0.09-1.14)	0.08	-	-
eGFR at Week 0	4.40 (2.70-6.65)	<0.01	1.19 (1.00-1.32)	0.01
Proteinuria >1+	0.05 (0.01-0.19)	<0.01	0.18 (0.01-1.46)	0.10
Hematuria >1+	0.08 (0.02-0.25)	<0.01	0.77 (0.04-10.0)	0.86
c-RBC >1+	0.20 (0.05-0.64)	<0.01	0.89 (0.09-8.39)	0.91
PSL (mg/day)	1.08 (0.96-1.04)	0.94	-	-
IVCY	0.77 (0.26-2.16)	0.62	-	-

PSL, prednisolone; IVCY, intravenous cyclophosphamide

*deterioration of renal function was defined as more than 25%eGFR decline from baseline [1].

independently associated with the deterioration of renal function (OR 1.2, 95%CI 1.00-1.32, $p=0.01$) (Table 1). Renal specimen showed a higher percentage of interstitial cell infiltrate was observed in patients with high eGFR (≥ 60 ml/min) at baseline than those with low (< 60 ml/min).

Conclusion: Renal outcome of pulmonary-limited MPA was not significantly different from that of pulmonary-renal and renal-limited MPA for 5 years observation. Subclinical renal involvement or interstitial inflammation may proceed in some patients with pulmonary-limited MPA and careful observation is required.

Rheumatoid Factor Titer Is Inversely Correlated with ANCA Titer and Relates to Characteristic Manifestations in Patients with Eosinophilic Granulomatosis with Polyangiitis

Jun Inamo, Yuko Kaneko, Yuichiro Ota and Tsutomu Takeuchi, Division of Rheumatology, Department of Internal Medicine, Keio University School of Medicine, Tokyo, Japan

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Vasculitis – ANCA-Associated Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Eosinophilic granulomatosis with polyangiitis (EGPA) is a rare antineutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV), which is characterized by vasculitis with allergic features such as asthma and eosinophilia. Although rheumatoid factor (RF) positivity is known to be as high as 37-50% in AAV patients [1] the clinical significance of RF-positivity remains unknown. The aim of this study is to investigate clinical features in patients with RF in EGPA.

Methods: Consecutive patients who were diagnosed with EGPA between January 2008 and January 2018 in Keio University Hospital were enrolled. Clinical information were collected from medical records retrospectively. We divided patients into 2 groups according to RF positivity, and compared clinical features.

Results: Seventeen patients were enrolled in the study. The mean age was 57.4 years old, and 82% were female. Among them, 11 patients were RF positive (RF positive group) and 6 patients were negative (RF negative group). The female rate tended to be higher in the RF positive group than the negative group (82% vs 50%, $p=0.087$). While the Birmingham Vasculitis Activity Score was comparable between the two groups (21.5 vs 17.3, $p=0.329$), general symptoms (fever and weight loss) and gastrointestinal lesions were more frequent in the RF positive group (55% vs 17%, $p=0.072$; 45% vs 17%, $p=0.137$) and central nervous involvement was less frequent (18% vs 67%, $p=0.024$). No patient with negative RF presented with arthralgia/arthritis. The count of eosinophil and IgA levels at diagnosis were significantly higher in the RF positive group than the RF negative group (15704/ μ L vs 4751/ μ L, $p=0.009$; 238mg/dL vs 162mg/dL, $p=0.048$). Interestingly, ANCA positivity was negatively correlated with RF positivity. MPO-ANCA was positive in 27% of the RF positive group and in 66% of the RF negative group, and PR3-ANCA was positive in none of the RF positive group and 17% of the RF negative group. Double negative was more frequent in RF positive group (73% vs 33%, $p=0.060$).

Conclusion: RF positivity was associated with clinical and serological characteristics in patients with EGPA, suggesting different pathogenesis or immunological disturbances is related.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Vasculitis – ANCA-Associated Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Interstitial lung disease (ILD), rarely described in ANCA-associated vasculitis (AAV) patients, was mainly associated with anti-MPO ANCA. ILD's prognostic value remains unclear. This study focused on the outcomes of patients with ILD associated with AAV (ILD–AAV).

Methods: This case–control study compared ILD–AAV cases and to AAV patients without ILD (controls). Case AAVs were microscopic polyangiitis (MPA) or granulomatosis with polyangiitis (GPA) (meeting Chapel Hill definitions) and ILD was either usual interstitial pneumonia (UIP) or nonspecific interstitial pneumonia (NSIP) (satisfying the 2001 American Thoracic Society/European Respiratory Society criteria). Eosinophilic granulomatosis with polyangiitis, non-fibrosing pulmonary involvement, ILD without AAV criteria and late ILD (>2 yr after AAV diagnosis) were excluded. Two controls with MPA or GPA without ILD were matched to each case for age (> or ≤65 years), ANCA status (PR3- or MPO-positive, or negative) and creatininemia (≥ or <150 µmol/L).

Results: Sixty-five cases were included: 88% MPO-ANCA–positive and 83% with MPA. Median (IQR) age at AAV diagnosis was 65.7 (56.6–74.0) yr. ILD was mainly diagnosed before (53%) or simultaneously (39%) to AAV. CT-scan pattern was mostly UIP (65%). Median case follow-up was 40 (21–62) months vs. 60 (27–128) months for controls ($P=0.001$). Cases, compared to 130 controls, had less frequent fever ($P=0.002$), peripheral neuropathy ($P=0.03$), or ear nose & throat ($P=0.03$) or gastrointestinal involvement ($P=0.002$). Five Factor Scores (1996 version) at AAV diagnosis were similar for the 2 groups ($P=0.08$). Cases more frequently received immunosuppressants for induction (91% vs. 76%; $P=0.01$) and maintenance (84% vs. 58%; $P<0.001$). Notably, 17/65 (26%) cases suffered relapses vs. 56/130 (43.1%) controls ($P=0.03$). Relapses were mainly minor for cases (12/17; 70.6%) vs. controls (19/56; 33.9%) ($P=0.01$). Only 2 cases experienced ILD exacerbation at relapse. Major-relapse–free survival was comparable for cases and controls ($P=0.90$). During follow-up, 19 cases died: 6 of acute respiratory failure related to pulmonary fibrosis exacerbation, 2 end-stage respiratory failure, 2 infections (1 pneumonia, 1 endocarditis), 1 lung cancer, 1 digestive hemorrhage and 7 unknown causes. For cases and controls, respective 1-, 3- and 5-year overall survival rates were: 97%, 83% and 77% vs. 93%, 91% and 87% ($P=0.008$). Compared to controls, case survival was shorter for those with UIP ($P<0.001$) and unchanged for NSIP ($P=0.50$). Multivariate analyses retained age >65 yr (hazard ratio (HR) 4.366; $P<0.001$), alveolar hemorrhage (HR 2.38; $P=0.01$) and UIP (HR 2.63; $P=0.003$) as independently associated with shorter survival.

Conclusion: For ILD–AAV patients, UIP, but not NSIP, was associated with poorer prognosis. Although the greater majority of ILD–AAV patients included in this study received immunosuppressants for induction and maintenance, their survival was shorter than that of controls, mainly due to pulmonary fibrosis exacerbation, suggesting that anti-fibrosing agents should be evaluated in these patients.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Vasculitis – ANCA-Associated Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Eosinophilic Granulomatosis with Polyangiitis (EGPA) is a rare systemic small-vessel necrotizing vasculitis presenting with asthma and eosinophilia. Anti-neutrophil cytoplasmic antibodies (ANCA) association may influence disease presentation, treatment and outcomes. Rituximab (RTX) is effective in ANCA-associated vasculitis (AAV), but specific potential benefits in EGPA are less clear. Difficult-to-treat or glucocorticoid (GC) dependent asthma is one of the main challenges in EGPA management. Our aim was to characterize asthma control and GC dependency in EGPA patients treated with RTX.

Methods: Retrospective cohort study of patients diagnosed with EGPA between 2000 and 2017 presenting with GC dependent asthma and treated with RTX for remission induction in a single center. Standardised data collection was performed, including disease activity assessment, RTX treatment, asthma characterization and control.

Results: A total of 17 patients (52.9% men) were included. According to BVAS/WG, lower respiratory tract was most commonly affected at presentation (16, 94.1%), followed by nervous system (15, 88.2%) and ENT (14, 82.4%). There were no differences in disease extent index (DEI). Five Factor Score was ≥ 1 in 11 patients (64.7%). At diagnosis, the majority were myeloperoxidase (MPO)-ANCA positive (13, 76.5%). Non-controlled asthma symptoms were present in 13 (76.5%) patients. Atopy was present in 13 (76.5%) and radiographic changes in 8 (47.1%).

RTX was used in three different clinical scenarios: for initial remission induction (5, 29.4%) in patients with new onset of severe disease (BVAS/WG >3), after failed remission induction attempts with other immunosuppressants (12, 70.6%) or for remission maintenance (9, 52.9%). GC were used in all maintenance regimens at a median dose of 25 (16.25 – 37.5) mg/day.

Median time of *follow-up* since EGPA diagnosis was 38 (17-107) months. Three patients (17.6%) relapsed after RTX and 6 (35.3%) were refractory to RTX. As maintenance treatment in 9 (52.9%) patients, RTX choice was guided mainly by B-cell reconstitution during the follow-up (7, 41.2%). At the end of follow-up, remission was achieved in 15 (88.2%) patients. After induction with RTX, more than one asthma exacerbation occurred in 8 (47.1%) patients but the use of bronchodilators was not significantly different after the relapse. Mepolizumab was used for refractory symptomatic asthma in 2 patients (11.8%), after RTX effect worn off.

At the end of follow-up, median serum eosinophils and C-reactive protein were lower than before RTX treatment (0.10 vs. 1.06 $\times 10^9/L$, $p=0.012$; 5 vs. 27 mg/dL, $p=0.001$; respectively). Pulmonary function tests (PFTs) remained unchanged.

Induction treatment with RTX allowed a more predictable GC tapering: to a median dose of 5 mg/day at 12 months and a rise from 12 to 24 months was seen (no GC pattern pre RTX treatment). However, in the patients on maintenance treatment with RTX, asthma symptom control was not dependent on GC at 12 months.

Conclusion: RTX seems a safe drug with some GC sparing efficacy in EGPA. Improvement in inflammatory markers and eosinophilia was observed, but not in PFTs. RTX deserves more detailed studies in prospective randomized controlled clinical trials in EGPA.

