SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Sclerosis and Related Disorders – Clinical I: Clinical Trial Results & Insights

Session Type: ACR Concurrent Abstract Session

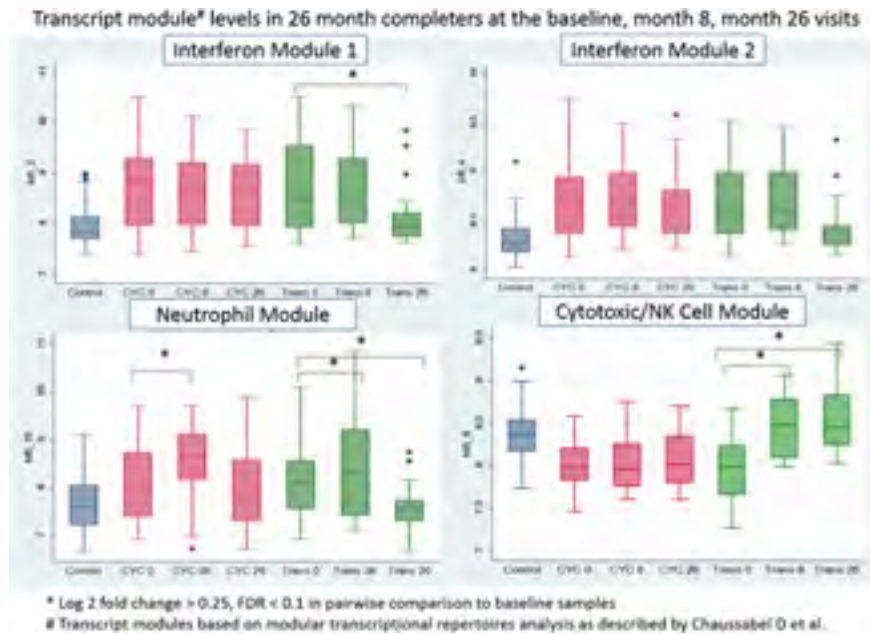

Session Time: 2:30PM-4:00PM

Background/Purpose: Myeloablation followed by autologous hematopoietic stem cell transplantation (HSCT) led to improved clinical outcomes compared to 12 monthly infusions of cyclophosphamide (CYC) in patients with severe diffuse systemic sclerosis (SSc) in SCOT trial¹. Global molecular studies in SSc patients undergoing HSCT have not been reported. Herein, we suggest that HSCT leads to changes in SSc related immune signatures after immune recovery at 26 month visit at the whole blood RNA and serum protein levels.

Methods: Sixty-two SCOT participants (HSCT= 27, CYC = 35) and 62-matched controls were investigated. Whole blood global transcript profiling and determination of 102 serum proteins in concomitantly collected serum samples were performed. All available samples at pretreatment baseline (n=62), 8 months (n=46), and 26 months (n=35) post-randomization were included.

Results: This subset of SCOT participants had a mean disease duration of 2.2 years and 93.5% of them had interstitial lung disease.

At the baseline visit, two interferon (IFN) and one neutrophil transcript modules were upregulated and the cytotoxic/NK module was down-regulated in comparison to controls. A paired comparison of the 26-month to the baseline samples revealed a significant decrease of the IFN and neutrophil modules and significant increase in the cytotoxic/NK module after HSCT but no significant change compared to baseline in the CYC recipients (Figure). Moreover, comparison of 26-month samples in the HSCT arm to healthy controls no longer showed upregulation of IFN or neutrophil modules or

downregulation of cytotoxic/NK module. A decline in the IFN and neutrophil modules was associated with an improvement in lung volumes and an increase in the cytotoxic/NK module correlated with improvement in the skin score at 26-month (Table).

Serum proteins correlating with the IFN and neutrophil transcript modules were identified. The serum protein IFN and neutrophil composite scores also decreased significantly at 26 months after HSCT (fold change (FC)=0.8, $p<0.001$; FC=0.85, $p=0.003$) while similar changes were not observed in the CYC arm at 8 or 26 months, confirming the gene expression level findings at the protein level.

Conclusion: In this first multilevel, global molecular study of HSCT in SSc, HSCT recipients contrary to CYC recipients had significant changes in SSc molecular signatures at both the RNA and serum protein levels at Month 26. The results at Month 26 provide an interim look, but need to be validated at the Month 54 primary endpoint.

Session Title: Systemic Sclerosis and Related Disorders – Clinical I: Clinical Trial Results & Insights

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Abatacept (ABA) is a recombinant fusion protein including extracellular domain of human CTLA4 and hinge-CH2-CH3 of the Fc domain of human IgG. This phase 2 trial assessed the safety and efficacy of ABA 125 mg subcutaneous (SC) versus placebo SC given every week on skin fibrosis using the modified Rodnan skin score (mRSS) in diffuse cutaneous SSc (dcSSc; clinicaltrials.gov NCT02161406).

Methods: A 12-month, investigator-initiated, double-blind, randomized placebo-controlled trial was conducted between 2014 to 2018 at 27 US, Canadian and UK sites. Eligible subjects were randomized in a 1:1 ratio to either ABA or matching placebo, stratified by duration of dcSSc (≤ 18 vs >18 to ≤ 36 months). Key inclusion criteria included dcSSc with disease duration of ≤ 36 months (defined as first non-Raynaud phenomenon) and mRSS ≥ 10 and ≤ 35 units for disease duration of ≤ 18 months and mRSS ≥ 15 and ≤ 45 units with evidence of active disease for disease duration of >18 -36 months. Escape therapy was allowed at 6 months for worsening SSc. Primary outcomes included safety and change in mRSS over 12 months (Δ mRSS). Secondary endpoints included Δ FVC%, Δ HAQ-DI, Δ patient and Δ physician global assessment, and ACR CRIS (composite measure in dcSSc). The primary endpoint of Δ mRSS was assessed using a linear mixed model with primary end point data censored after initiation of escape therapy.

Results: 88 subjects were randomized (44/group) and formed the mITT group; 34 (77%) and 35 (80%) completed the 12-month double-blind treatment period in ABA and placebo groups, respectively. At baseline, the mean age was 49 years, 75% were female, mean disease duration was 1.59 years, 60% had disease duration ≤ 18 months, mRSS was 22.4, mean FVC% was 85.3%, and mean HAQ-DI was 1.0. Compliance with both drugs was $>98\%$. ABA was well tolerated with comparable adverse events (AEs), serious AEs, and AEs of special interest (e.g., infections and malignancies) between treatments. There were 3 deaths during the treatment—2 in ABA (both scleroderma renal crisis-days 11 and 46) and 1 in placebo (sudden cardiac arrest- day 310). The primary endpoint showed an adjusted mean decrease of mRSS of -6.24 in ABA vs. -4.49 in placebo, $p=0.28$ (Table). The secondary outcome measures were statistically significant (HAQ-DI,

physician global assessment, and ACR CRISS) or showed numerical results favoring ABA (Table). A larger proportion of placebo subjects required escape immunosuppressive therapy vs. ABA (36% vs. 16%, $p=0.03$).

Conclusion: In patients with early dcSSc, ABA was well tolerated, but Δ mRSS was not statistically significant. Secondary outcome measures showed evidence in favor of ABA, including greater requirement of escape therapy in the placebo group. mRSS showed large variability, despite recruiting an early dcSSc population.

Outcome at Month 12	Abatacept N=44	Placebo N=44	Difference (ABA - Placebo)	P-value
Δ mRSS	-6.24	-4.49	-1.75	0.28
Δ Patient Global Assessment	-0.31	-0.09	-0.22	0.73
Δ Physician Global Assessment	-1.30	-0.35	-0.95	0.03
Δ FVC% predicted	-1.34	-4.13	2.79	0.11
Δ HAQ-DI	-0.17	0.11	-0.28	0.005
ACR CRISS index, Median (IQR)	0.68 (1.00)	0.01 (0.86)		0.03

Estimates are from a linear mixed model with treatment group, month (3, 6, and 12), treatment x month interaction, duration of dcSSc (≤ 18 vs >18 to ≤ 36 months), and baseline outcome measure as fixed effects and participant as a random effect (except for ACR CRISS). For ACR CRISS, the treatment differences, adjusted for duration of dcSSc, were assessed by the non-parametric Van Elteren test. Multiple imputation was used for CRISS analysis.

Session Title: Systemic Sclerosis and Related Disorders – Clinical I: Clinical Trial Results & Insights

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Scleroderma related interstitial lung disease (SLD) is a major cause of morbidity and mortality in severe systemic sclerosis (SSc). The Scleroderma: Cyclophosphamide or Transplantation (SCOT) trial) demonstrated that myeloablation followed by autologous hematopoietic stem cell transplant (HSCT) significantly improved event-free and overall survival of SSc patients at 54 months compared with 12 monthly treatments with intravenous cyclophosphamide (CYC) (Sullivan KM, *et al*, N Engl J Med 2018;378:35-47). The aim of the present study was to follow the changes in lung parenchymal abnormalities between baseline and serial follow-up high-resolution CT (HRCT) scans performed in SCOT participants at least yearly for up to 5 years.

Methods: Quantitative scores of SLD were measured using computer based quantitative image analysis of standardized non-contrast volumetric thin section thoracic HRCT. The same CT machine was used for all time points (except for one subject) with careful attention to breath hold reproducibility and image quality. Quantitative CT texture-based scores of disease-extent including Quantitative interstitial lung disease (QILD) and quantitative lung fibrosis (QLF) were derived from a previously described supervised texture classification model (Kim et al Clin Exp Rheumatol, 28 (5 Suppl 62) (2010), S26–S35). Mixed effect models with an interaction between treatment arms and duration were used to compare the changes from the baseline in QLF and QILD scores in whole lung (WL) and the most severe lobe (MSL). Spearman rank correlations were used to test the association between the changes in QLF and QILD versus pulmonary function tests (PFT) in the overall study population

Results: All 75 randomized subjects had baseline lung CT studies. Quantitative scores were calculated for subjects with available follow-up HRCT scans at 14, 26, 48, and 54 months. Baseline characteristics were not different between the two groups. WL QILD scores decreased significantly for the HSCT vs no change in CYC groups ($p=0.024$). There was a significant difference in WL increasing QLF in CYC vs stability in the HSCT arm ($p=0.047$). Changes in means (\pm SE) at 54 months in treatment completers were $-7\%(\pm 2)$ for HSCT and $0\%(\pm 5)$ for CYC in QILD, and $-1\%(\pm 1)$ for HSCT and $+3\%(\pm 3)$ for CYC in QLF. Similarly, significant differences in treatments were also found in MSL ($p=0.004$ in QILD and $p=0.002$ in QLF). The direction of change in structural measures of QILD and QLF for both WL and MSL tracked with physiologic PFT measures in the overall study population as shown in the table

Conclusion: Changes in quantitative lung CT scores of SLD provide independent validation of benefit of HSCT compared to CYC in severe SSc. Imaging improvements after HSCT continue for up to 54 months after randomization providing radiologic confirmation of long-term benefit.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Sclerosis and Related Disorders – Clinical I: Clinical Trial Results & Insights

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: The Scleroderma: Cyclophosphamide or Transplantation (SCOT) study established the long-term superiority of hematopoietic stem cell transplant (HSCT) over cyclophosphamide (CYC) [Sullivan KM, et al. N Engl J Med.378:35-47]. The primary endpoint, a global rank composite score (GRCS) at 54months, integrated multiple disease features, but is not a clinical score. Longitudinal trends in the GRCS components can identify changes in clinical progression. Because dropouts, death, or organ failure lead to early loss of subjects, analysis methods must account for data that are not “missing completely at random.”

Methods: Data are from 33 HSCT recipients and 34 who completed ≥ 9 CYC doses. Diffusing capacity of carbon monoxide (DLCO), forced vital capacity (FVC), the Disability Index of the Health Assessment Questionnaire (HAQ-DI), and the modified Rodnanskin score (mRSS) were evaluated regularly up to month 72. For each, trends are compared using a mixed model (MX) that assumes data for subjects lost prematurely continue on their observed trajectories. Joint longitudinal/survival shared-parameter (SP) models that assume missingness is not “ignorable” are used for sensitivity. Figures display trends for observed means and model based fixed effects.

Results: In both arms, observed means for FVC increase over time; as those with poor FVCs are lost, the means for “survivors” go up (Figure1, dotted line). After accounting for subject loss, trends differ between the treatments. For HSCT, after an expected initial fall, the mean increase per year after month 14 was 0.53 percentage points compared to -

Figure 1. Estimate trends for forced vital capacity by treatment arm
The x-axis indicates times for scheduled assessments; subjects available over time are above the axis. Dotted lines connect means for the observed data over fixed intervals among subjects with available data.

Figure 2. Estimate trends for modified Rodnan skin score by treatment arm
The x-axis indicates times for scheduled assessments; subjects available over time are above the axis. Dotted lines connect means for the observed data over fixed intervals among subjects with available data.

3.44 for CYC ($p=0.005$, MX). Trends for MX and SP models are similar for HSCT, but the SP model suggests an even greater fall for CYC.

mRSS declined exponentially over time in both arms. The yearly decay rate was 0.41 for HSCT and 0.26 for CYC ($p=0.05$, MX). In both arms, MX and observed trends track closely suggesting that trajectories are similar for those lost early and those completing follow up. Trends for SP models are similar with slower decay rates. (Figure 2)

DLCO and HAQ-DI trends are summarized in Table 1. :

Conclusion: Failure to account for early loss of longitudinal data may distort estimates of trends over time. Using two models, these analyses demonstrate the clinical superiority of HSCT over CYC for all components of GRCS even though mRSS improved in both arms.

Table 1. Model-based estimates for trend parameters

	Trend parameter [2]	Mixed Model (MM)			Shared Parameter Model (SP) [1]		
		HSCT	CYC	p-value	HSCT	CYC	p-value
FVC	change per month after month 14 (95% CI)	0.53 (-0.15, 1.21)	-1.44 (-5.98, -0.90)	0.006	0.61 (-0.25, 1.48)	-1.50 (-5.49, 1.49)	0.109
DLCO	change per month after month 14 (95% CI)	0.61 (-0.17, 1.21)	-1.25 (-3.55, -0.95)	0.001	0.43 (-0.35, 1.25)	-2.57 (-6.88, 1.74)	0.125
HAQ-DI	change per month after month 14 (95% CI)	-0.086 (-0.111, -0.032)	0.124 (-0.041, 0.287)	<0.001	-0.087 (-0.173, -0.011)	0.142 (-0.037, 0.237)	0.002
mRSS	decay rate per year (95% CI)	0.41 (0.29, 0.53)	0.29 (0.16, 0.35)	0.048	0.33 (0.21, 0.45)	0.16 (-0.07, 0.38)	0.022

Abbreviations: CI, confidence interval; DLCO, Diffusion Capacity Lung for Carbon Monoxide (% of predicted); FVC, Forced Vital Capacity (% of predicted); HAQ-DI, Health Assessment Questionnaire-Disability Index; mRSS, modified Rodnan skin score.

[1] Estimates from SP models tend to have less precision than MM models, because more parameters are being estimated, which reduces available degrees of freedom.

[2] For all endpoints, model-based means at month 54 favored HSCT, but all p-values for treatment comparisons were >0.05 except for mRSS (p-value=0.023).

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Sclerosis and Related Disorders – Clinical I: Clinical Trial Results & Insights

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: There are few disease-modifying therapies for the treatment of systemic sclerosis (SSc), particularly the more severe diffuse cutaneous form (dcSSc). The soluble guanylate cyclase stimulator riociguat showed antifibrotic effects in animal models and efficacy in patients with pulmonary arterial hypertension associated with connective tissue disease. It was therefore hypothesized that patients with dcSSc might benefit from riociguat therapy. We present results from the Phase IIb, multicenter, randomized, double-blind, placebo-controlled RISE-SSc study (NCT02283762), which investigated the efficacy and safety of riociguat in patients with early dcSSc.

Methods: Inclusion criteria were a diagnosis of SSc (fulfilling 2013 ACR/EULAR criteria) with diffuse cutaneous involvement (based on LeRoy criteria), disease duration ≤18 months, modified Rodnan skin score (mRSS) ≥10 and ≤22 units, forced vital capacity (FVC) ≥45% of predicted, and diffusion capacity of the lung for carbon monoxide ≥40% of predicted at screening. Patients were randomized to either placebo or riociguat individually adjusted from 0.5 mg up to 2.5 mg 3 times daily. The primary endpoint was change in mRSS from baseline to Week 52. Secondary endpoints included ACR Combined Response Index for Systemic Sclerosis (CRISS), Health Assessment Questionnaire-Disability Index (HAQ-DI), and change in FVC % predicted. A prespecified exploratory analysis investigating mRSS progression rate (increase in mRSS >5 units and ≥25% from baseline) and a post hoc analysis on prevention of lung function decline (FVC % predicted decline ≥10% absolute) were also performed. The primary endpoint was analyzed using mixed-model repeated measures including all mRSS assessments from baseline up to Week 52.

Results: In total, 121 patients (riociguat n=60, placebo n=61) were randomized (mean±SD age 51±12 years; 76% female). Baseline mRSS was comparable in riociguat and placebo groups (mean±SD 16.88±3.38 and 16.71±4.06, respectively). At Week 52, mean±SD mRSS was 14.63±6.56 for riociguat vs 15.73±10.48 for placebo (least squares mean treatment difference -2.34 [95% CI -4.99, 0.30; p=0.08]). The difference in mRSS progression rate showed significant effects favoring riociguat (riociguat - placebo: -18% [95% CI -33.57, -2.40; p=0.02, Mantel-Haenszel method]). The proportion of patients with ACR CRISP probability ≥0.60 (considered improved) at Week 52 was the same in both treatment arms (18%). Mean±SD change from baseline to Week 52 in other secondary endpoints for riociguat vs placebo: FVC % predicted, -2.38±7.52 vs -2.95±9.73; HAQ-DI, +0.05±0.38 vs +0.13±0.42, respectively. At Week 52, prevention of lung function decline was observed in 89% of riociguat patients vs 80% with placebo. Fewer serious adverse events occurred with riociguat vs placebo (15% vs 25%, respectively) and no new safety signals were observed.

Conclusion: The primary efficacy endpoint of mean change in mRSS did not reach statistical significance. Exploratory data suggest prevention of disease progression with riociguat in this early dcSSc population. Medical writing support was provided by Adelphi Communications Ltd, Bollington, UK.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Vasculitis – ANCA-Associated

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Potential therapy-related toxicities are important causes of morbidity in patients with the ANCA-associated vasculitides granulomatosis with polyangiitis (GPA) or microscopic polyangiitis (MPA). Long-term safety studies of rituximab in GPA/MPA are limited. This study characterized the safety of rituximab in a 4-yr observational registry of patients with GPA or MPA.

Methods: Analysis of RaVeR (NCT01613599), an open-label real-world study of adult patients with GPA or MPA receiving rituximab (dosing regimen determined by treating physician according to standard practice and discretion), was conducted after ≤ 4 yrs of observation or until withdrawal of consent, loss to follow-up or death. Adverse events (AEs) of interest included serious AEs (SAEs), serious infection events (SIEs), infusion-related reactions (IRR), serious cardiac or vascular events, and malignancies. Crude incidence rates and 95% CI were calculated.

Results: A total of 97 patients (338 patient-yrs [PYs]; median age 56.3 yrs; mean [SD] baseline VDI 2.0 [2.7]) received rituximab (mean of 8 infusions [range 1-28]). Median duration on study was 3.94 (range 0.05-4.32) yrs. 74% of patients completed the study. 91% of patients were ANCA-positive and 74% had GPA. 20% were receiving rituximab plus cyclophosphamide at baseline. During the study, 38 patients had 94 SAEs, 14 had 24 SIEs, and 10 had 17 serious cardiac events, most of which were arrhythmias (described in the existing label for rituximab; **Table 1**). Six patients had 8 serious

vascular events and 3 patients had malignancy-related events. There were no serious IRRs or SAEs within 24 hours of rituximab infusion. There were 9 deaths; none were considered by the treating physician to be related to rituximab. Causes of death included septic shock, interstitial lung disease, congestive heart failure, cardio-respiratory arrest, lung adenocarcinoma and 4 of unknown etiology. The severe disease flare (worsening disease activity prompting treatment) rate was 4.44/100 PYs (95% CI: 2.49-7.33). Among patients who received rituximab repeat treatment, the rates of SAEs (23.90/100 PYs) and SIEs (6.07/100 PYs) were not increased compared with the overall cohort.

Conclusion: In this cohort study there were no new safety findings related to the use of rituximab for GPA/MPA, and rates for any AE including SIEs, cardiovascular events, malignancies or fatal AEs did not increase over time with repeated rituximab infusions. These results are consistent with the known safety profile of rituximab in GPA/MPA and other autoimmune diseases in which rituximab is approved and provides clinicians with long-term, practice-level safety data.

Table 1 Observed Adverse Events of Interest Among Patients With GPA or MPA Receiving Rituximab

	Number of events	IR per 100 PY (95% CI)
All SAEs	94 in 38 pts (39%)	27.84 (22.50 to 34.07)
Serious infections	24 in 14 pts (14%)	7.11 (4.55 to 10.58)
Serious cardiac events	17 in 10 pts (10%)	5.03 (2.93 to 8.06)
Deaths	9 in 9 pts (9%)	2.67 (1.22 to 5.06)
Serious vascular events	8 in 6 pts (6%)	2.37 (1.02 to 5.96)
Malignancies	3 in 3 pts (3%)	0.89 (0.11 to 3.30)

GPA = granulomatosis with polyangiitis; MPA = microscopic polyangiitis; IR = incidence rate; PY = patient year; CI = confidence interval; SAE = serious adverse event

Session Title: Vasculitis – ANCA-Associated

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: The deregulated overproduction of interleukin (IL)-6 has been implicated in several inflammatory and antibody-mediated autoimmune diseases. We aimed to investigate serum IL-6 levels (sIL-6) during active disease, remission, and relapse in antineutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV), and to explore the association of changes in sIL-6 with repopulation of blood B cells and disease relapse.

Methods: sIL-6 levels were measured longitudinally over 18 months in 78 patients with AAV enrolled in a prospective, double-blinded, randomized, control trial comparing treatment with rituximab (RTX) (n=45) or cyclophosphamide (CYC)/azathioprine (AZA) (n=33). Outcome variables included baseline clinical features, ANCA type and titers, disease activity (status of active disease versus complete remission (CR)), time to B cell repopulation, relapse and severe relapse.

Results: Baseline sIL6 levels were detectable ($>0.49\text{pg/ml}$) in 81% of patients. At baseline, sIL-6 positively correlated with levels of proteinase (PR3)-ANCA ($r_s=0.36$, $p<0.01$), but not with levels of myeloperoxidase (MPO)-ANCA levels ($r_s=-0.17$, $p=0.47$). Higher baseline sIL-6 levels were associated with the presence of fever, pulmonary nodules/cavities, PR3-ANCA, conductive deafness and absence of urinary red blood cell casts ($p<0.05$ for all comparisons).

The median sIL-6 level was higher at baseline and promptly declined with induction therapy at following time-points (baseline, median [25%-75% IQR], 2.66 [0.76-20.98]; month 6th, 0.49 [0.49-1.16]; $p<0.01$) in a similar fashion in both treatment arms.

An increase in sIL-6, but not CRP, during clinical remission was a predictor for subsequent severe relapse in RTX-treated patients (Hazard Ratio (HR) 7.24, $p=0.01$), but not in CYC/AZA-treated patients (HR 0.62, $p=0.50$). In RTX-treated B cell depleted patients (CD19+ B cell/microliter <10), the rise of sIL-6 levels did not precede B cell reappearance, regardless of whether a cut-off of ≥ 10 CD19+B cell/microliter (HR=0.97; $p=0.97$) or of ≥ 69 CD19+B cell/microliter (HR=1.50; $p=0.41$) was considered.

Eighty percent of the patients who subsequently had a severe relapse in the RTX arm had B cell redetection before or at the time of the IL-6 increase, whereas, of the RTX-treated patients who did not have a severe relapse, 79% had B cell redetection but only 21% of those had B cell redetection before or at the same time of the sIL6 increase.

Conclusion: At baseline, sIL-6 correlates with PR3-ANCA titers and associates with specific clinical manifestations of AAV. A rise in sIL-6 levels, but not CRP levels, after complete remission is associated with subsequent severe relapse in RTX-treated patients. The observed discrepancies between treatments deserve confirmation and further study.

Session Title: Vasculitis – ANCA-Associated

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Although a link between gut microbiome and autoimmune diseases has been suggested, there is a gap in the understanding of the gut microbiome in ANCA-associated vasculitis (AAV). This study evaluated the gut microbiome in AAV (granulomatosis with polyangiitis (GPA), microscopic polyangiitis, and eosinophilic granulomatosis with polyangiitis) compared to healthy controls.

Methods: Using cross-sectional and longitudinal designs, the gut microbiome was compared among patients with i) newly-diagnosed AAV (active and remission); ii) chronic AAV (active and remission), and iii) healthy controls. Fecal samples were collected using standardized methods and analyzed by sequencing the bacterial 16S rRNA gene (V1-V2 region). Taxa with mean abundance $>1\%$ were compared using Wilcoxon rank sum test, correcting for multiple comparisons. Disease severity was assessed with the Birmingham Vasculitis Activity Score for Wegener's Granulomatosis (BVAS/WG). Effects of medications were studied using mixed effects models.

Results: 63 fecal samples were studied: 29 active AAV (15 new diagnosis/14 chronic), 20 in remission, and 14 healthy controls. Compared to controls, patients with active AAV had a different microbial composition ($p=0.01$). There was no statistical difference between the gut microbial composition of controls and patients in remission ($p=0.16$). The relative abundance of the taxa *Dialister* and *Prevotella* were different between active and remission AAV. The relative abundance of the genera *Faecalibacterium* and *Sutterella* were different between active and remission newly-diagnosed AAV (Figure 1A). The relative abundance of *Dialister* was significant in patients with high BVAS/WG compared to patients with low BVAS/WG ($p<0.01$) (Figure 1B). High BVAS/WG was associated with greater dysbiosis (Figure 2); similar results were

found in a multivariate linear model ($p=0.02$). The gut microbiome in patients with GPA on immunosuppressive agents was similar to controls ($p=0.54$), whereas the gut microbiome of patients with GPA not on these therapies was significantly different from controls; similar results were found with glucocorticoids and antibiotics use.

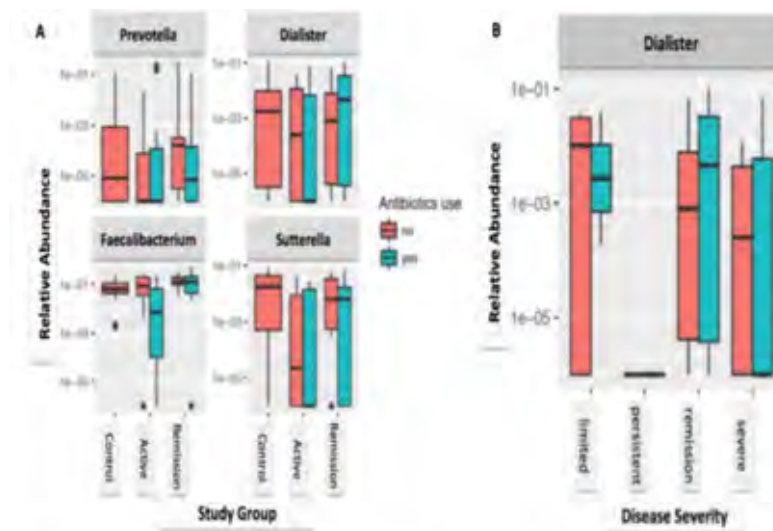

Figure 1. Bacteria with Differential Abundance Between Various Subgroups of Patients with ANCA-Associated Vasculitis (AAV). (A) Compared to patients with AAV in remission, patients with active AAV had a lower proportion of the taxa *Dialister* and *Prevotella* ($p=0.02$ and $p=0.03$, respectively and corrected for false discovery rate). Compared to patients with a new diagnosis of AAV in clinical remission, patients with a new diagnosis of active AAV had a lower proportion of the genera *Faecalibacterium* and *Sutterella* ($p=0.02$ and $p=0.05$, respectively, corrected for false discovery rate). (B) Compared to patients with less disease activity, patients with severe disease had a lower proportion of *Dialister* ($p<0.01$, corrected for false discovery rate).

Figure 2. Scatter Plot of BVAS/WG by Shannon Diversity Index in Patients with Active AAV. High BVAS/WG correlated with a greater gut microbiome dysbiosis (lower Shannon diversity index) in patients with active AAV (Pearson coefficient=-0.35; $p<0.01$).

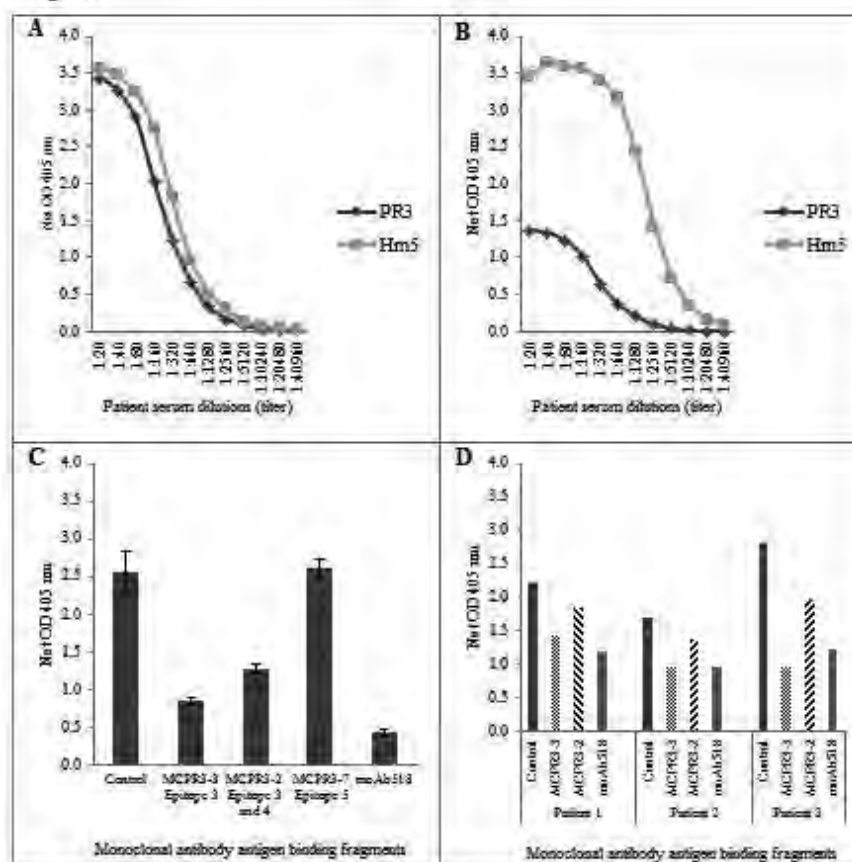

Conclusion: Active AAV is associated with an altered gut microbial composition. Patients in clinical remission have microbial composition similar to healthy controls. Immunosuppressive agents, glucocorticoids, and antibiotics may re-establish a healthy gut microbiome. Severe disease activity is associated with worsening gut dysbiosis suggesting a potential role of gut bacteria in the pathogenesis of AAV.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Vasculitis – ANCA-Associated

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Human-murine chimeric variants have been used to study specific epitope recognition by anti-neutrophil cytoplasmic antibodies (ANCAs) targeting proteinase 3 (PR3) in patients with ANCA-associated vasculitis. In prior work, a human-murine chimeric PR3 variant (Hm5) was generated by substituting the three human hydrophobic amino acids in Epitope 5 of PR3 by their murine hydrophilic counter parts.¹ Rather than loss of binding of PR3-ANCA to Hm5¹ we observed more avid binding of Hm5 by PR3-ANCAs compared with the mature conformation of PR3. Further studies were completed to better characterize this phenomenon.

Methods: Recombinant target antigens carrying C-terminal poly-HIS tags (PR3, Hm5, myeloperoxidase [MPO], human neutrophil elastase [HNE]) were anchored to nickel-coated plates and used for PR3- and MPO-ANCA detection. Serum samples were obtained from participants in the Wegener's Granulomatosis Etanercept (WGET) and in Rituximab versus Cyclophosphamide for ANCA-Associated Vasculitis (RAVE) trials. DNA barcode-enabled sequencing of the antibody repertoire of plasmablasts from 5 participants in the RAVE trial was performed, and 25 human monoclonal antibodies (moAb) were selected for recombinant expression and tested for reactivity with PR3, Hm5, MPO and HNE. Antigen-binding fragments (Fab) of anti-PR3 moAbs were used for inhibition.

Results: All PR3-ANCA positive samples reacted equally with or had increased recognition of Hm5 compared to PR3 (Figure 1A and 1B). In 2 of 52 serum samples from MPO-AAV patients included in RAVE, ANCA binding was detected when using Hm5 as antigen, but not when using PR3; all other samples were unreactive with either PR3 variant. All 25 human moAb derived from patient plasmablasts tested negative for reactivity with PR3, MPO and HNE, but one of these (moAb518) had strong selective reactivity with Hm5. The binding of moAb518 could be inhibited by Fabs from moAbs specific for Epitope 3, but not those specific for Epitope 5 where the 3 mutated residues of Hm5 are located (Figure 1C). The preferred binding of PR3-ANCA from patients to Hm5 could be reduced by inhibition with Epitope-3 specific Fabs in the same way as inhibition with moAb518 (Figure 1D).

Conclusion: (1) Hm5 can serve as an antigen for high sensitivity PR3-ANCA immunoassays. (2) The plasmablast-derived human moAb518 binds selectively to Epitope 3 on Hm5, indicating an unexpected mutational effect on Epitope 3 that is located on the opposite side of Epitope 5. (3) New studies are needed to explain how mutational effects of distal residues can affect conformational epitopes of an antigen.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Vasculitis – ANCA-Associated

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Eosinophilic granulomatosis with polyangiitis (EGPA) (Churg–Strauss) is a small-vessel necrotizing vasculitis characterized by blood and tissue eosinophilia and asthma. Glucocorticoids (GCs) effectively control the disease, but relapses and/or GC-dependence are frequent. Recently, efforts were made to improve nosology of EGPA patients. Evolving concepts tend to distinguish vasculitis-related symptoms from asthma and/or ENT manifestations. That distinction has become even more important, since the development of new targeted biotherapies. This study aimed to describe and identify characteristics predicting long-term EGPA outcomes.

Methods: We created a multicenter European collaborative initiative that included 257 EGPA patients from tertiary referral centers. Based on recent consensus, we distinguished 4 EGPA-evolutionary profiles: GC-dependent asthma and/or ENT manifestations (requiring prednisone >7.5 mg/d), at least 1 vasculitis relapse (excluding asthma and/or ENT manifestations), both phenotypes, and prolonged remission (no GC-dependent asthma/ENT signs and no vasculitis relapse). Baseline and follow-up characteristics predicting those outcomes were analyzed.

Results: After median follow-up of 60 months, 24% had GC-dependent asthma and/or ENT manifestations, 18% had at least 1 vasculitis relapse, 8% had both phenotypes, and 50% were in prolonged remission (Table). Patients with GC-dependent asthma/ENT manifestations were younger at diagnosis, had more frequent asthma requiring GCs before overt EGPA and pulmonary infiltrates, less frequent general symptoms and ANCA-positivity, and tended to have lower eosinophil counts. Their daily GC dose and eosinophil counts were higher at every time point; at last follow-up, they had more active asthma and less frequent neurological sequelae. In contrast, patients with only vasculitis relapse(s) had more frequent general symptoms at diagnosis, ANCA-positivity and higher BVAS, and less frequent pulmonary infiltrates. Median diagnosis-to-1st-vasculitis-relapse interval was 15 (9–42) months. During follow-up, their daily GC dose was lower than for those with GC-dependent asthma and/or ENT manifestations but similar to that of those in prolonged remission. At last follow-up, neurological sequelae were more frequent but active asthma less common. Finally, patients in prolonged remission were older, had less frequent asthma requiring GCs before EGPA, and lower daily GC dose and eosinophil counts during follow-up and less frequent sequelae.

Conclusion: Distinct baseline and follow-up characteristics defined 4 evolutionary EGPA profiles predicting patients' long-term outcomes. Each evolutionary pattern was identifiable soon after diagnosis, which would allow early choices of the best therapeutic option in the future.

Table

Characteristic	Evolutionary profile				P
	Prolonged remission (n=129)	GC-dependent asthma/ENT (n=62)	Vasculitis relapse (n=45)	GC-dependent asthma/ENT & vasculitis relapse (n=21)	
Age at diagnosis, yr	57 (44–67)	47 (36–58.2)	52 (44.5–66.5)	43 (31.5–52.2)	<0.0001
Asthma before EGPA	109/129 (84.5)	55/59 (93.2)	36/45 (80)	21/21 (100)	0.0498
Asthma duration, yr	5 (2.1–15.4)	5 (2–14.7)	3 (1–10.3)	2 (1–4.3)	0.02
General symptoms	102/129 (79.1)	41/62 (66.1)	39/45 (86.7)	13/21 (61.9)	0.03
Manifestation					
Cutaneous	45/129 (34.9)	24/62 (38.7)	22/45 (48.9)	8/21 (38.1)	0.43
ENT	91/129 (70.5)	48/62 (77.4)	35/45 (77.8)	15/21 (71.4)	0.67
Pulmonary	123/129 (95.3)	61/62 (98.4)	44/45 (97.8)	21/21 (100)	0.52
Infiltrates	74/129 (57.4)	38/62 (61.2)	19/45 (42.2)	17/21 (81)	0.024
Cardiac	39/129 (30.2)	25/62 (40.3)	16/45 (35.6)	7/21 (33.3)	0.57

SESSION INFORMATION

Session Date: Sunday, October 21, 2018
Session Title: Vasculitis – ANCA-Associated
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: Comorbidity is common in patients with ANCA-associated vasculitis (AAV). However, this comorbidity and its burden over time remains unexplored. In this large multicenter study, we aimed to compare the risk of a broad set of comorbid diseases in AAV patients with the general population and identify potential temporal changes in the risk of their occurrence.

Methods: AAV patients fulfilling European Medicines Agency criteria were identified at seven hospitals in Scotland. Each was matched with up to five controls in the general population by age (± 2 years), sex and geography. Diagnoses of selected comorbidities were retrieved from the Inpatient or Day Case Hospitalisations Database using International Classification of Disease codes. Cohorts were followed from the date of AAV diagnosis until death or 02/28/2017, whichever came first. Comorbidity incidence was assessed using modified Poisson regression. Temporal patterns in comorbidity incidence were assessed using discrete regression analysis at the following intervals: 2-<5 years, 5-<10 years and 10+ years after follow-up.

Results: A total of 543 AAV (53.5% male) patients were matched with 2672 general population controls. The median (interquartile range) follow-up time was 5.1 (2.5 to 9.4) years. Overall, after AAV diagnosis, these patients were at a higher risk of developing the following comorbid diseases compared to the general population (Incidence Rate Ratio; 95% Confidence Interval): osteoporosis (8.0; 4.6-14.2), pulmonary circulation disorders (5.5; 3.3-9.1), hypothyroidism (3.4; 2.0-6.0), valvular disease (3.0; 2.1-4.4), hypertension (2.4; 1.8-3.1), cardiac arrhythmias (2.2; 1.5-3.1), chronic pulmonary disease (2.2; 1.6-3.1), diabetes mellitus (2.1; 1.4-3.0), and major cardiovascular events (1.4; 1.1-1.9). Temporal analyses showed that differences in risk were most apparent in the first two years following diagnosis, and they tended to reduce, if not disappear, for many comorbidities over time (See Figure 1).

Conclusion: To our knowledge, this is the first study to comprehensively examine the breadth and timing of comorbidity risk in AAV. Our findings showed that AAV patients face an increased risk of comorbidity, especially within the first two years of diagnosis. These data should help inform the management of these patients. Further analysis incorporating prescription data might help explain the reduction of risk over time.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Epidemiology and Public Health – ACR/ARHP

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: This study aimed to analyze the prevalence rates and treatment patterns of male and female ankylosing spondylitis (AS) patients in the United States (US) adult insured population from 2006 to 2016.

Methods: Trends in AS prevalence were calculated for the 10-year period covering January 1, 2006 to December 31, 2016. Adult (18+ years old) AS patients were included in this retrospective analysis of medical and pharmacy claims data from the Truven Marketscan Commercial, Medicaid and Medicare-Supplemental Claims database. Prevalence was determined using two AS definitions; A) ≥ 2 AS diagnostic codes (ICD-9:720.0; ICD-10:M45.x), or B) ≥ 1 AS diagnostic code by a rheumatologist. Trends in treatment patterns were also analyzed and stratified by gender.

Results: The AS prevalence ranged from 0.04% to 0.09% from 2006 to 2016. The mean age between 2006 and 2016 ranged from 49.52 -50.00 years. In 2006, approximately 40% of AS patients were female, while in 2016 over 47% of AS patients were female. Rates of use of TNF inhibitors (TNFi) and oral glucocorticoids increased, while NSAIDs and non-biologic DMARDs (sulfasalazine & methotrexate) rates decreased. Opioid use rates were stable (Figure 1). In 2016, males were more likely to be prescribed TNFi, while females were more likely to be prescribed methotrexate, sulfasalazine, NSAIDs, muscle relaxants, anticonvulsants, opioids, and glucocorticoids (Table 2).

Conclusion: The prevalence of AS diagnosis codes more than doubled between 2006 and 2016, but the very low prevalence suggests that AS continues to be under diagnosed and under-addressed in routine clinical practice. Despite the increase in female AS patients, females were less likely to be prescribed TNF inhibitors compared to male AS patients.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Epidemiology and Public Health – ACR/ARHP

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Spine osteoarthritis (OA) has been defined by the presence of: 1) disc space narrowing (DSN) and vertebral osteophytes (OST), or 2) facet joint OA (FOA). However, anatomical differences of these structures used in these two definitions suggest they may have different etiologies. Our aim was to determine if differences in associations exist between demographic (age, race, sex) and clinical characteristics (body mass index [BMI]), coincident knee, hip or hand OA, and low back symptoms) and OA involvement in the lumbar spine, defined as 1) FOA only and 2) Spine OA only (DSN plus vertebral OST) or 3) FOA and Spine OA, when compared to those with neither Spine OA nor FOA.

Methods: Data were collected from 2003-2010 in the Johnston County OA Project. Each lumbar spine level was graded for OST and DSN in a semi-quantitative fashion (0-3) while FOA was graded as present or absent, according to the Burnett Atlas. Spine OA was defined as the presence of DSN and OST grade ≥ 1 at the same lumbar level. Participants reported the presence of low back symptoms (pain, aching, and/or stiffness) on most days of any one month in the last 6 months and their history of back injury (yes/no). Knee OA and hip OA were both defined by a Kellgren-Lawrence score (K-L) of 2-4. Hand OA was defined as K-L 2-4 in a minimum of one distal interphalangeal (IP) joint and 2 other joints (IP or carpometacarpal). Age, race and sex were collected by self-report and BMI measured at clinical examination. Adjusted odds ratios (OR) and 95% confidence intervals (CI) were estimated with multinomial logistic regression.

Results: Complete data were available for 1,874 participants. The table presents the counts and percentages for spine OA groups, demographics and clinical characteristics.

Table 1a presents demographic adjusted associations. All age categories were strongly associated age categories compared to none with the strength of association increasing with greater age. African Americans were 32% less likely to have FOA only and 49% less likely to have both FOA and Spine OA. Women were 64% more likely to have FOA alone.

Table 1b presents clinical characteristic adjusted associations. Those with FOA only were 74% more likely to have BMI ≥ 30 kg/m². Similar associations were found between knee OA and both FOA only and Spine OA only, though stronger with both FOA and Spine OA. Back injury was strongly associated with Spine OA only. Symptoms, hip OA, and hand OA were not significantly associated with any spine OA involvement.

Conclusion: The differences in demographic characteristics (race and sex) and clinical characteristics (BMI and back injury) suggest pathophysiologic processes may vary for these definitions lumbar spine OA involvement. Increasing associations across categories of age suggests changes over time, however longitudinal studies may elucidate whether those with FOA only or Spine OA only remain an isolated lumbar spine OA phenotype over time.

Variable	FOA only* (n=424, 22.6%)	Spine OA Only* (n=244, 13.0%)	FOA and Spine OA* (n=861, 45.9%)

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Epidemiology and Public Health – ACR/ARHP

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Adiposity is associated with increased risk of knee osteoarthritis; cartilage thickness, cartilage volume and subchondral bone area are established biomarkers in knee osteoarthritis. We aimed to describe the longitudinal associations of childhood and adulthood adiposity measures with knee cartilage thickness, volume and bone area in young adults.

Methods: Childhood and adulthood adiposity measures (weight, height, waist circumference and hip circumference) of 186 participants were collected in 1985 (aged 7-15 years) and during 2004-2006 (aged 26-36 years). Knee magnetic resonance imaging was conducted during 2008-2010 (aged 31-41 years), and cartilage thickness, volume and bone area were measured using a quantitative approach (Chondrometrics, Germany). Linear regressions were used to examine the above associations.

Results: The prevalence of overweight was 7.6% in childhood and 42.1% in adulthood. Childhood weight was negatively associated with adult patellar bone area ($\beta = -6.24$, 95% confidence interval (CI) -10.25 to -2.22 mm²/kg), while adult weight

Figure. Scatter plots and linear regression lines for associations between adulthood WHR and knee cartilage thickness (A: patella; B: MFTC; C: LFTC). Linear regression lines are from models adjusted for adulthood age, duration of follow-up, gender and adulthood knee injury. WHR, waist-hip ratio; MFTC, medial femoral tibial compartment; LFTC, lateral femoral tibial compartment.

Table 1. Associations between adulthood adiposity measures and knee cartilage thickness, cartilage volume and subchondral bone area

	Cartilage thickness (mm) β (95% CI)	Cartilage volume (mm ³) β (95% CI)	Bone area (mm ²) β (95% CI)

Weight z-score change	-0.047 (-0.114 to 0.019)	-22.13 (-125.77 to 81.53)	0.81 (-20.44 to 22.27)
BMI z-score change	-0.037 (-0.095 to 0.021)	-9.71 (-84.07 to 108.49)	10.02 (-12.13 to 32.17)
WHR z-score change	-0.021 (-0.070 to 0.027)	-83.28 (-162.97 to -3.23)	-21.35 (-39.88 to -3.60)
MFTC			
Weight z-score change	0.034 (-0.11 to 0.062)	-3.66 (-102.32 to 99.01)	8.19 (-18.32 to 34.70)
BMI z-score change	-0.033 (-0.100 to 0.033)	-0.20 (-95.89 to 95.36)	11.34 (-7.72 to 40.00)
WHR z-score change	-0.054 (-0.109 to -0.003)	-83.84 (-158.87 to -8.80)	-13.50 (-36.32 to 9.33)
LFTC			
Weight z-score change	-0.048 (-0.129 to 0.033)	-89.69 (-203.75 to 24.38)	-18.79 (-43.83 to 5.47)
BMI z-score change	-0.093 (-0.118 to 0.055)	-64.10 (-177.37 to 49.58)	-13.75 (-43.82 to 15.30)
WHR z-score change	-0.039 (-0.090 to 0.012)	-100.55 (-190.28 to -10.81)	-24.47 (-47.36 to -1.58)

^a Bold denotes statistical significance, $p < 0.05$.

Adjusted for childhood and adulthood age, gender, childhood and adulthood knee injury, childhood and adulthood height (if weight z-score change is the predictor).

CI, confidence interval; BMI, body mass index; WHR, waist-hip ratio; MFTC, medial femorotibial compartment; LFTC, lateral femorotibial compartment.

was positively associated with bone area in medial femorotibial compartment (MFTC) ($\beta=3.09$, 1.44 to 4.74 mm²/kg) and lateral femorotibial compartment (LFTC) ($\beta=1.85$, 0.19 to 3.51 mm²/kg). Adult waist-hip ratio (WHR) was negatively associated with cartilage thickness (MFTC: $\beta=-0.011$, -0.022 to 0.000; LFTC: $\beta=-0.013$, -0.025 to -0.002 mm/0.01 unit), volume (Patella: $\beta=-21.85$, -37.77 to -5.93; LFTC: $\beta=-23.87$, -42.18 to -5.57 mm³/0.01 unit) and bone area (Patella: $\beta=-4.69$, -8.26 to -1.12; LFTC: $\beta=-4.76$, -9.47 to -0.06 mm²/0.01 unit). The change in WHR z-scores from childhood to adulthood was negatively associated with cartilage thickness (MFTC: $\beta=-0.056$, -0.109 to -0.003 mm), volume (patella: -83.10, -162.97 to -3.23; MFTC: -83.04, -158.07 to -8.00; LFTC: -100.55, -190.28 to -10.81 mm³) and bone area (patella: -21.35, -39.00 to -3.69; LFTC: -24.47, -47.36 to -1.58 mm²).

Conclusion: Childhood weight was negatively but adult weight was positively associated with adult bone area. Adult WHR and the change in WHR from childhood to adulthood were negatively associated with cartilage thickness, volume and bone area. These suggest early life adiposity measures may affect knee structures in young adults.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Epidemiology and Public Health – ACR/ARHP

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Pain exacerbation on walking is common among patients with knee osteoarthritis and often lead to activity avoidance. To date, few risk factors for pain flares have been identified, limiting the development of target prevention and treatment approach. We examined several knee-specific risk factors for this disabling pain experience.

Methods: Participants in the Osteoarthritis Initiative underwent a 20-meter walking test at the 24-month visit. We defined a knee as experiencing pain exacerbation on walking if its pain severity increased by ≥ 1 point from before participating to that during the walking test on a numeric rated scale (0-10). Among subjects who had unilateral knee pain exacerbation on walking, we conducted a within-person between-knee matched case-control study to examine the relation of recent knee injury (i.e., knee injury occurred in the past 12 months that was bad enough to limit the ability to walk for at least two days), Kellgren and Lawrence (KL) grade and isometric extensor muscle strength (IEMS) to unilateral knee pain exacerbation on walking using conditional logistic regression adjusting for each other. We consider a difference in IEMS $\geq 4\%$ as meaningful difference. We depicted the dose-response relationship between IEMS and the risk of knee pain exacerbation on walking using restrictive cubic spline curve.

Results: Among 277 people who experienced unilateral knee pain exacerbation during the walking test, 63.9% were women, mean age = 63.6 years, and the mean body mass index = 29.2 kg/m^2 . Recent knee injury was associated with pain exacerbation on walking with an odds ratio (OR) of 3.4 (95% confidence interval (CI): 1.3, 9.2). Compared with knees with KL=0, the ORs of pain exacerbation on walking were 1.3 (95% CI: 0.7, 2.7), 3.3 (95% CI: 1.5, 7.1), and 8.1 (95% CI: 3.1, 21.1) for knees with KL=2, 3 and 4, respectively. Knees that had 4% lower IEMS than their contralateral knees were at 1.4 (95% CI: 1.0-1.9) higher risk of pain exacerbation on walking.

Conclusion: Recent knee injury, KL grade and IEMS were associated with knee pain exacerbation on walking. Our findings reinforce the vital role of pain management in the early stage of radiographic knee OA in preventing pain-related

Figure 1. Associations of Kellgren and Lawrence grade with knee pain exacerbation on walking*

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Epidemiology and Public Health – ACR/ARHP

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Adverse Childhood Experiences (ACEs) are associated with increased risk of chronic disease and poorer health in children and adults. Emerging data suggest an association between exposure to ACEs and autoimmune diseases in adults, but the relationship between ACEs and childhood-onset rheumatologic diseases has not been examined. Our objective was to investigate the relationship between ACEs and arthritis, the most common manifestation of childhood-onset rheumatologic disease, and to examine the relationship between ACEs and health-related outcomes in children with arthritis.

Methods: We examined data from the 2016 National Survey of Children's Health (NSCH) to describe the distribution of ACEs among children with current arthritis compared to 1) children with other chronic acquired physical conditions (CAPC)* and 2) all other children. The NSCH is a survey of sampled households with children < 18 years conducted by the US Census Bureau. We performed bivariate and multivariable logistic regression to determine associations between arthritis and cumulative ACE scores, measured as a categorical variable (0 ACEs, 1 ACE, 2-3 ACEs, ≥ 4 ACEs). Chi-square tests and non-parametric tests for linear trends were used to assess associations between cumulative ACE scores and health-related outcomes.

Results: Among 138 children with current arthritis, 123 had complete ACE data and were included in the analysis. Sixty-five percent of children with arthritis were reported to have at least one ACE, while 40% ($p < 0.001$) of children without arthritis and 53% ($p < 0.001$) of children with other CAPC were exposed to ACEs. Children with a high exposure (≥ 4 ACEs) were more likely to have arthritis compared to those without ACE exposure, odds ratio (OR=5.4, 95% confidence interval (CI) (3.2, 9.2) ($p < 0.001$)). High ACE exposure compared to none was associated with higher likelihood of having arthritis versus having other CAPC, OR=3.4, 95% CI (2, 5.8) ($p < 0.001$). A graded relationship was observed between ACE scores and arthritis in logistic regression models for both children with CAPC and all children (Table 1). Among children with arthritis, children with high ACE exposure had the highest proportion of physical impairment (95%) and comorbid depression/anxiety (68%) with significant linear trends of increasing proportions of affected children for both outcomes across increasing ACE scores, ($p = 0.001$, $p < 0.001$)

Conclusion: A markedly high prevalence of ACEs is reported among youth with arthritis from a large national survey. Higher ACE scores were associated with increased odds of arthritis and among children with arthritis, increased proportions of mental illness and physical impairment. Future investigations should examine how adversity may play a role in arthritis development, disease severity, and physical and mental health outcomes.

Table 1: Odds Ratios (OR) for Arthritis by Adverse Childhood Experience (ACE) Exposure

Number of ACEs	Arthritis among all children** (N = 46,599)			Arthritis among children with CAPC** (N = 12,225)		
	OR	Confidence Interval	p value	OR	Confidence Interval	p value
0 ACEs	1	---	---	1	---	---

The Association between Structural and Symptomatic Progression in Knee Osteoarthritis

Jamie E. Collins¹, Swastina Shrestha² and Elena Losina³, ¹Department of Orthopedic Surgery, Orthopedic and Arthritis Center for Outcomes Research, Brigham and Women's Hospital, Boston, MA, ²Orthopaedic and Arthritis Center for Outcomes Research, Brigham and Women's Hospital, Boston, MA, ³Harvard Medical School, Boston, MA

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Epidemiology and Public Health – ACR/ARHP

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: The link between progression of structure and symptoms in knee osteoarthritis (OA) is not well understood. This uncertainty hinders the effort to develop therapies to treat OA symptoms because it is unclear how treating structure or halting structural progression might alleviate symptoms.

Methods: We used data from the Osteoarthritis Initiative (OAI), a multicenter, longitudinal, observational study of knee OA. We selected patients with baseline (BL) Kellgren-Lawrence (KL) grade 1 – 3 and knee pain. Medial minimum joint space width (JSW) was assessed with a fixed-flexion knee radiograph annually through year 4 and then at years 6 and 8. WOMAC pain was assessed annually. We censored subjects at the time of any reported TKR. We used latent class growth analysis (LCGA) to identify distinct subgroups of JSW progression and pain progression. We included random effects to allow for within-subject variability. We analyzed data from years 1 to 8. We used logistic regression to evaluate the association between JSW and pain trajectories identified in LCGA analysis.

Results: We used data from 1,909 OAI study participants. BL radiographic severity was KL1 in 16%, KL2 in 52%, and KL3 in 32%. The mean (SD) JSW was 4.0mm (1.3). LCGA identified 2 distinct JSW trajectories: most patients (89%) had stable JSW over 8 years of follow-up, while a subgroup of patients (11%) experienced rapid disease progression [Figure 1]. We found 4 distinct pain trajectories. Most patients (75%) had stable low pain. There were also distinct trajectories of decreasing (5%), increasing (10%) and high stable (11%) pain [Figure 2]. The probability of being a rapid JSW progressor in each pain trajectory was 14% (high), 14% (increasing), 16% (decreasing), and 9% (low). This translates to an increased odds of being in the JSW progressor group in the high stable pain (OR: 1.6; 95%CI: 1.0, 2.4); increasing pain (OR 1.5; 95%CI: 0.98, 2.4) and decreasing pain (OR: 1.9; 95%CI: 1.0, 3.4)) groups compared to low stable pain group.

Conclusion: We found distinct subgroups of both JSW and pain progression. While subjects in the low stable pain trajectory had a slightly decreased odds of JSW progression, we did not find differences in the risk of being a rapid JSW

Figure 1. JSW Progression: JSW over time with 95% confidence intervals by trajectory group.

Figure 2. WOMAC Pain Progression. WOMAC Pain over time with 95% confidence intervals by trajectory group.

progressor between the increasing, decreasing, and high pain groups. Future work should consider whether additional joint features as visualized on MRI, such as cartilage, osteophytes, bone marrow lesions, and synovitis, may help to elucidate the link between structural and symptomatic progression.

Session Title: Genetics, Genomics and Proteomics: Precision Medicine

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Systemic Lupus Erythematosus (SLE) is a chronic autoimmune disease with heterogeneous disease manifestations and outcomes. We aimed to define how molecular differences underlie this clinical heterogeneity through an integrative approach leveraging methylation, genetic, and phenotypic data from a well characterized multiethnic cohort of SLE patients.

Methods: 274 participants from diverse ethnic backgrounds were recruited as part of this study. 272 met 4 SLE ACR criteria, the rest had a diagnosis of lupus nephritis or met 3 ACR criteria and had a rheumatologist's diagnosis. In addition to clinical characterization, molecular measurements were collected on the individuals. DNA extracted from blood was analyzed on the illumina EPIC Beadchip. Single nucleotide polymorphism (SNP) genotype data was generated on the Affymetrix LAT1 World Array. First, we defined the phenotypic patient subgroups by clustering analysis - we performed principal component analysis on the ACR clinical criteria and used the top 2 eigenvectors as input for K-means clustering. We identified three stable clusters based on a stability score >0.8 determined by a bootstrap re-sampling method. Second, we applied a multivariate linear regression model adjusting for population stratification, cell composition, sex, smoking history, and age to identify differentially methylated CpGs across the phenotypic clusters. Lastly, we investigated whether the differentially methylated CpG were under genetic control in a methylation quantitative trait loci analyses (cis-meQTLs).

Results: We identified three stable clusters based on ACR criteria: cluster 1 was characterized by a higher proportion of participants of white ethnicity with malar rash, photosensitivity, serositis, arthritis, oral ulcers and fewer subserologies; cluster 2 was characterized by a higher proportion of lupus nephritis and anti-dsDNA antibodies; cluster 3 was characterized by higher proportion of hematologic manifestations, lupus nephritis, anti-dsDNA and anti-Sm antibodies. We identified 196 CpGs in 107 genomic regions that were differentially methylated between the clusters (FDR<0.05). Of these, pathway analysis revealed significant enrichment of genes relating to Type 1 interferon signaling and IFN-gamma (adjusted $p < 1E-08$). Overall, Interferon-alpha responsive genes were hypomethylated in cluster 3, hypermethylated in cluster 1, with cluster 2 presenting an intermediate signature. We then investigated whether the differentially methylated CpG were under genetic control in a *cis*-meQTLs analysis, which identified 542 *cis*-meQTL pairs (FDR<0.01) with 97 CpGs under proximal genetic control, which were enriched for IFN-alpha and IFN-gamma responsive genes (hypergeometric $p < 0.01$).

Conclusion: Overall, we identified three clinically relevant clusters of patients in our multiethnic SLE cohort. The three clusters could be differentiated by 196 CpGs of which 97 were under genetic control and enriched for IFN-gamma and IFN-alpha responsive genes. In this work, we were successful in applying integrative computational methods to elucidate the epigenetic and genetic mechanism behind the role of Type 1 interferon in SLE pathology.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Genetics, Genomics and Proteomics: Precision Medicine

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Low cost, patient-administered, "from home" genomic tests for monitoring disease activity and therapy response could revolutionize treatment and management of Systemic Lupus Erythematosus (SLE) patients by minimizing the use of ineffective therapies and detecting changes in disease activity before a flare occurs. Here we demonstrate the ability to test gene expression levels associated with Type 1 Interferon (IFN), plasmablast, T-cell

exhaustion and other SLE disease pathways using a multi-module gene expression assay in a large “from home” cohort of self-reported SLE and MS patients.

Methods: 1,278 patients with SLE or multiple sclerosis (MS) were recruited under an IRB-approved, Direct-to-Patient observational study in which participants provided self-collected blood samples. The study included 832 SLE patients, 446 MS patients, 269 demographic normal donors and 189 participants with known common medical conditions. SLE patients provided longitudinal samples resulting in the 2,129 samples for SLE. Testing was performed using a 47-gene, multi-module gene expression assay based on chemical ligation dependent probe amplification (CLPA) which enables direct from stabilized blood testing with no RNA isolation steps.

Results: 13.8% of the normal patients were found to be IFN high while SLE patients were 36.8% IFN High and MS patients were 20% IFN High. The difference in IFN activity between SLE and MS was statistically significant ($p < 0.001$). In the 17 common disease sub-cohort, immunocompromised patients ($n=28$, 32.1%), heart disease ($n=11$, 27.3%) and participants with influenza ($n=12$, 91.7%) displayed above normal IFN levels.

High IFN was associated with ethnicity and age at time of diagnosis in the SLE cohort. Caucasian samples ($n=1,721$) were IFN high 31% of the time, while African American ($n=204$, High IFN 68.1%) and Asian patients ($n=32$, High IFN 90.6%) showed a higher prevalence. IFN activity in SLE participants correlated with age of diagnosis with samples from participants diagnosed under 18 being IFN high 70.4% ($n=115$), 18 to 30 IFN high 45.4% ($n=610$), and over 30 ($n=942$) IFN high 27.3%.

Conclusion: A significant percentage of SLE and MS patients display elevated IFN levels, especially in younger SLE patients, as well as African Americans and Asians. Testing for IFN activity in suspected autoimmune disease patients may improve SLE diagnosis resulting in improved patient care and a reduced cost to the healthcare system.

Sample Set	Sample Count	IFN High Count	IFN Low Count	% IFN High	% IFN Low
Normal	269	11	258	13.8	86.2

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Genetics, Genomics and Proteomics: Precision Medicine

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Behcet's disease (BD) is a heterogeneous multifactorial auto-inflammatory condition characterized by recurrent episodes of oral and genital ulceration, uveitis and skin lesions, with less frequent involvement of the gastrointestinal tract, large blood vessels and central nervous system. The NF- κ B pathway is a 'master-regulator' of immune and inflammatory signaling, with the ability to control the expression of key inflammatory genes and genes associated with apoptosis and proliferation.

Methods: This study involved a 3-generation family with Behcet's-like mucocutaneous ulceration syndrome; primarily involving childhood-onset chronic oral and genital ulcers (figure 1). ISGBD criteria were used to diagnose Behcet's Disease (BD). DNA was isolated from PBMCs from affected patients and non-affected familial controls. DNA sequencing identified a cysteine deletion at position 1459 in *RELA* which segregated with the condition. Immunoblot analysis of *RELA* confirmed protein truncation. PBMCs were stimulated with TNF and NFκB phosphorylation was measured relative to unstimulated controls.

Results: A heterozygous cysteine deletion at position 1459 in *RELA* was detected in affected individuals. This mutation is coding, inducing a frameshift His487ThrfsTer7, predicted to produce a truncated protein of 492 amino acids which would result in a ~6kDa smaller protein. This truncation was confirmed by immunoblot, with the affected individuals producing two bands: the wild-type and truncated protein whereas unaffected controls produced only the wildtype protein. Preliminary data indicates RelAHis487ThrfsTer7 heterozygotes have different kinetics in response to TNF, as measured by phosphorylation of *RELA*.

Conclusion: This study gives novel information on both the genetic basis and biological mechanisms of BD in individual families. Familial mutations that induce haploinsufficiency of *RELA* have recently been associated with BD. However, the His487ThrfsTer7 results in protein truncation rather than haploinsufficiency. Crucially, the His487ThrfsTer7 mutation interrupts the two C-terminal *RELA* transactivating domains. Our study supports several recently published studies that loss-of-function mutations in the NF-κB pathway are linked with the development of familial early-onset BD-like syndromes. Understanding both the genetic basis and biological mechanisms facilitates personalized medicines approaches that target the primary disease mediators, which result in earlier disease control and reduced tissue damage.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Genetics, Genomics and Proteomics: Precision Medicine

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: High-throughput gene expression profiling of skin biopsies from patients with systemic sclerosis (SSc) has identified four “intrinsic” gene expression subsets conserved across multiple cohorts and tissues. These are the inflammatory, fibro proliferative, normal-like, and limited subsets. In order to classify patients in clinical trials or for diagnostic purposes, supervised methods that can assign a single sample to a molecular subset are required. Here, we introduce a novel machine learning classifier which is a robust predictor of intrinsic subset and test it on multiple independent patient cohorts.

Methods: Three independent gene expression cohorts were curated and merged to create a training dataset covering 297 skin biopsies from 102 SSc patients and controls to train a classifier. Supervised machine learning algorithms were rigorously trained and evaluated using repeated three-fold cross-validation. We performed external validation using three SSc cohorts (GSE66321, GSE65405, GSE58095), including a gene expression dataset generated by an independent laboratory on a different microarray platform. In total, 427 skin biopsies from 213 individuals were analyzed in the training and test cohorts. We used weighted gene co-expression network analysis and g: Profiler to identify and functionally characterize gene modules associated with the intrinsic subsets.

Results: Repeated cross-fold validation identified consistent and discriminative gene expression biomarkers using multinomial elastic net, which performed with an average classification accuracy of 88.1%. All molecular subsets were classified with high sensitivity and specificity (Fig. 1A). In external validation, the classifier achieves an average accuracy of 85.4% (Fig.1B). In a re-analysis of gene expression data from GSE58095, the classifier identified subsets of patients that represent the canonical inflammatory, fibroproliferative, and normal-like subsets (Fig. 1C). The inflammatory subset showed upregulated gene modules significantly enriched in biological processes such as inflammatory response, lymphocyte activation, and stress response. Similarly, gene modules enriched for cell cycle processes were increased in the fibroproliferative subset.

Conclusion: We developed a highly accurate and reliable classifier for SSc molecular subsets for single samples analyzed on multiple gene expression platforms. Prior methods relied on agglomerative methods that could not be applied to single samples. These analyses show that the intrinsic gene expression subsets are a common feature of SSc found across multiple

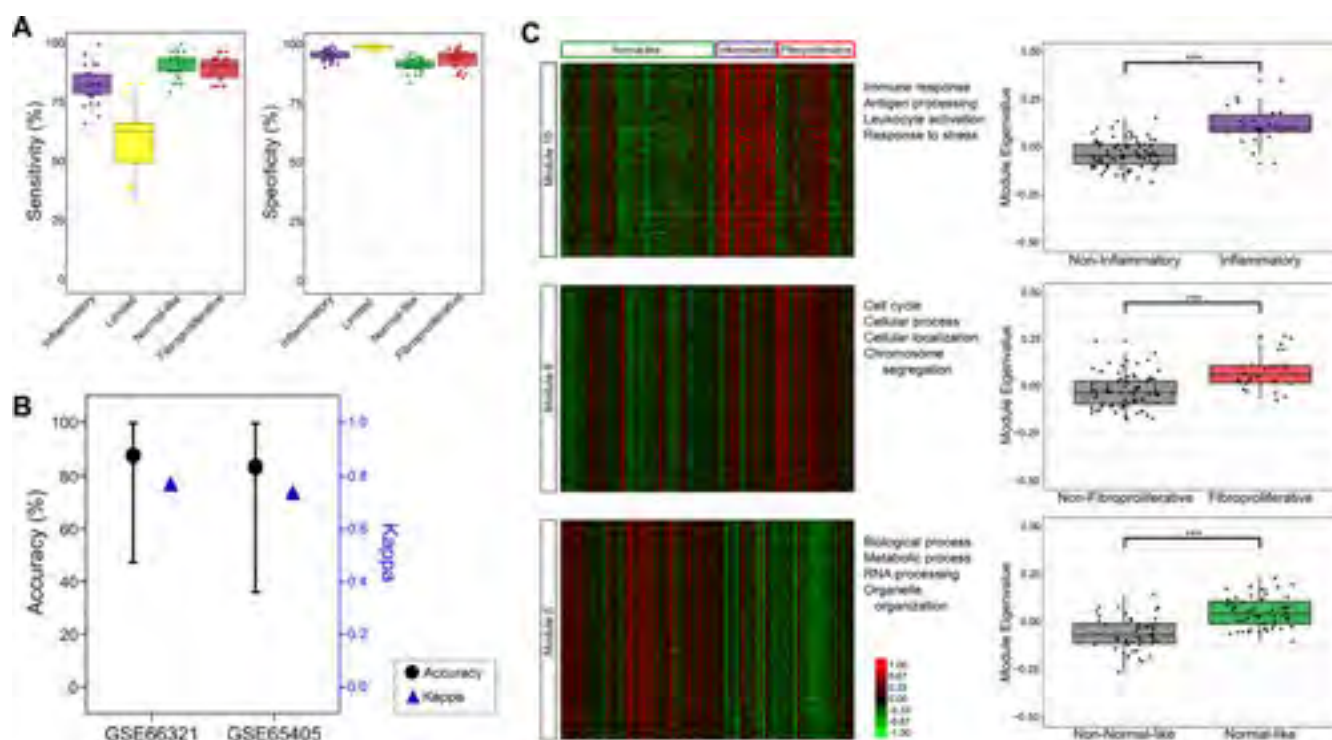

Figure 1: (A) Sensitivity and specificity for all four intrinsic SSc subsets are plotted from repeated cross-fold validation for the final model, (B) in external validations, accuracy of intrinsic subset assignment is plotted in black and Cohen's Kappa in blue. (C) Expression values are shown for gene annotated to modules 10, 6, and 5. The module eigenvalues were further compared for the inflammatory samples vs all others, fibroproliferative samples vs all others, and normal-like samples vs all others using Wilcoxon Rank Sum Test (***) $p < 0.0005$.

validation cohorts. Machine learning methods provide a robust and accurate mechanism for stratifying intrinsic gene expression subsets and can be used to aid clinical decision-making and interpretation for SSc patients and in clinical trials.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Genetics, Genomics and Proteomics: Precision Medicine

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: To explain the complex regulatory changes associated with RA synovitis and the diversity of responses to targeted therapies, we developed and applied a novel integrative epigenetic profiling method. This method, known as Taiji, focuses on differences between patients with RA in addition to the traditional RA vs. non-RA methodology. Using Taiji, we identified transcription factors (TFs) central to regulatory patterns in fibroblast-like synoviocytes (FLS) that vary between RA patients that could contribute to variable responses to targeted therapies.

Methods: Whole genome ATAC-seq data from 11 RA and 11 osteoarthritis [OA] FLS lines) were evaluated for overlaps between ATAC-seq peaks and known gene promoter regions (4Kb upstream and 1kb downstream from the TSS). Peaks not assigned to promoters were linked with the nearest gene. 745 TFs, with binding motifs curated from the CIS-BP database, had binding sites within 150-bp of ATAC-seq peaks. 22 network topologies were constructed by forming directed edges between any parent node TF and child node gene or child node TF. Via the integration of our whole genome RNA-seq expression data, edge weights were assigned according to the pooled ATAC-seq peak intensity and the expression of the TF parent node. For each sample, the Personalized Page Rank (PPR) algorithm was run to measure the global influence of each node and variability between RA patients.

Results: Analysis focused on differences between RA patients. We first clustered the patient using the log₂ transcripts per million expression for all genes resulting in two clusters of 7 and 4 RA patients. The mean PPR z-score was calculated for all TFs from each cluster of patients and the absolute difference between the two clusters (DPPR) was calculated. Analysis of the PPR z-score of TF regulatees was conducted to gain statistical power. Ranking TFs by DPPR, the top 200 were intersected with the 310 TFs that have significantly different regulatee PPR z-score values ($p < 0.003$) yielding 80 RA patient-specific TFs that distinguished patients from each other (see Figure showing inter-patient differences in the clusters). High DPPR TFs identified in the two RA clusters included the retinoic acid receptor alpha (RARA) and E2F7 ($p = 0.003$ and $p = 0.010$). RARs play a role in the immuno modulation of synovial inflammation in RA. The E2F TF family member E2F7, plays a role in angiogenesis.

Conclusion: Our novel epigenetic profiling approach defines patient-specific TFs that could contribute to RA patient-to-patient differences. This unique computational approach helps elucidate the mechanism of differential responses to highly targeted agents in RA. Key transcription factors, including genes such as RARA and E2F7, emerge as potential patient-specific TF targets from this *in silico* method to individualize treatment.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Genetics, Genomics and Proteomics: Precision Medicine

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Rheumatoid arthritis (RA) is the most common inflammatory arthritis affecting up to 1% of the population. Tumor Necrosis Factor (TNF) inhibitors have significantly improved the management of many RA patients. However, ~30% of anti-TNF treated patients do not show a significant clinical improvement. To date, little is known on the biological mechanisms that underlie the differential response to anti-TNF agents. The objective of this study was to identify genetic variation associated with the clinical response to anti-TNF therapy in RA using a sequential multi-omics approach.

Methods: We performed a genome-wide multi-omics analysis integrating multiple sources of molecular information. First, we aimed to identify the gene expression modules associated with anti-TNF response. For this objective, we extracted the RNA from synovial biopsies of 11 RA patients starting anti-TNF therapy and determined the gene expression profiles using Illumina microarrays. Modules of coexpressed genes were subsequently identified using the WGCNA approach. The association between the synovial gene coexpression modules and anti-TNF response was then performed using the first principal component of variation from each module. Clinical response was determined at week 14 using the EULAR criteria. To analyze the association between the transcriptomic modules and the anti-TNF response at the genetic level, we used a cohort of 348 anti-TNF treated RA patients from Spain recruited by the *IMID Consortium*. The statistical association analysis was performed using genome-wide data from the Spain cohort ($N=1,387,382$ SNPs) and the set-based test implemented in PLINK. The gene modules that were significantly associated with the anti-TNF response were subsequently tested for validation in an independent GWAS cohort of 2,706 anti-TNF treated RA patients available from the Synapse public repository. The functional implication of the validated modules was evaluated via pathway and cell type epigenetic enrichment analyses.

Results: The genome-wide coexpression analysis in RA synovial biopsies identified a total of 148 gene coexpression modules. From these, 15 transcriptomic modules were found to be associated with the clinical response to anti-TNF therapy ($P<0.05$). At the genetic level, we detected two of the 15 gene modules to be significantly associated with the response to adalimumab ($P=0.015$) and infliximab ($P=0.021$) in the Spain cohort. Using the independent cohort of RA patients, we replicated the association of the gene coexpression module associated with the response to adalimumab

($P=0.0019$). The validated module was found to be significantly enriched in genes that are involved in the metabolism of nucleotides ($P=2.41e-05$). The epigenetic analysis revealed a significant enrichment of the adalimumab-associated variants in key epigenetic marks from different immune cell types including Tregs ($P=0.04$).

Conclusion: These findings show the existence of a genetic basis for the clinical response to anti-TNF therapy. Our results also suggest that the genetic variation affecting clinical response is treatment-specific and, therefore, biomarker development in RA should take into account this diversity at the molecular level.

Session Date: Sunday, October 21, 2018

Session Title: Pediatric Rheumatology – Basic Science

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Kawasaki disease (KD) is an acute, febrile illness of childhood with sequelae of coronary artery aneurysms and cardiac fibrosis, and is the most common cause of acquired heart disease among children in the developed world. Acutely, a subset of patients with KD will demonstrate echocardiographic evidence of impaired myocardial function, as well as increased left ventricular mass presumed to be due to myocardial edema and inflammation. Further, some patients will develop profound cardiac dysfunction known as Kawasaki Shock Syndrome. Here, we investigated whether inhibition of interleukin-1 activity via anakinra would correct development of the myocardial mechanical dysfunction and myocardial inflammation seen in KD.

Methods: KD was induced via the established model of lactobacillus casei cell wall extract (LCWE) injection in 4-6 week old male mice. For echocardiography and MRI, groups of mice either injected with LCWE alone, LCWE and anakinra, or normal controls were compared. Myocardial inflammation was scored by a blinded pathologist.

Results: Both imaging modalities demonstrated normalized left ventricular function in anakinra treated KD mice via measurements of ejection fraction, fractional shortening (echo) and end diastolic and systolic volumes (MRI). These were significantly ($p<0.05$) normalized as compared to untreated diseased KD mice. Additionally, while KD mice demonstrated increased left ventricular mass index, this was markedly attenuated ($p<0.01$) in anakinra treated mice. Myocardial inflammation scores were significantly ($p<0.05$) lower in anakinra treated vs. untreated mice.

Conclusion: Anti-interleukin-1 therapy in the mouse model of KD prevents the development of myocardial mechanical dysfunction and left ventricular mass enlargement as well as myocardial inflammatory changes. This demonstrates functional efficacy of this therapy in the treatment of children with KD, and also raises the clinical implication of anakinra treatment in patients with severe cardiac dysfunction of Kawasaki Shock Syndrome. Additionally, the demonstration of these findings in the mouse model of KD greatly bolsters the applicability of this model for human KD.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Pediatric Rheumatology – Basic Science

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Systemic juvenile idiopathic arthritis (SJIA) is a chronic childhood arthropathy with features of autoinflammation. New-onset SJIA is associated with expansion and activation of neutrophils with a sepsis-like phenotype, but neutrophil phenotypes in longstanding and clinically inactive disease (CID) is unknown. The objective of this study was to examine activated neutrophil subsets, S100 alarmin release, and gene expression signatures in children with a spectrum of SJIA disease activity.

Methods: This protocol was approved by the Institutional Review Board, and informed consent was obtained from all patients and/or their legal guardians. Highly-purified neutrophils were isolated using a two-step procedure of density-gradient centrifugation followed by magnetic-bead based negative selection using the MACSexpress kit. Neutrophils were then stained for imaging flow cytometry, or RNA isolated using MagMax Total RNA Isolation Kit. Alternatively, neutrophils were cultured for 4hr with or without PMA to quantify S100 protein release. Gene expression analysis was performed with the Ampliseq Transcriptome kit using the Ion Torrent platform.

Results: Patients with SJIA and active systemic features demonstrated a higher number of the immunosuppressive subset CD16⁺CD62L^{lo} neutrophils compared to controls. This neutrophil subset was not seen in patients with inactive disease or those with active arthritis only without systemic features. Using imaging flow cytometry, CD16⁺CD62L^{lo} neutrophils from patients with active SJIA had mildly increased nuclear hypersegmentation compared to CD16⁺CD62L⁺ neutrophils. Serum levels of S100A8/A9 and S100A12 were strongly correlated with peripheral blood neutrophil count (R=0.53 and R=0.64, respectively; p<0.001). Neutrophils from active SJIA patients cultured *in vitro* did not show enhanced resting S100 protein release compared to inactive disease or control neutrophils. However, regardless of disease activity, neutrophils from SJIA patients did show enhanced S100A8/A9 release upon PMA stimulation compared to control neutrophils (P<0.05). Whole transcriptome analysis of highly purified neutrophils from children with active SJIA identified 214 differentially expressed genes compared to control neutrophils (fold change >2.0, p<0.05). The most significantly upregulated gene pathway was Immune System Process (adjusted p=3.4x10⁻¹⁶) including *AIM2*, *IL18RAP*, *NLRC4*, *TLR2*, *TLR5*, and *TNFAIP3*. Interestingly, this gene set showed intermediate levels of expression in neutrophils from patients with long-standing inactive disease but persistent serum IL-18 elevation. Indeed, all patient samples regardless of disease activity demonstrated elevated inflammatory gene expression, including inflammasome components and *S100A8*.

Conclusion: We identify features of neutrophil activation in SJIA, including a proinflammatory gene expression signature in patients with longstanding CID but elevated serum IL-18, reflecting persistent innate immune activation. Taken together, these studies expand understanding of neutrophil function in chronic autoinflammatory disorders such as SJIA.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Pediatric Rheumatology – Basic Science

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Towards understanding the molecular mechanisms that link maternal anti-Ro antibodies to the development of conduction system disease in a second trimester fetus, single cell (scRNA-seq) and bulk RNA-seq were applied to a fetal heart dying with complete congenital heart block (CHB) and a gestational age-matched healthy heart from an elective termination.

Methods: The CHB heart was obtained from a 20-week fetus identified to have complete block at 19 weeks. The mother (35 y/o Asian with SS on no hydroxychloroquine) declined dexamethasone or IVIG and elected to terminate, thus no exposure to maternal medications confounded interpretation of findings. Both hearts were obtained under identical conditions. Freshly collected single-cell suspensions were generated using a Langendorff preparation with cannulation and perfusion of the aorta with collagenase and trypsin enzymes. Two approaches were taken to mine the transcriptome in the resulting cell suspensions: agnostic evaluation applying 10X Genomics platform-based scRNA-seq and low input RNA-seq of flow sorted cells upon leukocytes (DAPI negative, CD45+) and fibroblasts (DAPI negative, CD45-, podoplanin-positive).

Results: For scRNA-seq, we obtained 2,693 and 5,408 high-quality scRNA-seq profiles from the control and CHB hearts, respectively. We applied a graph-based clustering method and identified 13 and 14 major clusters of cells from the control and CHB hearts, respectively, as visualized by *t-distributed stochastic neighbor embedding* (*t-SNE*). Differential gene expression analysis guided by established lineage markers revealed four cardiomyocyte clusters (CM1-CM4), three fibroblast clusters (FB1-FB3), endothelial cells (EC), erythroblasts (EB), macrophages (MAC), dendritic cells (DC), T cells (TC) and B cells (BC). Ranked by abundance, the control heart exhibited CM>FB>EC>MAC>DC>EB, BC, TC; the CHB heart exhibited CM>FB>EC, MAC>TC, BC, EB. The CHB heart also contained natural killer cells (NK) and mast cells (MC, lowest abundance). Given the high abundance of MACs among the immune cells (control:108;CHB:606) and the consistent identification of MACs on histologic analysis of CHB hearts, differential expression analysis demonstrated overexpression of interferon-induced genes (4-fold or greater, i.e. $\log_2(\text{CHB-control}) > 2$) in CHB MACs. In CHB, most cell types expressed high levels of ISG1, IFITM1 and IFITM3, whereas in the control only IFITM3 showed widespread expression. For SIGLEC1, expression was restricted to MACs and was expressed by 18% of CHB MACs and only 6% of control MACs. While the transcriptome using low input RNA-seq of anti-CD45 flow-sorted CHB leukocytes did not allow granular analysis of leukocyte subpopulations, expression of SIGLEC1 and interferon-related genes were increased in CHB versus control. Applying 10X Genomics, proliferating fibroblasts expressed MKI67 and TOP2A in CHB but not control fibroblasts.

Conclusion: This unprecedented opportunity to obtain CHB tissue absent any exposure to maternal medications support scRNA-seq's utility to survey landscape and heterogeneity not possible with low input RNA-seq of flow-sorted cells. IFN- and SIGLEC1-positive macrophages may contribute to fibrosis.

Abortive Viral Infection Becomes Macrophage Activation Syndrome in Mice with Chronically Elevated Interleukin-18: Evidence for Synergy with Cytotoxic Impairment

Paul Tsoukas¹, Corinne Schneider², Lauren Van Der Kraak² and Scott Canna³, ¹Pediatric Rheumatology, Children's Hospital of Pittsburgh, Pittsburgh, PA, ²RK Mellon Institute for Pediatric Research, University of Pittsburgh/Children's Hospital of Pittsburgh of UPMC, Pittsburgh, PA, ³RK Mellon Institute for Pediatric Research, University of Pittsburgh/Children's Hospital of Pittsburgh of UPMC, Pittsburgh, PA

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Pediatric Rheumatology – Basic Science

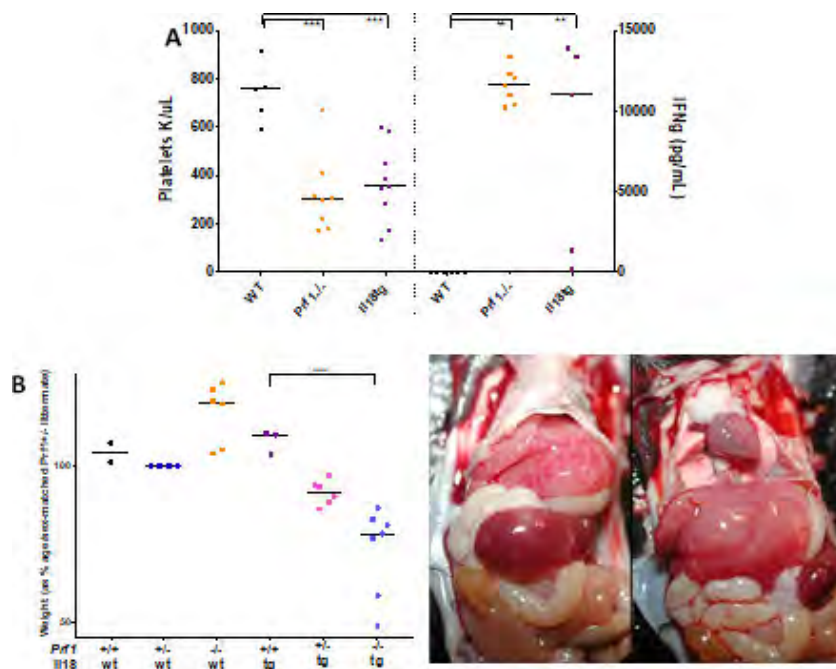

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Macrophage Activation Syndrome (MAS) and Hemophagocytic lympho histiocytosis (HLH) are clinically similar life-threatening hyperinflammatory syndromes, often triggered by viral infection. HLH is associated with cytotoxic impairment (e.g. Perforin deficiency). The causes of MAS remain unknown, but both cytotoxic impairment and elevated Interleukin (IL)-18 may contribute.

Methods: Mice were infected with the typically self-limiting LCMV-Armstrong virus, and assessed for systemic inflammation, serum cytokines, antigen-specific responses, and viral clearance.

Results: Whereas LCMV-infected WT mice developed no outward inflammation, Il18tg mice developed features of MAS (weight loss, splenomegaly, cytopenias, transaminitis, cytokinemia) nearly as severe as *Prf1*^{-/-} (Fig 1A). Unlike *Prf1*^{-/-}, Il18tg mice had no appreciable impairment in viral clearance and showed normal upregulation of cytotoxic proteins. Consistent with their systemic hyperinflammatory phenotype, Il18tg mice had a larger effector CD8 T-cells response than WT. Unexpectedly, mice with both hyperinflammatory susceptibility factors (*Prf1*^{-/-};Il18tg mice) were born in Mendelian ratios but quickly developed a spontaneous inflammatory phenotype characterized by weight loss, cytopenias, cytokinemia and hepato splenomegaly (Fig 1B). *Prf1*^{-/-};Il18tg mice have a concomitant increase in splenic myeloid and activated CD-8 T cells, all consistent with a spontaneous MAS-like phenotype.

Conclusion: Chronic IL-18 promotes systemic hyperinflammation despite apparently normal viral clearance during LCMV infection, consistent with MAS. Spontaneous MAS in *Prf1*^{-/-}; Il18tg demonstrates the complementary and non-redundant nature of these mechanisms. It also indicates a homeostatic immunoregulatory function for Perforin. Our data suggest clinical assessment of both pathways could improve targeted treatment in these life-threatening hyperinflammatory disorders.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Pediatric Rheumatology – Basic Science

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: The Sterile Alpha Motif Domain Containing 9 Like protein that is encoded by *SAMD9L* plays a role in endosome fusion, and deletions (haploinsufficiency) of *SAMD9L* including loss of the chromosome 7 where *SAMD9L* is located (monosomy 7) have been associated with myelodysplasia in humans and mice. Recently missense mutations in *SAMD9L* were described in patients presenting with ataxia-pancytopenia syndrome. Here we describe 6 patients with *de novo* frameshift mutations in *SAMD9L* who present with early-onset systemic inflammation, variable interstitial lung disease and cytopenias.

Methods: Whole exome/genome sequencing (WES/WGS) on trios using Illumina HiSeq 2000 platform were performed. An interferon-response-gene score was assessed using a customized Nanostring assay. Toll-like receptor (TLR) stimulation assays, STAT phosphorylation assay and immunofluorescence staining were performed in patients and healthy controls (HCs), PBMCs, monocytes and T cells, and fibroblasts, respectively.

Results: We identified 6 patients with 4 *de novo* frameshift variants in *SAMD9L*. All 6 patients had disease onset between 1 and 7 days of life with generalized nodular skin rashes, fever and increased inflammatory markers (ESR and CRP). Skin biopsies from all 6 patients revealed a neutrophilic panniculitis. Four patients (67%) had developed severe interstitial lung disease (ILD) in infancy, all 4 developed pancytopenia, low B-cell count and hypogammaglobulinemia, and two of those underwent bone marrow transplant. The other 2 patients developed leukopenia, a low B cell count, hypogammaglobulinemia and recurrent pulmonary infiltrates at the age of 3 and 5 years, respectively. Additionally, brain imaging revealed basal ganglia calcifications and/or demyelinating changes in 4 out of the 6 patients. Tertiary structure modelling of *SAMD9L* protein predicted that the 4 variants lie in the p-loop containing the hydrolase domain (amino acids 692-946) of the molecule. qRT-PCR of healthy control cell subsets and tissues showed that *SAMD9L* mRNA relative expression is high in B and NK lymphocytes, moderate in T cells, monocytes, neutrophils, lung and muscle, and low in skin, liver, heart and kidney tissues. Analysis of each individual gene expression level by nanostring in comparison with healthy controls demonstrated significantly higher levels of the following IRGs: *DDX60*, *EPSTI1*, *GBP1*, *IFI6*, *ISG15*, *LY6E*, *OAS1*, *OAS2*, *OAS3*, *RSAD2*, *RTP4* and *SOC1*. Stimulation of PBMCs with the TLR ligands poly I:C, ODN, and LPS induced a 200-fold increase in *IFI27* and a 30-fold increase in *IFNA1* and *IFNB1* transcription compared to baseline. IF staining of patient fibroblasts showed a 1.5-fold increase in EEA1 early endosome formation and a 2.5-fold decrease in RAB5 late endosome formation compared to healthy fibroblasts. Patient had constitutive upregulation of STAT1 and STAT6 in monocytes and of STAT1 and STAT3 in T cells.

Conclusion: We describe a novel immunedysregulatory disease caused by *de novo* truncating variants in *SAMD9L* that presents similar to CANDLE with neutrophilic panniculitis and points to an important role of *SAMD9L* on regulation of adaptive and innate immune responses.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Pediatric Rheumatology – Basic Science

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Systemic juvenile idiopathic arthritis (sJIA) is characterized by fever and rash at disease onset, which are mediated in part by IL-1 β and IL-6. In 40-50% of patients, the disease resolves while in others a chronic inflammatory arthritis develops. The mechanisms that drive the establishment of chronic arthritis are unknown. IL-1 β and IL-6 promote Th17 differentiation and impair regulatory T (Treg) cell function. We aimed to characterize Treg cells in sJIA to determine if these inflammatory cytokines polarize Treg cells to a Th17 fate, potentially contributing to the development of arthritis in this disease.

Methods: Peripheral blood (PB) and/or synovial fluid (SF) samples were collected from acute sJIA (disease duration < 4 months), chronic sJIA (disease duration > 4 months with persistent arthritis), and control subjects. For flow cytometry, PBMCs were stimulated, stained for cell surface markers, fixed, and permeabilized for intracellular staining. For mass cytometry, PBMC/SFMCs were stained for cell surface markers, barcoded, fixed, permeabilized, and then samples were randomized to 1 of 2 mass cytometry runs. RNA was extracted from sorted PB and SF Treg (CD4⁺CD25⁺CD127^{lo}) and effector T (CD4⁺CD25⁻) cells. The Smart-Seq2 platform was used for RNA sequencing. Data analysis was done with GraphPad Prism, FlowJo, Cytobank, and Gene Set Enrichment Analysis.

Results: 10 acute sJIA, 15 chronic sJIA, 5 pediatric control, and 5 adult control subjects were studied. viSNE plots of mass cytometry of SF samples from sJIA patients showed a distinct population of activated Treg cells in the arthritic joints that expressed high levels of CD45RO, HLADR, PD1, Ki67, ICOS, and CD39. A similar population of Treg was also identified in PB of acute and chronic sJIA patients but not adult or pediatric controls. By flow cytometry, acute sJIA patients had a significantly higher frequency of Helios^{hi} Treg cells (78.8 \pm SD 8.4%) than chronic sJIA patients (62.3 \pm 12.3%) and pediatric controls (57.5 \pm 10.6%) (p=0.004). In addition, the percentage of Treg cells from acute sJIA patients expressing IL-17 (5.8 \pm SD 3.2%) was significantly higher than chronic sJIA patients (1.2 \pm 1.1%), pediatric controls (0.45 \pm 0.3%), and adult controls (1.4 \pm 1.0%) (p<0.0001). There was a trend towards increased IL-17⁺ and CCR6⁺ CD4⁺ memory T cells in chronic sJIA patients vs adult controls. Compared to pediatric controls, acute sJIA PB Treg cells upregulated Th17 pathway and downregulated Treg signature genes. Similarly, sJIA SF Treg cells overexpressed IL6/JAK/STAT3 and Th17 pathway genes.

Conclusion: Our data demonstrate an evolving Th17 immune response in sJIA. Treg cells in acute and chronic sJIA express high levels of activation markers, which are not seen in controls. In acute sJIA, Treg cells are subverted to a Th17 phenotype and the generation of peripherally induced Treg cells (Helios^{lo} Tregs) is impaired. In patients with chronic arthritis, there is a trend towards increased Th17 cells in the PB and sJIA SF Treg cells up regulate Th17 related genes. These data suggest that IL-1 β and IL-6 may be reprogramming Treg cells into Th17 cells in sJIA.

Session Title: Rheumatoid Arthritis – Etiology and Pathogenesis I

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: In rheumatoid arthritis (RA), tissue resident fibroblasts orchestrate chronic inflammation and regulate pathologic bone and cartilage remodeling that causes irreversible joint damage. Recently, we and others have identified the selective expansion of CD90+ sublining fibroblasts in RA patients with active, leukocyte-rich synovial histological features. Here, we leveraged droplet-based single cell RNA-sequencing (scRNA-seq), confocal microscopy, and ex vivo tissue organoid cultures to elucidate molecular pathways that govern the expansion of pathologic synovial fibroblasts in RA.

Methods: Single cell RNA-seq. Synovial stromal and endothelial cells from RA and OA synovial tissues were isolated and subjected to droplet-based single cell RNA-sequencing. Gene mapping, read alignment, pseudotime and trajectory analyses were performed.

Confocal Microscopy. RA and OA synovial tissue sections were stained with antibodies against (PRG4)/Lubricin, CD90, MCAM (CD146), VWF, and NOTCH3.

3-D synovial organoids. Synovial organoids comprised of fibroblasts and endothelial cells were reconstituted using an *in vitro* micromass culture system.

Results: ScRNA-seq of 32,000 single synovial stromal cells identified lining (*PRG4+*) fibroblasts, sublining (*CD90+*) fibroblasts, pericytes (*ACTA2+*), and endothelial cells (*VWF+*) as the major tissue resident cells in the synovium. Pseudotime and trajectory analysis revealed unexpected fibroblast transcriptional programs that follow anatomical spatial localization. Confocal microscopy visualization of fibroblast markers CD90, Lubricin and MCAM confirmed a spatial gradient along a perivascular to synovial lining axis. Isolation of spatially-restricted fibroblasts followed by serial passages and parallel transcriptomic profiling revealed spatial transcriptomic signatures diminish after serial passages, suggesting spatial gradients is maintained by local signals derived in situ in the synovial microenvironment. Receptor-ligand analysis followed by an *in vitro* ligand screen identified endothelial-derived Notch signaling as a key driver in establishing the spatial gradient between that perivascular and lining layer fibroblasts. Direct fibroblast-endothelial cell contact using a novel 3-D organoid system recapitulates the in vivo fibroblast-endothelial structure in a Notch-dependent manner. Inhibition of Notch signaling by small molecules and siRNA-mediated silencing of Notch3 abolishes sub-lining formation *in vitro*. In RA, synovial fibroblasts were overrepresented in the perivascular zone characterized by marked increase in Notch signaling, suggesting Notch regulates pathologic synovial remodeling in RA.

Conclusion: Using scRNA-seq, we identified a spatial gradient in synovial fibroblasts regulated by endothelium-derived Notch signaling. In RA, Notch signaling drives expansion of sublining (*CD90+*) synovial fibroblasts. Inhibition of Notch3 signaling prevents *CD90+* synovial sublining expansion, highlighting fibroblast Notch3 signaling as a novel therapeutic target in RA.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Etiology and Pathogenesis I

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Rheumatoid nodules are the most common cutaneous manifestation in patients with RA, often associated with longstanding and a more severe disease course. Paradoxically, therapy including methotrexate (MTX) and TNF-antagonists, which is effective for synovial inflammation, has been linked to the development of subcutaneous nodules. We employed RNAseq to generate a transcriptome profile of rheumatoid subcutaneous nodules with the aim of identifying pathogenic mechanisms and genes differentially expressed in association with methotrexate therapy.

Methods: Eight subcutaneous nodules were obtained from 8 separate patients with rheumatoid arthritis as defined by ACR criteria, undergoing elective surgery for nodule removal. The patient cohort included 4 patients (3 females) grouped as never/previously (discontinued ≥ 25 months prior) receiving MTX therapy, and 4 patients (3 females) taking MTX (7.5 -20 mg/week) at the time of nodule removal. RNA was extracted using an RNeasy mini kit (Qiagen), including DNase digestion. All nodule RNA passed stringent criteria for purity and integrity (RIN >5.2). Libraries were prepared using a TruSeq RNA library preparation kit (Illumina) and sequenced as 125-bp paired end reads on a HiSeq2000 platform. RNAseq read quality was assessed using FastQC, reads were aligned using STAR aligner, and gene count tables and FPKM values obtained using packages within StringTie. To better characterise the cell types responsible for gene expression differences in nodule tissues, we applied CIBERSORT to estimate cell type composition

Results: Immune genes expressed within nodules were identified using the Immunome database as reference. Immune gene set enrichment analysis highlighted cytokine signalling, neutrophil degranulation and IFN γ -signalling pathways as potential candidates for driving inflammation within nodules. Complement and its regulation and IL-4/IL-13 signalling also feature. RNAseq data further identified 10 genes differentially expressed in nodules (FDR < 0.05), associated with MTX therapy. The expression of two genes (ABI3 and EMCN) was validated using digital PCR; both show expression that is down-regulated (~ 2.3 -fold and ~ 3.9 -fold respectively) in association with MTX therapy. CIBERSORT application to estimate cell type composition within nodules was consistent with a macrophage-dominated granuloma, characterised by an inferred large fraction of M2 macrophages as well as M1 macrophages and monocytes. Nodules exposed to MTX harboured an inferred fraction of M0 macrophages (5-26% of leucocytes) that was absent from nodules lacking MTX exposure.

Conclusion: Cytokine signalling, particularly from IFN γ and IL-4/IL-13, are key to inflammatory pathways operating within nodule tissue. Genes differentially expressed within nodules in association with MTX therapy for RA are not directly part of immune/inflammatory mechanisms, implicating diverse pathogenic mechanisms. Nodules from patients with RA receiving MTX contain M0 macrophages suggesting macrophage depolarisation and/or local proliferation associated with MTX therapy.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Etiology and Pathogenesis I

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Recent studies suggest that epigenetic marks distinguish FLS isolated from different joints in RA. Hip and knee joint-derived FLS, in particular, have distinctive DNA methylation and transcriptome patterns that implicate the “IL-6 signaling pathway” and the “JAK-STAT pathway”. In this study, we determined how hip and knee FLS in RA differ in terms of the response to IL-6 to define the functional sequelae of joint-specific epigenetic imprinting.

Methods: RA FLS lines from hip and knee arthroplasties were used from passage 5-7 (5 each). FLS were serum starved and then stimulated with IL-6 or medium for 2h and RNA-seq was performed. Differential gene expression was determined using edgeR. Gene set enrichment analysis was performed using MSigDB curated gene sets. Differentially modified epigenetic regions (DMERs) between hip and knee FLS were analyzed from published ATAC-seq and histone ChIP-seq using DiffBind (FDR<0.05). Published whole genome bisulfite sequencing (WGBS) datasets were analyzed using DSS. Western blot analysis and/or solid phase immunoassay were performed using antibodies to P-STAT3, STAT3, JAK1 and GAPDH.

Results: RNA-seq data were normalized and principal component analysis was performed (Fig 1). Unstimulated hip and knee FLS transcriptomes segregate, consistent with previous studies. The hip and knee FLS also segregated after IL6 treatment, indicating that joint-specific differences are maintained after IL6 treatment and do not converge. Differentially expressed genes (DEGs) were identified and we focused on hip vs knee differences present in both medium and IL6-treated FLS. Gene Set Enrichment Analysis indicated that the knee was enriched in genes in “Cell adhesion molecules” and “Integrin pathway”, while the hip was enriched in “p38_alpha downstream pathway”. Next, ATAC-seq, histone ChIP-seq and WGBS datasets from RA FLS were explored to identify additional epigenomic differences between the hip and knee in IL6-signaling. In unstimulated FLS, WGBS data showed 4 differentially methylated sites associated with JAK1 and 5 sites associated with gp130. ATAC-seq showed differences in chromatin accessibility in the IL6 receptor and JAK1. The histone H3K27ac was differentially marked for the STAT3 gene. To understand the mechanism of differential IL6 responses, we evaluated hip and knee RA FLS after IL6 stimulation. P-STAT3 levels peaked after 30min and returned to baseline at 4h. Knee FLS had significantly higher P-STAT3 than hip FLS at 30 minutes (1.2 ± 0.4 vs 0.5 ± 0.2 , $p < 0.05$), indicating that enhanced STAT activation accounts for some transcriptome differences between RA hip and knee FLS.

Conclusion: RA hip and knee FLS have distinct transcriptomes, epigenetic marks, and STAT3 activation patterns in the IL6 pathway. These differences could contribute to joint-location responses to targeted therapies such as JAK inhibitors.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Etiology and Pathogenesis I

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: An atypical subgroup of patients with seropositive rheumatoid arthritis (RA) has been identified with confirmed synovitis but normal levels of the acute phase protein C-reactive protein (CRP), often considered an accurate marker of disease activity. We questioned whether this presentation was associated with delayed diagnosis and/or relative under treatment, risking worse disease outcome, and whether there were distinct immunological features.

Methods: 48 RA patients with active synovitis confirmed on Power Doppler ultrasound were recruited; 30 had normal (n)CRP ($\leq 5\text{mg/L}$) and 18 had high (h)CRP ($>5\text{mg/L}$) levels. In all other measures, disease activity was equivalent between the two groups.

Results: Time to diagnosis and time to first disease modifying anti-rheumatic drug (DMARD), were both significantly longer in the nCRP cohort. One and two year follow-up revealed that nCRP patients needed escalation to biologics significantly earlier in their disease. Serum Interleukin (IL)-6, IL-1 β , and tumour necrosis factor (TNF)- α , were appropriately elevated in both patient groups compared to healthy donors (HCs), but while IL-6 expression was positively correlated with other pro-inflammatory cytokines and acute phase reactants in hCRP patients, this synergy was lost in nCRP patients. Moreover, nCRP patients had an anti-inflammatory immune cell phenotype with significantly increased regulatory T-cell (Treg) frequencies and elevated Treg IL-10 production compared to hCRP patients. Proteomics identified differential expression of complement components in serum from hCRP compared to nCRP patients; specifically a significant upregulation of alternative complement pathway factors (eg Factors I, H and B) was seen in hCRP patients and an upregulation of kallistatin, an inhibitor of the alternative pathway in nCRP patients. Complement activation measured by serum C3 cleavage product was similarly elevated in both patient groups compared to HCs ($P<0.01$ HC vs nCRP, $p<0.05$ HC vs hCRP). However, a strong positive correlation was observed between C3 cleavage product and levels of anti-CCP antibodies ($R^2=0.53$, $p<0.05$) in nCRP patients but not hCRP patients. Finally, analysis of complement activation pathways revealed that nCRP patients preferentially activated complement via Classical and Mannose Lectin pathways compared to hCRP patients suggesting that nCRP and hCRP patients have an altered disease pathogenesis.

Conclusion: Patients with normal CRP during flares of RA had an altered immunological profile and altered activation of complement pathways compared to hCRP patients, experienced diagnostic delays and appeared to respond less well to conventional treatment.

Session Title: Rheumatoid Arthritis – Etiology and Pathogenesis I

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Inflammation is an important component of most age-related disorders. Cellular changes associated to aging are tightly connected with pro-inflammatory mechanisms. The purpose of this study is to analyze cellular senescence in synovial fibroblasts and its potential influence in the pathogenesis of chronic arthritis, including rheumatoid arthritis (RA) and osteoarthritis (OA).

Methods: The expression of senescence associated markers p16INK4 (p16) and Nanog was analyzed by immunohistochemistry (IHC) and immunofluorescence (IF) in synovial tissues from RA (n=43), OA (n=18), and non-inflammatory synovial tissues (n=15). Senescent synovial fibroblasts (SF) were quantified in cultures by senescence-associated beta-galactosidase (SA- β -gal) staining. For a model of stress-induced senescence, SF were cultured for 14 days after a short course of oxidative stress with H₂O₂ (200 mM for 1h on day 5) or exposure to TNF α (100 ng/ml for 72h on day 2). At 14 days, senescence and further response to stimulation with TNF α 20 ng/ml for 24h were analyzed. RNA was extracted to quantify IL-6, IL-8, MMP-3, MCP-1, p16 and p21 mRNA expression by qRT-PCR and culture supernatants were analyzed for IL-6 and IL-8 production by ELISA. Quantitative data were statistically analyzed by Pearson or Spearman correlation coefficient or Mann-Whitney test where appropriate.

Results: Synovial tissue expression of both p16 and Nanog was detected by IHC and correlated positively with the age of the donors regardless of their origin (p16: p=0.008/r=0.307; Nanog: p=0.001/r=0.413). p16(+) cell density was significantly higher in OA tissues (p=0.01) and Nanog(+) was higher in both RA (p=0.0006) or OA (p<0.0001) tissues compared to controls. p16(+) and Nanog(+) cell density were higher in young (age <40 y/o) RA patients compared to the same group of age in non-inflammatory donors (p= 0.04 and p=0.02 respectively). Double p16 and hsp47 IF labelling confirmed that both hsp47(+) SF and hsp47(-) non-fibroblastic cell fractions contained p16(+) senescent cells. The percentage of SA- β -gal(+) in non-inflammatory control SF after 14 days in culture was positively correlated with age (p=0.008/r=0.75). This fraction was higher in RA (p=0.03) compared to healthy control SF, and increased upon SF exposure to H₂O₂ or TNF α (p=0.004 for both). Stress-induced senescence enhanced the senescence associated secretory phenotype (SASP) in SF, up-regulating the mRNA expression of pro-inflammatory factors such as IL-6, IL-8, MCP-1, and MMP-3. Consistently, senescent SF released more IL-6 and IL-8 than non-senescent SF. Finally, further stimulation with TNF α induced a higher increase in IL-6, IL-8 and MMP-3 mRNA expression in senescent SF compared to non-senescent SF.

Conclusion: Synovial tissues from patients with RA and OA shows an increased proportion of senescent SF. Stress-induced senescence in SF increases the production of pro-inflammatory mediators, and gives rise to an activation state that enhances the responsiveness to TNF α . Our data suggest that SF senescence is linked to the activation of a pro-inflammatory phenotype that may contribute to the pathogenesis of chronic arthritis.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Etiology and Pathogenesis I

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: The central nervous system is not the primary target in rheumatoid arthritis(RA). However, neuropsychiatric symptoms including pain, depression and anxiety are common and may be critical for patients' quality of life. The aim of the present study was to investigate how insulin-like growth factor receptor (IGF1R) signaling in RA associates with morphometric changes of the brain, and ultimately impairment of their functional ability.

Methods: Arthritis was induced in DBA/1 mice by collagen II and the RA-mice were filmed to evaluate behavioral changes. IGF1R was inhibited with short hairpin RNA. At termination, brains were analyzed by quantitative PCR and immunohistochemistry. 15 RA patients, all of them satisfying ACR classification criteria, underwent magnetic resonance imaging (MRI) for volumetric analysis of hippocampus at 3Tesla and processed with brain morphometry software (MAPER). Physical functioning was assessed by the Health Assessment Questionnaire (HAQ). Pain threshold was measured by algometer. Statistical analysis included the Mann-Whitney U-test and Spearman's rank correlation coefficient.

Results: Evaluation of MRI and physical functioning in RA patients revealed that smaller hippocampus volume was linked with exaggerated response of induced pain ($p=0.0006$), higher functional disability (HAQ, $p=0.009$), and lower serum levels of IGF1 ($p=0.05$). RA-mice had signs of inflammation in the hippocampus, presented by higher density of IBA1⁺ microglia and higher transcription of microglia activation marker CD68 ($p=0.0006$) and interleukin-1 β ($p=0.002$). Enrichment of microglia was observed in the pyramidal layer of cornu ammoni (CAsp, $p=0.02$) and the molecular layer of the dentate gyrus (DGmo, $p=0.02$). This coincided with inhibitory phosphorylation of insulin receptor substrate-1 (IRS1) in the subgranular layer of DG (DGsg, $p=0.03$) and CAsp ($p=0.05$), and up-regulation of IGF1R in the CAsp ($p=0.03$). These changes reproduce the molecular signature of IGF1/insulin resistance. DGsg, the site of life-long neurogenesis, became thinner ($p=0.03$) and the reduced thickness correlated with a smaller number of DCX⁺ developing neurons in this area ($r=0.7$, $p=0.005$). There was also a reduction in the total hippocampus area of RA-mice ($p=0.02$). Inhibition of IGF1R in RA-mice led to reduced inhibitory phosphorylation of IRS1 ($p=0.004$) and partial improvement of neurogenesis, seen as an increased number of GFAP⁺ neuronal stem cells in DGsg ($p=0.02$).

Conclusion: We offer a mechanistic link between pain perception in RA and reduced hippocampal volume. Our experimental study demonstrates that inflammation reproduces the molecular signature of IGF1/insulin resistance, which leads to inadequate maintenance of hippocampal neurons and consequently reduced hippocampal volume.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Lupus Erythematosus – Animal Models

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Systemic lupus erythematosus (SLE) is a chronic autoimmune disease characterized by loss of tolerance to nuclear components; this results in production of autoantibodies, immune complex formation, and tissue damages. Because SLE is a multifactorial disease with an underlying pathogenic mechanism that is poorly understood, few effective treatments are available. Human and mouse studies indicate a role for Th17 in progression of SLE. Renal damage, which occurs in about half of patients with SLE, is the leading cause of morbidity and mortality. We recently showed that serum concentrations of s-CD95L (also known as FasL) in SLE patients are higher than those in healthy subjects and are associated with disease severity via promotion of Th17 trafficking to inflamed kidneys (*Immunity*, 2016). CD95L is a transmembrane ligand that is cleaved by metalloproteases to release a soluble ligand (s-CD95L). Both s-CD95L and its transmembrane counterpart (m-CD95L) bind CD95. In the presence of m-CD95L, the death domain (DD) of CD95 recruits FADD, which in turn aggregates caspase-8 to trigger apoptosis. By contrast, interaction between s-CD95L and CD95 fails to recruit caspase-8 and FADD but instead induces a Ca^{2+} response via docking of PLCg1 to a novel domain within CD95, called the calcium-inducing domain (CID). In patients with SLE, this pathway induces accumulation of inflammatory Th17 cells in damaged organs, thereby aggravating disease pathology.

Methods: Here, we developed a protein-fragment complementation assay (PCA) and performed a high-throughput screening (HTS) to identify drugs that disrupted the CD95/PLCg1 interaction without affecting CD95/FADD binding. In parallel, a structure-activity relationship approach was performed to synthesize CID peptidomimetics that abrogated both the CD95-driven Ca^{2+} response and transmigration of CD4^{+} Th17 cells. Finally, we established the in vivo therapeutic effects of both the peptidomimetic and the best lead identified from the HTS assay in lupus-prone mice (MRL^{lpr/+}).

Results: HTS identified the HIV protease inhibitor *ritonavir* as a potent disruptor of the CD95/PLCg1 interaction. Lymphocytes from HIV patients treated with *ritonavir* or its structural derivatives failed to respond to the inflammatory cytokine s-CD95L. The second structure-activity approach revealed that *ritonavir* is a peptidomimetic that shares structural characteristics with both human and mouse CID with respect to docking to the SH3 domain of PLCg1. Administration of lupus mice with either ritonavir or a peptidomimetic designated DB550 led to: 1/ a significant reduction in the mesangial proliferation and in the adhesion of the Bowman's capsule; 2/ a significant reduction of inflammatory infiltrates (especially of Th17 cells) and the normalization of kidney architecture; 3/ a reduced C3 deposition and dsDNA antibody levels, as well as an improvement of blood filtration of creatinine.

Conclusion: Overall, this study establishes that HIV protease inhibitors and the peptidomimetic DB550 represent novel and attractive drugs that can be used in the treatment of human lupus.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Lupus Erythematosus – Animal Models

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Although the pathogenesis of neuropsychiatric lupus (NPSLE) is not fully understood, neuroinflammation plays a major role in disease. Lipocalin-2, an acute phase reactant protein upregulated in SLE, promotes neuroinflammation through inducing brain barrier disruption, glial activation, and neurotoxicity. In this study, we

examined the effects of LCN2 deficiency on the development of neurobehavioral deficits in the lupus-prone B6.Sle1.Sle3 (Sle1,3) mouse strain.

Methods: Sle1,3, Sle1,3-LCN2 knockout (KO), B6.LCN2KO, and B6 mice were evaluated for cognitive dysfunction and depression-like behavior at 7-10 months of age (n=5-10/group). Brains were either paraffin-embedded for immunofluorescence staining, or cortex and hippocampal samples were snap frozen for analysis of gene expression. Indicators of systemic disease, including serum IgG anti-dsDNA titers, spleen weight, and renal pathology were assessed. Brains from a separate cohort of age-matched mice were analyzed by flow cytometry, and CD11b+CD64+CD45-low microglia were sorted for RNA sequencing.

Results: Sle1,3 mice exhibited significant impairment in spatial and recognition memory when compared with B6 mice, and these deficits were significantly attenuated in Sle1,3-LCN2KO mice. Sle1,3 mice also demonstrated anhedonia (abnormal pleasure seeking behavior), and this depression-like behavior was significantly reduced with LCN2 deficiency. Flow cytometry showed a significant increase in brain infiltrating cells, including CD4+ and CD8+ T cells, that was not reduced with LCN2 deficiency. When compared with B6 mice, Sle1,3 mice exhibited increased anti-dsDNA titers, splenomegaly, and glomerular and tubular pathology, but these findings were not attenuated with LCN2 deficiency. In the hippocampus, there was a significant increase in TUNEL-positive cells in Sle1,3 compared with B6 mice, while apoptosis was reduced in the Sle1,3-LCN2KO mice when compared with Sle1,3 brains. Moreover, Iba-1 staining revealed amoeboid (activated) microglial morphology in Sle1,3 hippocampi but a more ramified (resting) morphology in Sle1,3-LCN2KO mice. RNA sequencing of sorted microglia showed that several genes, upregulated in Sle1,3 mice and involved in inflammation and memory (e.g. *Plp1*, *Mal*, and *Apod*), were normalized in Sle1,3-LCN2KO mice. Additionally, in two large independent human cohorts, patients with NPSLE displayed high cerebrospinal fluid levels of LCN2 compared to healthy controls.

Conclusion: Our findings demonstrate that LCN2 deficiency significantly attenuates neurobehavioral deficits, reduces apoptosis in the brain, and modulates microglia morphology in the Sle1,3 lupus-prone strain. Moreover, LCN2 regulates microglial expression of genes essential to NPSLE development, suggesting LCN2 as a novel therapeutic target.

Selective Deficiency of Serine Arginine-Rich Splicing Factor 1 (SRSF1) in T Lymphocytes Leads to mTORC1 Activation, Treg Dysfunction and Systemic Autoimmune Disease

Takayuki Katsuyama¹, Hao Li¹, Denis Comte², Michael W. Mosho³, Andrew R. Gillooly³, George C Tsokos⁴ and Vaishali R. SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Lupus Erythematosus – Animal Models

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: T cells from patients with systemic lupus erythematosus (SLE) exhibit defects in signaling and cytokine production, and aberrant numbers and/or function of regulatory T cells (Treg). By discovery approaches we previously identified the serine arginine-rich splicing factor 1 (SRSF1) in human T cells. We showed that SRSF1 promotes normal expression of the CD3 zeta signaling chain, and upregulates IL-2 production in human T cells. SRSF1 expression levels are decreased in SLE T cells, and associate with worse disease. Force expression of SRSF1 into SLE T cells rescued IL-2 production. These results indicate that the SRSF1 deficiency is important in SLE T cell dysfunction. However, it is unknown how SRSF1 deficiency contributes to immune-mediated disease. To this end, we have generated mice with a T cell-restricted deletion of SRSF1, and our goal is to evaluate the mechanistic role of SRSF1 in T cell dysfunction and the development of immune-mediated disease *in vivo*.

Methods: *Srsf1*-conditional knockout (*Srsf1*-cko) mice were generated by crossing *Srsf1*-flox mice with d.*Lck.Cre* mice to delete SRSF1 in mature T cells. Peripheral lymphoid organs were analyzed for immune cell phenotype and function by flow cytometry. T cells were stimulated with anti-CD3, anti-CD28 and PMA plus Ionomycin. Serum and urine were

collected at monthly intervals to assess autoantibodies and proteinuria. Tissues (lung, liver, kidney) were fixed and processed for histopathology. Suppressive function of Tregs was assessed in vitro by Treg-Teffector co-culture assays, and in vivo by adoptive transfer of Tregs followed by induction of dextran sodium sulfate (DSS)-induced colitis in B6 mice. Activity of the mammalian target of rapamycin complex (mTORC) 1 pathway was analyzed after T cell stimulation by western blot and phospho-flow cytometry. Phosphatase tensin homolog (PTEN) expression levels were analyzed by qPCR and western blot.

Results: *Srsf1*-cko mice develop a systemic autoimmune disease phenotype with elevated autoantibodies and systemic inflammation in peripheral organs including lungs, liver, kidneys and increased proteinuria. Kidney histopathology shows glomerular hyperproliferation, glomerular capillary hyperplasia, and interstitial infiltration of mononuclear cells suggestive of lupus-like nephritis. CD4 T cells exhibit an activated phenotype with increased frequencies of IFN- γ and IL-17 producers but lower amounts of IL-2 upon ex vivo stimulation. Tregs from *Srsf1*-cko mice are dysfunctional in vitro, and are unable to suppress DSS-colitis in vivo. Tregs exhibit an inflammatory phenotype with increased IFN- γ and IL-17 production upon ex vivo stimulation. Increased activity of the mTORC1 pathway is observed in Tregs from the *Srsf1*-cko mice, and expression levels of PTEN, an inhibitor of the mTORC1 pathway, are decreased.

Conclusion: SRSF1 is a novel regulator of Treg function, and its deficiency in T cells leads to autoimmunity and lupus-like nephritis. Therefore, deficiency of SRSF1 in T cells may represent a molecular defect that contributes to the pathogenesis of systemic autoimmune disease.

Cuda³, ¹Northwestern University Feinberg School of Medicine, Chicago, IL, ²Albert Einstein College of Medicine, Bronx, NY, ³Department of Medicine Division of Rheumatology, Northwestern University Feinberg School of Medicine, Chicago, IL, ⁴Division of Rheumatology, Albert Einstein College of Medicine, Bronx, NY, USA, Bronx, NY

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Lupus Erythematosus – Animal Models

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Systemic lupus erythematosus (SLE) is a complex autoimmune syndrome affecting multiple organs, including the brain. More than 60% of patients experience neuropsychiatric symptoms of SLE (NPSLE) that often occur early in disease and go undiagnosed. Despite the devastating impact of NPSLE on health-related quality of life, the underlying disease mechanisms are unknown. Microglia are the resident innate immune cells in the brain, and accumulating evidence points to microglia as a source of neurotoxic factors that drive neurodegenerative disease. However, very few studies have examined microglia in the context of NPSLE. Here, microglia isolated from two lupus-prone mouse strains with NPSLE-like disease were evaluated at the transcriptional level to ascertain the existence of a common gene signature.

Methods: Mice with caspase 8 flanked by *loxP* sites (*Casp8^{fl/fl}*) were bred to mice expressing Cre under control of the CD11c gene promoter (*Cre^{CD11c}*) to generate *Cre^{CD11c}Casp8^{fl/fl}* mice. The bicongenic B6.Sle1.Sle3 (Sle1,3) strain was derived from the introgression of 2 lupus susceptibility loci from the NZM2410 spontaneous SLE model onto non-autoimmune C57BL/6 (B6) mice. *Casp8^{fl/fl}*, *Cre^{CD11c}Casp8^{fl/fl}*, B6 and Sle1.3 mice were evaluated for behavioral deficits at 8-10 months of age (n=4/group). Cellular infiltration into the brain was assessed using 10-color flow cytometric analysis. Microglia were sorted for RNA-seq analysis.

Results: We have shown that CD11c-specific deletion of caspase 8, an enzyme in the Fas pathway classically linked to apoptosis initiation and necroptosis suppression, induces an inflammatory disease reminiscent of both human and classic murine models of SLE. *Cre^{CD11c}Casp8^{fl/fl}* mice also exhibit significant impairment in coordination/balance and working memory/learning behaviors similar to patients with SLE. Likewise, the lupus-prone Sle1,3 mouse strain exhibits depression-like behavior and significant impairment in spatial and recognition memory, symptoms detected in SLE patients. In both lupus-prone strains, behavioral deficits correlate with increased leukocyte infiltration including T cells and macrophages. Of the significantly upregulated genes (p<0.05, fold change in expression>1.5) observed in *Cre^{CD11c}Casp8^{fl/fl}* (276) and Sle1,3

(246) microglia compared to their respective controls, 22 genes are shared ($p=3.23 \times 10^{-5}$, hypergeometric distribution). These shared genes are involved in 'cell chemotaxis' ($p=7.99 \times 10^{-4}$; *Vcam1*, *Slamf8*, *Cxcl16*), 'scavenger receptor activity' ($p=1.27 \times 10^{-4}$; *Cxcl16*, *Lgals3bp*), 'negative regulation of inflammatory response' ($p=1.83 \times 10^{-4}$; *ApoE*, *ApoD*, *Slamf8*), 'negative regulation of lipid metabolic process' ($p=1.38 \times 10^{-4}$; *ApoE*, *ApoD*, *Niacr1*) and 'response to external stimulus' ($p=1.31 \times 10^{-4}$; *Igax*, *Slfn2*, *ApoE*, *Axl*, *Pkd2*, *Cxcl16*, *Slamf8*).

Conclusion: These data substantiate a common microglial transcriptional signature associated with NPSLE-like disease suggestive of a more regulatory role. In future studies, through examination of other NPSLE models, we will assess the penetrance of this common signature to further interrogate how defective microglial function may incite NPSLE.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Lupus Erythematosus – Animal Models

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Proper function of lymphatic vessels is needed to limit the magnitude and duration of tissue inflammation. Chronic inflammatory states such as obesity and psoriasis are associated with lymphatic dysfunction, but lymphatics in lupus models have not been well characterized. SLE patients are photosensitive, developing inflammatory skin lesions upon exposure to even ambient ultraviolet radiation (UVR). We hypothesized that lymphatic dysfunction may contribute to photosensitivity in lupus.

Methods: 8-10 week old MRL/MpJ-*Fas*^{lpr/lpr} (*lpr*) mice and age-/sex-matched MRL controls were evaluated at baseline, and after exposure to UVR. The source of UVR was a set of 4 FS40T12 sunlamps emitting UVA and UVB at 40:60 ratio. The overall dose of the total radiation ranged from 2000-2500 J/m². Lymphatic function was assessed with an intradermal injection of 1μL of 2% Evans blue (EB) to the ear, followed by measurement of EB concentration in the draining auricular lymph node (LN). Flow cytometry of ears and auricular LN allowed quantification of resident cell populations, and local mRNA expression of vascular endothelial growth factor-C (VEGF-C) was evaluated by real-time PCR. Mann-Whitney *U* test was used to compare the groups; data is presented as mean ± SE, with a two-tailed *p*-value of <0.05 considered significant.

Results: At baseline, auricular LNs of *lpr* mice are bigger and are about 10-fold more cellular than controls (21523860 ± 3861631 cells vs. 2184360 ± 464267 cells, respectively; $p=0.008$), but there is no compensatory increase in dermal lymphatic endothelial cells (LEC) to allow for an increase in local lymphatic transit to the LN (8918 ± 2142 LEC in *lpr* vs. 6106 ± 1023 LEC in controls; $p=0.421$). Accordingly, already at baseline, the effective flow of EB from the ear to the LN in *lpr* mice is only 44% that of controls, when accounting for the weight of the LN. Importantly, post-UVR, EB drainage in *lpr* mice is reduced to only 10% that of controls, and this value persists both 1 week after UVR and 1 month later. Interestingly, we have observed that at the peak of local inflammation that occurs at around 7 days post-UVR, VEGF-C mRNA levels are suppressed in both *lpr* and MRL strains, compared with non-UV exposed controls.

Conclusion: Dermal lymphatic network of lupus models have never been characterized, despite evidence for a major role of lymphatics in the regulation of chronic inflammation. Here we provide indications to impaired local lymphatic drainage in the *lpr* lupus strain, which can lead to reduced inhibitory signals arriving at the overactive lymph node from the lymphatic circulation, contributing to the unchecked inflammation known to occur in SLE. UVR is shown to further impair local lymphatics, particularly in the lupus strain, possibly through suppression of VEGF-C production.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Lupus Erythematosus – Animal Models

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Lupus nephritis is most common cause of mortality and morbidity in systemic lupus erythematosus (SLE) patients and 60% of SLE patients develops lupus nephritis. HRES-1/RAB4 genomic locus has been associated with disease manifestations in SLE patients (Arthritis Rheum. 58:532-520). Inhibition of Rab geranylgeranyl transferase prevented nephritis in lupus-prone mice (Ann. Rheum. Dis. 73:1887-1897). To investigate the role of Rab4A in lupus pathogenesis, we developed a mouse model Rab4A-KO^{CD4Cre} (Rab4A^{KO}; mice lacking expression of Rab4A in T cells relative to C57Bl/6 wild-type (WT) and floxed Rab4A^{Q72L} knock-in (Rab4A^{Q72L}) as a control. Previously we showed that Rab4A^{Q72L} knock-in prevents ANA production, immunoglobulin and C3 depositions in glomeruli and lymphocytic infiltration in kidneys relative to Rab4A^{KO} mice. These preliminary results provided rationale for testing our hypothesis that HRES-1/Rab4 plays a crucial role in SLE, including the pathogenesis of lupus nephritis.

Methods: Age and gender matched WT, Rab4A^{Q72L} and Rab4A^{KO} female mice were injected with 0.5 mL pristane per 20 g of body weight, intraperitoneally. 14 days post pristane injection, kidneys were fixed in formalin for H&E and PAS staining or snap freeze in OCT for confocal microscopy. To assess the podocyte injury, 8 µm frozen kidney sections were analyzed anti-podocin and anti-CD51 (Integrin αV). Frozen kidney sections were further analyzed using anti-CCR6 and anti-IL17. To study the effect of Rab4A on GLUT1 glucose transporter, Kidney sections were stained with anti-GLUT1. Splenic germinal centers were investigated using 6 µm frozen spleen sections stained with anti-B220, anti-F4/80, anti-CD3 and anti-CD138. Kidney histology was blindly evaluated by an expert pathologist.

Results: Kidney histology revealed accelerated glomerulonephritis (GN) (3-fold; $p=7.6 \times 10^{-4}$), glomerulosclerosis (GS) (8-fold; $p=0.0106$) in Rab4A^{KO} mice relative to Rab4A^{Q72L} mice. Further, we found 1.7-fold reduction in podocin and 1.9-fold reduction in CD51 expression in kidneys of Rab4A^{KO} relative to WT mice (podocin, $p=0.0027$; CD51, $p=0.0002$) or Rab4A^{Q72L} mice (podocin, $p=0.03$; CD51, $p<0.0001$), suggesting podocyte injury in Rab4A^{KO} animals. In addition, CCR6 and IL-17 expression by kidney-infiltrating lymphocytes was significantly higher in Rab4A^{KO} as compared to WT and Rab4A^{Q72L} mice. GLUT1 expression was elevated 4-fold and confined to the kidney medulla of Rab4A^{KO} mice relative to Rab4A^{Q72L} ($p=0.004$) and WT controls ($p=0.0001$). Relative to WT controls, splenic germinal centers exhibited 1.3-fold increased size in Rab4A^{KO} mice ($p=0.0452$) with 3-fold expansion of T cell zones ($p<0.0001$) and 2-fold accumulation of plasma cells ($p=0.0197$). Interestingly, spleen sections from Rab4A^{Q72L} mice had smaller splenic germinal centers with fewer CD138⁺ plasma cells in comparison to WT ($p=0.0002$; $p=0.0427$) and Rab4A^{KO} mice ($p=0.0083$).

Conclusion: The results suggest that Rab4A protects from nephritis in the pristane-induced model of SLE by limiting the germinal center formation and pro-inflammatory expression of GLUT1 and Integrin αV by renal epithelial cells.

Inactivated Influenza Vaccine Prevents Respiratory Infections and Improves All-Cause and Cause-Specific Mortality in Immunosuppressed People with Autoimmune Rheumatic Diseases: Propensity Score Adjusted Cohort Study Using Data from Clinical Practice Research Datalink

Georgina Nakafero¹, Matthew Grainge², Puja Myles², Christian Mallen³, Weiya Zhang¹, Michael Doherty⁴, Jonathan Nguyen-van-tam² and **Abhishek Abhishek**¹, ¹Academic Rheumatology, The University of Nottingham, Nottingham, United Kingdom, ²Epidemiology and Public Health, The University of Nottingham, Nottingham, United Kingdom, ³Research Institute for Primary Care and Health Sciences, Keele University, Keele, United Kingdom, ⁴The University of Nottingham, Nottingham, United Kingdom

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Epidemiology and Public Health I: Morbidity and Mortality

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: To assess the effectiveness of inactivated influenza vaccine (IIV) in preventing influenza like illness (ILI), lower respiratory tract infection (LRTI), pneumonia, chronic obstructive pulmonary disease (COPD) exacerbation and death in adults with autoimmune rheumatic diseases (AIRDs).

Methods: Adults with AIRDs e.g. RA, Spondyloarthritis, SLE etc., and treated with immunosuppressive drugs in the 3 month period before the 1st September of each year, 2006-2009, and 2010-2015 were identified in the Clinical Practice Research Datalink (CPRD). CPRD is a longitudinal anonymised electronic database containing health records of over 13 million people, registered with >680 general practice surgeries in the UK. It contains details of all diagnoses, prescriptions, immunisations etc. recorded as part of usual medical care. Data for this study were extracted from the CPRD, and from linked Hospital Episode Statistics and Office for National Statistics databases. The 2009-2010 influenza pandemic period was excluded due to co-vaccination with pandemic vaccine and predominance of pandemic virus in community. Propensity score (PS) for vaccination on the 1st September of each year was calculated using previously published and validated methods. Cox-proportional hazard ratio (HR) and 95% confidence intervals (CIs) were calculated to examine association between vaccination and first occurrence of each outcome of interest upto 31st August of the next year. Vaccination was regarded as a time-varying covariate, and the protected period began 14 days from the date of vaccination. Sensitivity analysis restricting to the period in which the flu virus was in circulation in the community was performed. The exposure and outcome variables reverted to unexposed and no-outcome on the 1st September of each year. The association was adjusted for PS for vaccination, year, and included a clustering term to account for data from same participant in multiple years. Stata v14 was used for data analyses.

Results: Data for 30,788 participants (66% female), 76% with RA, 61% treated with methotrexate, and contributing 125,034 person-seasons were included. PS for vaccination predicted vaccination status (area under the curve 0.87). Vaccination reduced the risk of hospitalization for pneumonia, hospitalization for COPD exacerbation, all-cause mortality and death due to pneumonia in that flu season (aHR (95%CI) 0.59(0.51-0.69), 0.59(0.44-0.80), 0.52(0.47-0.59), 0.47(0.35-0.63) respectively). Vaccination also reduced the risk of primary care consultation for ILI (aHR (95%CI) 0.75 (0.60-0.95)) when the analysis period was restricted to the time when influenza viruses circulated. Other protective effects also remained statistically significant in this restricted analysis. These associations did not change when seasons with exposure to sulfasalazine alone were excluded. IIV did not reduce the risk of primary care consultations for LRTI and COPD exacerbations.

Conclusion: This is the first study to demonstrate and quantify the effectiveness of IIV in people with AIRDs. The results provide justification to educate health professionals and actively promote flu vaccination to the immunosuppressed people with AIRDs.

Session Title: Epidemiology and Public Health I: Morbidity and Mortality

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: RA is associated with increased total, cardiovascular, and respiratory mortality compared to the general population. This excess RA mortality may be mediated through lifestyle, clinical, or RA-specific factors occurring

Table: Hazard ratios for total and cause-specific mortality for women with RA (reference: matched comparators), adjusted for time-varying covariates before and after the index date of RA diagnosis using marginal structural modeling.

Model and covariates	Total mortality HR (95% CI)	Cardiovascular mortality HR (95% CI)	Respiratory mortality HR (95% CI)
All RA			
(1) Baseline confounder model	1.42 (1.27-1.58)	1.25 (0.97-1.62)	3.79 (2.87-5.40)
(2) Baseline confounder + Time-updated lifestyle factors model	1.52 (1.35-1.71)	1.42 (1.10-1.84)	2.64 (1.95-3.56)
(3) Baseline confounder + Time-updated lifestyle/multimorbidity factors model	1.06 (0.97-1.21)	0.97 (0.75-1.24)	1.64 (1.15-2.06)
Seropositive RA			
(1) Baseline confounder model	1.84 (1.33-1.77)	1.35 (0.97-1.88)	4.85 (3.23-7.29)
(2) Baseline confounder + Time-updated lifestyle factors model	1.67 (1.45-1.92)	1.49 (1.00-1.97)	3.22 (2.29-4.51)
(3) Baseline confounder + Time-updated lifestyle/multimorbidity factors model	1.25 (1.09-1.44)	1.03 (0.78-1.47)	2.13 (1.54-2.94)
Seronegative RA			
(1) Baseline confounder model	1.24 (1.03-1.50)	1.12 (0.75-1.68)	1.95 (0.81-4.24)
(2) Baseline confounder + Time-updated lifestyle factors model	1.18 (1.14-1.67)	1.46 (0.98-2.18)	1.43 (0.71-2.89)
(3) Baseline confounder + Time-updated lifestyle/multimorbidity factors model	0.97 (0.80-1.16)	0.90 (0.61-1.32)	0.72 (0.34-1.51)

Comparator status is the reference in all models.

The all RA analyses included 998 women with all RA and 9,921 matched comparators. The seropositive RA analyses included 617 women with seropositive RA and 6,144 matched comparators. The seronegative RA analyses included 379 women with seronegative RA and 3,777 matched comparators.

Among women with RA, there were 410 (41.2%) total, 75 (18.3%) cardiovascular, and 50 (12.2%) respiratory deaths. Among comparators, there were 2,799 (28.1%) total, 524 (18.9%) cardiovascular, and 195 (7.0%) respiratory deaths.

(1) Baseline confounder model: Adjusted for matching factors (age and calendar year) at index date of rheumatoid arthritis diagnosis as well as baseline factors assessed prior to index date: annual family income, pre-index smoking, body mass index, Alternate Healthy Eating Index, menopausal status and postmenopausal hormone use, physical activity, aspirin use, and Multimorbidity Weighted index.

(2) Baseline confounder + Time-updated lifestyle factors model: Adjusted for variables in (1) as well as time-updated lifestyle factors assessed after index date. Adjustment through inverse probability weighting.

(3) Baseline confounder + Time-updated lifestyle/multimorbidity factors model: Adjusted for variables in (2) as well as time-updated Multimorbidity Weighted Index after index date. Adjustment through inverse probability weighting.

after diagnosis. Causal inference methods, such as marginal structural models, can adjust for both confounders as well as mediators on the causal pathway between RA diagnosis and mortality. We aimed to decipher the mechanism through which RA increases total and cause-specific mortality accounting for potential mediators after RA diagnosis using causal inference methods.

Methods: We used a prospective cohort study, the Nurses' Health Study (n=121,700), to investigate RA and mortality, accounting for lifestyle/clinical covariates before/after RA diagnosis. We identified incident RA meeting ACR criteria during follow-up. We matched each RA case to 10 comparators by age and year at RA diagnosis (index date). We considered lifestyle/clinical factors assessed by biennial surveys as baseline confounders (before index date) or mediators (after index date). Lifestyle factors included smoking, BMI, diet, and physical activity. We used the validated Multimorbidity Weighted Index, composed of 64 prevalent/serious health conditions (interstitial lung disease [ILD] was unmeasured). We used inverse probability weights to adjust for the confounding/mediating effects of covariates on mortality risk for RA vs. comparators. We compared RA effect estimates for mortality in models composed of baseline confounders and time-updated mediators.

Results: At index date, mean age was 60.1 years (SD 10.2). Among 996 women with incident RA, 410 (41.2%) died during mean follow-up of 19.8 years (SD 9.1). Among 9,921 matched comparators, 2,789 (28.1%) died during mean follow-up of 19.5 years (SD 9.7). Adjusting for baseline factors and time-updated lifestyle factors after index date, RA was associated with excess total (HR 1.52, 95%CI 1.35-1.71), cardiovascular (HR 1.42, 95%CI 1.10-1.84), and respiratory (HR 2.64, 95%CI 1.95-3.56) mortality. When accounting for incident multimorbidities after index date, RA was no longer associated with total (HR 1.08, 95%CI 0.96-1.20) or cardiovascular (HR 0.98, 95%CI 0.77-1.25) mortality, but excess respiratory mortality remained (HR 1.54, 95%CI 1.15-2.08). Seropositive RA remained associated with respiratory mortality before (HR 4.85, 95%CI 3.23-7.29) and after adjustment for all covariates (HR 2.13, 95%CI 1.54-2.94).

Conclusion: In this large prospective study using causal inference methods, excess total and cardiovascular RA mortality was explained by incident multimorbidities after diagnosis. For seropositive RA, excess respiratory mortality remained after accounting for measured lifestyle/clinical factors, emphasizing the importance of monitoring other factors (such as ILD, infections, or medications), that may mediate the RA respiratory mortality burden.

Session Date: Sunday, October 21, 2018

Session Title: Epidemiology and Public Health I: Morbidity and Mortality

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: While biologics are known to be associated with risk of serious infections, data on head-to-head comparison of different biologic drugs for the risk of infection are limited. We aimed to investigate the rate of incident serious bacterial, viral or opportunistic infection in rheumatoid arthritis (RA) patients starting tocilizumab (TCZ) versus TNF inhibitor (TNFi).

Methods: We conducted a cohort study using data from 3 U.S. healthcare claims databases: Medicare (2010-2015), 'IMS' PharMetrics Plus (2011-2015) and 'Truven' MarketScan (2011-2015). We identified patients with RA aged ≥18 years who initiated TCZ or a TNFi with prior use of at least one different TNFi, abatacept or tofacitinib. Patients with recent infection, malignancy or rituximab use were excluded. The primary endpoint was incident composite serious infection including bacterial, viral or opportunistic infection with ≥1 inpatient principal diagnosis code. Secondary outcomes were specific subtypes of serious infection (**Table**). To control for >70 potential confounders including demographics, prior DMARD and antibiotic use, comorbidities, medications, and healthcare utilization in each database, TCZ initiators were

Table. Risk of incident serious infection associated with initiating tocilizumab versus TNF inhibitors: a 1:3 variable ratio propensity score matched as-treated analysis

Outcome	Tocilizumab (n=16,074)		TNF inhibitors (n=33,109)	
	IR per 100 PY (95% CI)	HR (95% CI)	IR per 100 PY (95% CI)	HR (95% CI)
Primary				
Serious infection	4.68 (4.31-5.05)	1.05 (0.95-1.16)	3.69 (3.28-4.22)	REFERENCE
Secondary				
Serious bacterial infection	3.95 (3.61-4.29)	1.19 (1.07-1.33)	3.97 (3.27-3.17)	REFERENCE
Herpes zoster	0.11 (0.08-0.17)	0.80 (0.48-1.08)	0.13 (0.07-0.15)	REFERENCE
Opportunistic infection	0.13 (0.07-0.20)	0.99 (0.55-1.79)	0.13 (0.08-0.17)	REFERENCE
Pyelonephritis/UTI	0.49 (0.37-0.69)	0.77 (0.56-1.04)	0.54 (0.40-0.63)	REFERENCE
Skin/soft tissue infection	0.28 (0.19-0.39)	2.38 (1.47-3.86)	0.12 (0.08-0.15)	REFERENCE
Diverticulitis	0.52 (0.40-0.64)	2.34 (1.64-3.34)	0.21 (0.16-0.26)	REFERENCE

Septicemia/bacteremia	1.72 (1.50-1.96)	1.04 (0.98-1.22)	1.51 (1.37-1.65)	REFERENCE

Notes: 1. For the primary as-treated analysis, follow-up time started the day after cohort entry (and ended on treatment discontinuation, outcome occurrence, disenrollment, death, or the end of study period).

2. Hazard ratios for tuberculosis and viral hepatitis (secondary outcomes) are not reported since no events occurred for these endpoints in either TCZ or TNFi group.

3. Hazard ratios (HR) from the 3 PS-matched cohorts were combined by an inverse variance-weighted, fixed-effects model.

propensity score (PS)-matched to TNFi initiators with a variable ratio of 1:3 within each database. We then calculated incidence rates (IR) and hazard ratios (HR) of the primary and secondary outcomes.

Results: A total of 16,074 TCZ initiators were PS-matched to 33,109 TNFi initiators. Mean age was 72 years in Medicare, 51 in IMS and 53 in Truven. At baseline, 69-73% patients used methotrexate and 70-79% used corticosteroids. In the as-treated analysis, the median follow-up time (days) ranged from 181 (MarketScan) to 213 (IMS) in the TCZ group and 198 (Medicare) to 235 (IMS) in the TNFi group. A total of 618 serious infections occurred in TCZ and 1,155 in TNFi group across the 3 databases. In the TCZ group, the IR for serious infections per 100 person-years ranged from 3.07 (Truven) to 7.05 (Medicare), and in the TNFi group, it ranged from 2.47 (Truven) to 7.05 (Medicare). The risk of incident composite serious infections was similar in TCZ versus TNFi initiators with a combined HR of 1.05 (95% CI 0.95-1.16) across all 3 databases. However, TCZ was associated with an increased risk of serious bacterial infection (HR 1.19, 95% CI 1.07-1.33), skin and soft tissue infections (HR 2.38, 95% CI 1.47-3.86) and diverticulitis (HR 2.34, 95% CI 1.64-3.34) compared to TNFi initiators. Secondary and subgroup analyses showed similar results.

Conclusion: This large multi-database cohort study found a similar risk for the composite primary endpoint of serious infection requiring hospitalization in RA patients who initiated TCZ versus TNFi after failing ≥ 1 biologic drug or tofacitinib. However, the risk of serious bacterial infection, skin and soft tissue infections, and diverticulitis was higher in TCZ initiators versus TNFi.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Epidemiology and Public Health I: Morbidity and Mortality

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Patients with rheumatoid arthritis (RA) are at a small, but significantly increased risk of cancer compared with the general population. This risk varies by cancer type, with highest risk observed in lymphoma and lung cancer. Findings relative to prostate cancer are conflicted (standardized incidence ratio [SIR] 1.15, 95% CI 0.98-1.34, in recent meta-analysis). Recognizing the male predominance and large number of cases available in the Veterans Health System, we estimated the risk of prostate cancer in a national population of male US Veterans with RA.

Methods: We identified male patients with RA using an algorithm that required ≥ 2 diagnostic codes ≥ 30 days apart, rheumatologist diagnosis, and either a DMARD prescription or positive RF or anti-CCP within the VA Corporate Data Warehouse (1/2000-4/2018). We excluded individuals with diagnostic codes for psoriatic arthritis or ankylosing spondylitis, and those with prostate cancer or prostatectomy prior to the index date. Prostate cancer and prostate cancer death were identified from the VA Central Cancer Registry (VACCR; captures up to 90% of cancers in the VA) and the National Death Index. Prostate cancer incidence rates (IR; per 1,000 pt-yrs) and 95% CIs were calculated from the index date (first date RA diagnosis by algorithm). SIR and 95% CI were calculated from age- and race-matched rates in the Surveillance, Epidemiology, and End Results Program (SEER). Multivariable Cox regression models assessed the association of seropositivity (RF or anti-CCP positive) with prostate cancer risk adjusting for age, race, smoking status, and Agent Orange exposure (reported risk factor for prostate cancer).

Results: RA patients included in analyses (n=50,870) had a mean (SD) age of 64 (11) years, 74% were white, 11% were black, 75% were ever smokers, and most were positive for either RF (67%) or anti-CCP (66%). Over 361,419 pt-yrs of follow-up, there were 1,243 incident prostate cancers (IR 3.4; 95% CI 3.3-3.6 per 1,000 pt-yrs). Similar rates were observed in seropositive (IR 3.5, 95% CI 3.3-3.7) and seronegative (IR 3.2, 95% CI 2.8-3.6) RA patients. Relative to SEER rates, SIR of prostate cancer was 0.89 (95% CI 0.85-0.95). Stratified by seropositivity, prostate rates were lower than those in SEER for seronegative patients (SIR 0.81, 95% CI 0.71-0.92) but similar for seropositive patients (SIR 0.94, 95% CI 0.88-1.01). In multivariable models, age, black race, and Agent Orange were independently associated with prostate cancer risk, while seropositivity was marginally associated (HR 1.15, 95% CI 0.97-1.36).

Conclusion: In one of the largest studies of its kind to date, we estimated prostate cancer rates to be slightly lower in RA than in the general population. However, this small difference may be accounted for by cases not captured within VACCR (estimated to approach 10%). Autoantibody status does not appear to portend substantial risk, however, additional investigation will be needed to identify whether other disease-related factors are associated with prostate cancer risk in this population.

Abstract Number: 944

Gout: A Potential Risk Factor for Uveitis in the Older Adults?

Jasvinder A. Singh and John Cleveland, Rheumatology, University of Alabama at Birmingham, Birmingham, AL

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Epidemiology and Public Health I: Morbidity and Mortality

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Elevated intraocular levels of these pro-inflammatory cytokines and systemic levels of C-reactive protein are seen in uveitis, which leads to 30,000 new cases of legal blindness annually in the U.S. Limited epidemiological information is available for risk factors for uveitis. Our objective was to assess whether gout in the elderly is associated with a risk of incident uveitis.

Methods: We used the 5% Medicare claims data from 2006-2012 for this cohort study. Gout was identified by the presence of two claims for gout at least 4 weeks apart, with International Classification of Diseases, ninth revision, common modification (ICD-9-CM) code of 274.xx. Study outcome was incident uveitis, identified by two claims for uveitis with an ICD-9-CM code of 364.xx, at least 4 weeks apart and an absence of uveitis claims in the baseline 365-day period, a valid approach. We used multivariable-adjusted Cox proportional hazard models to assess the association of gout with incident uveitis, adjusting for potential confounders/covariates including demographics (age, race, gender), comorbidities (Charlson-Romano comorbidity index), and medications commonly used for cardiac diseases (statins, beta-blockers, diuretics, and angiotensin converting enzyme (ACE)-inhibitors) and gout (allopurinol and febuxostat; Model1).

Results: We found 8,459 incident uveitis cases in our cohort of 1,240,681 Medicare recipients, 464 in people with and 7,995 in people without gout, leading to respective incidence rates of 179 and 93 per 100,000 person-years. The mean [standard deviation (SD)] time from gout diagnosis to the new diagnosis of uveitis was 804 days [SD, 572] (median, 694 days; interquartile range, 329, 1190 days). Compared to people without incident uveitis, people with uveitis were significantly more likely to be older, female, Black and have higher medical comorbidity. After multivariable-adjustment (model 1), gout was associated with 1.53-fold higher hazard of uveitis (95% confidence interval (CI), 1.39, 1.69; $p < 0.0001$) (**Table 1**), as were older age, female gender, Black or other race/ethnicity, and comorbidities including diabetes, chronic pulmonary disease, connective tissue disease or any tumor/leukemia/lymphoma (**Table 1**). Sensitivity analysis that replaced continuous Charlson-Romano index with categorized scale (Model 2) or individual comorbidities plus hyperlipidemia, coronary artery disease and hypertension (Model 3) confirmed the findings from the main analyses with minimal attenuation of hazard ratios.

Conclusion: Gout was independently associated with 1.5-fold higher risk of uveitis in the older individuals after adjustment for demographics, comorbidity and medications, and the risk could be between 1.4 to 1.9-fold higher risk. Future studies need to confirm this finding and evaluate the underlying mechanism of this novel association.

Pain, Functional Limitations and Physical Activity Participation Trajectories in Patients with Symptomatic Knee and Hip Osteoarthritis: A Multi-Trajectory Analysis

Maud Wiecezorek¹, Christine Rotonda¹, Francis Guillemin^{1,2} and Anne-Christine Rat^{1,3}, ¹Université de Lorraine, EA4360, APEMAC, Nancy, France, ²Inserm, CIC-1433 Epidémiologie Clinique, Vandoeuvre-lès-Nancy, France, ³Rheumatology Department, CHRU Nancy, Vandoeuvre-lès-Nancy, France

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Epidemiology and Public Health I: Morbidity and Mortality

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: The aims of this study were to identify homogeneous subgroups of knee and/or hip osteoarthritis (OA) patients with distinct trajectories of the combination of pain, physical function (PF) and physical activity (PA) intensity and to identify the baseline predictive factors associated with these trajectories.

Methods: The KHOALA cohort is a French population-based multicenter cohort of 878 patients with symptomatic knee and/or hip OA (ACR criteria), aged between 40 and 75 years old. Three outcomes assessed annually over 5 years were modeled in a multi-trajectory model. Pain and PF were measured with the WOMAC questionnaire while PA intensity (in Metabolic Equivalent of Task, MET) was assessed by the Modifiable Activity Questionnaire. First, trajectory models were estimated with varying number of groups for each of the outcomes separately and then, included in the multi-trajectory model. The selection of the optimal models was based on maximization of the Bayesian information criterion, the proportion of patients in each group (>5%) and the statistical significance of the equation modeled. Multinomial logistic regressions were performed to identify the predictive baseline characteristics associated with each group and were adjusted for sociodemographic and clinical factors.

Results: Comparison of separate trajectories of pain and PF showed that 2/3 of patients (66.7%) included in the trajectory of severe functional limitations (FL) also belonged to the more severe pain trajectory (Cramer V statistic = 0.59). Group-based multi-trajectory modeling revealed 3 distinct trajectories of pain, PF and PA intensity (Figure 1). The first (N=199, 32.1%) included patients with low pain levels, no FL and who practiced intense PA. The second (N=259, 41.8%) included patients with moderate levels of pain and FL; who practiced a less intense PA. Patients included in the third group (N=162, 26.1%) had severe pain, severe FL and a low-intensity practice. Overall, a decrease in PA intensity was observed in all groups over 5 years, even in the first group. In multivariate analyses, female sex (Odds ratio [OR]=2.93, 95% confidence interval [CI]=1.63-5.27), an increasing age (OR=1.04, 95%CI=1.01-1.08), a primary education level (OR=2.91, 95%CI=1.30-6.54), a high number of comorbidities (OR=1.50, 95%CI=1.23-1.83), a low vitality score (reflecting a high level of fatigue; OR=0.93, 95%CI=0.91-0.95) and a high Kellgren grade (reflecting a high radiological severity; OR=4.07, 95%CI=1.87-8.84) were associated with the third group membership.

Conclusion: Over 5 years, we identified 3 distinct trajectories combining pain, PF and PA intensity. The management of comorbidities and fatigue and slowing radiological progression seem important to maintain PF, limit pain and maintain intensity of PA practice in patients with symptomatic knee and/or hip OA.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Infection-related Rheumatic Disease

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Brazil faced a new yellow fever (YFV) outbreak that reached the state of São Paulo in December 2016. The fractional dose was used in this campaign to extend vaccine supplies. Due to the YFV high risk of fatality, the vaccination may be also indicated for autoimmune rheumatic disease (ARD) patients under low immunosuppression. There is, however, no prospective evaluation of YFV safety in these patients. The aim of this study was to evaluate the short-term safety of immunization with the fractional YFV in patients with ARDs.

Methods: One hundred and sixty adult ARD patients [65 systemic lupus erythematosus, 11 rheumatoid arthritis, 8 ankylosing spondylitis, 16 systemic sclerosis, 2 psoriatic arthritis, 8 Behçet's disease, 4 mixed connective tissue disease, 13 primary antiphospholipid syndrome, 7 dermatomyositis/polymyositis, 11 primary Sjögren's syndrome, 3 Takayasu's arteritis, and 2 granulomatosis with polyangiitis, 10 juvenile idiopathic arthritis] and 160 age and gender-matched healthy controls

Figure 1A. Neutrophils and lymphocytes in Control and ARD Patients groups at the day and after fractional YFV

Figure 1B. Neutrophils kinetics in neutropenic and non-neutropenic ARD patients

* P<0.05 - ANOVA (longitudinal analysis - D0 as reference)

Figure 1C. Lymphocytes kinetics in lymphopenic and non-lymphopenic ARD patients

were vaccinated with a 5-fold fractional-dose (0.1mL, subcutaneous route) of the 17DD YFV. All participants were evaluated at entry (D0), 5 days (D5), 10 days (D10) and 30 days (D30) post-vaccination for clinical and laboratory parameters (AST, ALT, complete blood count, CRP) and disease activity according to specific tools for each ARD. Participants were instructed to seek medical attention, if necessary, and a rigorous follow-up of adverse events was performed during the first 30 days after vaccination. Serious adverse events were defined as those resulting in hospitalization or death. ANOVA was performed for longitudinal analysis of laboratory exams.

Results: All disease activity parameters of ARD patients (SLEDAI-2K, DAS28, BASDAI, ASDAS, BR-BDCAF, MMT, ESSDAI, BVAS, ESR and CRP) remained stable 30 days after YFV ($P < 0.05$). ARD patients had higher frequencies of fever, muscle pain, abdominal pain, arthralgia and diarrhea compared to controls ($p < 0.05$). Kinetics of neutrophils and lymphocytes in patients and controls had a similar pattern ($r = +0.99$ and $r = +0.81$) characterized by a significant transient decrease in neutrophils (D10) and lymphocytes (D5) and a full recovery to baseline levels for both in D30 (Figure 1A). In contrast, kinetics of ARD patients with neutropenia/lymphopenia at baseline had a distinct pattern with stable/increase in levels of these cells (Figures 1B and 1C). No serious adverse effect was reported neither mild abnormalities in liver enzymes or renal function.

Conclusion: The 17DD YFV was safe and did not induce flares in ARD patients with low immunosuppression and may be indicated in yellow fever outbreak situations. Further studies are necessary to determine if the observed distinct immune microenvironment kinetics will be relevant for YFV viremia and/or vaccine seroconversion (ClinicalTrials.gov, NCT03430388)

Clinical Characteristics and Outcome after Treatment of a National Cohort of PCR-Positive Lyme Arthritis

Marc Scherlinger^{1,2}, Antoine Grillon³, Jean Sibilia⁴, Benoit Jaulhac³ and Laurent Arnaud^{4,5}, ¹Department of Rheumatology, Bordeaux University Hospital, Bordeaux, France, ²Rheumatology, UMR CNRS 5164 - Immunconcept, France, Bordeaux, France, ³Centre national de référence Borrelia, CHU de Strasbourg, Strasbourg, France, ⁴Université de Strasbourg, Strasbourg, France, ⁵Service de rhumatologie, CHU de Strasbourg, Strasbourg, France

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Infection-related Rheumatic Disease

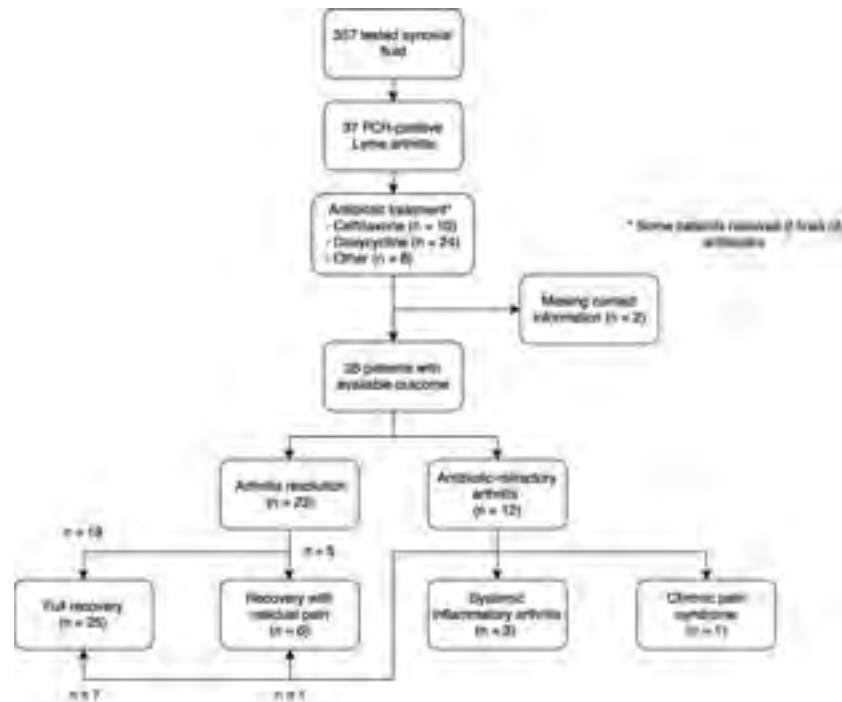

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Lyme arthritis (LA) is a disseminated *Borrelia* infection whose prevalence is lower in Europe than in the USA, probably because of difference in *Borrelia* species ecology. Few data concerning treatment efficacy and long-term outcome of LA in Europe are available. The aim of our study was to describe clinical characteristics and treatment outcomes of a national cohort of patients with LA confirmed with synovial fluid PCR.

Methods: We conducted a retrospective observational study using the French *Borrelia* reference centre database. Patients presenting with a PCR positive for *Borrelia* DNA in their synovial fluid between 2011 and 2016 were included. PCR-positive patients were offered by their referring physician to participate to a standardized telephonic interview. Patients' medical files were also retrieved. The main objectives were to describe patient characteristics, disease presentation and outcomes after antibiotic treatment.

Results: Between 2011 and 2016, among 358 synovial fluids tested at the national reference center, 37 were positive for *Borrelia* DNA. Among these patients, 35 were contacted (2 missing contact information). Median age was 36 years with 31% minors and 63% men. Tick exposure was reported by 88% patients whereas tick bite and erythema migrans were only reported in 40% (10/25) and 14% (3/21), respectively. The presentation was monoarticular in 91% (32/35) cases and oligoarticular in others. The knee was involved in 97% (34/35) cases and 21% presented fever. The diagnosis was often delayed with a median time from symptom onset to diagnosis of 3 months (range 1 to 112, figure 1). The serology performed before or at the time of the PCR testing was IgG-positive in all cases but only IgM-positive in 40%. All but one positive IgG serologies were also positive with Western-Blot. In the synovial fluid, the identified species of *Borrelia* were *B. burgdorferi sensu stricto*, *B. garinii* and *B. afzelii* in 54%,

29% et 17% of cases, respectively. Antibiotics prescribed were mostly doxycycline and ceftriaxone in 17 and 9 patients, respectively, sometime in combination. Follow-up data were available for 35 patients with a median follow-up time of 27 months (range 1-73). Although proper antibiotic treatment, 34% (12/35) of patients had persistent synovitis lasting at least 2 month justifying intra-articular glucocorticoid use in 75%, with good efficacy. Three patients developed chronic inflammatory arthritis leading to the introduction of DMARDs with good outcomes.

Conclusion: Our study present the biggest European cohort of PCR-positive Lyme arthritis. Although proper antibiotic treatment, one third of patients developed persistent synovitis of the affected joint necessitating anti-inflammatory medication and a small proportion of patients developed inflammatory oligo or polyarthritis justifying DMARD introduction.

Session Title: Infection-related Rheumatic Disease

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Bone alterations have been observed in the course of HIV infection, with a notable decreases in bone mineral density (BMD) and fractures due to fragility. Anti-retroviral drugs may have a direct or indirect effect on

bone cells, via alterations in RANK/RANKL, cytokines profile, mitochondrial function and changes in phosphate/Vitamin D metabolism. The aim of this study was to evaluate the deleterious effects in bone metabolism and systemic inflammation, produced by Tenofovir vs. other HIV treatment in naïve patients.

Methods: A cohort of 114 HIV-naïve patients were included in the study. Patients were separated by treatment: 1) Tenofovir Disoproxil Fumarate (TDF) (n=23), 2) Tenofovir Alafenamide (TAF) (n=22), 3) Abacavir/Dolutegravir/Lamivudin combo (ADL) (n=39), 4) Protease Inhibitors (PI) (n=12), and 5) patients who changed treatment during the study (n=18). Epidemiological, immunological, and metabolic parameters, as well as BMD were evaluated. Bone markers, proinflammatory and anti-inflammatory cytokines were analyzed in serum at basal and 3 months post-treatment by MILLIPLEX® MAP Luminex® Technology. The diagnosis of osteopenia/osteoporosis was made according to the WHO criteria.

Results: The mean age was 34.7 years (range 19-50 years). 91% was on CDC stage A. The median CD4 was 481 cell/ μ L (IQR=339.5), 10% had CD4 under 200 cell/ μ L, and 42% had CD4/CD8 under 0.4. 71% (71/143 p) had low Vitamin D levels, 4% low BMI (<18.5). Osteopenia (op) or osteoporosis (OP) was found in 53% and 11% respectively. In the serum we found differences at molecular level among different treatments (Tables 1 and 2). We observed that both TDF and TAF presented an osteoclastic profile but not the other treatments. All treatments reduce proinflammatory cytokines 3 months after treatment but no differences among treatments were found.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Infection-related Rheumatic Disease

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Between December 2013 and April 2016, the largest epidemic of Ebola virus disease (EVD) to date generated more than 28,000 cases and more than 11,000 deaths in the large, mobile populations of Guinea, Liberia, and Sierra Leone. However, based on the small size of past outbreaks in remote and resource-poor locations that hinder systematic study, there is little knowledge of the frequency of various sequelae post-EVD, their pathogenesis, and optimum treatment. Some short-term and long-term health problems have been reported such as arthralgia and/or myalgia¹.

Methods: The Postebogui study is a prospective multicenter cohort aiming to evaluate the long-term clinical, psychological and socio-behavioral outcomes of EVD survivors infected during the 2014-2015 outbreaks². Nearly 80% of survivors in Guinea were included in the Postebogui cohort. We organized the systematic rheumatic screening of all patients included in the Postebogui cohort (Conakry) regardless of the disease status. A musculoskeletal (MS) Doppler ultrasound (DUS) assessment was performed (Esaote MyLab). Data were collected using a standardized questionnaire and entered into an electronic database.

Results: Of the 382 participants included in the Postebogui cohort in Conakry, 313 patients underwent a complete interview by a rheumatologist nearly 3-year after viral infection: 36 patients never presented joint or muscle pain, 61 patients had experienced previous pain and 216 patients still reported chronic MS pain (69%). No demographic differences were found between both groups except that children significantly reported less chronic MS pain. In the painful group, 58% were female; median age was 29.1 years; median time from Ebola Treatment Center (ETC) discharge to rheumatologic examination was 36 months. Pain manifestations started before EVD for 41 patients (19%). Morning stiffness was present in 46% of patients. Patients had mechanical pain (48%), inflammatory pain (18%) or both (34%). Axial and peripheral were largely involved (84%). Large joints were most frequently affected (89%). Polyarticular presentations were predominant with a symmetrical pain distribution. Furthermore, 91% had at least one painful enthesitis. DUS showed 5 patients with tenosynovitis and 4 patients with synovitis but without hyperemia. One patient suffered with Pes anserine tendonitis. Diagnoses were mainly non-specific MS disorders (67%) and low back pain (39%). No rheumatoid arthritis was retained but axial spondyloarthritis with enthesitis was suspected in few cases (2%).

Conclusion: Our study provides the largest accurate description of MS disorders in the Post-Ebola syndrome with a long-term follow-up (3 year after Ebola infection). Rheumatic sequelae are frequent and pathophysiological mechanisms need to be explored in the future.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Infection-related Rheumatic Disease

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Lyme arthritis (LA), the most common late manifestation of Lyme disease, usually occurs months to up to 2 years after the initial infection. Joint involvement is characterized by proliferative synovitis predominantly affecting the knees. Most patients respond to antibiotic treatment, but a subset have persistent inflammatory arthritis despite resolution of the infection and others may have continued pain despite resolution of synovitis on examination. It is unclear why arthritis onset is delayed after initial spirochetal infection and hematogenous dissemination. It has been postulated that prior to clinical synovitis, less well-vascularized tissues such as tendons or ligaments may harbor spirochetes. Imaging

studies, such as ultrasound (US) may offer further insights, however information is limited about US characteristics of Lyme arthritis.

Methods: We retrospectively reviewed images and clinical characteristics of adult LA patients who underwent musculoskeletal US examinations of the knee joints in the Rheumatology Clinic at Massachusetts General Hospital. Examinations were included when complete diagnostic examination was performed (including longitudinal and transverse suprapatellar views, medial and lateral longitudinal views, posterior transverse and longitudinal views). All LA patients met the diagnostic criteria of the Centers for Disease Control and Prevention (CDC) for Lyme disease. Images from control subjects with osteoarthritis were reviewed as a comparison group. All images were reviewed by 2 ultrasound-trained rheumatologists with inter-reader agreement.

Results: Forty-nine knee examinations were reviewed in 31 individual LA patients. The median age of the patients was 52, and 18 of the 31 patients (58%) were male. Of the LA patients, the majority, 24, had arthritis which was refractory to oral and IV antibiotic treatment, while 7 had arthritis which was responsive to oral or IV antibiotic treatment. The median semi-quantitative synovitis score was 2 (range 0 to 3). Effusion was seen in 67% of examinations and presence of a Baker's cyst was observed in one-quarter of examinations. Presence of radiographic erosion was observed in only one patient. Of the 31 patients, 28 (90%) were found to have abnormalities in posterior knee tendons, most commonly the semimembranosus, and less frequently the semitendinosus, tendons. These abnormalities included hyperechoic deposits with tendinopathy and tenosynovitis. Abnormalities were rarely seen in other tendons and were not seen in control subjects. In several patients who had serial examinations, the tendon abnormalities persisted although synovitis measures improved.

Conclusion: It has not been previously recognized that hamstring tendons are commonly affected in LA. Calcific tendinitis and tendinopathy may contribute to the persistence of knee pain in some LA patients despite resolution of synovial inflammation. Further, evidence of calcification suggests that tendons may be a prior site of *B. burgdorferi* infection. As a privileged site, tendons may initially allow protection of spirochetes from the immune system and may contribute to seeding of synovium later in the disease.

IFN-Gamma Production in Lyme Arthritis Synovial Tissue Promotes Differentiation of Fibroblast-like Synoviocytes into Inflammatory Effector Cells

Robert Lochhead¹, David Ordonez-Del Valle¹, Sheila Arvikar², Allen C. Steere² and Klemen Strle³, ¹Center for Immunology and Inflammatory Diseases, Massachusetts General Hospital, Harvard Medical School, BOSTON, MA, ²Division of Rheumatology, Allergy, and Immunology, Massachusetts General Hospital, Harvard Medical School, Boston, MA, ³Department of Immunology and Inflammatory Diseases, Massachusetts General Hospital, Harvard Medical School, BOSTON, MA

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Infection-related Rheumatic Disease

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Lyme arthritis (LA), a late-disease manifestation of *Borrelia burgdorferi* infection, usually responds to antibiotic therapy. However, some patients may develop a proliferative synovitis lasting months to several years after spirochetal killing, called post-infectious LA. Their synovial lesion is associated with robust expression of interferon (IFN)-responsive genes and suppressed expression of genes associated wound healing. However, it is not yet clear which cell populations contribute to these LA-associated gene signatures.

Methods: Hematopoietic and stromal cell populations in the post-infectious LA synovial lesion were analyzed at the cellular level by flow cytometric analysis and immunofluorescence microscopy. Observations in human patients were validated *in vitro* using primary human fibroblast-like synoviocytes (FLS) derived from post-infectious LA synovial tissue, and *ex vivo* using murine LA models.

Results: T cells and NK cells were highly abundant in synovial tissue and were IFN γ -positive by intracellular cytokine staining. HLA-DR+ FLS were present throughout the synovial lesion, particularly in areas of inflammation. Primary human FLS stimulated with IFN γ expressed HLA-DR molecules and a large number of genes associated with autoimmune/autoinflammatory inflammatory responses, similar to *ex vivo* findings. Co-stimulation of FLS with *B. burgdorferi* and IFN γ potentiated a significantly greater inflammatory cytokine and chemokine response than either *B. burgdorferi* or IFN γ stimulation alone. Tissue from joints of *B. burgdorferi*-infected C57BL/6 mice, which develop mildly inflammatory LA, had a wound-healing myofibroblast phenotype, whereas tissue from severely arthritogenic C3H/HeN and Il10^{-/-} (B6) mice had a pro-inflammatory phenotype, dominated by excessive IFN responses, similar to human findings.