Interstitial Lung Disease in ANCA-Associated Vasculitis Defines a Unique Subgroup of Patients at High Risk for Respiratory Death: A Cluster Analysis

Zachary Wallace¹, Yuqing Zhang², John H. Stone³ and Hyon K. Choi⁴, ¹Division of Rheumatology, Allergy and Immunology, Massachusetts General Hospital, Harvard Medical School, Boston, MA, ²Department of Rheumatology, Allergy and Immunology, Massachusetts General Hospital, Boston, MA, ³Home Address, Sudbury, MA, ⁴Division of Rheumatology, Allergy, and Immunology, Massachusetts General Hospital, Boston, MA

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Vasculitis – ANCA-Associated Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: ANCA-associated vasculitis (AAV) has a propensity for heterogeneous organ involvement. ANCA specificity has increasingly been favored over clinical diagnosis (e.g., microscopic polyangiitis) for subgrouping AAV patients but also has its limitations. Latent class analysis (LCA) is an unbiased method to identify patient subgroups who share similar manifestations and might therefore share risk factors and/or outcomes.

Methods: The Partners AAV (PAAV) Cohort is a retrospective cohort established at Partners HealthCare, a large US hospital system. All PAAV patients are PR3- or MPO-ANCA+. We performed LCA to identify clusters according to baseline manifestations. We fitted models with 2-5 clusters and analyzed the one with superior fit statistics. Cases were assigned to a cluster based on posterior probability. We compared the distribution of baseline features between clusters using Chi square tests or analysis of variance, as appropriate. We used multivariable Cox regression to compare the rates of cardiovascular disease (CVD), deep vein thrombosis/pulmonary embolism (DVT/PE), end-stage renal disease (ESRD), and all-cause and cause-specific death between clusters. We adjusted for the competing risk of death and cause-specific death.

Results: A 3 cluster model fit best. Cluster 1 (N=143) was characterized by GN whereas cluster 2 (N=236) was characterized by upper respiratory tract disease and lung nodules more often than renal disease (**Table 1**). Cluster 3 (N=35) was distinguished by interstitial lung disease (ILD) which was present in <1% of clusters 1 and 2. In contrast to clusters 1 and 2, cluster 3 patients tended to be male (51%) and older (63.9 ± 13.4 yrs vs 58.9 ± 18.4 yrs and 54.1 ± 17.6 yrs, respectively). PR3- and MPO-ANCA status were distributed evenly in cluster 2 (PR3-ANCA=53%) whereas MPO-ANCA+ was more common in clusters 1 (71%) and 3 (91%). Compared to cluster 2, patients in cluster 1 had a higher risk of ESRD (HR 6.48, 3.39-12.36), DVT (HR 2.98, 1.65-5.39), and death (HR 1.62, 1.12-2.34). Patients in cluster 3 had a higher risk of death from respiratory causes compared to cluster 2 (HR 4.43, 1.19-16.58); a similar trend was noted when comparing clusters 3 and 1 (HR 3.89, 0.95-16.04). The risk of CVD was not different across the 3 clusters.

Conclusion: In contrast to traditional AAV phenotyping by ANCA type or clinical diagnosis (e.g., granulomatosis with polyangiitis), LCA identified three unique AAV clusters. Besides organ involvement, clusters were distinguishable by baseline features and risk of key outcomes. AAV patients with ILD represent a unique subgroup, characterized by MPO-ANCA positivity, older age, and death from respiratory causes. In contrast, patients with primarily GN (i.e., Cluster 1) are at higher risk of DVT, ESRD, and all-cause death. Future studies might evaluate the cluster-specific response to treatment.

Table 1. AAV Clusters: Baseline Features and Long-Term Outcomes

Clinical and Economic Characteristics of Patients Diagnosed with Eosinophilic Granulomatosis with Polyangiitis (EGPA, formerly Churg-Strauss Syndrome) in the United States

Christopher F Bell¹, Matthew Lau¹ and Qin Shen², ¹GlaxoSmithKline, Research Triangle Park, NC, ²GlaxoSmithKline, Collegeville, PA

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Vasculitis – ANCA-Associated Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Eosinophilic granulomatosis with polyangiitis (EGPA), formerly Churg-Strauss Syndrome, is a rare, complex multisystem disorder belonging to a group of autoimmune inflammatory diseases characterized by vascular inflammation, multisystem organ damage that manifests as chronic rhinosinusitis, asthma, and peripheral blood eosinophilia. In part due to the rare nature of EGPA and lack of specific ICD-9 codes, there is an absence of burden of illness data. Introduction of an EGPA-specific ICD-10 diagnosis code (M30.1) should facilitate such analyses. In this regard, this study aims to describe EGP Aburden of illness in the United States (US).

Methods: This is a retrospective analysis of two US administrative claims databases. The index date was defined as the first medical claim with an ICD-10 diagnosis for EGPA. The study period spanned from ICD-10 introduction (01 October 2015) through the most recent data availability (Database #1 [DB#1]: 31 December 2016; Database#2 [DB#2]: 31 March 2017). Patients were \geq 18 years of age, had \geq 1 medical claim with an ICD-10 diagnosis code for EGPA, and had 6 months of continuous health plan enrollment post-index. Six-month post-index clinical and economic characteristics are reported as counts (percentages) and means (standard deviations [SD]).

Results: Approximately 0.0017% of the population had an EGPA diagnosis (DB#1: 567/33,293,530; DB#2:413/23,796,590) (Table 1). Mean (SD) age was 54.9 (14.1) in DB#1 and 59.7(16.0) in DB#2; and overall, approximately 60% of patients were female. Mean (SD) Quan-Charlson Comorbidity Index score was 1.3 (1.3) in DB#1 and 1.6 (1.7)in DB#2 (AHRQ top 5 comorbidities were similar across databases). Post-index concomitant medications included (DB#1/DB#2): asthma-related medications (non-biologic: 65.5%/55.9%; biologic: 5.2%/3.4%), immunosuppressive medications (84.8%/75.5%), and oral corticosteroids (OCS; 73.5%/59.0%). Among patients receiving OCS, mean (SD) prednisone-equivalent daily dose was 53.9 mg/day (248.1) in DB#1 and 18.8 mg/day (13.8) in DB#2 (median dose was 15 mg/day in both databases). Post-index, all-

cause healthcare resource utilization was similar across databases with 16.9% of patients in DB#1 incurring an inpatient admission (mean [SD] admissions: 1.5 [1.1] and 20.3% of patients in DB#2 (mean [SD] admissions: 1.3 [0.7]). Mean (SD) all-cause total costs incurred in the post-index period were \$32,388 (113,895) in DB#1 and \$20,865 (33,665) in DB#2.

Conclusion: This study descriptively characterizes the substantial clinical and economic burden associated with EGPA. While EGPA is a rare disease, the introduction of an EGPA-specific ICD-10 diagnosis code should allow researchers to better quantify the burden of illness.

Burden of Illness Associated with Eosinophilic Granulomatosis with Polyangiitis (EGPA, formerly Churg-Strauss Syndrome): Evidence from a Managed Care Database in the United States

Christopher F Bell¹, Cori Blauer-Peterson² and Jianbin Mao², ¹GlaxoSmithKline, Research Triangle Park, NC, ²Optum, Eden Prairie, MN

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Vasculitis – ANCA-Associated Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Eosinophilic granulomatosis with polyangiitis (EGPA), is a rare, complex multisystem disorder, characterized by vascular inflammation and multisystem organ damage. EGPA manifests as asthma, rhinosinusitis, blood/tissue eosinophilia, and vasculitis. In part due to its rare nature, there is an absence of burden of illness data. This study aims to quantify healthcare resource utilization and costs associated with EGPA from the managed care perspective in the United States (US).

Methods: A retrospective analysis was conducted using a large, US administrative claims database (study period: 01 July 2007 to 31 March 2017). Patients were 18 years of age or older with continuous health plan enrollment (6-months pre-index and 12-months post-index). The index date was the date of EGPA diagnosis. Prior to the implementation of ICD-10 (October 2015), EGPA diagnosis was based on published algorithms.^{1,2} Post October 2015, EGPA diagnosis was based on ICD-10 code M30.1 (polyarteritis with lung involvement [Churg-Strauss]). An unmatched asthma control group was identified to evaluate the incremental impact of EGPA. Clinical and economic characteristics are reported as counts, percentages and means, with statistical comparisons evaluated at $\alpha=0.05$ level.

Results: The study included 2,226 EGPA and 48,252 asthma patients (Table 1). The EGPA cohort was older, predominantly female and had greater comorbidity (top three: hypertension, other lower respiratory conditions and other connective tissue conditions) as compared with the asthma cohort. In the pre-index period, the proportion of patients utilizing services and the mean number of services utilized were significantly greater in the EGPA cohort compared with the asthma cohort (all $p<0.001$, except ambulatory). Pre-index costs were significantly greater in the EGPA cohort compared with the asthma cohort (mean: \$14,325 vs.\$5,050; $p<0.001$). In the 12-month post-index period, significant differences between the EGPA and asthma cohorts were observed for the proportion of patients utilizing services (ambulatory: 73.0% vs. 77.0%, $p<0.001$; emergency department [ED]: 42.1% vs. 31.7%, $p<0.001$; inpatient [IP]: 29.0% vs. 16.2%, $p<0.001$; prescriptions (Rx): 70.3% vs. 75.9%; $p<0.001$), the mean number of services utilized (ambulatory: 31.7 vs. 18.5, $p<0.001$; ED: 1.4 vs. 1.0, $p<0.001$; IP: 0.6 vs. 0.2, $p<0.001$, IP length of stay [days]: 5.4 vs. 1.9, $p<0.001$; Rx: 45.1 vs. 32.9, $p<0.001$) and mean costs (total: \$31,914 vs.\$13, 822; $p<0.001$; medical: \$26,441 vs. \$10,694; $p<0.001$; pharmacy: \$5,473 vs. \$3,128, $p<0.001$).

Conclusion: This study provides valuable real-world data about the substantial burden of EGPA, which was significantly greater in terms of resource utilization and costs when compared with an asthma cohort.

Systematic Review of the Clinical Effectiveness of Treatments in Eosinophilic Granulomatosis with Polyangiitis

Scott Doyle¹, Annete Njue², Matthew Lyall², Rebecca Rushton², Anne Heyes² and Maebh Kelly³, ¹Value Evidence and Outcomes, GlaxoSmithKline, London, United Kingdom, ²RTI Health Solutions, Manchester, United Kingdom, ³Pope Woodhead, London, United Kingdom

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Vasculitis – ANCA-Associated Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: To better understand the available clinical effectiveness data in eosinophilic granulomatosis with polyangiitis (EGPA), a systematic literature review was undertaken. The primary objective of this review was to collect randomised controlled trial (RCT) data on the efficacy, impact on quality of life, safety, and tolerability of all available treatments for EGPA. Secondary objectives were to collect similar endpoint data in observational-study or single-arm trials.

Methods: The review was undertaken to meet the requirements of the National Institute for Health and Care Excellence (NICE), the Centre for Reviews and Dissemination's Guidance for Undertaking Reviews in Health Care, the Cochrane Collaboration and Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) reporting methods. Searches were conducted in electronic databases (PubMed, Embase, Cochrane and BIOSIS); conference abstracts (EULAR; ACR), and trial registry sites. Searches were not limited by date, language, or geographical location. The quality assessment of each RCT was performed to standards recommended by NICE and Cochrane guidance. The quality assessment of each observational study was performed using the Critical Appraisal Skills Programme (CASP) Cohort Study or Case-Control Study checklists.

Results: A total of 1,063 records were selected for manual screening. After the initial screening of titles/abstracts, 217 publications were progressed for further screening. 57 articles were included after the second screening, and an additional data-on-file article was added. The review identified five RCTs that assessed various treatments in EGPA (e.g. mepolizumab, prednisone, immunosuppressants). Most RCTs included a small sample of patients (n=30-136); therefore, the conclusions derived regarding the efficacy and safety of the treatments are limited. Twenty-one prospective studies were included with seven different comparators treatments. Generally, the treatments identified in the prospective studies were effective in inducing remission, reducing relapse rates, and reducing corticosteroid use in patients with EGPA, but maintenance treatments were limited in their efficacy. In many of the studies, there was no comparative arm and low numbers of patients with EGPA (n=3-118), and the outcomes reported were not consistent, making it hard to draw definitive conclusions on the effectiveness of many of the therapies for EGPA. Of the 30 retrospective studies that assessed

treatments in EGPA, 26 were single-arm. Most patients received other medications in combination with the treatments of interest, and as there was no control arm in all but three studies, the interpretation of outcomes is limited.

Conclusion: The clinical evidence for treatments of EGPA is sparse with many trial featuring small sample sizes, inconsistent reporting of outcomes, open trial designs, or lack of comparators. Additional RCTs would be beneficial to further evaluate treatment efficacy in patients with EGPA, particularly in relation to outcomes such as symptom scores, steroid sparing, and HRQOL due to the minimal amount of data available from the included RCTs.

An Economic Systematic Literature Review of Eosinophilic Granulomatosis with Polyangiitis

Scott Doyle¹, Emily Moss², Louise Hartley², Chris Knight², Judith Bell², Outi Ahdesmäki² and Maebh Kelly³, ¹Value Evidence and Outcomes, GlaxoSmithKline, London, United Kingdom, ²RTI Health Solutions, Manchester, United Kingdom, ³Pope Woodhead, London, United Kingdom

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Vasculitis – ANCA-Associated Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: To better understand the available economic evaluations in eosinophilic granulomatosis with polyangiitis (EGPA), a systematic literature review was undertaken. The primary objective of this review was to collect economic evidence including economic evaluations and models, cost-utility analyses, utility studies, and prospective and retrospective studies reporting costs or resource utilisation for patients treated for EGPA. Secondary objectives were to explore the natural history of EGPA.

Methods: The review was undertaken to meet the requirements of the National Institute for Health and Care Excellence (NICE), the Centre for Reviews and Dissemination's Guidance for Undertaking Reviews in Health Care, the Cochrane Collaboration, and Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) reporting methods. Searches were conducted in electronic databases (PubMed, Embase, Cochrane, BIOSIS, Econlit); conference abstracts (ISPOR; EULAR; ACR), and key international health technology assessment websites. Searches were not limited by date, language, or geographical location. Quality assessments were conducted on economic evaluations using the Drummond checklist in line with NICE requirements. Quality assessments were not conducted for other types of economic evidence.

Results: The databases yielded a total of 2,055 titles (439 duplicates), internet searches yielded 335, and hand-searching 12. After initial screening of abstracts, a total of 294 publications were progressed for further screening leaving 85 articles deemed acceptable for data extraction. Of the 85 studies identified:

- Only a single economic evaluation was identified which had limited applicability to the research question as it focused on the cost-effectiveness of pneumonia prophylaxis in Wegener's granulomatosis (WG);
- 31 studies reported health related quality of life or symptom burden outcomes (17 reported SF-36 Health Survey (SF-36), 4 reported Health Assessment Questionnaire (HAQ) outcomes, and 1 reported EQ-5D outcomes);
- 22 reported cost and resource-use outcomes (14 studies reported medication usage, 9 studies reported productivity lost, 4 studies reported on impact of disease on income, 3 studies reported resource use, 2 reported overall cost, and 1 study reported medication costs);
- 45 natural history studies were identified (18 reported the outcome 'achieved remission', and 26 reported relapse rates. 34 of the studies reported all-cause mortality; 14 studies reported EGPA-related mortality).

Conclusion: This systematic literature review has identified many gaps in the literature regarding EGPA and its treatments, particularly in economic evaluations. This is perhaps not surprising, given that EGPA is a rare disease with limited treatment options. Of the studies identified there was a considerable amount of heterogeneity. The lack of standardised data collection methods makes the synthesis of economic evidence in EGPA challenging.

A 24 Month Analysis of Rituximab Safety and Efficacy in Eosinophilic Granulomatosis with Polyangiitis

Vítor Teixeira¹, Aladdin Mohammad¹, David Jayne¹, Vítor Teixeira¹, Aladdin Mohammad¹ and David Jayne, ¹¹Department of Medicine, University of Cambridge, Cambridge, United Kingdom, ¹Rheumatology Department, CHLN - Santa Maria Hospital, Lisbon Academic Medical Center, Lisbon, Portugal, ¹Rheumatology, Department of Clinical Sciences, Lund, Lund University, Lund, Sweden

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Vasculitis – ANCA-Associated Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Eosinophilic granulomatosis with polyangiitis (EGPA) frequently pursues a refractory course leading to high glucocorticoid exposure and toxicity. A previous retrospective study found rituximab (RTX) to result in remission in a proportion of patients with refractory and relapsing EGPA, but the observation time was limited to 12 months (M) and the report focused on response to a single course. We aim to report a two years evaluation of RTX efficacy and safety in a cohort of EGPA patients with relapsing or refractory disease.

Sex F/M	44/25
Age at first RTX, median (IQR)	51 (39.5-58.0)
ANCA, number of patients (%)	
Positive (including IF)	24 (34.8)
Negative (including IF)	45 (65.2)
Positive C- or P-ANCA (only IF)	20 (29.0)
PR3-ANCA	9 (13.0)
MPO-ANCA	16 (23.2)
Number of prior immunosuppressive therapies: Mean ± SD; Median (IQR)	2.37 ± 1.46; 2 (1-3)
Immunosuppressive drugs prior to RTX, number of patients (%)	
Cyclophosphamide	34 (49.3)
Azathioprine	46 (66.7)
Mycophenolate mofetil	39 (56.5)
Methotrexate	17 (24.6)
Intravenous immunoglobulin	11 (15.9%)
Sulfasalazine	1 (1.4)
Alemtuzumab	3 (4.3)
Etanercept	1 (1.4)
Infliximab	2 (2.9)
Mepolizumab	1 (1.4)
Omalizumab	1 (1.4)
DEI score at first RTX treatment, mean ± SD	8.8 ± 2.4
BVAS at first rituximab, mean ± SD; median (IQR)	7.05 (±5.22); 6 (3-8.5)
Organ involvement according to DEI, number of patients (%)	
Lung (including asthma)	68 (98.6)
Ear, nose and throat	61 (88.4)
Arthralgia/Arthritis	32 (46.4)
Skin	41 (59.4)
Peripheral nervous system	40 (58)
Renal	11 (15.9)
Gastrointestinal tract (including biliary system)	12 (17.4)
Heart	15 (21.7)
Eyes	8 (11.6)
Central nervous system	3 (4.3)
Urogenital tract	2 (2.9)
Refractory asthma	46 (66.6%)
Refractory ENT disease	23 (33.3%)
Eosinophilia at diagnosis	60 (87)

Mean relapses/person	0.9 ± 1.27	
Percentage of patients who suffered relapse(s)	53.6%	
Median time to relapse after RTX start	ANCA negative: 21 months (95% CI 13.37 to 28.63) ANCA positive: 33 months (95% CI 9.57 to 56.43) $\chi^2(2) = 2.166, p = .141$.	
Median time to relapse after RTX suspension	ANCA negative: 6.4 months (95% CI 0 to 24.5) ANCA positive: 13.6 months (95% CI 0 to 49.6) $\chi^2(2) = 1.497, p = .22$	
Manifestations driving relapse during RTX treatment, mean relapses/person (% persons who suffered at least one relapse)		
Asthma/Lung	0.68 ± 1.13	(43.5%)
ENT	0.17 ± 0.38	(17.4%)
Skin	0.26 ± 0.8	(13.0%)
Kidney	0	(0)
Heart	0.03 ± 0.169	(2.9%)
Joint	0.16 ± 0.41	(14.5%)
Digestive	0.03 ± 0.17	(2.9%)
Number of patients who suffered a severe infection, N (percentage)	11 (15.9%)	
Severe infections/patient, mean ± SD	0.25 ± 0.60	
Type of infections, N (%)		
Respiratory tract	12 (71%)	
Urogenital tract	3 (17.6%)	
Mastoiditis	1 (5.9%)	
Cellulitis	1 (5.9%)	

Methods: Retrospective analysis of single-center cohort of EGPA patients who received RTX and standardised data collection of baseline clinical characteristics, disease activity (Birmingham Vasculitis Activity Score(BVAS)), eosinophilia, prednisolone (PDN) dose and serious infections over the two years from first RTX treatment. Remission was defined as a BVAS of zero and partial response as a $\geq 50\%$ reduction in BVAS compared with baseline. Relapse was an increase in BVAS and in PDN dose $\geq 5\text{mg/day}$ or institution of i.v. corticosteroids or new DMARD.

Results: 69 patients were identified and 54 received > 12 months treatment (Table 1). Remission at 6 and 12 months after RTX was achieved in 40.6% and 49.3% of patients, respectively, and increased at 18 and 24 months in those patients who received repeat dose RTX (Figure 1). Median time to remission was less in the ANCA positive group. RTX led to a median decrease in the BVAS of 4 at 12 M and of 6 at 24 M ($p < .0005$). At 12 months there was a median decrease of 5 mg/day in the PDN dose and of 7.25 mg/day at 24 months. No differences were found in eosinophilia. During treatment, 53.6% of patients relapsed at least once (mean 0.9 ± 1.27 (SD) relapses/patient). Relapses were mainly driven by asthma (Table 2). Median survival time to relapse after RTX was less for ANCA negative patients. Severe infections occurred in 15.9% of patients during treatment, mainly derived from the respiratory tract (Table 2).

Conclusion: RTX led to overall decreases in disease activity and prednisolone requirements in our cohort with additional benefit from repeat dosing over 24 months. However, fewer than 50% achieved stable remission and there lapse rate was high, driven mainly by asthma. The risk of severe infections was consistent with previous studies of refractory vasculitis.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Vasculitis – ANCA-Associated Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: To compare clinical features at diagnosis, relapse rates, therapy as well as long-term outcome of a cohort of patients with Eosinophilic Granulomatosis with Polyangiitis (EGPA) based on their ANCA status.