Conclusion: These results suggest that post-infectious LA may be initiated during infection if accompanied by dysregulated IFN γ responses. Under these conditions, *B. burgdorferi* infection may lead to differentiation of FLS into a highly inflammatory phenotype that may persist if IFN γ -producing lymphocytes are chronically activated within the synovial lesion after the infection is cleared, resulting in excessive inflammation and tissue damage.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Osteoarthritis – Clinical

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Accelerated kneeosteoarthritis (AKOA) is a unique endotype of knee osteoarthritis (KOA) that is characterized by a sudden onset of advance-stage disease and greater prodromal knee symptoms than those who develop a more gradual onset of KOA. Effusion-synovitis and infrapatellar fat pad (IFP) edema, may be potential early markers of AKOA because both are associated with pain and predict KOA incidence or progression. We aimed to determine whether greater effusion-synovitis and IFP edema on MRI differentiate incident AKOA from a gradual onset of KOA or no KOA.

Methods: We classified 3sex-matched groups of participants in the Osteoarthritis Initiative who had a knee without radiographic KOA at baseline (Kellgren-Lawrence [KL]<2;n=125/group): 1) AKOA: ≥ 1 knee progressed to KL grade ≥ 3 within 48 months, 2) common KOA: ≥ 1 knee increased in radiographic scoring within 48 months without meeting AKOA criteria, 3) no KOA: both knees had the same KL grade at baseline and 48-months. Observation period included up to 2 years before and after an index visit, which was when the AKOA or common KOA criteria were met (no KOA index visit was matched to AKOA). Two musculoskeletal radiologists reported presence of IFP edema using the MOAKS grading system. Independent readers used a semi-automated method to segment intermediate-weighted fat-suppressed MRIs for effusion-synovitis volume and measurements were finalized by the senior reader. We used generalized linear mixed models with group and time as independent variables, as well as tested a group-by-time interaction.

Results: Table 1 provides descriptive characteristics of each group. Starting at 2 years before disease onset and continuing to up to 2 years after onset, adults who developed AKOA had greater effusion-synovitis volume compared to adults with common or no KOA ($p=0.015, p=0.003$; Figure 1). Individuals who developed AKOA have at least two times the odds of having IFP edema compared to those with no KOA starting at 2 years prior to disease onset, and those with common KOA starting at 1 year prior to disease onset (Table 2, Figure 1).

Conclusion: As early as 2 years prior to disease onset AKOA is characterized by IFP edema and/or greater effusion-synovitis. Clinicians should be aware that people with greater effusion-synovitis and/or IFP edema in the absence of radiographic KOA may be at high risk for AKOA.

Figure 1. Effusion-Synovitis Volume and Infrapatellar Fat Pad (IFP) Edema Among Those with Accelerated Knee Osteoarthritis (AKOA), Common Knee Osteoarthritis (KOA), and No KOA.

Table 1 Descriptive Characteristics of those with Accelerated Knee Osteoarthritis (AKOA), Common Knee Osteoarthritis (KOA), and No KOA at Osteoarthritis Initiative Baseline

Variables (means, SD; except where noted)	AKOA (n=125)	Common KOA (n=125)	No KOA (n=125)
Females (n, %)	79 (63%)	79 (63%)	79 (63%)
Index knee KL Grade=0 (n, %)	42 (34%)	71 (57%)	92 (74%)

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Osteoarthritis – Clinical

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Some patients do not experience clinical improvement after total knee replacement (TKR). Presence of structural abnormalities on MRI before surgery may inform pain prognosis following TKR. Our objective was to evaluate MRI-detected knee inflammation before TKR as a risk factor for failure to experience clinically important pain reduction two years later.

Methods: Osteoarthritis Initiative participants with MRI assessment at the clinic visit before TKR and 2 year follow-up post-TKR, were selected. Effusion-synovitis (ES) and Hoffa synovitis (HS) on 3T MRI were scored using the MRI Osteoarthritis Knee Score (MOAKS). Pain was assessed at the clinic visit before TKR as well as 2 years later, with WOMAC pain (0-20) and knee pain severity in the past 7 days (0-10). Mean WOMAC pain and knee pain severity before TKR and 2 years later were estimated using a mixed model for repeated measures. Clinically important reduction in WOMAC pain (-1.5) and pain severity on NRS (-1.7) were defined based on previous literature. Participants with no/small ES/HS and those with medium/large ES/HS were compared based on the proportion reporting no clinically important pain reduction; odds ratios were estimated with logistic regression, adjusted for age, sex, race, and BMI.

Results: Participants (n=156) were predominately white(87%), women (60%), with mean age 66.2 years (SD 8.6) and mean BMI of 29.9 kg/m²(SD 5.1). Before TKR, 62% of the knees had medium/large ES, with higher mean WOMAC pain score compared to those with no/small ES (7.9 [95%CI: 7.1, 8.6] vs. 6.3 [95%CI:5.3, 7.3]). Two years following TKR, the mean WOMAC pain was modestly higher for knees that had no/small ES before TKR (1.8 [95%CI: 1.2, 2.4] vs 2.7 [95%CI:1.9, 3.4]). Knees with medium/large ES prior to TKR had greater pain reduction compared to those with no/small ES (6.7 [95%CI: 5.5, 7.9] vs 4.0 [95%CI: 2.8, 5.3]), a significant difference in mean pain reduction of 2.7 [95%CI: 1.3, 4.1] p=0.002 (Figure 1A). Participants with no/small pre-operative ES had an increased odds of reporting no clinically important pain reduction compared to participants with medium/large ES (29% vs 13%; OR=2.98, 95%CI: 1.26, 7.04). Similarly, knees with no/small ES had less mean pain severity reduction (p=0.006; Figure 1B), and with increased odds of no clinically important pain reduction (27% vs 10%; OR=4.35, 95%CI: 1.69, 11.23). We observed a similar trend for HS, detected in 37% of knees, though pain reduction was not significantly different between the groups (p=0.07).

Conclusion: Participants with no/small ES on MRI before TKR reported less pain reduction 2 years later compared to those with medium/large ES, and had significantly greater odds of no clinically important pain reduction following TKR.

Pre-operative ES, potentially in combination with other features of MRI-detected structural abnormalities, may serve as predictive biomarkers of pain reduction following TKR.

Session Date: Sunday, October 21, 2018

Session Title: Osteoarthritis – Clinical

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: For some rheumatologic diseases (e.g. lupus), separate scores evaluate cumulative damage and disease activity. No such strategy exists for osteoarthritis (OA). The prevailing approach to evaluate OA focuses on individual structural features or developing composite scores. Our group aimed to define an MRI composite score that accounted common features of knee OA: articular cartilage damage, bone marrow lesions (BMLs), and effusion-synovitis volume. However, we struggled to find such a composite score. We had greater success when we considered OA from the perspective of measuring a cumulative damage score and a disease activity score. The cumulative damage score – based on articular cartilage – measures damage over time and does not wax and wane. In contrast, the disease activity score – based on BMLs and effusion-synovitis – fluctuates over days or weeks. We aimed to evaluate the construct validity of these two scores.

Methods: A convenience sample of 197 participants in the Osteoarthritis Initiative with complete clinical, radiographic, and MRI data at baseline and 24-months was selected. We generated quantitative measures of articular cartilage using the Double-Echo Steady State sequence, and BML and effusion-synovitis volumes using the Intermediate Weighted Fat Suppressed sequences. We assessed BMLs and cartilage damage index at the medial and lateral patella, tibia, and femur. A single effusion-synovitis volume was assessed. All MRI measures were standardized to bone width, and the 2-year difference was standardized so all measurements were on the same scale. The cumulative damage score was calculated by summing the change for each of the 6 locations with cartilage measures. Similarly, a disease activity score was calculated by summing the change in effusion-synovitis volume and the BML volumes for 6 regions. To evaluate construct validity we used logistic regression to estimate odds ratios (OR) for the outcomes of Kellgren Lawrence (KL) progression, joint-space width (JSW) progression (change > the median change) and worsening in WOMAC pain.

Results: Our sample was 54% female, 93% with KL grade 2 or 3, mean age of 61 years and mean body mass index of 30.1 kg/m². Mean WOMAC pain at baseline was 5.0. Worsening cumulative damage score was associated with KL progression (OR=1.52, 95% CI=1.11 to 2.08) and JSW progression (OR=1.67, 95% CI= 1.22 to 2.33), but not with WOMAC pain progression (Table). Conversely, the disease activity score was associated with WOMAC pain (OR=1.67, 95% CI= 1.14 to 2.45), but not KL or JSW progression.

Conclusion: The cumulative damage score (based on cartilage damage) had good construct validity for structural outcomes, while the disease activity score (based on BML and effusion-synovitis volumes) was associated with pain. This suggests that separate scores for cumulative damage and disease activity may have important utility in studying OA and provide critical insights into the disease.

Table 1 A Cumulative Damage Score was Associated with Structural Progression While a Disease Activity Score was Associated with Worsening Knee Pain.

Outcome	Knee Score	Odds Ratio (95% Confidence Interval)
KL Progression (any worsening in KL score)	Cumulative Damage Score	1.52 (1.11, 2.08)
	Disease Activity Score	1.17 (0.85,1.61)
JSW Progression (change greater than the median change)	Cumulative Damage Score	1.67 (1.22, 2.33)
	Disease Activity Score	1.02 (0.77, 1.35)
WOMAC pain worsening by at least 3 points	Cumulative Damage Score	1.27 (0.88, 1.82)
	Disease Activity Score	1.67 (1.14, 2.45)

The cartilage damage score was calculated by summing the change over 2 years for each of the 6 surfaces (standardized so that higher is worse). Similarly, the BML - effusion score was calculated by summing the change in effusion and the same in BMLs for each of the 6 surfaces (higher is worse).

KL = Kellgren-Lawrence, JSW = joint space width

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Osteoarthritis – Clinical

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Lower limb muscle weakness has been proposed as a factor contributing to functional decline and structural progression. Hip abductor strengthening, in addition to quadriceps strengthening, has been advocated in exercise regimes for persons with knee OA. Individuals with hip weakness are likely to have concomitant quadriceps weakness. It is unknown if strong hip muscles confer additional benefits in the context of strong quadriceps. We examined associations of baseline hip abductor strength with functional decline 5 years later and cartilage damage worsening 2 years later, stratified by baseline quadriceps strength.

Methods: Participants all had knee OA (K/L ≥ 2) in at least one knee. Isometric hip abductor and knee extensor strength were measured at baseline, using a Biodex Dynamometer. Peak torques were averaged from 3 trials and normalized to body weight. LLFDI (Late-Life Function and Disability Instrument) and chair stand rate were recorded at baseline and 5-year follow-up; scores were analyzed using quintiles. Poor outcomes were defined as remaining in the same low-function quintiles (worst 2 quintiles) or moving into a worse quintile over 5-year follow-up. Participants underwent 3.0T MRI of both knees at baseline and 2 years later. Baseline-to-2-year cartilage damage progression, defined as any worsening of WOMS cartilage damage score, was assessed at each TF and PF articular surface. Knees graded K/L 4 or with severe PF narrowing at baseline were excluded. We assessed associations of baseline hip abductor strength with functional decline and cartilage damage worsening, using logistic regression with generalized estimating equations, adjusting for age, sex, pain, and K/L grade, stratified by strong vs. weak baseline quadriceps strength and by sex.

Results: 187 persons comprised the function outcome sample and 275 knees from 164 persons the structural outcome sample. In persons with stronger knees, greater hip abductor strength was associated with a reduced risk of poor function outcomes, especially in the chair stand rate and LLFDI disability frequency of participation (Table 1). Among stronger knees, greater hip abductor strength was associated with a reduced risk of cartilage damage worsening in the TF compartments (Table 2). For both outcomes, women-only analyses showed similar findings.

Conclusion: In the setting of strong quadriceps, greater hip abductor strength appeared to confer additional beneficial effects on both joint health and long-term function and disability, suggesting an important role for hip abductor strengthening in persons with knee OA.

Table 1 Person-based subgroup analyses stratified by baseline knee extensor strength and sex: Associations of baseline BW-normalized hip abductor strength (per 0.1 Nm/kg) with baseline-to-5-year poor outcomes by chair stand rate and LLFDI function and disability scores

[Odds Ratio (95% CI)]							
Hip Abductor Strength (Nm/kg)	Chair Stand Rate	LLFDI Total Function	LLFDI Basic Lower Extremity Function	LLFDI Advanced Lower Extremity Function	LLFDI Disability Frequency of Participation	LLFDI Disability Limitation	LLFDI Disability Instrumental Role Limitation

Bone Mineral Density Is a Causal Risk Factor for Knee and Hip Osteoarthritis: A Population-Based and Mendelian Randomization Study in the UK Biobank

Thomas Funck-Brentano¹, Maria Nethander², Sofia Moverare Skrtic¹, Pascal Richette³ and Claes Ohlsson¹, ¹Center for Bone and Arthritis Research, Department of Internal Medicine, Sahlgrenska Academy, Gothenburg University, Gothenburg, Sweden, ²Bioinformatics Core Facility, Sahlgrenska Academy, Gothenburg University, Gothenburg, Sweden, ³Lariboisière Hospital, Lariboisière, University of Paris 7, Paris, France

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Osteoarthritis – Clinical

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Osteoarthritis (OA) involves the whole joint, with alterations of cartilage, synovium and bone. Whether bone changes are a cause or consequence of the disease remains controversial. As there is no curative treatment for OA, identifying causal factors is of major importance. Thus, our aim was to compare observational and causal associations between BMD and different OA phenotypes.

Methods: Individual level clinical and genetic data on 384 838 unrelated participants of European ancestry from the UK Biobank were analysed. As DXA was only available for 1% of the participants, we first tested estimated BMD of the heel (eBMD) as a risk factor for OA at all sites (n= 48 431 cases), at the knee (n= 19 727) or at the hip (n= 11 875), respectively, using hospital diagnoses. The analyses were replicated using knee and hip joint replacement therapy as definitions for severe OA. To assess causality, mendelian randomization (MR) analyses were performed using genetic instruments as proxies for femoral neck (FN) BMD and lumbar spine (LS) BMD. As they are randomly assigned at birth, they are not affected by confounders. Four MR methods were performed with sensitivity analyses excluding genetic instruments associated with body mass index (BMI), to preclude pleiotropy with a known causal confounder. The level of significance after Bonferroni correction was set at 0.05/6 : $P < 0.0083$. All participants gave their written consent to take part in the UK Biobank settings. This project was approved by the UK Biobank committee and has ethical permission.

Results: Linear regression models adjusted for age, sex and BMI revealed that an increase in eBMD by 1 SD was associated with increased risk of all OA (OR= 1.03 [95% CI 1.02 to 1.04]), knee OA (OR= 1.07 [95% CI 1.05 to 1.09]) and hip OA (OR= 1.09 [95% CI 1.07 to 1.11]). Results were similar when considering only incident OA cases or severe OA.

MR analyses by the inverse-variance weighted method demonstrated a causal effect of genetically determined FN BMD, that was associated with all OA (per 1 SD increase, OR=1.15 [95% CI: 1.06 to 1.25]) and both knee (OR=1.20 [95% CI: 1.05 to 1.37]) and hip OA (OR=1.23 [95% CI: 1.12 to 1.36]). Similar findings were demonstrated with joint replacement therapy definitions. The weighted median, the penalized weighted median and Egger's regression method provided similar results. LS BMD was only causally associated with knee OA.

Conclusion: This study demonstrates that high BMD is a risk factor for knee and hip OA and for severe OA, independently of age, sex and BMI. To our knowledge, this is the first evidence of a causal effect of FN BMD. Increasing BMD may not be beneficial for the prevention or the treatment of OA.

Biomechanical Therapy for Osteoarthritis of the Knee: A Randomized Controlled Trial

Stephan Reichenbach^{1,2}, Sarah Heldner¹, Armando Lenz³, David T. Felson⁴ and Peter Jüni⁵, ¹Institute for Social and Preventive Medicine, Bern, Bern, Switzerland, ²Department of Rheumatology, Immunology and Allergology, Bern, Bern, Switzerland, ³CTU Bern, University of Bern, Bern, Switzerland, ⁴Clinical Epidemiology Research and Training Unit, Boston University School of Medicine, Boston, MA, ⁵Applied Health Research Centre (AHRC), Toronto, Toronto, ON, Canada

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Osteoarthritis – Clinical

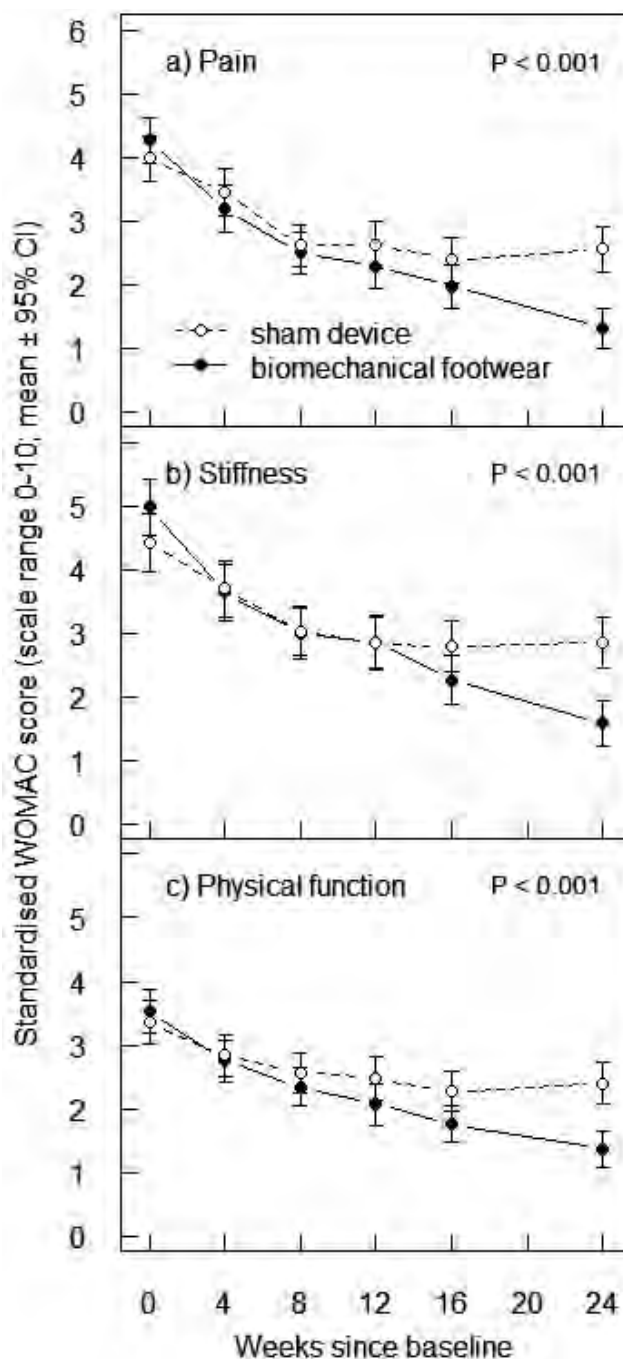

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Biomechanics plays an important role in knee osteoarthritis (OA). A new biomechanical footwear system aims at altering knee loading patterns and retraining neuromuscular control of the lower extremities. It consists of shoes with two adjustable convex pods at the soles, which are adjusted based on gait analysis, with the hypothesis that adjustments of the location of the pods will alter limb biomechanics so as to unload diseased compartments of the knee and that walking on the convex pods will facilitate muscular retraining.

The aim was to compare the efficacy and safety of the new biomechanical footwear with an identical appearing shoe with flat pods (the sham device) in relieving pain and improving physical function in patients with knee OA.

Methods: In this randomized sham-controlled trial, patients with radiological knee OA (K/L grade ≥ 2) and moderate pain on the WOMAC pain subscale (≥ 3 on a standardized scale from 0 to 10) were randomly assigned 1:1 to the biomechanical footwear or the sham device. The same shoe was provided for bilateral use. Patients in both groups were instructed to use

the footwear for 30 minutes/day during the first week, and to increase use by 10 minutes/day each week to a maximum of 5 hours/day at 24 weeks. After 4, 8, 12, and 16 weeks, each patient's footwear was re-calibrated by technicians. Because the sham device had no adjustable pods on the soles, technicians pretended to make appropriate changes. The primary endpoint was knee pain at 24 weeks in the knee with more pain at screening, assessed with the WOMAC pain subscale. Secondary outcomes were WOMAC physical function and stiffness subscales. These outcomes were analyzed using linear models adjusted for baseline values and the two stratification factors uni- vs. bilateral, and medial vs. lateral osteoarthritis at randomization, using multiple imputation.

Results: Of 697 patients assessed for eligibility, 220 were randomized: 111 to the experimental footwear and 109 to the sham device. The mean age was 65.2 years (SD 9.2) and the mean body mass index was 28.0 (SD 4.6). Overall, 47.3% were women and 88.2% had medial knee OA in the index knee. The mean WOMAC pain score at baseline was 4.1 (SD 1.9). Seven patients in the experimental group and 13 in the sham group dropped out. At the end of the trial, the adjusted mean difference for WOMAC pain was 1.34 (95% CI 0.92 to 1.77) in favor of the experimental footwear. The adjusted mean difference was 1.42 (0.93 to 1.91) for WOMAC stiffness and 1.12 (0.73 to 1.50) for WOMAC physical function (Figure 1). Three serious adverse events occurred in the experimental group, compared with 9 in the sham group; none were treatment-related. Thirty adverse events occurred in the experimental group, compared with 36 in the sham group; 18 and 17 of these, respectively, were possibly treatment-related.

Conclusion: This trial suggests that the new biomechanical footwear system is both efficacious and safe in relieving knee pain in patients with knee OA.

Tocilizumab and the Risk for Cardiovascular Disease Events Among Rheumatoid Arthritis Patients: A Direct Comparison in Real World Setting

Fenglong Xie¹, Huifeng Yun¹, Emily Levitan², Paul M. Muntner² and Jeffrey R. Curtis¹, ¹University of Alabama at Birmingham, Birmingham, AL, ²Department of Epidemiology, University of Alabama at Birmingham, Birmingham, AL

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Treatments II: Safety

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Multiple studies have observed unfavorable changes in lipid profile associated with tocilizumab (TCZ, anti-IL6 receptor antagonists) and some other rheumatoid arthritis (RA) therapies. The real-world cardiovascular disease (CVD) risk associated with the first anti IL-6R medication for RA, TCZ, remains uncertain. Our objective was to assess the CVD risk associated with TCZ compared to individual tumor necrosis inhibitor (TNFi) therapies, as well as to other biologics used for RA (e.g. rituximab, abatacept).

Methods: Using 2006-2015 Medicare and MarketScan claims data, we conducted a retrospective cohort study among RA patients who initiated biologic disease-modifying antirheumatic drugs (bDMARDs) after January 1, 2010 and had at least 365 days medical and pharmacy coverage before initiation. The primary outcome was a composite of myocardial infarction (MI), stroke, and fatal CVD assessed using a validated method. Subgroups analyses were done for RA patients experienced to other bDMARDs before initiation and by stratifying patients with respect to key CVD risk factors to identify both higher and lower CVD risk patients. Incidence rates and 95% confidence intervals were calculated using Poisson regression. COX regression was used to generate unadjusted and adjusted hazard ratio.

Results: We identified 354,486 RA patients and 463,446 initiations of bDMARDs. After applying inclusion and exclusion criteria, the final cohort contained 88,463 RA patients and 117,493 episodes. The mean (SD) age was 64.7 in Medicare and 52.2 in Market Scan. The majority were female (83.9% Medicare; 80.5% Market Scan), and 68.6% were non-Hispanic White in Medicare. TCZ users were similar to abatacept and rituximab users except that TCZ users were less likely to be naïve to bDMARDs. Compared to TNFi users, TCZ users were likely to be white, have a history of CVD (other than MI or stroke), heart failure, atrial fibrillation, hospitalization, and more physician visits in baseline. TCZ users were less likely to be diabetic, use methotrexate in baseline, and naïve to bDMARDs. The crude incidence rate (IR) per 1000 patient-years for composite CVD among Medicare patients ranged from 13.3 (95% CI: 11.1-16.0) for etanercept to 19.4 (95% CI: 16.3-20.9) for rituximab users. The crude incidence rate for pooled TNFi users was 16.4 (15.2-17.7). Compared to TCZ, the adjusted hazard ratios were 1.03 (0.82-1.29) for abatacept, 1.25 (0.96-1.61) for rituximab, 1.13 (0.84-1.52) for etanercept, 1.33 (0.99-1.80) for adalimumab, and 1.57 (1.21-2.05) for infliximab.

(Figure). There were no significant differences in CVD risk between tocilizumab and any other biologic using Market Scan data.

Conclusion: Consistent with findings of a recently completed safety trial in RA, tocilizumab was associated with a comparable CVD risk compared to etanercept, as well as a number of other RAbiologics, in two large data sources.

Session Title: Rheumatoid Arthritis – Treatments II: Safety

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: MTX has become the cornerstone in treatment of many rheumatologic disorders including rheumatoid arthritis and psoriasis. Although MTX can have a profound impact on disease management, and is generally continued as lifelong therapy, the feared potential for hepatotoxicity can result in early discontinuation of the drug. Unfortunately, liver function tests demonstrate a low diagnostic accuracy for detection of fibrosis with only a 38%. The purpose of our study is to establish the prevalence of liver toxicity in patients on MTX therapy at our large tertiary hospital setting and to identify characteristics of patients who are more susceptible for hepatotoxicity while on MTX therapy.

Methods: Retrospective cohort of all patients on MTX therapy for any rheumatologic disease including rheumatoid arthritis and psoriatic arthritis, in the in-patient and out-patient settings at NorthShore University Health System, a large tertiary health system, were taken into analysis between January 1, 2006 and December 31, 2016. Out of these approximately 5,000 patients, we screened for patients who had a liver biopsy and/or transient elastography testing done. Variables we looked at included age, gender, liver function tests, cumulative dose of MTX, CKD, history of hepatitis B or C, triglyceride levels, diabetes mellitus, and alcohol use.

Results: Out of the large number of patients who have been on methotrexate therapy (~5,000 patients over ten years of treatment), only 1% underwent further work-up for suspected liver disease by performing a liver biopsy and/or transient

elastography (Fibro Scan). From these 48 patients with suspected liver disease, liver biopsy and/or Fibro Scan revealed 26% had steatosis, 14.4% had fibrosis, 13% had NASH cirrhosis, 34% were normal findings with no liver disease, 5% had acute hepatitis, 2.6% chronic hepatitis, and only 5% had methotrexate associated cirrhosis.

Conclusion: Our findings demonstrate a very low prevalence of MTX associated hepatotoxicity in the rheumatologic patients. Less than 3% of patients had persistent transaminitis on MTX therapy, and even a smaller percentage underwent follow-up imaging with a liver biopsy or FibroScan. Based on our results, the likelihood of developing liver damage on MTX treatment is extremely low, and careful consideration needs to be made before potentially prematurely discontinuing this treatment for elevated liver function tests. Patients more susceptible to liver disease included increased BMI, diabetes mellitus, and elevated triglyceride levels, all at increased risk of fatty liver disease and NASH cirrhosis, consistent with the literature.

Abstract Number: 960

The Risk of Gastrointestinal Perforations Associated with Biologic Disease-Modifying Anti-Rheumatic Drugs Used in Rheumatoid Arthritis: A Nationwide Swedish Cohort Study

Andrei Barbulescu¹, Thomas Frisell¹, Johan Askling² and Bénédicte Delcoigne¹, ¹Clinical Epidemiology Unit, Department of Medicine, Solna, Karolinska Institutet, Stockholm, Sweden, ²Unit of Clinical Epidemiology, Department of Medicine, Solna, Karolinska Institutet, Stockholm, Sweden

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Treatments II: Safety

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Gastrointestinal (GI) perforations occur more often than expected in patients with RA. Reports indicate that tocilizumab may be associated with an increased risk of GI perforations compared to synthetic DMARDs (1) or to TNF inhibitors (TNFi) (2). Replications are needed, and there is little data on other biologic DMARDs. In this analysis, we compare GI perforation rates among RA patients exposed to rituximab, abatacept, tocilizumab, or TNFi.

Methods: In this register-based cohort study we included all Swedish RA patients, with follow-up from 2010 to 2016. All initiations of treatment with TNFi, rituximab, abatacept, or tocilizumab were extracted from the Swedish rheumatology register (SRQ); each patient could contribute to several exposure cohorts. Follow-up under each exposure episode ended with a GI perforation event or at censoring by emigration, death, treatment switch or discontinuation, or end of study period. GI perforations were identified in the Swedish National Patient Register as any inpatient or outpatient diagnosis with an International Statistical Classification of Diseases and Related Health Problems (ICD) 10 code from a predefined list. Crude incidence rates were tabulated for each treatment cohort and relative effects were estimated as adjusted hazard ratios (HR) in multivariable Cox regressions, conditioning on baseline characteristics measured at the start of each episode (demographic, disease activity, co-medication, disease history).

Results: We found some evidence for outcome relevant channeling, with patients starting abatacept or rituximab more often having a history of diverticular disease or GI perforation, and some differences in age and co-medication (Table 1). Table 2 presents observed person-time, number of events (95% of which were lower GI perforations), crude rates and adjusted comparisons. The crude GI perforation rate was lowest in the TNFi, and highest in the abatacept cohort. None of the adjusted comparisons of each non-TNFi biologic with TNFi biologics yielded hazard ratios significantly different from 1.

Conclusion: We could not replicate an increased rate of GI perforations for tocilizumab. Taking measured channeling of treatment into account, none of the non-TNFi biologics showed an increased risk compared to TNFi biologics. Effects of residual or unmeasured factors cannot be excluded.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Treatments II: Safety

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: High dose tumour necrosis factor inhibitor (TNFi) drugs are associated with an increased serious infection (SI) risk [1]. It is feasible that high biologic levels predict dose-dependent adverse events such as SI. No registries have systematically evaluated the effect of drug levels on infection risk. The objective was to assess the effect of biologic drug levels in rheumatoid arthritis (RA) patients on (i) all infections (AI) (ii) SI(infections requiring hospitalization, IV antibiotics or lead to death) **Methods:**

Patients recruited to both the British Society for Rheumatology Biologics Register-RA (safety data) and the Biologics in RA Genetics & Genomics Syndicate (serological samples) were included. Both are large national prospective RA cohorts. Biologic drug levels were measured at 3/6/12 months after biologic initiation and stratified as low/normal or high drug levels (HL) as per thresholds defined using concentration-effect curves for each drug. The risk of first and total infections within the first year was analysed. Events occurring on drug or within 90 days of last dose were included. The risk of an event was compared between low/normal vs. HL groups using Cox proportional-hazard models. Factors affecting both drug levels and infection risk were adjusted for in the models. **Results:**

703 patients (286 etanercept, 179adalimumab, 120 certolizumab, 104 tocilizumab and 14 infliximab) had clinical data and serological samples. 74% were women, mean (SD) age 58 (12) years, on a first biologic (89%). The crude rate/1000 pyrs was 314 and 464 for AI; 54 and 76 for SI in the low/normal and HL groups respectively. The adjusted hazard ratio for AI within the first year differed significantly between the two groups with the HL group having 50 percent higher risk of AI (HR: 1.51; 95% CI:1.14, 2.01) (table). The most common types of AI in the HL group were lower(34%) and upper (16%) respiratory tract infections, urinary tract infections(15%), skin infections including shingles (8%).

* p<0.05†Adjusted for age, gender, DAS score, methotrexate use

Image/graph: :

Conclusion: RA patients with high biologic drug levels have a higher risk of infection. Monitoring drug levels may be helpful in prediction of infection. In disease remission patients with high drug levels, biologic dose tapering may lower infection risk.

95% CI for IR are based on Poisson distribution.

^aData from treatment period up to Week 24, with data up to rescue / treatment switch.

^bAll analysis based on an as-treated method (data censored at rescue or dose change) unless otherwise specified.

^cOn the "as-randomized" analysis for malignancy excluding NMSC, all data were attributed to the initial randomized treatment group & not reporting rescue or dose changes. The patient-years of observation time with the as-randomized analysis were 1208 and 1214 years for 2mg and 4mg groups, respectively.

^dPotential cardiovascular (CV) adverse events from the Pbo 3 study and LTE, identified by investigators or according to a predefined list of event terms, were adjudicated by an independent, external Clinical Endpoint Committee who remained blinded to treatment assignments; includes follow up period.

^e*P<0.01 for bari 4 mg vs placebo based on the proportion of patients with the event.

AE, adverse event; Bari, baricitinib; CI, confidence interval; DC, discontinuation; EIR, exposure-adjusted incidence rates per 100 patient years (exposure time not censored at event); IR, incident rate per 100 patient years (observation time censored at event); GI, gastrointestinal; MAACE, major adverse cardiovascular event; NMSC, non-melanoma skin cancer; n, number of patients in a specified category; PBO, placebo; TB, tuberculosis; yrs, years.

Methods: Long-term safety of once-daily bari was evaluated in the “all-bari-RA” dataset, which includes all patients (pts) with active RA exposed to any bari dose from 8 randomized trials (4 Phase 3, 3 Phase 2, 1 Phase 1b) and 1 LTE study (data up to 01-April-2017). Previous all-bari-RA analyses¹ are provided for comparison (data up to 10-Aug-2015 and 01-Sept-2016).² Dose responses were evaluated based on the 4 Phase 2/3 trials in which pts were randomized to 2 or 4mg including data from the LTE (the “2mg-4mg-extended” dataset). Data were censored at rescue or dose change (as-treated analysis). Because of the latent period for malignancy, 2mg-4mg-extended was also analyzed without censoring for rescue or dose change (as-randomized analysis). Incidence rates (IR) per 100 patient-years (PY) were calculated.

Results: In the current analysis, 3492 pts received bari for 7860 total PY of exposure (an increase in over 1200 PY; 18% from 01-Sept-2016) for up to 6 years (Table 1). Of these, 2723 (78.0%) were treated for at least 52 weeks and 1788 (51.2%) were treated for at least 130 weeks. Adverse events (AEs) IRs did not increase with prolonged exposure (Table 1). Malignancy (excluding non-melanoma skin cancer (NMSC)) IR were 0.5 and 1.2 for 2mg and 4mg, respectively, with as-treated analysis and 0.8 and 0.8 with as-randomized analysis. For the above events, the current IRs in all-bari-RA are similar to those previously reported (Table 1). The following IRs were observed in the current all-bari-RA: gastrointestinal (GI) perforation (0.04), and tuberculosis (TB) (0.14). Fewer than 1% of pts discontinued due to abnormal lab results.

Conclusion: In this updated integrated analysis of patients with moderately to severely active RA, including patients exposed for up to 6 years, baricitinib maintained a safety profile that was similar to that previously reported^{1,2} acceptable in the context of demonstrated efficacy.^{3,4}

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Treatments II: Safety

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Tofacitinib is an oral Janus kinase inhibitor for the treatment of RA. Here, we report the largest integrated safety analysis of tofacitinib to date using data from Phase (P)1, P2, P3, P3b/4, and open-label long-term extension (LTE) studies in adult patients (pts) with RA.

Methods: Data were pooled for pts who received ≥ 1 tofacitinib dose, as monotherapy or with background conventional synthetic DMARDs (csDMARDs), integrated across 2 P1, 10 P2, 6 P3, 1 P3b/4, and 2 LTE studies (ORAL Sequel LTE main study database locked at time of analysis: March 2017). Incidence rates (IR; pts with events per 100 patient-years [PY]) and 95% confidence intervals were obtained for safety events of special interest. Additionally, IRs for deep vein

thrombosis(DVT) and pulmonary embolism (PE) are reported. IRs were based on the number of pts with incident events during the time between the first and last dose plus 28days, which was the clinical trial observation period (previous analyses included events outside of the observation period).

Results: This analysis included 7061 pts, representing 22,875 PY of tofacitinib exposure, with a median exposure of 3.1 years, and 30% of pts had >5years of exposure. A total of 1634 (23.1%) pts discontinued due to adverse events (AEs; IR: 7.1[6.8, 7.5]). The most common treatment-emergent AEs by MedDRA v20.0 preferred term were viral upper respiratory tract infection (17.3%), upper respiratory tract infection (17.2%), and urinary tract infection (11.8%). The IR for serious AEs was 9.0 (8.6, 9.4), of which infections were the most common. Serious infections occurred in 576 pts (8.2%; IR: 2.5 [2.3, 2.7]), and pneumonia was the most frequently reported serious infection (124 pts [22% of all pts with serious infections]). Overall, 782 pts (11.1%) developed herpes zoster (HZ; IR: 3.6 [3.4, 3.9]); in most pts HZ involved a single dermatome (90.2%). Serious HZ was reported in 57 pts (7.3% of all pts with HZ). Opportunistic infections (excluding tuberculosis [TB]) were reported in 90 pts (1.3%; IR: 0.4 [0.3, 0.5]) and TB was reported in 38 pts (0.5%; IR: 0.2 [0.1, 0.2]). Malignancies (excluding non-melanoma skin cancer [NMSC]) occurred in 177 pts (2.5%; IR: 0.8 [0.7, 0.9]), NMSC in 129 pts (1.8%; IR: 0.6 [0.5, 0.7]) and lymphomas in 12 pts (0.2%; IR: 0.1 [0.0, 0.1]). Gastrointestinal perforations were reported in 28 pts (0.4%; IR: 0.1 [0.1, 0.2]) and major adverse cardiovascular events in 85 pts (1.3%; IR: 0.4 [0.3, 0.5]). DVT was reported in 27 pts (0.4%; IR: 0.12 [0.08, 0.17]) and PE in 28 pts (0.4%; IR: 0.12 [0.08, 0.17]). There were 59 deaths (0.8%; IR: 0.3 [0.2, 0.3]). IRs for AEs of interest were stable across 6-month intervals.

Conclusion: This long-term integrated safety analysis with up to 9.5years of follow-up and 22,875PY of tofacitinib exposure represents one of the largest clinical datasets to date for an advanced RA treatment. The safety profile of tofacitinib remained consistent with those of previous randomized controlled trials in the RA clinical development program.

Psoriatic Arthritis Impact of Disease (PsAID12) Was Provisionally Endorsed at Omeract 2018 As Core Instrument to Measure Psoriatic Arthritis-Specific Health-Related Quality of Life in Randomized Controlled Trials and Longitudinal Observational Studies

Richard Holland¹, Robin Christensen², Niti Goel³, Pil Hoejgaard⁴, William Tillett⁵, Laure Gossec⁶, Maarten de Wit⁷, Neil McHugh⁸, Philip J. Mease⁹, Beverly Shea¹⁰, Ying Ying Leung¹¹, Dafna D Gladman¹², Christine Lindsay¹³, Laura C. Coates¹⁴, Alexis Ogdie¹⁵, Vibeke Strand¹⁶, Lara Fallon¹⁷, Julie Birt¹⁸, Kristina Callis Duffin¹⁹, Oliver FitzGerald²⁰, Peter Tugwell²¹, Dorcas Beaton^{22,23} and Ana-Maria Orbai²⁴, ¹Royal Prince Alfred Hospital Medical Centre, Sydney, Australia, ²Musculoskeletal Statistics Unit, The Parker Institute, Bispebjerg and Frederiksberg, Denmark, ³Kezar Life Sciences; Duke University School of Medicine, Durham, NC, ⁴Center for Rheumatology and Spine Diseases - Gentofte, Rigshospitalet, Hellerup, Denmark, ⁵Royal National Hospital for Rheumatic Diseases and University of Bath, Bath, United Kingdom, ⁶Sorbonne Universités, Paris, France, ⁷EULAR standing committee of PARE, Zurich, Switzerland, ⁸Rheumatology, Royal National Hospital, Bath, Great Britain, ⁹Swedish Medical Center and University of Washington, Seattle, WA, ¹⁰School of Epidemiology, Public Health, and Preventive Medicine, Faculty of Medicine, University of Ottawa, and Ottawa Hospital Research Institute, Clinical Epidemiology Program, Ottawa, ON, Canada, ¹¹Singapore General Hospital, Singapore, Singapore, ¹²University of Toronto, Toronto Western Hospital, Toronto, ON, Canada, ¹³Medical Affairs, Amgen Inc, Thousand Oaks, CA, ¹⁴University of Oxford, Oxford, United Kingdom, ¹⁵Medicine/Rheumatology and Epidemiology, University of Pennsylvania, Philadelphia, PA, ¹⁶Stanford University School of Medicine, Palo Alto, CA, ¹⁷Pfizer Canada, Montreal, QC, Canada, ¹⁸Eli Lilly and Company, Indianapolis, IN, ¹⁹Department of Dermatology, University of Utah, Salt

Methods: We used a multi-step process (Fig1). PsAID12 psychometric evidence to fulfill Filter 2.1 was gathered in a systematic literature review (SLR) of patient reported outcomes (PROM) in PsA³, and additional analyses conducted in an LOS. Analyses that not been published were independently reviewed by the OMERACT technical advisory group. Data were presented to stakeholders [WG, patient research partners (PRP), workshop at the GRAPPA 2017 annual meeting⁴] followed by a survey to vote on domain match and feasibility. All data were summarized as PsAID12 OMERACT pre-conference reading material. Data and process were presented, discussed in 8 breakout groups, and voted on, at the OMERACT 2018 conference (Terrigal, Australia, May 2018).

Results: An excerpt of the PsAID12 evidence presented at OMERACT 2018 is represented in Fig2. PsAID12 fulfilled with green (good to go) domain match, feasibility, reliability, and construct/longitudinal construct validity. Discrimination was assessed in an LOS within change groups. Minimal clinically important improvement in 2 LOS^{2,5} were 3 and 1.4. PsAID12 fulfilled with amber (provisional endorsement) discrimination and thresholds of meaning. The overall WG recommendation was formulated: **amber/provisional endorsement of PsAID12 for measuring PsA specific-HRQoL in RCTs and LOS**. Of 113 participants at the PsA OMERACT workshop 87% (97) voted “yes” endorsing this recommendation. 17 were PRPs and 93% voted “yes”. The WG set a research agenda to fully endorse PsAID12.

Conclusion: At OMERACT 2018, PsAID12 was the first PROM provisionally endorsed as core instrument to measure PsA-specific HRQoL in RCTs. PsAID12 discrimination and improvement thresholds will be studied in RCTs.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical II: PsA Epidemiology

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: The Psoriatic Arthritis (PsA) Impact of Disease questionnaire (PsAID12) score allows an assessment of patient-important symptoms and life impact in PsA. It is provisionally recommended as core outcome measure

Table 1. Cutoffs for PsAID12-defined disease activity states using different external anchors.

	Remission		Low disease activity		Moderate disease activity	
	ROC (AUC)	75th	ROC (AUC)	75th	ROC (AUC)	75th
DAPSA	1.7 (0.94)	1.4	3.1 (0.89)	3.1	4.8 (0.85)	4.5
VLDA / MDA	1.4 (0.94)	0.8	2.0 (0.91)	1.9		
Patient's question	1.7 (0.77)	2.4	3.7 (0.83)	3.7		
Physician's question	1.8 (0.75)	3.0	4.2 (0.77)	4.1		
Mean value for all external anchors	1.7	1.9	3.2	3.2	4.6	4.6

PsAID12: Psoriasis Activity Index (PsA) Impact of Disease questionnaire; ROC: Receiver Operating Characteristic; AUC: area under curve; DAPSA: Disease Activity Index for Psoriatic Arthritis; VLDA: Very Low Disease Activity; MDA: minimal disease activity.

byOMERACT (ref). To date, no cutoffs have been established to help clinicians interpret its results. The objective was to develop such cutoffs for PsAID12 corresponding to disease activity states (i.e. remission (REM), low disease activity (LDA) or moderate disease activity).

Methods: ReFlap (NCT03119805) is an ongoing cross-sectional study in 14 countries of consecutive adult patients with definite PsA and more than 2 years of disease duration. The PsAID12 (0-10 score where 0 is no impact) was collected. Disease activity was defined using the following external anchors: (a) Disease Activity in Psoriatic Arthritis (DAPSA) score (cutoffs of ≤ 4 , ≤ 14 , ≤ 28 for REM, LDA and moderate disease activity, respectively) (b) Very Low Disease Activity (VLDA) / Minimal Disease Activity (MDA) scores (cutoffs of 7/7 and 5/7 criteria met for REM and LDA, respectively) (c) single questions for patient and physician-defined REM and LDA. For each level of disease activity and for each external anchor, cutoffs of PsAID12 were calculated using Youden's index on Receiver Operating Characteristic (ROC) curve analyses and the 75th percentile method. Finally, author consensus was sought on final proposed cutoffs.

Results: Of 466 patients, 436 were analyzed: 218 (50.8%) were men, mean age (standard deviation) was 53.6 (12.7) years, mean disease duration was 11.3 (8.3) years, 62.3% were taking conventional synthetic DMARDs and 60.1% a biologic. Mean PsAID12 was 3.4 (2.5). The frequency of REM varied from 12.8% (VLDA) to 38.5% (Physician REM question) and of LDA from 25.5% (MDA) to 43.1% (Patient LDA question). PsAID functioned well against the external anchors as indicated by high areas under the ROC curves (range, 0.75-0.94). The VLDA and MDA criteria were more difficult to reach than the DAPSA REM and LDA cutoffs, reflected by much lower cutoffs for the PsAID12 score (Table 1). PsAID12 cutoffs varied between 1.7-1.9, 3.2-3.3 and 4.5-4.8 for REM, LDA and moderate disease activity, respectively (Table 1). Proposed final cutoffs of PsAID12 are < 2 for REM, ≤ 3 for LDA and < 5 for moderate disease activity.

Conclusion: It was possible to define cutoffs for PsAID12 corresponding to PsA disease activity states with good known groups validity. This indicates patients' assessment reflects the disease process in PsA. One strength of our study is the use as external anchors to define disease activity based on both composite scores and the patient's opinion. Proposed cutoff values for PsAID12 will be useful when defining treatment targets for PsA. Further validation is needed.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical II: PsA Epidemiology

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Accurate triage methods for patients with psoriasis who have musculoskeletal symptoms could lead to earlier access to rheumatology care for patients with psoriatic arthritis (PsA). We aimed to describe a novel model of care involving a central triage clinic for psoriasis patients with musculoskeletal (MSK) symptoms and to compare the efficacy of several triage methods for PsA.

Methods: Patients with a physician-confirmed diagnosis of psoriasis who experienced musculoskeletal symptoms and did not have a prior diagnosis of PsA were evaluated. Patients could access the triage clinic by self-referral or following referral by their family physician or dermatologist. Participants were assessed in the central triage clinic to determine their likelihood of having PsA. The following triage methods were used: 1) three PsA screening questionnaires (TOPAS-2, PEST, PASE); 2) MSK ultrasound assessment of 14 pre-specified enthesal sites and 8 joint sites in addition to symptomatic joints and entheses; 3) clinical assessment by an advanced practice physiotherapist; 4) levels of CRP and ESR and 5) The presence of *HLA-B*27* allele. Each patient was then assessed by a rheumatologist to determine whether they have PsA. Patients were classified by the rheumatologist to “Not PsA”, “Possible PsA” or “PsA”. The rheumatologist was blinded to the results of the triage methods. The performance of each triage method to identify PsA was assessed by calculating its sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV).

Results: Of the 203 psoriasis patients assessed in the triage clinic, 137 (67.5%) did not have PsA, 48 (23.5%) had possible PsA, and 18 (9%) had PsA. The performance of triage methods is presented in Table 1. The advanced practice physiotherapist's assessment in detecting clinical PsA was highly sensitive (89%) with moderate specificity (58%). The screening questionnaires varied by their sensitivity and specificity with PEST showing highest sensitivity (76%) and PASE with highest specificity (79%). The prevalence of positive MSK inflammation by ultrasound (at least 1 joint or enthesis with positive power Doppler signal) was 50.7%. The sensitivity of positive MSK ultrasound was high (83%) but its specificity was moderate (52%). 43.3% of the study participants who had positive MSK ultrasound findings were not classified by the rheumatologist as having PsA. The performance of CRP, ESR and HLA-B27 as triage methods was poor.

Conclusion: MSK ultrasound and advanced practice physiotherapist were highly sensitive in identifying patients with PsA among psoriasis patients with MSK symptoms. A significant proportion of patients with positive MSK inflammation by ultrasound were not identified as having PsA by the rheumatologist.

Table 1 Properties of various triage methods in detecting clinical PsA among patients with psoriasis and musculoskeletal symptoms (N=203)

Triage Method	Sensitivity	Specificity	PPV	NPV
Positive MSK ultrasound (Definition 1) at least 1 joint or enthesal sites with positive power Doppler signal	83%	52%	15%	97%
Positive MSK ultrasound (Definition 2) at least 2 joint or enthesal sites with positive power Doppler signal	67%	76%	21%	96%
Advanced Practice Physiotherapist: Positive assessment	89%	58%	17%	98%
Positive TOPAS-2 questionnaire	72%	72%	21%	96%
Positive PEST questionnaire	76%	70%	15%	93%
Positive PASE questionnaire	61%	79%	23%	95%
Elevated CRP (>5 mg/dL)	44%	79%	19%	94%
Elevated ESR (Men: >15 mm/hr, Women: >20 mm/hr)	63%	78%	21%	96%
HLA-B*27 allele	6%	92%	7%	91%

MSK – Musculoskeletal, TOPAS – Toronto Psoriatic Arthritis Screening, PEST – Psoriasis Epidemiology Screening Tool, PASE – Psoriatic Arthritis Screening and Evaluation, CRP – C-Reactive Protein, ESR – Erythrocyte Sedimentation Rate

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical II: PsA Epidemiology

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Numerous studies have shown delays in diagnosis of psoriatic arthritis (PsA) among patients with psoriasis. The heterogeneous nature and frequently insidious onset of PsA may contribute to the delayed diagnosis. There are limited data about the pre-diagnosis phases of PsA. We aimed to assess health care utilization in a primary care setting during a 5-year period prior to the diagnosis of PsA in comparison to the general population.

Methods: We conducted a matched cohort study using the primary care Electronic Medical Record Administrative data Linked Database (EMRALD) in Ontario, Canada (comprised of >350 primary care physicians and >400,000 patients). EMRALD data were linked with provincial administrative data to obtain information about health care services utilization. Patients with PsA were identified using a validated algorithm (PPV85%). The date of PsA diagnosis (index date) was defined as the first date an inflammatory arthritis billing code was administered by a rheumatologist. Five age- and sex-matched controls from the same family practice clinic were matched for each PsA case. The controls were assigned the same index date as their corresponding case. The primary outcome was visits to primary care physicians for non-specific musculoskeletal (MSK) issues during the 5-year period prior to the index date. We compared the rates of visits and the proportion of patients visiting primary care physicians between PsA and controls using GEE models with negative binomial distribution (for rates) and binary distribution (for probabilities).

Results: We studied 462 PsA patients and 2310 matched controls with a mean (SD) age of 54.2±13.8 (55.6% females). Relative rates and odds of visits were higher in each of the 5 years prior to the index dates for PsA patients vs. controls (Figure 1 and Table 1). The odds ratios (OR) related to visiting a primary care physician for nonspecific MSK issues in patients with PsA vs. controls was 2.14 (95% CI 1.74, 2.63) in the first year prior to the index date and was similarly elevated up to 5 years prior (Table 1). Additionally, the Relative Rates (RR) for MSK-related visits prior to the index date were higher in PsA patients compared to controls (RR ranging from 1.93 to 2.12; Figure 1).

Conclusion: We identified the presence of a prolonged period of non-specific MSK symptoms occurring prior to the diagnosis of PsA, which is greater than the control group. Our findings suggest that there may be a pre-clinical phase of the disease characterized by non-specific MSK symptoms, which may lead to delays in diagnosis of PsA in the primary care setting.

Table 1 - Odds ratios for at least one visit to a primary care physician for non-specific musculoskeletal issues in individuals ultimately developing PsA vs. Controls

Years prior to the index date	Odds Ratio	95% Confidence Interval
1	2.14	1.74, 2.63
2	1.88	1.53, 2.32
3	1.73	1.40, 2.14
4	1.74	1.40, 2.15
5	1.77	1.43, 2.19

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical II: PsA Epidemiology

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Although MRI of the sacroiliac joints (SIJ) is the most sensitive imaging modality for early diagnosis of axial spondyloarthritis (axSpA) it is costly and not readily available. Therefore, clinicians still rely primarily on radiography. The relative degree to which radiography and MRI changes diagnostic ascertainment of axSpA in patients presenting with undiagnosed back pain has not been formally studied. We aimed to assess the relative impact of radiography and MRI evaluation on diagnostic ascertainment of axial SpA in patients presenting with undiagnosed back pain to rheumatologists, and the impact of central reading on diagnostic ascertainment.

Methods: The multicenter Screening for Axial Spondyloarthritis in Psoriasis, Iritis, and Colitis (SASPIC) Study is aimed at early detection of axial SpA in consecutive patients presenting with undiagnosed back pain. Consecutive patients ≤ 45 years of age with ≥ 3 months undiagnosed back pain with any one of psoriasis, acute anterior uveitis (AAU), or colitis undergo routine clinical evaluation by a rheumatologist for axial SpA and MRI evaluation is ordered per rheumatologist decision. The rheumatologist determines the presence or absence of axial SpA and the degree of confidence in the diagnosis (-10 (definitely not SpA) to +10 (definite SpA) on a numerical rating scale) at 3 consecutive stages: 1. after the clinical evaluation; 2. after the results of labs (B27, CRP) and radiography; 3. After the results of MRI evaluation. We assessed diagnostic ascertainment at each step at the categorical level (axial SpA yes/no) and also according to the degree of confidence (mean (SD) confidence). Two central readers assessed radiographs and MRI scans.

Results: 234 patients (51.3% male, mean age 34.6 years, mean symptom duration 7.0 years, mean back pain duration 7.1 years, B27+36.3%) were referred with AAU (29.9%), psoriasis (18.8%), Crohn's colitis (32.1%), and ulcerative colitis (19.2%). The number of patients diagnosed clinically with axSpA decreased after radiography and then decreased further after MRI while confidence in the diagnosis progressively increased (Table 1). After central reader assessment of imaging, the number of patients diagnosed with axSpA decreased substantially compared to assessment by local readers (Table 2).

Conclusion: In a setting of undiagnosed back pain and higher risk for axial SpA, imaging is primarily helpful in ruling out SpA and reducing false positives. Despite this, central reading of imaging raises concerns regarding ascertainment of false positive SpA in routine practice.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical II: PsA Epidemiology

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Outcomes of pregnancy are well studied in a number of rheumatic diseases such as Rheumatoid Arthritis (RA) and systemic lupus erythematosus. However, there is very limited data in pregnancy outcomes in patients with psoriasis and psoriatic arthritis (PsA). This study was undertaken to determine the frequency of complications occurring during pregnancy for women with psoriasis and/or PsA and to compare these outcomes with the general obstetric population by using the largest inpatient care database.

Methods: By using the 2003-2011 Nationwide Inpatient Sample of Healthcare Cost and Utilization Project, we estimated the number of obstetric hospitalization, deliveries and caesarean deliveries in women between the age group 18-50 years. Patients hospitalized with psoriasis and/or PsA were identified. Demographic characteristics and in-hospital outcomes were recorded for both psoriasis and/or PsA as well as control group. Subsequently, obstetric complications for all pregnancy-related admissions for women with and without psoriasis and/or PsA were compared. Multivariate logistic regression analysis was used to obtain adjusted odds ratio (OR).

Results: The total number of obstetric hospitalization was 42.32 million, of which 11204 were women with diagnosis of psoriasis and/or PsA. The mean maternal age of this population was higher (30.32 years) than the control group (27.32 years) { $p < 0.001$ }. After adjusting for potential confounders, the results suggest that maternal Psoriasis/PsA population had no significant increase in inpatient mortality or fetal death. Prevalence of preterm delivery, premature rupture of membranes, postpartum hemorrhage and cesarean delivery was also similar among the two groups. Interestingly, the odds of hypertensive diseases in psoriasis/PsA patients was significantly lower. The results do suggest that psoriasis/PsA patients may have a higher risk of intrauterine growth retardation. The frequencies of the above outcomes along with Odds Ratio are provided in Table 1.

Conclusion: Based on our study of national cohort, we conclude that pregnancies in women with psoriasis and PsA are relatively safe without any increase in maternal or fetal mortality despite having a higher maternal age. These data are reassuring that these women also do not have higher risk of adverse outcomes of pregnancy than women without psoriasis and PsA. In contrast, RA patients have worse outcomes based on the same analysis. These findings highlight that psoriasis and PsA patients may have a positive/normal physiologic response to pregnancy than RA patients. We suggest that continued close antenatal and post-delivery monitoring pregnancy be performed until these results are further clarified.

Table 1. Obstetric Outcomes for Pregnancy Related Hospitalizations in Psoriasis and Psoriatic Arthritis

	Total	Psoriasis/PsA	Controls	OR	p-value
Number of Pregnancies	42317648	11204	42306444	N/A	N/A
Mean Age		30.34	27.32		<0.001

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Lupus Erythematosus – Clinical I: Clinical Trials

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Baricitinib (Bari), an oral selective inhibitor of Janus kinase (JAK)1 and JAK2, has been approved for the treatment of RA in the Europe and Japan. The purpose was to report results from a 24-week(wk) global, Phase 2, double-blind, placebo (PBO)-controlled study of Bari in patients with SLE receiving standard therapy.

	PBO (N=105)	Bari 2-mg (N=105)	Bari 4-mg (N=104)
Efficacy measure	Week 24		
Resolution of arthritis or rash (SLEDAI-2K)	56 (53.3)	61 (58.1)	70 (67.3)*
SRI-4	50 (47.6)	54 (51.4)	67 (64.4)*
Flare (SFI, any severity)	54 (51.4)	45 (42.9)	34 (32.7)*
Flare (SFI, severe)	12 (11.4)	10 (9.5)	6 (5.8)
LLDAS	27 (25.7)	35 (33.3)	40 (38.5)*
ΔTJC	-5.56	-6.50	-6.80*
ΔSJC	-4.60	-4.12	-4.76
ACLA3 activity score	-2.80	-1.60	-2.27
ΔWorst pain	-0.50	-1.17	-1.31*
ΔWorst fatigue	-1.10	-1.13	-1.52*
Safety measure	Weeks 0-24†		
TEAEs	80 (54.8)	75 (71.4)	76 (73.1)
SAEs	5 (4.8)	11 (10.5)	10 (9.6)
Serious infections	1 (1.0)	2 (1.9)	6 (5.8)
Deep vein thrombosis	0	0	1 (1.0)

Data are n (%) patients, unless otherwise indicated. *least squares mean change from baseline. †includes up to 36 days post treatment. ACLA3=Cutaneous Lupus Erythematosus Disease Area and Severity Index; N=number of patients in the analysis population; n=number of patients in the specified category; TEAE=treatment-emergent adverse event. *p<0.05.

Methods: Patients with SLE (positive ANA or anti-dsDNA, clinical SLEDAI-2K ≥4, arthritis or rash required) receiving stable background SLE therapy were randomized 1:1:1 to PBO, or Bari (2- or 4-mg) once daily. The primary endpoint was resolution of SLEDAI-2K arthritis or rash at Wk24.

Results: Of 314 patients randomized, 79%, 82%, and 83% completed 24 wks of treatment in PBO, Bari 2-mg, and Bari 4-mg groups, respectively. At Wk24, a significantly greater proportion of patients in Bari 4-mg group compared to PBO achieved resolution of SLEDAI-2K arthritis or rash (67% vs 53%, p<0.05); and SLE Responder Index (SRI)-4 response (64% vs 48%, p<0.05). At Wk24, the proportion of patients achieving flare reduction (SELENA-SLEDAI Flare Index [SFI]), Lupus Low Disease Activity State (LLDAS), and tender joint count (TJC) change from baseline were also significantly improved for Bari 4-mg compared to PBO (Table). No statistically significant differences were observed between Bari 2-mg and PBO in any of the above endpoints. Rates of adverse events leading to treatment discontinuation and serious adverse events (SAEs) were higher for both Bari dose groups compared to PBO. There were no deaths, malignancies, major adverse cardiovascular events, tuberculosis, or serious herpes zoster infections; 1 SAE of deep vein thrombosis was reported in a patient with risk factors (Bari 4-mg group).

Conclusion: In patients with SLE receiving standard background therapy, once-daily oral Bari 4-mg was associated with significant clinical improvements compared to PBO and an acceptable benefit/risk profile. These findings support further study of Bari 4-mg as a potential therapy for patients with SLE.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018
Session Title: Systemic Lupus Erythematosus – Clinical I: Clinical Trials
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Figure 3. Anti-Double Stranded DNA Mean Change From Baseline From Years 1 to 3 (All Subjects)

Background/Purpose: The tenets of novel treatment (tx) strategies for active class III/IVlupus nephritis (LN) aim to improve renal response rates, decrease extra-renalSLE disease activity and provide an acceptable tx-related safety profile. The study compared efficacy and safety of IV abatacept (ABA) vs placebo (pbo) on background therapy for active proliferative LN.

Methods: This was a 24-month (M), randomized, Phase III, multicenter, double-blind study with a blinded long-term extension. Patients (pts) were randomized 1:1 to pbo or IV ABA 30mg/kg for 3M, followed by ABA ~10 mg/kg every 4 wks on a background ofmycophenolate + corticosteroids (CS). Primary endpoint, complete renal response (CR) at 1 yr, was a composite measure requiring maintenance of glomerularfiltration rate (GFR), urine protein-to-creatinine ratio (UPCR) ≤ 0.5 , absence of urinary cellular casts and CS ≤ 10 mg/day. We report all blinded data up to 3 yrs of tx (as-observed analysis).**Results:** 405pts were randomized (ABA n=202, pbo n=203). At baseline mean age=33 yrs, meanUPCR=3.78, mean eGFR=95 mL/min. Yr 1 study completion rates: ABA 77%, pbo 79%;fewer ABA pts discontinued in Yr 2 (ABA 14%, pbo 22%) and beyond. There were nosignificant differences between tx arms in proportion of pts with CR after 52wks of tx (ABA 35.1%, pbo 33.5%, $p=0.73$). Sustained CR (2 successive visits) occurred earlier and more frequently in ABA-treated pts (Fig 1). Renal response rates were higher and non-response rates were lower in ABA arm in Yr 2 and 3. These benefits were driven by improvement in proteinuria seen as early as 3M and sustained up to 3 yrs (Fig 2).There was no between-group difference in eGFR over 3 yrs. Few non-renal adjudicated BILAG A or B events occurred in Yr 1 and over 3 yrs; BILAG scores were lower in ABA arm. Safety in Yr 1 was consistent with known profile of ABA(serious AE [SAE] rate: ABA 24%, pbo 19%). SAE rates after Yr 1 improved (ABA6%, pbo 13%). Deaths over 3 yrs were equal (7 each). Greater improvements inSLE-related biomarkers (C3, C4, anti-dsDNA autoantibodies) were sustained inABA-treated pts over 3 yrs (Fig 3).

Conclusion: The study failed to meet its primary endpoint of higher CR rate in pts with active LN after 1 yrof abatacept tx. Abatacept-treated pts had more rapid improvement inproteinuria, which led to more sustained CR up to 3 yrs. There were favorable efficacyand safety profiles in Yr 2 and 3 of abatacept tx.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Lupus Erythematosus – Clinical I: Clinical Trials

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: The T cell costimulatory molecule, CD28, is critical for the activation of pathogenic T cells in autoimmune diseases.^{1,2} An anti-CD28 domain antagonist antibody, lulizumab pegol (lulizumab), was evaluated in a Phase 2 study in subjects with active systemic lupus erythematosus (SLE).

Methods: In a 24-week randomized, multicenter, double-blind study of subjects meeting the American College of Rheumatology criteria for SLE^{3,4}, lulizumab was administered SC at doses of 1.25 mg every other week (EOW), 5 mg EOW, 12.5 mg EOW, or 12.5 mg weekly, or placebo (PBO) SC, on a background of standard of care (SOC) medications. Subjects were required to have elevated serum antinuclear antibodies, as well as BILAG “A” (severe) or “B” (moderate) arthritis and/or cutaneous manifestations, and SLEDAI ≥ 6 (at least 4 from clinical features). The maximum dose of corticosteroids could not exceed 30 mg/day of prednisone or equivalent at screening and no more than 10 mg/day at Day 1. The primary endpoint was the proportion of responders using the British Isles Lupus Assessment Group (BILAG)-based Composite Lupus Assessment (BICLA) at Day 169 (Week 24).

Results: 349 subjects with SLE were randomized in five treatment arms (N=68-71/arm). There were no differences in the BICLA response rate at Day 169 (PBO = 59.2%, 1.25 mg EOW = 58.6%, 5 mg EOW = 57.4%, 12.5 mg EOW= 63.2% and 12.5 mg weekly=59.4%). Additional efficacy outcome measures (e.g. SRI-4, SRI-6, SRI-8, SLEDAI change from baseline, CLASI change from baseline, CLASI20 and CLASI50) also did not reveal significant differences between groups. Dose-dependent CD28 receptor occupancy correlated with drug exposure. Lulizumab treatment resulted in effects on T and B cell subsets and on markers consistent with the proposed CD28 mechanism of action. Lulizumab appeared to be well-tolerated overall (Table 1).

Table 1. Summary of safety over 24 weeks

	PBO (N=71)	1.25 mg EOW (N=70)	5 mg EOW (N=68)	12.5 mg EOW (N=68)	12.5mg W (N=69)
Deaths, n (%)	0	2 (2.9)	0	0	0
SAEs, n (%)	6 (8.5)	8 (11.4)	9 (13.2)	4 (5.9)	5 (7.2)
Related SAEs, n (%)	1 (1.4)	0	5 (7.4)	3 (4.4)	3 (4.3)
Discontinued due to SAEs, n (%)	1 (1.4)	5 (7.1)	4 (5.9)	2 (2.9)	3 (4.3)
Total subjects with AEs, n (%)	61 (85.9)	59 (84.3)	60 (88.2)	56 (82.4)	59 (85.5)
Discontinued due to AEs, n (%)	3 (4.2)	9 (12.9)	9 (13.2)	5 (7.4)	8 (11.6)

• 2 deaths in 1.25 mg EOW group were due to cerebral haemorrhage and SLE

Conclusion: There was no significant difference between lulizumab and placebo for the primary (BICLA response rate) or secondary endpoints at Week 24, although PD activity was observed. Lulizumab had a favorable safety profile.

Low-Dose IL-2 Combined with Rapamycin Efficiently Promoted Disease Remission and Recovered the Balance of Th17/Regulatory T Cells in Patients with Refractory Systemic Lupus Erythematosus

Xiaona Jing¹, Chong Gao², Liran Hao¹, Meihua Hao¹, Zhaoyun Liang¹, Xiao-Feng Li³ and Junwei Chen¹, ¹The Second Hospital of Shanxi Medical University, Taiyuan, China, ²Department of Pathology, Brigham and Women's Hospital, Harvard Medical School, Boston, MA, Cambridge, MA, ³Rheumatology, the Second Hospital of Shanxi Medical University, Taiyuan, China

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

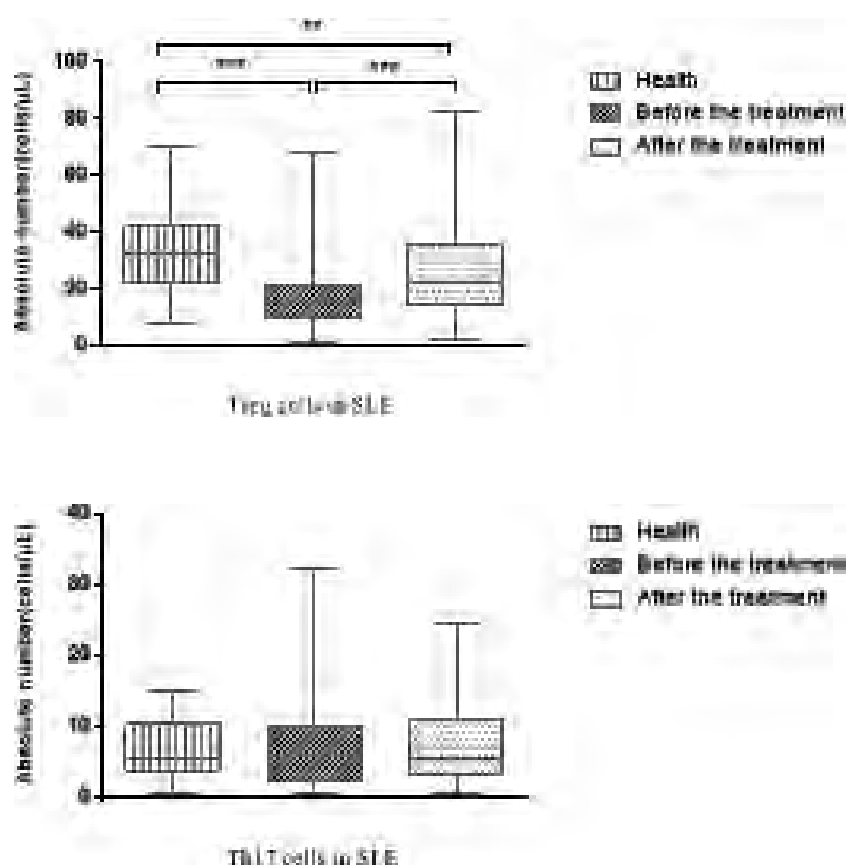

Session Title: Systemic Lupus Erythematosus – Clinical I: Clinical Trials

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: To observe the clinical effect of low-dose IL-2 combined with rapamycin on the balance of Th17/Treg cells and on remission of patients with refractory SLE.

Methods: Ninety refractory SLE patients (96.7% women; mean age 35.85 ± 12.41 years; mean duration 76.98 ± 47.24 months) were enrolled. They were in line with the standard of ACR in 1997 and did not achieve remission by the treatment of glucocorticoid and immunosuppressant for more than one year. Low-dose IL-2 was used among these patients at a dosage of 50 WIU every day for five days and rapamycin (0.5mg each time, twice per week). At baseline, 6, 12, and 24 weeks, respectively, after the therapy combined with conventional drugs, absolute numbers of Th17 and Treg cells were assayed by flow cytometry and other clinical and laboratory data, including the dosage of corticosteroids and immunosuppressant, were collected.

Results: After 24 weeks, administration of low doses of IL-2 and rapamycin promoted 26.2% of patients with refractory SLE to achieve remission, leading to an increase in the absolute number of Treg cells from a median of 14.17 cells/ μ l (at week 0) to 21.66 cells/ μ l (at week 24) ($P=0.001$). The ratio of Th17/Treg cells showed a reduction from a median of 0.44 at week 0 to 0.29 at week 24 ($P=0.029$), indicating a restored balance of them. No significant differences were observed in the absolute number of Th17 cells before and after the combined treatment. At week 24, the mean dosage of prednisone, which refractory SLE patients were receiving, decreased from 18.64 mg/d to 8.80 mg/d. And the categories of DMARDs used were also reduced ($P<0.001$).

Conclusion: Our results suggest that refractory SLE is mainly associated with the decreased number of peripheral Treg cells but not increase in that of Th17 cells. Low-dose IL-2 combined with rapamycin treatment promoted patients with refractory SLE to achieve remission and recovered the balance The Th17 and Treg cells due to an increase in the number of Treg cells. This treatment also reduced the usage of glucocorticoid and DMARDs.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Lupus Erythematosus – Clinical I: Clinical Trials

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Previous studies have compared mycophenolate mofetil (MMF) and azathioprine (AZA) as maintenance therapy of lupus nephritis(LN). Leflunomide(LEF) is an immunosuppressive agent widely used in the treatment of rheumatoid arthritis. In 2009, China Food and Drug Administration approved leflunomide for the treatment of LN. However, a randomized controlled trial of LEF for the maintenance treatment in patients with LN has not been reported. The aim of the investigator-initiated study was to compare the efficacy and safety of LEF versus AZA as maintenance therapy for LN.

Methods: 270 adult patients with biopsy-confirmed active LN (class III/IV/V) were enrolled in 7 Chinese rheumatology centers from 2010 to 2015. All patients received induction therapy with six monthly intravenous cyclophosphamide (0.5 g per square meter of body-surface area) plus steroids (starting from 1mg/kg/d and tapering according to protocol). The patients who achieved remission (complete or partial remission ,CR or PR) were randomized to receive prednisone (10mg/

d) in combination with either oral LEF (20mg/d) or oral AZA (initial dose 50mg/d, and after one month increased to 100mg/d) as maintenance therapy for 24 months.

The primary efficacy end point was the rate of renal flare in 24 months. Secondary outcomes included clinical parameters, extrarenal flare and adverse effects. The clinical and laboratory parameters were compared during follow-up by using nonparametric statistical tests. Time to event analysis was performed by the Kaplan-Meier method. This study has been registered on ClinicalTrials.gov (NCT 01172002).

Results: A total of 215 patients who had achieved CR or PR were randomly allocated to LEF group (n=108) and AZA group (n=107). The baseline clinical, biological and pathological characteristics of patients in two groups did not differ. Renal flares were observed in 12 (11.1%) LEF-treated and 15 (14.0%) AZA-treated patients (p=0.520). Time to renal flare did not statistically differ (LEF 9.83 months vs. AZA 10.93 months, p=0.241). For LN patients who achieved CR in induction phase, lower risk of renal flare was observed in LEF group than in AZA group (6.7% vs. 14.3 %, p=0.116). The CR rate in both groups continued to increase with time (LEF: from 60.2% to 87.7% after 24 months, and AZA: 71.9% to 88.7%). Over a 2-year period, 24h proteinuria, serum creatinine, serum albumin, serum C3 and serum C4 improved similarly in both groups. Sustained doubling of serum creatinine or end-stage renal failure was not observed in both groups. Extrarenal flare occurred in 2 patients from AZA group and 1 patient from LEF group. The incidence of adverse events during the 2-year treatment was similar in the two groups: LEF (43.5%, 47/108) and AZA (42.1%, 45/107), respectively. There was no significant difference in the incidence of leukopenia (28.7% and 28.97%), abnormal elevation of liver enzyme (21.3% and 20.56%), and anaemia (12.0% and 12.2%) between groups.

Conclusion: LEF is non-inferior to AZA for maintenance therapy of LN in terms of efficacy and safety profile. With maintenance therapy for 2 years, a trend of lower rate of relapse and higher CR rate was observed in the LEF group. LEF may become a new candidate medicine for maintenance therapy of LN.

Session Date: Sunday, October 21, 2018

Session Title: Systemic Lupus Erythematosus – Clinical I: Clinical Trials

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Cardiovascular disease is a leading cause of death for patients with systemic lupus erythematosus (SLE), and the disease is widely known to feature premature atherosclerosis promoted by immune dysregulation. Neutrophil extracellular traps (NETs) can induce endothelial dysfunction and promote inflammatory events. Furthermore, sources of reactive oxygen species released during NET formation promote oxidized high-density lipoprotein, leading to deficient cholesterol efflux capacity (CEC). Type I interferons (IFNs) stimulate NET formation and inhibit vascular repair. Anifrolumab is a fully human, IgG1 κ monoclonal antibody that binds to IFNAR1 and blocks signaling of all type I IFNs. Thus, anifrolumab may decrease mechanisms of vascular damage in SLE. We evaluated the ability of anifrolumab to reduce *in-vivo* NET formation and improve CEC relative to standard of care (SOC) in MUSE.¹

Methods: Baseline IFN gene signature (IFNGS) test status (high/low) of MUSE patients was determined as described.¹ All patients satisfied the ACR classification criteria for lupus.¹ Plasma samples from fasting patients (n=190) were obtained at days 1 and 365 of the MUSE study. Plasma MPO-, HNE- and CitH3-DNA NET complexes were quantified by ELISAs in the MUSE and healthy donor (HD) samples (n=20) as described.² Wilcoxon rank-sum test assessed differences between groups. Post-treatment samples from the 300 mg anifrolumab (n=73) and placebo (n=52) groups were compared with baseline samples. Significance of change from baseline was determined using Wilcoxon signed-rank test. CEC was tested as described.³ Reproducibility of the CEC assay was assessed using percent coefficient of variation (CV) from the analysis of variance (ANOVA). SLE patients with defective baseline CEC were identified as those with CEC < (the HD mean value - 2 standard deviations) in the same testing run.

Results: All 3 neutrophil NET complexes (NNCs) were elevated in SLE patients ($p<0.01$) and were significantly enriched in IFN test-high patients ($p<0.05$). Anifrolumab significantly decreased all 3 NNCs at Day 365 vs. Day 1 ($p\leq 0.05$), whereas in the placebo group, complexes did not change or increased. The repeatability of the CEC assay was 7.5% across 2 days of testing for a subset of 26 baseline samples, and longitudinal changes in steroid dosage for the placebo group did not affect CEC. Greater baseline NET complex levels significantly correlated with poor baseline CEC ($p<0.05$). Anifrolumab significantly increased CEC in IFNGS test-high patients with defective CEC at baseline ($p<0.001$), whereas no significant changes occurred in the placebo group.

Conclusion: Circulating NNCs were significantly elevated in patients with moderate to severe SLE compared with HDs. Anifrolumab decreased circulating NNCs. Although changes in steroid dosages during MUSE did not affect CEC, anifrolumab significantly improved CEC. This work supports continued assessment of anifrolumab effects on vascular diseases and endothelial damage in SLE.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Pediatric Rheumatology – ACR/ARHP

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: The transfer from the supportive and guided environment of paediatric to adult care with its increased emphasis on autonomy and self reliance poses challenges for patients and clinicians. Challenges, which if not recognised, and adequately met, can lead to poor health outcomes.

We sought to develop an integrated programme incorporating patient and carer perception of important issues and information from published models of transition.

Project Aims :

1. To develop a disease relevant, location and community appropriate value transition pathway and package
2. To set up a dedicated clinic for adolescents and young adults with rheumatic disease (AYARD)

Methods: Programme Development

Stage 1: Review of existing programmes

- literature search and personal contact with other institutions and local transition services

Stage 2: Determination of patient and carer perspectives

- Systematic qualitative study of patient attitudes and experiences (Kelly A, Niddrie F, Tunnicliffe D, Hanson C, Major G, Singh-Grewal D, Tong A. Patients' attitudes and experiences of transitional care in paediatric rheumatology: A systematic review of qualitative studies, *Arthritis Rheumatol.* 2017; 69(S10):1-4481)
- Survey by anonymous questionnaire of local >13 year old clinic patients and parents/carers, inviting feedback on the need for an AYARD clinic

Stage 3: Pathway development

- Focus meetings of key personnel (paediatric, adult and adolescent medical, nursing specialists and administrative staff)

- Utilise findings from stage 1 and 2

Results:

1. Identified key components for effective transition
 - Literature review
 - Written transition protocol
 - Dedicated coordinator
 - Age and skill appropriate progression
 - Flexibility in timing
 - Shared care between paediatric and adult team
 - Programme evaluation
 - Systematic qualitative study of patient/carer perspectives
 - Building trust in familiarity
 - Creating a sense of belonging
 - Facilitating the quest for autonomy
2. Patient and Parent/carer attitude to transition.
 - Questionnaire response with 92% strongly supportive of AYARD clinic
3. Programme development
 - Dedicated local coordinator appointed
 - Orientation visit and guided tour for new patients
 - 3 stage transition based on individual needs and skill development
 - Package of documents, including transition pathway, information booklet, skills assessments, clinician checklists, transition plans, transfer document
 - Annual combined paediatric and adult consultations
4. Effectiveness assessment
 - An evaluation tool focused on key programme objectives and incorporating patient reported outcomes is being developed

Conclusion: Paediatric and adult rheumatology services at one location allows a collaborative and coordinated approach to transition. A dedicated clinic, designated coordinator, formal transition pathway, and service specific resources, is anticipated to improve outcomes for patients transitioning from paediatric to adult rheumatology services. Evaluation is required to demonstrate effectiveness.

Abstract Number: 977

Nurse Led Safe Switching from Original Reference Product Infliximab to Biosimilar in Patients with Juvenile Idiopathic Arthritis and Uveitis – a Single Centre Experience Including Baseline and Post Switch Infliximab Levels and Antibodies

Andrew Fell¹, Emma Carson¹, Gillian Coyle¹, Neil Martin¹, Jo Walsh¹ and Janet Gardner-Medwin², ¹Paediatric Rheumatology, Royal hospital for Children, Glasgow, United Kingdom, ²School of Medicine, Dentistry & Nursing, Child Health, University of Glasgow, Glasgow, United Kingdom

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Pediatric Rheumatology – ACR/ARHP

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Original Reference Product (ORP) Infliximab lost market exclusivity in Europe in early 2015. The Scottish National Health service (SNHS), runs a national procurement system called the Clinical Advisory Panel (CAP). CAP recommended all patients new to Infliximab were commenced on biosimilar Infliximab (BIFX). To encourage

switching a project run by NHS Healthcare Improvement Scotland, produced targets for biosimilar uptake and advised the setting up of local drug efficiencies committees. In early 2017 we had a cohort of young people remaining on ORP that we are asked to consider their infliximab preparation.

Methods: The Royal Hospital for Children in Glasgow (RHCG) had a cohort of children principally with Juvenile Idiopathic Arthritis (JIA) and uveitis remaining on ORP infliximab. This use is off market label both with the European Medicine Agency and the Federal drug administration. After a review of evidence the RHCG Rheumatology team regarding the safety of switching elected to create a patient evaluation protocol for switching and patient information. Patients were identified from the Health-board wide IT system. Within the same time period a trial project for measuring trough drug levels and antibodies was introduced in Scotland using the Grifols promonitor system. It was decided to monitor these variables whilst switching. A drug and antibody level was to be taken immediately preceding the planned dose of Biosimilar Infliximab, then again 3 to 4 doses after switching or not. All patients and families were sent out information regarding the possible swap and met individually by a member of the nursing team to discuss the possible change of preparation. At point of switch offer, 12 young people were identified on ORP; 8 with JIA + Uveitis, 2 with idiopathic Uveitis, 1 with sympathetic Uveitis, 1 with JIA. All had clinically inactive disease, from last clinical review.

Results: Of the young people; 6 completed the switch, however 1 was found clinically flaring with active uveitis 4 days after switching. Their pre switch drug levels were low with high antibodies causing a change of therapy and are now in clinical remission. The five who completed the switch remain in clinical remission, this group is too small for any statistical interpretation but drug levels and antibodies are comparable pre and post switch. The 6 who did not swap at original offer to BIFX; 1 did not qualify for switching to biosimilar, 1 elected not to switch, 1 stopped, 1 changed therapy due to geography, 2 changed therapy due to personal choice. Within this group of 6, 3 maintained no active disease, 2 remaining on ORP and one swapped to Adalimumab. 3 developed active disease, 1 has commenced Adalimumab, 2 have attempted multiple biologics and have returned recently to IFX one on ORP and one BIFX. Both are returning to low disease activity. Of the initial group of 12, 4 are on ORP, 5 on BIFX, 3 are on Adalimumab. Pre and post switch period Infliximab levels and antibodies are available for 8 young people. They are comparable regardless of switch. **Conclusion:** Switching was not associated with any adverse events. Disease activity measures for those remaining on IFX were unchanged on either ORP or Biosimilar. Stopping Infliximab was associated with disease flare.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Pediatric Rheumatology – ACR/ARHP

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Juvenile idiopathic arthritis (JIA) is one of the most prevalent chronic diseases of childhood and adolescence. Evidence suggests that early effective treatment is important to minimize the burden of disease during childhood and in further life. We hypothesize that a guided treat to target (T2T) approach as recommended by the German Society for Pediatric Rheumatology (1) is superior to routine care in polyarticular JIA (pJIA) in terms of reaching a clinical state of remission after 12 months of treatment.

Methods: After informed consent, patients with early (disease duration ≤ 12 months) and active (JADAS10 ≥ 5.4) pJIA were enrolled. Targets for treatment were defined by the level of improvement and are progressively more rigorous with ongoing treatment. Failure to meet a defined target required modification of treatment at specified intervals. Initially, all patients received methotrexate (MTX). The choice of biologic was made by shared decision between the investigator and the patient/parent and not influenced by the protocol. Minimal treatment target defined as recognizable improvement of

disease activity (2) was demanded after 3 months of treatment. Until month 6, a JADAS acceptable disease status, until month 9 JADAS MDA and at month 12 JADAS-remission should be reached.

Results: Altogether 58 patient with non-systemic JIA (44/7 RF negative/RF positive polyarthritis, 3 extended Oligoarthritis, 1 ERA, 1PsA) were included (mean age 9.2+/-4.9 years, disease duration 0.4+/-0.6 years). At month 3; 37/51 (72.5%) of patients showed JADAS improvement. In 13 (25.5%) treatment with a biologic was started. At month 6, 32/41 (78%) had JADAS improvement and 30/41 (73.2%) reached JADAS acceptable disease. In 6 (14.6%) a biologic agent was started. At month 9, 34/37 (92%) showed JADAS improvement, 28/37 (76%) reached JADAS acceptable disease and 23/37 (62%) reached JADAS-MDA. In 4 (10.8%) a biologic was started and one patient switched biologics. So far, 30 patients completed 12 months of observation. JADAS MDA was reached by 22 (76%) and JADAS remission was reached by 13 (45%). In total 24 patients were treated with a biologic agent, 12 (41%) of those were followed until month 12 with 3 patients (25%) reaching JADAS remission and 7 (58%) JADAS MDA. 17 patients were treated with MTX only over 12 months of whom 10 (59%) reached JADAS remission and 15 (88%) JADAS MDA.

N	Baseline n=58	Month 3 n=51	Month 6 n=41	Month 9 n=37	Month 12 n=30
JADAS- minimal response	n.a.	72,5%	78,0%	91,9%	96,5%
JADAS acceptable disease (≤ 5.4)	0,0%	43,1%	73,2%	75,7%	79,3%
JADAS MDA (≤ 3.8)	0,0%	33,3%	61,0%	62,2%	75,8%
JADAS Remission (≤ 1)	0,0%	19,6%	31,7%	43,2%	44,8%
NSAIDs	41,4%	25,5%	12,2%	5,4%	0,0%
Steroids	36,2%	31,4%	12,2%	5,4%	3,3%
MTX	100,0%	88,2%	100,0%	83,8%	76,7%
Biologics	0,0%	25,5%	36,6%	40,5%	41,4%
2nd biologic	0,0%	0,0%	0,0%	2,7%	3,3%

Conclusion: These preliminary data indicate that a T2T concept is feasible. A high rate of patients reached JADAS MDA and JADAS remission after 12 months of treatment. Interestingly, about 60% of patients did not need to be treated with a biologic to reach predefined T2T (2). Thus, the early response seems advantageous indicating a window of opportunity to successfully treat polyarticular JIA.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Pediatric Rheumatology – ACR/ARHP

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Prior research has focused on factors important to clinicians in decisions about withdrawing JIA therapy. Based on recent interviews with patients and caregivers about stopping JIA therapy, we conducted an online survey to study the trade-offs patients and caregivers consider when deciding to stop treatments.

Figure: Comparison of considerations for decision-making between those who reported and did not report complications from JIA or treatment

Numbers reflect differences in percentage of ranks for each consideration between those with and those without complications of JIA (grey) or treatment (black). * $P < 0.01$

Table: Most highly ranked considerations when deciding to stop treatment

Caregivers	Adults with JIA	Adolescents with JIA
1. Damage from JIA	1. Damage from JIA	1. Damage from JIA
2. Concern for future treatment effects	2. Experience of severe treatment effects	2. Duration of disease inactivity
3. Trust in physician's treatment plan	3. Concern for future treatment effects	3. Trust in physician's treatment plan
4. Experience of severe treatment effects	4. Cost of treatment	4. Concern for future JIA flare
5. Duration of disease inactivity	5. Duration of disease inactivity	5. Concern for future treatment effects
6. Concern for future JIA flare	6. Concern for future JIA flare	6. Ability to skip medicines without problems

Methods: From June 2017 to February 2018, we conducted an anonymous online survey in English and Spanish using REDCap software. We recruited volunteer participants via social media, email, and flyers in pediatric rheumatology clinics in the US and Canada. Eligible participants were (1) adolescents with JIA (13-17y), (2) adults with JIA ($\geq 18y$), or (3) caregivers of children with JIA. Survey questions focused on factors that might influence decisions about stopping JIA treatment. Questions were based on findings from prior interviews and refined via pilot testing. We analyzed responses using descriptive statistics.

Results: 1456 individuals opened the survey and 839 (58%) completed it, including 782 eligible participants (40 adolescents, 120 young adults, and 622 caregivers). A majority of the participants were from the US, had a history of severe JIA flares, and used systemic anti-rheumatic medicines. Overall, adult patients were more likely than caregivers or adolescents to report having more severe disease and more complications from JIA and treatment. Among all groups, damage from JIA was the most highly ranked consideration in deciding whether to stop treatment (Table). Those with prior disease complications (e.g., severe flare, disability) were more likely to prioritize risk of flares in decision-making and generally less concerned about future drug effects (Figure). In contrast, those with prior treatment complications were more likely to prioritize risk of drug side effects (Figure). Trust in physicians was especially important for caregivers and adolescents (Table). Those reporting greater trust in physicians were more willing to accept physicians' recommendations to continue or stop treatment ($P < 0.01$).

Conclusion: Among survey respondents, JIA-related damage was the top consideration in deciding whether to stop treatments for well-controlled JIA. Past complications from JIA or from treatment influenced the ranking of other considerations. Greater trust in physicians increased willingness to accept physicians' recommendations. These findings can help inform shared decision-making when considering whether to stop medicines for well-controlled JIA.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Pediatric Rheumatology – ACR/ARHP

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Involvement of the temporomandibular joint (TMJ) is a common finding in patients with juvenile idiopathic arthritis (JIA), but the long-term outcome in a non-selected cohort remains unknown. The aims of the study were to assess the symptoms and dysfunction related to TMJ involvement in JIA compared to healthy controls and to describe the frequency of radiological TMJ abnormalities more than 17 years after disease onset.

Methods: From a Nordic, prospective, close to population-based, JIA cohort of 510 consecutive cases with disease onset between 1997 and 2000, 420 were eligible for orofacial evaluation of TMJ involvement.

The follow-up visit included demographic data and a standardized, clinical orofacial examination according to the consensus-based international recommendations¹ and a cone-beam computed tomography (CBCT). Two hundred age-matched healthy, Danish controls were used for comparison. IRB approval was granted.

Results: Out of 420 eligible JIA participants 265 (63%) participants were included (mean age 23.5 (±4.2) years). Of the 265 participants completing the clinical orofacial examination 245 had a full-face CBCT performed. The distribution of the JIA categories was as follows: 4% systemic, 21% persistent oligo articular, 22% extended oligo articular, 20% polyarticular RF negative, 2% polyarticular RF positive, 5% psoriatic, 10% enthesitis-related arthritis (ERA) and 17% undifferentiated JIA.

Orofacial symptoms: In 89/265 (33%) of the participants jaw or facial pain was reported within the last two weeks; of these 53% reported pain less than once a week and 27% reported several times per day or all the time. Compared to the controls, the participants with JIA had significantly more frequent orofacial pain (p=0.027). Of the 265 participants 87

(33%) reported at least one TMJ symptom including TMJ chewing pain, reduced chewing function, TMJ morning stiffness or locking of the TMJ within the last two weeks.

Orofacial dysfunction: Mean maximal incisal opening was significantly reduced in the JIA group (47.2 mm (± 7.7)) when compared to the controls (56.5 mm (± 6.8)) ($p < 0.001$). An asymmetric mouth opening was found in 29/265 cases (11%).

Radiologic TMJ appearance: At least one abnormal radiologic appearance was found in 254/490 (52%) TMJs in 150 participants. Only 95/245 (39%) of the cases demonstrated normal bilateral CBCT findings (Table 1).

Conclusion: To our knowledge, this is the first study on the long-term consequences of TMJ arthritis in a population-based JIA cohort.

1. The participants had significantly more often orofacial pain compared to controls.

2. Maximal incisal opening was significantly lower in the JIA participants.

3. 52% of the TMJs showed abnormal radiological appearance. Only 39% of the participants were without any TMJ abnormalities.

Session Title: Pediatric Rheumatology – ACR/ARHP

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: The current JIA Core Set (ACR Pediatric 30) to assess efficacy of medications in randomized controlled trials (RCTs) was published in 1997 and developed without input from patients or caregivers. The current core set includes 6 variables: physician global assessment, parent/patient global assessment of overall wellbeing, physical functional ability, count of joints with active arthritis, count of joints with restricted motion, an acute phase reactant and - for systemic JIA - fever in past week. Outcome Measures in Rheumatology (OMERACT) recommends four core areas to include in RCTs and longitudinal observational studies (LOS) – 1) life impact, 2) pathophysiologic manifestations, 3) resource use, 4) adverse events – and conceptualizes domains along three levels of requirements for inclusion: inner circle – mandatory for all RCTs and LOS; middle circle - important, but optional; outer circle – research agenda. Since 2015, the OMERACT JIA Core Set working group has obtained global stakeholder input from JIA patients, caregivers, health care providers and researchers to update the JIA core domain set. At the OMERACT 2016 meeting, a special interest group voted to reconsider the entire core set. This abstract reports subsequent work.

Methods: Online discussion boards (ODBs) were held with JIA patients and parents in Australia and Italy, and results compared to USA ODBs to generate candidate domains. Three rounds of a Delphi process to prioritize these domains

were held with stakeholders identified by patient advocacy groups, pediatric rheumatology clinical trials organizations and regulators. In the final Delphi round, domains were rated for inclusion in inner, middle or outer circles. Results were presented at the OMERACT conference in May 2018 for consensus among participants, with level of consensus set at $\geq 70\%$.

Results: 53 JIA patients (ages 15-24) and 55 parents participated in ODBs. Three rounds of Delphi considering 27 domains were completed by 196 (response rate 80%), 201 (81%) and 182 (77%) stakeholders, respectively, from 42 countries. Result of the final voting at the OMERACT 2018 conference approved the following core domains for JIA RCTs and LOS with 83% endorsement. Inner circle: pain, activity limitation/physical function, joint inflammatory signs (active joints), patient global assessment, adverse events. Middle circle: extra-articular inflammation (including uveitis), joint damage, labs, physician global assessment, stiffness, growth/maturation, participation restriction, imaging signs of inflammation, fatigue, impact on emotional function/mood/cognition, physical activity. Outer circle: coping with illness, healthcare utilization, sleep, social relationships, personal factors.

Conclusion: We have developed an updated JIA Core Domain Set following OMERACT methodology with qualitative input from patients/parents and broad stakeholders through a Delphi process and consensus voting. A notable change is pain is now recommended as a core domain for all JIA RCTs, LOS. Multiple patient reported domains were also voted as important to consider for inclusion in JIA trials, including fatigue, emotional function, and participation restriction.

In the Presence of IL-18, IL-10 but Not IL-6 Induces IFN- γ Production and the Surface Expression of TRAIL on NK Cells

Kojiro Sato, Yoshimi Aizaki, Hiroaki Yazawa and Toshihide Mimura, Department of Rheumatology and Applied Immunology, Faculty of Medicine, Saitama Medical University, Saitama, Japan

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Cytokines and Cell Trafficking Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Adult-onset Still's disease (AOSD) is a systemic inflammatory disease, the cause of which is largely unknown. AOSD has been recently classified as one of the auto inflammatory diseases in which innate rather than acquired immunity plays an important role in the pathogenesis. Serum IL-18 has been shown to be high in AOSD patients. In this study, we first quantified the levels of multiple cytokines in the serum of AOSD patients and then compared the cytokine profile with that of healthy controls. We next evaluated the effects of the cytokines detectable in the AOSD serum on natural killer (NK) cells, since NK cells are cells of innate immunity and IL-18 has been shown to enhance their cytotoxicity.

Methods: Our patients fulfilled Yamaguchi's criteria for the diagnosis of AOSD. We quantified the serum levels of 10 cytokines (IFN- α , IFN- γ , IL-1 β , IL-2, IL-4, IL-6, IL-10, IL-12p70, IL-17A and TNF- α) using multiplex bead array assays and IL-18 using ELISA. We next sorted NK cells from peripheral blood mononuclear cells of healthy controls and stimulated them *in vitro* in the presence of cytokines that were detected in the AOSD serum. We quantified the level of IFN- γ in the culture supernatant by ELISA and assessed the surface expression level of tumor necrosis factor-related apoptosis-inducing ligand (TRAIL) on NK cells by flow cytometry.

Results: The level of IL-18 was high in all of the AOSD samples. IL-6 was detectable in 8 out of 16 patients and IL-10 in 3 out of 16. In contrast, serum IFN- γ was not detected in any sample. When NK cells were stimulated *in vitro* with IL-18 alone, IFN- γ was undetectable in the culture supernatant. The combination of IL-10 and IL-18, but not IL-6 and IL-18, induced IFN- γ . We evaluated the expression of the receptors for IL-6 and IL-10 on NK cells and found that IL-10R and

IL-10RB were present, while IL-6R and gp130 were absent. The combination of IL-10 and IL-18 also induced TRAIL expression on NK cells.

Conclusion: Since IL-18 was originally identified as an inducer of IFN- γ , it was surprising that IFN- γ was not detected in the serum despite the high level of IL-18. Indeed, IL-18 alone did not induce the production of IFN- γ from NK cells *in vitro*. The combination of IL-10 and IL-18, but not IL-6 and IL-18, induced the production of IFN- γ and surface expression of TRAIL on NK cells. As IL-6 is a classic pro-inflammatory cytokine and IL-10 is considered anti-inflammatory, this result was also rather unexpected. The unresponsiveness to IL-6 may be explained by the absence of IL-6 receptor on NK cells. Locally-produced IFN- γ can be detrimental to the body by activating macrophages. As the liver is rich in NK cells and TRAIL has been reported to cause liver injury, TRAIL on NK cells may be responsible for one of the characteristics of AOSD, liver dysfunction. Although IL-10 may be produced to prevent excessive inflammation, in the presence of IL-18, it can exert the opposite effect.

A MAPK Activated Kinase 2 Inhibitor Attenuates Inflammatory and Destructive Arthritis in Human Ex Vivo Models

Tue Wenzel Kragstrup^{1,2}, Anders Mellemkjær³, Morten Aagaard Nielsen⁴, Line Dam Heftdal², Marie Iversen³, Peter Schafer⁵ and Bent Deleuran², ¹Randers Regional Hospital, Randers, Denmark, ²Department of Biomedicine, Aarhus University, Aarhus, Denmark, ³Aarhus University, Aarhus, Denmark, ⁴Of Biomedicine, Aarhus University, Aarhus, Denmark, ⁵Celgene Corporation, Summit, NJ

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Cytokines and Cell Trafficking Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Targeting intracellular pathways with oral small molecules is an attractive therapeutic approach for treating immune mediated inflammatory diseases. The mitogen-activated protein kinase (MAPK) pathway is activated by environmental stressors, growth factors and inflammatory cytokines. However, the inhibition of central MAPK proteins has so far had undesirable side effects. The MAPK-activated protein kinase 2 (MK2) is a downstream mediator in the MAPK signaling pathway and could therefore be inhibited without the same side effects. The objective of this study was to study the effects of a small molecule inhibiting MK2 on inflammation and structural changes in ex vivo models of immune mediated inflammatory arthritis.

Methods: Synovial fluid mononuclear cells (SFMCs), fibroblast like synovial cells (FLSs) and peripheral blood mononuclear cells (PBMCs) were obtained from a study population consisting of patients with active RA or peripheral SpA with at least one swollen joint (for obtaining synovial fluid) (n=14). SFMCs were cultured for 48 hours with and without addition of a MK2 inhibitor (Celgene) at 1000 nM, 333 nM and 111 nM and supernatants were analyzed by the Olink proseek multiplex interferon panel and commercially available ELISA assays. Because FLSs are only found in small amounts among SFMCs, autologous co-cultures of FLS and PBMCs and SFMCs were also used. SFMCs cultured for 21 days were used to study inflammatory macrophage differentiation and osteoclastogenesis.

Results: In SFMCs cultured for 48 hours, the MK2 inhibitor decreased the production of CXCL9 (P<0.001), CXCL10 (P<0.01), HGF (P<0.01), CXCL11 (P<0.01), TWEAK (P<0.05), and IL-12B (P<0.05) and increased the production of CXCL5 (P<0.0001), CXCL1 (P<0.0001), CXCL6 (P<0.001), TGF α (P=0.01), MCP-3 (P<0.01), LAP TGF β (P<0.05) dose-dependently after Bonferroni correction (all corrected P values). At the highest concentration, the MK2 inhibitor also decreased MCP-1 production (P<0.05). In FLS-SFMC co-cultures, the MK2 inhibitor decreased MCP-1 production (P<0.05) but did not change the production of DKK1 and MMP3. In FLS-PBMC co-cultures, the MK2 inhibitor decreased the production of MCP-1 (P<0.0001), increased MMP3 production (P<0.05) but did not change DKK1 production. In SFMCs cultured for 21 days as a model of inflammatory macrophage differentiation and osteoclastogenesis, the MK2 inhibitor decreased the production of MCP-1 (P<0.05) and tartrate-resistant acid phosphatase (TRAP) (P<0.05) but did not change the production of IL-10.

Conclusion: This study reveals the effects of a MK2 inhibitor in ex vivo models of immune mediated inflammatory arthritis. The MK2 inhibitor changed the secretory profile of SFMCs and decreased inflammatory osteoclastogenesis. Taken together, this points to a role of this MK2 inhibitor in attenuating inflammatory and destructive arthritis.

Reduced Expression of CX3CR1 in Peripheral CD14⁺⁺CD16⁺monocytes Is a Novel Feature of Patients with Systemic Lupus Erythematosus

Keiko Yoshimoto¹, Katsuya Suzuki¹, Shuntaro Saito², Jun Kikuchi¹ and Tsutomu Takeuchi¹, ¹Division of Rheumatology, Department of Internal Medicine, Keio University School of Medicine, Tokyo, Japan, ²Department of Rheumatology and Clinical Immunology, Saitama Medical Center, Saitama Medical University, Saitama, Japan

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Cytokines and Cell Trafficking Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Fractalkine (FKN, CX3CL1) and its receptor, CX3CR1, play an important role in chemotaxis of immune cells, such as cell adhesion, migration and infiltration into the organs. Several lines of evidence indicated that serum level of FKN was elevated and correlated with disease activity in patients with rheumatoid arthritis (RA) and the expression of CX3CR1 is upregulated especially in peripheral intermediate monocytes, CD14⁺⁺CD16⁺ in RA patients as compared to healthy controls (HC). On the other hand, it has been reported that elevated expression CX3CR1⁺ macrophages were infiltrated in the kidney of lupus patients and CD16⁺ monocytes within the glomerular blood vessels of the patients corresponds to the high CX3CR1⁺ expressing monocytes. In this study, we investigated the expression level of CX3CR1 in peripheral monocytes and T cells from patients with systemic lupus erythematosus (SLE) and HC to elucidate the possible involvement of CX3CR1 in immunological features of SLE.

Methods: The expression level of CX3CR1 in peripheral monocytes (classical monocytes: CD14⁺⁺CD16⁻, intermediate monocytes: CD14⁺⁺CD16⁺, non-classical monocytes: CD14⁺CD16⁺⁺), CD4 and CD8 T cells was analyzed by FACS with whole blood samples from patients with SLE active (SLEDAI : >10, n = 22), inactive (SLEDAI: <4, n = 22) and HC (n = 34). Differences between the groups were examined for statistical significance using the t test for single comparisons. Correlation analysis was employed for evaluation of the linear relationship between two continuous variables.

Results: FACS analysis revealed that the proportion of CD14⁺⁺CD16⁺ monocytes among CD14⁺ cells was significantly elevated in SLE active (p = 0.0017) and SLE inactive (p = 0.0002) patients as compared to HC, whereas no significant difference was observed in that proportion between SLE active and inactive patients. Notably, the proportion of CX3CR1 positive cells in CD14⁺⁺CD16⁺ monocytes was significantly lower in SLE active patients than patients with SLE inactive (p = 0.014) and HC (p = 0.002), whereas that proportion was not significantly different between SLE inactive and HC. In addition, the proportion of CX3CR1 positive cells in CD4 and CD8 T cells was not significantly different among the groups.

Conclusion: These results give the possibility that FKN binds its receptor, CX3CR1, expressed on CD14⁺⁺CD16⁺ monocytes in SLE, and the cells consequently migrate into the organs through peripheral blood. Our data suggest that targeting FKN signaling may be effective for suppressing inflammatory monocyte recruitment to the organs in SLE.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Cytokines and Cell Trafficking Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Rheumatoid Arthritis (RA) is a chronic inflammatory disease characterized by a tumor-like synovial overgrowth leading to joint destructions. IL-6 and TNF- α play an important role in the pathogenesis of RA, and the proliferation of RA-synoviocytes (FLS) is controlled by cell cycle regulators including Cyclins, Cyclin dependent kinases (CDK), CDK inhibitors (CKDIs) and retinoblastoma protein (RB).

To reveal actions of proinflammatory cytokines on the cell cycle of RA-FLS, we examined the expressions of the cell cycle regulators and the cellular viability under stimulations of IL-6 and TNF- α .

Methods: RA-FLS were treated with or without IL-6/soluble IL-6 receptor (sIL-6R) (100ng/ml) or TNF- α (10ng/ml). The expressions of CDK4/6 CDKIs (*p16^{INK4a}*, *p21^{Cip1}*, *p27^{Kip1}*) and *Cyclin E1/2* mRNA were measured by Real-time PCR, the protein expression of CYCLIN D, CYCLIN E, RB and the phosphorylation of RB were measured by Western blot, the expression of CYCLIN D and the phosphorylation of RB were observed by immunofluorescence, and the cellular viabilities were measured by WST-8 and BrdU assay. In addition, siRNA/CDK6 was introduced into RA-FLS to measure the cellular viabilities, under stimulations with or without IL-6/sIL-6R or TNF- α .

Results: IL-6/sIL-6R decreased the mRNA expression of *p16^{INK4a}*, whereas increased the protein expression of CYCLIN D and RB. TNF- α decreased the mRNA expressions of *CDK4*, whereas increased the mRNA expressions of *p27^{Kip1}*, *CDK6*, *Cyclin E1/2* mRNA, the protein expression of CYCLIN D, RB and the phosphorylation of RB. The protein expression of CYCLIN D and the phosphorylation of RB were synergistically increased by IL-6 and TNF- α . The cellular viabilities were increased by IL-6 and TNF- α , which were suppressed by siRNA/CDK6.

Conclusion: Results indicate that IL-6 and TNF- α interact with each other in regulating the cell cycle of RA-FLS, and TNF- α dominantly increases the cellular viability *via* CDK6.

Abstract Number: 986

Fucosylated Tumor Necrosis Factor α Is Expressed in Rheumatoid Arthritis Synovial Tissues and Is Involved in Monocyte Adhesion

Takeo Isozaki, Shinichiro Nishimi and Tsuyoshi Kasama, Div of Rheumatology, Showa University School of Med, Shinagawa-ku Tokyo, Japan

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Cytokines and Cell Trafficking Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Glycosylation has been reported to associate with tumor invasion and metastasis. Fucosylation is involved in the biological functions of adhesion molecules and growth factor receptors. In regards to arthritis, we have previously reported that glycan in rheumatoid arthritis (RA) serum was higher than that in normal subjects serum. However, a direct role for fucosylated cytokines in RA has not been demonstrated. Here, we examined fucosylated tumor necrosis factor (TNF)- α was expressed in RA synovial tissues, as TNF- α is a central cytokine in RA pathology and the role it plays in monocyte adhesion.

Methods: To determine if the fucosylated TNF- α was expressed in RA and osteoarthritis (OA) synovial tissues, we performed immunofluorescence. In order to indicate that the expression of fucosylated TNF- α was in RA synovial fluids, immunoprecipitation and lectin blotting were performed. 2-deoxy-D-galactose (2-dGal) is an analog of hexose that inhibits fucosylation. In addition, to clarify the mechanism of fucosylation in monocyte adhesion, human umbilical vein endothelial cells (HUVECs) were treated with 2-dGal (15 mM) for 5 days. THP-1 (human acute monocyte leukemia cell line) adhesion to 2-dGal treated or nontreated HUVEC was measured. Finally, to confirm which adhesion molecules were involved in fucosylation, cell surface ELISA was performed.

Results: Fucosylated TNF- α was expressed in RA synovial tissues. Hence, fucosylated TNF- α in RA synovial tissues was significantly highly expressed compared with that in OA synovial tissues. Fucosylated TNF- α in RA synovial fluids was also significantly higher compared with in OA synovial fluids. Fucosylated proteins in 2-dGal treated HUVECs were decreased compared with these in nontreated HUVECs. Adhesion of THP-1 cells to 2-dGal treated HUVECs in response to TNF- α was significantly decreased compared with nontreated HUVECs (adhesion index of THP-1 to HUVECs \pm SEM; 1.2 ± 0.1 and 1.4 ± 0.1 , $p < 0.05$, respectively). In addition, intercellular adhesion molecule 1 (ICAM-1) on TNF- α stimulated 2-dGal treated HUVECs were decreased compared to nontreated HUVECs (fold change of ICAM-1 expressed \pm SEM; 5.5 ± 0.2 and 9.0 ± 0.2 , $p < 0.05$, respectively).

Conclusion: Fucosylated TNF- α was expressed in RA synovium, and inhibition of fucosylation in ECs had less monocyte adhesion. These data indicate that cytokine fucosylation is involved with RA and plays a role in inflammation, suggest that targeting fucosylation may provide a method by which to decrease inflammation.

Abstract Number: 987

CCL11 Is Involved in Cell Migration in Rheumatoid Arthritis

Kuninobu Wakabayashi, Takeo Isozaki, Shinichiro Nishimi and Tsuyoshi Kasama, Div of Rheumatology, Showa University School of Med, Shinagawa-ku Tokyo, Japan

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Cytokines and Cell Trafficking Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Chemokine C-C motif ligand 11 (CCL11) also known as eotaxin-1 is produced by a variety of cell types. By interacting with C-C chemokine receptor 3 (CCR3), CCL11 stimulates the migration of several types of cells. High levels of CCL11 and CCR3 have described in rheumatoid arthritis (RA). Previously, we reported that the expression of CCL11 was increased by tumor necrosis factor (TNF) - α stimulation in RA fibroblast-like synoviocytes (FLS). A recent study reported that receptor activator of nuclear factor kappa-B ligand stimulated CCR3 expression in osteoclasts and the addition of CCL11 caused an increased migration of pre-osteoclast and an increase in osteoclastic bone resorption. The aim of this study is to investigate the expression and the function of CCL11 in RA.

Methods: The levels of CCL11 were determined in serum from healthy control (HC) and RA patients in onset using enzyme-linked immunosorbent assay (ELISA). We also measured the levels of CCL11, TNF- α and MCP-1 in synovial fluids (SFs) from the patients with RA and osteoarthritis (OA). To investigate the expression of CCL11 or CCR3 in RA FLS, cells were left unstimulated or were stimulated with recombinant TNF- α or CCL11. After stimulation, the protein expression levels in the culture medium were measured by ELISA and the messenger (mRNA) expression levels were measured by quantitative polymerase chain reaction analysis. The expression of CCL11 or CCR3 on RA FLS were also demonstrated by immunohistochemistry. To confirm the role of CCL11 in cell migration, RA FLS were stimulated with recombinant CCL11 and were allowed to migrate through uncoated transwell chambers. Finally, to block the expression of CCL11, RA FLS were transfected with small interfering RNA (siRNA) against CCL11, and proinflammatory cytokines in TNF- α stimulated RA FLS conditioned medium were measured using ELISA.

Results: The levels of CCL11 in the serum from RA ($n=26$) were higher than those in the serum from HC ($n=28$) (median [IQR]; $78.3 [62.7-114.1]$ pg/mL and $46.8 [30.9-67.7]$ pg/mL, $p < 0.05$, respectively). The levels of CCL11 in SFs from the patients with RA ($n=15$) were higher than those in SFs from the patients with OA ($n=16$) ($20.3 [5.3-26.3]$ pg/mL and $4.1 [0.2-9.0]$ pg/mL, $p < 0.05$, respectively) and were positively correlated with the levels of TNF- α ($r=0.74$, $p < 0.05$) and MCP-1 ($r=0.64$, $p < 0.05$). The mRNA expression of CCL11 and CCR3 in RA FLS were increased by TNF- α stimulation ($p < 0.05$). In addition, we confirmed that the expression of CCL11 and CCR3 were increased with TNF- α stimulation using immunohistochemistry. Furthermore, the expression of CCR3 mRNA were increased by CCL11 stimulation ($p < 0.05$). CCL11 stimulated cells were significantly higher efficient at migration than unstimulated cells ($p < 0.05$). CCL11 siRNA treatment decreased the expression of MCP-1 in TNF- α treated RA FLS conditioned medium ($p < 0.05$).

Conclusion: These data show that CCL11 and CCR3 are increased by TNF- α stimulation in RA FLS and CCL11 is associated with RA FLS migration and the secretion of MCP-1. CCL11 may play an important role of inflammation in RA.

Regulatory T Cells with Skewed Responses and Propionate-Producing Gut Bacteria Increased Simultaneously in Patients with Relapsing Polychondritis

Jun Shimizu¹, Takao Kubota² and Noboru Suzuki³, ¹Department of Immunology and Medicine, St. Marianna University School of Medicine, Kawasaki, Japan, ²St. Marianna University School of Medicine, Kawasaki, Japan, ³Department of Immunology and medicine, St. Marianna University School of Medicine, Kawasaki-shi, 216-8511, Japan

Session Information

Session Date: Monday, October 22, 2018

Session Title: Cytokines and Cell Trafficking Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Several intestinal bacteria produce short-chain fatty acids (SCFA) by the fermentation of dietary fibers. SCFA in the intestine differentiate regulatory T (Treg) cells by stabilizing the expression of the master gene, Foxp3. We have reported that SCFA-producing bacteria increased significantly in patients with relapsing polychondritis (RP) (Arthritis Rheumatol. 2017; 69 Suppl 10: 2477–2478.). Here, adding to the metagenomic analysis with newly recruited samples, we evaluated T cell cytokine gene expression titers of peripheral blood mononuclear cells (PBMC) in RP patients and compared the data with those in normal individuals.

Methods: We explored fecal microbiota of 25 patients with RP and 27 normal individuals by sequencing of 16S rRNA gene. The effect size of each bacterium in the two groups were estimated by LEfSe software. We cultured PBMC of 22 RP patients and 11 normal individuals with and without mitogen stimulation and measured T cell cytokine gene expressions of the cells. We measured serum matrix metalloproteinase protein (MMP3) concentrations, an RP-related biomarker, in RP patients using an Elisa assay kit.

Results: We found that annotated species numbers were significantly higher in the intestine of RP patients than those of normal individuals. In the RP gut microbiota, we observed several predominant species which were reported to associate with propionate production in human intestine. Propionate was reported to induce IL-10-producing Treg cells in the intestine and we measured IL-10 gene expressions in PBMC of RP patients and normal individuals. We found that IL-10 gene expressions were significantly higher in freshly isolated PBMC of RP patients than those of normal individuals ($P < 0.0001$). In contrast, 6 hours after the initiation of the PBMC culture, IL-10 gene expressions of RP patients were significantly lower than those of normal individuals, regardless of the presence and absence of the mitogen stimulation ($P = 0.0011$ and $P < 0.0001$, respectively). Serum MMP3 concentrations were significantly higher in RP patients than those in normal individuals and correlated well with IL-10 gene expression levels in freshly isolated PBMC of the RP patients ($P < 0.0001$).

Conclusion: We suggest that propionate continuously stimulates intestinal Treg cells and induce hypo-responsiveness of the cells to antigenic stimulation in RP patients. Treg skewed cells may play a role in the chondritis of RP patients through inappropriate chondrocyte secretion of MMP3.

Reduction of Serum IL17F and IL22 By IL23p19 Blockade with Guselkumab Is Associated with Improvement in Joint Symptoms in Psoriatic Arthritis

Qingxuan Song, Matthew Loza, Karen Leander, Brittney Scott, Patrick Branigan and Kristen Sweet, Janssen Research & Development, LLC, Spring House, PA

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Cytokines and Cell Trafficking Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Guselkumab (GUS) is a fully human monoclonal antibody that binds to the p19 subunit of IL23. In a recent Phase 2 study, GUS demonstrated clinical reduction of signs and symptoms of arthritis and improvement of psoriatic lesions in patients with active psoriatic arthritis (PsA). Longitudinal analysis on serum proteins was performed to evaluate the impact of IL23 blockade on effector cytokines associated with the IL23/Th17 axis and biomarkers that may be impacted by treatment or associated with clinical response to GUS over 16 weeks.

Methods: In a double-blind, placebo-controlled, multicenter study (CTA:2014-003697-17), patients with active PsA and $\geq 3\%$ body surface area (BSA) of plaque psoriasis despite current or previous treatment with standard of care therapies, including those previously exposed to anti-TNF α agents, were randomized 2:1 to receive GUS 100 mg subcutaneously (SC) (n=97) or placebo (PBO) (n=45) at weeks 0, 4, and every 8 weeks (q8w) thereafter through week 44. The study included 149 patients fulfilling the American College of Rheumatology 2012 criteria for the classification of PsA. Serum samples were collected at week 0, week 4, and week 16. Acute phase (C-reactive protein (CRP), serum amyloid A (SAA), soluble cell adhesion molecules (sICAM1, sVCAM1)) (Meso Scale Discovery Platform) and Th17 effector cytokines (IL17A, IL17F, and IL22) (SMC Immunoassay platform) were measured in the serum samples. Baseline protein levels were fitted in Generalized linear model (anti-TNF usage as covariate) to test for association with treatment group, baseline demographic and clinical phenotypes of PsA, PsA medicine history, and clinical response for major study endpoints. Within-subject change from baseline levels were used to test the pharmacodynamic effect of GUS and association with clinical response.

Results: Acute phase proteins (CRP, SAA, sICAM, sVCAM) and Th17 effector cytokines (IL17A, IL17F, and IL22) were elevated at baseline in patients with PsA compared to healthy (Mean levels $\geq 50\%$ higher than healthy, $P < 0.05$). Baseline IL17A, IL17F and IL22 levels were positively correlated with BSA ($R > 0.4$ and $P < 0.05$). No correlation was identified with other demographics and ACR component measures evaluated. GUS treatment significantly decreased all 7 analytes at week 16 ($P < 0.05$), with significant down-modulation of IL17A, IL17F, IL22, and SAA already observed by week 4, which is consistent with clinical observations. Week 24 ACR20 responders to GUS had a significantly larger down-modulation of IL17F, IL22, and CRP compared to non-responders ($P < 0.05$). Week 24 PASI75 responders to GUS had a significantly larger down-modulation of sVCAM1 and IL17A compared to non-responders ($P < 0.05$).

Conclusion: In patients with active PsA in this study, GUS significantly decreased the levels of acute phase inflammation proteins and Th17 effector cytokines. These decreases were significant by the week 4 visit, suggesting a rapid pharmacodynamic effect of GUS. Down-modulation of IL17F, IL22, and CRP was associated with benefit to joint symptoms, while down-modulation of IL17A and sVCAM1 was associated with improvement in plaque psoriasis activity.

Guanylate Binding Protein 5 (GBP5) Inhibits Rheumatoid Arthritis Synovial Fibroblast Mediated Inflammation and Tissue Destruction

Mahamudul Haque¹, Anil K. Singh¹ and Salahuddin Ahmed^{1,2}, ¹Department of Pharmaceutical Sciences, Washington State University, College of Pharmacy, Spokane, WA, ²Division of Rheumatology, University of Washington, Division of Rheumatology, School of Medicine, Seattle, WA

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Cytokines and Cell Trafficking Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Guanylate binding protein 5 (GBP5), an interferon gamma (IFN- γ) inducible protein, helps to defend against invading pathogens. However, its role and properties beyond anti-viral or anti-bacterial action remains unknown. In the present study, we evaluated the role of GBP5 and its corroboration with IFN- γ in regulating rheumatoid arthritis synovial fibroblast (RASf) mediated inflammation and tissue destruction.

Methods: Cell lysates from RASfs and non-diseased SFs (NLSFs) were prepared to evaluate the expression levels of GBP5 using Western immunoblotting and qRT-PCR methods. siRNA mediated knockdown of GBP5 was conducted to study its effect on IFN- γ (10 ng/ml), IL-1 β (10 ng/ml) and/or TNF- α (20 ng/ml)-induced downstream signaling pathway in RASfs. Conditioned media was used to quantitate IL-6, IL-8, matrix metalloproteinase-1 (MMP-1), and CXCL5

production by ELISA. The lentiviral delivery method was used to overexpress GBP5 to evaluate its potential regulatory effects in RASFs.

Results: Our Western blot analysis showed that the expression of GBP5 is significantly reduced in RASFs compared to NLSFs ($p < 0.05$; $n = 6$). We observed a higher expression of GBP5 upon IFN- γ stimulation and the expression was further augmented with IL-1 β stimulation ($p < 0.05$; $n = 6$). Co-treatment of RASFs with IFN- γ significantly downregulated IL-1 β -induced IL-6, IL-8, and MMP-1 production in RASFs ($p < 0.05$; $n = 3$). To our surprise, siRNA-mediated knockdown of GBP5 reduced the inhibitory potential of IFN- γ and resulted in further upregulation of IL-1 β -induced IL-6, IL-8, MMP-1, and CXCL5 production by 84%, 66%, 8-fold, and 72%, respectively ($p < 0.05$; $n = 3$). Evaluating the impact of GBP5 knockdown on the RASF signaling pathways, we observed that GBP5 knockdown in human RASFs selectively amplified the constitutive as well as IL-1 β -induced phosphorylation of ERK1/2 and JNK mitogen-activated protein kinases, which are important mediators of inflammation and tissue destruction in RA. Intriguingly, lentivirus-mediated restoration of GBP5 abrogated IL-1 β -induced proinflammatory cytokine production, suggesting that GBP5 plays an anti-inflammatory role by inhibiting RASF mediated inflammation.

Conclusion: Our findings suggest that the lack of GBP5 contributes to synovial inflammation, and its restoration suppresses RASF-mediated inflammation and tissue destruction.

Critical Role of Interleukin-1 α (IL-1 α) in IL-1 β -Induced Inflammatory Responses: Cooperation with NF- κ Bp65 in Transcriptional Regulation

Anil K. Singh¹, Sabrina Fechtner¹, Mukesh Chourasia², Jerry Sicalo¹ and Salahuddin Ahmed¹, ¹Department of Pharmaceutical Sciences, Washington State University, College of Pharmacy, Spokane, WA, ²Department of Pharmacoinformatics,, National Institute of Pharmaceutical Education and Research, Hajipur,, India

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Cytokines and Cell Trafficking Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Interleukin-1 β (IL-1 β) and IL-1 α are cytokines of IL-1 family that orchestrate acute and chronic inflammatory diseases. However, their distinct role or the extent of overlap in the inflammatory processes remains poorly understood. This prompted us to explore the role of IL-1 α in IL-1 β -activated signaling pathways causing synovial inflammation in rheumatoid arthritis (RA).

Methods: Normal and RA synovial tissues were obtained from total joint replacement surgery or synovectomy under an Institutional Review Board approved protocol in compliance with the Helsinki Declaration. RNA isolated from these tissues were subjected to RNA sequencing using Illumina platform. Synovial fibroblasts from RA tissues (RASFs) were treated with various IL-1 β , tumor necrosis factor- α (TNF- α), or lipopolysaccharide (LPS) to study the expression of IL-1 α using Western blotting, immunofluorescence (IF), and qRT-PCR methods. Native immunoprecipitation (IP) and chromatin IP (ChIP) methods were used to study protein-protein interactions and chromatin remodeling function of IL-1 α . Small interfering RNA (siRNA) method was used to study the role of IL-1 α in IL-1 β signaling pathway. Molecular dynamics (MD) simulation were performed to assess binding patterns of IL-1 α or IL-1 β as ligand on IL-1 receptor (IL-1R) crystal structure to identify functional differences in activating phosphorylation of key IL-1 signaling proteins.

Results: IL-1 β selectively induced the expression of IL-1 α transcript ($p < 0.01$; $n = 4$), which reached to >1,000-fold within 6 hours stimulation. Evaluation of the signaling inhibitors showed that IL-1 β significantly stimulated IL-1 α expression, which was selectively inhibited by blocking NF- κ B pathway, whereas further exacerbated by p38-MAPK inhibition. Interestingly, knockdown of IL-1 α using siRNA abolished IL-1 β -induced pro-IL-1 α and pro-IL-1 β expression and suppressed inflammation ($p < 0.05$; $n = 3$). IF results showed that IL-1 α primarily resides in nuclear and chromatin bound fractions of RASF and interacts with p65 subunit of NF- κ B protein upon IL-1 β stimulation. Native IP and ChIP studies showed that IL-1 α cooperates in NF- κ Bp65 binding to the distal region of IL-1 α promoter and to the proximal region of IL-1 β promoter upstream of the transcription start site to stabilize their gene transcription. Furthermore, MD simulation of IL-1 α or IL-1 β binding to IL-1R crystal structure showed distinct interaction sites for each cytokine, where more π - π interactions were observed with IL-1 β over IL-1 α with IL-1R indicating stable complex formation. These results corroborate with the ability of IL-1 α to differentially activate phosphorylation of signaling proteins compared to IL-1 β ,

where phosphorylation of proteins such as IRAK1^{Ser387}, IRAK4^{Ser345}, TAK1^{Thr184/187/412} and the degradation of IRAK1 were more rapid in IL-1 β stimulated RASFs compared to IL-1 α stimulation.

Conclusion: These results suggest that IL-1 β relies on IL-1 α to stabilize its expression and propagate inflammation. It may be postulated that IL-1 α targeted therapies may have some benefit over IL-1R antagonists in regulating inflammation.

Epigallocatechin-3-Gallate (EGCG) Suppresses Systemic Inflammation By Inhibiting IL-6-Induced STAT3 Activation in Cultured Hepatocytes and in Liver Tissue of Adjuvant-Induced Arthritis (AIA) Rats

Anil K. Singh¹, Sabrina Fechtner², Dorothy Wang², Mukesh Chourasia³ and Salahuddin Ahmed^{2,4}, ¹Washington State University, College of Pharmacy, Spokane, WA, ²Department of Pharmaceutical Sciences, Washington State University, College of Pharmacy, Spokane, WA, ³Department of Pharmacoinformatics, National Institute of Pharmaceutical Education and Research, Hajipur, India, ⁴Division of Rheumatology, University of Washington, Division of Rheumatology, School of Medicine, Seattle, WA

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Cytokines and Cell Trafficking Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: In rheumatoid arthritis (RA), the pro-inflammatory cytokine interleukin-6 (IL-6) induces systemic inflammation by activating hepatocytes through IL-6 receptor (IL-6R)- mediated JAK/STAT3 signaling pathway. The present study was undertaken to determine the role of epigallocatechin 3-gallate (EGCG), an active compound found in green tea, in regulating IL-6-induced JAK/STAT3 pathway in Hep3B cells and in a rat adjuvant-induced arthritis (AIA) model.

Methods: Hep3B cells were starved, pretreated overnight with EGCG (5-20 μ M), and then stimulated with IL-6 (50 ng/ml). Cells were harvested after 30 minutes to evaluate the effect on different phosphorylation sites on JAK/STAT3 using Western immunoblotting, or after 24 hours of IL-6 stimulation for C-reactive protein (CRP) expression using Western blotting and qRT-PCR methods. Nuclear and cytoplasmic extracts were prepared to study nuclear translocation and DNA binding activity using ELISA kit. Liver homogenates and nuclear extracts were prepared from naïve, AIA, and AIA+EGCG (50 mg/kg, i.p.) treated rats. A molecular docking study of EGCG to STAT3 was performed using an X-ray crystal model of mouse STAT3 (PDB ID: 1BG1) as a template and EGCG as a ligand.

Results: Pretreatment of Hep3B cells with EGCG inhibited IL-6-induced STAT3^{Ser727} and STAT3^{Tyr705} activation in a dose-dependent manner, which may partially be attributed to the inhibition of pJAK1^{Tyr1022/1023} and pJAK2^{Tyr1007/1008} expression by roughly 37% and 27%, respectively ($p < 0.05$). Inhibition of pSTAT3^{Ser727} was more prominent than pSTAT3^{Tyr705} inhibition with EGCG pretreatment. Evaluation of the nuclear fractions from the treated Hep3B cells showed that EGCG significantly inhibited the nuclear translocation of IL-6-induced STAT3 ($p < 0.05$). This resulted in ~25% decrease in STAT3 DNA binding activity by EGCG treatment and a dose-dependent decrease in CRP expression ($p < 0.05$). Surprisingly, EGCG exhibited no effect on the endogenous STAT3 regulator, SOCS3. Administration of EGCG (50 mg/kg, i.p.) daily for 10 days significantly reduced the severity and incidence of arthritis compared to the untreated rats ($p < 0.05$; $n = 6/\text{group}$). Evaluation of the liver homogenates from these rats showed that EGCG inhibited pSTAT3^{Ser727} by ~70% and reduced its nuclear translocation. Molecular docking studies showed that EGCG can bind to R382, R417, R423, S465, and N469 residues on STAT3, which may potentially inhibit the DNA binding activity of STAT3.

Conclusion: Our results suggest that the EGCG may elicit its beneficial effects in part through the suppression of IL-6-induced systemic inflammation.

Session Title: Cytokines and Cell Trafficking Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Psoriasis is a common T-cell driven inflammatory skin disorder that is featured by immune cell infiltration, and vasculopathy of both blood and lymphatic vasculature. Psoriatic arthritis (PsA) is a destructive joint disease that occurs in up to 30% of psoriasis patients, but how the disease progresses from only skin inflammation to also synovial membrane involvement of the joints and entheses is unclear. The T helper 17 (Th17) subpopulation has been put forward as the main driver of the disease manifestations in psoriasis and PsA. Recently, our group showed that lymphatic endothelial cells (LEC) lining the interior surface of the lymphatic vasculature, have the capacity to suppress Th17 differentiation and alter the chemokine receptor profile that controls their specific tissue homing. We hypothesize that the LECs in the skin of PsA patients are dysregulated and allow pathogenic Th17 cells to migrate to extracutaneous sites. To get a better understanding of how these regulatory mechanisms affect Th17 migration from skin to synovial joints in PsA, we investigated LEC derived from different sources, and compared LEC with another disease-relevant stromal cells.

Methods: Human dermal LEC and dermal fibroblasts (DF) were cell-sorted from skin discarded from healthy individuals undergoing elective skin surgery. Also, LECs were cell-sorted from human lymph nodes derived from patients undergoing vascular surgery without a medical history of chronic inflammatory disorders. We determined the expression of immunomodulatory and co-stimulatory molecules across LEC populations in skin and lymph node, and in DF using flow cytometry and real-time quantitative PCR (qPCR). Subsequently, we assessed the inflammatory responses of dermal LEC and DF by qPCR during a 24 h culture with the cytokines IL-17A, IL-22, TNF α , and IL-1 β .

Results: Flow cytometric analysis demonstrated that both lymph node LEC and dermal LEC, but not DF, expressed the MHC class II molecule HLA-DR. In line, qPCR analysis revealed that both lymph node LEC and dermal LEC, but not DF, expressed fundamental immunomodulatory molecules that affect T-cell activation and polarization including programmed death-ligand 1 and 2 (PD-L1/2), galectin 1,3 and 9, glucocorticoid-induced TNFR-related ligand (GITRL), OX40 ligand, and inducible T Cell Costimulator Ligand (ICOS-L). Secondly, a 24 h culture with IL-17A, IL-22 and TNF α , strongly induced ICOS-L and the chemokine ligand 20 (CCL20) in dermal LEC, whereas DF showed no effect upon cytokine stimulation.

Conclusion: We found that human LEC populations in both skin and lymph nodes, as compared to DF, are endowed with immunomodulatory properties underscoring the essential role for LECs in shaping peripheral T-cell responses. Under inflammatory conditions, particularly dermal LECs, but not DF, seem to be important in regulating T-cell activation and recruitment of CCR6-expressing T-cell subpopulations responding to CCL-20. Further studies on LEC populations that originate from skin, lymph node and synovial joints from patients with psoriasis and PsA to validate and expand on the abovementioned results are underway.

Platelet Derived Growth Factor Receptors (PDGFRs) and Their Implication in Inflammatory Arthritis

Bhanupriya Madarampalli¹, Joon Kyung Kim², Paul Panipinto¹, Hannah Labinsky¹ and Vineet Mahajan¹, ¹Medicine, Division of Rheumatology, University of Washington, Seattle, WA, ²Rheumatology, University of Washington, Seattle, WA

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Cytokines and Cell Trafficking Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis(RA) is inflammatory joint disease characterized by immune infiltration and synovial hyperplasia. Hyperplastic synovium contains increased numbers of activated synovial fibroblasts, which amplify inflammation and directly invade cartilage. Fibroblast proliferation and invasion is stimulated *in vitro* by platelet-derived growth factor receptor (PDGFR) ligands. PDGFR and ligand expression are upregulated in RA, suggesting a pathogenic role. However, PDGFR signaling is complex, involving differential activation of PDGFR- α (PDGFR α) and PDGFR- β (PDGFR β) homo- and heterodimers by five ligands. Our hypothesis is that PDGFR α and PDGFR β function differently in RA, with PDGFR α having a more homeostatic role while PDGFR β promotes a more invasive phenotype.

Methods: Human synovial fibroblast PDGFR expression was determined by quantitative reverse transcription-polymerase chain reaction (qRT-PCR), western blot, and flow cytometry. PDGF ligand expression was determined by qRT-PCR. Fibroblast proliferation and appearance was determined after activation with PDGFR α - or PDGFR β -specific ligands. Cadherin-11 signaling was induced with cadherin-11 extracellular binding domains linked to human Fc domains.

Results: Synovial fibroblasts expressed significantly higher levels of PDGFR α compared to PDGFR β . In addition, they expressed high levels of the PDGFR α -specific ligands, PDGF-CC and PDGF-AA. In contrast, fibroblasts expressed less PDGFR β -specific ligands, with low PDGF-DD and undetectable PDGF-BB levels. Both PDGFR α and PDGFR β ligands increased fibroblast proliferation. However, only PDGFR α interacted with the fibroblast cell adhesion molecule cadherin-11 to induce proliferation. Conversely, only stimulation with PDGFR β -activating ligands (PDGF-BB and -DD) induced a rounded, more migratory cell phenotype.

Conclusion: After evaluating PDGF ligand expression and the effects of PDGFR α versus PDGFR β activation, our hypothesis is that PDGFR α and PDGFR β have functionally distinct roles in inflammatory arthritis. Our model is that PDGFR α ligands, especially highly expressed PDGF-CC, maintain fibroblast proliferation in autocrine fashion. In contrast, release of PDGFR β ligands by infiltrating macrophages promotes fibroblast migration and invasion, contributing to RA cartilage damage. Better understanding of how PDGFR α and PDGFR β function to promote inflammatory arthritis will help to target activated synovial fibroblasts in RA treatment.

Anti-Fractalkine Monoclonal Antibody Inhibits Joint Destruction through Suppression of Osteoclast Precursor Migration and Induces Synovial Cell Death in Collagen-Induced Arthritis Model Mice

Kana Hoshino-Negishi¹, Masayoshi Ohkuro², Tomoya Nakatani¹, Wataru Ikeda¹, Yoshikazu Kuboi¹, Naoto Ishii¹, Nobuyuki Yasuda¹ and Toshio Imai³, ¹KAN Research Institute, Inc., Kobe, Japan, ²Research Project Promotion Group, EA Pharma Co., Ltd., Kawasaki, Japan, ³President & CEO, Chief Scientific Officer, KAN Research Institute, Inc., Kobe, Japan

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Cytokines and Cell Trafficking Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: In the Phase 1/2 clinical study, E6011, a novel humanized anti-fractalkine (FKN) mAb demonstrated a promising efficacy in active RA patients who were inadequately controlled by MTX and/or TNF- α inhibitors. FKN is expressed on endothelial cells and fibroblast-like synoviocytes in synovium and also expressed on osteoblasts. CX3CR1, the receptor for FKN, is expressed on monocytes/macrophages and osteoclast precursors (OCPs). Therefore, the FKN-CX3CR1 interaction might play pivotal roles in these cells function. To elucidate the precise roles of the FKN-CX3CR1 pathway in joint destruction, we examined the effect of treatment with anti-mouse FKN (mFKN) mAb, using the CIA model mice.

Methods: For the induction of CIA, mice were immunized with bovine type II collagen. Anti-mFKN mAb was injected twice a week. The clinical arthritis score was monitored, and joint destruction was evaluated by soft X-ray and histology. The mRNA expression levels were assessed by quantitative RT-PCR. Blood parameters were measured using ELISA. In *in vitro*, effect of immobilized FKN on RANK ligand (RANKL)-induced osteoclast differentiation was examined. In *in vivo*, bone marrow-derived OCPs were fluorescein-labeled and transferred to CIA mice to evaluate the migration of OCPs into synovium. Inhibitory effect of anti-mFKN mAb, etanercept or tofacitinib against OCP migration was assessed. To examine the effect of anti-mFKN mAb against CIA synovium, propidium iodide (PI) was injected to anti-mFKN mAb-treated CIA mice to detect the synovial cell death.

Results: Anti-mFKN mAb significantly reduced the arthritis and soft X-ray scores in both prophylactic and therapeutic treatment. Anti-mFKN mAb histologically improved synovitis, cartilage destruction and bone damage, with marked reduction of osteoclast numbers. Plasma levels of COMP and were also decreased, while those of serum amyloid A, TNF- α and IL-6 were unaffected after the anti-mFKN mAb treatment. Interestingly, anti-mFKN mAb significantly suppressed Tnf and Il6 mRNA expression in the affected joints. In *in vitro*, RANKL-induced osteoclast differentiation was enhanced by immobilized FKN, and anti-mFKN mAb suppressed FKN-dependent osteoclast formation. In *in vivo*, anti-mFKN mAb

Figure1: The effects of tofacitinib in cell culture by concentration A: Skin Fibroblast cell line B: Liver Fibroblast cell line

strongly inhibited the migration of OCPs into the CIA synovium, whereas etanercept or tofacitinib had no effect. Importantly, synovial cell death was abundantly found in CIA synovium after the anti-mFKN mAb treatment.

Conclusion: In CIA model mice, anti-mFKN mAb suppressed local inflammatory cytokine expression in the inflamed joints, without affecting systemic inflammatory parameters. Anti-mFKN mAb remarkably ameliorated the joint destruction with the reduction of osteoclasts by the inhibition of both OCP migration and osteoclast formation in inflamed joint. In addition, anti-mFKN mAb immediately induced synovial cell death in the synovium, suggesting the direct inhibitory effect in the synovitis. These results indicate that inhibition of FKN-CX3CR1 axis by a humanized anti-FKN mAb, E6011, could be an attractive and affected joints-selective therapeutic option for the treatment of both inflammatory synovitis and joint destruction in RA patients.

Neutralizing Effect of Anti-Infliximab Antibodies on Infliximab-Stimulated Human Coronary Artery Endothelial Cells

Manca Ogrič¹, Katjuša Mrak Poljšak¹, Katja Lakota^{1,2}, Polona Žigon¹, Sonja Praprotnik¹, Saša Čučnik^{1,3} and Snezna Sodin Semrl^{1,2}, ¹University Medical Centre Ljubljana, Department of Rheumatology, Ljubljana, Slovenia, ²University of Primorska, Faculty of Mathematics, Natural Science and Information Technology, Koper, Slovenia, ³University of Ljubljana, Faculty of Pharmacy, Ljubljana, Slovenia

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Cytokines and Cell Trafficking Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: As a consequence of endothelial dysfunction, patients with rheumatoid arthritis (RA) have an increased risk of atherosclerosis and early development of cardiovascular disease. Serum amyloid A (SAA), tumour necrosis factor- α (TNF- α) and interleukin-1 β (IL-1 β) up-regulated in the sera of RA patients were previously reported to activate human coronary artery endothelial cells (HCAEC), however their combined effects are unclear. Furthermore, the effect of anti-TNF- α drugs, such as infliximab, in the presence and absence of their anti-infliximab antibodies, has not yet been elucidated.

In our study, we aimed to investigate the combined effects of TNF- α , IL-1 β , SAA, infliximab and anti-infliximab antibodies on IL-6 released levels in HCAEC.

Methods: Primary HCAEC (Lonza), passage 5, were grown to confluency in 5% FBS/EGM-2M medium, serum starved for 2 hours and incubated with human recombinant cytokines (SAA1/2 (Peprotech, 500nM), TNF- α (Thermo Fisher Scientific, 2.5 ng/mL) and IL-1 β (Thermo Fisher Scientific, 1 ng/mL)), infliximab, anti-infliximab antibodies and their combinations. After 24 hours, supernatants were collected, centrifuged, aliquoted and frozen at -20°C.

Infliximab was used at a final concentration of 10 μ g/mL, in combination with the cytokines. For the neutralizing effect of anti-infliximab antibodies (final concentration 0.55 μ g/mL) on infliximab (final concentration 0.1 μ g/mL), polyclonal anti-infliximab antibodies were purified by affinity chromatography from sera samples of 2 patients with chronic rheumatic diseases, who exhibited positive levels of anti-infliximab antibodies, as previously determined by an *in-house* competitive and bridging ELISA. IL-6 was measured by ELISA (Invitrogen). One-way ANOVA was used for statistical analysis.

Results: Triple stimulation of HCAEC with TNF- α /IL-1 β /SAA significantly and synergistically elevated the release of IL-6 levels in cell supernatants (3-fold above IL-1 β alone). Double stimulation with IL-1 β /SAA, TNF- α /SAA, as well as TNF- α /IL-1 β and IL-1 β alone, also led to significantly higher levels of IL-6, while TNF- α alone did not increase IL-6 levels. Infliximab was effective in lowering released IL-6 levels in the TNF- α /IL-1 β double treatment, however the strongest inhibition was observed in TNF- α /IL-1 β /SAA triple-stimulated HCAEC, where it significantly reduced IL-6 released levels by around 50%.

Anti-infliximab antibodies significantly restored IL-6 released levels from HCAEC treated with infliximab and TNF- α /IL-1 β /SAA (complete neutralization of the infliximab inhibition).

Conclusion: TNF- α , IL-1 β and SAA synergistically elevated IL-6 release in supernatants of HCAEC, with infliximab substantially inhibiting its levels. Isolated polyclonal anti-infliximab antibodies were capable of neutralizing infliximab, in the presence of TNF- α /IL-1 β /SAA, thereby promoting chronic inflammation in HCAEC.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Cytokines and Cell Trafficking Poster

Session Type: ACR Poster Session B

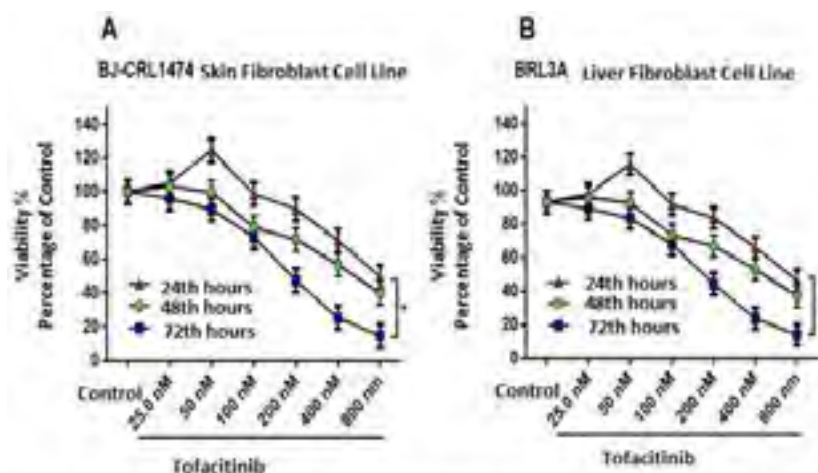

Session Time: 9:00AM-11:00AM

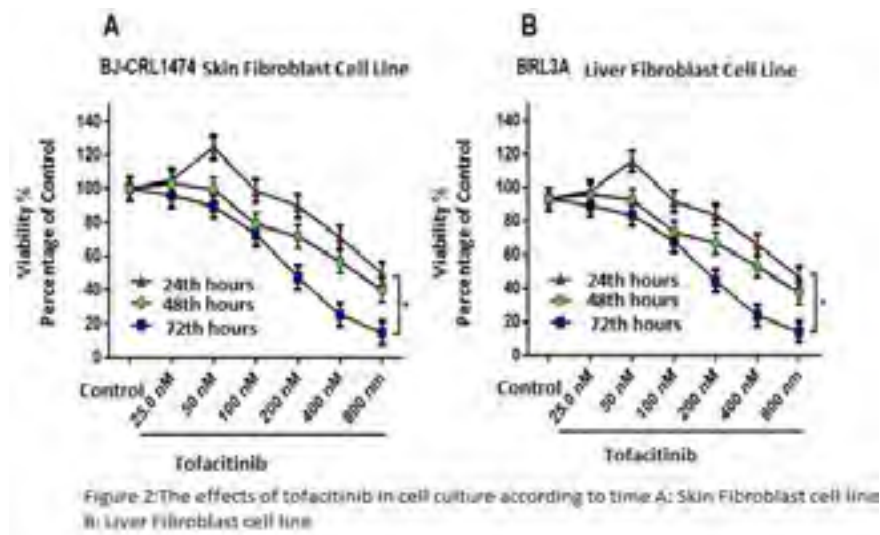

Background/Purpose: Uncontrolled collagen synthesis and deposition occur in various diseases such as hepatic fibrosis, scleroderma. Tofacitinib is a selective JAK-kinase (1/3) inhibitor. Currently it is used in the treatment of rheumatoid arthritis. The aim of the study is to investigate the effect of JAK-STAT signal pathway inhibition on collagen biosynthesis in fibroblast cell-culture.

Methods: BJ-CRL1474[®] (skin) and BRL3A[®] (hepatic) fibroblast cell cultures were proliferated in the appropriate medium. Tofacitinib was administered to fibroblast cells proliferating on 96-well flasks at concentrations of 25 nM, 50 nM, 100 nM, 200 nM, 400 nM and 800 nM, respectively. Cell viability and quantity were read by spectrophotometer. Tissue metalloproteinase inhibitor (TIMP-1), matrix metalloproteinase-3 (MMP-3), transforming growth factor (TGF-1 β) and hydroxyproline levels were measured by ELISA method.

Results: The cytotoxic effect of tofacitinib started at 100 nM concentration ($p < 0.05$). The highest effect was obtained at 800 nM. The cytotoxic effect at concentrations of 400 nM and 800 nM was higher than at 100 nM and 200 nM concentrations ($p < 0.05$) (Figure 1). The time-dependent cytotoxic effect of tofacitinib was significantly higher at 72th hours than at 24th and 48th hours at all concentrations ($p < 0.05$) (Figure 1). TGF-1 β , the major stimulus of collagen synthesis, was found to be significantly low even at 25 nM concentration ($p < 0.05$). The lowest concentration was reached at 800 nM ($p < 0.05$). There was a significant decrease in MMP-3, TIMP-1 and hydroxyproline levels respectively ($p < 0.05$). The decline in all three biomarkers started at a concentration of 100 nM. The maximum decrease in the levels of four biomarkers was observed at a concentration of 800 nM (Figure). The results in both cell cultures were similar and not statistically significant ($p > 0.05$).

Conclusion: Tofacitinib was shown to reduce fibroblast proliferation and viability in fibroblast cell culture. The decrease in the levels of TGF- β , which is also the main stimulus of collagen synthesis and is also released from fibroblasts, may be due to reduced release of TGF- β . The level of hydroxyproline in the collagen structure is expected to decrease. We found that the level of MMP-3 was also reduced. MMP-3 was not needed in conditions such as collagen synthesis decreased and

in vitro. We found a decrease in TIMP-1, an inhibitor of MMP-3. JAKkinase inhibitor, tofacitinib inhibited fibroblast cell proliferation in fibroblast cell culture by time and concentration.

Table-1: Effect of Tofacitinib on levels of TGF-1 β , MMP-3, TIMP-1 and hydroxyproline.

Tofacitinib	TGF-1 β (pg/mg)	MMP-3	TIMP-1 (pg/ml)	Hydroxyproline (Ratio of control)
Control	23,4 \pm 2,6	12,9 \pm 2,6	860,5 \pm 23,3	1
25 nM	18,6 \pm 3,5*	11,3 \pm 2,8	840,2 \pm 21,9	0,91 \pm 0,13
50 nM	17,2 \pm 1,9*	10,8 \pm 1,9	800,0 \pm 20,3	0,85 \pm 0,08
100 nM	11,3 \pm 2,1**	4,2 \pm 1,1*	621,3 \pm 25,6*	0,61 \pm 0,07*
200 nM	10,6 \pm 1,8**	3,8 \pm 0,9*	324,3 \pm 17,5**	0,52 \pm 0,05*
400 nM	3,6 \pm 0,9#	3,6 \pm 0,6*	321,9 \pm 16,2**	0,48 \pm 0,03*
800 nM	2,1 \pm 0,7#	1,2 \pm 0,4**	310,2 \pm 18,8**	0,12 \pm 0,02**

Transcription Factor Fli-1 Impacts Renal IL-17 Expression in Adult MRL/Lpr Mouse Despite Similar Interstitial Immune Cell Infiltration into the Kidney

Shuzo Sato¹, Xian Zhang², Yuya Fujita¹, Makiko Yashiro¹, Tomoyuki Asano¹, Hiroko Kobayashi¹, Hiroshi Watanabe¹ and Kiyoshi Migita³, ¹Rheumatology, Fukushima Medical University School of Medicine, Fukushima, Japan, ²Division of Rheumatology & Immunology, Department of Medicine, Medical University of South Carolina, Charleston, SC, ³Fukushima Medical University, School of Medicine, Fukushima, Japan

SESSION INFORMATION

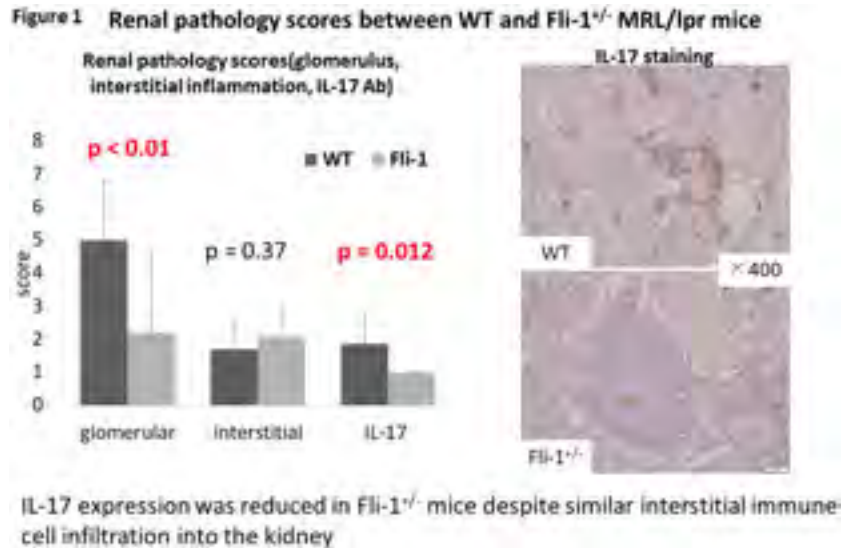

Session Date: Monday, October 22, 2018

Session Title: Cytokines and Cell Trafficking Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Fli-1 is a member of Ets transcription factor and plays an important role in lupus nephritis development. Reduced Fli-1 expression (heterozygote Fli-1: Fli-1^{+/-}) results in improvement of kidney inflammation and prolongs overall survival in lupus model mouse. Previously, we have reported that Fli-1 directly regulates cytokine/chemokine expression (MCP-1, RANTES, CXCL2, IL-6, and G-CSF) and impacts lupus nephritis development in lupus model mouse. IL-17 is a cytokine with powerful inflammatory properties. Past reports indicate that IL-17 is associated with disease activity in patients with lupus nephritis. The relationship between Fli-1 and IL-17 is unknown. The aim of this study is to elucidate whether reduced Fli-1 expression affects IL-17 production and impacts lupus nephritis development into the kidney.

Methods: Serum IL-17 concentrations of adult (4-months-old or older) Wild-type (WT) and Fli-1^{+/-} MRL/lpr mice were measured by ELISA and compared between the two groups. Kidneys were removed from these mice and evaluated using pathology scoring system (glomerular and interstitial lesions). Immunostaining of IL-17 in the kidney was also performed and compared between the two groups. Expression of mRNA of IL-17, IL-18 and IL-1 β in the kidney tissue were also compared.

Results: Serum IL-17 concentrations were relatively decreased but not significant in Fli-1^{+/-} MRL/lpr mice (WT: 55.7 vs Fli-1^{+/-}: 3.12 pg/mL, respectively, p=0.35). Relative mRNA expression of IL-17 in the kidney was decreased (19.7%) in Fli-1^{+/-} MRL/lpr mice compared to WT MRL/lpr mice. Relative expression of IL-18 and IL-1 β mRNA in the kidney were significantly decreased in Fli-1^{+/-} MRL/lpr mice (p=0.02). In histological examination, glomerular inflammation was significantly decreased in Fli-1^{+/-} MRL/lpr mice. However, interstitial inflammation was similar between the two groups. In contrast, immunostaining of IL-17 showed significantly decreased IL-17 positive immune cells in the kidney of Fli-1^{+/-} MRL/lpr mice (Figure 1).

Conclusion: Fli-1 impacts lupus nephritis progression through affecting the reduction of IL-17-positive immune cell infiltration into the kidney. Reduced expression of IL-1 β and IL-18 in the kidney can also affect IL-17 expression in Fli-1^{+/-} MRL/lpr mice.

Development of an Affimab Engineered to Simultaneously Target IL-6 and Tnf α for Therapeutic Use in Rheumatoid Arthritis

Kyu-Tae Kim, Jong-Seo Lee and Bong-Kook Ko, AbClon Inc., Seoul, Korea, Republic of (South)

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Cytokines and Cell Trafficking Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Antibodies may be functionalized using Affibody® molecules to create bispecific AffiMabs. We used protein engineering to develop single-construct biologics suitable for blocking inflammation driven by a combination of cytokines. AM201 is an AffiMab simultaneously targeting interleukin 6 (IL-6) and the tumor necrosis factor alpha (TNF α).

Methods: A set of affinity matured Affibody molecules binding to IL-6 were fused to either the N- or C-terminus of both the heavy and light chains of an anti-TNF monoclonal antibody based on adalimumab to produce bi-specific AffiMabs.

Among these bi-specific antibodies, AM201 was determined on the basis of internal selection criteria including the efficacy and stability.

Results: AM201 blocks the interaction between complexes of the soluble IL-6 receptor (sIL-6Ra) and IL-6 and the co-receptor gp130 (IL-6 trans-signaling pathways) whilst it blocks IL-6 cis-signaling less potently. AM201 neutralize both TNF α and IL-6 simultaneously *in vitro*. AM201 was subsequently evaluated in an acute serum amyloid alpha (SAA) model in mice for *in vivo* activity. AM201 efficiently blocks combined IL-6 and TNF-triggered SAA secretion *in vivo*. We confirmed that AM201 potentially reduce arthritic score in Tg197, human TNF α transgenic mouse. The quantitative PCR using human samples showed that AM201 efficiently block the gene expressions associated with bone removal including RANK, MMP9 and RANKL. We pursue efficacy test against non-human primate collagen-induced arthritis model and a drug development process with the aim to develop an innovative bi-specific AM201 simultaneously targeting TNF α and IL-6.

Conclusion: AM201 can be a novel potent therapeutic option for the treatment of rheumatoid arthritis patients who commonly develop aberrant expression of both TNF α and IL-6.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Cytokines and Cell Trafficking Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Extracellular ATP and adenosine are potent immunomodulatory molecules that accumulate in states of inflammation. ATP/ADP are released from damaged or stressed cells and sequentially catabolized to AMP which is then catabolized to adenosine by the action of the ecto nucleotidases CD39 and CD73, which promotes a shift from an ATP-driven pro-inflammatory environment to an anti-inflammatory milieu induced by adenosine. AMPD2 encodes one of three known AMP deaminase homologs. Intracellularly, it executes AMP deamination to IMP thereby reducing adenosine formation. Here, we postulate that this mode of action is also present on the cell surface of immune cells, which may lead to an increased state of inflammation such as found in chronic inflammatory diseases (**Fig. 1**).

Therefore, we analyzed surface AMPD2 expression and its modulation on distinct cell lines and primary immune cells.

Figure 1: Model: possible role of surface AMPD2

Methods: To this end, surface AMPD2 expression was evaluated on cell lines (THP1, Jurkat, HMEC1, and HEK293), human PBMCs and isolated monocytes by flow cytometry. Moreover, co-expression of surface AMPD2, CD73 and CD39 was analyzed on PBMCs and isolated monocytes. Association of surface AMPD2 and cell death was visualized using annexin V and 7-AAD staining and examined by flow cytometry. In addition, expression of AMPD2 was analyzed by immunoblot of precipitated AMPD2 from membrane fractions and by mass spectrometry after precipitation from membrane fractions and from biotinylated surface-molecules using the surface AMPD2-positive cell lines HEK293 and HMEC1.

Results: Here, we show that (i) surface AMPD2 is present on T cells and monocytes in PBMCs from healthy donors, (ii) LPS enhances surface expression of AMPD2 in monocytes after 24h whereas AMPD2 surface expression is reduced in T cells treated with LPS and PHA, respectively, (iii) LPS significantly decreases CD73 expression on monocytes in PBMC co-culture, and (iv) all cell lines analyzed are capable of expressing surface AMPD2. Surface AMPD2 expression was significantly reduced after Golgi transport inhibition in both PBMCs and HEK293. AMPD2 surface expression was not accompanied by enhanced cell death. AMPD2, CD39 and CD73 co-staining revealed an opposing expression pattern on lymphocytes and monocytes in PBMC co-culture. Expression of AMPD2 could be confirmed in membrane fractions of HEK293 and HMEC1 using immunoblot of precipitated AMPD2 and mass spectrometry, respectively.

Conclusion: We demonstrate for the first time surface expression of AMPD2 on immune cells enabling these cells to extracellularly convert AMP into IMP constituting a shunt-like mechanism to control the levels of adenosine and extracellular ATP formed from adenine nucleotides thereby controlling immunomodulation.

Anti-Fractalkine Monoclonal Antibody Dislodges Intravascular Monocytes Involved in Exacerbation of Synovial Inflammation in Collagen-Induced Arthritis Model

Wataru Ikeda¹, Kana Hoshino-Negishi¹, Eri Fusaoka-Nishioka¹, Tomoya Nakatani¹, Yoshikazu Kuboi¹, Naoto Ishii¹, Nobuyuki Yasuda¹ and Toshio Imai², ¹KAN Research Institute, Inc., Kobe, Japan, ²President & CEO, Chief Scientific Officer, KAN Research Institute, Inc., Kobe, Japan

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Cytokines and Cell Trafficking Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: In the Phase 1/2 clinical study, E6011, a novel humanized anti-fractalkine (FKN) mAb demonstrated a promising efficacy in active RA patients who were inadequately controlled by MTX and/or TNF- α inhibitors. In preclinical study, anti-FKN mAb significantly lowered arthritis score of CIA model, and reduced infiltration of inflammatory cells and bone erosion in the synovium (Nanki et al., J Immunol 2004). Furthermore, anti-FKN mAb reduced the migration of adoptively transferred splenic monocytes/macrophages into the inflamed synovium. FKN is expressed on endothelial cells and fibroblast-like synoviocytes and also expressed on osteoblasts. CX3CR1, the receptor for FKN, is expressed on monocytes/macrophages and osteoclast precursors. Moreover, intravascular monocytes contribute vascular inflammation. However, the roles of FKN and CX3CR1 in the pathogenesis of RA, especially the behavior of intravascular monocytes, remain unclear. In this study, we evaluated the role of FKN-CX3CR1 axis on intravascular monocyte behavior in synovium of CIA model by intravital imaging and tissue-clearing techniques.

Methods: For the induction of CIA, mice were immunized with bovine type II collagen. The effect of anti-FKN mAb on synovium of MCP joint was examined by intravital imaging and three-dimensional (3D) tissue analysis with tissue-clearing technique. In intravital imaging, we established a system for MCP joint observation by two-photon laser scanning microscope (TPLSM), and the behavior of intravascular monocytes visualized by anti-CD115 mAb were compared in the presence or absence of anti-FKN mAb or control IgG. 3D tissue analysis was performed by tissue-clearing reagent LUCID (WO 2014115206 A1) and TPLSM. One hour after anti-FKN mAb or control IgG administration, the mice underwent to low-speed perfusion fixation so that the cells attached to the blood vessels did not detach. Before fixation, intravascular monocytes and blood vessels were visualized by anti-CD115 mAb and RCA-1, respectively. The number of intravascular monocytes were quantified. In order to clarify the difference of point of action with other biologics, the same experiment was carried out with TNF- α inhibitor or CTLA4-Ig administration.

Results: In intravital imaging, angiogenesis in the synovium of CIA occurred actively, and adhered and/or slow-paced monocytes appeared in the vasculature. At thirty minutes after anti-FKN mAb administration, the intravascular monocytes were reduced, but control IgG did not change compared to before administration. In tissue transparency analysis, the number of intravascular monocytes was markedly reduced by anti-FKN mAb as compared with control IgG. When the same experiments were performed with TNF- α inhibitor or CTLA4-Ig, intravascular monocytes were not reduced.

Conclusion: Intravital imaging and tissue-clearing techniques revealed that anti-FKN mAb dislodges intravascular monocytes in inflamed synovium. These results suggest that the FKN-CX3CR1 axis regulates intravascular monocyte behavior in inflamed synovium, such as enhancement of vascular inflammation and infiltration of osteoclast precursors. FKN-CX3CR1 blockade may be a novel attractive strategy for the treatment of RA.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Innate Immunity Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Neutrophil NETosis is a form of cell death characterized by nuclear envelope rupture, nuclear chromatin release, and neutrophil extracellular trap formation. NETosis is important in various human diseases, including autoimmune diseases. We recently found involvement of neutrophil NETosis in UVB-induced murine skin inflammation. UVB is known to induce multiple agents including the lipid mediator Platelet activating factor (PAF). We also found that PKC α may mediate neutrophil NET release through regulation of nuclear envelope rupture. The goal of our study is to explore the causal role of PAF Receptor (PAFR) signaling and PKC α in neutrophil NETosis and its effect on skin inflammation.

Methods: Peritoneal- and bone marrow-derived neutrophils were isolated from wildtype, PAFR KO mice, or PKC α deficient mice and purified by anti-Ly-6G micro bead kit. To study NETosis, neutrophils were stimulated with or without PAF for 3 hours, then fixed with 2% PFA, stained by Sytox Green, and assayed for NET formation, finally confirmed by fluorescent microscopy. For UVB-irradiation, PKC α deficiency mice and their litter wildtype mice were exposed with/without 150 mJ/cm²/day under anesthesia for consecutive 5 days. Dorsal skin tissues were harvested. H&E and IHC staining were conducted.

Results: We found that PAF can induce NETosis in neutrophils from human and WT mice, while depletion of PAF receptor (PAFR) attenuated NETosis in neutrophils from PAFR KO mice, suggesting the role of PAF in neutrophil NETosis was mediated by PAFR. To study the role of PKC α , we found PAF increased PKC α phosphorylation in a time-dependent manner in parallel to the induction of neutrophil NETosis. Moreover, pharmacologic inhibition of conventional PKC with Go6976 decreased PKC α phosphorylation, nuclear envelope rupture and neutrophil NETosis. Furthermore, PKC α deficiency significantly impaired PAF-induced NETosis in neutrophils from PKC α deficient mice. Importantly, PKC α deficiency attenuated UVB-induced skin inflammation with decreased neutrophil NETosis and decreased proinflammatory cytokines (TNF α and IL-17A) in the inflamed skin of PKC α deficient mice as compared to those of the wildtype mice under UVB exposure.

Conclusion: These findings suggested that PAF might be a potential mediator of neutrophil NETosis in the skin of the UVB irradiated mice. PKC α appears to play vital roles in neutrophil NETosis in UVB-induced skin inflammation. The PAFR and PKC α might be potential therapeutic targets in human diseases related to UVB-induced skin inflammation.

Neutrophil Response to Ultraviolet Light in Normal and Lupus Conditions

Sladjana Skopelja-Gardner¹, Xizhang Sun², Joyce Tai³, Lucrezia Colonna³, Lena Tanaka⁴ and Keith B. Elkon⁵, ¹Division of Rheumatology, Department of Medicine, University of Washington, Seattle, WA, ²Rheumatology, University of Washington, Seattle, WA, ³Division of Rheumatology, University of Washington, Seattle, WA, ⁴Medicine/Rheumatology, University of Washington, Seattle, WA, ⁵University of Washington, Seattle, WA

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Innate Immunity Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Two-thirds of systemic lupus erythematosus (SLE) patients are sensitive to sunlight and artificial light. Ultraviolet (UV) B light induces sterile inflammation in the skin and results in both localized cutaneous and systemic disease, including lupus nephritis. The precise mechanisms of photosensitivity-triggered systemic reactions in SLE are unknown.

Methods: Mice (C57BL/6J, 3-4mo female and male) were exposed to a single dose of UVB (500mJ/cm²). Individual mice were euthanized on 1, 2, or 6 days after UVB and perfused with saline; non-irradiated age and sex matched mice were used as controls. Immune cells isolated from the skin, bone marrow (BM), blood, spleen, lung, and kidney were profiled and neutrophil phenotype characterized by flow cytometry (FC). Cytokine and chemokine gene expression in skin was evaluated by QPCR. Tissue apoptotic cells and IgG were examined by immunofluorescence and kidney pathology evaluated by PAS staining.

Results: Following skin UVB exposure, the decline in the number of BM neutrophils associated with an increase in blood and skin neutrophil numbers at days 1-2 (d1-2). Of considerable interest, neutrophil numbers also increased in the lung, spleen, and kidney, with a peak on d6 post-UVB. While a similar migration pattern was seen in both male (M) and female (F) mice, the dynamic of the immune response was sex-dependent. Neutrophils in F mice infiltrated the irradiated skin more rapidly (d1 in F vs. d2 in M), a response reflected by faster gene induction of neutrophil chemoattractants (G-CSF, KC, LIX) and inflammatory cytokines (IL1b, IL6, IL33) in the F mice. Significantly higher levels of circulating neutrophils were found on d6 following UVB in F, relative to their M counterparts. In both M and F mice, immediately following UVB, circulating neutrophils expressed increased CXCR2, while later on (d6) CXCR4^{hi} neutrophils were detected in the kidney and the BM and ICAM1^{hi}CXCR1^{lo} neutrophils were found in the kidney, lung, BM, and blood. To investigate the effects of UV exposure in a lupus prone model we studied *Sle1.Mfge8-/-C3-/-* mice. These mice were particularly sensitive to UVB, with persistent skin lesions and increased accumulation of apoptotic debris and IgG in the skin. UV exposure in this lupus model led to nephritis and premature death. Preliminary data indicate that UVB exposure resulted in glomerular antibody deposition associated with CXCR4^{hi} and ICAM1^{hi}CXCR1^{lo} neutrophil infiltration.

Conclusion: Our findings provide several novel insights into the neutrophil response to UVB exposure: i) localized skin sterile injury triggers neutrophil migration to peripheral organs, including the kidney, ii) the dynamics of neutrophil infiltration into the skin are sex-dependent, and iii) presence of CXCR4^{hi} and ICAM1^{hi}CXCR1^{lo} neutrophil populations in peripheral organs suggests that a subset of activated skin-infiltrating neutrophils has migrated to distal organs, possibly via reverse transmigration. Evidence of a similar neutrophil population in a UV-sensitive lupus model associated with kidney injury strongly suggests neutrophil involvement in UV-triggered systemic pathology in SLE.

Reevaluating Citrullination and Peptidylarginine Deiminases in Neutrophil Extracellular Trap-like Structures

Caitlyn L. Holmes¹, Daeun Shim², John Kernien¹, Chad J. Johnson¹, Jeniel E. Nett³ and Miriam A. Shelef^{4,5}, ¹University of Wisconsin - Madison, Madison, WI, ²Medicine, University of Wisconsin - Madison, Madison, WI, ³Medicine and Medical Microbiology and Immunology, University of Wisconsin - Madison, Madison, WI, ⁴Department of Medicine, Division of Rheumatology, University of Wisconsin - Madison, Madison, WI, ⁵William S. Middleton Memorial Veterans Hospital, Madison, WI

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Innate Immunity Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Neutrophil extracellular traps (NETs) are webs of chromatin and proteins extruded from neutrophils during NETosis. NETs are increased and display citrullinated proteins that are targeted by autoantibodies in rheumatoid arthritis. Citrullination, the posttranslational deimination of arginines to citrullines, is catalyzed by the peptidylarginine deiminases (PADs). Thus, NETs and PADs are thought to be important in the pathophysiology of rheumatoid arthritis. However, not all stimuli induce NETs with citrullinated proteins and, further, it has been suggested that different stimuli may induce different types of NET-like structures defined in part by the presence or absence of citrullination. Also, the requirement for PAD2 and PAD4, the main PADs expressed in neutrophils, in the formation of different NET-like structures has not been clearly defined, in part because many studies assess only citrullinated NETs. Here, we determine if

specific stimulants induce citrullinated and/or uncitrullinated NET-like structures in humans and mice and if those structures require PAD2 or PAD4.

Methods: Neutrophils were isolated from human peripheral blood or the bone marrow of wild type, PAD4^{-/-}, and PAD2^{-/-} mice and were treated for 4 hours with no stimulant, ionomycin, monosodium urate (MSU) crystals, phorbol myristate acetate (PMA), or *Candida albicans*. Cells were fixed, stained with 4'6-diamidino-2-phenylindole (DAPI) and an anti-citrulline antibody (F95) and imaged at preset locations at 400x. NET-like structures, defined as highly decondensed DNA, were quantified in a blinded manner. A t-test was used to analyze results with p<0.05 considered significant.