Methods: This study was conducted as a retrospective analysis of EGPA patients who were treated between 2008 and 2017 in a tertiary referral center. Diagnosis for EGPA was based both on American College of Rheumatology criteria and Chapel Hill definitions. Patient characteristics, clinical manifestations, organ involvement, therapy regime, relapse rates and follow-up outcomes were evaluated and compared in sub groups based on ANCA status.

Table 1. Clinical features, relapses and therapy regimen

	PR3-ANCA positive	MPO-ANCA positive	ANCA negative	Total	p-value
No. of patients (n=55)	1	5	49	55	
Female sex	1	2	27	30	
Age (mean)	40	55.8	46.75	47.45	
Asthma	1	5	47	52 (94.5%)	n/a
Eosinophilia	1	3	46	49 (89.9%)	0.10
Neuropathy	1	4	21	26 (47.3%)	0.03

Follow-up time [mean]	32	38.8	32.69	33.23	
	32	0-111	0-115	0-115	
Relapse free up to year	22.5	8	41.53	34.88	
	25	0-15	0-99	0-99	

Table 2. Specific organ involvement in lung, heart and other manifestations

	PR3-ANCA positive	MPO-ANCA positive	ANCA negative	Total
Lung				
Asthma	1	5	47	53
Pulmonary infiltrates	1	2	35	38
Alveolar haemorrhage	0	0	2	2
Heart				
Perimyocarditis	0	0	8	8
Hypertension	0	0	2	2
Arrhythmia	0	0	1	1
Coronariitis	0	0	1	1
Myocarditis	0	1	4	5
Pericardial effusion	0	1	2	3
Congestive heart failure	0	0	1	1
Necrotizing myocarditis	0	0	1	1
Not specified	0	0	2	2
Other				
Polyserositis	0	0	1	1
Myositis	0	0	2	2
GI symptoms	0	1	4	5
Raynaud's	0	0	2	2
Muscle fascitis	0	0	1	1
Eosinophilic colitis	0	0	1	1
Mediastinal lymphadenopathy	0	0	1	1

Results: Six ANCA-positive (5 with MPO-ANCA, one with PR3-ANCA) and 49 ANCA-negative patients were included overall. Patients were followed up for a median \pm SD of 33.2 (\pm 32.7 SD) months. The most common clinical features (table 1 and 2) were asthma (94.5%), ear, nose and throat (ENT) manifestations (74.5%), pulmonary infiltrates (69.1%), peripheral neuropathy (47.3%) and skin lesions (38.1%).

ANCA-positive patients had a higher incidence of peripheral neuropathy (83.3% vs. 42.8%) and glomerulonephritis (33.3% vs. 0%). ANCA-negative patients had more frequent cardiac involvement (44.8% vs. 33.3%). Relapse rates were significantly higher in ANCA-positive patients (83.3% vs., 36.7%). Severe relapses also occurred more often in ANCA-positive patients (33.3% vs. 8.1%). Initial eosinophil count did not predict severity both at diagnosis or relapse.

Interestingly, three patients suffered from a major relapse with peripheral neuropathy while presenting normal eosinophil counts. All ANCA-positive patient had severe disease and required induction therapy with cyclophosphamide or rituximab either at diagnosis or at the time of a severe relapse. Among the ANCA-negative patients, 67.3 % had no severe manifestations and were successfully treated with a combination of glucocorticoids and conventional immunosuppressants like methotrexate and azathioprine.

Conclusion: Our observations support recent reports showing that the ANCA status of EPGA patient is both relevant for clinical manifestations as well as relapse rates and relapse severity. ANCA-positive patients often require a more aggressive immunosuppressive therapy than ANCA-negative patients.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Vasculitis – ANCA-Associated Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: While prior studies have demonstrated that granulomatosis with polyangiitis (GPA; Wegener's) is associated with an altered composition of nasal bacteria and that use of an antibiotic may reduce the risk of relapse, no studies have evaluated the role of nasal fungi in GPA. It has been suggested that fungi may stabilize bacterial communities and interact with the immune system. Using deep sequencing methods, this study evaluated the composition of nasal fungi in GPA compared to healthy controls and examined interactions between nasal fungi and bacteria.

Methods: Fungal internal transcribed spacer (ITS) and bacterial 16S rRNA gene sequencing were performed on DNA isolated from nasal swabs of 60 participants with GPA and 41 healthy controls. Main results of bacterial DNA sequencing were previously reported. Total fungal content was determined by PicoGreen-quantification. Using Wilcoxon rank sum test and generalized linear models, the abundance of total fungi and the most abundant fungal taxa (*Malasseziales*) were compared in GPA vs controls as well as within GPA subgroups: disease activity according to the BVAS/WG, ANCA type, sinonasal damage, and use of medications (immunosuppressants and antibiotics). Correlation in the abundance of fungi and bacteria were assessed using Spearman's correlation coefficient.

Results: *Malasseziales* was the most abundant fungal taxa present followed by the genera *Penicillium* and *Aspergillus*. There was a non-significant trend towards lower abundance of total fungi in GPA vs controls ($p = 0.06$). When evaluating the most abundant taxa *Malasseziales*, we found a significantly lower abundance of *Malasseziales* in GPA vs controls ($p = 0.04$) and this difference was most pronounced in the group with active GPA which had a significantly lower abundance compared to GPA in remission ($p = 0.04$) and healthy controls ($p = 0.01$) (Figure 1). No associations were found among the other co-variables. There was significant positive correlation in the 5 most common bacterial species present in the samples and abundance of total fungi (Figure 2) as well as abundance of *Malasseziales* (data not shown).

Conclusion: The abundance of *Malasseziales* is significantly lower in the nasal mucosa of GPA vs controls and is associated with disease activity in GPA. Co-variation in the abundance of fungi and several bacterial species suggests fungi and bacteria may interact in the nose. These results support the possibility that commensal fungal communities and their interactions with bacteria may be involved in disease pathogenesis of GPA.

Figure 1. Differential abundance of *Malasseziales* between controls and patients with granulomatosis with polyangiitis (GPA) stratified by disease activity. Abundance of *Malasseziales* was significantly lower in GPA with active disease (red) compared to controls (blue) ($p = 0.01$) and GPA in remission (gray) ($p = 0.04$). No difference was seen between participants with GPA in remission and controls ($p = 0.19$).

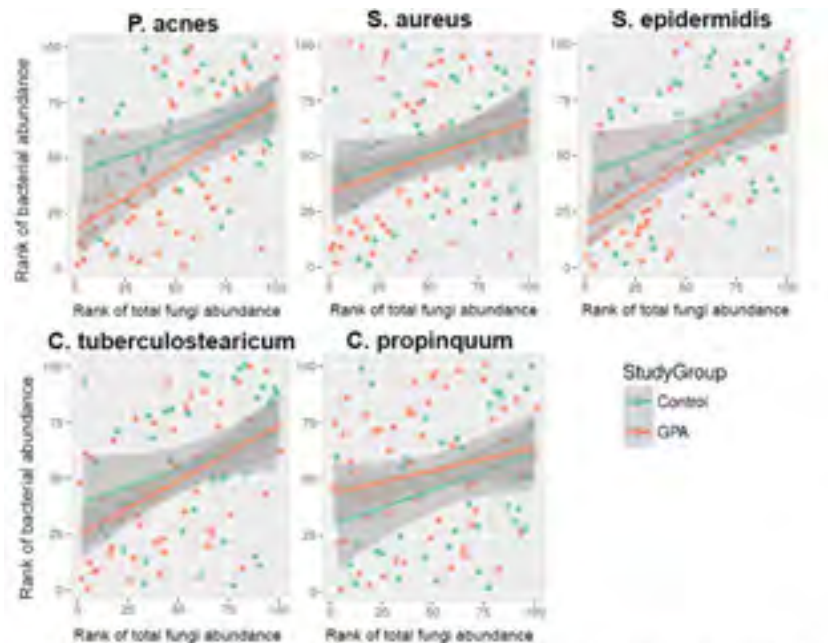

Figure 2. Abundance of total fungi is correlated with abundance of several types of bacteria, suggesting a possible interaction between fungi and bacteria. Among all participants, there was a significant correlation between abundance of total fungi and *Propionibacterium acnes* ($r = 0.51$, $p < 0.01$), *Staphylococcus aureus* ($r = 0.31$, $p < 0.01$), *S. epidermidis* ($r = 0.50$, $p < 0.01$), *Corynebacterium tuberculostrictum* ($r = 0.43$, $p < 0.01$), and *C. propinquum* ($r = 0.23$, $p = 0.02$). In linear regression models, fungi abundance remained independently associated with abundance of *P. acnes* and *S. epidermidis*, the same species which our group previously demonstrated have differential abundance in GPA vs controls. Similar findings were seen when examining abundance of *Malassezia* species. This suggests fungi may interact with nasal bacteria and these interactions may be involved in the disease process of GPA.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Vasculitis – ANCA-Associated Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: ANCA-associated vasculitis (AAV) are relapsing diseases with high morbidity and mortality. The vascular damage present in these patients requires continuous repair with the participation of the endothelial progenitor cells (EPC). The circulating EPC have a fundamental role in angiogenesis, repair and vascular homeostasis. These cells isolated from peripheral blood generate in vitro endothelial colony-forming cells (ECFC) that have high proliferative capacity and stable phenotype throughout the culture. It is believed that there is a deficiency of the EPC's repair capacity in AAV. There are no studies on the functional capacity of EPC and ECFC in AAV. Understanding the functional disturbances of EPC in AAV patients will result in a better knowledge of its pathogenesis and possible future therapeutic targets. The aim of the study was to evaluate the functional capacity of ECFC in patients with AAV in vitro through angiogenesis and migration assays.

Methods: Patients with a previous diagnosis of AAV without immunosuppression for at least 18 months and healthy controls were selected. First, we isolated ECFC from peripheral blood and characterized them by flow cytometry (FACS). After expansion, we evaluated angiogenesis on Matrigel™ plates and ECFCs migration capacity. For angiogenesis, ECFC were evaluated and photographed 15 and 24 hours after the preparation. The ECFC migration was performed by the scratch (wound-healing assay) methodology and photographed hourly in an phase-contrast microscope using the Aviocam 506zen 2Pro, for 24 hours after the scratch. The images obtained in both experiments were analyzed using the Image J® software. All the tests consisted of the evaluation of ECFC from patients, healthy controls and human umbilical vein endothelial cells (HUVEC), performed in triplicate.

Results: Peripheral blood was collected from 12 patients diagnosed with AAV. The collection of 7 of these patients was performed at the diagnosis, 5 with granulomatosis with polyangiitis (GPA) and 2 with eosinophilic granulomatosis with polyangiitis (EGPA). The other 5 patients were on follow-up and without immunosuppression for at least 18 months and had a maximum prednisone dose of 10mg daily, three of which were diagnosed with GPA, one with EGPA and one with microscopic polyangiitis (MPA). Success in the isolation and growth in ECFC culture was obtained in 8/12 (66%) of the cases. ECFC from GPA patients had lower rates of migration compared to healthy controls and HUVEC ($p=0.002$ and $p=0.0079$, respectively). ECFC from patients with AAV had a higher angiogenesis capacity as shown by a significantly higher number of structures (meshes, nodes and junctions) when compared with ECFCs from healthy controls ($p=0.0023$, $p<0.00001$ and $p=0.0371$, for each structure) and HUVEC ($p=0.00001$, $p=0.0001$ and $p=0.056$).

Conclusion: These findings suggest distinct functional profiles in ECFC from patients with AAV, which could influence disease pathogenesis.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Vasculitis – ANCA-Associated Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: C3, the central protein of the complement cascade, participates in an amplification loop that can lead to complement deposition and host tissue damage. If elevated, downstream C3 activation products, including C3a and iC3b, can reflect an underlying tissue inflammation and potential disease activity, such as previously demonstrated in lupus nephritis. Complement 5a, which is preceded by iC3b in the complement cascade, and its receptor C5aR (CD88), are involved in the pathogenesis of anti-neutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV). This study examined plasma iC3b levels as a biomarker of active disease in AAV.

Methods: Data and plasma samples from patients with AAV enrolled in a prospective multicenter longitudinal cohort were utilized for this analysis. The index visit was defined as a time of severe active disease with any new/worse major item, or

Figure 1. Box plots of ln iC3b levels by visit type

³³ minor items, on the BVAS/WG. Plasma iC3b levels were measured at 1-2 visits prior to, and at 1-2 visits after the index visit; all pre and post index visits were at time of remission (BVAS/WG=0). To evaluate the association of the plasma iC3b levels with disease activity, a mixed effect model was used with the biomarker measurement as the outcome, adjusting for ANCA type (c-ANCA/MPO or p-ANCA/PR3), sex, age, race, time to index, and visit type (pre- or post-index). Plasma iC3b levels were log transformed for all analyses.

Results: Data from 110 patients with active AAV were included. 89% of the patients were Caucasian, and 66% were female. 80% of the patients had GPA with c-ANCA/PR3 positivity, with a median disease duration of 4.1 years at baseline (range 0.2 - 23.8 years). The median Ln (iC3b) at the time of active disease was 1.3 µg/ml (range 0.0 - 4.5 µg/ml). Plasma for measurement of iC3b levels were available for 147 pre-index visits and 161 post-index visits.

In an adjusted mixed effects model where plasma iC3b level served as the dependent variable, the mean plasma iC3b level at index visit (active disease) was not higher than the mean plasma iC3b level at pre-index visit ($p=0.17$) or at post-index visit ($p=0.37$) (Table 1 and Figure 1). In the same adjusted mixed effects model, patients positive for p-ANCA/MPO, had higher levels of plasma iC3b compared to patients positive for c-ANCA/PR3 ($p<0.01$). Plasma iC3b levels increased for each one year increase in age ($p=0.05$) (Table 2).

Conclusion: In AAV, plasma iC3b levels are not associated with disease activity. Older patients and patients with positive p-ANCA/MPO have higher levels of plasma iC3b, possibly indicating increased systemic inflammation in these patients. Total number of characters: 2241

Session Date: Monday, October 22, 2018

Session Title: Vasculitis – ANCA-Associated Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: To explore the mechanisms by which an altered gut microbiota might predispose to ANCA-associated vasculitis (AAV), a comprehensive metabolic profiling of fecal and plasma bile acids, amino acids, and short chain fatty acids was performed in patients with AAV (granulomatosis with polyangiitis; microscopic polyangiitis; and eosinophilic granulomatosis with polyangiitis) and in healthy controls.

Methods: Using cross-section a land longitudinal designs, the fecal and plasma metabolomes of patients with newly diagnosed AAV (active and in remission) were compared to chronic AAV(active and in remission), and to healthy controls. All samples were collected using standardized methods, and analyzed by Liquid Chromatography/Mass Spectrometry for bile acids, amino acids, and short chain fatty acids. The gut microbiome was analyzed on the same fecal samples by sequencing the bacterial 16S rRNA gene (V1-V2 region). The association between bacterial tax a and fecal metabolites was studied using logistic regression models, correcting for multiple comparisons. Bacterial taxa were tested if their mean abundance was >1%.

Results: 78 fecal samples were studied: 37 active AAV (20 new diagnosis and 17 chronic), 25 remission, and 16 controls. 32 plasma samples were studied: 20 active AAV, 6 remission, and 6 controls.

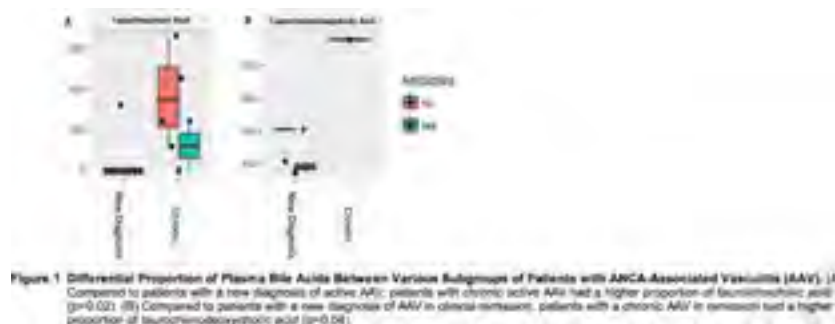

Compared to remission states, the fecal amino acid sphenylalanine and tyrosine were significantly diminished in active disease. Patients with chronic AAV in remission had higher levels of plasma phenylalanine and tyrosine compared to patients with a new diagnosis of AAV in remission ($p=0.02$ for both).

There was no statistical difference in fecal bile acids between the disease states of AAV. Patients with a chronic active AAV had higher levels of plasma tauroolithocholic bile acid compared to patients with an active new diagnosis of AAV (**Figure 1A**). *Faecalibacterium* was found to be associated with this plasma bile acid ($p=0.02$). Plasma glycholic and glycodeoxycholic acids were strongly associated with active disease ($p<0.01$ and $p=0.01$ for both).

Patients with chronic AAV in remission had higher levels of plasma taurochenodeoxycholic bile acid compared to patients with a new diagnosis of AAV in remission (**Figure 1B**). *Phascolarctobacterium*, *Sutterella*, and *Ruminococcus* were found to be associated with this plasma bile acid ($p<0.05$).

There was no statistical difference in plasma or fecal short chain fatty acids.

Conclusion: Active AAV is associated with an altered fecal and plasma metabolome. Plasma taurochenodeoxycholic bile acid, and plasma and fecal amino acids are higher in chronic remission states compared to new diagnosis remission states, suggesting potential anti-inflammatory effects of these metabolites. Diminished metabolic diversity may be a feature of active AAV and potential biomarker to predict disease activity in AAV.

Abstract Number: 1764

The Utility of Serum Angiopoietin-1 and Angiopoietin-2 in Patients with Anti-Neutrophil Cytoplasmic Autoantibody-Associated Vasculitis

Yoko Wada¹, Takeshi Kuroda², Masaaki Nakano³ and Ichiei Narita¹, ¹Division of Clinical Nephrology and Rheumatology, Niigata University Graduate School of Medical and Dental Sciences, Niigata, Japan, ²Health Administration Center, Niigata University, Niigata, Japan, ³Department of Medical Technology, School of Health Sciences, Faculty of Medicine, Niigata University, Niigata, Japan

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Vasculitis – ANCA-Associated Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Angiopoietin-1 (Ang-1) and Angiopoietin-2 (Ang-2) are antagonistic ligands which bind with similar affinity to the extracellular domain of the tyrosine kinase with Ig-like and epidermal growth factor-like domains 2 (Tie-2) receptor, which is almost exclusively expressed by endothelial cells. Ang-1/Tie-2 signalling maintains vessel integrity, inhibits vascular leakage, suppresses inflammatory gene expression and prevents recruitment and transmigration of leukocytes. In contrast, binding of Ang-2 disrupts protective Ang-1/Tie-2 signalling and facilitates endothelial inflammation. The purpose of this study is to examine the serum Angpt1 and Angpt2 levels in patients with AAV, and explore the utility as biomarkers.

Methods: Seventy-one patients who had been diagnosed as AAV and referred to Niigata University Medical and Dental Hospital between 2009 and 2017, were participated in this study. Serum Ang-1 and Ang-2 levels were measured by enzyme-linked immunosorbent assay, before the initiation of remission-induction therapy. Laboratory findings, disease activity using Birmingham vasculitis activity score (BVAS) at the time of diagnosis, and patients' kidney and overall prognosis at August 2017, were corrected from patients' clinical records. The correlations between these findings and serum Ang-1, Ang-2 levels, and Ang-1/Ang-2 ratio were analyzed by Spearman correlation coefficient and stepwise multiple regression analysis. A value of $p < 0.05$ was taken to indicate statistical significance.

Results: In Spearman correlation coefficient analysis, serum Ang-1 was positively correlated with estimated glomerular filtration ratio (eGFR) ($r=0.3979$, $p=0.0006$) and C-reactive protein (0.2574 , $p=0.0302$), and negatively correlated with serum creatinine (Cr) ($r=-0.3438$, $p=0.0033$), initiation of dialysis therapy ($r=-0.2559$, $p=0.0312$), and death ($r=-0.3057$, $p=0.0095$). Serum Ang-2 was positively correlated with age ($r=0.2466$, $p=0.0382$), BVAS ($r=0.3090$, $p=0.0087$), serum Cr ($r=0.3945$, $p=0.0007$), and negatively correlated with eGFR ($r=-0.4278$, $p=0.0002$). The Ang-1/Ang-2 ratio was positively correlated with eGFR ($r=0.5715$, $p<0.0001$), and negatively correlated with age ($r=-0.2359$, $p=0.0476$), BVAS ($r=-0.3456$, $p=0.0032$), Cr ($r=-0.5234$), 24-hour urinary protein excretion ($r=-0.2863$, $p=0.0155$), initiation of dialysis therapy ($r=-0.3251$, $p=0.0057$), and death ($r=-0.2556$, $p=0.0314$). In stepwise multiple regression analysis, eGFR was selected as a positive independent variable for serum Ang-1 levels ($\beta=0.4138$, $p=0.0003$) and Ang-1/Ang-2 ratio ($\beta=0.4305$, $p=0.00017$), whereas initiation of dialysis therapy was selected as a positive independent variable ($\beta=0.2803$, $p=0.033$), and UP/Cr ($\beta=-0.3908$, $p=0.0043$) and eGFR ($\beta=-0.4897$, $p=0.0001$) were selected as negative independent variables for serum Ang-2 levels.

Conclusion: These findings showed the protective effect of kidney functions for Ang-1 and the utility of Ang-2 as a predictive factor for kidney prognosis.