Results: PMA, MSU, and *C. albicans* were strong activators of NET-like structures in human neutrophils with MSU and *C. albicans* inducing primarily citrullinated NET-like structures and PMA primarily uncitrullinated. Ionomycin was a weak inducer of NET-like structures, about a third of which were citrullinated. In contrast, ionomycin and *C. albicans* were strong inducers of NET-like structures in murine neutrophils with ionomycin-induced NETs mostly citrullinated. MSU variably induced NET-like structures and PMA induced very few NET-like structures in mice, which were almost all uncitrullinated. Murine *C. albicans*- and MSU-induced NET-like structures were a mix of citrullinated and uncitrullinated. PAD4^{-/-} neutrophils generated almost no citrullinated NET-like structures, with similar numbers of uncitrullinated NET-like structures to PAD4^{+/+} neutrophils. PAD2^{-/-} neutrophils demonstrated no defects in any NET-like structures.

Conclusion: Different stimuli induce varying proportions of citrullinated and uncitrullinated NET-like structures in mice and humans making it difficult to define NET subsets by citrullination status and stimulant. PAD4 is required for the generation of citrullinated NET-like structures only, whereas PAD2 is dispensable for any murine NET-like structure. These findings critically inform the design and interpretation of studies evaluating the role of citrullination, PADs, and NET-like structures in rheumatoid arthritis.

Regulation of Neutrophil Activation in Systemic Lupus Erythematosus

Neelakshi R. Jog¹, Teresa Aberle¹, Eliza Chakravarty¹, Cristina Arriens¹, Joel M. Guthridge¹, Melissa E. Munroe¹ and Judith A. James^{2,3}, ¹Arthritis and Clinical Immunology, Oklahoma Medical Research Foundation, Oklahoma City, OK, ²Arthritis & Clinical Immunology, Oklahoma Medical Research Foundation, Oklahoma City, OK, ³Department of Pathology, University of Oklahoma Health Sciences Center, Oklahoma City, OK

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Innate Immunity Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic Lupus Erythematosus (SLE) is a systemic autoimmune disease characterized by immune dysfunction and autoantibody production. In addition to the adaptive immune system, neutrophils likely also play an important role in SLE pathogenesis. Neutrophils are terminally differentiated cells and are highly sensitive to environmental cues, including infections, sterile inflammation and medication. This study examined whether the increased levels of inflammatory cytokines in SLE induce neutrophil activation and whether the regulation of neutrophil function differs in SLE patients compared to controls.

Methods: Neutrophils from 19 SLE patients with varying disease activity and 11 controls were enriched by dextran sedimentation and density gradient centrifugation. Basal and stimulated levels of activation marker L-selectin (CD62L) and exocytosis marker CD66b were measured by flow cytometry. Percentage of cells with neutrophil extracellular traps (NET) were determined by microscopy. Plasma cytokines were measured by xMAP assays. Expression of mRNA and microRNA were determined by quantitative PCRs.

Results: Basal levels of CD62L were not different between SLE patients and controls; however, upon stimulation with TLR7/8 ligand, SLE patients showed reduced activation compared to controls ($p < 0.0001$). The CD62L levels negatively correlated with inflammatory cytokines IL1 β ($r = -0.7866$, $p = 0.0094$), IL23 ($r = -0.845$, $p = 0.0033$), IL6 ($r = -0.75$, $p = 0.0159$), MIP1 α ($r = -0.8424$, $p = 0.0037$), TNF β ($r = -0.7091$, $p = 0.0268$) in controls, suggesting increased downregulation of CD62L or increased activation of neutrophils due to exposure to inflammatory mediators. No correlation between these cytokines and CD62L levels were observed in SLE. CD66b levels were significantly lower in SLE patients compared to controls ($p = 0.0030$). In this small cohort, no significant differences between basal levels of NET forming cells between

SLE and controls were found. However, CD66b levels in SLE patients, but not in controls, positively correlated with the percentage of netting neutrophils ($r = 0.5858$, $p = 0.015$), suggesting a role for reactive oxygen species in NET formation in SLE. CD66b levels in SLE patients negatively correlated with BAFF ($r = -0.4848$, $p = 0.0354$), while the levels in controls did not correlate with plasma cytokines. Fold changes in surface markers upon stimulation with formyl peptide were similar between SLE and controls. The levels of surface markers on SLE neutrophils were not influenced by prednisone or hydroxychloroquine use. SLE neutrophils had significantly higher levels of genes involved in NF κ B signaling and lower levels of micro RNA miR223 and miR27a, suggesting hypersensitivity to infectious stimuli and reduced apoptosis.

Conclusion: SLE neutrophils had higher activation thresholds for mediators of sterile inflammation. Our data suggest that the regulation of neutrophil responses in SLE may be through pathways distinct from those in unaffected individuals, although the neutrophils maintain their ability to respond to external stimuli.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Innate Immunity Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Exercise was originally believed to exacerbate inflammation in rheumatic disease, however, recent studies have shown that regular physical activity is anti-inflammatory. In gout, there have been only a few pilot studies examining the effects of exercise on inflammation. Consequently, there are no exercise recommendations for gout patients in the clinical practice recommendations by the American College of Rheumatology (2012) and the American College of Physicians (2016). The objective of this study was to immunologically and mechanistically characterize the effects of different exercise intensities in a murine model of acute gout.

Methods: Using a model of acute gout we previously developed using transgenic mice harboring an NF κ B-luciferase reporter, we examined the effects of regular exercise at varying intensities on inflammation. Mice were exercised daily by treadmill walking (45 min/day for 2 weeks) at low intensity, moderate intensity, and high intensity and were subsequently injected with monosodium urate (MSU) crystals (0.5mg) into the tibio-tarsal joint (ankle). Localized NF κ B activity was measured 16 hours later in the injected ankle via bioluminescent imaging and tissue was collected and processed for immunohistochemical (IHC) and immunofluorescent (IF) analysis. Expression of Toll-like receptor (TLR) 2/4 and chemokine receptors on peripheral monocytes and neutrophils was determined using flow cytometry. Serum was collected for systemic chemokine expression.

Results: Mice in the low/moderate intensity exercise groups had measurably less swelling and significantly less NF κ B activity at the site of MSU crystal injection compared to the high-intensity group and non-exercised controls. Similarly, IHC of the synovial space of low/moderate intensity groups had decreased F4/80+ macrophages and MPO+ neutrophils relative to both high-intensity or non-exercised controls. Analysis by IF confirmed that both neutrophils and macrophages were secreting IL-1 β in the ankle joints. Considering that MSU crystals, at least in part, induce their inflammatory response with activation of TLR2, surface expression was measured by flow cytometry on peripheral neutrophils and demonstrated a decrease of 17% in the low-intensity and 48% in the moderate-intensity groups. In concordance, localized IL-1 β expression via IHC was reduced in low/moderate intensity exercise conditions. While there was little difference in chemokine receptor expression (CCR1, CCR2, CCR4, and CXCR2) on peripheral monocytes/neutrophils, the peripheral chemokine CXCL1 was significantly reduced with low and moderate exercise.

Conclusion: We hereby report that regular low/moderate intensity exercise regimens can reduce localized MSU crystal-induced inflammation, while high intensity training negates this response. An exercise-mediated suppression of NF κ B activity and IL-1 β expression locally can be explained, at least in part, by a reduction of TLR2 expression on peripheral neutrophils recruited to the site of inflammation and a down-regulation of CXCL1 expression.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Innate Immunity Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: K/B.g7 TCR transgenic mice spontaneously develop both autoimmune arthritis and valvular carditis. We utilize this model to define mediators of rheumatic disease-associated cardiovascular inflammation and fibrosis. We recently demonstrated that CX3CR1- and CD301b-expressing macrophages are critical drivers of valvular carditis in this system. Here we investigated the molecules that these macrophages use to promote cardiovascular inflammation.

Methods: We evaluated specific macrophage activation pathways using whole-animal and macrophage-specific (CX3CR1) conditional gene deletion, as well as in vivo antibody-blocking studies. We focused on prototypic M1 macrophage-associated molecules (IFN γ , TLR4, iNOS, IRF5) and on M2 macrophage-associated molecules (IL-4, IL-13, IL-4R α). We used immunofluorescent staining and flow cytometry to identify key cell types in the inflamed mitral valves of K/B.g7 mice as well in valve specimens from patients with rheumatic heart disease (RHD).

Results: Arthritis and valvular carditis develop normally in K/B.g7 mice lacking the M1-associated genes *Ifng*, *Tlr4*, or *Nos2* and or with macrophage-specific deletion of the M1 transcription factor IRF5. In contrast, macrophage-specific deletion of IL-4R α appears to protect K/B.g7 mice from valvular carditis without influencing the development of arthritis. IL-4R α and IL-13R α 1 are highly expressed in the inflamed valves of K/B.g7 mice and in human patients with RHD. Blockade of IL-13 but not IL-4 reduces valve inflammation.

Conclusion: Valvular carditis in K/B.g7 mice depends on CD301b- and IL-4R α -expressing macrophages but not on canonical M1 macrophage-associated molecules. IL-13 is a critical driver of disease in this model and may also be involved in human RHD. We speculate that targeting this pathway could reduce rheumatic disease-related cardiovascular disease.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Innate Immunity Poster

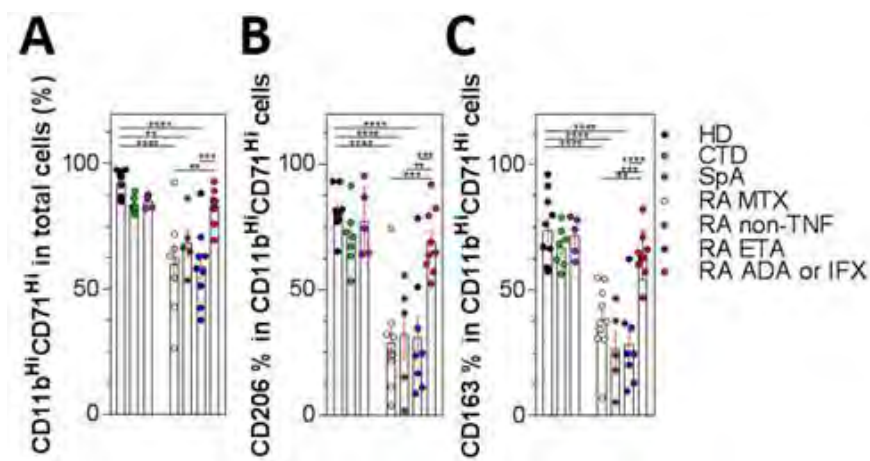

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Macrophages contribute in situ to the RA pathogenesis. Two distinct states of polarization for macrophages have been recognized: the **classically activated macrophage phenotype** (M1), considered to be pro-inflammatory and the **alternatively activated macrophage phenotype** (M2) considered to be regulatory. miRNAs are recently discovered class of post-transcriptional regulators. miR-155 is upregulated in RA synovial monocytes, macrophages and fibroblasts, but also in blood CD14⁺ monocytes. Here, we assessed monocytes capacity of differentiation into M2 macrophages and implication of miR-155 in RA patients or controls (healthy donor (HD), connective tissue disease (CTD) or spondylarthritis (SpA)).

Methods: CD14-CD16 monocytes were isolated from PBMCs by negative selection. To generate monocyte-derived macrophages(MDM), monocytes were incubated 6 days in the presence of M-CSF (M2) or GM-CSF(M1). Expressions of total macrophages markers (**CD11b** and **CD71**), M2 macrophage polarization markers (**CD163**, **CD206**, **IL-10** and **Arginase**) and M1 macrophage polarization markers (**INOS**, **IFR5** and **IL1 β**) were evaluated. The microRNA transfections were performed using **AMAXA technology**.

Results: We observed a significant decrease of macrophages induction by M-CSF in RA patients as shown by a decreased expression of **CD11b-CD71**. We have found a specific decreased level of M2 markers (**IL-10** Mean **26.4** HD versus **2.5** pg/mL RA-**Arginase** Mean **86.8** HD versus **26.9** RA **Fig1 A-C**). Moreover, we found that Adalimumab but not Etanercept is able to partially correct this defect (IL-10 **17.6** pg/mL and Arginase **69.9**%). We confirmed that under M-CSF treatment, RA monocytes have a propensity for preferential maturation towards M1 phenotype (**INOS** Mean **0.8** HD versus **25**% RA - **IFR5** expression Mean **1.35** HD versus **3.2** $\Delta\Delta$ Ct RA and **IL-1 β** secretion Mean **3.4** HD versus **20.9** pg/mL RA). We have hypothesized the involvement of **miR-155** on this defect. In M1 macrophages, the level of miR-155 was the same in controls and RA, whereas it was increased in M2 RA macrophages (Mean **0.6** HD versus **2.3** $\Delta\Delta$ CtRA). Subsequently preliminary experiments of transfected monocytes from healthy donors with **miR-155 mimic** leads to decrease M2 differentiation, conversely on RA monocytes transfection with amiR-155 inhibitor allowed the restoration of M2 polarization.

Conclusion: RA patients have a specific impaired maturation of monocytes to M2 while the differentiation to M1 phenotype is maintained. The use of monoclonal anti-TNF restores M2 polarization while Etanercept or non- anti-TNF drugs do not restore M2 polarization. This lack is associated with miR-155 increase that leads to IFR5 INOS and IL-1 β increase. Preliminary experiments showed that transfection of RA monocytes with an antagomiR may correct this lack, justifying the proof of concept trial of monocytes-targeted nanoparticles containing microRNA in mouse models of RA.

Monocytes Membrane TNF Expression and Anti-TNF Treatment in Rheumatoid Arthritis

Audrey Paoletti¹, Julien Rohmer², Juliette Pascaud³, Bineta Oumouly¹, Elodie Rivière³, Samuel Bitoun⁴, Gaetane Nocturne² and Xavier Mariette⁵, ¹U1184 IMVA, INSERM U1184, IMVA, Paris Sud University, LabEx LERMIT, le kremlin bicetre, France, ²INSERM U1184, IMVA, Paris Sud University, LabEx LERMIT, Le Kremlin Bicêtre, France, ³Immunology of viral Infections and Autoimmune Diseases, IDMIT, CEA - Université Paris Sud - INSERM U1184, Le Kremlin Bicêtre & Fontenay aux Roses, France, ⁴INSERM U1184, IMVA, Paris Sud University, LabEx LERMIT, le kremlin bicetre, France, ⁵Rheumatology department, Center for Immunology of Viral Infections and Autoimmune Diseases, Assistance Publique- Hôpitaux de Paris, Hôpitaux Universitaires Paris-Sud, Le Kremlin-Bicêtre, Université Paris Sud, INSERM, Paris, Paris, France

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Innate Immunity Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Three monocyte subsets have been described based on their CD14 and CD16 expression profiles. The subpopulation CD14⁺CD16⁺ being expanded in rheumatoid arthritis (RA) patient. Monocytes are one of the blood cellular populations expressing the most membrane TNF. TNF antagonist is the most popular biological drug in RA but after 20 years of use, we do not have any biomarker for predicting the response to this class of drug. Some studies suggested that serum soluble TNF and expression of TNF in the synovium could be predictive of response to anti-TNF but, curiously, possibly because of technical issues, no study addressed the level of expression of membrane TNF on blood monocytes and subtypes of monocytes in RA patients. Here, we assessed monocytes subsets and their mTNF expression in RA patients (treated or not with classical DMARDs or biologics) or controls (healthy donor (HD), connective tissue disease (CTD) or spondylarthritis (SpA) patients)

Methods: PBMCs were isolated and we first determined monocytes subpopulations and looked at expression of mTNF by flow cytometry. CD14CD16 monocytes were isolated by negative selection, and culture in RPMI with or without anti-TNF (Etanercept, Adalimumab or Certolizumab) during 3 days at 10 µg/ml corresponding to a mean serum concentration in treated patients.

Results: We have confirmed that the CD14⁺CD16⁺ monocyte subset was expanded in RA patients. For the first time, we have demonstrated *ex vivo* that mTNF expression was significantly increased only in monocytes in RA patients. Furthermore, mTNF is significantly increased in the three populations of monocytes in RA patients (**Fig1 A,B**). Very interestingly, mTNF expression on monocytes correlated with the activity of the disease assessed by DAS28 CRP (Spearman r **0.48** p-value **0.05**).

We wanted to look at *ex vivo* impact of anti-TNF on mTNF expression. We demonstrated that mTNF expression is equal between RA monocytes and RA anti-TNF treated monocytes in patients with a DAS28 ≤ 4 (Mean **7.42%** RA versus **7.26%**

in RA treated). To go further, we have tested *in vitro* monocytes treatment by anti-TNF from healthy donors or RA patients, but unfortunately, we have found no impact of anti-TNF on mTNF expression (**Fig1 C**).

Conclusion: Increased expression of mTNF on blood monocytes is a specific biomarker of RA not present in healthy controls or in patients with other inflammatory diseases like CTD or SpA. This increase in mTNF is linked to disease activity and is not influenced by the treatment *in vivo* or *in vitro*. Conversely to a recent publication (Ehrenstein et al) we did not observe an increase in monocytes mTNF with treatment with adalimumab. The possible link between the increased monocytes mTNF expression and macrophages abnormalities seen in RA, as well as the predictive value of monocytes mTNF expression for response to anti-TNF or to other treatments of RA remain to be evaluate.

Inhibition of Bruton's Tyrosine Kinase (BTK) Prevents Inflammatory Macrophage Differentiation: A Potential Role in RA and SLE

Yasemin Beguem Alankus¹, Roland Grenningloh², Philipp Haselmayer¹, Andrew Bender³ and Julia Bruttger¹, ¹Merck KGaA, Darmstadt, Germany, ²EMD Serono Research and Development Institute, Billerica, MA, ³TIP Immunology, EMD Serono Research and Development Institute, Billerica, MA

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Innate Immunity Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Bruton's Tyrosine Kinase (BTK) mediates B cell receptor (BCR) and Fc receptor (FcR) signalling in several hematopoietic cell lineages, including B cells, macrophages and neutrophils. The BTK inhibitor evobrutinib silences B cells and prevents innate immune activation via FcR and is efficacious in preclinical models for rheumatoid arthritis (RA) and systemic lupus erythematosus (SLE). Macrophages can have pro-inflammatory and anti-inflammatory properties and thus they play a crucial role in exacerbation versus control of autoimmune disease. BTK function has been implied downstream of certain cytokine receptors that control macrophage differentiation. The aim of this preclinical study was to investigate the effect of BTK inhibition on the differentiation and activation of monocytes and macrophages.

Methods: Monocytes were isolated from the peripheral blood of healthy volunteers. BTK activation was analyzed by Western blot following a 30-minute BTK inhibitor treatment and a subsequent granulocyte-macrophage colony-stimulating factor (GM-CSF) stimulation time course. Survival of GM-CSF differentiated M1 cells was analyzed by flow cytometry following AnnexinV/PI staining. Expression levels of IL-1 β and IL-10 were determined by qPCR following 48 hours of GM-CSF stimulation and BTK inhibitor treatment. TNF- α levels in cell culture supernatants were measured by ELISA following overnight LPS stimulation and BTK inhibitor treatment. The uptake of apoptotic cells by M2 macrophages was analyzed by flow cytometry.

Results: BTK was activated downstream of the GM-CSF receptor. In line with this finding, *in vitro* GM-CSF differentiated M1 macrophages underwent apoptosis upon BTK inhibition using evobrutinib. Monocytes treated with GM-CSF in the presence of BTK inhibitor secreted less TNF- α and expressed less IL-1 β , and the expression of anti-inflammatory genes, such as IL-10, was upregulated. Furthermore, treatment with BTK inhibitor increased the rate of phagocytosis by anti-inflammatory M2 macrophages *in vitro*.

Conclusion: Our findings show that BTK inhibition hinders M1 macrophage differentiation and skews monocytes towards an anti-inflammatory M2 phenotype, while enhancing apoptotic cell uptake by M2 cells. Therefore, BTK inhibition could have additional benefits in the treatment of autoimmune diseases such as RA and SLE, by targeting both B cells and myeloid cells simultaneously.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Innate Immunity Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Monocytes and Macrophages play critical roles in immune homeostasis and host defense. Recent studies identified that macrophages are highly heterogeneous in terms of location, origin and function. However, the sources of macrophages in the synovium and their functions are not yet clear. We performed BrdU incorporation and RNAseq profiling of blood monocytes and synovial macrophages from normal C57BL/6 mice under homeostatic conditions to identify functional differences.

Methods: Five distinct macrophage populations in synovium were determined by flow cytometry, based on subsetting CD45⁺CD64⁺CD11b⁺ cells by their expressions of Ly6C, MHCII and F4/80. Three F4/80^{int} (FI) subsets defined as Ly6C⁺MHCII⁻ (FI1), Ly6C⁺MHCII⁺ (FI2) and Ly6C⁻MHCII⁺ (FI3); and 2 subsets of F4/80^{hi} (FH) cells defined as MHCII⁻ (FH1) and MHCII⁺ (FH2) were identified. BrdU was used to identify proliferating cells. Populations of synovial macrophages and classical (CM) and non-classical (NCM) circulating monocytes were sorted by flow cytometry. High quality mRNAs from each of the cell populations was processed for RNAseq. The gene expression profiles and pathways were analyzed by Gene software and GOrilla database.

Results: BrdU⁺ CM and FI1 and FI2 macrophages that originated from bone marrow monocyte progenitors were detected within 24 hours. NCM and FI3 macrophages were BrdU⁺ on day 3. The FH1 and FH2 subsets were not renewed by circulating monocytes over 5 days, but were slowly proliferating. The distinct gene expression patterns were identified for each cell type by principal component analysis and pairwise correlation among cell groups. Genes that were highly expressed in CM were enriched in immune system processes, leukocyte activation, and signal transduction pathways such as Irf8, Stat1, Syk and Lyn. The majority of genes (65%) expressed in FH1 macrophages were maintained compared with CMs. This ratio of maintained genes gradually decreased going from the FI3, FH2 to FH1 subsets (60-54%). Further, comparing each macrophage subset to CMs, the ratio of differentially expressed genes (DEGs) increased from 14% (FI1), 23% (FI3), 27% (FH2) to 30% in FH1 macrophages. Of interest, host defense genes were highly represented in the FI1 macrophages compared with CMs. Expression of genes in the FH1 subset was highly correlated with those expressed in microglia and alveolar macrophages.

Conclusion: CM rapidly enter synovial tissue under homeostatic conditions but differentiate no further the FI3 population. FH macrophages are long-lived tissue resident macrophages of the joints. These observations suggest that under homeostatic conditions the FH1 subset provides a niche that prevents the further differentiation of FI1 macrophages to tissue resident macrophages. Further studies will address the mechanisms contributing to this niche.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Innate Immunity Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic sclerosis (SSc) is a chronic autoimmune disease of unknown etiology that is characterized by vasculopathy, fibrosis, and inflammation. Our work and that of others have implicated MØs in SSc pathogenesis and thus targeting MØs may have significant therapeutic benefit. We have shown that MØs are aberrantly activated in SSc, releasing inflammatory mediators and inducing activation of fibroblasts. We now show that the synthetic oleanane triterpenoid CDDO-methyl ester (CDDO-Me) inhibits immune activation and oxidative stress in SSc MØs, resulting in inhibited expression of TGF- β , CCL2, and IL-6 and enhanced activation of Nrf2 signaling.

Methods: Plasma and PBMCs were obtained from whole blood of 7 SSc patients or 5 healthy age and gender-matched control subjects following informed written consent. CD14⁺ monocytes were isolated from PBMCs using magnetic bead selection, and were cultured with either autologous or allogeneic plasma for 7 days to differentiate the cells into MØs. Immune activation studies were performed using 10 ng/ml LPS. RNA expression in MØs was analyzed using qRT-PCR, and protein expression and secretion were monitored using flow cytometry and by ELISA.

Results: CDDO-Me markedly inhibits basal mRNA and protein expression of TGF- β , CCL2, and IL-6 in SSc MØs, and attenuates surface expression of CD163 and CD206, which are upregulated on pro-fibrotic SSc MØs. We further demonstrate that CDDO-Me upregulates targets of Nrf2 activation in SSc MØs, suggesting CDDO-Me attenuates oxidative stress in these cells. CDDO-Me treatment does not impair SSc MØ viability.

Conclusion: Our data suggest that CDDO-Me attenuates inflammatory activation and induces anti-oxidant activity in SSc MØs. For the first time, we have shown that CDDO-Me treatment attenuates the pro-fibrotic activation profile of SSc MØs. For the first time, we have also shown that CDDO-Me inhibits expression of surface markers and cytokines associated with SSc inflammation and pathogenesis. In addition to regulating these factors, CDDO-Me also induces Nrf2 activation in SSc MØs. As CDDO-Me is currently undergoing Phase III clinical trial testing in patients with pulmonary arterial hypertension, a frequent complication and leading cause of death in SSc, potential repositioning of this drug to treat SSc is especially exciting. Because there are still no FDA-approved disease-modifying therapies that target innate immune activation in SSc, CDDO-Me may be a potentially important drug in our arsenal of therapeutics to combat MØ activation in this disease.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Innate Immunity Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic sclerosis (SSc) is an autoimmune disease characterized by immune system alterations, vasculopathy and fibrosis [1]. SSc-related interstitial lung disease (ILD) represents a common and early complication of SSc, being the leading cause of mortality [2]. Monocytes/macrophages seem to have a key role in SSc-related ILD. Interestingly, the classically (M1) and alternatively (M2) activated monocyte/macrophage phenotype categorization is currently under revision [3]. Our aim was to evaluate if circulating monocyte/macrophage phenotype could be hypothesized as a pathogenic factor and/or used as biomarker for SSc-related ILD. To this purpose we developed a wide phenotype characterization of circulating monocyte/macrophage subsets in SSc patients and evaluated relations with lung involvement parameters.

Methods: A single centre, cross-sectional study was performed, in fifty-five consecutive SSc patients (50 females/5 males, mean age of 63 ± 13 years, 36 with a diffused cutaneous disease form and 19 with a limited cutaneous disease). All clinical and instrumental tests requested for SSc follow up and in particular: lung computed tomography (CT) scan, pulmonary function tests (PFTs), Doppler echocardiography with systolic pulmonary artery pressure (sPAP) measurement, blood pro-hormone of brain natriuretic peptide evaluation, were performed in each patient. Flow-cytometry characterization of circulating monocytes/macrophages was performed using surface markers attributed both to M1 and M2 cell subsets. Non-parametric tests were used for statistical analysis and any p-value lower than 0.05 was considered as statistically significant.

Results: Several mixed M1/M2 monocyte/macrophage subsets showed higher percentages in patients positive for anti-topoisomerase antibody, a well-known lung involvement predictor. A higher percentage of circulating cells positive for both CD204, CD163, CD206 (M2 markers) and TLR4, CD80, CD86 (M1 markers), was identified to characterize patients affected by SSc-related ILD and higher systolic pulmonary artery pressure. Higher percentages of circulating M1/M2 subsets showed a linear negative correlation with diffusion lung capacity of carbon monoxide (DLCO)%. A FVC/DLCO ratio higher than 1.5 correlated with higher circulating M1/M2 percentages.

Conclusion: The present study shows for the first time, through a wide flow cytometry surface marker analysis, that higher circulating mixed M1/M2 monocyte/macrophage cell percentage significantly correlated with anti-topoisomerase antibody positivity, ILD and sPAP in SSc, opening the path for research on their possible role as pathogenic or biomarker elements for SSc lung involvement. **References.**[1] Cutolo M, et al. Session Title: Innate Immunity Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Synovial macrophages play a key role in RA disease progression, yet the diversity of macrophage subsets within the joint remains unknown. The concept of macrophage polarization into M1 inflammatory macrophages and M2 tissue-resolving macrophages, paralleled by changes in the bioenergetic cell profile, has received much attention. However the diversity and plasticity of macrophage subsets and their metabolic profile within the joint has yet to be elucidated.

Methods: Synovial tissue biopsies from Rheumatoid Arthritis (RA), Psoriatic Arthritis (PsA) and Osteoarthritis (OA) were obtained through key-hole arthroscopy. To phenotype distinct macrophage subtypes in the RA joint, synovial tissue biopsies (~10-15) were enzymatically and physically digested using an enzymatic cocktail and the GentleMACs dissociation system to yield a synovial single cell suspension. RA, PsA and OA synovial cell suspensions along with synovial fluid mononuclear cells were stained using a specific antibody panel (CD40, CD45, CD64, CD68, CD163, CD206, CD253) and analysed by advanced-multicolour flow cytometry analysis. Blood was also obtained from healthy and RA donors, CD14⁺ cells sorted and differentiated into macrophages for 8 days and polarised to either M1 (LPS/IFN γ) or M2 (IL-4) macrophages.

Inflammatory and metabolic genes were measured by RT-PCR. The two major energy-using pathways, glycolysis (ECAR) and oxidative phosphorylation (OCR) were measured by Seahorse XFE technology.

Results: M1 cells displayed higher expression of pro-inflammatory genes and demonstrated a pro-glycolytic phenotype with significant increases in HIF1 α , HK2, LDHA and PFKFB3, compared to M2, this effect was then further exacerbated in RA macrophages compared to healthy control. Using seahorse technology we demonstrate that in RA, both M1 and M2 macrophages display higher ECAR and OCR profiles compared to HC indicating that RA macrophages are more metabolically active compared to HC. Furthermore we note increased ECAR:OCR profiles in RA vs HC, thus RA macrophages utilise glycolysis more readily than HC. Flow cytometry analysis of RA synovial tissue and fluid revealed that CD68+ macrophages display markers typical of both M1 (CD40+CD253+) and M2 (CD206+CD163+). A significant increase in the frequency of CD68+ and CD64+ macrophages in the synovial tissue compared to fluid was observed, along with significant increases in marker expression of CD40, CD163 and CD206. Further analysis revealed a spectrum of macrophage subtypes exists within the inflamed joint, with a dominant macrophage subtype consisting of double positive CD206+ CD163+ identified, which is enriched in the synovial tissue compared to synovial fluid. Furthermore, we demonstrate that the frequency of this enriched population is significantly increased in RA synovial tissue compared to that of PsA and OA synovial tissue.

Conclusion: This study demonstrates distinct metabolic profiles in M1/M2 RA macrophages; associated with differences in key inflammatory mediators. Furthermore, we have identified, for the first time, a dominant subtype of RA tissue-specific macrophages, suggesting that these cells remain plastic and their function dependent on their microenvironment.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Innate Immunity Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Myeloid cells with a monocyte/macrophages phenotype are present in large numbers in the rheumatoid arthritis (RA) joint, significantly contributing to disease. This study aimed to assess whether peripheral monocytes in RA are pre-programmed to become M1 pro-inflammatory macrophages.

Methods: Blood was collected from healthy donors, at-risk individuals (Those with arthralgia, ACPA+/RF+, normal CRP and no evidence of synovitis) and established RA patients. CD14+ monocytes were isolated from peripheral blood mononuclear cells using a CD14 magnetic bead separation kit. Cells were stimulated with LPS (100ng/ml) for 3-24 hours and to assess the effects of STAT3 inhibition, cells were pre-treated with STAT3i (10 μ M) for 30mins. A Human Cytokine and Chemokine PCR array was carried out and those genes most differentially expression were further validated in a larger cohort of patients using RT-PCR. The metabolic profile of cells was analysed using Seahorse XFE Technology, which concomitantly analysis glycolysis and mitochondrial respiration in real-time. Gene and protein expression of key inflammatory and glycolytic markers was also carried out by RT-PCR, western blotting and ELISA.

Results: CD14+ RA monocytes are hyper-inflammatory upon stimulation, with significantly higher expression of IL-1 β , TNF α , IL-6, IL-27, CXCL10 and CXCL11 compared to healthy controls, which is indicative of a M1-like pro-inflammatory phenotype. These hyper-inflammatory cells are highly glycolytic, with increased expression of HIF1 α and PFKFB3, a key glycolytic enzyme. Both baseline glycolysis and the maximal glycolytic capacity are increased in RA CD14+ monocytes, with no changes observed in mitochondrial respiration. This hyper-inflammatory, hyper-glycolytic phenotype is mediated by STAT3, as selective STAT3 inhibition can significantly decrease M1-like cytokines and PFKFB3 expression.

Finally, this pro-inflammatory phenotype is evident in CD14⁺ monocytes from arthralgia ACPA⁺/RF⁺ people at risk of developing disease, demonstrating that these processes may precede clinical manifestations in RA.

Conclusion: This study demonstrates the unique inflammatory and metabolic phenotype of RA monocytes, suggesting that peripheral CD14⁺ monocytes may be pre-programmed to become M1-like pro-inflammatory macrophages. In addition, the observation of this phenotype in at-risk individuals indicates that these features may precede clinical manifestations of RA and therefore could be useful as a biomarker for early diagnosis.

The Distinct Profile of Ly6c^{lo} Monocytes in the Murine Joint Compared with Those in Circulation Suggests a Unique Role in Inflammatory Arthritis

Anna B Montgomery¹, Philip J. Homan², Deborah R. Winter² and Harris Perlman³, ¹Division of Rheumatology, Northwestern University Feinberg School of Medicine, Chicago, IL, ²Department of Medicine Division of Rheumatology, Northwestern University Feinberg School of Medicine, Chicago, IL, ³Northwestern University Feinberg School of Medicine, Chicago, IL

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Innate Immunity Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Populations of monocytes in mice are distinguishable by expression of Ly6c. Ly6c^{hi} monocytes are associated with pro-inflammatory responses, while Ly6c^{lo} are involved in lining and patrolling endothelial membranes. Both Ly6c^{hi} and Ly6c^{lo} monocytes can differentiate into macrophages and have been implicated in inflammatory arthritis and we have previously shown Ly6c^{lo} monocytes are essential for development of serum transfer induced arthritis (STIA). In the present study we show that NR4A1-deficient mice, which have a marked reduction of circulating Ly6c^{lo} monocytes but retain Ly6c^{lo} monocytes attached to endothelial vessels, also develop arthritis. Thus, we postulate that Ly6c^{lo} monocytes may be a heterogeneous population with distinct functions (circulating vs patrolling).

Methods: Female NR4A1^{-/-} and C57Bl/6 mice were bred in house to 8-10 weeks old. STIA was induced by intravenous (IV) administration of KBxN sera at 85µl/20g. Arthritis was measured using clinical score, and mean clinical scores of N=4 per group were calculated. Monocytes were depleted using IV administration of clodronate-loaded liposomes (Clo-Lip). PBS-loaded liposomes were used as a negative control. Mice were euthanized by CO₂. Blood was collected by cardiac puncture and distal joints were collected following perfusion with PBS. Blood and joint monocytes were isolated by FACS and characterized by flow cytometry and RNA-sequencing (RNA-seq). Statistical analysis of disease and flow cytometry was carried out in GraphPad Prism. Statistical significance was considered at $P \leq 0.05$.

Results: NR4A1^{-/-} mice displayed a significant reduction in Ly6c^{lo} monocytes in the blood compared to C57Bl/6 controls, although joint Ly6c^{lo} monocytes in the joint were not significantly reduced. No significant differences were observed between arthritis severity between genotypes. In C57Bl/6 mice, Clo-lip administration resulted in over 90% depletion of CD115⁺ blood monocytes, however over 35% of synovial monocytes remained, suggesting they are not in the circulation. Of these, Ly6c^{hi} and Ly6c^{int} populations were significantly reduced ($P < 0.05$), while Ly6c^{lo} monocyte numbers were unaffected. Further, flow cytometric analysis of blood and synovial macrophages identified a population of Ly6c^{lo} monocytes in the joint of C57Bl/6 mice which express endothelial cell surface marker CD105. 60% of Ly6c^{lo} monocytes in the joint were CD105⁺ compared to 14% and 16% of Ly6c^{hi} and Ly6c^{int} respectively. Finally, transcriptional profiling of Ly6c^{lo} monocytes reveals upregulated genes in blood Ly6c^{lo} cells are enriched for processes such as monocyte activation and differentiation processes, compared to processes involved in cell migration and localization enriched in Ly6c^{lo} cells isolated from the joint.

Conclusion: These findings suggest a population of Ly6c^{lo} monocytes reside in the murine joint and have a distinct phenotype from blood Ly6c^{lo} monocytes measured by cell surface markers and transcriptional profile. Combined with the finding that NR4A1^{-/-} mice are susceptible to KBxN arthritis, this sub-population of Ly6c^{lo} monocytes is likely to have unique pro-inflammatory capabilities.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Innate Immunity Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: A delayed diagnosis and therapy of ACPA (Anti cyclic citrullinated peptide antibody)-negative RA patients might be associated with effective serum biomarkers in clinic.

Methods: In the present study, we performed protein chip analysis in 30 HC, 60 patients with RA (including 30 ACPA-positive and 30 ACPA-negative), and 30 with other Autoimmune diseases.

Results: We found that anti-pentraxin 3 autoantibodies were significantly up-regulated in both ACPA negative and positive RA patients compared with healthy controls and other AIDs with high sensitivity and specificity. Enlarged samples of small protein chip confirmed the up-regulated anti-PTX3 level in ACPA negative RA patients. Further ELISA analysis of anti-PTX3 and its autoantigen pentraxin 3 in serum and synovial fluid showed that both anti-PTX3 and PTX3 was significantly up-regulated in ACPA positive and negative RA patients and positively correlated with clinical manifestations of DAS28 and RF as well as serum inflammatory cytokines, IL-1 β , IL-6 and TNF- α . We also showed that increased PTX3 secretion was derived from CD19⁺ B cells and preferentially bound to CD14⁺ monocytes in a C1q-dependent manner. Serum C1q level was higher in RA patients compared with HC and AIDs and positively correlated with PTX3 expression in RA patients. Moreover, PTX3 treatment of CD14⁺ monocytes combined with C1q in vitro could significantly up-regulate the activation marker CD40 expression and increased 7-AAD⁺Annexin V⁺ double positive late apoptotic cells in some RA patients. The induction of CD14⁺ monocytes apoptosis strongly inhibited RA-related inflammatory cytokine IL-1 β , IL-6 and TNF- α secretion after LPS stimulation in vitro. LDH release and the cleaved GSDMD and caspase-1 was significantly down-regulated while cleaved caspase-3 and Bcl-2 was significantly up-regulated after C1q and PTX3 combined treatment.

Conclusion: Our results demonstrated a detection of Anti-Pentraxin-3 autoantibodies in ACPA-negative RA Patients and autoantigen PTX3 combined with C1q could effectively inhibit GSDMD mediated pyroptosis and inflammatory cytokine release.

Tofacitinib Impairs Monocyte-Derived Dendritic Cell Differentiation in Rheumatoid Arthritis and Psoriatic Arthritis.

Viviana Marzaioli¹, Mary Canavan¹, Achilleas Floudas¹, Siobhan C. Wade¹, Candice Low², Douglas J. Veale² and Ursula Fearon¹, ¹Molecular Rheumatology, School of Medicine, Trinity Biomedical Sciences Institute, Trinity College Dublin, Dublin, Ireland, ²Centre for Arthritis and Rheumatic Diseases, Dublin Academic Medical Centre, University College Dublin, Dublin, Ireland

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Innate Immunity Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Tofacitinib (Pfizer) is an oral Janus kinase inhibitor, recently approved for the treatment of rheumatoid arthritis (RA) and psoriatic arthritis (PsA). Although its mechanism of action has been explored in circulating

cells, in particular neutrophils and lymphocyte, its effect on dendritic cells development and function remains still to be elucidated.

Monocyte-derived dendritic cells are a subset of inflammatory DC derived from circulating monocytes and have a key role in inflammation and infection. The aim of this project is to evaluate the effect of Tofacitinib on inflammatory monocyte-derived dendritic cells (Mo-DC) from RA and PsA patients, and in particular on the ability of monocyte to differentiate into dendritic cells, an important step in innate immunity.

Methods: Monocytes were isolated from blood of healthy donor (HC), RA and PsA patients by magnetic separation and plated in presence/absence of GM-CSF/IL-4 cocktail for 7 days, to acquire immature dendritic cells (DC) phenotype. To evaluate the effect of Tofacitinib on Mo-DC differentiation, monocyte were treated with 1 μ M Tofacitinib (or DMSO as control) for 15 minute prior to cytokine stimulation. CD209 (immature DC marker) and CD14 (monocyte marker) were evaluated by flow cytometry in the CD11c positive population. Non-specific macropinocytosis (using Lucifer Yellow) and receptor-mediated endocytosis (using DQTM Ovalbumin) were investigated by flow cytometry. Western blot analysis was utilized for analysis of the effect of Tofacitinib on NADPH oxidases (NOX) 5 and 2, known player in Mo-DC differentiation. Finally, the frequency of CD209 cells was evaluated by flow cytometry in both peripheral blood (PBMC) and synovial fluid (SFMC) mononuclear cells from RA and PsA patients.

Results: Pre-treatment of Mo-DC with Tofacitinib inhibited Mo-DC differentiation in RA and PsA patients, as shown by reduced CD209 marker expression, paralleled by an increase of CD14 marker expression. The decreased ability of monocytes to differentiate into DC in the presence of Tofacitinib was translated into a function impairment of phagocytic ability, in particular in PsA patients, as observed by the decreased uptake of both DQTM Ovalbumin (receptor-mediated endocytosis) and Lucifer Yellow (micropinocytosis).

When comparing the ability of monocyte to differentiate into DC, we observed that RA monocytes differentiated faster than HC and PsA, expressing CD209 marker already at day 1.

NOX5 has previously been shown to play a key role in Mo-DC differentiation, therefore we sought to investigate whether the effect of Tofacitinib on Mo-DC differentiation is mediated through modulating NOX5. Interestingly, Tofacitinib decreased NOX5 and increased NOX2 protein expression in Mo-DC in both PsA and RA Mo-DC. Finally, we identified the CD209 population in PBMC cells from RA and PsA patients, and we observed an increased frequency of this population at the site of inflammation in SFMC cells from PsA and RA patients.

Conclusion: Together, these observations suggest a novel mechanism of action of Tofacitinib in RA and PsA, by inhibiting Mo-DC development, which may alter migration of DC to the joint and subsequent activation of the immune response.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Innate Immunity Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: There is an emerging view that mast cells may play a pivotal role in several inflammatory and autoimmune diseases. However, the role of mast cells in Sjögren's syndrome remains unclear. We examined whether mast cells play a critical role in immune-mediated inflammation and fibrosis in patients with Sjögren's syndrome.

Methods: Labial salivary gland samples were collected from 22 individuals with primary Sjögren's syndrome and 10 with sicca syndrome (controls) and were examined using histological and immunohistochemical methods. Saliva production was evaluated by Saxon's test. Mast cell density in the minor salivary glands was calculated at x400 magnification. Five fields

were counted in all cases. The lymphocyte focus score was evaluated based on the number of inflammatory cell aggregates containing >50 lymphocytes per 4 mm². The degree of fibrosis in the minor labial salivary glands was graded on a quantitative scale as previously reported (Clin Exp Rheumatol.1998;16:63-65). We used immunohistochemistry to identify and quantify tryptase-positive mast cells and vimentin-positive fibroblasts. Fibrous tissue was identified using elastic Van Gieson (EVG) staining. Human mast cell line 1 (HMC-1) cells were cocultured with pulmonary fibroblasts for 7 days using a transwell system, and type I collagen synthesis in fibroblasts was evaluated by quantitative RT-PCR.

Results: We found that the number of mast cells in the labial salivary glands of patients with primary Sjögren's syndrome was significantly increased compared to that in control subjects ($p<0.0001$). There was a significant negative correlation between the Saxon's test results and the number of mast cells ($r=-0.6742$, $p=0.006$), suggesting the involvement of mast cells in the decreased salivary secretion. There was no significant correlation between the intensity of lymphoid infiltration assessed by the focus score and the mast cell density ($r=0.01545$, $p=0.58$). In contrast, a significant correlation between the number of mast cells and the degree of fibrosis was observed ($r=0.5911$, $p=0.0038$). Consistent with these findings, histochemical analysis revealed that mast cells were usually present in close proximity to EVG-stained fibrous tissue in the labial salivary glands. Furthermore, double immunostaining revealed that the mast cells were located proximal to vimentin-positive fibroblasts. We hypothesized that mast cells were involved in the development of tissue fibrosis via modulation of fibroblast immune function in sialadenitis and conducted an in vitro co-culture of HMC-1 cells and pulmonary fibroblasts. Significant up-regulation of Col1a mRNA was observed in fibroblasts co-cultured with HMC-1 cells compared to that in fibroblast monocultures ($p=0.02$).

Conclusion: These results suggest a novel role for mast cells in the development of sialadenitis in patients with primary Sjögren's syndrome by induction of tissue fibrosis via fibroblast collagen synthesis.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Innate Immunity Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Natural killer (NK) cells participate in systemic lupus erythematosus (SLE) pathogenesis by promoting dendritic cell (DC) activation and/or interferon (IFN) γ over-production. NK cell activation pathways remain unknown. One mechanism leading to plasmacytoid DC activation in SLE is the binding of auto-antigens (nucleic acids) with their cognate intracellular toll-like receptors (TLR), which includes TLR-9. Using synthetic CpG-ODN-A-2216 as TLR-9 ligand, the aim of this study was to determine if this pathway is similarly involved in NK cell activation and if hydroxychloroquine (HCQ) has an effect on this pathway.

Methods: From 2013-2018, 41 HCQ-free and 8 HCQ-treated SLE patients were compared to 29 controls. SLEDAI ≥ 6 defined active patients. Fresh CD3⁺CD56⁺ NK cells were stained with anti-CD69-ECD and TLR-9-PE after permeabilization. Polyfunctionality assays detected both degranulation (anti-CD107a-FITC) and intracellular IFN γ (anti-IFN γ -AF700) after a 5-hour-co-culture of either PBMCs or purified NK cells with K562 target cells to a 1:1 ratio. CpG-ODN-A-2216 was added overnight to 10⁶ cells/ml cultures at 12.5 mM/ml. When added, soluble HCQ was used at 0.1, 0.5, 1, or 5 mg/ml.

Results: In HCQ-free SLE patients, % of TLR9⁺-NK cells was increased in active patients as compared to inactive patients: 31 ± 17% vs. 13 ± 15%. TLR-9 expression correlated with the % of CD69⁺-activated NK cells ($r^2=0.68$; $p=0.004$). Overnight stimulation of PBMCs by CpG-ODN-A-2216 led to activation of NK cells (CD69 increasing from 31 ± 18% to 70 ± 18%, $p<0.001$) and resulted in degranulation and slight production of IFN γ with similar effects in patients and controls: 50 ± 14% vs. 49 ± 16% and 7 ± 6% vs. 8 ± 6%, $p<0.001$, respectively. CpG-ODN-A-2216 had a direct effect in purified-NK cell activation: % CD69 increasing from 25 ± 15% to 39 ± 19%, $p=0.008$. However, it was not sufficient to induce both their degranulation and IFN γ production in patients vs. controls. Adding HCQ prior to the PBMCs stimulation inhibits CpG-ODN-A-2216, with a dose effect *in vitro*. Interestingly, the significant effect started at the *in vivo*-target dose of 1 mg/ml: % CD69 decreasing from 70 ± 24% to 38 ± 31%, $p=0.036$. Furthermore, CpG-ODN-A-2216 stimulation of both PBMCs and purified NK cells from patients treated with HCQ (concentration > 0.77 mg/ml) did not show any effect: CD69 remaining stable at 24 ± 20% vs. 34 ± 24%, $p=0.5$ and 16.5 ± 10% vs. 16 ± 11%, $p=1$, respectively.

Conclusion: Although CpG-ODN-A-2216 had only a partial direct effect on NK cell polyfunctionality, these results indicate that TLR-9 pathway is involved in NK cell activation in SLE. Further investigations are needed to determine if the “physiological” auto-antigens act like the CpG-ODN-A-2216.

Impact of TLR7 Ligation in RA Pathology

Sadiq Umar^{1,2}, Katrien Van Raemdonck^{1,2}, Karol Palasiewicz^{1,2} and Shiva Shahrara^{1,2}, ¹Medicine, Division of Rheumatology, University of Illinois at Chicago, Chicago, IL, ²Jesse Brown VA Medical Center, Chicago, IL

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Innate Immunity Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Expression of Toll-like receptor 7 (TLR-7) is highly elevated in rheumatoid arthritis (RA) and osteoarthritis (OA) compared to normal (NL) synovial tissue lining and sublining macrophages. Interestingly in RA blood monocytes, TLR7 expression closely correlates with disease activity score (DAS28) and TNF- α transcription levels. We recently uncovered a novel endogenous TLR7 ligand; miR-Let7b, that is predominately packaged in RA synovial fluid macrophages. To document the impact of miR-Let7b ligation to TLR7 in RA pathogenesis, studies were performed using RA cells and preclinical models.

Methods: To understand the mechanism by which synovial fluid miR-Let7b promotes RA pathology, ligation of TLR7 was investigated on inflammatory response provoked by myeloid and T cells. Next, the impact of ectopic expression of miR-Let7b was examined in naïve mice and collagen induced arthritis (CIA) preclinical models.

Results: We found that TLR7 endogenous ligands, single strand (ss)RNAs, were undetectable in NL and RA plasma while these ligands were highly expressed in RA synovial fluid (SF). Consistent with the distribution of RA SF ssRNA, we show that miR-Let7b is markedly elevated in RA SF compared to OA SF (14 fold lower), RA (260 fold lower) and NL plasma (450 fold lower). We reveal that exosomes released from RA SF macrophages are an important source of miR-Let7b storage (78 copies; shown as 1 fold) and that cell death mediated by apoptosis (660 copies, 8 fold) or necrosis (74820 copies, 950 fold) can further potentiate the discharge of exosomal miR-Let7b into RA SF. Moreover, we determined that stimulation with miR-Let7b or TLR7 agonist can markedly accentuate TNF- α and IL-6 transcription and production (50-100 fold increase respectively) in RA peripheral blood (PB) *in vitro* differentiated macrophages. In contrast, neither TLR7 agonist nor miR-Let7b stimulation had any effect on IL-10 transcription. We also found that in PB mononuclear cells (T cells plus myeloid cells), TH-17 cells are strongly polarized by TLR7 ligation, in part due to secretion of IL-6 and IL-1 β from RA myeloid cells. We next show that ligation of TLR7 by local injection of miR-Let7b, results in significantly elevated joint inflammation. Consistently, when CIA mice were ectopically treated with miR-Let7b, joint swelling was markedly potentiated, while the control ankle circumference remained at a plateau phase. We uncovered that levels of monokines secreted from CIA ankle joints, including TNF- α , CCL2, CCL5 and IL-1 β were exacerbated by local administration of miR-Let7b in comparison to the control mice. Extending our observations in RA cells, we document that miR-Let7b treatment in CIA mice can amplify joint TH-17 cells/IL-17 differentiation. Our results indicate that RA disease activity is augmented by miR-Let7b ligation to TLR7 which activates effector myeloid and T cells function in these patients.

Conclusion: Overall our findings suggest that ligation of miR-Let7b to TLR7 perpetuates RA inflammation and blockade of this pathway may be an attractive target for RA therapy.

Session Date: Monday, October 22, 2018

Session Title: Innate Immunity Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Human plasmacytoid dendritic cells (pDCs) play a vital role in modulating immune responses. pDCs can produce massive amounts of type I IFNs in response to nucleic acids via toll-like receptors (TLRs) and they are known to possess weak antigen-presenting properties inducing CD4⁺ T cell activation. Previous data showed a cross-regulation between TNF- α and IFN- α but the effect of TNF- α on pDCs remains unclear. The aim of this study was to investigate how TNF- α regulates the immune function of human pDCs.

Methods: Freshly isolated peripheral blood mononuclear cells were treated with TNF- α , TLR7 and TLR9 synthetic agonists. pDCs were immunophenotyped using flow cytometry. RNA from sorted pDCs was extracted and sequenced using Smart-seq2 for sensitive full-length transcriptome profiling. For pDC/T cell co-culture, fresh or TNF- α -treated pDCs were cultured with naïve CD4⁺ T cells for 5 days. The production of cytokines was measured by intracellular staining and ELISA.

Results: Upon stimulation with TLR7 and TLR9 agonists, there were three main pDC populations: non-producers, TNF- α -producers, TNF- α /IFN- α -producers. Exogenous TNF- α significantly reduced the production of both IFN- α and TNF- α in TLR9-stimulated pDCs but only IFN- α in TLR7-stimulated pDCs. Neutralization of autologous TNF- α with anti-TNF antibody partially sustained IFN- α secretion by TLR9-stimulated pDCs after 24 hours. Exogenous TNF- α significantly promoted pDC maturation by upregulation of costimulatory molecules and chemokine receptors such as CD80, CD86, HLA-DR, and CCR7. RNA-sequencing data analysis suggested that TNF- α inhibits IFN- α production by interfering with the IRF7 and NF κ B pathways but promotes antigen processing and presentation pathways as well as T cell activation and differentiation. Indeed, the *in vitro* co-culture showed that TNF- α -treated pDCs induced higher CD4⁺ T cell proliferation and favoured Th1/Th17 polarization.

Conclusion: Although pDCs possess weak antigen-presenting properties, TNF- α can enhance pDC maturation by switching their main role as IFN- α -producing cells to a more conventional DC phenotype. The functional status of pDCs might be strongly influenced by overall inflammatory environment and TNF- α might regulate IFN- α -mediated aspects of a range of autoimmune and inflammatory diseases.

Plasmacytoid Dendritic Cells That Infiltrate the Lungs Produce Profibrotic Cytokines and Chemokines in Bleomycin-Induced Model of Systemic Sclerosis

Isela Valera¹ and Ram R. Singh², ¹Autoimmunity and Tolerance Laboratory, Division of Rheumatology, Department of Medicine, UCLA, Los Angeles, CA, ²UCLA, Los Angeles, CA

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Innate Immunity Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: In bleomycin-induced model of systemic fibrosis and patients with systemic sclerosis, plasmacytoid DC (pDC) are unaffected or reduced systemically (spleen/peripheral blood) but they increase in the lungs (Kafaja S, et al, JCI Insight 2018). Depletion of pDCs ameliorated fibrosis in the bleomycin model and altered the expression levels of proteins and genes implicated in chemotaxis, inflammation, and fibrosis in the lungs. In resonance with animal findings, the frequency of pDCs in the lungs of patients with SSc correlated with the severity of lung disease. Treatment with a tyrosine kinase inhibitor imatinib that has been reported to reduce and/or prevent deterioration of skin and lung fibrosis profoundly reduced pDCs in lungs but not in peripheral blood of patients with systemic sclerosis. In patients with systemic sclerosis, the frequency of pDCs also correlated with levels of proteins implicated in inflammation, vasculopathy and fibrosis. It is unclear if pDCs directly contribute to inflammatory and profibrotic milieu in the development of systemic fibrosis. Here, we asked if pDCs as compared to other immune cells contribute to proteins that are differentially expressed in the lungs after bleomycin exposure.

Methods: Female C57Bl/6 mice were injected with bleomycin (4 U/kg body weight) subcutaneously daily for 2 weeks. Lungs were harvested from bleomycin or control PBS injected animals on day 28. Lung extracts were analyzed for proteins by Western blot and ELISA, and freshly isolated single cells were analyzed for the expression of proteins on pDCs, myeloid dendritic cells (CD11c⁺CD11b⁺; mDC), other myeloid cells (CD11b⁺CD11c⁻, monocyte/macrophages and neutrophils), B cells, and T cells by multiparameter flow cytometry. Relative expression of proteins was expressed as the ratio of the mean fluorescent intensity of cells stained with respective antibodies and isotype controls.

Results: Scavenger receptor CD36 that is implicated in platelet-collagen adhesion, oxidative stress and inflammation was significantly increased on pDCs ($p < 0.01$) but not on mDCs, other myeloid cells, B cells and T cells in the lungs of bleomycin-injected animals as compared to control animals. TLR7 was also increased more on pDCs than on all other immune cells examined, whereas TLR2 was increased more on mDCs and other myeloid cells but not significantly on pDCs and B cells in the lungs of bleomycin-injected animals as compared to control animals. TGF β latent peptide was higher on the surface of all immune cells examined in the lungs of bleomycin-injected animals than in control lungs. Among chemokine receptors examined, CCR2, CCR3, CCR6, CCR9 and CXCR4 were higher on pDCs than most other cells examined. CCR2 and CCR9 were also higher on mDCs, and CXCR4 was higher on B cells and mDCs in the lungs of bleomycin-injected animals as compared to control animals.

Conclusion: Our data suggest an important role of pDCs in eliciting pro-inflammatory and profibrotic milieu in the development of systemic fibrosis. These observations along with recently published studies identify the increased trafficking of pDCs to the affected organs as a potential therapeutic target in systemic sclerosis and other fibrotic diseases.

Unique Pattern of Lectin Pathway Complement Protein Levels in Axial Spondyloarthritis

Anne Trolborg^{1,2,3}, Steffen Thiel¹, Clara Mistegaard Joergensen⁴, Kristian Stengaard-Pedersen^{3,5} and Anne Gitte Loft^{3,6}, ¹Biomedicine, Aarhus University, Aarhus, Denmark, ²clinical medicine, Aarhus University, Aarhus, Denmark, ³Rheumatology, Aarhus University Hospital, Aarhus, Denmark, ⁴Emergency Medicine, Regional Hospital Horsens, Horsens, Denmark, ⁵Clinical medicine, Aarhus University, Aarhus, Denmark, ⁶Clinical Medicine, Aarhus University, Aarhus, Denmark

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Innate Immunity Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Spondyloarthritis (SpA) represents a group of immune-mediated inflammatory diseases that exhibit overlapping clinical features, genetic predisposition and a not fully understood pathogenesis. Inflammation and structural damage of target tissue are clinical characteristics. Growing evidence indicates that parts of the pro-inflammatory profile in SpA is caused by abnormal innate immune responses. In SpA it is believed that immune system failures result in insufficient removal of dead cells from the body, leading to an increased or abnormal pressure on the immune system. This may lead to activation of the Lectin Pathway (LP) of the complement system. The LP of the complement system plays a role in the clearance of apoptotic and necrotic cells. We hypothesize that a characterization of the lectin pathway proteins in SpA patients compared to controls may provide new insight into the pathogenesis of SpA.

Methods: Prospectively, blood samples (EDTA plasma) and disease activity scores (ASDAS, BASDAI and BASMI) were collected in a well-defined cross sectional SpA cohort of 120 patients (median age 36.5 years, range 18-72; 85% HLA-B27 positive, 61% male; 45% bDMARD treated) fulfilling the ASA 2009 criteria and of 120 controls. Ten proteins of the LP were measured in plasma using in-house developed assays. As indicators of complement consumption and activation the complement proteins C3 and C3dg were assessed.

Results: Concentrations of the LP proteins were altered in a specific pattern in this cross-sectional SpA cohort compared with healthy controls. High concentrations in plasma of H-ficolin, MAP44 and M-ficolin and low concentrations of CL-L1 were observed for patients with SpA compared to healthy individuals (p-values all <0.001). The differences in LP proteins observed between patients and controls were not significantly associated with complement activation or disease activity (ASDAS, BASDAI). Using the 75-percentile in healthy controls as cut-off for an elevated concentration of H-ficolin, MAP44, and M-ficolin and the 25-percentile as cut-off for a reduced concentration in CL-L1, we then used resulting elevated or reduced values as disease biomarkers. Using the cumulative presence of the four altered LP concentrations in patients and controls, we could to a high degree separate SpA patients from healthy controls. Among controls with LP concentrations within the normal range a negative predictive value of 0.90 was found and among SpA patients with three altered LP concentrations a positive predictive value of 0.87 was found.

Conclusion: In this cross-sectional SpA cohort we observed specific changes in 4 of 10 LP proteins. The specific pattern (high H-ficolin, L-ficolin, MAP44 and low CL-L1) clearly differentiated to a high degree SpA patients from healthy individuals. Potentially, this could improve the diagnosis of SpA. These novel findings may substantiate the involvement of LP proteins in the pathogenesis of SpA.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Innate Immunity Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Micro RNAs (miRNAs) play a crucial role in the regulation of bone metabolism. MiR-146a, an important anti-inflammatory miRNA, was found to negatively impact osteogenesis and bone regeneration *in vitro*, by controlling the differentiation of mesenchymal stem cells. But to date the role of miR-146a in bone remodelling, its influence on bone stability and development of osteoporosis is not known.

Methods: Systemic bone, tibiae and femur, of wt and miR-146a deficient animals was assessed histologically and via μ CT analysis, over a period of 3 to 18 months of age. Serum cytokine levels were analysed by Elisa. mRNA expression levels in bone were analysed by qPCR. To induce osteoporosis, ovariectomy (OVX) induced bone loss was performed.

Results: When we analysed bone volume of long bones histologically as well as with μ CT analysis we detected significantly increased trabecular bone mass in miR-146a deficient compared to wt animals, starting at an age of 6 months. However, cortical thickness of systemic bones from miR-146a knock out animals was significantly reduced compared to control mice. Analysis of serum in aged miR-146a deficient animals displayed elevated activity of bone resorbing osteoclasts as amounts of CTX I in miR-146a^{-/-} mice were significantly increased compared to wt animals. Q-PCR analysis of important osteoclast as well as osteoblast marker genes in bones *ex vivo* displayed elevated expression of signature molecules of both cell types in aged miR-146a deficient mice, suggesting a regulatory role of miR-146a in both osteoclasts as well as osteoblasts. When we induced osteoporosis using the OVX disease model, histological analysis of long bones showed significant trabecular bone loss in ovariectomized wt mice. In contrast, we detected no trabecular bone loss in ovariectomized miR-146a knock out animals, suggesting that loss of miR-146a deficiency protects bone loss induced by estrogen deficiency.

Conclusion: MiR-146a seems to control bone turnover and miR-146a deficient mice accrue bone over time. Moreover this miRNA has a negative influence on bone loss occurring during oestrogen loss induced osteoporosis. Therefore miR-146a could be possibly used as a therapeutic target in the treatment of osteoporosis.

Autoinflammatory Diseases, Particularly SAVI and Candle, Are Driven By Chronically Active Type I Interferons

Bernadette Marrero¹, Katherine R. Calvo², Yin Liu³, Angelique Biancotto⁴, Yan Huang¹ and Raphaela Goldbach-Mansky¹, ¹Translational Autoinflammatory Disease Section (TADS), Laboratory of Clinical Investigation and Microbiology (LCIM), NIAID/NIH, Bethesda, MD, ²Department of Laboratory Medicine, Hematology Section, National Institutes of Health Clinical Center, Bethesda, MD, ³Scientific Review Branch, NIAMS/NIH, Bethesda, MD, ⁴Center for Human Immunology Autoimmunity and Inflammation (CHI), NIAID, NIH, Bethesda, MD

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Innate Immunity Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: STING Associated Vasculopathy with onset in Infancy (SAVI) is caused by gain-of-function mutations in *TMEM173*/STING and Chronic Atypical Neutrophilic Dermatitis with Lipodystrophy and Elevated Temperature (CANDLE) by loss-of-function mutations in proteasome subunits. Both are IFN-mediated disease but the origin of the IFN production has not been systematically evaluated in patients. The purpose of our study was to determine the cellular origin of IFNs, from SAVI and CANDLE patients (PTs) compared to healthy controls (HC).

Methods: We evaluated sorted PBMCs (n=5 HC, PTs) and lesional skin biopsies (n=2-3 HC, PTs) for detection of IFN production by qRT-PCR.

Results: In both diseases, pan-interferon (IFN)- α serum levels are 8 and 25-fold increased, respectively. PTs had a mean of 12-fold increase in IFN-response-gene (IRG) signatures compared to HC. SAVI pts. constitutively expressed elevated IFN-transcript levels and qPCR results showed a 450-fold and 280-fold increase in *IFNB1* [IQR 0.5-61, 60.6], and 3.5-fold and 4.4-fold increase in *IFNA17* [IQR 0-2.93, 2.93] transcription in monocytes (n=5) and dendritic cells (n=3) respectively, compared to CANDLE and HC. During disease flares but not at rest, CANDLE monocytes increased *IFNB1* production 4.6 and 184-fold and *IFNA72.5* to 110-fold (n=2). In contrast to CANDLE and HC monocytes, SAVI monocytes cannot be differentiated into macrophage and 82% \pm 14 SD died in culture within 24-hours. SAVI monocytes expressed 24-fold increase of actively cleaved caspase-1 in the supernatant from the immunoblot analysis compared to HC and did not show active form of caspase-3. ELISA demonstrated low expression of IL-1 β in the supernatant and immunofluorescence showed elevated intracellular staining of gasdermin-D and NLRP3, suggesting cell death occurs through pyroptosis.

Conclusion: The cellular sources of IFN production vary in CANDLE and SAVI; Type I IFN transcription in SAVI patients occurs mainly in monocytes and in dendritic cells, in contrast, in CANDLE patients, Type I IFNs are only expressed in monocytes prior to JAK inhibitor treatment during a disease flare (Tx). However interferon-response genes

are expressed in all cell types. Constitutively active STING from SAVI monocytes undergo rapid cell death in culture, which may indicate rapid cell turnover in the blood. Studies evaluating the mechanism that leads to monocyte death is ongoing. Understanding the signaling pathways in autoinflammatory diseases associated with high IFN signatures is important in our ability to identify and interpret biomarkers that will aid in the diagnosis and the design of targeted treatments.

A Novel IL-1 Mediated Autoinflammatory Disease Caused By a Specific Gain-of-Function Mutation in Dysferlin

Farzana Bhuyan¹, Adriana Almeida de Jesus¹, Gina A. Montealegre Sanchez¹, Deborah Consolini², Ronit Herzog³, Steven Holland⁴ and Raphaela Goldbach-Mansky¹, ¹Translational Autoinflammatory Disease Section (TADS), Laboratory of Clinical Investigation and Microbiology (LCIM), NIAID/NIH, Bethesda, MD, ²A.I.duPont Hospital for Children, Wilmington, DE, ³NYU Langone Medical Center, New York, NY, ⁴Division of Intramural Research, NIAID/NIH, Bethesda, MD

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Innate Immunity Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Genetically defined IL-1 mediated autoinflammatory diseases are caused by monogenic defects that regulate inflammasome activity. By whole exome sequencing (WES) analysis we identified one *de novo* mutation in *DYSF* encoding dysferlin, in 2 unrelated patients (pts.) with systemic inflammation and sterile pulmonary abscesses. Unlike dysferlin mutations that cause muscular dystrophies, the patients have no muscle disease. A robust clinical response to IL-1 blockade suggested a link to overproduction of IL-1. We studied monocytes and neutrophils to assess the mechanism of the IL-1 dependent inflammation. The aim of our study is to understand the role of *DYSF* on the upregulation of IL-1 production and the development of lung abscesses.

Methods: Flowcytometry, ELISA, cytokine array, survival assay and immunofluorescence techniques were used to study monocyte and neutrophil function in patients and controls.

Results: Lipopolysaccharides (LPS) and ATP-stimulated IL-1 production in monocyte and monocyte-derived macrophages (MDM) was significantly higher in the *DYSF* pts. compared to IL-1 production in NOMID pts. ($p=0.029$) and healthy controls (HC) ($p=0.038$). Dysferlin colocalizes with NLRP3 and expression of Asc, and caspase-1 were increased in the *DYSF* pts. compared to healthy controls, which is linked to higher IL-1 β production. Our data confirmed NLRP3 and Caspase-1 co-localization in patient monocytes as well. The development of sterile neutrophilic abscesses in the lung raised questions of the role of dysferlin in neutrophil activation and clearance. In contrast to MDMs, IL-1 was not upregulated in patient neutrophils, however MIF (5 fold) and IL-16 (2-3 fold) were significantly upregulated compare to HC and NOMID but not in monocytes or macrophages. Neutrophils had a higher survival rate and lower LDH release compared to healthy controls upon stimulation with LPS and ATP. Elevated MIF and IL-16 release may prevent neutrophil apoptosis and enhance persistence of sterile neutrophils in the lung. Mechanistic studies to explore these pathways are ongoing.

Conclusion: Consistent with clinical responses of IL-1 blocking treatment, our *in vitro* results confirm mutant monocytes and MDMs as the source for the high IL-1 production in two patient with a *de novo* mutation in dysferlin. Moreover, the upregulation of MIF and IL-16 in neutrophils from dysferlin patients but not NOMID patients or healthy controls and the impairment of neutrophil apoptosis may provide a mechanism to explain the development of sterile abscesses in the patients' lungs. This is the first report that links dysferlin to the regulation of the NLRP3 inflammasome and to neutrophil survival and adds to a number of intracellular pathways that control inflammasome activation and suggest novel targets for treatment.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Innate Immunity Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Both IL-23 and phosphodiesterase (PDE) 4 inhibition are ineffective in RA but show efficacy in PsA-related synovitis despite similar cytokine and molecular profiles between synovitis in both disease settings. We hypothesised that enthesitis resident innate immune cells, especially myeloid cells, might be capable of IL-23 production that could be modulated by blockade of PDE4, which controls intracellular cyclic AMP (cAMP) levels.

Methods: Human entheses (n=6) were digested and myeloid cells (CD14+) sorted from both the adjacent bone (EB) and soft tissue (ST) fractions. Both CD14+ sorted and CD14- unsorted cells were stimulated with bacterial and fungal adjuvants (TLR and CLR agonists) in the presence and absence of a PDE4 inhibitor and analysed by ELISA and flow cytometry for production of disease-relevant mediators (IL-23, TNF α , and CCL20). Corresponding peripheral blood populations were also stimulated with and without a PDE4 inhibitor and other cAMP-elevating agents to assess the role of cAMP in regulating IL-23 associated inflammation.

Results: A CD45+/CD14+ myeloid cell population could be isolated from the normal enthesitis in both the ST and EB fractions but with a much higher abundance in EB. This purified population from both ST and EB produced IL-23, TNF α and CCL20 following TLR/CLR receptor stimulation. IL-23 and TNF α production was negligible in the CD14- fraction. Moreover, IL-23 and TNF induction was inhibited by the PDE4-selective inhibitor rolipram. In blood derived myeloid cells, rolipram and other cAMP-elevating agents (histamine and 8-bromo-cAMP), also inhibited IL-23 release.

Conclusion: These findings demonstrate that the human enthesitis harbours an IL-23-producing myeloid cell population which can be modulated by cAMP elevation and PDE4 inhibition. These findings support the idea of the IL-23/17 pathway genetic architecture of SpA in the context of enthesal biology and offer a "reverse translation" explanation for divergent therapeutic pathways between SpA and RA.

Fibroblast-like Synoviocytes As Immune Effectors in the Pathogenesis of Synovial Lesion in Antibiotic-Refractory Lyme Arthritis

Klemen Strle¹, Robert Lochhead², Ruslan Sadreyev³, Allen C. Steere⁴ and John Aversa⁵, ¹Department of Immunology and Inflammatory Diseases, Massachusetts General Hospital, Harvard Medical School, BOSTON, MA, ²Center for Immunology and Inflammatory Diseases, Massachusetts General Hospital, Harvard Medical School, BOSTON, MA, ³Department of Molecular Biology, Massachusetts General Hospital, Boston, MA, ⁴Division of Rheumatology, Allergy, and Immunology, Massachusetts General Hospital, Harvard Medical School, Boston, MA, ⁵Orthopaedics and Rehabilitation, Yale Medical Group, Yale University School of Medicine, New Haven, CT

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Innate Immunity Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Antibiotic-refractory Lyme arthritis (LA) is characterized by marked proliferative synovitis that persists for months-to-years after oral and IV antibiotic therapy for *Borrelia burgdorferi*. Although the infection serves as the initial trigger for LA, the processes that shape the post-antibiotic phase of refractory LA are incompletely understood. Herein we assessed the role of fibroblast-like synoviocytes (FLS), the predominant cell type in synovial lesion, in modulating the responses to infection with highly virulent *B. burgdorferi* RST1 strain and the prototypical Th1 effector cytokine, IFN γ ; the key microbial and immune factors in antibiotic-refractory LA.

Methods: FLS were derived from synovia of antibiotic-refractory LA patients undergoing arthroscopic synovectomies. Low passage FLS were stimulated with *B. burgdorferi*, IFN γ , or a combination for 16h. After stimulation, genome-wide transcriptome profiles were assessed using RNASeq and protein levels of inflammatory mediators were measured using Luminex.

Results: FLS sense and respond to *B. burgdorferi* by upregulating the expression of 68 genes associated primarily with pathogen sensing and innate immune responses, such as TLR2, NOD2, IL-1 β , and IL-6. In contrast, stimulation with IFN γ leads to marked upregulation >2000 genes involved in pathways associated with immune dysregulation, cancer, and autoimmunity. These responses were amplified in FLS costimulated with *B. burgdorferi* and IFN γ which acted in synergistic fashion to induce a unique signature of differentially expressed genes that most closely resembled the transcriptome profiles in patients' synovial tissue, including high upregulation of antigen-presenting molecules (HLA-DR, CIITA, CD40, and PD-L1; $P < 1 \times 10^{-12}$). Moreover, cytokine and chemokine protein profiles secreted by FLS in response to costimulation, mimicked those in synovial fluid and tissue from patients with antibiotic-refractory LA, linking FLS to excessive inflammation in the joint.

Conclusion: FLS play an important role in arthritis pathogenesis by initially shaping the immune responses to *B. burgdorferi* infection, and later by perpetuating dysregulated inflammatory responses in patients with antibiotic-refractory LA by responding to inflammatory milieu in the joint. The highly-activated state of FLS, including antigen-presentation, suggests an immune effector function of these cells even in the post-infectious period. These findings help explain how the initial host-pathogen interactions such as infection with an RST1 strain in patients with a TLR1-1805GG SNP, which lead to excessive IFN γ responses, may contribute to synovial hypertrophy and dysregulated immunity in the post-antibiotic period when few if any intact spirochetes remain.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Innate Immunity Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The regenerative and immunomodulatory properties of Adipose-Derived Mesenchymal Stem Cells (ASCs) make them a potential therapeutic approach for the treatment of chronic inflammatory diseases, such as osteoarthritis and rheumatoid arthritis. However, their effect in the treatment of acute joint inflammation, where the activation mostly depends on innate immunity, remains elusive. Gouty arthritis is characterized by the deposition of monosodium urate (MSU) crystals in the joints, associated with acute flares. Frustrated phagocytosis of MSU crystals by resident leukocytes leads to NLRP3 inflammasome activation and subsequent amplification of the inflammatory response. Our aim was to study the effect of ASCs administration in the clinical inflammatory response, and the molecular mechanisms involved.

Methods: Acute gout flare was induced in 15 rabbits by intra-articular injection of MSU crystals in both knees. A single dose of 2.5×10^6 ASCs/kg was administered to 7 of these rabbits through the right femoral artery 1h after MSU injection (MSU+ASC), whereas 8 animals were not treated (MSU). This route of administration allowed to study the effect of a direct ASC administration in the right knee synovial membrane (SM) and the contralateral knee, which received the cells after their distribution through the organism. Four rabbits were used as healthy (H) controls. Inflammation was followed up measuring knee swelling and serum CRP. Animals were sacrificed 72h after MSU injections, and SM were collected for further studies.

Results: ASCs ameliorated joint swelling in both knees 24h after MSU injections, and a significant decrease in serum CRP was observed (H: 73 ± 51 ; MSU: $818 \pm 238^*$; MSU+ASCs: 270 ± 241 mg/ml*#; $p < 0.05$ *vs. H; # vs. MSU). Histopathological analysis showed that ASCs significantly diminished SM inflammation 72h after MSU injection (Krenn Score: H: 0.2 ± 0.4 ; MSU: $5.6 \pm 2.3^*$; MSU+ASC: $3.4 \pm 1.2^{* \#}$). SM vascularization was also reduced in treated animals (%CD31+ staining: H 0.5 ± 0.2 ; MSU $0.8 \pm 0.2^*$; MSU+ASC $0.6 \pm 0.2^{\#}$). ASCs treatment evoked a reduction of the inflammasome components in the SM: pro-IL1 β (H: 0.9 ± 0.2 ; MSU: $1.5 \pm 0.5^*$; MSU+ASC: $1.1 \pm 0.2^{* \#}$), pro-caspase-1 (H: 1 ± 0.6 ; MSU: $3.5 \pm 3.1^*$; MSU+ASC: $1.4 \pm 0.5^{* \#}$), NALP3 (H: 1 ± 0.3 ; MSU: $2.9 \pm 2.1^*$; MSU+ASC: $1.4 \pm 0.7^{* \#}$), and NF κ B activity was attenuated (H: 0.12 ± 0.01 ; MSU: $0.22 \pm 0.07^*$; MSU+ASC: $0.16 \pm 0.03^{* \#}$). Synthesis of pro-inflammatory cytokines COX-2 (H 0.9 ± 0.1 ; MSU $4.2 \pm 3.3^*$; MSU+ASC $2.1 \pm 1.4^{* \#}$) and TNF α (H: 0.9 ± 0.3 ; MSU: $1.3 \pm 0.3^*$; MSU+ASC: $0.9 \pm 0.2^{* \#}$) were also reduced in the MSU+ASC animals, while TGF β (H: 0.9 ± 0.2 ; MSU: $0.7 \pm 0.2^*$; MSU+ASC: $1.3 \pm 0.3^{* \#}$) and IL10 (H: 1.1 ± 0.5 ; MSU: $1.1 \pm 0.7^*$; MSU+ASC: $1.8 \pm 0.5^{* \#}$) were increased in comparison to MSU group. No differences between the direct and the indirect treatment were found, since both right and left SMs were equally damaged.

Conclusion: Our data showed that a single parenteral dose of ASCs is able to decrease the inflammatory response in an acute gouty arthritis model in rabbits by inhibiting NALP3 inflammasome activation. Therefore, this therapeutic approach may be considered for treating gouty flares, as a pharmacological alternative in patients with comorbidities that preclude conventional treatment.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Innate Immunity Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Gout is caused by the inflammation induced from the precipitation of monosodium urate (MSU) crystals in joints and is the most common inflammatory arthritis in the United States, occurring mostly in males and in up to 4% of the population. Since high levels of systemic uric acid and inflammation are both contributors to this chronic inflammatory condition, the pharmacological armamentarium includes both urate-lowering and anti-inflammatory therapeutic regimens. In adjunct to drugs to reduce inflammation, natural methods including dietary modifications and supplementation with nutraceutical compounds known to reduce inflammation have demonstrated some success in previous studies. In agreement, we have previously shown that cherry juice can reduce the incidence of flares in gout patients and significantly suppress IL-1 β secretion in vitro in human cells. The objective of this study was to establish the anti-inflammatory influence of cherry juice in a murine model of gout to create a model experimental platform to use in future work investigating the molecular mechanism suppressing inflammation.

Methods: Cherry juice concentrate was administered daily by oral gavage (240 μ L/kg) to commercially available BALB/C-Tg (NF κ B-RE-luc)-Xen mice that harbor a firefly luciferase cDNA reporter under the regulation of 3 NF κ B responsive elements. After 14 days, gouty inflammation was induced by intra-articular injection of monosodium urate (MSU) crystals

(0.5 mg) into the tibio-tarsal joint (ankle) under anesthesia. NFκB activity was measured locally in the injected ankle using the Xenogen *in vivo* imaging system (IVIS 200) and decalcified feet/ankles were paraffin-embedded and stained by H&E for histopathological analysis.

Results: Oral administration of cherry juice concentrate significantly reduced NFκB activity in mouse feet/ankles by IVIS analysis relative to control mice treated with PBS. Bioluminescent imaging signals correlating to NFκB activation and measured by total photon counts were inhibited almost 2-fold with the entire foot used as the region of interest in the analysis. Furthermore, histopathology by H&E showed a suppression of infiltrates into the space of the tibio-tarsal joint in mice receiving cherry juice concentrate when compared to PBS-treated control counterparts.

Conclusion: The results of this study demonstrate a significant inhibition of inflammation, as measured by histology and NFκB activity, in the joint space of mice injected with MSU to induce gout; thereby recapitulating the conclusions of our previous work in human cells and gout patients and establishing a viable mouse model to use in future experiments delineating the molecular mechanism of this immunosuppressive response. Near future experiments include a comprehensive analysis of proinflammatory cytokines in the serum of these mice and long-term work will include *in vitro* assays investigating the effects of cherry juice concentrate on oxidative burst and IL-1β secretion following inflammasome activation.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Innate Immunity Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Components of the innate immune system, such as High Mobility Group Box Protein 1 (HMGB1), may contribute to the initiation, perpetuation and resolution of the idiopathic inflammatory myopathies (IIMs). HMGB1 is a ubiquitous nuclear DNA-binding protein that can translocate to the cytoplasm and extracellular space, where it exerts pro-inflammatory or pro-repair effects depending on its molecular state and the surrounding cytokine milieu. Given HMGB1 undergoes rapid, passive release from necrotic cells, we postulate a key role for this protein in the aetiopathogenesis of necrotising myopathy (NM). Herein, we evaluate sarcoplasmic expression of HMGB1 in different forms of IIM and correlate it with clinical, serological and histological parameters.

Methods: Consecutive muscle sections were stained for HMGB1, CD68 (macrophages), CD45 (lymphocytes), neonatal myosin heavy chain (nMHC, regenerating myofibres) and LC3 (an autophagic protein) using immunohistochemistry. Standard H&E stains were performed to assess the degree of necrosis. Slides were independently graded by a muscle pathologist. Clinical and demographic data were prospectively collected. Dermatomyositis (DM) and polymyositis (PM) patients satisfied EULAR/ACR criteria. Inclusion Body Myositis (IBM) patients satisfied European Neuromuscular Centre Criteria. The diagnosis of necrotising myopathy (NM) was made where necrotic muscle fibres were the predominant abnormal histological feature and macrophage infiltration exceeded lymphocyte infiltration.

Results: Samples from 132 IIM patients with NM (n = 59), DM (n = 17), PM (n = 19), IBM (n = 22) and non-specific IIM (NSIIM, n = 15) were analysed, in addition to 18 control samples. Sarcoplasmic HMGB1 was significantly elevated in all IIM subtypes compared with controls (p < 0.001). Levels correlated positively with creatine kinase (Rs 0.31, p = 0.002) and physician's global assessments of disease activity (Rs 0.89, p = 0.001), negatively with manual assessments of muscle strength (MMT8, Rs -0.77, p = 0.009) and negatively with cumulative prednisolone dose (Rs -0.24, p = 0.03). Patients with NM and IBM had significantly increased sarcoplasmic HMGB1 compared with DM, PM and NSIIM. In NM patients,

HMGB1 grades were highly correlated with the degree of necrosis (R_s 0.74, $p < 0.001$) and inflammatory infiltration (CD68: R_s 0.66, $p < 0.001$; CD45: R_s 0.62, $p < 0.001$). In IBM, HMGB1 grades were highly correlated with regenerating myofibers (R_s 0.81, $p < 0.001$) and autophagic proteins (R_s 0.85, $p = 0.002$).

Conclusion: Sarcoplasmic levels of HMGB1 are significantly elevated in NM and IBM compared with other IIM subtypes. The mechanisms underpinning aberrant sarcoplasmic expression in these subtypes are likely to be distinct and may reflect differing roles for this protein in these particular subtypes. Our finding of a negative association with cumulative prednisolone exposure supports earlier work demonstrating a reduction in tissue HMGB1 with treatment. Understanding the role of HMGB1 in the pathogenesis of these complex conditions may lead to novel diagnostic paradigms and therapeutic interventions.

Gross morphology of the rat knee joint at the 9th week of MIA injection (8th week of DIA treatment). The treated groups were divided as follows: (a) MIA, (b) MIA+NPs, (c) MIA+DIA solution, (d) MIA+1%DIA/NPs, (e) MIA+5%DIA/NPs, (f) MIA+oral DIA, and (g) control. Yellow arrows indicate erosions.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Osteoarthritis and Joint Biology – Basic Science Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Osteoarthritis(OA) treatment is typically administered to control symptoms. Diacerein (DIA) reduces interleukin (IL)-1receptor on chondrocytes and prevents structural degradation of joint tissue. Direct injection of DIA into joint is preferred to increase its bioavailability and reduce systemic side effects. We investigated whether poly(d,l-lactide-co-glycolide) (PLGA)nanoparticles (NPs) could effectively deliver DIA and inhibit the inflammatory reaction.

Methods: Monosodiumiodoacetate (MIA)-induced OA rats were divided into seven groups with injection of MIA alone (group 1) and with, NPs (2), 5% DIA (3), 1% DIA/NPs (4) or 5% DIA/NPs (5), oral DIA (6), and non-treated healthy control rats (7). The mRNA expression of pro-inflammatory cytokines and derived enzymes were investigated, including interleukin (IL)-1, IL-6, tumor necrosis factor-alpha (TNF- α), matrix metalloproteinase (MMP)-3, MMP-13, cyclooxygenase (COX)-2, and a disintegrin and metalloproteinase with thrombospondin motifs (ADAMTS)-5. Macroscopic, radiographic, and histologic evaluations of the joints were done at 8 weeks of DIA treatment.

Results: In group 5, the mRNA expression of inflammatory cytokines and derived enzymes decreased gradually and significantly compared with groups 1–4. Group 3 levels of mRNA expression were decreased at 5 weeks similar to that of group 5, but increased at 9 weeks. Group 6 displayed the lowest mRNA levels of inflammatory cytokines and derived enzymes, except for IL-6, which was lowest in group 5. Macroscopic erosions were fewest in group 5, followed in order by

The mRNA expression of pro-inflammatory cytokines and derived enzymes and anti-inflammatory cytokines, (a) IL-1, (b) IL-6, (c) TNF- α , (d) MMP-3, (e) MMP-13, (f) COX-2, and (g) ADAMTS-5 in the whole blood at baseline, and at the 1st, 5th, and 9th week of MIA injection.

groups 6, 4, and 3. Micro-computed tomography revealed only slight irregularity of the joint surface and minimal erosion of articular cartilage in group 5 and 6.

Conclusion: Intra-articular injection of DIA/NPs inhibited the inflammatory reaction and progression in OA, with histologically less cartilage damage detected than induced by oral DIA. The 5% DIA/NPs dose produced significant reductions of the serum IL-6 levels compared with oral administration, and is a candidate treatment for the inhibition of inflammation and protection of the cartilage in OA.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Osteoarthritis and Joint Biology – Basic Science Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Different studies showed interesting genetic associations between mtDNA haplogroups and OA-related features, including prevalence, incidence and progression of the disease. The aim of this work is to study the influence of mtDNA variation in the degree of joint deterioration of knees from a conplastic mouse model of aging

Methods: For this purpose, mtDNAs from C57BL/6 and NZB/OlaHsd mice were used. These mtDNAs differ by 12 missense mutations, 10 non-coding-region mutations, 8 ribosomal RNA mutations and 4 transfer RNA mutations. A conplastic mice strain was developed with the C57BL/6 nuclear genome and the NZB/OlaHsd mtDNA (named BL/6^{NZB}) to compare with the original C57BL/6 strain (named BL/6^{C57}) in animals of 25 and 75 weeks (25w and 75w). A total of 38 limbs from 19 mice were processed to perform different histologic analysis: 8 BL/6^{NZB} 25w, 10 BL/6^{NZB} 75w, 10 BL/6^{C57} 25w and 10 BL/6^{C57} 75w. Appropriate non-parametric statistical procedures were applied using SPSSv24

Results: Cartilage and epiphyseal plate were the joint tissues with the most relevant findings. Mankin score data showed significantly increased values in all knees from both animal models at 75 weeks compared with 25 weeks (p<0,001), confirming the aging of the joint. When 75-week mice were selected (table 1), the BL/6^{C57} strain showed a significantly increased score in whole joint (p=0.038), medial femoral condyle (p=0,015) and femoral condyle (p=0,021) than BL/6^{NZB} strain. Safranin-O/Fast-green ratio value at 75w was higher in the medial compartment (both tibial plateau and femoral condyle) of BL/6^{NZB} compared with BL/6^{C57}; however, only the differences detected in the medial compartment of the tibial plateau reached the statistical significance (p<0,001), whilst the differences detected in the femoral condyle borderline the statistical significance (p=0,091).

The width of the epiphyseal plate was analyzed in both femur and tibia bones. The results showed significantly decreased values in BL/6^{C57} 75w compared with the same strain at 25 weeks in femoral condyle (p=0,049) and tibial plateau

Table 1. Mankin score grading of cartilage destruction in conplastic mice BL 6^{C57} and BL 6^{NZB} at 75w

	LTP	LFC	MTP	MFC	TP	FC	Med comp	Lat comp	Whole joint
BL 6 ^{C57}	5,80±1,81	4,40±1,07	4,67±2,06	6,00±1,07	10,44±3,43	10,37±1,85	10,14±3,02	10,20±2,39	19,71±4,57
BL 6 ^{NZB}	5,00±2,11	4,38±0,92	4,40±2,12	4,44±1,24*	9,40±1,78	8,71±1,70*	8,44±2,60	9,13±1,55	17,43±1,72*

LTP: lateral tibial plateau; LFC: lateral femoral condyle; MTP: medial tibial plateau; MFC: medial femoral condyle; TP: tibial plateau; FC: femoral condyle; Med comp: medial compartment; Lat comp: lateral compartment; *p<0,05 with respect to BL 6^{C57}

($p < 0.001$); however, these differences were not observed in animals belonging to BL/6^{NZB} strain. In addition, the BL/6^{C57} 75wstrain also showed significantly lower values in tibial plateau than BL/6^{NZB} strain at the same age ($p = 0.032$).

Conclusion: mtDNA variation plays an important role in the process of joint deterioration associated to age, leading to consider both mitochondria and mtDNA as potential therapeutic targets and complementary biomarker, respectively, for the age-associated phenotype of OA

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Osteoarthritis and Joint Biology – Basic Science Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Despite distinct aetiologies of joint diseases, the osteoarthritic end-stage of primary osteoarthritis (OA) and rheumatoid arthritis (RA) are described using similar radiological features. However, primary and secondary osteoarthritis may be different at the cartilage-bone unit depending on the pathogenesis. Therefore, the main purpose was to investigate the histological differences in the cartilage-bone unit of the hip joint in patients with primary OA and patients with secondary OA due to RA.

Methods: Femoral heads were obtained during arthroplasty from twelve patients with primary OA and six patients with secondary OA due to RA. The primary OA patients mean(SD) age was 62(5) years and consisted of six males and six females. The RA patients had a mean age of 63(3) years and consisted of three males and three females. The entire femoral heads were investigated, using design-based stereology methods that utilise random, systematic sampling to provide unbiased and quantitative data. The volume and thickness of the articular cartilage, calcified cartilage and subchondral bone plate were obtained. Osteophytes were, however, studied based on simple area measurements. Data were normalised if not normally distributed, and statistical significance was tested using Student's t-test.

Results:

	Units	Osteoarthritis (n = 12)	Rheumatoid arthritis (n = 6)	P-value
Femoral head Volume#	cm ³	21.8 [18.6-25.0]	20.6 [16.8-24.4]	0.60
Articular Cartilage Volume*	cm ³	2.4 [2.0-3.0]	1.3 [0.8-2.3]	0.04
Articular Cartilage Thickness#	µm	1134.1 [930.7-1337.6]	721.4 [403.3-1039.5]	0.02
Subchondral bone thickness	µm	406.2 [285.3-527.1]	408.6 [185.8-631.5]	0.98
Calcified cartilage thickness*	µm	119.3 [94.1-151.3]	56.6 [25.3-126.5]	0.01
Osteophyte area*	mm ²	70.9 [41.4-121]	49.2 [4.7-513]	0.66

*Data are presented as geometric mean and [95% confidence interval]. #Data are presented as mean and [95% confidence interval]. The results were considered significant at $P < 0.05$.

Conclusion: Patients with RA had thinner articular and calcified cartilage but were otherwise not significantly different compared with OA patients. Thus, the inflammatory joint in RA was associated with a more pronounced loss of cartilage than the degenerative joint disease in primary osteoarthritis. The increased thickness of calcified cartilage in primary osteoarthritis has been attributed to endochondral ossification, which does not seem to be the case in RA.

Effects of Three Potential Anabolic Disease-Modifying Osteoarthritis Drugs – Sprifermin, Insulin-like Growth Factor 1 and Bone Morphogenetic Protein 7 – on Matrix Production and the Phenotype of Articular Chondrocytes

Sylvia Muller, Martin Michaelis, Sven Lindemann and Anne Gigout, Merck KGaA, Darmstadt, Germany

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Osteoarthritis and Joint Biology – Basic Science Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Disease-modifying osteoarthritis drugs with an anabolic mode of action should stimulate the growth of new hyaline cartilage. For instance, recombinant human fibroblast growth factor 18 (FGF18; sprifermin) has been shown to increase cartilage volume in knee OA patients. *In vitro* studies have also shown that sprifermin stimulates proliferation and the production of hyaline cartilage matrix molecules in articular chondrocytes. Other growth factors, such as insulin-like growth factor 1 (IGF1) and bone morphogenetic protein 7 (BMP7), also exert an anabolic effect on cartilage or cartilage cells *in vitro* and *in vivo*. How these three growth factors compare with each other is unknown. The aim of this study was to differentiate the effects of sprifermin, IGF1 and BMP7 on matrix production and cell phenotype in articular chondrocytes.

Figure 1: Comparison of IGF1 and sprifermin. Biochemical analysis (GAG and HPro) and gene expression analysis (type I collagen) of the 3D constructs. The mean and standard error of the mean (SEM) are presented. Statistical analysis consists of a two-way ANOVA corrected for multiple comparison with a Dunnett test. **, *** and **** mean difference from control for the same exposure with $p < 0.01$, 0.001 or 0.0001 , respectively.

Figure 2: Comparison of BMP7 and sprifermin. Biochemical analysis (GAG and HPro) and gene expression analysis (type I collagen) of the 3D constructs. The mean and standard error of the mean (SEM) are presented. Statistical analysis consists of a two-way ANOVA corrected for multiple comparison with a Dunnett test. *** and **** mean difference from control for the same exposure with $p < 0.001$ or 0.0001 , respectively.

Methods: Primary bovine chondrocytes were cultured as 3D scaffold-free constructs for 4 weeks with sprifermin 100 ng/mL, IGF1 100 ng/mL or BMP7 300 ng/mL with permanent or cyclic exposure (24h at the beginning of each week) or left untreated (control). Two experiments were made: sprifermin versus IGF1 and sprifermin versus BMP7. At the end of the culture, the 3D constructs were harvested for biochemical (glycosaminoglycan or GAG and hydroxyproline or HPro) and gene expression analysis (N=3-4).

Results: As previously shown, cyclic exposure to sprifermin increased the GAG and HPro content of the 3D constructs while permanent exposure had a lower effect on GAG production and no effect on HPro (Figs. 1 and 2). Similarly, expression of *col2a1* (type II collagen) and *acan* (aggrecan) increased with cyclic exposure. Furthermore, sprifermin reduced *colla2* (type I collagen) expression and had no effect on hypertrophy markers. IGF1 increased extracellular matrix (ECM) production (GAG and HPro content, Fig. 1) as well as expression of *col2a1* and *acan*, but only with permanent exposure. *Colla2* expression was increased with permanent exposure. Similarly, BMP7 increased ECM production but also increased *colla2* expression (with cyclic exposure) and hypertrophy marker expression.

Conclusion: A similar stimulation of cartilage ECM molecule expression in chondrocytes was obtained with permanent exposure to IGF1, permanent or cyclic exposure to BMP7 and cyclic exposure to sprifermin. However, sprifermin was the only growth factor that both influenced the chondrocytes towards the production of hyaline cartilage and prevented two unwanted phenomena: production of fibrous cartilage (containing type I collagen) and cartilage hypertrophy.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Osteoarthritis and Joint Biology – Basic Science Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Mitochondrial dysfunction is well documented in OA and has the capacity to alter chondrocyte function and viability, contributing to cartilage degeneration. Several studies have showed that chondrocytes from OA patients have mitochondrial alterations. With this background, it is important to evaluate the influence of mitochondria in the pathogenesis of OA using an in vitro model to explain the functional consequences of this association and help us to identify potential diagnostic biomarkers and/or therapeutic targets. Trans-mitochondrial cybrids are a useful cellular model to study the mitochondrial role in the cellular behavior, since they carry different mitochondrial variants with the same nuclear background. The aim of this work is to use an *in vitro* model based in cybrids with mtDNA from healthy and OA donors and characterize them. Comparing the data with data obtained from human articular chondrocytes.

Methods: mtDNA Cybrids were developed using 143B.TK⁺Rho⁻ cell as nuclear donor, and platelets from patients N and OA. Human articular chondrocytes were obtained from patients with hip replacement. The mtDNA copy number was measured by real-time PCR method. The O₂⁻ production was evaluated using flow cytometry. The glucose oxidation assay was measured using D-[¹⁴C(U)]glucose during 4 h CO₂ trapping. The glycolytic activity was measured after addition of

glucose, oligomycin and 2-dioxyglucose using Seahorse XFp (ECAR). The OXPHOS function was evaluated by SeaHorse XFp (OCR) after addition of oligomycin, FCCP and Rotenone/Antimycin. Appropriate statistical analyses were performed with GraphPad Prism v6.

Results: mtDNA copy number showed that OA have higher levels than N in cybrids and human chondrocytes showed the same results. The analysis of O_2^- production showed that OA had higher levels than N in both types of cells. The metabolic status analyzing glucose oxidation and total glucose cellular uptake reflected higher values in OA cybrids than N cybrids. But the analysis of glycolysis showed lower values in OA than N cybrids. The analysis of OXPHOS function showed that OA had lower basal respiration and maximal respiratory capacity than N in both types of cells.

Conclusion: In this study, we showed that OA cybrids behave differently from cybrids from healthy (N) donors, while they have a similar behavior to OA and N articular chondrocytes. This information enhances our understanding of the role of mitochondria in OA and suggests that cybrids are a possible model for the study of OA pathogenesis. All these data support that N cybrids and chondrocytes use mitochondria with more efficiency.

Session Title: Osteoarthritis and Joint Biology – Basic Science Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Human Immunodeficiency Virus (HIV) infection devastates the immune system but also affects tissues and organs such as kidney, liver, central nervous system, heart and bone. Bone alterations have been observed in HIV disease for nearly two decades, in particular a higher risk of low bone mineral density (BMD) and fragility fractures. Treatment of patients with Tenofovir alone or in combination (as part of HAART), leads to further changes in bone catabolism markers and significant reductions in BMD in children and young adults. Tenofovir is taken up by cells and phosphorylated; tenofovir-phosphate inhibits HIV-reverse transcriptase by mimicking AMP. We have recently found that Tenofovir inhibits Pannexin-1/Connexin-43-mediated ATP release from cells and decreases extracellular adenosine levels and fibrosis in murine models. As adenosine and ATP are key regulators of bone homeostasis, we determined whether Tenofovir directly affects bone by an adenosine- or ATP-dependent mechanism.

Methods: M-CSF/RANKL-induced osteoclast (OC) and stimulated osteoblast (OB) differentiation were studied in primary murine bone marrow culture as the number of TRAP-positive or Alizarin Red-positive cells, respectively, after challenge with Tenofovir (1nM-100µM) alone or in combination with Dipyrindamole (1nM-100µM), an agent that increases extracellular adenosine by blocking cellular adenosine uptake. Pannexin-1 and Connexin-43 expression were permanently knocked down in RAW264.7 cells by lentiviral infection with appropriate shRNA or scrambled shRNA and these cells were induced to differentiate into OC by RANKL. OC/OB differentiation markers were study by RT-PCR, and intracellular pathways by Western Blot.

Results: Tenofovir produced a dose-dependent increase in OC differentiation (EC₅₀=44.5nM) that was reversed by Dipyrindamole (IC₅₀=0.3µM). Tenofovir increases Cathepsin K and NFATc1 mRNA levels during OC differentiation, and the effect was reversed by Dipyrindamole. When both Pannexin-1 and Connexin-43 were absent, Tenofovir did not increase OC number. Dipyrindamole reversed the effect of Tenofovir on pERK1/2, pp38 and NFκB nuclear translocation. Tenofovir inhibits OB differentiation in a dose-dependent manner (IC₅₀=0.4µM) and treatment with Dipyrindamole reversed this

effect ($EC_{50}=10nM$). Tenofovir increases RANKL mRNA expression and decreases OPG mRNA expression during OB differentiation; these effects are reversed by Dipyridamole. We have also found alterations in beta catenin signaling pathway due to Tenofovir treatment.

Conclusion: Tenofovir enhances osteoclast differentiation and inhibits osteoblast differentiation by an adenosine-dependent mechanism, a finding that suggests that treatment with agents that increase local adenosine concentrations, like Dipyridamole, might prevent bone loss due to Tenofovir treatment.

Session Date: Monday, October 22, 2018

Session Title: Osteoarthritis and Joint Biology – Basic Science Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Osteopenia and fragility fractures have been associated with HIV infection. Tenofovir, one of the most commonly used antivirals in HIV, also leads to increases in bone catabolism markers and decreased bone mineral density (BMD) in children and young adults. In murine models and human cell lines, Tenofovir inhibits ATP release and decreases extracellular adenosine levels. Adenosine, acting at its adenosine A2A and A2B receptors, inhibits osteoclast formation, and increasing local adenosine concentration with Dipyridamole, an agent that blocks adenosine cellular uptake, stimulates new bone formation as well as rhBMP-2 by an A2A receptor-dependent effect. We hypothesized that Tenofovir regulates bone resorption by diminishing endogenous adenosine levels and determined whether Dipyridamole could counteract the deleterious effects of Tenofovir on bone.

Methods: Male C57Bl/6 mice were treated as follows: IP injection of saline (control), Tenofovir 75mg/Kg/day, Dipyridamole 25mg/Kg/day, combination Tenofovir/Dipyridamole (n=10, 4 weeks). Female C57Bl/6 mice were ovariectomized and treated as follow: sham (no surgery), saline (control), Tenofovir 75mg/Kg/day, Dipyridamole 25mg/Kg/day, combination Tenofovir/Dipyridamole (n=10, 5 weeks). Weekly weight was annotated. DXA scanning was performed before sacrifice. Calcein/AlizarinRed-labelling of newly formed bone was used, and long bones were prepared for microCT/histology.

Results: Male mice treated with Tenofovir lost nearly 10% of body weight ($p<0.001$). DXA scanning showed a decrease in BMD in mice treated with Tenofovir that was reversed with Dipyridamole. microCT revealed decreased BMD and diminished trabecular bone in Tenofovir-treated mice and reversal by Dipyridamole treatment. TRAP-staining showed increased osteoclasts in Tenofovir-treated mice ($p<0.005$) an effect reversed by Dipyridamole. Similar results were obtained for Cathepsin K and CD68. RANKL-positive-cells were increased in Tenofovir-treated mice whereas OPG-positive-cells decreased, and both effects were reversed by Dipyridamole. In the case of female OVX mice, Tenofovir treatment also produced a decreased in body weight ($p<0.05$) that was reversed with Dipyridamole. DXA scanning showed decreased BMD in Tenofovir-treated mice and microCT revealed diminished trabecular bone, similar to findings in male mice. Similar results were found for Cathepsin K, CD68, RANKL and OPG-positive-cells.

Conclusion: These results suggest that treatment with agents that increase local adenosine concentrations, like Dipyridamole, might prevent bone loss following Tenofovir treatment.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Osteoarthritis and Joint Biology – Basic Science Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Osteoarthritis (OA) is the most common joint disease and a leading cause of disability. Cartilage degeneration is the central characteristic of OA, and low-grade synovitis can promote OA progression. In OA, both chondrocytes and synoviocytes undergo metabolic alterations and shift from a resting regulatory state to a highly metabolically active state. Choline kinase (ChoK) is an enzyme that catalyzes the conversion of choline to phosphocholine, which serves as a precursor for the production of phosphatidylcholine (PtdCho). PtdCho is the major phospholipid constituent of membranes and substrate for the synthesis of lipid signaling molecules such as lysophosphatidic acid (LPA) and phosphatidic acid (PA). Here, we determined whether ChoK is a key regulator of OA synoviocytes and chondrocytes phenotype.

Methods: ChoK expression in OA synovial and cartilage tissues was evaluated by immunohistochemistry (IHC). Human fibroblast-like synoviocytes (FLS), mouse macrophages (tioglycollate-elicited), human knee chondrocytes, synovial and cartilage explants were stimulated with proinflammatory mediators (IL-1b (2ng/ml), TNFa (10ng/ml) and LPS (100ng/ml)) in the presence or absence of MN58b (5mM), an inhibitor of ChoKa. Release of IL-1 β , IL-6 and MMP3 was quantified from conditioned media by ELISAs. Phosphorylation of AMPK in FLS and chondrocytes was examined by Western Blot analysis. Expression of fibrosis-related genes including collagen (COL) 1 α 1, COL2 α 1, COL10 α 1, α smooth muscle actin (α SMA) and procollagen-lysin,2-oxoglutarate 5-dioxygenase 2 (PLOD2) was quantified in FLS treated with TGFb (10ng/ml) by quantitative RT-PCR.

Results: IHC studies demonstrated that ChoK expression was upregulated in human knee OA cartilage and synovium, and in normal cartilage with aging *in situ*. In addition, ChoK activity was increased in human OA FLS, and was significantly enhanced by inflammatory mediators in synoviocytes and chondrocytes. Moreover, pharmacological inhibition of ChoK activity by MN58b significantly decreased IL-1 β -induced nitric oxide (NO) secretion from $8.3 \pm 4 \mu\text{M}$ to $0.72 \pm 0.3 \mu\text{M}$ ($p = 0.0004$, 3 donors) in OA chondrocytes, and MMP-13 release in chondrocytes and cartilage explants. At the same time, it attenuated IL-6 secretion from $31.4 \pm 4.85 \text{ ng/ml}$ to $26.6 \pm 6.3 \text{ ng/ml}$ ($p = 0.02$) in OA synovium explants. MN58b also impaired IL-1 β secretion in macrophages and synovium explants (from $0.46 \pm 0.09 \text{ ng/ml}$ to $0.015 \pm 0.009 \text{ ng/ml}$; $p = 2.64 \times 10^{-5}$, 3 donors) in response to LPS+ATP stimulation. These were associated with increased phosphorylation of AMPK in chondrocytes, FLS and in synovium explants. Furthermore, MN58b suppressed by $>50\%$ ($p < 0.05$) the expression of fibrosis related genes, COL1 α 1, COL2 α 1, COL10 α 1, α SMA and PLOD2 in OA FLS in response to TGF β 1.

Conclusion: Dysregulation of ChoK is likely involved in OA pathogenesis, and ChoK could potentially be a novel target for OA. Further translational and mechanistic studies of pharmacologic inhibition of ChoK on OA progression are warranted.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

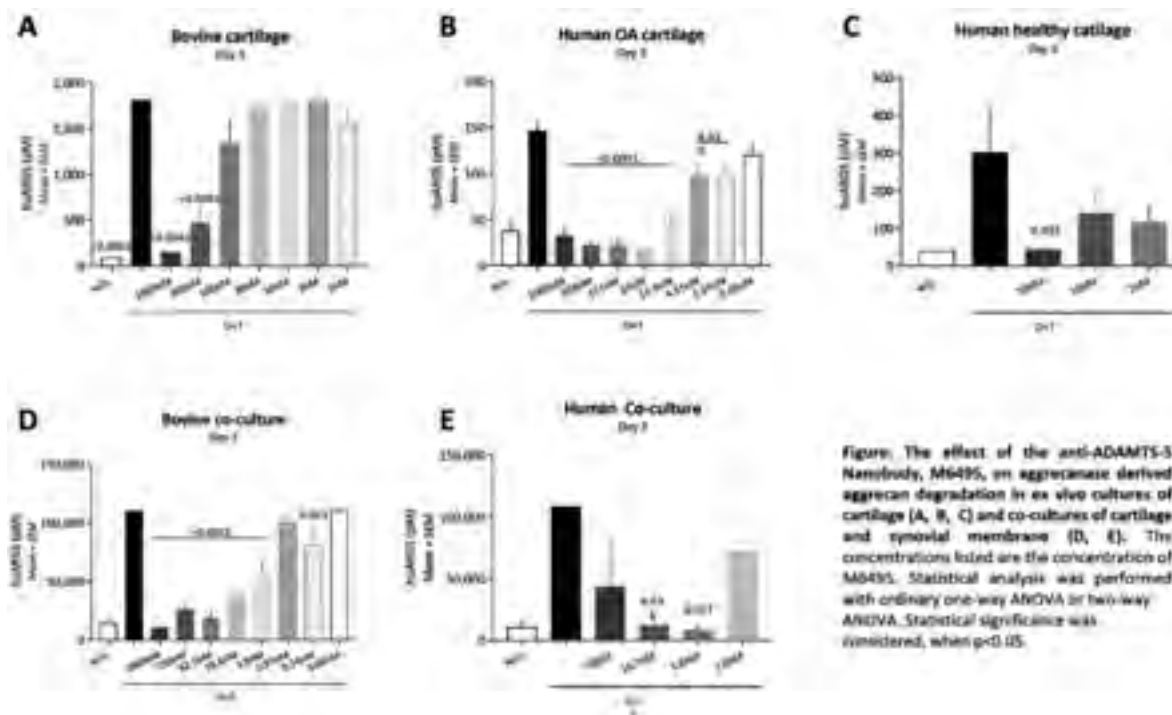

Session Title: Osteoarthritis and Joint Biology – Basic Science Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Osteoarthritis (OA) is associated with cartilage breakdown, where degradation of aggrecan by ADAMTS-5 (a disintegrin and metalloproteinase with thrombospondin motifs5) is thought to be an early event of the breakdown. Animal studies have suggested that inhibition of aggrecan degradation inhibits cartilage breakdown, whereas inhibition of the later collagen degradation has limited effect on cartilage preservation. We investigated the effect of M6495, an anti-ADAMTS-5 inhibiting Nanobody®, on cartilage turnover in explant cultures.

Methods: Bovine cartilage explants (BEX, N=4), human OA cartilage explants from replaced knee joints (HEX, N=8), and from 1 healthy human knee joint (hHEX) were cultured for 21 days in medium alone (w/o), in pro-inflammatory cytokines (on costatin M [10 ng/mL] + TNF α [20 ng/mL] (O+T)) or O+T with M6495 [1 μ M–1 nM]. Cartilage and synovium from cows (bCC) and OA human knee joints (hCC, N=4) were co-cultured for 28 days in w/o, with O+T or O+T plus M6495 [1 μ M–0.6 nM]. Metabolic activity was assessed by Alamar Blue. Cartilage tissue turnover was assessed by ELISA (huARGS, AGNxI, C2M and ProC2) in conditioned medium, which are measurement of type II collagen and aggrecan degradation and type II collagen formation. Data was analyzed by 1-way and 2-way ANOVA.

Results: Metabolic activity of BEX, HEX, and bCC was stable throughout the culture period, whereas the metabolic activity in hCC and hHEX dropped markedly from day 14 in O+T treated conditions compared to w/o. In cultures stimulated with O+T, metabolites of ADAMTS-5 degraded aggrecan peaked within the first week of the culture, except for hHEX in which huARGS and exAGNxI increased slightly later. Type II collagen degradation, C2M, by O+T peaked after day 19. Type II collagen formation, ProC2, remained relatively stable throughout the cultures, compared to the w/o control. In BEX, treatment with M6495 in combination with O+T decreased huARGS with the highest doses on day 5 (8% of O+T); in HEX (40% of O+T), bCC (10% of O+T), hCC (40% of O+T), and hHEX (24% of O+T) (Fig.). The effect of

M6495 on exAGNxl was similar to huARGS in the cultures tested. M6495 also reduced C2M (marker for type II collagen degradation) significantly, albeit the effect was less than for aggrecan degradation markers. M6495 had no effect on ProC2.

Conclusion: Here, we have shown that the Nanobody® M6495 has cartilage protective effects due to its inhibition of ADAMTS-5-mediated aggrecan degradation and MMP-mediated type II collagen degradation in pro-inflammatory conditions of bovine and human cartilage cultures and in co-cultures of cartilage and synovium.

Session Title: Osteoarthritis and Joint Biology – Basic Science Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Phenotypic changes of chondrocytes toward hyper trophy might be fundamental in the pathogenesis of OA, of which type X collagen is a well-known marker. The purpose was to develop a specific immunoassay for quantification of a newly identified neo-epitope of type X collagen to assess its diagnostic value for radiographic knee osteoarthritis (OA).

Methods: A neo-epitope of type X collagen was identified in human urine from OA patients by liquid chromatography-mass spectrometry (LC-MS/MS). A monoclonal antibody against the neo-epitope was produced. To identify the enzyme responsible for the cleavage of Col10, articular cartilage isolated from patients who underwent total knee replacement (TKR) was cleaved by numerous proteases *in vitro* and *immuno detected*. Immunohistochemical detection of this neo-epitope was performed on human OA cartilage from femoral condyle. A specific enzyme-linked immunoassay was developed by employing the neo-epitope antibody and quantified in plasma samples of two clinical studies: the C4Pain-003 and the NYU OA progression study. ROC curve analysis was carried out to evaluate the discriminative power of Col10neo between OA and RA.

Results: A mAb 2F4 targeting Cathepsin K- generated ⁴⁷⁹GIATKG neo-epitope was produced. In knee cartilage sections with mild or moderate cartilage degradation stained with Safranin O/Fast green, GIATKG neo-epitope was localized to the pericellular matrix of chondrocytes, while specimen with advanced cartilage degradation, its presence was extended to the territorial matrix of chondrocyte clusters and more prominent in superficial fibrillation. In the C4Pain study, there was a trend toward a higher level of Col10neo in subjects with greater KL. The greatest percent of subjects with KL3-4 was in the group of the highest tertile of Col10neo. In the NYU study, Col10neo was statistically higher in OA than control or RA. No significant difference was seen between control and RA (Figure 1). When adjusted for age, gender, and BMI, Col10neo remains significantly higher in OA compared to control and RA (Figure 2A). ROC curve analysis revealed area under the curve (AUC) was 0.88 (95% CI 0.81-0.94) (Figure 2B).

Fig. 1

Fig.2

Conclusion: Our findings indicate that Col10neo could be used as a diagnostic biochemical marker for knee OA.

Session Title: Osteoarthritis and Joint Biology – Basic Science Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Recent work in a subpopulation of individuals with osteoarthritis (OA) suggests that T cells are (1) responding to auto-antigenic stimuli (e.g. peptidoglycan epitopes), (2) not being effectively quieted by peripheral tolerance mechanisms, and (3) driving local inflammation. In this study, we assessed the possibility that in OA, T cells are responding to self-antigen peptides (SAP) bound more tightly to HLA by measuring OA-HLA associations and SAP-HLA binding distributions in a large community-based cohort, the Johnston County (JoCo) OA Project.

Methods: We included 1477 JoCoOA participants of European Ancestry (EA) and defined hip or knee OA as having both symptoms and a Kellgren-Lawrence grade of 2 or more in a given joint. We imputed HLA from SNP data using SNP2HLA and verified imputation accuracy using 1000 Genomes Project data. To evaluate the effect of cumulative potential SAP-HLA binding, we used NetMHC pan to predict binding of the reference peptidome to each sample HLA for coding transcripts from the top 100 genes and nonsense mediated decay (NMD) transcripts from the top 1000 genes expressed in synovium. Chi-square tests for HLA with allele frequency >2% were used to discover individual HLA

association with knee and hip OA, accounting for multiple comparisons with Bonferroni and Benjamini-Hochberg FDR adjustment. Mann-Whitney U tests were used to compare cumulative potential SAP-HLA binding distributions for participants with and without OA.

Results: HLA imputation identified 94% of 2-digit HLA types and 87% of 4-digit subtypes in the European1000 Genomes Super-Population. HLA-B*35:01 associated with knee OA from within the group of B alleles after adjustment (**Table 1**). Cumulative potential SAP-HLA binding for both protein coding transcripts and NMD transcripts also associated with knee OA (**Figure 1**).

Conclusion: An individual's HLA type affects the potential space of SAP which can bind tightly and be presented to T cells. HLA-B*35:01 was weakly associated with knee OA in the EA JoCo subset. We hypothesize that it is the cumulative propensity for highly expressed synovial peptides to bind to an individual's HLA that determines a baseline level of knee OA risk, which is then augmented by joint injury, obesity, aging, or other factors that increase local inflammation and/or expose a higher burden of synovial SAP to T cells.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Osteoarthritis and Joint Biology – Basic Science Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The most common cause of total joint replacement revision surgeries is loosening of the implant due to loss of bone around the prosthesis. Wear particles shed from the prosthesis plays a critical role by increasing local inflammation and osteoclast number and activity, ultimately causing osteolysis. We have previously reported that an A_{2A} adenosine receptor selective agonist (CGS21680, CGS) prevents osteolysis in wear particle-induced osteolysis model in mice. Frequent administration requirements and potential toxicity make it a less than optimal treatment for inflammatory osteolysis. We therefore generated and tested a novel alendronate-CGS conjugate (MRS7216) that specifically localizes to bone targeting the agonist to the site of tissue injury and thereby diminishing the frequency of administration and curtailing systemic side effects.

Methods: The conjugate was synthesized from CGS by sequential activation of the carboxylic acid moiety and reacting with the appropriate amino acid under basic conditions. A PEG₆ linker was incorporated to alendronic acid by direct coupling. Osteolysis in 6–8-week-old C57BL/6J mice was induced by surgical implantation of 3mg of ultrahigh-molecular-weight-polyethylene particles over the calvaria. Mice received a weekly 10mg/kg intraperitoneal dose of MRS7216 conjugate, starting at the time of surgery. Other groups of mice were treated with equivalent weekly doses of alendronate-PEG₆ (AlenP) or saline respectively. An additional control group underwent sham surgery. After 2 weeks, animals were sacrificed and microCT and histology analyses were performed. The studies were approved by the Institutional Animal Care and Use Committee of NYU School of Medicine.

Results: Receptor binding studies demonstrate that the K_i for CGS, 7216 conjugates and the control AlenP molecules were 21.5 nM, 69.2 nM and >10,000 nM respectively, indicating that MRS7216 efficiently binds the A_{2A} adenosine receptor. MicroCT studies showed that mice treated with weekly doses of 7216 had a significant reduction in bone damage of 40% (p=0.04) compared to saline treated mice. In contrast, AlenP molecules did not prevent bone erosion. Histological analysis of TRAP stained samples showed a significant decrease of osteoclast number/high-power field (HPF) of 55% (p=0.03) in AlenP treated mice compared to the saline treated group. The osteoclast depletion was more dramatic in MRS7216 treated group with an 81% reduction of osteoclasts number/HPF (p= 0.002). Additionally alkaline phosphatase staining in MRS7216 treated group, showed a significant increase in osteoblast number/HPF compared to saline (55%, p=0.01) and to AlenP group (45%, p=0.03).

Conclusion: Alendronate-CGS conjugates represent a novel therapeutic approach to prevent osteolysis and prosthetic failure in patients with prosthetic joints.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Osteoarthritis and Joint Biology – Basic Science Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: We evaluated the inflammatory effect of Coll2-1 peptide in osteoarthritic synoviocytes and rats by comparing peptide-induced inflammatory reaction with the one induced by bovine type II collagen or streptococcal cell wall.

Methods: Human synoviocytes from knee OA patients (n=10) were pre-treated with AS0619 or CLI-095 (500nM, 1 and 2.5μM) before a 24 hours treatment with Coll2-1 peptide (¹⁰⁸HRGYPGLDG¹¹⁶; 0.45 or 4.5nmol). Expression of Interleukin (IL)-8, Vascular Endothelium Growth Factor (VEGF) and phosphorylation of the IκB-α and p65 were evaluated. Either Coll2-1 peptide, bovine type II collagen (CIA), streptococcal cell wall (SCW) or saline solution (100μl SC or 50μl IA) were injected into Lewis rats (n = 108). The Coll2-1 peptide was injected subcutaneously (SC; 20 and 200μg/100μl/animal) or intra-articular (IA; 0.5 and 5μg/50μl/animal). The bovine type II collagen was SC injected (200μg/100μl/animal), streptococcal cell wall in IA (5μg/50μl/animal). The animals were injected on day 10 and monitored for 21 or 28 days. Visual evaluation of the severity of arthritis and histological lesions were performed.

Results: Coll2-1 at 0.45 nmol (**P<0.01) and 4.5 nmol (*P<0.05) significantly increased IL-8 gene expression and tended to increase VEGF expression by synoviocytes. With AS0619, a specific antiserum for Coll2-1 peptide, IL-8 expression significantly decreased (*P<0.05). Coll2-1 also induced both translocation of p65 and IκBα degradation. The latter being reduced with oxidative stress inhibitors. With CLI-095, we observed a decrease of IL-8 expression. *In vivo*, bovine type II collagen injection and Coll2-1 peptide injection resulted in an increase in visual arthritis score from D7. The global histological score was also increased by bovine type II collagen on D21 (p=0.0005) and on D28 (p<0.0001) and by the peptide Coll2-1 on D21 at the concentration of 200μg (p=0.0252) and on D28 at the concentration of 20μg (p=0.0025). Compared to control, all the components of the histological score were similarly modified by bovine type II collagen and the peptide Coll2-1 at both on D21 and on D28: increase in the inflammatory parameter (D21 200μg p=0.0217 and D28 20μg p=0.0021), reduction of proteoglycan contents (D28 200μg p=0.0072 and 20μg p=0.0024), increased cartilage degradation (J28 200μg p=0.0070 and 20μg p=0.0024) and modification of the subchondral bone (D21 200μg p=0.0025 and D28 20μg p=0.0065). Similarly, both the injection of SCW and that of Coll2-1 peptide induced an increase in the visual score from D10. The effect of Coll2-1 peptide on this score was identical to that of the SCW. Compared to control, SCW and Coll2-1 peptide increased the global histological score (D21 p=0.0119 and D28 p=0.0045). Like SCW, the injection of Coll2-1 peptide caused both inflammatory reaction, loss of proteoglycan, appearance of cartilage structural lesions (D28 0.5μg p=0.0201) and subchondral bone modification.

Conclusion: Coll2-1 peptide is able to induce an inflammatory reaction and structural changes. Coll2-1 may initiate nonspecific natural immunity and therefore be a therapeutic target for biotherapy.

Distinct Balance of TNF-α/IL-10 in Circulating and Infiltrating CD163+ Macrophages between Rapidly and Slowly Progressive Symptomatic Knee Osteoarthritis

Li Wang, Wenmin Wang, Hui Chu, Xifu Shang and Xiaomei Li, Department of Rheumatology and Immunology, The First Affiliated Hospital of USTC, Division of Life Sciences and Medicine, University of Science and Technology of China, Hefei, China

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Osteoarthritis and Joint Biology – Basic Science Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: There is a subtype of osteoarthritis (OA), which shows higher level of inflammation and higher risk of disease progression. In the current study, we analyzed the TNF- α and IL-10 level in circulating and infiltrating macrophages, and correlation of CRP and BMI between rapidly and slowly progressive patients.

Methods: We categorized 41 patients (32 female and 9 male) with symptomatic knee osteoarthritis for primary total knee arthroplasty (TKA) into rapidly progressive group (ROA, n=20) and slowly progressive group (SOA, n=22), based on disease duration less than 5 years, or more than 5 years. The average disease duration of ROA was 3.3 ± 2.105 years, and the SOA was 12 ± 5.385 years. 5 patients (3 female and 2 male) with knee joint fracture fixation were selected as control (FX). Circulating macrophages were separated from patients' peripheral blood. Infiltrating macrophages were separated from knee synovial tissue from TKA. The expression of IL-10 and TNF- α in the CD163+ macrophages in the synovial membrane and peripheral blood were detected by flow cytometry. The difference of the correlation of CRP and BMI between the ROA and the SOA were analyzed.

Results: ROA patients showed significantly increased CD163+ macrophages in peripheral blood (ROA $12.53 \pm 4.56\%$, SOA $3.59 \pm 3.92\%$, FX $0.52 \pm 0.57\%$, $p < 0.05$), and even more in synovium (ROA $41.06 \pm 10.02\%$, SOA $20.06 \pm 3.96\%$, FX $0.594 \pm 0.50\%$, $p < 0.05$). CD16+ macrophages from ROA patients showed trends to TNF- α in both peripheral blood (ROA *VS* SOA: $42.32 \pm 6.91\%$ *VS* 26.01 ± 5.28 , $p < 0.05$), and synovium (ROA *VS* SOA: $36.6 \pm 5.7\%$ *VS* $23.33 \pm 4.14\%$, $p < 0.05$). However, CD16+ macrophages from SOA patients showed advantage in IL-10 (peripheral blood ROA *VS* SOA: $2.11 \pm 2.17\%$ *VS* $4.71 \pm 3.46\%$, $p < 0.05$; synovium ROA *VS* SOA $1.96 \pm 1.44\%$ *VS* $3.80 \pm 2.33\%$, $p < 0.05$). In ROA group, CRP was positively correlated with BMI ($r = 0.680$, $P < 0.05$); but in SOA group, CRP was not related to BMI.

Conclusion: Both circulating and infiltrating macrophages from patients with ROA and SOA display distinct inflammatory characters.

Signaling at Adenosine A2A Receptor (A2aR) in Osteoblasts; Crosstalk with Wnt/ β -Catenin Signaling Pathway

Soheila Borhani¹, Carmen Corciulo², Ane Larrañaga Vera³ and Bruce N. Cronstein⁴, ¹Medicine, Division of Translational Medicine, New York University School of Medicine, New York, NY, ²Department of Medicine, Division of Rheumatology, New York University School of Medicine, New York, NY, ³Medicine, New York University School of Medicine, New York, NY, ⁴Rheumatology, New York University School of Medicine, Division of Rheumatology, New York, NY

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Osteoarthritis and Joint Biology – Basic Science Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The Wnt/ β -catenin signaling pathway plays a key role in regulating bone formation and maintaining bone hemostasis. Wnt activates a pathway that leads to stabilization of β -catenin and its translocation to the nucleus. Osteoblast differentiation and proliferation are also regulated by adenosine receptors, among other signals. We recently reported that A2aR signaling promotes Wnt/ β -catenin signaling in fibroblasts via activation of Akt and p38MAPK. In the present study we sought to determine whether there is a similar interaction between these pathways in osteoblasts.

Methods: We studied murine osteoblast cell line (MC3T3-E1) and primary osteoblasts derived from bone marrow-derived mesenchymal stem cells of mice. The cells were treated with CGS21680, a selective A2aR agonist, at doses ranging from 0 to $10 \mu\text{M}$, and for varying incubation periods up to 240 minutes. Levels of phosphorylated β -catenin at Ser552 (p-Ser552), a β -catenin isoform with enhanced transcriptional activity, were measured by Western Blot assays before and after A2aR activation. We also analyzed nuclear translocation of p-Ser552 β -catenin in the osteoblastoid cell line and primary cell cultures using immunofluorescence (IF) staining. Cellular levels of activated AKT were measured by immunoblotting assays before and following administration of CGS21680.

Results: We observed a significant increase in p-Ser552 β -catenin levels in the osteoblastoid cells treated with $1 \mu\text{M}$ CGS21680 compared to the control, starting at 15 minutes following A2aR activation ($253 \pm 122\%$, $p < 0.05$, $n = 5$). Western blot analysis showed a significant increase in nuclear translocation of p-Ser552 β -catenin at 15 minutes after treatment with A2aR agonist in MC3T3-E1 cells ($153 \pm 37\%$, $p < 0.05$, $n = 4$), and primary osteoblasts ($148 \pm 31\%$, $p < 0.05$, $n = 4$). Similarly, immunofluorescence revealed approximately a 40% increase in nuclear accumulation of p-Ser552 β -catenin in CGS21680-

treated MC3T3-E1 cells as well as in primary osteoblasts. We also found a significant increase in the levels of phosphorylated AKT at Ser473 among osteoblastoid cells following A2aR stimulation ($203 \pm 47\%$, $p < 0.05$, $n = 4$).

Conclusion: These findings demonstrate cross-talk between A2aR and Wnt/ β -catenin signaling pathways in osteoblasts. Moreover, our results suggest that A2aR activation can bypass blockade of Wnt ligands at the cell surface and thereby maintain bone homeostasis.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Osteoarthritis and Joint Biology – Basic Science Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Disease-modifying treatments for Osteoarthritis (OA) are not available. Aging-related features such as failure of homeostasis mechanisms, including autophagy, cause extracellular matrix damage, chondrocyte senescence and death, which leads to articular cartilage degeneration and joint dysfunction. *The objective of this study was to identify Senolytic and Pro-Autophagy molecules to prevent cartilage degeneration and OA.*

Methods: Cellular senescence and defective autophagy was induced in immortalized human chondrocytes (T/C28-a2) with IL-6, a SASP factor, at 20ng/ml for 72 or 18 hours, respectively. Then, chondrocytes were incubated with Prestwick Chemical Library at 10 μ M for 72 hours. To identify senolytics, SA- β -gal activity was determined by Imagene Green C12FDG substrate reporter. To identify molecules activating autophagy flux, pBABE-mCherry-EGFP-LC3 reporter was used to generate stable expression in chondrocytes by retrovirus transfection. Imaging was done by using Operetta® High Content Screening system. Confirmatory assays with readouts for senescence, autophagy, inflammation and apoptosis were performed in primary human chondrocytes. The anabolic effect was evaluated by Safranin O staining and Nitric Oxide production in human cartilage. To establish the senomorphic or senolytic nature of the candidate, senescent cells and total cells were counted with Cell Analyzer 6000 Confocal Imaging System. Navitoclax 2,5 μ M and Rapamycin 10 μ M were used as controls for senolytic and senomorphic activity, respectively. The functional consequence of treatment with the candidate was evaluated in blood, chondrocytes and cartilage from non-OA and knee OA patients.

Results: Primary screen yielded 279 senolytic compounds. Secondary screen identified 37 compounds with both senolytic and pro-autophagy activity. Fenofibrate (FN), a PPAR α agonist approved for dyslipidemia was selected as candidate. FN reduced senescence ($p < 0.001$) and increased autophagic flux ($p < 0.0001$), protecting against defective autophagy and inflammation in response to IL-6 and IL-1 β . This protection was confirmed in articular cartilage explants by a reduction of proteoglycans loss ($p < 0.05$) and in primary human chondrocytes by a reduction of NO production and death by apoptosis ($p < 0.0001$). Moreover, a senolytic effect was observed in human chondrocytes ($p < 0.05$) by selective reduction the number of senescent cells by apoptosis. Furthermore, FN upregulated PPAR α target genes and FoxO1 expression. These effects were also observed for structurally distinct PPAR α agonists, suggesting that pharmacological modulation of PPAR α may provide therapeutic benefits in OA. Remarkably, PPAR α expression was reduced in blood and cartilage from knee OA patients.

Conclusion: Our cell-based imaging assay provides a unique opportunity to identify novel drugs and mechanisms to prevent cartilage pathology. Dual senolytic and pro-autophagy effects may provide benefits in cartilage degeneration associated to aging and inflammation. A positive outcome of ongoing efficacy studies focused on PPAR α might provide the basis to propose proof-of-concept studies in patients with OA.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Osteoarthritis and Joint Biology – Basic Science Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Osteoarthritis (OA) is a rheumatic disease characterized by articular cartilage degradation. On its early stages, OA is asymptomatic and its current gold-standard diagnosis (X-Rays), focused on changes on the adjacent tissue – bone – presents a limitation to the early diagnosis of this disease. Raman spectroscopy (RS) has been recently described as a non-invasive tool to detect molecular changes in biological tissues, producing a unique fingerprint. For this reason, its application for the diagnosis of different diseases offers high potential. Beyond its clinical application, RS offers

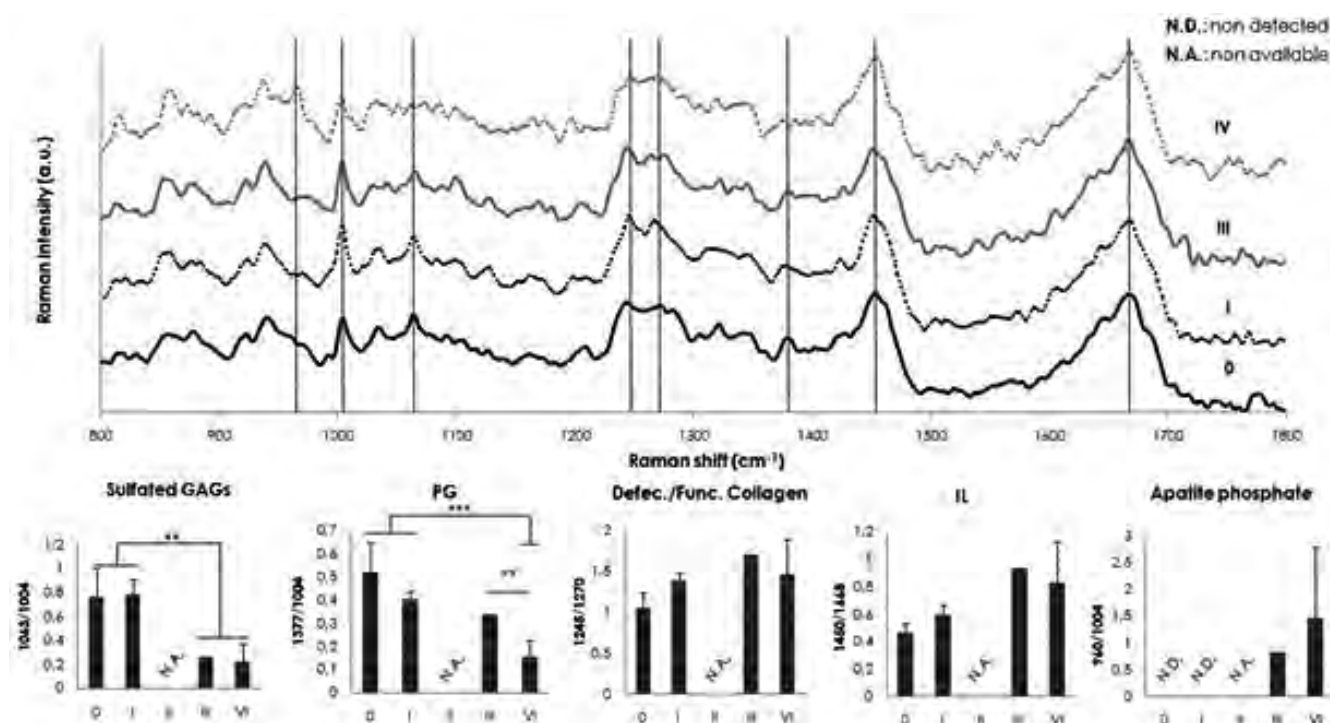

Fig.1. A. Raman spectra for H and OA cartilage (K-L: 0 to IV) and assigned peaks. **B.** Quantitative analysis of the main components found: glycosaminoglycans (GAGs), proteoglycans (PG), Defective/Functional Collagen, lipid index (LI) and phosphate apatite. Significant differences are represented as **p<0.01 or ***p<0.001.

value as a molecular quantification technique for tissue engineered cartilage characterization. The aim of this work was to evaluate the potential of RS for the early diagnosis of OA.

Methods: Human hip cartilage explants (n=14), from healthy (H) and OA donors, with Kellgren-Lawrence (K-L) radiological grades from 0 to IV, were obtained after informed consent. Raman analysis was performed on fresh tissue, using a Bruker RFS100 Spectrometer with a Nd:YAG laser ($\lambda=1064$). Main peaks were assigned according to literature³, following their area's measurement after a normalization process. One-way ANOVA statistical analysis was performed and differences considered significant for $p<0.05$. We further analyzed correlations (Pearson's coefficient) between peaks and K-L grade.

Results: RS cartilage spectra (Fig.1A) revealed the following assignments: 1245-1270 cm^{-1} amide III doublet (random coil and α -helix collagen), 1063 cm^{-1} (sulfated glycosaminoglycans, GAGs), 1377 cm^{-1} (proteoglycans, PG), 1450 cm^{-1} (nonspecific signal of lipids and proteins) and 1668 cm^{-1} (carbonyl group in proteins). For higher K-L grades, a peak appeared at 960 cm^{-1} (apatite phosphate), related to tissue mineralization. After quantitative analysis (Fig.1B) we observed the main molecular changes: GAGs and PG peaks showed a significant decrease with OA severity ($p<0.01$), supported by high correlation coefficients ($R^2=0.7361$ and $R^2=0.7999$, respectively), related to GAGs' degradation; an increase in 1245/1270 ratio (defective/functional collagen) could reveal collagen arrangement loss, although there was a low correlation vs K-L ($R^2=0.3764$); an indirect lipid index (IL), calculated as A1450/A1668, showed an increase of lipids in OA tissues.

Conclusion: RS analysis revealed a hip cartilage molecular fingerprint. Variations found between H and OA tissue are representative of the molecular changes during OA progression. A set of parameters is suggested as an optical biomarker panel: defective/functional collagen (1245-1270 cm^{-1}), GAGs (1063 cm^{-1}), PG (1377 cm^{-1}) and IL (1450/1668).

Pharmacokinetic and pharmacodynamic modelling of the novel anti-ADAMTS-5 nanobody M6495 using the neo-epitope ARGS as a biomarker

Joao Pereira¹, Ingrid Ottevaere², Benedikte Serruys², Eline Dejonckheere², Anne C. Bay-Jensen³, Anne Sofie Siebuhr⁴, Samer El Bawab¹, Christoph Ladel¹ and Sven Lindemann¹, ¹Merck KGaA, Darmstadt, Germany, ²Ablynx NV, Zwijnaarde, Belgium, ³Nordic Bioscience, Herlev, Denmark, ⁴Biomarkers and Research, Nordic Bioscience, Herlev, Denmark

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Osteoarthritis and Joint Biology – Basic Science Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The anti-ADAMTS-5 Nanobody®, M6495, is a first-in-class, highly selective, bifunctional Nanobody® and apotent inhibitor of ADAMTS-5, with the potential to be the first self-administered disease modifying osteoarthritis drug (DMOAD). A model-based approach was used to explore the relationship between plasma concentrations of M6495

Pharmacokinetics and Pharmacodynamics of M6495 after a single dose (mg/kg) in cynomolgus monkeys

and the reduction of serum concentrations of the target engagement biomarker, the ADAMTS-5 generated neo-epitope of aggrecan (ARGS), in cynomolgus monkeys.

Methods: A dedicated single dose pharmacokinetics and pharmacodynamics (PK/PD) study was conducted in cynomolgus monkeys receiving subcutaneous (SC) M6495 at doses ranging from 0.01 to 6 mg/kg or vehicle. An additional group received intravenous M6495 which allowed the estimation of bioavailability. Both M6495 and ARGS concentrations were measured over time. The data were then pooled with PK/PD data collected in a separate multiple-dose study in cynomolgus monkeys that received weekly M6495 at doses up to 150 mg/kg. Plasma concentrations of M6495 and decrease in ARGS serum concentrations upon drug administration were modelled with a non-linear mixed effects PK/PD model.

Results: A 2-compartment model including linear and non-linear elimination from the central compartment and first order absorption upon SC administration, adequately described the drug concentration-time profiles of M6495. The non-linear PK indicated a mechanism of target-mediated drug disposition which can be saturated at higher serum concentrations of M6495. ARGS levels decreased upon drug administration, with higher decrease demonstrable at higher doses (see Figure), reaching levels below the lower limit of quantification (LLOQ) for M6495 doses of 6 mg/kg and higher, indicating a strong inhibition of ADAMTS-5 (higher than 70%). Furthermore, the bioavailability after SC injection was estimated to be close to 100%. A marked decrease in serum ARGS levels, lasting several weeks, could already be observed after a single dose of M6495. The decrease in ARGS serum concentrations was delayed in relation to the exposure, and could be described with an indirect response model.

Conclusion: A single injection of the anti-ADAMTS-5 Nanobody®, M6495, in cynomolgus monkeys lead to a long-lasting decrease in ARGS at the highest dose tested, indicating a long-term inhibition of ADAMTS-5. This PK/PD model can be used to explore the exposure/pharmacodynamic response relationship between M6495 serum concentrations and the ARGS serum biomarker.

Hoxd Genes Regulate Arthritis-Relevant Pathways

Kerstin Klein¹, Mojca Frank Bertoncelj¹, Monika Krošelj¹, Matija Tomšič², Christoph Kolling³, Oliver Distler⁴ and Caroline Ospelt¹, ¹Center of Experimental Rheumatology, Department of Rheumatology, University Hospital Zurich, Zurich, Switzerland, ²University Medical Centre Ljubljana, Department of Rheumatology, Ljubljana, Slovenia, ³Upper Extremity Dept., Schulthess Clinic Zurich, Zurich, Switzerland, ⁴Department of Rheumatology, University Hospital Zurich, Zurich, Switzerland

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Osteoarthritis and Joint Biology – Basic Science Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Gene expression and functions of synovial fibroblasts (SF) differ profoundly between distinct joints. This might lead to site-specific activation of arthritis-relevant pathways with implications for arthritis pathogenesis and drug targeting¹. Homeobox (HOX) transcription factors guide the proper morphogenesis of limb structural elements and appear to influence site-specific development of various diseases. Here we analyzed the expression and epigenetic regulation of HOXD genes in SF from different joints of the hand and identified their target genes and functional effects.

Methods: The expression of HOXD in SF was analyzed by RNA sequencing (n=21), quantitative Real-time PCR (qPCR; n=14) and Western blotting (n=10). The histone marks H3K4me1 (enhancers), H3K4me3 (promoters), H3K27me3 (repressed chromatin) and H3K27ac (active chromatin) were analyzed by Chromatin Immuno precipitation DNA sequencing (ChIPseq) in SF from one RA (finger II) and one osteoarthritis (OA; thumb) patient. HOXD10, HOXD11 and HOXD13 were silenced using antisense LNATM GapmeRs in finger II-IV SF (n=4). The expression of potential target genes was analyzed by qPCR in joints of the hand (n=7). Growth of transfected SF (n=3) was analyzed using an impedance-based system (xCELLigence).

Results: Among the genes in the HOX cluster, HOXD10, HOXD11 and HOXD13 transcripts and proteins were significantly increased in SF in digits II-IV (MCP, PIP) and wrists compared to SF from the thumb (CM I, MP I). This signature was independent of disease and recapitulated the embryonic HOXD expression pattern in the developing hand. ChIPseq showed an increase of H3K27ac and H3K4me3 marks in the genomic region between HOXD9 and HOXD13 in

SF from an RA finger II compared to SF from an OA thumb. This was paralleled by a loss of the repressive histone mark H3K27me3 in this region in RA finger II. Similar to the low expression of HOXD10-13 in thumbs, the expression of thrombospondin 2 (THBS2; $p<0.05$), receptor tyrosine kinase like orphan receptor 2 (ROR2; $p<0.05$), collagen type XI alpha 1 chain (COL11A1; $p<0.01$) and ATP binding cassette subfamily C member 9 (ABCC9; $p<0.05$) was decreased in joints of the thumb compared to joints of digits II-IV as measured by RNAseq and qPCR. Accordingly, silencing of HOXD13 decreased the expression of THBS2 ($p<0.001$), ROR2 ($p<0.001$) and COL11A1 ($p<0.01$), whereas ABCC9 ($p<0.01$) was decreased by silencing of HOXD10 ($p<0.01$) and HOXD13 ($p<0.01$). Silencing of HOXD13 but not HOXD10 and HOXD11 reduced the proliferation of SF by 83,7% ($p<0.01$).

Conclusion: HOXD10-13 exhibit an epigenetically regulated, increased expression in fingers II-IV compared to thumb that determines the site-specific signature of downstream target genes and the proliferative capacity of SF. This might influence the differential activation of arthritis-relevant pathways and patterns of OA and RA in the small joints of the fingers II-IV versus the thumb.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Osteoarthritis and Joint Biology – Basic Science Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Proinflammatory cytokines play an important role in bone destruction in rheumatoid arthritis (RA), as inferred by the efficacy of biologics. Previously, we reported that novel osteoclast-like cells (OLCs) were induced, both *in vitro* and *in vivo*, from mouse bone marrow-derived macrophages by a combination of TNF α and IL-6 (Yokota K *et al.*, *Arthritis Rheumatol* 2014, 66:121-129). Herein, we aimed to examine the differentiation of OLCs, which were induced by a combination of TNF α and IL-6 from human peripheral blood mononuclear cells (PBMCs) and CD14⁺ monocytes and to identify differences in molecular expression patterns between OLCs and conventional osteoclasts. Furthermore, we identified OLCs and osteoclasts on the bone tissue of the joint in patients with RA.

Methods: PBMCs and CD14⁺ monocytes from healthy volunteers and/or RA patients were stimulated with TNF α and IL-6 or RANKL. Quantitative RT-PCR was used to measure mRNA expression levels of osteoclastogenesis-related genes. Prepared undecalcified tibial bone from 6 RA or osteoarthritis (OA) patients undergoing joint surgery were stained by tartrate-resistant acid phosphatase (TRAP) staining and immunohistochemistry with anti-RANK antibody, expression of which were analyzed. Osteoclasts and OLCs were identified as multinucleated TRAP⁺/RANK⁺ cells and TRAP⁺/RANK⁻ cells, respectively, adherent to the bone surface.

Results: The number of osteoclasts treated with RANKL and OLCs treated with a combination of TNF α and IL-6 from PBMCs or CD14⁺ monocytes in RA patients was significantly increased compared to that in healthy volunteers. Expression levels of *TRAP* mRNA was clearly up-regulated in osteoclasts and OLCs compared to that in osteoclast precursors. On the other hand, expression levels of *RANK* mRNA was obviously up-regulated in osteoclasts, and was down-regulated in OLCs. In cancellous bone, the number of TRAP⁺/RANK⁺ osteoclasts and TRAP⁺/RANK⁻ OLCs was significantly increased in RA patients compared to that in OA patients. Interestingly, numerous TRAP⁺/RANK⁻ OLCs were present in the cancellous bone of RA patients, while almost none were observed in the cancellous bone of OA patients.

Conclusion: The combination of TNF α and IL-6 strongly induced the differentiation of OLCs from PBMCs or CD14⁺ monocytes in RA patients. OLCs was characterized with TRAP⁺/RANK⁻ multinucleated cells, which can be distinguished from conventional TRAP⁺/RANK⁺ multinucleated osteoclasts. TRAP⁺/RANK⁻ OLCs also were present in the bone tissue of RA patients. These results suggest that conventional osteoclasts and novel OLCs could be involved in the pathogenic mechanisms of inflammatory bone destruction such as RA.

Noss³, ¹Medicine, Division of Rheumatology, University of Washington, Seattle, WA, ²Benaroya Research Institute at Virginia Mason, Seattle, WA, ³Rheumatology, University of Washington, Seattle, WA, ⁴Orthopedics, Virginia Mason Hospital, Seattle, WA

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Osteoarthritis and Joint Biology – Basic Science Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Synovial membrane inflammation is common in osteoarthritis (OA). Inflammation may be present at all disease stages, increases the risk of cartilage injury, and is heterogeneous histologically, with variable synovial hyperplasia, inflammatory infiltrates, and angiogenesis. Our objective in this study was to develop an approach to characterize this variability in inflammation using flow cytometry and multiplex assays. We focused particularly on IL-6, as this inflammatory cytokine independently associates with poor OA outcomes.

Methods: Cell composition and soluble protein release was measured in synovium collected from thirty-five knee OA patients undergoing joint replacement surgery. Correlation-based clustering identified patient-specific inflammatory networks.

Results: We first measured release of thirteen inflammatory cytokines and adipokines by intact synovium. These proteins separated into at least two expression groups: (1) strong correlation between IL-6 and IL-8, linked through IL-8 to correlations with adipsin, CCL2, CXCL10, and adiponectin (potential fibroblast/macrophage pattern); and (2) correlations between IL-10, IFN- γ , resistin, TNF α and IL-1 β (potential T cell pattern). We next enzymatically disaggregated synovium and found that identifying mesenchymal and hematopoietic cell populations required different digestion conditions. Collagenase with higher dispase concentrations markedly improved total cell yield and mesenchymal marker staining. However, it negatively impacted T and natural killer (NK) cell staining. Intracellular IL-6 expression was detected in many cells, but was highest in mesenchymal cells, especially those expressing both CD90 and CD34. IL-6⁺ synovial cell numbers correlated strongly with IL-6 tissue release, validating our flow cytometry assay. IL-6 release did not correlate with leptin or body mass index, suggesting adipocytes produce little IL-6. OA synovial T cell infiltration was highly variable, with increased percentage of T cells correlating with CD8⁺ cytotoxic T cell influx. CD8⁺ T cells showed variable CD45RA and CD45RO expression and their presence correlated positively the soluble T cell pattern above. Finally, combining flow cytometric and multiplex data identified at least five possible OA synovial inflammation patterns, expanding on the networks identified by soluble protein analysis alone.

Conclusion: We have developed a novel approach to analyze OA inflammation that has identified patient-specific inflammatory clusters, including an unexpected involvement of CD8⁺ T cells. This study argues that identifying synovial inflammatory will provide new insights into OA patient heterogeneity and biomarker development.

Study of the Metabolic Effect of MSCs on Their Chondroprotective and Regenerative Properties: Modulating Their Metabolism to Improve Their Therapeutic Potential for the Treatment of Osteoarthritis

Luna Martinez-Viola¹, Patricia Luz-Crawford² and Rafael A. Contreras², ¹Laboratorio de Inmunología Celular y Molecular, Universidad de Los Andes, Santiago, Chile, ²Immunology, Universidad de Los Andes, Santiago, Chile

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Osteoarthritis and Joint Biology – Basic Science Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Mesenchymal Stem Cells (MSCs) are stromal multipotent cells with wide regenerative and immunomodulatory properties and have been proposed as a powerful therapeutic tool. Among the mechanisms associated with their regenerative potential are their ability to differentiate into several cell lineages, as well as the production of paracrine factors, which promote the survival and proliferation of cells in damaged tissues. On the other hand, their ability to regulate the immune response, allows them to inhibit the inflammation associated with tissue damage, promoting efficient and coordinated tissue regeneration. More recently, it has been described that some biological functions of MSCs, such as their differentiation potential are regulated by their metabolic activity, suggesting that changes in their metabolic state could also be regulating their therapeutic potential. For example, for chondrogenesis, cells need maintain a glycolytic-dependent metabolism during their differentiation process². Therefore, the hypothesis of the present study is that the induction of a glycolytic state on MSCs will promote their chondrogenic differentiation, as well as their chondroprotective and immunosuppressive properties.

²Pattappa, G., Heywood, H.K, de Bruijn, J. D., & Lee, D. A. (2011) The metabolism of human mesenchymal stem cells during proliferation and differentiation. *Journal of Cellular Physiology*, 226(10), 2562-2570. <https://doi.org/10.1002/jcp.22605>

Methods: MSCs were pretreated with either an inhibitor of glycolysis or mitochondrial metabolism during 24 hours. After that, cells were cultured in presence of a chondrogenic differentiation media. Chondrogenesis was evaluated by staining with safranin O and qRT-PCR for the chondrogenic genes aggrecan and collagen II. Separately, pretreated MSCs were co-cultured with chondrocytes (HC-a) and HC-a proliferation was measured with WST1 kit assay. Statistical analysis was performed with the Kruskal-Wallis test for the comparison of medians and Mann-Whitney as a post-hoc test.

Results: MSCs pretreated with an inhibitor of mitochondrial metabolism (glycolytic-MSCs), have a higher level of expression of chondrogenic genes after 11 days of differentiation compared to control MSCs. Moreover, MSCs pretreated with a glycolysis inhibitor (OXPHOS-MSCs) significantly reduced their chondrogenic potential. Interestingly, it was observed that glycolytic-MSCs were able to differentiate into chondrocytes without the need of differentiation medium. Additionally, glycolytic-MSCs significantly increase the proliferation of HC-a when they are incubated in co-culture without cell contact.

Conclusion: The inhibition of mitochondrial metabolism was able to induce chondrogenesis without the needed of a specific differentiation media. Our results suggest that the potentiation of a glycolytic state on MSCs to favor the proliferation of chondrocytes is associated to a mechanism dependent of soluble factors. These results present a new method to increase the therapeutic effect of MSCs in osteoarthritis, where the etiology of the disease is associated with inflammation and tissue destruction of the joint.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Osteoarthritis and Joint Biology – Basic Science Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Osteoarthritis (OA) is a complex joint disease characterized by a progressive loss of articular cartilage (AC) and synovial inflammation. The latest theories of OA pathogenesis implicate the interplay between mechanical damage and chronic inflammation that has been associated to the activation of the innate immune system, intricately involved in the development of this low-grade inflammation. During the course of OA, Toll-like receptor (TLR) activation has been related to the release of cytokines and inflammatory mediators, which further aggravates synovitis and AC damage. In this scenario, hyaline chondrocytes seem to acquire a hypertrophic-like phenotype associated to AC degradation. 6-shogaol (6S), an effective anti-inflammatory ginger derivative, is able to inhibit TLR4-mediated innate immune responses. Our aim was to study the therapeutic benefit of 6-shogaol treatment in an OA mice model and its effect in the modulation of hypertrophic markers in chondrocyte cultures.

Methods: C57BL/6 male mice were randomly assigned to two groups: control (n=7) and OA (n=17). OA was induced by transection of the medial menisco-tibial ligament. Nine OA mice started receiving 6S (15mg/kg/day; OA+6S) since surgery. After 8 weeks, animals were euthanized and joints were collected. Chondrogenic differentiation was induced *in vitro* in the pre-chondrogenic cell line ATDC5 by ITS (insulin-transferrin-selenium) in presence or absence of 5×10^{-6} M 6S. Gene expression of hypertrophic markers as well as mineralization and proteoglycan synthesis were determined.

Results: Both synovial inflammation and AC damage were more severe in OA animals (Control: 0.1 ± 0.1 ; OA: 3.0 ± 0 ; $p < 0.05$, and Control: 0.5 ± 0.2 , OA: 5.4 ± 0.6 ; $p < 0.05$, respectively) with a significant reduction in OA+6S animals (2.4 ± 0.2 ; $p < 0.05$ and 2.6 ± 0.5 $p < 0.05$ vs. OA, respectively). Type X Collagen X (Col X) and MMP13 immunohistochemistry showed an increase in the AC of OA and OA-6S mice vs control animals (ColX: Control: 0.13 ± 0.03 , OA: 0.93 ± 0.10 ; OA-6S: 0.43 ± 0.10 ; $p < 0.05$ vs Control and MMP13: Control: 0.35 ± 0.10 , OA: 0.68 ± 0.10 , OA-6S: 0.28 ± 0.07 , $p < 0.05$ vs Control), while a significant reduction was found in 6S-treated mice ($p < 0.05$ vs OA). Similar results were found in the synovium and meniscus for MMP13 and in meniscus for Col X. In addition, 6S was able to significantly inhibit the expression of Collagen X, Ihh and MMP13 in ITS-stimulated cells after 14 and 21 days of culture. Furthermore, 6S prevented the increase in mineralization and proteoglycan synthesis in ITS-stimulated ATDC5 cells after 14 days of culture ($p < 0.05$ ITS vs basal, and $p < 0.05$ ITS-stimulated vs ITS), assessed by Alizarin red and Alcian blue staining, respectively.

Conclusion: Our results showed that 6S significantly prevented cartilage degradation and synovial inflammation, in parallel to a reduction of the presence of hypertrophic markers in the cartilage of OA mice. *In vitro*, 6S inhibited the chondrogenic differentiation of ATDC5 cells. These results suggest that 6S could work as a good treatment in OA both inhibiting hypertrophic differentiation markers and reducing the severity of joint damage in an OA murine model.

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Etiology and Pathogenesis Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Paraoxonase 1 (PON1) is a high density lipoprotein (HDL) associated enzyme, which promotes the anti-oxidant and anti-inflammatory properties of HDL. PON1 polymorphisms and enzyme activity have previously been associated with cardiovascular (CV) events in the general population. The current work investigated the relationship of

genetic and biochemical determinants of PON1 activity with progression of carotid atherosclerosis (ATH) in a longitudinal cohort of patients with rheumatoid arthritis (RA).

Methods: Carotid ultrasounds were performed at 2 time points separated by a mean \pm SD of 5.6 ± 1.2 years on a longitudinal cohort of 149 RA patients at a single academic center. The number and type of carotid plaques were assessed and an ATH score provided by the same radiologist for all scans. Fasting blood was collected for lipoprotein analysis and inflammatory markers done by standard assays, and PON1 activity was measured using paraoxon as the substrate. Genotyping for the PON1 Q192R polymorphism (SNP rs662) was done for all patients as described previously (Arthritis Rheum. 2013 Nov;65(11):2765-72). Traditional cardiovascular risk factors, medication use, and RA disease characteristics were assessed for all patients at baseline and follow-up visits.

Results: The PON1 genotype demonstrated a significant dose dependent association with PON1 activity (RR192 > QR192 > QQ192) ($p \leq 0.003$) at baseline and follow-up visits. Compared to patients with either the PON1 RR192 or QR192 genotype, patients with the QQ192 genotype demonstrated increased risk of carotid plaque progression measured by \geq one unit increase in carotid ATH score in multivariate analysis controlling for significant traditional CV risk factors, RA disease characteristics, medication use, and the presence of carotid plaque on baseline ultrasound ($p < 0.05$). Similar results were noted when defining ATH progression by \geq one new carotid plaque from the baseline scan. Separate multivariate logistic regression analysis controlling for the same significant RA and traditional CV risk factors also revealed a significant association of mean plasma PON1 activity with carotid ATH progression in RA patients. Lower mean plasma PON1 activity was associated with increased risk of carotid ATH progression as assessed both by \geq one unit increase in carotid ATH score, or by \geq one new carotid plaque from the baseline study in individual multivariate models ($p < 0.05$). Mean total, LDL, and HDL cholesterol levels were not associated with carotid ATH progression in this cohort.

Conclusion: The current work suggests a relationship between the genetic determinants and activity of PON1 with cardiovascular risk in RA patients as assessed by the progression of carotid ATH over 5 year longitudinal follow-up. Further CV outcome studies may be warranted to determine if PON1 is a useful biomarker of CV risk in patients with RA.

Autophagy Promotes Citrullination of Vimentin and Its Interaction with Major Histocompatibility Complex Class II in Synovial Fibroblasts

Eri Sugawara, Masaru Kato, Yuki Kudo, WenShi Lee, Yuichiro Fujieda, Toshiyuki Bohgaki, Olga Amengual, Kenji Oku, Shinsuke Yasuda and Tatsuya Atsumi, Department of Rheumatology, Endocrinology and Nephrology, Faculty of Medicine and Graduate School of Medicine, Hokkaido University, Sapporo, Japan

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Etiology and Pathogenesis Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Citrullinated vimentin (cVIM) is one of the major autoantigens in patients with rheumatoid arthritis (RA), recognized by anti-citrullinated peptide antibodies. Autophagy is a self-cannibalism system to adapt to starvation but also regulates various cellular functions. Since autophagy is involved in antigen presentation with major histocompatibility complex (MHC) class II and accelerates peptidylarginine deiminase activity, we hypothesized that activation of autophagy causes citrullination of vimentin and its interaction with MHC class II in synovial fibroblasts (SF), one of the effector cells in RA.

Methods: SF were derived from synovial tissue specimens obtained from RA patients during joint replacement surgery. To evaluate antigen presenting capacity of SF, the cell surface expression of MHC class II and B7 molecules were analyzed by flow cytometry after 72h treatment with IFN- γ . Anti-cVIM antibodies were measured in RA patients' sera using enzyme-linked immunosorbent assay. Intracellular citrullinated autoantigens in SF were analyzed by western blotting using anti-cVIM antibody positive patient's serum as a primary antibody. To induce autophagy, SF were incubated in serum-free medium for 2h or treated with 10 μ M of the proteasome inhibitor MG132 for 24h. To inhibit autophagy, SF were treated with 5 mM of 3-methyladenine. Intracellular cVIM was evaluated by western blotting and immunocytochemistry using anti-vimentin and -citrulline antibodies. To evaluate the interaction between MHC class II and cVIM, lysates of IFN- γ treated SF were immunoprecipitated by anti-HLA-DR antibody, followed by western blotting for vimentin and citrulline. In addition, proximity ligation assay was performed using anti-HLA-DR, -vimentin, and -citrulline antibodies.

Results: MHC class II, B7-H1, and B7-DC were expressed on SF following treatment with IFN- γ , while B7-H3 was expressed on SF regardless of the presence of IFN- γ . Anti-cVIM positive RA patients' sera recognized 54 kDa protein in SF. By co-immunoprecipitation using anti-vimentin and -citrulline antibodies, the 54 kDa protein recognized by RA sera was revealed to be citrullinated vimentin. Following induction of autophagy by serum-free starvation or proteasome inhibition, intracellular cVIM was increased in SF but the effect was cancelled by the autophagy inhibitor 3-methyladenine. The interaction between MHC class II and cVIM was demonstrated by co-immunoprecipitation. Furthermore, proximity ligation assay revealed that the MHC class II-cVIM interaction significantly increased following induction of autophagy.

Conclusion: Our current data indicate that SF contribute to the autoimmunity in RA through citrullination of vimentin and its interaction with MHC class II promoted by autophagy.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Etiology and Pathogenesis Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Oxidative stress plays a role in the progression of inflammatory diseases such as Rheumatoid Arthritis (RA) due to the imbalance between levels of reactive oxygen species (ROS) and endogenous antioxidant defense mechanisms. Resulting from oxidative stress, Malondialdehyde-Acetaldehyde-protein adduct (MAA) formation is increased in RA joint tissues where these co-localize with citrullinated proteins, acting as potent immune adjuvants. Doxycycline (DOX) and other tetracycline derivatives demonstrate efficacy in the treatment of RA. Interestingly, this clinical benefit does not appear to stem from their antibacterial properties, and the anti-inflammatory properties of DOX are currently unknown. Therefore, we tested the hypothesis that DOX directly scavenges ROS and inhibits the formation of redox-mediated MAA-adduct formation.

Methods: To test whether DOX inhibits the formation of MAA-Albumin, a cell-free system was used by adding DOX to human serum albumin (ALB) in the presence of 2mM malondialdehyde (MDA) and 1mM acetaldehyde (AA). MAA-

Figure 1.

ALB formation was monitored by autofluorescence at 498 nm. Electron paramagnetic resonance(EPR) was used to quantify free radical production and superoxide scavenging in the presence/absence of DOX. HEK 293cells transfected with the nuclear factor erythroid 2-relatedfactor/antioxidant response element (Nrf2/ARE) were used to determine whether DOX alters intracellular redox signaling pathways activated by MAA-adduct generation. Nrf2 activation was quantified by measuring the amount of luciferase via cellular luminescence.

Results: Cell-free studies showed that DOX reduced MAA-adduct formation at all time points investigated ($p < 0.0001$). EPR revealed that DOX significantly inhibited free radical production related to MAA-adduct formation and scavenged superoxide($p < 0.0001$ vs. sham). Finally, incubation of AA, MDA and/or ALB increased Nrf2 activation (Figure 1), an effect that was significantly reduced($p < 0.001$) in the presence of DOX.

Conclusion: DOX, a drug used sparingly in the management of RA and other chronic inflammatory diseases, scavenges ROS produced in the process of MAA-adduct formation. Additionally, DOX inhibits MAA-induced Nrf2 activation, a redox-sensitive transcription factor, thus demonstrating its ability to alter intracellular redox signaling. Together, these data strongly indicate a novel antioxidant property of DOX that could explain its clinical benefit in the context of select chronic inflammatory conditions that are characterized by oxidative stress.

Differentially-Utilized Transcription Factors and Enhancers in Rheumatoid Arthritis (RA) Fibroblast-like Synoviocytes

Jonathan Mills¹, Gary S. Firestein² and Brian Pedersen², ¹Rheumatology, University of California, San Diego, San Diego, CA, ²Medicine, University of California San Diego, La Jolla, CA

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Etiology and Pathogenesis Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: RA fibroblast-like synoviocytes (FLS) display a unique aggressive phenotype with a distinct epigenetic profile marked by altered chromatin accessibility. We hypothesized that differentially utilized transcription factors (TFs) and/or promoters correlating with open chromatin regions may contribute to RA FLS behavior. We utilized ATAC-sequencing data to compare regions of open chromatin in RA FLS that are the most different when compared to OA. This filter allowed us to identify DNA sequence motifs of TFs most likely to account for RA-specific cell functions.

Methods: ATAC-seq data from the FLS derived from RA and OA arthroplasty samples and differences corresponding to chromatin accessibility were identified using DiffBind. Loci were filtered for those present in all 11 RA samples but $\leq 5/10$ OA samples or loci present in ≥ 5 RA samples but in ≤ 1 OA sample (and vice versa) to identify the extremes of RA-OA differences. These loci were then analyzed for DNA sequence biases using MEME (Multiple EM for Motif Elicitation). Identified motifs were compared to known TFs found in multiple databases using Tomtom. Motifs were identified with high confidence if they corresponded with known patterns in all databases and expressed in FLS.

Results: Multiple relevant TFs motifs were associated with the extremes of RA-OA chromatin accessibility differences. Motifs for KLF4 and the E2F family of TFs were identified and among the most highly significant. The motif for the E2F family of TFs was identified in 159/575 total sites where chromatin was more open in the RA vs OA samples (MEME $e = 1.2e-64$, HOCOMOCO $q = 2.2e-2$). There were 84 genes found within 1000 kb of these 159 sites, and of these, 9 sites were found within gene bodies. RNA-seq was then utilized to identify which genes associated with E2F family binding sites in open chromatin are differentially expressed. Seven of these genes were associated with significant differential expression (CRYBG3, Metazoa_SRP, ANGPTL2, ITGB3, PMP22, GLS and U4; $q < 0.05$). The motif for the KLF family of TFs was identified in 18/1156 total sites where chromatin was more open in the OA vs RA samples (MEME $e = 3.4e-2$, TFBSshape $q = 0.19$). There were 18 genes identified within 1000 kb of these 1156 sites, and of these, 7 sites were found within gene bodies. None of these were differentially expressed.

Conclusion: Using differences in chromatin access we identified TFs that are associated with neighboring genes with differential expression that distinguish RA from OA. Protein coding genes identified by this approach include proteins involved with cell adhesion that could participate in the pathogenesis of RA.

Variation in the Synovial Fluid Metabolome According to Disease Activity in Rheumatoid Arthritis

Joong Kyong Ahn¹, Jiwon Hwang², Jaejoon Lee³, Eun-Mi Koh³ and Hoon-Suk Cha³, ¹Department of Medicine, Kangbuk Samsung Hospital, Sungkyunkwan University School of Medicine, Seoul, Korea, Republic of (South), ²Department of Internal Medicine, National Police Hospital, Seoul, Korea, Republic of (South), ³Department of Medicine, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Korea, Republic of (South)

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Etiology and Pathogenesis Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is a chronic, inflammatory disease characterized by persistent inflammation and joint damage with a heterogeneous course and different pathogenic mechanisms. Metabolomics, defined as the comprehensive analysis of the small-molecule metabolites in a biological system, is a rapidly developing biomedical research area. This study was to investigate metabolic perturbation in the synovial fluid (SF) of RA patients according to the degree of disease activity using gas chromatography/time-of-flight-mass spectrometry (GC/TOF-MS) to gain more insight into the pathologic metabolic alterations in RA.

Methods: We included 47 patients with diagnosed active RA (15 male, 32 female). Disease activity was assessed using DAS28-ESR. SF metabolomic profiling was performed using GC/TOF MS, in conjunction with multivariate statistical analyses and pathway analyses such as metabolite set enrichment analysis (MSEA).

Results: A total of 125 metabolites were identified from SF of RA, which were classified into various chemical classes, such as amino acids (21% of identified metabolites), organic acids (21%), sugar and sugar alcohols (18%), fatty acids (14%), amines (9%), and phosphates (5%).

We indicated statistical significant correlation between DAS28-ESR value and the intensities of 12 metabolites (β -alanine, asparagine, citrate, cyano-L-alanine, indol-3-lactate, leucine, nicotinamide, citrulline, methionine, oxoproline, salicylaldehyde, and glycocyamine). The intensities of glycocyamine and indol-3-lactate positively correlated with DAS28-ESR value ($\rho = 0.311$, $p = 0.017$; $\rho = 0.345$, $p = 0.033$). On the other hand, β -alanine, asparagine, citrate, cyano-L-alanine, leucine, nicotinamide, citrulline, methionine, oxoproline, and salicylaldehyde negatively correlated with DAS28-ESR.

To investigate whether metabolism is affected by disease activity in RA, we have performed MSEA and metabolic pathway analysis by using MetaboAnalyst. We found that the higher the disease activity, the more amino acid metabolic processes were affected. In MSEA, we found six unique pathways, namely, fructose and mannose degradation, phenylalanine and tyrosine metabolism, citric acid cycle, galactose metabolism, tryptophan metabolism and pyrimidine metabolism that were significantly associated with disease activity in RA.

Conclusion: Synovial metabolite perturbations, especially perturbation in amino acid metabolism, are suggested to be correlated with disease activity of RA. SF metabolomic approaches based on GC/TOF-MS can provide important information relating to monitor disease activity in RA and be important approach to understanding the altered metabolism and pathophysiology of RA.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Etiology and Pathogenesis Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Metabolomics is an emerging field of biomedical research that may offer a better understanding of mechanisms underlying conditions that could include inflammatory arthritides. Perturbations caused by inflamed synovial tissue can lead to correlated changes in concentration of certain metabolites in the synovium and thereby function as potential biomarkers in blood. Here, we explore the hypothesis of whether characterization of patients' metabolomic profiles in blood, utilizing ¹H-nuclear magnetic resonance (NMR), predicts synovial cytokine profiling in rheumatoid arthritis (RA).

Methods: Nineteen active seropositive RA patients on concomitant methotrexate were studied. One of the involved joints was a knee or a wrist appropriate for arthroscopy. A Bruker Avance 700 MHz spectrometer was used to acquire NMR spectra of serum samples. Gene expression in synovial tissue obtained by arthroscopy was analyzed by real-time PCR. Data processing and statistical analysis were performed in Python and SPSS.

Results: Analysis of the relationships between each synovial cytokine-serum metabolite pair, using linear regression and controlling for age and gender, revealed significant clustering structure in these data. We observed an association of serine/glycine/phenylalanine metabolism and aminoacyl-tRNA biosynthesis with lymphoid cell gene signature. Alanine/aspartate/glutamate metabolism and choline derived metabolites correlated with TNF- α synovial expression. Circulating ketone bodies were associated with gene expression of synovial metalloproteinases. Discriminant analysis identified serum metabolites that classified patients according to their synovial cytokine levels.

Conclusion: The relationship between serum metabolite profiles and synovial biomarker profiling suggests that NMR may be a promising tool for predicting specific pathogenic pathways in the inflamed synovium of RA patients.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Etiology and Pathogenesis Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Neoangiogenesis is a crucial event to promote the development of the hyperplastic proliferative pathologic synovium in Rheumatoid arthritis (RA). Ultrasound (US) is sensitive for detection of power Doppler (PD) vascularization. Our aim was to explore the associations between a set of complementary circulating angiogenic markers reflecting different angiogenic processes and a comprehensive US assessment in patients with RA.

Methods: Serum levels of eight angiogenic markers (Vascular Endothelial Growth Factor (VEGF), Placenta Growth Factor (PlGF), Tie-2, Angiopoietin-1, soluble Vascular Cell Adhesion Molecule-1 (sVCAM-1), Interleukin-8 (IL-8, CXCL8), CYR61 (CCN1) and Angiostatin), reflecting endothelial cell activation, proliferation, survival, growth and migration, as well as vessel maturation and stabilization, were measured by quantitative ELISAs in a total of 125 patients with RA, who were all systematically assessed in parallel by PDUS, performed on 32 joints.

Results: Synovitis was detected in 84 patients with RA (67.2%). Among these patients, 53 patients (42.4%) had positive Doppler signal, including 31 with moderate to marked hyperemia. Serum levels of soluble Vascular Cell Adhesion Molecule-1 (sVCAM-1) (808 ± 293 ng/mL vs. 697 ± 240 ng/mL, $P=0.022$) and Tie-2 (16.2 ± 7.5 ng/mL vs. 13.8 ± 4.9 ng/mL, $P=0.038$), were more likely to be increased in patients with synovial hyperemia detected on at least one joint (Power Doppler grade ≥ 1). sVCAM-1, Tie-2 and Angiostatin concentrations gradually increased together with the grade of the semiquantitative PDUS scale and concentrations of these three markers were markedly increased in patients with moderate to marked hyperemia (Power Doppler grade 2 and 3). Levels of sVCAM-1 ($r=0.20$, $P=0.028$), Tie-2 ($r=0.28$, $P=0.001$), and Angiostatin ($r=0.25$, $P=0.006$) correlated with a global arthritis sum score, defined by the sum of the semiquantitative PDUS scores for all joints examined.

Among the 81 patients with a DAS28-CRP ≤ 3.2 , 22 patients had synovial hyperemia detected on at least one joint (Power Doppler grade 1 in 13 patients, grade 2 in 6 patients and grade 3 in 3 patients). Patients with synovial hyperemia on at least one joint were more likely to have significantly increased levels of PlGF (18.9 ± 11.2 pg/mL vs. 13.1 ± 9.5 pg/mL, $P=0.022$) and Tie-2 (15.7 ± 5.8 ng/mL vs. 12.6 ± 3.4 ng/mL, $P=0.004$) than patients with absence of synovial hyperemia.

Conclusion: Serum levels of the angiogenic markers Tie-2, sVCAM-1 and Angiostatin were strongly associated with synovial vascularization and inflammation assessed by PDUS among patients with established RA. Moreover, Tie-2 and PlGF were associated with persistent disease activity in RA patients in low disease activity. These findings suggest that it may be possible to find surrogate serum angiogenic biomarkers of active synovitis that might replace PDUS examination, in case of further confirmation of their pertinence.

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Etiology and Pathogenesis Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Hexokinases (HKs) catalyze the first step in glucose metabolism. HK2 constitutes the principal inducible isoform with a restricted distribution in normal adult tissues. Fibroblast-like synoviocytes (FLS) are a key component of rheumatoid arthritis (RA) invasive synovium, and display unique aggressive features, including increased migration and invasion. We have recently showed a critical role of glucose metabolism and specifically of HK2 in RA FLS phenotype. Of interest, HK2 localizes not only in the cytosol but also at mitochondria and protects mitochondria against apoptosis. We hypothesize that mitochondrial-bound HK2 is key regulator of RA FLS phenotype.

Methods: HK2 localization at baseline and after RA FLS activation with platelet derived growth factor (PDGF, 10ng/ml) was evaluated by cell fractionation and western blot (WB), and confocal microscopy. RA FLS were infected with GFP, full-

length (FL)-HK2 or HK2 lacking its mitochondrial binding motif (HK2ΔN) expressing adenovirus (ad). RA FLS were also incubated with methyljasmonate (MJ, 2.5mM), which dissociates HK2 from mitochondria. FLS function in medium and PDGF stimulated cells was evaluated by measuring 1) migration of cultured FLS monolayers (scratch assay); 2) in vitro invasion assay using matrigel. For arthritis experiments, mice were injected with K/BxN sera on day 0. MJ (25mg/kg) was injected daily i.p. beginning on day 0 after serum administration or starting at the peak of arthritis (from day 5). Clinical arthritis scores were serially assessed. Joint histology was evaluated using a semiquantitative scoring system.

Results: 30 minutes after PDGF stimulation, cell fractionation and confocal microscopy revealed that PDGF induced the translocation of HK2 to the mitochondrial fraction. Overexpression of the HK2 mutant reversed the invasive phenotype induced by full-length HK2 after PDGF stimulation, and also FLS migration rate, GFP-ad: 101.2 ± 12.69 ; FL-HK2-ad: 135.7 ± 38.88 ; HK2ΔN-ad 112.6 ± 35.72 (FL-HK2-ad vs. HK2ΔN-ad: $p < 0.01$). MJ treatment also significantly reduced RA FLS invasion from 46.79 ± 8.961 to 22.45 ± 7.48 ($p < 0.001$) and migration rate from 253 ± 14 to 152 ± 6 ($p < 0.001$) after PDGF stimulation. Finally, MJ treatment significantly decreased arthritis severity. Day 10 scores were 4.8 ± 0.9 and 1.2 ± 0.58 ($P < 0.01$) for vehicle and MJ-treated mice respectively, when mice were treated from day 0 after serum administration, and 12.5 ± 0.5 and 9.2 ± 0.663 ($p < 0.05$) for vehicle and MJ-treated mice when mice were treated from day 5. Joint histology scores for vehicle and MJ-treated mice from day 0 were: for inflammation 0.9 ± 0.821 and 0.4 ± 0.42 ($p < 0.05$), bone erosion scores were 1.5 ± 0.61 and 0.3 ± 0.45 ($p < 0.01$), and cartilage damage scores were 1.9 ± 0.42 and 0.3 ± 0.45 ($p < 0.01$), respectively.

Conclusion: Our results suggest that mitochondrial HK2 is key regulator of aggressive FLS phenotype, which contributes to joint destruction in RA. Targeting HK2, as an isoform-specific contributor to RA FLS phenotype, offers a safer approach than global glycolysis inhibition. Other possible strategy to improve selectivity would be to target HK2 binding to the mitochondria.

Session Title: Rheumatoid Arthritis – Etiology and Pathogenesis Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is characterized by high clinical variability and an underlying cellular and molecular heterogeneity. Efforts to find tools for the classification of disease phenotypes and patient stratification are key to develop tailored therapies and improve RA management. According to this, specific pathological phenotypes of synovial tissue (pathotypes) have arisen as possibly associated to diverse clinical evolution and response to therapy (Humby et al., 2017). In the present work, we aimed to identify signatures of circulating proteins that correlate with the synovial pathotype in patients with RA.

Methods: A proteomic analysis was carried out on samples from patients enrolled in the Pathobiology of Early Arthritis Cohort (PEAC). Ultrasound-guided synovial biopsies allowed their classification into three groups according to the phenotype of the synovial tissue (lymphoid, myeloid or fibroid), as described previously (Pitzalis et al., 2013). The study was performed using 54 serum samples at baseline: 22 of lymphoid phenotype (L), 18 myeloid (M), and 14 fibroid (F). Sera were depleted from the most abundant proteins by affinity chromatography to remove background, and analysed by reversed-phase nanoliquid chromatography coupled to mass spectrometry using a SWATH strategy and a triple TOF MS (Sciex). The quantitative data were processed using the ProteinPilot 5.0.1 and PeakView 2.1 software (Sciex). A two-stage support vector machine (TSSVM) with RBF kernel and 10 cross-fold validation was applied using the Classyfire, e1071 and caret R packages.

Results: The proteomic analysis led to the identification and quantification of 229 proteins. The screening analysis was performed on the data obtained from a first group of 30 samples (Train set: 10 L, 10 M and 10 F). Data were pre-

processed by PCA for dimension reduction. Then, application of machine learning tools led to the identification of a panel of 11 proteins whose different abundance is associated with a specific phenotype of the synovial tissue (either Lymphoid, Myeloid or Fibroid) in rheumatoid arthritis patients. Table 1 shows the most relevant metrics obtained with this analysis. A very high accuracy and Kappa coefficient were achieved using this classification tool. The results were then confirmed on an independent validation set of 24 samples (12 L, 8 M and 4 F) with also good performance. This protein signature allowed the correct classification of the samples into the three pathotypes with very high sensitivity and specificity.

Table 1. Metrics of the performance of the 11-protein panel to classify the synovial pathotype of the patient. Cut-off for significance was p-value < 0.05.

Train set				Classes in the train set			
Accuracy	0.9667	95% CI	(0.8278 - 0.9992)	Sensitivity/ Specificity	Fibroid	Lymphoid	Myeloid
					1.000/1.000	1.000/ 0.9524	0.9091/ 1.000
Kappa	0.95	P-Value	4.48E-09	Pos/Neg Pred Value	1.000/ 1.000	0.9000/ 1.000	1.000/ 0.9500
					Classes in the validation set		
Accuracy	0.875	95% CI	(0.6764 - 0.9734)	Sensitivity/ Specificity	Fibroid	Lymphoid	Myeloid
					1.000/ 0.9524	0.8462/ 0.9091	0.8750/ 0.9375
Kappa	0.7907	P-Value	0.0005881	Pos/Neg Pred Value	0.7500/ 1.000	0.9167/0.8333	0.8758/0.9375

Conclusion: We have identified a signature of 11 circulating proteins associated with synovial pathotypes in RA patients. The putative correlation of this protein profile with the clinical evolution and/or response to therapy of the patients remains to be elucidated.

Artesunate Can Synergize with Methotrexate on Inhibiting Migration and Invasion of Fibroblast-like Synoviocytes from Patients with Rheumatoid Arthritis

Jian-Da Ma¹, Jun Jing¹, Jun-Wei Wang¹, Tao Yan², Yun-Shan Mou², Ying-Qian Mo¹ and **Lie Dai**¹, ¹Department of Rheumatology, Sun Yat-Sen Memorial Hospital, Sun Yat-Sen University, Guangzhou, China, ²Zhongshan School of Medicine, Sun Yat-Sen University, Guangzhou, China

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Etiology and Pathogenesis Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Fibroblast-like synoviocytes (FLS) play important roles on joint destruction in rheumatoid arthritis (RA). Recent reports showed that antimalaria drug artesunate presents anti-cancer potential by suppressing cancer cells invasion and metastasis. We have found that artesunate could inhibit migration and invasion of RA-FLS as well as MMP-2/9 expression. Methotrexate (MTX) is the anchor drug for RA treatment. Here we aimed to investigate the synergistic effect of artesunate with MTX on inhibiting aggressive ability of RA-FLS.

Methods: Synovial tissues were obtained by closed needle biopsy from 6 active RA patients and FLS were isolated. Primary RA-FLS were cultured in vitro and pretreated with 60 μ M artesunate, 10nM MTX, or combination of 60 μ M artesunate and 2.5nM~10nM MTX respectively for indicated times. Their effects on cell viability and proliferation were measured by CCK-8 assay, while effects on migration and invasion capacity of RA-FLS were detected by wound healing and transwell assays. Differential expression of MMP-2/9 and tissue inhibitors of metalloproteinases (TIMP) -1/2 were detected by quantitative real-time PCR, western blot and ELISA.

Results: (1) Compared with untreated group, 60 μ M artesunate, 10nM MTX or combination of 60 μ M artesunate and 2.5nM~10nM MTX showed no significant effect on cell viability and proliferation of RA-FLS for 72 hours (Fig 1A). (2) Both 60 μ M artesunate and 10nM MTX alone significantly inhibited migration and invasion of RA-FLS. The combination of 60 μ M artesunate and 7.5nM MTX had stronger inhibitory effect on migration and invasion than 60 μ M artesunate or 10nM

Figure 1 Effects of artesunate and MTX on primary RA-FLS. **A** Effects of 60μM artesunate, 10nM MTX or combined of 60μM artesunate and 2.5nM–10nM MTX on viability and proliferation of primary RA-FLS was measured by CCK-8 assays at 6, 12, 24, 36, 48 and 72 hours. **B** Effects of combined treatment with artesunate and MTX on migration and invasion capacity of primary RA-FLS was measured by wound healing and transwell assays. **C** Effects of combined treatment with artesunate and MTX on the expression of MMP-2, MMP-9, TIMP-1 and TIMP-2 in primary RA-FLS were measured by quantitative real-time PCR, western blot and ELISA. Bar are representative as means ± SD from six RA patients. * $P < 0.05$, ** $P < 0.01$, *** $P < 0.001$, compared with RA-FLS without any treatment. $\Delta P < 0.05$, $\Delta\Delta P < 0.01$, compared with RA-FLS treatment with 10nM MTX.

MTX alone (Fig 1B). (3) Both 60μM artesunate and 10nM MTX alone significantly inhibited MMP-2/9 expression but promoted the expression of TIMP-2. The combination of 60μM artesunate and 7.5nM MTX had stronger effect on regulating MMP-9 and TIMP-2 than 60μM artesunate or 10nM MTX alone (Fig 1C).

Conclusion: Artesunate can synergize with MTX on inhibiting migration and invasion of primary RA-FLS by inhibiting MMP-9 and promoting TIMP-2 expression, which implies the potential of combination therapy of artesunate and MTX for RA.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Etiology and Pathogenesis Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Several inducers of angiogenesis have been shown to play a central role in rheumatoid arthritis (RA) pathogenesis: VEGF (Vascular Endothelial Growth Factor), EMMPRIN (Extracellular Matrix Metalloproteinase Inducer), a transmembrane immunoglobulin which stimulates secretion of MMPs (Matrix Metalloproteinases); and NGAL (Neutrophil Gelatinase-Associated Lipocalin), a pro-inflammatory adipokine which binds MMP9 and inhibits its degradation, but which has also anti-inflammatory properties. IL-6 blockade by Tocilizumab (TCZ), an effective treatment for RA, may inhibit angiogenesis.

Aim: To explore the effect of TCZ treatment on serum levels of the above pro-angiogenic factors in RA patients compared to healthy controls (HC).

Methods: Clinical data and blood samples were collected from 40 active RA patients and 40 age and sex-matched HC. Serum levels were analyzed for high sensitivity C-Reactive Protein (hsCRP), VEGF, EMMPRIN, MMP-9 and NGAL by Enzyme-Linked Immunosorbent Assay (ELISA) before initiation of TCZ treatment and 4 months following treatment in the RA group compared to HC. Student's t-test was used for analysis of EMMPRIN, MMP-9, and NGAL levels and Mann-Whitney Test and Pearson Chi-square Test were used for analysis of VEGF levels. Results were considered statistically significant for p values ≤ 0.05 .

Results: The majority of the patients responded to TCZ treatment and reduced their disease activity scores (DAS) from DAS28 score of 5.45 ± 1.06 to 3.46 ± 1.37 ($p < 0.0001$). The levels of hsCRP were higher in RA patients than in HC and decreased 4 months after initiation of TCZ treatment (3.37 ± 2.0 , 0.74 ± 1.36 mg/dl, $p < 0.001$). EMMPRIN levels were higher in RA patients than HC (43.55 ± 10.77 ng/ml, 34.44 ± 10.00 ng/ml respectively, $p < 0.0002$) and were reduced significantly following initiation of treatment (40.01 ± 8.43 ng/ml, $p < 0.006$). VEGF levels were very low, and therefore separated into two groups (equal to 0, above 0 pg/ml), 15% of RA patients had detectable levels as compared to 41% of HC ($P < 0.01$) and it did not change significantly following 4 months of treatment. Interestingly, serum NGAL levels were higher in HC than RA patients (91.78 ± 31.44 ng/ml, 73.21 ± 20.80 ng/ml, respectively $p < 0.003$), and increased in the RA group following TCZ treatment (85.27 ± 28.9 ng/ml, $p < 0.001$). Similarly, MMP-9 levels were higher in the serum of HC than RA patients (119.76 ± 45.49 ng/ml, 75.85 ± 47.47 ng/ml, respectively, $p < 0.0001$) but were not affected by TCZ (75.89 ± 44.91 ng/ml, $p < 0.84$).

Conclusion: Our results demonstrate that IL-6 pathway blockade using TCZ was effective in reducing the serum level of EMMPRIN in RA patients, implying its clinicopathologic role in the disease pathogenesis. Our results suggest that IL-6 blockade did not affect serum VEGF, NGAL and MMP-9 levels, either because they are active at the joint level and not peripherally, or because NGAL may play an anti-inflammatory role in RA, so that IL-6 blockade increased its levels. Future studies may help elucidate the site of action and mechanism of action of the various pro-angiogenic factors in RA pathogenesis.

Simulating the Pathogenesis of Arthritis in Vitro By Developing a Human-Based Multicomponent 3D Joint Model

Alexandra Damerou^{1,2}, Annemarie Lang^{1,2}, Moritz Pfeiffenberger^{1,2}, Timo Gaber^{1,3} and Frank Buttgerit^{1,2}, ¹Department of Rheumatology and Clinical Immunology, Charité - Universitätsmedizin Berlin, Berlin, Germany, ²Deutsches Rheuma-Forschungszentrum Berlin, Berlin, Germany, ³Deutsches Rheuma Forschungszentrum (DRFZ) Berlin, Berlin, Germany

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Etiology and Pathogenesis Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Although arthritis is a matter of research since more than 140 years, there is currently no valid 3D model available, which is able to mimic an inflamed joint. Thus, our ultimate goal is to develop a valid human *in vitro* 3D joint model in order to simulate arthritis. The model will contain all involved tissue components and cell types enabling the interactions between cells by cell contacts, signaling molecules and metabolites. As an alternative experimental setup for traditional animal models, our *in vitro* model will enable us to study the influence and efficacy of drug treatment. To this end, we firstly developed all single components of the joint, namely the (1) osteogenic and (2) chondrogenic part, (3) the joint space with synovial fluid and (4) the synovial membrane, separately.

Methods: The osteogenic component was synthesized by seeding human bone marrow-derived mesenchymal stromal cells (hMSC) on β -tricalcium phosphate (TCP) coated with an additional hMSC monolayer cell-sheet and cultured for a total of 6 weeks. Survival, adhesion and structural integrity of the cells were evaluated by Scanning Electron Microscopy (SEM), LIVE/DEAD staining and cellular release of LDH. Osteogenic differentiation was analyzed both by μ CT for mineralization and on gene expression level using qPCR. To mimic the chondrogenic part, a scaffold-free 3D cartilage construct was generated by chondrogenic differentiation of hMSC with intermittent mechanical stimulation. Constructs were analyzed by histology and qPCR. Non-animal stabilized hyaluronic acid was used to simulate the synovial fluid component. In order to model the synovial membrane, hMSC were differentiated towards the fibroblast lineage and then a confluent layer was formed on a polycarbonate membrane, which was visualized by histology.

Results: We developed an *in vitro* 3D osteogenic model by successfully seeding hMSC on a β -TCP scaffold. Cells consistently adhere onto the scaffold for up to 6 weeks as observed by SEM. The analysis of cell viability via LDH detection and LIVE/DEAD staining showed no toxic effects on the cells as compared to the corresponding control. Osteogenic differentiation of

hMSC grown in 3D was verified demonstrating an increase in mineralized bone volume and the induction of bone-related gene expression (*RUNX2*, *SPPI* and *COL1A1*) as compared to the corresponding control. Chondrogenic phenotype was verified by HE and Alcian Blue staining as well as by the reduced expression of *COL1A1* and an abundant expression of *COL2A1*. Interestingly, co-cultivation of the osteogenic and chondrogenic part for up to 3 weeks demonstrated successful colonization, connectivity and initial calcification implying a functional transitional bridging area. Modelling the synovial membrane, we successfully and reproducibly created a confluent monolayer of hMSC, which is easily transferable to the model.

Conclusion: In summary, we confirmed and validated in a standardized manner phenotypic integrity and stability of each single component. To finalize the development of healthy joint model we will combine the established parts to provide suitable 3D joint model that enables us to study the efficacy of drug treatment *in vitro*.

Session Title: Rheumatoid Arthritis – Etiology and Pathogenesis Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The endocannabinoid system (ECS) is comprised of two evolutionary conserved cannabinoid receptors 1 and 2 (CB1 and CB2) which participate in pain management through G_{ai/o} mediated signaling. Recent studies show that the expression of CB2, not CB1, is upregulated at both the mRNA and protein levels in rheumatoid arthritis synovial fibroblasts (RASFs) as compared to normal synovial fibroblasts, however, the role the ECS receptors in pro-inflammatory cytokine signaling in RASFs remains poorly understood. In the present study, we used a selective agonist of CB2 (JWH-133) to characterize the role of CB2 activation in interleukin-1 β (IL-1 β)-induced inflammation in human RASFs.

Methods: Human RASFs were obtained from patients diagnosed with RA according to the ACR guidelines (8 female, 2 male, average age 47.7 \pm 5.7 years). Human RASFs were pre-treated with JWH-133 (10-20 μ M) for 10 minutes prior to the addition of IL-1 β (10 ng/mL) stimulation for 30 minutes for signaling studies or for 24 hours to evaluate the inflammatory mediators. The role of CB2 in IL-1 β signaling was examined by employing a small interfering RNA (siRNA) method or using overexpression plasmid specific for CB2. Conditioned media was used for the quantification of IL-6 and IL-8 by ELISA and cell lysates were prepared for the analysis of IL-1 β signaling proteins and nuclear translocation of transcription factors NF- κ Bp65 or AP-1 using Western immunoblotting. To study protein-protein interactions, RASFs treated with JWH-133 or IL-1 β were incubated with TAK-TAB_V5 protein. Associated partners were pulled down by immunoprecipitation of V5 beads and analyzed using a Western blotting method.

Results: Pretreatment of JWH-133 exacerbated IL-1 β -induced IL-6 and IL-8 production by 21% and 12%, respectively, in human RASFs (p<0.05; n=3). Furthermore, we observed that JWH-133 selectively increased the expression of IL-1 β -induced Cox-2 by >2-fold (p<0.05; n=3), suggesting a proinflammatory role of CB2 in IL-1 β signaling in human RASFs. Knockdown of CB2 using siRNA inhibited IL-1 β -induced IL-6 and IL-8 production by more than 50% and completely abrogated Cox-2 expression in RASFs (p<0.05; n=3). In contrast, the overexpression of CB2 further increased IL-1 β -induced IL-6 and IL-8 by approximately 3-fold and 4-fold, respectively (p<0.05; n=3), confirming its proinflammatory role in RASF mediated pain and inflammation. Analysis of immunoprecipitation studies revealed that CB2 associates with active TAK1 upon JWH-133 stimulation to coordinate with IL-1 β signaling pathways as observed with an increased nuclear translocation of NF- κ Bp65 and AP-1.

Conclusion: Our study provides novel evidence that CB2 elicits proinflammatory role in IL-1 β signaling in RASFs and suggests CB2 as a potential therapeutic target in the management of pain and inflammation in RA.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Etiology and Pathogenesis Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Non-Receptor Protein Tyrosine Phosphatase 14 (PTPN14) was identified in a phosphatase expression profile survey to be highly expressed in synovial fibroblasts derived from patients with rheumatoid arthritis (RA FLS). PTPN14 is a negative regulator of transcriptional co-activator YAP -a key Hippo pathway player- in cancer cells. Here we aimed to investigate the role of PTPN14 in RA FLS.

Methods: Gene expression level in RA FLS and FLS from osteoarthritis patients (OA FLS) was measured by qPCR. Specific gene knockdown was achieved using antisense oligonucleotides. PTPN14, YAP and SMAD3 protein expression levels were visualized in Western blotting and immunofluorescence. Immunoprecipitation was used to detect protein-protein interaction. The passive K/BxN arthritis and RA FLS/cartilage co-implantation models were used to assess effects of chemical inhibition of YAP.

Results: RA FLS displayed TGFbeta-dependent overexpression of PTPN14 compared to OA FLS ($p < 0.01$). PTPN14 knockdown in RA FLS impaired TGFbeta-dependent expression of matrix metalloproteinase 13 ($p < 0.05$) and potentiation of inflammatory cytokine signaling. In RA FLS, PTPN14 forms a complex with YAP, promoting TGFbeta-dependent YAP and SMAD3 nuclear localizations. Chemical inhibition of YAP inhibited RA FLS pathogenic behavior and ameliorated arthritis severity *in vivo* ($p < 0.0001$).

Conclusion: In RA FLS, TGFbeta-dependent PTPN14 overexpression acts as a positive feedback TGFbeta-signaling regulator. Surprisingly, in RA FLS PTPN14 enhances nuclear YAP-mediated promotion of SMAD signaling. YAP promotes a wide range of RA FLS pathogenic behaviors, pointing to the Hippo pathway as a potential important regulator of RA FLS and a player in RA pathogenesis.

Seroreactivity Against Recombinant Citrullinated Myosin Is Associated with Measures of Diastolic Dysfunction in Patients with Rheumatoid Arthritis

Christian Geier¹, Justyna Fert-Bober², Jon T. Giles¹, Cesare Russo¹, Sabahat Bokhari³, Aylin Tugcu¹, Jenny Van Eyk² and Joan Bathon¹, ¹Columbia University, New York, NY, ²Cedars-Sinai Medical Center, Los Angeles, CA, ³Cardiology, Columbia University, New York, NY

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Etiology and Pathogenesis Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Diastolic dysfunction and heart failure with preserved EF are more prevalent in RA. We have previously shown increased staining for citrullinated substrates in necropsied hearts of RA patients. We hypothesized that individuals with RA may generate antibodies against citrullinated myocardial proteins and that such antibodies may be associated with left ventricular (LV) dysfunction.

Methods: 59 sera from RA patients enrolled in a cohort study were incubated with uncitrullinated or citrullinated (exposed topeptidyl-arginine-deiminase-2 [PAD-2]) myocardial proteins (actin, myosin, tropomyosin, and troponin). Fluorescent anti-human IgG Fc antibody was added, rinsed, and mean fluorescence intensities (MFI) were recorded. Demographics, RA characteristics, and measures of LV function were compared between highest and lowest MFI tertiles for each protein in both citrullinated and uncitrullinated forms. The associations of anti-myocardial antibodies with measures of cardiac function, assessed by 3D echocardiography, were modeled using generalized linear models, adjusting for relevant confounders (variables associated with both LV function and seroreactivity to anti-myocardial proteins).

Results: Patients era with the highest tertile of seroreactivity against citrullinated (but not uncitrullinated) myosin showed multiple differences ($p < 0.05$) in measures of diastolic function: E/A ratio (0.95 vs 1.05), mean S wave (8.80 vs 10.09) and E/E' ratio (9.64 vs 7.86) all indicated better diastolic function for patients in the lowest tertile. Systolic function between the seroreactivity tertiles was not different. Levels of other myocardial protein antibodies were not associated with diastolic function with the exception of S wave for citrullinated tropomyosin ($p = 0.021$). Multivariable analyses showed that the diastolic parameters E/E' ratio and S wave (mean) remained significantly associated after controlling for RA duration and Tender Joint Count, previously identified potential confounders (Fig. 1).

Conclusion: These data suggest that RA patients may generate antibodies against citrullinated myosin and that this may contribute to myocardial dysfunction in RA. Analyses of additional patient sera and ultimately verifying this observation in human myocardial tissue are needed.

Fig. 1: E/E' ratio and S wave (mean) by tertiles of reactivity to citrullinated myosin.

E/E' ratio and S wave (mean) are echocardiographic parameters that are increased (E/E' ratio) and decreased (S wave [mean]) in diastolic dysfunction

Session Title: Rheumatoid Arthritis – Etiology and Pathogenesis Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: RA is associated with the development of cardiovascular (CV) disease and subclinical atherosclerosis, which leads to an increased risk of CV mortality in RA patients¹. The presence of carotid plaques assessed by ultrasonography studies is a surrogate marker for subclinical atherosclerosis². Proprotein convertase subtilisin/kexin type 9 (PCSK9) is involved in homeostasis of cholesterol, a traditional CV risk factor related to RA and atherosclerosis^{1,3}. *PCSK9* polymorphisms can both increase and decrease the risk of CV disease in patients with atherosclerosis³. However, there are no information on *PCSK9* polymorphisms in RA. In the present study, we assess the role of several *PCSK9* polymorphisms in RA as well as determine if these ones may influence on *PCSK9* protein levels.

Methods: *PCSK9* rs562556, rs505151, rs2495477, rs2483205, rs2495482, rs2479409, rs11591147 and rs11583680 polymorphisms were genotyped in 1,170 Spanish RA patients, who met the 1987 ACR and the 2010 ACR/EULAR criteria for RA^{4,5}, and 528 healthy controls. Hardy-Weinberg equilibrium and allelic frequencies for each *PCSK9* polymorphism was checked and compared by X² test. Associations were estimated using odds ratios (OR) and 95% confidence intervals (CI). The potential association between significant *PCSK9* polymorphisms and carotid plaques was evaluated by logistic regression. In addition, *PCSK9* serum levels were determined by ELISA. All the results were adjusted by sex, age and traditional CV risk factors.

Results: Significant differences in the allele frequencies of rs2495477 between RA patients and controls were found (risk allele: p=0.014, OR=0.55, CI=0.34-0.89). A significant association between risk allele of rs2495477 and carotid plaques was also disclosed in RA patients (p=0.023, OR=0.76, CI=0.59-0.96). *PCSK9* protein levels were significant decreased in RA patients carrying rs2495477 risk allele compared to controls (p=0.0001).

Conclusion: Our study shows for the first time a protective role of *PCSK9* rs2495477 in a large cohort of RA patients, suggesting this polymorphism as a marker of RA. Furthermore, the risk allele of rs2495477 revealed a protective effect against the development of subclinical atherosclerosis in RA patients. Finally, rs2495477 decrease *PCSK9* levels in patients that may be crucial to control RA.

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Etiology and Pathogenesis Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Pannus infiltration and inflammatory cytokines are the main responsible factors for cartilage damage in rheumatoid arthritis (RA). Moreover, the crosstalk between inflammation and coagulation amplifies and maintains chronic inflammation. Whilst extravascular fibrin deposits in synovial fluid and synovial membrane being hallmarks of RA, there are no reports on direct fibrin deposition and its relation to cartilage damage in RA so far. The first aim is to investigate if fibrin deposition occurs in murine and human RA cartilage, and if there is a direct relation with cartilage degradation. Moreover, we want to determine the possible mechanism by which fibrin could play a role in the pathogenesis of RA.

Methods: Full-thickness cartilage explants were obtained from RA patients undergoing total knee replacement. Immunohistochemistry was performed on paraffin sections to study fibrin deposition, while Safranin-O staining was used to investigate cartilage damage. An *in vitro* model of chondrosynovial adhesion was established using primary human RA synoviocytes seeded on human RA cartilage explants. Adherent synoviocytes to cartilage were evaluated on H&E-stained histological sections and fibrin immunohistochemistry was performed on consecutive sections. An experimental RA model (antigen induced arthritis -AIA-) was applied in wild-type (WT) and fibrinogen knock-out mice and paraffin sections of knee joints assessed for fibrin deposition, cartilage damage, and chondrosynovial adhesion.

Results: In human RA cartilage, the amount of fibrin deposits positively correlated with the degree of cartilage degradation. In knees from WT mice fibrin deposition was preferentially found on damaged cartilage and on cartilage areas in direct contact with synovial membrane (i.e chondrosynovial adhesions). In contrast, cartilage degradation and chondrosynovial adhesion were significantly lower in fibrin deficient mice. Mechanical stripping of superficial cartilage layers by fibrin was observed in regions of chondrosynovial adhesion, indicating waxing properties of fibrin. Finally, fibrin-mediated chondrosynovial adhesion was confirmed in the *in vitro* model, where synoviocytes were found to adhere to human OA cartilage especially in severely damaged and fibrin-rich areas.

Conclusion: Our results demonstrate that fibrin deposition on cartilage is highly associated with chondrosynovial adhesion and subsequent cartilage damage in RA. We hypothesize that fibrin mediates chondrosynovial adhesion especially during joint resting periods (i.e night-time), leading to mechanical stripping of superficial cartilage layers following motion.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Etiology and Pathogenesis Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Aberrant angiogenesis has been considered as one of important factors for pathogenesis of rheumatoid arthritis (RA). Several angiogenetic mediators are reported to be massively expressed in synovial tissues of RA patients. Among the mediators, Notch-1 has been reported as one of important angiogenetic mediators in RA. A series of our previous studies have demonstrated that connective tissue growth factor (CTGF) was highly expressed in synovial tissue of RA. CTGF is a multifunctional cytokine and well known as strong mediator for fibrosis. Although we found that CTGF played an important role for the disease progression of RA by multiple mechanisms such as osteoclastogenesis, CTGF interestingly has also been reported as a potent angiogenetic mediator in other diseases. Therefore, this study was conducted to clarify whether CTGF associates with angiogenesis of RA, especially in terms of relation to Notch-1. Furthermore, the therapeutic efficacy of CTGF blockade for prevention of aberrant angiogenesis was also evaluated in animal model of RA.

Methods: Synovial tissue samples of RA patients were used for immunohistochemical analysis. CTGF association for angiogenesis was evaluated by tube formation assay and Boyden chamber assay using human umbilical vein endothelial cells (HUVECs) *in vitro*. CTGF-mediated Notch-1 activation were evaluated by immunofluorescence, immunoblotting, and quantitative RT-PCR analysis in HUVECs. Therapeutic efficacy of CTGF blockade for prevention of increased angiogenesis was evaluated in collagen induced arthritis (CIA) mice by administration of the neutralizing anti-CTGF antibodies.

Results: Synovial tissues of RA patients showed upregulation of Notch-1 pathway indicated by strong expression of Notch-1, Notch-1 transmembrane domain (NICD), and DLL-4. CTGF functioned as angiogenetic mediator and was able to activate Notch-1 signaling pathway *in vitro*. Administration of neutralizing anti-CTGF antibodies prevented the development of angiogenesis through inhibition of Notch-1 expression in CIA mice.

Conclusion: CTGF is able to mediate activation signal against Notch-1 which has been recently postulated as important factor of angiogenesis in RA. CTGF was considered to play an important role for aberrant angiogenesis of RA in combination with Notch-1. CTGF may become a novel target molecule for treatment of RA as CTGF blockade may ameliorate RA by multiple therapeutic mechanisms including suppression of aberrant angiogenesis.

Session Title: Rheumatoid Arthritis – Etiology and Pathogenesis Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: A great deal of recent attention has been directed at a possible link between intestinal microbial metabolism and inflammation. Metabolites represent the intermediate products of physiological processes that are influenced by the mechanisms of disease, environment, microbiota, and the digestion and biotransformation of foods and their constituents. Metabolomics captures the global metabolic status of individuals by assaying an extensive set of metabolites simultaneously. This study was undertaken to investigate discriminant metabolites in urine from patients with established rheumatoid arthritis (RA) from healthy individuals and patients with systemic lupus erythematosus (SLE). We further identified the *in vivo* role of metabolites in the animal arthritis model and human clinical data.

Methods: Urine samples were collected from 148 established RA patients, 41 SLE patients and 104 healthy participants. Urinary metabolomic profiles were assessed using ¹H-NMR spectroscopy. The relationships between discriminant metabolites and clinical variables were assessed in a large clinical cohort. Collagen-induced arthritis was induced in mice to determine if a choline-rich diet reduces arthritis progression.

Results: The urinary metabolic fingerprint of patients with established RA differs from that of healthy controls and SLE patients. Metabolites of gut microbiota and diet (trimethylamine-N-oxide; TMAO), and oxidative stress (dimethylamine) were upregulated in patients with RA. Metabolites of mitochondrial dysfunction (citrate and succinate) and metabolic waste products (p-cresol sulfate; p-CS) were downregulated. Urine metabolites were associated with RA disease activity. Particularly, urine levels of TMAO were negatively associated with serum inflammatory markers in patients with RA. Moreover, a more rapid radiographic progression over two years was observed in patients with lower p-CS levels. The *in vivo* functional study demonstrated that mice fed with 1% choline, a source of TMAO, showed a less severe form of collagen-induced arthritis than those fed with normal diet.

Conclusion: Patients with RA showed a distinct urinary metabolomics pattern. Urinary TMAO and p-CS can serve an indicative of inflammation or accelerated radiographic progression of RA. A choline-rich diet reduces experimentally-induced arthritis, suggesting that interaction of diet with intestinal microbiota contributes to the phenotype of RA.

Smith⁶, Jenny Walker¹ and Mihir D Wechalekar^{1,3}, ¹Rheumatology, Flinders University, Adelaide, Australia, ²Cellular Imaging, Flinders University, Adelaide, Australia, ³Royal Adelaide Hospital, Adelaide, Australia, ⁴Medicine, The University of Adelaide, Adelaide, Australia, ⁵Rheumatology, Royal Adelaide Hospital, Adelaide, Australia, ⁶Rheumatology, Flinders University, Adelaide, Australia

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Etiology and Pathogenesis Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Figure 1. Automated multiparameter imaging and analysis of RA ST. A, whole slide scanning. B, high-resolution multiparameter microscopy for CD20 (red), CD45RO (green) and CD68 (cyan). C, cell segmentation map. D, cellular phenotyping and E, automated cellular counting. F, tissue phenotyping and G, automated phenotype assessment.

Background/Purpose: Currently, histological assessment of synovial tissue (ST) in Rheumatoid Arthritis (RA) is hampered by 3 main factors: 1) tissue is a finite resource, 2) sequential sections of single conventional immunohistochemistry stains do not adequately preserve architectural and co-staining data, and, 3) image analysis and quantification is open to interpretation and human error. Furthermore, in RA, growing evidence implicates heterogeneous histopathological phenotypes with different disease outcomes and treatment responses, critical, as 30-40% of patients do not respond to current therapies and long-term drug-remission is rare, reflecting differential recruitment of inflammatory pathways and cell types. Thus, there is an unmet need for tools that can perform automated multi-parameter cellular identification and phenotype analysis on tissue sections, enabling translational research to assist in the development of personalised medicine.

Methods: Sequential 4µm thick RA ST sections were prepared for Opal multispectral imaging. In brief, for Opal; primary antibodies identifying memory T (CD45RO), B (CD20) and macrophage cell (CD68) are stained in turn, each followed by specific Opal reactive fluorophores. Primary antibody stripping prepares the section for the next primary antibody ready to repeat the process. Once all Opal targets have been developed, DAPI nuclear staining is performed prior to whole slide scanning (Figure 1A) and high-resolution (x20 magnification) image acquisition for CD45RO (green), CD20 (red), CD68 (cyan) and DAPI nuclear stain (blue) (Figure 1B) on the Perkin Elmer Vectra 3.0 automated imaging system.

Results: The image analysis and machine learning software package, in Form® was used to segment individual cells (Figure 1C), identify and quantify cellular phenotype (Figure 1D&E) and distinguish regions with “follicular” and “diffuse” staining patterns (Figure 1F&G).

Conclusion: Due to the recent surge in interest in ST biology, in particular in clinical trials investigating biologic therapies, there is a need for effective, reproducible and high-throughput technologies for immune-histological examination. Thus, a tool such as Opal can be utilised for whole slide scanning and automated analysis of ST infiltrates and tissue phenotype analysis. ST phenotype is thought to influence treatment outcomes in patients, therefore, comprehensive analysis of ST histology will result in more personalised and stratified medicine regimes for patients.

Phospholipase C-eta2, As a C2 Domain-Containing Protein, Regulate Aggressiveness of Fibroblast-like Synoviocytes and Ameliorate Arthritis in Experimental Animal Models of Rheumatoid Arthritis

Mingyo Kim, Hyun Min Jeon, Hae Sook Noh, Sang Mi Yi and Sang-Il Lee, Department of Internal Medicine and Institute of Health Science, Gyeongsang National University School of Medicine, Jinju, Korea, Republic of (South)

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Etiology and Pathogenesis Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The C2 domain is a Ca²⁺-dependent membrane-targeting motif found in many cellular proteins involved in signal transduction or inflammatory pathway. However, the effects of C2 domain-containing proteins in the pathogenesis of rheumatoid arthritis (RA) have not yet been elucidated. This study aims at screening the novel C2 domain-containing proteins related to the aggressiveness of RA fibroblast-like synoviocyte (RA-FLS) and confirm its precise roles in RA.

Methods: A recombinant adenovirus library expressing 145 kinds of C2 domains was transduced into RA-FLS to check the effects on the proliferation and NF-κB activation. Phospholipase C-eta2 (PLCH2) was selected as a target for C2 domain-containing protein. Recombinant adenovirus expressing PLCH2 (Adv-PLCH2) or C2 domain of PLCH2 (Adv-PLCH2_C2) were used for *in vitro* experiments using RA-FLS and MH7A cell line. The effect on the cell death of PLCH2 was assessed *in vivo* using a mouse Matrigel-plug model. Collagen-induced arthritis (CIA) model is also used to investigate the anti-arthritic effects of Adv-PLCH2, Adv-PLCH2_C2, and m-3M3FBS (PLC activator).

Results: PLCH2 levels were decreased in the RA-synovium and RA-FLS compared to osteoarthritis (OA), and further reduced after stimulation of LPS. Adv-PLCH2 and Adv-PLCH2_C2 suppressed proliferation, migration, invasion, NF-κB activation, cytokines/proteases production of RA-FLS and MH7A cell line. Adv-PLCH2 and Adv-PLCH2_C2 sensitized RA-FLS to apoptosis *in vitro* and *in vivo* model. Adv-PLCH2 or Adv-PLCH2_C2, as an intra-articular delivery, and m-3M3FBS, as systemic delivery of PLC activator, ameliorated inflammation and bone destruction in CIA mice.

Conclusion: Our data identify that PLCH2 and its activation efficiently suppress the aggressiveness of RA-FLS and inflammatory arthritis of CIA and suggest that PLCH2 may be an intriguing therapeutic target in RA.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Etiology and Pathogenesis Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Inflammation is part of the complex biological response of body tissues to harmful stimuli, involving immune cells, blood vessels, and molecular mediators. At the initial phase, characterized by an increase in pro-inflammatory cytokines aiming to neutralize the tissue injury, the resolution process must follow to down-regulate the inflammation and to promote tissue repair. That latter phase is driven by the so called Specialized Pro-Resolving Mediators (SPMs), such as Resolvin (RvD and RvE), Protectins, Maresins and Lipoxin A4 (LXA4), bioactive metabolites of omega-3 fatty acids that act by interacting with specific cellular receptors: CMKLR1, FPR2 and GPR32. In rheumatoid arthritis (RA) the reactive inflammation becomes persistent and the innate immune response turns into the adaptive immune activation. Nowadays there is no evidence whether SPMs are involved in RA pathogenesis. Purpose of this study was to evaluate the expression of CMKLR1, FPR2 and BLT1 in RA patients and to correlate it to the disease activity.

Methods: Patients affected with RA, according to the 2010 EULAR/ACR classification criteria, were enrolled in this study. Exclusion criteria were: minority age, status of pregnancy or breastfeeding, concomitant any other autoimmune disease. At entry, ESR, CRP, DAS28-ESR, CDAI, Health Assessment Questionnaire Disability Index (HAQ) and peripheral venous blood sample were collected. Based on DAS28-ESR, patients were divided into high-moderate (H-Mo/RA if DAS28-ESR ≥ 3.2) and low-remission (L-Rem/RA if DAS28 < 3.2) disease activity group. The expression of CMKLR1, FPR2 and BLT1 in peripheral T cells (CD3) and B cells (CD19), monocytes (CD14) and granulocytes (gated by high side scatter), was evaluated by flow-cytometry assay. Differences for continuous variables were evaluated using the Mann-Whitney test, while for categorical data the Fisher's probability test. Correlations were assessed using the Spearman test.

Results: Thirty RA patients, 21 H-Mo/RA and 9 L-Rem/RA, and 6 healthy control (HC) were studied. While no difference in the expression of CMKLR1, FPR2 and BLT1 in RA vs HC was found, SPMs receptors were differently expressed on CD14-monocytes: BLT1⁺CD14⁺ cells were significantly higher in L-Rem/RA (90,96%) than in H-Mo/RA / RA (56,70%) (p: 0.0001). Likewise, FPR2⁺CD14⁺ cells were significantly higher in L-Rem/RA (92,29%) than in H-Mo/RA / RA (79,94%) (p: 0.01). We also demonstrated an inverse correlation between BLT1 level in monocytes and ESR (p: 0.01), CRP levels (p: 0.008), DAS28-ESR (p: 0.03), CDAI (p: 0,0076) and HAQ (p: 0,0138) and a weak correlation between FPR2 expression and HAQ (p: 0.05).

Conclusion: In this study, FPR2 and BLT1 expression seem to be regulated by the activity of RA disease. As FPR2 and BLT1 should be involved in down-regulating inflammation by monocytes, it might be hypothesized that a defective signalling through these SPMs receptors may contribute to prevent the beginning of resolution phase, perpetuating chronic inflammation in active RA. However, further studies are needed to explore the intrigue mechanisms beyond inflammation and its resolution.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Etiology and Pathogenesis Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Synovial biopsies are increasingly performed in both clinical setting and translational research. Synovial tissue analysis role in prediction of response to treatment is to be yet considered and regarding that most studies involve multicentric participation, an unmet need is the standardization of synovial biopsies procedures. The aim of this collaborative work was to create a consensual set of items for handling and analysis of synovial biopsies in clinical practice and translational research.

Methods: EULAR Synovitis Study Group (ESSG) and Synovial Tissue Special Interest Group (SIG) members were consulted through a Delphi survey. 3 sequential rounds occurred between June 2016 and June 2017. The items were identified and formulated based on a comprehensive literature review. Members were sent a written questionnaire containing items divided in 2 parts. The first part of the questionnaire referred to clinical practice containing 5 subsections: biopsy sampling, biopsy handling, histological analysis, staining and immunohistochemistry (IHC), biopsy analysis and pathologist's report. The second part referred to translational research and contained 6 subsections (same 5 plus RNA analysis).

Every participant was asked to score each item with a 5 points Likert (0: strongly disagree, 5: strongly agree), comments were allowed for each item. Items with a median score above 3.5 on 5 and a percentage of agreement above 70% were for the next round. Items with lower score were either suppressed or modified according to participants' comments. Anonymized detailed results were circulating through participants between each round. Last round occurred orally at ESSG meeting in June 2017.

Results: 27 ESSG members from 19 centers were contacted by email. 20 participants from 17 centers answered (response rate of 74%). Response rates for next rounds were 100%. First questionnaire contained 44 items for Part 1 Clinical practice and 43 items for the second part about translational research. The flow chart is described in Figure 1. Third oral round allowed to obtain a final set of items unanimously (Figure 2).

Figure 1. Delphi Flow Chart

Figure 2. Final list of items

CLINICAL PRACTICE

1. Biopsy sampling

- A minimum of 4 synovial biopsies needs to be retrieved in small joints.
- Biopsies shall be retrieved in different areas of the joint, if possible.
- If it is clinically relevant, bacteriological, fungal and mycobacteriological assessment should be performed.
- Polymerase chain reaction analysis for AIN (ES) should be performed if clinically relevant, especially if empiric antibiotic course has been started.
- If it is clinically relevant, Polymerase chain reaction analysis for Lyme and Whipple diseases should be performed.

2. Biopsy processing

- The biopsies should spend 24 hours in formalin 4%.
- At least 2 biopsies should be formalin-fixed and paraffin-embedded.

3. Histological criteria

- Synovial biopsy surface should be more than 2.5mm².
- A lining layer should be seen.
- Morphology of the synovial tissue should be preserved.

4. Staining and immunohistochemistry (IHC)

- H&E staining should always be performed.
- CD68 staining should be performed.
- In particular clinically relevant cases, additional staining should be performed (CD3, CD20, CD138, CD31 or FvII).
- If performed, IHC results can be given using a semi-quantitative score.

5. Biopsies interpretation and Pathologist's report

- A synovitis score should be performed, analyzing: lining layer hyperplasia, inflammatory infiltrate and resident cell activation (Kern, other).
- Lining layer hyperplasia should be scored.
- Synovial pathology should be described.
- Presence or absence of lymphoid follicles within the membrane should be described.
- Analysis can be semi-quantitative or quantitative depending on the question.
- If a semi-quantitative or quantitative analysis is performed for multiple biopsies, an average score should be calculated and given for the analysis of inflammation and vascularization.
- The pathologist should mention the presence of granulomas.

TRANSLATIONAL RESEARCH

1. Biopsy sampling

- A minimum of 6 synovial biopsies needs to be retrieved in large joints.
- A minimum of 4 synovial biopsies needs to be retrieved in small joints.
- Biopsies shall be retrieved in different areas of the joint, if possible.

2. Biopsy processing

- The biopsies should spend 24 hours in formalin 4%.

3. Histological criteria

- Synovial biopsy surface should be more than 2.5mm².
- A lining layer should be seen.
- Morphology of the synovial tissue should be preserved.

4. Staining and immunohistochemistry (IHC)

- H&E staining should always be performed.
- CD68 staining should be performed.
- CD3, CD19 or CD20 staining should be performed.
- Additional CD 31 or FvII, CD4, CD8, CD138 staining might be performed depending on the question.

5. Biopsies interpretation and Pathologist's report

- A synovitis score should be performed, analyzing: lining layer hyperplasia, inflammatory infiltrate and resident cell activation (Kern, other).
- Lining layer hyperplasia should be scored.
- Synovial pathology should be described.
- Presence or absence of lymphoid follicles within the membrane should be described.
- Analysis can be semi-quantitative or quantitative depending on the question.
- If a semi-quantitative or quantitative analysis is performed for a single biopsy, at least 3 area of the biopsy should be assessed.

6. RNA Analysis

- Biopsies of one patient can be pooled for RNA extraction if needed.

Conclusion: We hereby propose a set of consensual points to consider on analysis of synovial biopsies in clinical practice and translational research to be further used in multicentric clinical trials and therefore ensure reliability.

Session Date: Monday, October 22, 2018

Session Title: Systemic Lupus Erythematosus – Etiology and Pathogenesis Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Recently, many reports on immune metabolism have been accumulated and metabolic changes are now considered to be a key factor for controlling immune cell differentiation, proliferation and function. Although precise mechanism of tuning metabolic status in immune cells has been clarified, these results have mainly come from the mice experiments and metabolomics analysis on human autoimmune diseases gets underway. The aim of this study is to get some insights on metabolomic regulation in SLE by comprehensively measuring plasma metabolites.

Methods: We collected plasma samples from patients with SLE (n=41) who met the 1997 American College of Rheumatology criteria for SLE and had the history of lupus nephritis. Gender- and age-matched healthy controls (HCs) (n=30) were recruited. For comparison, plasma from 19 rheumatoid arthritis (RA) patients were also collected. Metabolic profiles were analyzed with capillary electrophoresis (CE)- and liquid chromatography (LC)- time of flight mass spectrometry (TOFMS) in conjunction with multivariate statistical analysis. Transcriptome data of SLE patients were obtained from our RNA-sequencing data of each immune cell subset (total 20 subsets).

Results: About 180 peaks were detected from CE-TOFMS including absolutely quantified 110 metabolites and about 160 peaks were detected from LC-TOFMS. Random Forest, one of the machine learning algorithms, revealed the importance of histidine (His) to classify SLE patients from HCs. Partial least squares discriminant analysis (PLS-DA) also showed the significance of His, whose plasma level was lower in SLE patients. In addition, we divided SLE patients into two groups by using transcriptome data; interferon (IFN)-signature high and low. Interestingly, we found some amino acids were associated with IFN-signature level. In addition, inverse correlation between His level and titer of ds-DNA was detected. His level was also decreased in RA patients compared to HCs and was inversely correlated with DAS28-ESR and CRP in RA. Weighted gene co-expression network analysis (WGCNA), one of network analysis, showed positive correlation between mitochondria-related module and plasma His level in B cells.

Conclusion: Plasma metabolic changes in autoimmune diseases might not only reflect the chronic activated immune-status but also associate with their pathogenesis themselves. His may be an important factor for SLE pathogenesis especially in B cells independently from IFN signal. SLC15A4, a transporter of His on lysosome, is one of the SLE GWAS SNPs and has been reported to play an important role in IFN production in B cells through regulation of TLR7/9 activation. Low plasma level of His could be a useful marker of SLE activity and maintenance of His homeostasis could become a novel treatment target for SLE.

Hypomethylation of STAT1 and HLA-DRB1 in CD8+ T Cells Is Associated with Type-I Interferon-Dependent HLA-DRB1 Overexpression and Activation of Autologous CD4+ T Cells in Systemic Lupus Erythematosus

Shaylynn Miller¹, Patrick Coit¹, Elizabeth Gensterblum-Miller¹, Paul Renauer^{1,2}, Nathan Kilian^{1,3}, Mark Schonfeld¹, Pei-Suen Tsou¹ and Amr H Sawalha¹, ¹Division of Rheumatology, University of Michigan, Ann Arbor, MI, ²Department of Genetics, Yale University, New Haven, CT, ³Medical School, Georgetown University, Washington, DC

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Lupus Erythematosus – Etiology and Pathogenesis Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic lupus erythematosus is a chronic autoimmune disease characterized by epigenetic dysregulation, and increased autoantibody and type-I interferon (IFN) production. The goal of this study was to explore possible pathogenic roles of CD8+ T cells in lupus through characterizing DNA methylation changes.

Methods: Genome-wide DNA methylation of lupus and age, sex and ethnicity-matched control CD8+ T cells was measured using the Infinium MethylationEPIC arrays. Data preprocessing and statistical analysis of differentially methylated CpG sites was performed using GenomeStudio (Illumina). Gene ontology analysis of differentially methylated sites was performed with DAVID. Measurement of HLA-DRB1 expression on the surface of lupus and control CD8+ T cells with and without interferon alpha (IFN α) was performed by flow cytometry. Co-incubation of IFN α -treated CD8+ T cells from lupus patients and controls with autologous naïve CD4+ T cells to assess effects on CD4+ T cell stimulation were performed. CD8+ T cell mRNA levels normalized to β -actin were quantified by qPCR.

Results: Lupus CD8+ T cells had 188 hypomethylated CpG sites compared to healthy matched controls. Among the most demethylated were sites associated with *HLA-DRB1* (Db = -0.33) and *STAT1* (Db = -0.15). The proportion of CD8+ T cells expressing HLA-DRB1 was significantly higher in lupus compared to controls. IFN α treatment upregulated cell surface expression of HLA-DRB1 on CD8+ T cells of lupus patients but not healthy controls. Co-incubation of naïve CD4+ T cells with IFN α -treated autologous CD8+ T cells led to increased expression of the stimulation marker CD69 on CD4+ T cells in lupus patients, but not in healthy controls. This effect can be abrogated using HLA-DR blocking antibodies. Lupus and control CD8+ T cells significantly increased STAT1 mRNA levels after treatment with IFN α . The expression of CIITA, a key interferon/STAT1 dependent MHC-class II regulator, is induced by IFN α in lupus CD8+ T cells, but not healthy controls.

Conclusion: *HLA-DRB1* and *STAT1* loci are hypomethylated and epigenetically poised for overexpression in lupus CD8+ T cells in the presence of type-I interferon. IFN α -treated lupus CD8+ T cells stimulate autologous CD4+ T cells *in vitro* and blocking of HLA-DR on CD8+ T cells can abrogate this effect. These data suggest a possible pathogenic role for CD8+ T cells in lupus that is dependent upon a high type-I interferon environment and epigenetic priming.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Lupus Erythematosus – Etiology and Pathogenesis Poster II

Background/Purpose: Low or no alcohol intake (0-5gm/day or <0.5 drinks/day) has been associated with increased SLE risk among women. Several cytokines and chemokines are involved in disease pathogenesis and are upregulated prior to SLE onset. We investigated whether alcohol intake was associated with B-lymphocyte stimulator (BLyS), stem cell factor (SCF), interferon alpha (IFN- α) and interferon-gamma induced protein (IP-10) concentrations in a large cross-sectional study of women.

Methods: The Nurses' Health Study (NHS, n=121,700 and NHSII n=116,429) cohorts began in 1976 and 1989, collecting exposure and outcome data on detailed biennial questionnaires. In 1988-1989, ~25% participants donated a blood sample. Cumulative average intake of beer, wine or liquor in drinks per day was assessed prior to the blood draw. We identified 1177 women without SLE prior to blood draw with banked plasma samples and alcohol data. Samples were tested by ELISA assays for BLyS, SCF, IFN- α and IP-10 (each passed quality control [QC] using blinded split samples). We adjusted for inter-batch variation using common QC samples and natural log-transformed all biomarkers to improve normality. ANA (hep2 IF) and ELISAs for anti-dsDNA and extractable nuclear antigens (ENAs; anti-Ro, anti-La, anti-Sm and anti-RNP) were tested. We assessed relationships between alcohol intake (0-5 [low] vs. >5 [high] grams/day) and biomarker concentrations overall and among women with SLE autoantibody positivity in age-adjusted and then multivariable models adjusting for age, race, body mass index, smoking status, and history of depression. SCF and BLyS were assessed using general linear regression, and IP-10 and IFN- α were assessed using Tobit regression due to the high proportion below threshold (IP-10 undetectable=165 [14%] and IFN- α undetectable=754 [64%]).

Results: Mean age at blood draw was 56 years (SD 10). Low alcohol intake was associated with increased circulating SCF concentration among all women (β [SE]= 0.10 [0.02], $p<0.0001$) and among the 295 ANA, dsDNA or ENA positive women (β [SE]=0.11[0.04], $p=0.05$). (Table) In age-adjusted models, BLyS and IP-10 were higher (BLyS β [SE]= 0.05[0.02], $p=0.03$; IP-10 β [SE]=2.04 [0.51], $p<0.0001$) among women with low alcohol intake, while IFN- α concentration was lower (β [SE]=-5.9 [2.3]; $p=0.01$).

Conclusion: Low or no alcohol intake was associated with increased SCF concentrations, but not with other SLE-related cytokine/chemokine concentrations in this cross-sectional sample of women without SLE in the NHS and NHSII cohorts. Stem cell factor (SCF) plays a role in T-cell differentiation and hematopoiesis. It is thought to be upregulated prior to SLE diagnosis. Decreased SLE risk among women with moderate alcohol intake may be related to inhibition of SCF.

Table. A: Mean Daily Alcohol Intake (≤ 5 gm vs. >5 gm) and Continuous Log Concentrations of BLyS and SCF-1 within a cross-sectional sample of women in the Nurses' Health Study Cohorts

	Log BLyS				Log SCF			
	Age-adjusted Models		Multi-variable Models		Age-adjusted Models		Multi-variable Models	
≤ 5 gm vs. >5 gm per day Alcohol Intake	β (SE)	P	β (SE)	P*	β (SE)	p	β (SE)	P*
Among all women (n=1177)	0.05 (0.02)	0.03	0.04 (0.02)	0.07	0.10 (0.02)	<0.0001	0.08 (0.02)	0.0001
Among ANA/dsDNA/ENA+ women (n=295)	0.01 (0.05)	0.76	0.03 (0.05)	0.50	0.11 (0.04)	0.005	0.08 (0.04)	0.05

Table. B: Mean Daily Alcohol Intake (≤ 5 gm vs. >5 gm) and Continuous Log Concentrations of IP-10 and IFN- α within a cross-sectional sample of women in the Nurses' Health Study Cohorts

	Log IP-10**				Log IFN- α **			
	Age-adjusted Models		Multi-variable Models		Age-adjusted Models		Multi-variable Models	
≤ 5 gm vs. >5 gm per day Alcohol Intake	β (SE)	P	β (SE)	P*	β (SE)	p	β (SE)	P*
Among all women (n=1177)	0.03 (0.11)	0.82	0.08 (0.11)	0.47	-0.42 (0.45)	0.35	-0.22 (0.46)	0.62
Among ANA/dsDNA/ENA+ women (n=295)	2.04 (0.51)	<0.0001	0.32 (0.22)	0.14	-5.9 (2.3)	0.01	-0.22 (0.95)	0.82

* Multivariable general linear regression and Tobit models, adjusted for age (continuous), race (Black vs. other), smoking (current/recent quit vs. never or remote quit), body mass index (continuous), history of depression (present vs not)

** Tobit analysis is utilized for maximum usage of cytokines/chemokines if there are many undetectable values.

Peripheral Blood CD11c+ CD21- Age-Associated B Cells (ABCs) in Human Systemic Lupus Erythematosus Are Associated with Innate Type III Interferon and Disease Activity

Jennifer L. Barnas, Lin Gao, Mary O'Connell, Jennifer Albrecht, Nida Meednu, R. John Looney and Jennifer Anolik, Medicine- Allergy, Immunology and Rheumatology, University of Rochester Medical Center, Rochester, NY

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Lupus Erythematosus – Etiology and Pathogenesis Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is characterized by an interferon-stimulated gene (ISG) signature typically attributed to interferon (IFN)- α . However, ISGs can be induced by other innate type I interferons (such as β) as well as type III IFN (λ). Type I IFNs may contribute to disease pathogenesis through immune dysregulation, including activation of the B cell compartment. One recently described B cell abnormality associated with lupus in mouse models is the presence of age-associated B cells (ABCs), a population expanded by self-antigen and type II adaptive IFNs (γ), enriched for autoreactivity, and poised for plasma cells differentiation. ABCs have been characterized as CD11c+, CD21- and T-bet+ B cells. The precise frequency and triggers of ABCs in human lupus remain unclear. The purpose of this study was to characterize the ABC population in SLE patients and relationship with disease activity and innate IFN serum levels.

Methods: Peripheral blood leukocytes from 26 lupus patients with a range of disease activity as well as 6 normal healthy donors (ND) were analyzed by flow cytometry using a panel which included CD3, CD11c, CD19, CD20, CD21, CD24, CD27, CD38, CD95, CXCR3, IgD, and T-bet. All lupus patients met ACR criteria. Lupus patients were divided into groups based upon SLEDAI score. IFN- α , IFN- β , and IFN- λ 1 (IL-29) levels were quantitated by ELISA from sera drawn on the same day.

Results: CD11c+ CD21- identified a distinct B cell population. The majority of these putative ABCs (CD3- CD19+ CD11c+ CD21-) were distributed in the IgD- CD27- double negative B cell compartment (mean \pm SEM% of ABC; 61.5 \pm 2.8 in SLE, 66.8 \pm 4.3% ND) followed by IgD+CD27- total naive (23.0 \pm 3.0% SLE, 17.9 \pm 3.4% ND), then switched memory IgD-CD27+ (12.2 \pm 1.4% SLE, 11.0 \pm 1.2% ND). ABC were primarily CD24- (84.4 \pm 1.9% SLE, 78.3 \pm 8.3% ND). Thus, activated naive represented the majority ABC in the total naive compartment. Putative ABCs comprised a greater percentage of total B cells in lupus patients (4.7 \pm 1.1%) compared to ND (0.99 \pm 0.1%, unpaired T test with Welch's correction p-value = 0.0026 with significant difference in variances). Within this CD11c+CD21- B cell population, a subset of cells expressed T-bet (46.2 \pm 4.3% SLE, 58.1 \pm 5.4% ND). IFN- λ 1 serum level positively correlated with CD11c+CD21- (Spearman r =+0.415, p =0.018), double negative IgD-CD27-CD24-CD21- (Spearman r =+0.454, p =0.009) and T bet+ (Spearman r =+0.304, p =0.09) expressing B cells. IFN- β serum level positively correlated with the percentage of transitional B cells (Spearman r =+0.428, p =0.015). ABCs made up a statistically significant greater percentage of total B cells in patients with a SLEDAI >8 compared to patients grouped by lower disease activity scores (p =0.01, 2-tailed unpaired T test). No correlation between B cell subsets or SLEDAI was found with serum IFN- α level as measured by an all alpha subtype ELISA.

Conclusion: Our data highlights the importance of innate IFNs other than IFN- α (such as IFN- λ 1 and IFN- β) in B cell abnormalities in SLE, including the expansion of ABCs and transitional B cells. Functional characterization of the ABC subset is needed to better understand how it contributes to disease pathogenesis and further define therapeutic target potential.

Changes of Innate Lymphoid Cells in Peripheral Blood of Patients with Systemic Lupus Erythematosus and Its Correlations with Clinical Markers

Hui Chu, Xiaomei Li, zhen Tan, ruolan Wu, Xiangpei Li, xuan Fang, xu Zhen and Guosheng Wang, The first affiliated hospital of university of Science and Technology of China, Hefei, China

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Lupus Erythematosus – Etiology and Pathogenesis Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

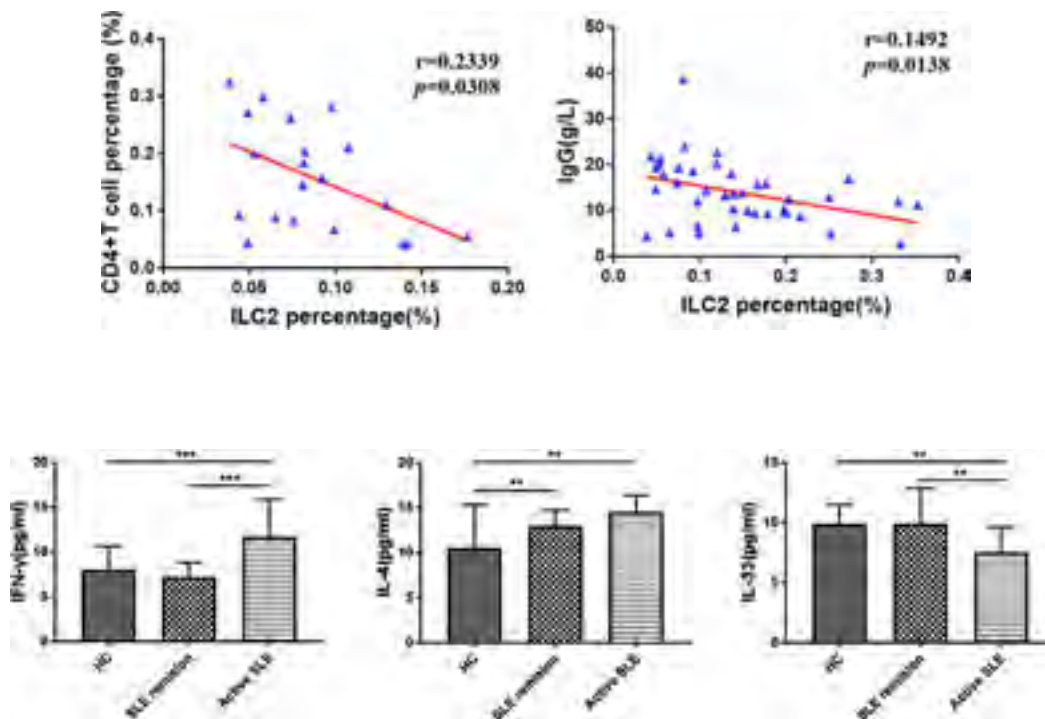

Background/Purpose: Innate Lymphoid Cells (ILCs) are a novel group of innate immune cells, according to the cytokine profile, they were divided into three major subsets: ILC1(Lin⁻CIL7R+NKp46+ILCs), ILC2(Lin⁻CIL7R+CRTH2+ILCs) and ILC3(Lin⁻CIL7R+CRTH2⁻CCD117+ILCs). Little research on ILC in the pathogenesis of systemic lupus erythematosus. Our purpose is to explore the function and role of innate lymphoid cells(ILCs) in the pathogenesis of systemic lupus erythematosus at different disease activity levels.

Methods: 40 patients with SLE were included, according to the SLEDAI-2K, patients were divided into active group(n=20) and remission group(n=20), 15 age-matched healthy non-immune-related diseases controls. The frequency of ILCs, B cells, CD4+T and CD8+T cells from PBMCs was detected by flow cytometry. Analysis the subsets of ILCs in each group which compared with B cells and T cell subsets respectively and correlated with clinical serologic markers. Analyze the level of IL-4, IL-33 and IFN- γ in each group by ELISA.

Results: Compared with the control group, ILC1 percentage was significantly increased in SLE active group(P=0.0181); ILC2 was decreased significantly in both remission(P<0.0001) and active groups(P<0.0001); ILC3 was decreased significantly in active group(P=0.0013). The frequency of ILCs in all patients positively correlated with SLEDAI score(P=0.0172). The frequency of ILCs in the remission(P=0.0462) and activity group (P=0.0037) are both increased significantly (**Figure1**). Moreover, the frequency of ILC2 in active group was negatively correlated with CD4+T cells(P=0.0308), and the serum IgG inpatients was negatively correlated with ILC2 of all patients (P=0.0138)(**Figure2**). Compared with either control group or the remission group, the levels of IFN- γ (P=0.0001) and IL-4 (P=0.0047) in active group were remarkable higher. However, IL-33 was significantly reduced in active group(P=0.0027)(**Figure3**). (*,p<0.05; **,p<0.01; ***,p<0.001).

Conclusion: The frequency of ILCs is related to disease activity, and ILCs play a “double-edged” role in the pathogenesis of SLE. Its function and mechanism are worth further exploration.

Buyn¹ and Boris Reizis¹, ¹NYU School of Medicine, New York, NY, ²Medicine, Division of Rheumatology, NYU School of Medicine, New York, NY, ³Medicine, NYU School of Medicine, New York, NY

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Lupus Erythematosus – Etiology and Pathogenesis Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: DNASE1L3 is a unique secreted DNase that is capable of degrading DNA complexed with proteins and/or encapsulated in membranes, such as chromatin within microparticles from apoptotic cells. The role of DNASE1L3 in the pathogenesis of SLE is supported by the nearly universal association of DNASE1L3 null mutations with familial SLE, the linkage of a hypomorphic variant to sporadic SLE, and the development of anti-DNA response and SLE-like disease in DNASE1L3-deficient mice. Accordingly, this study was initiated to delineate the role of microparticle-associated antigens sensitive to DNASE1L3 digestion as targets of antibody reactivity in human SLE.

Methods: Antibodies to DNA on microparticles were measured using an in vitro assay. Jurkat human T cells were treated with staurosporine to induce apoptosis, and microparticles were isolated. After mock-treatment or treatment with recombinant DNASE1L3, the microparticles were subsequently incubated with sera, washed, and stained with fluorescently labeled anti-human IgG prior to evaluation using flow cytometry. The ratio of binding values with or without DNASE1L3 pre-treatment indicates the binding to DNASE1L3-sensitive antigens (including DNA and/or DNA-associated proteins) versus other antigens exposed on microparticles.

Results: Evaluation of sera (76 from 66 SLE patients, 19 controls, 34 anti-Ro positive neonatal lupus mothers) revealed three types of reactivity to microparticles: i) no binding; ii) binding insensitive to DNASE1L3; and iii) binding that is

sensitive to DNASE1L3. Notably, the only two patients heterozygous for the DNASE1L3 (R206C) hypomorphic variant belonged to this latter group. Samples from 30 (45%) of the SLE patients showed DNASE1L3-sensitive binding while this reactivity was absent in all controls. Although hypomorphic allelic variants are restricted to European ancestry, sensitive binding was observed in all ethnic/racial groups. SLE patients with sensitive vs insensitive binding had a significantly higher frequency of past/present renal disease (87% vs 44%, $p=0.0007$). Moreover, at the time of blood sampling, sensitive binding was associated with the presence of >0.5 uPCR (61% vs 30%, $p=0.012$) and low complement levels (78% vs 53%, $p=0.031$). Overall, sensitive binders were more active with SLEDAI score ≥ 8 in 47% vs 21% ($p=0.007$). Supporting that DNASE1L3 can disrupt pre-formed complexes of IgG with antigen on microparticles, binding to the native microparticles could be abrogated by subsequent addition of the enzyme. Several subjects within the group of high titer anti-Ro positive mothers (asymptomatic, UAS, SS, SLE but no history of nephritis) showed strong binding to native microparticles, but this binding was not DNASE1L3-sensitive.

Conclusion: These data support that reactivity to physiological DNA-associated antigens from apoptotic cells is relevant in lupus nephritis and suggest DNASE1L3 as a novel pharmacological approach to forestall organ injury.

Natural Gingerols Inhibit Neutrophil Extracellular Trap Release Elicited By Lupus Autoantibodies

Ramadan A. Ali¹ and Jason S. Knight², ¹University of Michigan, Ann Arbor, MI, ²., University of Michigan, Ann Arbor, MI

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Lupus Erythematosus – Etiology and Pathogenesis Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Recent studies have revealed a role for neutrophils in the pathogenesis of lupus and antiphospholipid syndrome (APS). Indeed, neutrophils are activated by various disease-relevant stimuli including ribonucleoprotein (RNP)/anti-RNP complexes and antiphospholipid antibodies (aPL) to release tangles of DNA and protein known as neutrophil extracellular traps (NETs). Ginger is known to have anti-inflammatory and anti-oxidative effects, and has traditionally been used as an herbal supplement in the treatment of inflammatory diseases. Here, we hypothesized that compounds isolated from ginger might mitigate NET release (NETosis) in response to lupus- and APS-relevant stimuli.

Methods: Control human neutrophils were prepared from healthy volunteers and stimulated with phorbol 12-myristate 13-acetate (PMA); *E. coli* lipopolysaccharide (LPS); total IgG fractions prepared from primary APS patients (aPL); or RNP/anti-RNP complexes prepared from lupus patients. Stimulation was in the presence of various bioactive compounds derived from ginger root. NETosis was quantified via chromogenic measurement of the enzymatic activity of NET-associated myeloperoxidase.

Results: So-called “gingerols” are the major bioactive compounds of ginger root. We first tested the efficacy of three related compounds, 6-gingerol, 8-gingerol, and 10-gingerol, for their ability to suppress NETosis by control neutrophils (of these compounds, 6-gingerol is the most abundant in ginger root). At doses ranging from 1 to 10 micromolar, both 6- and 8-gingerol completely neutralized aPL- and LPS-triggered NETosis, while 10-gingerol reduced NETosis by about 75%. 6-gingerol also effectively suppressed RNP/anti-RNP-induced NETosis at low micromolar concentrations. Interestingly, none of the compounds were efficacious against PMA-induced NETosis. Mechanistically, we reasoned that gingerols might suppress NETosis by preventing the neutrophil oxidative burst, as reactive oxygen species (ROS) are required for most forms of NETosis. Interestingly, aPL, LPS, and PMA all triggered significant hydrogen peroxide production by neutrophils, but gingerols only neutralized peroxide elicited by aPL and LPS.

Conclusion: We demonstrate for the first time that various natural gingerols found in ginger root can attenuate NET release and ROS production in response to various lupus-relevant stimuli (but not PMA) *in vitro*. Studies are underway to determine the extent to which these natural compounds may mitigate NET release, endothelial dysfunction, and venous thrombosis in mouse models of lupus and APS.

Low-Dose IL-2 Combined with Rapamycin Efficiently Promotes Remission of Refractory Systemic Lupus Erythematosus

Zhaoyun Liang¹, Xiaona Jing¹, Meihua Hao¹, Chong Gao², Xiao-Feng Li³ and Junwei Chen¹, ¹The Second Hospital of Shanxi Medical University, Taiyuan, China, ²Department of Pathology, Brigham and Women's Hospital, Harvard Medical School, Boston, MA, Cambridge, MA, ³Rheumatology, the Second Hospital of Shanxi Medical University, Taiyuan, China

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Lupus Erythematosus – Etiology and Pathogenesis Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is a potentially fatal autoimmune disease. Regulatory T (Treg) cells and T helper type 17 (Th17) cells play opposite roles in immune tolerance and autoimmune diseases. It was reported previously that elevated Th17 and/or decreased Treg cells caused an imbalance of Treg/Th17 in SLE. Since low-dose IL-2 can selectively stimulate the differentiation of CD4⁺Treg cells and rapamycin can promote the proliferation of Treg cells and inhibits differentiation of Th17 cells, the combined treatment of the low-dose IL-2 and rapamycin may increase the remission rate of SLE.

Methods: Sixty-six refractory SLE patients (53 women and 3 men), with an average course of 74.22±40.91 months and average age of 33.10±11.72 years, were enrolled. They fulfilled the 1997 ACR criteria and had been treating with glucocorticoid and immunosuppressant for more than one year, but had not yet reached the disease remission. The standard for remission is defined as meeting all the following conditions: sustained remission of clinical symptoms, no organ damage indication, normal inflammatory index and normal immune function. The eligible patients were given IL-2 and rapamycin in combination with conventional therapy. At 0, 6, 12, 24 week respectively after medication, the absolute numbers of Th17 cells and Treg cells in blood were examined by flow cytometry. Also, the clinical symptoms, blood routine, urine routine, ESR, the dosage of corticosteroids and immunosuppressant, or the remission rate was registered respectively.

Results: As compared with healthy controls, the absolute number of Treg cells in the patients with refractory SLE significantly decreased, whereas that of Th17 cells did not increase clearly. At 24 week after treatment with low-dose IL-2 combined with rapamycin, 36.0% of patients with refractory SLE achieved remission, accompanying increase in the absolute numbers of peripheral Treg cells from a median of 17.08 cells/μl (at week 0) to 28.16 cells/μl (at week 24) (P=0.002). Accordingly, the ratio of Th17/Treg cells showed a reduction from a median of 0.87 at week 0 to 0.31 at week 24 (P=0.019), indicating a restored balance of them. No significant difference was observed in the absolute numbers of Th17 after combined treatment. At week 24, the mean dosage of prednisone used in refractory SLE patients was decreased from 17.19 mg/d to 9.11 mg/d. And the categories of immunosuppressant used were also reduced (P<0.05).

Conclusion: Our findings indicate that refractory SLE is associated with the decreased absolute number of Treg cells but not increased Th17 cells in blood. Low-dose IL-2 combined with rapamycin treatment can restore the balance of Th17 and Treg cells in refractory SLE due to the significant increase in Treg cells. This therapy can induce higher remission rate of the patients after 24-week treatment and reduce the usage of glucocorticoid and immunosuppressant.

Association between Cigarette Smoking and Systemic Lupus Erythematosus – a Bayesian Multivariate Meta-Analysis of Case-Control and Cohort Studies

Monica Hui Yan Chua¹, Irene Ai Ting Ng¹, Mike Wai-Leung Cheung² and Anselm Mak³, ¹Yong Loo Lin School of Medicine, National University of Singapore, Singapore, Singapore, ²Psychology, Faculty of Arts and Social Sciences, National University of Singapore, Singapore, Singapore, ³Medicine, Yong Loo Lin School of Medicine, National University of Singapore, Singapore, Singapore

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Lupus Erythematosus – Etiology and Pathogenesis Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The association between cigarette smoking and the occurrence of SLE has been studied over the past two decades but results are conflicting. The global increase in women smokers and the availability of prospective data addressing the risk of the development of SLE and cigarette smoking warrant an update on the evidence of the relationship between cigarette smoking and the occurrence of SLE. This study aims to refine the association between cigarette smoking and the odds of SLE occurrence by Bayesian multivariate meta-analysis of case-control and cohort studies.

Methods: An extensive literature search using the relevant keywords including “systemic lupus erythematosus”; “lupus”; “smoking”; “cigarette smoking”; “environmental”; “autoimmune disease” and “connective tissue disease” in various combinations was performed in order to identify case-control and cohort studies addressing the relationship between cigarette smoking and SLE published in English in computerized databases including PubMed (from 1966 to Jan 2018), Embase (1980 to Jan 2018) and Cochrane Central Register of Control Trials (last quarter of 2017). A Bayesian multivariate meta-analysis was conducted by computing the log odds ratios (ORs) between current and never smokers, and between ex-smokers and never smokers. Following which, the sampling covariances of the effect sizes were calculated and heterogeneity variances of the case-control and cohort studies were assumed to be the same. The average log ORs, the heterogeneity (SDs) and their corresponding 95% credible intervals (CIs) of the posterior distributions were then reported.

Results: Twelve relevant studies (10 retrospective case-control and 2 cohort) were eligible for the meta-analysis. Data were aggregated based on smoking statuses comprising current, ever and never smoking. Bayesian analysis of combination of the case-control and cohort studies revealed significant relationship between the occurrence of SLE and current smoking (log OR 0.43, 95% CI [0.07, 0.81]), and a smaller and insignificant association between SLE and ever smoking (log OR 0.33, 95% CI [-0.05; 0.74]). The year of publication, patients’ mean age and the proportion of female subjects in the studies were not mediators for the aggregated effect sizes.

Conclusion: Current smoking is associated with the occurrence of SLE based on the Bayesian aggregation of effect sizes from case-control and cohort studies. The higher risk of development of SLE in current but not among ex-smokers compared to never smokers warrants further mechanistic studies to unravel the actual immunologic impact of cigarette smoke on SLE development in different subsets of SLE patients, and highlights the importance of smoking cessation.

Pro-Inflammatory and Regulatory Soluble Mediator Pathways Vary between African American and European American SLE Patients

Samantha Slight-Webb¹, Miles C. Smith¹, Holden T. Maecker², Paul J. Utz³, Joel M. Guthridge¹ and Judith A. James⁴,
¹Arthritis and Clinical Immunology, Oklahoma Medical Research Foundation, Oklahoma City, OK, ²Stanford University, Stanford, CA, ³Medicine, Stanford University School of Medicine, Stanford, CA, ⁴Arthritis & Clinical Immunology, Oklahoma Medical Research Foundation, Oklahoma City, OK

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Lupus Erythematosus – Etiology and Pathogenesis Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic lupus erythematosus(SLE) is an autoimmune disease that primarily affects women, and is associated with periods of elevated and suppressed clinical symptoms. SLE prevalence varies between ethnic groups, with African American women having higher rates and increased disease severity. Understanding how dysregulated immune pathways associate with disease activity within different ethnic groups is critical for optimizing effective and personalized treatment options for SLE.

Methods: Plasma cytokine levels of European or African American healthy controls (n=18) and SLE patients with either higher(SLEDAI≥4) (n=20) or lower (SLEDAI<4) (n=20) disease activity were assessed by 37-plex xMAP assays and ELISAs. Further, peripheral whole blood samples collected from subjects were stimulated for 24 hours with either PMA

Figure 1. Pro-inflammatory cytokines are elevated in SLE patients, most significantly in patients of African American descent. Pro-inflammatory soluble mediators were measured by multiplex or ELISA. Overall trends in relative plasma soluble mediator levels are depicted by heatmap using Z-scores.

and ionomycin, PHA and ionomycin or Toll-like receptor (TLR) ligands TLR4, TLR7/8 and TLR9 for cytokine analysis of cell culture supernatants. All SLE patients met ACR classification criteria.

Results: Plasma levels of SCF ($p=0.0051$), sICAM-1 ($p=0.0097$), TNF α ($p=0.0302$), BlyS ($p=0.0312$), and IL-1RA ($p=0.0422$) were higher in African American SLE patients compared to European American SLE patients, whereas eotaxin ($p=0.0055$) was only higher in European American patients (Figure 1). In European American SLE patients with higher disease activity, SCF and sICAM-1 ($p<0.05$) were elevated compared to SLE patients with lower disease activity. African American SLE patients with higher disease activity were distinguished from lower disease activity patients by elevated levels of MCP-1 ($p=0.0048$), eotaxin ($p=0.029$), IL-7 ($p=0.03$), IL-9 ($p=0.041$) and CXCL13 ($p=0.032$). Following TLR stimulation, SLE patients with higher disease activity had a reduced fold change in most soluble mediators compared to SLE patients with lower disease activity and healthy controls, specifically with Type I and II IFN and IFN associated cytokines ($p<0.05$). This is likely due to the cell pathways being previously activated before stimulation. In addition, European American higher disease activity patients were distinguished from African American SLE patients by a higher fold change in IL-10 ($p=0.0068$) and IL-1RA ($p=0.045$) following TLR stimulation. African American patients were characterized by a higher fold change in most soluble mediators following PMA and ionomycin stimulation, whereas only the fold change in IL-10 ($p=0.023$) was higher in European American controls compared to patients.

Conclusion: Elevated soluble mediators contribute to heightened disease activity that is influenced by race with African American SLE patients having higher levels of pro-inflammatory cytokines and less involvement of regulatory pathways compared to European American patients.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Lupus Erythematosus – Etiology and Pathogenesis Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Anti-Ro60 autoantibodies are present in asymptomatic individuals years before onset of disease. We hypothesize that differences in autoreactivity-inducing commensal abundances may drive progression to autoimmune diseases such as SLE. This study tests whether gut pathobionts associate with disease outcome in high titer anti-Ro⁺ women of children with neonatal lupus.

Methods: The study included 25 healthy controls and 85 anti-Ro⁺ mothers recruited from the Research Registry for Neonatal Lupus (RRNL); the RRNL consisted of 27 asymptomatic or undifferentiated autoimmune syndrome (UAS) (incomplete) and 58 Sjögren's Syndrome and/or ACR/SLICC SLE (complete), and 77 SLE patients (non-RRNL, recruited from NYU Specimen and Matched Phenotype Linked Evaluation (SAMPLE)). The rheumatologic diagnoses of the RRNL women were independently determined by two rheumatologists via questionnaire, telephone, and/or in-person history/physical exam, and review of medical records. After extraction of host and non-host genomic DNA from stool, the microbiome was assessed using 16S rRNA gene amplification using standard protocols (mean of 20k sequences per sample). Operational taxonomic units (OTUs) were identified by closed-reference OTU-picking using Green Genes as reference. Shannon's index (H') and relative abundance were tested for differences using the Kruskal-Wallis tests. To adjust for multiple comparisons, tests of lower taxa required significance at all higher taxonomic levels, similar to a Fisher's protected least significant multiple comparisons procedure.

Results: H' was different for phylum (p=0.0023), class (p<0.0001) and order (p<0.0001), but not family (p=0.62), between controls, RRNL and SLE (non-RRNL). For these three taxonomic levels, the non-RRNL SLE cases had greater diversity than either the controls or RRNL subjects. The strongest differences in relative abundance were for multiple subtaxa of the phylum *Firmicutes* (p=5.9x10E-4). Within *Firmicutes*, class *Clostridia* (p=9.3x10E-6), order *Clostridiales* (p=9.3x10E-6) show the strongest differences in mean abundance (controls 0.727, RRNL 0.717, SLE (non-RRNL) 0.620). Multiple families within *Clostridiales* showed significant differences (p<0.01) with *Peptostreptococcaceae* exhibiting the strongest statistical evidence (mean abundance controls 0.0248, RRNL 0.0303, SLE (non-RRNL) 0.0117; p=3.2E-07). Within RRNL, the complete and incomplete groups had comparable abundances at the order level (complete 0.7156, incomplete 0.7158), suggesting the primary distinction is with non-RRNL SLE cases.

Conclusion: Non-RRNL SLE showed significant increases in fecal diversity and significant reduction in relative abundance at multiple taxa compared to high titer anti-Ro RRNL subjects who in aggregate more closely resemble healthy subjects. Fecal microbiome differences between preclinical and established disease may provide insight regarding anti-Ro positivity and the progression to complete SLE.

Cell-Free Mitochondrial DNA As a Novel Biomarker in Systemic Lupus Erythematosus

Bhargavi Duvvuri¹, Richard Moore¹ and Christian Lood², ¹Division of Rheumatology, University of Washington, Seattle, WA, ²Department of Medicine, Division of Rheumatology, University of Washington, Seattle, WA

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Lupus Erythematosus – Etiology and Pathogenesis Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: We recently described a fundamental role for mitochondrial (mt)-mediated inflammation in systemic lupus erythematosus (SLE). Briefly, mtROS promoted formation of neutrophil extracellular traps (NETs), and extrusion of cell-free mitochondria and highly oxidized interferogenic mtDNA propagating disease in lupus-prone mice. However, though our data clearly demonstrate a role of mtDNA in vitro as well as in animal models, the clinical utility of cell-free mtDNA in human SLE was not known. Thus, the aim of the current study was to investigate the clinical utility of cell-free mtDNA as a non-invasive biomarker in SLE patients.

Methods: DNA isolated from plasma samples of healthy individuals (HC, n=20) and SLE patients (n=39) was analyzed for mtDNA (Cytochrome C Oxidase Subunit II) and nuclear (nu) DNA (Ribosomal Protein Lateral Stalk Subunit P0) using qPCR. NETs were analyzed by an in-house MPO-DNA ELISA. Anti-mitochondrial antibodies (anti-cardiolipin antibodies, aCL) were analyzed by ELISA. Patients were stratified based on mtDNA, aCL and NET levels using classification and regression tree (CART) analysis.

Results: SLE patients had significantly elevated levels of mtDNA as compared to HC ($p<0.0001$, 166576 vs. 36781 copies/ml of plasma). Surprisingly, in contrast to the elevated mtDNA levels, SLE patients had significantly lowered nuDNA compared to HC ($p<0.001$, 6799 vs. 15551 copies/ml of plasma), resulting in a skewed mtDNA/nuDNA ratio ($p<0.0001$, 30.82 vs. 2.602). Consistent with our hypothesis, mtDNA levels were particularly elevated in patients with evidence of NETosis as compared to patients with no NETs ($p<0.01$, 227404 vs. 124422 copies/ml of plasma). Further, mtDNA levels were associated with markers of inflammation and disease activity: erythrocyte sedimentation rate ($r=0.49$, $p<0.01$), hemoglobin ($r=-0.59$, $p<0.01$) and complement consumption ($p<0.05$). In addition to mtDNA, mitochondrial-specific autoantibodies are also indicative of mitochondrial extrusion. Accordingly, we found a significant correlation between mtDNA levels and autoantibodies specific for cardiolipin, an important mitochondrial phospholipid ($r=0.38$, $p<0.05$). A subgroup analysis revealed that aCL-positive patients had elevated mtDNA levels compared to aCL-negative patients ($p<0.05$, 183291 vs. 128096 copies/ml of plasma). In CART analysis, aCL levels, mtDNA copies/mL and NETs were identified as major predictors to stratify patients into non-active (SLEDAI 0-5) and active disease groups (SLEDAI ≥ 6 to 18) with a sensitivity and specificity of 79% and 71% respectively.

Conclusion: SLE patients have evidence of markedly elevated levels of mtDNA associated with mitochondrial autoimmunity and disease activity, indicating exaggerated mitochondrial extrusion and impaired mitochondrial clearance partaking in the lupus pathogenesis. Though a limited number of patients, the ability to stratify patients into active and inactive disease suggest that mtDNA may be a promising novel biomarker in SLE. Thus, therapies targeting mitochondrial extrusion are expected to reduce inflammation, as well as long-term morbidities, including cardiovascular disease.

Serine Arginine-Rich Splicing Factor 1 (SRSF1) Is Essential for T Lymphocyte Homeostasis and Decreased Levels of SRSF1 Correlate with Lymphopenia in SLE Patients

Takayuki Katsuyama¹, Kotaro Iida² and Vaishali R. Moulton¹, ¹Division of Rheumatology, Department of Medicine, Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA, ²Beth Israel Deaconess Medical Center, Harvard Medical School, Division of Rheumatology, Department of Medicine, Boston, MA

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Lupus Erythematosus – Etiology and Pathogenesis Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Lymphopenia is one of the most common clinical features in patients with systemic lupus erythematosus (SLE), and associates with severe disease and comorbidities such as infections. However, the mechanisms of lymphopenia in SLE are still unclear. T cells from SLE patients exhibit numerous defects in gene expression, including altered expression the Bcl-2 family genes, which have pro- and anti-apoptotic alternative splice isoforms. By discovery approaches we previously identified the serine arginine-rich splicing factor 1 (SRSF1) in human T cells and showed that it is an important regulator of signaling and cytokine genes. SRSF1 expression levels are decreased in T cells from SLE patients, and this decrease associates with severe disease. Because SRSF1 is an important survival factor known to regulate alternative splicing of Bcl-2 genes, we evaluated the role of SRSF1 in T cell homeostasis and correlation with lymphopenia in patients with SLE.

Methods: To delete *Srsf1* selectively in T cells, we crossed *Srsf1*-flox mice with *d.Lck*.Cre transgenic mice to generate *Srsf1*conditional knockout (*Srsf1*-cko) mice, and analyzed lymphoid tissues (spleen and lymph nodes). Apoptosis was assessed in splenocytes ex vivo or after crosslinking with anti-CD95 (Fas), and flow cytometry staining for 7AAD and Annexin V. Apoptosis associated genes were analyzed by RT-qPCR. Naïve CD4 T cells from *Srsf1*-wt and -cko mice were stimulated with anti-CD3 and anti-CD28 antibodies for 72hrs, and total RNA was subjected to RNA-sequencing. Peripheral blood was collected from 42 SLE patients, and age-, race- and gender-matched healthy individuals. T cells were isolated by negative selection, and SRSF1 protein levels assessed by western blots. Clinical and lab tests for all patients were recorded. SLE patients were divided into lymphopenic ($<1000/\mu\text{L}$) and non-lymphopenic groups, and correlations were assessed with relative SRSF1 expression levels.

Results: Peripheral T cell lymphopenia was observed in the *Srsf1*-ckomice. Lymphopenia was evident in young mice compared with aged mice, and was more profound in CD8 than CD4 T cells. Crosslinking with anti-CD95 (Fas) antibody led to increased apoptosis in T cells from *Srsf1*-cko mice. Gene set enrichment analysis (GSEA) of RNA-sequencing data from effector CD4 T cells of *Srsf1*-cko mice showed aberrant expression of genes in the apoptosis and cell cycle pathways.

We validated expression levels of the Bcl-x gene and found that its anti-apoptotic long (L) isoform was decreased in spleen cells from *Srsf1*-cko mice. In parallel, examination of SRSF1 levels in T cells from SLE patients revealed that reduced SRSF1 protein levels correlated positively with lymphopenia in SLE patients.

Conclusion: These results suggest that SRSF1 controls expression of survival/apoptosis-related genes in T cells and is a vital regulator of T lymphocyte homeostasis *in vivo*, and its reduced expression levels associate with lymphopenia in SLE patients. Therefore, the deficiency of SRSF1 may represent a molecular defect that contributes to the pathophysiology of autoimmune disease.

Immune Complex-Driven Neutrophil Activation and BAFF Production Promote B Cell Activation and Autoantibody Production in Human SLE

Andrew Vasconcellos¹, John Marken¹, Sladjana Skopelja-Gardner¹, Christian Lood² and Natalia V. Giltiay¹, ¹Division of Rheumatology, Department of Medicine, University of Washington, Seattle, WA, ²Division of Rheumatology, Division of Rheumatology, Department of Medicine, University of Washington, Seattle, WA

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Lupus Erythematosus – Etiology and Pathogenesis Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The production of anti-nuclear auto-antibodies (Ab) and the formation of immune complexes (IC) are hallmarks of Systemic Lupus Erythematosus (SLE). Enhanced neutrophil (PMN) activation and formation of neutrophil extracellular traps (NETs), through engulfment of nucleic acid-containing ICs, have been implicated in disease pathogenesis, particularly in the acceleration of tissue inflammation, end-organ and vascular damage. Upon activation, PMNs may contribute to B cell activation and auto-Ab production by three main mechanisms: indirectly by NETs-stimulated interferon production, or directly, by releasing B cell activating factor (BAFF) and extruding autoantigens, such as mitochondria, during NETosis. Still, little is known about the link between the PMN activation and B cell immune responses in human SLE. This study was undertaken to test whether IC-driven PMN activation and NET formation contribute to BAFF increase, auto-Ab production and B cell activation in SLE patients.

Methods: BAFF levels were analyzed in serum samples from 60 SLE patients and 20 healthy controls (HC) by ELISA. Markers of neutrophil activation and NETosis (S100A8/A9, MPO-DNA complexes, cell-free oxidized (8-OHdG) DNA and mitochondrial (mt) DNA levels) were analyzed by ELISA, fluorimetric assays, and qPCR. FcγRIIA internalization, a bioassay for IC quantification, was analyzed by flow cytometry. Anti-DNA IgG titers, anti-cardiolipin (CP) IgM and IgG, C3 and C4 complement and CRP levels were obtained from clinical records. PMNs from healthy donors were stimulated with RNP-containing ICs and PMN activation, BAFF production, and B cell activation were studied *in vitro*.

Results: Levels of BAFF were markedly elevated in SLE as compared to HC serum samples ($p < 0.0001$). Consistent with our hypothesis of neutrophil-driven BAFF release in SLE, levels of BAFF correlated with markers of PMN activation (S100A8/A9) and NET-derived components, including mtDNA and cell-free 8-OHdG DNA ($r = 0.34-0.38$, $p < 0.05$ for both analyses). Increased BAFF levels associated significantly with decreased serum C3 and C4 levels, suggesting an association with ongoing IC-driven disease. Furthermore, levels of serum ICs correlated with an increase in BAFF levels ($r = 0.38$, $p = 0.02$) as determined by a flow cytometry-based bioassay. Auto-Ab analysis showed positive correlations between anti-DNA and anti-CL Ab titers, BAFF levels and markers of NETosis, including 8-OHdG DNA and S100A8/A9 levels. Stimulation of PMNs with ICs *in vitro* induced PMN activation, NET formation, and a significant increase in BAFF release three-to-six hours post-stimulation. PMN-B cell co-culture experiments showed increased B cell activation in response to IC-induced PMN activation.

Conclusion: Our results support the hypothesis that PMNs, through IC-mediated activation, release BAFF and auto-Ags, including DNA and mitochondrial components, which may contribute to B cell activation and production of pathogenic auto-Abs. These findings bring new insight into the mechanisms of PMN-B cell interactions involved in the pathogenesis of SLE.

Session Title: Systemic Lupus Erythematosus – Etiology and Pathogenesis Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: SLE is a clinically heterogeneous disease oftentimes characterized by a waxing and waning course. Mechanisms of SLE flare remain elusive. This study examined relationships between SLE disease activity, immune pathways and serologic evidence of viral exposures and reactivation in molecular subsets of SLE patients.

Methods: Serial or single samples of plasma and RNA (n=290) were collected from 184 adult SLE patients who met ACR classification and cohort matched controls (n=49). Disease activity was assessed by the SELENA- modified SLEDAI. Immune pathways were evaluated by modular transcriptional analysis of gene expression data (Illumina Beadchip) and by soluble mediators (n=32; multiplex bead-based assay and ELISAs). These data were used in random forest modeling to group patients into seven molecular defined subsets. Viral seropositivity and antibody concentrations were detected by

International Standardized Ratio of Viral Antibodies in SLE Patients with High and Low Disease Activity, and Controls						
	Higher Disease Activity (n=126) ¹	Lower Disease Activity (n=166) ²	Control	Higher vs Control P-value	Lower vs Control P-value	Higher vs Lower P-value
EBV-VCA IgG	4.44 (3.42, 5.15)	4.38 (3.47, 5.19)	3.52 (2.75, 4.65)	0.0045	0.0037	1
EBV VCA IgA	0.714 (0.304, 1.39)	0.713 (0.313, 1.55)	0.524 (0.225, 0.899)	0.031	0.033	0.85
EBV EA IgG	0.822 (0.324, 2.23)	0.540 (0.242, 1.46)	0.045 (0.206, 0.630)	9 X 10⁻⁵	0.013	0.033

¹SLEDAI-high, ²SLEDAI-low

ELISA for antibodies against Epstein Barr virus (EBV)-Viral Capsid Antigen (VCA; IgG and IgA), EBV-Early Antigen (EA; IgG), Cytomegalovirus (CMV; IgG), and Herpes Simplex Virus (HSV1; IgG).

Results: Serologic evidence of EBV reactivation was more common in SLE patients versus controls as measured by antibodies against EBV-EA (IgG; 40% vs 13%; OR=4.57, $p=0.0006$) or EBV-VCA (IgA; 36% vs 17%; OR=2.70, $p=0.019$). CMV1 and HSV1 seropositivity rates showed no differences between patients and controls. IgG responses against EBV-VCA were nearly universal in these adult patients and controls, but concentrations of EBV-VCA (IgG and IgA) and EBV-EA (IgG) were higher in SLE patients (Table). In cross sectional analysis SLE patients with higher disease activity had higher concentrations of EBV-EA IgG than those with lower disease activity (Table). SLE patients with serologic evidence of EBV reactivation by EA IgG responses had higher levels of interferon (IFN) associated molecules IP10 ($p=3.4 \times 10^{-14}$), BLYS (5.5×10^{-5}), and IL10 ($p=0.00013$). HSV1 IgG positive SLE patients also showed higher levels of IP10 (2.2×10^{-7}). EBV-EA IgG responses were enriched in molecularly defined patient clusters with higher expression of IFN and inflammatory modules and soluble mediators (Figure). Patients in these clusters were also more likely to have major organ involvement, such as renal or neurologic disease.

Conclusion: Serologic evidence of EBV reactivation is more common in SLE patients compared to healthy controls. EBV-EA IgG is elevated in SLE patients with active disease and corresponds with increases in IFN-associated mediators. This study provides serologic evidence suggesting a possible role for viral reactivation in SLE disease activity.

Abstract Number: 1094

Endogenous $\text{IFN}\beta$ Production Is Required for Efficient BCR Crosslinking and Survival of SLE B Cells

John D. Mountz¹, Shanrun Liu², PingAr Yang³, Qi Wu⁴, Bao Luo⁵, W. Winn Chatham⁶ and Hui-Chen Hsu⁴, ¹University of Alabama at Birmingham and Birmingham VA Medical center, Birmingham, AL, ²Biochemistry & Molecular Genetics, University of Alabama at Birmingham, Birmingham, AL, ³Department of Medicine, Clinical Immunology & Rheumatology, University of Alabama at Birmingham, Birmingham, AL, ⁴Department of Medicine, University of Alabama at Birmingham, Birmingham, AL, ⁵Division of Clinical Immunology and Rheumatology, Department of Medicine, University of Alabama at Birmingham, Birmingham, AL, ⁶Medicine/Clinical Immunology and Rheumatology, University of Alabama at Birmingham, Birmingham, AL

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Lupus Erythematosus – Etiology and Pathogenesis Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Increased type I interferon (IFN) has been shown to affect survival and activation of B cells in SLE. This study investigated novel mechanisms of endogenous production and autocrine activity of $\text{IFN}\beta$ in SLE B cells at the single-cell level.

Methods: $\text{IFN}\beta$ in B cells from SLE patients was analyzed using t-SNE platform based high dimensional flow cytometry. Intracellular $\text{IFN}\beta$ expression was visualized and analyzed by super-resolution confocal imaging and ImageStream analysis. Single cell gene expression analysis was carried out using the Fluidigm/BioMark system for targeted expression of low abundance genes, and the 10x Chromium platform for unbiased transcriptome analysis of up to 4,000 B cells per subject. Functional production of type I IFNs by B cells was analyzed using a human type I IFNs SEAP reporter HEK293 cell line.

Results: High dimension flow cytometry analysis identified intracellular $\text{IFN}\beta$ expression in pDCs, B cells, and CD4 T cells. There was increased expression of $\text{IFN}\beta$ in B cells from PBMCs of African American SLE patients compared to European SLE patients and healthy controls. B-cell intracellular $\text{IFN}\beta$ was associated with serum positivity of ANA and renal disease. Using a Fluidigm targeted-gene approach, B cells could be divided into three subpopulations, namely $\text{IFN}\beta$ +, $\text{IFN}\alpha$ +, and ISG + subpopulations, suggesting B cells not only respond to type I IFNs but also express type I IFNs including $\text{IFN}\beta$ and different $\text{IFN}\alpha$ genes. TLR7 and TLR3 were mainly expressed by $\text{IFN}\beta$ + and $\text{IFN}\alpha$ + cells, respectively. The production of functional $\text{IFN}\beta$ and $\text{IFN}\alpha$ protein by single B cells from SLE subjects and was verified using a novel AP live staining of HEK-blue reporter cells. There was enhanced IFNAR signaling by reporter cells in direct

contact with SLE B cells which was blocked by anti-IFN β and anti-IFN α . Unbiased single cells transcriptome analysis of SLE B cells using the 5' 10X Chromium platform and Loupe™ V(D)J Browser indicated that gene clusters in type I IFN expressing or responding SLE B cells exhibited unique heavy- and light-chain gene expression repertoires.

Conclusion: (i) B cells are an important source of type I IFNs in modulating TLR and BCR responses in SLE; (ii) well-orchestrated and distinct programs in type I expression and responses genes in subsets of B cells, and (iii) distinct pathways of B cell survival and activation based on combined signaling through TLR, BCR and IFNAR with a distinct BCR heavy- and light-chain repertoire.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

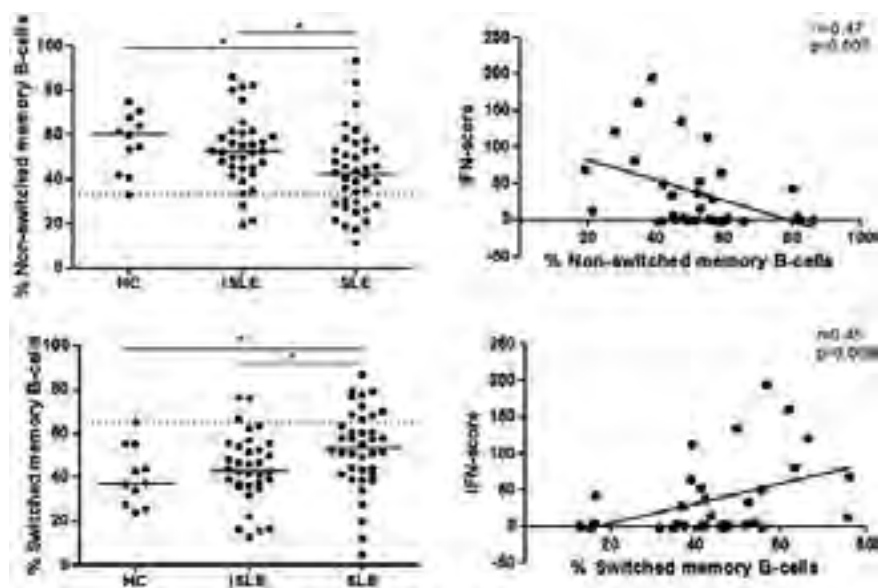

Session Title: Systemic Lupus Erythematosus – Etiology and Pathogenesis Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Incomplete systemic lupus erythematosus (iSLE) includes patients with typical features of SLE, who do not meet classification criteria. Still, up to 50% will develop SLE in the future. Follow-up of these iSLE patients can potentially unravel the pathogenesis of SLE. Interferon (IFN) type-I is an important early mediator in SLE. Furthermore, B cells are considered to be the main culprits in SLE pathogenesis, owing to their production of autoantibodies. The purpose of this research is assessing whether IFN gene upregulation is associated with alteration in B-cell subset distribution in iSLE patients.

Methods: Thirty-four iSLE patients (ANA titer $\geq 1:80$, ≥ 1 ACR clinical feature), 38 SLE patients with quiescent disease (SLEDAI ≤ 4) and 11 HC were included. B-cell subsets were determined in peripheral blood mononuclear cells (PBMC) by flow cytometry based on surface markers and were subdivided into naïve B-cells (CD27⁺CD38^{low}), transitional B-cells

(CD27⁺CD38^{High}), plasma cells (CD27^{High}CD38^{High}), and memory cells (CD27⁺), of which the latter were subdivided into switched (IgD⁻IgM⁺) and non-switched (IgD⁺IgM⁺) memory B cells. Simultaneously, RNA was isolated from whole blood using PAX gene tubes and reversely transcribed to cDNA and quantitatively analyzed by RT-PCR. IFN score was calculated based on cumulative expression of 3 IFN-related transcripts (IFI44L, LY6E, MX1).

Results: Baseline characteristics are shown in Table 1. SLE patients had decreased non-switched memory cells and increased switched memory cells in comparison with iSLE patients and HC (figure 1). Other subsets were statistically comparable between the groups. The IFN score was increased in 17/32 iSLE patients (53%) and 24/38 SLE patients (63%). Remarkably, in iSLE patients, IFN score correlated positively with percentages of switched memory cells (figure 2, $r=0.45$, $p=0.009$), plasma cells ($r=0.42$, $p=0.01$), transitional B-cells ($r=0.47$, $p=0.006$) and negatively with non-switched memory cells ($r=-0.47$, $p=0.007$). In SLE, IFN score correlated with transitional B-cells ($r=0.47$, $p=0.003$), naïve B-cells ($r=0.47$, $p=0.003$) and negatively with total memory B-cells ($r=-0.41$, $p=0.01$), but not with switched or non-switched memory cells.

Conclusion: Although lower proportions of circulating switched memory B cells were seen in iSLE compared to SLE patients, IFN score in iSLE patients correlates strongly with switched memory cells. This could imply that IFN expression triggers progression to SLE by stimulating isotype switching of B-cells.

Unexpected Association between Health-Related Quality of Life and the Blood Interferon Modular Transcriptional Signatures in Patients with Systemic Lupus Erythematosus

Laurent Chiche¹, julie seguier², stephanie gentile², stephane burtey², bertrand dussol², philippe halfon³, wahiba bidaut³, elisabeth jouve² and Noémie Jourde-Chiche⁴, ¹Internal medicine, Hopital europeen, Marseille, France, ²aphm, marseille, France, ³hopital europeen, marseille, France, ⁴Vascular Research Center of Marseille, Aix-Marseille Univ., Vascular Research Center of Marseille, Marseille, France

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Lupus Erythematosus – Etiology and Pathogenesis Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: SLE has important effects on health-related quality of life (HRQOL) and is not well correlated to disease activity. As most SLE patients in remission have a consistent interferon (IFN) signature, it is assumed that persistent fatigue and/or impaired HRQOL is mediated by insufficiently controlled IFN response. The objective of the study was to test whether blood transcriptomic IFN signatures were associated with HRQOL.

Methods: Patients fulfilling the ACR revised criteria for SLE were included at a referral center for autoimmune diseases and followed up prospectively. Each assessment included demographic, clinical and laboratory evaluations, as well as whole blood transcriptomic data (Illumina beadchips). Disease activity was evaluated by the SELENA-SLEDAI score. HRQOL was assessed at each visit by the self-administrated SF-36 questionnaire, which includes two summary scores, the Physical Component Summary (PCS) and the Mental Component Summary (MCS), and eight domains: physical function (PF), role

physical (RP), bodily pain (BP), general health (GH), vitality (VT), social functioning (SF), role emotional (RE) and mental health (MH). SF-36 scores ranged from 0 to 100, with higher scores reflecting better HRQOL. Transcriptomic analyses were performed using the second generation of a modular framework. Three IFN modules defined the modular IFN score: M1.2, M3.4 and M5.12.

Results: 57 SLE patients were evaluated. Median age was 38 years (18-70), 86% were women and 88% were caucasian. Median SLEDAI was 4 (0-22). At inclusion, SLE was clinically quiescent in 27 (47%) patients, while 30 (53%) were experiencing a flare, with active lupus nephritis in 19 (33%). Compared to the French general population (n=18754, mean age of 42 years), SLE patients had a marked reduction of HRQOL in all SF-36 domains and summary scores ($p<0.0001$), with delta of SF-36 scores ranging from 6 (MCS) to 27 (RP). In univariate analysis, the 3 IFN modules showed no significant correlation with any of the SF36 domains except for SF ($r=0.44$, $p<0.01$; $r=0.33$, $p<0.05$; $r=0.28$, $p<0.05$ for M1.2, M3.4 and M5.12 respectively), revealing unexpectedly that the higher the IFN signature, the better SF score. In multivariate analysis, taking into account other parameters associated with HRQOL such as flares, age, ethnicity, smoking and renal severity (nephrotic syndrome), SF was independently associated with the IFN score ($p = 0.027$). Analyses restrained to only quiescent patients ($n=27$, defined as clinically quiescent patients with or without immunological activity) yielded greater association between IFN score and SF (for the 3 modules) as well as MH (for M3.4). Additional analysis on all samples from quiescent visits ($n=51$) confirmed the association between the 3 IFN modules activity and SF, as well as MH and BP.

Conclusion: Far from confirming our hypothesis, this study demonstrates an unexpected positive association between IFN signature and HRQOL in SLE patients. These findings, consistent with the absence of impact on fatigue or HRQOL of recently tested IFN-blockade strategies, needs to be confirmed by other studies.

Spatial-Time Cluster Analysis of SLE Disease Activity

George Stojan¹, Anton Kvit², Frank Curriero² and Michelle Petri³, ¹Division of Rheumatology, Johns Hopkins University, Baltimore, MD, ²Bloomberg School of Public Health, Baltimore, MD, ³Johns Hopkins University School of Medicine, Baltimore, MD

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Lupus Erythematosus – Etiology and Pathogenesis Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Cluster detection is an essential tool in the public health domain with the goal of detecting anomalous clusters of disease cases. We performed a spatial-time cluster analysis of the Hopkins Lupus cohort with the goal of identifying potential spatial-time clusters of SLE organ specific disease activity.

Methods: 1844 patients who fulfilled ACR or SLICC classification criteria for SLE and who had recorded home addresses were included in the analysis. Cluster detection analysis in both space and time of disease activity expressed as Physician Global Estimate (PGA) was performed. The area utilized in this analysis was a 350 kilometer radial buffer around the Hopkins Lupus Center, and included all of Maryland, Delaware, and District of Columbia, as well as parts of Pennsylvania, New Jersey, Virginia, and West Virginia. This area was considered due to the high and consistent density of study participants. The data ranged from 1987 to 2017, with the spring, summer, fall, and winter seasons serving as time units for the temporal based analyses.

Results: CNS, renal, and joint flares have both seasonal patterns as well as large-scale multi-year trends. CNS flares clustered between Annapolis, MD and Frederick, MD between 1987 and 2000, renal flares clustered in central Maryland and northern Virginia between 2002 and 2006, and a joint flares cluster included Delaware, Delaware Bay area, and Chesapeake Bay area between 2003 and 2014. Maps were generated highlighting the study area, flares, and identified clusters from all analyses.

Conclusion: We describe the first space-time clusters of lupus organ-specific disease activity, strongly supporting the role of environmental factors as drivers of lupus activity.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Lupus Erythematosus – Etiology and Pathogenesis Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Cutaneous lupus erythematosus (CLE) and dermatomyositis (DM) are autoimmune diseases. The histopathological pattern of skin involvement can be similar, i.e. interface dermatitis, but the systemic manifestations are very different. While dermatomyositis commonly affect muscles, lupus erythematosus may affect any organ system. Autoantibodies against intracellular targets are common in both conditions, but the specific targets of the autoantibodies differ between the two conditions.

Our aim was to investigate a whole proteome of inflammatory foci of the CLE and DM lesions in a comparator manner and identify disease unique mechanisms of inflammation.

Methods: Patients with CLE (n=6), DM (n=5) and controls (n=6) were included and biopsied at diagnosis or disease exacerbation. Skin biopsies were examined by a pathologist, and selected inflammatory foci were laser microdissected. The total protein content of the microdissected tissue was then analyzed using mass-spectrometry.

Results: In DM, there were 25 highly upregulated proteins, while CLE infiltrates were more protein rich and there were 88 proteins with up to 9-fold upregulation. Protein expression comparison between CLE and DM identified 22 differentially upregulated proteins, and all had higher abundance in CLE than in DM. A protein network analysis was performed by STRING platform (string-db.org). The network of interferon (IFN)-regulated proteins was abundant in both CLE and DM, including: IFIT, MX, OAS, STAT gene families and also EIF2AK2. Also, proteins involved in oxidative stress and antigen processing: IL4I1, TAP1 and TAP2 were highly upregulated in both CLE and DM. Proteins expressed differentially in CLE covered complement proteins (C1b), including membrane attack complex (C5, C6, C7, C8A and B) and complement regulators (CFHR1, CFHR2, CFHR5). Also, regulators of coagulation: thrombospondin 2 (THBS2), thrombin (F2) and annexin A3 (ANXA3) were highly abundant in CLE.

Conclusion: Inflammatory foci in the interface dermatitis in CLE and DM contain high abundance of IFN-regulated proteins, as well as regulators of oxidative stress and antigen processing. The proteomics technique allowed identification of pathways differentially activated in CLE, including complement activation products and regulators of coagulation. Our study identified multiple pathways activated at the site of inflammation which will be of interest in further search of new therapeutic targets.

Session Date: Monday, October 22, 2018

Session Title: Systemic Lupus Erythematosus – Etiology and Pathogenesis Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Recent data highlight that patients with Systemic Lupus Erythematosus (SLE) have defects in two main DNA repair pathways, namely nucleotide excision repair (NER) and DNA double-strand break repair and that increased apoptosis observed in SLE may be partly attributed to the deregulated DNA damage response (DDR) network. Herein, we tested the hypothesis that ongoing DNA damage is present in patients with systemic autoimmune rheumatic diseases.

Methods: Peripheral blood mononuclear cells (PBMCs) were isolated from patients with SLE (n=14), Rheumatoid Arthritis (RA) (n=23), Systemic Sclerosis (SSc) (n=8) and 34 healthy controls (HC). Endogenous DNA damage levels were assessed using single-cell gel electrophoresis (comet assay) of untreated PBMCs. Repairing capacity of the two sub pathways of NER, i.e. global genome repair (GGR) and transcription-coupled repair (TCR), as well as interstrand cross-links (ICL) repair were assessed after *ex vivo* treatment of PBMCs with genotoxic agents. Chromatin organization and expression of critical DNA repair-associated genes were also examined.

Results: Higher levels of endogenous DNA damage were present in patients compared to HC [Olive Tail Moment units of HC: 4.0 (1.5-9.9), SLE: 9.0 (2.4-23.0), RA: 11.5 (3.4-35.6) and SSc: 12.1 (5.4-29.3, all $p < 0.01$]. SLE patients and HC displayed similar DNA repair efficiencies of the transcribed strand of the active N-ras gene (repaired by TCR), but in SLE the repair in the non-transcribed strand of the active N-ras gene was slower, as well as in both strands of a non-coding DNA region located outside the N-ras gene (repaired by GGR, all $p < 0.001$), showing that the previously observed deficiency of NER in SLE patients may be specifically attributed to reduced GGR capacity while TCR is preserved. Of interest, we found that the repair efficiency of GGR in different genomic loci was inversely correlated with the local chromatin condensation, with autoimmune disease patients exhibiting more condensed chromatin structures. Moreover, critical molecular components of NER [such as DDB1 and XPC genes (associated with the GGR sub pathway) and XPA, LIG1, RPA1, ERCC2 genes (associated with both NER sub pathways)] were significantly down-regulated in SLE, RA and SSc patients versus HC. Finally, although the repairing capacity of cytotoxic ICL-lesions was similar in both HC and autoimmune disease patients, higher accumulation of these lesions was observed in patients' PBMCs, possibly due to the higher burden of unrepaired NER lesions (precursors of ICLs). Interestingly, individual ICL repair efficiencies were inversely correlated with apoptosis rates in the same cells, underlying the cytotoxic character of this lesion.

Conclusion: Our study demonstrates that increased ongoing, spontaneous DNA damage is present in SLE, RA and SSc, possibly due to epigenetically regulated defective DNA repair mechanisms. Further studies to uncover a potentially crucial role of these mechanisms in the pathogenesis of systemic autoimmunity are underway.

Session Title: Systemic Lupus Erythematosus – Etiology and Pathogenesis Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: This study, developed within the IMI-JU project PRECISESADS framework, aimed to determine the enrichment on CD14+ and CD16+ monocyte subpopulations in SLE, APS and APS+SLE patients, and to investigate their profiles and role in the pathogenesis of these diseases.

Methods: The frequencies of monocyte subpopulations in the peripheral blood of 146 healthy donors and 140 SLE patients included in the PRECISESADS study were determined by flow cytometry. Two additional cohorts of 21 APS+SLE and 19 APS patients were also evaluated. Clinical features, proinflammatory circulating mediators, as well as the prothrombotic/proinflammatory/pro-oxidative profiles of monocytes subsets -at both gene and protein levels- were analyzed.

Results: The frequencies of CD14+CD16++ (non-classical) monocytes were reduced in SLE patients, while CD14+CD16+ (intermediate) monocytes were increased. The reduced frequencies of CD16+ monocytes were negatively associated with the positivity for anti-dsDNA autoantibodies, as well as with renal involvement -demonstrated by biopsy-confirmed nephritis, proteinuria, and presence of macrophages in urine samples-, all of which might reflect a recruitment process of this subset in renal tissues. Correlation studies indicated a link between the reduced frequency of non-classical monocytes and increased levels of circulating inflammatory mediators. Conversely, in SLE patients with augmented cardiovascular risk, increased frequencies of CD14+CD16+ monocytes were observed. These results prompted us to evaluate the proportion and profile of this inflammatory subtype in parallel cohorts of SLE+APS and APS patients, on which thrombosis is the main clinical disorder.

SLE+APS patients showed enrichment in both CD16+ subsets of monocytes, associated with the positivity for anti-dsDNA antibodies and the presence of atheroma plaques. Correlations among the frequency of those monocyte subsets and circulating inflammatory mediators were also demonstrated. Moreover, these subsets displayed an increased inflammatory and prothrombotic profile when compared with classical CD14+ monocytes.

In APS patients we also saw enrichment of the CD16+ inflammatory subsets, associated to recurrent thrombotic events and pathologic carotid intima-media thickness. The scores of various markers related to autoimmunity, oxidative stress and prothrombotic molecules correlated with the proportions of CD16+ monocytes, which showed an activated profile similar to that observed in SLE+APS patients.

Conclusion: Circulating CD16+ monocytes might constitute a subpopulation of proinflammatory cells whose frequency and molecular profiles might identify APS, APS+SLE and SLE patients suffering thrombosis, atherosclerosis and organ involvement.

Supported by the EU/EFPIA –IMI-JU PRECISESADS (n° 115565), FIS PI15/1333, Co-funded with FEDER.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Lupus Erythematosus – Etiology and Pathogenesis Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: In lupus nephritis (LN), genetic and environmental factors drive the chronic activation of antiviral defenses leading to immune complex-mediated glomerular and tubular damage. Increasing evidence suggests the involvement of extracellular vesicles (EVs) in autoimmune disease. Currently a role for EVs in the pathogenesis of lupus nephritis has not been proposed. Objectives: To investigate the role of EVs in the pathogenesis of LN.

Methods: To determine the presence of EVs in kidneys, biopsies from LN patients and IgA- nephropathy and Focal Segmental Glomerulosclerosis control patients were used. Serum samples from SLE patients and from RA patients as controls were used to determine the presence of circulating EVs. Primary renal tubular epithelial cells (TEC) were cultured, and Kidney injury molecule-1 (KIM1) expression was assessed by FACS. Exosomes were analyzed by electron microscopy and western blot. mRNA analysis was performed by qPCR. TLR3 inhibition was performed with TLR3/dsRNA complex inhibitor and with hydroxychloroquine.

Results: We show that EVs deliver virus-derived small RNA and activate TEC via toll-like receptor 3 (TLR3). Highly specific stem-loop RT-PCRs revealed Epstein Barr Virus (EBV)-encoded small RNAs in LN biopsies while quantitative EBV-DNA PCR, sensitive to a single copy was negative. In situ hybridization failed to detect nuclear EBV-EBER1 (i.e. EBV-infected cells) in LN biopsies. However, we observed atypical EBER signal in the cytoplasm of TECs in LN but not in disease control biopsies, suggestive of uptake of extra-renal EBER. Consistent with this, we detected EBER1 in circulating EVs of SLE sera. The LN tissues express strongly elevated levels of TLR3, Interferon induced transmembrane-1 and -3, and TNF α . Primary TEC cultured in vitro endocytose EBER1-EVs secreted by EBV-infected B cells via phosphatidylserine receptors such as KIM-1. Importantly, EV-EBER1 uptake by TEC triggers antiviral immunity and pro-inflammatory cytokine secretion in a Toll-like receptor 3 (TLR3)-dependent manner. Treatment with hydroxychloroquine (HCQ) or a small molecule inhibitor that blocks TLR3-RNA interactions strongly reduced the pro-inflammatory effects of EBER1.

Conclusion: We propose that small RNA-loaded EVs exacerbate pre-existing autoimmunity in SLE patients by engaging tubular epithelial TLR3, supporting the rationale for TLR3-blockade as therapeutic strategy in the treatment of lupus nephritis.

Session Title: Systemic Sclerosis and Related Disorders – Basic Science Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Internal organ involvement is the primary cause of morbidity and mortality in systemic sclerosis (SSc). Here we tested the hypothesis generated from a meta-analysis of ten different SSc datasets, that any single patient

with SSc would have the same deregulated molecular signatures across multiple organ systems, consistent with the systemic nature of the disease.

Methods: RNA sequencing (RNA-seq) was performed on at least four organ biospecimens (skin, esophagus, fundus, duodenum, and blood) from 16 patients who met 2013 ACR/EULAR criteria for SSc. RNA was sequenced by 75bp paired-end RNA-seq at >80 million reads per sample and aligned to the reference genome (hg19). DESeq2 was used to identify differentially expressed genes across the various tissue pairs. Each sample was assigned to an intrinsic gene expression subset (inflammatory, proliferative, limited, or normal-like) using a Support Vector Machine (SVM) classifier and unsupervised hierarchical clustering with profiles of normalized Reads Per Kilobase of transcript per Million mapped reads (RPKM) values. Weighted Gene Co-Expression Analysis (WGCNA) was used to identify modules across tissues.

Results: Hierarchical clustering shows that biospecimens from the same tissue type cluster together regardless of whether a patient has SSc. We normalized each tissue specific dataset to allow comparative analyses of SSc biology across the tissues. We recapitulated the intrinsic subsets previously identified in the skin and esophagus of SSc patients. SVM classification further identified intrinsic subsets in the duodenum, fundus, and blood of patients with SSc. The majority of our patients (9/16) exhibit >60% concordance of intrinsic subset assignment across tissues. Importantly, all five organs were represented in the SVM calls of inflammatory, proliferative, and normal-like intrinsic subsets. WGCNA identifies modules of genes in blood of patients with SSc that are significantly associated with clinical variables. Most notably, four modules positively associated with interstitial lung disease in patients contain genes (STAT3, IL1B, TGFBR2) and are enriched in pathways (Immune response, cell cycle, chemokine signaling) that have been implicated in SSc pathogenesis.

Conclusion: We have completed collection of >4 biospecimens from 16 individuals with SSc. Our data shows that the intrinsic gene expression subsets, first identified in skin, exist systemically in patients with SSc. These molecular profiles are more consistent than chance within single individuals and are thus, a common feature in end-organ pathology in SSc. We have identified modules of genes in easily accessible tissues that can be used to assess interstitial lung disease (ILD) in patients. Modules associated with additional clinical variables (antibody status, esophageal pathology, and treatment) are currently being evaluated.

Session Title: Systemic Sclerosis and Related Disorders – Basic Science Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Proteomic studies with an extensive panel of measured proteins are still scarce in systemic sclerosis (SSc). The Scleroderma: Cyclophosphamide or Transplantation (SCOT) trial showed improved clinical outcomes in participants randomized to myeloablation followed by autologous hematopoietic stem cell transplantation compared to monthly cyclophosphamide (1). In the present study, we performed a proteomic analysis of baseline serum samples collected in the SCOT trial to investigate clinical correlates of serum protein dysregulation at baseline in early diffuse cutaneous SSc (dcSSc).

Methods: A panel of 232 baseline serum proteins in 66 SCOT participants (mean disease duration=2.2 years) compared to 66 age and gender matched controls was analyzed by RBM Human Discovery Multi-Analyte Profiling multiplexed assays. Proteins with levels below the lower limit of detection in more than 50% of SCOT participants, were excluded. Proteins were considered differentially expressed with false discovery rate (FDR) of <5%.

Results: Ninety proteins were differentially expressed in dcSSc versus controls (FDR<0.05). Sixty-five proteins were upregulated, of which 42% (27 molecules) were Type I IFN inducible accordingly to the Interferome database. The ten most up- and down-regulated proteins are presented in Table 1. Serum protein correlates of modified Rodnan Skin Score (mRSS) are shown in Table 2. Carcinoma Antigen 15.3 (CA 15.3) and Epithelial Derived Neutrophil Activating Protein 78 (CXCL5) were inversely correlated with forced vital capacity (FVC) ($r=-0.33$, $p<0.006$; $r=-0.34$, $p<0.06$ respectively) and positively correlated with HRCT fibrosis score ($r=0.28$, $p<0.023$; $r=0.28$, $p<0.025$) showing an association with lung fibrosis. The Ingenuity Pathway Analysis (IPA) revealed hepatic fibrosis, granulocyte adhesion and diapedesis and agranulocyte adhesion and diapedesis as the top three over-represented pathways, indicating that the serum protein profile of SSc reflects fibrotic as well as immunological dysregulations in SSc.

Conclusion: SSc has a distinct serum protein profile including a prominent upregulation of IFN inducible proteins. The IPA pathway analysis showed top over-represented pathways in SSc serum proteomic analysis parallels those found to be dysregulated in SSc skin global gene expression studies. (2). Finally, we identified several serum proteins that correlate with the extent of skin and lung fibrosis in SSc.

Session Title: Systemic Sclerosis and Related Disorders – Basic Science Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Aberrant CD4⁺ T cell activation is implicated in disease progression in systemic sclerosis (SSc). Activated T cells release various cytokines that may drive inflammation, microvasculopathy and fibrosis. Emerging evidence indicates the critical role of complement dysregulation of CD4⁺ T cell responses in autoimmunity. The aim of this study was to further characterise complement signature on CD4⁺ T cells in SSc.

Methods: We developed a method that could provide a rapid and comprehensive exploration of T cell-complement axis in patients. We therefore employed mass cytometry (CyTOF) technology. We first generated a 35member antibody-conjugate panel designed to delineate CD4⁺T sub-populations, recognize cytokines and transcription factors indicative of population expansion or contraction, and quantify 18 complement intracellular and surface proteins. Using the panel and a combinatorial pipeline for data analysis (t-SNE/viSNE followed by SPADE and Marker Enrichment Modeling), we examined T cells from healthy donors, fully recapitulating at single-cell resolution all published data assessed via 'classical' FACS, confocal microscopy and Western blot analyses. Pharmacological intervention with selective antagonists and agonists were used to explore the autocrine C3/C5 system in activated CD4⁺T cells. Cytokine profiles in cell supernatants were assessed following T cell activation by ELISA.

Results: 23 patients (18 females, age(mean±SEM), 49.6±2.2 years) with early diffuse SSc (mean disease duration 11.6±2.4 months) and mean baseline modified Rodnan skin score 21±2 were recruited for this study. Compared with healthy donors, circulating T cells from SSc patients displayed an aberrant complement signature and hyperactive phenotype. *Invitro* stimulation with immobilized antibodies to the T cell receptor CD3, together with antibodies to CD46, further increased complement dysregulation (in particular, increased C3 and C5 activation fragment generation and C5aR1 expression) and IFN-γ and IL-17 secretion with increased IFN-γ/IL-10 ratio (p<0.05, **Figure 1**). Furthermore, reducing activity of the autocrine 'C5 system' with a C5aR2 agonist corrected this deregulated phenotype with normalization of T cell activity.

Conclusion: By combining multidimensional mass cytometry with an unbiased data-driven analysis pipeline, we demonstrated, for the first time, biological coupling of dysregulated complement with aberrant T cell responses in SSc. Altered cytokine secretomes and intracellular complement activation involving C5 are critical features of T cell activation in SSc. This technique may potentially be useful for early detection of T cell dysregulation and this distinct complement signature may represent a novel biomarker in this subset of SSc patients.

Figure 1: Circulating CD4⁺T cells from SSc patients have reduced capacity for Th1 contraction (*p<0.05, blue: healthy donors, red: patients)

Session Title: Systemic Sclerosis and Related Disorders – Basic Science Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: A previous report showed that abatacept (IgG-CTLA-4) prevented and induced regression of inflammation-driven dermal fibrosis in two different mouse models of systemic sclerosis (SSc) (1). We aimed to investigate the efficacy of abatacept in preclinical mouse models of digestive involvement, pulmonary fibrosis and related pulmonary hypertension (PH), mimicking internal organ involvements of SSc.

Methods: Abatacept has been evaluated in the chronic graft-versus-host disease (cGvHD) mouse model (abatacept 1 mg/mL for 6 weeks), characterized by liver and intestinal fibrosis and in the Fra-2 mouse model (1 mg/mL or 10 mg/mL for 4 weeks), characterized by interstitial lung disease (ILD) and pulmonary vascular remodeling leading to PH.

Results: Treatment with abatacept was well tolerated in all mouse models. In the cGvHD model, treatment of allogeneically transplanted mice with abatacept led to a significant reduction of alanine aminotransferase (24%, $P=0.014$) and aspartate aminotransferase levels (61%, $P<0.001$). Pathological analysis of colon revealed decreased inflammatory infiltrates and destruction of crypts in allogeneically mice receiving abatacept. When assessed by chest micro-CT imaging, Fra-2 transgenic mice treated with abatacept displayed a significant 12% decrease in lung density (10 mg/ml, $P=0.037$) as well as a marked increase in functional residual capacity as compared to IgG1-treated mice (16% for 1 mg/ml, $P=0.001$ and 14% for 10 mg/ml, $P=0.005$). Consistent with these results, abatacept 10mg/L decreased histological fibrosis score (Ashcroft score) as well as hydroxyproline content by 79% ($P=0.009$) and 31% ($P=0.044$) respectively, as compared to IgG1-treated mice. Treatment with abatacept 10mg/mL markedly reduced protein levels in the lesional lungs of Fra-2 transgenic mice of the fibrogenic markers MCP1 by 79% ($P=0.043$) and osteopontin by 87% ($P=0.039$). Levels of TGF- β were also reduced with abatacept (61% for 1mg/mL, $P=0.037$ and 69% for 10mg/mL, $P=0.013$). Further, abatacept dramatically decreased M1 and M2 macrophages infiltration as well as T-cell proliferation in the lesional lungs of Fra-2 mice. Upon treatment with abatacept a substantial reduction of right ventricular systolic pressure (28.1 ± 1.5 mmHg vs. 36.0 ± 5.1 mmHg, $P=0.037$ for 10mg/mL) and right ventricular hypertrophy (0.29 ± 0.01 vs. 0.33 ± 0.010 , $P=0.037$ and $29\pm0.01\%$ vs. $0.33\pm0.01\%$ for 10mg/mL, $P=0.037$) was observed compared to IgG1-treated mice. Consistent with these findings, abatacept 10mg/mL was associated with significant decrease in percent medial wall thickness and numbers of muscularized distal pulmonary arteries.

Conclusion: Abatacept improves digestive involvement, prevents lung fibrosis and attenuates PH. These findings suggest that abatacept might be an appealing therapeutic approach beyond skin fibrosis for organ involvement in SSc.

Session Title: Systemic Sclerosis and Related Disorders – Basic Science Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Signaltransducer and activator of transcription 3 (STAT3) is a transcription factorregulated by phosphorylation of key tyrosine residues that regulates pivotal cell processes such as growth and proliferation, apoptosis, and immune responses[1]. STAT3 pathway has been evaluated in different inflammatory rheumatic diseases, and findings from ex vivo and animal experimental model proposed theSTAT3 pathway as a novel core mediator of fibrosis in systemic sclerosis (SSc)[2]. We evaluated the phosphorylated (p) STAT3 in peripheral blood mononuclear cells (PBMCs) from SSc patients.

Methods: Intracellular expression of phosphorylated and thus activated STAT3 was analysed in 35 SScpatients (female 30; 82% - median disease duration 96 months; 95%-CI 87-172), diagnosed according to the 2013 ACR/EULAR classification criteria, and 10 healthy matched subjects (HS) by FACS analysis and Western Blot. The level of STAT3 gene was studied by qPCR. pSTAT3 was correlated to demographic, clinical, laboratory and instrumental findings of SSc patients.

Results: pSTAT3 was found significantly higher in SSc patients compared to HS (3-folds higher;P=0.007) [Figure 1], and specifically with higher expression in CD14+ cells, while no difference in the expression of STAT3 levels was found. Patients with disease duration longer than 2 years showed higher pSTAT3 (P=0.01) and a direct correlation was found between months from diagnosis and pSTAT3 (r 0.38;P=0.01). We observed an inverse correlation between pSTAT3 and the modifiedRodnan Skin Score (mRSS) (r -0.37; P=0.02). Significantly lower pSTAT3 activity was detected in patients with interstitial lung disease (ILD) compared to patients without ILD (P=0.006). Furthermore, we observed an inverse significant correlation between pSTAT3 and body mass index (BMI) (r -0.34; P=0.02). No correlations with markers of inflammation and specific auto antibodies were detected. Moreover, no differences in diffuse vs limited cutaneous subsets of the disease, pulmonary hypertension, or gastrointestinal involvement, steroid or immunosuppressive cumulative dose or ongoing treatment were found.

Conclusion: We have preliminary demonstrated higher pSTAT3 in SSc PBMCs with a specific expression in CD14+ cells without any modification of STAT3 expression. Patients with longer disease duration, lower mRSS and BMI, and no ILD presented an increasedpSTAT3 activation. The changes in metabolic pathways related to disease duration may explain our findings [3]. Further studies could explain our intriguing results.

Session Title: Systemic Sclerosis and Related Disorders – Basic Science Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic Sclerosis (SSc) is a complex systemic autoimmune disorder characterized by fibrosis of the skin and internal organs. Genetics and environmental factors contribute both to the etiology of the disease. Most variants discovered by GWAS locate in non-coding regions, which impedes immediate interpretation. Expression quantitative trait locus (eQTL) mapping is one tool to discover the molecular mechanisms by which SSc- genetic variants exert their risk.

Methods: In this study, we performed genome-wide eQTL analysis using GWAS and RNA-Seq data derived from whole blood samples of 220 SSc patients and 325 healthy control subjects. All samples analyzed are of European ancestry and form part of the PRECISESADS project dataset. We used matrixEQTL with 8 cofactors to condition on batch, RIN, age, sex, medication, fever, genetic background and blood cell composition.

Results: We show that SSc-associated variants have widespread effects on genome-wide DNA expression levels. By means of stratified and interaction analyses we further show the gender and disease-specific context of SSc-eQTL variants. Interestingly, in SSc patients we found two independent variants, which affect expression levels of the SPARC gene an effect not seen in control subjects. SPARC is overexpressed in SSc and related to the profibrotic effect of TGFbeta. We modeled the expression of SPARC using both variants and assessed the variance explained.

Conclusion: Our results will show how SSc context-specificity works at the molecular level and serve to illustrate the possible regulatory downstream effects of risk variants. This will ultimately inspire the generation of new hypotheses needed to increase our understanding of the biology of SSc and autoimmunity.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Sclerosis and Related Disorders – Basic Science Poster II

Background/Purpose: Myeloablative autologous hematopoietic stem-cell transplantation (HSCT) was recently demonstrated to provide benefit over monthly cyclophosphamide (CYC) in the treatment of diffuse cutaneous systemic sclerosis (dcSSc) (1). As the dysregulation of the B cell compartment is implicated in the pathogenesis of SSc (2), we used antibody repertoire sequencing to characterize B cell repertoire dynamics over the course of HSCT and CYC treatment with the goal of identifying characteristics that differentiate responders from non-responders.

Methods: Immunoglobulin heavy-chain (IGH) sequencing from peripheral blood RNA was performed on HiSeq2500 using an approach adapted from previously described methods (3). Fastq files de-multiplexed by sample were processed with MIGEC and MIXCR software to establish consensus sequences and identify unique clonotypes within each patient's repertoire. Further analysis was performed using VDJtools, Immcantation, and IMGT-HiVQuest software. Samples yielding fewer than 3,500 sequences aligned to IGH genes were excluded from analysis. Event-free survival (EFS) at 54 months post treatment, characterized by no significant organ damage, was used to define treatment responders. The cohort included 13 HSCT recipients (8 responders), 14 CYC treated patients (7 responders) and 15 healthy controls. Responders were assessed at 3-4 time points (baseline and at 26 and/or 36 and/or 48 months post-treatment), non-responders at 2-3 time points (baseline and any time points leading up to and including EFS failure) and healthy controls at a single time point.

Results: Mean IGH repertoire diversity as assessed by the Inverse Simpson Diversity Index was equivalent in both dcSSc treatment groups and healthy controls at baseline (HSCT 1037 ± 604.7 , CYC 919 ± 735.5 , and healthy controls 1232 ± 600.6). At last study time point, HSCT recipient responders exhibit an increase in mean IGH repertoire diversity compared to baseline (1100 ± 578.9 vs. 1638 ± 420.5 , $p=0.037$, paired t-test) which was not observed in HSCT non-responders. Although in comparing last study point to baseline, there was no difference observed in CYC treated patients, CYC treated non-responders exhibit lower mean IGH repertoire diversity at last study time point than healthy controls (1232 ± 600.6 vs. 551.2 ± 365 , $p=0.012$, unpaired t-test).

Conclusion: Increased mean IGH repertoire diversity from baseline is seen in HSCT responders. CYC treated non-responders have decreased mean IGH repertoire diversity as compared to healthy controls.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Sclerosis and Related Disorders – Basic Science Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Pulmonary arterial hypertension (PAH) is prominent as a vascular involvement of systemic sclerosis (SSc), which remains a leading cause of death in spite of current best treatments. As the pulmonary vascular disease (PVD) can be well compensated for, more than a half of the pulmonary circulation is impaired before PAH is detected. So far, the underlying molecular mechanisms have not been fully elucidated, especially at the early stage of SSc. In this study, we focused on the stage of subclinical PVD, and try to detect candidate genes involved in the pathogenesis of exercise-induced pulmonary hypertension (exPH) at the early stage of SSc.

Methods: Total of 88 patients who had not met PAH criteria with Raynaud phenomenon (n=75), skin sclerosis (n=58) or SSc-related autoantibody (n=59) was enrolled. To detect the early PVD, exercise Doppler echocardiography was carried out. The exPH group was segregated from normal response group (exN) with using the reported definition.¹ For gene expression analysis, total RNAs from whole peripheral blood cells were extracted by PAXgene system and multiplex sequencing was done. To identify changes of transcriptomes for developing exPH, hierarchical clustering, weighted gene co-expression network analysis (WGCNA), pathway enrichment analysis (PathVisio) and volcano plots were performed with using differentially expressed genes (DEGs) between exPH and exN group.

Results: After applying 1204 DEGs to hierarchical clustering analysis, 5 major clusters were identified and 93% of exPH samples were segregated into 2nd cluster. WGCNA and pathway analysis revealed 6 co-expression modules and they were significantly enriched with genes of several pathways, such as Wnt, endothelin, IL-1, TNF-alpha, prostaglandin, toll-like receptor, EGF, VEGF-A, type3 interferon and integrin-mediated cell adhesion. Volcano plots were scatter plots calculated to visualize fold-changes and p-values of DEGs. It indicated that expressions of TMEM176A and TMEM176B (\log_2 fold-change >1.25 and $-\log_{10}$ p-value >3.5) were prominent in exPH patients. We also found that the expressions of these genes were highly correlated with each other ($R^2=0.9724$, $p<0.01$).

Conclusion: The paradigm of SSc-PAH management should ideally be aimed at starting treatment before development of PAH. Although elucidating the mechanisms for progression of PVD in the early stage of SSc remains a major challenge, (1) we found exPH patients were segregated from exN group by gene expression profiles of peripheral blood; (2) DEGs were enriched with genes of several important pathways for pathogenesis of SSc, which reported previously; (3) up-regulation of TMEM176A and TMEM176B were prominent in exPH group. The trans-membrane protein TMEM176A and TMEM176B were found initially to be a regulator for DC maturation in mice², but functions of human ortholog of these genes remain still unclear. As our findings revealed active changes of transcriptomes in peripheral blood prior to fulfilling PAH criteria in SSc patients, it will encourage the therapeutic intervention at early stage of SSc to prevent PVD.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Sclerosis and Related Disorders – Basic Science Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Recently, it has been demonstrated that a subset of T cells expresses the B-cell marker CD20. It has been postulated that in rheumatoid arthritis (RA) and multiple sclerosis (MS) the effect of rituximab (RTX), an antibody against this molecule, is partly due to the depletion of this T cell subset. Interestingly, nothing is known about CD20⁺ T cells in another autoimmune disease that is effectively treated by RTX, viz. systemic sclerosis (SSc). The aim of our study was to determine the frequency of CD20⁺ T cells and further characterize this specific subpopulation in SSc.

Methods: Peripheral blood mononuclear cells from healthy controls (HC; n=10), SSc patients treated with RTX (SSc⁺^R; 500mg for 2x, every 3 month; n=16) or not treated with RTX (SSc⁻^R; n=11) were characterized by flow cytometry for the surface expression of T cell specific markers as well as the production of different cytokines, i.e. TNF α , IFN γ , IL-17, after stimulation with PMA and ionomycin. In addition, apoptosis was analyzed before and after heat induction (65 °C for 5 min).

Results: SSc patients had significantly less CD20⁺ T cells compared to HC, independent of RTX-therapy. Thus, in SSc⁻^R the frequency of CD20⁺ T cells was $1.63 \pm 0.32\%$ (mean \pm SE), in SSc⁺^R $0.11\% \pm 0.09\%$ and in HC $2.89\% \pm 1.5\%$ ($p < 0.023$ and $p < 0.001$; respectively).

RTX therapy predominantly eliminated the CD8⁺CD20⁺ T cells. The ratio of CD4/8 in CD20⁺ T cells of SSc before RTX was 0.6 similar to HC and increased during RTX to 2.1 ($p < 0.001$).

In SSc patients, as well as in HC, the CD20⁺ T cell helper (Th) population is dominated by the Th1-subset ($42.7 \pm 15.0\%$ and $42.9 \pm 11.6\%$; respectively). In contrast, in CD20⁺ T cells, the Th17 population was most often found ($34.6 \pm 19.3\%$ and $38.0 \pm 14.0\%$; respectively). CD20⁺ T cell of SSc⁻^R produced more IFN γ , TNF α and IL-2 compared to HC. During RTX therapy these cells were less capable to produce the cytokines.

In SSc⁻^R a higher frequency of CD20⁺ T cells, were already in the early apoptotic phase compared to HC ($32.17 \pm 13.66\%$ vs. $7.5 \pm 13.49\%$) and after heat exposure significantly more of these cells were found in the late apoptotic phase (LAP). Thus, in SSc patients $28.00 \pm 24.88\%$ were found in the LAP compared to $5.29 \pm 4.30\%$ in HC. This effect on apoptosis seemed to be restricted to CD20⁺ T cells, since it was not found in B cells of HC or SSc.

Conclusion: SSc patients have a lower percentage of CD20⁺ T cells compared to HC and to the reported frequency in RA or MS. Whether patients with SSc have per se a lower number of this cell subset in general or these cells might localize into tissue has to be determined. Furthermore, the cytotoxic T cell population of SSc is enriched in CD20⁺ cells that produce a higher number of pro-inflammatory cytokines. The role of IFN γ -production by these cells in the fibrotic process in SSc is still unclear since there are reports, that indicate pro- as well as anti-fibrotic effects of this cytokine. Similar to previous reports the CD20⁺ T cell population is prone to apoptosis. Whether the therapeutic effect of RTX is related to the preferential elimination of CD20⁺CD8⁺ T cells needs further investigation.

Session Title: Systemic Sclerosis and Related Disorders – Basic Science Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Human plasmacytoid dendritic cells (pDCs) have been implicated in the pathogenesis of Systemic Sclerosis (SSc) through their ability to infiltrate the skin and secrete interferons (IFN), interleukin-6 (IL-6) and other proinflammatory chemokines directly, or through type-I IFN response of resident cells. Blood dendritic cell antigen 2 (BDCA-2) is a human-specific pDC-type II C-type lectin that potentially inhibits IFN secretion. Here we determined the effects of CBS004, a novel monoclonal antibody against BDCA-2, on Toll-like receptor (TLR)-induced transcriptome and

IFN secretion in pDCs from healthy volunteers (HV) or patients with SSc *in vitro*, and developed a xeno-transplant mouse model of human pDC activation.

Methods: Peripheral blood mononuclear cells (PBMCs) were collected from 16 SSc patients and 12 HV. IFN and CXCL-4 secretion were evaluated by ELISA. TLR7-9 stimulation was induced by Imiquimod or CpG-oligodeoxynucleotides. pDCs were isolated by magnetic cell sorting. Full transcriptome was analysed by RNA-sequencing. For the xeno-transplant model, NOD/SCID mice were injected in the tail vein with 25×10^4 human pDCs, 12 h after topical application of Imiquimod with or without intra-peritoneal (IP) injection of CBS004 (5 mg/kg). Harvested skin was analysed by FACS for human pDC infiltration and by real-time PCR using a mouse type-I IFN response array (Qiagen).

Results: PBMCs from SSc patients spontaneously produced higher levels of IFN-I and CXCL-4 compared to HV *ex vivo* (206.7 ± 23.4 vs. 43.4 ± 6.8 pg/ml, $P < 0.0001$ and 216.6 ± 36.6 vs. 8.6 ± 0.3 ng/ml, $P < 0.05$, respectively). CBS004 significantly inhibited basal levels of IFN-I in 83% of SSc samples. TLR7 or 9 stimulation showed only modest induction of CXCL-4 in both HV and SSc PBMC. TLR9 stimulation of SSc PBMCs induced >30-fold increase in IFN-I secretion (7167 ± 4377 pg/ml), which was completely abrogated by treatment with CBS004 (209 ± 40.5 pg/ml, $P < 0.001$). RNA-seq analysis of human pDCs (Lineage⁻HLA-DR⁺CD123⁺CD304⁺) stimulated with TLR-9 agonist revealed 168 Differentially Expressed Genes (DEGs, FDR <1%) mapping to IFN, JAK/STAT, IL-6, NF- κ B and angiogenesis pathways. Pre-treatment with CBS004 prevented upregulation of most DEGs, which drove an expression profile similar to non-stimulated pDCs. In the xeno-transplant model, Tail vein injection of pDC resulted in detection of human CD123⁺CD304⁺ cells in the skin (0.3%) with at least 2-fold upregulation of 35/74 mouse type-I IFN response genes including Ccl2, 4, 5 and Cxcl10, Ifit1, 2 and 3, Mx1 and 2, Oas1, Tlr7, 8 and 9 compared to imiquimod treatment alone ($P < 0.005$). Mice receiving IP injection of CBS004 had a 3-fold reduction in infiltrating pDCs (0.1%) and suppression of 85% of the type-I IFN response genes upregulated by pDC injection and Imiquimod treatment (Anova $P < 0.01$).

Conclusion: Our study demonstrates that pDCs from SSc patients are in active status in the blood and can be functionally inhibited by BDCA-2 targeting with CBS004 mAb. Further, we show for the first time that TLR stimulation and BDCA-2 inhibitory effects go beyond IFN secretion including proinflammatory and proangiogenic response and we develop a novel xeno-transplant mouse model for studying human pDC function *in vivo*.

Session Title: Systemic Sclerosis and Related Disorders – Basic Science Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic sclerosis (SSc) is a multisystem connective tissue disease characterized by autoimmunity, vasculopathy, and excessive organ fibrosis. Although the etiology of the disease is still unknown, several lines of evidences suggest the monocytes/macrophages involvement in the pathogenic process of SSc. Interferon regulatory factor 8 (IRF8), a member of IRF family, is a transcriptional regulator that plays essential roles in the differentiation and function of monocytes and macrophages. Genetic association of IRF8 with SSc was reported by genome-wide association study, however, its detailed function is yet to be discovered. In this study, we determined the expression level of IRF8 in circulating monocytes of SSc patients and further analyzed those phenotypic function.

Methods: IRF8 expression levels in peripheral blood mononuclear cells (PBMCs) and circulating monocytes were evaluated by quantitative PCR in 33 patients with SSc (diffuse cutaneous SSc (dcSSc); n=13, limited cutaneous SSc (lcSSc); n=20) and 15 healthy controls in association with clinical characteristics. IRF8 in circulating human monocytes was silenced by RNA interference, then those monocytes were differentiated into macrophages. Cell surface markers, cytokine/

chemokine profiles, and expressions of pro-fibrotic factors and extracellular matrix were assessed by flow cytometry and quantitative PCR.

Results: Although no significant difference was observed on IRF8 levels of PBMCs between total SSc patients and healthy controls, dcSSc patients had significantly lower levels of IRF8 compared with healthy controls and lcSSc patients. In addition, that particular downregulation of IRF8 was observed in circulating monocytes from patients with dcSSc. Differentiated macrophages from IRF8-silenced human monocytes tended to exhibit M2 phenotype. Furthermore, mRNA expression levels of tissue growth factor- β , early growth response-1, α -smooth muscle actin, and monocyte chemoattractant protein-1 were significantly upregulated in macrophages from IRF8-silenced monocytes than that in control macrophages. There was also a trend toward increased levels of IL-6 and tumor necrosis factor- α in those macrophages compared to that in controls.

Conclusion: IRF8 was significantly downregulated in circulating monocytes from dcSSc patients and pro-fibrotic phenotype was observed in macrophages differentiated from IRF8-silenced monocytes. IRF8 may play an important role as a key regulator in the pathogenic process of SSc.

Distinct Pathways in Anti-RNP-Associated Pulmonary Hypertension and Anti-RNP-Associated Raynaud's Phenomenon

Lisa Harlow¹, Ying Wang², YunJuan Zang², Vineet Gupta³, Karen Young⁴, Jian Huang⁴, Bethly Aubourg² and Eric Greidinger⁵, ¹Rheumatology and Clinical Immunology, University of Miami Miller School of Medicine, Miami, FL, ²Rheumatology, University of Miami, Miami, FL, ³Rush University, Chicago, IL, ⁴Pediatrics, University of Miami, Miami, FL, ⁵Miami VA Medical Center, Miami, FL

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Sclerosis and Related Disorders – Basic Science Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Anti-RNP Autoimmunity is associated with multiple manifestations of vasculopathy, including Raynaud's Phenomenon (RP) and Pulmonary Hypertension (PH). We have previously linked anti-K10 antibodies to RP. However, since RP typically presents early in disease whereas PH is typically a late manifestation of disease, we hypothesize that they are mediated by differing factors.

Methods: Using IRB-approved studies on a human cohort of anti-RNP autoimmunity, as well as IACUC-approved protocols to study murine models of anti-RNP-associated autoimmunity, we performed studies to assess the contribution of autoantibodies, T cell-mediated autoimmunity, and cellular components of the innate immune system to the development and persistence of anti-RNP-associated RP and PH.

Results: In a cohort of 130 patients with anti-RNP autoimmunity, 19 patients (15%) had PH (by criteria and/or clinical diagnosis). RP was present in 79/111 patients without PH (71%), but only in 10/19 patients with PH (53%, Fisher's $p = 0.12$). Anti-K10 antibodies were present in 7/19 PH patients (37%) but in 67/111 not PH patients (60%, $p = 0.08$). Thus, trends disfavored associations between PH and either RP+ or anti-K10+ status.

Spontaneously autoimmune Trex1-deficient mice developed anti-K10 antibodies only concurrent with or after the development of anti-RNP antibodies (12/38 RNP+ vs 0/13 RNP- mice, $p = 0.02$). Spontaneous ischemic thermoregulatory tissue loss was observed infrequently (2/12), but only in the subset of mice that developed anti-K10 antibodies. However, up to 18 weeks after the development of anti-RNP antibodies, there were no differences in (normal) BNP levels observed in mice with versus without anti-K10 antibodies.

In contrast, study mice that received CD11c+ spleen cells from RNP+ syngeneic donors uniformly developed RNP+ status with increased serum BNP levels and increased right heart pressures by direct catheter measurements, but without clinical evidence of RP. Treatment with a small molecule antigen presenting cell toxin targeted to CD11b+ cells rapidly reversed established pulmonary hypertension in 4/5 (80%) mice (vs 0/6 controls, $p = 0.02$). Likewise, an RNP antigen-specific T cell vaccination induced reductions in BNP levels in 6/9 treated mice with induced anti-RNP lung disease, with substantially lower BNP values than in mock-treated controls (Mann-Whitney $p = 0.007$) while causing no changes in anti-RNP antibody levels.

Conclusion: While anti-K10 antibodies may be sufficient to induce RP in anti-RNP autoimmunity, anti-RNP-associated PH shows trends toward a negative association with anti-K10 and instead may be mediated by T cells and cellular innate immune constituents.

Proteomic Aptamer Analysis Reveals a Distinct Profile of Very Early Systemic Sclerosis (SSc) Patients at Risk for Progression Toward Definite SSc

Chiara Bellocchi¹, Shervin Assassi², Jun Ying³, Chandra Mohan⁴, Alessandro Santaniello¹ and Lorenzo Beretta¹, ¹Scleroderma Unit, Referral Center for Systemic Autoimmune Diseases, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico di Milano, Milan, Italy, ²University of Texas McGovern Medical School, Houston, TX, ³Department of Internal Medicine - Rheumatology, University of Texas Health Science Center at Houston, Houston, TX, ⁴Department of Biomedical Engineering, University of Houston, Houston, Texas, USA, Houston, TX

SESSION INFORMATION

Session Date: Monday, October 22, 2018
Session Title: Systemic Sclerosis and Related Disorders – Basic Science Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: To determine via SOMAscan aptamer proteomic analysis(>1200 proteins analyzed) the factors associated with disease transition from very early systemic sclerosis (EaSSc) to definite SSc.

Methods: Serum samples from 13 EaSSc, defined according to LeRoy and Medsger criteria (Raynaud phenomenon plus a positive nailfold capillaroscopy and SSc-specific auto-antibodies without any other sign of definite disease) [1] and 8 age-, sex-, matched healthy controls (HCs) were analyzed via SOMAscan aptamer assay [2]. Prospective data were available up to 4.9 years from sampling (median=4.1, IQR=3.5-4.5 yrs) to determine the progression to definite SSc according to the EULAR/ACR 2013 criteria [3]. Relevant proteins were selected among those with relative fluorescence units (RFU) >1.5-fold HCs via predictive modeling (bagging). Gene Ontologies (GO terms) of proteins with corrected p<0.05 after 10,000-fold permutation testing, were aggregated to determine the relevance of biological processes in patients at risk of evolution.

Results: Seven patients (54%) did evolve into definite SSc, while 6 did not progress. Nonprogressors and progressors were similar regarding baseline characteristics (ACA+, 66% vs 57%; FVC, 105[97-102] vs 110 [109-115]; DLco, 92 [87-105] vs 85[82-101]). Ten proteins were significantly associated with evolution (Table); the relative RFUs are represented via heatmaps in Figure, left panel. GO term analysis revealed that patients at risk for progression shared several biological processes (Figure, right panel) related to fibrosis, vascular function and angiogenesis and that these were upregulated compared to non-progressors.

Conclusion: Increased expression of proteins and pathways related to angiogenesis, extracellular matrix remodeling and fibrosis distinguish EaSSc at risk of progression from those with stable disease up to 5 years from referral. This is the very first proteomic study to determine the baseline factors associated with disease evolution in very early SSc patients. Our findings may have relevance for early therapeutic intervention and disease interception.

Figure 1: Amelioration of the fibrotic response to bleomycin and unbuffered saline in TgTGF- β and wildtype Blomale mice using pan-PPAR agonist lanifibranor.

Results: As expected, TG mice demonstrated an exaggerated fibrotic response to or pharyngeal aspiration of bleomycin compared to WT, and to unbuffered saline compared to WT animals (figure 1); demonstrating similar impact when compared with the more invasive intra-tracheal administration published previously.

TG mice treated with higher dose lanifibranor demonstrated significantly greater protection from lung fibrosis than those treated with vehicle or lower dose lanifibranor, for instance: mean Ashcroft score TG-bleo IVA100 3.8 ± 0.58 ; TG-bleo vehicle 4.4 ± 0.58 ; $p < 0.01$. Treatment with lanifibranor in WT animals was less effective at preventing fibrosis (WT-bleo IVA100 3.5 ± 0.46 ; WT-bleo vehicle 3.2 ± 0.5 ; not significant), suggesting that the pro-fibrotic phenotype due to TGF- β upregulation in this model is substantially ameliorated by lanifibranor.

In this study, administration of bleomycin to a transgenic mouse resulted in an Ashcroft score 65% higher compared to saline administration in WT mice. This excessive fibrosis was then reduced by 15% with the use of lanifibranor at 100mg/kg.

Conclusion: Treatment with 100 mg/kg lanifibranor ameliorates lung fibrosis in the TgTGF- β mouse model of scleroderma. This model, which demonstrates severe and persistent fibrosis compared to WT mice, provides mechanistic support for trials of lanifibranor in scleroderma including cases with pulmonary involvement.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Sclerosis and Related Disorders – Basic Science Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic sclerosis (SSc) is an autoimmune disease characterized by fibrosis of skin and internal organs and has a predilection for women. The strongest genetic contribution to SSc is from the Human Leukocyte Antigen (HLA) class II region. Previous studies have reported increased *DRB1**11, especially *DRB1**1101 and *1104, and decreased *DRB1**07 and *DRB1**15 in Caucasian women with SSc.(1) The third hypervariable region (HV3), corresponding to amino acid sequences from positions 67 to 74 of the DR β 1 molecule, forms the primary T-cell recognition site.(2)

Peptide and T-cell interactions are influenced by charge and SSc risk evaluation according to HV3 charge could provide insight into the immunological basis of HLA associations with SSc. We therefore asked whether SSc patients differ from healthy individuals for HV3 amino-acid charge.

Methods: High resolution *HLA-DRB1* genotyping was conducted for 420 adult females, 157 SSc and 263 healthy controls. Alleles were classified into 4 groups based on the 67–74 amino acid sequence charge: –2, 0, +1, and +2 (no individual had a –1 charge). Odds Ratios (OR) were calculated for 9 of 10 possible genotypic combinations accounting for 99% of subjects. P-values were calculated by Fisher Exact test.

Results: In 9 comparisons, the genotypic OR of SSc risk according to HV3 charge ranged from 0.42 to 2.14. Risk was statistically significant when both alleles encoded for HV3 with a charge of 0, OR [and 95% confidence interval] 2.14 [1.33–3.37], 30/157 SSc vs. 77/263 controls; $p = 0.0016$, $p = 0.014$ after correcting for 9 comparisons. Protection from SSc was significant for the combination of 0 charge encoded by one allele and +1 charge by the other allele, OR 0.57 [0.35–0.92], 49/157 in SSc vs. 46/263 in controls; $p = 0.028$, however this was not significant after correcting for 9 comparisons $p = 0.25$. The most frequent alleles with a 0 charge in our population were *DRB1**07:01 (23% of cases and 25% of controls), *DRB1**15:01 (18% of cases and 25% of controls), and *DRB1**11:01/4 (31% of cases and 13% of controls); the latter was significantly increased in cases ($p < 0.0001$; OR 2.88 [1.75–4.67]) as expected, consistent with previous studies. Homozygosity for these 3 alleles (5/157 SSc and 10/263 controls) did not explain the observation of SSc risk when both alleles encode 0 charge HV3. Furthermore, having a single “dose” of 0 charge did not differ in cases vs. controls (71% vs. 70%, respectively).

Conclusion: SSc risk is associated with inheritance of a 0 charge DRβ1 molecule for positions 67–74 encoded by both parental haplotypes, independent of the allelic identity of the *DRB1* gene. Inheritance of one allele encoding a 0 charge and the other a +1 charge was associated with protection but was not significant after correction for multiple comparisons. The amino-acid sequence of the HV3 is thought to be particularly important in the HLA-peptide-Tcell interaction. The current observation regarding HV3 charge on both haplotypes points to an aspect of that interaction that may help elucidate the role of HLA molecules in SSc pathogenesis.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Sclerosis and Related Disorders – Basic Science Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic Sclerosis (SSc) is an autoimmune disease characterized by fibrosis and inflammation. Multiple organ systems are affected including the skin, gastrointestinal tract, vasculature, and lungs (Katsumoto, Whitfield, & Connolly, 2011). It is a heterogeneous disease but gene expression analyses have defined four distinct molecular subtypes (inflammatory, fibroproliferative, normal-like, and limited). Prior studies have implicated microbial dysbiosis in SSc (Arron et al., 2014; Volkmann, 2017), but have not assessed the relationship between host immune processes/molecular subtype and microbial community characteristics. In this study we characterize the esophageal microbiome of patients with SSc and explore its relationship to host gene expression.

Methods: RNA-sequencing was performed on 19 patient and 4 healthy control (paired upper and lower) esophageal biopsies. Raw reads were aligned to hg19 via STAR and normalized to reads per kilobase million (RPKM). Intrinsic Gene

Conclusion: SSc esophageal tissues recapitulate SSc processes and show an increase in abundance of potentially pathogenic commensal microbes when compared to healthy controls. Microbes do not hierarchically cluster samples by site, implicating a disease driven difference in microbial communities potentially also divided by SSc subtype.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Sclerosis and Related Disorders – Basic Science Poster II

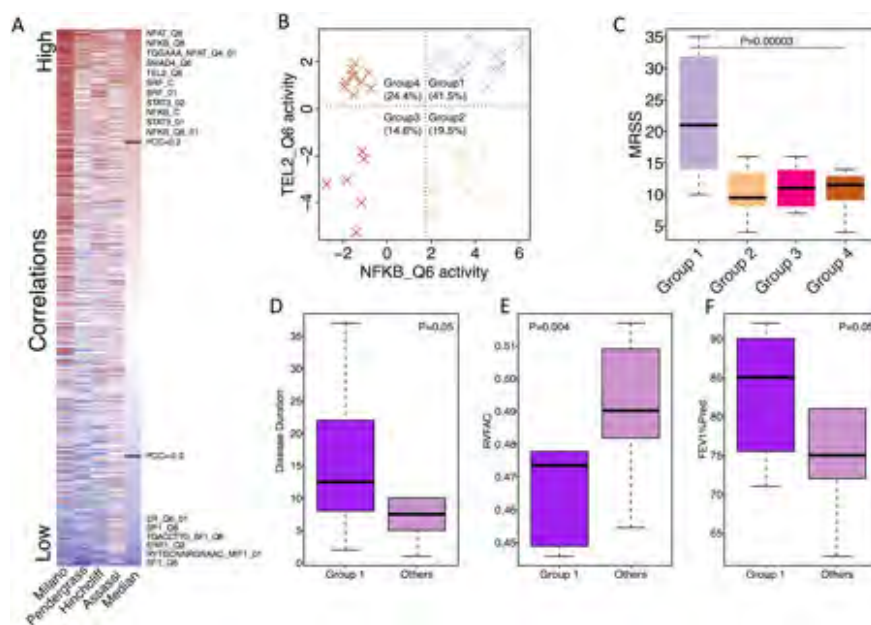

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic sclerosis (SSc) is a heterogeneous autoimmune disorder with poor outcomes and no FDA-approved therapies. Prior work has shown gene expression patterns associated with inflammation and innate immune system activation in multiple affected organ systems. Networks of activating transcription factors (TF) and miRNAs that underlie SSc molecular subsets and clinical co-variates have not been characterized in detail. We analyzed transcriptional regulatory networks underlying the inflammatory intrinsic gene expression subset of SSc and associated clinical covariates.

Methods: Gene expression profiles were downloaded from Milano et al (GSE9285; 75 samples), Pendergrass et al (GSE32413; 89 samples), Hinchcliff et al (GSE59787; 165 samples) and Assassi et al (GSE58095; 102 samples). In total 431 samples from 244 patients were analyzed. The C3 target gene set (836 regulators) was downloaded from the MSigDB. Gene expression and target gene profiles were integrated using the BASE algorithm to calculate sample-specific regulator activity scores. TF activity scores were positively correlated and miRNAs activity scores were negatively correlated with gene expression. Correlations were calculated between activity scores and samples MRSS. Regulators were selected from those that had correlations greater than 0.15 or lesser than -0.15 in at least 3 cohorts. A transcriptional interaction network was created by Cytoscape.

Results: We identified 60 regulators whose activity scores were consistently, positively correlated with MRSS in inflammatory patients in all datasets. Examples include core binding factors, innate immune-related pathways, and telomere maintenance (NFAT, NFkB, STAT3, TEL2; Fig. 1A). We also found that using the activities of NFkB and TEL2, inflammatory samples were clustered into 4 subtypes (Fig. 1B). Doublehigh samples in group 1 had much worse skin

disease (Fig. 1C, $P=0.00003$) with longer disease duration (Fig. 1D, $P=0.05$) compared to other samples. Group 1 samples tended to have worse pulmonary hypertension (Fig. 1E, $P=0.004$) and were less likely to have pulmonary fibrosis (Fig. 1F, $P=0.05$) than the remainder of samples. Lastly, a regulator interaction network was created to provide novel insights for SSc and visualize the connectivity between different components of the regulator network.

Conclusion: We have identified a subtype of samples classified as the inflammatory gene expression subset that show increased expression of innate immune pathways NFAT, NFkB and STAT3. Patients with high expression of two of these pathways, which we have termed “double high”, had evidence of increased disease severity. This further highlights the role of innate immune transcriptional activators in SSc pathogenesis. The framework can be easily applied to any samples with molecular gene expression data to develop transcriptional activity networks.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Sclerosis and Related Disorders – Basic Science Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Localized scleroderma (LS) is a progressive disease of the skin and underlying tissue that causes significant functional disability and disfigurement, especially in developing children. During the active inflammatory stage of the disease, systemic immunosuppressive therapy intervention can halt disease progression and ameliorate disease features such as joint contractures. The existing clinical process for determining when LS is active and susceptible to intervention and when to gradually stop intervention is often convoluted. Commercially available inflammatory serologic markers currently have limited utility in the clinical assessment of active disease. RNA sequencing (RNAseq) technology allows for improved understanding of relevant cellular expression through transcriptome analysis of specific time points

during LS disease progression. It also permits the use of RNA extracted from existing paraffin-embedded skin tissue increasing the availability of samples.