Cerebrospinal Fluid Biomarker of Disease Activity: Significance in ANCA-Related Hypertrophic Pachymeningitis

Yasuhiro Shimojima¹, Dai Kishida² and Yoshiki Sekijima², ¹Department of Medicine Neurology and Rheumatology, Shinshu University School of Medicine, Matsumoto, Japan, ²Department of Medicine Neurology and Rheumatology, Shinshu University School of Medicine, Matsumoto, Japan

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Vasculitis – ANCA-Associated Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Hypertrophic pachymeningitis (HP), which becomes the cause of chronic headache, seizure, and cranial neuropathy, is an inflammatory disorder demonstrating focal and diffuse thickening of dura mater. It has been recognized that ANCA-associated vasculitis is the underlying disease as the common cause of HP whose histopathology indicates inflammatory cells infiltration and granulomatous lesion as well as fibrosis; meanwhile, definite immune-mediated mechanism is still elusive. In this study, we demonstrated the useful cerebrospinal fluid (CSF) biomarkers in ANCA-related HP (ANCA-HP).

Methods: We reviewed the clinical records of 22 Japanese patients with immune-mediated HP (mean age, 65 years; 9 women and 13 men). They were divided into patients with ANCA-HP (n = 11), or those with other autoimmune disorders related HP (other HP) including IgG4-related disease/multifocal fibrosclerosis (n = 4), relapsing polychondritis (n = 1), sarcoidosis (n = 2), and idiopathic HP (n = 4). HP associated with infection and/or neoplasm was excluded in this study. As the controls, 11 patients with multiple sclerosis (MS) and 8 with non-inflammatory neurological disorders (NIND) were enrolled. The routine laboratory examinations of serum C-reactive protein (CRP) levels and CSF, including cell counts, protein levels, and IgG-index were detected. In addition, B-cell activation factor of the TNF family (BAFF) and a proliferation-inducing ligand (APRIL) in the CSF and serum samples were measured using commercially available ELISA kits. To determine the characteristics of ANCA-HP, the laboratory data from them were statistically compared between patients with ANCA-HP, other HP, and controls.

Results: CSF levels of BAFF and APRIL were significantly higher in patients with both ANCA-HP and other HP than in patients with MS and NIND ($p < 0.05$). Serum levels of BAFF and APRIL were significantly higher in patients with both ANCA-HP and other HP than in patients with NIND ($p < 0.05$). In patients with both ANCA-HP and other HP, neither BAFF nor APRIL expression indicated no correlation between in the CSF and serum, suggesting that BAFF and APRIL were locally produced within the central nervous system (CNS). Meanwhile, both BAFF and APRIL expression in the CSF significantly demonstrated the correlation with IgG-index in patients with ANCA-HP ($p < 0.05$). In patients with other HP, BAFF and APRIL expression in the CSF had significant correlation with cell counts and protein levels ($p < 0.05$).

Conclusion: BAFF and APRIL expression in the CSF is associated with disease activity as the immunological biomarker in immune-mediated HP. Furthermore, it was suggested that increased levels of BAFF and APRIL produced in the CNS may impact on developing ANCA-HP by promoting the B cell lineage.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Vasculitis – ANCA-Associated Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Cardiovascular (CV) events are highly prevalent in patients with systemic necrotizing vasculitides (SNV). The visceral/subcutaneous adipose tissue (VAT/SAT) ratio has been shown to be associated with CV events in various diseases. Using prediction scores, we found elevated VAT/SAT ratios to be associated with higher CV risk in SNV patients. However, no prospective data are available to confirm those findings for incident major CV events (MCVE).

Methods: Patients with ANCA-associated vasculitides or polyarteritis nodosa (PAN) were successively included in a longitudinal study assessing CV complications and other sequelae. At inclusion, DXA evaluation of body composition and abdominal adipose tissue (SAT and VAT) was obtained. Patients were prospectively followed for MCVEs, defined as myocardial infarction, unstable angina, stroke, arterial revascularization and/or hospitalization for or death from CV causes.

Results: Among the 120 patients enrolled (54 men; mean age 53 ± 18 years; median disease duration: 54 months), at inclusion, 28 (23%) had high CV risk, including 16 (13%) with preexisting CV disease, 11 (9%) with diabetes and 9 (8%) with a Framingham CV risk score $\geq 20\%$. Age and VAT/SAT ratio were independently associated with high CV risk. Framingham CV risk score was correlated with the VAT/SAT ratio ($r^2 = 0.36$, $P < 0.0001$). Also, the high VAT/SAT-ratio tertile (according to gender-specific tertiles) was associated with age and metabolic risk factors.

After median follow-up of 42 months, 19 (16%) patients experienced MCVE: arterial revascularization for 6 (including 4 with myocardial infarction or unstable angina), stroke for 5, hospitalization for CV causes for 5 and 3 CV-caused deaths. The highest VAT/SAT ratio was significantly associated with higher cumulative incident MCVE ($P < 0.0001$; log rank test and log rank test for trend). Hazard ratios (95% CI) for incident MCVE compared with 1st tertile were 7.22 (1.02-51.3; $P = 0.048$) and 9.90 (3.15-31.2; $P = 0.0002$) in the 2nd and 3rd tertile, respectively (Fig). In contrast, age > 65 years (HR 1.98 [0.72-5.43]; $P = 0.19$) and body mass index > 30 kg/m² (HR 1.37 [0.41-4.61]; $P = 0.61$) were not associated with higher cumulative incident MCVE. The VAT/SAT ratio remained associated with incident MCVEs even for only patients > 65 years ($P = 0.07$, log rank test; and $P = 0.03$ log rank test for trend) (Fig).

Conclusion: This study shows a significant association between a high DXA-assessed VAT/SAT ratio and incident MCVE in SNV patients. The VAT/SAT-ratio prognostic value remained significant even for patients > 65 years. Abdominal adipose tissue should be probably be evaluated routinely in these patients to assess CV risk.

Koster⁴, ¹Internal Medicine, Mayo Clinic, Rochester, MN, ²Pathology, Mayo Clinic, Rochester, MN, ³Health Sciences Research, Mayo Clinic College of Medicine and Science, Rochester, MN, ⁴Rheumatology, Mayo Clinic, Rochester, MN, ⁵Rheumatology, Division of Rheumatology, Mayo Clinic College of Medicine, Rochester, MN

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Vasculitis – ANCA-Associated Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: This study aimed to characterize the presenting features and outcomes of patients with small- or medium-vessel vasculitis and gastrointestinal perforation.

Methods: Using a retrospective cohort design, we identified cases with verified granulomatosis with polyangiitis (GPA), eosinophilic GPA (EGPA), microscopic polyangiitis (MPA), or polyarteritis nodosa (PAN) by ACR criteria along with confirmed gastrointestinal perforation at our institution between 1998 and 2017. The standardized mortality ratio (SMR) was estimated using persons of the same age, sex, and calendar year derived from United States white population life tables.

Figure 1. Overall survival of entire cohort (solid) compared to expected (dashed)

Results: Over the twenty year time period, 20 total patients with small or medium-vessel vasculitis experienced bowel perforation. Three had EGPA, 11 GPA, three MPA, and three PAN. Four of the twenty cases experienced vasculitis-induced perforation. Cases with perforations due to vasculitic involvement had more small bowel involvement, longer duration of abdominal pain prior to perforation (41 days vs 0 days, $p = 0.005$), and a higher proportion of active tobacco use (75% vs 7%, $p = 0.01$) compared to the cases with non-vasculitis perforation. A majority (88%) of the non-vasculitis-induced perforations were associated with glucocorticoid use. The median cumulative glucocorticoid dose at perforation in patients with additional, non-vasculitic risk factors for perforation was 4,320 mg prednisone and was 22,170 mg for those without such risk factors. Mortality rates for the whole cohort were higher than the general population (SMR 2.19, 95% confidence interval 1.05 to 4.02, Figure 1). The cases with vasculitis-induced perforation tended to have increased number of surgeries and length of stay; however, those differences failed to reach statistical significance.

Conclusion: In patients with known history of vasculitis, small bowel location and longer abdominal pain duration may help distinguish vasculitis-induced bowel perforation from other etiologies. Overall mortality in patients with vasculitis and bowel perforation is increased, highlighting the importance of a high index of suspicion and prompt management.

Kidney Involvement, Poor Performance Status, and Higher Cumulative Dose of Glucocorticoid Are the Risk Factors of the Discontinuation of Immunosuppressant in Patients with Antineutrophil Cytoplasmic Antibody Associated Vasculitis

Takamasa Murosaki, Takeo Sato, Katsuya Nagatani and Seiji Minota, Department of Internal Medicine, Division of Rheumatology/Clinical Immunology, Jichi Medical University, Shimotsuke, Japan

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Vasculitis – ANCA-Associated Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The use of immunosuppressant (IS) with glucocorticoid is recommended as remission induction treatment for severe cases with antineutrophil cytoplasmic antibody (ANCA) associated vasculitis (AAV). However, we sometimes experience the discontinuation of IS due to its adverse event. We examined the clinical characteristics of patients with AAV who received IS treatment to identify the risk factors of the discontinuation of IS.

Methods: We retrospectively analyzed the clinical data of patients with AAV from 2005 to 2016. The clinical data included patients-demographics, the use of IS, the adverse event of IS, the cumulative dose of glucocorticoid until the start of IS, and the continuity of IS. The definition of discontinuation of IS was switch to glucocorticoid-single therapy, switch to another IS, or delay of IS re-administration due to the adverse event of IS. First IS used for remission induction treatment was analyzed in each patient. Activity of daily living was assessed by performance status (PS) proposed by Eastern Cooperative Oncology Group. The survival of IS use was estimated by Kaplan-Meier method, and the difference between the survival curves was statistically analyzed by log rank analysis.

Figure 1. The survival curve of immunosuppressant use in patient with or without kidney involvement.

Figure 2. The survival curve of immunosuppressant use according to performance status.

Figure 3. The survival curve of immunosuppressant use according to the cumulative dose of glucocorticoid.

Results: We found 162 patients with AAV, and 50 patients were treated with IS for remission induction treatment. Among 50 patients, 26 patients experienced the discontinuation of IS due to its adverse event. The use of IS were as follows: intravenous cyclophosphamide 34, oral cyclophosphamide 11, methotrexate 4, and cyclosporine 1. Kaplan Meier analysis showed significant differences in the survival rate of IS use between patients with or without kidney involvement (30.0% vs. 58.2%, $p = 0.008$, Figure 1), between PS scores with 0 to 2 and 3 to 4 (48.8% vs. 20.0%, $p = 0.029$, Figure 2), and between the cumulative doses of glucocorticoid of less and more than 1500 mg (70.3% vs. 17.7%, $p < 0.001$, Figure 3) at 6 months.

Conclusion: This study showed that kidney involvement, poor PS, higher cumulative dose of glucocorticoid until the start of IS were the risk factors of the discontinuation of IS. We suggest that physicians should pay attention to these factors to reduce the risk of discontinuation of IS when treating patients with AAV using IS.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Vasculitis – ANCA-Associated Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Though rituximab(RTX) has become a standard of care for remission induction and maintenance in Granulomatosis with Polyangiitis(GPA), there is very limited data on the efficacy and safety of biomimic RTX in GPA. The purpose of this study was to analyse the efficacy and safety of biomimic RTX in GPA since these drugs are widely used in various developing countries due to their lower costs.