Methods: RNAseq was performed on paraffin-embedded skin (n=15 LS, n=5 pediatric healthy) and RNAlater preserved skin specimens (n=2 LS, n=4 healthy) using the Illumina HTS using TrueSeq Access library preparation and collected through IRB#PRO11060222. Paired end RNA sequencing data was aligned using STAR and analyzed for differential gene expression (DEGs) using DESeq2. Genes were reanalyzed using DEG cutoffs of log₂fold change > ±2.5, adjusted p<0.05, and a false discovery rate (FDR) cutoff of <0.01 for enrichment software (GSEA®). PCA and hierarchical clustering was performed using Cluster3.0 and Partek® softwares. Clinical subtype data (active/inflammatory vs. stable/disease damage) was applied to these clustering techniques.

Results: A strong correlation ($r_s=0.90$, $p=0.0001$) was observed between the comparison of genes expressed between fresh (RNAlater) and paraffinized skin in healthy and LS subjects. When compared to healthy controls, we observed distinct expression of an inflammatory response gene signature (IRGS) composed of IFN γ , IFN α and TNF α associated genes. GSEA® enrichment analysis showed the IRGS, including interferon inducible chemokines such as CXCL9, CXCL10, CXCL11 and IFN γ itself, was more highly expressed in LS patients with more inflammatory lesions (see Figure).

Conclusion: The use of paraffinized skin for sequencing was proven to be an effective substitute for fresh skin by comparing gene expression profiles. The prevalence of the IFN γ signature in the lesion biopsies of active LS patients indicates these genes are reflecting clinical parameters and provide insight into disease propagation, possibly a Type 1 monocyte or T-cell response, which will be further investigated in regard to disease propagation.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Sclerosis and Related Disorders – Basic Science Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Anti-fibrillarin (nucleolar, AFA) and anti-topoisomeraseI (ATA) autoantibodies are specific to systemic sclerosis (SSc) and are common in African Americans (AA). These auto antibodies define clinically distinct phenotypes but the genetic risk factors contributing towards them are largely unknown.

Methods: Data from the genome-wide association study (GWAS) of AA SSc collected under the Genome Research in African American Scleroderma Patients (GRASP) cohort were utilized. 207 AFA and 245 ATA positive patients were compared to 946 controls. After quality control filtering, SNP imputation was performed using Beagle and classical *HLA* types were imputed using HLA*IMP:03 web server. Odds ratios for *HLA* alleles and amino acid residues were calculated using a dominant model.

Results: In the GRASP cohort, 22.2% of patients had nucleolar ANA pattern (AFA) after removing other nucleolar staining, SSc specific auto antibodies. In the AFA+ subset, *HLA-DRB1*08:04* demonstrated the strongest association with $P=4.2 \times 10^{-27}$, OR=5.98 (95% CI 4.2-8.5) (Figure 1A). *HLA-DRB1*08:04* is a predominantly African ancestry allele and its leucine 74 residue in the peptide binding groove was strongly associated with AFA+ SSc with OR=5.12 (95% CI 3.7-7.1). The top SNP in the *HLA* region was rs573310147 with $P=1.3 \times 10^{-19}$. ATA positivity was seen in 26.2% of patients in the GRASP cohort. In the ATA+ subset, rs28667353 was the top SNP with $P=1.4 \times 10^{-19}$ (Figure 1B). *HLA-DPB1*13:01* was

Figure 1. GWAS of Illumina MEGA array with imputed SNPs (triangles) and classical *HLA* types (blue squares). A: 207 AFA+ SSc and 946 controls; B: 245 ATA+ SSc and 946 controls. Pink line denotes p-value for genome-wide significance ($P=5 \times 10^{-8}$).

seen in 15.8% of ATA+ SSc as compared to 6.2% in ATA- SSc and 5.1% in controls. *HLA-DPB1*13:01* demonstrated the strongest association with $P=1.1 \times 10^{-16}$, OR=4.1 (95% CI 2.9-5.8) in the ATA+ subset. *HLA-DPB1*13:01* has been reported as a risk loci in ATA+ subset in SSc patients from several different ancestries. Meta-analysis with the European ancestry SSc yielded a highly significant $P=2.18 \times 10^{-61}$. On examining the amino acid residues, isoleucine 76 in the peptide binding groove of HLA-DPB1 increased risk for SSc with OR=2.8 (95% CI 2.1-3.8). Six other previously unreported, non-*HLA* loci were identified in the AFA+ subset and two in the ATA+ subset at genome-wide significance with the top one being *FSD2* (Fibronectin type III and SPRY domain containing 2).

Conclusion: *HLA-DRB1*08:04* is a predominantly African ancestry allele that increases SSc risk 6-fold in AFA subset which is primarily observed in AAs with SSc. This may help explain the increased prevalence and severity of SSc in AAs. *HLA-DPB1*13:01* increases risk of SSc in not only AAs but all ancestral populations. Also, *HLA-DPB1*13:01* control frequency in a population correlates with the prevalence of SSc in that ancestral population. Functional roles of these novel non-*HLA* loci need to be experimentally evaluated. Understanding the mechanism of peptide presentation by these two *HLA* alleles will lead to a better recognition of the trigger that leads to autoimmunity in SSc.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Sclerosis and Related Disorders – Basic Science Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: T cell receptors (TCRs) are a vital component of the adaptive immune system and TCR repertoire diversity is considered a measure of the immune system's strength and competency. T cells have been implicated in the progression of systemic sclerosis (SSc), yet the TCR repertoire in SSc remains understudied. Here, we present findings from TCR sequencing in SSc patients to characterize their TCR repertoire.

Methods: Peripheral blood mononuclear cells (PBMCs) were collected from 11 patients with SSc and 7 controls, matched for age, gender, and race. We performed TCR sequencing on genomic DNA isolated from CD14⁺ lymphocytes. RNA-seq was also performed on RNA isolated from these cell populations. We used various metrics including CHAO1, Shannon Index, and Inverse-Simpson to quantify diversity of the TCR repertoire in each sample. Pearson correlation and Wilcoxon Rank Sum Test were used to relate clinical covariates to TCR repertoire diversity in SSc patients and controls. We used edgeR (Bonferroni-Holmes corrected $p < 0.05$) to identify differentially expressed genes from RNA-seq data and identified significantly enriched Gene Ontology biological pathways using g:Profiler (g:SCS corrected $p < 0.05$).

Results: We quantified measures of TCR repertoire diversity for each individual sample and correlated these measures with clinical variables. Reduced TCR repertoire diversity was associated with increased age in both SSc and controls, as

previously reported ($R=-0.44$, $p=0.06$). There was a statistically significant reduction in TCR diversity in SSc patients compared to controls ($p=0.0154$). Reduction in TCR diversity was most notable for patients with limited cutaneous SSc, though this did not reach statistical significance in our small sample size. There were no statistically significant relationships between TCR repertoire diversity and FVC, DLCO, or disease duration. We identified a total of 5735 differentially expressed genes (2651 up-regulated, 3084 down-regulated) in SSc samples compared to healthy control samples. Upregulated biological processes for SSc lymphocytes included *CD4+*, *alpha beta activation*, *Type I interferon production*, *T cell differentiation*, *mRNA processing*, and *cell cycle* ($p<0.05$). Upregulated biological processes for control samples included *leukocyte degranulation*, *lipid oxidation*, and *translational termination*.

Conclusion: We find a reduced diversity of TCR repertoire in patients with SSc relative to healthy controls. Gene expression analyses indicate that circulating T cells of SSc patients may be different from healthy controls, favoring suppression of effector Th1 generation, consistent with the development of autoimmunity.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Sclerosis and Related Disorders – Basic Science Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The Scleroderma: Cyclophosphamide or Transplantation Trial (SCOT) study compared stem cell transplant to monthly cyclophosphamide (CYC) in patients with scleroderma (SSc). We studied baseline lymphocyte subsets comparing age and gender matched controls with SCOT participants who were previously treated in the prior 12 months and those who received no treatment during this period.

Methods: Lymphocytes from 123 controls and 72 SCOT participants at baseline were analyzed by flow cytometry. For each lymphocyte subset count, the significance of difference was determined using the Mann-Whitney-Wilcoxon on rank sum test.

Results: Compared to controls, those with SSc showed significant reductions in central memory CD8 T cells, memory B cells, myeloid and plasmacytoid dendritic cells, and in FOXP3+CD25+ T regulatory (Treg) cells (Table 1). Conversely, participants had increases in naïve CD4 cells and effector CD8 T cells. No significant differences in any lymphocyte subset were observed between those previously treated ($n=57$) and untreated ($n=15$). Additionally, no differences were observed between participants previously treated with CYC ($n=23$) and those that were not ($n=49$). All participants had an increased Th2/Th1 CD4 cell ratio compared to controls.

Conclusion: We found a number of differences between healthy controls and participants in terms of T cell subsets (including Tregs) and B cells attesting to the profound immune dysregulation in severe early diffuse SSc. Increased numbers of induced Th2 CD4 T cells supports the theory that Th2 (rather than Th1) cell play a role in the pathogenesis. Furthermore, the decreased numbers of Tregs may transformation to pathogenic effector T cells of Th17 or Th2 lineages with respective pro-inflammatory or pro-fibrotic activity. The role of memory B cells is unclear, although reduced numbers may represent trafficking to sites of inflammation or disease activity. The counts of abnormal cell subsets were similar in the treated and untreated patients suggesting that even in the treated patients the subset counts were abnormal primarily due to scleroderma itself rather than immune modulatory treatment. Even treatment with cyclophosphamide resulted in a baseline lymphocyte profile that was not significantly different from those patients treated with other agents. In other words, our data suggests severe disease was more influential than drug immunosuppression in producing the

immunophenotype abnormalities. The hypothesis that correction of lymphocyte aberration will affect clinical disease progression needs to be studied in a prospective trial.

Table 1: Lymphocyte subset counts (per microliter of blood) in patients with SSc and healthy controls.

Lymphocyte subset	Healthy Controls (n=123) Median (10 th -90 th percentile)	Untreated Patients (n=15) Median (10 th -90 th percentile)	Treated Patients (n=57) Median (10 th -90 th percentile)	Treated vs. untreated patients (p-value)	Healthy controls vs. all SSc patients (p-value)

Plasmacytoid Dendritic Cells in Bronchoalveolar Lavage Correlate with Pulmonary Artery Diameter and Infiltrate Perivascular Areas in the Lungs from Patients with Systemic Sclerosis Associated Pulmonary Hypertension

Isela Valera¹, Anagha Divekar², Dinesh Khanna³, Fereidoun Abtin⁴, Rajan Sagar⁴ and **Ram R. Singh⁴**, ¹Autoimmunity and Tolerance Laboratory, Division of Rheumatology, Department of Medicine, UCLA, Los Angeles, CA, ²Biolegend, San Diego, CA, ³Division of Rheumatology, Department of Internal Medicine, University of Michigan Scleroderma Program, University of Michigan, Ann Arbor, MI, ⁴UCLA, Los Angeles, CA

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Sclerosis and Related Disorders – Basic Science Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: In patients with systemic sclerosis (SSc), plasmacytoid dendritic cells (pDCs) increase in the bronchoalveolar lavage (BAL) and lung tissues (Kafaja S, et al, JCI Insight 2018). Importantly, the frequency of pDCs in the lungs of patients with SSc correlated with the severity of interstitial lung disease, and with the frequency of CD4⁺ and IL-4⁺ T-cells in the lung. A pivotal role of pDCs was shown in animal studies, where the depletion of pDCs ameliorated fibrosis in the bleomycin model. These data suggest a role of pDCs in the pathogenesis of fibrosis. Fibroblast proliferation and accumulation around pulmonary vessels is also an early and important event during the development of pulmonary arterial hypertension (PAH). Here, we explore a possible relationship between pDCs and pulmonary hypertension.

Methods: Previous studies have suggested the utility of HRCT-determined pulmonary artery diameters in predicting pulmonary hypertension. In one study, right pulmonary artery diameter of more than 18.7 ± 2.8 mm was considered abnormal, and main pulmonary artery diameter of >29 mm was predictive of pulmonary hypertension. Hence, to begin to investigate a relation between immune cell subsets and subclinical pulmonary arterial hypertension, we analyzed correlation between diameters (mm) of main or right pulmonary arteries and frequencies (% of total) of cell types in BAL. Frequencies of cellular subsets from RML and RLL were averaged. Next, we stained lung tissue slides from patients with SSc-PAH using markers for pDCs and blood vessels (alpha-smooth muscle cells and endothelial cells).

Results: The frequencies of pDCs correlated with the diameters of both main ($r = 0.45$) and right pulmonary arteries ($r = 0.57$). There was no correlation between the frequencies of T-cells ($CD4^+$, $CD8^+$, Th2 and Tc2) and pulmonary artery diameters. We further found increased pDCs around blood vessels and other areas of lungs from patients with SSc-PAH as compared to control lungs.

Conclusion: These data argue for a possible role of pDCs in SSc-associated pulmonary vascular disease.

Abstract Number: 1124

Epidemiological Characteristics of Inpatient Admissions for Acute Inflammatory Gout Arthropathy and Factors Affecting Length of Stay: A National Level Study

Vagishwari Murugesan and Jennifer Tran, Internal Medicine, Medstar Washington Hospital Center, Washington, DC

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Epidemiology and Public Health Poster II: Gout, Ankylosing Spondylitis, Osteoarthritis, Osteoporosis, Pain, and Function

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Gout is a common cause of inflammatory arthritis due to accumulation of monosodium urate crystals in joints, bones and soft tissues. The aim of the study will be to understand the epidemiological characteristics of acute gout (ICD 9 code: 274.01) as a primary diagnosis in hospital discharges in the year 2014 using the National Inpatient Sample (NIS).

Methods: The NIS is a nationally representative sample of 20% of all non-federal hospitals in the USA with information from approximately 1000 hospitals pertaining to records from 7 million inpatient hospital admissions. The epidemiological characteristics we studied were age, gender, race, payer (Medicare/Medicaid/private insurance/uninsured), patient residence (large central metro, suburbs, medium and small metro and rural areas) and region (northeast, mid-west, southern and west) and associated co-morbidities: hypertension, diabetes, heart failure, chronic kidney disease, osteoarthritis & heart failure. Multiple linear regression was used to analyze factors that were associated with an increased length of stay.

Results: For 2014, from a total of nearly 7 million records (7,071,762), there were 11,415 admissions for acute gout as the primary diagnosis (0.16%) which translated to 3.6 admissions per 100,000 persons. The majority of admissions were in the age group of 65 – 84 years (46.1 %) followed by 45-64 age group (34.3%). A majority of the admissions were males (67.3%) compared to females (32.3%). Gout was most prevalent among Caucasians (65.8%). African Americans represented 14.8% of all admissions followed by Hispanics at 12.1%. Asian or pacific islanders were 2.8% whereas Native Americans represented 0.6%. The total aggregate costs were \$76,249,619 for 2014 amounting to a mean of \$6,654 per admission. Medicare remained the highest payer (62.8%) followed by private insurance (17.7%) and finally Medicaid (12.9%). Uninsured patients accounted for 5.2% of all admissions. Patients from a large central metro were the majority of inpatient admissions (39.1%) followed medium and small sized metro (25.1%). 24.1% of patients were from the suburbs and whereas only 11% were from a rural area. The southern region accounted for majority of admissions (33.2%) followed by northeast region (26.9%). 23.8% were from Midwest and Western region had only 15.9% of all admissions. The mean length of stay (LOS) was 3.9 ± 0.06 days. CKD was present in 47.8%, hypertension in 37.5%, CAD in 35.5%, heart failure in 35.1%, diabetes in 28.4% and osteoarthritis in 16% of patients. Using multivariate analysis the only factors significantly affecting LOS were female gender and presence of heart failure. Female gender was inversely related to LOS ($p < 0.001$) whereas heart failure exacerbation resulted in an increased LOS ($p < 0.001$).

Conclusion: Acute gout places a significant burden on in-hospital resources. Although CKD was present in nearly half of patients, only gender & heart failure resulted in significantly affecting LOS.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Epidemiology and Public Health Poster II: Gout, Ankylosing Spondylitis, Osteoarthritis, Osteoporosis, Pain, and Function

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Hyperuricemia is increasing worldwide, and is emerging as a potential biomarker and predictor for metabolic syndrome and related complications. We aimed this study to investigate the association between hyperuricemia and metabolic syndrome with or without obesity.

Methods: We performed multivariate logistic regression analyses using the 2016 Korea National Health and Nutrition Examination Survey (KNHANES) data collected in a representative sample of Korean adults (defined by age ≥ 20 years). Hyperuricemia was defined by serum uric acid level ≥ 7.0 mg/dl for men and ≥ 6.0 mg/dl for women. Obesity was based on body mass index (BMI) ≥ 25 kg/m².

Results: Among a total of 5,591 Korean adult participants, 685 (12.3%) individuals were classified as having hyperuricemia. Hyperuricemia was significantly associated with metabolic syndrome in both men (Odd ratio (OR) = 1.74, 95% CI: 1.29-2.34) and women (OR = 2.47, 95% CI: 1.55-3.93) after adjustments for age, sex, smoking, alcohol, exercise, BMI and estimated glomerular filtration rate (eGFR). Obesity was also independently related to hyperuricemia in both sex (OR = 1.70, 95% CI: 1.31-2.19 in men, OR = 3.73, 95% CI: 2.57-5.41 in women). Among the components of metabolic syndrome, elevated blood pressure, elevated triglyceride and reduced high-density lipoprotein (HDL)-cholesterol in men, and increased waist circumference, hyperglycemia, elevated triglyceride in women were risk factors for hyperuricemia. In subgroup analyses, individuals who had metabolic syndrome with obesity were at the highest risk of hyperuricemia, followed by those with metabolic syndrome without obesity in overall population (OR = 3.91, 95% CI: 3.00-5.09, OR = 3.21, 95% CI: 2.28-4.52, respectively). In population with metabolic syndrome, the presence of obesity posed higher risk for hyperuricemia in women compared with men (OR = 7.24, 95% CI: 4.56-11.50 versus OR = 2.90, 95% CI: 2.12-3.96).

Conclusion: Our results indicate that hyperuricemia is independently associated with metabolic syndrome and obesity in both sex. The effect of obesity in increasing the risk of hyperuricemia was more pronounced in women compared to men.

Abstract Number: 1126

Gout and Chronic Pain in Older Adults: A Medicare Claims Study

Jasvinder A. Singh and John Cleveland, Rheumatology, University of Alabama at Birmingham, Birmingham, AL

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Epidemiology and Public Health Poster II: Gout, Ankylosing Spondylitis, Osteoarthritis, Osteoporosis, Pain, and Function

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: To assess if gout is associated with a higher risk of incident chronic pain in older adults, 65 years or older.

Methods: This study used the 2006-2012 Medicare claims data. We used multivariable-adjusted Cox regression analyses to examine the association of pre-existing diagnosis of gout with incident (new) diagnosis of chronic pain, adjusting for demographics, medical comorbidity and use of common medications for cardiovascular disease and gout. Sensitivity analyses substituted Charlson-Romano score with acategorical variable or each Charlson-Romano comorbidity. Gout was identified by the presence of two claims for gout at least 4 weeks apart, with International Classification of Diseases, ninth revision, common modification (ICD-9-CM) code of 274.xx. Study outcome was incident (new) chronic pain, with an absence of this diagnosis in the baseline period of 1 year, that occurred in patients with or without pre-existing gout diagnosis that preceded the diagnosis of chronic pain. We identified chronic pain by the occurrence of at least two claims 4-weeks apart containing any of the following ICD-9-CM codes [12]. 307.80, 307.89, 338.0, 338.2, 338.4, 719.41, 719.45 - 719.47, 719.49, 720.0, 720.2, 720.9, 721.0 - 721.4, 721.6, 721.8, 721.9, 722, 723.0, 723.1, 723.3 - 723.9, 724.0 - 724.6, 724.70, 724.79, 724.8, 724.9, 729.0 - 729.2, 729.4, 729.5. This approach has been shown to be valid, with positive predictive value of 95%, sensitivity of 70% and specificity of 99%. We used multivariable-adjusted Cox proportional hazard models to assess the association of gout with incident GCA, adjusting for potential confounders/covariates including demographics (age, race, gender), comorbidities (Charlson-Romano comorbidity index), and medications commonly used for cardiac diseases (statins, beta-blockers, diuretics, and angiotensin converting enzyme (ACE)-inhibitors) and gout (allopurinol and febuxostat; Model 1).

Results: There were 1,321,521 eligible people, of whom 424,518 developed incident chronic pain. Crude incidence rates of chronic pain were as follows: gout, 158.1 per 1,000 person-years and no gout, 64.5 per 1,000 person-years. In multivariable-adjusted Cox regression analyses, gout was associated with higher hazard ratio of chronic pain, 2.02 (95% CI, 1.98, 2.05), confirmed in sensitivity analyses 1.96 (95% CI, 1.93, 1.99) (model 2) and 1.77 (95% CI, 1.74, 1.80) (model 3). No meaningful differences were found by gender and race in subgroup analyses; slightly lower hazard of gout with chronic pain was seen in oldest people (Table 1).

Conclusion: Gout was associated with a doubling of the risk of chronic pain. Efforts must be made to optimize gout control and gout inflammation, so that long-term sequelae of gout, including chronic pain can be avoided and when present, treated early and appropriately.

Table 1. Association of gout with chronic pain, in pre-defined subgroup analyses, by age, gender, and race

Risk of Stroke Among Patients with Gout in Taiwan: A Nationwide Population Study

Ping-Han Tsai and Chang-Fu Kuo, Division of Rheumatology, Allergy and Immunology, Chang Gung Memorial Hospital, Taoyuan, Taiwan

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Epidemiology and Public Health Poster II: Gout, Ankylosing Spondylitis, Osteoarthritis, Osteoporosis, Pain, and Function

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: To determine whether the Taiwanese patients with gout have a higher risk of stroke.

Methods: Using the National Health Insurance database, we identified a cohort of new-onset gout patients in Taiwan between 2000 and 2005, follow up till 2015. The gout cohort was frequency-matched according to birth year and gender with patients without gout (control cohort). Cumulative probability and multivariable hazard ratio (HR) adjusted by age, sex, Charlson comorbidity index and co-medication was performed to evaluated the risk of stroke, including ischemic and hemorrhage stroke.

Results: In this study, we identified 646,983 incident patients with 1:1 matched of control group without gout. The incidence (100 person-years) of ischemic stroke and hemorrhagic stroke were both higher in gout group [7.26 (95% CI, 7.19-7.33); 2.47 (95% CI, 2.42 - 2.51) respectively] than control group [5.95 (95% CI, 5.88- 6.01); 2.04 (95% CI, 2-2.07), respectively]. Both risk of ischemic stroke and hemorrhage stroke were higher in gout group (HR 1.15, 95% CI 1.14-1.17; HR1.17, 95% CI 1.14-1.20, respectively) (**Table**).

Conclusion: Patients in Taiwan with gout have a higher risk of stroke, including ischemic stroke and hemorrhagic stroke. The incidence of ischemic stroke was three-fold than hemorrhagic stroke in gout patient.

Table: Clinical characteristics of patients and Hazard ratios for incidence of stroke.

	Gout (n= 646,983)	No Gout (n= 646,983)	P Value

Impact of Urate-Lowering Therapy on the Risk of Cardiovascular Events and All-Cause Mortality Among Individuals with Gout

In Ah Choi¹, Hoyeon Jang² and Gil-Won Kang², ¹Division of Rheumatology, Department of Internal Medicine, Chungbuk National University Hospital, Cheongju, Korea, Republic of (South), ²Department of Health Informatics and Management, College of Medicine, Chungbuk National University, Cheongju, Korea, Republic of (South)

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Epidemiology and Public Health Poster II: Gout, Ankylosing Spondylitis, Osteoarthritis, Osteoporosis, Pain, and Function

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Gout results from an increased body pool of urate that occurs with hyperuricemia. Although urate-lowering therapy (ULT) is beneficial to prevent gout attack, current recommendations do not advise every patient with gout to receive a ULT. In this study, we evaluated the impact of ULT on the risk of major cardiovascular (CV) events and all-cause mortality among individuals with gout.

Methods: We conducted an incident user cohort study with 1:1 propensity score matching by using the National Health Insurance Service-National Sample Cohort (NHIS-NSC), a Korean population-based cohort of individuals who submitted medical care claims between 2002 and 2013, linked with the results of the National Health Checkup Service in Korea. Incident gout cases were defined as newly used *International Classification of Diseases (ICD)* code M10 from 2003 to 2013, excluding patients who had an M10 code in 2002. For propensity score matching, age, sex, income, presence of diabetes mellitus, hypertension, hyperlipidemia and atrial fibrillation, smoking, alcohol consumption, body mass index, and Charlson comorbidity index scores were considered. Major CV events were defined as acute myocardial infarction (*ICD* codes I21 and I22) and stroke (I63).

Results: In the NHIS-NSC cohort, 37730 incident gout cases were identified between 2003 and 2013. Among the cases, 9387 were treated with allopurinol, febuxostat, or benzbromarone more than twice (ULT initiators) and the other 28333 were not (comparators). Of the 9387 and 28333 patients, 948 (10.1%) and 2117 (7.5%), respectively, developed major cardiovascular events in the first 10 years of the disease (mean follow-up: 4.1 years), and 714 (7.6%) and 962 (3.4%), respectively, died in the first 10 years of the disease (mean follow-up: 4.4 years). After propensity score matching, 4034 ULT initiators and 4034 matched comparators were compared. Among the initiators and comparators, 349 and 288, respectively, had new major CV events in the first 10 years of the disease (mean follow-up: 4.1 years), and 23 and 16, respectively, died in the first 10 years of the disease (mean follow-up: 4.3 years). ULT initiation was associated with a higher risk of CV events (matched HR, 1.196; 95% confidence interval [CI], 1.022–1.399) and all-cause mortality (matched HR, 1.355; 95% CI, 1.078–1.702).

Conclusion: The current population-based matched-cohort study does not support the beneficial effects of ULT initiation on the cardiovascular outcomes or all-cause mortality in patients with gout during the first 10 years of the disease. Further study regarding the effects of steady ULT maintenance in the whole population cohort would be needed.

Prevalence, Incidence, Determinants, and Impacts of Depression and Anxiety in Gout: A Systematic Review

Alyssa Howren^{1,2,3}, Enay Z. Zusman^{1,2,3}, Sharan K. Rai^{2,4,5}, Kam Shojania^{2,6} and Mary A. De Vera^{1,2,3}, ¹Faculty of Pharmaceutical Sciences, University of British Columbia, Vancouver, BC, Canada, ²Arthritis Research Canada, Richmond, BC, Canada, ³Collaboration for Outcomes Research and Evaluation (CORE), Vancouver, BC, Canada, ⁴Program in Population Health Sciences, Graduate School of Arts and Sciences, Harvard University, Boston, MA, ⁵Division of Rheumatology, Allergy, and Immunology, Massachusetts General Hospital, Harvard Medical School, Boston, MA, ⁶Division of Rheumatology, Department of Medicine, University of British Columbia, Vancouver, BC, Canada

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Background/Purpose: A previously synthesized positive association between gout and depression has combined studies of both prevalent and incident depression. To disentangle these data and provide a comprehensive understanding of the burden, risk, impacts, and determinants of psychiatric complications in gout, our objective was to conduct a systematic review of observational studies of depression as well as anxiety among patients with gout.

Methods: We conducted a mapped search of Medline, Embase, and Cochrane Database of Systematic Reviews on the Ovid platform, and CINAHL Complete and PsycINFO on Ebscohost to identify full-length articles published in English meeting the following inclusion criteria: 1) observational design; 2) study sample including gout patients with or without a comparator group; 3) depression and/or anxiety evaluated as a comorbidity, outcome, or predictor of a health outcome and assessed using routinely reported measures; and 4) reporting of relevant estimates (e.g. prevalence proportion, odds ratio [OR], hazard ratio [HR]) or sufficient data to allow calculation. We extracted information on study setting and design, patient population and sample size, gout ascertainment, and methods of assessing depression and anxiety. Where relevant and sufficient data permitted, we pooled estimates using random effects models.

Results: From 771 articles identified with our search strategy, we included 16 studies with 9 assessing both depression and anxiety and 7 assessing depression alone. With respect to depression, the pooled prevalence proportion based on 8 studies and a total of 57,103 gout patients was 10% (95% confidence interval [CI], 8% to 12%) and pooled OR was 1.19 (95% CI, 1.03 to 1.35). The incidence of depression in gout patients as compared to the general population was reported in 3 studies and meta-analysis yielded a pooled adjusted (a)HR of 1.09 (95% CI, 0.93 to 1.26). With respect to anxiety, pooled prevalence proportion based on 5 studies and a total of 36,708 gout patients was 6% (95% CI, 3% to 10%) and pooled OR was 1.54 (95% CI, 1.43 to 1.65). Only 1 study assessed the incidence of anxiety among gout patients (aHR, 1.01; 95% CI, 0.87 to 1.16). Determinants of psychiatric complications include a higher frequency of gout attacks, having oligo/polyarticular gout, greater number of tophi, disability, quality of life, and education level (anxiety only). Finally, both depression and anxiety in gout significantly impact patients' health-related quality of life.

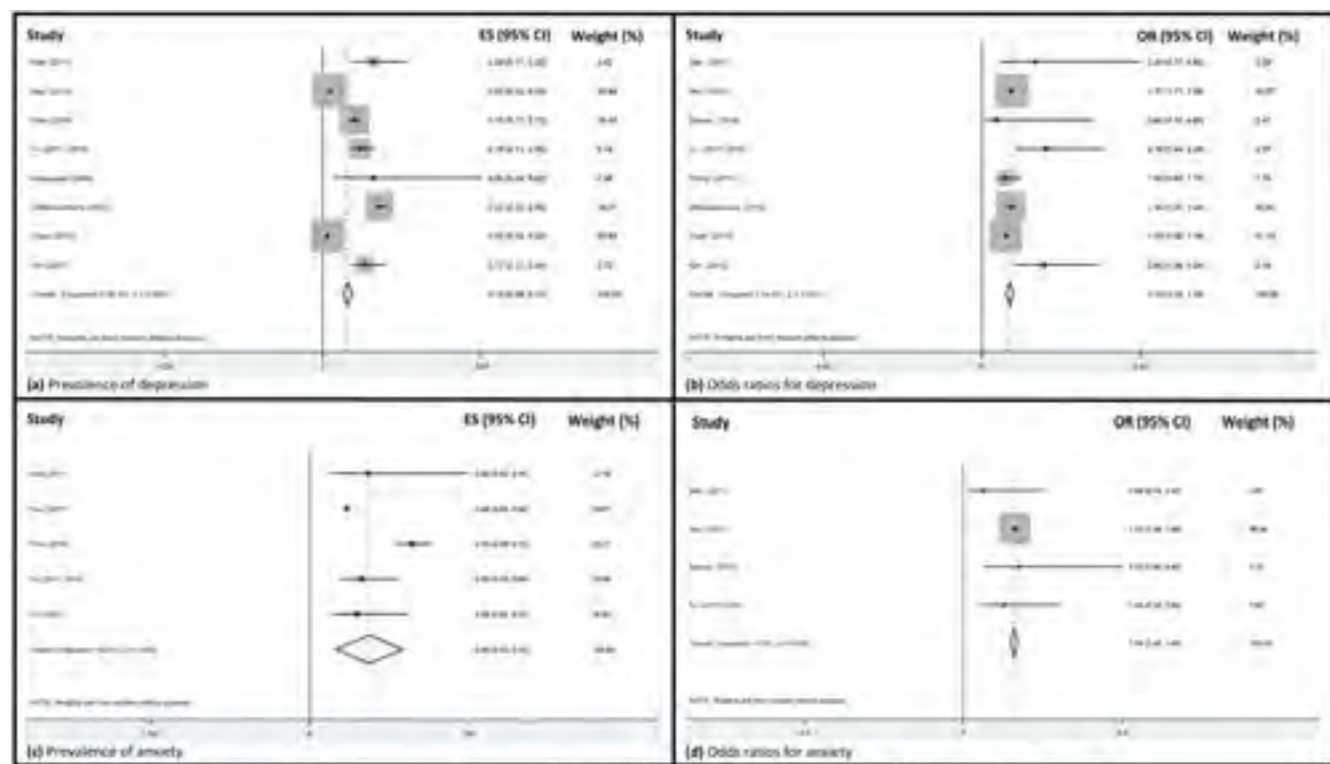

Figure 1. Pooled prevalence estimates (ES) and odds ratios (OR) for depression (a-b) and anxiety (c-d) in gout.
Abb: CI = confidence interval

Conclusion: Our findings establish a substantial prevalence of both depression and anxiety among gout patients. This highlights the need for further research to better understand the onset (incidence) of psychiatric complications after gout diagnosis as well as identify potential targets for intervention.

Chronic Risk Factors for Recurrent Gout Flares Among Established Gout Patients: A Prospective Cohort Analysis

Yuqing Zhang¹, Jie Wei², Chio Yokose², Sharan K. Rai^{3,4} and **Hyon K. Choi**², ¹Department of Rheumatology, Allergy and Immunology, Massachusetts General Hospital, Boston, MA, ²Division of Rheumatology, Allergy, and Immunology, Massachusetts General Hospital, Boston, MA, ³Division of Rheumatology, Allergy and Immunology, Massachusetts General Hospital, Boston, MA, ⁴Graduate School of Arts and Sciences, Harvard University, Cambridge, MA

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Epidemiology and Public Health Poster II: Gout, Ankylosing Spondylitis, Osteoarthritis, Osteoporosis, Pain, and Function

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Understanding the risk factors for recurrent flares among established gout patients is directly relevant to clinical care; however, relevant data are scarce. A previous prospective study of 197 gout patients found that chronic risk factors such as age, sex, education level, obesity, gout disease duration, and the presence of hypertension, diabetes, renal disease, or congestive heart failure (CHF) were not significantly associated with the risk of recurrent gout, although some point estimates were suggestive of an association. We re-examined the same risk factors among 997 gout patients in an expanded follow-up study.

Methods: We conducted a cohort analysis of a prospective study designed to examine the associations of putative risk factors with recurrent gout attacks. Individuals with gout were recruited and followed up online for one year. Participants were asked to provide the following information regarding their gout attacks: date of gout attack onset, symptoms and signs, medications (including anti-gout medications), and exposure to potential risk factors at baseline and during the follow-up in relation to gout flares. We used Cox proportional hazard models to calculate hazard ratios for the risk of recurrent gout attacks related to age, sex, education level, body mass index, gout disease duration, and the presence of hypertension, diabetes, renal disease, and CHF at baseline.

Results: Among 997 gout patients (mean age, 53.6 years; 78.4% male), we documented 361 gout flares during a mean follow-up of 0.49 years. Overall, the annual incidence rate was 75 per 100 person-years (**Table**). Younger age (<60 years), disease duration (>1 year), and the presence of CHF were independently associated with a 45%, 71%, and 57% higher risk of gout flares, respectively (**Table**). Female sex, obesity, and diabetes tended to be associated with a higher risk of gout flares (**Table**), although not statistically significant.

Conclusion: This large prospective gout cohort study suggests that younger age, longer disease duration, and having CHF all confer a higher risk of gout flares, independent of other risk factors. While these associations may be due to higher serum urate levels and pools associated with these factors even among gout patients, it remains conceivable that these factors may contribute to the risk of flares independent of their urate level impact. Regardless, these data suggest a potential need for more aggressive therapy among patients with these risk factors.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Epidemiology and Public Health Poster II: Gout, Ankylosing Spondylitis, Osteoarthritis, Osteoporosis, Pain, and Function

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The most common type of inflammatory arthritis in Germany is gout, however the last epidemiological study was done a decade ago (Annemanns, 2007). This study aimed to provide an up-to-date analysis on the prevalence and incidence of gout, associated comorbidities, and current treatment patterns.

Methods: The InGef research database, comprising a sample of ~4 million healthcare claims, was used for the analyses. Patients were included based on hospital discharge or ambulatory diagnoses of gout (ICD10M10) or hyperuricemia (E79.0) in combination with uric acid tests, prescription of urate lowering therapy (ULT), and treatment of gout flare. Prevalent gout cases were analysed according to comorbidities and pharmacological treatment. Additionally, a comparison to an age- and sex-matched control group without gout was performed.

Results: The study included 62,425 gout claims. Prevalence was 1.63% (standardized), corresponding to 1.325 million gout patients in Germany. Incidence was 0.45% (standardized). Male-to-female ratio was 3.2 for prevalence and 2.7 for incidence. The mean age of diagnosis was 66 years. Gout patients suffered significantly more from comorbidities than patients without gout (Table 1). The most common comorbidities were hypertension (80%), hyperlipidemia (58%), diabetes (38%), and obesity (32%). About 70% of gout patients received ULT (63% Allopurinol, 6% Febuxostat, 0.6% Benzbromarone). Overall, gout patients received an average of 8.7 (SD: 5.5) medications; 44% took ≥9 different medications in comparison to 20% of patients without gout (Table 2). Most common medications were NSAIDs (49%) and beta blocking agents (49%), lipid lowering drugs (35%), and antidiabetic drugs (23%). Accordingly, mean costs for drug treatment were substantially higher (1,148€ vs. 815€). About 29% of gout patients had ≥1 hospital visits in 2016 compared to only 21% of patients without gout (p<0.001).

Conclusion: The prevalence of gout (1.63%) was slightly higher compared to a previous analysis of German claims data (1.4%; Annemanns, 2007). This study confirms that gout patients suffer from more comorbidities with a high need for multiple medications, resulting in significantly greater mean drug costs compared to patients without gout.

Table 1: Comorbidities of patients with gout and without gout

Comorbidities	Prevalent gout cases (n,%)		Control group without gout (n,%)		p-value (Fisher's exact test)
Alcohol intake	3,508	5.62	1,744	2.79	<0.001
Chronic kidney disease	14,222	22.78	4,942	7.92	<0.001
Diabetes mellitus	23,437	37.54	13,322	21.34	<0.001
Heart failure	12,281	19.67	6,053	9.70	<0.001
Hyperlipidemia	35,956	57.60	25,325	40.57	<0.001
Hypertension	49,801	79.78	35,701	57.19	<0.001
Hyperuricemia	31,899	51.10	4,727	7.57	<0.001
Obesity	19,910	31.89	8,529	13.66	<0.001
Osteoarthritis	5,034	8.06	2,898	4.64	<0.001

Table 2: Comedications of patients with gout and without gout

Comedications	Prevalent gout cases (n,%)		Control group without gout (n,%)		p-value (Fisher's exact test)
Acetylsalicylic acid	7,311	11.71	5,476	8.77	<0.001
Antidiabetic drugs (incl. insulin)	14,298	22.90	8,190	13.12	<0.001
Beta blocking agents	30,656	49.11	18,806	30.13	<0.001
Glucocorticoids	9,906	15.87	4,936	7.91	<0.001
Lipid lowering drugs	21,827	34.97	14,472	23.18	<0.001
NSAIDs	30,823	49.38	16,977	27.20	<0.001
Opioids	9,089	14.56	5,790	9.28	<0.001
Other analgesics	15,942	25.54	10,104	16.19	<0.001
Other antihypertensive agents	45,858	73.46	30,703	49.18	<0.001
Thiazide and loop diuretics	7,437	11.91	3,805	6.10	<0.001

Diet Modification for Gout Patients: Effects on Gout Attacks and Risk Factors for Metabolic Syndrome

Michelle DiFiore¹, Maida Wong² and Juliana Chang³, ¹Internal Medicine, University of California, Irvine, School of Medicine, Orange, CA, ²Division of Rheumatology, Tibor Rubin Veterans Affairs Medical Center Long Beach, Long Beach, CA, ³UC Irvine Medical Center, Orange, CA

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Epidemiology and Public Health Poster II: Gout, Ankylosing Spondylitis, Osteoarthritis, Osteoporosis, Pain, and Function

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Gout affects 8 million individuals in the US and is prevalent among patients with metabolic syndrome. Although there are many medications to control gout attacks and to lower serum uric acid (sUA), they come with potential side effects, and many patients are refractory to pharmacological treatment. Less emphasis has been placed on dietary counseling, which may provide a cost-effective benefit in controlling gout and as a supplement to medications. The aim of this study is to investigate if counseling gout patients on diet and lifestyle modifications will decrease the number of gout flares and further improve their risk factors for metabolic syndrome.

Methods: A retrospective study involving Long Beach Veteran Hospital patients was performed (N= 159). Gout patients were identified by their International Classification of Disease version ICD 9 or 10 from 2013 to 2016, and were grouped into those that received 1) no diet counseling (n=42), 2) diet counseling since their gout diagnosis (n=92) and 3) diet counseling 2 years after initial gout flare (n=25). Extensive electronic medical record review was performed for a 24-month period to evaluate the effectiveness of diet counseling in gout management based on the change in frequency of gout flares, renal function (eGFR) and sUA. Risk factors for metabolic syndrome, including blood pressure, BMI, lipid profile and HgA1c levels were obtained as outcome measures of diet modification that are associated with gout attacks.

Results: Patients who received diet counseling had fewer accumulative gout attacks (2.68 vs. 1.3 p=0.002) and more pronounced decrease in sUA (28.7% vs 3.1%, p =0.01) when compared to those without counseling over the 24-month period. With diet counseling, the patients' HDL increased (10.1% p <0.05) and LDL decreased (7.5%, p<0.01) but their BMI and blood pressure were comparable irrespective to diet counseling.

Conclusion: Gout patients who underwent diet counseling had fewer gout attacks afterwards. Patients who received documented diet counseling by their primary care physicians or rheumatologists had more effective reduction in serum uric acid and cholesterol levels over 24 months. Diet counseling may further benefit gout patients by decreasing risk factors that contribute to metabolic syndrome to provide better control of gout flares long term. A larger study over a longer period of time is needed to elucidate the impact of the risk factors for metabolic disorders in relation to gout management.

Factors for Opioids Use in the Early Treatment Options for the Knee Osteoarthritis Patients

Soo-Kyung Cho¹, Seongmi Choi², Seul Gi Im², Hyoungyoung Kim¹, Sun-Young Jung³, Eun Jin Jang⁴ and Yoon-Kyoung Sung⁵, ¹Rheumatology, Hanyang University Hospital for Rheumatic Diseases, Seoul, Korea, Republic of (South), ²Statistics, Kyungpook National University, Daegu, Korea, Republic of (South), ³College of Pharmacy, Chung-Ang University, Seoul, Korea, Republic of (South), ⁴Information Statistics, Andong National University, Andong-si, Korea, Republic of (South), ⁵Hanyang University Hospital for Rheumatic Diseases, Seoul, Korea, Republic of (South)

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Epidemiology and Public Health Poster II: Gout, Ankylosing Spondylitis, Osteoarthritis, Osteoporosis, Pain, and Function

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Current guidelines for osteoarthritis (OA) treatment recommend a range of nonpharmacological and pharmacological interventions to alleviate pain, improve function and quality of life. Most guidelines do not recommend opioids for OA treatment as an early treatment option, but some guidelines suggest using opioids on a restricted basis for short-term use in select patients with refractory symptoms. Although opioids can emerge as a treatment option that may provide effective pain relief with less risk than NSAIDs, they have the potential to cause harm. Until now, the current burden of opioid use for knee OA in Korea is not well understood. We investigated how many prescriptions of opioids for early knee OA treatment are given in Korea, and examined the factors related with opioid use in the early treatment options for knee OA.

Methods: Using the Korean nationwide claims database, all knee OA patients during 2013-2015 were identified by our validated operational definition. Among them, we extracted incident cases to identify opioid use in the early treatment options for knee OA patients. Opioids included tramadol as a weak opioid, and the utilization of opioids was analyzed by dividing strong opioids and weak opioids. A multivariable model was constructed to examine the factors related with opioids use.

Results: Among a total of 2,857,999 incident knee OA patients, 12.2% (n=348,516) were treated with opioids in their first year after diagnosis. However, strong opioid use (not including tramadol) was only 0.07% among the knee OA patients (n=1,972). Opioid users were slightly older (64.2 vs. 64.0 years old, $p<0.01$) and more likely to be male (44.0% vs. 37.8%, $p<0.01$) than opioid non users. Most of the opioids (88.6%) were prescribed in community hospitals and clinics. The frequency of opioid prescription was highest in the department of orthopedic surgery (70.1%), followed by internists (9.7%). Elixhauser comorbidity index score was higher in opioid users (4.51 ± 6.36 vs. 4.43 ± 6.23 , $p<0.01$). Related factors with early opioid use were older age (≥ 70 years old: odds ratio [OR], 1.02; 95% confidence interval [CI], 1.01-1.03, reference 50-59 years old), male (OR 1.29; 95% CI, 1.28-1.30), and medical aid patients (OR 1.13; 95% CI, 1.12-1.15). In terms of comorbidities present, there were peptic ulcer disease (PUD) (OR 1.03; 95% CI, 1.02-1.04), depression (OR 1.05, 95% CI, 1.04-1.06), and musculoskeletal diseases (low back pain: OR 1.12; 95% CI, 1.12-1.13, intervertebral disc: OR 1.11, 95% CI, 1.10-1.13, spinal stenosis: OR 1.27, 95% CI, 1.26-1.29, fibromyalgia: OR 1.14, 95% CI, 1.11-1.17), while diabetes (OR 0.98, 95% CI, 0.97-0.99) and malignancy (OR 0.89, 95% CI, 0.88-0.90) were protective.

Conclusion: In Korea, strong opioid use is not common as a treatment option for early knee OA treatment, but tramadol use is common. Being elderly, male, having comorbidities such as PUD and musculoskeletal diseases, and medical aid patients were more likely to be treated with strong opioids or tramadol.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Epidemiology and Public Health Poster II: Gout, Ankylosing Spondylitis, Osteoarthritis, Osteoporosis, Pain, and Function

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: This study evaluated physical activity and sedentary times to identify a evidence-based threshold related to remaining free of disability over 4 years among adults with lower extremity joint symptoms.

Methods: Remaining free of disability over 4 years (i.e., no disability onset) was assessed from self-report of no limitations in activities of daily living (ADL-disability free) and objective gait speed ≥ 1 meter/second (mobility-disability free). Adults with symptomatic lower extremity (hip, knee, ankle, foot) joint pain/aching/stiffness who participated in an accelerometer substudy of the Osteoarthritis Initiative (OAI) included n=1564 ADL-disability free (n=1460) or mobility-disability free (n=1370) persons at baseline (OAI 48-month clinic visit). Optimal thresholds predicting 4-year disability-free status were assessed by maximum area under the receiver operating characteristic curve (AUC) and classification tree analysis.

Results: Over four years 84% (1222/1460) participants remained free of ADL-disability and 89% (1223/1370) remained free of mobility-disability. Figure 1 shows total MV activity per week was the strongest predictor of all Table 1 candidate measures based on the greatest AUC of remaining free of ADL-disability (AUC=0.61) and free of mobility-disability (AUC=0.80). Classification tree analyses selected total MV > 55 minutes/week over all possible activity/sedentary candidate thresholds as the best discriminator between remaining free of versus developing ADL-disability and mobility-disability. Observed disability onset rates over four years were almost double (23% versus 12%) for developing ADL-disability and 8 times greater (24% versus 3%) for mobility-disability among persons below compared to those above this threshold.

Figure 1. Receiver Operating Characteristic (ROC) Curves for Remaining Free of Disability over 4 Years by Physical Activity Measures among Adults with Lower Extremity Joint Symptoms

A. Remaining Free of ADL-Disability over 4 Years ROCs (n=1460)

B. Remaining Free of Mobility-Disability over 4 years ROCs (n= 1370)

Table 1. Baseline Candidate Physical Activity/Sedentary Measures in adults with lower extremity joint symptoms free of baseline ADL and/or mobility disability			
Baseline Candidate Physical Activity/Sedentary Measures in minutes/week	Overall (n=1564*) Mean±SD	Men (n=895) Mean±SD	Women (n=669) Mean±SD
Total physical activity time	2122.2 ± 583.9	2096.4 ± 588.4	2197.3 ± 578.8
Total moderate-vigorous (MV) time	129.2 ± 134.9	154.7 ± 154.0	100.5 ± 109.2
MV-bout time*** (Legacy measure)	58.1 ± 98.0	75.0 ± 113.1	44.6 ± 81.3
Light activity time	1993.0 ± 538.1	1901.7 ± 527.2	2098.7 ± 537.5
Sedentary time	4128.5 ± 818.7	4231.5 ± 860.6	4020.4 ± 820.7

*Free of ADL-disability (n=1460) or free of mobility disability (n=1370) at baseline and followed over four years
 ** Total (light+MV) physical activity
 *** MV activity accrued in bouts lasting 10 minutes or more, the legacy metric used in federal recommendations

Meeting the 55total MV minute/week threshold significantly increased the odds for remaining free of ADL-disability (odds ratio [OR]: 2.0, 95% CI: 1.5 to 2.7) and free of mobility disability (OR 8.6, 95% CI: 5.7 to 13.1). Thresholds were consistent acrosssex, BMI, age, and radiographic knee OA status.

Conclusion: Meeting an evidence-based threshold of at least 55 total MV minutes/week increased the likelihood of remaining free of both ADL-disability and mobility-disability over 4 years among adults with lower extremity joint

symptoms. This evidence-based threshold supports future disability-free status and may help motivate sedentary adults with joint conditions to begin their path towards attaining the federal recommendation which promotes a wide range of health benefits.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Epidemiology and Public Health Poster II: Gout, Ankylosing Spondylitis, Osteoarthritis, Osteoporosis, Pain, and Function

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Hallux valgus(HV) is a common foot disorder that is highly heritable. A genome-wide association study (GWAS) conducted in 4,409 Caucasians from the Framingham Heart Study(FHS), the Genetics of Generalized Osteoarthritis (GOGO) Study, and the JohnstonCounty Osteoarthritis (JoCoOA) Project did not find genome-wide significant(GWS) associations with HV in both gender-specific and sex-combined GWASmeta-analyses. In this analysis, we expand the sample by including data from Caucasians enrolled in the Osteoarthritis Initiative (OAI), and impute genotypes to the most current Haplotype Reference Consortium (HRC) reference panel. Our objective was to identify novel genetic variants associated with HV in this expanded sample of Caucasian adults with deeper imputation.

Methods: We included 5,925 participants of European Ancestry (EA) from four cohorts: FHS,GOGO, JoCoOA and OAI. HV was considered present if determinedby trained examiners using validated protocol (FHS, GOGO, JoCoOA),or the participant reported a bunionectomy or Manchester grade (MG) was 3 or 4in one or both feet (OAI). Controls included those without surgery and MG of one in both feet and those who did not meet examiner's criterion. Genotyping was performed using commercially available arrays with imputation to the HRCreference panel. In OAI and JoCoOA, GWAS was performed using logistic regression models with additive genetic effects to examine association betweenSNPs and HV.

For FHS and GOGO, GEE models were used to account for the within-family correlations. All models were adjusted for age, gender, body mass index and study specific covariates. After harmonization and quality control of WAS results, fixed-effect inverse-variance weighted meta-analysis was conducted for the total sample and for men and women, separately. The genome-wide significance (GWS) level was set at $p < 5 \times 10^{-8}$.

Results: Two intronic variants in the gene CLCA2 on chromosome 1 were GWS for HV: rs55807512 (OR=0.48, $p=2.96 \times 10^{-9}$, MAF=0.04) and rs12124247 (OR=2.20, $p=7.38 \times 10^{-9}$, MAF=0.03). The SNPs were in weak LD ($r^2=0.46$). No other loci reached GWS although four variants of suggestive significance were located near the MIR2054 gene on chromosome 4. The association signals diminished in gender-specific analyses.

Conclusion: We identified two novel variants in the gene CLCA2 associated with HV. This gene encodes a member of the calcium-activated chloride channel regulator family of proteins. CLCA2 plays a role in modulating chloride current across the plasma membrane in a calcium-dependent manner, and cell adhesion. These findings require replication.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Epidemiology and Public Health Poster II: Gout, Ankylosing Spondylitis, Osteoarthritis, Osteoporosis, Pain, and Function

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Hand osteoarthritis (OA) can be a painful, disabling condition, with an increased prevalence in women, the elderly, and has a strong genetic component (heritability index= 60%). Mitochondrial DNA haplotypes (mDNA haplotypes) track maternal genetic inheritance and have been used in understanding population genetics. Recently mDNA haplotypes have been associated with knee OA in the OAI and CHECK cohorts. Basic science studies of mDNA haplotypes have demonstrated that mDNA haplotypes modulate critical cell functions including ATP production, oxygen consumption, generation of oxidative species, mitochondrial and nuclear gene expression which impact bioenergetics, inflammatory responses, apoptosis, aging-related responses, and calcium metabolism. We explored, given the strong gender and genetic associations with Hand OA, whether mDNA haplotypes were associated with prevalent hand OA, symptomatic hand OA, thumb-base OA, symptomatic thumb OA in cross-sectional analyses, and incident hand OA, symptomatic hand OA, thumb-base OA, symptomatic thumb-base OA and hand OA progression in prospective analyses.

Methods: 3558 Caucasian participants in the Osteoarthritis Initiative (OAI) had hand xrays in the dominant hand read for radiographic severity (Kellgren-Lawrence [KL] grade) at baseline and year 4, and had mDNA haplotypes assessed at baseline. Eleven mDNA haplotypes were categorized into 5 groups (H, UK, T, J, other) with 103 samples excluded due to technical and sampling errors. Age and sex adjusted odds ratios were calculated comparing all mDNA haplotypes to the H haplotypes. Hand OA was defined as two joints on different rays with $KL \geq 2$ excluding the thumb-base joints, thumb OA as $KL \geq 2$ in CMC or ST-T joints. Symptomatic hand OA was defined as either new interphalangeal joint (IPJ) OA at year 4 in a previous symptomatic individual, new symptoms in a participant with previous hand OA, or both new symptoms and meeting the hand OA definition. Hand OA progression was defined the mean change in number of joints with a new KL grade over the four-year period.

Results: For Incident disease, mDNA haplotypes of UK (OR=0.70, 95%CI 0.53,0.92) and T (OR=0.57, 95% CI 0.38,0.86) were associated with protective effects compared to H for symptomatic hand OA and symptomatic thumb-base OA of UK (OR=0.68, 95%CI 0.52,0.89) and T (OR=0.49, 95% CI 0.32,0.79). False Discovery Rate (FDR) $p < 0.05$. Evaluating hand OA progression, the T group compared to the H group had a reduced mean rate of progression of -0.11, $p < 0.01$. FDR $p < 0.08$. No association was found for prevalent OA or incident radiographic hand or thumb OA.

Conclusion: In a sample of Caucasian participants in the OAI, the mDNA haplotype T and Uk appear to be inversely associated with incident symptomatic hand and thumb OA and T with hand OA progression. This differs from the findings of an inverse association with knee OA incidence and progression with mDNA haplotype J compared to H previously reported in this same OAI sample. Given multiple comparisons, caution should be used in interpreting our results and our findings need to be replicated in other cohorts.

KOOS QOL item + how often unable to perform with knee ³	1.27 (1.07, 1.52)	7.04 (p = 0.008)	1316.03
KOOS QOL item + modified lifestyle to avoid potentially damaging activities to knees ³	1.49 (1.24, 1.80)	18.08 (p = 0.0001)	1347.12
KOOS QOL item + how much trouble with lack of confidence in knees ³	1.47 (1.18, 1.84)	16.78 (p = 0.001)	1350.93
KOOS QOL item + in general, how much difficulty with knees ³	1.88 (1.18, 3.02)	3.07 (p = 0.002)	1360.81

¹**BASE MODEL** includes age, gender, BMI, knee osteoarthritis, history of knee surgery, number living in household, walking & standing for arthritis, medication use, hand OA, back pain, hip pain, ankle pain, deep knee symptoms, community activities, comorbidity, education, self-reported health, existing SBC for base model = 1359.65.

²Higher is worse.

³Higher is better.

Among 1197 persons, 95 (8.3%) experienced the outcome. Each row represents a separate model and shows results (LR test) comparing the adjusted hazard ratio for slow gait speed, after adding the specific questionnaire or item score to the base model. Higher LR test statistic and lower SBC indicate model improvement for specified row (model compared to base model). (HR = hazard ratio)

are likely to be effective. Our objectives were: 1) develop prediction models for poor function outcomes, and 2) test if adjusting for variables linked to behavior change, modified lifestyle to avoid damaging activities to knees, or lack of knee confidence, improves prediction.

Methods: In 1197 OAI participants KL0 in both knees, baseline predictors analyzed included: demographic, socioeconomic, psychological, comorbidity; WOMAC Pain (P), WOMAC Function (F), KOOS Symptoms (Sx), KOOS QOL (higher worse); KOOS QOL items (higher better). Proportional hazards (PH) regression models were used to develop prediction models for each outcome, unable to complete sit-to-stand without arms, and slow gait speed (< 1m/sec), over up to 10 years follow-up. For each outcome, a base model included predictors with univariate hazard ratio $p \leq 0.20$; separate models also included P, F, Sx, and QOL. Comparisons of nested PH models used a likelihood ratio (LR) chi-square test and Schwarz Bayesian Information Criterion (SBC). We calculated the AUC of the ROC for logistic regression models including variables that improved prediction in the corresponding PH model. Hosmer-Lemeshow X^2 statistics (H-L) tested goodness-of-fit; large H-L p-values and high AUC indicate good calibration and discrimination, respectively.

Results: For *gait speed outcome*, the expanded prediction model vs. base model was significantly improved by including WOMAC and KOOS variables, particularly WOMAC-F, KOOS-QOL, and KOOS-QOL items (Table 1, LR tests). For *sit-to-stand outcome*, prediction was significantly improved by KOOS-QOL and KOOS-QOL items (Table 2). For both outcomes, among the models, performance was best with base model + modified lifestyle to avoid potentially damaging activities to knees: for slow gait speed, AUC 0.80 (95% CI 0.76, 0.84), H-L $p = 0.55$; and for sit-to-stand, AUC 0.78 (95% CI 0.74, 0.82), H-L $p = 0.56$.

Conclusion: In persons at high risk for knee OA, improved prediction and best performance for poor function outcome was achieved by including modified lifestyle to avoid potentially damaging activities to knees. Such a model, achieving excellent AUCs using easily assessed variables, may help early-stage identification of persons at high risk for poor outcome and inform focus of prevention strategies.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Epidemiology and Public Health Poster II: Gout, Ankylosing Spondylitis, Osteoarthritis, Osteoporosis, Pain, and Function

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The benefits of physical activity (PA) in persons with OA are well-documented: PA reduces OA pain, improves mental health, and reduces the risk of cardiovascular disease (CVD), diabetes mellitus (DM), and some cancers. Despite this, the majority of knee OA patients are physically inactive. The public health impact of low uptake of PA in this population has not been evaluated.

Methods: We used data from the Osteoarthritis Initiative and Centers for Disease Control to estimate the proportion of the US knee OA population that is inactive, insufficiently active, and active, defined as 0-10, 10-149, and 150+ minutes of moderate-to-vigorous PA per week. Using the Osteoarthritis Policy Model (OAPol), a widely published and validated micro simulation of knee OA, we estimated survival and quality-adjusted survival losses among cohorts of individuals with knee OA and different levels of PA. We calculated the per person quality-adjusted years of life (QALYs) lost among those who are inactive or insufficiently active compared to those who are active. We estimated the negative public health impact by multiplying the per-person QALYs lost due to physical inactivity or insufficient activity by the number of persons with knee OA in each of those activity groups. We also calculated the positive public health impact of increasing PA levels among knee OA patients (assuming interventions that could lead 5% or 10% of the population at lower PA levels to increase their activity) by calculating QALYs saved and cases of CVD, DM, and cancer prevented due to such interventions. OAPol data inputs were derived from national and multicenter cohorts and included: 1) background mortality rates; 2) prevalence of and mortality attributable to CVD, DM, and cancers; 3) reduction in quality of life due to physical inactivity and major comorbidities; 4) increased risk of comorbidities due to physical inactivity.

Results: Currently, of 11.7 million persons in the US with knee OA, 47% are inactive and 41% are insufficiently active, resulting in 6.7 million QALYs lost over their remaining lifespan. Table 1 presents the positive public health impact of PA interventions. If an intervention could simultaneously lead 10% of inactive persons to become insufficiently active and 5% of insufficiently active persons to become active over their remaining life spans, 316,181 QALYs would be saved (191,718 + 124,463, Table 1, QALYs row, shaded cells). This would also prevent 80,379 (63,817 + 16,562, Table 1, CVD row, shaded cells) cases of CVD and 85,425 (71,768 + 13,657, Table 1, DM row, shaded cells) cases of DM.

Conclusion: These results suggest that even modestly effective programs focused on increasing PA among knee OA patients could have a tremendous public health impact. Our projections of improvements in morbidity and mortality could be useful in setting realistic goals for activity promotion among knee OA patients.

	% Inactive Becoming Active		% Inactive Becoming Insufficiently Active		% Insufficiently Active Becoming Active	
	5%	10%	5%	10%	5%	10%

Session Title: Epidemiology and Public Health Poster II: Gout, Ankylosing Spondylitis, Osteoarthritis, Osteoporosis, Pain, and Function

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Obesity is a major risk factor for knee osteoarthritis (OA), but the mechanisms by which obesity confers OA risk remains unclear. There is a recognized sex disparity in knee OA prevalence, and also a recognized distinct sex-specific distribution of fat depots especially after menopause in women. Visceral fat which accumulates after menopause is a major source of adipokines and other cytokines and its accumulation is associated with an increased heart disease risk. How these same metabolic products may affect OA risk is not clear. Given the recognized sex disparity in the occurrence of knee OA, whether body composition contributes to this disparity merits evaluation.

Methods: We used data from participants free of OA at baseline in the Multicenter Osteoarthritis Study (MOST), a NIH-funded longitudinal cohort of persons with or at risk of knee OA. Incident radiographic OA (ROA) was defined as those who developed either radiographic knee OA (Kellgren-Lawrence (KL) ≥ 2) (irrespective of symptoms) or had a knee replacement (KR) during follow-up. We defined incident symptomatic OA (SOA) as those who developed radiographic knee OA (KL grade ≥ 2) with frequent knee pain, or a KR during follow-up over 5 years. Body composition was assessed at baseline using whole body dual-energy x-ray absorptiometry and analyzed using Hologic software to delineate visceral and subcutaneous fat, total fat mass, gynoid fat mass, android fat mass, and gynoid:android ratio. We evaluated the relation of sex-specific body composition parameters, categorized as quintiles, to risk of incident ROA and SOA using Cox proportional hazards model, adjusted for potential confounders.

Results: We identified 514 participants with incident ROA (331 women and 183 men) and 433 with incident SOA (273 women and 160 men). The adjusted hazard ratio for risk of incident ROA in women compared with men was 1.24 (95% CI: 1.01-1.51) and was 1.14 (95%CI: 0.92-1.41) for incident SOA. Other measures of adiposity assessed were not associated with either OA outcome. Gynoid mass and gynoid-to-android ratio were associated with elevated risk of incident ROA and SOA, while total fat mass was only associated with incident ROA (**Table**).

Conclusion: Our study indicates that differences in body composition related to total fat mass as well as the anatomic distribution of the fat mass, particularly a high gynoid-to-android ratio, were associated with elevated risk of OA and may explain the sex disparity in risk of OA. In contrast, the purported metabolic differences between visceral and subcutaneous fat did not impact OA risk.

Association between body composition and risk of incident OA

	Radiographic OA		Symptomatic OA	
	Q5 vs. Q1	P trend	Q5 vs. Q1	P trend
Total body fat mass, %	1.01 (0.75-1.36)	0.005	1.06 (0.77-1.46)	0.23
Visceral fat, %	1.24 (0.93-1.64)	0.09	1.08 (0.80-1.44)	0.73
Subcutaneous fat, %	1.00 (0.80-1.24)	0.02	1.08 (0.85-1.37)	0.02
Ratio of Gynoid vs. Android fat mass	1.67 (1.31-2.13)	0.002	1.48 (1.13-1.92)	0.002
Android fat, %	0.60 (0.47-0.77)	<0.001	0.68 (0.52-0.88)	0.001

Abstract Number: 1140

Cause-Specific Mortality in Knee, Hip and Hand Osteoarthritis

Aleksandra Turkiewicz, Aliasghar Kiadaliri and **Martin Englund**, Clinical Sciences Lund, Clinical Epidemiology Unit, Lund University, Lund, Sweden

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Epidemiology and Public Health Poster II: Gout, Ankylosing Spondylitis, Osteoarthritis, Osteoporosis, Pain, and Function

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: All-cause mortality in osteoarthritis (OA) is reported to be increased. However, the knowledge about cause-specific mortality in OA is still very limited. Thus, our purpose was to estimate cause-specific mortality in osteoarthritis compared to the general population.

Methods: We identified all residents in southern Sweden aged 45 to 84 years in 2003. Through the Skane Healthcare Register we identified those diagnosed with osteoarthritis (OA) in peripheral joints between 1998 and 2003. We followed all residents from 2004 until relocation outside of the region, death, or end of 2014. We classified the underlying cause of death from death certificates into: cardiovascular, neoplasms, diabetes, infections, dementia, digestive, or other causes. For estimation, we used multi-state adjusted Cox proportional hazards models.

Results: We identified 15 901 patients (mean age [SD] 67 years [10], 41% men) with prevalent doctor-diagnosed OA in knee, 9347 in hip, 4004 in hand and 5447 with diagnosed OA in other peripheral joints among 469 177 residents. For most causes of death in OA patients, we found no increased mortality, with hazard ratios (HR) close to 1. However, for knee and hip OA and cardiovascular death, HRs were non proportional and increased to 1.19 (95%CI 1.10, 1.28) and 1.13 (1.03, 1.24) during 9 to 11 years of follow-up, mostly due to excess mortality from chronic ischemic heart diseases and heart failure in patients with OA (Figure 1 and 2).

Conclusion: The risk of cardiovascular excess death increases with duration of knee and hip OA. The major contributors are chronic ischemic heart diseases and heart failure. Our results call for improved implementation of guidelines in OA treatment, with major focus on maintaining physical activity and weight-management as well as other preventative measures to reduce cardiovascular deaths.

Figure 1. Cardiovascular mortality in patients with *knee OA* as compared to the general population - adjusted hazard ratios with 95%CI from Cox regression model during 3 periods of the follow-up time.

*CVD – cardiovascular diseases, IHD – ischemic heart diseases, MI – myocardial infarction

Figure 2. Cardiovascular mortality inpatients with *hip OA* as compared to the general population - adjusted hazard ratios with 95%CI from Cox regression model during 3 periods of the follow-up time.

*CVD – cardiovascular diseases, IHD – ischemic heart diseases, MI – myocardial infarction

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Epidemiology and Public Health Poster II: Gout, Ankylosing Spondylitis, Osteoarthritis, Osteoporosis, Pain, and Function

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Too much sitting has been recognized as a major public health issue. However, it is unknown if distinctive patterns of extensive sitting over time exists among unique groups of persons at high risk for osteoarthritis(OA) or if sitting behavior changes over time. The purpose of this study was to examine whether there are distinct extensive sitting trajectories over up to 8years of follow-up, then to identify baseline demographic or clinical predictors for membership in specific sitting trajectories.

Methods: Prospective cohort data from 1194 OAI participants without OA in either knee (bilateral KL 0 on baseline x-rays) were collected at 4 US sites through 8 years of follow-up. Extensive sitting was defined as a self-report of 5 or more days of sitting activities over the past week and more than 4hours per day during those days using PASE sitting items. Latent mixture modeling was used to identify trajectories in extensive sitting (yes vs. no) over time. Baseline demographic and clinical predictors were examined using multinomial logistic regression to identify predictors for membership in extensive sitting trajectories.

Figure 1. Trajectories of extensive sitting over 8 years among persons at high risk of knee OA (n=1194)

Extensive sitting defined by sitting often (5-7 days per week) for greater than 4 hours per day. Actual (dot) and estimated (solid line) proportion of extensive sitting and their 95% confidence intervals (dotted line) by extensive sitting trajectory groups: 1 (blue): low frequency of extensive sitting, 2 (red): moderate frequency of extensive sitting, 3 (green): high frequency of extensive sitting.

Table 1. Association of Baseline Predictors with Each Extensive Sitting-Time Trajectory Membership (n=1107)

Baseline Predictors	Moderate vs. low frequency of extensive sitting groups	High vs. low frequency of extensive sitting groups
	RRR ^a (95% CI)	RRR ^a (95% CI)
Age per 5 years	1.14 (1.06, 1.23)	1.26 (1.12, 1.43)
Female vs. Male	0.66 (0.49, 0.94)	0.61 (0.37, 1.02)
BMI per 5 kg/m ²	1.18 (1.01, 1.37)	1.48 (1.17, 1.87)
Depressive Symptoms per 5 units	1.09 (0.98, 1.21)	1.22 (1.05, 1.42)
Comorbidity	1.25 (1.05, 1.51)	1.32 (1.05, 1.66)
WOMAC ^b Knee Pain per 3 units	1.00 (0.88, 1.16)	1.17 (0.95, 1.44)
Knee Extensor Strength per 60 Newton	0.94 (0.84, 1.00)	0.89 (0.79, 1.00)

^a Relative risk ratio; ^b Western Ontario & McMaster Universities Osteoarthritis Index

Results: Three distinct extensive sitting trajectories were identified from the 1194 participants (mean age 58.4 years [SD 8.9], 58.4%female, mean BMI 26.8 kg/m² [SD 4.5]): low frequency of extensive sitting (54%), moderate frequency of extensive sitting (36%), and high frequency of extensive sitting (10%) (Figure 1). All trajectories were fairly stable over time. Compared to the low-frequency of extensive sitting group, persons in high-frequency were significantly more likely to be older (relative risk ratio [RRR]=1.26 per 5 years increase; 95% confidence interval (CI)=1.12,1.43), have higher BMI (RRR=1.48 per 5 kg/m² increase; 95% CI=1.17,1.87), report higher depressive symptoms (RRR=1.22; 95% CI=1.05, 1.42), and more comorbidities (RRR=1.32, 95% CI=1.05, 1.66 per 3 unit increase) after adjusting for confounders (Table 1); persons in moderate-frequency of extensive sitting had similar findings, but depressive symptoms was not statistically significant (RRR=1.09 per 3 unit increase, 95% CI=0.98, 1.21).

Conclusion: We identified three distinct extensive sitting trajectories among persons at high risk of knee OA. Baseline factors including depressive symptoms and comorbidity independently predicted trajectory membership in high vs. low frequency of extensive sitting. These factors could be considered in future interventions to reduce extensive sitting in persons at high risk of knee OA.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Epidemiology and Public Health Poster II: Gout, Ankylosing Spondylitis, Osteoarthritis, Osteoporosis, Pain, and Function

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Past epidemiologic studies have consistently demonstrated a link between Rheumatoid Arthritis (RA) and lymphomas and have posited that high systemic inflammatory activity is a major risk determinant for lymphomagenesis. In 2010, RA treatment guidelines recommended a treat to target (T2T) approach, but the impact of this approach on lymphoma incidence remains poorly understood. This study examined and compared temporal trends in lymphoma incidence in US veterans with RA versus veterans with osteoarthritis (OA), who are not expected to be impacted by T2T implementation.

Methods: Patients with RA or OA were identified in the Veteran Affairs (VA) Corporate Data Warehouse. The RA cohort included patients with 2 or more RA diagnostic codes at least 6 months apart during 2002-2017, with at least one visit in a rheumatology clinic. We used a similar algorithm to identify OA patients. Patients with other autoimmune diseases like lupus, celiac disease, inflammatory bowel disease were excluded. Lymphoma incidence was identified from the VA Central Cancer Registry. We used proportional hazards regression to compare the relative hazard of lymphoma for patients diagnosed with RA or OA during 2002-2005, 2006-2009, 2010-2013, and 2014-2017, while controlling for age, sex, and race. Censoring events included death or end of follow-up, with a maximum follow-up period of 5 years for each patient.

Results: We identified 105,297 patients diagnosed with OA and 50,298 diagnosed with RA. We observed 356 RA patients and 558 OA patients with lymphoma onset within 5 years of initial fulfillment of RA or OA algorithm. The hazard of lymphoma decreased significantly for patients diagnosed with RA during 2014-2017 relative to patients diagnosed in 2002-2005 (Hazard Ratio [HR] = 0.63; p=0.02) (Figure 1). Among OA patients, the hazard of lymphoma also decreased, although the decrease was not statistically significant (HR=0.74; p=0.09). There was no significant difference in trends between the OA and RA patients (p=0.55).

Conclusion: We observed a decline in lymphoma incidence in RA patients after adjusting for race, age, and sex, although the decline was not significantly different between OA and RA veterans.

Figure 1. Kaplan-Meier curves showing time to lymphoma for RA patients stratified by the year of diagnosis.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Epidemiology and Public Health Poster II: Gout, Ankylosing Spondylitis, Osteoarthritis, Osteoporosis, Pain, and Function

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Abstract:

Background/Purpose: The association between periodontal disease and rheumatoid arthritis is well-recognized. Recent studies have suggested a similar association between periodontal disease and ankylosing spondylitis although the data are still limited. The current systematic review and meta-analysis was conducted with the aims to identify all available studies on this association and summarize their results together.

Methods: Two investigators independently searched for published studies indexed in MEDLINE and EMBASE database from inception to April 2018 using the search strategy that included the terms for periodontal disease and ankylosing spondylitis. Studies were included if they fulfilled all the following criteria: (1) Case-control or cohort studies comparing the risk of ankylosing spondylitis in individuals with and without periodontal disease (2) Individuals without periodontal disease were used as comparators in cohort studies while individuals without ankylosing spondylitis were used as controls in case-control studies and (3) Effect estimates and 95% confidence intervals (CI) of the association were provided. Point estimates and standard errors from each study were extracted and combined together using the random effect, generic inverse variance technique of DerSimonian and Laird.

Results: Of 524 retrieved articles, a total of 7 case-control studies comprising of 41,575 participants met the inclusion criteria and were included in this meta-analysis. The risk of ankylosing spondylitis among patients with periodontal disease was significantly higher than individuals without periodontal disease with the pooled odds ratio of 2.16 (95% CI, 1.48–3.16). The statistical heterogeneity was low with an I^2 of 45%. The forest plot of this meta-analysis is shown as figure 1.

Conclusion: A significantly increased risk of ankylosing spondylitis among patients with periodontal disease was observed in this study.

Abstract Number: 1144

Risk of Osteoporotic Fractures in Patients with Rheumatoid Arthritis and End Stage Renal Disease. Findings from the Usrds Database

Renee Peterkin-McCalman, Jennifer Waller, Brian Le, Alyce Oliver, Evan Manning, Stanley Nahman and Laura Carbone, Medical College of Georgia at Augusta University, Augusta, GA

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Epidemiology and Public Health Poster II: Gout, Ankylosing Spondylitis, Osteoarthritis, Osteoporosis, Pain, and Function

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) and End Stage Renal Disease (ESRD) are independent risk factors for osteoporotic fractures. Approximately one percent of persons with ESRD have RA. To our knowledge, there are no reports of whether persons with RA and ESRD are at greater risk for osteoporotic fracture than the general ESRD population. The purpose of this study was to determine whether RA is a risk factor for fractures in patients with ESRD and to characterize risk factors for these fractures.

Methods: A cohort study of ESRD patients with and without RA within the United States Renal Data System (USRDS) from 2006-2008 followed through 2011. The International Classification of Diseases, ninth revision (ICD-9) codes 714.0, 714.1, 714.2, 714.81 were utilized to identify those with a history of RA using the hospital claims data occurring on or before their dialysis start date. Fractures were identified using ICD-9 codes for fracture of the vertebrae (805.xx-806xx), upper (812.xx-817.xx), hip (820.xx-822.xx), lower extremity (823.xx-825.xx), pathological fracture (733.0, 733.1, 733.11, 733.12, 733.13, 733.14, 733.15, 733.16, 733.19) and stress fracture (733.93-733.98).

Results: There were 10,706 persons with ESRD and no history of RA in the analysis data set of whom 1570 (14.5%) had an incident fracture and 1040 persons with RA of whom 14.5% (266 persons) had an incident fracture. In multivariable adjusted models including age, gender, race, ethnicity, BMI, type of dialysis, smoking, alcohol use, vitamin D deficiency, hyperparathyroidism, secondary osteoporosis (of renal origin), hypogonadism, hyperthyroidism and prevalent fractures (within 5 years prior to start of dialysis), RA was a significant risk factor for any incident fracture (RR 1.83 (95% CI 1.59-2.11)) and incident hip fractures (RR 1.86 (95% CI 1.50-2.30)). Prevalent fractures (in the five years prior to initiation of dialysis) were significantly associated with all and hip fractures ($p < 0.01$) and Black and Other race and BMI were significantly inversely associated with all and hip fractures.

Conclusion: In patients with RA and ESRD, the risk of osteoporotic fractures including hip and spine fractures is almost twofold greater than that of the general ESRD population. Risk factors for fractures in patients with RA and ESRD are similar to that of the general population. Attention to osteoporosis prevention is important in patients with RA and renal disease.

Abstract Number: 1145

Association of Niacin Intake with Osteoporosis. the Cardiovascular Health Study

Brian Le¹, Petra Bužková², Howard Fink³, John Robbins⁴, Mattie Raiford¹, Carlos Isales¹, James Shikany⁵, Steven Coughlin¹ and Laura Carbone¹, ¹Medical College of Georgia at Augusta University, Augusta, GA, ²Washington University, Seattle, WA, ³Minneapolis VA Health Care System, Minneapolis, MN, ⁴University of California-Davis, Sacramento, CA, ⁵University of Alabama, Birmingham, AL

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Epidemiology and Public Health Poster II: Gout, Ankylosing Spondylitis, Osteoarthritis, Osteoporosis, Pain, and Function

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Interest in niacin has increased in the setting of reports suggesting that niacin plays a role in diseases of aging, including Parkinson's disease and nonmelanomatous skin cancers. Because niacin regulates NAD-dependent deacetylase Sirtuin 1 expression and decreases inflammation, it plausibly may improve skeletal health. However, experimental studies in chicks suggest that higher niacin intake may result in impaired bone strength. No study to date has examined the association of dietary niacin intake with multiple skeletal health parameters including bone mineral density (BMD), hip fractures, and body composition, and none have included both African-American and Caucasian men and women.

Methods: Participants included 5187 men and women ≥ 65 y from the Cardiovascular Health Study (CHS) who had complete dietary information by FFQ on niacin intake in 1989-1990 and had data collected on incident hip fractures (ascertained from hospital discharge ICD-9 codes 820.xx) from their 1989-90 study visit through June 30, 2013. A subset (n=1336) also underwent Dual Energy X-ray absorptiometry (DXA) measurements of the hip and total body and body composition assessments in 1994-1995. Risk of incident hip fracture per 10 mg increment of daily dietary niacin intake was estimated using Cox regression.

Results: Mean daily dietary niacin intake was 32.6 mg, with quartiles 1 through 4 defined as 3.6-21.8 mg/day, 21.9-30.2 mg/day, 30.3-40.9 mg/day and 41.0-102.4 mg/day, respectively. During a median follow-up of 13 years, 725 participants had an incident hip fracture. The overall incidence rate for hip fractures was 1.08 per 100 person-years (95% CI: 0.91, 1.3). In multivariable-adjusted models adjusted for age, gender, race, clinic site, BMI, cystatin C, diabetes, education, calcium and vitamin D intake, medications associated with osteoporosis, smoking, alcohol, frailty, total energy (kcal/day) and protein intake, higher niacin intake was significantly associated with hip fractures (hazard ratio (HR) 1.12 (95% CI: 1.01, 1.24). In multivariable-adjusted models both the lowest (HR, 1.31; 95% CI, 1.04-1.66) and highest (HR, 1.53; 95% CI, 1.20-1.95) quartiles of niacin intake were associated with an increased risk of incident hip fracture versus quartiles 2 and 3. In multivariable adjusted linear regression models, there was a trend for a significant inverse association of niacin intake with hip BMD (p=0.06). There was no significant association of niacin intake with total body BMD or any measures of body composition.

Conclusion: In this cohort of elderly, community-dwelling African American and Caucasian men and women, both high and low dietary niacin intakes were associated with a significantly increased risk of subsequent hip fracture, suggesting a possible U-shaped association. By comparison, dietary niacin may have an inverse linear association with hip BMD. There may be an optimum intake of dietary niacin (approximately 22-41 mg/day) which does not impair skeletal health.

The Association of Raas Inhibitor Use with Osteoporosis. Findings from the Women's Health Initiative

Laura Carbone¹, Sowmya Vassan², Ross Prentice², Greg Harshfield¹, Bernhard Haring³, Jane A. Cauley⁴ and Karen Johnson⁵, ¹Medical College of Georgia at Augusta University, Augusta, GA, ²Fred Hutchinson Cancer Research Center, Seattle, WA, ³University of Wurzburg, Bavaria, Germany, ⁴University of Pittsburgh, Pittsburgh, PA, ⁵University of TN Health Science Center, Memphis, TN

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Epidemiology and Public Health Poster II: Gout, Ankylosing Spondylitis, Osteoarthritis, Osteoporosis, Pain, and Function

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Experimental studies have implicated a role for the Renin Angiotensin Aldosterone System (RAAS) in osteoporosis. However, the relationship of pharmacological inhibition of the RAAS to skeletal health is controversial. Therefore, the purpose of this study was to determine the relationship of use of RAAS Inhibitors (Angiotensin Receptor Blockers (ARBs), Angiotensin Converting Enzyme Inhibitors (ACE), Direct Renin Inhibitors, Selective Aldosterone Receptor Blockers and RAAS inhibitors in combination with other antihypertensive medications) to incident fractures, changes in bone mineral density (BMD) and body composition measurements in postmenopausal women.

Methods: 155,565 women from the WHI Observational study (OS) and Clinical Trials (CT) were included. The BMD and body composition analyses included the 11,437 women with a Dual Energy X-ray Absorptiometry measurement. Change in BMD and body composition were modeled using linear regression. Cox proportional hazards models were fit for each fracture outcome. Change in RAAS inhibitor use over time was evaluated by entering use as a time dependent exposure variable. Unadjusted and models adjusted for demographic and clinical covariates and medication use associated with osteoporosis and a final multivariable model adjusted for all covariates plus BMD were determined.

Results: There were 13,749 (9%) users and 141,816 (91%) nonusers of RAAS inhibitors at the baseline visit of WHI. In 16.8 years of follow-up there were 34,276 total fractures, 2,912 (annualized percentage 2.20%) in the baseline users of RAAS inhibitors, 31,364 (annualized percentage 2.16%) in baseline nonusers. In unadjusted models with time-dependent covariate defined as any prior use of RAAS inhibitors, there was a significant positive association of RAAS inhibitor use with all (HR 1.05 (95% CI 1.01, 1.09)), other (HR 1.11. (1.06-1.16)) and composite fragility fractures (HR 1.11 (95% CI 1.03, 1.20)) and a significant negative association with forearm fractures (HR 0.89 (0.82, 0.97)). In final multivariable models including baseline BMD, there was no significant association of use of RAAS inhibitors with all fractures or any fracture site (clinical vertebral, forearm, hip or composite fractures (hip, humerus, clavicle, scapula)), ($p \geq 0.13$ for all) or with change in BMD of the total hip, femoral neck or lumbar spine from baseline to three ($p \geq 0.20$ for all) or six years ($p \geq 0.70$ for all). There was no significant association of RAAS inhibitor use with changes in total body, lean body mass or fat mass from baseline to three ($p=0.06$, $p=0.24$, $p=0.09$ respectively) or six years ($p=0.41$, $p=0.08$ and $p=0.95$ respectively).

Conclusion: In postmenopausal women, use of RAAS inhibitors does not appear to be importantly related to osteoporosis endpoints. However, there may be differences among individual classes of RAAS inhibitors and their relationship to skeletal health, which deserve further exploration.

Golimumab Improves Work Productivity and Activity Impairment in Patients with Rheumatoid Arthritis (RA), Ankylosing Spondylitis (AS) and Psoriatic Arthritis (PsA): 1-Year Results from a Non- Interventional Trial in Germany

Klaus Krüger¹, Sven Remstedt², Astrid Thiele³ and Ines Klaudius⁴, ¹Medical Centre of Rheumatology, Munich, Germany, ²Rheuma Praxis Berlin, Berlin, Germany, ³Krankenhaus St. Josef Wuppertal, Wuppertal, Germany, ⁴MSD Sharp & Dohme GmbH, Haar, Germany

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Epidemiology and Public Health Poster II: Gout, Ankylosing Spondylitis, Osteoarthritis, Osteoporosis, Pain, and Function

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Non-interventional studies (NIS) are essential instruments in pharmaceutical research not only for pharmaceutical companies but also for regulatory authorities or reimbursement bodies in Germany. Aside from direct costs caused by a disease, German sick funds as well as health authorities have a keen interest in indirect costs, such as costs derived from loss of work productivity.

Methods: As primary endpoint, the change of work productivity impairment and ability for daily activities in month 3 (V1) vs baseline visit (V0) was evaluated.

All 4 subscores of the WPAI were analysed: disease related absence from work (absenteeism), working while sick (presenteeism), total work productivity impairment (TWPI) and activity impairment with TWPI as primary score. In addition, an evaluation of the activity impairment in the mITT population (**modified-Intention-To-Treat**) was performed. For the secondary analysis of the primary endpoint, the change in work productivity/activity impairment after 6 months and 12 months vs baseline as measured by WPAI for PsA, RA and AS pts treated with Golimumab (GLM) in German clinical practice was evaluated.

Results: Of 748 pts (100%) who started treatment with GLM at V0 (baseline), 666 (89.0%), 634 (84.8%) and 552 pts (73.8%) continued treatment until V1 (Mo 3), V2 (Mo 6), and V3 (Mo 12/end of observation period), respectively. Efficacy analyses were performed on the mITT population which included 700 pts (RA=237, PsA=235, AS=228) who had at least 2 documented visits.

The primary efficacy endpoint was analyzed in the mITT subset of 493 pts (RA=158, PsA=157, AS=178) with full-time or

part-time **employment** at baseline (mITTe).

The statistically significant improvements in the mean WPAI domain scores were maintained over the 12-month observation period in all 3 indications with a higher treatment effect regarding “activity impairment” and “presenteeism” than with “absenteeism” (Table 1). The magnitude of improvements in the 4 WPAI domains and the time course of improvements varied between the underlying disease (RA, PsA, AS).

In general, the improvements in the 4 WPAI domains were greater in pts with AS and PsA compared to RA. A continuous improvement over time was seen in AS pts regarding the domain “activity impairment” (Table 1). A positive effect of pre-treatment with biologics (i.e. better improvement in WPAI) was seen in RA pts for 3 domains (TWPI, absenteeism, presenteeism), and in PsA pts for 2 domains (absenteeism, activity impairment).

Conclusion: GLM s. c. 1 x monthly is an effective treatment in pts with RA, AS and PsA.

All scores of the WPAI showed a significant ($p < 0.05$) reduction in mean score values in each indication.

GLM leads to an improvement of work productivity and daily activities in all pts already within the first 3 months of treatment and provided sustained improvement in WPAI in pts with RA, PsA and AS.

Table 1: WPAI - Changes in the 4 domain scores from baseline to Months 3, 6 and 12 (mITTe)

The Effects of Physical Activity on Bone Density of High School Girls: A Prospective Study

Ria Desai¹, Brian Carpenter¹, Matthew Kennedy¹, Milind Desai², Lisa Damour¹ and Chad Deal^{3,4}, ¹Laurel School, Shaker Heights, OH, ²Cleveland Clinic, Cleveland, OH, ³Orthopedic and Rheumatology Institute, Cleveland Clinic Foundation, Cleveland, OH, ⁴Cleveland Clinic, Shaker Heights, OH

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Epidemiology and Public Health Poster II: Gout, Ankylosing Spondylitis, Osteoarthritis, Osteoporosis, Pain, and Function

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: More than 50% of peak bone mass (PBM) is gained during adolescence and high impact exercise has been shown to impact bone accrual. We evaluated bone mass in age and gender matched teenagers who were more or less physically active using calcaneal ultrasound.

Methods: Forty-six consecutive high school girls (14-18 years) were prospectively recruited between February-April 2018 after obtaining written informed parental consent. Subjects were divided into two groups, athletes (who reported ≥ 4 hours of aerobic physical activity/week) and non-athletes with < 1 hour. No subject had any orthopedic injuries or metabolic bone disorders. Each study participant self-reported their a) use of calcium (with or without vitamin D) supplementation and b) weekly servings of 8 oz. dairy products. BMD (bone mineral density) was measured (g/cm²) using a Sahara, Hologic Clinical Bone Sonometer). Continuous variables are reported as mean \pm standard deviation and compared using Student's

Figure 1a: Baseline data of the study sample (n=46)

Variable	Total (n=46)	Athletes (n=23)	Nonathletes (n=23)	P-value
Age (years)	16 \pm 1	15 \pm 1	16 \pm 1	0.32
Height (cm)	163 \pm 10	163 \pm 8	163 \pm 10	0.62
Vitamin D and calcium supplementation				
None	29 (63%)	14 (61%)	15 (65%)	
Vitamin D or calcium supplementation	7 (15%)	4 (17%)	3 (13%)	0.62
Vitamin D and calcium supplementation	10 (22%)	5 (22%)	5 (22%)	
Number of 8 oz. dairy servings/week	8 \pm 0	7 \pm 5	9 \pm 6	0.22

Figure 1b: Box and whisker plot demonstrating the significant differences in BMD between athletes and nonathletes

Figure 1c: Univariable linear regression analysis between bone mineral densities and various potential impacting factors in the study sample

	Standardized Beta	P-value
Age	0.09	0.57
Height	-0.03	0.83
Amount of weekly dairy intake	0.08	0.58
Calcium/vitamin supplementation vs. none	0.12	0.21
Athletes vs. nonathletes	0.41	0.009

t-testing, while categorical variables are reported as percentage of total and compared using Chi-square. Linear regression analysis was also performed to test the association between BMD and various predictors. A p-value < 0.05 was considered significant.

Results: The baseline data are shown in Figure 1a. Mean BMD was significantly higher in athletes vs. nonathletes (0.58 ± 0.1 vs. 0.49 ± 0.1 g/cm², $p=0.01$, Figure 1b). The association between BMD and various potential factors, using linear regression analysis, is shown in Figure 1c. The groups were well matched for age, height, and dairy intake with nonsignificant differences.

Conclusion: In high school girls who had heel BMD testing, participants who were physically active had higher BMD vs. those who were not. The findings were independent of age, dietary dairy intake as well as calcium/vitamin D supplementation. This study shows the importance of exercise in adolescent girls for accruing bone and attaining a higher PBM which will have a significant effect on bone mass later in life, potentially resulting in a lower lifetime risk for fracture. These findings need to be validated in a larger sample.

Abstract Number: 1149

Contemporary Prevalence of Gout and Hyperuricemia in the United States (National Health and Nutrition Examination Survey [NHANES] 2015-2016) and Decadal Trends (NHANES 2007-2016)

Michael Chen-Xu¹, Chio Yokose², Michael Pillinger³ and Hyon K. Choi², ¹General Medicine, Wairarapa District Health Board, Masterton, New Zealand, ²Division of Rheumatology, Allergy, and Immunology, Massachusetts General Hospital, Boston, MA, ³Medicine/Rheumatology, NYU School of Medicine, New York, NY

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Epidemiology and Public Health Poster II: Gout, Ankylosing Spondylitis, Osteoarthritis, Osteoporosis, Pain, and Function

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The prevalences of gout and hyperuricemia from the National Health and Nutrition Examination Survey (NHANES) 2007-2008 were 3.9% (8.3 million) and 21.4% (43.3 million individuals), respectively, representing increases of 44% and 18% from a decade earlier (Zhu et al., *Arthr Rheum.* Oct 2011, pp 3136-3141). Our objective was to determine the latest national prevalence estimates (NHANES 2015-2016) of gout and hyperuricemia and their decadal trends from NHANES 2007-2016.

Methods: Using data from 5,467 participants in the NHANES 2015-2016, we estimated the prevalence of gout and hyperuricemia. During the home interview in each NHANES survey cycle, all participants were asked about a history of health professional- or physician-diagnosed gout. Our definition of hyperuricemia was a serum urate level (SUL) >7.0mg/dL in men and >5.7mg/dL in women. We explored potential secular trends in these estimates and their possible explanations by comparing the latest estimates with those from 22,654 participants from NHANES 2007-2014. All statistical analyses were conducted using survey commands of Stata (Version 15.1, Stata Corporation, College Station, Texas) to adjust for clusters and strata of the complex sample design as well as incorporate sample weights to generate estimates for the total civilian, non-institutionalized population of the US. Population estimates (in millions) were calculated as per the NHANES analytic guidelines.

Results: The prevalence of gout was 3.9% (9.2 million) among US adults in 2015-2016 (5.2% [5.9 million] among men and 2.7% [3.3 million] among women) (**Table**). The mean SULs were 6.0mg/dL among men and 4.8mg/dL among women, which corresponds to hyperuricemia prevalences of 20.2% and 20.0%, respectively. The prevalence of gout and hyperuricemia among US adults was stable over the past decade (P-value for trend= 0.69 and 0.24 for men and women, respectively). The decadal trends for gout remained stable when stratified by sex, hypertension, chronic kidney disease (CKD) and obesity (all P-values for trend> 0.05).

Conclusion: These findings from this nationally-representative sample of US adults suggest that the prevalences of gout and hyperuricemia remain substantial (9.2 and 47.1 million adults, respectively), although they appeared to have plateaued over the past decade. This may be related to plateauing frequency of CKD (Murphy et al., *Ann Intern Med.* Oct 2016, pp 473-481), and hypertension (Fryar et al., *NCHS data brief*, no., 289. Oct 2017).

Table. Prevalence of Gout and Hyperuricemia and Number of Affected Adults in the US, NHANES 2015-2016*

	Gout		Hyperuricemia	
	Prevalence, % (95% CI)	N of US adults, millions	Prevalence % (95% CI)	N of US adults, millions
All	3.9 (3.3, 4.7)	9.18	20.1 (17.8, 22.4)	47.13
Sex				
Male	5.2 (4.4, 6.2)	5.86	20.2 (16.6, 24.3)	22.76
Female	2.7 (2.0, 3.8)	3.33	20.0 (17.8, 22.4)	24.37
Age				
20-39	0.7 (0.3, 1.5)	0.56	16.6 (13.6, 20.1)	14.07
40-59	3.4 (2.2, 5.3)	2.89	18.7 (15.1, 22.9)	15.71
60-79	8.8 (7.2, 10.7)	4.77	26.1 (22.7, 29.8)	14.20
≥ 80	8.7 (5.8, 12.7)	0.97	27.8 (21.0, 35.8)	3.10
Race/ethnicity				
Non-Hispanic White	4.0 (3.1, 5.3)	6.13	21.4 (18.1, 25.1)	32.59
Non-Hispanic Black	4.8 (3.8, 6.0)	1.31	22.6 (20.9, 24.3)	6.15
Hispanic	2.0 (1.4, 2.9)	0.73	14.9 (12.6, 17.5)	5.33
Other	5.2 (3.4, 7.9)	0.99	17.0 (13.8, 20.7)	3.23

* The data were adjusted for clusters and strata of the complex sample design of the National Health and Nutrition Examination Survey (NHANES) 2015–2016, with incorporation of sample weights. 95% CI = 95% confidence interval

The Potential Uses of an Infodemiology Approach for Health-Care Services in Rheumatology

Aldo Barajas-Ochoa¹, Stephanie Ramos-Gomez¹, Gerardo Martinez-Arroyo¹, Kaleb Rojero-Gil¹, Jose Yanez², Dionisio Castillo-Ortiz¹, Patricia Bustamante-Montes³ and Cesar Ramos-Remus^{1,3}, ¹Unidad de Investigacion en Enfermedades Cronico-Degenerativas, Guadalajara, Mexico, ²Psychology, Universidad Iberoamericana A.C., Mexico, Mexico, ³Universidad Autonoma de Guadalajara, Zapopan, Mexico

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Epidemiology and Public Health Poster II: Gout, Ankylosing Spondylitis, Osteoarthritis, Osteoporosis, Pain, and Function

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Infodemiology can help achieve the patient-centered care model. It is the science of determinants and distribution of information on electronic media. It can provide data to develop, collect, and evaluate metrics and indicators for information and communication patterns that are related to epidemiologic data or are useful for public health, policy making or even clinical practice. Google Trends (GTr) and Google AdWords (GAd) are two useful tools to assess demand-based infodemiology indicators. Its use is scanty in rheumatology.

To illustrate the potential use of GTr and GAd, we present three case-studies: A) What search terms related to rheumatology are typed by people in Mexico (MX), the United States of America (USA), and Canada (CAN)? B) What is the search volume for specific DMARDs typed by people in MX, USA, and CAN?, and C) What is the positioning of the search term “arthritis” compared with two non-rheumatic diseases (“hepatitis C”, “breast cancer”) among MX, USA, and CAN?

Methods: GTr output is a relative search volume (the biggest volume is transformed to 100 and the rest are given as a proportion of it) and GAd output is the average number of searches per unit of time. We ran 3 different queries (MX, USA, CAN) for each case-study using GTr and GAd for years 2015-2017. Results were exported to a database for further analysis. Search volumes were adjusted per country’s population and expressed as crude rates (searches per million; spm) when appropriate.

Results: To look for information on “rheumatology” people used 298 (MX), 654 (USA), and 637 (CAN) associated terms. “Arthritis” had 656, 550, and 548 associated terms in MX, USA, and CAN, respectively. For “arthritis treatment” there were 635, 569, and 569 associated terms in MX, USA, and CAN, respectively. Regarding DMARDs, there were 1,053 million searches during this period: methotrexate (28.5%), adalimumab (15.6%), rituximab (10.4%), and infliximab and etanercept (8.6% each). However, for every b- or tsDMARD search, there were fourteen (USA, CAN) to fifty-eight (MX) “turmeric” searches for the “treatment of arthritis”. In 2015, search volume for “arthritis” was 120, 638, and 668 spm in

MX, USA, and CAN, respectively. For 2016 and 2017, figures remained similar for MX and CAN, but showed a 12% increase for the USA. In MX, “hepatitis C” had 114 spm in 2015, with a 32% increase by 2017. The USA and CAN had 1,131 and 648 spm in 2015, with a 5% increase and an 8% decrease by 2017, respectively. For “breast cancer”, search rates were 4 times higher than for “arthritis” for the three years in MX, with an average increase of 250% each October, concurrent with public awareness campaigns. In the USA and CAN, search volume was 36% and 56% less than that for “arthritis”, with a 57% and 33% increase each October, respectively.

Conclusion: Infodemiology can have an added value to traditional research designs. It can serve for diverse purposes, such as assessing the penetration and impact of public awareness campaigns, patients’ perceived needs, the appearance of new remedies, the positioning of diseases, disease-related cultural differences in ethnic groups, people perceptions on specific health-care systems, etc.

Mikuls⁴, Justin K Owensby¹ and Kenneth Saag⁵, ¹University of Alabama at Birmingham, Birmingham, AL, ²Department of Biostatistics, University of Alabama at Birmingham, Birmingham, AL, ³Department of Medicine, Division of Immunology and Rheumatology, University of Alabama at Birmingham, Birmingham, AL, ⁴Internal Medicine, Division of Rheumatology, VA Nebraska-Western Iowa Health Care System and University of Nebraska Medical Center, Omaha, NE, ⁵UAB, Birmingham, AL

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Epidemiology and Public Health Poster II: Gout, Ankylosing Spondylitis, Osteoarthritis, Osteoporosis, Pain, and Function

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Health activity tracker devices(e.g. Fitbit) are increasingly used component of medical evaluation. However, the validity and suitability of the data from such devices for research is not clear, specifically, methods are lacking to ascertain whether patients are consistently wearing the device and if the data is complete. We compared various methodologic approaches to describe the completeness of data capture in the context of a pilot study of patients with inflammatory arthritis.

Methods: We evaluated active & passively collected data from a trial of patients with gout who had a recent flare. All patients were given a Fit bit Charge HR2. Fit bit data (step count, sleep, heart rate [HR]) was evaluated in 1-minute increments. Minute-level HR data was compared with a gold standard for ‘Complete Wear’ as composite of step count, sleep, and HR, with imputation to 60-minute increments. Imputation of wear was performed for shorter intervals (1, 15, 30-minutes). Definitions for Complete of wear at a person-day level were evaluated using various parameters (e.g. ≥ 1200 minutes, or ≥ 800 minutes for days without sleep data). Variability in step count data was decomposed as between-person; within-person, between-day; and within-person, within-day (including error) based upon comparing sums of squares to total variance.

Results: At time of evaluation, 36 people contributed 4,534 person-days of observation. A total of 60% of person-days were considered Complete data with sleep, 14% as Complete data without sleep, and 26% with Partial Data. On days with Complete wear with sleep (gold standard), 13% of person-minutes were misclassified if only minute-level HR data was used, and step count & sleep data were ignored, while 8% were misclassified if only HR data was used, with imputation. Adding sleep and step count data, 12% of person-minutes were misclassified if minute-level data without imputation was used; 6% of person-minutes were misclassified if imputation to 60-minutes was applied, but the 1200/800 minute thresholds for Complete wear over a day were not required.

Imputation at 60-minute intervals yielded similar results to imputation at 1, 15, and 30-minute increments. There were intervals as long as 3+ hours where patients were wearing the device (based on gold standard) yet had no HR data. Among Complete wear days, variance in the step count data was much more related to between-person variability (36%) rather than within-person, between-day variability (<1%). With imputation at 60-minute increments, wear patterns are shown in the heat map (Figure).

Conclusion: Fit bit and other health tracker data appear useful as part of arthritis research, but several methodologic issues must be considered to maximize validity and interpretation.

Figure: Heat Map - Data of Complete Wear with Sleep(>1200 minutes) [Black], Complete Wear without Sleep [Dark Gray], and Incomplete Wear [Light Gray]

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Epidemiology and Public Health Poster II: Gout, Ankylosing Spondylitis, Osteoarthritis, Osteoporosis, Pain, and Function

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Arthritis symptoms reported by patients have been anecdotally associated with weather changes, but large-scale, systemic evaluations are few in number. A variety of parameters associated with weather that might underlie arthritis-related pain and related symptoms have been inconsistently reported.

Methods: Patients participating in the ArthritisPower registry and contributing data via a Smartphone or computer App from the continental U.S. were eligible for analysis. Geolocation (latitude/longitude) was extracted from the Smartphone's physical location or computer IP address. Various weather parameters (e.g. temperature, humidity, wind speed/direction, barometric pressure) were obtained from the nearest National Oceanic and Atmospheric Administration (NOAA) weather station based on patient's geolocation. Various restrictions in the maximal allowable distance to the nearest weather station (e.g. <25 miles) were evaluated. Patient disease activity by the RAPID3, and patient reported outcomes (PROs) including pain interference, fatigue and physical function measured by the NIH PROMIS instruments (using computer adaptive testing) were obtained from the registry, and associated with NOAA weather data at that same time (to the nearest hour) and location, and at the same location 24 hours before and after each patient observation. Cross-sectional correlation between various weather parameters and PROs were quantified as r values using Pearson correlation coefficients. A “cold front” definition was proposed based on the confluence of longitudinal change over 3 days in relative humidity, wind direction, barometric pressure, and dew point.

Results: At the time of this analysis, 1334 unique patients contributed 2425 PRO observations with linkable NOAA weather data. Mean(SD) age was 53.9(10.3) years, 91% women, 90% white. In terms of various arthritis conditions represented in Arthritis Power, 45% had rheumatoid arthritis, 10% psoriatic arthritis, 9% ankylosing spondylitis, and 62% osteoarthritis (with or without a concomitant inflammatory arthritis). Many of the correlations between various weather parameters and PROs were statistically significant ($p < 0.001$) albeit numerically weak (all r values < 0.2). For patients contributing any PRO data at the time of an evolving cold front using the proposed definition, patient symptoms were not different as measured by various PROs (Table).

Conclusion: Weather is quantitatively related to patient's arthritis symptoms. Additional work is ongoing to refine specific weather parameters and their associations with PROs in order to provide potentially actionable information to patients and their healthcare providers.

Table: Association between Patient Symptoms and the Presence of a Cold Front based on Geolocation and Linked Weather Data (n=2425)

	Cold Front	No Cold Front
RAPID3 (0-30)	15.0 (9.0, 20.0)	17.0 (13.0, 21.0)
PROMIS Pain Interference (1-100)	63 (55, 67)	66 (62, 70)
PROMIS Fatigue (1-100)	60 (51, 64)	64 (59, 71)
PROMIS Physical Function (1-100)	63 (55, 67)	66 (62, 70)

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Epidemiology and Public Health Poster II: Gout, Ankylosing Spondylitis, Osteoarthritis, Osteoporosis, Pain, and Function

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Recommendations and strategies have been developed for early referral, diagnosis and treatment of rheumatic diseases. These strategies, however, can only be implemented if sufficient manpower is available. An estimation of how many rheumatologists are needed to meet current and future population needs must be provided in order to counsel health care planners and decision makers. Current methods used for forecasting manpower are disparate, as are the variables incorporated into workforce projection models. Consequently, projections for the need of rheumatologists

may vary by a factor of five between studies. The objective of these EULAR points to consider (PTC) was to guide future workforce studies in adult rheumatology in order to produce valid and reliable manpower estimates.

Methods: The EULAR Standardised Operating Procedures were followed. A multidisciplinary task force with experts including patients with rheumatic diseases from 11 EULAR countries and the USA was assembled. A systematic literature review (SLR) was conducted to retrieve workforce models in rheumatology and other medical fields. PTC were based on expert opinion informed by the SLR, followed by group discussions with consensus obtained through informal voting. The level of agreement with the PTC was voted anonymously.

Results: A total of 10 PTC were formulated (Table). The task force recommends models integrating supply (= workforce available to rheumatology), demand (= health services requested by the population) and need (= health services that are considered appropriate to serve the population). Projections of workforce requirement should consider all factors relevant for current and future workload in and outside direct patient care. Forecasts of workforce supply should consider demography and attrition of rheumatologists, as well as the effects of new developments in health care.

Conclusion: These EULAR endorsed PTC will provide guidance on the methodology and the parameters to be applied in future national and international workforce requirement studies in rheumatology.

Table 1. EULAR points to consider for the conduction of workforce requirement studies in rheumatology

No	Point to consider	LoA	LoE
1	Workforce models should integrate supply, demand and need of the respective geopolitical entity (e.g. municipality, region, state, country), and should express results as full time equivalents and as number of rheumatologists.	9.5 (0.9) 95% \geq 8	5
2	Workforce models should provide projections over a period of 5-15 years.	9.1 (1.1) 90% \geq 8	5
3	Workforce models should not assume a current balance between supply and need.	9.6 (0.7) 100% \geq 8	5
4	Workforce models should, where possible, rely on several data sources and include uncertainty analyses.	9.8 (0.4) 100% \geq 8	5
5	Workforce models should be regularly updated; updates should include an analysis of the actual performance (i.e. prediction validity) of the previous model.	9.5 (0.6) 100% \geq 8	5
6	Workforce need for patient care should be based on the prevalence and referral rates of diseases managed by rheumatologists as well as on an estimation of time needed per patient.	9.7 (0.7) 100% \geq 8	5
7	Workforce need for patient care should consider current and future demographics, sociocultural characteristics of the population and disease patterns.	9.5 (0.9) 95% \geq 8	5
8	Workforce need and supply should consider work outside rheumatology patient care (e.g. administrative tasks, research, teaching, non-rheumatologic disease management), as well as patient care performed by other health professionals in rheumatology.	9.4 (0.9) 95% \geq 8	5
9	Workforce supply should account for demographic composition of rheumatologists, the number of rheumatologists entering and leaving the workforce, and generational attitudes of rheumatologists towards scope of practice and work-life balance.	9.1 (2.3) 85% \geq 8	5
10	Workforce models should consider the effects of medical developments, including new technologies, medications, artificial intelligence and e-health, on demand and supply.	9.4 (1.1) 85% \geq 8	5

Numbers in column 'LoA' indicate the mean and SD (in parentheses) of the LoA, as well as the percentage of task force members with an agreement \geq 8. None of the studies identified corresponded to any of the categories of Oxford Centre for Evidence-Based Medicine (OCEBM). Evidence level was therefore set as "5", which is the lowest level of evidence. LoA, Level of Agreement; LoE, Level of Evidence according to OCEBM 2011 levels of evidence.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Epidemiology and Public Health Poster II: Gout, Ankylosing Spondylitis, Osteoarthritis, Osteoporosis, Pain, and Function

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with moderate-to-severe hip or knee arthritis often use opioids before undergoing total joint replacement (TJR). Preoperative opioid use may lead to persistent opioid use and poor clinical outcomes after TJR. We aimed to describe patterns of opioid use before TJR.

Methods: Using Medicare (Parts A/B/D, 2010-2014) data, we conducted a cohort study among patients aged ≥ 65 who underwent incident total hip replacement (THR) or total knee replacement (TKR). Index date was the incident TJR date. Eligible patients were required to have continuous enrollment in Part A/B/D for at least 360 days before the index date. We excluded patients with: 1) no medical and/or pharmacy claims in the 360-days before the index date, and 2) both THR and TKR on the same date. Any opioid use was defined as having ≥ 1 opioid dispensing during the 12-month period; continuous opioid use was characterized as having ≥ 1 opioid dispensing in each of 12 months during the before the index date. We calculated mean morphine milligram equivalent (MME) per day and proportion of days covered (PDC) in each month. 50 MME is equivalent to 50 mg hydrocodone. We assessed variables potentially associated with opioid use, such as demographics, pain/fractures, other comorbidities, medication use, and healthcare use in 360 days prior to the surgery. A multivariable logistic regression model estimated the associations between patient characteristics and preoperative opioid use patterns.

Results: We identified a total of 473,781 patients who underwent TJR: 155,516 THR and 318,265 TKR. Mean (SD) age was 75 (7) years for THR and 74 (6) for TKR patients. 67.4% were female and 91.5% were White. Back pain was a common comorbidity in both THR (62%) and TKR (46.8) patients. 60.2% patients had any use of opioids before the surgery. Of those, 12.4% used opioids at least once a month continuously over the 12-month preoperative period. Hydrocodone was most commonly used agent, followed by tramadol and oxycodone. Among any users of opioids, MME per day and PDC both increased toward the TJR date. Continuous opioid users had over 90% PDC in the month before TJR and used higher MME dose of opioids per day (58mg in THR, 51mg in TKR) compared to any users (16mg in THR, 12mg in TKR) (p -values < 0.0001) (**Figure**). Correlates of continuous opioid use included history of drug abuse (OR=5.19, 95% CI=3.96-6.84) and back pain (OR=2.32, 95% CI=2.24-2.40). African American patients had a 2-fold higher odds of using opioid continuously compared with White Americans (OR=2.14, 95% CI=2.01-2.28).

Conclusion: Among patients in Medicare who underwent TJR, 60.2% had any use of opioids and 7.5% had continuous use of opioids in the year before the surgery. Use of opioids and MME increased gradually toward the index TJR date. History of drug abuse, back pain, and race African American were strongly associated with continuous use of opioids preoperatively.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Epidemiology and Public Health Poster II: Gout, Ankylosing Spondylitis, Osteoarthritis, Osteoporosis, Pain, and Function

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with inflammatory arthritis are at increased risk for atherosclerotic cardiovascular (CV) disease. This has been under-recognized in clinical practice. Additionally, the current risk stratification methods underestimate risk in this population.

The purpose of our study was to describe the population characteristics of patients attending a Cardio-Rheumatology Clinic, a new collaborative initiative at a large academic medical centre in Canada, which aims to improve CV care of patients with inflammatory arthritis, and to report changes in treatments for CV prevention initiated during their clinic visit.

Methods: This study is a cross sectional analysis of patients assessed in the Cardio-Rheumatology Clinic from July 2017 to May 2018. Patients with rheumatoid arthritis (RA), psoriatic arthritis (PsA) and ankylosing spondylitis (AS) with no known CV disease were referred to the clinic. Information about their rheumatic disease, lifestyle habits, medications and co-morbidities was recorded. Each patient was evaluated by a cardiologist focusing on CV risk assessment. All patients underwent blood tests for lipids and cardiac biomarkers, electrocardiogram, coronary artery calcium scoring, stress echocardiography and carotid ultrasound.

Results: 95 patients with RA (49.5%), PsA (38.9%) and AS (11.6%) were evaluated (mean age 59.5 years, 67.4% female). Hypertension was reported in 31.6%, dyslipidemia in 26.3%, diabetes mellitus in 8.4% and family history of premature CVD in 30.1%. History of current smoking was present in 10.2%. Sedentary lifestyle was common; only 20% of patients reported 3 hours or more of vigorous exercise per week and functional capacity was rated as below average for age and sex in 31.8%, and 72.3% were overweight or obese. Table 1 summarizes the CV risk factors and laboratory findings and Table 2 describes key CV abnormalities in imaging. Importantly, 53.8% of patients had a change in pharmacological therapy as a result of evaluation in the clinic, including 39.7% for lipid lowering, 32.1% for antiplatelet, 14% for antihypertensive therapy, 1.3% were retreated for heart failure and 1.3% were placed on lifelong anticoagulation therapy for atrial fibrillation. One patient underwent percutaneous coronary stenting.

Conclusion: A dedicated Cardio-Rheumatology Clinic has led to identification of increased CV risk, early atherosclerosis and optimization of CV care in a large proportion of our clinic population. Further work in this area is needed to help raise awareness of this increased risk and to help develop more accurate tools to assess CV risk in this population.

Table 1. Baseline characteristics of the study population (N=95)

Variable	Mean (SD)/Frequency (%)

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Epidemiology and Public Health Poster II: Gout, Ankylosing Spondylitis, Osteoarthritis, Osteoporosis, Pain, and Function

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The objective of this study was to evaluate the work productivity and its relationship with the degree of physical work demand in patients with rotator cuff tendinopathy.

Methods: We included consecutive patients over 18 years of age, working actively, with rotator cuff tendinopathy, diagnosed clinically and ultrasonography. Patients with diagnosis of inflammatory arthropathies, fibromyalgia and any other condition that prevents reading or understanding of the questionnaires were excluded. Demographic variables and work characteristics were determined. Work productivity was assessed using the WPAI:GH questionnaire, and the degree of physical work demand through the Pujol scale.

Results: 48 patients were evaluated, 66.6% were women. The mean age was 48 ± 10 years. The median of duration of symptoms was 3 months (RIC 2-6), and the time of occupation was 40 hours per week (RIC 30-50). The most frequent occupations were domestic staff (34.04%), construction workers (12.77%) and nurses (10.64%). The percentage of patients who performed sedentary or mild work was 47.9% (23/48), while 52.1% (25/48) performed jobs with intermediate, heavy or very heavy physical demand. The tendon most frequently affected was the supraspinatus (64.5%). The median of absenteeism was 20% (RIC 0-41.43 - IC 95: 17.53 to 32.44). We observed a reduced on the job effectiveness (Presenteeism) of 75% (RIC 55-100 - IC 95: 61.26 to 78.31) and a work productivity loss of 85.8% (RIC 60-100 - IC 95: 65.15 to 82.32). The impairment in activities of daily living (ADL) was 60% (RIC 50-80 - IC 95: 53.82 to 69.07). No statistically significant differences were found in any of the WPAI variables in terms of sex, the correlation was low and not significant with respect to age. Significant differences were observed regarding the degree of physical work demand (light work vs. intermediate / heavy work), those who performed intermediate / heavy work had greater impairment at work (85% (RIC 60-100) vs 40% (RIC 20-80) $p = 0.008$) and loss of total work productivity (90% (RIC 69-100) vs 45% (RIC 20-81.7) $p = 0.007$).

Conclusion: In patients with rotator cuff tendinopathy an impairment was observed in the four WPAI variables, being more marked in those patients with occupations that require greater physical demand.

Acknowledged Biostatistical Help and the Quality of Statistical Analyses in Randomized Controlled Trials in Rheumatology

Elif Dincses¹, Gul Guzelant², Gulen Hatemi² and Hasan Yazici³, ¹Istanbul University, Cerrahpasa Medical Faculty, Department of Internal Medicine, Division of Rheumatology, Istanbul, Turkey, ²Istanbul University, Cerrahpasa Medical Faculty, Department of Internal Medicine, Division of Rheumatology, Istanbul, Turkey, ³Istanbul Academic Hospital, Istanbul, Turkey

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Epidemiology and Public Health Poster II: Gout, Ankylosing Spondylitis, Osteoarthritis, Osteoporosis, Pain, and Function

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The quality of statistical analysis reporting is wanting even in our most prestigious journals. It stands to reason that active participation of biostatisticians/epidemiologists (b/e) in reporting would improve the situation. We tested the hypothesis that more close cooperation with a b/e would improve the quality of reporting randomized clinical trials (RCTs) in rheumatology. We defined this *close cooperation* as the inclusion of a formal b/e among the co-authors and/or a declaration of formal statistical help in the study reports.

Methods: Two independent observers screened both by reading and electronic scanning, when applicable, the texts of all RCTs in *Annals of the Rheumatic Diseases*, *Arthritis Care and Research*, *Arthritis and Rheumatology*, *Rheumatology Oxford* published in 2015 and 2016. Using a pre-prepared worksheet, the observers specifically tabulated the presence of a b/e among the co-authors and/or formal acknowledgement of statistical help in the methods, the inclusion of effect sizes (the kind, whether they were specifically voiced as effect sizes, whether they could be calculated by the reader from the data presented or not given at all) and the presence of associated confidence intervals for the given effect sizes. Also tabulated were the improper aspects of *p* value reporting, including giving relative ($>p>$) instead of exact ($p=$) *p* values and the erroneous inclusion of *p* values in tables depicting trial entry data in randomized trials, since these tables, by definition, display randomized features (1). An arbiter (HY) decided the final tabulation when there were discrepancies between the 2 observers and there were up to 15 discrepancies in total where more than 1 discrepancy was possible per article.

Results: The total number of RCTs was 134. There were 29 (22%) articles (Group I) in which a formal statistical help was acknowledged. In 26/29 this was a co-authorship and in 3, only a mention in the text. The remaining 105 (78%) of the articles made up Group II. The Table gives the findings. It is seen that the reporting of effect sizes and the desired way of reporting exact *p* values were significantly more common in Group I. On the other hand, reporting of confidence intervals and including *p* values for baseline data after randomization did not show significant differences between the groups.

Conclusion: The inclusion of a b/e, interestingly formally present in only 29/134 (22%) of the analyzed manuscripts, improved the reporting of effect sizes -at least rendering them calculable- and in reporting exact *p* values. The same cannot be said for reporting confidence intervals for effect sizes and giving *p* values for baseline data. A limitation of our work was the relatively small number of manuscripts in Group I.

Table: The differences of the parameters between two groups

	Group I (n=29) with a b/e	Group II (n=105) without a b/e	Differences between the Groups I and II
Effect size reporting, n (%)	26 (90)	61 (58)	32% (95% CI 13.1-43.3), $p=0.001$
Given directly, n (%)	2 (7)	5 (5)	
Can be calculated (given HR, OR, RR, β coefficient), n (%)	24 (83)	56 (53)	30% (95% CI 9.8-42.9), $p=0.004$
NNT and NNH calculated, n (%)	0	2 (1)	
Confidence intervals for effect size reporting, n (%)	16 (55)	43 (41)	14% (95% CI -5.8 -32.9), $p=0.18$
Reporting exact <i>p</i> values, n (%)	25/27 (93)	63/91 (69)	23% (95% CI 5.2-34.7), $p=0.014$
Inclusion of <i>p</i> values for the baseline data, n (%)	3/27 (11)	20/91 (22)	11% (95% CI -7.5-22.8), $p=0.21$

Privacy-Preserving Linkage between the Arthritis power Registry and Commercial Payer Claims Data to Support Comparative Effectiveness and Outcomes Research

W. Benjamin Nowell¹, Jeffrey R. Curtis², Lang Chen², Biruk Eshete³, Abiy Agiro³, Xiaoxue Chen³, Jennifer Ostertag-Stretch³, Toan Ong⁴, Kelly Clayton¹, Kelly Gavigan¹ and Kevin Haynes³, ¹Global Healthy Living Foundation, Upper Nyack, NY, ²University of Alabama at Birmingham, Birmingham, AL, ³HealthCore, Wilmington, DE, ⁴University of Colorado, Denver, CO

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Epidemiology and Public Health Poster II: Gout, Ankylosing Spondylitis, Osteoarthritis, Osteoporosis, Pain, and Function

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Integration of registry information with administrative claims data may be used to conduct patient-centered outcomes research (PCOR), including comparative effectiveness and safety studies, and to improve the quality of clinical care. While a variety of methods exist to link data, the unique requirements for linking data provided by patients in a research registry to claims data held by health plans and payers may present unique obstacles. These challenges are even greater if 1) no patient identifiers can be directly shared, and 2) no unique identifiers (e.g. social security number) are acceptable for use given privacy concerns. We evaluated results of a method to link data from a patient registry to the clinical outcomes research subsidiary of a large commercial payer under these two constraints.

Methods: A novel, preliminarily validated encryption algorithm using a secure HIPAA-compliant cryptographic one-wayhash function was developed to convert a vector of non-unique patient identifiers (first name, last name, sex, date of birth) into unique hashed identifiers. Both the Arthritis Power registry and HealthCore,Anthem Inc.'s research subsidiary, utilized the hashing algorithm and exchanged only these identifiers; exact match on the hashed identifiers was required. The diagnoses self-reported by patients in the Arthritis Power registry were compared with ICD9/10-based diagnoses in the claims data for the same conditions, and similar autoimmune conditions, varying the amount of health plan coverage available (any, or >5 years), using both a sensitive (≥ 1 outpatient diagnosis) and a more specific (≥ 2 diagnoses from relevant specialist)claims-based definition, and considering whether the condition matched exactlyvs. matched a broader set of inflammatory arthritis diagnosis codes (e.g. RA, PsA, ankylosing spondylitis).

Results: Of 11,343 ArthritisPowerregistry participants enrolled at time of data integration with any health condition, 19.1% (n=2166) were linked to Anthem claims data with no minimum coverage duration requirement; 1600 were commercially insured. Of these, mean (SD) age was 49 (10.7), 93% women, and they resided in the Northeast (12%), Midwest (29%), South (37%) and West (22%). Among patients with more than 5years of coverage and who met the ICD9/10 definition for the computable phenotypes of RA, PsA or psoriasis, confirmation rates varied modestly according to the various parameters permuted (Table).

Conclusion: Information from a patient-ledarthritis research registry where in-person visits are not required can be linked to data from a research subsidiary of a large commercial payer using a hashing algorithm that does not require unique identifiers nor sharing of individual patient information. Ongoing work is underway to maximize the accuracy of linkage and confirmation rates using various approaches.

Table: Confirmation Rates (%) between Patient Self-Reported Health Conditions and Claims-Based Algorithms for RA, PsA, and Psoriasis

Health Condition	Sensitive Definition		Specific Definition	
	Exact condition	Related Conditions	Exact condition	Related Conditions
Rheumatoid Arthritis	67	68	59	61
Psoriatic Arthritis	67	67	47	77
Psoriasis	79	80	47	74

Fat Mass Is Associated with Musculoskeletal Pain in Women : A Three-Year Longitudinal Study

Hyun Ah Kim and Jeong-Im Hong, Hallym University Sacred Heart Hospital, Kyunggi-do, Korea, Republic of (South)

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Epidemiology and Public Health Poster II: Gout, Ankylosing Spondylitis, Osteoarthritis, Osteoporosis, Pain, and Function

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Increase in fat mass is correlated with musculoskeletal pain. The aim of this study was to examine the relationship between fat mass and the musculoskeletal pain prospectively in Korean community residents.

Methods: In the Korean Health and Genome Study, participants (mean age 60.2 years, 56.2% women) completed pain questionnaires and underwent dual x-ray absorptiometry to calculate body composition. Three-year follow-up data on pain was available for 1,325 participants. Pain was categorized according to number of pain regions. At three years of follow-up, participants were classified as follows: 1) no pain both at baseline and at three years (no pain), 2) any pain (one, two or more, or widespread regions) at baseline and no pain at three years (transient pain), 3) no pain at baseline and any pain at three years (new pain) 4) any pain both at baseline and at 3 years (persistent pain). 1) and 2) were grouped as no/transient pain group (no pain) and 3) and 4) as new/persistent pain group (pain).

Results: Female gender and obesity were two significant factors associated with the persistence or development of pain. Total fat mass and fat:muscle mass ratio were associated with pain among female participants only, and the odds ratios for pain were significantly increased in female participants in the highest quartile of total fat mass and fat muscle ratio after adjustment. Among normal weight participants, those without metabolic syndrome were less likely to belong to the pain group, especially among women.

Conclusion: In conclusion, both female gender and obesity were two significant factors associated with pain. Fat mass parameters and pain were significantly associated only among females.

Non-Elderly Adults Who Have Never Seen a Health-Care Provider for Chronic Joint Symptoms- Updated Results from National Health Interview Survey 2015

Changchuan Jiang and Yiming Luo, Department of Medicine, Mount Sinai St Luke's and Mount Sinai West Hospitals, Icahn School of Medicine at Mount Sinai, New York, NY

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Epidemiology and Public Health Poster II: Gout, Ankylosing Spondylitis, Osteoarthritis, Osteoporosis, Pain, and Function

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Arthritis and chronic joint symptoms (CJS) are a leading cause of disability among adults in the United States. For some forms of arthritis, early diagnosis and aggressive treatment are essential to limit permanent joint damage and disability, especially in relatively younger population. Approximately 10.3 million adults (21.7% of adults with CJS) never had seen a health-care provider for their joint symptoms in 2001.

Methods: Data were extracted from the population-based National Health Interview Survey 2015. Never Seen a Health-Care Provider for Chronic Joint Symptoms was defined as negative answer to the question: "Have you EVER seen a doctor or other health professional for these joint symptoms?" Respondents were classified as having CJS if they fit two

criteria 1) had any symptoms of pain, aching, or stiffness in or around any joint except for back or neck; 2) the duration of joint symptoms exceed 3 months. Adults aged 18 to 64 years were included. SAS was used to calculate estimations with weighted analyses. Logistic regression was used to produce odds ratios for a full model that adjusted for all variables.

Results: 50 million non-elderly adults (25.5%) were identified with chronic joint symptoms in NHIS 2015. Approximately 12.5 million (27.3%) of them have never seen doctors or other health professionals for their chronic joint symptoms. Never seen doctors or other health professionals for CJS were associated with Male ($p=0.02$), Hispanic ethnicity ($p=0.06$), No insurance ($p<0.001$), No primary care provider ($p<0.001$), and better general physical health ($p<0.001$). Patients with \neq Other Coverage \pm (Disability-related Medicare and Military Care) ($p<0.001$), higher age ($p<0.001$) were significantly more likely to see healthcare professional for their chronic joint pains.

Conclusion: After 14 years, there is still a significantly proportion of non-elderly adults who have never seen a health-care provider for their chronic joint symptoms. It calls for further efforts in patient education and health policy. A large group of underserved patients might benefit from intervention and their potential disabilities from arthritis might be prevented.

Table 1. Estimated Prevalence of Non-Elderly Adults (Aged 18-64 Years) With Chronic Joint Symptoms (CJS) Who Have Never Seen A Health-Care Provider For CJS, By Selected Characteristics- National Health Interview Survey 2015

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Epidemiology and Public Health Poster II: Gout, Ankylosing Spondylitis, Osteoarthritis, Osteoporosis, Pain, and Function

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Traumatic knee injuries, such as injuries to the anterior cruciate ligament and menisci, are associated with the early onset and progression of osteoarthritis (OA). However, our understanding of the pathobiologic processes underlying this association is limited. This study examined the precipitating effect of knee ligament and/or meniscal injury on radiographic OA in military officers, a population at high risk of knee injury that also experiences sustained biomechanical loads on the knee joint.

Methods: Radiographic OA was assessed in military officers with a prior history of knee ligament and/or meniscal injuries (injury group) and comparison participants (injury-free group), both selected from a cohort of 6452 military officers enrolled between 2004 and 2009, when participants matriculated at the U.S. Air Force Academy, U.S. Military Academy, or U.S. Naval Academy. The injury group had knee ligament and/or meniscal injuries prior to, during, or after their 4-year academy career (n=115). The injury-free group was site-matched from the same source cohort but had no history of knee ligament and/or meniscal injuries (n=114). Both groups had bilateral knee radiographs taken by radiographic technicians at military treatment facilities who followed a standardized image acquisition protocol using fixed-flexion knee positioning. All images were digitally transferred to a single, highly-experienced musculoskeletal radiologist reader (JBR). Radiographic OA was defined as Kellgren-Lawrence grade 2 or greater. Injury status was established using a standardized questionnaire (first surveys completed between 08/15/15 and 12/13/17; all injuries were verified by clinical record review).

Results: Mean age was 27.7 years (injured: 27.7 years; non-injured 27.7 years) and 38% were women (injured: 34%; non-injured: 42%). Mean weight was 77.4 kg and body mass index was 25.1 kg/m². Mean time from first knee ligament and/or meniscal injury ("knee injury" hereafter) to radiographic assessment was 8.8 years. Officers with a history of knee injury had a greater prevalence of radiographic OA (16.5%) than injury-free officers (0.0%, $p<0.001$). Officers with knee injury were more likely to have osteophytes (40.9% vs. 7.0%, $p<0.001$) and joint space narrowing (22.6% vs. 0.9%, $p<0.001$). Surprisingly, OA prevalence was only weakly related to timing of injury. Specifically, prevalence differences (PDs, injury-free as reference) were similar for those who sustained their first knee injury at high school age (PD=14%, 95%CI: -2%, 31%), collegiate age (PD=20%, 95%CI: 3%, 36%), and post college graduation (PD=13%, 95%CI: -13%, 38%). Similar PDs were obtained from sub-analyses of the unilateral injury subgroup using non-injured limbs (rather than non-injured people) as the reference category.

Conclusion: Nearly 1 out of every 5 officers with knee injury progresses to radiographic OA before age 30. This progression rate may reflect the physically-demanding nature of their occupation. We observed no relationship to timing of injury, suggesting that these "early-progressors" react quickly to the physical insults of knee trauma and surgery.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Epidemiology and Public Health Poster II – ARHP

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Physical function and balance often decline in older adults, and joint hypermobility, a condition in which joint range of motion is greater than normal, may be related to impaired physical function and balance. This cross-sectional study examined the association of joint hypermobility with measures of lower extremity function (standing balance and walking time) in a community-based cohort of older adults.

Methods: Data were collected during 2003-2010 from Johnston County Osteoarthritis Project participants. The Beighton criteria were used to assess hypermobility at nine body sites: the trunk and bilaterally for the first and fifth fingers, elbows, and knees. General joint hypermobility (GJH) was defined as a Beighton score ≥ 4 (range 0-9). Knee hypermobility was defined as hyperextension of at least one knee, and trunk hypermobility was defined as the ability to place one's palms on floor during forward trunk flexion with knees extended. Physical function outcomes were: 8-foot walk (unable to do or ≥ 3.5 seconds [s] vs. < 3.5 s), standing balance (full tandem unable to do or < 10 s vs. $10+$ s), and functional reach test (< 28.0 cm vs. ≥ 28.0 cm). Separate logistic regression models were used to estimate associations between joint hypermobility and physical function, adjusting for age, body mass index (BMI), sex, race (African American vs. White), self-reported physical activity from standard questionnaire (≥ 150 vs. < 150 minutes moderate physical activity per week), and presence/absence of symptomatic osteoarthritis (sxOA) separately at the knee and hip.

Results: Data were available for 1695 participants (6.5% with GJH, mean age 69 years, mean BMI 31 kg/m^2 , 67% women, 31% African American, 38% achieving ≥ 150 minutes of moderate physical activity per week, 23% knee sxOA, 127% hip sxOA). In unadjusted analyses, presence of GJH was associated with the better-performing groups for tandem stance time and 8-foot walk time, but associations were no longer statistically significant in adjusted models (see Table). Knee hypermobility models, both unadjusted and adjusted, showed no statistically significant differences in physical function measures. Crude models of trunk hypermobility were associated with better functional reach and 8-foot walk time, but results were attenuated and not statistically significant after adjusting for covariates.

Conclusion: While unadjusted models indicated associations of GJH with balance and walk-time, once covariates were taken into account, particularly age, the associations were attenuated. Trunk hypermobility (signifying increased hamstring flexibility) may be a marker of better lower body physical function and balance. Prospective studies may determine how the presence or absence of joint hypermobility relates to physical function and balance over time.

Table. Associations of Physical Function Measure and Joint Hypermobility.

Physical Function Measure	General Joint Hypermobility		Knee Hypermobility		Trunk Hypermobility	
	OR (95% CI)	aOR* (95% CI)	OR (95% CI)	aOR* (95% CI)	OR (95% CI)	aOR* (95% CI)
Functional Reach Test	1.53 (0.94, 2.51)	1.07 (0.63, 1.82)	0.99 (0.53, 1.85)	0.78 (0.40, 1.52)	1.83 (1.00, 3.34)	1.50 (0.78, 2.90)
Tandem Stance time	1.80 (1.13, 2.86)	1.51 (0.90, 2.53)	1.05 (0.60, 1.82)	0.91 (0.50, 1.68)	1.56 (0.96, 2.55)	1.18 (0.67, 2.02)
8-foot walk time	1.62 (1.09, 2.41)	1.36 (0.86, 2.17)	0.88 (0.53, 1.48)	0.76 (0.43, 1.40)	1.73 (1.12, 2.68)	1.43 (0.86, 2.38)

odds ratio = OR (> 1.0 indicates better physical function), adjusted odds ratio = aOR, 95% confidence interval = 95% CI

Patterns of Depressive Symptoms before and after Surgery for Hip, Knee and Lumbar Spine Osteoarthritis

J. Denise Power, Prtha Kudesia, Alina Nadeem, Anthony V. Perruccio, Y. Raja Rampersaud, Nizar Mahomed and Rajiv Gandhi, Arthritis Program, Krembil Research Institute, University Health Network, Toronto, ON, Canada

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Epidemiology and Public Health Poster II – ARHP

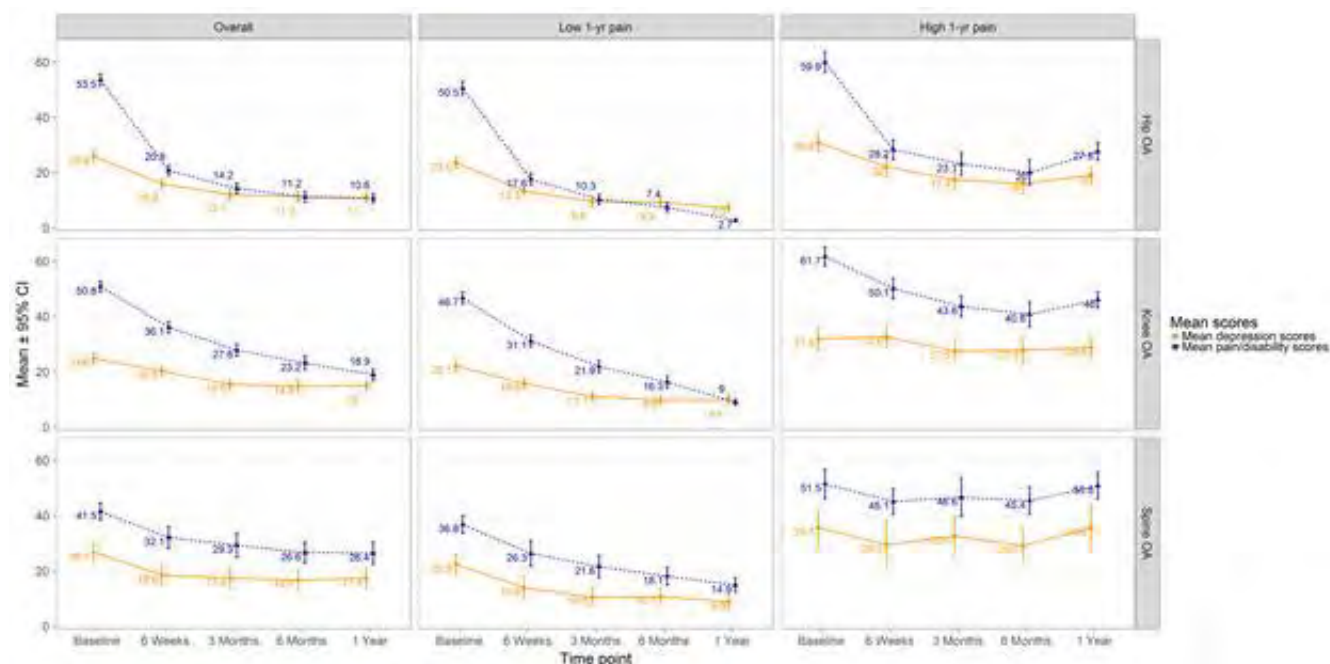

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Although pain and decreased function are the primary symptom targets of OA surgeries, OA is also associated with depression. The impact of surgery on depressive symptoms is not clear. Further, since 20% or more of patients report residual pain post-surgery, and pain and depression are closely linked, the impact of surgery on depression may vary dependent on pain-related outcomes. The objective our study was to examine patterns of depressive symptoms before and over the year following OA surgery, stratified by 1-year post-surgical outcome and surgical joint. We also examined patterns of patient reported depression diagnoses and treatment.

Methods: Participants were 747 patients with hip (n=287), knee (n=360) and lumbar spine (n=100) OAscheduled for joint replacement or decompression surgery +/- fusion. One pre- and 4 post-surgery questionnaires were completed. Depressive symptoms were quantified using the Hospital Anxiety and Depression Scale (HADS). Pain was measured using the WOMAC pain subscale for hip and knee patients. Oswestry Disability Index (ODI) measured disability due to low back pain for spine patients. One-year pain-related outcomes were categorized as 'high' (worse) (top pain/disability tertile) vs. 'low' (2 lower pain/disability tertiles). Based on the 5 study time points, 2 sets of plots were generated stratified by 1-year outcome and surgical joint: 1) mean pain/disability and depressive symptom scores; 2) percentage of patients meeting the HADS cut-off for 'caseness' of depression, reporting depression, and reporting current treatment for depression.

Results: Post-surgical changes in mean depression scores varied by joint and 1-year outcome groups. There were notable decreases in depression scores for patients with better pain outcomes across all joint groups. However, for those with poorer outcomes, decreases were smaller for hip and particularly knee patients, and no change was observed among spine patients (Figure). Among those with poorer outcomes, 25% of spine and knee patients were depression 'cases' pre- and post-surgery; an additional 16% of spine and 10% of knee patients developed new depression 'caseness' post-surgically. The proportion of these knee and spine patients deemed depression 'cases' by symptom score was much higher than the proportion reporting depression diagnosis/treatment.

Conclusion: Although depressive symptoms decrease overall in OA patients post-surgery, patterns and degrees of change vary by joint and surgical outcome. Findings support that greater attention to mental health pre- and post-surgery is warranted, particularly among knee and spine patients. Given the close interrelationship of pain and depression, appropriate assessment and treatment of depression in OA patients may lead to decreases in post-surgical pain and improved surgical outcomes, in addition to better overall quality of life.

Koehn³, Kelly English⁴, Allan Stordy⁵ and Linda Li^{1,6}, ¹Arthritis Research Canada, Richmond, BC, Canada, ²Physical Therapy, The University of British Columbia, Vancouver, BC, Canada, ³Arthritis Consumer Experts, Vancouver, BC, Canada, ⁴Arthritis Patient Advisory Board, Arthritis Research Canada, Richmond, BC, Canada, ⁵Canadian Skin Patient Alliance, Calgary, AB, Canada, ⁶Department of Physical Therapy, The University of British Columbia, Vancouver, BC, Canada

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Epidemiology and Public Health Poster II – ARHP

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Findings from health research using “big data” (large sets of routinely-collected healthcare data) have benefitted individual arthritis patients and society as-a-whole. However, growing public concerns about personal information being accessed for unintended purposes could erode trust in this research and its potential benefits. We conducted this study to elucidate the public's views on the role of big data in health research.

Methods: This was a partnership between researchers at Arthritis Research Canada and consumer-patient leaders from three joint and skin disease patient organizations. We developed an online survey assessing: 1) Perceptions about the role of big data in health research and access and privacy controls, 2) Willingness to participate in projects using big data, 3) Major concerns, and 4) Interest in learning more. Respondents were recruited via the websites, e-mail lists, and social media channels of Canadian health research groups, including the three patient organisations.

Survey: Our three-part, ~20-min. survey was open from Jan-Aug 2017. Part 1 asked about respondents' familiarity and initial perceptions about using big data in health research. In Part 2 they were provided with some background information, and then asked their views on specific topics (i.e. benefits of using big data, data access and privacy). In Part 3 respondents were queried further about their perceptions of big data and ongoing educational needs.

Analysis: For each question, we calculated the percentage of respondents selecting each response option.

Results: 151 individuals completed the survey (117=77% female; 47% aged 50-69 years, 28% aged 30-49 years). 101 (67%) had chronic disease.

At the start of the survey (Part 1), 79% of respondents felt positively about the use of big data for health research and 95% knew the term “electronic health/medical record”, but only 58% knew the terms “administrative data/health database”. In Part 2, respondents felt the ability to study large numbers of people (selected by 73%) and long-term effects and rare events (76%) were the top benefits of using big data; long-term treatment effects and disease complications were the most important research topics (see Table).

59% felt the use of big data should be approved by university research ethics boards, and 67% wanted to learn more about how data stewards grant access to data. De-identifying personal information was the most important privacy measure (selected by 89%).

At the end of the survey (after viewing background information about big data), 93% felt positively about big data (vs. 79% at the start), but only 58% were confident about privacy and security measures in place.

Conclusion: While ethics board approvals and de-identification of healthcare data were highly regarded, more public education, especially about data access and privacy controls, may enhance public trust about using big data in health research.

Table: Percentage of Respondents Selecting Each Feature and Data Access/Privacy Measure Described in Part 2 of the Survey (Most- to Least-Frequently Selected)

Restless Sleep Trajectories over 8 Years: Data from the Osteoarthritis Initiative

Jing Song¹, Julia (Jungwha) Lee¹, Yvonne C. Lee¹, Alison H. Chang¹, Pamela Semanik², Linda S. Ehrlich-Jones¹, Rowland W. Chang¹ and Dorothy D. Dunlop¹, ¹Northwestern University, Chicago, IL, ²College of Nursing, Rush University, Chicago, IL

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Epidemiology and Public Health Poster II – ARHP

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Sleep disturbance has been recognized as a major public health issue. Evidence has shown that individuals with osteoarthritis (OA) are more likely to have disturbed sleep. However, it is unknown if distinctive patterns of sleep disturbance over time exist among adults with OA. The purpose of this study is to examine trajectories of restless sleep in adults with or at high risk for knee OA and to identify modifiable risk factors associated with these trajectories.

Methods: We analyzed baseline to 8-year data from Osteoarthritis Initiative. Restless sleep was identified annually as self-report of 3 or more nights of restless sleep during the past week. Group-based modeling (PROC TRAJ) was conducted to identify homogeneous clusters of restless sleep trajectories over 8 years. Baseline descriptive (age, sex, race, education, BMI, Kellgren-Lawrence grade, chronic knee symptoms, prior knee injury) and potentially modifiable (cardiovascular disease, high depressive symptoms, pulmonary disease, bodily pain interference, smoking, WOMAC function, gait speed, PASE physical activity) factors were examined using multiple logistic regression to identify predictors for membership in restless sleep trajectories.

Results: Four distinct restless sleep trajectories (Figure) were identified from the 4290 participants (mean age 61.1 years [SD 9.1], 58% women, mean BMI 28.5 kg/m² [SD 4.8]): good - persistently low (11.4%), worsening - low to high (66.4%),

poor - persistently high (9.5%), improving - high to low (12.7%) probabilities of restless sleep. Compared to the good group, individuals with worsening probabilities for restless sleep were more likely to report at baseline high depressive symptoms (odds ratio [OR]=2.04, 95% confidence interval [CI]=1.37, 3.05), pain in non-knee joints (OR=1.63, 95% CI=1.17, 2.26), smoking (OR=1.61, 95% CI=1.05, 2.47), and pulmonary disease (OR=1.46, 95% CI=1.06, 2.02), and were less likely to report physical activity scores above the median (OR=0.77, 95% CI=0.61, 0.96), adjusting for descriptive and other modifiable risk factors. Compared to the poor group, those who improved by reducing restless sleep probabilities were less likely to have baseline high depressive symptoms (OR=0.56, 95% CI=0.39, 0.81).

Conclusion: We identified four distinctive restless sleep trajectories among people with or at high risk of knee OA. Baseline factors including less physical activity, high depressive symptoms, pain in other joints, smoking, and pulmonary disease independently predicted a worsening probability trajectory of restless sleep. Future interventions may want to target these factors to address sleep quality.

Abstract Number: 1166

Friend or Foe: Does Walking at Higher Intensities Increase or Decrease the Risk of Total Knee Arthroplasty over Five Years?

Hiral Master¹, Louise Thoma², Meredith Christiansen¹, Dana Mathews³, Erin Macri², Melissa Ziegler⁴, Joshua J. Stefanik⁵ and Daniel White⁵, ¹Physical Therapy and Biomechanics and Movement Science, University of Delaware, Newark, DE, ²Physical Therapy, University of Delaware, Newark, DE, ³Physical Therapy, Biomechanics and Movement Science, University of Delaware, Newark, DE, ⁴University of Delaware, Newark, DE, ⁵Department of Physical Therapy, University of Delaware, Newark, DE

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Epidemiology and Public Health Poster II – ARHP

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: There is contradicting evidence whether walking more is associated with structural worsening and total knee arthroplasty (TKA). One reason for inconsistent findings is that walking can occur at different intensities. However, little is known about the association of walking intensity with the risk of TKA. The purpose of this study was to examine the extent to which walking intensity is associated with the risk of TKA over five years in adults with or at high risk of knee OA.

Methods: Using data from the Osteoarthritis Initiative (OAI), we included participants who did not have TKA at or before the 48-month follow-up visit, which we considered our study baseline. Time spent in different walking intensities was quantified by step cadence recorded by an accelerometer (Actigraph GT1M). We defined <1 step/min as non-walking,

1-49 steps/min as very-light, 50-100 steps/min as light, and >100 steps/min as moderate-to-vigorous intensities of walking. Time to TKA was quantified in months from the baseline visit date to TKA date if received in the subsequent five years, i.e., until the 108-month OAI visit. Participants without TKA at the 108-month OAI visit or lost to follow-up were censored. We examined effects of replacing time not walking with walking at very-light, light, or moderate-to-vigorous intensities with the risk of TKA over five years using temporal substitution within a Cox proportional hazard model. Specifically, we calculated hazard ratios (HR) and 95% confidence interval (CI) adjusted for potential confounders. We repeated analyses restricting our sample to participants with radiographic (ROA) and symptomatic (SxOA) knee OA (see Table).

Results: Of the 1854 participants without TKA at baseline and who wore the accelerometer for ≥ 4 days ([mean \pm sd] age: 65.0 ± 9.1 years, BMI: 28.4 ± 4.8 kg/m², 55% female), 108 (6%) participants received a TKA over five years. Replacing 5 minutes of non-walking time with 5 min of walking at moderate-to-vigorous intensity reduced the risk of TKA by 16% (HR 0.84, 95% CI [0.72, 0.98]). There was no effect for very-light and light intensity. We found similar results for ROA and SxOA only samples (see Table).

Conclusion: Replacing time not walking with walking at moderate-to-vigorous intensity was associated with not more but less risk of TKA over five years. Our findings suggest that small changes in walking behavior could delay the need for TKA in people with or at high risk of knee OA.

The Role of Fear-Avoidance Model on Pain and Disability in Knee Osteoarthritis Patients

Leticia Leon^{1,2}, Marta Redondo², Sara Lopez de Felipe², Daniel Garriguez³, Lydia A Alcazar⁴ and Luis Rodriguez-Rodriguez⁵, ¹Rheumatology Department, Hospital Clínical San Carlos, and IdISSC, Madrid, Spain, ²Health Sciences, Universidad Camilo Jose Cela, Madrid, Spain, ³Orthopedics Unit, Hospital Clinico San Carlos, Madrid, Spain, ⁴Rheumatology Department and Health Research Institute (IdISSC), Hospital Clinico San Carlos, Madrid, Spain, ⁵Department of Rheumatology, Hospital Clínico San Carlos, Madrid, Spain

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Epidemiology and Public Health Poster II – ARHP

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The model of Fear-Avoidance of pain (anxiety, catastrophization and hypervigilance) appears when the pain has maladaptive interpretations, being associated with greater pain and limitations of the activity. Our purpose was to determine the influence of the Fear-Avoidance model in the levels of pain and disability in knee osteoarthritis patients.

Methods: Patients diagnosed with knee osteoarthritis in the last year of our outpatient clinic who gave their consent completed the evaluation battery and performed the experimental task of hypervigilance. The Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) was used to assess pain, stiffness and function of the patient. The variable pain anxiety was measured by the Pain Anxiety Symptoms Scale (PASS-20), *catastrophization* by the Pain Catastrophizing Scale (PCS), and hypervigilance with an attention task (dot-probe) using E-Prime Software. Secondary variables as sociodemographic (age, sex, work status), clinical (previous knee surgeries and radiological damage with the Kellgren-Lawrence scale [KL] and treatment (analgesic drugs) were also recorded. Descriptive, bivariate and linear regression models (adjusted by secondary variables) were performed to determine the variables of the Fear-Avoidance model associated with pain and disability.

Results: A total of 33 patients with knee osteoarthritis were included in the study. 70% were women with a mean age of 77.4 ± 10.3 years. 8.5% had previous surgeries. 27.5% were active workers, 44.8% were retired and 25.5% housewives. 82% were on non-opioid drugs, and 11.4% weak opioids. Radiographic disease severity was 51.8% early stage (K/L <2), 48.2% advanced-stage (K/L >2). In bivariate analyses, for global WOMAC, pain anxiety, *catastrophization*, and work status (active worker) were founded as predictors. For the pain subscale, pain anxiety and age result statistical significant. Finally for physical function subscale pain anxiety *catastrophization* and work status (active worker) were founded predictors. Regression models adjusted for secondary variables, included all variables that showed significant differences or trend ($p=0.1$) in the bivariate. In multivariate models, for global WOMAC, the pain anxiety achieved signification ($p=0.005$). For the pain subscale, active work status was founded a predictor ($p=0.04$), with a tendency for pain anxiety ($p=0.06$). For

the physical function subscale, pain anxiety was significant ($p=0.002$).Hypervigilance showed a tendency to increase the stiffness ($p=0.05$) and worsen the physical function ($p=0.1$) and the global WOMAC ($p=0.1$).

Conclusion: Variables that integrate the Fear-Avoidance model were the main predictors of the total WOMAC and its subscale, together with the active work status in the pain scale. Identifying these variables in knee osteoarthritis patients will allow us to explain the high levels of pain or disability in patients, which sometimes do not correlate with their damage or injury, and can complicate the prognosis or evolution.

Is a Change in Physical Activity Associated with a Change in Health-Related Quality of Life after Total Knee Replacement?

Meredith Christiansen¹, Louise Thoma², Hiral Master¹, Dana Mathews³, Erin Macri² and Daniel White⁴, ¹Physical Therapy and Biomechanics and Movement Science, University of Delaware, Newark, DE, ²Physical Therapy, University of Delaware, Newark, DE, ³Physical Therapy, Biomechanics and Movement Science, University of Delaware, Newark, DE, ⁴Department of Physical Therapy, University of Delaware, Newark, DE

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Epidemiology and Public Health Poster II – ARHP

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Health-related quality of life (HRQoL) is the impact health status has on quality of life. The ability to maintain or increase physical activity (PA) is important for the physical domain of HRQoL in older adults. However, little is known about this relationship for people after TKR, who often elect to have surgery due to decline in HRQoL. As well, this association may differ for younger vs. older adults since also HRQoL declines with age. Therefore, the purpose of this study was to examine the association of a change PA at least 1-year prior to TKR to 1-year after TKR stratified by older and younger adults with a change in HRQoL after TKR.

Methods: We used data from the Osteoarthritis Initiative (OAI) and included participants who had a TKR after enrolling in the study. The exposure was change in self-reported PA at least 1-year before or after TKR. We quantified PA using established categories from the Physical Activity Scale for the Older (PASE) as Low PA ≤ 94 , Moderate PA 95-146, High PA 147-206, Very High PA ≥ 207 . Next we classified study participants who stayed in the same category or went up one more PA levels as Increased/Maintained PA, and those who went down one level as Decreased PA. We stratified by the median age of 68 to classify older and younger adults. Our primary outcome was a change in HRQoL before TKR to after TKR which was quantified using 12-item Short Form Survey Physical Component Summary (PCS). We dichotomized PCS scores using the minimal clinically important difference of 2; < -2 Decline HRQoL and ≥ -2 Maintained HRQoL. We

moderate-to-vigorous intensity		0.86 (0.73, 1.01)

^a Adjusted for age (continuous), sex, race, BMI, and self-reported TKA, osteoarthritis, pain, the presence of OOA, joint, or immobilization, and previous knee surgery.

^b ROA was defined as participants with Kellgren and Lawrence grade ≥ 1 in every knee joint.

^c SaOA was defined as participants with OOA and pain, lasting or affecting at least days of a month during the previous year.

Table: Adjusted odds ratios and 95% confidence intervals for Decline in HRQoL		
	Equivalent Decline in HRQoL, n (%)	*Adjusted OR (95%CI)
< 65 years of age		
Decreased PA (n=35)	7 (21.1)	1.0 (REFERENCE)
Increased/Maintained PA (n=71)	15 (21.1)	0.79 (0.29-2.7)
≥ 65 years of age		
Decreased PA (n=37)	13 (35.1)	1.0 (REFERENCE)
Increased/Maintained PA (n=78)	12 (15.1)	0.28 (0.10-0.82)
*Adjusted for baseline age, BMI, sex (sex=other), race (race=other), education (education=other), income (income=other), marital status (marital status=other), smoking (smoking=other), comorbidity (comorbidity=other), depression (depression=other), knee pain (knee pain=other) and 12-item SF-36 (SF-36=other) (n=4486).		
95% CI = 95% confidence interval.		

calculated odds ratios and 95% confidence intervals (95%CI) to examine the association between change in PA with a change HRQoL in older and younger adults adjusted for age, body mass index (BMI), sex, race, education, income, marital status, smoking status, comorbidity, depression, and knee pain (Table).

Results: Of the 421 participants who had unilateral or bilateral TKR since enrollment, 220 participants had complete PASE and PCS data (61% female, age 64 ± 8 years, BMI 29.9 ± 4.8 kg/m²). Older adults who Increased/Maintained PA after TKR had 71% (0.29-0.82) less risk of a Decline in HRQoL compared to those who Decreased PA after TKR (Table). Change in PA was not associated with HRQoL in younger adults (Table).

Conclusion: Decreasing PA after TKR may be an important risk factor for older adults, who already engage in less PA than younger adults. Increasing and/or maintaining PA after TKR may protect against a decline in HRQoL in older adults.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Epidemiology and Public Health Poster II – ARHP

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Latent and modifiable factors, such as depressive symptoms, may affect the course of knee OA. Depression is clinically heterogeneous, and effects on pain and disability may manifest differently by depressive symptom subtypes. This study evaluated trajectories of pain and disability by depressive symptom subtypes among individuals who have or are at risk for knee OA.

Methods: Participants (n=4486) were reenrolled in the Osteoarthritis Initiative. Latent class analysis was applied to the 20-Item Center for Epidemiological Studies Depression Scale measured at baseline and used to assign participants to one of four depressive symptom subtypes identified previously (“No Symptoms”, “Catatonic”, “Anhedonic”, and “Melancholic”). OA disease severity was assessed annually over four years using the pain and disability subscales (rescaled range = 0-100) of the WOMAC. Analyses were stratified by those with (n=1626) and without (n=2860) symptomatic knee OA at baseline, defined as pain on most days of a month in the past 12 months. Propensity score weights were used to balance the four depressive symptom subtypes on baseline confounders: age, sex, race, education, smoking status, alcohol consumption, health insurance, employment status, BMI, Kellgren-Lawrence grade, history of knee injury, analgesic use, and total WOMAC score. Non-response weights were computed with logistic regression and were used to account for missing data. Weighted estimating equations were used to estimate pain and disability trajectories and to evaluate between-group differences in disease severity by baseline depressive symptom subtype during the follow-up period.

Results: Among participants with symptomatic knee OA, the “Melancholic” depressive symptom subtype had more severe pain ($\beta=3.61$; 95% CI: -0.15, 7.39; $P=0.060$) and significantly greater disability ($\beta=5.36$; 95% CI: 1.41, 9.32; $P=0.007$) than the “No Symptoms” subtype (Table 1). In individuals without symptomatic knee OA, the “Anhedonic” subtype had significantly worse pain ($\beta=1.33$; 95% CI: 0.20, 2.47; $P=0.020$) and disability ($\beta=1.34$; 95% CI: 0.27, 2.42; $P=0.014$) compared to the “No Symptoms” subtype (Table 1). Differences in pain and disability between the “Catatonic” and “No Symptoms” subtypes were small and not statistically significant in both participants with and without symptomatic knee OA.

Conclusion: Findings indicate that the effects of depressive symptoms on pain and disability are largest in persons with symptomatic knee OA who exhibit “Melancholic” symptom logy. “Melancholic” depressive symptoms are characterized by the inability to feel pleasure, decreased energy and movement, and somatic complaints; and thus, may be a modifiable risk factor for worsening disease severity and potential target for intervention in patients with symptomatic knee OA.

Table 1. Differences in pain and disability by baseline depressive symptom subtype among Osteoarthritis Initiative participants with (n=1626) and without (n=2860) symptomatic knee OA over four years of follow-up.

Sex-Specific Associations between Systemic Inflammatory Cytokines and Osteoarthritis Knee Pain

Anthony V. Perruccio^{1,2}, J. Denise Power¹, Mayilee Canizares¹, Elizabeth M. Badley^{1,2}, Mohit Kapoor¹, Rajiv Gandhi¹ and Y. Raja Rampersaud¹, ¹Arthritis Program, Krembil Research Institute, University Health Network, Toronto, ON, Canada, ²Dalla Lana School of Public Health, University of Toronto, Toronto, ON, Canada

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Epidemiology and Public Health Poster II – ARHP

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Significant challenges remain in mitigating OA pain and despite growing evidence of sex differences, including in pain and in response to NSAIDs, sex has received little attention in clinical studies of potential OA drug treatment strategies. In this study, we investigated the association between knee-specific OA pain and systemic markers of inflammation, focusing on whether associations differed by sex.

Methods: Study participants were 231 patients with knee OA scheduled for total joint arthroplasty at a tertiary care hospital in Toronto, Canada. Eligibility: 35+ years of age; English fluency. Exclusions: acute trauma/injury or inflammatory arthritides. Health questionnaires were completed and blood samples drawn in-clinic prior to surgery. Questionnaires collected data on knee pain (WOMAC pain subscale) and sex, age, height and weight (used for BMI calculation), comorbidity, depressive symptoms (HADS depression scale), symptomatic joint count, and pain medication use. Blood cytokine analyses included IL-6, -8, -10, -1 β and TNF- α using Luminex bead-based ELISA assays. A series of linear regression models were estimated with knee pain as the outcome. The final model included sex, age, BMI, comorbidity count, depressive symptom score, symptomatic joint count, log-transformed cytokine concentrations, and interaction terms between sex and any factors found to have sex-specific influences. Sensitivity analyses: final model a) in individuals aged 55+ only (age-based proxy for post-menopausal status) and b) with consideration for medication use.

Results: Participants were of mean age 65 years (range 43-89); women comprised 57.6% of the sample. Women had higher comorbidity and joint counts, and worse depressive symptoms and knee pain scores than men. No sex differences were found in median cytokine concentrations, except for higher TNF- α in men (8.1 vs. 6.9 pg/ml; $p=0.006$). In adjusted linear regression, initially not allowing for sex-specific effects, only 2 cytokines were significantly associated with knee pain scores; higher IL-10 with lower pain ($p=0.002$), and higher TNF- α with worse pain ($p=0.031$). With consideration of potential sex-specific effects, the association between knee pain and IL-10 and TNF- α remained unchanged and was similar for women and men. However, the association between knee pain and IL-8 (interaction term $p<0.001$), IL-6 (interaction term $p=0.023$) and IL-1 β (interaction term $p=0.047$) differed significantly between women and men. In addition, higher BMI for men, and higher depressive symptoms and joint count for both sexes were significantly associated with worse knee pain scores. Findings from sensitivity analyses were consistent with primary analyses.

Conclusion: While cytokine-targeted treatments exist, indiscriminate use in OA populations may limit effectiveness. Our findings provide evidence of sex-specific associations between individual inflammatory cytokines and knee OA pain, and suggest that sex-specific targets of anti-inflammatory treatments for OA need to be considered.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Epidemiology and Public Health Poster II – ARHP

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Measures of socioeconomic status (SES) have been shown to be associated with increased OA and disability. However, it is unknown whether changes in SES measures over time can predict death. We therefore examined whether SES measured over time was associated with death among those with radiographic OA (rOA).

Methods: We analyzed data from 2,605 participants in a community-based cohort of African American (AA) and Caucasian men and women aged ≥ 45 years. Participants completed assessments at baseline and up to 3 follow-ups and all had rOA, defined as Kellgren-Lawrence grade ≥ 2 in at least one knee/hip. SES measures were 1) high school (HS) education ($< \text{HS diploma}$ vs. $\geq \text{HS diploma}$), 2) professional occupation (PRO) (non-PRO vs. PRO), and 3) block group poverty (BGP) ($\geq 20\%$ BGP vs. $< 20\%$ BGP). Date of death was assessed through December 31, 2015. Comorbidities and demographic characteristics were considered as covariates (see Table legend). Multiple imputation was used to impute missing values of covariates. Follow-up time was calculated from baseline until death or censoring which took place when a participant was lost to follow-up or reached the end of study period. Cox proportional hazards regression with time-varying covariates (TVC) changing at irregular intervals was used to estimate hazard ratios (HR) and 95% confidence intervals (CI) for all-cause mortality. In the TVC analysis, SES and covariates were allowed to change from “unexposed” to “exposed” from prior assessments to ensure HRs accurately represent the risk of mortality as one’s SES and covariate status changed. Additional analyses stratified by sex, race and age were carried out.

Results: Mean age at baseline was 65.4 years, with 64.0% women and 34.1% AA. Overall, 37.7% had $< \text{HS}$ education, 41.3% lived in areas with $\geq 20\%$ BGP, and 61.0% had a non-PRO occupation. Through 2015 there were 1,154 deaths (44.0%), and median follow-up time was 10.2 years.

In covariate adjusted models where individual SES measures were considered, we observed an increased risk of all-cause mortality in participants with $< \text{HS}$ education (HR=1.30, 95% CI=1.15-1.48) and non-PRO occupation (HR=1.21, 95% CI=1.06-1.39) (Table). However, when all SES measures were considered simultaneously, only $< \text{HS}$ education remained associated with death (HR=1.25, 95% CI=1.09-1.43). In stratified analyses, the observed association with education was restricted to women. Living in an area with high BGP appeared to be a predictor of mortality among Caucasians only.

Table. Hazard ratios for the association between SES measures and all-cause mortality

	<HS Education HR (95% CI)	Non-professional Occupation HR (95% CI)	Block Group Poverty ≥20% HR (95% CI)
Overall			
Single SES measure‡	1.30 (1.15-1.48)	1.20 (1.04-1.38)	1.13 (0.99-1.28)
All SES measures§	1.25 (1.09-1.43)	1.12 (0.95-1.28)	1.10 (0.97-1.26)
Stratified			
Men§	1.07 (0.86-1.33)	1.25 (0.99-1.58)	1.18 (0.96-1.44)
Women§	1.40 (1.17-1.67)	1.02 (0.84-1.25)	1.09 (0.92-1.29)
African American§	1.33 (1.05-1.69)	1.05 (0.78-1.42)	0.98 (0.79-1.22)
Caucasian§	1.20 (1.02-1.43)	1.13 (0.95-1.35)	1.17 (1.00-1.37)
Age <65 years§	1.39 (1.05-1.84)	1.15 (0.82-1.60)	1.27 (0.97-1.66)
Age ≥65 years§	1.21 (1.03-1.42)	1.10 (0.93-1.30)	1.05 (0.91-1.22)

‡ Adjusted for age, sex, race, birth cohort, enrollment wave, ever alcohol drinker, ever smoker, obesity, physical activity, cancer, liver, CVD, diabetes, high blood pressure, depressive symptoms, NSAIDs

§ Additionally adjusted for other SES measures

Conclusion: As noted in other chronic conditions, we demonstrated increased mortality among individuals with knee or hip OA with low education, particularly among women. Our results were independent of other comorbidities and demographic measures linked to increased mortality. Individuals with OA and lower education may represent a high risk group in need of more focused clinical care and resource allocation.

Symptoms Compatible with Osteoarthritis and Self-Reported Osteoarthritis in the Population: Findings from the Canadian Longitudinal Study on Aging

Elizabeth M. Badley^{1,2}, Calvin Yip² and Anthony V. Perruccio^{1,2}, ¹Dalla Lana School of Public Health, University of Toronto, Toronto, ON, Canada, ²Arthritis Program, Krembil Research Institute, University Health Network, Toronto, ON, Canada

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Epidemiology and Public Health Poster II – ARHP

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: To report on the prevalence of self-reported doctor-diagnosed knee, hip and hand osteoarthritis (OA) in the population aged 45-85 years, and the prevalence of knee, hip and hand symptoms compatible with an OA diagnosis.

Methods: Data are from the baseline 'Comprehensive' subsample of the population-based Canadian Longitudinal Study on Aging (CLSA) (n=30,097, ages 45 to 85 years). Respondents were asked whether a doctor had ever told them they had arthritis, including OA in the knee, hip, or hand. All CLSA respondents, irrespective of arthritis diagnosis, were asked about symptoms compatible with OA (Sx-OA). These were pain during the past 4 weeks on most days in the knee, hip (groin or upper inner thigh) or hand (base of thumb or small joints close to fingernails), swelling in the knee, pain in the knee or pain in the hip while walking down stairs or climbing down slopes, and enlargement of the hand joints.

Results: Overall 53% (n= 16,024) of the sample reported either doctor diagnosed OA or Sx-OA in at least one of the 3 sites (knee, hip or hand). Specifically, 26% reported OA and 27% reported Sx-OA but not OA. 80% of those with OA and 37% of those without OA reported Sx-OA. Over 40% of respondents with OA and over 50% of those with Sx-OA but not OA were aged less than 65. Of respondents with OA, 57% reported knee OA, 32% reported hip OA, and 49% reported hand OA, with 30% reporting OA at more than one site. Of individuals with only Sx-OA, 55% reported knee symptoms, 12% reported hip symptoms, and 54% reported hand symptoms, with 20% of respondents reporting Sx-OA at more than one site. The proportion with OA at more than one site increased with age, from 20% for respondents aged 45-54 to 35% for respondents aged 75-85, with the corresponding increase for only Sx-OA from 17% to 23%. The proportion of respondents reporting overall general pain (not specific to arthritis) was 55% for those with OA, 40% for those with only Sx-OA. There was little variability in this proportion by age for both these groups. The proportion needing help with at least one daily living activity was 27% for the OA group, and 17% for the only Sx-OA group with an increase with age for both groups.

Conclusion: Similar proportions of this population-based sample reported having OA (knee, hip or hand) or joint symptoms compatible with OA in these joints. Though overall proportions differed, similar age and multijoint patterns were found between OA and Sx-OA without OA groups. The proportion of Sx-OA without OA reporting general pain or needing help was somewhat lower than those with OA but still substantial. Whether Sx-OA represents as yet undiagnosed OA is unknown until follow-up data from the next cycle of the CLSA are available. The high proportion of people with OA-compatible symptoms represent a potential target for the attention of primary care physicians, arthritis organizations and public health to encourage seeking a diagnosis and to stress the value of participation in physical activity and other arthritis pain management strategies.

Measuring the Advanced Clinician Practitioner in Arthritis Care (ACPAC) Program Trained Extended Role Practitioner (ERP) Workforce in Canada: A Profile of Practice Settings, Roles and Participation in Models of Arthritis Care in Canada

Katie Lundon¹, Rachel Shupak² and Amanda Pullan³, ¹University of Toronto, Office of Continuing Professional Development, Faculty of Medicine, Toronto, ON, Canada, ²Medicine, St. Michael's Hospital, Toronto, ON, Canada, ³Office of Continuing Professional Development, Faculty of Medicine, Toronto, ON, Canada

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Health Services Research Poster II – ACR/ARHP

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 9:00AM-11:00AM

Background/Purpose: 1. To measure and map the ACPAC ERP workforce in Canada. 2. To present a snapshot of general practice characteristics relating to the ACPAC-trained ERP including the nature of their settings, roles and participation in the workforce as ERPs, and models of arthritis care in which they practise.

Methods: As part of quality assurance measures, graduates of the ACPAC program (www.acpacprogram.ca) were asked to contribute data pertaining to their current practice in the following categories: discipline, geographic location/setting (urban, community, remote/rural), participation in workforce as an ERP (% FTE), nature and percent of practice (orthopaedic, rheumatology) as an ERP, age groups treated, and participation in different models of arthritis care. General practice locations of ACPAC program trained ERPs were geospatially plotted by province across Canada, as well as superimposed upon Ontario-derived LHIN (local health integrated network) based maps representing Rheumatologist distribution in Ontario.

Results: There have been 69 graduates of the ACPAC program with 66 in the current workforce (2 retired, one deceased); base disciplines include Physical Therapists (n=49), Occupational Therapists (n=13) and Registered Nurses (n=7). 9 remain working in traditional roles and 3 are in leadership roles leaving a residual of 54 in active ERP roles. The practice settings of these ERPs are as follows: urban (50%); community (35%); and remote/rural (15%). The nature and percent of practice of these ERP roles are as follows: triage rheumatology 100% FTE (20%) and fractional <100% (46%); triage orthopaedics 100% FTE (6%) and fractional <100% (15%); triage rheumatology and orthopaedics 100% FTE (9 %) and fractional <100% (4%). The patient age-groups treated are adults/seniors (83%), adults and paediatrics (7%), and paediatrics (10%). The ACPAC ERPs currently practise in community-based home care, community-based Rheumatologists' clinics, telehealth/ECHO, family health teams, hospital-based, visiting Rheumatologist and visiting ERP/ fly in models of arthritis care.

Conclusion: It is important to understand the distribution and nature of practice settings of the highly trained advanced clinician practitioners in arthritis care, and recognize their potential to improve capacity in Rheumatology services delivered through different models of arthritis care. Aside from resource planning, this information is a practical step toward achieving improved connectivity between Rheumatologists and a network of ACPAC program trained ERPs which will ultimately benefit access to arthritis care for patients. Next steps include issuing a Pan-Canadian workforce survey which will explore attributes of all identified non-physician arthritis care specialists (Stand Up and Be Counted Too (2).

Comparative Cost per Response for Four Clinical Outcomes of Tocilizumab Monotherapy Versus Adalimumab Monotherapy in a Head-to-Head Randomized Double-Blind Superiority Trial in Patients with Rheumatoid Arthritis

Jennie H. Best and Jinglan Pei, Genentech, Inc., South San Francisco, CA

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Health Services Research Poster II – ACR/ARHP

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 9:00AM-11:00AM

Background/Purpose: The cost-effectiveness of different biologic therapies is an important component in guiding treatment decisions for patients with rheumatoid arthritis (RA). The objective of this analysis was to compare drug and adverse event costs and cost per successful clinical response with tocilizumab (TCZ) monotherapy vs adalimumab (ADA) monotherapy in patients with RA.

Methods: Patients in the ADACTA trial were randomized to either TCZ 8 mg/kg intravenously every 4 weeks or ADA 40 mg subcutaneously every 2 weeks as monotherapy for 24 weeks. Drug costs of \$397.71 per 80-mg vial for TCZ (plus \$136 administration cost per infusion) and \$2220.62 per 40 mg for ADA were based on WAC drug prices (July 2017). Outcomes included patient-level drug costs and cost of hospitalization due to adverse events, and cost per response. Cost per response was calculated by dividing the mean drug plus administration cost by the proportion of patients achieving Disease Activity Score-28 joints (DAS28) < 2.6 (remission) or American College of Rheumatology response criteria 20%/50%/70% (ACR20/ACR50/ACR70). The proportions of patients achieving DAS28 < 2.6, ACR 20, ACR50 and ACR70 were 39.9%, 65.0%, 47.2% and 32.5% for TCZ, respectively, and 10.5%, 49.4%, 27.8% and 17.9% for ADA, respectively; $P < 0.0001$, $P = 0.0038$, $P = 0.0002$, $P = 0.0023$ for TCZ vs ADA, respectively. Hospitalization costs were calculated using the daily hospital cost of \$2433 (2017) and number of hospital days.

Results: Among the 163 patients treated with TCZ and 162 with ADA, mean total drug and administration costs per patient over 24 weeks were \$16,674.74 and \$23,357.63, respectively. Mean drug and administration costs were lower per each clinical response achieved with TCZ compared with ADA (DAS28 < 2.6: \$41,791 vs \$222,454; ACR20: \$25,653 vs \$47,283; ACR50: \$35,328 vs \$84,020; ACR70: \$51,307 vs \$130,490). The total hospital days/costs were 32/\$77,856 for TCZ and 43/\$104,619 for ADA.

Conclusion: In this comprehensive comparative assessment, the cost to achieve all four clinical responses was lower for patients receiving TCZ than for ADA.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Health Services Research Poster II – ACR/ARHP

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 9:00AM-11:00AM

Background/Purpose: Outcome inequities exist for Indigenous patients in Canada with inflammatory arthritis conditions. Primary health services innovations that better support urban Indigenous patients exist, but these innovations have not been adopted broadly by specialty care systems. To inform specialty care systems and providers so as to better respond to urban Indigenous patient needs, develop care alliances with patients and primary health service providers, and ultimately resolve care gaps, we conducted a qualitative study using novel patient-driven methodology to identify experiences in accessing and navigating the health system for inflammatory arthritis care.

Methods: The Patient and Community Engagement Research Program (PaCER) method is a qualitative research method led by patients using an iterative three phase process: *Set*, *Collect* and *Reflect*. The *Reflect* phase was completed with urban First Nations and Métis patients engaged in a multidisciplinary urban Indigenous primary health service with integrated rheumatology specialty services using an adapted interview guide and referring to the themes identified in a parallel non-First Nations and non-Métis inflammatory arthritis patients study. Experiences and challenges in: 1) Initial access to rheumatology care; 2) Ongoing access to rheumatology care; 3) Information about the disease and resources for those living with arthritis; 4) Fear of the future; and 5) Collaborative and continuous care; were explored. Multiple rounds of coding, theme determination and review were conducted to ensure authentic representation of patient experiences, and full incorporation of Indigenous perspectives in the research.

Results: Eleven First Nations and Métis women with inflammatory arthritis representing a spectrum of recent-onset to established disease, and ranging from 39-70 years of age, consented to be interviewed. Access to care, continuity of care and collaboration were facilitated by a supportive and culturally safe environment that addressed care needs, assisted patients in navigating complex networks of primary and tertiary providers and social services, and that recognized the value in offering traditional approaches to health and wellness. Despite the overall positive experiences reported by participants, there was still tension and discomfort around pharmacotherapy for inflammatory arthritis. Experiences of incomplete effect, occurrence of side effects and fear of addiction were shared.

Conclusion: The results draw attention to the need for specialty care system change to build on culturally responsive models of care that already exist. Initial access and continuity of specialty care can be facilitated with collaboration between primary and specialty care in an urban Indigenous health service model. Enhanced patient education and resource coordination is required, as is support for decisions around pharmacotherapy to optimize inflammatory arthritis management.

Session Title: Health Services Research Poster II – ACR/ARHP

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 9:00AM-11:00AM

Background/Purpose: Chronic musculoskeletal pain (e.g. back and neck pain, pain due to arthritis, leg pain, and arm pain) affects up to 24% of the general population. Various approaches, both pharmacologic and nonpharmacologic, have been developed to manage chronic pain. With respect to pharmacological treatments, the overuse of opioid medications has led to an epidemic, even though many other evidence-based treatments are available and effective. Current guidelines recommend pharmacologic and nonpharmacologic treatments should be optimized before initiating a trial of opioids. The goal of this study was to explore initial clinical management of chronic musculoskeletal pain. We sought 1) to explore what treatments are prescribed at the initial visit with the physician for chronic musculoskeletal pain: i.e. medications, physical therapy, counseling; and 2) to describe factors associated with these prescribed treatments or services: more specifically clinician-related factors and patient-related factors.

Methods: We analyzed data from the National Ambulatory Medical Care Survey and National Hospital Ambulatory Medical Care Survey-Out Patient Department (NAMCS) between 2007 and 2015. Visits with a new chronic musculoskeletal pain condition were identified using pre-determined diagnostic criteria. We documented the following treatment prescriptions: opioids, non-opioid pain medication, physical therapy, mental health counseling, stress management, injury prevention, exercise, diet, weight reduction and health education. We used logistic regression to explore associations between patient and provider factors and each of these prescription categories. Data were programmed using SUDAAN and descriptive statistics are presented. Logistic regression models to determine physician and patient-related factors associated with treatment prescription will be calculated.

Results: There were 19,341 *initial visits* over the 9-year period with a diagnosis of chronic musculoskeletal pain in the NAMCS database translating into 528,715,590 weighted *initial visits*. Mean age of patients at these initial visits was 49.4 years (95% confidence interval: 48.7-50.0) and 58.9% were female. The proportions of patients that were prescribed the following medications: NSAIDs, opioids, acetaminophen and muscle relaxants were 27.98, 19.15, 16.8, and 10.19% respectively. The proportion of visits with referral to physical therapy was 9.73%, counseling for mental health 0.3%, stress management 0.92%, injury prevention 5.52%, exercise 10.60%, diet 6.47%, weight reduction 2.66%, and health education 14.03%. Ongoing analyses will elucidate patient and physician related factors associated with these various categories of treatment prescriptions.

Conclusion: There is a high frequency of visits for chronic musculoskeletal pain conditions. The frequency for opioid prescription was nearly double that of physical therapy. This result is troubling in view of the evidence and current guidelines that support non-opioid treatments for chronic musculoskeletal pain conditions.

Patients' and Healthcare Professionals' Resource Preferences for a Knowledge Translation Toolkit for Hip and Knee Replacement Rehabilitation

Marie Westby¹, Cheryl L. Koehn², Sheila Kerr³ and Alison Hoens⁴, ¹Centre for Hip Health and Mobility, Vancouver, BC, Canada, ²Arthritis Consumer Experts, Vancouver, BC, Canada, ³Patient Advisor, Vancouver, BC, Canada, ⁴Physical Therapy, University of British Columbia, Vancouver, BC, Canada

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Health Services Research Poster II – ACR/ARHP

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 9:00AM-11:00AM

Background/Purpose: Widely varying rehabilitation practices for total joint replacement (TJR) for hip and knee osteoarthritis (OA) contribute to inconsistent patient outcomes and satisfaction. Informed by high quality evidence and expert consensus, quality indicators (QIs) were developed to guide improvements in the quality and consistency of TJR rehabilitation care. This study aimed to identify patients' and healthcare professionals' (HCPs) resource preferences and priorities for knowledge translation toolkits for implementing the QIs into routine clinical practice.

Methods: We conducted online patient (termed 'EQUIP-TJR') and HCP (termed 'QUICK-TJR') surveys in May and November 2017 respectively. Patients were adults on a surgical waitlist for TJR for hip or knee OA OR who had a TJR in past year and HCPs treated or educated patients before or after TJR. Posters, social media, targeted e-mail blasts, and e-newsletters were used for recruitment and a \$100 gift card prize draw was included. Surveys had 4 sections: 1) Rating toolkit resources on 5-point scale; 2) Rating toolkits' impact on rehabilitation care and outcomes on 5-point scale; 3) Toolkit dissemination strategies; and 4) Participant demographics. Surveys took 15 minutes to complete. Descriptive analyses were performed. The UBC Behavioural Research Ethics Board approved the study.

Results: Totals of 137 and 164 individuals completed the EQUIP-TJR and QUICK-TJR surveys respectively. In both surveys, a majority were from the Western Provinces and female. About 80% of EQUIP-TJR respondents were aged 55-74 years, equal proportions were undergoing hip and knee surgery and 68% were post-operative. QUICK-TJR respondents were predominantly physical therapists (77%), of varied age groups, and from public and private practice settings. Patients' five highest rated QI resources were: 1) Education booklets-98%; 2) QI questionnaire-84%; 3) QI checklist-80%; 4) QI passport-72%; and 5) Patient video vignette-71%. The first three of these tools were also among HCPs' top five plus QIs embedded in assessment forms (51%) and QI pocket cards (41%). Patients and HCPs agreed that the toolkit resources would help to improve the rehabilitation care provided (65% and 84%), track quality of care (85% and 68%) and communicate expectations (83% and 78%), respectively. Respondents suggested a wide range of targeted toolkit dissemination strategies including print and electronic formats, traditional and social media for local and national audiences.

Conclusion: There is considerable overlap in patient and HCP preferences and perceived value of QI resources. Results will inform development of EQUIP-TJR and QUICK-TJR toolkits and future research of their impact on quality and outcomes of rehabilitation care.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Health Services Research Poster II – ACR/ARHP

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 9:00AM-11:00AM

Background/Purpose: Understanding the impact of the time of achievement of important improvement (II) in pain and function may further understanding of outcome and inform care pathways for people with TKR. This work evaluated if the

Figure 1: Predictors of satisfaction following TKR

time to achieve II in WOMAC pain and function and Late Life Disability (LLDI) higher demand function was associated with satisfaction.

Methods: We followed 354 patients to 1-year post-TKR. Demographic and health information, WOMAC pain and function and LLDI limitation subscales and outcome expectations for pain, other symptoms, mobility/activities of daily living (ADL), and participation in social roles/instrumental activities of daily living (IADL) were completed pre-surgery. WOMAC and LLDI also were completed 3, 6, and 12 months post-surgery. Satisfaction was completed at 12 months. All were scored 0-100 with higher scores indicating better outcome. We derived an ordinal variable of achieved II by 3, 6 or 12 months post-surgery or not achieved for each outcome. We categorized those with baseline scores precluding II achievement who reached the measure ceiling as achieving II. We used a Bayesian path model with non-informative priors to evaluate if time to II achievement was associated with satisfaction, adjusting for age, sex, education, obesity, depression, comorbidity count and self-rated health. Expectations were modeled as individual predictors. The Bayesian model (model 1) provided a single estimator for ordinal II variables, so we fit a generalized linear model to understand which time of II achievement was associated with satisfaction (model 2).

Results: Mean age 65 years; 65% female. Mean pre-surgery pain, function and high demand activities scores were 47.8 (sd=17.8), 50.3 (sd=18.5) and 59.2 (sd=11.0). Mean satisfaction was 80.7 (sd=21.9). Those with II in pain, function and high demand activities by 3 months had higher satisfaction scores (range 87.8-89.3 vs 64.7-69.8). Fifty-seven, 47, 57 and 15% expected improvement in pain, other symptoms, mobility/ADL and social roles/IADL. In model 1 (Figure 1), earlier II achievement in pain (estimate -0.191) and function (estimate -0.389) was directly associated with more satisfaction and higher expectation for mobility/ADL improvements (-0.106) was directly associated with less satisfaction. Earlier achievement of II in function was associated with higher demand II achievement (0.628); II in higher demand activities was not associated with satisfaction. Other significant effects were indirect. Achievement of II in pain, function and high demand activities by 3 months was significantly associated with higher satisfaction as compared to achievement by 6 or 12 months (2-5 fold impact) or not achieving II (12-17 fold impact) (model 2).

Conclusion: Efforts to minimize recovery time post TKR should be tested to determine if more people recover more quickly and are satisfied with their outcomes.

The Economic Burden of Systemic Lupus Erythematosus (SLE) within a Commercially-Insured Population in the United States Stratified By Disease Severity

Ann E. Clarke¹, Shaum Kabadi², Emily Durden³, Isabelle Winer³, Kirstin Bacani², Karen Costenbader⁴ and Jinoos Yazdany⁵, ¹Department of Medicine, Cumming School of Medicine, University of Calgary, Calgary, AB, Canada, ²AstraZeneca, Gaithersburg, MD, ³Truven Health Analytics an IBM Company, Ann Arbor, MI, ⁴Division of Rheumatology, Immunology and Allergy, Brigham and Women's Hospital, Boston, MA, ⁵University of California, San Francisco, San Francisco, CA

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Health Services Research Poster II – ACR/ARHP

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 9:00AM-11:00AM

Background/Purpose: Most currently available estimates of the economic burden of SLE in the US do not consider disease severity. The purpose of this study is to compare the economic burden between patients receiving treatment indicative of mild versus moderate-to-severe SLE.

Methods: Individuals ages 18-64 years, with an SLE ICD-9-CM code, treated with antimalarials, biologics (abatacept, belimumab, and rituximab), immunosuppressants, or systemic glucocorticoids from 1/1/2010 through 12/31/2014 were identified in a large administrative claims database. The first prescription fill date was the index date. Patients were required to have ≥ 1 inpatient claim or 2 non-diagnostic outpatient claims >30 days apart for SLE in the 12 months prior to index. If the patient had only outpatient claims, ≥ 1 SLE diagnoses must have been made by a rheumatologist or nephrologist. Patients were categorized according to SLE treatment during a 6-month exposure period after the index as: 1) mild SLE: either antimalarial or low-dose oral glucocorticoid (≤ 5 mg/day) monotherapy or 2) moderate-to-severe SLE: any immunosuppressive or combinations of SLE medications other than either antimalarial or low-dose oral glucocorticoid monotherapy. All-cause healthcare utilization and costs were evaluated during the 12 months following the initial exposure period (in 2016 US dollars). Generalized linear modeling with log link and gamma error distribution estimated: 1) total costs and 2) total costs excluding outpatient pharmacy costs during follow-up, adjusting for demographic and clinical characteristics.

Results: 8,231 treated SLE patients were identified; based on treatment during the exposure period, 32.6% were classified as having mild SLE (mean age [SD]: 47.7 years [10.2]; 92.2% female) and 67.4% as having moderate-to-severe SLE (mean

Figure 1: Mean unadjusted total costs, total and by type of service, and multivariable-adjusted total costs during 12-month follow-up period compared between commercially-insured moderate-to-severe and mild SLE patients. Generalized linear modeling with log link and gamma error distribution estimated total healthcare costs adjusting for differences in age, sex, urbanicity of residence, health plan type, and mean Charlson Comorbidity Index (CCI). *p-value < 0.05 **p-value < 0.001

age [SD]: 46.6 years [10.6];90.2% female). Patients receiving treatment indicative of moderate-to-severe SLE had significantly ($p<0.001$) more lupus nephritis (20.2% vs. 8.1%), and more comorbidities including cardiovascular disease (13.3% vs. 10.3%), type 2 diabetes (10.3% vs. 6.9%), and hypertension (41.9% vs. 34.0%). Mean unadjusted total costs and by type of service and multivariable adjusted total costs are shown in Figure 1. The mean multivariable-adjusted total costs and total costs excluding pharmacy costs, respectively, were \$47,542 and \$39,021 among moderate-to-severe patients and \$28,298 and \$23,519 among those with mild SLE ($p<0.0001$ for both).

Conclusion: The mean 12-month adjusted total costs for patients with moderate-to-severe SLE were 68% higher than those of patients with mild SLE. These differential costs are important to consider in future studies examining cost-effectiveness and in designing interventions to improve health and reduce health spending for SLE.

Abstract Number: 1181

Hydroxychloroquine: Do We All See Eye to Eye? a Single-Site Analysis of Hydroxychloroquine Dosing Compared to 2016 American Academy of Ophthalmology Guidelines

Vaneet K. Sandhu¹, Noopur Goel² and Jamileh Hanna², ¹Division of Rheumatology, Loma Linda University, Loma Linda, CA, ²Loma Linda University, Loma Linda, CA

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Health Services Research Poster II – ACR/ARHP

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 9:00AM-11:00AM

Background/Purpose: Hydroxychloroquine is universally recommended to treat patients with SLE, stressing the importance of appropriate dosing. The 2016 American Academy of Ophthalmology (AAO) guidelines recommend a maximum dose of hydroxychloroquine $\leq 5\text{mg/kg/day}$ actual body weight (ABW),¹ which correlates more with retinal toxicity risks than using ideal body weight to calculate dosage. We evaluated the extent of adherence to dosing guidelines by SLE providers to encourage further prospective analysis and intervention to prevent retinal toxicity.

Methods: Data collected from the Southern California Lupus Registry (SCOLR), an academic single-center cohort of 162 SLE patients, was analyzed. Patients were identified to have SLE by either ACR or 2012 SLICC criteria.^{2,3} Chart review identified patients prescribed hydroxychloroquine, dose prescribed, if this dosing was aligned with AAO guidelines, and, if dosed in excess, the amount (in mg) of excess daily hydroxychloroquine.

Results: Of 162 patients with SLE, 136 received hydroxychloroquine. Fifty-six (41%) of those patients on hydroxychloroquine were on doses exceeding 5mg/kg ABW and eighty (58%) were in line with AAO recommendations. The remaining 26 patients were not on hydroxychloroquine; reasons included adverse reactions or underlying or consequential retinal disease.

Among patients on excessive doses of hydroxychloroquine, the prescribed dose was in excess of recommended dosing by 1.1mg/kg on average (absolute dose 6.1mg/kg). 23 of these patients were dosed greater than 6mg/kg and 6 were receiving doses higher than 7mg/kg.

Conclusion: Recent uptick in retinopathy in patients on hydroxychloroquine for 5 years or more has reiterated that daily dosing of hydroxychloroquine is the most critical determinant of retinal toxicity risk. This, combined with our findings, implicates the dire need for physicians to appropriately dose hydroxychloroquine in SLE management. We found patients in our cohort dosed in excess as per both 2011 and 2016 American Academy of Ophthalmology Guidelines. This data underscores the importance of reviewing or adjusting hydroxychloroquine doses on regular clinic visits. Further, while use of weight-based dosing of hydroxychloroquine has demonstrated reduced risk of retinopathy, feasibility of dose adjustments as low as 50 milligrams warrants review of available doses of this medication. Perhaps the availability of 50-100mg dosing will be beneficial in avoiding long term adverse events.

The Disproportionate High Risk of Re-Fracture after Osteoporotic Treatment in Patients with Autoimmune Diseases

Wen-Nan Huang¹, Yi-Ming Chen¹, Wei-Ting Hung², Yu-Wan Liao³ and Yi-Hsing Chen¹, ¹Division of Allergy, Immunology and Rheumatology, Taichung Veterans General Hospital, Taichung, Taiwan, ²Division of Allergy, Immunology and Rheumatology, Department of Internal Medicine, Taichung Veterans General Hospital, Taichung, Taiwan, ³Taichung Veterans General Hospital, Taichung, Taiwan

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Health Services Research Poster II – ACR/ARHP

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with autoimmune diseases are associated with an increased risk of osteoporotic fracture. Anti-osteoporotic treatment could diminish re-fracture rates in post-menopause women. However, treatment failure of anti-osteoporotic medication in patients with autoimmune diseases remained unknown. The aim of study is to investigate the outcome of anti-osteoporotic treatment in patients with autoimmune rheumatic diseases.

Methods: We conducted a retrospective case-control study analyzing hospital database of a tertiary referral center in Taiwan. From January, 2002 to December 2016, subjects with osteoporotic fracture and anti-osteoporotic treatment were enrolled. Diagnosis of rheumatoid arthritis, systemic lupus erythematosus and primary Sjogren's syndrome were identified using ICD-9-CM and ICD-10-CM codes. Cases with re-fracture were compared with age-, gender-matched controls (1:4) without re-fracture. Re-fracture incidences were compared among anti-osteoporotic drugs and autoimmune diseases.

Results: In total, 9,384 fracture patients with anti-osteoporotic drugs were identified; 1,829 patients with autoimmune diseases. Patients receiving teriparatide were older and had lower bone density compared with those receiving bisphosphonates, raloxifene and denosumab, respectively. Participants with previous hip fractures had higher chance of re-fracture compared with their counterparts of previous spine fractures or other fractures. Patients with autoimmune diseases were at higher risk of recurrent fractures (19.3% vs. 10.6%, $p < 0.001$). Moreover, bisphosphonates-treated patients also had higher re-fracture rates compared with those treated with raloxifene, denosumab and teriparatide.

Conclusion: Our results indicated that rheumatic patients were at increased risk of treatment failure in osteoporosis. Adherence of anti-osteoporotic drugs and fall prevention are essential to prevent re-fracture in patients with autoimmune diseases.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Health Services Research Poster II – ACR/ARHP

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 9:00AM-11:00AM

Background/Purpose: Having health insurance coverage is important for people with chronic conditions. Those with systemic lupus erythematosus (SLE) are particularly vulnerable given the disproportionate impact on young minorities and women. This is the first description of health insurance changes over time overall and by sociodemographic groups on a population level.

Methods: The Georgians Organized against Lupus (GOAL) is a cohort of validated patients with SLE living in Atlanta, predominantly derived from the population-based and Centers for Disease Control and Prevention (CDC) funded Georgia Lupus Registry. Participants have been surveyed annually, including sociodemographics, health insurance, disease activity (Systemic Lupus Activity Questionnaire), and damage (Self-Administered Brief Index of Lupus Damage). Self-reported health insurance was categorized into no insurance, private, Medicare, Medicaid, and Medicare/Medicaid. Those reported being in a different category the year before were classified as having changed insurance.

Results: An average of 642 individuals were surveyed annually from 2012 to 2016. At 2012 baseline, the average age was 46.4 ± 13.4 and disease duration was 13.6 ± 9.2 years. 93.6% were female and 78.5% black. 35.1% had a high school education level or less, 45.8% were at or below the Federal poverty level, 34.6% were married or with a partner, and 35% were employed. Figure 1 shows the distribution of insurance categories from 2012 through 2016. Compared to the year before, 23.8% changed insurance in 2013, 22.2% in 2014, 24.1% in 2015, and 26.8% in 2016. Those who changed insurance were more likely to be black, lower in educational attainment, poorer, unemployed, and have greater disease activity and damage.

Conclusion: In a population-based cohort in Georgia, the majority (~60%) with SLE have private insurance and Medicare, which has grown over time while those uninsured have dropped. The decrease in the uninsured mirrors national trends as the Affordable Care Act expanded coverage through Medicaid expansion and insurance exchanges. Georgia is one of the states that has not expanded Medicaid, the impact of which is not entirely clear in the SLE population and deserves further exploration. There also appears to be a slight increase in those who switch insurance categories. It is important to learn how types of and changes in insurance coverage affect healthcare utilization, disease treatment and outcomes, self-reported health, and mortality in SLE, particularly given the disproportionate impact on socially vulnerable groups. Studies

utilizing administrative data should also be aware of insurance coverage distributions and regional variations in policy that impact these distributions.

Cause and Rate of Hospitalization of Lupus Patients

Reem Aldarmaki¹, Hiba Khogali² and Ali AIDhanhani³, ¹Medical Student, UAEU, College of Medicine, Al Ain, United Arab Emirates, ²Rheumatologist, Tawam hospital, SEHA, Al Ain, United Arab Emirates, ³Assistant professor, UAEU, College of Medicine, Al Ain, United Arab Emirates

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Health Services Research Poster II – ACR/ARHP

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is a chronic multiorgan disease that is associated with significant morbidity and mortality. Literature suggests improvement in the survival rates among SLE patients over the last decades. However, economic burden of SLE including health care and hospitalization is significantly high. The aim of this study is to evaluate the burden of hospitalization among SLE patients and assess the risk factors of hospitalization among SLE patients.

Methods: All patients who are followed in rheumatology clinics (Tawam hospital) and fulfilled the American college of Rheumatology (ACR) SLE criteria were identified. Retrospective chart reviews for previous admissions in this hospital or any other Abu Dhabi Health Services Company (SEHA) hospitals were performed using electronic health records (available since 2009). Demographic data, reason for hospitalization, duration of hospitalization, ICU admission, and SLE features at time of admission were collected. Hospitalization rate was calculated as number of hospitalization divided by disease duration. Regression analysis for factors associated with hospitalization and with duration of hospitalization were performed.

Results: Ninety one patients (88, 97%, females) were identified who fulfil ACR criteria with mean disease duration of 10.16 (SD \pm 5.5) years. Mean number of criteria of those patients are 5.6. Sixty six (72.5%) of these patients were admitted at least once to the hospital with a total of 222 admissions over the years and with the mean annual rate of hospitalization calculated at 27.5 %. Mean hospitalization duration was 5.9 days (SD \pm 5.98). In 41 admissions, there were 2 reasons for admission. In total, 32.4% admitted for SLE disease activity, 25.2% for infection, 30.2% for pregnancy and related conditions, 2.3% for medication side effects and 27.5% for other medical and surgical causes. SLE features during SLE activity admissions include lupus nephritis (50%), hematological manifestation (34.6%), arthritis (21.2%) and Neuropsychiatric lupus (19.2%). In 6% of hospital admissions, patients needed an intensive care (ICU) admission. In multivariable regression, the number of hospitalization was significantly associated with younger age at diagnosis ($P=.02$), and ever lupus nephritis ($P=.003$). In another multivariable analysis, increased duration of hospitalization was significantly associated with being admitted for SLE disease activity ($p=.009$), presence of DsDNA antibodies ($P<.001$), and admission to ICU ($P<.001$).

Conclusion: Significant proportions of SLE patients were hospitalized during their disease course, with one third of hospitalizations due to active disease. Hospitalization of SLE patients carries a substantial economic burden on the healthcare system.

Comparison of Biologic Discontinuation in Patients with Elderly-Onset Vs Younger-Onset Rheumatoid Arthritis

Michael Richter¹, Eric L. Matteson², John M. Davis III², Sara J. Achenbach³ and Cynthia S. Crowson³, ¹Internal Medicine, Mayo Clinic, Rochester, MN, ²Division of Rheumatology, Mayo Clinic College of Medicine and Science, Rochester, MN, ³Health Sciences Research, Mayo Clinic College of Medicine and Science, Rochester, MN

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Health Services Research Poster II – ACR/ARHP

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 9:00AM-11:00AM

Background/Purpose: Several studies have suggested that patients with elderly-onset rheumatoid arthritis (EORA) receive biologic treatments less frequently than patients with younger-onset RA (YORA). This has been demonstrated even in patients with comparable disease activity. Risk of treatment complications and financial challenges associated with Medicare reimbursement may also contribute to this disparity. Our objective was to compare biologic drug discontinuation rates for older vs. younger onset RA, as this is a key outcome measure that could impact prescribing practices.

Methods: A retrospective medical record review was performed of all patients who fulfilled the 1987 ACR criteria for adult-onset RA in 1980-2013 among residents of a geographically defined area with follow up until death, migration or July 1, 2016. EORA was defined as RA diagnosis at age ≥ 65 years and YORA was defined as age 18-64 years. Discontinuation rates were estimated using cumulative incidence adjusted for the competing risk of death. Risk factors were examined using Cox models adjusted for age, sex and calendar year of RA incidence.

Results: 171 cases of EORA and 435 cases of YORA were identified (67% and 71% female respectively, $p=0.33$). EORA patients had a lower rate smoking at time of RA diagnosis (8% vs. 18%, $p=0.002$), though ever smoking was not a significant risk factor for starting a biologic ($p=0.42$). There were no significant differences in rheumatoid factor (RF) or anti-cyclic citrullinated peptide antibody (CCP) positivity ($p=0.26$) or body mass index (BMI) ($p=0.23$) at time of diagnosis. Cumulative incidence of biologic initiation was lower among EORA compared with YORA (11% vs 19% at 2 year after RA diagnosis, respectively, $p<0.001$). Among those treated with a biologic, years from RA diagnosis to first biologic was not significantly different between the two groups ($p=0.17$). Cumulative incidence of first biologic discontinuation was 38% at 1 year (95% confidence interval [CI], 23-61%) and 56% at 2 years (95% CI, 40-79%) for EORA compared with 39% at 1 year (95% CI, 31-49%) and 55% at 2 years (95% CI, 46-65%) for YORA ($p=0.61$). Concurrent glucocorticoid use at initiation of first biologic was statistically significantly associated with a lower risk for discontinuation in EORA (hazard ratio: 0.19; 95% confidence interval: 0.06-0.59), but not in YORA (interaction $p=0.06$). There were no significant predictive factors for discontinuation in YORA.

Conclusion: Discontinuation rates of biologic medications did not differ significantly between patients with EORA and YORA.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Health Services Research Poster II – ACR/ARHP

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 9:00AM-11:00AM

Background/Purpose: The objective of this study was to evaluate the impact of a nurse-led program of self-management and self-assessment for disease activity program in axSpA

Methods: Study design: Prospective, randomized, controlled, open, 12-month trial (NCT02374749). **Participants** 1/Patients: consecutive Axial SpA patients (according to rheumatologist) attending a clinic of the participating centers were invited. 2/Nurses: all participated at a 1 day meeting prior the start of the study.

Study treatment: a program including: 1) Self-management = a) a video explaining the disease, the interest of smoking cessation in axial SpA, the role of NSAIDs as cornerstone treatment in axSpA in the absence of contra-indications, the interest of physical activity and exercise, followed by a discussion with the nurse; b) physical examination by the nurse to check for the presence of spinal deformities suggesting a severe disease, and depending on the absence/presence of such deformities projection of a specific video of home-based exercises examples for patients with severe/not severe disease. 2) Self-assessment: Video presentation of the rationale of the use of a composite index such as ASDAS and BASDAI, followed by discussion with the nurse. Explanation by the nurse of the collection, calculation of BASDAI and ASDAS (via a calculator provided to the patient) and reports of the results on a sheet form. Monthly evaluation at home recommended by the nurse. **Treatment allocation:** after written informed consent, the treatment was allocated randomly via an electronic system (e.g. either this above program or an evaluation of potential co-morbidities (not reported here). **Outcome variables:** Primary: The level of coping (0-10, where 0= very well) after 12 months. Other variables: Successful smoking cessation, NSAID intake, Number of home-based or supervised exercise, international physical activity questionnaire (IPAQ)

Results: There was no difference in the baseline characteristics of the 502 recruited patients (250 and 252 in the active and control groups, respectively): Age: 46.7±12.2 years, male gender: 62.7%, disease duration: 13.7±11.0y, Xray sacroiliitis 62.8%, MRI sacroiliitis 65.7%, current biologic treatment: 78.3%, ASDAS-CRP: 1.9 ± 0.8, BASFI: 25.6±22.3. After the 1year follow-up period, the coping level was lower in the active group, but this difference was not significant (2.8±2.0 vs. 3.0±2.1, p=0.3). However, there was a significant decrease in the BASDAI in the active group (- 1.2 ± 15.8 vs. +1.4 ± 15.7, p=0.03), a significant increase in the number (6.1± 28.8 vs. -0.4±26.9, p=0.03) and duration (4.3±20.1 vs. -1.7±20.7, p<0.01) of the home-exercises in the active group, and a greater IPAQ score in the active group at the end of follow-up (138.4±227 vs. 95.6±173, p=0.02). Neither smoking cessations nor NSAID intake were different after one year in both groups.

Conclusion: This study highly suggests a short-term benefit of a nurse led program on the self-management and self-assessment for disease activity in a young axSpA population in particular with regard to the frequency and the duration of home exercises

Are Residents Choosing Wisely? Analysis of Adherence to Recommendations of Ordering Anti-Nuclear Antibody Testing in an Internal Medicine Residency Primary Care Clinic

Aparna Das, Rajarajan Panneerselvan, Annum Faisal, Jubran Rind and Rima Shah, Internal medicine, Michigan state university, grand rapids, MI

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Health Services Research Poster II – ACR/ARHP

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 9:00AM-11:00AM

Background/Purpose: A positive anti-nuclear antibody (ANA) is considered very useful for the diagnosis of SLE and systemic sclerosis, and somewhat useful for the diagnosis of Sjögren's syndrome and polymyositis/dermatomyositis. Higher the prior probability that a patient has a systemic autoimmune disease, the more likely the results of an ANA test will assist in establishing the diagnosis. However, ANA testing is ordered indiscriminately leading to high false positive results, increased unnecessary downstream testing and referral to rheumatology. ACR Choosing Wisely campaign in 2013 recommended not to test ANA sub-serologies without a positive ANA and clinical suspicion of immune-mediated disease. Our study aimed to study the adherence to these recommendations by residents in their outpatient primary care clinic of a community teaching hospital.

Methods: Retrospective analysis of electronic medical records of patients seen by internal medicine residents in the primary care clinic during the duration of January 1, 2012 to December 31, 2016 was performed. The method of ANA testing used was EIA (Enzyme immunoassay). If positive ($> 1:80$), reflex EIA for individual ANA sub serologies were performed. We analyzed the frequency of ANA ordering, reasons for ANA ordering and adherence to current ACR recommendations for subserology testing.

Results: 57 patients (out of total 757) had ANA tested during this period. Only 38/57(66%) had a documentation of strong clinical suspicion of an autoimmune disorder. 54 tests were complete at the time of data collection, two results were pending and one screen never completed. Of the 54 completed tests, 44/54 (81.5%) were negative and 10/54 (18.5%) were positive. The most common symptom for which ANA was ordered was joint pain 18/52 (34.6%) of which 5/18 patients had knee pain. In 9/54 patients (16.6%), ANA was ordered more than once (twice in 7 patients and thrice in 2 patients). Most common antibodies tested positive following a positive ANA were anti-double stranded DNA (anti-Ds DNA) in 5/10(50%) followed by anti-Jo1 antibody (antibody against anti-histidyl t RNA synthetase) 4/10(40%). Other antibodies positive were anti-c ANCA (1/10, 10%) and anti-SSA antibodies (1/10,10%). Most common diagnoses among the patients tested for ANA was osteoarthritis 7/54 (12.9%) followed by fibromyalgia (3/54,5.5%). 16/54 (29.6%) had no diagnosis. Among the 44 patients who were tested negative for ANA, 13/44 (29.5%) had other autoantibodies ordered.

Conclusion: ANA testing was ordered without a strong clinical suspicion for a rheumatic/autoimmune disorder in 33% of patients. ANA was ordered more than once in 16.6% of the patients. Additional antibody testing was in 29.5% of patients with negative ANA in whom there was no clinical suspicion of a rheumatic/autoimmune disorder, which is against the "ACR Choosing Wisely recommendations". Our study demonstrates that non-adherence to ACR recommendations for ordering ANA and ANA subserology testing is prevalent among trainees in the outpatient primary care setting. Educational and electronic medical record based interventions could be instituted to check this practice.

Secukinumab Versus Adalimumab for the Treatment of Ankylosing Spondylitis: A Cost per Responder Analysis from Korean Perspective

Dam Kim¹, Hyojin Kim², Seongha Cho² and Min-Chan Park¹, ¹Division of Rheumatology, Department of Internal Medicine, Yonsei University College of Medicine, Gangnam Severance Hospital, Seoul, Korea, Republic of (South), ²Patient Access Team, Novartis Korea, Seoul, Korea, Republic of (South)

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Health Services Research Poster II – ACR/ARHP

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 9:00AM-11:00AM

Background/Purpose: Various kinds of biologic agents are available for treating ankylosing spondylitis (AS). However, there is considerable economic burden for patients and society. This study was performed to estimate the response rate of secukinumab (fully human anti-interleukin 17A) and adalimumab in AS patients, and to compare the cost-effectiveness between secukinumab and adalimumab from Korean perspective.

Methods: A systematic literature search was performed via PubMed for relevant randomized controlled trials (RCTs) for response rate. The cost per responder for each treatment was estimated by dividing drug acquisition cost for the treatment course with its response rate of Assessment of Spondyloarthritis International Society (ASAS) outcomes. Response rates in anti-TNF-naïve subjects were extracted from RCTs of secukinumab and adalimumab, respectively. All analyses were calculated in case of both with or without loading condition of secukinumab. Cost was expressed with US dollars (USD) (1USD = 1,082 Korean Won).

Results: Of the 295 articles retrieved, five RCTs were identified including long-term response data. The ASAS 20 and 40 response rates from selected studies were comparable between secukinumab and adalimumab. The cost per ASAS 20 responder were lower by 40% in secukinumab compared with adalimumab: USD 9,637 vs. USD 16,129 at 52 weeks and USD 20,051 vs. USD 32,699 at 104 weeks for secukinumab vs. adalimumab (in case of maintenance condition), respectively. In addition, the cost per ASAS 40 responder were also lower by about 40% in secukinumab: USD 12,179 vs. USD 22,395 at 52 weeks and USD 27,338 vs. USD 41,655 for secukinumab vs. adalimumab, respectively. Even in case of loading condition with secukinumab at 52 and 104 weeks, secukinumab showed lower cost per responder by approximately 25% than adalimumab.

Conclusion: The response rates of secukinumab and adalimumab were comparable. The costs per responder for ASAS 20 and 40 were consistently lower for secukinumab compared with adalimumab. The treatment with secukinumab for biologic-naïve AS patients could be the cost-effective treatment option in Korea with a given budget.

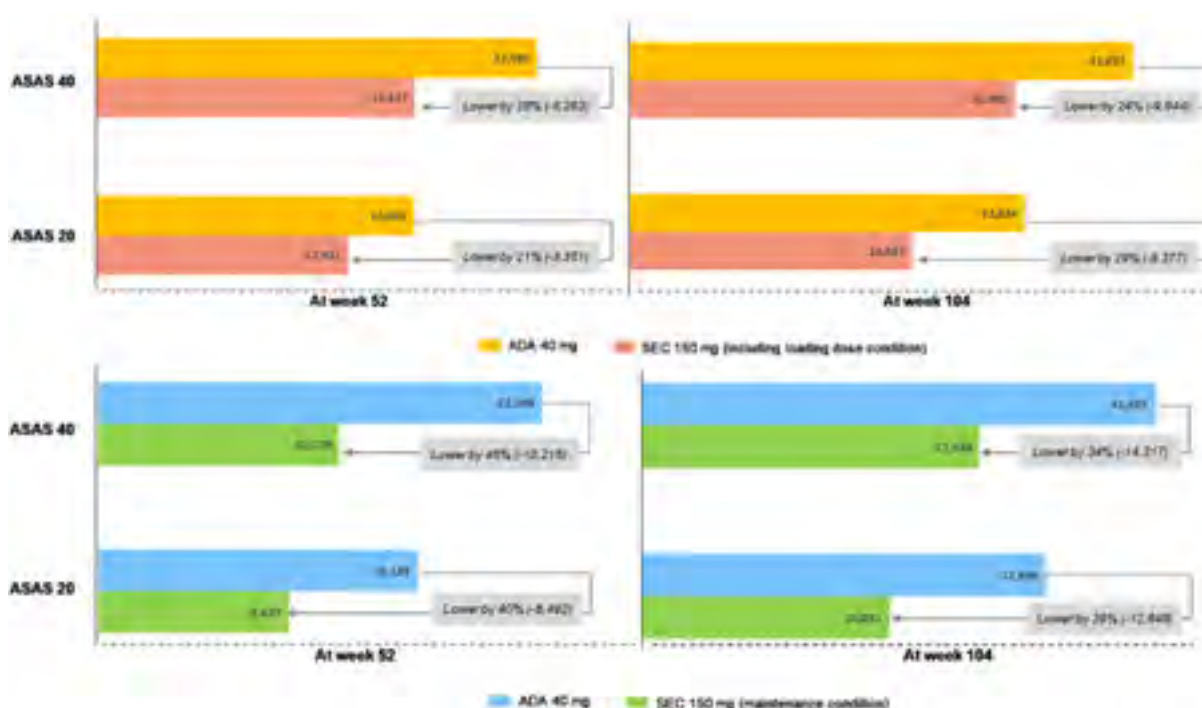

Figure 1. Cost per response of ASAS 40 and 20 for secukinumab (SEC) vs. adalimumab (ADA) for the treatment of AS at week 52 and 104 (upper: with SEC loading condition, bottom: with SEC maintenance condition)(unit: USD)

Session Date: Monday, October 22, 2018

Session Title: Health Services Research Poster II – ACR/ARHP

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 9:00AM-11:00AM

Background/Purpose: National registries of biologic drugs have proven to be valuable tools in following patients with rheumatic disease and some outcomes in real-life situations. The objective of this study was to describe Mexican Rheumatologists' preferences when treating patients with biologic drugs and to analyze factors associated to the use of this therapy.

Methods: Data from patients undergoing biologic treatment in Mexico is gathered into the BIOBADAMEX online database, which is part of the BIOBADAMERICA initiative and based on the BIOBADASER Phase 3 platform. Phase 3 in Mexico started gathering patient data in April 2016 and to date has information on 283 patients. The database collects information such as gender, age, diagnosis, disease duration, biologic treatment, DMARD treatment, concomitant therapy, motives for discontinuation of biologics, comorbidities, adverse event (AE) severity, infection site and germ involved. Descriptive statistics were applied on the data collected from April 2016 to April 2018.

Results: We analyzed data on the use of 267 biologic treatments in 289 patients. Most of them receive biologic therapy through socialized medical insurance programs which may have led to bias. 82% of patients were female, mean age 49 ± 15.2 (4-85) years, 42.5% belonging to the <50 group. 70.9% of patients in the registry have RA, 15.9% AS and 5.1% PsA. Mean disease duration is 11 ± 8.9 (0-58) years. The most commonly used biologic overall is Abatacept (15.3%), followed by Adalimumab (13.8%), Tocilizumab (11.2%), Certolizumab (10.1%), Golimumab (8.6%), Rituximab (8.2%), and Etanercept biosimilar (7.4%), Etanercept (6.3%), Infliximab (4.1%) and Benlystia (1.1%). All others, including JAK inhibitors, are used in <1% of patients. The preference for first biologic drug was Etanercept (32.4%), followed by Adalimumab (12%), Infliximab (8.3%), Rituximab and Tocilizumab (5.5% each) and Abatacept (2.7%). The most commonly used second-line biologics were golimumab, the etanercept biosimilar and abatacept. Most treatments were stopped due to lack of efficacy (60.4%), disease remission (7.4%), other causes (20.1%), AE (4.4%), with the rest of the causes each affecting <5% of patients. 18.5% of AE were considered severe. Comorbidities were present in 87 patients (40%), the most common being Hypertension (13.4%), Diabetes (7.8%) and Dyslipidemia (6.9%). Non-lymphoma neoplasms were reported in 1.3%. 25% of AE were considered serious but most (70%) were mild. Only 6 patients reported infections with the most common sites being the skin (33.3%), urinary tract (16.6%) and middle-ear (16.6%). The causal germ was undetermined in half of the cases of infection.

Conclusion: When using biologic drugs, TNF inhibitors are the most commonly used initial mechanism of action for the treatment of rheumatic diseases in the BIOBADAMEX registry. Upon treatment failure, patients often undergo a switch to another mechanism of action, mainly using Abatacept. Adverse events and infections related to the use of biologics are infrequent, but 40% of patients present chronic comorbidities.

The Importance of Quantitative Assessment of Joint/Organ Damage and Patient Distress in Addition to Inflammatory Activity in Routine Clinical Care

Theodore Pincus, Isabel Castrejón and Joel A. Block, Division of Rheumatology, Rush University Medical Center, Chicago, IL

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Health Services Research Poster II – ACR/ARHP

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 9:00AM-11:00AM

Background/Purpose: Quantitative measures such as laboratory tests and pooled indices have advanced clinical rheumatology care far beyond narrative decisions. These measures generally are directed to assess inflammatory activity, based on the primary concern of rheumatologists to control inflammation in order to prevent damage to joints and other organs. However, structural damage and patient distress, seen as fibromyalgia, depression, etc., are important clinical problems in many patients, in addition to active inflammation, but are not assessed quantitatively in routine clinical care, or even much clinical research concerning inflammatory rheumatic diseases. We introduced quantitative assessment of inflammation, damage, and distress in care of individual rheumatology patients, and hypothesized that structural damage and distress would be at least as important in current practice as inflammation. Here, we assess the relative contribution of each to physician global assessment.

Methods: As part of routine care, rheumatologists at one academic site complete a 0-10 physician global assessment (DOCGL) VAS, as well as 3 further 0-10 VAS to assess inflammation (reversible disease) (DOCINF), joint and other organ damage (irreversible disease) (DOCDAM), and patient distress (fibromyalgia, depression), etc. (DOCSTR). The proportion of DOCGL attributed to inflammation, damage, and distress (total=100%) also is estimated. Mean values were analyzed in a cross-sectional study of 570 patients, and compared in subgroups of 98 with rheumatoid arthritis (RA), 131 with osteoarthritis (OA) and 89 with fibromyalgia (FM), using t tests and analysis of variance (ANOVA).

Results: Mean 0-10 DOCGL scores were 4.4 in all patients, 4.4 in OA, 4.6 in RA, and 5.2 in FM (Table) ($p=0.04$). Highest mean scores were seen for DOCINF in RA, DOCDAM in OA, and DOCSTR in FM, and differing significantly in each diagnosis (Table), confirming face validity. Importantly, damage VAS scores (DOCDAM) were higher than inflammation (DOCINF) scores in all groups, including in RA, and mean estimates of the proportion of DOCGL attributed primarily to damage were greater than to inflammation in all conditions (Table). Scores for DOCSTR were higher than for DOCINF in all patients and subgroups, other than in RA.

Mean VAS Scores and % of physician global assessment (DOCGL) attributed to inflammation (DOCINF), damage (DOCDAM), and distress (DOCSTR) in patients with rheumatic diseases

	ALL	RA	OA	FM	P*
N	570	98	131	89	
Mean VAS Scores					
VAS DOCGL	4.4 (1.6)	4.6 (1.8)	4.4 (1.5)	5.2 (1.6)	0.04
VAS DOCINF	1.8 (2.0)	2.8 (2.4)	0.7 (1.1)	0.8 (1.3)	<0.001
VAS DOCDAM	3.1 (2.2)	3.8 (2.3)	4.4 (1.8)	1.7 (1.9)	<0.001
VAS DOCSTR	2.1 (2.9)	1.2 (2.2)	1.5 (2.5)	6.0 (2.5)	<0.001
P (DOCINF vs DOCDAM)	0.001	0.01	<0.001	<0.001	
P (DOCINF vs DOCSTR)	0.11	<0.001†	<0.001	<0.001	
Mean % of clinical management decision attributed to...					
%inflammation	29 (31)	39 (29)	12 (19)	6 (11)	<0.001
%damage	48 (35)	52 (30)	73 (31)	18 (23)	<0.001
%distress	22 (34)	9 (20)	15 (27)	76 (27)	<0.001

*ANOVA - RA vs OA vs FM † -only comparison in which DOCINF higher than DOCSTR

Conclusion: Physician VAS scores and DOGCL sub-scores attributed to damage and distress in individual patients were higher than for inflammation in all diagnosis groups, even in RA patients as a group. Control of inflammation remains the primary concern for rheumatologists, but modern therapeutics have been largely effective, leaving structural damage and patient distress as more prominent issues among individual patients in routine patient care and Systematic quantitation may be critical to understand the effects of these problems on patient well being and limited responses to anti-inflammatory therapies.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Health Services Research Poster II – ACR/ARHP

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 9:00AM-11:00AM

Background/Purpose: The AbbVie patient (pt) support program (PSP) is offered to pts prescribed adalimumab for RA and other indications. The purpose of this analysis was to evaluate the incidence of disease flare and the regain of disease control after flare among pts treated with adalimumab in the PASSION study according to PSP participation.

Methods: Pts with moderate to severe RA were enrolled in a 78-wk post marketing, global, observational study (PASSION) and received adalimumab in routine clinical care. Pts achieving low disease activity (LDA), defined as a 28-joint Disease Activity Score using C-reactive protein (DAS28[CRP]) ≤ 3.2 , were evaluated for the incidence of disease flare and recovery of LDA through wk 78. Disease flare was defined as an increase in DAS28(CRP) ≥ 0.6 at 2 consecutive visits (current and previous visits) and DAS28(CRP) > 3.2 at either visit if pts had achieved DAS28(CRP) LDA or better at or before the previous visit. The proportion of PSP users and PSP non-users with LDA experiencing disease flare and the proportion who re-established LDA following disease flare were summarized by visit. Differences between PSP users and PSP non-users were evaluated using a Chi-square test.

Results: Of the 1025 pts enrolled in PASSION, 695 pts achieved LDA through wk 78 (357/499 [72%] PSP users; 338/526 [64%] PSP non-users); 124 (18%) of whom experienced disease flare at ≥ 1 time point (59/357 [17%] PSP users; 65/338 [19%] PSP non-users). Of pts who experienced a flare, similar proportions of PSP users and PSP non-users were female (46/59 [78%] PSP users; 55/65 [85%] PSP non-users) and < 65 years (48/59 [81%] PSP users; 46/65 [71%] PSP non-users); however, significant differences ($P < 0.001$) were observed for race (white; 44/59 [75%] PSP users; 64/65 [99%] PSP non-

Figure: Proportion of Patients With LDA Experiencing Disease Flare And Regaining LDA

users), ethnicity (Hispanic/Latino; 17/59 [29%] PSP users; 3/65 [5%] PSP non-users), and prior biologic DMARD use (4/59 [7%] PSP users; 22/65 [34%] PSP non-users). Flares occurred in similar proportions of PSP users (3.4%–5.3%) and PSP non-users (3.3%–7.1%) with LDA at assessed time points (**Figure**). Greater portions of PSP users (50%–53%) vs PSP non-users (29%–42%) regained LDA after flare through wk 52; 12 PSP users and 11 PSP non-users experienced disease flare at wk 78 and were unable to be assessed for LDA achievement following flare.

Conclusion: Flares occurred in <20% of pts receiving adalimumab and achieving LDA in the 78-wk PASSION study. Greater proportions of PSP users than PSP non-users regained disease control after flare through study wk 52.

Cannella⁶ and Eugene Kissin⁷, ¹Loma Linda University Medical Center, Loma Linda, CA, ²John Muir Hospital, Walnut Creek, CA, ³Division of Rheumatology, University of Rochester Medical Center, Rochester, NY, ⁴Stanford University, Palo Alto, CA, ⁵Loma Linda University, Loma Linda, CA, ⁶Section of Rheumatology, University of Nebraska Medical Center, Omaha, NE, ⁷Boston University, Boston, MA

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Imaging of Rheumatic Diseases Poster II: Ultrasound

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Point-of-care (POC) musculoskeletal ultrasound (MSUS) over the past decade has increasingly been adopted to evaluate patients with rheumatic diseases. In 2011, a group of rheumatology MSUS experts developed a document on documentation, scanning conventions, and tiered-mastery designation for anatomic region views. This study aims to update consensus reflective of the current usage MSUS in rheumatology. This consensus statement will guide development of a Rheumatology MSUS fellowship curriculum and professional training in the United States.

Methods: A 3-round Delphi method study was done utilizing a 96-item questionnaire. Agreement/disagreement on documentation and scanning conventions covered 5 items each; other items included demographics; and tier designations for anatomic-regions. Comments were solicited for each question. Dissemination was done via Qualtrics[®] to 101 respondents, with a target participant number of 38. Respondent selection was based on: identified lead MSUS academic faculty, course instruction, certification by ACR (RhMSUS), and publication. Informed consent process was done. Questionnaire initiation and completion indicated consent. We used McNemar's chi-square to test agreement in the paired responses for scanning and documentation. High agreement was defined as agreement of $\geq 85\%$. Comments were reviewed for content analysis. This study was approved by the Institutional Review Board of Loma Linda University Medical Center.

Results: 46 respondents completed all three rounds. 73% were full time academic faculty. 73% had RhMSUS certification. Table 1 shows results of levels of agreement/disagreement with the original consensus statements and with proposed alternative statements. . 4 (80%) of the documentation and 5 (100%) of the scanning convention statements reached or maintained high consensus. For the documentation statement that did not reach consensus ("A dynamic scan should be saved as a clip"), 9 out of the 39 who agreed with this statement in Round 1, disagreed with it at Round 3 and this change was statistically significant ($p=0.021$). Commentary analysis showed three main themes: 1) the need for a more clinically

realistic and rheumatology-specific “complete” vs “limited” scan, possibly applying these terms towards disease-specific (eg. rheumatoid arthritis) evaluation as opposed to utilizing anatomic region-based descriptions determined largely by radiologists; 2) current coding and billing constrain the “complete scan” definition.

Conclusion: Many scanning conventions from 2011 remain relevant in current practice. Documentation standards from 2011 may need revision. Current definitions of “complete” and “limited” scans may not accurately reflect relevant usage of MSUS in current rheumatology practice, and descriptions based on disease-based evaluations should instead be considered.

Table 1. Scanning Conventions and Documentation: Levels of Agreement and Disagreement with 2011 Consensus Statement, Delphi rounds 1-3, N=46

2011 Consensus Statements	Agreement vs. Disagreement	Proposed Alternative statement
Scanning Conventions		
The radiologic anatomic position is used as a reference with palms facing forward, hence the left side of the ultrasound monitor screen is medial, cranial, ulnar or tibial. (SC1)	44 (95.7%) vs. 2 (4.3%)	The radiologic anatomic position can be used as a reference with palms facing forward, hence the left side of the ultrasound monitor screen is medial, cranial, ulnar or tibial or individual sonographer consistent orientation is maintained. Agreement with alternative: 14 (30.4%) Disagreement with alternative: 32 (69.6%)
The left side of the ultrasound monitor screen is designated anterior when a choice exists to scan posterior or anterior in the sagittal plane (for example: lateral hip). (SC2)	40 (87%) vs. 6 (13%)	When a choice exists to orient the probe anterior or posterior for lateral examinations, individual sonographer consistent orientation is maintained. Agreement with alternative: 8 (17.4%) Disagreement with alternative: 32 (82.6%)
“Longitudinal” scans imply alignment of the probe in the longitudinal axis of the structure under examination. (SC3)	45 (97.8%) vs. 1 (2.2%)	-
“Transverse” scans imply alignment of the probe transverse to the structure under examination. (SC4)	44 (95.7%) vs. 2 (4.3%)	-
“Orthogonal” scans imply that longitudinal and transverse scans have been done. (SC5)	44 (95.7%) vs. 2 (4.3%)	“Orthogonal” scans imply that longitudinal and transverse scans have been done to document pathology in two perpendicular planes. Agreement vs. Disagreement with alternative: 24 (52.2%) Vs. 22 (47.8%)
Documentation		
All static normal scans should be documented. (D1)	43 (93.5%) vs. 3 (6.5%)	-
All abnormal scans should be documented. (D2)	44 (95.7%) vs. 2 (4.3%)	-
A dynamic scan should be saved as a clip. (D3)	31 (67.4%) vs. 15 (32.6%)	A dynamic scan can be saved as a clip or as static images of abnormal findings or as images of accurate procedure performance. Agreement vs. Disagreement with alternative: 33 (71.7%) vs. 13 (28.3%)
A complete musculoskeletal ultrasound examination of an extremity consists of real time scans of a specific joint that includes examination of the muscles, tendons, joint, other soft tissue structures, and any identifiable abnormality. (D4)	42 (91.3%) vs. 4 (8.7%)	A comprehensive rheumatology musculoskeletal ultrasound examination consists of real time scans of a specific region that can include examination of the muscles, tendons, joints, other soft tissue structures, and any identifiable abnormality relevant to a rheumatic differential diagnosis or a multi structure rheumatic disease assessment tool. Agreement vs. Disagreement with alternative: 30 (65.2%) vs. 16 (34.8%)
A limited musculoskeletal examination of an extremity looks at a specific anatomic structure in the extremity region. (D5)	46 (100%) vs 0	A limited or focused musculoskeletal examination of an extremity looks at a specific anatomic structure in an extremity region. Agreement vs Disagreement with alternative: 29 (63%) vs 17 (37%)

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Imaging of Rheumatic Diseases Poster II: Ultrasound

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Entheses are exposed to biomechanical stress throughout life and sonographic enthesal abnormalities may not reflect an underlying inflammatory arthritis in all cases. In this study, we aimed to determine the prevalence of enthesal abnormalities in healthy subjects and explore factors that are contributing for the occurrence and severity of these findings.

Methods: Eighty healthy subjects who had no joint pain, recent joint trauma or surgery had ultrasound (US) scans for the insertions of the triceps, quadriceps, Achilles tendons and plantar fascia and the origins and insertions of the patellar tendons. The enthesis were scored for hypoechogenicity, thickening, Doppler signals, enthesophytes, erosions and calcifications, semi quantitatively between 0-3, calculating the total enthesitis score. The correlation between the total enthesitis score and various demographic and lifestyle factors was evaluated. A multiple linear regression was calculated to predict total US score based on age, sex, smoking status, BMI, and physical activity.

Results: Doppler signals and erosions were detected in 10% and 6.25% of the participants, respectively. Thickening was the most frequent sonographic enthesal lesion that could also be seen in the absence of hypoechogenicity (70% of the proximal patellar tendon origin). Enthesophytes were common at the Achilles tendon insertion seen in 78.7% of the participants. The total US scores correlated with age ($r:0.561$, $p<0.001$) and body mass index ($r:0.344$, $p:0.022$). Smokers had higher scores (14.0 ± 10.6 vs 9.02 ± 9.6 , $p:0.010$), similar to participants who were exercising more (13.53 ± 11.1 vs 7.94 ± 8.4 , $p:0.005$). In addition, men had higher scores than women (15.73 ± 11.6 vs 8.06 ± 8.2 , $p:0.001$) (Figure 1). In linear regression model age, gender, BMI and physical activity independently predicted to total US score (Table 1).

Figure 1: Differences within US scores and gender, BMI, smoking status and physical activity.

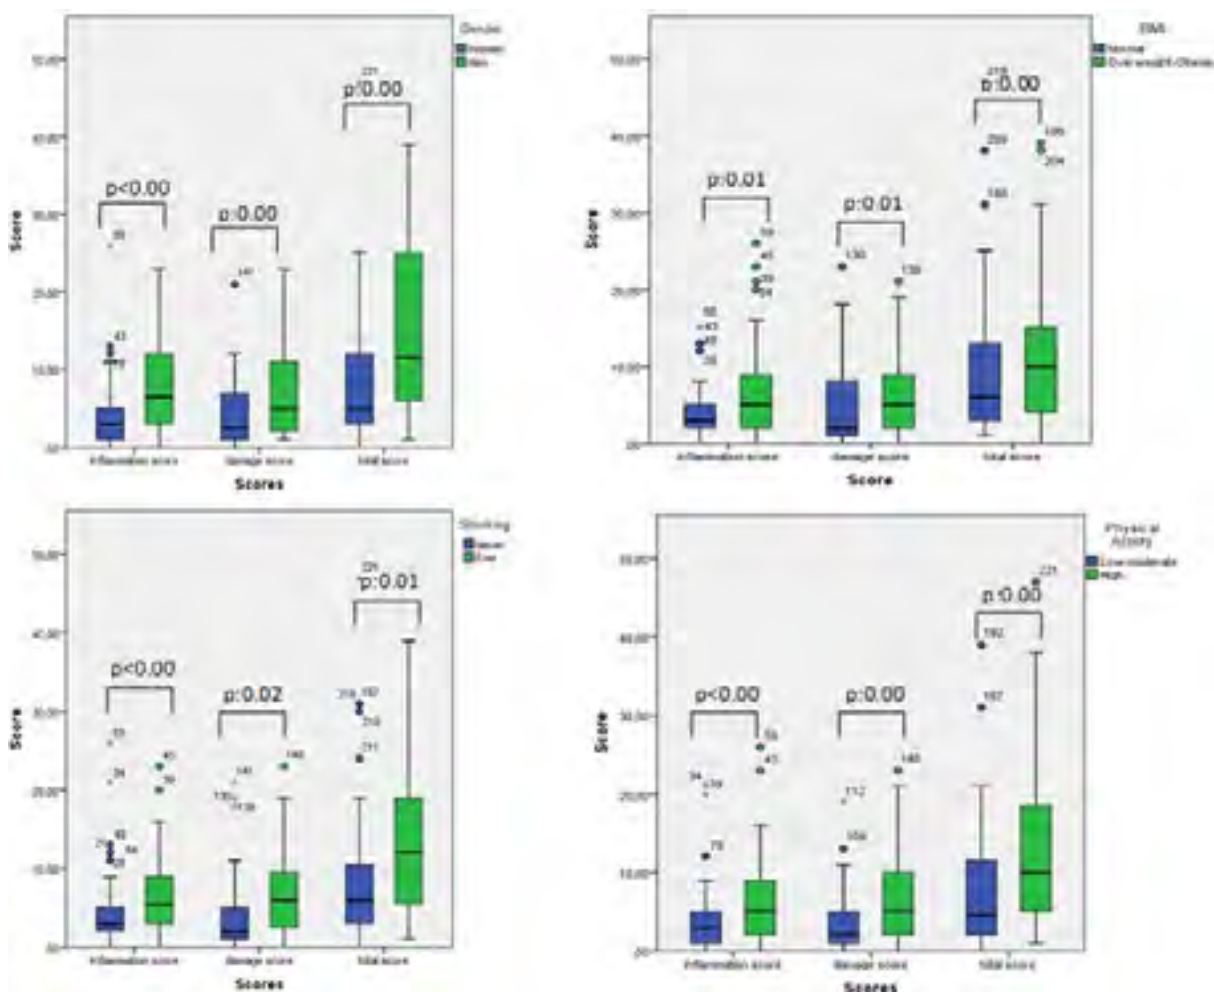

Table 1. Linear regression results of the factors affecting total US score

	Coefficients (B)	95 % CI	P
Age	0.358	0.253-0.463	<0.001
Gender	5.053	1.820-8.287	0.003
Smoking status	-0.146	-3.461-3.168	0.930
BMI	0.613	0.248-0.978	0.001
Physical activity	4.418	1.253-7.583	0.007

Conclusion: There are physiological changes within the enthesis that are associated with older age, higher BMI and physical activity. The enthesal abnormalities observed in the healthy enthesissupport the impact of biomechanical forces on the enthesis, not necessarily reflecting a pathology leading to any symptoms. Men and smokers, both of which are risk factors for radiographic severity in AS, have higher enthesal scores on ultrasound and the effect of these factors on the enthesis may be an explanation for the severe abnormal response on the spine in AS.

The Evaluation of the Small Enthesis of the Hands By Ultrasound: A Study on Healthy Subjects

Sibel Bakirci¹, Dilek Solmaz², Wilson Stephenson³, Lihi Eder⁴, Johannes Roth⁵ and Sibel Zehra Aydın⁶, ¹79 Cresthaven Drive, University of Ottawa, Ottawa, ON, Canada, ²Rheumatology, University of Ottawa, Ottawa, ON, Canada, ³Internal Medicine, University of Ottawa, Ottawa, ON, Canada, ⁴Women's College Research Institute, University of Toronto, Women's College Hospital, Toronto, ON, Canada, ⁵Pediatric Rheumatology, Children's Hospital Eastern Ontario, Ottawa, ON, Canada, ⁶University of Ottawa, Ottawa, ON, Canada

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Imaging of Rheumatic Diseases Poster II: Ultrasound

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The literature on sonographic enthesitis is primarily based on the large enthesis, ignoring the involvement of the small enthesis such as the hands. In this study, we aimed to determine the prevalence of enthesal abnormalities in small enthesis of the hands in healthy subjects and explore factors that are contributing to the occurrence of these findings.

Methods: Healthy subjects who had no joint pain, recent joint trauma or surgery had US scans of the flexor and extensor tendon insertions to the DIP and extensor tendon insertions to the middle phalanx at the level of the PIP, on the 3rd digits, on both hands. The enthesis were scored as present or absent for elementary lesions of enthesitis (hypoechoogenicity, thickening, Doppler signals, enthesophytes, erosions and calcifications) and osteophytes were also recorded.

Results: Within 80 healthy subjects (mean age: 45.0 ± 16.1; 62.5% female) 8 had OA. The enthesophytes were the most frequent elementary lesion of enthesitis that could also be seen in the absence of other lesions and were detected in 15% of the DIP extensor tendon insertions, 3.75% of the DIP flexor tendon insertions and 3.75% of the PIP extensor tendon insertions (Figures 1 and 2). 41% of the patients with enthesophytes at the DIP extensor tendon insertion also had osteophytes at the same site, which was significant higher than people without any enthesophytes (5/12 vs 1/68 p<0.001). Patients with enthesophytes were older (67.5 ± 12.6 vs 41.3 ± 13.3; p<0.001) and more frequently men (8/12 vs 22/68; p:0.048). The other elementary lesions were seen in the minority of the digits (Figure 1).

Conclusion: Enthesophytes of the small enthesis are frequent in healthy people and these lesions can be seen in the absence of other elementary lesions. It can be challenging to differentiate enthesophytes from osteophytes at the level of the DIP joints. Therefore the definition of enthesitis for the small enthesis may exclude enthesophytes not to overall patients with enthesitis. The other features of enthesitis were not common in healthy people, suggesting a good specificity to reflect pathology when detected, however studies on disease groups are needed to clarify.

Figure 1. Elementary lesions of enthesitis on extensor and flexor tendon insertions at the DIP joint and flexor tendon insertion at the PIP joint level.

Figure 2. Longitudinal scans of the extensor tendon insertion to the distal phalanx. A: A healthy enthesis B: Thickening and hypoechoogenicity with enthesophyte as well as an osteophyte. MP: Middle Phalanx; DP: Distal Phalanx; o: osteophyte; e: enthesophyte

Enthesal Involvement in Asymptomatic Healthy Subjects: Prevalence and Distribution of the Ultrasound Elementary Lesions of Enthesitis, with a Particular Focus on Those Indicating “Active” Inflammation

Andrea Di Matteo¹, Emilio Filippucci¹, Edoardo Cipolletta², María Victoria Martire³, Diogo Jesus⁴, Martina Isidori¹, Davide Corradini¹ and Walter Grassi¹, ¹Polytechnic University of Marche, Rheumatology Clinic, Jesi, Italy, ²Polytechnic University of Marche, Rheumatology Clinic, Jesi, Italy, ³Instituto Médico Platense, La Plata, Argentina, ⁴Rheumatology Department, Centro Hospitalar e Universitario de Coimbra, Coimbra, Portugal

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Imaging of Rheumatic Diseases Poster II: Ultrasound

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: According to the OMERACT definitions, thickening, hypoechogenicity and power Doppler (PD) signal represent the US findings indicative of enthesal “active” inflammation. However, these US elementary findings can be detected also in healthy subjects as shown in other studies, and a variable prevalence has been reported. Despite an experts agreement has been obtained, further investigation is still required to gather more data especially regarding entheses in healthy subjects. To explore the prevalence and distribution of the US findings indicative of enthesitis, defined according to the OMERACT definitions, in a group of asymptomatic healthy subjects.

Methods: US and clinical assessment of quadriceps, patellar and Achilles tendons, and plantar fascia entheses were performed on 82 healthy volunteer subjects. Exclusion criteria: previous surgery or procedural interventions in the knees and/or ankles, clinical enthesitis on the physical examination, history of enthesal pain in the 3 months preceding the evaluation, previous diagnosis of rheumatic disease, family history of psoriasis or inflammatory bowel disease. The US examination was carried out with a My Lab Twice (Esote S.p.A. Genoa, Italy), working with a high frequency linear probe (6-18 MHz) and at a Doppler frequency of 9.1-11.3 MHz. The US enthesal abnormalities of “structural damage” (enthesophyte, bone erosion and calcification) and “active enthesitis” (thickening, hypoechogenicity and PD signal) were identified according to the OMERACT definitions. Moreover, a semiquantitative score for the PD signal was used (0-3).

Results: Eight hundred and twenty entheses were evaluated in 82 subjects [age (mean \pm SD) 44.0 \pm 14.8, 59.8% females]. The prevalence and distribution of the US findings indicative of enthesitis are reported in Table.1. One or more US finding indicative of “active” inflammation were found in at least one entheses in 30 out of 82 healthy subjects (34.1%), in 69 out of 820 entheses (8.4%). US findings of “active” inflammation were found as isolated in 61 out of these 69 entheses, (38 thickening, 12 hypoechogenicity, 11 PD signal) and in combination in the remaining 8 entheses (thickening + hypoechogenicity).

Table 1. Prevalence and distribution of the US abnormalities at the lower limb entheses in healthy subjects

Ultrasound findings	Healthy subjects		Entheses of the lower limbs							Total		
			Quadriceps tendon	Patellar tendon proximal insertion	Patellar tendon distal insertion	Achilles tendon	Plantar fascia					
Thickening	22	26.8%	07	8.1%	5	3.7%	17	8.1%	15	7.0%	44	5.4%
Hypoechogenicity	11	13.4%	4	2.4%	0	0.0%	3	1.8%	8	4.0%	4	2.4%
PD signal ≥ 1	7	8.1%	3	2.4%	1	0.6%	4	2.0%	0	0.0%	8	1.0%
PD signal > 1	1	1.2%	1	0.1%	0	0.0%	0	0.0%	0	0.0%	1	0.1%
Entesophyte	20	24.4%	18	8.5%	2	0.2%	1	0.2%	14	6.3%	4	2.4%
Bone erosion	0	0.0%	0	0.0%	0	0.0%	0	0.0%	0	0.0%	0	0.0%
Calcification	21	25.0%	11	6.7%	0	0.0%	12	5.3%	10	5.1%	0	0.0%

Percentages refer to the total number of patients (n=82) and entheses (n=820), respectively. Legend: PD: power Doppler

Conclusion: The prevalence of the US findings of “active” inflammation, defined according to the OMERACT definitions, in a group of asymptomatic healthy subjects was low in relation to the total number of entheses but remarkable at subject-level. Combining US elementary lesions of “active” inflammation (i.e. PD signal ≥ 1 + enthesal thickening and/or hypoechogenicity) or considering as pathological only PD scores > 1 may increase the diagnostic accuracy of the US findings.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Imaging of Rheumatic Diseases Poster II: Ultrasound

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Synovial vascularity as measured by power Doppler (PD) of MSKUS is correlated to rheumatoid arthritis disease activity, and PD signal reveals the prevalence of subclinical synovitis overlooked on physical examination. It is frequently difficult to distinguish bone erosion from normal concave surface of the bone. It is necessary for us to know these normal structures well in evaluating disease activity by using MSKUS. Here we examine the age-specific differences of normal feeding vessels and bone surface irregularity between in wrist joints. To elucidate the differences of distribution of feeding vessels and bone surface irregularity in wrist joints both young and older adults of healthy volunteers.

Methods: The dorsal side of wrist joints was scanned with 2D-probe in healthy volunteers (young <50 y.o., elder ≥50 y.o.). The distribution of feeding vessels in the capsule and the extensor (E.) tendon sheath (TS), and the evaluation of bone surface irregularity at lunate (Lu) were examined. The comparative review between young and elderly adults was validated.

Results: The distribution of feeding vessels in younger healthy volunteers (n=30; mean age 32.2±8.0) vs elderly healthy volunteers (n=21; mean age 66.0±7.2) were near-Trapezoid (Rt100.0%vs100.0%, Lt100.0%vs100.0%; p=1.00), E. digitorum TS (Rt86.7%vs81.0%; p=0.59, Lt66.7%vs76.2%; p=0.47), E. digiti minimi TS (Rt30.0%vs52.4%; p=0.11, Lt30.0%vs66.7%; p=0.0089), near-Capitate (Rt23.3%vs42.9%; p=0.14, Lt30.0%vs47.6%; p=0.21), near-TFCC (Rt16.7%vs19.0%; p=0.83, Lt30.0%vs38.1%; p=0.56), distal radial side of radiocarpal joint (Rt20.0%vs42.9%; p=0.08, Lt23.3%vs28.6%; p=0.68), distal end of Ulna (Rt10.0%vs42.9%; p=0.006, Lt16.7%vs28.6%; p=0.31). Feeding vessels from vascular channels were depicted at Lu (Rt53.3%vs52.4%; p=0.95, Lt46.7%vs66.7%; p=0.16), Radius (Rt20.0%vs33.3%; p=0.29, Lt16.7%vs23.8%; p=0.54), Triquetrum (Rt10.0%vs42.9%; p=0.0057, Lt16.7%vs33.3%; p=0.17) and Capitate (Rt6.7%vs33.3%; p=0.013, Lt10%vs33.3%; p=0.0395). The bone surface irregularity as a transverse diameter (Mean±S.D.) at Lu of dominant hand in both groups were 1.26±0.33vs1.14±0.2mm; p=0.21, respectively.

Conclusion: The frequency of feeding vessel's distributions in elderly adults were significantly higher at E. digiti minimi TS, distal end of Ulna and Triquetrum/ Capitate vascular channels compared to those of younger adults. It is suggested that these differences are crucial to evaluate the age-specific synovitis by ultrasound.

Ultrasound-Detected Joint Erosions in Rheumatoid Arthritis: What Every Sonographer Should Know

York Kiat Tan^{1,2,3}, HuiHua Li⁴, John Carson Allen Jr⁵ and Julian Thumboo^{1,2,3}, ¹Department of Rheumatology and Immunology, Singapore General Hospital, Singapore, Singapore, ²Duke-NUS Medical School, Singapore, Singapore, ³Yong Loo Lin School of Medicine, National University of Singapore, Singapore, Singapore, ⁴Health Services Research, Singapore General Hospital, Singapore, Singapore, ⁵Centre for Quantitative Medicine, Duke-NUS Medical School, Singapore, Singapore

SESSION INFORMATION

Session Date: Monday, October 22, 2018
Session Title: Imaging of Rheumatic Diseases Poster II: Ultrasound
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Previous work in rheumatoid arthritis (RA) on bone erosion(s) using ultrasound (US) focused mostly on small joints of the fingers and toes. We aim to gain further insight into US-detected bone erosion(s) by including a larger number of joints and studying them in relation to US inflammatory joint findings.

Methods: 36 joints and 60 joint recesses were scanned per patient (table 1). At each joint recess scanned, US power Doppler (PD) and grey-scale (GS) joint inflammation were graded semi-quantitatively (0-3) and these scores were summed to obtain a combined US (CUS) score, while bone erosion(s) was scored dichotomously (1=yes/0=no). As US findings for different joints in the same patient may not be independent, Generalized Estimating Equations (GEE) analysis was used to compare mean PD, GS and CUS scores between (a) joint recesses scanned with bone erosion(s) detected and (b) joint recesses scanned without bone erosion(s) detected. Means and 95% CIs were estimated using GEE with robust Huber-White variance estimates.

Results: 1080 joints and 1800 joint recesses were scanned in 30 RA patients all of whom fulfilled the 1987 and/or 2010RA classification criteria. The patients' baseline characteristics were: mean age, 61.7 years; 93.3% female; 76.7% Chinese; mean (SD) disease duration, 70.3(61.2) months; mean (SD) DAS28, 3.58 (1.20). 144/1080 (13.3%) joints and 189/1800(10.5%) joint recesses scanned exhibited bone erosion(s), respectively. Figure 1 shows the frequency distribution of US-detected bone erosion(s) at the jointsites. Of the 144 joints with bone erosion(s), the 5 joints most frequently encountered were: wrist, n=49 (34.0%); first MTPJ, n=19 (13.2%); thumb IPJ, n=13 (9.0%); second MCPJ, n=11 (7.6%) and third MCPJ, n=11 (7.6%). Comparing joint recesses scanned with bone erosion(s) detected versus those scanned with no bone erosion (s) detected, mean (95% CI) PD, GS and CUS scores were 0.36 (0.21, 0.50) vs. 0.013 (0.002, 0.024), 1.77 (1.54, 2.00) vs. 0.47 (0.40, 0.55), and 2.13 (1.78, 2.47) vs. 0.49 (0.41, 0.57), respectively. P-values were all <0.001.

Conclusion: From the literature, second and fifth MCPJ and fifth MTPJ were recommended US target joints in RA. In our study cohort, other than the second MCPJ, the wrist, first MTPJ, thumb IPJ and third MCPJ were among the 5 joints most commonly affected by bone erosion(s). Joint sites with bone erosion(s) were more likely to exhibit greater joint inflammation severity seen on both PD and GS US. Sonographers assessing structural joint damage should pay particular attention to these joints when scanning for bone erosions in RA.

The Use of Musculoskeletal Ultrasound to Assess Remission in Patients with Rheumatoid Arthritis

Myriam Allen¹, Maggie Larche² and Karen A. Beattie², ¹Rheumatology, McMaster University, Hamilton, ON, Canada, ²Medicine, McMaster University, Hamilton, ON, Canada

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Imaging of Rheumatic Diseases Poster II: Ultrasound

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with rheumatoid arthritis (RA) should achieve remission rapidly to avoid irreversible joint sequela. Studies have shown that patients with apparent clinical remission have positive power Doppler on ultrasound examination, suggestive of ongoing inflammatory disease activity. The purpose of this study was to retrospectively determine the flare rate at 12 months in patients with RA, who had a diagnosis of clinical remission and ultrasound remission compared with patients who had only a diagnosis of clinical remission.

Methods: In this retrospective study, we used medical charts to identify patients with RA and a diagnosis of remission made between January 2012 and January 2017. Patient demographics and information on treatment and outcome were retrieved from the medical charts (Table 1). Patients were defined to be in remission when they had ≤ 1 swollen joint and diagnosis of remission by clinician. We then separated patients in 2 groups based on whether the patient had undergone ultrasound. We retrospectively compared the flare rate at 12 months, in patients who had a clinical diagnosis of remission and an ultrasound diagnosis of remission versus patients who had a clinical diagnosis of remission. Flare during follow-up was defined by clinician diagnosis and >1 swollen joint and/or need to change the medication regimen for RA. We also calculated the time between diagnosis of remission and flare.

Results: A total of 121 patients were included, 108 females and 13 males. Clinical and ultrasound remission was diagnosed in 34 patients while 87 patients were diagnosed with clinical remission. Baseline characteristics in 2 groups were similar, except for longer duration of disease, more biologic therapy received in the past and more smokers in the group without ultrasound (Table 1). Of the patients who had a diagnosis of remission with ultrasound, 7 (20.6%) flared during follow-up compared to 37 (42.5%) who did not have an ultrasound. After accounting for smoking as a covariate, this difference in flare rates was statistically significant ($p=0.047$). The time to first flare appeared longer in the ultrasound group compared to the clinical group, although this difference was not significant ($p=0.105$).

Conclusion: This retrospective study demonstrated a smaller incidence of RA flare at 12 months in patients who had a clinical diagnosis of remission with ultrasound compared to patients who had a diagnosis of remission without ultrasound. Further prospective studies comparing the clinical approach with combined approach are needed to identify the real value of ultrasound for RA remission diagnosis

SESSION INFORMATION

Session Date: Monday, October 22, 2018
Session Title: Imaging of Rheumatic Diseases Poster II: Ultrasound
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Several unilateral scoring systems have been proposed to increase the feasibility of ultrasound (US) for joint evaluation in rheumatoid arthritis (RA) patients. Both the clinically most affected side and the dominant hand have been proposed as the default monitoring approach during treatment, however, no consensus exists on which side to choose. The aim is to evaluate if the dominant hand or the hand with more clinically swollen joints is per default the more inflammatory active side, as judged by US, to be chosen for unilateral scoring systems in RA patients.

Methods: We performed an agreement study exploring the impact on US scoring methods in a cross-sectional study of an early RA (ARCTIC trial, n=230) and established RA cohort (ULRABIT trial, n=212) with patients initiating conventional and biological Disease Modifying Anti-Rheumatic Drugs, respectively. Tender and swollen joint count for 28 joints (TJC28 and SJC28) and C-reactive protein (CRP mg/L) were obtained. Using the hands as model, bilateral MCP 1-5, PIP 2+3 and wrists were evaluated by US using a 0-3 scoring system for both grey-scale (GS) and power Doppler (PD) US according to the atlas by Hammer et al. A GS sum score, a PD sum score and a global synovitis score (GLOSS) were calculated for each hand (0-30). According to our prespecified protocol a reasonable equivalence margin in this study (agreement between groups) was defined to correspond to a 95% Confidence Interval around the observed paired mean difference: -2.99 to +2.99; a difference of at least 3 in sum score defined a clinical significant difference defining which hand was more inflammatory active.

Results: In total, 442 RA patients were included; 71% women, 79% anti-CCP pos, 71% RF pos, median(IQR) age 54(42-62) years, CRP 7(3-16), SJC28 5(3-26) and TJC28 6(2-28). The median(IQR) PD sum score was 3(0-7) for right hand and 2(0-5) for left hand, GS sum score was 5(2-9) for both hands, and GLOSS was 5(2-10) for right hand and 5(2-9) for left hand.

The dominant hand was not more inflammatory active than the non-dominant (mean difference, 95%CI) for PD sum score -0.58(-1.35 to 0.2), GS sum score -0.69(-1.61 to 0.24) and GLOSS -0.79(-1.76 – 0.18). This was in clear contrast to analyses of the hand with more swollen joints which was statistically significantly more inflammatory active (p<0.0001): for PD sum score 1.70(0.94 to 2.47), GS sum score 2.21(1.30 to 3.12) and GLOSS 2.31(1.36 to 3.26) – see table.

Table Ultrasound inflammatory activity in the dominant hand versus non-dominant hand and in the hand with clinically more swollen joints versus less swollen joints using different unilateral scoring systems			
	Doppler sum score (0-30)	GS (0-30)	GLOSS (0-30)
	Mean (95% CI)	Mean (95% CI)	Mean (95% CI)
*Dominant hand			
Dominant	4.3 (4.1 – 4.4)	7.3 (7.1 – 8.4)	6.3 (7.4 – 8.8)
Non-Dominant	4.3 (3.3 – 4.8)	7.1 (6.4 – 7.7)	7.8 (8.6 – 8.2)
Difference	-0.58 (-1.15 – 0.10)	-0.69 (-1.61 – 0.24)	-0.79 (-1.6 – 0.18)
P-value	0.14	0.15	0.17
*Clinical assessment			
Hand with more clinically swollen joints	5.37 (4.8 – 5.9)	8.5 (7.9 – 9.16)	8.8 (8.2 – 9.5)
Hand with less clinically swollen joints	3.64 (3.1 – 4.2)	8.3 (6.7 – 8.9)	6.5 (5.8 – 7.2)
Difference	1.73 (1.24 – 2.47)	0.2 (1.32 – 1.85)	2.31 (1.63 – 3.4)
P-value	<0.0001	<0.0001	<0.0001

*Analysed using a t-test for the specific analysis and test (ARCTIC and ULRABIT, respectively) as a main effect, and the patient ID was included as a random effect

Conclusion: Based on this study, the dominant hand is not significantly more affected than the non-dominant hand regarding inflammatory activity evaluated by US. As the hand with clinically more swollen joints are more inflammatory active by PD sum score, GS sum score and GLOSS, the hand with most swollen joints is suggested to be chosen as basis for unilateral scoring systems.

Abstract Number: 1201

Finger Extensor Tendon Involvement Is Frequent in Early Rheumatoid Arthritis

Mihaela Maruseac¹, Patrick Durez^{2,3}, Adrien Nzeusseu Toukap⁴ and Maria Stoenoiu⁵, ¹Rheumatology, Cliniques Universitaires Saint-Luc, Brussels, Belgium, ²Pôle de Maladies Rhumatismales, Institut de Recherche Expérimentale et Clinique, Université catholique de Louvain, Brussels, Belgium, ³Pôle de Recherche en Rhumatologie, Institut de Recherche Expérimentale et Clinique, Université Catholique de Louvain, Brussels, Belgium, ⁴Department of Rheumatology, Rheumatology - Cliniques universitaires Saint-Luc - Université Catholique de Louvain - Institut de Recherche Expérimentale et Clinique (IREC), Brussels, Belgium, ⁵Rheumatology, Cliniques Universitaires Saint-Luc, Institut de Recherche Expérimentale et Clinique (IREC), Brussels, Belgium

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Imaging of Rheumatic Diseases Poster II: Ultrasound

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Finger extensor involvement (FET) at ultrasound examination (US) was previously described in patients suffering from early psoriatic arthritis. Contradictory results were published in patients suffering from rheumatoid arthritis. We aimed to assess the involvement of FET in early rheumatoid arthritis (ERA) patients and in asymptomatic subjects (CTR)

Methods: Inclusion criteria for ERA patients were: less than 6 months since the ERA diagnosis; age >18 years; without DMARD treatment or oral glucorticoids at US examination. Inclusion criteria for CTRL subjects were : age >18 years; no pain in hands and fingers (VAS pain =0/100); no known rheumatic disease such a systemic diseases, rheumatoid, psoriatic arthritis, spondyloarthritis, hand osteoarthritis, gout, chondrocalcinosis; no psoriasis, no inflammatory bowel diseases. US assessments were performed blindly to the clinical and laboratory data. FET were assessed in longitudinal and in transverse view at the metacarpo phalangeal joint (MCP) and proximal phalangeal joint (PIP) level both in grey-scale (GS), power Doppler (PD) and in color Doppler (CD) mode. In addition the following joints were assessed for the presence and grade (0-3) of GS/PD synovitis

Results: Sixty-two consecutive ERA patients and 34 CTR were included in this study. Mean age and gender distribution were comparable between ERA and CTR (47,3±14,5 vs. 43,4±12,5). ACPA were present in 61%, rheumatoid factor in 54% and bone erosions in 27% of ERA patients. 57% of ERA patients presented with FET and 0% of CTR (p<0.001). The delay between the first symptom and diagnosis, the DAS28CRP, SDAI, CDAI, CRP level, 44TJC, 44SJC, HAQ did not differ significantly between patients with FET involvement and those without. In univariate analysis, the presence of FET involvement was significantly associated with the presence of bone erosions (p=0.02), ACPA (p=0.002), rheumatoid factor (RF) (p=0.02) and tobacco use (p=0.02). In multivariate analysis, the presence of FET involvement was significantly associated with the presence of bone erosions (p=0.01), ACPA (p=0.001) and RF (p<0.01).

Conclusion: FET is relatively frequent in ERA patients and it is not present in asymptomatic subjects. Our results show that FET involvement is associated with the presence of ACPA, rheumatoid factor and bone erosions, thus identifying patients with possibly more aggressive or severe disease at baseline.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Imaging of Rheumatic Diseases Poster II: Ultrasound

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatologists commonly use synovial fluid analysis to help establish a diagnosis in patients with joint effusions. Although tenosynovial (TS) effusions are common in rheumatic conditions, there is no guide to inform the interpretation of fluid aspirated from tendon sheaths. Musculoskeletal ultrasound (MSUS) has allowed for routine aspiration of TS effusions. To better characterize TS fluid and MSUS findings in rheumatic diseases, we organized a multi-center collaboration to prospectively analyze TS findings on patient aspirations. This is an interim report of the first eight months of the study.

Methods: Patients with TS aspiration planned as part of routine care were included. We are collecting information on patient demographics, underlying rheumatic disease, involved tendon location, duration of TS symptoms, TS fluid characteristics, MSUS appearance and tendon specific diagnosis. Specific TS fluid data collected includes volume (hemocytometer used if fluid volume below clinical laboratory threshold), gross appearance, leukocyte count, and crystal identification. This interim descriptive analysis reports on the patient and disease characteristics of subjects enrolled to date.

Results: 59 of 100 subjects have been enrolled at 10 participating sites. Table 1 reports the patient characteristics, involved tendons and volume of TS fluid aspirated. Four patients presented after trauma to the involved tendon. 78% of all TS aspirations were derived from 5 locations: 4th extensor compartment, bicipital tendon, extensor carpi ulnaris, posterior tibial and peroneal tendons. 14 (24%) of the aspirations had a fluid volume of <0.5mL. Table 2 shows the established rheumatologic diagnosis, and diagnosed cause of TS effusion after the aspiration. Of note, only 4 aspirations were from patients known to have a crystalline diagnosis, but a total of 12 were diagnosed after aspiration. Rheumatoid arthritis was the most common patient diagnosis to require a TS aspiration. Only one case of infection - coccidioidomycosis was diagnosed so far.

Vasculitis	2	0
Polymyalgia rheumatica	0	3
Tendonitis	3	0
Drug-induced	0	2
Systemic lupus erythematosus	2	1
Infection	1	1
Osteoarthritis	1	0
IRIS	0	1

CPPD: calcium pyrophosphate deposition; IRIS: immune reconstitution inflammatory syndrome; N: number.

Conclusion: TS pathology occurs in a variety of inflammatory and non-inflammatory diseases commonly seen in rheumatology. MSUS guidance allows aspiration of very small volumes of TS fluid. Automated cell counts may not be possible on the small volumes obtained, but can be determined using a manual hemocytometer. TS aspirates can be used to establish a diagnosis, particularly crystalline forms of arthritis. The distribution of TS effusions could be used to focus teaching and performance of MSUS to the most frequently affected areas.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Imaging of Rheumatic Diseases Poster II: Ultrasound

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The urgent need for identifying imaging and serological markers that early predicts rheumatoid arthritis (RA) is clinically important. We aim to identify ultrasound findings that precedes arthritis onset in Anti-Citrullinated Protein Antibody (ACPA) positive subjects at risk for developing RA.

Methods: Patients with musculoskeletal complaints and a positive ACPA test were referred from primary-care units to the rheumatology department for specialized care. Those lacking arthritis by clinical and ultrasound (US) examination were included in the prospective Risk-RA program, and monitored by a multidisciplinary team. Hand (Wrists, MCP's, PIP's, DIP's) and feet (symptomatic joints included), were US-assessed for synovial hypertrophy and Doppler activity according to the EULAR-OMERACT definitions. Hand tendons [extensor wrist tendon compartments (1-6) and flexor finger tendons (2-5)] were examined for signs of tenosynovitis (tendon sheath thickening and/or fluid, with/without Doppler activity). Serum samples from inclusion were analysed on a multiplex immunoassay.

Results: At inclusion, 66 Risk-RA patients [85% female, median(range) age 50(22-82)yrs] were US-evaluated, and followed until arthritis onset. Within 2½ yrs [median 8(1-27) months] from recruitment, 27 patients [41%, 86% female, median age 52(22-74) yrs] developed an arthritis diagnosis. Of these 27 patients, 7 had tenosynovitis detected by US at inclusion, and 7 more developed tenosynovitis at follow-up visits (n=14). At the time of diagnosis, 20 out of 27 patients presented with both tenosynovitis and synovitis.

Majority of patients with tenosynovitis (12 out of 14, 86%) and a minority without tenosynovitis (15 out of 52, 29%) developed arthritis, resulting in an increased relative risk of 3.0 (95% CI 1.8-4.8) to develop arthritis for those presenting with tenosynovitis at baseline or follow-up visits (p=0.001). The extensor-carpi-ulnaris wrist tendons (7 of 12 patients) and 2nd finger flexor-tendons (5 of 12 patients) were commonly affected.

Concentrations of the ACPA specific antibodies tended to be higher in tenosynovitis patients developing arthritis [n=12, median of 70(2-175) AU/ml for anti-CCP, median of 68(0-673) AU/ml for anti-CEP, median of 53(0-644) for anti-vimentin] as compared to those without tenosynovitis developing arthritis [n=15, median of 35(1-100) AU/ml for anti CCP, median of 12(0-1179) for anti-CEP, median of 29(0-332) for anti-vimentin]. Same trend was noted in tenosynovitis patients developing arthritis vs those without-tenosynovitis not-developing arthritis. The 2 tenosynovitis patients' not developing arthritis had lower levels of the antibodies compared to the tenosynovitis patients that developed arthritis.

No significant differences were noted in other patient baseline characteristics in those with tenosynovitis versus those without tenosynovitis [86 vs 85 % female, median age 54(29-71)yrs vs 50(22-82)yrs, mean visual analogue scale pain 34 vs 31, mean CRP 2.7 vs 3.2; and tender joint count 1.2 vs 0.7].

Conclusion: Tenosynovitis detected by ultrasound is highly predictive of rapid arthritis onset in ACPA positive subjects at risk for developing arthritis.

Experience Matters in Ultrasound Assessment of Gout

Burak Elkiran¹ and Eugene Y. Kissin², ¹Internal Medicine, Steward Carney Hospital, Boston, MA, ²Rheumatology, Boston University, Boston, MA

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Imaging of Rheumatic Diseases Poster II: Ultrasound

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Ultrasound has emerged in the field of rheumatology as a diagnostic aid for gout and other similar forms of arthritis. While a number of studies have looked into the test characteristics of ultrasound in diagnosing gout, only a few studies have examined the correlation between user experience with soft tissue ultrasound and diagnostic precision. Our study seeks to examine the correlation between the diagnostic accuracy of clinicians for gout using ultrasound and factors pertaining to experience and training.

Methods: Graduates of a MSUS (musculoskeletal ultrasound) training program were asked to anonymously complete a set of multiple-choice questions (single best answer type) asking for the most likely patient diagnosis based on de-identified ultrasound images of bilateral knee and 1st metatarsophalangeal joints from patients with non-tophaceous, crystal proven gout (n=6), crystal proven calcium pyrophosphate arthropathy (n=5), or synovial fluid and radiograph supported osteoarthritis (n=2). No normal images were included in the questionnaires. They were also asked information regarding the use of MSUS within the participant's practice/fellowship, years in practice, MSUS CME (Continuing Medical Education) scores. Participants were categorized into quartile groups based upon prior final exam scores. We used Wilcoxon Signed Rank Test and Spearman's Rank Correlation Co-efficient methods for the statistical analysis.

Results: Survey was sent to 240 clinicians, 32 graduates responded to the survey, 10 of which did not answer demographic questions. Clinicians with 5 or more years of practice had more correct answers in gout questions than the ones who practice less than 5 years (76% accurate answers in gout questions vs 54%, $p<0.05$; $r=0.54$). They also had more correct answers in overall questions including gout, pseudo-gout and OA compared to the clinicians who practice for less than 5 years, however this was not clinically significant (64% accurate answers in overall questions vs 52%, $p=0.08$; $r=0.32$). Differences in gout diagnosis accuracy based on CME credits was not statistically significant ($p=0.2$). There was no correlation found between general MSUS training exam scores and accuracy in diagnosing gout.

Conclusion: This is the first study which shows how the length of time in practice affects the accuracy in diagnosing gout, and that this effect is more significant than extent of CME hours or MSUS training exam performance. However, it should be noted that the training exam performance was not specific to gout.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Imaging of Rheumatic Diseases Poster II: Ultrasound

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Conventional radiography (CR) and, more recently, US play a key role in the diagnosis of CPPD. To date, only a very few studies have investigated the diagnostic ability of US and CR in the assessment of hip joint in CPPD patients. To the best of our knowledge, there is no study that has compared the diagnostic accuracy of these two imaging techniques in the detection of calcium pyrophosphate (CPP) crystal deposits at the hip in patients with CPPD.

The aims of this study are to investigate the prevalence of the US findings indicative of CPP crystal deposits at the hip in patients with CPPD and to evaluate the diagnostic performance of US and CR and the agreement between these two imaging techniques in the evaluation of CPP crystal deposits at the hip in patients with CPPD.

Methods: Consecutive patients with “definite” CPPD, diagnosed according to the Ryan and McCarty criteria, and age/sex/body mass index-matched disease controls were enrolled. Inclusion criteria: knees and hips CR performed within the previous 6 months and synovial fluid analysis. Exclusion criteria: prior remarkable hip injuries, surgery procedures or severe osteoarthritis.

A rheumatologist, blinded to clinical data, performed bilateral US examinations of the hip in all patients, assessing the presence of CCP crystal deposits both at the acetabular fibrocartilage and at the hyaline cartilage of the femoral head. The OMERACT definition for the identification of CPPD by US were used. The US examination was carried out using a My Lab Twice US machine (Esaote S.p.A. Genoa, Italy), working with a linear (3-13 MHz) and, when necessary, a convex probe (2-7 MHz).

Two independent radiologists, blinded to the clinical and US findings, evaluated the presence/absence of CR calcifications at hip joints in both groups.

Results: Forty-three patients with CPPD [age (mean±standard deviation) 72.0±9.2; 24 females] and 40 controls were included in the study.

US findings indicative of CPP crystal deposits were found in at least one hip in 39 out of 43 (90.7%) patients with CPPD, in 62 out of 86 (72.1%) hips. US and CR sensitivity was 91% and 86%, respectively, whereas US and CR specificity was 85% and 90%, respectively. Sixty-nine patients were assessed using a linear probe (34 patients with CPPD, 35 controls) whereas the remaining 14 patients were studied using a convex probe (9 patients with CPPD, 5 controls).

The inter-reader agreement between the two radiologists which evaluated the CR images was $k=0.77$ (95%CI 0.67-0.87).

The agreement between the US and CR finding was $k=0.76$ (95%CI 0.67-0.87).

Conclusion: Our results show a high prevalence of CPP crystal deposits at the hip in patients with CPPD. This study supports the role of US as a first-line safe and more sensitive imaging technique compared to CR.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Imaging of Rheumatic Diseases Poster II: Ultrasound

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Spondyloarthritis is characterized by inflammatory back pain. Anterior chest wall (ACW) pain is common and a previous study reported a prevalence à 35.5 % of ultrasonographic lesions of this anatomical region [1]. The objective of this study is to evaluate the prevalence of ACW ultrasonographic lesions after a follow up of 5 years and to identify factors associated with the development of new lesions.

Methods: This a monocentric and prospective study including patients with Spondyloarthritis meeting the ASAS 2009 criteria. Patients were followed during five years. ultrasound B mode and power Doppler examination of the two sternoclavicular joint and the manubrio-sternal joint were performed by the same two examiners at baseline and five years later. The presence of erosion, synovitis, ankylosis, power Doppler signal, joint effusion and bone margin narrowing were assessed. Clinical characteristics and disease activity were evaluated at 5 years.

Results: In the 136 patients at baseline, 30 patients were evaluated 5 years later. The mean age was 48 +/- 10 years old, with 80% of male and 85 % of HLA B27. 53,5 % of these patients had a history of pain of the ACW. The prevalence of ultrasonographic involvement of the ACW was 36,7 % at baseline and 63 % five years later. The most frequent lesions were erosions of the sternoclavicular joint (36,5 %) and ankylosis of the manubriosternal joint (33,5%). At 5 years, patients with lesions of the ACW are older but not significantly (49,9 +/- 9,9 VS 44,6 +/- 10,1, p=0,15) and use statistically more anti TNF (p= 0,047). There were no differences concerning the presence of HLA B27 and the presence of a radiographic sacroilitis or syndesmophytes. Among these 30 patients, 14 developed a new lesion of the ACW. There is a trend on an association between a higher ASDAS CRP and new lesions of the ACW (1,97 +/- 1,14 VS 2,7 +/- 0,768, p = 0,07) and with the level of CRP (6,33 +/- 9,63 VS 15 +/- 20,9, p = 0,13). Nevertheless, the ASDAS CRP at baseline is not predictive of the occurrence of new lesions of the ACW.

Conclusion: The prevalence of ultrasonographic lesions of the ACW increased after 5 years of follow up. The use of anti TNF is associated with more lesions and patients with new lesions had a trend of a more active disease. These data must be completed with a higher number of patients.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Imaging of Rheumatic Diseases Poster II: Ultrasound

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Enthesitis is a hallmark of spondyloarthritis (SpA), which occurs in 30 to 50% of psoriatic arthritis patients [1]. Evaluation of tenderness at the site of an enthesitis with a standard palpation approach remains the gold standard for detection of enthesitis. However, inter- and intra-observer variability is rather high. All existing clinical enthesitis scoring systems lack validity. Imaging could avoid these drawbacks. The objective of this study is to compare the performance of ultrasound (US) and magnetic resonance imaging (MRI) with clinical examination (CE) of joints and entheses in peripheral (p)SpA.

Methods: Clinical REmission in peripheral SPondyloArthritis (CRESPA) is a placebo-controlled trial of golimumab treatment in 60 early (symptom duration < 12 weeks) pSpA patients. CE included tender and swollen joint count, dactylitis and enthesitis (evaluation of palpation tenderness) count. All patients underwent Power Doppler (PD) US of entheses and knee, talocrural (TC) and subtalar (ST) joints. Synovitis was scored according to the OMERACT-EULAR-US composite PDUS scale, giving a score of 0-3 for each joint. Enteseal sites were evaluated for hypoechogenicity and intraenthesitis Doppler signal and were scored on a scale of 0 –3. Modified whole-body MRI was performed at baseline. Bone marrow edema (BME), synovitis and soft tissue inflammation (STI) were scored (scale 0-3) by 3 readers at several anatomical sites of pelvis and lower limbs. For each site a mean of the scores of the 3 readers was calculated.

Results:

Table 1. Prevalence of synovitis and enthesitis on CE, US and MRI

Joints/entheses	CE	US	MRI
Hip joint	3/60 (0)	-	4/60 (1)
Knee joint	21/60 (6)	25/60 (8)	24/60 (7)
Talocrural joint	14/60 (1)	9/60 (1)	24/60 (13)
Subtalar joint	7/60 (2)	10/60 (12)	15/60 (0)
Quadriceps tendon	10/60 (2)	9/60 (1)	4/60 (0)
Superior patellar ligament	8/60 (2)	8/60 (1)	7/60 (3)
Inferior patellar ligament			6/60 (1)
Achilles tendon	14/60 (2)	11/60 (2)	17/60 (4)
Plantar fascia	15/60 (4)	7/60 (1)	17/60 (9)

Prevalence of bilateral involvement is indicated between brackets.

Synovitis detected by US and MRI was most prevalent at knee joints (Table 1). A discrepancy was noted between TC synovitis detected by CE, US and MRI. Enthesitis was most prevalent at Achilles tendon and plantar fascia. Regarding enthesitis, agreement between CE and US ranged from no (kappa -0.082) to moderate agreement (kappa 0.562). The highest agreement was observed at the enteseal sites of Achilles tendon (left 0.511, right 0.350) and plantar fascia (left 0.321, right 0.507). MRI did not correlate better with CE than US (kappa from -0.077 to 0.446). The correlation between MRI and US was overall poor and only in the Achilles tendon moderate (range -0.106 to 0.656).

Conclusion: There was a weak agreement between CE and imaging in detecting enthesitis. In general, US detects less enthesitis compared to CE, while MRI detects more.

Session Title: Imaging of Rheumatic Diseases Poster II: Ultrasound

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Although some global composite measures (DAPSA, DAS28) reflect musculoskeletal ultrasound (MSUS) findings of psoriatic arthritis (PsA), there is little knowledge on how to predict whether certain joints have US active findings. We examined the relationship between composite measure score of PsA and MSUS findings for each body part, and searched for useful indicators for active MSUS findings.

Methods: Total 98 PsA consecutive cases who fulfilled CASPAR criteria were evaluated. PASDAS, DAPSA, PASI, DAS28-CRP, DAS28-ESR, BASDAI, SDAI, CDAI, CPDAI were calculated using clinical examinations of 68 tender joints, 66 swelling joints, 6 enthesitis and 20 dactylitis. 5 body parts (hand, elbow, shoulder, knee, foot) specific PASDAS, DAPSA were also calculated. MSUS evaluated 60 joints, 16 entheses and 24 tendons. Enthesitis was assessed according to the MASEI investigating the inflammatory scores (entheseal thickening, structural changes, bursitis and vascularization) and chronic damage scores (calcifications, enthesophytes, and erosions). US findings were grouped into 7 body parts (finger, wrist, elbow, shoulder, knee, ankle, toe), and the relationship between composite measure score of PsA and MSUS findings we reanalyzed using Receiver Operating Characteristic (ROC) curve analysis.

Results: MSUS PD \geq 1 in joints were frequent in wrist (13.9 % 3.4%), knee (7.65 % 6.5%) and elbow (13.9 % 3.4%). MSUS enthesitis were frequent in Achilles tendon (inflammatory 18.9%, chronic 29.5%) and knee quadriceps (inflammatory 11.5%, chronic 32.8%). Composite measures predicting active MSUS findings (PD \geq 1 in joint or tendon, or positive for inflammatory scores of enthesitis) were different among body parts (Table 1). In fingers, DAS28-CRP, SDAI, CDAI predictive MSUS findings with moderate accuracy. In wrist, ankle and toe, hand-specific PASDAS, foot-specific PASDAS or foot-specific DAPSA predictive MSUS findings than global PASDAS and DAPSA. On the other hand, in elbow, shoulder and knee, BASDAI predict active MSUS findings with the highest accuracy.

Conclusion: Composite measures predicting active MSUS findings were different according to body parts. Parts-specific composite measure improved predicting wrist or ankle MSUS findings. Since there is laterality of arthritis or enthesitis of PsA, location specificity is considered to be important than global composite measures. BASDAI is important when

considering elbow, shoulder and knee, which is presumably related to the importance of the element of enthesitis in these parts. Careful evaluation according to each part is considered important for prediction of MSUS.

Table 1: Relationship between activeMSUS findings in body parts and composite measures (value = AUC).

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Imaging of Rheumatic Diseases Poster II: Ultrasound

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Metacarpophalangeal joint (MCPj) swelling in PsoriaticArthritis (PsA) can be produced both by synovitis (IAS) and peritenonextensor tendon inflammation (PTI), having been this last lesion reported by some authors as an enthesitis-like lesion. Our objective was to explore the association of PTI and IAS with enthesitis in PsA,using the enthesitis US score MASEI (Madrid Sonographic Enthesis Index).

Methods: 27 consecutive non selected PsA patients were included. An expert rheumatologist obtained US images from the dorsal aspect of 2nd to 5th MCPj of both hands evaluating IAS and PTI in grey scale (GS) and power Doppler (PD), and also performed the MASEI examination. In addition to the PD item of MASEI (defined as signal in bone profile or intratendon or bursa at the enthesitis), PDOMERACT was evaluated as present or absent (defined as signal in the enthesitis 2 mm to the bone profile). We used a MyLab 70 XVG machine, Esaote, Genoa, Italy, with a GS 13 MHz probe and 7.1 MHz PD frequency, PRF 750 Hz and 60 Gain. 3-5 seconds videos of each MCPj and enthesitis were obtained in transverse and longitudinal views for further reliability analysis. Reliability of IAS and PTI was performed by 5 readers (true US result was the consensus of at least three) and MASEI«s by 3 readers (true US result was the consensus of at least two). For qualitative reliability analysis, mean Cohen kappa was used for PD, IAS and PTI, and intraclass correlation coefficient (ICC) for MASEI based on a mean-rating of three readers, absolute-agreement, two-way mixed effect model. Statistical association between IAS, PTI and MASEI was analyzed with T student test. SPSS statistical package version 20 (SPSS Inc, Chicago, IL) was used.

Results: Eighteen patients had PTI PD (66,7%) and same value for SIA PD. The inter-reader reliability for PTI and IAS was good with kappa values of 0.685 and 0.680 respectively. The inter-reader reliability for MASEI was excellent with ICC 0,922 (CI 95% 0,846-0,960). The inter-reader reliability for PD MASEI was ICC 0,921(CI 95% 0,855-0,963) and for PD OMERACT ICC 0.895 (CI 95% 0,802-0,949). Table 1 shows the existence of association between PTI and enthesitis

identified by PD. This association was not found with IAS. PTI, both GS and PD, showed a significant relation with IAS PD (p 0.009 and p 0.037, respectively). IAS GS didn't show any relation with PTI both PD (p 0.055) and GS (p 0.334).

Table 1. Relation between IAS and PTI with MASEI and different PD subtypes. Results are expressed as mean \pm standard deviation (SD).

	PTI		p value	IAS		p value
	Present	Absent		Present	Absent	
Mean MASEI \pm SD	32,44 \pm 15,62	27 \pm 9,33	0,270	32 \pm 6,16	27,89 \pm 7,72	0,380
Mean PD MASEI \pm SD	8 \pm 6	3,67 \pm 3,28	0,023	6,83 \pm 6,15	6 \pm 4,5	0,694
Mean PD OMERACT \pm SD	1,61 \pm 1,33	0,56 \pm 1,01	0,033	1,39 \pm 1,46	1 \pm 1	0,426

Conclusion: The present study finds PTI to be associated with enthesitis as opposed to MCPjsynovitis, which may support a functional association between PTI and enthesitis, and reinforces the role of PTI in PsA as an enthesitis-like lesion.

Session Title: Imaging of Rheumatic Diseases Poster II: Ultrasound

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The use of ultrasound in the assessment of muscle conditions has grown over the years. Various myopathies have shown an increase in echo intensity compared to healthy muscle¹. The objective of this study was to compare muscles affected by myositis with normal controls on the basis of echo intensity, and to assess for differences in subjective appearance among particular forms of myositis.

Methods: : Sixty-two subjects were included in this study, consisting of 9 patient with polymyositis (PM), 7 with dermatomyositis (DM), 18 with inclusion body myositis (IBM), and 28 healthy controls. All patients met the ACR classification criteria for their particular disease. Seven muscle groups were examined bilaterally using ultrasound, including

Figure 1. Mean Heckmatt Score and echo intensity per muscle group

Figure 2. Representative images of the biceps muscle in each subgroup. A: Healthy muscle showing a hypoechoic muscle and subcutaneous fat layer, with a hyperechoic speckled pattern of perimysium. B: An affected muscle from a DM patient showing focal areas of increased echo intensity and increased echo intensity of the fat layer. C: An acute case of PM (necrotizing) showing homogeneously increased echo intensity and loss of perimysial septa. D: An atrophic biceps muscle in IBM with markedly increased echo intensity.

	IBM	PM	DM	Healthy controls
Total #	18	9	7	28
Female : Male	9 : 9	8 : 1	2 : 2	15 : 13
Mean age (years)	54	57	55	48
Age range	32 – 84	28 – 70	35 – 82	21 – 74
Duration of symptoms (months)	118	45	55	Not A.
Average muscle strength (based on MMFT)	64	92	85	18
Blood creatine phosphokinase	578	284	218	864
Antibodies (percentage)	CNLS	100% IL, RNP, Jo-1	PM-S/40, PM-S/L, SAE, PL-7, Jo-1	Not A.

the deltoids, biceps, flexor carpi radialis (FCR), flexor digitorum profundus (FDP), rectus femoris, tibialis anterior and gastrocnemius muscles using a standardized protocol. Echo intensity was measured both subjectively using the Heckmatt scale (1-4)¹ and quantitatively by mean gray-scale analysis using the program ITK-SNAP. Other parameters measured were duration of symptoms, muscle strength and muscle enzyme levels.

Results: Echo intensity was increased in patients with myositis across all muscle groups studied when compared with normal muscles. Although numbers per subgroup were small, some visual patterns could be noted. Subcutaneous edema and increased echo intensity of fat could be seen in active DM. Focal areas of increased echogenicity were also noted within involved muscles, and other stigmata of DM such as calcinosis could be seen. PM, made up mostly of necrotizing myopathies, usually showed a more homogenous distribution of increased echo intensity in involved muscles and preserved fat echo intensity. IBM showed the most severely increased echo intensity and atrophy of the involved muscles.

Conclusion: In the inflammatory myopathies, a higher echo intensity is seen in affected muscles. Additionally, disease specific characteristics may be seen on visual inspection and can make ultrasound a useful tool in the evaluation of muscle involvement in myositis.

Contribution of Ultrasonography Examination in Symptomatic Radiographic Knee OA

Oriane BAZIN¹, Willy Nguéyon Sime², Alexandra Desvignes³, Emmanuel Spitz⁴, Francis Guillemin⁵, Anne-Christine Rat⁵, Isabelle Chary-Valckenaere⁶ and Damien Loeuille⁷, ¹service de Rhumatologie, CHU Nancy, Vandoeuvre les Nancy, France, ²Université de Lorraine, Nancy, France, ³service de Rhumatologie, Groupement hospitalier Eaubonne -Montmorency, EAUBONNE, France, ⁴Rheumatology Strasbourg, Strasbourg, France, ⁵Université de Lorraine, EA4360, APEMAC, Nancy, France, ⁶Rheumatology, CHRU Nancy, Vandoeuvre les Nancy, France, ⁷Rheumatology, University Hospital of Nancy, NANCY, France

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Imaging of Rheumatic Diseases Poster II: Ultrasound

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: To evaluate and to compare ultrasonographic (US) features to clinical data and structural damage in symptomatic radiographic (RX) knee osteoarthritis (OA).

Methods: Patients with symptomatic (VAS-pain > 30/100) and RX (Kellgren-Lawrence (KL)≥2) knee OA responding to ACR criteria (1986) were included in a clinical trial N° NCT01544647. Clinical knee effusion, VAS-pain, WOMAC scores and radiographic severity (KL>2) were recorded. On US, effusion (≥ 4 mm), synovitis (depicted in the three subquadricepsal ramps on B- and PD-modes) and Baker's cyst (BC) were assessed according to binary and semi quantitative manners. Total US score (sum of effusion (0 to 6), synovitis scores (0- 15) and presence of BC (0-1)) varied from 0 to 22.

Results: 283 patients were evaluated (67% of women, mean age (SD): 64.1(±9.1) years, BMI: 29.1(±5.7), 58.4% with KL>2). Knee effusion was detected in 82 patients (29.1%) by clinical examination and in 185 patients (65.6%) by US. On US, synovitis was detected in 60.3% on B-mode and 28.0% on PD-mode. BC was observed in 70 patients (24.9%). The mean +/-SD effusion, synovitis and total US scores were 0.8±1.2, 2.5±2.6 and 3.6±3.4 respectively. For an US effusion score >2, more than 50% of knee effusions were clinically detected. Only effusion score was associated with VAS-pain (p=0.01) on univariate analysis. There was a significant association between RX severity and US effusion and synovitis scores (B-mode and DP-mode) in univariate and multivariate analysis (p<0.05).

Conclusion: US detected two times more knee effusion than clinical examination and only US effusion score demonstrated association with pain. US effusion and synovitis were strongly associated to structural damages.

Superiority of Musculoskeletal Ultrasound (MSUS) over Clinical Examination Regarding Detection of Arthritis in Patients with Systemic Sclerosis

Daria Feldmann¹, Reinhard Voll², Florian Kollert³ and **Stephanie Finzel**¹, ¹Department of Rheumatology and Clinical Immunology, University Medical Center Freiburg, Faculty of Medicine, University of Freiburg, Freiburg, Germany, ²Clinic for Rheumatology and Clinical Immunology, University Medical Center Freiburg, Faculty of Medicine, University of Freiburg, Freiburg, Germany, ³Department of Rheumatology, Immunology, and Allergology, Inselspital, University Hospital Bern, Bern, Switzerland

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Imaging of Rheumatic Diseases Poster II: Ultrasound

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Arthralgia is frequent in patients with systemic sclerosis (SSc). However, correct clinical assessment of arthritis remains a challenge especially in patients with severe soft tissue edema and/or scleroderma. This study investigates the frequency of arthritis in SSc using musculoskeletal ultrasound (MSUS) compared to clinical investigation and in SSc.

Methods: Synovitis in B- and PD-mode as well as effusion was assessed in 56 consecutive patients with SSc using MSUS. Wrist, finger, upper and lower ankle joints as well as metatarsophalangeal (MTP) joints were scanned totaling 2016 joints. In all patients carotid intima media thickness (CIMT) as well as prevalence of carotid plaques was assessed by Doppler ultrasound. Arthritis disease activity was evaluated by the health assessment questionnaire (HAQ), and the DAS66/68. Joint pain and patient global health (PGH) were quantified on a visual analogue scale (VAS). Skin involvement was quantified using the modified Rodnan Skin Score (mRSS). CVRF such as smoking, hypertension or positive family history were recorded.

Results: All patients were negative for ACPA and rheumatoid factors. 15/56 patients had elevated CRP-levels. Doppler ultrasound found 12 pathological CIMT in 10 individual patients; 44/112 carotid arteries had at least one plaque. Patients with CIMT and/or carotid plaques were elderly (62.3 years +/- 11.02), long term sick (148.61 +/- 127.58 months), and had at least one cardiovascular risk factor. 8/15 CRP-positive patients had carotid plaques (53.3% vs 4.88% CRP-negative), and had a significantly higher number of CVRF than CRP-positive patients without carotid plaques (median 3.5 [1-5] vs. 1[0-5]). A cutoff diameter of >13mm² was deemed pathologic for median nerves, >11mm² and <13mm² was intermediate. 11/56 patients had either pathologic or intermediate median nerves. 46.43% (n=26) of patients had joint pain, 16.07% (n=9) clinical joint swelling. In MSUS, 167 joints with effusion were detected in 38 patients (I°: n=93 joints, II°: n=74 joints). 36 joints in 17 patients were detected by B-mode synovitis (I°: 13 joints, II°: 23 joints). 12 joints in 5 patients showed PD-synovitis (I°: 4 joints, II°: 8 joints). In 15 patients MSUS could detect effusion where clinical examination could not; none of the clinically suspicious joints had effusion in MSUS. B-mode synovitis was detected in 5 clinically normal patients, in 7 patients with joint pain, and in 5 patients with joint pain and swelling. The overall correlation of MSUS with clinical examination was poor (p>0.05). B-mode synovitis and PD-mode synovitis prevailed the MTPs (69.44%, n=25 and 58.33%, n=7, respectively).

Conclusion: In patients with arthralgia MSUS could detect clinically inapparent arthritis. Especially in joints with soft tissue edema and sclerotic skin MSUS was superior to clinical examination. Interestingly, arthritis was most frequently found in the MTP and wrist joints supporting recent data (Iagnocco 2013). In this small cohort there was no significant correlation between CRP positivity and arthritis. Not surprisingly, carotid plaques were more frequent in elderly, long-term patients with over 1 CVRF.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Imaging of Rheumatic Diseases Poster II: Ultrasound

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Sjögren's syndrome is an autoimmune disease involving multiple organs, especially the lacrimal and salivary glands. Salivary gland ultrasonography (SGUS) provided a rapid and direct method for evaluation the conditions of salivary glands. Several parameters or evaluation protocols were proposed for stratification the severity of salivary glands. In previous published method, bilateral parotid and submandibular glands were scored from 0 to 4, which resulted in a total score of 0-16. The applications of SGUS was still under investigation and with technique-based barriers.

Methods: Total SGUS with 102 patients were retrospectively evaluated. SGUS was conducted by a 10MHz-13MHz linear probe at both parotid and submandibular glands. Each gland was scored from 0 to 4 according to the scoring scale proposed previously. The total maximum score was 16. Simplified SGUS score was conducted through combinations of each two glands from right side and left side.

Results: The average SGUS score of 102 patients was 7.75 (SD 4.769). The correlations between right side and left side was fair (parotid gland, Pearson coefficient 0.889, $p < 0.001$; submandibular gland, Pearson coefficient 0.843, $p < 0.001$). Compared with parotid gland and submandibular gland in the same side, the correlation was also good (right side, Pearson coefficient 0.640, $p < 0.001$; left side, Pearson coefficient 0.570, $p < 0.001$). The average score of parotid gland and submandibular gland were similar (parotid gland: left side 1.84 (SD 1.426), right side 1.74 (SD 1.528); submandibular gland: left side 2.08 (SD 1.208), right side 2.06 (SD 1.201)). The combination of right side two glands and left side two glands revealed good correlations ($p < 0.001$) with similar score (right side 3.79, left side 3.92). Each side of score correlated well with original score of summation of 4 glands. Both side of SGUS correlated with the severity of small salivary gland biopsy (right side $p = 0.008$, left side $p < 0.001$) and sialocintigraphy (both sides $p < 0.001$).

Conclusion: SGUS could be conducted via only one side of parotid and submandibular gland, which correlated well with the severity of small salivary gland biopsy and sialocintigraphy. This may shorten the examination time and more feasible for practice in clinic. However, SGUS was technique-based and should be trained for certification.

Session Information

Session Date: Monday, October 22, 2018

Session Title: Imaging of Rheumatic Diseases Poster II: Ultrasound

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Salivary gland enlargement occurs in conditions such as Sjögren's syndrome (SS), sarcoidosis (SAR), and AL amyloidosis (AL). Salivary gland ultrasound (US) has been shown to be useful in diagnosing SS. Our purpose is to compare salivary gland ultrasound features in SAR and AL with those in patients with SS, and controls (C) without known salivary gland disease.

Methods: In this 1 year cross-sectional study, we enrolled consecutive adult clinic out patients. Enrollment inclusion criteria include: clinical diagnosis of either primary or secondary SS fulfilling American-European Consensus 2002 classification criteria; clinical diagnosis of SAC or AL with histological confirmation from any tissue; and rheumatology outpatients without these diagnoses or other autoimmune rheumatic disease.

Subjects underwent clinical examination including Schirmer testing, and unstimulated salivary flow measurement, and bilateral parotid and submandibular salivary gland ultrasound by single unblinded investigator, using an ultrasound machine with an 18-6 MHz ultrasound probe. Another investigator, blinded to underlying diagnosis, analyzed ultrasound images for salivary gland ultrasound score (SGUS) per Hoyer protocol (parenchymal echogenicity, homogeneity, hypoechoic areas, hyperechoic foci, border visibility, and color Doppler signals), lymph nodes, and hyperechoic septae. US findings are compared between the groups using T test and Mann Whitney test as appropriate with P -value of < 0.05 as being statistically significant.

Results: Subjects enrolled, with mean age (A), % abnormal Schirmer (Sch), and % abnormal salivary flow (Sf) as follows: 27 SAC (A 55, Sch 65, Sf 4), 22 AL (A 66, Sch 86, Sf 32), 21 SS (A 49, Sch 57, Sf 62), and 16 C (A 58, Sch 38, Sf 25). In the control group, there was no correlation between age and SGUS score. By Shapiro-Wilk test of normality, only the AL group violated the assumption of normality. ANOVA of the mean SGUS showed significant difference among the four groups ($p < 0.00008$). SS SGUS was significantly higher than SAC, AL, and C groups (20 vs. 11, 14, 9 respectively all with $p < 0.05$). AL SGUS was higher than C (14 vs. 9, $p < 0.05$), but SAC was not different from C (11 vs. 9, $p = \text{NS}$). Intraglandular lymph node number, size, shape, and Doppler flow did not differ between the groups ($p = \text{NS}$). Gland septae

score was greater for SS and AL groups than SAC and C groups (0.39 and 0.44 vs. 0.18 and 0.16, $p=0.0040$). Hypoechoic area score was higher for SS and AL than SAC and C groups (1.6 and 1.2 vs. 0.95 and 0.77, $p=0.0039$). There was a trend towards greater difference between groups in the percentage of subjects with hyperechoic area scores for the SS and AL groups than SAC and C groups (0.37 and 0.35 vs. 0.19 and 0.063, $p=0.051$).

Conclusion: While SGUS was highest in SS, US abnormalities of SS were more similar to those of AL than those of SAC. Hyperechoic foci and septae, may be most helpful in distinguishing patients with SS and AL from those with SAC and patients without a systemic disease of the salivary glands.

Abstract Number: 1215

Characterizing Changes in the Median Nerve during Hand Grip Using Dynamic Sonographic Imaging

Shawn Roll¹, Ariana Cristino¹ and Jennifer Mitchell², ¹Chan Division of Occupational Science and Occupational Therapy, University of Southern California, Los Angeles, CA, ²Power Imaging Services, Inc., Los Angeles, CA

Session Information

Session Date: Monday, October 22, 2018

Session Title: Imaging of Rheumatic Diseases Poster II – ARHP

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Sonography is used to evaluate inflammation, identify joint changes, and measure morphology; dynamic assessment of tissue movement is an additional benefit. Dynamic sonographic identification of median nerve entrapment at the wrist during finger motion could improve understanding of carpal tunnel syndrome (CTS) etiology, as

well as inform strategies to avert secondary CTS in patients with inflammatory conditions. This study aimed to evaluate a method for identifying and characterizing median nerve entrapment during functional grasp.

Methods: Healthy participants sat with their forearm on a table, palm up, and fingers in a relaxed position. A 12-MHz, linear transducer was placed in cross-section of the wrist at the level of the pisiform. Dynamic videos were obtained while the participant flexed the fingers until the tips touched the palm. Any compression of the median nerve was noted, nerve shape was identified at beginning and end of motion (Fig. 1), and direction and distance of nerve displacement was measured (Fig. 2). Frequencies/averages were calculated and chi-square/t-tests were used to compare right to lefthands.

Results: Participants (N=51) were predominantly right-handed (92.5%) females (88.7%) with an average age of 24.4 years (SD, 3.5). During gripping, 72.5%/68.6% of participants had compression of the nerve in the right/left hands. From rest to grip, the frequency of angular or irregular shapes nearly doubled from 13.7% to 25.4%. Maximum nerve movement (mm) ranged from 0.76-1.08, 2.70-4.02, and 0.06-4.07 for vertical, horizontal, and endpoint displacement respectively; in 20% of hands, essentially no movement occurred. There were no significant differences between left and right, and no direction of movement predominated.

Conclusion: Despite being young and healthy, most participants had nerve compression during finger movement; some with significant entrapment (e.g., angular/irregular shapes). Longitudinal studies are needed to determine if these measures are a CTS predictor or risk factor. These methods can also be translated to clinical practice to inform personalized care for reducing or preventing symptoms in individuals with CTS and other inflammatory conditions.

Abstract Number: 1216

To Study the Frequency of Persistent Arthritis, in Patients with Chikungunya Fever, in a Tertiary Health Care Center

Hamza Alam¹, Tahira Perveen¹, Lubna Nazir¹ and Iffat Khanum², ¹Rheumatology, Liaquat National Hospital, Karachi, Pakistan, ²Infectious Diseases, Liaquat National Hospital, Karachi, Pakistan

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Infection-related Rheumatic Disease Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Chikungunya virus is an alphavirus, belonging to the Togaviridae family. It is transmitted by several species of mosquitoes, with *Aedes* species being main culprit. The symptoms generally start 4–7 days after the bite. Acute infection lasts for 1–10 days and is characterized by abrupt onset of fever, headache, fatigue, nausea, vomiting, rash, myalgia, and severe arthralgia. Painful polyarthralgia is the typical symptom causing serious economic and social impacts on both the individuals and the affected communities. This study was meant to look at frequency of patients coming with persistent arthritis and to share our experience in treating it.

Methods: This cross-sectional study was conducted in Liaquat National Hospital, Karachi. It comprised of collected data of patients who presented with arthritis and positive chikungunya serology. Data was collected on a pre-designed proforma. It was analysed by using the Statistical package for social science (SPSS) version 20.0. Response to treatment was characterized according to visual analogue scale (VAS) taken at baseline, 2 weeks and 4 weeks. Stratification was done according to age, gender, duration of fever, number of joints, duration of symptoms, laboratory parameters and co-morbidities. Post stratification Chi square test was applied taking p value ≤ 0.05 as significant.

Results: A total of 112 patients were included in the study, of which 31 (27.7 %) were male and 81 (72.3 %) were female. Symmetrical arthritis was reported in 85 (75.9%) patients, while asymmetrical arthritis was seen in 27 (24.1%) patients. 75 (66.9%) had polyarthralgia involving small, medium and large joints ($P=0.000$). Morning stiffness was reported in 68 (60.7%) of patients ($P=0.000$). ESR was raised in 78 (69.6%) patients ($P=0.000$), while raised CRP was seen in 69 (61.6%) patients ($P=0.001$).

37 (33%) patients were given NSAIDs, 66 (58.9%) received steroids, and other forms of analgesics were prescribed to 9 (8%) patients. In nearly half of the patients, i.e. 62 (55.4%) partial response was seen, 13 (11.6%) showed complete response, while 37 (33%) had persistent arthralgia. Out of 66 patients treated with steroids, 48 (72.7%) showed partial response (VAS score <5), 13 (19.7%) showed complete response (VAS score 0), while 5 (7.57%) patients had persistent arthralgia (VAS score >5) ($P=0.000$).

Out of the 5 patients having persistent arthralgia in the steroid group, 3 patients later after 6 months of follow-up on repeating had anti-CCP positive, while 2 were negative. They were treated as inflammatory arthritis with DMARDS.

Conclusion: This study shows post-chikungunya arthritis to be a great mimicker of inflammatory arthritis. This study brought us to the conclusion that a single dose of methylprednisolone was helpful in successfully treating patients experiencing post-chikungunya arthritis and this did not have a significant impact on patients monetary wise. With all this said further research needs to be conducted on establishing the link between chikungunya virus and development of inflammatory arthritis.

Abstract Number: 1217

Trend of Frequency and Outcome of Reactive Arthritis in Japanese Patients with Bladder Cancer Following Intravesical BCG Therapy over the Last 20 Years

Satoshi Inotani¹ and Yoshinori Taniguchi², ¹Endocrinology, Metabolism, Nephrology and Rheumatology, Kochi Medical School, Kochi, Japan, ²Endocrinology, Metabolism, Nephrology and Rheumatology, Kochi University, Kochi, Japan

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Infection-related Rheumatic Disease Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Reactive arthritis (ReA) is a sterile arthritis occurring in a genetically predisposed individual, secondary to an extra-articular infection, usually of the gastrointestinal or genitourinary tract. Intravesical instillation of Bacillus Calmette-Guerin (iBCG) is used as an effective immunotherapy of bladder cancer. Despite of the clinical efficacy, ReA could develop as adverse event and the frequencies are known as about 0.5 to 1 % in Western countries. To assess the trend of frequency, HLA phenotype and outcome of iBCG-induced ReA in Japanese patients with bladder cancer following iBCG therapy.

Methods: The clinical findings of Japanese patients who received iBCG ($n = 555$) for bladder cancer from March 1997 to February 2017 were retrospectively assessed, with specific attention to frequency and HLA phenotype of ReA. Because of the change of using iBCG dosage, iBCG-induced ReA patients diagnosed from 1997 to 2007 were also compared with ReA from 2007 to 2017 and the trend of frequency was examined. Furthermore, we assessed outcomes of iBCG-induced ReA patients over the 20 years.

Results: Patients' mean age was 72 ± 10 years and male/female ratio was 438/117. Of the 555 cases, ReA was revealed in 11 (2.0%). 9.1% of 11 ReA patients had HLA-B27. Although the protocol of iBCG therapy was not statistically different over the 20 years, but a half dose of iBCG was used in 2007 to 2017 more than in 1997 to 2007. Despite the increase of half dose using of iBCG in 2007 to 2017, the overall frequency of iBCG-induced ReA was not significantly different between from 1997 to 2007 and from 2007 to 2017 (2.1% and 1.9%, respectively). Finally, as outcomes, all iBCG-induced ReA patients did not progress to chronic peripheral arthritis type and axial SpA, even if with sacroiliitis.

Conclusion: The 2.0% iBCG-induced ReA frequency in Japanese patients exceeds that in Western countries. Despite iBCG dosage was different, the trend of frequency has been stable, which suggested possible dose-independent development. Furthermore, all iBCG-induced ReA, even if revealing sacroiliitis, did not progress to chronic peripheral arthritis type and SpA over the last 20 years.

Synovial Fluid Culture: Comparison of Two Culture Methods

Ayman Natsheh¹, Daniel Cohen², Elyahu Ben Chetrit³, Gideon Neshet⁴ and Gabriel S Breuer¹, ¹Rheumatology, Shaare Zedek Medical Center, Jerusalem, Israel, ²Orthopedics, Shaare Zedek Medical Center, Jerusalem, Israel, ³Infectious Diseases, Shaare Zedek Medical Center, Jerusalem, Israel, ⁴Medicine, Shaare Zedek Medical Center, Jerusalem, Israel

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Infection-related Rheumatic Disease Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Septic arthritis (SA) is one of the emergencies in rheumatology. This pathology is more common due to the increased usage of artificial joints. Culture is the “gold standard” for diagnosis of the disease which in many cases is quite obscure, due to nonspecific clinical symptoms and laboratory results. Optimal treatment of this condition depends on timely and accurate culture report. A major goal is to optimize the essential culture method. Different essays suggested adding Bactec™, a blood culture system (BC), to the basic conventional culture (CC). The original culture is based on an agar plate being a platform for growth of bacteria. The organism is identified and analyzed regarding sensitivity to different antibiotics. The instrumented blood culture systems are based on media that permits screening for microorganisms present in blood allowing growth of microorganisms that may not occur with conventional media. This greater recovery leads to more accurate diagnosis and effective treatment, which can in turn lead to shorter hospital stays, lower patient costs, and greater overall laboratory and institutional efficiency. However the cost is increased and the false positive rate may increase leading to unnecessary antibiotic treatment. The aim of this study is to evaluate cases where both methods were used regarding a possible added value of operating both methods.

Methods: After obtaining ethical permission we assessed consecutive synovial fluid samples submitted to the microbiology laboratory. Samples that had been submitted in both methods i.e. CC and BC were included in the cohort. All cases with a positive result by either method were reviewed for clinical and demographic data. Specimens were defined as contamination when there was an alternative infectious diagnosis, when the white cell count was lower than 50,000 and in most cases of coagulase negative staphylococcus. Data was analyzed regarding sensitivity, specificity, and positive and negative predictive values (PPV, NPV).

Results: 1024 samples were reviewed, 803 of them showed no growth by either method. 221 cultures were positive, 67 by BC method only and 73 on by CC method, and 81 of the samples positive by both methods. All cases were reviewed regarding the clinical diagnosis. Cases were considered as having SA when there were clinical signs of joint infection and no other source of infection was found. Most of these cases had more than 50,000/μl leukocytes in the synovial fluid. 225 cases were defined clinically as septic arthritis. The sensitivity, specificity, positive and negative predictive values are shown in the following table.

	Sensitivity	Specificity	PPV	NPV
Blood Culture (BC)	.50 (.45 - .54)	.95 (.94 - .96)	.76 (.69 - .82)	.87 (.86 - .88)
Conventional Culture (CC)	.42 (.37 - .47)	.92 (.91 - .94)	.62 (.55 - .69)	.85 (.83 - .86)
Both	.60 (.55 - .65)	.89 (.88 - .90)	.62 (.56 - .65)	.89 (.87 - .90)

Conclusion: BC carries better sensitivity, specificity, positive and negative predictive values in comparison to CC. It should be considered as the preferred method for synovial culture in cases when SA is suspected. The added value of co-culture with CC is relatively low.

Abstract Number: 1219

Antibiotic Resistance Trends Among Bacteria Causing Septic Arthritis at One Medical Center between 2002-2016

Gabriel S Breuer¹, Amit Zamir², Gideon Neshet² and Elyahu Ben Chetrit², ¹Rheumatology, Shaare Zedek Medical Center, Jerusalem, Israel, ²Medicine, Hebrew University School of Medicine, Jerusalem, Israel

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Infection-related Rheumatic Disease Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Septic arthritis (SA) is caused mainly by Staphylococcus aureus (S. aureus). Methicillin-resistant S. aureus (MRSA) SA is increasing and accounts for 25-50% of all S. aureus SA cases in the US. Most coagulase- negative

staphylococci (CNS) isolated from joints represent a contamination, however after surgical arthroscopy, multiple procedures, and joint replacement these may be true infection. Gram negative pathogens are less common. The purpose of this study is to examine the prevalence of *S. aureus* in comparison to other pathogens and whether there is an increase in the prevalence of antibiotic resistance in adults with natural and prosthetic joints in one medical center over 15 years (2002-2016).

Methods: The study population included patients aged 18 years and older who were diagnosed with culture positive SA between January 2002 and December 2016, based on ICD-9 encoding. Cases were reviewed regarding culture and treatment for septic arthritis. Children under the age of 18, patients in whom a diagnosis of contamination was made and cases with culture negative SA were excluded.

Results: A diagnosis of SA or suspected SA was made in 323 cases of which 85 had proven SA. In 9 cases a diagnosis of culture negative SA was made. Two-thirds of the patients were males. Median age was 74 (23-95) years, and most SA cases were community acquired, and in natural joints. The most common joint involved was the knee and in almost all cases it was monoarthritis. 10% of the patients had evidence of previous infection in a joint in the past year. The median duration of in-hospital treatment was 16 days. Fifteen patients had an infection of a prosthetic joint. In 3 cases the infection occurred in a prosthesis in which a revision was performed during the past year. Polymicrobial growth was found in three cases.

Conclusion: The most common cause of SA is *Staph. aureus*. This finding is consistent with the literature. Our study suggests that there is no evidence of an increase in antibiotic resistance among pathogens that cause SA in prosthetic and natural joints in adults. In addition we did not find increase in the rate of MRSA SA over the course of 15 years.

Figure 1: Pathogens isolated in cases of SA

Beta hemolytic streptococcus: Group A, B and G Streptococci.

Gram negative: *Haemophilus parainfluenzae*, *E. Coli*, *Enterobacter cloacae*, *Pseudomonas aeruginosa*, *Moraxella catarrhalis*, *Neisseria* spp, *Salmonella* group and *Stenotrophomonas koreensis*.

Other: *Propionibacterium acnes*, *Leuconostoc* sp., *Enterococcus* sp., *Strep. pneumoniae* and *Listeria monocytogenes*.

Session Information

Session Date: Monday, October 22, 2018

Session Title: Infection-related Rheumatic Disease Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Approximately 20,000 cases of septic arthritis (SA) occur in the United States each year with 2-10 cases per 100,000 person-years in the general population. SA is more common in men while women are three times less likely to have joint replacement surgery. It is currently unknown whether gender-related differences exist in the presentation, intervention and outcomes of patients with native joint septic arthritis (NJSA).

Methods: We conducted a retrospective study that included patients aged 18 and older admitted to a single tertiary care hospital between 1998 and 2015 diagnosed with monoarticular NJSA and treated surgically. We excluded all cases of osteomyelitis, septic bursitis, and prosthetic joint infection. We reviewed the patients' charts and collected specific data including the patients' demographic information, comorbidities, clinical presentations, microbiology, management and outcomes. A comparison was made between men and women with p-values of < 0.05 defined as the threshold for significance.

Results: Of the 324 patients with NJSA, 130 were female (40.1%). Women were significantly older at presentation than their male counterparts (mean age: 63.6 versus 58.3 years; $p = 0.006$). Overall, the frequency of comorbid conditions was similar between groups. Prior joint pathology in the involved joints was more common among female patients, including osteoarthritis (20.8% vs 12.9%; $p = 0.042$) and rheumatoid arthritis (10% vs 3.6%; $p = 0.032$). The knee was the most commonly involved joint (~50% in both groups). A trend towards a higher frequency of hip involvement was observed in women (17.7% vs 10.8% $p = 0.05$). There were no observed differences in the clinical presentation, culture results, management (e.g. antibiotics and surgery), or outcomes between the groups.

Conclusion: Compared to men with NJSA, women with NJSA present at an older age, with more prior joint pathology and a higher frequency of hip involvement. It appears that these differences have no significant impact on the presentation, management, and outcomes.

Serologic Screening for Coccidioidomycosis Among Medicare Beneficiaries with Rheumatic Diseases on Biologic Response Modifiers, Corticosteroids, and Dmards

Shubha Kollampare¹, C. Kent Kwoh^{1,2}, Wei-Hsuan Lo-Ciganic³, Lili Zhou^{2,4}, Erin L. Ashbeck² and Dominick Sudano¹,

¹Division of Rheumatology, Department of Medicine, The University of Arizona, Tucson, AZ, ²University of Arizona Arthritis Center, Tucson, AZ, ³Department of Pharmacy, Practice and Science, College of Pharmacy, University of Arizona, TUCSON, AZ, ⁴College of Pharmacy, University of Arizona, Tucson, AZ

Session Information

Session Date: Monday, October 22, 2018

Session Title: Infection-related Rheumatic Disease Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The 2016 Infectious Disease Society of America (IDSA) guidelines recommend serologic screening for coccidioidomycosis (Cocci) prior to initiation of biologic response modifiers (BRMs). Current screening practices for Cocci in endemic communities have not been described. Our objective was to estimate serologic screening rates for Cocci by state, medication class, physician specialty (rheumatologist vs. non-rheumatologist), and by year.

Methods: In a retrospective cohort study using 2011-2015 Medicare claims data (a 5% representative sample), we identified fee-for-service beneficiaries residing in 7 endemic states (Arizona, California, New Mexico, Nevada, Texas, Utah, and Washington), with any of 10 rheumatic/autoimmune diseases (RA, PsA, AS, SLE, ReA, PM/DM, SSc, Psoriasis, BID). We included beneficiaries with at least one prescription for a BRM, DMARD, and/or CS between 2012-2015 with continuous Parts A and B coverage in the 365 days preceding the prescription date in the analysis. Screening was considered current if the beneficiary had undergone serologic screening 365 days prior to the prescription date. Logistic regression was used to estimate the proportion of prescriptions that were current for serologic screening, by state, medication class, physician specialty, and by year, with 95% CIs. A sensitivity analysis was conducted to assess the serologic screening rate for newly initiated BRMs, defined as no supply of BRMs within the past 365 days. Generalized estimating equations were used to account for prescriptions written by the same provider.

Results: Among 296,987 prescriptions for 19,109 beneficiaries filled across the 7 endemic states, 3,004 had current serologic screening. In Arizona, 10.6% (95% CI: 8.6, 12.9) of all prescriptions (n=19,822) were current for serologic screening, compared to less than 1% in the other 6 states, prompting us to focus on Arizona for remaining analyses. Prescriptions for BRMs, CSs, and DMARDs had current screening for 20.6% (95% CI: 15.2, 27.4), 8.8% (95% CI: 7.2, 10.8), and 9.5% (95% CI: 7.6, 11.9), respectively. Screening rates for BRMs increased from 18.7% (95% CI: 11.3, 29.4) in 2012 to 28.5% (95% CI: 20.2, 38.5) in 2015. Rheumatologists and non-rheumatologists screening practices were similar (Table 1). Screening prior to newly initiated BRMs was 27.8% (95% CI: 19.8, 37.6) in a limited sample (n=115).

Table 1: Screening rates for medication classes by physician specialty in Arizona

Physician specialty	Medication class	Number of prescriptions	Current serologic screening, # (%)	(95% CI)
Rheumatologist	DMARD	5,070	528	10.4 % (7.3, 14.7)
Non-rheumatologist	DMARD	4,191	337	8.0 % (6.1, 10.5)
Rheumatologist	BRM	1,589	336	21.2 % (14.0, 30.7)
Non-rheumatologist	BRM	857	147	17.2 % (10.9, 26.1)
Rheumatologist	CS	1,937	285	14.9 % (10.1, 21.5)
Non-rheumatologist	CS	5,517	367	6.7 % (5.3, 8.3)

Conclusion: Serologic screening rates for Cocci among Medicare beneficiaries with rheumatic/autoimmune diseases on BRMs, CSs, and DMARDs was low in the 7 endemic states, with almost no screening outside of Arizona. IDSA guidelines recommend Coccidioides serologic screening prior to initiation of BRMs, though not repeated annual serologic screening. Further, while the IDSA guidelines recognized increased risk of disseminated Cocci with use of CSs, no screening recommendations have been issued.

Suboptimal Immunization Coverage Among Rheumatology Patients in Routine Clinical Care

Tedi Qendro¹, María Laura de la Torre², Pantelis Panopalis³, Elizabeth Hazel⁴, Ines Colmegna⁵ and Marie Hudson⁶,
¹Medicine, McGill University, Montreal, QC, Canada, ²Internal Medicine, Rheumatology and Immunology, CEMIC, Buenos Aires, Argentina, ³Division of Rheumatology, McGill University, Montreal, QC, Canada, ⁴Rheumatology, McGill University Health Centre, Pointe-Claire, QC, Canada, ⁵The Research Institute of the McGill University Health Centre, Division of Rheumatology, Department of Medicine, McGill University, Montreal, Quebec, Canada, Montreal, QC, Canada, ⁶Division of Rheumatology, Jewish General Hospital, Lady Davis Institute for Medical Research, Montreal, QC, Canada

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Infection-related Rheumatic Disease Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Vaccine-preventable infections pose an increased risk of infection and complications in patients with rheumatic diseases. While recommendations highlight the importance of vaccination in this at-risk population, immunization coverage in this population remains largely unknown. We assessed vaccination rates and predictors of vaccination among rheumatology patients in routine clinical care.

Methods: In this cross-sectional study, consecutive patients presenting to a tertiary rheumatology clinic at the McGill University Health Center between May and September 2015 were asked to fill a survey on vaccination. Patients self-identified as having rheumatoid arthritis (RA) (RA, juvenile idiopathic arthritis), systemic autoimmune rheumatic diseases (SARD) (e.g., vasculitis, lupus, systemic sclerosis, myositis), spondyloarthropathies (SpA) (psoriatic arthritis, ankylosing spondylitis), or other non-inflammatory problems (Control). Multivariate logistical regression analyses were performed to evaluate patient and physician factors associated with vaccination (influenza, pneumococcus, hepatitis B virus [HBV], and herpes zoster [HZ]).

Results: 352 patients were included in the analysis (RA: 136, SARD:113, SpA:47, Control:56). Vaccination rates were reported as: (1) influenza: RA 48.5%, SARD 42.0%, SpA 31.9%, Control 88.9%; (2) pneumococcal: RA 42.0%, SARD 37.8%, SpA 29.7%, Control 33.3%; (3) HBV: RA 33.6%, SARD 55.6%, SpA 73.5%, Control 36.8%; and (4) HZ: RA 5.6%, SARD 28.6, SpA 25.0%, Control 16.7%. In multivariate analysis, the association between age and vaccination varied by vaccine (influenza: odds ratio (OR) 1.03, 95% confidence interval (CI) 1.01-1.05; pneumococcus: OR 1.01, 95% CI 0.97-1.04; HBV: OR 0.96, 95% CI 0.94-0.99). Moreover, physician recommendation was the strongest independent predictor of vaccination across all vaccine types (influenza: OR 8.56, 95% CI 2.80-26.2; pneumococcus: OR 314, 95% CI 73.0-1353; HBV: OR 12.8, 95% CI 5.27-31.1). Disease group, disease duration, comorbidities (cancer, diabetes, renal disease), treatment type (disease-modifying anti-rheumatic drugs and/or biologics), and access to a primary care physician were not significantly associated with vaccination.

Conclusion: Despite national guidelines and recommendations for vaccination in this at-risk population, immunization coverage against influenza, pneumococcus, HBV, and HZ is far from optimal among ambulatory rheumatology patients. An important role for both patient and physician education is highlighted from our study, especially as physician recommendation of vaccination was strongly predictive of vaccine uptake. These results can help inform strategies aimed at optimizing vaccination rates in this at-risk population.

Reduced Antibody Titers Against Pertussis in Rheumatoid Arthritis

Caitlyn L. Holmes¹, Chloe Peyton², Amy Bier³, Tobias Donlon², Christie M. Bartels⁴ and Miriam A. Shelef^{5,6}, ¹University of Wisconsin - Madison, Madison, WI, ²University of Minnesota Medical School, Minneapolis, MN, ³Stritch School of Medicine of Loyola University Chicago, Chicago, IL, ⁴Rheumatology/Medicine, University of Wisconsin - Madison,

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Infection-related Rheumatic Disease Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with rheumatoid arthritis, an autoimmune disease affecting ~1% of the population, have an increased risk of infection. Interestingly, data are mixed for response to vaccination with rheumatoid arthritis patients showing a reduced response to some vaccine antigens, but relatively normal antibody titers in response to others, like the highly efficacious tetanus vaccine. Little is known about the response to pertussis vaccination in rheumatoid arthritis, a concerning omission given the relatively low efficacy of the pertussis vaccine, the rise in pertussis infections in the last 20 years, and the increased susceptibility of rheumatoid arthritis patients to infection. The purpose of this study is to determine if pertussis titers are reduced in vaccinated subjects with rheumatoid arthritis versus controls as well as to determine if clinical factors in rheumatoid arthritis, including the use of immune suppressing medications, correlate with pertussis titers.

Methods: Serum from 98 subjects with seropositive rheumatoid arthritis not using rituximab (a B cell depleting drug) and 77 controls, all vaccinated within 10 years of serum collection with the Tdap (tetanus, diphtheria, and pertussis) vaccine, were selected from our biorepository. Serum was subjected to enzyme-linked immunosorbent assay to detect IgG titers against pertussis and tetanus toxoid. Titers were compared by unpaired t-test and the rates of immunity based on manufacturer cut-offs were compared by a Fisher's exact test. Univariate and multivariate logistic regression was used to identify clinical factors that correlate with pertussis titers. A p value <0.05 was considered significant.

Results: Subjects with rheumatoid arthritis had significantly lower IgG titers against pertussis, but not tetanus, compared to controls and fewer rheumatoid arthritis subjects were immune to pertussis. At less than 5 years post-vaccination, there was no significant difference in pertussis titers between rheumatoid arthritis patients and controls. However, at 5-10 years post-vaccination, rheumatoid arthritis patients had 50% lower titers than controls and fewer rheumatoid arthritis subjects met immune thresholds. Multivariate regression demonstrated that rheumatoid arthritis, female sex, and longer length of time since vaccination correlated with lower than median pertussis titers. Interestingly, the use of leflunomide or methotrexate at the time of serum collection correlated with higher and lower than median pertussis titers, respectively. No correlation was seen between TNF-inhibiting medications and pertussis titer.

Conclusion: Patients with rheumatoid arthritis have lower IgG titers against pertussis, especially 5-10 years post-vaccination. Reduced titers could be due to the relatively low efficacy of the pertussis vaccine, a dysregulated immune system in rheumatoid arthritis, and/or the use of certain medications. Future studies are needed to determine the mechanism for reduced immunity to pertussis, if more frequent vaccination would improve titers against pertussis, and if susceptibility to pertussis infection is increased in patients with rheumatoid arthritis.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Infection-related Rheumatic Disease Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Baseline screening for tuberculosis (TB) with tuberculin skin testing (TST) and/or interferon-gamma release assays (IGRAs) is recommended for all rheumatic patients starting biologic DMARDs (bDMARDs). Spontaneous conversions (from negative to positive) and reversions (from positive to negative) of available tests have questioned the value of re-screening patients during therapy. The aim of this study was to assess the long-term conversion and reversion rates of TB screening tests (TST and one IGRA: T.SPOT-TB) during long term bDMARD treatment.

Methods: Prospective study of rheumatic patients with negative baseline TB screening (TST and T.SPOT-TB, LTBI-1) prior to TNFi initiation who were re-screened for a 2nd (LTBI-2: 1.4 ± 0.6 years) and 3rd time (LTBI-3: 6.9 ± 1.0 years) after the 1st screening. Data regarding patient and disease characteristics, treatment patterns as well as conversion and reversion rates at LTBI-2 and LTBI-3 were recorded.

Results: 50 patients were included in the study; 4 patients who were treated with isoniazid due to a positive testing at LTBI-2 were excluded and thus 46 patients were available for final analysis. Twenty-eight (61%) were women and the mean age at LTBI-3 was 58.9 ± 13.5 years. RA was the most common diagnosis (n=22, 48%), followed by AS (n=13, 28%), PsA (n=9, 20%) and other rheumatic disease (n=2, 4%), with a mean disease duration of 15.6 ± 10 years. Forty-three (93%) patients were still on bDMARDs at LTBI-3 [TNFi: n=24 (56%), non-TNFi: n=19, (44%)] while 35% were on csDMARDs (n=16) and 15% on corticosteroids (n=7, mean daily prednisone dose = 4.5 ± 1 mg). Only one patient reported possible TB exposure during follow-up. Twelve (26%) patients had history of BCG vaccination. During follow-up, 35 patients (76%) remained persistently negative with both tests at the 2 re-screenings (“non-converters”). Among the “converters” (n=11), 4 (9%) had a transient conversion to positivity at LTBI-2 (3 with TST and 1 with T.SPOT-TB) that reversed to negative at the 3rd re-screening (“transient converters”), 5 (11%) had a late conversion to positivity (“late converters”) between the 2nd and 3rd re-screening (4 with TST and 1 with T.SPOT-TB) while only 2 (4%) were “persistent converters” (both with TST). There was no statistically significant difference between “converters” (n=11) and “non-converters” (n=35), with the exception of a higher non-RA diagnosis among “converters” (73%) compared to “non-converters” (46%, p=0.04). Among the 11 conversions/reversions, 9 were observed with TST (20%) and 2 with T.SPOT-TB (4%); none of the patients developed TB during follow-up.

Conclusion: In a low-TB prevalence country, approximately one out of four rheumatic patients with negative TB screening at baseline displayed a positive TB screening test during long term biologic treatment (~7 years); most of the conversions/reversions were seen with TST than with the IGRA test (T.SPOT-TB). These data emphasize the need for large scale studies assessing the value of TB re-screening in this patient population.

Screening for Acquired Latent Tuberculosis in Patients with Rheumatoid Arthritis(RA) on Anti-Tnf α Therapy (TNF-I) in Southern California

Noopur Goel¹, Karina Torralba², Lorena Salto¹ and Christina Downey³, ¹Loma Linda University, Loma Linda, CA, ²Division of Rheumatology, Department of Internal Medicine, Loma Linda University, Loma Linda, CA, ³Loma Linda University Medical Center, Loma Linda, CA

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Infection-related Rheumatic Disease Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: There is increased risk of tuberculosis in patients treated with TNF-I. ACR guidelines recommend annual screening for latent tuberculosis infection (LTBI) in RA patients with risk factors. Few studies in the United States (US) assess risk of sero-conversion to positive TB test in patients on TNF-I. Conversion rates have been found to low, 0.138/100 patient year.¹ Studies in Greece and Argentina (TB incidence 4.4 and 24 per 100,000) show conversion rate of 30% and 9.4% respectively^{2,3}. Incidence of TB in California (5.2/100,000) is twice the national rate of 2.8/100,000 cases, with some Southern California counties with incidence up to 7.1/100,000. This study aims to analyze screening practices at academic centers in Southern California and to assess sero-conversion in RA on TNF-I agents.

Methods: Data was extracted from the electronic health record for 400 adult patients with RA (based on ICD 9 and 10 codes) across 3 academic centers from January 2010- 2017. Inclusion criteria were TNF-I use for ≥ 1 year and negative QuantiFERON Gold status prior to use. Tuberculin skin test was not used at these sites. Demographics, drug type, duration of use and QuantiFERON test results were collected. Risk factors (birth in or travel to endemic areas,

incarceration, homelessness, congregate residency, known exposure to contacts with TB) were assessed. Subjects with exposure to anti-mycobacterial drugs or use of non-TNF-I biologics were excluded. Rates of re-screening, sero-conversion and its association with drug use and other factors were calculated.

Results: A total of 203 subjects were identified. 106 (52.2%) subjects had been rescreened for LTBI at a median time of 28 months post drug initiation. LTBI was diagnosed in 10 (9.4%) of the rescreened subjects: 5 on infliximab, 2 on adalimumab and golimumab each, 1 on etanercept. Median drug intake duration prior to seroconversion was 31 months and none had known risk factors. Testing for association of TNF-I with LTBI showed that 50% of patients in sero-conversion group were on Infliximab vs 27% of those in the negative conversion group. Comparison of risk with ethnicity showed that patients in the sero-conversion group were more likely to be Hispanic (75%) than non-Hispanic whites (25%).

Conclusion: LTBI development was seen in 9.4% of patients with lack of known risk factors or exposure. This seroconversion was considerably higher than previous US-based studies and more in line with results from endemic countries. We conclude that annual screening for LTBI on TNF-I should take into consideration local/state TB prevalence, ethnicity, drug type and duration of drug use. For our local population, annual screening should be strongly considered.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Infection-related Rheumatic Disease Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Biologics are widely used and effective treatments for rheumatoid arthritis (RA), but generally biologics are avoided when patients have active infections on the day of administration.

In Japan, nurses are not authorized to assess whether patients have active infections or not. In our hospital, doctors in charge of the pre-administration assessments conventionally checked patient's status by taking history and physical examinations on the day of intravenous biologics, but it does not seem to be time efficient. We implemented new method in which nurses systematically screen according to pre-determined questionnaires on infections before doctors see patients. Our aim of this study is to reveal effectiveness of this new method of assessments.

Methods: We retrospectively review charts of patients with RA who received intravenous biologics at our hospital in Tokyo, Japan from June 2016 to April 2018. We investigated basic demographics, kinds of biologics and other treatments, underlying diseases, numbers and sites of serious infection (SI), and opportunistic infections. SI was defined as infections

Figure 1. Scheduled administration of intravenous biologics and its decision after assessments

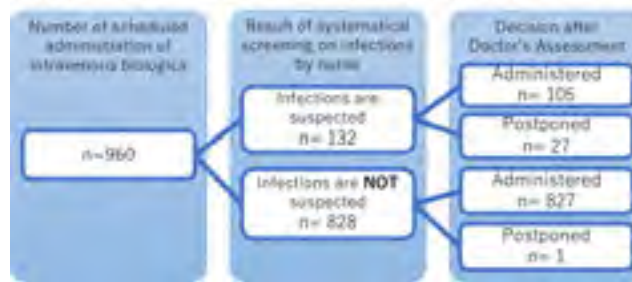

Table 1. Baseline characteristics and univariate analysis

	Overall (n=360)	Conventional method (n=189)	New method (n=171)	p value
Age	58 [18-90]	58 [18-90]	58 [18-89]	0.581
Female (%)	261 (72.5)	136 (72.0)	125 (73.1)	0.814

DMARDs				
MTX (%)	263 (73.1)	138 (73.0)	125 (73.1)	1
SASP (%)	166 (46.1)	88 (46.6)	78 (45.6)	0.916
MZR (%)	87 (24.2)	48 (25.4)	39 (22.8)	0.622
IGU (%)	94 (26.1)	51 (27.0)	43 (25.1)	0.72
BUC (%)	124 (34.4)	66 (34.9)	58 (33.9)	0.912
TAC (%)	24 (6.7)	14 (7.4)	10 (5.8)	0.673
Steroid (%)	272 (75.6)	147 (77.8)	125 (73.1)	0.327
Serious Infection (%)	16 (4.4)	8 (4.2)	8 (4.7)	1
TB (%)	0 (0.0)	0 (0.0)	0 (0.0)	NA
PCP (%)	0 (0.0)	0 (0.0)	0 (0.0)	NA
Candida (%)	9 (2.5)	5 (2.6)	4 (2.3)	1
Zoster (%)	2 (0.6)	2 (1.1)	0 (0.0)	0.5

requiring intravenous antibiotics, hospitalization, or resulting in death. We compared numbers of infections in the new method with those in conventional one. Univariate analysis and Chi-square test were performed.

We also calculated the number of scheduled administrations and evaluated results of screening by nurse and doctor's assessment.

Results: We identified 360 cases in total. There are 189 and 171 patients who received intravenous biologics from June 2016 to May 2017 with conventional assessment and from June 2017 to April 2018 with new-style assessment.

The baseline characteristics are shown in table 1. Though there are no significant differences in the number of SI between new and conventional methods, the rate of SI was 4.4% and lower than that reported in previous studies.

The number of scheduled administration of biologics and its decision after assessments by nurse and doctors are shown in figure 1. There was just 1 case in which doctors postponed biologics even the patient was assessed not to have active infections by nurse.

Conclusion: Systematical screening by nurse with pre-determined questionnaires is very sensitive so that doctors can carefully see cases in which infections are suspected by the screening. Our new-method of pre-administration assessments can contribute to time-efficient practice without any increasing risk of SI.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Infection-related Rheumatic Disease Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Biologic disease-modifying anti-rheumatic drugs (bDMARDs) may be associated with opportunistic infections. Our purposes were to describe their incidence in Rheumatoid Arthritis (RA) taking bDMARDs, and compare the risk of development between TNF-targeted and non-TNF-targeted biologics.

Methods: Retrospective longitudinal study from 2007 to 2017. We included RA patients, from our outpatient clinic, whom started treatment with a TNF-targeted bDMARD [etanercept (ETN), golimumab (GOLI), certolizumab (CTZ), infliximab (IFX), adalimumab (ADA)], or non-TNF-targeted bDMARD [rituximab (RTX), abatacept (ABA), or tocilizumab (TCZ)]. We consider OI according to microbiologist criteria [An “indicator opportunistic infection after biological (IOIb)” according to consensus recommendations of the presence, or specific presentation, of a pathogen that suggests a greater probability of an alteration in the immunity in a host under treatment with bDMARDs¹]. Independent variable was the type of targeted bDMARD: TNF vs non-TNF. Secondary variables: sociodemographic; clinical and treatments. We used survival techniques to estimate the incidence of IOIb, per 1000 patient-year [CI 95 %]. The exposure time was defined from the start date of each bDMARD to the development of an IOIb, loss of follow up or end of study. We performed a Cox multivariate regression model to compare the risk of IOIb. Results were expressed in Hazard ratio (HR).

Results: 441 RA patients were included, starting 761 different courses of bDMARDs. 81% were women with a mean age at first bDMARD of 57.3±14 years. 71.3% of the courses were TNF-targeted bDMARDs and 28.7% non-TNF-targeted bDMARDs. There were 38 OI [26 Viral infections (18 Herpes Zoster, 2 VHB reactivation, 3 VHC reactivation, 1 Epstein Bar virus, 1 H1N1 flu, 1 CMV reactivation), 6 Fungal infections (5 Invasive-oropharyngeal candidiasis, 1 dermatophytosis by *Trichophyton* spp), 5 Bacterial infections (1 Legionellosis, 1 Salmonellosis and 3 Tuberculosis), 1 parasitic (Leishmaniasis)]. 9 of them required hospitalization and one died. The median time from onset of bDMARD until IOIb was 3.1 years [0.5-4.6]. The global incidence of IOIb was 21.8 [15.9-30]. TNF-targeted bDMARDs had 26 IOIb, incidence 19.8 [13.4-29.1], and non-TNF-targeted bDMARDs had 12 IOIb, incidence 28.1 [16-49.6]. In the multivariate analysis (adjusted by age, sex and calendar-time), we did not find statistical difference between type of targeted bDMARDs (HR 1.37, p=0.4), whereas male sex achieved a significant risk for IOIb (HR 2.18, p=0.04). Age (HR 1.02, p=0.08), concomitant treatment with glucocorticosteroids (HR 6.67, p=0.05) and leukopenia (HR 2.73, p=0.08) showed a tendency to increase the risk of IOIb.

Conclusion: Incidence of IOIb due to bDMARDs was near 22 cases per 1000 patients-year. Crude incidence was higher for non-TNF-targeted bDMARDs compared to TNF-targeted bDMARD, moreover this difference was not maintained in the multivariate analysis. Close monitoring should be taken in those RA patients treated with bDMARDs and glucocorticoids, and those with leukopenia, mainly elderly and male patients.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Infection-related Rheumatic Disease Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: In a previous work, we showed that neurological complication can occur in up to 40% of patients with vertebral osteomyelitis (VO). Bed rest and spine immobilization are usually prescribed to prevent those complications. There is currently no consensus about the best immobilization protocol to follow in VO. Objectives of our work were to assess the prescription of spine immobilization for VO and its effect of neurological complications.

Methods: A prospective study was performed in 10 centers. All patients with native VO were included and followed prospectively: neurological complications, imaging findings, type and duration of immobilization were reported and patients were divided in two groups: “Immobilization” or “No Immobilization”, regarding if they had a prescription of spine bracing or not. We present here the data of our study after 6 months of follow-up.

Results: To date, 102 patients were included: 72 in the “Immobilization” group, and 30 in the “No Immobilization” group. Median duration of symptoms before diagnosis was 27 days, IQR (11-40). Thirty-six percent of the patients (n=37) had an abnormal neurological exam at baseline: 23.5% (n=24) had minor neurological signs (sensory loss or radiculopathy), and 12.7% (n=13) had major neurological signs (motor deficit or cauda equine syndrome). During hospital stay, 4 patients developed major neurological signs (median 5 days after diagnosis) and 5 patients developed minor neurological signs (median 6 days after diagnosis). Half of the patients with abnormal neurological exam at baseline had a normal neurological examination at 6 months. Median duration of bed rest was 9 days (IQR 7-18). In the “Immobilization” group (n=72), median duration of spine bracing was 8 weeks, IQR (6-12) and it was rigid bracing in 90% of cases. Main characteristics of the 2 groups are described in Table 1. They were no significant differences in age, associated diseases, or pathogen. Only one patient in the “No Immobilization” Group developed a paraplegia during follow-up, and the reason of the absence of immobilization was unclear. All patients with cervical involvement had a prescription of spine immobilization, whereas only half of the patients with lumbar involvement were immobilized. There were significantly less thoracic spine involvement in the “Immobilization” group. There were no differences in terms of neurological complications during follow-up between the two groups.

	Immobilization n= 72 (%)	No immobilization n=30 (%)	p
Demographical characteristics			
Age, years (standard deviation)	65 (+/- 15)	72 (+/- 14)	NS
Male	51 (70.8)	17 (56.6)	0,18

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Infection-related Rheumatic Disease Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with inflammatory arthritis (IA) are at increased risk of prosthetic joint infections, yet differentiating between septic and aseptic failure is a challenge in patients with IA. Synovial fluid biomarkers, may be helpful for detection of PJI. The aim of our systematic review is to evaluate synovial fluid biomarkers and their efficacy at diagnosing PJI in patients with IA.

Methods: A comprehensive literature search was performed in the following databases from inception – January 2018: Ovid MEDLINE, Ovid EMBASE, and The Cochrane Library. Studies retrieved were screened for eligibility against predefined criteria. Searches across the databases retrieved 367 results. After de-duplication, 2 of 5 (SM, CK, SR, JB, SG) independently screened a total of 298 citations. Discrepancies were resolved by a 3rd reviewer. After review of titles and

For all available patients, biomarkers are summarized with medians [interquartile ranges] and were compared using the Kruskal-Wallis test.

Table 2. Optimal cutpoints for each marker to identify infections

Marker	Cutpoint	Sensitivity	Specificity	Negative predictive value (NPV)	Positive predictive value (PPV)
%PMN	78	0.952	0.850	0.987	0.603
WBC	6.5	0.864	0.484	0.908	0.375
RBC	16,000	0.806	0.413	0.846	0.347
CRP, ratio to normal	1.89	0.629	0.885	0.875	0.462
ESR, ratio to normal	2.05	0.732	0.764	0.911	0.466
Synovial					
IL-6	339.9	0.846	0.589	0.869	0.444
IL-8	954.9	0.759	0.667	0.847	0.532
IL-1b	5.215	0.704	0.833	0.849	0.679
OCSP	34.25	0.389	0.868	0.756	0.606
CRP	5.2	0.791	0.623	0.879	0.462
TfR _h	49.22	0.294	0.867	0.717	0.517
IFN gamma	4.566	0.640	0.870	0.800	0.640
IL-12p70	6.540	0.357	0.956	0.710	0.769
IL-2	1.699	0.536	0.872	0.759	0.714
IL-10	28.121	0.720	0.818	0.837	0.692

Optimal cut points were chosen based on the maximum Youden index value (equal to sensitivity + specificity - 1).

abstracts, full text articles were pulled for further screening and data extraction. 20 articles were included, in this review. Due to methodological differences findings could not be pooled for meta-analysis. 5 studies that specifically investigated PJI in IA patients and non-IA patients were included and used to derive optimal cut points for common synovial tests.

Results: Our final analysis included 1435 non-IA aseptic patients, 426 non-IA septic patients, 64 IA aseptic patients and 26 IA septic patients. There was a significant difference in detection amongst the four groups when using %PMN, WBC, serum CRP and ESR, synovial IL-6, IL-8, IL-1b and CRP (Table 1). Median values of WBC count, IL-6, IL-8, and serum CRP were significantly higher in patients with IA, and although sensitivity was high, specificity was low (Table 2). PMN% had the highest sensitivity (95.2%) and specificity (85.0%) to detect infections with a threshold of optimum sensitivity and specificity of 78%.

Conclusion: Few studies address the diagnosis of PJI in patients with inflammatory arthritis and no synovial biomarker demonstrates high sensitivity and specificity. In contrast to PJI in patients with OA, we did not find synovial WBC count to be sensitive or specific in diagnosing PJI in IA patients. While diagnostic tests for synovial WBC, IL-6, IL8 and serum CRP appear higher in patients with inflammatory arthritis, there is overlap with those who are not infected. Further studies are needed to explore diagnostics tests that will better detect PJI in patients with IA

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Infection-related Rheumatic Disease Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is a multisystem autoimmune disorder with immunodeficiency associated with the disease itself and immunosuppressive treatment. Infections are very frequent events and one of the

main causes of morbidity and mortality. However, fungal infections have a low incidence, being those associated with *Cryptococcus neoformans* (CN) the most frequently described.