Methods: The details of GPA patients diagnosed according to the ACR/EMA criteria who received biomimic RTX from July 2009 to May 2018 for remission induction or maintenance were analysed retrospectively. Patients achieving complete remission (BVAS-v3 =0) at 6, 12 and 24 months was noted. The details of relapses, infections and deaths were also noted.

Results: Out of 184 GPA patients seen during the study period, 56 (30.43%) received biomimic RTX. The baseline characteristics of the study population are given in table 1. Forty five patients (80.36%) received biomimic RTX for remission induction (primary induction in 20 and re-induction in 25) and 43(76.79%) received biomimic RTX maintenance. Mean BVAS-v3 at the start of induction with biomimic RTX was 14.63 (SD 10.37). Complete remission at 6,12 and 24 months was achieved in 71.43%, 71.43% and 85.71% respectively. Mean BVAS-v3 at 6 , 12 and 24 months was 1.22 (SD 2.46), 1.02 (SD 2.28) and 0.45 (SD 0.98) respectively. Fifteen relapses were noted in 13 patients. Average time to first relapse was 10.15 months. 18 episodes of infections were noted in 17 patients (30.36%). The infections noted were UTI in four; sepsis in three; hepatitis C and superficial mycosis in two patients each; pulmonary tuberculosis, bacterial pneumonia, lung abscess, aspergilloma, H1N1 influenza, pyomyositis and bacterial nasal septal abscess in one patient each. Mean duration of follow up on biomimic RTX therapy was 23.66 months (SD 18.25). Seven patients (12.5%) died during follow up. The cause of death was disease activity in four and sepsis in three patients. Of the four patients who died due to disease activity, three died at the time of presentation and the fourth died within two months of biomimic RTX initiation.

Conclusion: Biomimic RTX is effective in controlling disease activity in patients with GPA. Infections though common were treatable in most of the patients.

Table 1. Characteristics of 56 GPA patients receiving biomimic rituximab

Characteristics	Numbers	Percentage (%)
Number of GPA patients	184	
No. of patients receiving biomimic rituximab	56	30.43

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Vasculitis – ANCA-Associated Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Damage to the large airways is a devastating complication of granulomatosis with polyangiitis (GPA). Identification of patient sub sets at particular risk for airway disease and development of non-invasive screening methods to detect tracheobronchial disease is an unmet need in GPA. This study aimed to characterize patients with subglottic stenosis (SGS) and bronchial disease and test whether dynamic expiratory-phase CT is useful to detect airway damage in patients with GPA.

Methods: i) A retrospective analysis of a multi-center cohort of patients with GPA identified demographic and clinical features associated with the presence of SGS or endobronchial involvement; ii) A sub set of patients with GPA underwent a dynamic chest CT at a single center, assessed by a central reader blinded to clinical status. Differences were assessed by the chi square test and ANOVA with post-hoc Tukey test to account for multiple comparisons.

Results: Data from 962 patients with GPA from 9 centers were used for the initial phase analyses. As outlined in Table 1, SGS was identified in 95 (10%) patients with no differences in ANCA subtype in patients with SGS compared to the overall cohort. Patients with SGS were more likely to be female (72% vs 53%, $P < 0.01$), younger at time of diagnosis (36 vs 49 years, $p < 0.01$), and less likely to have constitutional, cardiovascular, renal, or nervous system involvement. Among 95 patients in the cohort within nasal septal perforation and saddle nose deformities, 28 (29%) and 27 (30%), respectively, also had SGS.

Endobronchial disease was seen in 59 (6%) patients. Compared to the full cohort, patients with endobronchial involvement were younger at time of diagnosis, more likely to have ENT involvement and be PR3-ANCA positive (78% vs 63%, $p = 0.02$), but less likely to be ANCA-negative (0% vs 9%, $p = 0.02$) or have renal disease. There was no association between endobronchial involvement and sex. Patients with SGS were more likely to have endobronchial involvement. Concomitant SGS and endobronchial involvement (25 patients) was not associated with sex (60% vs 55% female, $p = 0.60$).

Six of ten patients screened by dynamic chest CT had large-airway pathology. Isolated SGS was confirmed by imaging in two female patients. Previously unknown tracheobronchomalacia was discovered in 4 patients, including one male patient thought to have isolated SGS.

Conclusion: Both SGS and endobronchial disease are moderately common in GPA and each manifestation is associated with various other aspects of GPA. SGS is more commonly seen in female patients with GPA, whereas bronchial

involvement is not associated with sex. There should be a low threshold to evaluate airway disease in GPA, especially in younger patients, and those with destructive sinonasal disease. Dynamic expiratory phase chest CT is a potential non-invasive screening test for tracheobronchial disease in GPA.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Figure 1. Graft and patient survival

Session Title: Vasculitis – ANCA-Associated Poster I

Session Type: ACR Poster Session B

Session Time: 9:00am-11:00am

Background/Purpose: Rapidly Progressive Glomerulonephritis (RPGN) is characterized histology by presence of crescents and clinically by rapid and severe decline in kidney function. Thus, it may lead to an end stage renal disease (ESRD), with renal transplantation (RT). RPGN can be primary, with no extra-renal involvement (RPGN-renal-limited), or secondary to systemic autoimmune disorders (RPGN-SAD), infections or drugs. RT in RPGN-SAD may be associated to a worse outcome. In a series of patients with first RT due to RPGN our aim was to assess: **a)** long-term post-transplant survival (PTS) in RPGN-SAD, **b)** comparison of PTS between RPGN-SAD and RPGN-renal-limited and **c)** comparison of both RPGN(SAD and renal-limited) with a control group of non-immunological disorder, the polycystic kidney disease (PCKD).

Methods: We studied 3 groups: **a)** RPGN-SAD (granulomatosis with polyangiitis (3), microscopic polyangiitis (6), Good pasture syndrome (2)), **b)** RPGN-renal-limited and **c)** PCKD (control). All were transplanted in a single reference University Hospital. Main outcome variables were: **a)** graft and patient PTS up to 20 years and **b)** evolution of renal function (serum creatinine and proteinuria) in the first 5 years. Cumulative survival rates after RT were estimated by the Kaplan-Meier method and compared between groups with the log-rank test. Kruskal-Wallis or chi²/Fisher's exact tests were used to compare quantitative or qualitative variables, respectively.

Results: We included 100 patients with RT: **a)** RPGN-SAD group (11), **b)** RPGN-renal-limited group (32), and **c)** PCKD group (57). There were no significant differences at baseline between the two RPGN groups in sex, age and cardiovascular risk factors. RPGN group showed higher cholesterol levels than PCKD at the time of RT ($p=0.041$) with no other significant differences. Renal biopsy had been performed in the 43 patients with RPGN: types I (27.9%), II (4.7%) and III RPGN (41.9%); 25.6% had not classified RPGN (no immunofluorescence was performed at the time of the biopsy). From 89 patients (of 100) in which a renal biopsy was performed during the first-year post-transplant, rejection was found in 33 patients (37.1%) with no significant differences between the 3 groups (5 cases in RPGN-SAD group, 11 in RPGN-renal-limited group and 17 in PCKD group; $p=0.592$). Evolution of serum creatinine and the proteinuria after the transplant is shown in TABLE 1. There were no significant differences between the 3 groups in serum creatinine, graft and patient PTS.

Conclusion: RT could be the best option in ESRD due to RPGN regardless of systemic manifestations.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Vasculitis Poster II: Behçet's Disease and IGG4-Related Disease

Session Type: ACR Poster Session B

Session Time: :00AM-11:00AM

Background/Purpose: Behçet's disease (BD) is characterized by recurrent oral and/or genital ulcers accompanied by ocular, cutaneous, articular, gastrointestinal, and/or neurologic manifestations. Oral and/or genital aphthous ulcers are often refractory to conventional treatment. Apremilast is an orally-active small molecule which inhibits phosphodiesterase-4 (PDE-4) that modulates some inflammatory pathways. Our aim was to assess the efficacy and safety of apremilast in BD patients with oral and/or genital ulcers refractory to conventional treatment.

Methods: National multicenter open-label study on 37 BD patients treated with apremilast at maintained standard dose of 30 mg twice daily, with the initial 5-day titration schedule in 31 cases. The main outcome was achievement of oral and/or genital ulcers remission. The diagnosis of BD was performed according to the proposed International Criteria for BD (1990) in 30 patients and according to the recently proposed criteria (2014) for BD in the rest of cases.

Results: We included 37 patients (26 women/11 men), mean age of 43.4±12.9 years. Before apremilast, all patients had received several systemic conventional drugs: oral corticosteroids (34), colchicine (36), methotrexate (21), azathioprine (20), mycophenolate mofetil (1), cyclosporine (7), dapsone (5), adalimumab (10), infliximab (5), tocilizumab (3), etanercept (1), and/or golimumab (1). The main clinical symptoms for starting apremilast were oral aphthous ulcers (36) and genital ulcers (22). Other manifestations present at apremilast onset were folliculitis/pseudofolliculitis (9), arthralgia/arthritis (8), asthenia (7), furunculosis (2), paradoxical psoriasis by TNFi (2), deep venous thrombosis (2), erythema nodosum (1), erythematous and scaly skin lesions (1), ileitis (1) and fever (1). None of the patients presented visual

manifestations at apremilast onset. TABLE shows the evolution of the patients. After a median follow-up of 6 [interquartile range, 4.5-11.5] months, most of the patients experienced clinical improvement. In this period of time, 26 patients developed any side-effect, most of them mild and during the first 3 months of treatment: nausea (10), diarrhea (10), dyspepsia (5), abdominal pain (5), headache (5), loss of appetite (4), weight loss (1), halitosis (1) and dry mouth (1). Four patients had to reduce the dose to 30 mg/day. Apremilast was discontinued in 10 patients due to: not obtaining the expected improvement (5), intense gastrointestinal adverse effects (3), desire of pregnancy (1) and development of neurological involvement (1).

Conclusion: Apremilast leads to a rapid and maintained improvement in many patients with refractory mucocutaneous ulcers of BD. Even in patients refractory to several systemic drugs including biologic therapy.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Vasculitis Poster II: Behçet's Disease and IgG4-Related Disease

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Uveitis is one of the major causes of disability of Behçet's disease (BD). According to the "Expert panel recommendations" (Ophthalmology. 2014; 121:785-96), anti-TNF therapy with infliximab (IFX) or adalimumab (ADA) may be considered as first- or second-line therapy for patients with ophthalmic manifestations of BD. Our aim was to compare IFX versus ADA as first biologic drug in refractory uveitis due to BD for 1-year period.