The aim of this study was to describe clinical, biochemical and outcomes of the invasive fungal infection (IFI) produced by CN in patients with SLE assisted in our hospital.

Methods: A retrospective and observational study of the IFIs by CN was carried out in adult patients with SLE (ACR82-97), assisted between January 1, 1993 and 1 May 2018.

Detection of capsular antigen in cerebrospinal fluid (CSF), a positive result of the ink test or isolation of the fungus from sterile sites according to EORTC/MSG 2008 criteria (European Organization for Research and Treatment of Cancer / Invasive Fungal Infections Cooperative Group and the National Institute of Allergy and Infectious Diseases Mycoses Study Group) were defined as IFI tested by CN. Evolution time of SLE at infection diagnosis, time of hospitalization, SLE activity measured by SLEDAI, clinical manifestations and immunosuppressive treatment were analyzed.

Results: Twenty one SLE patients with IFI were identified, and 7 (33%) of them presented CN infection. Rest of IFIs were caused as follows: 7 (33%) by *Candida* spp., *Aspergillus* spp: 2 (14,3%), *H. capsulatum*: 3 (9,52%), *P. jiroveci*: 1 (4,8%), *H. capsulatum* / *Alternaria* spp (mixed infection): 1 (4,8%). Seven cases infected with CN occurred in women with a mean of 40 years \pm 16. Mean evolution time of SLE at fungal infection was 9.7 years (9-180 months). Mean SLEDAI was 10 (0-24). 86% (6/7) of the patients had nephropathy and 57% (4/7) required hemodialysis. 43% (3/7) received treatment with cyclophosphamide but only 2 patients presented neutropenia. 86% (6/7) received corticosteroid therapy with meprednisone at doses greater than 20 mg/day and 29% (2/7) were treated with pulses of methylprednisolone. Other treatments were: Azathioprine, intravenous gammaglobulin, Mycophenolate Mofetil.

All the patients presented symptoms related to meningoencephalitis and Chinese ink test, antigenemia and CSF culture were positive in all cases. In 2 patients, CN was also isolated in the blood culture and in one of them also in sputum (disseminated infections). All were treated with Amphotericin B (liposomal amphotericin B was used in one patient due to renal failure and in another patient associated with fluconazole). Two patients continued with secondary prophylaxis with fluconazole. 5/7 patients died during hospitalization (71.4%), in most cases directly related to the infection.

Conclusion: Invasive fungal disease by *Cryptococcus neoformans* in SLE patients was associated to active disease, renal compromise and immunosuppressive treatment. Meningoencephalitis was the most prevalent clinical manifestation of cryptococcosis and in all cases the germ was isolated in the CSF. Two patients had a disseminated infection (blood cultures and positive sputum). All were treated with amphotericin B. The mortality was 71.4%.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Infection-related Rheumatic Disease Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Vertebral Osteomyelitis is an infectious disease of the vertebral body which could involve the intervertebral space (spondylodiscitis). Early diagnosis and treatment are essential in order to achieve the best chance of a good outcome, but these are often delayed because it tends to present nonspecific manifestations. Our purpose was to identify risk factors and outcome variables in our cohort.

Methods: Single center longitudinal retrospective observational study including patients diagnosed of Vertebral Osteomyelitis from January 2010 to March 2018. Demographic, clinical, microbiology and radiological data were compiled.

Long hospital stay, readmission, vertebral destruction, neurological damage and death were chosen as outcome variables. Patients aging under 18 were excluded. The statistical analysis was performed with the software R, version 3.3.2.

Results: 116 patients were included, with a mean age of 62.05 (16.94) years old. Male sex accounted 68.10%. 58.62% had medical history of spine pathology. 18 patients (15.51%) presented immunosuppression (rheumatic or inflammatory bowel disease on treatment, malignancy, HIV or solid organ transplantation). Most frequent symptom was back pain (99.14%), fever was only in 45 patients (38.79%). Acute paraparesis was presented in 21 patients (19.10%) at diagnosis. Mean diagnosis delay was 54.14 days. 14 patients had underlying endocarditis (12.07%). Most of patients (94.83%) showed high CRP levels at diagnosis, with an average value of 103.47 mg/L, which was not related to worse outcome. Mean length of hospital stay was 34.24 (34.3) days and readmission rate was 34.9%. Blood cultures were positive in 46 patients (39.66%). Punction-aspiration was performed in 84 patients (72.10%) and its culture were positive in 48 samples (57.14%). Median delay from suspicion to biopsy was 6 days. Gram positive predominated (73.86%), followed by Gram negative species (12.5%), mycobacteria (10.23%) and fungi (3.41%). No microorganism was identified in 28 patients (24.14%). On imaging, most of the patients (92.24%) had paravertebral or epidural abscess. 63 cases (54.31%) showed vertebral destruction and 39 (33.62%) cord compression. Vertebral destruction was related to epidural abscess ($p=0.006$). 22 patients (18.97%) required further surgical procedures. Age trend to be related to worse outcome with no statistical signification. Diabetes mellitus was associated to greater vertebral destruction ($p=0.01$) and cord compression ($p=0.02$). Longer pain duration correlated with neurological damage ($p=0.02$). Underlying infectious endocarditis patients showed higher vertebral destruction ($p=0.01$). 11 patients (9.48%) died during follow-up.

Conclusion: Delay in diagnosis is still an important issue that is associated to higher complication rates, mainly related to structural damage of the spine. It has been also found that the presence of an epidural vertebral abscess is related to greater vertebral destruction. Elderly, diabetic and immunosuppressed patients had the worse chance of a good outcome, so these patients should be more careful managed (always try to obtain an imaging-guided biopsy, correct antibiotic treatment, and a functional and clinical follow-up).

Synovial Fluid Profile in Neutropenic Patients with Septic Arthritis

Samantha Minkin¹ and Adam Carlson², ¹Internal Medicine, Department of Medicine, University of Virginia, Charlottesville, VA, ²Department of Medicine, Division of Rheumatology, University of Virginia Health System, Charlottesville, VA

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Infection-related Rheumatic Disease Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: In patients with septic arthritis, the white blood cell count in the synovial fluid is classically $>50,000$ cells/ μ L. While a microorganism must be identified in the synovial fluid to make a definitive diagnosis, the clinician often relies on the synovial white cell count to guide management prior to the culture results. There are few studies detailing the synovial fluid profile of patients with acquired neutropenia and septic arthritis. We performed a retrospective study to investigate synovial fluid white cell counts in neutropenic patients with culture positive septic arthritis.

Methods: Using ICD-9 and ICD-10 codes, we identified patients who carried both “septic arthritis” and “neutropenia” diagnoses at the University of Virginia Medical Center between January 2000 – January 2018. Twenty-six patients fulfilled these initial criteria. Charts were then reviewed individually to identify patients with an absolute neutrophil count (ANC) of less than 1000 cells/ μ L and synovial fluid cultures that confirmed septic arthritis.

Results: Three patients met the above criteria. The first patient was a 62 year old male with acute myelogenous leukemia. After induction chemotherapy, he presented with neutropenic fever secondary to *Candida tropicalis* candidemia. His course was complicated by septic arthritis of the right shoulder with synovial fluid cultures growing the same species of *Candida*. Aspiration of the joint revealed a synovial fluid count of 2 WBCs/ μ L. His total peripheral WBC count at the time of the arthrocentesis was 122 cells/ μ L (ANC undetectable). The second case was an 80 year old female with acute myelogenous leukemia. She presented after induction chemotherapy with neutropenic fever secondary to *coagulase-negative*

Staphylococcus bacteremia. She developed septic arthritis of the right knee that grew this bacteria as well. Aspiration of the synovial fluid yielded a cell count of 9 total WBCs/ μ L. Her ANC was 110 cells/ μ L. The final patient was a 64 year old male with multiple myeloma and ESRD. He presented with neutropenic fever secondary to Vancomycin-resistant *Enterococcus faecium* (VRE). He developed septic arthritis of the right knee with synovial fluid cultures also growing VRE. His synovial fluid cell count was 22,125 WBCs/ μ L. His ANC was 730 cells/ μ L at that time of his septic arthritis diagnosis.

Conclusion: In patients with acquired neutropenia and septic arthritis, the degree of peripheral neutropenia correlates with the synovial fluid white blood cell count. Neutropenic patients with a total ANC above 500 cells/ μ L appear to be able to mount a modest inflammatory response in the infected joint, whereas patients with an ANC below 500 cells/ μ L may have normal synovial fluid white cell counts. Clinicians should maintain a high level of suspicion for septic arthritis in neutropenic patients with joint pain and swelling even in the face of a normal synovial fluid white cell count. Synovial fluid cultures are essential in establishing the diagnosis of septic arthritis.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Infection-related Rheumatic Disease Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Rituximab (RTX) is a chimeric monoclonal antibody approved for the treatment rheumatoid arthritis (RA) patients who failed to respond to tumornecrosis factor inhibitors. Due to its effect on induction of B cell depletion, the administration of multiple cycles can lead to a decrease in immunoglobulins (Ig) which may increase the risk of infection. We aim to evaluate the long-term safety of RTX in RA patients.

Methods: Retrospective observational study was conducted including RA patients treated in a tertiary hospital between June 2006 and May 2017 who had received at least two RTXcycle. At RTX initiation we analyzed: comorbidities and Charlson score, presence of rheumatoid factor (RF) / anti-citrullinated protein antibodies (APC),previous biological DMARD (bDMARD); concomitant treatment (csDMARD /glucocorticoids (GC)) as well as demographic and clinical features.Serum Ig levels before every RTX cycle, the number ofRTX cycles and adverse events (AE), including serious and opportunistic infections were also analyzed. Non-disseminated Herpes-Zoster (HZ) were not considered opportunistic infection.

Results: 53patients were included (86.8% women, mean age 55.5 ± 13.5 years), 58% had aCharlson score ≥ 3 . Mean disease duration was 16 ± 9.1 years; 84.9% and92.5% were RF and ACPA positive, respectively. Before starting RTX, 81% of patients had received other bDMARD ($58.5\% \geq 2$), 88% received concomitantcsDMARD, (52% methotrexate and 32% leflunomide) and 81% were treated with GC(median dose 10 mg, P25-75 5-10 mg). The median number of RTX cycles received per patient was 5 (P25-75 2-6). 80 AE were reported: 12 infusion reactions, 8cases of neutropenia, 51 infections (18 respiratory, 8 urinary, 4 skin and soft tissues, 8 gastrointestinal, 4 cases of non-disseminated HZ, 1 bacteremia, 2 septic shock and 6 other) of which 19 were serious. 5 malignancies (2melanomas, 2 cervix, and 1 bladder) were also notified. The incidence rate of serious infections was $6.75 / 100$ PY, and its appearance remained stable throughout the follow-up time (Figure.1). No opportunistic infections or HBVreactivations were reported. Ig levels were obtained for 41 subjects: 7,5 and 1 patients had low levels of IgG, IgM and IgA, respectively. Patients who developed infections received a greater number of RTX cycles ($p<0.0002$) and had more frequently low levels of serum IgG during follow-up ($p<0.044$) than those who did not have infections. >0.002) and had more frequently low levels of serum IgG during follow-up ($p<0.044$) than those who did not have infections.

Conclusion: Long-term exposure to RTX showed a good safety profile with a low incidence of serious infectious and no opportunistic infections. Only number of cycles received and low serum levels of IgG at any point during follow-up were associated with the development of infections.

Abstract Number: 1234

Incidence of Conversion of Screening Tests for M. Tuberculosis (PPD, GIF-release assay) in a Metropolitan Cohort of Patients Treated with TNF- α Inhibitors

Hung Trinh and Darren Tabechian, Medicine, Division of Allergy, Immunology and Rheumatology, University of Rochester Medical Center, Rochester, NY

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Infection-related Rheumatic Disease Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Tumor necrosis factor alpha (TNF- α) inhibitors are used to reduce the inflammatory process in many autoimmune diseases. Due to the risk of reactivation of latent tuberculosis, screening for latent infection with either purified protein derivative (PPD) skin testing or gamma interferon (GIF) release assay is necessary prior to initiation of treatment. Recommendations for subsequent testing while on TNF- α inhibitors vary, and there is a lack of data regarding the incidence of screening test conversion for patients on TNF- α inhibitors.

Methods: Between March 29, 2010 and October 19, 2016, patients over the age of 18 who had had an encounter with a rheumatologist at one of the University of Rochester Medical Center rheumatology practice clinics were identified through a search of our electronic medical record. Our physicians provide care for an estimated 60% of the patients in the referral catchment population of approximately 1.1 million residents (including 5 suburban and agricultural counties and a medium sized city of 210,000). The charts of those who had been prescribed a TNF- α inhibitor (adalimumab, certolizumab, etanercept, golimumab, or infliximab) and who had been identified by ICD coding for positive PPD or GIF release assay testing, were reviewed.

Results: Of the 2807 rheumatology clinic patients treated with TNF- α inhibitors, 89 cases (2.9%) of latent tuberculosis were identified and verified by chart review to have a confirmed positive PPD reading or GIF release assay. 25 (28.1%) of these cases were identified after the initiation of a TNF- α inhibitor as new converters. The rate of PPD or GIF-release assay conversion with TNF- α inhibitor use amongst our cohort is 0.89% (25 of 2807 patients).

Conclusion: We documented a 0.89% PPD/GIF conversion rate in our patients on TNF- α inhibitors. Our data suggests that continued screening of patients maintained on TNF- α inhibitor therapy will improve identification of these patients unknowingly exposed to mycobacterial infection.

Isoniazid Monotherapy As a Prophylaxis for Tuberculosis in Patients with Rheumatic Diseases Exposed to Prolonged, High-Dose Glucocorticoids

Jun Won Park¹, Jeffrey R. Curtis², Hajeong Lee³, Yeong Wook Song⁴ and Eun Bong Lee¹, ¹Division of Rheumatology, Department of Internal Medicine, Seoul National University College of Medicine, Seoul, Korea, Republic of South, ²University of Alabama at Birmingham, Birmingham, AL, ³Division of Nephrology, Department of Internal Medicine, Seoul National University Hospital, Seoul, Korea, Republic of South, ⁴Seoul National University College of Medicine, Seoul, Korea, Republic of South

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Infection-related Rheumatic Disease Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Although use of glucocorticoid increases the risk of tuberculosis (TB) disease, there has been few studies investigating its incidence and risk/benefit assessment of the prevention in rheumatic disease patients with this treatment. Furthermore, result of tuberculin skin test and interferon gamma release assay (IGRA) could be significantly influenced by steroids itself. In this study, we investigated the efficacy and safety of isoniazid (INH) monotherapy as a prophylaxis of TB disease in rheumatic disease patients receiving prolonged, high-dose steroids.

Methods: This single center cohort study analyzed 1618 treatment episodes with prolonged (4 weeks or more), high-dose (30mg/day or more of prednisone) steroids from 1160 patient's between 2004 and 2016. IGRA was performed in 187 (11.6%) episodes and selection of patients for INH monotherapy and its duration was mainly determined by treating physician. Overall, 152 episodes (INH group) received isoniazid monotherapy with steroid while other 1466 episodes did not receive prophylaxis (control group). Primary outcome was 1-year incidence of TB disease between the two groups, which was compared using Cox regression. Incidence rate of adverse drug reaction (ADR) related to INH was also investigated. Risk-benefit analysis of INH monotherapy was performed by comparing the number needed to be treated (NNT) to prevent 1 case of TB disease vs. the number needed to harm (NNH) due to ADR. As part of a sensitivity analysis, propensity score matching was used to minimize baseline imbalances, and the same analysis was performed in post-matched population (n=147 in each group).

Results: Patients in the INH group were older (45.1 vs. 42.1 years) and more frequently had SLE (56.6% vs. 48.7%) and MPA (5.3% vs. 0.9%) than those in the control group. Median (IQR) steroid dose at initiation was also higher in the INH group (55.0 [30.0] vs. 60 [15.0] mg/day of prednisone). During a 1579.8 person-year, a total of 21 cases of TB disease occurred. Prophylaxis with INH trended toward a reduced 1-year incidence of TB in the multivariable model where SLE, cumulatively used steroid dose and risk factors for TB disease were adjusted (adjusted HR = 0.57 [95% CI 0.13 to 2.52]) (Figure). The sensitivity analysis performed in the post-matched population was consistent with the main results (adjusted

Figure. Kaplan-Meier curve indicating 1-year incidence of tuberculosis disease between the control group and isoniazid (INH) group.

HR = 0.67 [0.10 to 4.38]). In contrast, incidence rate of any ADRs during the INH treatment was 113.0 (90.5 to 139.3)/100 person-year including one case of fulminant hepatitis. Because absolute risk for TB disease was higher in the INH group, NNT was calculated as a negative value whereas NNH for any ADR and serious ADR were 2 (1.6 to 2.1) and 76 (32.0 to 110), respectively.

Conclusion: Isoniazid monotherapy as a prophylaxis for TB in rheumatic disease patients receiving prolonged, high-dose steroids shows partial efficacy, but high incidence of ADR limits its role as a general practice.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Infection-related Rheumatic Disease Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Whipple's disease (WD) is a rare, systemic, disease caused by the intracellular Gram-positive bacterium *Tropheryma whippie* (TW). This ubiquitous commensal organism is transmitted among humans via the oro-fecal route. Chronic WD and the immune system are closely linked. To our knowledge, no studies have evaluated the potential role for B cells in WD. We noticed lymphocyte subset abnormalities similar to those seen in primary Sjögren's syndrome in patients whose symptoms suggested ankylosing spondylitis (inflammatory low back pain) or rheumatoid arthritis (chronic polyarthritis). We then observed the same abnormalities in patients with infectious rheumatic diseases due in particular to *Bartonella* (cat-scratch disease) or TW. We therefore designed the present study with the aim of describing peripheral-blood lymphocyte subsets, with special attention to B cells, in patients with WD. We aimed to assess whether any abnormalities found were sufficiently characteristic to help in diagnosing and monitoring WD.

Methods: Consecutive patients seen between 2010 and 2016 for suspected inflammatory joint disease were identified retrospectively. Results of standardized immunological and serological tests and of peripheral-blood B-cell and T-cell subset analysis by flow cytometry were collected. Patients with criteria suggesting WD underwent PCR testing for *Tropheryma whippie*, and those with diagnosis of WD (cases) were compared to those without diagnosis (controls). We used ROC curve analysis to evaluate the diagnostic value of flow cytometry findings for WD.

Results: Among 2917 patients seen for suspected inflammatory joint disease, 121 had suspected WD, including 9 (9/121, 7.4%) with a positive PCR and a dramatic response to antibiotic therapy for WD. Proportions of T cells and NK cells were similar between cases and controls, whereas cases had a lower proportion of circulating memory B cells (IgD⁺CD38^{low}, 18.0%±9.7% vs. 26.0%±14.2%, $P=0.041$) and higher ratio of activated B cells over memory B cells (4.4±2.0 vs. 2.9±2.2, $P=0.023$). Among peripheral-blood B-cells, the proportion of IgD⁺CD27⁻ naive B cells was higher (66.2%±18.2% vs. 54.6%±18.4%, $P=0.047$) and that of IgD⁺CD27⁺ switched memory B cells lower (13.3%±5.7% vs. 21.4%±11.9%, $P=0.023$), in cases vs. controls. The criterion with the best diagnostic performance was a proportion of IgD⁺CD27⁻ naive B cells above 70.5 %, which had 73% sensitivity and 80% specificity.

Conclusion: Our study provides data on peripheral-blood B-cell disturbances that may have implications for the diagnosis and pathogenetic understanding of WD.

SESSION INFORMATION

Session Title: Infection-related Rheumatic Disease Poster

Session Type: ACR Poster Session B

Background/Purpose: Synovial biopsies are increasingly performed for research purposes but also in clinical practice. The development of US guided procedure has made this procedure simpler. In addition, both small and large joints as well as tendon sheaths and bursae are accessible. In clinical practice, synovial biopsies are traditionally performed in cases of suspected septic arthritis. The goal of this work was to assess the usefulness of synovial biopsies in a large cohort of synovial biopsies performed in clinical practice.

Results: 153 biopsies were performed between 2007 and 2018. 22 patients were finally diagnosed with septic arthritis. There were 11 females, mean age 63 years old (+/- 18). The biopsy was performed in the knee (n=9); wrist (n=3); shoulder, hip, elbow (n=2 each); ankle, sternoclavicular acromioclavicular and flexor of hand (n=1 each). Biopsy did not retrieve synovial tissue in 2 cases. Pathological analysis was characteristic of septic arthritis in 5 cases, compatible in 9 cases, not suggestive in 5 cases. Characteristics of the patients, synovial fluid and biopsy and blood test results are summarized in table 1. Overall, the bacteria were identified by culture or PCR in 16 cases. *Mycobacterium* sp. was identified in 2 cases with a positive synovial fluid analysis and/or lavage. Slow-growing bacteria were identified in 8 cases: Lyme disease (n=5), Whipple disease (n=2) and *coxiella burnetii* (n=1). In these cases, PCR was positive in the synovial tissue in 4 cases but negative in 4 cases (diagnosis based on blood serology or PCR of other tissues). Pyogenic bacteria were identified in 7 cases: diagnosis was made only on the culture of the synovial biopsy in 4 cases; on serum saline lavage of the joint in 2 cases (negative synovial tissue culture); on the blood culture in one case.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Infection-related Rheumatic Disease Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Little is known about the effects of antibiotic therapy on synovial and blood culture results among patients with prosthetic joint septic arthritis (PJSA). In this study we aimed to determine this effect.

Methods: We conducted a retrospective study of patients 18 years and older admitted to a single tertiary care center between 1998 and 2015 with culture-positive PJSA. Only patients with serial blood or synovial fluid cultures who received appropriate antibiotic treatment (i.e. matched to the bacterial antibiogram) and in whom the timing of initiation of antibiotic therapy was documented were included in this study. Time to conversion of cultures from positive to negative was calculated using Kaplan-Meier and Cox regression models. Log Rank (Mantel-Cox) test and Wald test were used to compare survival curves among groups and versus the general tendency. A p-value < 0.05 was considered significant for all tests.

Results: Among patients with culture- positive PJSA serial blood and synovial fluid cultures were obtained in 38 (36.5%) and 66 (63.5%) patients, respectively. Mean number of samples per patient was 10.7 and 2.4 for blood and synovial fluid cultures, respectively. Vancomycin was the most commonly prescribed antibiotic and was administered to 84.5% of the patients. Median time to conversion from positive to negative culture results was significantly longer for synovial fluid cultures compared with blood cultures (147.7 vs 34.9 hours; p-value <0.001). Median time of conversion from positive to negative blood culture results varied significantly for the top 3 pathogens; *Coagulase negative Staphylococcus* (CONS), *methicillin-sensitive Staphylococcus Aureus* (MSSA), *methicillin-resistant Staphylococcus Aureus* (MRSA) (22.9 vs 47.1 vs 37.3 hours, respectively; p= 0.006).

Conclusion: To our knowledge, this is the first study to demonstrate the effect of antibiotic administration on blood and synovial culture positivity over time. Blood cultures appear to be more sensitive than synovial fluid cultures to the effect of antibiotics. We also were able to demonstrate that the effect of antibiotics on blood culture sterility varies between different bacterial pathogens.

Organisms Associated with Prosthetic Joint Septic Arthritis over the Past Two Decades: Data from a Single Tertiary Medical Center Located in the Northeastern United States

Manny Menachem Arieli¹, Mary Louise Fowler², Sarah Lieber³, Robert Shmerling⁴, Mohammad Naffaa⁵ and Ziv Paz^{1,3},
¹Azrieli Faculty of Medicine, Bar-Ilan University, Sefad, Israel, ²Boston University School of Medicine, Boston, MA, ³Beth Israel Deaconess Medical Center, Boston, MA, ⁴Rheumatology, Beth Israel Deaconess Medical Center, Boston, MA, ⁵Galilee Medical Center, Israel, Nahariya, Israel

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Infection-related Rheumatic Disease Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: In recent years, joint replacement surgery (JRS) has become increasingly common. Prosthetic joint septic arthritis (PJSA) may complicate JRS in up to 1% of cases. As is true for other types of infections (e.g. cellulitis, pneumonia), the microbiologic causes of PJSA may change over time. Early, effective therapy of PJSA may be enhanced by improving our knowledge on the major causes of PJSA. In this study we aimed to determine the trends in the organisms associated with PJSA.

Methods: We conducted a retrospective study including all patients 18 and older with surgically-treated, culture-positive PJSA admitted to a single tertiary medical center in Boston between the years of 1997-2015. We excluded cases of culture negative SA, native joint SA, osteomyelitis and septic bursitis. Patients with prosthetic joint arthritis were considered culture-positive if pathogenic bacteria were isolated from synovial fluid, blood cultures or synovial biopsy.

Results: We identified 190 patients with culture- positive PJSA. The most commonly identified organisms over the study period were: *Methicillin sensitive Staphylococcus aureus* (MSSA) (34.2%), *coagulase negative Staphylococci* (CoNS) (18.9%), *methicillin resistant Staphylococcus aureus* (MRSA) (13.2%) and *group B Streptococcus* (GBS) (11.6%). When our cohort of patients was divided into 5 years intervals, a significant change in the rates of MRSA related PJSA was observed: 7.7% in 1997-2002, 28.9% in 2003-2008, 9.7% in 2009-2014, p value = 0.005.

Over the study period 12.6% of the patients presented with early PJSA (JRS≤42 days), 26.8% with delayed PJSA (365>JRS>42 days) and 54.2% with late PJSA (JRS>365 days). A trend toward a significant increase in GBS related late PJSA was observed (early GBS related PJSA= 4.2% delayed GBS related PJSA =5.9% late GBS related PJSA= 17.5%, p value=.060). *Enterococcus*, *Pseudomonas aeruginosa* and *Streptococci Viridins* were not isolated in the early PJSA group.

Conclusion: Similar to other studies we showed that MSSA, CoNS and MRSA are the top three causes of PJSA. The novel observations of our study include the falling incidence of MRSA in recent years, the higher rates of GBS in late PJSA and the absence of *Enterococci* and *Pseudomona Aeruginosa* in early PJSA.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Infection-related Rheumatic Disease Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Foot involvement is frequently pointed by patients with chronic inflammatory rheumatic diseases (IRD), such as rheumatoid arthritis (RA), spondyloarthritis (SpA) or psoriatic arthritis (PsA). According to previous studies, IRD patients are at higher risk of developing osteomyelitis (rate ratio 10.63), although incidence rate seems to be low (0,17/100 patients-years)¹. Given the increased infectious risk, especially induced by steroids or immunosuppressive drugs, our aim was to report the occurrence of foot osteomyelitis in the patients suffering from IRD and recruited in our center over the last twenty years.

Methods: We performed a monocentric retrospective observational study that collected MISP (Medicalized Information System Program) data in the Montpellier University Hospital, from August 1996 to May 2016. We included all patients with IRD who presented a clinical suspicion of osteomyelitis (classic inflammation signs, or fever), with confirmation by definite imaging (Magnetic Resonance Imaging, tomography, or radiographic) findings and at least one positive microbiological culture. We excluded patients with isolated soft tissue infection, no microbiological sampling, or no imaging finding, as well as patients with incomplete data about their IRD history (long-term treatments, immunology, erosive status). Two groups were dissociated: the first with foot osteomyelitis patients (FO), the other with osteomyelitis patients not affecting the foot (NFO). In the patient medical file, we collected demographic, clinical, biological and imaging data. The comparison between each group was performed using the Student test for quantitative variables and using a Chi-2 test for qualitative variables.

Results: Among the 235 MISP search findings, we identified 69 bone infections that met the inclusion criteria, of which 41 (59.4%) involving the foot. In the FO group, RA was highly predominant (92.6%), with an advanced (24.6 +/- 13.1 years of evolution) and severe illness (37 cases, 92.5% patients with erosions). Patients were mainly treated by corticosteroids (65.9%), methotrexate (32.1 %) and biologics (28.6%). Diabetes was the most frequent comorbidity (8 cases, 19.5%). Osteomyelitis mainly involved forefoot (75.6%), especially in the first ray (41.1% of infections). *Staphylococcus aureus* was the most involved organism (53.7%). We significantly found fewer systemic complications (sepsis or endocarditis) in the FO group compared to the NFO group (2.4% vs. 28.6%, $p = 0.002$). Furthermore, corticosteroids use was associated to a significant risk in the FO group compared to the NFO group (65.9% vs. 39.3%, $p = 0.03$). No increasing infectious risk was found for biological drugs users in the FO group (31.7% vs 28.6%, $p = 0.78$).

Conclusion: Description of FO is scarce in IRD. Our study reported a significant occurrence, especially in patients with severe RA using steroids. A special attention should be done to identify risk factors and possibly correct them.

Pneumococcal Vaccination Quality Improvement Initiative within a Rheumatology Clinic at an Academic Medical Center

Ali Goodson¹, Bonita Libman², Alana Nevares³, Melinda Edwards² and Amanda Kennedy⁴, ¹Pharmacy, The University of Vermont Medical Center, Burlington, VT, Afghanistan, ²Medicine/Rheumatology, University of Vermont Medical Center, Burlington, VT, ³Rheumatology, University of Vermont Medical Center, Burlington, VT, ⁴Internal Medicine, University of Vermont Medical Center, Burlington, VT

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Infection-related Rheumatic Disease Poster – ARHP

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatology patients are at an increased risk of infection secondary to immunosuppressive medications used for disease management. However, vaccination is underutilized and rates remain low in this population despite guideline recommendation for receipt. Our aim was to improve pneumococcal vaccination rates in patients receiving biologic medications and to identify barriers to vaccination.

Methods: We implemented a multifaceted intervention within an adult rheumatology clinic at an academic medical center. Intervention included pharmacist pre-visit review of vaccination status, flagging charts with recommended vaccine, physician face-to-face discussion, and optional in-clinic nurse administration.

Results: 514 patients were reviewed prior to their visit. 369 were identified as eligible for pneumococcal vaccination. Of patients who were current with pneumococcal vaccination at the time of their visit, 34% had vaccination records located outside of our electronic medical record, primarily found in state immunization registries. Following five months of our intervention, 343 patients are now current with pneumococcal vaccinations, shifting those with an updated status from 28% to 67%. Of those that did not receive vaccination at time of visit, most common documented reasons were, no recommendation was identified within visit note, followed by patient will discuss with primary care physician.

Conclusion: Our intervention significantly improved pneumococcal vaccination rates and highlights the benefit of a multidisciplinary approach to optimize vaccination. Barriers to vaccination identified in our study emphasize confusion surrounding current guideline recommendations and the need for a reliable, transparent immunization record.

Rheumatologists Participating in the RISE Registry Succeeded in the First Year of the Merit-Based Incentive Payment System (MIPS)

Tracy Johansson¹, Ryan Larosa², Rachel Myslinski³, Norlita Brown¹, Lindsay Lewis¹ and Jinoos Yazdany⁴, ¹Practice, Advocacy & Quality, American College of Rheumatology, Atlanta, GA, ²American College of Rheumatology, Atlanta, GA, ³Practice, Advocacy, & Quality, American College of Rheumatology, Atlanta, GA, ⁴University of California, San Francisco, San Francisco, CA

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Measures and Measurement of Healthcare Quality Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Under the Medicare Access and CHIP Reauthorization Act (MACRA), rheumatologists face financial repercussions through the Merit-Based Incentive Payment System (MIPS) based on performance on quality measures and use of electronic health records (EHRs). For the MIPS 2017 reporting year (Jan. 1, 2017-Dec. 31, 2017), providers were scored across 3 domains: Quality, Improvement Activities (IA), and Advancing Care Information (ACI). In this study, we sought to evaluate MIPS performance for practices that reported through the ACR's Rheumatology Informatics System for Effectiveness (RISE) registry.

Methods: The RISE registry continuously collects data from the EHRs of participating practices, allowing centralized aggregation and automated analysis of quality measures under the quality domain. RISE also allows providers to self-report on the other two domains that were active for 2017, IA and ACI. Using data from RISE, we calculated performance for all providers who reported for MIPS through the registry. We also evaluated the differences in performance on all three domains among providers who reported individually versus as part of a group.

Results: For the 2017 reporting year, 346 providers from 125 practices used the RISE registry to complete a total of 178 MIPS submissions for at least one domain, representing about 10% of MIPS-eligible rheumatology clinicians in the U.S. Most practices were either a group (47%) or solo practice (30%). Others were in some other clinical setting (5%), a health system (1%) or did not have practice setting information (18%). Of all submissions through RISE, 134 (76%) were considered full submissions on all 3 domains (Quality, IA and ACI). All full submissions exceeded the exceptional performance threshold of 70 points out of 100, earning all providers an additional bonus. While all rheumatologists submitting through RISE had high performance, those who submitted as part of a group had a slightly higher overall average performance (95.0 points) than those who submitted individually (92.1 points).

Conclusion: We found that all rheumatologists who completed full submissions through RISE were successful in the first year of MIPS, earning bonuses on their payment reimbursements for 2019. While some aspects of MIPS will be changing in 2018, RISE is continuously updated to track and maximize success in 3 of the 4 2018 MIPS domains. Further research is planned to investigate the workflows of group and solo practices who were top performers, as well as to assess the correlation between providers' MIPS scores and their patients' outcomes.

Disclaimer: This data was supported by the ACR's RISE Registry. However, the views expressed represent those of the authors, not necessarily those of the ACR.

Abstract Number: 1243

A Quality Improvement Initiative to Increase Adherence to Hydroxychloroquine Dosing Guidelines at an Academic Medical Center

Ryan Jessee, Stephanie L. Giattino, Atul Kapila, Katherine Kaufman, Jon Golenbiewski, Brian J. Andonian, David Leverenz and Lisa Criscione-Schreiber, Department of Medicine, Division of Rheumatology and Immunology, Duke University, Durham, NC

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Measures and Measurement of Healthcare Quality Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: In 2016, the American Academy of Ophthalmology published revised guidelines on HCQ dosing, recommending a maximum daily dose of 5mg/kg actual body weight as higher doses increase the risk of irreversible retinal toxicity. We conducted a QI initiative to increase provider adherence to these guidelines. We aimed to increase dosing compliance by 20 percentage points.

Methods: HCQ guideline compliance was measured every other week over 10 months by retrospectively reviewing all encounters with non-pregnant patients prescribed HCQ in an adult rheumatology clinic. We recorded date of visit, sex, weight, average daily HCQ dose, any change in dose, and HCQ indication. We used a strict threshold of 5mg/kg in assessing dosing compliance. We also surveyed providers regarding baseline perceptions towards HCQ dosing in clinical practice. Using Plan-Do-Study-Act methodology, we conducted these interventions: grand rounds lectures, modifications of electronic medical record templates, and an email reminder to providers. Charts were analyzed at baseline, between and following interventions.

Results: In the baseline survey (N=16) when asked, "How worried are you that discussing the new guidelines might lead to non-adherence?" 71% reported little or no concern while 29% of providers were "worried." Queried whether changing the

HCQ dose per guidelines has directly led to an adverse clinical outcome, 23% answered at least one occurrence; 15% recalled having at least one patient suffer significant visual impairment from HCQ.

We analyzed 1218 encounters (87% female) where HCQ was prescribed. The average daily dose was 350mg with 400mg daily being most commonly prescribed (65%). The average weight was 81.5kg. The top three indications for HCQ use were SLE (39%), RA (27%), and UCTD (16%). Baseline guideline compliance was 63% (N=169). During interventions, weekly compliance increased to a peak of 87%, with an overall average of 72% (Figure). Compliance was 99% in patients \geq 80kg and 44% in patients <80kg. Dose was decreased in 7% of encounters with a compliance of 62% after reduction. HCQ was started in 10% of encounters with 76% compliance. Dose was increased in 3% of encounters with resultant compliance of 59%. Compliance during interventions was lower among SLE (67%) than other diagnoses (75%).

Conclusion: Our QI initiative increased compliance by 10 percentage points, short of our aim of 20. This result is not surprising as 29% of providers were worried about flares with dose reduction. A dose decrease did not always result in improved adherence. New initiation of HCQ demonstrated improved adherence compared to the baseline. No one specific intervention appeared most effective. Patients with SLE and weight <80kg were less often within dosing guidelines potentially reflecting a focus for future targeted interventions. Additional studies are also needed to determine flare risk with dose reductions.

Abstract Number: 1244

Hydroxychloroquine Quality Improvement Project at UF Health Jacksonville Rheumatology Clinics

Shameik Brooks, Gurjit Kaeley and Lanh Dang, UF Health Jacksonville, Jacksonville, FL

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Measures and Measurement of Healthcare Quality Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Hydroxychloroquine (HCQ) is a treatment option for lupus erythematosus and rheumatoid arthritis. The risk of retinopathy in the first 5 years of therapy is estimated to be less than 1% in patients prescribed doses below 5 mg/kg per day. However, the risk increases to approximately 20% after 20 years of treatment. The American Academy of Ophthalmology (AAO) has identified the following risk factors for retinopathy secondary to HCQ: duration of treatment greater than 5 years, dose greater than 5 mg/kg actual body weight per day, kidney disease, concurrent tamoxifen use and history of macular disease. This study was conducted to identify patients who are at high risk for HCQ-induced retinopathy and to consider dose reduction if possible.

Methods: Data was obtained from the electronic health record (EHR) from July 1, 2016 to July 30, 2017. Clinic practice changed August 1, 2017 to identify patients at high risk for HCQ retinal toxicity and doses were decreased to below 5 mg/kg per day if possible. A repeat assessment was completed using EHR data from August 1 2017 to November 30, 2017 to determine the number of patients who remained at high risk for retinal toxicity, if dose reductions occurred, and if there was any impact on disease control.

Results: The initial assessment included 436 patients. One-hundred and five patients (24.1%) were prescribed HCQ at doses greater than 5 mg/kg per day. Sixty-three of the 105 patients had doses greater than 6 mg/kg per day and of those 63 patients, 20 of them had doses greater than 7 mg/kg per day. One patient was on concurrent tamoxifen therapy and HCQ was decreased to 200 mg per day. Twelve patients were identified to have an eGFR less than 60. There were 151 unique ophthalmology visits during the initial assessment.

The repeat assessment included 145 patients. Twenty-four patients (16.6%) were prescribed HCQ at doses greater than 5 mg/kg per day. Nine of the 24 patients had doses greater than 6 mg/kg per day and of those 9 patients, 3 of them had doses greater than 7 mg/kg per day. Doses did not exceed 8 mg/kg in any of the patients assessed. No patients in the repeat assessment were on concurrent tamoxifen therapy. One patient was identified to have an eGFR less than 60. There were 66 unique ophthalmology visits during the repeat assessment. After the conclusion of the study period, 1 patient with lupus erythematosus experienced increased disease activity since dose reduction from 8 mg/kg per day to 4 mg/kg per day. The HCQ dose was increased back to the previous dose in this patient.

Conclusion: Repeat assessment showed that less patients were prescribed HCQ at doses greater than 5 mg/kg/day compared to the initial assessment. Patient assessment to determine if HCQ dose reduction to less than 5 mg/kg per day is

clinically appropriate. However, it is important to monitor for increased disease activity in these patients. Assessing the number of ophthalmology visits was not fully informative as it does not indicate the number of patients specifically assessed for HCQ retinal toxicity. A more streamlined method to identify HCQ-related ophthalmology visits would be valuable in monitoring these patients.

Abstract Number: 1245

Methotrexate Quality Improvement Project at UF Health Jacksonville Rheumatology Clinics

Shameik Brooks, **Gurjit Kaeley** and Lanh Dang, UF Health Jacksonville, Jacksonville, FL

Session Information

Session Date: Monday, October 22, 2018

Session Title: Measures and Measurement of Healthcare Quality Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The diagnosis of interstitial lung disease (ILD) is comprised of a large group of respiratory disorders. ILD can lead to scarring of lung tissue. Factors such as environmental exposure, certain diseases (e.g. rheumatoid arthritis) and medications have been implicated. Methotrexate (MTX) has been identified as one of the medications with potential to cause ILD although the exact incidence of MTX-specific ILD remains unknown. Salliot et al conducted a systematic literature review to assess the long-term implications of MTX therapy. The results of 21 prospective studies (N= 3463) were combined to determine the frequency of adverse events (AEs). Eighty-four patients (2.4%) experienced respiratory-related AEs; The AEs experienced by 15 of those patients were attributed to MTX pneumonitis. Conway et al also conducted a systematic literature review to identify the risk of pulmonary disease in patients prescribed MTX. Seven studies were included in the review (N=1630) and 504 respiratory-related AEs were documented. MTX was not found to be associated with an increased risk of respiratory AEs. Burmester et al conducted a post hoc analysis including data from two studies: CONCERTO (N= 395) and MUSICA (N= 309), chronic dry cough as the only respiratory AE was 0.8% and 0.6% respectively. This study was conducted to determine how many patients prescribed MTX in the UF Health Jacksonville Rheumatology Clinics have completed chest imaging and if any patients were diagnosed with ILD.

Methods: Data was obtained from the electronic health record (EHR) from September 1, 2014 to September 30, 2017. Patients prescribed MTX from UF Health Jacksonville Rheumatology clinics, had chest imaging [chest x-ray, chest CT scan or chest MRI] and a diagnosis of ILD [ICD -10 code J84.9] were included. Patients with the diagnosis of ILD were further evaluated to determine the MTX dose and if MTX discontinuation occurred.

Results: A total of 701 patients were prescribed MTX during the evaluation period. Chest imaging was obtained on 137 patients (19.5%) and of these patients, 80 patients had a chest x-ray. Initially, 7 patients (0.9%) were identified to have the intended ICD-10 code J84.9 for ILD. On further evaluation, it was discovered that an additional ICD-10 code J84.10 for pulmonary fibrosis (PF) was included in the data, which accounted for 3 of the initial 7 ILD patients. Therefore, 4 patients (0.6% of 701 patients) had a diagnosis of ILD. Of the 4 ILD patients, MTX was discontinued in two patients. MTX was discontinued in all 3 patients with PF.

Conclusion: Based on the results of this retrospective study and low incidence of ILD cited in literature, it is difficult to justify routine chest imaging for MTX monitoring. Almost 20% of the patients prescribed MTX also obtained chest imaging during the evaluation period. A chest x-ray was the most common type of imaging performed in all patients prescribed MTX during the evaluation period. Four of 701 patients (0.6%) evaluated had a diagnosis of ILD based on the problem list. A limitations of this study was using only the ILD specific ICD-10 code to identify patients.

Practices of Hydroxychloroquine Dosing Based on the American Association of Ophthalmology (AAO) 2016 Recommendations: A Single Center Experience

Anthony Ocon¹, Muhammad Saad Shaukat², Vivek Mehta³, Mohamed Tageldin¹, David Morales⁴, Ernesto Acosta⁴, Jessica Calderone⁴, Marilyn Humantla⁴ and Ruben Peredo¹, ¹Medicine, Albany Medical Center, Albany, NY, ²Albany Medical Center, Albany, NY, ³Division of Rheumatology, Department of Medicine, Albany Medical College, Albany, NY, ⁴Medicine, Albany Medical College, Albany, NY

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Measures and Measurement of Healthcare Quality Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: In March 2016, the AAO updated antimalarial medication screening recommendations for retinopathy prevention, with a recommended dose of hydroxychloroquine (HCQ) ≤ 5.0 mg/kg total body weight (TBW) as compared to ≤ 6.5 mg/kg ideal body weight (IBW) previously. To assess guideline implementation at the two-year mark, we compared HCQ dosing before the March 2016 update and at March 2018. We also assessed whether there was adherence to screening eye exams and evidence of retinal toxicity.

Methods: We performed a retrospective chart review of patients on HCQ at Albany Medical Center between March 2009 through March 2018. HCQ doses based on TBW and IBW prior to the recommendation updates on March 2016 were compared to TBW-based dosing at March 2018 post-guidelines. We assessed frequency of eye examinations and evidence of retinal toxicity.

Results: Of 248 charts reviewed, 178 were excluded due to insufficient follow-up or insufficient data for paired analysis between 3/2016 and 3/2018. 70 subjects were analyzed; 64 were female. The mean age was 42.9-years-old (95% CI 39.2-46.6). Mean duration of HCQ therapy at 3/2018 was 62.2 months (95% CI 52.4-71.9). TBW did not change between initiation of HCQ (79.5 kg, 95% CI 74.0-85.2), at 3/2016 (83.0 kg, 95% CI 77.2-88.7), or at 3/2018 (82.9 kg, 95% CI 77.0-88.8) ($p=0.64$). TBW-based dosage was significantly less at 3/2018 (3.9 mg/kg, 95% CI 3.6-4.2) than TBW-based at 3/2016 (4.3 mg/kg, 95% CI 4.0-4.7) ($p<0.03$). The TBW-based dosage was significantly less at 3/2018 (3.9 mg/kg, 95% CI 3.6-4.2) than IBW-based dosage at 3/2016 (5.8 mg/kg, 95% CI 5.4-6.2) ($p<0.001$). At 3/2016, 34 subjects (49%) were dosed at >6.5 mg/kg IBW (mean 7.4 mg/kg, 95% CI 7.1-7.6) and 7 subjects (10%) at >6.5 mg/kg TBW (mean 7.6 mg/kg, 95% CI 7.2-8.1). At 3/2018, 6 subjects (9%) were dosed at >5.5 mg/kg TBW (mean 6.2 mg/kg, 95% CI 5.4-6.9). Comparing the overdosed groups, the number of subjects and the TBW dosage of HCQ at 3/2018 were less than the IBW dosage of HCQ prior to 3/2016 ($p<0.001$). 34 of 70 (49%) patients had documented retinal exams either annually or biannually. Of the 34 IBW-overdosed at 3/2016, 30 (88%) were appropriately dosed based on TBW by 3/2018, 13 of 34 (38%) and 4 of 7 (57%) overdosed subjects based on IBW and TBW dose at 3/2016, respectfully, did not have eye exams. 4 of 7 (57%) overdosed based on TBW at 3/2018 did not have eye exams. One incidence of retinal toxicity was found and was overdosed (7.5 mg/kg) based on the IBW at 3/2016.

Conclusion: After the AAO 2016 recommendations, dosing of HCQ decreased based on the change from IBW to TBW. The majority of patients with prior overdosing were re-dosed appropriately by 3/2018. The number of subjects overdosed on HCQ declined at two-year follow-up. Closer retinal exam follow-up is needed to improve screening and prevent toxicity. Overall, the proportion of patients at-risk based on dosage was reduced.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Measures and Measurement of Healthcare Quality Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The treat-to-target approach for serum uric acid is the recommended model in gout management according to the 2012 American College of Rheumatology (ACR) guidelines. Adherence to an urate-lowering therapy (ULT) can be difficult for patients due to barriers, including medication burden, financial hardship, and lack of medical literacy. Additionally, practice gaps may occur with providers in titration of ULT to targeted serum uric acid. We examined the practice gap in gout management at an academic rheumatology clinic, which cares for a complex county patient population. Our aim was to create a pharmacist-managed referral for the titration of ULT to target serum uric acid levels.

Methods: A clinical database was utilized to query patients seen in rheumatology clinic over a twelve-month period with ICD-10 diagnosis for gout. The inclusion criteria were indications for ULT per 2012 ACR guidelines with the most recent serum uric acid level above target (>6 mg/dL or >5 mg/dL if tophaceous and/or erosive disease).

Rheumatology providers were asked to consider referral for the identified patients to the clinical pharmacy for assistance with titration of ULT (allopurinol or febuxostat) to target serum uric acid levels based on ACR guidelines.

The intervention group consisted of 14 patients who were referred during the five-month study period. The control group consisted of 22 patients who met inclusion criteria and seen within the same time frame but not referred. Referral was based on provider preference. At the end of the study period, the most recent serum uric acid levels were collected to assess effectiveness of pharmacist-managed titration of ULT.

Results: The patients in the intervention group had an average age of 60.5 years, 78.6% were male, and 42.9% had erosive or tophaceous disease. The average serum uric acid was 8.26 mg/dL (SD 1.48) at the time of referral. At the end of the study period, the average serum uric acid was 6.78 mg/dL (SD 1.84), which was a 1.48 mg/dL decrease ($P = 0.03$). 4 out of 14 (28.57%) patients were at goal by the end of the study.

The patients in the control group had an average age of 54.2 years, 86.4% were male, and 45.5% had erosive or tophaceous disease. The average serum uric acid was 8.365 mg/dL (SD 2.037) at the start of the referral period. At the end of the study, the average serum uric acid was 7.645 mg/dL (SD 2.448), which is a decrease of only 0.72 mg/dL ($P = 0.166$). Only 2 out of 22 (9.09%) patients were at goal by the end of the study.

Conclusion: Our institution treats a complex patient population with significant barriers to treatment. This newly instituted pharmacist-managed titration program was able to achieve a significantly lower average serum uric acid than the control group who received standard gout management. Although the program remains novel, reasons for its success likely include more timely up-titration of ULT, more personalized education regarding gout and importance of medication adherence, and closer monitoring of side effects including flares. Pharmacists should be integrated into the rheumatology clinic to help patients reach their serum uric acid goals.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Measures and Measurement of Healthcare Quality Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Glucose 6 Phosphated hydrogenase (G6PD) deficiency is the most common enzymatic disorder of red blood cells, and its frequency varies among different ethnicities. People with G6PD deficiency may develop hemolytic anemia with certain drugs such as hydroxychloroquine, sulfasalazine and dapsone. Clinically, there is inconsistent practice

intesting G6PD level among rheumatologists before initiating drugs like hydroxychloroquine, and there are no set guidelines on testing the enzyme. G6PD deficiency occurs in 0.5-7% in Americans, and its frequency in patients with rheumatic diseases was not previously reported in America. This study aimed at determining the frequency of G6PD deficiency in the disease population.

Methods: This study is a retrospective chart review and was approved by the Institutional Research Board. Electronic Medical Records (EMRs) were reviewed of patients with systemic lupus erythematosus (SLE), rheumatoid arthritis (RA), Sjögren Syndrome, and seronegative spondyloarthritis between July 2013 and December 2016. These patients could be tested for G6PD due to concern for anemia from potential use of the above drugs. Patients aged 18 and older were included, and their demographics, rheumatic diseases, the medication use and G6PD testing results were recorded. G6PD deficiency was considered to be present if its value was less than 7.0-20.5 U/g. Descriptive statistics and chi-square/fisher exact tests were used for the data analysis.

Results: Eighty-nine (39%) of 228 patients with rheumatic diseases were screened for G6PD deficiency. In the 89 patients tested, 7 patients (7.9%) including 5 females and 2 males were found to be G6PD deficient. Their mean age was 34.9 years, and there were 5 (71%) Caucasians and 2 (29%) African Americans. Overall, the frequency of G6PD deficiency in patients with rheumatic diseases was close to that in the general American population. Caucasians patients had a frequency of 5.6%, and this may be due to higher Caucasians tested in our study. Demographics and relevant data in patients with G6PD tested and those with G6PD deficiency are shown in Table. The overwhelming majority of the patients tested were treated with hydroxychloroquine. G6PD deficiency is an x-linked disease, mainly affects male, and should be considered in female as well. There was a higher percentage of females with G6PD deficiency than males in this study as the disease population tested consisted of 97% of female patients.

Table 1. Demographics and Relevant Data in Patients with G6PD Tested and Those with Deficiency

N=89	G6PD Deficiency		P-Value

Dapsone			
No	82 (100.0)	7 (100.0)	N.A
Yes	0 (0.0)	0 (0.0)	
Duration of Drug Use in Years (94 missing)			
Median (IQR)	3.4 (2.6)	4.4 (6.0)	0.9502

Conclusion: This may be the first study to examine the frequency of G6PD deficiency in the American patient population with rheumatic diseases. Such testing might not be cost effective given the low incidence of G6PD deficiency in the patient population. Instead, we recommend to monitor for potential anemia with complete blood counts in the setting of hydroxychloroquine use.

Contraception Compliance in Patients with Rheumatological Diseases on Disease Modifying Antirheumatic and Cytotoxic Drugs

Sara Naji Rad¹, Paris Pacheco², Luis Calvo², Htet Htet Maung², Wajiha Illyas² and Prachi Anand³, ¹Internal Medicine, Nassau University Medical Center, East meadow, NY, ²Internal Medicine, Nassau University Medical Center, East Meadow, NY, ³Chief of Rheumatology, Nassau University Medical Center, East Meadow, NY

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Measures and Measurement of Healthcare Quality Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Women of child bearing age with autoimmune diseases are often prescribed teratogenic medications as Methotrexate, Mycophenolate Mofetil, Leflunomide and Cyclophosphamide. Contraceptive compliance in this group of patients has been shown to be low. Patients are required to use reliable methods of birth control to prevent undesirable consequences. Our goal was to improve documentation of variables which help physicians to assess contraception compliance in this group of patients and minimize the deviation from standard of care.

Methods: This study had two retrospective arms, pre and post-implementation of immunosuppressive section to rheumatology clinic note. Subjects are females (50 cases in each arm) aged 21-50 y/o on immunosuppressive medications who are sexually active. Females with hysterectomy, tubal ligation and prisoners were excluded. Variables subjected to review included plan to conceive, contraception use, contraception method, gynecology referral. We applied Chi-squared test to analyze the data.

Results: Documentation of four variables mentioned above was compared between two 50-patient groups (pre-intervention vs post-intervention). There was statistically significant improvement in documentation of all four variables following the intervention as follows: plan to conceive (84% vs 36%)(p=0.000001), contraception used (90% vs 54%)(p=0.00006), type of contraception (76% vs 50%)(p=0.007), gynecology referral (84% vs 38%)(p=0.000002).

Conclusion: Identification of variables which represent patients' compliance is essential and should be addressed in each patient visit. In this study we improved documentation of variables which could help clinician in early recognizing patients who do not follow the guidelines for contraception to consider them for close monitoring or switch to non-teratogenic medications. In this study in light of poor documentation in the first arm we were unable to compare contraception compliance of patients pre and post intervention.

An Evaluation of Utilization Patterns and Appropriateness of Laboratory Tests Among New Referrals to Rheumatologists: Choosing Unwisely!

Sierra Barrett¹, Azin Ahrari¹, Sherry Rohekar², Pari Basharat³ and Janet E. Pope⁴, ¹Schulich School of Medicine and Dentistry, London, ON, Canada, ²Western University, London, ON, Canada, ³St. Joseph's Health Care London, London, ON, Canada, ⁴Department of Medicine, University of Western Ontario, London, ON, Canada

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Measures and Measurement of Healthcare Quality Poster II

Background/Purpose: Laboratory testing comprises the highest volume procedure in medicine and is therefore an important target for improving healthcare spending and efficiency. Unnecessary testing both increases healthcare costs and results in higher false positive rates with associated costly downstream testing and procedures. Additionally, unnecessary testing increases the patient burden and may increase the probability of an adverse health event.

This study aimed to examine the utilization patterns, appropriateness, and associated cost of rheumatologic tests ordered for patients referred to a university rheumatology clinic. A secondary aim of this study was to determine whether demographic factors such as patient sex, reason for referral, and referring practice population size were predictive of inappropriate testing.

Methods: This study consisted of a chart audit of consecutive referrals to three rheumatologists at an academic university rheumatology clinic over one year. All new referrals that had proper documentation, were not transfers of care, and did not have previously established diagnoses were considered. Of referrals that met inclusion criteria (n=631), 398 accepted and 233 rejected referrals were reviewed. Ordering of specific tests (ANA, ENA, anti-dsDNA, RF, and complement levels) and their appropriateness based on clinical presentation were extracted from medical charts. Lab tests ordered within 2 years prior to referral were collected for accepted referrals. Additionally, the reason for referral, diagnosis (accepted referrals), reason for rejection (rejected referrals), patient age and sex, and the population size of the referring practice was collected to identify potential predictors of inappropriate testing.

Results: The number one reason for referral in accepted referrals and rejected referrals was seronegative spondyloarthritis and fibromyalgia respectively. Of the referrals reviewed (n=631), 41% had at least one instance of inappropriate testing. ANA was most frequently ordered inappropriately, with 20% of all referrals having ANA testing with no clinical indication. Additionally, 56% of ANA testing in accepted referrals was repeated testing. Family physicians and nurse practitioners were significantly more likely to order inappropriate tests than specialists ($p = 0.007$). Chi-squared testing found patient age ($p=0.445$), gender ($p=0.051$), and population size ($p=0.855$) were not predictive of inappropriate testing.

Conclusion: The results of this study showed a significant problem with inappropriate testing in referrals made to this institution. Cost estimation of inappropriate testing identified a potential cost reduction of 49%. Future research should focus both on implementing existing guidelines, and on creating interventions tailored to family medicine practice to produce the greatest reduction in cost.

Abstract Number: 1251

Guideline Adherence for Perioperative Use of Immunosuppressive Medications in Patients with Rheumatologic Disease

Grace Berlin, Carolyn Casey, Susan Kim and James Ross, Rheumatology, Lehigh Valley Health Network, Allentown, PA

Session Information

Session Date: Monday, October 22, 2018

Session Title: Measures and Measurement of Healthcare Quality Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: In response to the lack of clear data to dictate recommendations for use of DMARDs and biologic therapy in the perioperative period, The American College of Rheumatology and American Association of Hip and Knee Surgeons developed guidelines for management of these medications in patients undergoing elective hip or knee arthroplasty. Based on literature review, it is recommended to continue DMARDs through elective hip or knee arthroscopy and to hold biologic therapy during the perioperative period. This QI study examines compliance of a community hospital system with these preoperative guidelines and assesses patient outcomes, specifically infectious complications and rheumatologic disease flare.

Methods: Retrospective data was obtained using the community hospital's electronic medical record based on completion of an elective surgical procedure, use of maintenance DMARDs, biologic agents, and steroids, and ongoing care under the LVHN Rheumatology department for inflammatory arthritis, connective tissue disease, or giant cell arteritis between the dates of 1/1/2016 and 1/1/2018. Post-procedure disease flare was characterized as addition/increase of systemic steroids based on reported symptoms. Post-operative surgical site infection (SSI) was defined as the addition of antibiotic therapy due to concern for surgical site infection.

Results: A total of 54 patient charts met parameters, however 20 of these charts (37%) did not provide adequate data regarding perioperative medication use. From the remaining 34 patient charts, most patients had rheumatoid arthritis (76.5%), were female (76.5%), and had a median age of 58 years old. Orthopedic elective surgeries made up the majority of elective surgical procedures (47.1%). Sixteen out of 34 patients (47%) received correct instruction regarding perioperative medication use, and of these 44% were rheumatology-directed. When direction was identifiable, the patient's rheumatologist or surgeon was responsible for directing medication changes (29.4% and 26.5%, respectively), although 29.4% did not have clear provider ownership of given instructions. There were 2 postoperative SSI's which occurred in patients with inadequate pre-operative medication holding times. There were 4 post-operative flares, 50% associated with inappropriate hold of patient medication.

Conclusion: Although this project is ongoing, results thus far show that clear preoperative patient instruction regarding immunosuppressive medications is lacking. Multiple studies support the correlation between medication error and lack of clear patient instruction regarding medication use. Deviation from typical perioperative medication recommendations was seen in half of patients with unclear contributing factors. Medications dosed less frequently than monthly such as Rituximab and Infliximab tended to correlate with shorter than preferred pre-operative hold times while biologic agents given more frequently were held for a longer duration than recommended. Implementation of formatted written patient instructions as well as provider-directed education sessions with reassessment of guideline compliance are planned next steps for improved patient outcomes.

Abstract Number: 1252

Screening for Tuberculosis before Initiating TNF Inhibitors: How Well Do We Do? a Nationwide Experience

Karim Ladak¹, Ting Pan² and Catherine MacLean¹, ¹Rheumatology, Hospital For Special Surgery, New York, NY, ²Value Office, Hospital For Special Surgery, New York, NY

Session Information

Session Date: Monday, October 22, 2018

Session Title: Measures and Measurement of Healthcare Quality Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Tumor necrosis factor inhibitors (TNFi) revolutionized treatment of various conditions, however they drastically increase the risk of latent tuberculosis (LTBI) reactivation. Many national medical bodies recommend screening for LTBI prior to initiating TNFi, and this has been incorporated as a Merit-Based Incentive Payment System (MIPS) measure. We determined screening rates for LTBI across the United States, prior to initiating a TNFi.

Methods: We retrospectively analyzed patients in Truven MarketScan from 2011-2015. This dataset contains de-identified inpatient and outpatient claims records on over 100 million patients. We included patients' over 18 years with at least 1 filled prescription for TNFi. To ensure these were new TNFi starts we excluded patients without a 6-month washout period (i.e. during which time they could not receive biologic DMARDs). Continuous enrollment in the database was required during the washout period and 3 months after TNFi initiation. Our primary outcome was the proportion of patients screened for TB during the 6-month washout period, either by interferon gamma release assays (IGRA) or tuberculin skin testing (TST). Sensitivity analysis was performed to extend the eligible screening period to 12 months pre-drug. Descriptive statistics were represented as means and medians for continuous variables and as percentages for categorical variables.

Results: We identified 76,128 patients starting a TNFi. The mean age was 44.7 years, the cohort was 61% female. Adalimumab and Etanercept were the most common TNFi. 50.9% of patients had a rheumatologic diagnosis, 22.4% gastrointestinal, 17.6% dermatologic, and 0.8% ophthalmic. Most patients received specialty care, and a rheumatologist was involved in 40.9% of cases 40,282 (52.9%) were screened for TB in the 6-month washout. By extending the pre-drug washout to 12 months, the proportion of unscreened patients improved mildly to 59.3%. 48.5% were screened by IGRA, 27% by TST, and 24.5% unknown. Steroid and DMARD use, male sex, urban residence, low Charlson comorbidity score and specialty care were associated with increased TB screening rates. Patients cared for by a rheumatologist or dermatologist were more commonly screened than those seeing gastroenterologists. Care by an ophthalmologist was not associated with improved screening.

Conclusion: In the United States, screening for latent TB prior to initiating TNFi therapy was poor, such that only 52.9% received appropriate pre-drug screening. Our study population of over 75,000 patients starting a new TNFi represents nationwide, real world data across various specialties. As clinicians, these results suggest we need to improve compliance with guidelines and quality measures. Care by rheumatologists and dermatologists was associated with improved screening compared to that by gastroenterologists and ophthalmologists.

Lipid Screening and Treatment Patterns Among Patients with Rheumatic Diseases

Alexander Peck¹, Gilbert Ortega², Jawad Bilal³, Ella Starobinska², Phan Saligrama² and Dominick Sudano⁴, ¹Division of Internal Medicine, University of Arizona College of Medicine, Tucson, AZ, ²Internal Medicine, University of Arizona, Tucson, Tucson, AZ, ³Internal Medicine, University of Arizona, Tucson, AZ, ⁴University of Arizona Arthritis Center, University of Arizona, Tucson, AZ

Session Information

Session Date: Monday, October 22, 2018

Session Title: Measures and Measurement of Healthcare Quality Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The importance of lipid management is well recognized in rheumatic diseases. In fact, annual cardiovascular risk assessment is especially recommended for individuals with rheumatoid arthritis, ankylosing spondylitis, and psoriatic arthritis. The comorbid traditional cardiovascular risk factors compound the morbidity and mortality risk. Despite an abundance of data supporting that patients with rheumatic diseases have increased rates of major adverse cardiovascular events, patients are inadequately screened and often under treated.

Methods: We conducted a retrospective study between 2013 and 2017 at the two infusion centers affiliated with the University of Arizona Arthritis Center, and identified the patients on biological infusions with comorbid cardiovascular disease, diabetes, hyperlipidemia, hypertension or smoking, and then examined whether these patients had lipid testing done and/or were on statins during this period.

Results: Of the total 253 patients with rheumatologic diagnoses, the mean age was 62 years and 77.5% of the sample was female. 62.5% had rheumatoid arthritis, 8.7% had osteoporosis, 5.5% had systemic lupus erythematosus, 5.1% had psoriatic arthritis, 4.7% had ankylosing spondylitis, 2.8% had mixed connective tissue disease, 2.0% had juvenile idiopathic arthritis, 2.4% had anti-neutrophil cytoplasmic antibodies vasculitis, 1.6% had osteoarthritis, 0.8% had Bechet's disease, 0.8% had dermatomyositis, 0.8% had polymyositis, 0.8% had adult-onset still's disease, 0.4% had giant cell arteritis, 0.4% had inclusion body myositis, 0.4% had fibromyalgia, and 0.4% had gout. Of those with a rheumatologic diagnosis and at least one qualifying co-morbid condition, 38.72% had hypertension, 30.83% had hyperlipidemia, 18.04% had diabetes, 15% were smokers, and 6.39% of patients had known cardiovascular disease. The lipid testing was performed in 40.23% of patients, and only 29.41% were on statin therapy.

Conclusion: The findings of this study suggested that the majority of patients (60%) with rheumatic diseases lacked lipid testing, and subsequently, cardiovascular risk stratification. Given the increased cardiovascular morbidity and mortality in these patients, rheumatologists, in collaboration with primary care physicians, can ameliorate this clinical gap by ensuring that patients receive age- and disease-appropriate risk assessments. Such screening efforts may improve treatment responses and reduce the risk of adverse cardiovascular events.

Abstract Number: 1254

QI Project: Inpatient Practices in Ordering Fluorescent Anti-Nuclear Antibodies (F-ANA) and ANA Subserologies in a City Hospital in an Underserved Community

Ivan Emil Ramirez de Oleo¹, Beverly Johnson^{2,3} and Barbara Mendez-Agrusa⁴, ¹Internal Medicine, Jacobi Medical Center, Bronx, NY, ²Jacobi Medical Center, Albert Einstein College of Medicine, Bronx, NY, ³Rheumatology, Albert Einstein College of Medicine, Bronx, NY, ⁴Medicine, Department of Rheumatology, Albert Einstein College of Medicine, Bronx, NY

Session Information

Session Date: Monday, October 22, 2018

Session Title: Measures and Measurement of Healthcare Quality Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: It is important for internists to know how to appropriately and effectively order subspecialty labs. As part of the choosing wisely campaign in 2013, the American College of Rheumatology (ACR) issued a series of recommendations to improve clinical practice including not to test ANA subserologies without a positive F-ANA.¹ Multiple studies and laboratory guidelines have evaluated this algorithmic approach which begins with the clinical suspicion of a rheumatic disease and then assessment of F-ANA and ANA sub-serologies as indicated.²⁻⁶

Methods: A retrospective review of medical records of patients admitted to our large, urban medical center in an underserved area from June 2016 through June 2017 was performed. 460 patients in whom F-ANA or ANA-ENA panel testing was performed were examined. Case records were analyzed for the number of tests requested, the sequence of the testing, and test results. Indeterminate results in the ANA-ENA panel were not taken into consideration for the analysis. Data was analyzed using Excel 2013.

Results: One hundred ninety F-ANA and 429 ENA panels were ordered. Positive results were found in 56.3% (107/190) of F-ANA and 14.6% (63/429) of the ENA panels. When both F-ANA and ENA panels were requested, F-ANA was performed before the ENA panel as recommended in the minority of patients 7.5% (12/159). The majority had the two tests done at the same time 66.6% (106/159). 25.7% (41/159) had the F-ANA sent after the ENA panels. ENA panels were requested alone the majority of the time 62.9% (270/429). Females represented 57.6% of the patients.

Conclusion: The majority of the time a F-ANA was not ordered before the subserologies as per ACR recommendations. Therefore we conclude that in our hospital population the ACR guidelines are not being followed with the potential for decreased quality of care and missed diagnosis. This may be due to the cost constraints of the hospital where finances are limited and F-ANA costs \$14.81 and ANA-ENA panel costs \$6.09. Additionally, in our ordering system, it is not obvious that the ANA-ENA panel does not include the F-ANA. We suggest further education of the house staff about understanding the difference between the F-ANA and ANA-ENA panel as a point to start toward quality improvement in this area. Also, we feel that these results open the question of whether other hospitals and communities with limited resources are able to follow the ACR guidelines for F-ANA and ENA ordering due to financial constraints. Further study in this area could help further inform guidelines going forward.

Elevated Serum Globulin Gap As a Reliable and Cost-Savings Marker of Inflammation in Patients with Systemic Rheumatic Diseases

William Stohl¹, Beatrice Kenol², Andrew Kelly², Aditi Ananth Correa² and Richard Panush³, ¹Division of Rheumatology, University of Southern California Keck School of Medicine, Los Angeles, CA, ²Keck School of Medicine of University of Southern California, Los Angeles, CA, ³Rheumatology, Keck School of Medicine of University of Southern California, Los Angeles, CA

Session Information

Session Date: Monday, October 22, 2018

Session Title: Measures and Measurement of Healthcare Quality Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: In clinical practice, the two most commonly used markers of systemic inflammation are the serum CRP level and ESR. The economic costs of these tests are substantial, with Medicare allowable charges in Los Angeles in 2018 for CRP level and ESR being \$38.04 and \$62.76, respectively. An algorithm that reduces the need for these tests in the care of patients with systemic rheumatic diseases could lead to considerable cost savings without sacrificing the quality of patient care.

Methods: The electronic medical records of two independent cohorts (discovery and validation) of patients with systemic rheumatic diseases seen between May 2015 and June 2017 in the rheumatology clinics at a single academic medical center were retrospectively reviewed. Correlations and receiver operator characteristic (ROC) curves between serum CRP level and ESR vs serum globulin gap (the difference between levels of total protein and albumin) and albumin-to-globulin (A:G) ratio were determined.

Results: The discovery (263 subjects, 446 entries) and validation (438 subjects, 1959 entries) cohorts were predominantly female (89.0% and 82.9%) and Hispanic (93.9% and 87.9%), with median ages of 47.4 and 51.6 years at the time of sample collection and the majority (52.7% and 67.1%) of entries coming from RA or SLE patients. In each of these independent cohorts, the globulin gap and A:G ratio correlated significantly ($p < 0.001$) with CRP level and ESR, with the respective correlation coefficients being greater for ESR (discovery: 0.472 and -0.672; validation: 0.509 and -0.596) than for CRP level (discovery: 0.308 and -0.374; validation: 0.225 and -0.310). ROC curve analyses demonstrated better respective abilities of globulin gap and A:G ratio to discriminate between normal and elevated ESR (discovery area-under-curve [AUC]: 0.726 and 0.823; validation AUC: 0.738 and 0.771) than between normal and elevated CRP level (discovery AUC: 0.681 and 0.726; validation AUC: 0.602 and 0.656). These relationships were independent of sex (female vs male) or ethnicity (Hispanic vs non-Hispanic), and similar results were obtained when only RA or SLE was considered. Elevated globulin gap (≥ 4.0 g/dl) and low A:G ratio (< 0.8) had respective positive predictive values (PPVs) of only ≥ 0.554 and ≥ 0.788 for elevated CRP level, whereas the respective PPVs for elevated ESR were ≥ 0.962 and ≥ 0.960 . When only the first entry for a given patient was considered, the correlations between ESR and globulin gap ($r = 0.531$) and A:G ratio ($r = -0.648$) and the corresponding AUCs (0.742 and 0.795) were similar to those observed for all entries. Moreover, the abilities of elevated globulin gap and low A:G ratio to predict an elevated ESR remained very high, with PPVs of 0.976 and 0.966, respectively. Among patients with high globulin gap, the change in globulin gap over time faithfully reflected changes in ESR.

Conclusion: In patients with systemic rheumatic disease, elevated globulin gap (readily calculable from the routinely-obtained comprehensive metabolic panel) is a highly reliable marker of elevated ESR. Ordering an ESR (or CRP) test in such patients may frequently be unnecessary, resulting in an estimated savings of \$7.56 million per million patients with systemic rheumatic disease.

A Customized Health Information Technology Effectively Identifies and Directs Bone Health Services in Rural Veterans with Osteoporosis Risk Factors

Shardool Patel¹, Zachary L. Anderson¹, Grant W. Cannon², Brian C. Sauer² and Karla L. Miller², ¹Salt Lake City VA Medical Center, Salt Lake City, UT, ²Salt Lake City VA Medical Center and University of Utah, Salt Lake City, UT

Session Information

Session Date: Monday, October 22, 2018

Session Title: Measures and Measurement of Healthcare Quality Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Osteoporosis is under diagnosed and undertreated in the Veterans Health Administration (VHA), especially in rural Veterans. Tools to identify risk factors in Veterans are available. To address this issue, VHA Salt Lake City Rural Bone Health Team (BHT) developed the Enrollment Report, a health information technology (HIT). The Enrollment Report operationalizes evidence-based screening guidelines to capture risk factors. Identified Veterans were contacted to participate in the BHT program, a population health osteoporosis management program. This investigation compared the proportion of Veterans with risk factors receiving bone health services, based on participation in the BHT program.

Methods: This study evaluated the impact of a HIT, Bone Health Team Enrollment Report (BHT-ER), on directing bone health services to at-risk Veterans. Risk factors were captured using the VHA Corporate Data Warehouse, a health data repository. For this study, we included Veterans contacted for enrollment between 10/13/2017 and 02/01/2018. A non-experimental cohort design was used to evaluate for changes in the proportion of Veterans with completed diagnostic imaging, ≥ 1 clinical encounter with an osteoporosis diagnosis and prescribed pharmacotherapy, before and after the index date, defined as the first date BHT contacted the Veteran.

Table. Demographics, identified risk factors and bone health services received pre- and post-index date

	Enrolled		Non-Enrolled		p value
	n (%)	95% CI	n (%)	95% CI	
Veterans Contacted	234 (31.2)		516 (68.8)		
Age (mean)	78.8	(77.64 - 79.86)	78.3	(77.55 - 79.08)	0.527
Male	224 (95.7)	(93.14 - 98.32)	474 (91.9)	(89.50 - 94.22)	0.054
OST Score ^a (mean)	0.53	(0.05 - 1.00)	0.18	(-0.10 - 0.47)	0.197
Osteoporosis Risk Factors					
OST ≤ 1	165 (70.5)	(64.67 - 76.36)	375 (72.7)	(68.83 - 76.52)	0.541
Male ≥ 80	131 (56.0)	(49.62 - 62.34)	259 (50.2)	(45.88 - 54.51)	0.142
Female ≥ 65	8 (3.4)	(1.19 - 5.75)	34 (6.6)	(4.45 - 8.73)	0.080
Chronic Medication Use ^b					
Oral Glucocorticoids ^c	15 (6.4)	(3.27 - 9.55)	32 (6.2)	(4.12 - 8.28)	0.913
Aromatase Inhibitors ^d	0	-	0	-	-
Anti-Androgens ^e	5 (2.1)	(0.28 - 3.99)	11 (2.1)	(0.89 - 3.38)	0.997
Hormone Therapy ^f	8 (3.4)	(1.09 - 5.75)	18 (3.5)	(1.91 - 5.07)	0.962
Pre-Index Date					
DEXA Completed	21 (9.0)	(5.31 - 12.64)	71 (13.8)	(10.79 - 16.73)	0.064
≥ 1 Clinical Encounter with an Osteoporosis Diagnosis	8 (3.4)	(1.09 - 5.75)	49 (9.5)	(6.97 - 12.03)	0.004
Prescribed Anti-Resorptive	10 (4.3)	(1.68 - 6.86)	38 (7.4)	(5.11 - 9.62)	0.109
Post-Index Date					
DEXA Completed	190 (81.2)	(76.19 - 86.20)	17 (3.3)	(1.75 - 4.83)	<0.001
≥ 1 Clinical Encounter with an Osteoporosis Diagnosis	43 (18.4)	(13.41 - 23.24)	11 (2.1)	(0.89 - 3.38)	<0.001
Prescribed Anti-Resorptive	60 (25.6)	(20.05 - 31.24)	16 (3.1)	(1.61 - 4.60)	<0.001

^a OST: Osteoporosis Self-Assessment Tool. Calculated as $0.2 * (\text{weight [kg]} - \text{age})$. ^b Chronic medication use is defined as ≥ 83 continuous days of pharmacotherapy. ^c Oral glucocorticoids consists of hydrocortisone, cortisone, dexamethasone, prednisolone, methylprednisolone, prednisone and budesonide. ^d Aromatase inhibitors consists of anastrozole, exemestane and letrozole. ^e Anti-Androgens consists of abiraterone, bicalutamide, enzalutamide, flutamide and nilutamide. ^f Hormone Therapy consists of degarelix, leuprolide, triptorelin, goserelin and histrelin in male Veterans, and fulvestrant in female Veterans.

Results: Medical and pharmacy records for 81,116 rural Veterans at 4 healthcare systems were queried, with 9,845 (12.1%) Veterans having ≥ 1 risk factor. In the first batch, 750 Veterans have been contacted to participate, 234 (31.2%) have enrolled and 516 (68.8%) have not enrolled. Efforts to enroll the remaining 9,095 Veterans is ongoing. A higher proportion of males have enrolled in the BHT program, with a higher mean Osteoporosis Self-Assessment Tool (OST) score, compared to the Non-Enrolled group. An OST score ≤ 1 was the most commonly identified risk factor in both groups. In the 5 years preceding the index date, a higher proportion of the Non-Enrolled group received bone health services, compared to the Enrolled group. After the index date, a significantly higher proportion of the Enrolled group had a complete DEXA scan, ≥ 1 clinical encounter with an osteoporosis diagnosis and were prescribed anti-resorptive pharmacotherapy, compared to the Non-Enrolled group.

Conclusion: A higher proportion of Veterans received bone health services when enrolled in the BHT program, compared to Veterans who did not enroll. The synergy between the BHT-ER and the BHT program increased the delivery of bone health services to at-risk Veterans. Embedding evidence-based guidelines into HIT effectively identifies risk factors and reduces disparities in bone health care provided to rural Veterans. The BHT program concept and use of HIT can be replicated to increase the delivery of other important clinical services within VHA and medical communities outside VHA.

Abstract Number: 1257

Simple and Cost-Effective Intervention Doubled the Rate of Osteoporosis Screening in High Risk Rheumatology Patients

Mosaab Mohameden¹, Victoria Malkhasyan², Adam Shurbaji¹ and Candice Yuvenco³, ¹Internal Medicine, University of California San Francisco - Fresno Medical Education Program, Fresno, CA, ²University of California San Francisco - Fresno Medical Education Program, Fresno, CA, ³Internal Medicine, Division of Rheumatology Director, University of California San Francisco - Fresno Medical Education Program, Division of Rheumatology Director, Fresno, CA

Session Information

Session Date: Monday, October 22, 2018

Session Title: Measures and Measurement of Healthcare Quality Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Osteoporosis is a common bone disorder that places patients at risk of pathologic fractures. Osteoporotic fractures can be devastating and associated with significant morbidity, mortality and economic burden. Rheumatologic patients especially those with rheumatoid arthritis (RA) are known to have higher risk of low bone mineral density and osteoporosis. This is more pronounced in patients with active/severe disease and those taking glucocorticoids. Early diagnosis and treatment of osteoporosis can prevent fractures and their grave sequelae. In this study we aim to evaluate the rate of osteoporosis screening using the standard Dual-Energy X-ray Absorptiometry (DEXA) scans in our rheumatology clinic before and after introducing a simple and cost-effective intervention to improve this rate. Our target for screening is women at age of 65 or older, rheumatoid arthritis patients, and/or patients taking prednisone ≥ 7.5 mg daily for more than 3 months.

Methods: Patients seen in our rheumatology clinic during September-November 2016 were identified as baseline pre-intervention group. Intervention period was between January-March 2018. During this period, bright orange cards highlighting the indications for osteoporosis screening were added by clinic staff to every patient's chart at time of check-in. At the end of the intervention period, the data was collected by sorting patient's medical record numbers in descending numerical order and the top 100 patients in each group were analyzed. The following data was collected: age, gender, rheumatologic diagnosis, chronic moderate to high dose steroid use (defined as systemic steroid dose equivalent to prednisone ≥ 7.5 mg daily for more than 3 months), and DEXA scan orders. In each group, the total number of patients who had an indication for osteoporosis screening as defined in our study was determined as well as the total number of DEXA scan ordered for such indications.

Results: Combined analysis of both groups revealed that 84% (169/200) of total patients were women of all ages, 14% (28/200) were women age 65 or older, RA patients were 53% (107/200), and patients on moderate to high dose steroids were 37% (74/200). Separate analysis of each group revealed that 71 out of 100 patients in the pre-intervention group had an indication for osteoporosis screening as defined in our study, of those only 11 patients had a DEXA scan ordered (15%). In the intervention group, 75 out of 100 patients had an indication for screening and out of those 30 DEXA scans were ordered as indicated (40%).

Conclusion: Majority of rheumatologic patients are at high risk for osteoporosis. Analyzing the data from our rheumatology clinic has shown that the rate of osteoporosis screening based on indications mentioned above were low. However, simple cost-effective reminders in the form of cards has more than doubled the rate of screening. Considerable improvement seen with this simple intervention and further improvement can possibly be achieved by incorporating reminders in the electronic medical records. Rheumatologists and primary care physicians are encouraged to closely evaluate rheumatologic patients for osteoporosis screening, prevention and treatment when indicated.

Abstract Number: 1258

Can Patients Enter Medical History Data By Self-Report Directly into an Electronic Medical Record (EMR)? “Private Medical History” (PMH) Software for Physician Report in EMR Format and Patient Storage to Correct and Update Medical History for Any EMR

Theodore Pincus¹, Ricardo Gomez Lara² and Niels Steen Krogh³, ¹Division of Rheumatology, Rush University Medical Center, Chicago, IL, ²of ZiteLab ApS, Frederiksberg, Denmark, ³ZiteLab ApS, Copenhagen, Denmark

Session Information

Session Date: Monday, October 22, 2018

Session Title: Measures and Measurement of Healthcare Quality Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The electronic medical record (EMR) promised greater efficiencies in clinical medicine. This goal may be met in part in an ICU, operating room, and other settings in which large amounts of data are exchanged in real time, and a patient medical history contributes little to work-flow. However, in outpatient management of chronic diseases, particularly in rheumatology, in which the patient history contributes importantly to diagnosis and management, the EMR has been associated with serious compromises of doctor-patient communication and inefficient time-management. Many physicians spend considerable periods entering and/or dictating information into an EMR after the patient has left the exam room, and not infrequently during evening hours. Some rheumatologists have suggested that the EMR results in seeing fewer patients per day, leading to a reduction in income despite up coding of visits using EMR documentation. One approach to this problem involves application of a simple principle seen in customers of airlines printing boarding passes and of supermarkets checking out groceries, by having patients complete an electronic self-report history questionnaire that can be uploaded directly into an EMR in a traditional history format, with review by a physician, using software termed “private medical history” (PMH).

Methods: Patients enter medical history data on a structured self-report questionnaire, including all diagnoses, operations, illnesses, hospitalizations, allergies, family history, social history and demographic information, into PMH software. The data can be uploaded in a standard format into an EMR, although interaction with the EMR vendor is required to implement this feature. The PMH software also allows patients keep maintain the data at a password-protected, HIPAA compliant, secure PMH website, which can allow the patient to store the data for any health professional as a paper print out or PDF file, and, as more EMR organizations become compliant with the PMH system, to interact directly with any EMR. The patient web page allows the patient an option to indicate that each section of the history is correct or requires update(s) and/or correction(s).

Results: Preliminary studies indicate at least 80% agreement of patient self-report medical history information with what is reported in the EMR in more than 80% of patients. Some patients require help from family and/or health professionals to provide an accurate history. Most patients appear at least as accurate or more accurate than health professionals. Use of the system saves about 15 minutes for the doctor per new patient.

Conclusion: A large fraction of patients can enter much medical history information directly into an EMR and store the information to update and/or correct, and be available for any health professional or facility with any EMR for future visits. Rheumatologists who would like to implement such a system are encouraged to contact the authors of this abstract.

Session Title: Measures and Measurement of Healthcare Quality Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Automobile driving represents an instrumental activity of daily living (IADL). Symptoms accompanying RA, including fatigue, joint pain and stiffness, decreased strength, reduced mobility, and poor sleep quality, have the potential to adversely impact driving ability. In this systematic review, we aimed to identify whether is associated with driving performance and/or the use of assistive devices or modifications to improve driving performance.

Methods: We conducted a systematic literature review following PRISMA guidelines of RA and driving performance/modifications by searching CINAHL, Cochrane library, EMBASE, MEDLINE, PREMEDLINE, PsycINFO, Google Scholar, and Scopus databases from inception to April 2018. We excluded studies that were not in English, had no original or quantitative data, included <5 RA patients, or did not report specifically on RA.

Results: Our search yielded 1935 potential manuscripts, of which 22 fulfilled eligibility criteria. Most studies were cross-sectional (n=14). Studies reporting the prevalence of driving factors among persons with RA are summarized in the Table. Based on weighted means, of total RA patients studied 13% were involved in motor vehicle crashes (MVCs), 26% experienced difficulties with driving, 34% leveraged assistance or modifications to drive, and 26% were unable to drive. In at least one study, Repaints were involved in fewer MVCs than their age-matched controls (23% vs.35%) [Maki et al., 1976]. A separate investigation employing an independent driving assessment determined that 19% (n=37) of RA patients were not fit to drive [Jones et al., 1991].

Conclusion: There is a scarcity of data that quantitatively relates RA to driving performance and or related safety outcomes. Recognizing significant variability among individual reports, available data suggests that driving difficulties and the subsequent use of modifications are prevalent in those with RA. Given its importance as an IADL, further investigation of driving performance and potential driving modifications are needed.

Session Information

Session Date: Monday, October 22, 2018

Session Title: Measures and Measurement of Healthcare Quality Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Despite effective treatments, hospitalization due to acute gout is increasing and financially burdensome. Prior studies have primarily attributed the increased rate of gout hospitalizations to physicians' gaps in knowledge regarding gout management. However, these studies fail to address patient and systems factors which may be associated with this risk. Our aim was to assess the association between these factors and risk of hospitalization among patients visiting the emergency department (ED) using a statewide healthcare system.

Methods: Lifespan is the largest provider of healthcare in Rhode Island and has 3 EDs across the state. We identified gout patients 18 years of age or older who presented to the ED between 3/30/2015 and 9/30/2017 using ICD9 and ICD10 diagnostic codes. If the patient was seen more than once during this time only the first encounter was included. Outcome of interest was admission from ED to inpatient or observation. We collected information regarding: a) patients factors including demographics, medications and co morbidities assessed at presentation, b) clinical presentation of gout (single versus multiple joint involvement) and severity as assessed by the triage nurse on a 5-point ED severity scale (1 being the worst), and c) systems factors including time of day and time of year at presentation to the ED, and type of insurance (commercial versus state health agencies/governmental insurance). Multivariable logistic regression model was used to identify factors associated with hospitalization.

Results: A total of 458 patients (mean age 58.71 ± 16.36 years, 79.43% males) were included. Of these 458 patients, 51 patients (11.1%) were admitted; 29 (6.4%) to inpatient and 22 (4.8%) to observation. Older age, presence of comorbidities, pattern of joint involvement and severity and time of presentation to the ED were associated with increased odds of admission. In multivariable model, older age [aOR 1.05 (1.01 to 1.08)], having oligo- or polyarticular gout [aOR 8.67 (3.50 to 21.48)], diabetes [aOR 4.74 (1.86 to 12.11)], history of inflammatory arthritis [aOR 5.83 (1.36 to 25.01)] and time of presentation to the ED between 8 AM–4 PM [aOR 5.92 (1.28 to 27.46)] and 4 PM–12 AM [aOR 7.04 (1.35 to 36.66)] continued to remain significant.

Conclusion: Our study demonstrates increased hospitalization rates among older patients, and those with comorbid diabetes or pre-existing inflammatory arthritis. This may be related to fear that these patients are at higher risk of joint infection. The study highlights increased odds of admission in patients presenting between 8 AM and midnight compared to those presenting between midnight and 8 AM. It is likely that decision to admit in case of the latter is made during regular business hours. Hence, highlighting the need to improve systems for after hour care of gout patients.

Table 1. Baseline cohort characteristics

		Discharged from the ED (n=)	Admitted from the ED (n=)
Age (mean \pm SD)*		57.2 \pm 16.02	70.8 \pm 13.87

Session Information

Session Date: Monday, October 22, 2018

Session Title: Measures and Measurement of Healthcare Quality Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Shared decision making (SDM) improves decisional outcomes and patient-physician communication and holds great potential for improving the management of various rheumatology conditions. However, the lack of consensus on how to measure the effectiveness of SDM in clinical trials creates a barrier to further evaluation of SDM interventions. Members of the SDM Outcome Measures in Rheumatology (OMERACT) working group (WG) sought to determine a core domain set, distinguishing process and outcome domains, for measuring the effectiveness of SDM interventions in rheumatology clinical trials. The WG followed the OMERACT Filter 2.0 and developed a draft core set of SDM process and outcome domains based on a previous systematic review and a nominal group process conducted at the OMERACT 2014 meeting. In 2016, an international electronic Delphi survey was conducted among patients, caregivers, clinicians and researchers to refine the domains of the OMERACT draft core set. A workshop was held at the OMERACT 2016 meeting in which no agreement was reached on the core set.

Methods: To help address reasons for which consensus was not achieved, a white paper was drafted. The aim of the white paper was to clarify the background and development process of the draft SDM core domain set. Key stakeholders playing a leadership role within OMERACT were identified and contacted to participate in semi-structured interviews by telephone or virtually to determine how to modify the core set and inform the white paper to facilitate its endorsement.

Results: A preliminary sample of nine OMERACT members from North America and Europe participated in interviews, including eight scientists/clinicians and one patient. All participants felt that domains pertaining to the process and the outcomes of SDM are relevant but should be clearly delineated. Some mentioned that, since OMERACT pertains more to outcomes than process, consensus-building efforts should focus on outcome domains rather than process domains. Most felt that all SDM outcome domains were relevant, but suggested minor changes in language and the addition of definitions to clarify domains. Outcomes include: knowledge of the options and their features; accurate risk perceptions; match between values/preferences and chosen option; confidence in decision making; satisfaction with decision making process; and use of the chosen option. The white paper was felt to be helpful in understanding the core set.

Conclusion: Preliminary evidence from the interviews demonstrates a need to focus efforts on clarifying and gaining consensus on the outcome domains rather than on the process domains of SDM interventions. Further interviews will be conducted with all key stakeholders and this feedback will be used to improve the white paper and core set. International consensus-building efforts will also take place to ensure all key stakeholders endorse the core set of outcome domains used to measure in trials of SDM interventions.

Session Information

Session Date: Monday, October 22, 2018

Session Title: Measures and Measurement of Healthcare Quality Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Diagnostic and therapeutic arthrocentesis and soft tissue injections are routinely performed by Rheumatologists mostly in the outpatient and some in the inpatient settings. There are variations in technique and the dosing of medications used. Our aim was to assess the procedural variability among rheumatologists at a single academic

medical center in an attempt to standardize the process using evidence-based medicine when applicable, thereby improving clinic workflow and efficiency.

Methods: An anonymous 2 part questionnaire was completed by 12 rheumatology staff physicians and fellows. The 2nd part of the questionnaire covered the procedure clinic workflow using the Likert scale which was completed by 7 rheumatology clinic nurses as well. Review of literature was done using the PubMed. Medication information was referenced using www.lexicomp.com

Results: Part 1 of the questionnaire was notable for preference for lidocaine as local anesthetic of choice (Table 1). There was a wide variability in the dose of methylprednisolone and lidocaine used for the knee and glenohumeral intra-articular (IA) injections, trochanteric bursa and trigger finger injections in our clinic. Part 2 revealed concordance between the physicians and nursing staff regarding delays and inefficiency of the clinic workflow (75% and 86% respectively, were in agreement). 92% of physicians and 86% of nurses agreed that standardization would be beneficial despite 41% physicians and 57% nurses indicating satisfaction with the current clinic workflow.

Review of published literature was notable for the following: Utilization and type of gloves used (sterile vs non-sterile) or sterile vs aseptic techniques varied widely in clinical practice. Chlorhexidine was superior to iodine for skin sterilization. The choice of intraarticular glucocorticoids was largely driven by the training background of physicians, with lack of definitive data to support the use of one over the other. Mepivacaine and Ropivacaine are thought to be less chondrotoxic compared to lidocaine and bupivacaine. Use of directoral anticoagulants and warfarin with INR <2 do not increase the risk for hemarthrosis.

The next step is to implement the standardized procedure practice within the clinic using the information gathered and follow this with a post implementation survey and practice monitoring.

Conclusion: There are no specific consensus or common practice guidelines such as the use of sterile gloves to perform sterile technique vs aseptic technique, iodine use and use of lidocaine for I injections as certain practices are not evidence based and depend on previous training and individual preferences. Standardization may help improve efficiency and staff satisfaction and reduce potential errors. There is an unmet need for development of evidenced-based musculoskeletal procedure guidelines in rheumatology.

Table 1

Questionnaire-PART 1 (n=12)					
Parenthesis indicate number of rheumatologists performing the procedure or utilizing the medication.					
1. Preferred approach for knee IA injection	Superolateral (1) (8.3%)	Inferolateral (4) (33.3%)	Inferomedial (2) (16.7%)	Combination (3) (25%)	N/A(2) (16.7%)
2. Preferred approach for glenohumeral IA injection	Anterior (2) (16.7%)	Posterior (10) (83.3%)			
3. Preferred approach to subdeltoid bursa injections	Anterior (2) (16.7%)	Superior (0)	Lateral (7) (58.3%)	Combination (2) (16.7%)	N/A(1) (8.3%)
4a. Type of skin disinfectant used	Chlorhexidine Qtip (3) (25%)	Chlorhexidine sponge (5) (41.7%)	Iodine/betadine (1) (8.3%)	Combination (3) (25%)	
4b. Duration of skin contact (seconds)	5-120s (8/12) (66.7%)	N/A (4/12) (33.3%)			
5. Type of gloves used	Sterile (6) (50%)	Non-sterile (4) (33.3%)	Combination (2) (16.7%)		
6. Use of a topical anesthetic (ethyl chloride) prior to soft tissue or IA injection	Yes (12) (100%)	No (0)			
7. Use of lidocaine vs mepivacaine for soft tissue injections	Lidocaine (12) (100%)	Mepivacaine (0)			
8. Use of lidocaine vs mepivacaine as a local anesthetic during IA injections	Lidocaine (7) (58.4%)	Mepivacaine (4) (33.3%)	None (1) (8.3%)		
9. Use of lidocaine vs mepivacaine for IA injections in conjunction with steroids	Lidocaine (11) (91.7%)	Mepivacaine (0)	Combination (1) (8.3%)		
10. Medication dose for IA injections	Shoulder joint	Knee joint	Trochanteric bursa	Trigger finger	
a. Methylprednisolone	40-80mg	80-120mg	40-160mg	<10-40mg	
b. Lidocaine	10-40mg	20-60mg	20-60mg	<5-10mg	
	Yes (3) (25%)	No (9) (75%)			

Table . (Cont'd)

Questionnaire-PART 1 (n=12)

11. Routine use of USG for IA injections		
12. Agree with implementation of a standardized approach to the procedure clinic	Yes (10) (83.3%)	No (2) (16.7%)
PART 2 (n=19)	Physicians (n=12)	Nursing staff (n=7)
1. Delays have been encountered in clinic due to medication related questions	Agree (50%) Strongly agree (25%)	Agree (57%) Strongly agree (29%)
2. The current rheumatology procedure work flow is satisfactory	Agree (41%) Disagree (42%) Neither (17%)	Agree (57%) Disagree (43%)
3. Standardization will help improve clinic workflow	Strongly agree (50%) Agree (42%) Neither (8%)	Strongly agree (72%) Agree (14%) Neither (14%)

Session Information

Session Date: Monday, October 22, 2018

Session Title: Measures and Measurement of Healthcare Quality Poster II

Session Type: ACR Poster Session B

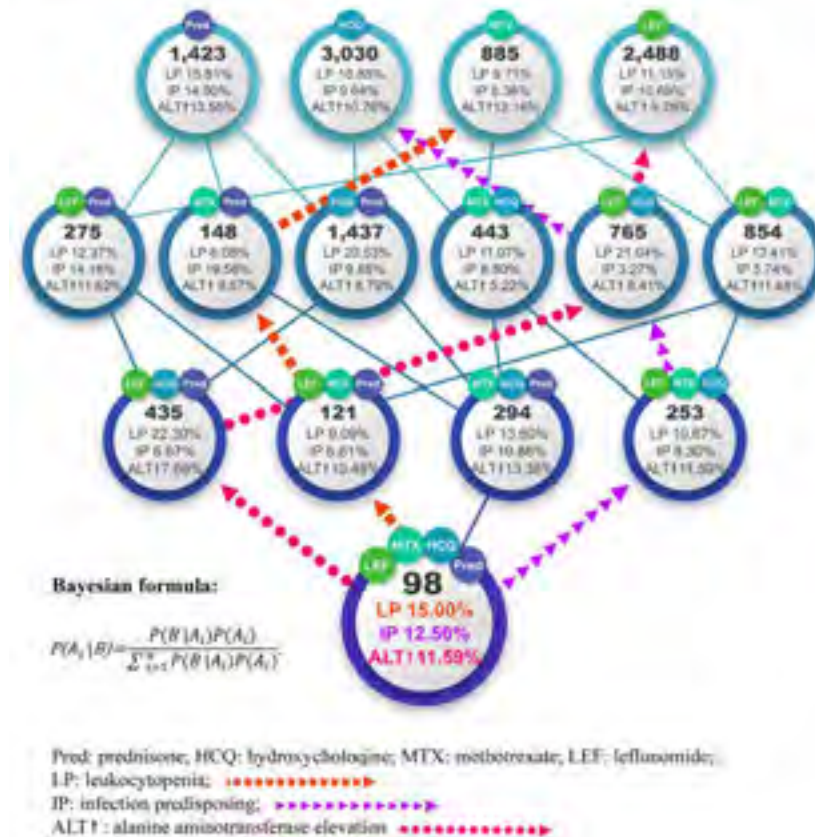

Session Time: 9:00AM-11:00AM

Background/Purpose: Combination therapy with DMARDs for treating RA is considered as standard of care. However, certain rates of adverse events (AEs) are unavoidable. The stigma is which drug should be stopped first once AEs emerge and the following sequence if AEs persist for optimal risk reductions. The decisions made by clinicians a real ways empirically. The purpose of this study is to develop an algorithm for decision-making on drug withdraw sequence in face of adverse events with combination therapy based on data mining and machine learning from the smart system of disease management (SSDM).

Methods: SSDM is an interactive mobile disease management tool, RA patients can input medical records (including medication and laboratory test results) and perform self-evaluation via applications (App). The data synchronizes to the mobiles of authorized rheumatologists through cloud and advices could be delivered.

In order to develop the master algorithm, abnormal white blood cell counts (WBC) and alanine amino transferase (ALT) elevation were targeted. WBC, ALT and medication data was collected, extracted, validated, and then based on Bayesian

Image 1. Bayesian network and data processing: patients' number (black bold as blow showed) and the rate of LP, IP and ALT in 15 regiments.

networks, data mining, modeling, calculating, analyzing were performed. WBC under 4,000/ml is defined as leukocytopenia (LP), over 10,000/ml as infection predisposing (IP), and ALT > 40 U/L as ALT elevation.

Results: From June 2014 to June 2018, 32,130 RA patients from 587 centers registered in SSDM. 7,086 are male and 24,144 are female with mean age of 49.82 year. 129 different drugs and 479 types of combination therapies are identified. Lab test results showed LP happened in 311 and IP 217, ALT 316 in 554 mono or combinational treatment regiments. Among them we selected prednisone (Pred), leflunomide (LEF), MTX, HCQ as an example to develop a master algorithm based on Bayesian networks and learning model. Image 1 shows Bayesian network and data processing, in which, quartet are correlating with 15 different regiments. Drug withdraw sequence for LP is HCQ, then LEF and then Pre, and the risks of LP are reduced by 39%, 33% and 23%, respectively. For IP, withdraw sequence is Pred, then MTX and then HCQ, and the risks of IP are reduced by 47%, 51% and 15%, respectively. For ALT, withdraw sequence is MTX, then Pred and then HCQ, and the risks of ALT are reduced by 51%, 28% and 16%, respectively.

Conclusion: Big data system can be built using SSDM via empowering patient. Through data mining, networking, modeling, and Bayesian calculation, a master algorithm for drug withdraw strategy in reduction of adverse events with combination therapy is developed, which can be applied on the other AEs in SSDM and may be replicated in other diseases. Following the continuing data inputs and machine learning, an artificial intelligent system in assisting clinical decision making may be achieved.

Limitations: This study only focus on rate of AE without considering the efficacy, without stratifying dosing.

Modeling the Costs and Outcomes Associated with Treatment Sequences, with and without Tofacitinib, for Moderately to Severely Active Psoriatic Arthritis in the US

George Bungey¹, Stacey Chang-Douglass¹, Ming-Ann Hsu², Joseph C Cappelleri², Pamela Young³ and **John Woolcott**³,
¹Decision Resources Group, London, United Kingdom, ²Pfizer Inc, Groton, CT, ³Pfizer Inc, Collegeville, PA

Session Information

Session Date: Monday, October 22, 2018

Session Title: Measures and Measurement of Healthcare Quality Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Psoriatic Arthritis (PsA) is a chronic progressive inflammatory condition associated with significant direct and indirect costs. Tofacitinib is an oral Janus kinase inhibitor for the treatment of PsA. Economic evaluations, alongside clinical data, help inform payers and formulary decisions in the USA. To better understand the impact of including tofacitinib on US payer formularies for treatment of patients (pts) with moderately to severely active PsA with a previous inadequate response (IR) to a conventional synthetic disease-modifying ant rheumatic drug (csDMARD), a decision tree model was designed to estimate and compare total costs, clinical responses, and per member per month (PMPM) costs between treatment sequences with and without tofacitinib.

Methods: The decision tree model was designed to estimate costs and outcomes from a third-party US payer perspective. In the base case, it was assumed the payer insured 1,000,000 individuals. The number of insured csDMARD-IR PsA pts was estimated from drug utilization and PsA epidemiology data. The analytical horizon was 2 years, with decision points for continuing/switching treatments occurring quarterly based on efficacy or occurrence of adverse events. The decision tree allowed for the comparison of multiple treatment strategies, each with up to four lines of advanced therapy for PsA. The base case compared a 'tofacitinib treatment sequence' (tofacitinib, adalimumab, etanercept, apremilast) vs a comparator sequence (adalimumab, etanercept, apremilast, secukinumab). Efficacy was measured using ACR20/50/70 and adverse event data were taken from US product information or published randomized clinical trials. The estimated total costs include the costs of treatment, monitoring, administration, and adverse events.

Results: Among 1,000,000 insurants, it was estimated that 274 csDMARD-IR PsA pts would receive an advanced therapy. The 'tofacitinib treatment sequence' was estimated to reduce total costs by \$5,223,990 vs the comparator sequence without tofacitinib, with estimated total 2-year costs of \$31,225,220 and \$36,449,210, respectively; the PMPM cost of the 'tofacitinib treatment sequence' was \$1.30 vs \$1.52 for the comparator sequence. Over 2 years, it was estimated that 261 (95%), 171 (62%), and 81 (30%) patients in the 'tofacitinib treatment sequence' will achieve ACR20/50/70 responses, respectively, vs 252 (92%), 169 (62%), and 81 (30%) patients in the comparator sequence, respectively. Sensitivity analyses on treatment sequences and key parameters including drug cost, efficacy, and switching probability showed the model results to be robust with treatment sequences including tofacitinib consistently being cost-saving sequences excluding tofacitinib.

Conclusion: This model suggests including tofacitinib in treatments for csDMARD-IR PsA pts is a cost-saving alternative to treatment sequences without tofacitinib. The inclusion of tofacitinib on formulary for payer insuring 1,000,000 individuals could reduce payer costs for PsA advanced therapies by more than \$5 million.

The Challenges of Managing Gout in Primary Care: Results of a Best Practice Audit

Lisa K. Stamp¹, Peter T. Chapman², Ben Hudson³, Greg Hamilton⁴ and Andrea Judd⁵, ¹University of Otago, Christchurch, New Zealand, ²Christchurch Hospital, Christchurch, New Zealand, ³University of Otago, Christchurch, Christchurch, New Zealand, ⁴Canterbury District Health Board, Christchurch, New Zealand, ⁵Kaikoura Medical Centre, Kaikoura, New Zealand

Session Information

Session Date: Monday, October 22, 2018

Session Title: Metabolic and Crystal Arthropathies – Basic and Clinical Science Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The majority of gout management occurs in primary care and may be suboptimal. While community based clinical trials have reported improvements whether such improvements can be replicated in routine clinical care is unknown. The aim of this study was to determine the effects of a package of care for (POC) gout in a real life primary care setting.

Methods: A POC was developed reflecting current gout management guidelines including patient education, a structured approach to the management of gout flares and urate lowering therapy (ULT) and screening for co-morbidities. An audit of gout management in a single rural general practice was undertaken before (2012) and after (2015) introduction of the POC.

Results: In 2012 one-hundred and twenty people with gout and in 2015 one-hundred and seventy one people with gout were identified. After the introduction of the POC more people with gout were prescribed ULT (79/120 (65.8%) vs. 127/171 (74.5%); $p=0.12$) and there was a significant increase in the median (IQR) number of prescriptions per individual over the 12 month period (1 (0-4) vs. 3 (0-4) $p<0.001$) (Figure). There was a significant increase in the number of individuals commenced on allopurinol ≤ 100 mg daily and a corresponding decrease in the number commenced on ≥ 200 mg daily ($p<0.001$) (Figure). There was a significant increase in the frequency urate testing between 2012 and 2015 ((median (range) 1 (0-3) vs 2 (0-10) respectively $p<0.001$). Of those individuals who had at least one urate measurement the proportion of individuals who never achieved target rate reduced from 43/67 (64.2%) in 2012 to 52/133 (39.1%) in 2015; $p=0.001$. With the exception of smoking, screening for important co-morbidities improved significantly after introduction of the POC. Of the 67 individuals who had a urate test in 2012 none received a ULT dose increase despite urate being above target in 46 instances. Of the 133 individuals who had a urate tested in 2015, 34 had at least one increase in allopurinol dose and of the 99 who were not dose escalated 28 were at target urate.

Conclusion: A structured POC can improve gout management in primary care although allopurinol dose escalation remains challenging.

Figure: Differences between 2012 and 2015 with regards to A) number of allopurinol prescriptions and B) allopurinol starting dose

Session Information

Session Date: Monday, October 22, 2018

Session Title: Metabolic and Crystal Arthropathies – Basic and Clinical Science Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Association of *ABCG2* Q141K (p.141Lys) with poor urate-lowering response to allopurinol has been reported although the mechanism is unclear. *ABCG2* has been reported to be an efflux pump for allopurinol and oxypurinol [1] and for oxypurinol alone [2]. Based on data from the HEK293 cell-line it has been suggested that dysfunctional variants of *ABCG2* such as p.141Lys could lead to decreased renal excretion of oxypurinol, higher oxypurinol levels and greater serum urate lowering [2]. To further investigate the apparent inconsistency between ref [2] and association of p.141Lys with poor allopurinol response, we examined the relationship between *ABCG2* p.141Lys and plasma oxypurinol.

Methods: We examined, using linear regression, plasma oxypurinol concentrations using participants from the Long-term Allopurinol Safety Study Evaluating Outcomes in Gout Patients and Genetics of Gout in Aotearoa studies based on the presence of the *ABCG2* p.141Lys.

Results: Of the 688 individuals, 294 (42.7%) were positive for \geq one p.141Lys allele. In a univariate model plasma oxypurinol concentration was significantly lower in these individuals compared to Gln/Gln homozygotes (mean (SEM) 84.8 (3.6) μ mol/l vs. 96.6 (3.1); $p=0.013$) despite higher allopurinol dose (mean (SD) 326 (101.3) vs. 297 (80.5)mg/d; $p<0.001$) and higher eGFR (72.7 (24.8) vs 67.5 (22.6) ml/min/1.73m²; $p=0.004$). Of those in the p.141Lys-positive group, fewer were receiving diuretics compared to the Gln/Gln group (22.4% vs. 31.0%; $p=0.08$). In a multivariate model that included allopurinol dose, eGFR and the use of diuretics, there was no statistically significant difference between plasma oxypurinol concentrations in the p.141Lys-positive and -negative groups, although levels were numerically lower in the p.141Lys-positive group (97.7 (3.5) μ mol/l vs. 104.3 (2.8) μ mol/l $p=0.12$).

Conclusion: Our results suggest that there are unidentified factors that influence plasma oxypurinol and, despite the evidence presented from the HEK293 cell-line model [2], plasma oxypurinol levels are not significantly different in individuals with the *ABCG2* p.141Lys variant. We recommend an individualised dose titration to target serum urate strategy for patients establishing on allopurinol.

Session Information

Session Date: Monday, October 22, 2018

Session Title: Metabolic and Crystal Arthropathies – Basic and Clinical Science Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Obesity is a moderate low-grade chronic inflammatory condition. Also, it has been reported to be a risk factor for inflammatory rheumatic diseases, seronegative inflammatory polyarthritis, and psoriatic arthritis. The cause of low-grade inflammation in obese patients who have non-specific musculoskeletal symptoms may be the subject of debate in clinical practice. Our aim is to determine whether inflammation is associated with obesity or rheumatic disease, and the association between leptin, chemerin, visfatin and inflammatory markers in obese patients with/without musculoskeletal symptoms.

Methods: In the period between March 2017 and January 2018, seventy-four obese patients (4 male, 70 female, with the mean age of 47.09 \pm 10.7 years) who admitted to our clinic with non-specific musculoskeletal symptoms were enrolled. The control group consisted of 40 obese patients (5 male, 35 female, with the mean age of 44.9 \pm 10 years) who have no rheumatic symptoms. Body mass index (BMI) is calculated in kg/m² with body weight ratio to height squared, and defined obesity BMI 30 or above. Age, gender, sedimentation, CRP, TNF- α , IL-6, IL-1, leptin, chemerin, and visfatin were

evaluated. The relationship between all parameters was assessed by Spearman correlation, Wilcoxon Signed-rank, and paired t-tests.

Results: There were no significant differences for sex, gender, and BMI between obese patients with non-specific musculoskeletal symptoms and control group. The mean TNF- α , IL-1 β , IL-6 concentrations were 60.8, 39.9, and 26.2 in obese patients with non-specific musculoskeletal symptoms respectively and significantly higher than the control group. Sedimentation and CRP levels were higher in those patients compared to control group without statistical difference. There were significant differences for chemerin, visfatin, but not for leptin between both group (Table 1). Also, the significant correlation was found between proinflammatory cytokines and visfatin, chemerin.

Conclusion: Visfatin and chemerin correlated with inflammation may be a useful indicator of undifferentiated inflammatory arthritis in obese patients who have non-specific musculoskeletal symptoms with low-grade inflammation.

Table 1. Demographic characteristics and laboratory values of obese patients with clinically suspect arthralgia and without any rheumatic symptoms

	With clinically suspect arthralgia	Without any rheumatic symptoms	p-value
Obese patients (n)	74	40	-
Age (years)	47.09 \pm 10.7	44.9 \pm 10	NS
Gender (female/male)	70/4	35/5	NS
Body Mass Index (kg/m ²)	37.6 \pm 7.2	36.9 \pm 4.8	NS
Sedimentation (mm/h)	32.9 \pm 15.1	27.5 \pm 16.1	NS
CRP (mg/dL)	8.4 [0.1-35.3]	7.9 [1-54.7]	NS
IL-1 β (pg/ml)	39.9 [4-347.5]	20.4 [0.7-266.1]	0,04*
IL-6	26.2 [3.8-350.9]	13.2 [3-63]	0,001*
TNF- α (pg/ml)	60.8 [11.3-301.6]	36.2 [5.6-243.3]	<0,001*

Assessment of the Persistence of Crystals Under Polarised Light Microscopy in Stored Synovial Fluid Samples

Sonia Pastor¹, Rocio Caño², Silvia Gomez-Sabater² and **Mariano Andrés**^{1,3}, ¹Departamento de Medicina Clínica, Universidad Miguel Hernández, Alicante, Spain, ²Seccion de Reumatología, Hospital General Universitario de Alicante-ISABIAL, Alicante, Spain, ³Sección de Reumatología, Hospital General Universitario de Alicante-ISABIAL, Alicante, Spain

Session Information

Session Date: Monday, October 22, 2018

Session Title: Metabolic and Crystal Arthropathies – Basic and Clinical Science Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Lacking an immediate access to a polarized light microscope is sometimes used to justify the clinical diagnosis of crystal-related arthritis. Some studies have assessed the persistence of crystals in stored synovial fluid samples, with disparities in methodology and results that hamper the extraction of firm conclusions. The aim of this study was to determine the influence of the time from sampling and the method of preservation on the crystal identification in the synovial fluid samples under polarized light microscopy at different time points.

Methods: A prospective, longitudinal, observational study was designed. Synovial fluid samples were obtained in clinical practice (T₀) and a trained rheumatologist identified crystals – monosodium urate (MSU) or calcium pyrophosphate (CPP). Fluids in which both types of crystals were detected, were excluded. On extraction, each fluid was divided into four samples. Two samples were stored in each type of tube - heparin or ethylenediaminetetraacetic acid (EDTA) as preserving agents -, at varying temperatures - room temperature or refrigerated at 4°C (39.2°F). Samples were analysed at around 24h (T₁), 72h (T₂), and 7days (T₃) by simple polarized light microscopy, and the presence of crystals was recorded. A medical student, who underwent training in crystal identification before the study, performed synovial fluid analyses; this training

was repeated after every ten samples. The student was blinded to baseline data, and synovial fluid samples containing no crystals were included to ensure blinding. Differences in the proportion of crystal-containing samples throughout the time-points were assessed using Cochran's Q and McNemar's tests.

Results: Thirty synovial fluid samples were analysed, 12 with MSU and 18 with CPP crystals at baseline. This meant a total of 120 samples at follow-up time points. A total of 360 microscope visualizations were performed, at a mean (SD) of 31.0h (10.3) for T₁, 90.5h (29.3) for T₂, and 7.5 days (0.7) for T₃. The Figure shows the rate of samples containing crystals at different time-points. The identification of crystals within the MSU samples did not modify throughout study, being observed in 11/12 (91.7%) of room temperature samples and in 12/12 (100%) of refrigerated samples at T₃. However, the identification of CPP crystals tended to decrease in all conditions, especially when preserved with EDTA and kept at room temperature (12/18 (66.7%) at T₃).

Conclusion: MSU crystals persisted in stored samples for over a week, but CPP crystals tended to disappear in the same period, especially when kept at room temperature and/or preserved with EDTA. Keeping samples preserved with heparin and refrigerated at 4°C appears to allow a delay microscope analysis for crystals. Foregoing crystal-proven diagnosis, due to immediate unavailability of a microscope, no longer appears justified.

Session Information

Session Date: Monday, October 22, 2018

Session Title: Metabolic and Crystal Arthropathies – Basic and Clinical Science Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Elevated serum urate and reduced fractional excretion of uric acid (FEUA) are common in people on diuretics. Changes in FEUA in response to frusemide are associated with changes in fractional excretion of sodium (FENa). Variants in renal sodium transporters NCC (encoded by *SLC12A3*) and ENaC (encoded by *SCNN1B* and *SCNN1G* beta and gamma subunits, respectively) have been associated with FENa responses to frusemide (Vormfelde

et al, Clin Pharmacol Ther 2007). The aim of this study was to determine whether variations in these sodium transporters also have an effect on FEUA or serum urate responses to frusemide administration.

Methods: Data were analysed from a short-term study of 100 healthy participants receiving a 40mg oral tablet of frusemide. The following single nucleotide polymorphisms (SNPs) were genotyped: *SCNN1B* rs152745, *SCNN1G* rs13306653 and *SLC12A3* rs1529927. A mixed-model approach to repeated measures (analysis of variance; ANOVA) all adjusted for age, sex, and ethnicity was employed. The key primary endpoint was FEUA and the secondary endpoints were serum urate, FENa, and fractional excretion of potassium (FEK).

Results: Oral intake of 40mg frusemide led to marked diuresis and increase in FENa and FEK throughout the study period (ANOVA $P < 0.0001$ for all). FEUA initially increased and then decreased over the study period ($P < 0.0001$). For *SCNN1B* rs152745, homozygosity for the frusemide response A allele (15% of participants) was associated with a greater increase in FENa (ANOVA $P_{\text{time} \times \text{SNP}} = 0.007$) and FEUA ($P_{\text{time} \times \text{SNP}} = 0.02$). For *SLC12A3* rs1529927, presence of the frusemide response C allele (3% of participants) was associated with a greater increase in FEUA ($P_{\text{time} \times \text{SNP}} = 0.00013$) and a trend to increase in FENa ($P_{\text{time} \times \text{SNP}} = 0.09$) following frusemide intake. No effects on diuretic responses were observed with *SCNN1G* rs13306653, and none of tested SNPs had significant effects on serum urate or FEK over the study period.

Conclusion: Two previously reported diuretic-response sodium transporter genes are associated with an elevated FEUA response to frusemide. These findings suggest that genetic variation in *SLC12A3* and *SCNN1B* influence renal uric acid handling in response to diuretics, perhaps through altered renal sodium handling.

Session Date: Monday, October 22, 2018

Session Title: Metabolic and Crystal Arthropathies – Basic and Clinical Science Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Hyperuricemia is common, and along with other comorbidities (CM), is increasing in prevalence. Though often asymptomatic, it is associated with subclinical urate deposition detectable by ultrasound (US) imaging. This study aims to evaluate the association of CM with urate deposition in individuals with asymptomatic hyperuricemia (ASU) via US.

Methods: ASU was defined as serum urate (sUA) $> 6\text{mg/dl}$; sUA $< 6\text{mg/dl}$ served as controls. Demographic factors, CM – (hypertension [HTN], hyperlipidemia [HLD], diabetes mellitus [DM], cardiovascular disease [CVD], renal disease [CKD], metabolic composite [presence of any CM, BMI > 30], osteoarthritis [OA]), diuretic use, and dietary data (alcohol [ETOH], red meat, seafood) were collected. US of joints (knee/1st MTP) and tendons (triceps, quadriceps/patella, Achilles) was performed via standard procedure, OMERACT parameters of urate deposition documented, and images read by an Expert ultrasonographer blinded to sUA and CM categories. Correlations between sUA levels and urate deposition with CM, medication and dietary risk factors were analyzed by multivariable logistic regression model.

Results: Of 95 predominantly Black patients (mean age 59.7 yrs, BMI $\sim 32\text{ kg/m}^2$) ASU subjects ($n=71$, median sUA = 8.0 mg/dl) were older men, with more frequent HTN, CVD, CKD, and alcohol ingestion versus controls (Table 1). Presence of

HTN, CVD, CKD and diuretic use were associated with higher sUA (>8 vs 6-7.9 mg/dl). In multivariate analyses adjusting for demographic and clinical characteristics, sUA>6mg/dl and advanced age were positively associated with joint urate deposition, (OR=5.23; 95%CI: 1.18-23.12, OR=1.06; 95%CI: 1.00-1.11, respectively) [Table 2]. There was however, no significant association between individual or composite CM and urate deposition at either joint or tendon, even when adjusting for sUA levels. Urate deposition at tendons was more frequent in men (OR=9.09; 95%CI: 1.08-76.68), but unrelated to sUA (p=0.23).

Conclusion: While ASU and age predict US urate deposition, the presence of comorbid conditions and diuretic use though themselves associated with higher levels of sUA, do not. A larger cohort with other imaging modalities such as DECT, may provide additional information.

Session Information

Session Date: Monday, October 22, 2018

Session Title: Metabolic and Crystal Arthropathies – Basic and Clinical Science Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose

Background: Gout is the most common form of inflammatory arthritis and its prevalence is increasing in more affluent countries in recent decades. Many studies have reported that gout and hyperuricemia are associated with an increase in all-cause mortality and cardiovascular mortality. Increased arterial stiffness is an independent marker of cardiovascular diseases and risk predictors. Many studies have shown a significant correlation between uric acid levels and arterial stiffness. Augmentation Index (AI) is an indirect measure of arterial stiffness.

Purpose: The aim of this study is to evaluate the predictors of increased arterial stiffness in gout and hyperuricemia patients.

Methods: Between June 2017 and June 2018, AI was measured using SphygmoCor for patients who visited Jeju National University Hospital in South Korea with gout or hyperuricemia. Medical records, laboratory and AI data were retrospectively analyzed and multivariate analysis was performed.

Results: One hundred twenty two patients participated in the study and AI was measured. Most (96.7%) of the patients were male. At the time of the examination, 99 patients (81.1%) were treated with uric acid lowering and the mean duration of the disease was 6.9 years. When the patients were divided into two groups according to the presence or absence of Tophi, the average age (60.2 ± 11.6 vs 53.4 ± 13.2 , $p=0.023$) of the patients with Tophi was significantly higher, duration of disease (13.0 ± 6.5 vs 5.4 ± 5.4 , $p=0.000$) was longer and the AI (28.7 ± 7.8 vs 20.7 ± 10.4 , $p=0.001$) was higher. When univariate regression analysis was performed, tophi was able to predict high AI ($b = 7.99$, 95% CI 3.50-12.49, $p=0.001$). When multivariate regression analysis was performed to exclude the effects of other variables (DM, HTN, hyperlipidemia, age, BMI, total cholesterol, creatinine), tophi was a predictor of high AI ($b = 6.10$, 95% CI 0.43-11.79, $p=0.035$)

Conclusion: This study suggests that the presence of tophi is an independent predictor of increased arterial stiffness in patients with gout and hyperuricemia.

Quality of Gout Management in a Rheumatology Clinic Using a Provider-Pharmacist Team-Based Approach

Jessica Michaud¹ and Jenna Beatty², Pharmacy, Froedtert & the Medical College of Wisconsin, Milwaukee, WI,
²University of Kansas, Kansas City, MO

Session Information

Session Date: Monday, October 22, 2018

Session Title: Metabolic and Crystal Arthropathies – Basic and Clinical Science Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Gout is the most common form of inflammatory arthritis.¹ The cornerstone of treatment for gout is urate-lowering therapy (ULT), which in the U.S. includes the xanthine oxidase inhibitors (XOI) allopurinol or febuxostat. Studies have shown poor adherence to quality indicators in gout, such as monitoring serum uric acid (SUA) and achieving goal SUA.^{1,2}

A clinical pharmacist has been a part of the Froedtert & the Medical College of Wisconsin (F&MCW) Rheumatology Clinic since January 2012. A collaborative practice agreement (CPA) for gout management by the pharmacist, reviewed by the rheumatology providers, has been in place since 12/19/14. Under this CPA, providers have had the opportunity to refer patients with gout to the pharmacist. Providers include referral information, such as preferred medications or how to manage flares, or can defer these decisions to the pharmacist. The CPA, updated yearly, guides therapy in relation to ULT including SUA checks every 3 weeks, flare prophylactic therapy, and treatment of acute flares.

The aim of this study is to measure quality of care in subjects with gout co-managed by rheumatology provider(s) and a pharmacist at the F&MCW Rheumatology Clinic.

Methods: This study is a retrospective analysis assessing patients newly starting ULT between January 1, 2015 and November 30, 2017, and followed 6 months after referral. Adults diagnosed with gout by microscopic evaluation or

provider clinical assessment were included. Patients were excluded if any non-XOI ULT was used, SUA was <6mg/dL at the time of ULT initiation, or the patient had an active cancer diagnosis.

Results: Thirty patients were included in the study. At baseline, mean age was 64 years, mean SUA was 9.4mg/dL, and 80% were crystal-proven. At the time of referral, 26 patients were started on allopurinol at a mean dose of 152mg/day, and 4 patients were started on febuxostat at a mean dose of 60mg/day. Twenty-two patients (73%) achieved SUA <6mg/dL during management (primary outcome), 4 patients were non-responsive to outreaches, and 4 patients are still being managed. On average, patients reached goal SUA <6mg/dL at 10 weeks, and SUA decreased by 61% to 5.7mg/dL. The mean ULT doses at the end of the study period were allopurinol 296mg/day and febuxostat 80mg/day. The percentage of patients that were prescribed flare prophylaxis was 100%. During management, the pharmacist had 154 encounters with patients, compared to 51 with providers.

Conclusion: Seventy-three percent of patients co-managed by rheumatology providers and a pharmacist were able to achieve SUA <6mg/dL, occurring at a mean of 10 weeks, and 100% were prescribed flare prophylaxis. Team-based gout management including a pharmacist may provide a method of achieving goals of therapy while reducing time required of providers.

Session Date: Monday, October 22, 2018

Session Title: Metabolic and Crystal Arthropathies – Basic and Clinical Science Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The impact of chronic gout and acute flares on daily activities is severely limiting. Yet only 40% of gout patients receive urate-lowering therapy (ULT), usually without titration to guideline targets (Doherty. *Ann Rheum Dis* 2012;71:1765-70; Kuo. *Ann Rheum Dis* 2015;74:661-7). Several barriers have been identified leading to suboptimal care. When patients are fully informed about their disease and involved in management decisions, uptake of ULT is higher and subsequent adherence can be improved (Rees. *Ann Rheum Dis* 2013;72:826-3). The aim of this study was to evaluate patient characteristics and key perceptions of gout in the US.

Methods: A 2017 cross-sectional survey of US adults assessed health conditions, health-related quality of life (HRQoL), and health care resource utilization. Participants aged ≥18 years were recruited using a random stratified sampling framework to ensure demographic composition representative of the US population. Participants who reported having gout completed a series of questions about current treatments, serum urate (sUA) laboratory assessments, disease severity, satisfaction with disease control, acute gout attacks (flares), and their own and physicians' level of concern about their gout. Population level characteristics, treatments, sUA testing, and patient descriptions of burden of gout are summarized using descriptive statistics.

Results: A total of 372 (3.1%) of 12,146 participants reported having gout. Patients' characteristics are presented in the Table. Less than half (42.5%) reported currently taking ULT. Of those on ULT, the majority (90.5%) reported taking allopurinol and, of these, most (83.8%) reported taking 300 mg or less/day. A total of 58.2% of those reported taking anti-inflammatory medication for their flares. Less than half (45.1%) had their sUA tested in the last 12 months and only 36.3% knew their test results. Among the tested, only 38.3% reported an sUA <6 mg/dL. Nearly 30% reported their condition as severe to very severe, and 22.7% reported a low concern. Despite the majority of patients failing to achieve target sUA goals, only 20% reported being dissatisfied with their treatment of gout. Patients described their gout pain as a "one of a kind, indescribable pain"; [like a] "broken or bruised bone"; "excruciating pain"; and "unbearable." A summary and classification of patient quotes illustrates the extreme burden experienced by patients with gout.

Table1: Patient Characteristics	
Patient characteristics	With gout
Male, %	75.0
White, %	82.4
Hispanic origin, %	3.1
Married, %	51.4
Age, mean	58.9
Income, median, \$	53,448
Income, mean, \$	65,989
Education, %	
High school or less	22.7
More than high school	77.3
Currently smoke, %	19.3
On a diet, ^a %	19.5
Body mass index, mean	32.1
Obesity, %	56.8
Exercise (including walking), %	
Less than 3 times per week	39.7
3 times or more per week	60.3
Exercise (excluding walking), %	
Less than 3 times per week	65.3
3 times or more per week	34.7
Depression, PHQ-9, %	
No or minimal depression	61.2
Mild to moderate	28.6
Severe depression	10.2
Anxiety, GAD-7, %	
No or minimal	69.0
Mild to moderate	24.5
Severe anxiety	6.4
Health-related quality of life (HRQOL) measures	
Physical Health Composite Score (PCS), ^b mean	41.1
Mental Health Composite Score (MCS), ^b mean	49.4
Health Utility (6D), ^c mean	0.7
^a Refers to any special diet, not specifically a gout-related diet	
^b Norm based scoring where 50=population average score	
^c Utility value derived from the VR-12, captures overall health status where a score of 0 is death and 1 is perfect health.	

Conclusion: In 2017 less than half of the gout patients from the US were being treated with ULT and the majority fell short of treatment goals, despite gout being described as one of the most debilitating painful conditions ever experienced. Improving the care for patients with gout continues to be clear unmet need that can potentially reduce the severity of this disease, thus significantly impact HRQoL.

Atmospheric Temperature and the Incidence of Gout Flare: Data from the Korea Meteorological Association and National Health Insurance Service

Rina So¹, Min Jung Kim², Sang Hee Kim², Sung Hyouk Choi¹, Hyung-Jin Yoon¹ and Kichul Shin³, ¹Department of Biomedical Engineering, Seoul National University College of Medicine, Seoul, Korea, Republic of (South), ²Division of Rheumatology, Department of Internal Medicine, SMG-SNU Boramae Medical Center, Seoul, Korea, Republic of (South), ³Kyungnam villa #102, Division of Rheumatology, Department of Internal Medicine, SMG-SNU Boramae Medical Center, Seoul, Korea, Republic of (South)

Session Information**Session Date:** Monday, October 22, 2018**Session Title:** Metabolic and Crystal Arthropathies – Basic and Clinical Science Poster I**Session Type:** ACR Poster Session B**Session Time:** 9:00AM-11:00AM

Background/Purpose: Gout management is mainly focused on life style modification and proper medications. Of note, seasonal variation of gout flare was also implemented to be a factor to consider. There is yet no study in which investigated the association of climate and gout flare by utilizing big data.

Methods: The operational definition of gout flare was developed and pre-tested in a single institute (BRMC). Patient data (2008-2014) were obtained from the National Health Insurance Service. Ambient and dew point temperature during the same period were acquired from the weather station located in Seoul. Using generalized additive and piecewise linear regression models, we estimated the number of gout flare admissions associated with daily apparent temperature after adjusting relevant covariates. We also compared this model in patients admitted for stroke or acute myocardial infarction.

Results: A total of 71,687 episodes were identified as gout flares in Seoul. The mean daily and dew point temperature were 12.6 °C, 4.4 °C, respectively, and the mean daily apparent temperature was 12.5 °C. Increase in gout flare admissions displayed a nonlinear relationship with the apparent temperature within 2 days of admission, at both low and high ends. Especially, the number of admissions increased by 7.77% (95% confidence interval 6.35, 9.22) per 1 °C decrease in apparent temperature below the -3 °C flexion point. This distinctive nonlinear pattern was not observed in admissions due to hemorrhagic, ischemic stroke or acute myocardial infarction.

Conclusion: Our data indicate that monitoring sudden changes of daily apparent temperature alongside abiding treatment guidelines could add additional benefit to gout patients in their daily lives.

Dual-Energy CT for the Diagnosis of Gout: A Prospective Study in Patients with No Prior History of Gout

Mihaela Gamala¹, Johannes W. G. Jacobs², Suzanne Linn-Rasker³, Maarten Nix⁴, Ben Heggelman⁴, Pieter Pasker⁵, Jacob van Laar⁶ and Ruth Klaasen³, ¹Rheumatology and Clinical Immunology, University Medical Center Utrecht, Utrecht, Netherlands, ²Rheumatology & Clinical Immunology, University Medical Center Utrecht, Utrecht, Netherlands, ³Rheumatology, Meander Medical Center Amersfoort, Amersfoort, Netherlands, ⁴Radiology, Meander Medical Center Amersfoort, Amersfoort, Netherlands, ⁵Meander Academy, Meander Medical Center Amersfoort, Amersfoort, Netherlands, ⁶Department of Rheumatology & Clinical Immunology, University Medical Center Utrecht, Utrecht, the Netherlands, Utrecht, Netherlands

Session Information**Session Date:** Monday, October 22, 2018**Session Title:** Metabolic and Crystal Arthropathies – Basic and Clinical Science Poster I**Session Type:** ACR Poster Session B**Session Time:** 9:00AM-11:00AM

Background/Purpose: Gout is associated with joint damage, and increased cardiovascular morbidity, so to diagnose and treat gout early is important. However, joint aspiration and microscopy not always yield the diagnosis. The latest diagnostic technique to visualize monosodium uric acid (MSU) depositions is Dual Energy CT scan (DECT).¹ We purpose to assess the sensitivity and specificity of DECT for diagnosing gout in patients with unclassified arthritis.

Methods: We included 87 consecutive patients with acute mono or oligo arthritis without prior gout diagnosis who presented to the outpatient clinic of the Department of Rheumatology of Meander Medical Centre, Amersfoort, the Netherlands, ClinicalTrials.gov number NCT03038386. Seven patients dropped out, see Figure. Patients underwent aspiration of the arthritic joint for the detection of MSU crystals (see Table) and a DECT scan of hands and wrists, knees, ankles and feet. The synovial fluid result for MSU crystals was the gold standard for gout.

Results: For demographic and clinical characteristics of the patients see Table, and for study data and outcomes see Figure. The sensitivity and specificity of DECT for gout deposition in the index joint were 0.58 (95% CI 0.43-0.72) and 0.75 (95% CI 0.57-0.89), respectively, with an area under the ROC curve of 0.67 (95% CI 0.55-0.79), $p < 0.05$. When

classifying DECT as positive if deposition was observed at the index joint and/or in other locations, sensitivity was higher: 0.77 (95% CI 0.63-0.88), but specificity lower: 0.69 (95% CI 0.48-0.86).

Conclusion: These preliminary data show the diagnostic value of DECT in patients with acute unclassified mono or oligoarthritis. Probably, DECT sensitivity is underestimated by false negative MSU results due to a sampling error, because of incorrect aspiration, or extra-articular locations of the gout, e.g. around tendons.

Table. The demographic and clinical characteristics of the patients (n=80) included in the study

	Patients MSU positive (n=48)	Patients MSU negative (n=32)
Age in years, mean (SD),	59.0 (15.6)	63.1 (13.0)
Sex, N (%)		
Male	41 (85.4)	25 (78.1)
Female	7 (14.6)	7 (21.9)
Arthritic joint aspirated (N, %)		
MTP1	29 (60.4)	6 (18.8)
Other joints	19 (39.6)	26 (81.2)
Period between 1 th arthritis attack and baseline visit in months, median (IQR)*	12 (56)	6 (35.8)
Serum uric acid (µmol/L) mean (SD)	465.72 (120.65)	403.50 (109.71)

Effect of Colchicine on Diabetes Incidence Among Gout Patients in a Veterans' Affairs Population

Anastasia Slobodnick¹, Virginia Pike², Michael Toprover¹ and Michael Pillinger¹, ¹Medicine/Rheumatology, NYU School of Medicine, New York, NY, ²Medicine/Rheumatology, New York Harbor VA Healthcare System, New York, NY

Session Information

Session Date: Monday, October 22, 2018

Session Title: Metabolic and Crystal Arthropathies – Basic and Clinical Science Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Previous studies suggest that patients with gout are at increased risk for developing diabetes.¹ One possible explanation for this increased risk is the activation of pathologic pathways common to both diabetes and gout, including IL-1b.² Among its many mechanisms, colchicine has been found to suppress activation of the NLRP3 inflammasome, inhibiting activation of IL-1b. Colchicine may also activate AMPK, a down regulator of inflammation and gluconeogenesis.³ In the present study, we investigated whether chronic colchicine use reduces diabetes incidence among patients with gout.

Methods: We reviewed the Computerized Patient Record System (CPRS) of the New York Harbor Veterans' Affairs Healthcare System to assess the incidence of diabetes between 2000 and 2015 among 140 randomly selected patients with gout who had taken colchicine daily for some or all of the study period. We compared the diabetes incidence among these patients with 115 randomly selected patients with gout who did not take colchicine during the same time period. At study entry, all subjects met a modified version of 1977 ARA gout classification criteria and had no diabetes diagnosis. Patients were excluded if their duration of colchicine use was <60 contiguous days. Incident diabetes was defined as a new hemoglobin A1c value of $\geq 6.5\%$ during the study period.

Results: Among gout patients who had taken colchicine, we observed no difference in diabetes incidence compared to patients not taking colchicine (17.1% versus 17.4%, OR = 0.983, $p = 1.0$). When patients were analyzed by duration of colchicine use, there was no significant difference in diabetes incidence between patients in the longest (36.5 to 114 months) compared to the shortest tertile (2.3 to 14 months) (27.3% versus 9.1%, $p = 0.24$) of colchicine exposure. Among patients in the colchicine group who experienced incident diabetes during the study period ($n = 24$), 50% ($n = 12$) were actively taking colchicine at the time of their diagnosis and 50% ($n = 12$) had discontinued colchicine use prior to their diabetes diagnosis.

Conclusion: We found no significant difference in the 15-year diabetes incidence between patients taking colchicine and those not taking colchicine, suggesting that colchicine is not beneficial to prevent incident diabetes. Larger and prospective studies will be needed to confirm this observation.

Session Information

Session Date: Monday, October 22, 2018

Session Title: Metabolic and Crystal Arthropathies – Basic and Clinical Science Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Gout is characterized by episodes of acute arthritis that are self-limiting. However, patients with gout can also develop tophi, bone erosions, joint deformity and dysfunction in advanced disease. Previous studies based on relatively small sample sizes or exclusively tophaceous gout cases suggested that the prevalence of erosions in gout could be substantial. However, the precise prevalence estimate, particularly among non-tophaceous gout cases remains unclear. The aim of this study was to determine the prevalence of erosions in patients with gout on urate-lowering therapy using dual-energy CT (DECT).

Methods: DECT of the bilateral feet and ankles were prospectively obtained on 153 patients who fulfilled the 1977 ARA gout classification criteria and were on allopurinol ≥ 300 mg daily for at least 3 months. Enrollment was conducted in a monitored fashion to ensure the population included approximately 25% of patients with palpable tophi and approximately 50% of patients with serum uric acid (SUA) < 6 mg/dL. The presence of erosions was evaluated at 12 anatomic sites (1st-5th interphalangeal (IP) joints, 1st-5th MTP joints, tarsals, and Achilles tendon calcaneal insertion) in the feet and ankles by 2 radiologists familiar with interpreting DECT.

Results: Our analysis included 153 patients (92% male) with gout (mean disease duration, 15 years) on allopurinol (mean duration of therapy, 5 years). Mean allopurinol dose was 333mg daily (range 300-750mg daily). Erosions in the feet and ankle were present in 72% of patients. Patients with tophi had significantly higher prevalence of erosions than those without tophi (83% vs 67% respectively, $p = 0.04$). The three sites most commonly affected by erosions overall were the first MTP joint, tarsals, and first IP joint (68%, 38%, and 13%, respectively) (Table). The pattern of erosion involvement in the feet/ankles did not differ significantly based on tophus status.

Conclusion: Among patients with gout on allopurinol, erosions in the feet and ankles are common, with 72% of all subjects demonstrating at least one erosion. The most frequent sites of erosions are the first MTP joint and themed-foot areas, common locations of gouty arthritis. While patients with clinical tophi have a higher prevalence of erosions, 67% of patients without tophi had at least one erosion.

Table. Prevalence of erosions on DECT of feet/ankles.

Site	All Patients N=153 Erosions	Clinical Tophi N=48 Erosions	No Tophi N=105 Erosions
Any site	72%	83%	67%
MTP 1	68%	75%	65%
Tarsals	38%	46%	34%
IP 1	13%	17%	12%
MTP 5	12%	23%	7%
MTP 2	9%	13%	7%
MTP 4	3%	8%	≤1%
IP 2	3%	4%	3%
MTP 3	3%	6%	2%
Achilles	≤ 1%	2%	≤1%
IP 4	2%	2%	2%
IP 3	≤ 1%	0%	≤1%
IP 5	≤ 1%	2%	≤1%

MTP = metatarsophalangeal joint; IP = interphalangeal joint

Session Information

Session Date: Monday, October 22, 2018

Session Title: Metabolic and Crystal Arthropathies – Basic and Clinical Science Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Mitochondria execute roles in diverse cellular pathways. As a danger signal, damaged mitochondria can induce inflammation in response to stress through NLRP3 inflammasome activation, which is central to gout. We recently reported association of reduced mitochondrial DNA (mtDNA) copy number with prevalent gout in New Zealand Māori and Pacific (Polynesian) people¹. However the cause-effect relationship is unknown. This could be evaluated by testing nuclear genetic variants that associate with mtDNA copy number for association with gout. Here the aims were: 1) Perform a genome wide association study (GWAS) to identify nuclear variants associated with mtDNA copy number; 2) test these identified variants for association with gout.

Methods: The mtDNA copy number GWAS comprised 1,340 Eastern Polynesian, 816 Western Polynesian and 4,579 European individuals (New Zealand, Europe) genotyped on the Illumina CoreExome v24 array. The median of the

absolute differences in X and Y probe intensities was used as a measure of mtDNA copy number. This measure was associated with genome-wide genotype calls, adjusted by age, sex and by principal component vectors calculated from the probe intensities of an additional 10,000 randomly selected autosomal SNPs. Nuclear variants identified as being associated with mtDNA copy number were then tested for association with gout, adjusting by age, sex and the first 10 principle component vectors generated from genotype calls for 3,000 independent autosomal SNPs.

Results: As previously reported mtDNA copy number negatively associated with gout in the Polynesian sample sets ($\beta=-2.81$, $P=2.9 \times 10^{-6}$ for East Polynesian and $\beta=-8.11$, $P=3.6 \times 10^{-16}$ for West Polynesian). However there was no evidence for association in the European sample set ($\beta=-0.16$, $P=0.66$). The nuclear variant *MUC17 rs78010183* T-allele associated with increased mitochondrial CN at an experiment-wide level of significant ($P<1 \times 10^{-7}$) in people of Eastern Polynesian ancestry ($\beta=0.07$, $P=4.7 \times 10^{-13}$). There were no other nuclear variants significantly associated with mtDNA copy number in the Western Polynesian or European sample sets. Association of the *MUC17 rs78010183* variant with increased mtDNA copy number replicated in Europeans, with the T-allele increasing copy number ($\beta=0.06$, $P=1 \times 10^{-4}$) but not in Western Polynesian ($\beta=0.09$, $P=0.15$). Testing for association with gout, the *rs78010183* T-allele was not significantly associated in Eastern Polynesian (OR=1.38, $P=0.17$) but was associated in European (OR=15.88, $P=1 \times 10^{-3}$) sample sets, with the mtDNA copy number-increasing allele associated with increased risk of gout.

Conclusion: Genetic variants associated with mtDNA copy number also associate with gout, providing evidence for a direct role of either mtDNA copy number, or another related factor such as mitochondrial dysfunction, in gout. However, the nuclear variant *rs78010183* supports a direct relation of increased mtDNA copy number with gout, conflicting with our previous observational report of association of reduced mtDNA copy number with gout.

Session Date: Monday, October 22, 2018

Session Title: Metabolic and Crystal Arthropathies – Basic and Clinical Science Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Gout is usually accompanied by metabolic diseases including obesity, hypertension, diabetes, and dyslipidemia. Obesity has been confirmed as a risk factor for gout. This study aims to explore the clinical and renal uric acid excretion features in gout patients with obesity.

Methods: Primary gout patients hospitalized from 2013 to 2017 were included. The diagnosis of gout fulfilled the 1977 ACR gout classification criteria or the 2015 ACR/EULAR classification criteria. The patients with estimated glomerular filtration rate (eGFR) $<30 \text{ ml/min/1.73m}^2$ and secondary gout were excluded. Baseline characteristics, fasting blood biochemical indexes, incidence of comorbid diseases were collected. The 24h urinary uric acid (UUA) and urinary creatinine excretion (UCr) were evaluated on unrestricted diet, which were used for the calculation of renal uric acid excretion variables. Obesity was defined as body mass index (BMI) $\geq 28 \text{ kg/m}^2$.

Results: ① Among 212 recruited patients, 89.2% were male, the median age of onset was 43 (33, 58) years old and median serum uric acid (sUA) was 545 (454, 663) $\mu\text{mol/L}$, 40 patients (18.9%) had obesity. ② Compared with non-obese group (n=172), the obese group presented a younger onset age [36 (26, 48) years vs. 46 (36, 59) years], significantly higher

Clinical characteristic	All patients (n=212)	Obese group (n=40)	Non-obese group (n=172)	P

Creatinine clearance rate, ml/min/1.73m^2	52(38,69)	60(49,88)	50(34,68)	0.005
Fractional excretion of uric acid, %	6.52(4.73,8.89)	1.53(3.90,7.39)	6.75(5.00,9.48)	0.007
Glomerular uric acid filtered load, mg/min	4.43(3.18,6.27)	5.20(4.08,7.14)	4.12(3.09,5.85)	0.084
UUA/UICr	0.33(0.26,0.42)	0.54(0.23,0.43)	0.32(0.26,0.41)	0.552

level of sUA [593 (522,697) $\mu\text{mol/L}$ vs. 531 (416,660) $\mu\text{mol/L}$], higher incidence of hypercholesterolemia (35.0% vs. 18.6%), high low-density lipoproteinemia (37.5% vs. 18.0%), and metabolic syndrome (45.0% vs. 24.4%, all $P<0.05$). There were no significant difference between two groups in gender, duration of gout, count of affecting joints, levels of serum creatinine and eGFR, and incidence of tophi, urolithiasis, chronic kidney disease, hypertension, diabetes mellitus, low high-density lipoprotein cholesterol and hypertriglyceridemia (all $P>0.05$, Table 1). ③ The glomerular uric acid filtered load [5.20 (4.08, 7.14) mg/min vs 4.12 (3.09, 5.85) mg/min] was significantly higher in the obese group. Although the 24h UUA excretion was significantly higher [2993 (2138, 4055) μmol vs. 2041 (1840, 3278) μmol], the fractional excretion of uric acid in the obese group was significantly lower [5.53 (3.90, 7.39) % vs. 6.75 (5.00, 9.48)%, Table 2].

Conclusion: High uric acid load of serum and glomerular filtration in gout patients with obesity may due to the relative insufficiency of renal uric acid excretion.

Higher Body Fat Percentage in Non-Obese Late-Onset Gout Patients

Qian-Hua Li, Kui-Min Yang, Yan-Hui Xu, Xin-Yun Du, Jin-Jian Liang, Jian-Zi Lin, Ying-Qian Mo and Lie Dai, Department of Rheumatology, Sun Yat-Sen Memorial Hospital, Sun Yat-Sen University, Guangzhou, China

Session Information

Session Date: Monday, October 22, 2018

Background/Purpose: There is a trend of younger gout onset related to higher obesity prevalence. BMI is limited to discriminate between fat and lean mass. Body composition (BC) analysis is an alternative tool to assess metabolic status. We aimed to investigate the characteristics of BC in early and late onset gout patients.

Methods: Consecutive gout patients who fulfilled the 2016 ACR/EULAR classification criteria were recruited between June 2017 and May 2018. BC was assessed by bioelectric impedance analysis. General obesity was classified by BMI ≥ 28 kg/m². Central obesity was defined as a waist-hip ratio (WHR) above 0.90 for males and above 0.85 for females. The patients with gout onset before age 30 years were defined as early-onset group while the others were defined as late-onset group.

Results: Among 230 gout patients recruited, mean age was 42.3 with standard deviation 22 years. Mean serum uric acid (sUA) was 9.2 with standard deviation 2.1mg/dl and 40 (17.4%) patients presented tophi. The prevalence of general obesity and central obesity was 23.4% and 64.8%, respectively. There were 91 (39.5%) patients in early-onset group. Late-onset group (n=149) showed lower prevalence of general obesity than early-onset group [25 (16.7%) vs. 29 (31.8%), P=0.017] but higher prevalence of central obesity [99 (71.2%) vs. 50 (54.9%), P=0.016]. Among obese outpatients, late-onset group showed lower estimated glomerular filtration rate (eGFR), higher prevalence of hypertension and diabetes mellitus, WHR without significant difference in other BC indicators compared with early-onset group (Table 1). Among non-obese gout patients, late-onset group presented significantly lower level of sUA and eGFR, higher prevalence of hypertension and metabolic syndrome compared with early-onset group (P<0.05, Table 1). Non-obese late-onset gout patients exhibited higher WHR, central obesity, total fat percentage and trunk fat percentage (P<0.05, Table 1) although there were no significant difference of BMI and prevalence of overweight between the two groups.

Conclusion: There were more BMI defined obese patients in early-onset gout patients but non-obese late-onset gout patients showed more central obesity and fat percentage without difference in BMI compared with on-obese early-onset gout patients.

Association of HFE Genotypes with Clinical Severity in Patients with Definite Calcium Pyrophosphate Arthritis

Fernando Perez-Ruiz^{1,2,3} and Joana Atxotegi⁴, ¹BioCruces Health Research Institute, Barakaldo, Spain, ²Rheumatology Division, Hospital Universitario Cruces, Barakaldo, Spain, ³University of the Basque Country (UPV/EHU), Bilbao, Spain, ⁴Rheumatology Division, Cruces University Hospital, Barakaldo, Spain

Session Information

Session Date: Monday, October 22, 2018

Session Title: Metabolic and Crystal Arthropathies – Basic and Clinical Science Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Several metabolic disturbances that reduce the activity of pyrophosphatases have been associated with development of pyrophosphate arthritis (PPA), but there is scarce data on their influence of clinical manifestations, as such disease-specific variables are not recorded in most available databases. To evaluate factors associated to severity of clinical joint involvement in patients with definite PPA.

Methods: Transversal study with prospective recruitment of cases (patients con a PPA diagnosis confirmed by microscopy plus presence fox-ray chondrocalcinosis in at least one joint) and controls (patients with synovial effusion shown to have no PP crystals and no chondrocalcinosis in hands and knee X-rays, paired by age and gender). Patients with hemochromatosis or primary hyperparathyroidism were not included. [[Population general variables were included along with plausible metabolic variables (Ca, P, Mg, iPTH, iron saturation [satFe%], ferritin, diuretics and type of diuretic, and HFE genotype), and joint involvement distribution (mono-oligo-polyarticular) and clinical manifestations (acute PPA [A-PPA] and chronic inflammatory PPA [CI-PPA]), as in EULAR recommendations.

Results: 340 patients and 316 controls were recruited, 53% were men, age at inclusion was 67±10 yr (IQ range 62-75), time from onset of symptoms 5.2±5.3 yr (IQ range 1-8). Regarding cases, A-PPA was present in 147(43.2%), CI-PPA in 193 (56.8%), monoarticular joint distribution in 102 (30.0%), oligoarticular in 176 (51.8%), and polyarticular in 62 (18.2%). Patients showed higher serum ferritin levels and lower Mg levels than controls (253mcg/dl and 2.00 mg/dl vs. 204 mcg/dl and 2.08 mg/dl, respectively), along with higher rate of any HFE gene mutations (Odds 2.30, 95% CI 1.66-3.20). Genotypes including heterozygotic mutations for C282Y allele (CY), homozygotic of H63D allele (DD), and double heterozygotic for C282Y and H63D (CYHD) were statistically associated with higher frequency of polyarticular involvement and with CI-PPA (Figure). Nonetheless, only CY genotypes were associated with the most severe phenotypes when time from onset of symptoms was considered in analysis, also showing the highest sat Fe%.

Conclusion: Patients with definite PPA show differences in magnesium and iron parameters compared to controls, and may contribute, along with other factors, to development of PPA. Nevertheless, only presence of some HFE genotypes, especially CY, were associated with more severe pattern of clinical involvement.

Session Date: Monday, October 22, 2018

Session Title: Metabolic and Crystal Arthropathies – Basic and Clinical Science Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

INFLUENCE OF RENAL FUNCTION ON THE VELOCITY OF TOPHUS RESOLUTION AND ACHIEVEMENT OF DISEASE REMISSION IN PATIENTS WITH CHRONIC REFRACTORY GOUT TREATED WITH PEGLOTICASE

Background/Purpose: Impaired kidney function is a recognized comorbidity of gout,¹ but it is not known whether chronic kidney disease (CKD) alters the velocity of resolution of tophi or time required to achieve disease remission in response to pegloticase therapy in subjects with chronic refractory gout.

Methods: This analysis used results from two 6-month randomized controlled trials of pegloticase² in patients with chronic refractory gout to address these issues. Velocity of tophus resolution was determined in 18 subjects with chronic refractory gout and visible tophi who responded to pegloticase (8 mg every 2 weeks) with sustained serum urate reductions (<6 mg/dL) over 6 months. Achievement of remission³ was evaluated in all 34 such subjects who had persistent lowering of serum urate in response to biweekly pegloticase. eGFR was determined at baseline and after 3 and 6 months of treatment. Tophi were photographed and measured at baseline, 3, 4, 5, and 6 months.

Results: At baseline, the mean area of photographed tophi was 585.8 mm². The velocity of tophus resolution for all subjects was 60.1 mm² per month. There was no significant relationship between baseline eGFR and velocity of tophus resolution (P=0.5) (Figure 1A). In addition, there were no significant differences in the velocity of tophus resolution for patients with Stage 1 chronic kidney disease (CKD) vs Stage 2 CKD (P=0.7), Stage 3 CKD (P=0.9), or Stage 4 CKD (P=0.7). The relationship between baseline CKD severity and time to achieve remission is shown in Figure 1B. Here, 29/34 (85.3%) subjects with persistent urate lowering in response to pegloticase achieved remission. There were no significant differences in the achievement of remission in those with various stages of CKD determined by eGFR. Notably, there was no significant change in eGFR in response to pegloticase therapy through the 6-month duration of the study.

Conclusion: The results from this analysis indicate that renal impairment does not compromise the ability of pegloticase to resolve tophi rapidly in patients who respond with sustained reductions in serum urate. They also suggest that severity of renal disease does not influence achievement of remission in pegloticase-treated subjects with chronic refractory gout who have persistent urate lowering.

Session Information

Session Date: Monday, October 22, 2018

Session Title: Metabolic and Crystal Arthropathies – Basic and Clinical Science Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Gitelman syndrome (GS) is a rare recessively inherited tubulopathy, caused by inactive mutations in *SLC12A3* gene encoding the thiazide-sensitive-sodium-chloride transporter. It is characterized by an hypokaliemic metabolic alkalosis with hypomagnesemia and hypocalciuria. Calcium pyrophosphate (CPP) crystals deposition is frequently described in cases-report GS but its prevalence and clinical phenotype are unknown.

Aims: to describe clinical, biological and radiological features of CPP in a cohort of patients with genetically proven GS.

Methods: All patients (pts) with genetically proven GS in the French national reference center of rare diseases were proposed to have a consultation with a rheumatologic senior. Demographic data, history of joint pain and flare and biology disorders were recorded. Other causes of CPP disease were systematically ruled out. CPP crystal deposition was assessed by X-Ray (all peripheral joints and cervical spine) and ultrasonography (US) (wrists, knees, ankles and symptomatic joints). Patients with history of cervical pain underwent computed tomography (CT).

Results: Forty-eight GS pts (20 men, mean age 46.6± 12.2 years) have been examined by a rheumatologist. Majority had a mutation on *SLC12A3* gene. Forty pts experienced joint pain, 22 joint flare and 25 cervical pain. X-rays were performed in 40 pts, US in 34 and CT in 21. CPP depositions were observed in 34 (85.0%) pts, 26 (76.5%) and 15 (71.4%) by X-Ray,

US and CT, respectively. They occurred in knees (n=25), wrists (n=19), cervical spine (n=17), shoulders (n=11), feet (n=10) and Achilles' tendon or plantar fascia (n=11). CPP depositions were widespread involving at least 3 joints in 19 (55.9%) pts. In knees, CPP depositions involved meniscus (n=15), hyaline cartilages (n=8) and ligament or joint capsule (n=5). Cervical spine CT demonstrated CPP deposition in vertebral disc (n=12), transverse ligament (n=13), yellow ligament (n=6), vertebral facets (n=3) and temporo-mandibular joint (n=5). Pts with CPP crystal deposition were older (49.8 ± 11.1 vs 34.0 ± 10.0 , $p < 0.01$), more symptomatic and had lower magnesemia at consultation (0.60 ± 0.11 vs 0.75 ± 0.15 mM, $p = 0.029$). CPP crystal deposition remained statistically correlated to serum magnesium level after age-adjustment. It was not associated with potassium level.

Table 1. Patients characteristics depending on the presence of CCP on radiographies

	CCP+ (n=34)	CCP- (n=6)	p value
Male sex, n (%)	14 (41.2)	1 (16.7)	0,381
Age, \pm SD	49.8 ± 11.1	34.0 ± 10.0	$p < 0,01$
SLC12A3 mutation, n (%)			
heterozygous	5 (14.7)	0	0,569
homozygous	23 (67,6)	5 (83.3)	
Clinical features, n (%)			
joint pain	30 (88.2)	3 (50.0)	0,055
joint flare	21 (61.8)	0	$p < 0,01$
cervical pain	20 (58.8)	2 (33.3)	0,381
CCP crystal deposition, n (%)			
shoulder	11 (32.4)		
wrist	19 (55.9)		
symphysis	9 (26.5)		
knee	25 (73.5)		
foot	10 (29.4)		
cervical spine	17 (50)		
≥ 3 sites	19 (55.9)		
Calcemia, \pm SD (mM)	2.4 ± 1.0	2.5 ± 1.4	0,188
Kaliemia at GS diagnosis, \pm SD (mM)	3.2 ± 1.6	3.1 ± 1.7	0,967
Magnesemia, \pm SD (mM)	0.60 ± 0.1	0.75 ± 0.15	0.029

Conclusion: CPP crystal deposition occurred in more than 80% of patients with GS, was widespread and often symptomatic. Most affected sites are wrists, knees and cervical spine. CPP crystal deposition was associated with long-standing GS, older age and low serum magnesium level. Further studies are necessary to understand how GS favors CPP crystal deposition.

Initial Pegloticase Serum Levels Predict Persistent Responsiveness in Patients with Chronic Refractory Gout

Kenneth Saag¹, Mitchell Feinman², Herbert S. B. Baraf³, Roy Fleischmann⁴, Arthur Kavanaugh⁵ and Peter E. Lipsky⁶,
¹Division Clinical Immunology & Rheumatology, University of Alabama at Birmingham, Birmingham, AL, ²ACME Research, LLC, Orangeburg, SC, ³Arthritis and Rheumatism Associates, Wheaton, MD, ⁴Metropex Clinical Research Center, University of Texas Southwestern Medical Center, Dallas, TX, ⁵University of California, San Diego, School of Medicine, La Jolla, CA, ⁶AMPEL BioSolutions, Charlottesville, VA

Session Information

Session Date: Monday, October 22, 2018

Session Title: Metabolic and Crystal Arthropathies – Basic and Clinical Science Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Pegloticase is a pegylated recombinant mammalian uricase approved for treatment of persons with chronic gout refractory to standard urate lowering therapy¹. Despite an initial profound reduction of serum urate, some patients may lose the urate-lowering effect of pegloticase owing to the development of anti-drug antibodies². The TRIPLE trial was undertaken to determine whether an additional dose of 8 mg of pegloticase 1week after the initial dose and 1 week before the subsequent dose might be sufficient to maintain high serum pegloticase levels and contribute to the development of high-zone tolerance and a more persistent rate lowering effect.

Methods: TRIPLE is a multi-center, open-label trial enrolling subjects with chronic gout whose serum urate was not maintained at ≤ 6 mg/dL. Background urate lowering therapy was discontinued and subjects were treated with 3 weekly

doses of 8 mg pegloticase followed by biweekly administration of 8 mg of pegloticase for a total of 10 doses over 17 weeks. Serum urate was measured immediately before each dose and after the first administration, and continued dosing was only permitted if the serum urate was ≤ 6 mg/dL. Trough serum pegloticase levels were measured before each dose. Standard infusion prophylaxis and gout flare prophylaxis were required. The primary outcome was the maintenance of serum urate at ≤ 6 mg/dL throughout the treatment period.

Results: Results are available for 50 subjects. There were 22 responders (44%), 21 nonresponders (42%) and 7 subjects who dropped out (14%). Responders had significantly higher trough levels of pegloticase than nonresponders 1 week after the initial infusion (Figure) that persisted throughout the trial. Pegloticase levels at 1 week post infusion predicted responsiveness. Fourteen of 19 subjects (73.7%) with trough pegloticase levels >1.22 mg/mL at 1 week were responders to treatment whereas only 6 of 19 patients (31.6%) with trough levels ≤ 1.22 mg/mL at 1 week were responders (Chi-square test with continuity correction, $P=0.023$).

Conclusion: To date, the TRIPLE strategy of adding an additional tolerizing dose of pegloticase between the first and second biweekly administrations showed an overall response rate of 44%. Pegloticase serum levels after the initial dose may predict subsequent persistent responsiveness and provide guidance regarding adjustment/continuation of treatment.

Comparison of Urate Burden in Well and Poorly Controlled Gout Patients: A Dual-Energy CT Study

Min Kyung Chung¹, Hyeran Hyun², Ji Young Hwang² and Jisoo Lee¹, ¹Division of Rheumatology, Department of Internal Medicine, Ewha Womans University School of Medicine, Seoul, Korea, Republic of (South), ²Department of Radiology, Ewha Womans University School of Medicine, Seoul, Korea, Republic of (South)

Session Information

Session Date: Monday, October 22, 2018

Session Title: Metabolic and Crystal Arthropathies – Basic and Clinical Science Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Dual-energy computed tomography (DECT) allows sensitive and quantitative detection of monosodium urate (MSU) crystals in patients with gout. Although its usefulness in diagnosing gout is well defined, its role in monitoring changes of MSU depositions after urate lowering therapy (ULT) is unclear. The aim of our study was to investigate the difference in MSU deposition amount and pattern detected by DECT in well and poorly controlled gout patients.

Methods: DECT scans of feet and ankles were performed in 109 gout patients. Sixteen joints of ankles and feet, and achilles tendon insertion sites were evaluated for the presence of MSU deposition. The total volume of MSU deposition was quantified using an automated software program of DECT. Clinical, laboratory, and radiologic features were obtained at the time of DECT evaluation. Patients who maintained serum uric acid (sUA) level < 6.0 mg/dL for more than 6 months prior to DECT evaluation were considered 'well-controlled' and otherwise, 'poorly-controlled'.

Results: Twenty-five (22.9%) well-controlled patients were compared with 84 (77.1%) poorly-controlled. Well-controlled group showed mean sUA of 4.97 ± 0.84 mg/dL while poorly-controlled group showed mean sUA of 8.01 ± 1.78 mg/dL. Well-controlled group had significantly lower mean volume of MSU deposition compared with the poorly-controlled group (0.12 cm^3 vs 0.78 cm^3 , $p=0.001$), and had lower number of MSU deposition (2 vs 4, $p=0.002$). Although volume and number of MSU depositions were significantly decreased, MSU depositions were still detected in the well-controlled group. In well-controlled group, MSU depositions were less frequently detected in MTP and ankle joints compared with the poorly-controlled group, whereas frequency of MSU deposition was not significantly different in the Chopart joint and Achilles tendon sites.

Conclusion: Well-controlled gout patients showed significantly reduced urate burden. However, since MSU deposition does not completely resolve even in well-controlled patients, continuous ULT is recommended for optimal management of the gout patients.

Pretreatment and Coadministration with Methotrexate Improved Durability of Pegloticase (Krystexxa) Response: A Prospective, Proof-of-Concept, Case Series

John Botson¹ and Jeff Peterson², ¹Orthopedic Physicians Alaska, Anchorage, AK, ²Western Washington Arthritis Clinic, Bothell, WA

Session Information

Session Date: Monday, October 22, 2018

Session Title: Metabolic and Crystal Arthropathies – Basic and Clinical Science Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Pegloticase is a recombinant DNA-produced porcine-like uricase enzyme which metabolizes relatively insoluble urate to highly soluble allantoin. It is used in the treatment of refractory gout which has failed maximal medical management, typically with xanthine oxidase inhibitors (XOI). Studies have shown a complete responder rate of 42% when defined as repeat serum uric acid levels <6.0 mg/dL for $>80\%$ of the time during months 3 and 6 of treatment. Therefore 58% of patients failed to maintain repeat serum uric acid levels <6.0 mg/dL during this time period. The driving mechanism of this failure has been proposed to be driven by neutralizing antibodies. As is done in treatment of other rheumatologic diseases, coadministration of other medications could potentially temper the development of these neutralizing antibodies. The aim of the current study was to identify and quantify the improvement (as defined by maintenance of response) in patients treated with pegloticase for refractory gouty arthropathy.

Methods: In this prospective, proof-of-concept, case series, 8 patients with refractory tophaceous gouty arthropathy being started on treatment with pegloticase 8mg every 2 weeks were identified. Methotrexate 15mg orally once weekly and folic acid 1mg orally once daily was started one month prior to the initial administration of pegloticase and continued throughout the pegloticase treatment. Serum uric acid was measured every two weeks, prior to each subsequent infusion. At the completion of pegloticase treatment (or end of the observation period, June 1, 2018) the number and percentage of patients able to maintain a serum uric acid at goal <6.0 mg/dL was recorded. The primary objective was to evaluate the response rates in patients coadministered methotrexate vs. published response rates (known to be 42%) in those on pegloticase monotherapy between 3 and 6 months of treatment.

Results: Eight patients were identified, from 3 separate infusion centers. Seventy-three total pegloticase infusions were performed within the observation period, with 7 patients receiving at least 8 infusions (4 months) and 3 patients receiving at least 12 infusions (6 months). Of the 8 patients followed, 100% of patients were responders as defined by $>80\%$ of serum uric acid levels being maintained at goal <6.0 mg/dL during the observation period. Furthermore, there were only 2 patients who each had a single uric acid level above 6.0mg/dL (one following the second infusion and one following the third infusion) and both returned to goal <6.0 mg/dL on all subsequent infusions.

Conclusion: Pretreatment and coadministration with methotrexate 15 mg orally once weekly significantly reduced failure rates in pegloticase treated patients with chronic gouty arthropathy. Although additional studies would be needed to corroborate these results, these data support a potential paradigm shift in treatment of refractory gout with pegloticase.

Strong Impact of Dysfunctional Variants of ABCG2 on Hyperuricemia and Gout in Children and Adolescents

Blanka Stiburkova^{1,2}, Katerina Pavelcova^{1,3}, Marketa Pavlikova¹ and Karel Pavelka⁴, ¹Institute of Rheumatology, Prague, Czech Republic, ²Department of Pediatrics and Adolescent Medicine, Charles University and General University Hospital in Prague, First Faculty of Medicine, Prague, Czech Republic, ³Department of Rheumatology, First Faculty of Medicine, Charles University, Prague, Czech Republic, ⁴Na Slupi 4, Institute of Rheumatology, Prague, Czech Republic

Session Information

Session Date: Monday, October 22, 2018

Session Title: Metabolic and Crystal Arthropathies – Basic and Clinical Science Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Common dysfunctional variants of ABCG2, a high-capacity urate transporter gene, that result in decreased urate excretion, are major causes of hyperuricemia and gout. However, the association of ABCG2 variants in pediatric-onset hyperuricemia and gout is unknown. In the present study, we analyzed the *ABCG2* gene in a Czech hyperuricemia and gout cohort concentrating on patients with pediatric-onset before 18 years of age.

Methods: In total, 234 Caucasians suffering from hyperuricemia (N = 59) or primary gout (N = 175) were recruited, 31 with pediatric onset of the condition (18 hyperuricemia/13 gout); 115 normouricemic controls were used for comparison. Patients suffering from secondary gout and other purine metabolic disorders associated with pathological concentrations of serum uric acid were excluded. The pediatrics subjects were specifically screened for kidney and metabolic genetic disorders. We amplified, directly sequenced, and analyzed 15 *ABCG2* exons¹. Chi-square goodness-of-fit test was used to compare minor allele frequencies, log-rank test to compare empirical distribution functions.

Results: The analysis of *ABCG2* revealed two common nonsynonymous variants: rs2231137 (p.V12M) and rs2231142 (p.Q141K) and two rare nonsynonymous variants rs750972998 (p.K360del) and rs199854112 (p.T421A) in pediatric-onset subcohort. Seven of the 31 pediatric-onset patients were homozygous for p.Q141K and 11 were heterozygous. This makes the minor allele frequency (MAF) of p.Q141K 38.7 % compared to adult onset MAF = 21.2 % (OR = 2.4, P = 0.005), to normouricemic controls cohort MAF = 8.5 % (OR = 6.8, P < 0.0001) and Caucasian Central Europe population MAF = 9.4 % (OR = 5.7, P < 0.0001). One adolescent patient was compound heterozygous for p.Q141K and a rare variant p.K360del and one other patient was heterozygous for a rare p.T421A variant. Among the 31 pediatric-onset patients we have found 23 (74 %) that had affected family members (in 19 cases, 61 %, there were first degree relatives). This was more than twice than among adult onset individuals (31 %, P < 0.0001). Alternatively, while patients without family history of hyperuricemia/gout had median age of onset 47 years, patients with affected family members had median age of onset 28 years (P < 0.0001).

Conclusion: Our data showed, for the first time, that ABCG2 dysfunction is strong independent risk in pediatric-onset of hyperuricemia and gout where other factors appearing in adulthood, such as alcohol consumption, diuretic use and increase in BMI, may further increase the risk of developing gout. The extremely high frequency of dysfunctional variants of the ABCG2 transporter among the patients with pediatric-onset of hyperuricemia and gout should be kept in mind during differential diagnostic procedures and probably also in therapeutic approach.

Association between Musculoskeletal Ultrasonography and Bone Remodeling Markers and the Role of Ultrasonography on Monitoring Treatment Responsiveness in Patients with Gout and Hyperuricemia

Ya-dan Zou^{1,2}, Ya-nan Fei¹, Hui Gao³, Lin-feng Xie¹, Yu-chao Zhong¹ and Xuewu Zhang³, ¹Peking University People's Hospital, Beijing, China, ²Peking University International Hospital, Beijing, China, ³Department of Rheumatology and Immunology, Peking University People's Hospital, Beijing, China

Session Information

Session Date: Monday, October 22, 2018

Session Title: Metabolic and Crystal Arthropathies – Basic and Clinical Science Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Musculoskeletal ultrasonography (US) is an invasive method to identify gout related bone damage, while Dickkopf-1 (DKK-1) and receptor activator of nuclear factor- κ B ligand(RANKL)are bone remodeling factors associated with bone destruction. The association between bone remodeling factors and US is unknown and the role of ultrasonography in the evaluation of response to treatment needs to be further explored.

Methods: To evaluate the association between DKK-1, RANKL and US manifestations in patients with gout and hyperuricemia, and to clarify the role of ultrasonography on disease monitor and treatment responsiveness.