Methods: Multicenter study of BD-associated uveitis refractory to conventional non-biologic treatment. Dosing schedule was: IFX: 3-5 mg/kg iv at 0, 2 and 6 weeks and then every 4-8 week, and ADA: 40 mg/sc/every other week without loading dose. The main comparative outcome measures were safety and efficacy, assessing the intraocular inflammation, macular thickness, visual acuity, degree of immunosuppression load, drug retention, and glucocorticoid-sparing effect.

Results: 177 patients (316 affected eyes) were included. IFX was used in 103 cases and ADA in 74. No significant differences at baseline were observed between IFX vs ADA groups regarding main demographic features, previous therapy and ocular severity. After one year of therapy, we observed an improvement in all ocular parameters in both groups; IFX vs ADA groups: AC inflammation (78.18% vs 92.31%; p=0.06), vitritis (78.95% vs 93.33%; p=0.04), retinal vasculitis (97% vs 95%; p=0.28), macular thickness (264.89±59.74 vs 250.62±36.85; p=0.15), and BCVA (0.67±0.34 vs 0.81±0.26; p=0.001). Drug withdrawal was observed in 57 (55.33%) of IFX group and in 21 (28.37%) of ADA group; p<0.01. TABLE 1 shows main baseline features and follow-up of both groups.

Conclusion: After one year of therapy in refractory BD-associated uveitis, ADA showed a statistically better outcome than IFX in improvement of BCVA, vitritis and drug retention.

Table 1. Main baseline features and follow-up of a series of 177 patients with refractory uveitis due to Behçet's disease undergoing infliximab (IFX) or adalimumab (ADA) therapy

	IFX group (N=103)	ADA group (N=74)	p
Number of patients/affected eyes, (n/n)	103/185	74/131	
Age, mean (SD) years	40.4 (10.1)	38.7 (11.3)	0.29
Sex, men/women, n/n	55/48	39/35	0.92
HLA-B51 positive, (%)	69.4	68.9	0.74
Duration of uveitis before anti-TNFα, median [IQR] months	36 [12-72]	24 [12-60]	0.69

Table 1. (Cont'd)

	IFX group (N=103)	ADA group (N=74)	p
Ocular features at the time of anti TNF- α onset			
AC cells, median [IQR]	1 [0-2]	1 [0-2]	0.25
Vitritis, median [IQR]	1 [0-2]	1 [0-2]	0.12
BCVA, mean (SD)	0.50 (0.35)	0.56 (0.34)	0.08
Macular thickness, mean (SD)	331.11 (131.97)	346.37 (136.14)	0.49
Presence of retinal vasculitis, n (%)	114 (58)	78 (55)	0.51
Presence of choroiditis, n (%)	41 (21)	10 (7)	<0.01
Pattern of uveitis, n (%)			
Bilateral	82 (79.61)	57 (77.03)	0.68
Unilateral	21 (20.39)	17 (22.97)	0.68
Anterior	11 (10.68)	14 (18.92)	0.19
Posterior	28 (27.18)	14 (18.92)	0.19
Panuveitis	64 (62.14)	45 (60.81)	0.19
Intermediate	0 (0)	1 (1.35)	0.19
Treatment before anti TNF- α onset, %			
Oral corticosteroids	95	88	0.08
Intravenous pulses of MP	31	31	0.98
CsA	75	78	0.65
AZA	57	42	0.049
MTX	44	42	0.77
Other treatments	3.84	1.92	0.41
Prednisone dose at anti TNF- α onset, mean (SD), mg/d	54.35 (15.84)	53.37 (17.52)	0.37
Combined treatment, %	76.5	70.3	0.35
AZA	21.8	19.2	
CsA	41.1	55.7	
MTX	33.3	21.1	
CFM	1.3	0.0	
MMF	1.3	3.8	
FK-506	1.3	0.0	
Follow-up on anti TNF α therapy, mean (SD), months	31.52 (23.51)	26.48 (18.57)	0.13
Remission, n (%)	78 (76.47)	61 (82.43)	0.34
Relapses, mean (SD)	1.13 (2.62)	1.66 (8.62)	0.61
Drug withdrawal, n (%)	57 (55.33)	21 (28.37)	<0.01
remission, n (%)	20 (19.41)	6 (8.45)	0.58
inefficacy, n (%)	18 (17.47)	11 (14.86)	0.09
severe side-effects/toxicity, n (%)	8 (7.76)	4 (3.88)	0.58
others, n (%)	11 (10.68)	0 (0)	0.03
Serious side-effects, n (per 100 patients/year)	4 (1.48)	4 (2.46)	0.40

The Relationship between Serum Cholinesterase, Dickkopf-1 and Number of Organ Involvement in Japanese Patients with IgG4-Related Disease

Hirofumi Nishikawa¹, Yoshinori Taniguchi¹, Satoshi Inotani¹, Mitsuhiro Kawano² and Yoshio Terada¹, ¹Endocrinology, Metabolism, Nephrology and Rheumatology, Kochi Medical School Hospital, Nankoku, Japan, ²Division of Rheumatology, Kanazawa University Hospital, Kanazawa, Japan

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Vasculitis Poster II: Behçet's Disease and IgG4-Related Disease

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: To evaluate the relationship between serum cholinesterase (ChE) level, number of organ involvement, serum fibrotic markers and imaginal outcomes in Japanese patients with IgG4-related disease (IgG4-RD).

Methods: The clinical symptoms, laboratory, pathological and FDG-PET/CT findings of Japanese patients with IgG4-RD (n=20) were assessed. Several laboratory data of IgG4-RD with multiple organs' involvements (IM) (n=10), IgG4-RD with limited organ's involvement (IL) (n=10), ANCA-associated vasculitis (AAV) (n=10) and Sjogren syndrome (SjS) (n=10) were comparatively examined. Furthermore, we studied the relationship between the numbers of organ involvement (NOI), several fibrotic markers (ELF score and serum Dickkopf-1 (Dkk-1)) and imaginal outcome in IgG4-RD group.

Results: Serum ChE levels were significantly lower in IM group than IL, AAV and SjS groups. In total IgG4-RD cases, ChE levels inversely correlated with NOI and fibrotic score, and fibrotic score positively correlated with NOI. Finally, Dkk-1, one of Wnt inhibitors, levels in IM were significantly lower than IL and healthy subjects ($p<0.05$). Moreover, low level of Dkk-1 before and after treatment could predict the progression of organ atrophy.

Conclusion: The ELF score and serum Dkk-1 level might be clinically useful indicators of active fibrosis and the extent of IgG4-RD. Notably, continuous lower levels of Dkk-1 were related to organ atrophy and serum ChE levels could predict these phenomena.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Vasculitis Poster II: Behçet's Disease and IgG4-Related Disease

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: IgG4-related disease (IgG4-RD) is a chronic fibro inflammatory condition that can affect almost any organ. Gold standard for diagnosis, biopsy, can shows lymphoplasmacytic infiltration, storiform fibrosis, obliterative phlebitis and IgG4+ plasma cell infiltrate. High serum IgG4 levels is observed only in 50% of patients. Disease is more frequent in males, around 60 years old, affecting one or multiple organs with sub acute development of tumors or organomegaly. Lymphadenopathies are common, and 40% of patients have a history of allergies. Umehara's diagnostic criteria (2012), based on clinical features, serum IgG4 levels and histopathology are the most accepted. Disease was described in 2003, and Chilean reports are scarce.

We describe clinical, laboratory, histopathology findings, and treatment on Chilean IgG4-RD patients.

Methods: We analyzed retrospectively clinical records of 48 patients with IgG4-RD from nine medical centers. Patients with possible, probable and definitive diagnosis, according to Umehara criteria, were included.

Results: Our cohort was 56% male, with a mean age of 52 (18-76) years. Histological confirmation of IgG4-RD was obtained in 44 of 45 patients who underwent a biopsy. Twenty-three percent of patients had allergic background, 27% had eosinophilia and 43% had elevated plasma levels of IgG4 (≥ 135 mg/dl). The clinical involvement was: pleural and lung disease 38%, kidney 27%, orbital pseudotumor 25%, lymphadenopathy 21%, retroperitoneal fibrosis 19%, aortitis 19%, sialoadenitis 17%, pancreas 17%, pericardium 15% and meninges in 8%. There were three patients with hypophysitis and two with mediastinal fibrosis.

Multiple organ involvement (≥ 2 organs), observed in 69%, was significantly more frequently in males ($p < 0.05$). There was a statistically significant association between renal disease and low complement levels ($p < 0.01$). All patients who had renal or pulmonary disease had multiple organ involvement. Multiple organ involvement was not related with immunosuppressive treatment requirement.

Pathology confirmation, in 44 patients, showed: lymphoplasmacytic infiltrate in 43 (98%), storiform fibrosis in 29 (66%) and none had obliterative phlebitis. All tissues had diagnostic IgG4 (+) immunohistochemical staining. Storiform fibrosis was present in all lung and kidney biopsy, but only half of salivary gland, orbital and retroperitoneal tissue.

Regarding treatment, all patients received glucocorticoids. In 30 patients (63%) was required immunosuppressive treatment: azathioprine, followed by methotrexate and mycophenolate mofetil were drugs most used. Rituximab was used in 8 patients. Clinical response was good, but one patient dies because extensive mediastinal disease.

Conclusion: IgG4-RD in Chilean patients is similar that described elsewhere. In most of patients serum levels of IgG4 were normal, then biopsy was essential to diagnosis. Multiple organ involvement was frequent, being pleuropulmonary, kidney, orbital and lymph node most usual localizations. Renal and pulmonary localization occurred always in context of multi organic disease.

Clinical Significance of Allergy in IgG4-Related Disease

Xia Zhang¹, Panpan Zhang² and Wen Zhang³, ¹Rheumatology, Peking Union Medical College Hospital, Chinese Academy of Medical Science & Peking Union Medical College, Beijing, China, ²Rheumatology, Peking Union Medical College Hospital, Chinese Academy of Medical Science & Peking Union Medical College, Beijing, China, ³Rheumatology, Peking Union Medical College Hospital, Beijing, China

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Vasculitis Poster II: Behçet's Disease And IgG4-Related Disease

Session Type: ACR Poster Session B

Session Time: 9:00am-11:00am

Background/Purpose: IgG4-related disease (IgG4-RD) is a relatively newly defined disease entity, which can affect multiple organs and exhibit clinical heterogeneity. Recently, it has been reported that allergy was associated with the pathogenesis and clinical performance of IgG4-RD in some part. Still, little is known about the role of allergy in IgG4-RD, large cohort study is needed. We aim to investigate the role of allergy in IgG4-RD patients in the largest prospective IgG4-RD cohort in China.

Methods: Three hundred and ninety IgG4-RD patients who referred to Peking Union Medical College Hospital between January 2011 and April 2018 were enrolled. Using the definitions of the European Academy of Allergy and Clinical Immunology, we classified the subjects as either allergic or non-allergic. Clinical features of all the participants were collected and analyzed statistically.