Results: (1) Gout patients were divided into three groups according to US manifestations: normal group, aggregates and/or double contour signs group, tophus and/or bone erosion group. Similarly, patients with hyperuricemia were classified into two groups: normal US group, abnormal US group (at least one of the following manifestations, i.e. aggregate, double contour signs, tophus or bone erosion). Levels of DKK-1 and RANKL of gout patients with US-evidenced aggregates and/or double contour signs was higher than that of normal US group. Gout patients with tophus and/or bone erosion had the highest levels of DKK-1 and RANKL ($P < 0.001$). (2)The levels of DKK-1 and RANKL in hyperuricemia patients with abnormal US were significantly higher than that of normal US hyperuricemia patients. (3) After one year ULT, US abnormalities disappeared in 12 gout patients and 8 hyperuricemia patients. Besides, the diameter of the largest tophus was shortened after treatment in patients with gout ($t=6.092$, $P<0.001$). Moreover, the concentrations of serum DKK-1 and RANKL significantly decreased after treatment for both gout and hyperuricemia patients. The lower the serum urate level was, the higher ratio of the normal US feature was in patients with gout and hyperuricemia. The levels of DKK-1 and RANKL, respectively, were positively correlated with the disease duration in both patients with gout ($r=0.430$, $P<0.001$; $r=0.359$, $P<0.001$) and hyperuricemia ($r=0.446$, $P<0.001$; $r=0.379$, $P<0.001$).

Conclusion: In patients with gout and hyperuricemia, musculoskeletal ultrasonography is remarkably associated with levels of DKK-1, RANKL, and ameliorates after ULT. Thus, US could be a useful tool on reflecting bone remodeling and monitoring disease responsiveness to treatment.

Immunosuppressant Use and Gout in the Prevalent Solid Organ Transplant Population

Andrew Milgroom¹, Mara Onita Lenco¹, Kevin Francis¹, Jeffrey D. Kent², Brian LaMoreaux³ and Brian F. Mandell⁴, ¹Trinity Partners, Waltham, MA, ²Medical Affairs, Horizon Pharma USA, Inc, Lake Forest, IL, ³Horizon Pharma USA, Inc, Lake Forest, IL, ⁴Rheumatology, Cleveland Clinic, Cleveland, OH

Session Information

Session Date: Monday, October 22, 2018

Session Title: Metabolic and Crystal Arthropathies – Basic and Clinical Science Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Gout is a frequent co-morbidity of solid organ transplant (SOT). Cyclosporine (CsA) is often cited as the main cause of gout in SOT, as other immunosuppressant (IS) regimens were associated with lower gout rates (e.g. 1980s studies of azathioprine monotherapy). In most guidelines & institutions, tacrolimus (TAC) has replaced CsA in SOT IS regimens. However, two questions are largely unknown: (1) to what degree is CsA still used among prevalent SOT patients? (2) Can CsA fully explain high rates of gout still seen among SOT patients? This retrospective patient claims data analysis was performed to evaluate IS use and gout in the prevalent SOT population.

Methods: IS regimens and gout prevalence among prevalent SOT patients were assessed via commercial claims data (IQVIA™ Real-World Data Adjudicated Claims – US). Definitions used were – SOT: claim with an SOT procedure code OR any claim with a history of SOT status code; IS: ≥ 1 claim for a given IS drug in the calendar year; Gout: ≥ 1 claim with any gout diagnosis code. IS use at time of transplant for 2016 recipients was obtained from the Organ Procurement and Transplantation Network (OPTN).

Results: The proportion of prevalent SOT patients on CsA declined from 2012 to 2016: heart 22% to 18%, kidney 21% to 17%, lung 16% to 11%, liver 15% to 12% (all $p < 0.01$). TAC use increased: heart 66% to 73%, kidney 67% to 74%, lung 75% to 80%, liver 77% to 82% (all $p < 0.01$). CsA use was higher in prevalent vs. incident SOT populations (e.g. 17% vs. 1.7% kidney 2016, $p < 0.0001$). 2016 gout prevalence was 16% vs. 8% among CsA vs. non-CsA patients. Among all SOT patients with gout, 69% and 26% were on TAC and CsA, respectively.

Conclusion: Despite declining CsA use, gout remains a problem in SOT patients. For one, this study finds that many prevalent SOT patients still receive CsA. Additionally, gout prevalence in the non-CsA population was much higher (8%) than established rates reported in the general population (e.g. 3.9%). This suggests CsA is not the sole driver of gout in SOT. In fact, this analysis finds that post SOT, more than twice as many gout sufferers are on TAC than on CsA. Physicians should be aware that with any transplant IS regimen including calcineurin inhibitors, gout is likely to remain a frequent co-morbidity of SOT.

Session Time: 9:00AM-11:00AM

Systemic inflammation and atherosclerosis in patients with gout. Results from the NOR-Gout study

Background/Purpose: The association between gout and cardiovascular disease (CVD) is well-known, whereas mechanisms behind this association are poorly understood. This study aimed to evaluate factors associated with asymptomatic carotid atherosclerosis in patients with gout.

Methods: In this prospective study patients with crystal-proven gout were included after recent disease flare, if the serum urate level was $>360 \mu\text{mol/L}$ ($>6 \text{ mg/dl}$). We analysed baseline data in patients without established CVD who were referred to a CVD risk evaluation, including ultrasound of the carotid arteries, blood pressure measurement and laboratory tests. Carotid atherosclerotic plaques were defined in the longitudinal view as protrusions into the lumen of $\geq 1.5 \text{ mm}$ or at least 2 times the adjacent intima-media thickness according to the Mannheim criteria.

Results: Of the 79 gout patients included, approximately 10% were females, and mean (SD) age was 52.1 ± 13.1 years. 32 (40.5%) had carotid plaques (Table). Only 9.3% were current smokers, while mean (SD) body mass index was high ($29.1 \pm 4.7 \text{ kg/m}^2$). Lipids were in the normal range, with a mean (SD) total cholesterol at $5.3 \pm 1.09 \text{ mmol/L}$ and low density lipoprotein cholesterol $3.12 \pm 0.95 \text{ mmol/L}$. Systolic blood pressure was in the normal range $134.0 \pm 15.1 \text{ mmHg}$, although 29.1% of the patients were treated with antihypertensive agents.

In univariate analyses, higher age, hypertension and higher erythrocyte sedimentation rate (as a marker of systemic inflammation) were significantly associated with the presence of carotid plaques ($p=0.01$ and $p=0.04$, respectively) (Figure). However, there were no statistically significant relations after adjusting for age, a strong predictor for development of atherosclerosis. Serum urate levels or disease duration were not associated with carotid plaques ($p=0.27$ and $p=0.44$, respectively).

Conclusion: Our results indicate an association between systemic inflammation and atherosclerosis in patients with gout. To be able to efficiently prevent CVD in this patient group, prospective studies with larger sample sizes are needed to elucidate the mechanisms behind the increased risk of CVD in gout patients.

Figure. Association between inflammation and atherosclerosis.

Table. Patients characteristics

	All	+carotid plaque	÷carotid plaque	p-value

Abstract Number: 1291

Efficacy and Safety of Anakinra in Congestive Heart Failure Patients, Including Lvad, with Acute Gouty Arthritis: A Retrospective Study of 36 Patients at an Academic Medical Center

Arash Hassantoufighi¹, Paloma Alejandro², Christopher E. Collins², Florina Constantinescu² and Juhi Bhargava³,

¹Rheumatology, MedStar Washington Hospital Center/Georgetown University Medical Center, Washington, DC,

²Rheumatology, MedStar Washington Hospital Center/Georgetown University Medical Center, Washington, DC, ³Internal Medicine, MedStar Washington Hospital Center/Georgetown University Medical Center, Washington, DC

Session Information**Session Date:** Monday, October 22, 2018**Session Title:** Metabolic and Crystal Arthropathies – Basic and Clinical Science Poster I**Session Type:** ACR Poster Session B**Session Time:** 9:00AM-11:00AM

Background/Purpose: Gout is the most common inflammatory arthritis worldwide and many patients with gout are 'complicated' by multiple comorbidities including metabolic syndrome, renal disease and congestive heart failure (CHF). Treatment of acute gout can be very challenging sometimes, especially in patients with CHF, including those managed with left ventricular assist devices (LVAD), as there are no guidelines or specific recommendations for the treatment of these patients. Due to concerns of LVAD infection, there is often hesitance to administer systemic corticosteroids, and drugs like NSAIDs are often contraindicated in these patients. Recent data has shown that interleukin (IL)-1 antagonism with anakinra is successful in improving acute gout symptoms in critically ill hospitalized patients with comorbid medical conditions. In this study, we aim to evaluate the efficacy and safety of anakinra for the treatment of acute gouty arthritis in a cohort of hospitalized CHF patients including those with LVAD placement.

Methods: We conducted a retrospective chart review of all patients who had a diagnosis of CHF and received inpatient anakinra for acute gouty arthritis over a three year period at an academic medical center. Data collected included demographics, use of LVAD, other medication use, and clinical response of gout to treatment. Patient's records were evaluated for up to a month post anakinra exposure for assessment of gout recurrence and adverse events.

Results: There were 36 hospitalized gouty patients identified, 6 were monoarticular and 30 polyarticular (26 men; mean age 64 ± 17 years, 10 women; mean age 70 ± 13) all of whom carried a CHF diagnosis (median EF 40-45%); 5 patients also had LVAD placement. The mean serum uric acid level was 8.9 (1.9-12.5) and the mean serum creatinine in the non-dialysis patients was 2.1 (0.8-4.8). 2 patients were ESRD and receiving hemodialysis. All patients received anakinra 100mg/d for 3 consecutive days for the management of an acute gouty flare. All patients were also noted to have contraindications to and/or failure of conventional acute gout therapies prior the selection of anakinra. Prior therapies primarily consisted of systemic corticosteroids. Most (35; 97%) patients demonstrated a good response ($>50\%$ improvement in pain as charted by the clinician) to anakinra within 3 days, with only one person who failed to demonstrate improvement in gouty arthritis symptoms. During the 1 month post observation period, 3 patients experienced a recurrence of gout flare. There was one death in a non-LVAD patient which was attributed to severe heart failure. There were no infections noted in the charts over a 1 month period of follow up for any patient who received anakinra.

Conclusion: Anakinra has been shown to be efficacious and safe for the management of acute gouty arthritis, and this study suggests that patients with CHF, including those with LVADs, and acute gout may also be an appropriate candidate population for IL-1 antagonist therapy. As this was a retrospective chart review, a more accurate assessment of safety and efficacy of anakinra in this group of patients warrants a larger prospective study.

Abstract Number: 1292

HLA-B*58:01 Genotype and the Risk of Allopurinol-Associated Severe Cutaneous Adverse Reactions in a Predominately Black or African American Population with Advanced Chronic Kidney Disease

Sarah Ford¹, Pamela Kimball¹, Gaurav Gupta¹ and Nehal Shah², ¹Virginia Commonwealth University, Richmond, VA, ²Medicine/Rheumatology, Virginia Commonwealth University, Richmond, VA

Session Information**Session Date:** Monday, October 22, 2018**Session Title:** Metabolic and Crystal Arthropathies – Basic and Clinical Science Poster I**Session Type:** ACR Poster Session B**Session Time:** 9:00AM-11:00AM

Background/Purpose: Allopurinol is the first line urate lowering drug used for treatment of gout. Its most feared side effect includes development of hypersensitivity drug reactions which may range from mild maculopapular eruption to life threatening severe cutaneous adverse reactions (SCARs) including drug rash with eosinophilia and systemic symptoms (DRESS), Stevens-Johnson Syndrome (SJS) and toxic epidermal necrolysis (TEN). HLA-B*58:01 is strongly associated with the development of allopurinol-associated SCARs in the Han Chinese, Thai and Korean populations. Interestingly, the association between HLA-B*58:01 and SCARs is not as strong in Japanese, European and Australian populations. This

suggests that this HLA association with allopurinol-induced SCARs varies with ethnicity. Studies in the United States have suggested that Asians and Blacks have substantially increased risk of allopurinol-associated SJS/TEN as compared to Whites and Hispanics which correlates with the allele frequency (7.4%, 4%, 1% and 1%, respectively). This study was conducted to evaluate the frequency of the HLA-B*58:01 allele and its possible relationship of allopurinol-associated SCARs in a predominately Black or African American population with advanced chronic kidney disease (CKD) undergoing evaluation for renal transplantation. Given that CKD is a risk factor for development of gout, this population of patients is at high risk for development of gout and thus for exposure to allopurinol.

Methods: All patients with advanced CKD undergoing evaluation for renal transplantation from 5/1/2012 to 8/2/2017 who were genotyped as part of the transplant evaluation within the inclusion period were included in the study and assessment was made of the presence or absence of the HLA-B58:01 allele. The entire cohort was assessed for the presence of a documented allergy to allopurinol.

Results: From 5/1/2012 to 8/2/2017, 2080 patients were assessed for renal transplantation and genotyped. Of these, 1355 (65%) were Black or African American, 587 (28%) were White, 42 (2%) were Asian. 92 patients were HLA-B*58:01 positive, 77 were HLA-B*58:02 positive and 42 were HLA-B58 positive, but the specific allele was not clear. Of the patients who were HLA-B*58:01 positive, 82 (89%) were Black or African American, 6 (6.5%) were White, 2 (2.2%) were Asian and 2 (2.2%) were another race. The prevalence of HLA-B*58:01 was 6% in this African American or Black population. Only one patient had allopurinol listed as a drug allergy with the reported reaction of DRESS. This patient was HLA-B*58:01 positive and was African American.

Conclusion: In this cohort of predominately African American patients undergoing evaluation for renal transplant, there was a higher frequency of the HLA-B*58:01 allele in the African American or Black population, however overall incidence of allopurinol-associated SCARs was uncommon. This suggests that despite the increased frequency of the HLA-B*58:01 allele in this population and its noted association with allopurinol-associated SCARs in other ethnicities, genetic testing for the HLA-B*58:01 allele prior to initiation of allopurinol therapy for gout is not warranted in the African American or Black population.

Session Title: Metabolic and Crystal Arthropathies – Basic and Clinical Science Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Early-onset or juvenile gout (EOG) without hypoxanthine-guanine phosphoribosyltransferase enzyme deficiency (*HPRT*, OMIM 300323) and not related to familial juvenile hyperuricemic nephropathy (*UMOD*, OMIM 300323) is a rare gout phenotype characterized by a first flare in adolescence or in young adulthood. While numerous genome wide association studies (GWAS) have been done in classical and late-onset gout, very few studies have been performed in EOG patients. Moreover, until now most genetic studies only assess association between pre-defined single nucleotide polymorphisms (SNP) and gout.

Our aim was to identify the genetic variants of clinically confirmed EOG by screening all exons of gout-associated genes with targeted Next-Generation Sequencing (NGS) approach

Methods: Twenty-six urate crystal-proven gout patients with first flare occurring before the age of 30 years were included. Gout history, comorbidities and patient characteristics were recorded. All participants provided written informed consent to genetic analysis. After DNA extraction from total blood samples, the NGS libraries were prepared with surselectQXT (Agilent) and sequencing was performed with miseq (Illumina).

The multigene panel included 80 genes described in GWAS and genes involved in rare diseases such as *HPRT* and *UMOD*.

Results: Twenty-six patients (24 men, 20 Caucasians, 5 Asians and 1 African) with crystal-proven gout had experienced their first flare at a mean age of 22.8 years [14-29]. Gout duration was 11.5 years [1-46] and clinical tophi observed in 9 patients. Mean age was 37.5 [24-69] years and mean body mass index 27.6 kg/m² [20.1-40.7]. Ten patients were overweight, 5 had obesity, 1 hypertension, 0 diabetes mellitus, 7 dyslipidemia and 10 chronic kidney disease stages 2-4. Mean serum urate level was 527 µmol/L [270-803]. Amongst 26 affected patients, 7 had a molecular anomaly (26.9%). Six patients harbored one rare or novel variant in *ABCG2* (three Caucasian patients), *ALDH16A1* (two Caucasian patients) and *SLC22A11* (one African patient). Two other patients (one Caucasian and one Asian) carried an association of variants in both *ABCG2* and *ALDH16A1*. All variants had a Minor Allele Frequency (MAF) below 0.3% or were never described in public databases. All variant were considered as probably pathogenic according to *in silico* predictive algorithms. Interestingly, the well-known p.Gln141Lys SNP of *ABCG2* was identified in 3 Asian patients (11.5%) at homozygous level.

Conclusion: Our finding of very rare and novel pathogenic variants in *ABCG2*, *ALDH16A1* and *SLC22A11* genes provides better insights of the molecular pathogenesis in early-onset juvenile gout. However, our results also highlight the involvement of yet undetermined genes in this population.

Session Information

Session Date: Monday, October 22, 2018

Session Title: Metabolic and Crystal Arthropathies – Basic and Clinical Science Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Pegylated uricases are therapies for treatment of severe chronic gout, particularly for rapid tophi resolution. However, uricases are limited by induction of anti-drug antibodies (ADA) that can compromise efficacy and safety. SEL-212 is a novel combination product consisting of pegadricase (also known as pegsiticase) co-administered with synthetic vaccine particles encapsulating rapamycin(SVP-R). We report initial data on gout flares from an ongoing Phase 2 study in symptomatic gout patients.

Gout is caused by deposition of monosodium urate (MSU) crystals in joints due to chronic hyperuricemia. Long term treatment focuses on reducing sUA levels, allowing MSU crystals to dissolve. Rapid dissolution of MSU crystals during initial phase of urate lowering therapy (ULT) is associated with an increased frequency of acute gout flares, which can

contribute to poor treatment compliance. During ULT initiation, colchicine, NSAIDs or corticosteroids are used for gout flare prophylaxis.

Methods: Patients with symptomatic gout (≥ 1 tophus, gout flare within 6 months or gouty arthropathy) and elevated serum uric acid (sUA) ≥ 6 mg/dL were treated with fixed doses of pegadricase (0.2 mg/kg or 0.4 mg/kg) alone or in combination with SVP-Rapamycin (0.05 to 0.15 mg/kg). SEL-212 was infused in 28-day cycles x3 doses followed by challenge with pegadricase alone on 28-day cycles x2 doses, or in 28-day cycles x5 combination doses off-Rapamycin and pegadricase. Safety, tolerability, sUA, and ADAs were monitored.

All randomized patients received colchicine (1.2 mg loading dose, 0.6 mg QD for the remainder of their participation in the trial) as premedication for gout flare prevention. If colchicine was contraindicated, patients received ibuprofen 600 mg TID or equivalent dose of aNSAID. If colchicine and NSAIDs were contraindicated, patients did not receive any premedication.

Results: As of 21 May 2018, demographics of the 140 treated patients were 32 - 75 years old (mean 54.9 years), male 90.7%, and white 67.1%. The mean BMI at baseline was 35.0 kg/m². 70.0% of patients were obese with mean duration of established or symptomatic gout as 10.8 years.

Flare incidence was 27.1% (months 1-3) and 10.2% (months 4-5), flare frequency was 0.41 flares/patient (months 1-3) and 0.14 flares/patient (months 4-5). Mean duration of the gout flares was 7.28 days, with majority of the gout flares (93.8%) being categorized as mild/moderate, with 6.1% (n=4 cases) noted as severe in intensity. Adjustments to gout flare prevention medication were not required for 43% of the patients. No gout flares resulted in a patient discontinuation or were reported as a serious adverse event.

Figure 1. Comparison of Gout Flare Incidence.

Conclusion: SEL-212 has been well-tolerated and lowers flares at the initiation of therapy relative to pegylated uricases alone, and the effect persists over the duration of therapy.

Anakinra Is More Effective at Reducing Pain from Acute Crystal Induced Arthritis When Compared to Conventional Therapy: A Retrospective Review at a Tertiary Care Center

Sukhraj Singh¹, Anthony Ocon², Vivek Mehta³, Samah Musa¹ and Ruben Peredo², ¹Internal Medicine, Albany Medical Center, Albany, NY, ²Medicine, Albany Medical Center, Albany, NY, ³Division of Rheumatology, Department of Medicine, Albany Medical College, Albany, NY

Session Information

Session Date: Monday, October 22, 2018

Session Title: Metabolic and Crystal Arthropathies – Basic and Clinical Science Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The management of Acute Crystal-Induced Arthritis (ACIA) relies on NSAIDs, colchicine, and glucocorticoids as conventional therapy. In presence of comorbidities (e.g. renal insufficiency, diabetes mellitus, etc.), conventional treatment may be challenging and may lead to poor hospital outcomes. The IL-1 receptor inhibitor anakinra has effectively treated diseases in which the inflammasome plays a main pathogenic role, including ACIA. We studied inpatients with ACIA receiving anakinra at Albany Medical Center compared to conventional therapy to determine differences in pain scores and length of stay.

Methods: Single center retrospective chart review of ACIA inpatients between January of 2016 and May 2018 was performed. Data collection included demographics, medications, comorbidities, and Visual Analog Pain Scale (VAS-pain). Response to treatment was defined as a decrease in VAS-pain by more than 2 points on a 0-10 scale at 24, 48, and 72 hours. A 1:2 case-control matched pairing (based on demographics, number of joints affected) were selected as controls from the conventional group. A total of 204 patients meeting ACR/EULAR criteria for ACIA were reviewed. Sixteen patients receiving anakinra for ACIA met selection criteria. Thirty-two patients with conventional treatment were matched

with the anakinra group. Repeated measures ANOVA was used to compare each group at each time-point of pain assessment. Tukey-Kramer multiple comparisons test was used for post-hoc comparisons.

Results: All the patients receiving anakinra had a good response, with statistically significant improvement in pain scores compared to the conventional group ($p < 0.001$). Within the anakinra group, pain was significantly improved at 24 hours ($p < 0.05$) and at 48 hours ($p < 0.001$) compared to baseline. The conventional therapy group had significant improvement at 48 hours compared to baseline ($p < 0.05$) but was not significantly improved at 24 hours ($p > 0.05$). Between groups, pain was not different at baseline or at 24 hours ($p > 0.05$) but was at 48 hours ($p < 0.001$). The average length of stay of patients on anakinra was nearly 2 days shorter in comparison to the conventional group. On average, 3.1 doses (95% CI 2.3 – 3.9) of Anakinra 100mg subcutaneously were required for pain relief. There were no significant adverse events noted.

Conclusion: Anakinra is an effective treatment for ACIA with faster resolution of symptoms compared to conventional therapy prompting a shortened length of stay. Anakinra may be a safe alternative for patients with contraindications to conventional treatment or who may be at high risk for complications from conventional treatment. Further evaluation of these findings in a prospective study may provide more information regarding a role of anakinra in management of ACIA.

Table 1. Patient Characteristics and Outcomes by Conventional Group versus Anakinra Group.

Variable	Conventional Group(n=32)	Anakinra Group (n =16)
PATIENT CHARACTERISTICS		
Age, Mean [95% CI]	63.9 [60.1 – 67.6]	69.0 [62.3 – 75.7]

Session Information

Session Date: Monday, October 22, 2018

Session Title: Metabolic and Crystal Arthropathies – Basic and Clinical Science Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: In most patients with gout, renal underexcretion of uric acid is the main mechanism for hyperuricemia. However, for the risk of uric acid kidney stone, uricosuric drugs are second-line treatment for hyperuricemia. It is also known that low urinary pH significantly increases the risk of uric acid crystallization and is strongly related with insulin resistance. Patients with gout frequently have metabolic syndrome, closely associated with insulin resistance. In this study, we describe a novel potent urate transporter 1 (URAT1) inhibitor, NC-2700, with pH-raising effect on low urinary pH.

Methods: HEK293 cells stably expressing URAT1 were treated with NC-2700, verinurad or lesinurad, and the inhibitory activity was determined by measuring the uptake of [¹⁴C]uric acid into the cells. To determine the selectivity of NC-2700 to URAT1, the effects on other transporters, including OAT1, OAT3 and ABCG2 were tested. The uricosuric effect and pH-raising effect of NC-2700 on low urinary pH were evaluated following single and/or multiple (once a day) doses in tufted capuchin monkeys and Zucker diabetic fatty rats (ZDF rats, type 2 diabetic model), respectively.

Results: NC-2700 inhibited URAT1 concentration-dependently with Ki value of 31.4 nmol/L. Inhibitory activity of NC-2700 against URAT1 was about 3-fold and roughly 1000-fold stronger than those of verinurad and lesinurad. In addition, NC-2700 showed high selectivity to URAT1 over other transporters. In *in vivo* studies, NC-2700 dose-dependently increased the fractional excretion of urinary uric acid in tufted capuchin monkeys and the effect of NC-2700 was great compared with verinurad. Moreover, unlike verinurad, NC-2700 raised urine pH levels lowered in ZDF rats to normal levels.

Conclusion: NC-2700 is a novel potent and highly selective URAT1 inhibitor, and has not just a great uricosuric effect compared with verinurad in monkeys, but also pH-raising effect on low urinary pH in ZDF rats. NC-2700 is a promising

Figure 1. Effects of NC-2700 and verinurad on low urinary pH in Zucker diabetic fatty rats, a model of type 2 diabetes

Risk of Dementia in Patients with Gout and the Impact of Urate-Lowering Therapies: A Large Population-Based Cohort Study

Louise Crowley, Alyshah Abdul Sultan, Edward Roddy, Christian Mallen, Joanne Protheroe and Lorna Clarkson, Research Institute for Primary Care and Health Sciences, Keele University, Keele, United Kingdom

Session Information

Session Date: Monday, October 22, 2018

Session Title: Metabolic and Crystal Arthropathies – Basic and Clinical Science Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Evidence is conflicting concerning dementia risk in gout patients, with hyperuricaemia proposed to exert a neuroprotective effect. Serum urate(sUA) targets guiding urate-lowering therapies (ULT) are poorly evidenced-based and there is a shifting consensus towards a more lenient target to attempt to balance the theoretical harmful effects of hypouricaemia. The aim of this study was two-fold; first, to estimate the risk of dementia among patients with gout, second, to assess the potential impact of ULT.

Methods: Retrospective population-based matched cohort study conducted using the Clinical Practice Research Datalink (CPRD), a large anonymized primary care database. Gout exposure was defined as a first entry of a medical code for gout (previously validated in CPRD with high accuracy (>90%))¹ between April 1998-February 2016. Each gout exposed patient was matched to 4 unexposed controls on age (± 5 years), gender, general practice and follow-up in CPRD (± 3 years). The absolute rate of dementia onset was calculated for gout exposed and unexposed and hazard ratios (HR) were modelled using Cox Proportional Hazards Regression. The analysis was stratified by dementia type (Alzheimer disease (AD), vascular dementia, other dementia types). Finally, among gout cases we assessed the impact of ULT on dementia onset. ULT exposure, defined as at least 6 month prescription, was assessed within 1 and 3 year exposure windows after gout diagnosis.

Results: Our cohort of 79,097 gout exposed and 276,808 unexposed had a median follow-up time of 5 years (interquartile range=6.2), mean age of 62 years (standard deviation=15.2) and 73% male. The absolute incidence rate of all-type dementia per 10,000 years was lower in the gout exposed cohort than the unexposed (35.6 (95% Confidence Interval (CI) 33.8 – 37.4) vs 40.7 (95% CI 39.8 – 41.7)) corresponding to a 17% lower risk (HR=0.83 95% CI 0.78 - 0.87) (Table 1). The incidence of AD and other dementia types was lower in the gout cohort, but nonvascular dementia (Table 1). Within gout cases, ULT exposure within 1 and 3 years after gout diagnosis did not significantly affect dementia risk after adjustment for potential confounders.

Table 1: Incidence rate of all-type dementia, Alzheimer's Disease and vascular dementia per 10,000 years and adjusted hazard ratios (HR) for gout-exposed vs unexposed with 95% confidence intervals (CI)

Variable	Gout Exposed		Unexposed		Adjusted*	
	Rate	95%CI	Rate	95% CI	HR	95% CI
All-type Dementia						
Overall	35.6	33.8, 37.4	40.7	39.8, 41.7	0.83	0.78, 0.87
Male	25.7	24.0, 27.5	30.0	29.0, 31.0	0.81	0.75, 0.87
Female	65.2	60.6, 70.2	72.6	70.0, 75.2	0.85	0.78, 0.93
Alzheimer's Disease						
Overall	9.4	8.5, 10.3	12.6	12.0, 13.1	0.74	0.66, 0.82
Male	6.7	5.9, 7.7	8.8	8.3, 9.4	0.74	0.64, 0.86
Female	17.5	15.1, 20.1	23.6	22.2, 25.1	0.74	0.63, 0.87
Vascular Dementia						
Overall	11.4	10.4, 12.4	11.0	10.5, 11.6	0.91	0.82, 1.00
Male	8.4	7.4, 9.4	8.9	8.4, 9.4	0.83	0.72, 0.95
Female	20.5	18.0, 23.4	17.3	16.1, 18.7	1.04	0.89, 1.21

*Adjusted for age, gender (only in overall analysis), Charlson Comorbidity Index, BMI, smoking and alcohol history

Conclusion: This provides observational evidence supporting the hypothesis that hyperuricaemia has a neuroprotective role, with gout patients having lower dementia risk. This risk was unaffected by ULT, but further studies are required to determine if this differs with longstanding ULT use, dose or magnitude of urate-lowering. This would help devise a more evidence-based sUA target for guiding gout management, which optimally balances a therapeutic target against the possible harmful effect of hypouricaemia.

Abstract Number: 1298

Gout and the Risk of Parkinson’s Disease in Older Adults: A Study of U.S. Medicare Data

Jasvinder A. Singh and John Cleveland, Rheumatology, University of Alabama at Birmingham, Birmingham, AL

Session Information

Session Date: Monday, October 22, 2018
Session Title: Metabolic and Crystal Arthropathies – Basic and Clinical Science Poster I
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: In the presence of limited available data, our objective was to assess the association of gout with the risk of incident Parkinson’s disease (PD) in older adults ≥65 years.

Methods: We used the 5% Medicare claims data from 2006-2012 for this cohort study. Gout was identified by the presence of two claims for gout at least 4 weeks apart, with International Classification of Diseases, ninth revision, common modification (ICD-9-CM) code of 274.xx. Study outcome was incident GCA, identified by two claims for PD with an ICD-9-CM code of 446.5, at least 4 weeks apart and an absence of PD claims in the baseline 365-day period, a valid approach. We used multivariable-adjusted Cox proportional hazard models to assess the association of gout with incident GCA, adjusting for potential confounders/covariates including demographics (age, race, gender), comorbidities (Charlson-Romano comorbidity index), and medications commonly used for cardiac diseases (statins, beta-blockers, diuretics, and angiotensin converting enzyme (ACE)-inhibitors) and gout (allopurinol and febuxostat; Model1).

Results: In a cohort of 1.72 million people, the mean age was 75 years (standard deviation [SD], 7.6), mean Charlson-Romano comorbidity index score was 1.60(SD, 2.39), 58% were female, 86% were White and 37% had Charlson-Romanocomorbidity index score of ≥2. Of these, 22,636 people developed incident PD during the study follow-up, 1,129 with gout and 21,507 without gout, with respective crude incidence rates of incident PD of 3.7 vs. 2.2 per 1,000person-years, respectively. Gout was associated with a higher risk of PD in the main analysis, 1.14 (95% CI, 1.07, 1.21). Sensitivity analyses confirmed main findings. No gender or race differences were noted, but the risk differed slightly by age; ages 65-75, 75-85 and >85 had hazard ratios of incident PD with gout of 1.27 (95% CI, 1.16, 1.39), 1.07 (95% CI, 0.97, 1.16) and 0.97 (95% CI, 0.79, 1.20), respectively (**Table 1**).

Conclusion: Gout was associated with a higher risk of incident PD in older adults. The risk of PD with gout was highest in the age group 65-75 years. Mechanisms of this increased risk need to be evaluated in future studies.

Table 1. Association of gout with Parkinson’s Disease, in pre-defined subgroup analyses, varying by age, gender and race

	Multivariable-adjusted (Model 1)		Multivariable-adjusted (Model 1)		Multivariable-adjusted (Model 1)	
	HR (95% CI)	P-value	HR (95% CI)	P-value	HR (95% CI)	P-value
Gout	65- <75 years 1.27 (1.16, 1.39)	<0.0001	75- <85 years 1.07 (0.97, 1.16)	0.17	≥85 years 0.97 (0.79, 1.20)	0.77
Gout	Female 1.17 (1.06, 1.30)	0.003	Male 1.11 (1.03, 1.20)	0.006

Session Date: Monday, October 22, 2018

Session Title: Metabolic and Crystal Arthropathies – Basic and Clinical Science Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

A novel recombinant oral urate oxidase (UrOx) ALLN-346 reduces severe hyperuricemia and normalizes hyperuricosuria in nephropathic UrOx knockout (*UrOxKO*) mice

Background/Purpose: Limitations in efficacy and/or tolerance of oral xanthine oxidase inhibitors, uricosurics, and intravenous uricase agents contribute to refractoriness to urate-lowering therapy (ULT) in gout. Renal excretion is the major route of uric acid elimination, but the gastrointestinal tract (GIT) plays an increasingly recognized role in urate homeostasis, especially in chronic kidney disease (CKD) where urate renal elimination is impaired. Here, we targeted gut elimination of urate *in vivo* with ALLN-346, an orally administered, engineered UrOx optimized for proteolytic stability in the GIT. We tested ALLN-346 in *UrOxKO* mice, with severe hyperuricemia, hyperuricosuria and uric acid crystalline obstructive nephropathy.

Methods: This was a parallel 21-day study of 3 periods (pre-treatment, treatment and follow up, each 7d) and 3 arms, ALLN-346 mixed with food (150 mg/day, n=8) compared to allopurinol (ALLO) doses of 150 mg/L (n=9) and 50 mg/L (n=8) supplemented in water. During the pre-treatment period, the maintenance dose of ALLO (150 mg/L) was removed. Plasma urate was measured in samples collected on the last day of each study period, and uric acid was measured in 24-hour urine samples collected during the last 3 days of pre-treatment and treatment periods (Cormay LiquickCor-UA 30 plus, PL).

Results: Hyperuricemia was reduced significantly ($p < 0.001$) and hyperuricosuria normalized with 7 days ALLN-346 oral therapy (Figure 1). On ALLN-346, mean (SEM) plasma urate decreased by 44% from pre-treatment (14.5 ± 0.9 to 8.1 ± 0.5 mg/dL), similar to 51% in the 50 mg ALLO group (13.2 ± 2.6 to 6.5 ± 1.1 mg/dL); $p = NS$. The highest reduction of 69% was in the ALLO 150 arm (13.8 ± 1.7 to 4.3 ± 0.6 mg/dL). Urine urate excretion normalized (< 2 mg/24h) with ALLN-346, mean (SEM) reduction was 86% (4.7 ± 0.6 to 0.7 ± 0.1 mg/24h); while in ALLO 50 and 150 arms reduction was 34% (4.9 ± 0.4 to 3.2 ± 0.3 mg/24h) and 66% (6.4 ± 0.7 to 2.2 ± 0.3 mg/24h) respectively. Removal of ALLN-346 or ALLO in follow up resulted in hyperuricemia returning to approximately pre-treatment levels. Analysis of chiefdom different GIT segments indicated the urate presence along the whole gut.

Conclusion: Novel targeting of enteric uric acid by oral ALLN-346 therapy successfully lowered serum urate and normalized urinary uric acid in nephropathic *UroXKO* mice. Enhanced elimination of urate via degradation in the GIT could be an effective addition to pharmacologic ULT and supports rationale for testing ALLN-346 in humans without and hyperuricemia, particularly in CKD.

Session Date: Monday, October 22, 2018

Session Title: Metabolic and Crystal Arthropathies – Basic and Clinical Science Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The metabolic syndrome (MS) is common among gout patients. The metabolic syndrome is diagnosed when a patient has at least 3 of the following 5 conditions: hyperglycemia, hypertension, hypertriglyceridemia, low high-density lipoprotein (HDL) cholesterol, abdominal obesity. Little is known about the relationship between the cumulative effects of all 5 MS conditions and the risk of mortality among adult patients with gout. The MS Severity Score (MSSS) is a validated summary score that accounts for the combined effects of all 5 metabolic features. Our goal was to use the MSSS to examine the overall associations between MS severity and the risk of mortality related to all-causes, cardiovascular disease and diabetes among United States (US) gout patients.

Methods: We analyzed mortality-linked data for 9,747 adults aged 20 to 74 years who participated in the Third National Health and Nutrition Examination Survey (NHANES III). Data from NHANES III were linked to national mortality records for all participants up to time of death or end of study (i.e. 23 years following initial recruitment). All 5 metabolic features were used to calculate gender-race/ethnicity specific MSSS Z-scores in gout patients. The calculated Z-scores are a continuous representation of all MS conditions while accounting for gender-race/ethnicity disparities. Cox proportional hazard models adjusting for age, marital status, gender, income, education, race, smoking, BMI, insurance, physical activity, alcohol intake and diet, were used to test the associations between MS severity and risk of mortality in gout patients. Complex survey methods with sampling weights, clusters and strata were applied to yield nationally representative prevalence and inference estimates.

Results: A total of 2,072 deaths were observed, of which 127 had gout. The prevalence amongst adults was 2.40% (95% CI; 1.93%-2.87%). Moderate to high MS severity was significantly prevalent among gout patients (47.33% vs. 21.16 % no gout; P-value <0.0001). The mean MSSS Z-score for gout patients was significantly higher than those without gout (0.71 vs. -0.04 no gout; P-value <0.0001). Among all patients, a one unit increase in MSSS score was associated with a higher risk of mortality in all adjusted models. For gout patients, a one-unit increase in MSSS score was associated with significant increase in the risk of all-cause mortality Adjusted Hazard Ratio (aHR) 1.46 (95% CI; 1.13, 1.87). In a disease-specific survival model, a one-unit increase in MSSS score was associated with 79% and 124% increases in cardiovascular and diabetes mortality risks, aHR 1.79 (95% CI; 1.20, 2.67) and 2.24 (95% CI; 1.21, 4.16), respectively.

Conclusion: Studies published to date have not accounted for the combined effects of all 5 MS features in gout patients. For gout patients, a one-unit increase in MSSS score was associated with significant increase in the risk of all-cause mortality and 79% and 124% increases in cardiovascular and diabetes mortality risks. The MSSS is a clinically accessible tool for predicting mortality risks in gout patients with the MS.

Organic Anion Transport Inhibitors Suppress Chondrocyte Pyrophosphate Production

Mohammed Faseehuiddin¹, Claudia Gohr², Elizabeth Mitton-Fitzgerald³ and Ann Rosenthal⁴, ¹Medicine/Rheumatology, Medical College of Wisconsin, Milwaukee, WI, ²Medicine, Medical College of Wisconsin, Milwaukee, WI, ³Rheumatology, Medical College of Wisconsin, Milwaukee, WI, ⁴Division of Rheumatology, Medical College of Wisconsin, Milwaukee, WI

Session Information

Session Date: Monday, October 22, 2018

Session Title: Metabolic and Crystal Arthropathies – Basic and Clinical Science Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Calcium pyrophosphate deposition (CPPD) disease results from articular calcium pyrophosphate deposition leading to arthritis. We currently lack specific and effective therapies for this commonly encountered entity. Prior studies have demonstrated excess pyrophosphate (PPi) production in the cartilage of patients with CPPD. Targeting the earliest phases of CPP crystal formation has the potential to reduce future joint damage and avoid inflammatory episodes. Previous studies demonstrated that probenecid reduced PPi production by chondrocytes. Probenecid is an organic anion transport inhibitor. It has some disadvantages in that it is highly insoluble in culture and may not achieve therapeutic levels in synovial fluids. In this project, we tested the ability of other FDA approved drugs that act as organic anion transport (OAT) inhibitors to suppress PPi levels in chondrocyte cultures.

Methods: Normal knee cartilage was obtained from mature pigs. Cartilage was enzymatically digested and chondrocytes were plated in high density serum-free culture conditions shown to preserve the chondrocyte phenotype. Chondrocytes were treated with various OAT inhibitors including diflunisal, ketoprofen, valsartan, telmisartan, and mefenamic acid at three separate concentrations for 72 hours. Media were collected and a luminescent PPi assay was utilized to measure PPi levels. PPi levels were corrected for cell protein and media LDH levels were used to assess for toxicity. Two of the OAT

Figure 1

A

Drug	PPi fold change	LDH (% control)
Diflunisal (500 μ M)	3.36 \pm 2.37	1.09 \pm 0.23
Ketoprofen (500 μ M)	2.46 \pm 1.04	0.68 \pm 0.30
Valsartan (50 μ M)	2.10 \pm 0.85	1.13 \pm 0.25
Telmisartan (50 μ M)	0.08 \pm 0.08	1.18 \pm 0.36
Mefenamic acid (200 μ M)	0.12 \pm 0.14	0.82 \pm 0.19

B

inhibitors, telmisartan and mefenamic acid, were further tested based on the initial results. Significant differences between groups were assessed utilizing a Kruskal-Wallis statistical test.

Results: Figure 1A summarizes average PPI changes and LDH levels in three experiments using the concentration of each drug that had the maximal effect on PPI. Of the 5 drugs tested, mefenamic acid and telmisartan displayed inhibition of PPI levels without causing toxicity. Figure 1B shows statistically significant suppression of PPI by mefenamic acid 200 μ M and telmisartan 50 μ M. (N=12 and $p < .01^{**}$, and $p < .001^{***}$)

Conclusion: We show here that PPI levels were decreased in the presence of two FDA-approved OAT inhibitors, mefenamic acid and telmisartan. These drugs show some promise in their ability to modulate PPI production, a process essential to CPP crystal formation. Further work will be needed to validate the clinical importance of this interesting finding.

Providence, RI

Session Information

Session Date: Monday, October 22, 2018

Session Title: Metabolic and Crystal Arthropathies – Basic and Clinical Science Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The Health and Human Services has declared the opioid epidemic as a public health emergency. It has been demonstrated that even short exposures to opioids could progress to episodic and ultimately long-term opioid use. Acute gout is among the most painful inflammatory arthritis. However, the burden of opioid use in acute gout has not been previously evaluated. Our aim was to assess the use of prescription opioids among patient discharged from the hospital with acute gout and factors associated with it.

Methods: Lifespan healthcare system, the largest in Rhode Island, comprises of 3 acute-care facilities with emergency departments (ED) and outpatient centers. Adult gout patients (greater than 18 years) discharged from the ED or inpatient facility were identified using ICD-9 and ICD-10 codes from the electronic health records. We included all patients seen between March 2015 and Sept. 2017. If a single patient was seen multiple times, only the first encounter was included. Outcome of interest was prescription opioid given at discharge from ED/inpatient stay. We collected information regarding patient demographics, comorbidities including history of chronic pain and substance abuse, prior to admission opioid use and time of presentation to ED. Information regarding single versus multiple joint involvement and severity of disease as assessed by the triage nurse on ED severity scale (1 being the most severe and 5 being least) was also abstracted. A multivariable logistic regression was used to assess factors associated with the use of prescription opiates at discharge from the hospital.

Results: A total of 456 patients (mean age 58.7 ± 16.4 years, 79% male) were treated for acute gout in the ED of which 11.2% were hospitalized. A total of 129 patients (28.3%) received prescription opioid at discharge. Of these, 102 (79%) patients were not on opioids at admission. In a multivariable model, diabetes [aOR 2.02 (1.13–3.59)], prescription opioid use at admission [aOR 2.1 (1.01–4.34)] and having a polyarticular gout attack [aOR 2.58 (1.33–4.99)] were associated with increased odds of prescription opioid use at discharge.

Conclusion: Despite the availability of effective treatments, opioids are commonly used for management of acute gout, even in patients who are not present on it at admission. Fear of steroid use in diabetics could have led to increased reliance on opioids. Similarly, polyarticular involvement led to increased use of opioids. The study highlights an opportunity to curb the opioid epidemic among acute gout patients.

Table 1. Baseline characteristics of the cohort.

		Opioids not used at discharge (n=327)	Opioids used at discharge (n=129)

Rituximab Versus Mycophenolate Mofetil in Interstitial Lung Disease Secondary to Connective Tissue Disease

Lisa Zhu¹, Shufeng Li², Laurence Gagne³, Susan Jacobs⁴, Julie Morisset³, Joshua Mooney⁵, Rishi Raj⁵ and Lorinda Chung⁶, ¹Stanford University Medical Center, Palo Alto, CA, ²Dermatology, Stanford University School of Medicine, Stanford, CA, ³Centre Hospitalier de l'Université de Montreal, Montreal, QC, Canada, ⁴Stanford University, Palo Alto, CA, ⁵Pulmonary and Critical Care, Stanford University Medical Center, Palo Alto, CA, ⁶Rheumatology, Stanford University Medical Center, Palo Alto, CA

Session Information

Session Date: Monday, October 22, 2018

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster II: Interstitial Lung Disease, Still's Disease, FMF, Polychondritis

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Interstitial lung disease (ILD) is a major cause of morbidity and mortality in connective tissue diseases (CTD). CTD-related ILD (CTD-ILD) has typically been treated with mycophenolate mofetil (MMF) and cyclophosphamide. B-cell depletion therapy with rituximab is increasingly being used in CTD-ILD based on the concept that B cells play a key role in the inflammatory process. The goal of this study was to compare the effect of rituximab versus MMF on pulmonary function in patients with CTD-ILD.

Methods: The study was conducted at two sites, Stanford and Centre Hospitalier de l'Université de Montreal. Retrospective chart review was performed on 83 subjects; the 15 patients in the treatment group received rituximab ± MMF (10/15 received both), and the 68 patients in the control group received MMF only. All had documented ILD and met validated classification criteria for a specific CTD, including systemic sclerosis (n=26), dermatomyositis/polymyositis (16), rheumatoid arthritis (15), Sjogren's syndrome (12), mixed connective tissue disease (8), and undifferentiated connective tissue disease (6). The difference in predicted forced vital capacity (FVC) and diffusion capacity of carbon

monoxide (DLCO) at baseline and after 6-12 months of therapy was compared between the treatment group and control group by Wilcoxon rank-sum test. Linear mixed models accounting for repeated measures assessed for changes in PFTs over time. Kaplan-Meier estimates compared survival between groups.

Results: There were no significant differences in age, gender, ethnicity, baseline FVC, presence of pulmonary hypertension, or concurrent use of other immunosuppressive medications. However ILD duration prior to treatment initiation was longer in the treatment group at 47 months (range 4-170 months) versus 6.5 months (range 0-164 months) in the control group ($p=0.0003$). Baseline DLCO was numerically lower in the treatment group at 51.5% (range 28-76%) versus 62.0% (range 27-116%, $p=0.058$) in the control group. Wilcoxon rank-sum testing revealed a 3.5% (range -11-21%) decrease in FVC in the treatment group compared to a 2.0% (range -14-25%) increase in the control group ($p=0.029$), and a 3.0% (range -10-12%) decrease in DLCO in the treatment group compared to a 4.5% (range -30-36%) increase in the control group ($p=0.046$).

Mixed model analysis controlling for ILD disease duration at treatment initiation, baseline DLCO, SSc vs. non-SSc, presence of pulmonary hypertension, and use of prednisone showed no significant difference in FVC between groups at 6 months (-1.77 (95% CI -10.25-6.72), $p=0.70$) and 1 year (-3.06 (95% CI -11.59-5.46), $p=0.48$). There was a non-significant decrease in DLCO in the treatment compared to control group at 6 months (-4.58 (95% CI -10.28-1.12), $p=0.11$), and a significant decrease at 1 year (-6.20 (95% CI -11.97--0.43), $p=0.04$). The all-cause mortality rate was 2/15 in the treatment group and 6/68 in the control group, with 1, 2, and 3 year survival rates of 100%, 100%, and 89% vs. 99%, 94%, and 92%, respectively ($p=0.45$).

Conclusion: Rituximab \pm MMF did not improve pulmonary function, but resulted in similar survival compared to MMF alone in a recalcitrant population of CTD-ILD.

Session Information

Session Date: Monday, October 22, 2018

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster II: Interstitial Lung Disease, Still's Disease, FMF, Polychondritis

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Interstitial lung disease (ILD) is a major cause of morbi-mortality in patients (pts) with CTD. Small studies have recently demonstrated a promising role for rituximab (RTX) in the treatment of CTD-ILD.

Methods: We conducted a retrospective multicenter study including CTD-ILD pts treated with RTX. ILD was based on high resolution CT (HRCT) and/or lung biopsy. Results of HRCT, pulmonary function tests (PFTs) and 6-minute walking test (6MWT) before and after RTX were collected and compared using Wilcoxon matched pair test.

Results: Forty-five pts were included (77.8% female, 62 ± 12.9 years (yrs) old at last follow-up and mean CTD duration of 12.8 ± 6.8 yrs). Eighteen pts (40%) were current/former smokers. Twenty-nine (64.4%) pts had RA, 4 (8.9%) primary SS, 3 (6.7%) SSc, 3 PM, 3 SLE, 1 (2.2%) DM, 1 anti synthetase syndrome and 1 overlap syndrome (SLE/SS). Among RA pts, 24 (82.8%) had positive RF and 28(96.6%) ACPA. ANA were positive in 26/44 pts (57.8%).

ILD was diagnosed after 4yrs [IQR 1-9.5] of CTD. Only 1 pt with overlap SLE/SS had ILD as a prior diagnosis. Non-specific interstitial pneumonia (NSIP) was present in 17 (37.8%) pts, usual interstitial pneumonia in 16 (35.6%),

Table 1

Revaluation	6-24 months	25-48 months	49-72 months
DLCO (n)	23	9	4
≥ 15% from baseline	19 (82.6%)	8 (88.9%)	3 (75%)
< 15% from baseline	4 (17.4%)	1 (11.1%)	1 (25%)
FVC (n)	32	11	5
≥ 10% from baseline	27 (84.4%)	11 (100%)	4 (80%)
< 10% from baseline	5 (15.6%)	0 (0%)	1 (20%)
HRCT (n)	25	9	4
Improvement/stabilization from baseline	22 (88%)	7 (77.8%)	4 (100%)
Worsening from baseline	3 (12%)	2 (22.2%)	0 (0%)

Legend: DLCO – gas transfer; FVC – forced vital capacity; HRCT - high resolution computed tomography

lymphocytic interstitial pneumonia in 2 (4.4%) and endogenous lipoid pneumonia in 1 (2.2%); 9 pts had unspecific ILD pattern in HRCT.

RTX was administered 1g twice, 2 weeks apart, with a median of 2 cycles [IQR 1-4]. Three pts received concomitantly AZA. Four pts were previously treated with CYC and/or MMF and/or AZA in association with steroids. The median interval between ILD diagnosis and first RTX administration was 1yr [IQR 0-4.5]. After 1yr on RTX there was a stabilization in gas transfer (+7.1%, p=0.15) and in forced vital capacity (+3%, p=0.49) in the whole group. At last follow-up (median 3yrs [IQR 1-6] after starting RTX), 30/31 pts (36.8%) had stabilized/improved dyspnea according to New York Heart Association criteria. Data on 6MWT were lacking for proper conclusions. Detailed responses to RTX are shown in table 1.

Thirteen (28.9%) pts stopped RTX, with infection being the main cause (4pts; none had hypogammaglobulinemia; 2 receiving concomitant LFN and 1 AZA). Infusion reaction, uncontrolled joint disease, suspected lung cancer and long-standing stable disease led to RTX suspension in 2 pts each. Five pts died, 2 yrs (IQR 1-5.25] after CTD diagnosis. One pt concomitantly treated with MTX died 1 week after the first RTX cycle due to chest infection; in the other pts the cause was unknown.

Conclusion: Our results reinforce the promising role of RTX in a wide range of CTD-ILD pts and demonstrate an association with long-standing disease stability, particularly in pts with NSIP (7/11 pts with FVC≥10% from baseline after more than 24 months on RTX had NSIP). Four pts suspended RTX and 1 died due to infection, making monitoring and prophylaxis (vaccines) of extreme importance, particularly in pts with underlying ILD.

Abstract Number: 1305

Risk of Progression of Interstitial Lung Disease with Autoimmune Features to a Systemic Autoimmune Rheumatic Disease

Michail Alevizos and Elana J. Bernstein, Rheumatology, Columbia University, New York, NY

Session Information

Session Date: Monday, October 22, 2018

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster II: Interstitial Lung Disease, Still's Disease, FMF, Polychondritis

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Approximately 15-25% of patients diagnosed with idiopathic interstitial lung disease (ILD) have some features of autoimmunity, yet do not meet classification criteria for a systemic autoimmune rheumatic disease (ARD). In 2015, the American Thoracic Society (ATS) and European Respiratory Society (ERS) proposed the term “interstitial pneumonia with autoimmune features” (IPAF) to describe these patients. The natural history of IPAF with regard to its potential progression to an ARD is largely unknown. The aim of this study was to compare the risk of progression to an ARD between patients with IPAF and those with idiopathic ILD without autoimmune features.

Methods: We performed a retrospective cohort study of patients with ILD who were evaluated at Columbia University Medical Center from 2009-2017. Data were extracted from the electronic medical record. Patients were identified using ICD-9 and ICD-10 codes for ILD. After excluding patients with ILD due to a secondary cause, the remaining patients

were labeled “idiopathic ILD” and were divided into 2 categories based on the ATS/ERS classification criteria for IPAF: (1) those who met IPAF criteria and (2) those who did not meet IPAF criteria at initial ILD diagnosis. We then determined the percentage of patients with idiopathic ILD who were diagnosed with an ARD by a rheumatologist in the follow up period. We performed multiple logistic regression modeling the presence of IPAF at initial ILD diagnosis as the independent binary variable and diagnosis of an ARD in the follow up period as the dependent binary variable, controlling for age, sex, smoking status and immunosuppressive therapy.

Results: Out of 650 patients with ILD who were screened, complete longitudinal data were available for 393 patients. Of these 393 patients, 225 had ILD due to a secondary cause (e.g., hypersensitivity pneumonitis, ARD, sarcoidosis) and 168 had idiopathic ILD at baseline. Of the 168 patients with idiopathic ILD, 48 met IPAF criteria at initial ILD diagnosis and 120 did not. Compared to patients without IPAF, those with IPAF were younger and a greater proportion (1) were female; (2) had positive autoantibodies; (3) had an NSIP pattern on HRCT; and (4) had pulmonary hypertension at initial ILD diagnosis. In the mean follow up period of 5.5 ± 3 years, 17% (8/48) of patients with IPAF were later diagnosed with an ARD compared to 2% (2/120) of patients without IPAF. In a multivariable model adjusted for age, sex, smoking status and immunosuppressive therapy, the odds of progressing to an ARD were 13 times higher in patients with IPAF than in those without IPAF (OR 13.3, 95% CI 1.3-130.5, p-value=0.03).

Conclusion: Among patients with idiopathic ILD, IPAF confers a significantly higher risk of progression to an ARD. Prospective studies are needed to further characterize the natural history of IPAF.

Clinical Characteristics and Treatment Patterns in Patients with Interstitial Pneumonia with Autoimmune Features (IPAF)

Giorgos Loizidis¹, Nikhil Jiwarajka², Colin Ligon³, Mary Porteous² and Michael D. George⁴, ¹Rheumatology, University of Pennsylvania, Philadelphia, PA, ²University of Pennsylvania, Philadelphia, PA, ³Internal Medicine, Rheumatology, University of Pennsylvania, Philadelphia, PA, ⁴Division of Rheumatology, University of Pennsylvania, Philadelphia, PA

Session Information

Session Date: Monday, October 22, 2018

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster II: Interstitial Lung Disease, Still's Disease, FMF, Polychondritis

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Interstitial pneumonia with autoimmune features (IPAF) has recently been defined to describe patients with interstitial lung disease (ILD) with certain clinical, serologic, and/or morphologic autoimmune characteristics who do not meet criteria for a specific CTD. It remains unclear, however, whether these patients have similar clinical presentations and prognoses to those with CTD-ILD. Our goal was to compare the characteristics of patients with IPAF to those with CTD-ILD, idiopathic pulmonary fibrosis (IPF), and IPF with positive autoantibodies.

Methods: We conducted a retrospective review of patients with ILD enrolled in a single-center, prospective pulmonary cohort from 2012-2017. All patients had undergone a comprehensive clinical, radiographic, and serologic evaluation with an ILD diagnosis established by a multidisciplinary panel including pulmonologists, a radiologist, and a pathologist. We reviewed medical records to collect additional information regarding patients' rheumatologic history at the time of their initial presentation to our center and identified patients with either: a) IPAF (meeting ≥ 2 of the published clinical, serologic, or morphologic criteria), b) CTD-ILD (meeting established criteria for a CTD) c) IPF without autoantibodies, or d) IPF with autoantibodies (not meeting criteria for IPAF). We compared clinical characteristics, imaging findings, baseline pulmonary function tests (PFTs), and treatment patterns between patients with IPAF and each of the other groups.

Results: We identified 46 patients with IPAF, 117 with CTD (including 33 RA, 31 SSc, 30 DM/PM, and 11 SS), 98 with IPF, and 37 with IPF with autoantibodies. IPAF and CTD-ILD patients were predominantly female and approximately 30% non-white, with similar rates of smoking, family history of autoimmunity, and baseline imaging characteristics (Table). Patients with IPF with or without antibodies were predominantly male and white, more likely to smoke, and less likely to have seen a rheumatologist. Baseline PFTs were similar across the groups. Treatment patterns during follow up were similar in patients with IPAF and CTD-ILD, with >50% receiving glucocorticoids and >30% receiving mycophenolate. A minority of patients with IPF with or without autoantibodies received glucocorticoids during follow-up and >25% of patients in both of these groups received pirfenidone.

Conclusion: Demographic and imaging characteristics were similar among patients with IPAF and CTD-ILD but quite different from those with IPF with or without autoantibodies, supporting the notion of a similar pathophysiology in IPAF and CTD-ILD. IPAF and CTD-ILD patients both commonly received immunosuppression; future work is needed to evaluate whether treatment response is similar in these population and whether immunosuppression can benefit patients with IPF with positive autoantibodies.

Session Information

Session Date: Monday, October 22, 2018

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster II: Interstitial Lung Disease, Still's Disease, FMF, Polychondritis

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The detection of autoantibodies plays a vital role in the diagnosis of occult connective tissue disease (CTD) in patients with interstitial lung disease (ILD), with major implications for prognosis and management. However, the prevalence and impact of autoantibodies in idiopathic interstitial pneumonia (IIP) and the newly defined research entity – interstitial pneumonia with autoimmune features (IPAF) whereby there are features suggestive but not diagnostic of an underlying CTD, is unclear.

Aim: Describe the prevalence of CTD autoantibodies in IIP, IPAF and connective tissue disease associated ILD (CTD-ILD).

Methods: Consecutive patients attending the Royal Prince Alfred Hospital ILD clinic (from 18 August 2016) were prospectively identified. Patients with IIP, IPAF and CTD-ILD defined by American Thoracic Society/European Respiratory Society, American College of Rheumatology (ACR), EULAR and complementary rheumatologic criteria were included. Extensive serological testing (ANA, ENA, SSA/Ro-60, Ro52, SSB/La, RNP, Scl70, Sm, centromere, PCNA, Ribosomal-P, SRP and myositis panel (Jo-1, PL-7, PL-12, EJ, OJ, Ku, Mi2, PMScl75, PM-Scl100)) was performed. All diagnoses were confirmed at ILD multidisciplinary meeting and rheumatology assessment if CTD-ILD or IPAF.

Results: 80 ILD patients (mean age 65 ± 10 (SD) years; 43% female; FVC% pred 74 ± 18 (SD); DLCO% pred 54 ± 17 (SD)) were included. 34 (43%) IIP, 22 (28%) CTD-ILD and 24 (48%) IPAF patients were identified. IIP and IPAF patients were older compared with CTD-ILD (mean age 70 and 65 vs. 57 years respectively; $p < 0.0005$ and 0.02). CTD-ILD and IPAF patients were more female predominant compared with IIP (68% and 54% vs. 21%, $p = 0.0006$ and 0.012). There was no difference in lung function parameters between ILD subgroups.

Table 1. Number of patients demonstrating autoantibodies by ILD subgroup

	IIP n=34	CTD-ILD n=22	IPAF n=24	TOTAL n=80
ANA $\geq 1:320$	2 (6)	9 (41) ^a	10 (42) ^a	21 (26)
Any ENA autoantibody	4 (12)	11 (50) ^a	8 (33)	23 (29)
SSA/Ro60/ Ro52	1 (3)	6 (27)	7 (29)	14 (18)
RNP	1 (3)	2 (9)	—	3 (4)
Scl-70	2 (6)	3 (14)	1 (4)	6 (8)
ACA	—	1 (5)	—	2 (3)
Ribosomal-P	1 (3)	—	—	1 (1)
Any myositis autoantibody	7 (21)	3 (14)	11 (46) ^b	21 (26)
Mi-2	1 (4)	—	1 (4)	2 (3)
Ku	2 (6)	1 (5)	1 (4)	4 (5)
PM-Scl100 and 75	3 (9)	1 (5)	5 (21)	9 (11)
Jo-1	2 (6)	—	1 (4)	3 (4)
PL-7 and PL-12	—	1 (5)	5 (21)	6 (8)
Anti-CCP and/or RF	—	3 (14)	3 (13)	6 (8)
dsDNA	—	1 (5)	1 (4)	2 (3)
Any Ab positive	12 (35)	13 (60)	21 (88) ^b	46 (58)

DATA are n(%). within ILD subgroup. ^a $p < 0.05$ compared with IIP. ^b $p < 0.05$ compared with IIP and CTD-ILD

At least one antibody was detectable in 46 (58%) of all patients, and most frequently in IPAF patients (88% vs. 35% IIP and 60% CTD-ILD, $p=0.0001$ and $p=0.04$ respectively). The prevalence of specific autoantibodies in each ILD subgroup is shown in Table 1.

IPAF and CTD-ILD patients were more likely to demonstrate ANA 1 1:320 compared with IIP (42% and 41% vs. 6%, $p=0.002$). CTD-ILD patients were more likely to demonstrate ENA versus IIP (50% vs. 12%, $p=0.004$). Myositis antibodies were most frequently demonstrated in IPAF compared with IIP and CTD-ILD (46% vs. 21% and 14%, $p=0.05$ and 0.026).

Conclusion: Autoimmune autoantibodies, including specific and myositis related, are frequently identified across ILD subtypes, including those without a defined autoimmune disease. Larger prospective studies are urgently required to validate the prevalence of autoantibodies in ILD, and determine the clinical implications for diagnosis, outcomes and management.

Session Information

Session Date: Monday, October 22, 2018

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster II: Interstitial Lung Disease, Still's Disease, FMF, Polychondritis

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Interstitial lung disease (ILD) is a fatal complication of connective tissue diseases (CTDs). Despite numerous advances in immunosuppressive agents, data on effective treatment for this challenging entity is limited. This study aims to evaluate the efficacy of rituximab (RTX) in patients with CTD-ILD and determine factors correlated with outcomes at 6, 12 and 24 months post-RTX.

Methods: We studied 47 patients with CTD-ILD, who met ACR classification criteria for a specific CTD. ILD was confirmed by high-resolution CT chest (HRCT) and pulmonary function tests with forced vital capacity (FVC) and diffusion capacity of lung for carbon monoxide (DLCO). We compared HRCT chest findings, %FVC and %DLCO at time of diagnosis and at 6, 12 and 24 months post-RTX. At diagnosis HRCT chest findings classified into 3 groups (mild, moderate, severe). At 6, 12 and 24 months after RTX, using the same semi-quantitative scoring system, HRCT chest findings were ranked as worsening, stable or improving.

Multiple patient characteristics (Table 1) were tested for their correlation with each outcome. For some variables, nonparametric statistical methods were used due to a small number of non-missing variables. The Spearman rank correlation and Wilcoxon signed rank test were used to determine % change in FVC and DLCO at 6, 12 and 24 months after RTX treatment.

Table 1.

% Change in	Mean±SD	# Missing	p-value ¹
FVC at 6 months	0.12±11.4%	23	0.66
FVC at 1 year	12.7±23.8%	32	0.08 ²
FVC at 2 years	-0.35±12.7%	32	0.91
DLCO at 6 months	1.5±10.6%	36	0.64
DLCO at 1 year	7.1±15.5%	35	0.18
DLCO at 2 years	6.9±13.8%	38	0.25

Characteristic / Outcome	Number (%) or Mean±SD	Number Missing
Gender:

Severe (3)	11 (23.4)	
HRCT at 6 months		20
Worsened	1 (3.7)	
Stabilized	21 (77.8)	
Improved	5 (18.5)	
HRCT at 1 year		28
Worsened (0)	1 (5.3)	
Stabilized (1)	16 (54.2)	
Improved (2)	2 (10.5)	
HRCT at 2 years		26
Worsened	0 (0)	
Stabilized	13 (61.9)	
Improved	8 (38.1)	
Age (years)	55.4±12.7	
CTD duration (years)	4.43±6.01	
ILD duration (years)	2.61±2.99	1
% FVC at diagnosis	64.7±22.9%	8
% FVC at 6 months	64.2±20.5%	20
% FVC at 1 year	71.7±29.3%	31
% FVC at 2 years	64.2±14.4%	25
% DLCO at diagnosis	45.6±14.9%	22
% DLCO at 6 months	48.7±16.8%	31
% DLCO at 1 year	52.2±16.3%	35
% DLCO at 2 years	55.2±19.3%	32
Number of drugs for PI ^a	1.4±1.0	

Results: Table 2.

1. Most patients were female and African American with median age of 60.
2. HRCT Chest findings after RTX showed either improvement or stability at 6, 12, 24 months (96.3%, 94.7%, and 100% respectively).
3. Given multiple missing variables, there was no statistical difference for changes in FVC and DLCO, however observed changes improved with the median %change ranging from 1 to 3.5. The largest changes were observed for FVC and DLCO at 1 year and DLCO at 2 years after treatment (12.7%, 7.1% and 6.9%, respectively) (table 2).
4. CTD duration showed negative correlation with FVC change at 1 year post-RTX with estimated 1.1% decrease in FVC for every year increase in CTD. ILD duration showed negative correlation with DLCO change at 2 years post-RTX with estimated 3.9% decrease in DLCO for every year increase in ILD.

Conclusion: RTX is an effective therapy for CTD-ILD. Our study suggests that using RTX earlier in the disease course may have long-term positive impact. RTX may help fill an unmet therapeutic need for CTD-ILD but larger randomized clinical trials are needed.

Session Information

Session Date: Monday, October 22, 2018

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster II: Interstitial Lung Disease, Still's Disease, FMF, Polychondritis

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: A particular subset of interstitial pneumonia, associated to one or more clinical and serological features, suggesting a possible underlying autoimmune disorder, has been described and recently named Interstitial Pneumonia with Autoimmune Features (IPAF). Its prevalence and prognosis remains controversial and seems to include a very heterogeneous population. Our objective was to evaluate patients with interstitial lung involvement seen at a university hospital in Latin America in order to determine IPAF frequency and characteristics.

Methods: All electronic medical records of patients seen by pneumonologists during a 1 year at our hospital because of an interstitial lung disease (ILD) were reviewed by a rheumatologist and a pneumonologist in conjunction. Patients were classified in 3 groups: Idiopathic Pulmonary Fibrosis (IPF), IPAF and Interstitial Pneumonia associated with a connective tissue disease (IP-CTD). Demographic and clinical data, images features, lung function tests, and survival were recorded. Patients' characteristics were compared between groups and a multivariate logistic regression analysis was performed in order to identify associations with an autoimmune ILD.

Results: 80 patients were seen in 1 year with ILD: 31 with IFP (38.8%), 3 with IPAF (3.8%) and 46 (57.5%) with IP-CTD. Patients' characteristics are shown in table 1. Rheumatologic diseases with IP-CTD were Lupus in 2 patients, Mixed Connective Tissue Disease in 6, Limited Systemic Sclerosis in 2, Diffuse Systemic Sclerosis in 19 and 1 Inflammatory Myopathy. During a median follow up of 4.8 years (IQR 3.8-6.9) after ILD diagnosis, 5 patients died (6.3%): 3 with IFP and 2 with IP-CTD. Gender, Age and Physiology score (GAP) was associated with mortality as it has been previously described (OR 1.76, 1.02-3.07). In patients with IFP, CT pattern was UIP in 41.9% (CI 25.7-60.1%) and NSIP in 35.5 % (CI 20.5-54.0%). On the other hand, patients with IP-CTD, NSIP was the most frequent pattern in 60.0% (CI 44.8-73.5%), and 24.4% (13.9-39.4%) had an UIP pattern. Although NSIP was more frequent in autoimmune related ILD, it was not independently associated to it. In the multivariable logistic regression analysis female sex (OR 10.5, CI 2.75-40.15) and a younger age (OR 0.94, CI 0.89-0.98) were associated with an autoimmune ILD diagnosis.

Conclusion: When evaluated together by a rheumatologist and a pneumonologist, IPAF diagnosis was very rare (3.8%). An autoimmune ILD disease must be suspected in females and younger patients.

Session Information

Session Date: Monday, October 22, 2018

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster II: Interstitial Lung Disease, Still's Disease, FMF, Polychondritis

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Interstitial Lung Disease (ILD) is a common manifestation of Connective Tissue Diseases (CTD), mainly Systemic sclerosis(SSc), Rheumatoid Arthritis and Idiopathic Inflammatory Myositis (IIM) spectrum diseases. New myositis specific (MSA) and associated (MAA) antibodies have shown to be useful in identifying underlying CTD in patients with ILD of unknown etiology. They have helped identifying diagnosis such as Anti-synthetase Syndrome (AS), MDA-5 associated IIM, overlap syndromes (OS) and Interstitial lung disease with autoimmune features (IPAF). Our purpose is to evaluate the diagnostic utility of the determination of MSA/MAA in a group of patients withheld of unknown etiology and clinical features suggestive of underlying CTD.

Methods: It is a descriptive study. Between January 2017 and March 2018, a commercially available myositis panel (16 antibodies, Immunoblot technique) was performed in 111 patients from a rheumo-pneumological clinic in the Instituto Nacional del Tórax in Santiago, Chile. All patients had confirmed ILD by high resolution chest tomography (HRCT) and clinical features suggestive of underlying CTD.

Results: Among 111 patients, 76 (72%) were female, and the average age was 51,5 +/- 12,9 y/o. All patients had confirmed ILD by high resolution chest tomography (HRCT). There were 56 (50,5%) positive patients for one or more antibodies of the panel; and 55 patients (49,5 %) were negative. Antibodies against Ro-52 were the most frequent (n= 35, 62,5 %), followed by PM/Scl-75 (n= 12, 21,4%); Ku (n=9, 16%) and PL-12 (n=7, 12,5%). AS was the most common final diagnosis (14 patients). Antibodies, final diagnosis and ILD patterns of the positive patients are detailed in Table 1. Final diagnosis of the 55 negative patients are detailed in Table2.

Conclusion: Myositis antibodies are useful in the study of patients with ILD of unknown etiology and clinical features suggestive of an underlying CTD. They can help establish a definite rheumatological diagnosis, and therefore offer the patient a proper treatment. We highlight the importance of Idiopathic inflammatory myopathies in this group of patients, mainly AS and MDA-5 myopathy. Our cohort shows low rate of Jo-1 because this antibody is widely available in our

A Multidisciplinary Cohort of Patients with Interstitial Pneumonia with Autoimmune Features

Gabriel Schroeder¹, April Barnado², Narender Annapureddy³, Rosemarie Dudenhofer⁴, Leslie Crofford² and Erin Wilfong⁵, ¹Internal Medicine, Vanderbilt University Medical Center, Nashville, TN, ²Division of Rheumatology and Immunology, Vanderbilt University Medical Center, Nashville, TN, ³Vanderbilt University Medical Center, Nashville, TN, ⁴Division of Allergy, Pulmonary, and Critical Care Medicine, Vanderbilt University Medical Center, Nashville, TN, ⁵Division of Rheumatology and Immunology, Vanderbilt University Medical Center, Nashville, TN

Session Information

Session Date: Monday, October 22, 2018

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster II: Interstitial Lung Disease, Still's Disease, FMF, Polychondritis

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Interstitial Lung Disease (ILD) remains a significant diagnostic and therapeutic challenge, especially for patients who do not meet criteria for a connective tissue disease (CTD) or idiopathic pulmonary fibrosis. In 2015, the ATS/ERS developed the classification criteria for Interstitial Pneumonia with Autoimmune Features (IPAF) to describe individuals with features of autoimmunity who do not meet classification criteria for a CTD. It is unknown whether these criteria identify patients who could benefit from immunosuppressive therapies, we aim to evaluate this in a prospective cohort of patients.

Methods: IRB approval for the MYSTIC cohort was obtained in 9/2017. Patients were identified in the Vanderbilt University pulmonary and rheumatology clinics; inpatients were referred by their treating providers. Clinical phenotyping was performed by chart abstraction, and biospecimens were banked for future study. Additional data on pulmonary outcomes (radiographic studies, pulmonary function tests, echocardiograms, 6 minute walk test, supplemental oxygen use) will be collected at 6 month intervals.

Multi-Compartment Involvement	
Pulmonary Hypertension	5 (17.2)
Other	1 (3.4)

Results: 29 patients meeting IPAF criteria were enrolled. The median age was 60, and 51.7% were female. 93% were evaluated by both pulmonologists and rheumatologists (table 1). Clinical criteria were present in 55.2%, serologic criteria in 100%, and morphologic criteria in 96.6% (table 2). The most common clinical features were Raynaud's phenomenon, inflammatory arthritis, and mechanic's hands. The vast majority of patients had a high resolution CT scan read as NSIP or "inconsistent with UIP"; only 3.4% had an HRCT scan consistent with UIP. 37.9% had an isolated positive ANA or rheumatoid factor, while 27.6% had anti-synthetase or anti-PM/Scl antibody.

Conclusion: IPAF undoubtedly encompasses a heterogeneous group of patients. Our cohort contains much less UIP than prior reports and has many patients with myositis associated antibodies. Additional work is needed to ascertain if (1) patients with myositis associated antibodies behave differently from patients with non-specific serologies and (2) whether these criteria identify patients who benefit from immunosuppression.

Abstract Number: 1312

Interstitial Pneumonia with Autoimmune Features (IPAF)-Nsis: Hurdles to Reclassification of Overlapping Ilds

Amaka Odonwodo¹ and Aman Pande², ¹Internal Medicine, Cleveland Clinic, Cleveland, OH, ²Pulmonary Medicine, Respiratory Institute, Cleveland Clinic, Cleveland, OH

Session Information

Session Date: Monday, October 22, 2018

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster II: Interstitial Lung Disease, Still's Disease, FMF, Polychondritis

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Interstitial lung disease (ILD) may occur in the presence of autoimmune elements without meeting criteria for a distinctive Connective Tissue Disease.

The European Respiratory Society/ American Thoracic Society proposed a term 'interstitial pneumonia with autoimmune features' (IPAF) to further classify these individuals based on a combination of features from three domains: clinical, serologic and pulmonary morphologic.

We sought to assess the incidence of IPAF previously classified as idiopathic interstitial pneumonia or ILD associated with undifferentiated connective tissue disease (UCTD). Hurdles in the reclassification process were also highlighted.

Methods: Our institution's pathology database was scanned for 10 years of surgical lung biopsy data. Patients with biopsy proven nonspecific interstitial pneumonia (NSIP) were studied. Their clinical and serologic data was collated. Cases with a prior diagnosis of idiopathic NSIP or ILD associated with UCTD were screened by the ERS/ATS criteria for IPAF and reclassified.

Results: 17 of 278 surgical lung biopsies performed from 2006 to 2016 for ILD were reported as NSIP. 41% of these NSIP cases were previously classified as idiopathic, 17.7 % as associated with UCTD and the remaining had established autoimmune etiologies for an ILD.

57% of the prior idiopathic cases were reclassified as IPAF and 100% of the prior UCTD were reclassified as IPAF. All cases met morphologic criteria (NSIP on lung biopsy), 57% had serologic criteria and 71% met clinical criteria. The serologic workup was incomplete in a few patients.

Conclusion: Previous diagnoses of UCTD-ILD and Idiopathic NSIP may be reclassified as IPAF. This will help promote future research to guide management of this unique population. It is important to stress the need for serologic work up of ILD patients, to enable complete assessment and appropriate classification of patients.

Clinical Features and Timing of Studies in Interstitial Lung Disease with Autoimmune Disease Features: Do Autoantibody Panels Improve Diagnostic Yields and/or Increase Costs?

Josephine Wright¹, Dorota Odrobina², Mary Beth Scholand¹, Anne E. Tebo³ and Tracy M. Frech⁴, ¹Internal Medicine, University of Utah, Salt Lake City, UT, ²Internal Medicine, Rheumatology, University of Utah, Salt Lake City, UT, ³Pathology, University of Utah, Salt Lake City, UT, ⁴Division of Rheumatology, University of Utah, Salt Lake City, UT

Session Information

Session Date: Monday, October 22, 2018

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster II: Interstitial Lung Disease, Still's Disease, FMF, Polychondritis

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The entity of interstitial lung disease with autoimmune disease features (ILD-AF) is increasingly gaining traction as condition that is best co-managed by pulmonologists and rheumatologists. In September 2016, our institution initiated a comprehensive ILD auto-antibody panel, including ANA, RF, CCP, Jo-1, PL-7, PL-12, EJ, OJ, SRP, MDA5, NXP2, Ku, PMSCL, U1RNP, and Scl-70 to assist in the diagnosis of ILD-AF. We compared the number of additional diagnostic studies ordered in patients that had an autoantibody panel ordered to determine if autoantibody panels improve diagnostic yields and/or increase costs.

Methods: In patients that had an autoantibody panel, we assessed whether the test resulted in hand radiographs (XR), creatinine kinase (CK), aldolase, electromyogram(EMG), muscle magnetic resonance imaging (MRI), capillaroscopy, age appropriate cancer screening, and whether a CTD or ILD-AF diagnosis was subsequently given by a comprehensive chart review. We compared the number of tests ordered when panel was positive versus negative by frequency (descriptive statistics). This project was IRB approved.

Results: In the course of 18 months, 170 comprehensive autoantibody panels were ordered. Of these, 100 patients (59%) had at least one positive autoantibody test. As expected both groups had the same number of HRCT chest, but the frequency of tests subsequently ordered after a positive vs. negative autoantibody panel are described in Table 1. A diagnosis of CTD or ILD-AF was given in 26% of patients with at least one positive autoantibody test identified on these panels, compared to 3% of patients with negative panels.

Conclusion: In a single center cohort retrospective analysis, positive auto-antibodies identified on ILD-AF panels resulted in more creatine kinase levels, aldolase levels, hand radiographs, and muscle MRIs, but was also more likely to result in a diagnosis of CTD or ILD-AF. In conclusion, a positive auto-antibody panel appears to increase costs by number of tests ordered, but also improves diagnostic yields. The role of capillaroscopy in ILD-AF diagnosis may be important.

Table 1. Tests and diagnostic yield in patients with ILD autoantibody panel.

	CK	Aldolase	Hand XR	Muscle MRI	EMG	Cancer Screening	Capillaroscopy	Diagnosis of CTD or ILD-AF
Positive Panel	0.34	0.24	0.09	0.07	0.12	0.13	0.07	0.26
Negative Panel	0.15	0.07	0.02	0.02	0.18	0.22	0	0.03

Autoantibodies and Clinical Outcomes in Pulmonary Arterial Hypertension Associated with Connective Tissue Diseases

Yuko Shiota¹, Tomonori Ishii², Tsuyoshi Shirai¹, Hiroshi Fujii¹ and Hideo Harigae¹, ¹Department of Hematology and Rheumatology, Tohoku University Graduate School of Medicine, Sendai, Japan, ²Clinical Research, Innovation and Education Center, Tohoku University Hospital, Sendai, Japan

Session Information

Session Date: Monday, October 22, 2018

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster II: Interstitial Lung Disease, Still's Disease, FMF, Polychondritis

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Pulmonary arterial hypertension (PAH) associated with SSc (SSc-PAH) has a substantially worse prognosis as compared to other connective tissue diseases(CTD)-PAH. Although SSc-PAH are generally treated with pulmonary vasodilators, they could be additionally considered with intensive immunosuppressive therapies (IIT), if overlapping inflammatory autoimmune diseases such as SS and SLE. However, it has not been known their outcome. We assessed the detailed autoantibodies and discriminative clinical symptoms and followed up their outcomes.

Methods: This retrospective study included 50 PAH patients associated with SSc (n=17), SLE (n=18), primary SS (n=8), and MCTD (n=7) referred to our hospital between 2000 and 2018. We performed right-heart catheterization and PAH defined as mean pulmonary arterial pressure (mPAP) ≥ 25 mmHg and the pulmonary arterial wedge pressure (PCWP) ≤ 15 mmHg at rest. We obtained their serum and determined autoantibodies against cytoplasmic and cell-nuclear antigens, including centromere, Scl-70, RNA-polymerase III, centriole, NuMA1, RNP, Sm, SSA/Ro, SSA/Ro52, SSB, PM-Scl, fibrillarin, Th/To, Ku, dsDNA, nucleosomes, histones, ribosomal P-proteins. We treated all patients with pulmonary

Figure. Cumulative survival rate of SSc-PAH subgroup

vasodilators, and additionally treated with IIT, including cyclophosphamide (IVCY500mg/month x 10 times) and steroid (prednisolone 1mg/kg for 4 weeks and tapered to 5-10mg) for most of SLE, pSS, and MCTD, and some of SSc overlapping inflammatory autoimmune symptoms. Survival analysis was performed using the Kaplan-Meier method, and cumulative survival rates were compared by log-rank tests.

Results: In terms of SSc, we divided into three groups because those were different outcomes, which were (1) overlapping SS diagnosed by ACR criteria (n=7), (2) with centriole antibodies(n=3), or (3) without SS/ centriole antibody(n=7). We treated some severe PAH with SS overlapping SS by IVCY with half dose steroid (0.5mg/kg) and PAH improved. All of centriole-SSc had discriminative digital ulcer. The one of them had quite severe ulcer and IVCY was remarkably effective for both ulcer and PAH, then treated in the same way for others. There was significantly worse cumulative survival rate in SSc than in SLE, pSS. In terms of SSc subgroup, there was a trend towards a better survival rate in centriole and overlapping SS than in other SSc (Figure). Th/To, which was one of the marker of lcSSc, existed in two patients although the one did not have scleroderma. Ribosomal P antibody existed in 4 patients, however, 3 of them did not have any neuro-psychiatric-SLE symptoms.

Conclusion: Although SSc-PAH has a substantially poor prognosis, we found that SSc overlapping SS and centriole type SSc-PAH might have better outcome than other SSc associated PAH and we could consider IIT for them. However, we should consider the risk of renal crisis, digestive symptoms other life-threatening symptoms before utilizing IIT for SSc.

Abstract Number: 1315

Japanese Relapsing Polychondritis Patients with Airway Involvement Were Mutually Exclusive with Those with Ear Involvement in the Clinical Characteristics

Jun Shimizu¹ and Noboru Suzuki², ¹Department of Immunology and Medicine, St. Marianna University School of Medicine, Kawasaki, Japan, ²Department of Immunology and medicine, St. Marianna University School of Medicine, Kawasaki-shi, 216-8511, Japan

Session Information

Session Date: Monday, October 22, 2018

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster II: Interstitial Lung Disease, Still's Disease, FMF, Polychondritis

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Relapsing polychondritis (RP) is a multisystem disorder of cartilaginous tissues. We previously found that, in a Japanese cohort study, RP patients with airway involvement and RP patients with external ear involvement were mutually exclusive in the clinical characteristics, suggesting an inverse relationship between airway involvement and ear involvement (Arthritis Rheumatol. 2018; 70: 148–9.). Here, we divided the patients into two subgroups by the patterns of clinical manifestations, namely a subgroup of patients with airway involvement (A subgroup) and those with ear involvement (E subgroup) and investigated the clinical and laboratory characteristics of each subgroup.

Methods: After categorizing 239 Japanese patients into two (A and E) subgroups, we compared patients' profiles, clinical features, laboratory findings, medicines, and prognosis using dummy variables and the Student's t-test. The presence and absence of these clinical and laboratory parameters formed dummy variables, 1 and 0, respectively. We measured serum matrix metalloproteinase-3 (MMP3) concentrations and anti-type II collagen antibody titers, disease-related biomarkers, of 26 samples obtained from 22 newly recruited RP patients.

Results: In Japanese RP patients, 47 patients (19.7%) and 118 patients (49.4%) were allocated to the A and E subgroups, respectively. In a comparison of the clinical data between the two subgroups, saddle nose deformity and progressive disease course were observed frequently in the A subgroup. Joint, eye, and CNS involvement were observed frequently in the E subgroup. The remaining RP patients formed the third subgroup (75 patients, 31.4%) and had both airway and ear involvement (termed as B subgroup). Disease duration of the B subgroup (5.70 ± 0.64 years) was significantly longer than that of the E subgroup (4.12 ± 0.45 years). We found that cardiovascular involvement was more predominant in the B subgroup than in the A and E subgroups. High concentrations of serum MMP3 were observed frequently in the B subgroup compared with A and E subgroups. In a new cohort of 26 serum samples, MMP3 concentrations were significantly higher in the B subgroup (n=10) than those in the A subgroup (n=6) and E subgroup (n=10).

Conclusion: RP patients in the A and E subgroups exhibited different characteristics from each other. Progressive disease course and CNS involvement were observed frequently in the A and E subgroups, respectively, in Japanese patients with RP. We did not observed cardiovascular involvement in the A subgroup of the RP patients.

Respiratory Involvement in Relapsing Polychondritis – a Single Centre Study

Catherine D Hughes¹, Begona Lopez Garcia¹, CheeKen Cheah¹, Yih Jia Poh², Shirish Sangle¹ and David D'Cruz³, ¹Louise Coote Lupus Unit, Guy's and St Thomas' Hospital, London, United Kingdom, ²Department of Rheumatology and Immunology, Singapore General Hospital, Singapore, Singapore, ³Louise Coote Lupus Unit, Guy's and St. Thomas' Hospital, London, United Kingdom

Session Information

Session Date: Monday, October 22, 2018

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster II: Interstitial Lung Disease, Still's Disease, FMF, Polychondritis

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Relapsing Polychondritis (RP) is a rare immune mediated inflammatory disorder that may result in destruction of cartilaginous tissues. Diagnostic delay is common due to its heterogeneous clinical spectrum and its rarity. RP is most commonly seen in Caucasians. Pulmonary manifestations are common and are associated with significant morbidity and mortality.

Methods: We completed a retrospective data analysis of patients attending the Louise Coote Lupus Unit with a clinical diagnosis of RP, focusing on those with respiratory involvement. We used McAdams classification criteria. All patients had lung function tests, high resolution CT scan imaging and bronchoscopy / laryngoscopy wherever necessary along with inflammatory markers and serology to rule out other diseases such as ANCA vasculitis.

Results: We identified 57 patients with a diagnosis of RP, with respiratory involvement in 23 patients (40%) (14 female and 9 male). 18 patients (78%) were Caucasian, 3 (13%) Afro Caribbean and 2 (9%) Asian. Sixteen (70%) patients presented with respiratory symptoms ranging from asthma like illness to the need for emergency tracheostomy. Median age at the symptom onset varying from 18-70 (median age of 41). There was a mean delay in diagnosis of 82 months. 32/57 patients fulfilled McAdams classification criteria. The other 25 patients had clinical presentations compatible with a diagnosis of RP.

Median ESR was 10 (5-70) mm per hour and CRP was 6 (1- 110)mg/l. : Respiratory complications: 6 patients had tracheomalacia, 5 had tracheal stenosis +/- thickening, 8 had tracheal and bronchial collapse +/-stents and 2 had an emergency tracheostomy.

Most patients were on a combination of oral prednisolone and disease modifying anti-rheumatic drugs.

Four patients received biologics. One received rituximab, two Infliximab and one adalimumab. Two patients did not respond to treatment (rituximab and infliximab). The remaining two patients had a good response.

Five patients required CPAP to maintain airways patency due to respiratory collapse.

Number of other organ involvement: 7/23 eyes 12/23 ears, 7/23 nose, 17/23 airways, 14/23 chest wall/joints

One patient had 5 organ involvement, three had 4 organ involvement, six had 3 organ involvement, nine patients had 2 organ involvement and four patients had only respiratory involvement.

Conclusion: Pulmonary involvement in RP may cause significant morbidity and mortality due to organ damage. All RP patients should be evaluated for pulmonary involvement and early detection may help to prevent the damage. Immunosuppressive agents should be considered as soon as the diagnosis of RP with respiratory involvement is established. The role of biologic therapies in treatment resistant patients is uncertain.

Pulmonary complications in RP.

Tracheomalacia in Coventry in UK

Grace Pink¹, Shirish Dubey², Asad Ali¹, Joanna Shakespeare³, Chris Taylor¹ and Colin Gelder⁴, ¹Respiratory medicine, University Hospital Coventry and Warwickshire NHS Trust, Coventry, United Kingdom, ²Rheumatology, University Hospital Coventry and Warwickshire NHS Trust, Coventry, United Kingdom, ³Respiratory Physiology, University Hospital Coventry and Warwickshire NHS Trust, Coventry, United Kingdom, ⁴University Hospital Coventry and Warwickshire NHS Trust, Coventry, United Kingdom

Session Information

Session Date: Monday, October 22, 2018

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster II: Interstitial Lung Disease, Still's Disease, FMF, Polychondritis

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Tracheomalacia (TM) is pathological diffuse or segmental narrowing of the tracheal lumen, caused by softening of the supporting cartilage and reduction in stiffness of the walls. If the weakness extends to the right or left main bronchi then it is termed tracheobronchomalacia (TBM). Tracheomalacia can occur due to relapsing polychondritis, other etiologies include mechanical compression due to intubation or goitre. Although there have been a number of descriptions of TBM, it has not been recognised as an entity in itself. We present here a series of patients who have TBM without an alternative diagnosis to explain TBM.

Methods: These patients were identified from the TBM database. Patients were identified from rheumatology or respiratory clinics or from acute admissions with severe breathing difficulties and found to have TBM. The TBM database was set up in 2017, although the first patient was diagnosed in 2013. Patients who were initially labelled as TBM and subsequently found to have RP or another explanation for TBM were excluded from this study.

Results: We found 25 patients who had TBM, of these mechanical causes were found in only 1 patient. The diagnosis was established through inspiratory and expiratory CT scans and/or bronchoscopy in most patients and supported with pulmonary function testing which suggested large airway obstruction (intrathoracic) for the majority of patients. Patients often had symptoms for a number of years prior. A number of patients had previous CT scans which had shown evidence of TBM, this was either missed or ignored. 15 patients were treated with immunosuppression, and most of them had extremely good response to immunosuppression. These have been labelled as 'inflammatory tracheobronchomalacia' as there is no alternative label for these patients. Drugs used in these patients include steroids (IV and oral), Methotrexate, Azathioprine, Mycophenolate and Rituximab. All patients have noticed very significant results with steroids, 9 patients have not been given immunosuppression currently. CPAP has been tried in 7 patients, only 1 patient struggled to tolerate

this. In one patient, tracheobronchomalacia evolved into relapsing polychondritis, suggesting that TBM could be a 'forme fruste' of an inflammatory condition.

Death has occurred in 6 patients who have been treated with immunosuppression and 2 patients who has not been treated with immunosuppression.

Conclusion: Tracheobronchomalacia is a relatively common condition with high mortality, which is not very well characterised. Optimal management strategies are yet to be defined.

This is the first report for 'inflammatory tracheobronchomalacia' suggesting that immunosuppression might have a significant role in management of TBM.

Clinical Utility of Ultrasonography (US) in Diagnosing and Monitoring Disease Activity of Relapsing Polychondritis (RP) and Comparison of Cartilaginous US Findings between RP, Repeated Trauma and Healthy Subjects

Satoshi Inotani¹ and Yoshinori Taniguchi², ¹Endocrinology, Metabolism, Nephrology and Rheumatology, Kochi Medical School, Kochi, Japan, ²Endocrinology, Metabolism, Nephrology and Rheumatology, Kochi University, Kochi, Japan

Session Information

Session Date: Monday, October 22, 2018

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster II: Interstitial Lung Disease, Still's Disease, FMF, Polychondritis

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Relapsing polychondritis (RP) is a rare systemic inflammatory disorder, and the diagnosis and treatment evaluation are often difficult. Therefore, the discovery of more convenient imaging modality than contrast-CT, MRI and FDG-PET/CT would be required on diagnosis and treatment. To assess the clinical utility of ultrasonography (US) in diagnosing and monitoring disease activity of relapsing polychondritis (RP).

Methods: Auricular and nasal chondritis of patients with RP (n=6) were initially assessed by US before and after treatments. Secondly, the changes of US findings and serum inflammatory markers were compared in RP. Finally, the auricular and nasal US findings between patients with RP (n=6), repeated trauma (n=6) which finding is similar to RP, and healthy subjects (n=6) were examined comparatively.

Results: In all cases of RP, US finding before treatment showed low-echoic swollen auricular and nasal cartilage with increased power Doppler signals (PDS), corresponding to biopsy findings. After treatment with prednisolone (PSL) combined with methotrexate, the swollen ear and nose completely resolved. Then, swollen cartilage on US also dramatically reduced with the decrease of PDS. When serum inflammatory markers completely improved, but PDS remained in 2 of 6 cases, and these cases showed flare due to early PSL tapering. Finally, the cartilage of RP on US could be apparently differentiated from repeated trauma and healthy subject due to thickness of cartilage, PDS and subperichondrial serous effusion.

Conclusion: Assessment of RP lesions by US possibly facilitates evaluation of cartilaginous lesions and monitoring of disease activity, especially when we consider the treatment response and the timing of drug tapering.

Session Date: Monday, October 22, 2018

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster II: Interstitial Lung Disease, Still's Disease, FMF, Polychondritis

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Familial Mediterranean Fever (FMF) is the most frequent auto-inflammatory disease caused by MEFV gene mutations. Although FMF is characterized by intermittent inflammatory attacks some patients exert chronic persistent inflammation that can result in damage of multiple organs. Available reports investigated only specific components of damage such as amyloidosis. All possible organ targets of damage have not been entirely evaluated before. To investigate all components of FMF related damage and associated factors with damage.

Methods: All patients recruited from FMF in Central Anatolia (FiCA) cohort, currently comprising 664 adult subjects (mean age 36±12.1, 63.5% female). All patients fulfilled Tel Hashomer criteria and all were using colchicine for at least 1 year. Demographic data, FMF disease and mutation (if available) characteristics and treatment features were recorded. FMF related damage was evaluated with recently validated auto-inflammatory disease damage index (ADDI). Association between damage and demographic, disease and treatment characteristics were analyzed.

Results: Proportions of FMF manifestations were fever 81.2%, peritonitis 90%, pleuritis 48.8%, arthritis 54.4% and skin rash 29%. Dominant attack types were fever in 7.1%, serositis in 62.7%, musculoskeletal in 16.7% and all attacks were common in rest of patients. MEFV mutations were available in 536 subjects and 77.6% of subjects harboring M694V mutation (28.8% homozygous for M694V). Among all 59.5% patients were well responded to colchicine and 9.2% were non-responders. Median ADDI score was 1 (min 0 max 11). Most common FMF related damages were observed in musculoskeletal, reproductive and kidney domains. Chronic musculoskeletal pain was present in 52.4%, joint deformity in 2.7%, infertility in 11.2%, amenorrhea in 7.1%, proteinuria in 7.8%, amyloidosis in 6.8% and severe renal failure in 4.1%. Age, M694V homozygous mutation, presence of persistent inflammation, dominant musculoskeletal attacks and colchicine nonresponse were found to be the independent predictors of damage.

Conclusion: M694V homozygous mutation, persistent inflammation, colchicine non-response and musculoskeletal dominant attacks are predictors of damage and effective therapeutic interventions must be undertaken to prevent from damage in these patients.

Session Time: 9:00AM-11:00AM

ActivityTracker bracelets captures Familial Mediterranean Fever attacks and their impact on daily physical activities

Background/Purpose: Familial Mediterranean fever (FMF) is a recessively inherited systemic auto-inflammatory disease characterized by recurrent febrile episodes. Typical FMF attacks are mostly devastating and exhausting and results in bed confinement. The objective of this study was to assess the impact of FMF attacks on daily physical activities and detection of FMF attacks by using a connected activity tracker.

Methods: Patients, who had definite diagnosis of FMF according to Tel- Hashomer criteria and agreed to use a validated activity tracker were included in this prospective observational study. Daily physical activities and whether patient wore the device were examined daily via the software of activity tracker. All-patient reported data including occurrence of an attack were collected weekly via mobile phone conversation to avoid memory bias. Median steps per day were calculated each patient. Wilcoxon rank test was used to compare median daily physical activities during attacks and attack free periods. Sensitivity and specificity thresholds for capturing attacks were set to 2/3 step number of median attack free days.

Results: Twelve patients completed the study. Median age of participants was 26 (18-32) and 5(42) of them were female. Median disease duration was 156 (36-300) months. Ten patients harbored homozygous or compound heterozygous, while one patient had single heterozygous exon 10 MEFV mutations.

While the duration of follow up was 514 days, the number of days that patient's wore activity tracker was 452 days (88%). Mean activity tracker use was 37.7 ± 21 days. Ten of the patients reported at least one attack in the observation period. In sum, patients reported 28 separate attacks with a total duration of 45 days (10%). Patients walked a median of 7302 (4500-10300) steps per/day in attack free days, while this number decreased to 1841 (590-4700) steps in attack days. For the assessment of whether activity tracker was capable of capturing an attack, cut off value was determined as two tertile of median steps-day. Activity tracker captured 42 of 45 attack days, 312 of 361 attack free days for each patient. Cut-off value was found 93% sensitive, and 86% specific for capturing attacks.

Conclusion: FMF attacks significantly affect daily physical activity of patients. Activity tracking may also be a reasonable way to capture and document FMF attacks. This might prevent errors due to memory bias and help to identify patients resistant to medical therapy. Thus, daily physical activity tracking maybe a better way of following up the patient aiding more accurate treatment decision for FMF patients who declares frequent attacks.

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Clinical and genetic analysis of the patients mimicking familial Mediterranean fever

Background/Purpose: Familial Mediterranean fever (FMF) is an auto-inflammatory disease characterized by recurrent episodes of fever and polyserositis. The differential diagnosis is sometimes difficult because the symptoms of FMF are nonspecific and the disease markers or auto antibody are not existed. We aimed to evaluate the diseases to watch out for differential diagnosis of FMF.

Methods: We analyzed 15 patients initially suspected as having FMF but diagnosed as other disease after the analysis of *MEFV* gene mutation. All patients were fulfilled diagnostic criteria (Livneh criteria). Their clinical symptoms, final diagnosis, effectiveness of colchicine, and genetic mutations were retrospectively investigated.

Results: The diagnosis of these 15 patients were as follows; Behcet's disease (n=4), malignant disease (n=2), infectious disease (n=2), periodic fever, aphthous stomatitis, pharyngitis, and adenitis (PFAPA) (n=2), and Crohn's disease, adult-onset Still's disease, calcium pyrophosphate dihydrate deposition disease, sarcoidosis, and adrenalism (n=1, each). All patients had recurrent fever. Eight patients (53.3%) had abdominal pain, 6 (40%) had chest pain, and 6 (40%) had arthralgia. Colchicine was prescribed for 10 patients and effective for 5 patients (50%) but ineffective for 4 patients (40%). Most of the colchicine-responsive patients had the colchicine effective disease such as Behcet's disease. Although known *MEFV* gene mutation were identified in 10 patients (66.7%), exon 10 mutations were not found.

Conclusion: Behcet's disease, malignancies, infection, and other auto inflammatory disease would be important differential diagnosis of FMF. The frequency of serositis and the prevalence of pathogenic mutations were lower than typical FMF. Patients not having the pathogenic mutation and refractory to colchicine treatment may be needed to re-examine malignancies and infections. Even if colchicine treatment was effective, we might have to pay attention to existence of specific symptoms of other auto inflammatory disease.

Comparison of Serum Hecpidin and Calprotectin Levels in Patients with Familial Mediterranean Fever (FMF) and Healthy Subjects

Gökmen ASAN¹, Mehmet Emin DERİN², Halef Okan DOĞAN³, Meliha BAYRAM⁴, Mehtap SAHİN³ and Ali Sahin⁵, ¹Internal medicine, Cumhuriyet University Medical Faculty, Sivas, Turkey, ²Rheumatology-internal medicine, Cumhuriyet University Medical Faculty, Sivas, Turkey, ³Biochemistry, Cumhuriyet University Medical Faculty, Sivas, Turkey, ⁴Internal medicine, Cumhuriyet University Medical Faculty, Sivas, Turkey, ⁵Department of Rheumatology, Cumhuriyet University Faculty of Medicine, Sivas, Turkey

Session Information

Session Date: Monday, October 22, 2018

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster II: Interstitial Lung Disease, Still's Disease, FMF, Polychondritis

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Familial Mediterranean fever (FMF) is an auto inflammatory disease which has self-limiting inflammatory attacks placing in polyserositis. Hepcidin is a protein in peptide structure and it is synthesized from the liver. Hepcidin plays a role in iron metabolism. Especially hepcidin increased at the during inflammation and it decreases the serum level of iron. IL-6 stimulation increases the level of hepcidin. The cause of anemia in chronic diseases is associated with hepcidin. Calprotectin is a recently defined cytokine released from monocytes and neutrophils in response to tissue trauma and inflammation. To compare the levels of hepcidin and calprotectin in healthy individuals and FMF patients with attack-free period and to show the relation with genetic mutations.

Methods: Between July 2017-December 2017, sixty patients diagnosed with FMF and sixty healthy volunteers enrolled in this study. All of FMF patients were used colchicine (1-1.5mg/day). Clinical findings and PRAS scores of all patients and were recorded. The blood from a peripheral vein using suitable blood tubes was withdrawn to measure serum prolidase and HIF-1 α levels. Bloodtest were examined by Elisa. The study protocol was approved by the local ethics committee.

Results: Laboratory findings and basic characteristics of FMF and healthy control group are shown in Table1. Mean serum hepcidin level was measured as 468.1(210.3-807.8) pg/ml in FMF group and 890.0 (495.0-1716.9) pg/ml in healthy control (HC) group ($p<0.001$). The mean serum levels of calprotectin in the FMF group were measured as 1331.4 (969.3-1584.6) pg/ml and 73.8(45.0-147.9)pg/ml in the HC group ($p<0.001$). According to ROC analysis optimal levels of serum hepcidin (<581.25 pg/ml; sensitivity was 66.7% and specificity was 71.7%, $p<0.05$) and calprotectin (>238 pg/ml; sensitivity was 96.7% and specificity was 100%, $p<0.05$). There was nonsignificant difference between serum hepcidin and calprotectin levels in FMF patients with M694V homozygous and M694V heterozygous ($p>0.05$). There was nonsignificant difference in serum hepcidin levels between FMF patients with and without arthritis, proteinuria and amyloidosis ($p>0.05$). There was nonsignificant correlation between laboratory findings, sex, age, and serum calprotectin and hepcidin levels ($p>0.05$ $r<0.25$).

Conclusion: Serum calprotectin levels in FMF patients with attack-free period were significantly higher than in the healthy control group. Serum hepcidin levels in FMF patients were significantly lower than in the healthy control group. Low levels of hepcidin may be explained that including FMF patients with attack-free period in to the study. Calprotectin may be an important biomarker in FMF. To understand the role of these biomarkers in the diagnosis of FMF are needed to evaluate in more comprehensive studies.

Evaluation of Prolidase and HIF-1 α Levels in Patients with Familial Mediterranean Fever (FMF)

Meliha BAYRAM¹, Mehmet Emin DERİN², Halef Okan DOĞAN³, Gökmen ASAN⁴, Mehtap SAHİN³ and Ali Sahin⁵,
¹internal medicine, Cumhuriyet University Medical Faculty, sivas, Turkey, ²Rheumatology-internal medicine, Cumhuriyet University Medical Faculty, sivas, Turkey, ³Biochemistry, Cumhuriyet University Medical Faculty, sivas, Turkey, ⁴Internal medicine, Cumhuriyet University Medical Faculty, sivas, Turkey, ⁵Department of Rheumatology, Cumhuriyet University Faculty of Medicine, Sivas, Turkey

Session Information

Session Date: Monday, October 22, 2018

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster II: Interstitial Lung Disease, Still's Disease, FMF, Polychondritis

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Familial Mediterranean Fever (FMF) is an auto inflammatory disease characterized by recurrent fever attacks, sterile peritonitis, pleural inflammation, arthritis and / or erysipelas like rash. Prolidase is a specific imidodipeptidase that plays a role in collagen degradation. HIF-1 α is an important protein in the regulation of immunological response, hemostasis, vascularization and anaerobic (oxygen-free) metabolism. Serum prolidase activity in patients with ankylosing spondylitis (AS) was statistically significantly lower than in the control and rheumatoid arthritis (RA) groups. Prolidase activity was not significantly different in patients with RA compared to the control group. In patients with Behcet's disease, prolidase activity was statistically significantly higher than in healthy control group. In FMF patients, the effect of prolidase enzyme is unknown. The aim of the study is to compare serum prolidase and HIF-1 α levels in patients with FMF in attack-free period and healthy control group.

Methods: Between August 2017 and December 2017, sixty patients who diagnosed FMF according to the criteria of the tel- and sixty healthy volunteers were enrolled in the study. All of FMF patients were under treatment of colchicine (1-1.5mg). Clinical findings and PRAS scores of all patients and were recorded. Blood tests were examined by Elisa method. The study protocol was approved by the local ethics committee.

Results: Laboratory findings and basic characteristics of FMF and healthy control group are shown in Table 1. In this study, mean serum prolidase level was measured as 72.1 (25.1-114.9) ng/ml in FMF group and 30.7 (21.3-86.2) ng/ml in healthy control (HC) group (Figure 1). There was statistically significant difference between two groups ($p=0.018$). The mean serum levels of HIF-1 α in the FMF group were measured as 482.0 (292.0-3967.0) pg/ml and 632.0 (362.0-927.0) pg/ml in the HC group. There was no statistically significant difference between the two groups ($p<0.05$). According to ROC analysis, optimal levels of serum prolidase (>54.03 ng/ml; sensitivity was 65% and specificity was 68.3%, $p<0.05$). There was no significant difference between serum prolidase and HIF-1 α levels in the mild, moderate and severe patient groups according to PRAS score ($p>0.05$). There was no significant correlation between laboratory findings, sex, age, and prolidase ($p>0.05$, $r<0.25$).

Conclusion: Serum prolidase enzyme levels in FMF patients with attack-free period were significantly higher than in the healthy control group. There was no significant difference between the two groups at HIF-1 α level. High prolidase enzyme levels may be associated with clinical or subclinical inflammation in FMF patients. However, the role of prolidase and HIF-1 α in the FMF disease needs to be clarified with more extensive and comprehensive studies.

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster II: Interstitial Lung Disease, Still's Disease, FMF, Polychondritis

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Despite methotrexate and steroid treatment, in cases of Adult-onset Still's disease (AOSD) it is usually difficult to maintain clinic stability. In refractory cases, Anakinra treatment has been reported to be efficacious (1). In this retrospective review, it is aimed to evaluate the AOSD cases treated with anakinra in our center.

Methods: Fourteen AOSD patients (11 female, 3 male) who were being followed in our outpatient clinic were reviewed retrospectively. The demographic characteristics, pre- and post-treatment clinical findings were reported.

Results: The mean follow-up period of the patient population was 33.5 ± 30.07 months (mean \pm SD). Initial prednisolone dose was 37.3 mg/day. Except for one, all of our patients were exposed to methotrexate before being treated with anakinra. This patient was being treated with cyclosporine instead, since she had concomitant Macrophage Activation Syndrome. The other medications, the patients were previously treated with, were Etanercept (n=2), Tocilizumab (n=3), Infliximab (n=1) and Adalimumab (n=1). All patients were on 100 mgs of Anakinra, daily, except for the one treated with 200 mg/day. The mean duration of Anakinra therapy was 11.4 months. Among 7 patients in whom anakinra therapy was terminated, 1 had drug induced urticaria, 1 was primary irresponsive, 4 were secondary irresponsive and the other had severe pneumonia. Primary irresponsiveness is the lack of response to the therapy since the drug was first introduced, whereas in secondary irresponsiveness the case responds to the medication for a while and starts to flare again after a symptom-free period on the medication. Among 14, 7 of our patients are still on 100 mg/d Anakinra. The mean level of C reactive protein (CRP) measures was reduced from 64.38 ± 61.95 mg/L to 34.3 ± 24.3 mg/L with Anakinra therapy ($p=0.003$). Similarly, mean Erythrocyte Sedimentation Rate (ESR) was dropped to 33 ± 22 mm/h from 59 ± 35 mm/h by the help of the therapy ($p<0.001$). Among patients who primarily responded Anakinra therapy the mean Ferritin measures dropped to 427.25 ng/mL from 910 ng/mL ($p=0.006$). On the other hand, the Ferritin level was not significantly reduced in patients who did not respond Anakinra. The mean Patient reported Global Visual Analogue Scale (PG-VAS) score was also decreased to 3.83 ± 4.7 from 9.5 ± 0.7 following the therapy ($p<0.001$). Unfortunately, one of our 7 patients who were followed in remission under Anakinra died of an unknown etiology.

Conclusion: Adult-onset Still's disease is a challenging disorder, lacking a sufficient long-time clinical control. In order to obtain a full remission, various efforts have been spent so far. One of these approaches is to treat refractory cases with Anakinra, an IL-1 blocking agent. According to our clinical experience we state that, anakinra has a relatively high efficacy in controlling refractory cases.

Session Information

Session Date: Monday, October 22, 2018

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster II: Interstitial Lung Disease, Still's Disease, FMF, Polychondritis

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: In Adult-onset Still's disease (AOSD), cases refractory to typical DMARDs, Canakinumab (an anti-IL-1 β monoclonal antibody) has been reported to be effective in a limited number of refractory cases (1). The aim of this retrospective study was to represent AOSD patients treated with Canakinumab in 3 centers.

Methods: The follow up data of 10 AOSD patients (8 female, 2 male), who were followed up in outpatient clinics of 3 tertiary centers were reviewed retrospectively. The initial characteristics and follow up findings were reported.

Results: The mean time span between the initial diagnosis and Canakinumab treatment 45.2 ± 29 months (mean \pm SD). Before the onset of Canakinumab therapy, all patients were exposed to methotrexate, 1 to leflunomide, 8 to Tocilizumab and 8 to Anakinra. As for the biologic agents, 3 patients were also treated beforehand with Infliximab, 2 with Adalimumab, 2 with Etanercept and 2 with Rituximab. Canakinumab therapy was initiated in all patients with the indication of refractory disease under other medications, except for the one in whom neutropenia became evident under anakinra. The mean number of Canakinumab injections was 9.3 ± 8 . The mean follow-up period of patients treated with Canakinumab was 43.1 ± 33 months. Seven out of 10 patients are still being treated with Canakinumab of 150 mg/month and one of 150 mg/every 2 months. One patient had a single injection and was fully controlled. The mean ferritin measure of 9 patients was reduced from 1292.3 ± 1530 ng/ml to 354 ± 530.2 ng/ml following the Canakinumab therapy ($p=0.035$). The mean of patient-reported global visual analogue scale (PG-VAS) scores was reduced from 7.4 ± 2.4 to 2.3 ± 2.2 with Canakinumab ($p<0.001$). Mean Erythrocyte sedimentation rate (ESR) was reduced from 44.2 ± 35.1 to 22.7 ± 26.5 with the help of Canakinumab therapy ($p = 0.005$). Six patients are still on prednisolone at a maximum dose of 10 mg/day. The indication of therapy termination in the remaining 1 patient was the diagnosis of tuberculosis at 9th month of the treatment despite isoniazid prophylaxis. The patient was also treated with multiple biological agents before hand, therefore it is not easy to conclude that treatment with Canakinumab induces tuberculosis flares.

Conclusion: Canakinumab treatment seems to be effective in refractory AOSD patients who were previously treated with various agents. We state that an IL-1 blocking agent, Canakinumab is a relatively safe and effective alternative in managing refractory AOSD cases. On the other hand, randomized controlled trials are needed to further investigate the role of Canakinumab in these cases as well as its use as the first choice of biologic agents.

Does Testing for SAA Is More Beneficial Than CRP for the Follow-up of Patients with Familial Mediterranean Fever ?

Serdal Ugurlu¹, Oguzhan Selvi², Bilgesu Ergezen¹ and Huri Ozdogan¹, ¹Istanbul University, Cerrahpasa Medical Faculty, Department of Internal Medicine, Division of Rheumatology, Istanbul, Turkey, ²Division of Rheumatology, Department of Internal Medicine, Cerrahpasa Medical Faculty, University of Istanbul, Istanbul, Turkey

Session Information

Session Date: Monday, October 22, 2018

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster II: Interstitial Lung Disease, Still's Disease, FMF, Polychondritis

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: In order to follow subclinical inflammation and adjust the therapy for an optimal disease control, clinicians seek for readily accessible, affordable and reproducible markers. C reactive protein (CRP) is widely used for this purpose. Some suggest that CRP measures are not conclusive in all cases, especially in initial stages of inflammation. It is suggested that Serum Amyloid A (SAA) may be more reliable and sensitive in predicting an ongoing inflammation.

Methods: In order to evaluate and to compare the sensitivity of SAA and CRP, 148 measurements from 33 FMF patients with M694V homozygous mutation were obtained during a mean follow-up of 4 months. For the analysis, the folds of normal CRP and SAA values were used for correlation. Serum levels of the given markers were measured with nephelometric kits (normal CRP levels <5 mg/L and SAA levels <6.8 mg/L).

Results: All patients were on prophylactic colchicine. Among 33 patients 1 patient was being treated with tocilizumab, 2 patients with adalimumab, 19 patients with anti-IL-1 regimens. There were a total of 143 measurements of CRP and SAA from 33 patients. Figure 1 demonstrates the correlation between CRP and SAA results. A similar significant correlation was found when we tested only the values obtained during 128 attack-free occasions ($r=0.743, p<0.001$). Both acute phase reactants were increased in 102 measurements, while in 9 CRP was high but SAA was normal and in 17 SAA was high however CRP was within normal limits. The mean increase in CRP of the population was 2.55 ± 5.26 fold, whereas mean increase in SAA was 6.78 ± 16.39 fold of the normal.

Conclusion: According to these results, serial testing of SAA does not provide any additional advantages over CRP. Readily accessible and affordable bio-marker CRP seems to be sufficient for follow-up of patients with FMF

The Effect of Etoposide on Inducing Remission in Refractory Adult-Onset Still's Disease: A Retrospective, Single-Center Study

Haiting Wang¹, Xiaodong Wang¹, Ting Li¹ and Shuang Ye², ¹Department of Rheumatology, Renji Hospital South Campus, Shanghai Jiao Tong University School of Medicine, Shanghai, China, ²Rheumatology, Ren Ji Hospital, South Campus, School of Medicine, Shanghai Jiaotong University, Shanghai, China

Session Information

Session Date: Monday, October 22, 2018

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster II: Interstitial Lung Disease, Still's Disease, FMF, Polychondritis

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Adult onset Still's disease (AOSD) is a rare inflammatory disorder of unknown etiology. Macrophage activation syndrome (MAS) is a life-threatening complication and has been recognized to complicate AOSD. Etoposide (VP-16) has been previously utilized in patients with MAS and induced a favorable and rapid response in cases. In this study, we conducted a single-center, retrospective survey to evaluate the efficacy of etoposide in inducing remission in a series of refractory AOSD patients.

Methods: We included 42 refractory AOSD patients who previously received high dose of steroids (≥ 2 mg/kg/day of prednisone), immunosuppressive drugs and biologic agents. HLH-2004 was used to define AOSD-MAS, and sJIA MAS-2016 was used to exclude those with MAS tendencies (pre-MAS). 23 patients were treated with etoposide (VP-16 group) and 19 patients were treated with methotrexate (MTX) or cyclosporine (CsA) (Control Group). We evaluated disease course, efficacy of treatment and potential adverse effects for at least one year. Efficacy was evaluated as \geq Partial response (PR: clinical improvement without normalization of inflammatory markers, nor $>50\%$ reduction in the dose of prednisone).

Results: The average age was 36 ± 14 years in VP-16 group and 37 ± 13 years in control group. MAS and Pre-MAS of each group were observed in 48% vs. 11% and 47% vs. 42%. At the time of VP-16/Control treatment, the most frequent clinical manifestation was fever (100%/100%), Rash (87%/100%) and Joints involvement (78%/79%). The laboratory parameters such as ferritin, triglycerides and alanine transaminase showed higher level in VP-16 group at baseline. The median dosages of VP-16 were 575mg (IQR 150-1400mg). The median treatment course were 4 weeks (IQR 2 weeks-10 months). The majority of patients showed clinical improvement after VP-16/Control therapy. A dramatic reduction of inflammatory laboratory markers and prednisone dose were achieved. 17 patients responded to VP-16 (PR 74%) and 10 patients responded to CsA or MTX (PR 53%) at 4th week. Besides, in Pre-MAS patients, compared with CsA or MTX, there was rapid increase of PR in VP group (Figure 1).

Adverse events were seen as follows: hemocytopenia ($n=2/n=1$), gastrointestinal effects ($n=3/n=1$), alopecia ($n=1/n=0$), and infections ($n=6/n=5$). 2 patients died (one with shock and one with infection) in VP-16 group and the rest survived. With an average follow-up of 21 ± 11 months/ 24 ± 14 months, a decrease in the dose of steroids and immunosuppressants was possible in all patients [discontinuation: 9%/16%; steroid monotherapy (≤ 15 mg/d): 13%/5%; steroids + DMARDs: 57%/42%].

Figure.1 Improvement following the initiation of VP-16 /Control therapy

Conclusion: Etoposide treatment was associated with rapid and maintained clinical and laboratory improvement in patients with AOSD refractory. It is necessary to carry out large samples and long-term follow-up clinical studies to evaluate its exact effects and safety.

Recurrent Pericarditis: A Challenge in Autoinflammatory Disease Clinic and the Role of Anakinra

Blas Betancourt¹, Amanda Ombrello², Ananta Subedi³, Patrycja M. Hoffmann² and Daniel L. Kastner⁴, ¹National Institute of Arthritis, Musculoskeletal and Skin Disease (NIAMS), Bethesda, MD, ²NHGRI, National Institutes of Health, Bethesda, MD, ³National Institutes of Health, NIAMS, Bethesda, MD, ⁴Inflammatory Disease Section, National Human Genome Research Institute, National Institutes of Health, Bethesda, MD

Session Information

Session Date: Monday, October 22, 2018

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster II: Interstitial Lung Disease, Still's Disease, FMF, Polychondritis

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Recurrent pericarditis is a common complication following an acute episode of pericarditis affecting about 15-30% of the cases. The etiology of this condition is unknown in most of the patients but it is thought that an auto inflammatory process has an important role in the pathogenesis. Anakinra is an interleukin-1 receptor antagonist that reduces systemic inflammatory responses. The aim of our study was to describe the clinical characteristics and response to anakinra in patients with recurrent pericarditis.

Methods: We retrospectively reviewed patients referred to our clinic with the diagnosis of recurrent pericarditis who were resistant to conventional therapy.

Results: A total of 11 patients were included. The majority were females (7 [64%]) with a median age at presentation of 20 years. Nine patients were diagnosed with recurrent idiopathic pericarditis, one case was found to have familial Mediterranean fever and another patient had a history of systemic lupus erythematosus. Autoimmune workup was negative in all of the cases except in the patient with a history of lupus. Standard doses of nonsteroidal anti-inflammatory drugs, colchicine, and steroids were used in all of the cases. Good response to steroids was noted in all patients (except in the case of lupus) but it was not possible to taper glucocorticoids completely because of recurrence of the pericarditis. Other immunosuppressive medications used were methotrexate, hydroxychloroquine, infliximab, azathioprine, and mycophenolate mofetil. Anakinra, doses between 100-300 mg daily, was associated with clinical response in most of the patients (complete response in 5 patients, partial response in 4 patients, and no response in 1 patient). One patient did not have a follow-up evaluation after anakinra treatment. Anakinra was well tolerated and the main adverse side effect was local reactions.

Conclusion: Anakinra is a safe and effective drug for the management of treatment-resistant recurrent pericarditis.

Combination of Methotrexate and Leflunomide in Refractory Chronic Adult Onset Still's Disease: Case Series and Literature Review

Eunyoung Emily Lee and Jin Kyun Park, Division of Rheumatology, Department of Internal Medicine, Seoul National University Hospital, Seoul, Korea, Republic of (South)

Session Information

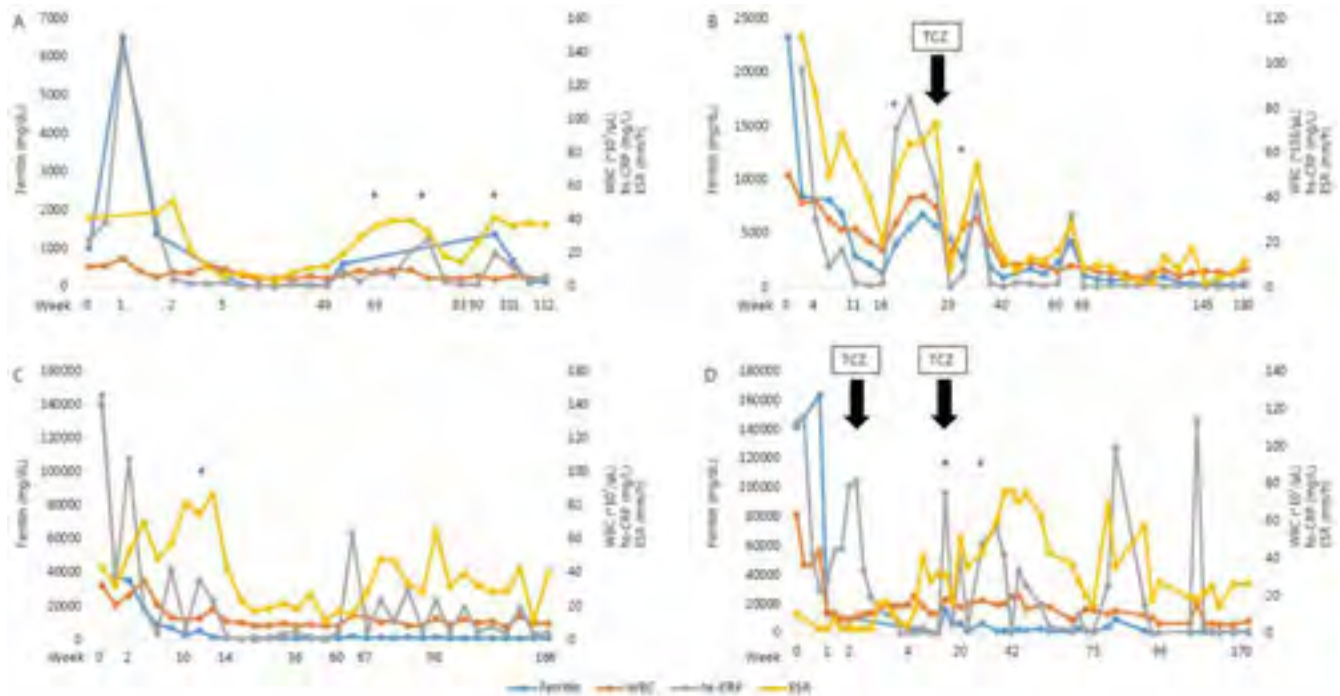

Session Date: Monday, October 22, 2018

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster II: Interstitial Lung Disease, Still's Disease, FMF, Polychondritis

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: To demonstrate the efficacy of methotrexate (MTX) and leflunomide (LEF) combination therapy in refractory chronic adult onset Still's disease (AOSD).

	Patient 1	Patient 2	Patient 3	Patient 4	Patient 5
Initial CS dose (PD equivalent) (day)	60 mg	30 mg → 60 mg	156 mg*3 days → 60 mg	60 mg	30 mg
CS dose at flare without MTX (day)	0 mg, 15 mg	NA	NA	7.5 mg	7.5 mg
Duration of remission with CS + MTX	24 weeks	22 weeks	4 weeks	14 weeks	2 weeks
CS dose at flare with CS + MTX (day)	15 mg	7.5 mg	20 mg	7.5 mg	7.5 mg
Duration of remission with MTX + LEF ± CS	13 weeks	147 weeks	154 weeks	106 weeks	46 weeks
Time to CS discontinuation after adding LEF	CS at remission	44 weeks	100 weeks	61 weeks	31 weeks
CS dose at last follow up (day)	3 mg	0 mg	0 mg	0 mg	0 mg
MTX dose (week)	15 mg	15 → 20 → 25 → 15 mg	15 mg	15 → 20 → 5 mg	15 mg
LEF dose (day)	10 mg	10 → 20 mg	10 → 20 mg	10 → 20 → 10 mg	30 mg
The time and reason for TCZ administration	NA	8 mg/kg once for systemic inflammation at 2nd flare	NA	8 mg/kg once for respiratory failure at diagnosis and once at 1st flare	NA
CRP (mg/L), ESR (mm/h), ferritin (ng/mL) at last visit	6.2, 37, 131.0	2.0, 12, 164.5	8.0, 11, 810.3	1.3, 52, 200.0	12.0, 39, 99.1

Methods: This is a retrospective case series of five consecutive patients with AOSD who were treated with MTX and LEF. Medical records were reviewed and laboratory findings and clinical features were assessed. Literature search was conducted.

Results: All five patients met the Yamaguchi criteria for AOSD and were treated with corticosteroid (CS) after the diagnosis of AOSD. Systemic inflammation deteriorated in one patient and one patient developed acute respiratory failure despite initial high-dose CS treatment. Tocilizumab was briefly given with prompt control of inflammation and respiratory failure. All five patients flared when PD was tapered to 0 - 20 mg/day. Along with a short-term increase in CS, MTX 15-25 mg/week was added. During further attempt to taper CS, patients flared again and LEF 10-20 mg/day was added. With MTX-LEF combination, all patients reached and remained in remission. CS was tapered off except in one patient who required 5 mg of prednisolone.

Conclusion: To the best of our knowledge, this is the first case series of chronic refractory AOSD that was successfully treated with the combination of MTX and LEF after initial MTX failure. Further prospective studies are warranted to definitively evaluate the efficacy and safety of MTX-LEF combination in AOSD.

Table 1. Summary of the treatment and clinical outcome of the five patients.
Figure 2. Clinical course after the diagnosis of AOSD of patient 1 (A), patient 2 (B), patient 3 (C) and patient 4 (D)

Dyskeratotic Cells in Persistent Pruritic Skin Lesions Are Apoptotic and Associated with High Levels of Serum IL-18, and Possibly Predict the Outcomes in Adult-Onset Still's Disease

Hirofumi Nishikawa¹, Yoshinori Taniguchi¹, Natsuki Maeda¹, Satoshi Inotani¹, Kimiko Nakajima², Kaoru Arai³ and Yoshio Terada¹, ¹Endocrinology, Metabolism, Nephrology and Rheumatology, Kochi Medical School Hospital, Nankoku, Japan, ²Dermatology, Kochi Medical School, Nankoku, Japan, ³Internal Medicine, Kochi Red Cross Hospital, Kochi, Japan

Session Information

Session Date: Monday, October 22, 2018

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster II: Interstitial Lung Disease, Still's Disease, FMF, Polychondritis

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: To assess the clinical significance of dyskeratotic cells (DCs) in skin lesions of adult-onset Still's disease (AOSD).

Methods: We assessed clinical characteristics, serum markers, outcomes and histology of skin lesions in Japanese patients with AOSD (n=15). Moreover, we comparatively studied the histological findings of AOSD, dermatomyositis (DM) (n=6), drug eruptions (DE) (n=7), and graft versus host disease (GVHD) (n=6).

Results: AOSD with persistent pruritic skin lesions (n=10) histologically showed DCs only in upper layer of epidermis and horny layer without inflammatory cells infiltrations, indicating dyskeratosis. AOSD with evanescent rash (n=5) histologically showed no DCs. In contrast, the histology of DM, DE and GVHD demonstrated that DCs existed in all layers of epidermis with inflammatory cells infiltrations. DCs in AOSD were positive by ssDNA staining, suggesting apoptotic cells. Serum IL-18 showed significantly higher in AOSD patients with DCs (n=10) than without DCs (n=5). The majority of AOSD patients with DCs required higher doses of glucocorticoids, immunosuppressants and biologic agents than without DCs. 2 of 10 AOSD patients with DCs died because of infectious complications or hemophagocytic syndrome.

Conclusion: Persistent pruritic skin lesions in AOSD are specific by prominent epidermal apoptosis involving the upper layers of epidermis, and hyper IL-18 is significantly related with dyskeratosis. The appearance of DCs in AOSD seems to be associated with poor prognosis.

Session Information

Session Date: Monday, October 22, 2018

Session Title: Muscle Biology, Myositis and Myopathies Poster II: Basic and Translational Science

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Dermatomyositis (DM) is a heterogeneous group of diseases ranging from skin limited disorders to non-specific auto-immune diseases with patients suffering from additional extra-cutaneous manifestations. The myositis specific antibody (Ab) anti-melanoma differentiation-associated gene 5 antibody (MDA5+) delineates a group of patients with a DM skin rash, arthralgia and an interstitial lung disease (ILD), sometimes severe because rapidly progressive (RP-ILD), whereas clinical signs of myositis are absent.

The variety and the predominance of the extra-muscle manifestations question the term of 'myositis specific Ab' and the homogeneity of the related disease. Precising the clinical phenotype, as well as the prognosis of MDA5+ patients is necessary to improve the management of this severe disease.

Methods: MDA5+ patients were defined as patients with a DM skin rash and/or arthralgia and/or ILD without other aetiology in presence of anti-MDA5 Ab. Clinical, laboratory and imaging data were collected (multicentric study). As control, a cohort of anti-MDA5- myositis patients was used. Unsupervised analyses were performed either on both groups (anti-MDA5+ and control) or on anti-MDA5+ patients only.

Results: Anti-MDA5+ patients' (n=121) characteristics were in line with the previous reports. Patients were mainly female, 49 years old [34-58], with a DM skin rash (87.5%) and signs of vasculopathy (Raynaud phenomenon, skin ulcers, calcinosis and/or digital necrosis), with ILD (77%; RP-ILD, 32.7%) and with arthralgia (69%). Death occurred in 25.4% of cases. MDA5+ patients' phenotype was clearly distinct from controls (n=323). Unsupervised analysis (without including data of the serological status) showed clearly two clusters. One was characterized by more frequent DM skin rash, skin ulcers, calcinosis, mechanics hands, ILD, arthralgia/arthritis and patients with a higher mortality rate. In this cluster 87% of patients were MDA5+.

Within MDA5+ group, analysis showed three clusters. As previously reported, one corresponds to patients with RP-ILD (ILD 100% and RP-ILD 95%; $p<0.0001$), but mechanics' hands were frequent (65%; $p<0.0001$). Two new subgroups were identified. One is an 'athro-cutaneo-form' (arthralgia/arthritis, 85%; $p<0.0001$; RP-ILD, 9.5%; $p<0.0001$) and another is a 'vasculo-cutaneo-muscular-form' corresponding to male patients (71.4%; $p<0.0001$) with a severe skin vasculopathy (frequent Raynaud phenomenon, skin ulcers, digital necrosis and calcinosis) and with frequent sign of myositis (weakness 71.3%; $p<0.0001$).

The outcome depends on the form of the disease. A very high mortality rate is observed in the 'RP-ILD form' (65%), in contrast to the good outcome in the 'athro-cutaneo-form' (0% of mortality) and intermediate one in the 'vasculo-dermatomyo-form' (19% of mortality).

Conclusion: MDA5+ patients are a distinct group from myositis patients, characterised by a systemic syndrome composed by three different entities with different outcomes.

Session Date: Monday, October 22, 2018

Session Title: Muscle Biology, Myositis and Myopathies Poster II: Basic and Translational Science

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: JDM is a complex heterogeneous autoimmune disease. To define biomarkers and better understand JDM pathogenesis, aptamer-based proteomic technology was used to mine the serum proteome in a well-characterized JDM cohort.

Methods: Sera from 41 JDM patients (prevalent cases on variable treatment) were compared with 28 age- and gender-matched healthy controls (HC). Broad proteomic analysis of 1306 targets with a slow off-rate modified aptamer-based assay (SomaLogic, CO) generated simultaneous quantitative serum levels. Internal discovery/validation was done with 2 independently-analyzed groups (Group1: JDM 27, HC 19; Group 2: JDM 14, HC 9) assessed for Mann Whitney U FDR corrected p values of <0.10 (JDM vs. HC) common to both groups with expression ratio of >1.3. Significant protein levels were positively correlated by Spearman rank with Physician Global Activity (PGA) and Physician Global Damage (PGD) by visual analog scale (VAS), Manual Muscle Testing (MMT8), Childhood Muscle Assessment Scale (CMAS), Childhood Health Assessment Questionnaire (CHAQ), and disease activity by VAS specific to skin and muscle using the Myositis Disease Activity Assessment Tool (MDAAT) selecting for p values <0.05. Proteins were also analyzed by Ingenuity Pathway Analysis (Qiagen, CA) and Gene Ontology (GO) (Ashburner et al, 2000) biologic processes to identify pathway clusters.

Table 1. Proteins with significant correlation with JDM clinical measures

PGA	PGD	Skin VAS	Muscle VAS	CHQ	Protein	Protein Full Name
				x	B7-H1	Programmed cell death 1 ligand 1
x					Calpain I	Calpain I
x					CXCL16, soluble	C-X-C motif chemokine 16
x					D-dimer	D-dimer
				x	Ferritin	Ferritin
x				x	Integrin $\alpha 1 \beta 1$	Integrin $\alpha 1 \beta 1$ complex
x		x	x	x	IP-10	C-X-C motif chemokine 10
		x	x	y	LEG9	Galectin-9
				x	Mcl-1	Induced myeloid leukemia cell differentiation protein Mcl-1
				x	MCP-3	C-C motif chemokine 7
x			x	x	MIC-1	Growth/differentiation factor 15
x					MMP-3	Stromelysin-1
x					NPS-PLA2	Phospholipase A2, membrane associated
x					NUDC3	NudC domain-containing protein 3
				x	RNase H1	Ribonuclease H1
	x				STAT1	Signal transducer and activator of transcription 1- α/β
x					tPA	Tissue-type plasminogen activator
		x			UCRP	Ubiquitin-like protein ISG15
x					vWF	von Willebrand factor
x	x				XTP3A	dCTP pyrophosphatase 1

This is an alphabetical list of proteins and the clinical measure with which there was a Spearman correlation with a p value of ≤ 0.05 . r_s values ranged from 0.31 to 0.54. No proteins were significantly associated with CMAS or MMT8.

Results: Fifty-nine proteins met significance criteria in both groups of JDM versus HC sera. Of those, 20/59 had significant correlation with 1 to 4 clinical measures (Table 1). Nine proteins correlated with PGA ($r_s = 0.31-0.37$), most commonly associated with acute phase response (APR) and endothelial activation/adhesion (Endo). Three proteins uniquely correlated with PGD ($r_s = 0.33-0.54$), and associated with Endo, IFN, and proteolysis/remodeling (Remodeling) pathway clusters. Four proteins correlated with skin VAS ($r_s = 0.37-0.41$); most associated with IFN and Th1 pathway clusters, with 1 unique to skin and 2 overlapped with muscle VAS. Nine proteins correlated with CHAQ and 4 proteins with muscle VAS (3 overlapping with CHAQ and 1 unique to muscle VAS); overall most associated with Endo and IFN ($r_s = 0.35-0.53$). Nonsignificantly correlated with MMT or CMAS.

Conclusion: Broad quantitative proteomic analysis identified some novel serum markers that point to key differentiating pathway clusters in JDM versus HC which may provide insights into JDM pathogenesis. Moderate correlation was observed between top proteins and clinical measures, including some distinct markers foreskin versus muscle activity, and for PGD. These proteins emphasize pathway clusters including APR, Endo, IFN, Th1, and Remodeling, that may be important to distinct aspects of JDM features and outcomes.

Session Information

Session Date: Monday, October 22, 2018

Session Title: Muscle Biology, Myositis and Myopathies Poster II: Basic and Translational Science

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Damage to the vascular endothelium is strongly implicated in the pathogenesis of dermatomyositis (DM) and to a lesser degree other idiopathic inflammatory myopathies (IIM). Normal high density lipoproteins (HDL) protect the vascular endothelium from damage due to oxidized phospholipids, which accumulate under conditions of oxidative stress. The current work evaluated the function of HDL in a longitudinal cohort of 182 IIM patients.

Methods: The anti-oxidant capacity of HDL was measured by a cell free assay as described previously (*A&R*2009; 60(10): 2870-9) and reported as the HDL inflammatory index (HII). Lipoprotein cholesterol levels were measured by standard methods and traditional cardiovascular risk factors, medication use, and myositis disease characteristics were assessed for all patients. Univariate analysis evaluated the clinical characteristics of IIM patients by three groups of HDL function defined by HII; tertile 1 contained patients with the highest HII, consistent with severe HDL dysfunction, and tertile 3 contained patients with the lowest HII, consistent with the most protective HDL. Multivariate logistic regression analyses were performed to evaluate correlates of dysfunctional HDL in the IIM cohort.

Results: Patients with the most dysfunctional HDL, (tertile 1 HII) had the highest myositis disease activity levels, as measured by both physician global visual analogue scales (VAS) as well as serum CPK levels, compared to lower HII tertiles (Table 1). DM diagnosis was most prevalent in tertile 1 of HDL function (Table 1). There were no significant differences in demographics or traditional cardiovascular risk factors between tertiles. Disease activity measures and DM diagnosis remained significantly associated with dysfunctional HDL in independent multivariate models, after controlling for variables significantly different between tertiles in univariate analysis, as well as variables previously associated with abnormal HDL function including age and statin use (Table 2).

Conclusion: Abnormal anti-oxidant function of HDL was significantly associated with myositis disease activity and DM diagnosis in a large cohort of 182 IIM patients. Abnormal HDL function may warrant further investigation as a mechanism of microvascular damage and increased cardiovascular risk in DM patients.

Session Information

Session Date: Monday, October 22, 2018

Session Title: Muscle Biology, Myositis and Myopathies Poster II: Basic and Translational Science

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Low density granulocytes (LDGs) are a subset of neutrophils that spontaneously produce neutrophil extracellular traps (NETs) and type I IFN. The latter correlates with disease activity and IFN regulated genes had been found in atrophic muscle fibers of patients with idiopathic inflammatory myopathies (IIM). However, the role of this subset of neutrophils has not been fully addressed in IIM. The aim of this study was to assess the relationship between LDGs, disease activity and damage in patients with IIM.

Methods: We recruited 65 adult patients with dermatomyositis, polymyositis, and anti-synthetase syndrome according to the respective classification criteria. The percentage and absolute number of LDGs were assessed by flow cytometry as those CD10⁺, CD15⁺ and CD14⁺ cells in the mononuclear fraction. Disease activity and damage were evaluated by two Rheumatologists. Complete clinical response was defined as the absence of muscular and extra muscular disease activity with immunosuppressive therapy.

Results: The most frequent diagnosis was adult onset dermatomyositis (67.6%). Patients with calcinosis and dysphagia had higher amount of LDGs (Table 1). There was a trend towards higher amount of LDGs in patients with anti MDA5 antibodies. LDGs correlated with disease activity scales (MMT8, muscle enzymes, the patient's and physician's visual analogue scale (VAS) of disease activity) as well as with the extension and severity of damage (Table 2). Only 23.9% of patients had clinical complete response and those subjects had significantly lower levels of LDGs (0.17 (0.08-0.49) vs 0.46 (0.23-1.35), P=0.030).

Conclusion: LDGs are expanded in subjects with active IIM, especially in those with signs of vasculopathy (calcinosis) and dysphagia. LDGs correlate with disease activity and damage scales. Also, patients with anti MDA5 antibodies whom are characterized by an intense IFN signature have higher amount of LDGs. Our findings support the role of LDGs in the induction of disease activity and damage in patients with IIM and suggest that they may serve as a biomarker to identify patients with active disease in contrast with those with complete clinical response.

Session Information

Session Date: Monday, October 22, 2018

Session Title: Muscle Biology, Myositis and Myopathies Poster II: Basic and Translational Science

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Extracellular vesicles (EVs) are micron-scale bilayer membrane vesicles released from almost all cell types under activation or apoptosis. They have been detected in various bodily fluids, organs, and tissues in different pathologic states. EVs harbor molecules from their parental cells, which may mediate intercellular communications, and are thought to play an important role in autoimmune inflammation as they have been shown to induce the synthesis of various proinflammatory cytokines in several immune cell types. Previous studies have demonstrated that circulating EVs are increased in a variety of autoimmune diseases, including dermatomyositis (DM). In the current study, we aim to characterize the induction of pro-inflammatory cytokines by EVs isolated from patients with dermatomyositis.

Methods: Fourteen DM patients and nine healthy controls were recruited in the dermatology clinic at the Hospital of the University of Pennsylvania. Peripheral blood mononuclear cells (PBMCs) were isolated from the DM patients and healthy controls and subsequently stimulated with either no treatment, EVs isolated from the homologous plasma, or homologous EV-free plasma. The levels of TNF- α , IFN- α , IFN- β , IL-8, and IL-6 secreted by the PBMCs in the conditioned medium were then quantified with an enzyme-linked immunosorbent assay (ELISA). A one-way analysis of variance (ANOVA) was used to compare cytokine levels secreted by cells stimulated with either EVs, EV-free plasma, or no treatment.

Figure 1: TNF-alpha release by PBMCs of DM patients and HCs stimulated with either no treatment (i.e. sham), EVs isolated from homologous plasma, or homologous EV-free plasma.

Figure 2: IFN-alpha release by PBMCs of DM patients and HCs stimulated with either no treatment (i.e. sham), EVs isolated from homologous plasma, or homologous EV-free plasma.

Results: In the DM patients, EVs significantly increased the cellular secretion of TNF- α , IFN- α , IL-8, and IL-6 from homologous PBMCs compared to no treatment ($p<0.001$, $p<0.001$, $p<0.001$, $p<0.001$, respectively) and EV-free plasma ($p<0.001$, $p<0.001$, $p<0.001$, $p<0.001$, respectively). In the healthy controls, EVs either did not significantly or less significantly increased TNF- α , IFN- α , IL-8, and IL-6 secretion from the homologous PBMCs compared to no treatment ($p>0.05$, $p>0.05$, $p<0.01$, $p<0.05$, respectively) and EV-free plasma ($p>0.05$, $p>0.05$, $p>0.05$, $p<0.05$, respectively). In both the DM patients and the healthy controls, the EVs did not significantly increase IFN- β secretion.

Conclusion: Therefore, EVs from DM patients induce secretion of key immuno stimulatory cytokines from their homologous immune cells, suggesting that EVs likely play a role in the pathogenesis of DM. Our preliminary studies indicate that circulating EVs are important proinflammatory mediators that amplify proinflammatory responses in patients with DM.

Functional, Radiographic and Serologic Correlates of Anti-SSA52 Kd – Associated Interstitial Lung Disease

Estefania Calle Botero¹, Benjamin Wang², Juan J Maya², Isabel Mira-Avendano³ and Andy Abril², ¹Rheumatology, Universidad de Antioquia, Medellin, Colombia, ²Rheumatology, Mayo Clinic Florida, Jacksonville, FL, ³Pulmonary and Critical Care, Mayo Clinic Florida, Jacksonville, FL

Session Information

Session Date: Monday, October 22, 2018

Session Title: Muscle Biology, Myositis and Myopathies Poster II: Basic and Translational Science

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Autoantibodies against the SSA52 Kd protein (anti-SSA52) have been cataloged as myositis-associated antibodies, occurring in up to 30% of cases idiopathic inflammatory myopathies (IIM), commonly with anti-synthetase (AS) antibodies, mainly anti-Jo1. This study sought to describe the association of ILD with the presence of anti-SSA52, including the pattern and severity of interstitial lung disease (ILD) and the correlation of other serological markers co-expressed with anti-SSA52 and ILD.

Methods: We retrospectively identified all anti-SSA52 positive patients evaluated at our center from 2015-2018 for myositis and/or ILD and had myositis-associated autoantibodies tested using a commercial panel (MyoMarker Panel 3®, RDL Reference Laboratories), and collected information on the high-resolution computed tomography (HRCT) pattern, pulmonary function tests (PFT) and serology. The presence of various antibodies were entered into a logistic regression model with ILD as the outcome, using interaction terms based upon univariate analyses.

Results: Our sample included 62 patients positive for anti-SSA52. They most commonly had dermatomyositis/polymyositis (22%), AS syndrome (21%) and systemic sclerosis (9%); 11.3% had non-rheumatic diagnoses. ILD was found in 66% with a HRCT pattern of non-specific interstitial pneumonia (NSIP) in 39%, organizing pneumonia (OP) in 27%, usual interstitial pneumonia (UIP) in 17% and NSIP/OP in 26.8%. Among those with ILD there was concurrent positivity for anti-SSA52 and other antibodies included in the MyoMarker Panel 3, mainly anti-Jo1 (24%), anti-MDA5, anti-TIF1 γ and anti-U1RNP (12.2% each). PFT in patients with ILD and anti-SSA52 showed diminished median FVC: 2.12 L (IQR 0.97) and DLCO: 36% (IQR 29). Those positive for both anti-SSA52 and anti-Jo1 had worse function, with median FVC: 1.6 L (IQR 0.89) vs 2.13 L (IQR 0.65) and median DLCO: 26% (IQR 10) vs 44% (IQR 33). No correlation for anti-Jo-1 was found in the multivariable model (β -coefficient 5.55, $p=0.96$). Anti-Mi2 (β -coefficient 17.2, $p=0.034$) and anti-PM-Scl (β -coefficient -17.2, $p=0.034$) were strongly correlated with ILD, with the latter showing an inverse correlation.

Conclusion: Anti-SSA52 antibody was commonly associated with IIM. NSIP and OP were the most frequent HRCT findings and PFT showed a restrictive pattern with worse FVC and DLCO in those co-expressing anti-SSA52 and anti-Jo1 than those mono-specific for anti-SSA52. In the presence of anti-SSA52 there was a positive correlation of anti-Jo1 and anti-Mi2 with ILD, and anti-PM-Scl seemed to be a protective factor for pulmonary involvement. Additional study of the interaction of autoantibodies with clinical outcomes is underway.

Session Information

Session Date: Monday, October 22, 2018

Session Title: Muscle Biology, Myositis and Myopathies Poster II: Basic and Translational Science

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Clinically amyopathic dermatomyositis (CADM) patients are frequently manifested by rapidly progressive interstitial lung disease (ILD) and associated with a poor prognosis. Recently cardiac involvement is recognized as a poor prognostic factor in several diseases including inflammatory myositis, however its clinical significance has been rarely investigated in CADM. Here, we determined factors associating with poor prognosis in patients with CADM by focusing on cardiac involvement using cardiac scintigraphy.

Methods: All patients who visited our hospital from 2009 to 2015 and performed cardiac scintigraphy using ^{99m}Tl and ¹²³I-BMIPP were retrospectively evaluated. Patients who fulfilled Bohan and Peter's criteria for DM and Sontheimer's criteria for CADM were selected. We calculated the mismatch score in cardiac scintigraphy by subtracting the uptake of ¹²³I-BMIPP (metabolism) from that of ^{99m}Tl (perfusion) on each 17 myocardial segments standardized by American Heart Association. The perfusion-metabolic mismatch indicates an area of hypometabolism without ischemia and a functional abnormality due to myocardial injury. We compared the mismatch scores between patients with classic DM and CADM. Furthermore, independent prognostic factor for poor outcome defined as death or receiving home oxygen therapy was determined in CADM group.

Table I. Multivariate analysis for prognostic factors

Parameters	Univariate		Multivariate	
	OR (95% CI)	P	OR (95% CI)	P
Mismatch score	1.10 (1.03-1.23)	<0.01	1.30 (1.00-1.71)	0.03
%VC	1.01 (0.98-1.10)	0.85		
Fe _{crit} (mmHg)	0.99 (0.98-0.99)	0.00	0.61 (0.42-1.01)	0.10
Lactate	0.95 (0.81-1.07)	0.43	—	—

Results: One-hundred and seventy-seven patients were evaluated. We investigated 68 patients with classic DM and 11 patients with CADM. Higher prevalence of poor outcome was seen in CADM patients than classic DM patients (27.2% vs 5.9%, $p=0.02$), but there was no difference in %VC and level of cardiac enzyme between the groups. We compared the result of cardiac scintigraphy and found the mismatch scores was not different between the 2 groups ($p=0.34$) (Figure 1). However, a significantly higher level of mismatch score was detected in patients with poor outcome in only CADM group ($p=0.02$). Multivariate analysis revealed mismatch score was selected as the predictive factor with poor outcome in CADM (odds ratio, 2.30; 95% confidence interval, 1.00–3.31; $p=0.04$) (Table 1).

Conclusion: High mismatch score in cardiac scintigraphy may predict poor outcome in CADM.

Session Title: Muscle Biology, Myositis and Myopathies Poster II: Basic and Translational Science

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Myositis-specific antibodies (MSA) and myositis-associated antibodies (MAA) are used for the diagnosis of idiopathic inflammatory myopathies (IIM). A careful evaluation of these antibodies is needed, because of their relevance for establishing the diagnosis and stratification into specific disease subsets. The aim of this study was to assess the diagnostic accuracy of a line immunoassay for IIM in a large real-life patient cohort and to determine the clinical significance of the Myositis-autoantibodies.

Methods: In this retrospective analysis, we retrieved the clinical diagnoses of all patients submitted to our diagnostic laboratory for MSA and MAA testing between October 2014 and October 2017. A line-immunoassay (Euroline

Autoimmune Inflammatory Myopathies Immunoblot, Lübeck, Germany) was used to detect autoantibodies directed against Jo-1, Mi-2 α , Mi-2 β , TIF1 γ , SRP, MDA-5, NXP-2, SAE, PL-7, PL-12, EJ, OJ, PM-Scl100, PM-Scl75, Ku as indicated by the manufacturer. We calculated specificity, sensitivity, negative (NPV) -and positive predictive values (PPV) as well as the positive and negative likelihood ratios (LR) for each autoantibody.

Results: In total, 3167 samples were analyzed. After exclusion of samples with repeated measurements, records were reviewed and patients without sufficient clinical data were excluded. In total 1111 patient were included in the final analysis. A total of 64 IIM patients were identified. 242 patients had at least one positive antibody testing result, of which 39 patients had an IIM diagnosis. 25 patients with a diagnosis of IIM tested negative for all autoantibodies. The test accuracy of the line-immuno-assay is shown in table 1.

Conclusion: Using the line-immuno-assay for diagnostic work-up for IIM in a real-life setting revealed that this method is a suitable alternative to more time-consuming procedures. However, clinicians should be aware that PPVs for most autoantibodies are low, due to a low pre-test probability.

Table 1: Test-accuracy of Myositis-antibodies.

Session Information

Session Date: Monday, October 22, 2018

Session Title: Muscle Biology, Myositis and Myopathies Poster II: Basic and Translational Science

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Autoimmune myositis (rheumatic muscle inflammation) associated with interstitial lung disease (ILD) and arthritis is strongly correlated with the presence of anti-histidyl tRNA synthetase (HisRS) autoantibodies. The aims of this study were to investigate: 1) myositis IgG reactivity against HisRS conformational epitopes; and 2) associations between clinical manifestations and anti-HisRS reactivity profiles.

Figure. Anti-full-length HisRS IgG reactivity in myositis patients diagnosed with either polymyositis (PM) or dermatomyositis (DM), and presenting manifestations of interstitial lung disease (ILD), arthritis, skin rash and dysphagia. Numbers represent the patients included in the analysis.

Methods: Serum IgG was isolated using a protein G affinity column (from 25 anti-HisRS negative (-) and 19 anti-HisRS positive (+) myositis sera and 24 age/gender matched healthy controls, HC). Autoantibody reactivity was tested by in house ELISA developed against HisRS full-length protein and three HisRS conformational epitopes (WHEP domain - localized in the N-terminal; HisRS without WHEP (HisRS_WHEP); and ABD - anticodon-binding domain located in the C-terminal). Correlations between diagnosis, clinical manifestations and anti-HisRSIgG reactivity were evaluated.

Results: HisRS⁺ myositis IgG displayed stronger reactivity against full-length HisRS and HisRS_WHEP (median 372 ng/mL and 334ng/mL, respectively), compared to WHEP and ABD (6.38 and 6.48 ng/mL). The strongest anti-full-length HisRS reactivity (>371 ng/mL) was detected in HisRS⁺ patients presenting ILD (10 of 10 of patients, figure below), arthritis (6/10) and polymyositis diagnosis (PM 9/10), in comparison to HisRS⁺ patients with low anti-HisRS reactivity (<23 ng/mL, ILD - 5 of 6; arthritis - 3/6; PM- 5/6) or subjects with no anti-HisRS reactivity (ILD - 10/28; Arthritis - 8/28; PM - 15/28). On the contrary, patients displaying no anti-HisRS reactivity were largely diagnosed with DM (11/28), skin rash (11/28) and dysphagia (6/28) when compared to patients with the highest anti-full-length HisRS reactivity (1 out of 10 patients was diagnosed with DM, skin rash or dysphagia). Similar associations were observed between anti-HisRS_WHEP, anti-WHEP or anti-ABD reactivity and manifestations of ILD, arthritis, skin rash or dysphagia, and DM or PM diagnosis. No anti-HisRS reactivity was detected in the HC group.

Conclusion: This study provides evidences for a possible underlying role of anti-HisRS autoantibodies in the pathogenesis of myositis with interstitial lung disease and joint involvement.

Session Information

Session Date: Monday, October 22, 2018

Session Title: Muscle Biology, Myositis and Myopathies Poster II: Basic and Translational Science

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Anti-aminoacyl-tRNA-synthetase (ARS) antibodies are myositis specific autoantibodies and associated with common clinical characteristics called anti-synthetase syndrome (ASS). Recently anti-ARS detecting enzyme-linked immunosorbent assay (ELISA) in which mixture of 5 ARS antigens are coated have been established and utilized in daily practice (MESACUPTM MBL, Japan). However, we sometimes encounter patients who are positive for anti-ARS by ELISA but negative by RNA-immunoprecipitation (IP). We verified the authenticity and clinical relevance of these anti-ARSs with discrepant results between different detection systems.

Methods: We examined medical records of 1628 samples that were screened for anti-ARS by ELISA between 2014 and 2017. There were 78 patients (134 samples) who were positive for anti-ARS by ELISA, and among these patient, we further analyzed 61 patients by RNA-IP. We found 16 patients who were positive for anti-ARS by ELISA but negative by RNA-IP. We examined clinical characteristics of these 16 patient sera. Statistical analysis was performed by using Fisher's exact test. Furthermore, 7 of 16 patients were examined by protein-IP and individual ELISA methods to verify the authenticity of the discrepant results. The individual ELISA was also confirmed whether the serum autoantibody was absorbed to the antigen.

Results: Compared to the previous report (Love LA. et al. Medicine (Baltimore), 1991), the frequency of all symptoms of ASS other than interstitial lung disease (ILD) were significantly lower in 16 discrepant cases (Table 1). The radiological patterns of ILD frequently showed nonspecific interstitial pneumonia and/or organizing pneumonia (11/16 cases). Most

Clinical Features	Frequency	Previous report	Statistical analysis
Fever	0% (0/16)	87% (41/47)	$p < 0.01$
Polymyositis	31% (5/16)	94% (44/47)	$p < 0.01$
Raynaud's phenomenon	25% (4/16)	82% (39/47)	$p < 0.05$
Mechanic's hands	6% (1/16)	71% (33/47)	$p < 0.01$
Myositis	19% (3/16)	100% (47/47)	$p < 0.01$
Interstitial lung disease	81% (13/16)	89% (42/47)	$p < 0.41$

No	RNA-IP	Protein-IP	Individual ELISA	Absorbed by
1	—	Jo-1	Jo-1	Jo-1
2	—	Jo-1	Jo-1	Jo-1
3	—	Jo-1	Jo-1	Jo-1
4	—	KS	KS	KS
5	—	Jo-1	Jo-1, EJ	Jo-1, EJ
6	—	—	EJ	EJ
7	—	—	KS	KS

cases showed good response to initial glucocorticoid therapy, but 46% of them had recurrence. The results of protein-IP showed that 5 of 7 patient sera reacted with either Jo-1 or KS but 2 did not immunoprecipitated any ARS proteins. The individual ELISA and absorption study showed all these samples reacted with some of the ARS antigens, of which Jo-1 was the most frequently recognized (Table 2).

Conclusion: There are some anti-ARS antibodies which are detected by ELISA but not RNA-IP. These antibodies might inhibit RNAs binding to ARS proteins or recognize denatured ARS antigens. Patients with such atypical anti-ARS showed significant association with ILD but less with the other characteristics of ASS. Furthermore, the ILD with atypical anti-ARS showed similar clinical response and course with that of ASS. Further investigation is needed to clarify whether such patients have distinct form of ASS.

Session Information

Session Date: Monday, October 22, 2018

Session Title: Muscle Biology, Myositis and Myopathies Poster II: Basic and Translational Science

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Myositis specific antibodies (MSA) represent not only important diagnostic tools, but also help stratify myositis patients with particular clinical features, treatment responses and disease outcomes. These antibodies also have the potential to be used in classification criteria. Consequently, standardization of MSA is of high importance. Many laboratories rely on immuno precipitation (IP) for the detection of MSA which, however, are met with logistic,

standardization, and regulatory challenges. Therefore, reliable alternatives to IP are mandatory. The objective of this study was to compare the results obtained from different assays for the detection of anti-Mi-2 antibodies.

Methods: The study included 82 patients (68 females/14 males), most of whom had dermatomyositis (DM, n=57), followed by polymyositis (PM, n=16) and juvenile DM (n=9). All samples were tested using a novel particle-based multi-analyte technology (PMAT, Inova Diagnostics, research use only; Mi-2b, OJ, TIF1y, PL-12, SAE, EJ, MDA5, HMGC, PL-7, SRP, NXP2) in parallel with a line immunoassay (LIA, Euroimmun, not FDA approved; OJ, EJ, PL-12, PL-7, SRP, Jo-1, PM-75, PM-100, KU, SAE, NXP2, MDA5, TIF1y, Mi-2b, Mi-2a). To assess clinical specificity for the PMAT assay, a total of 775 disease controls and healthy individuals were tested.

Results: A total of 24 patients were positive for anti-Mi-2a and 5 patients for anti-Mi-2b antibodies by LIA. For PMAT, 23 patients tested positive for anti-Mi-2b antibodies. The comparison shows varying agreement between the different methods as shown by *kappa* statistics (0.27-0.77). When the results obtained from the LIA were used as reference for ROC analysis,

Figure 1 Antibodies to Mi-2 Alpha and Mi-2 Beta measured using two different methods. In a.) - c.) using ROC analysis, the discrimination between line immunoassay (LIA) positive and negative samples is shown for anti-Mi-2 Beta antibodies using the particle-based multi-analyte technology (PMAT). Panel d.) shows the levels of antibodies by methods and panel e.) by myositis subform. Panel f.) exhibits the reactivity profile of all 29 samples that are positive by at least one method.

good discrimination and high area under the curve values were found for both PMAT vs. LIA Mi-2 Alpha and LIA Mi-2 Beta. A total of 29 samples were positive by at least one test for anti-Mi-2 antibodies. Of those, 24 were positive by Mi-2b LIA, 5 by Mi-2a LIA and 23 by Mi-2 PMAT. When analyzing the results in the context of the myositis phenotype, LIA Mi-2 Alpha was positive in 5/57 (8.8%) DM, in 0/16 (0.0%) PM and 0/9 (0.0%) JDM patients. For LIA Mi-2 Beta, 19/57 (33.3%) DM, 2/16 (18.8%) PM and 2/9 (22.2%) JDM patients were positive. In addition, for PMAT Mi-2 Beta, 21/57 (36.8%) DM, 0/0 (0.0%) PM and 2/9 (22.2%) JDM patients were positive. Lastly, in the control group, 3 controls were positive for anti-Mi-2 antibodies resulting in a sensitivity and specificity of 28.1% and 99.6%, respectively.

Conclusion: Overall good agreement was found between LIA and PMAT for anti-Mi-2 antibodies. Anti-Mi-2 Beta antibodies measured by PMAT tended to be more highly associated with the clinical phenotype of DM. Larger multicenter studies are needed to confirm the findings and to compare the results of LIA and PMAT to IP.

PM-75, PM-100, KU, SAE1,NXP2, MDA5, TIF1y, Mi-2b, Mi-2a). Principle component analysis (PCA) was carried out to analyze the relationship between the individual markers.

Results: In our cohort of Mexico, Central, and South American myositis patients, anti-Mi-2 antibodies were the most common autoantibody detected with an overall prevalence of 28%. The prevalence of the individual MSA antibodies in the sera of IIM clinical subsets is detailed in Table1. PCA analyses (based on PMAT results) displayed clusters of auto antibodies which are consistent with previously reported IIM clinical associations (see Figure 1). Close proximity was observed for the antibodies to synthetase (PL-7, PL-12, EJ, OJ), for HMGCR and SRP, as well as for NXP2 and TIF1y.

Figure 1. Principle component analysis (PCA) of the different auto antibodies in myositis. DM=Dermatomyositis; CADM=clinically amyopathic DM; IMNM=immune mediated necrotizing myopathies; PM=polymyositis;ASS=anti-synthetase syndrome

Conclusion: The novel PMAT used to detect spectrum of MSA in IIM represents a potential alternative to IP and other diagnostic assays. Our data was consistent with previously published associations of MSA with IIM clinical phenotypes and provides further evidence that autoantibodies are useful biomarkers for accurate diagnosis, patient stratification, as well as future classification criteria.

Session Information

Session Date: Monday, October 22, 2018

Session Title: Muscle Biology, Myositis and Myopathies Poster II: Basic and Translational Science

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Many kinds of autoantibodies are detected in idiopathic inflammatory myopathy (IIM) patients. Some of them are useful to diagnose, predict the clinical course, and assess therapy in IIM at an early stage. Here we describe and characterize the clinical significance of a novel autoantibody in IIM directed against the DNA damage binding protein1.

Methods: Three-hundred and eighty patients with various connective tissue diseases (CTDs) and 20 healthy controls (HCs) were screened for autoantibodies by immunoprecipitation with [³⁵S] methionine-labeled HeLa cells. The target autoantigen was immunoaffinity-purified from HeLa cell extracts and was subsequently identified by peptide mass fingerprinting. Antigen specificity of the serum was further examined by immunoblotting.

Results: An antibody directed against a 120kDa protein was detected in serum from 6 patients with IIM, but not in the serum of other CTD patients or HCs. No patient with anti-120kDa antibodies was positive for other myositis-specific autoantibodies. 50% (3 of 6) were underwent a muscle biopsy compatible with inflammatory myopathy. Most anti-DDB1 positive patients (4 of 6, 67%) showed spontaneous improvements without immunosuppressant treatment. Peptide mass fingerprinting identified the DNA damage binding protein-1 (DDB1) as the autoantigen recognized by anti-120KDa autoantibodies. Immunoblotting experiments using recombinant full-length DDB1 protein confirmed that this was the autoantigen recognized by the anti-120KDa autoantibodies.

Conclusion: Anti-DDB1 antibodies are found in mild forms of IIM. Its detection may be helpful for diagnosis and have prognostic and therapeutic implications in patients with IM. This finding may shed new insights into the pathogenesis of IIM.

Session Date: Monday, October 22, 2018

Session Title: Muscle Biology, Myositis and Myopathies Poster II: Basic and Translational Science

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Anti-melanoma differentiation-associated gene 5 (MDA5) autoantibodies are common among Japanese dermatomyositis (DM) and clinically amyopathic DM (CADM) patients who develop rapidly progressive interstitial lung disease (RP-ILD). Recently, autoantibodies recognizing the 100 kDa splicing factor proline/glutamine-rich (SFPQ) were discovered to co-exist in half of Japanese anti-MDA5-positive DM patients. Anti-SFPQ autoantibodies were often absent in initial serum samples but appeared later during the course of disease and in a seasonal pattern. Anti-MDA5-positive patients with anti-SFPQ autoantibodies were older and had a higher prevalence of mechanic's hands than those without the co-existing autoantibodies. To date, anti-SFPQ autoantibodies have not been described in anti-MDA5-positive patients outside of Japan. Thus, the purpose of this study was to identify the prevalence and clinical significance of anti-SFPQ autoantibodies among anti-MDA5-positive DM patients in a cohort of DM patients from the United States.

Methods: We included all anti-MDA5-positive DM patients enrolled in a longitudinal cohort study at the Johns Hopkins Myositis Center. Anti-SFPQ autoantibodies were detected in patient serum samples collected at the first and most recent visits by immunoprecipitating radioactively-labeled proteins from [³⁵S]-methionine-labeled HeK cells. The identities of immunoprecipitated proteins were confirmed by peptide mass fingerprinting.

Results: Fifty-five anti-MDA5-positive DM/CADM patients were included in this study. From among these, autoantibodies recognizing the 100kDa autoantigen were detected in 4 (7.3%) of the DM/CADM patients. The corresponding polypeptide was confirmed to be SPFQ by mass spectrometry. Among the 4 patients with co-existing anti-MDA5 and anti-SFPQ autoantibodies, 1 was also positive for anti-U1-RNP autoantibodies and 1 was anti-Ro52-positive. All anti-SFPQ autoantibodies were detected at the time of first visit to the Johns Hopkins Myositis Center rather than appearing later during the disease course. 75% (3/4) of the anti-SFPQ antibody positive patients at initial symptom onset in March-April, and all had ILD; one of these died from severe ILD. The remaining patient had diagnosis in October and did not have ILD.

Conclusion: Although more than half of Japanese anti-MDA5-positive DM patients eventually have co-existing anti-SFPQ autoantibodies, only 7.3% of anti-MDA5-positive DM patients in this United States cohort were positive for anti-SFPQ autoantibodies. These findings highlight an important difference between anti-MDA5-positive DM/CADM patients in the United States and Japan.

Session Date: Monday, October 22, 2018

Session Title: Muscle Biology, Myositis and Myopathies Poster II: Basic and Translational Science

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Antisynthetase syndrome (ASSD) is an inflammatory connective tissue disease characterized by the classic triad: arthritis, myositis, and interstitial lung disease (ILD) [1-3]. Raynaud's phenomenon, mechanic's hands, and fever are other relevant but less prevalent clinical findings observed in this condition [1, 3, 4]. The pathophysiology of ASSD is not entirely understood, but genetic predisposition, viral infections and medication use may play a role in the development of this disease [5]. In this regard, the human leucocyte antigen (HLA) region has been described as a genetic factor involved in ASSD in different populations. Taking all these considerations into account, the main objective of our study was to evaluate the potential influence of the HLA region in the susceptibility of ASSD in a cohort of patients from Spain.

Methods: Our study population included 83 Spanish patients diagnosed with ASSD and 303 sex and ethnically matched controls. Patients were recruited from Hospital Universitario Marqués de Valdecilla (Santander), Hospital Clínico San Cecilio (Granada), Complejo Hospitalario Universitario de Santiago (Santiago de Compostela), Hospital General Vall

d'Hebron (Barcelona) and Hospital Universitario La Princesa, Hospital Universitario Fundación Jiménez Díaz, Hospital Universitario La Paz and Hospital General Universitario Gregorio Marañón (Madrid). HLA-DRB1 alleles were determined using the polymerase chain reaction–sequence-specific oligonucleotide probe method.

Results: *HLA-DRB1*03* was significantly increased in patients with ASSD compared to controls (53.0% versus 18.2%, $p < 0.01$, odds ratio=5.09 [95% confidence interval: 2.92-8.84]). Specifically, the susceptibility effect of *HLA-DRB1*03* was due to the *HLA-DRB1*0301* allele.

Conclusion: Our study suggests that the *HLA-DRB1*0301* allele is associated with the susceptibility to ASSD in Spanish patients.

Session Information

Session Date: Monday, October 22, 2018

Session Title: Muscle Biology, Myositis and Myopathies Poster II: Basic and Translational Science

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Sporadic Inclusion Body Myositis (sIBM) is an insidious onset, idiopathic inflammatory myopathy (IIM) with high morbidity. There has not been a reliable biomarker to aid in the diagnosis until autoantibodies to the 44 kDa cytosolic 5'-nucleotidase 1A (NT5c1A: Mup44) were reported. The objectives of our study were to determine the sensitivity and specificity of anti-NT5c1A for sIBM in a cohort of neuromuscular patients and to determine if indirect immunofluorescence (IIF) anti-nuclear antibodies (ANA) assay is a useful serological screen for anti-NT5c1A.

Methods: Sera from sIBM patients, various rheumatic and neuromuscular disease comparator groups, and apparently healthy controls were stored at -80C until required for analysis. All sIBM and IIM patients satisfied the 2017 EULAR/ACR classification criteria for IIM. IgG antibodies to NT5c1A were detected by an addressable laser bead immunoassay (ALBIA) using a full length human recombinant protein (Origene, Rockville, MD: Cat. #TP324617). Autoantibodies to other autoimmune inflammatory myopathy antigens were detected by line immunoassay (LIA) (Euroimmun GmbH, Luebeck, Germany), chemiluminescence assay (CIA) (Inova Diagnostics, San Diego, CA, USA) or enzyme linked immunoassay (ELISA). ANA was detected by IIF (Inova Diagnostics) on HEp-2 substrates. Demographic and clinical data was obtained by chart review.

Results: 27/43 (62.7%) of the sIBM sera were positive for anti-NT5c1A (sensitivity 0.63). 3/43 (7.0%) and 1/43 (2.3%) were positive for anti-SMN (Survival of Motor Neuron) and anti-HMGCR (3-Hydroxy-3-Methylglutaryl-Coenzyme A Reductase), respectively, but all were negative for the other myositis-related antibodies (Jo-1, OJ, TIF1y, PL-12, SAE, EJ, MDA5, PL7, SRP, NXP2, MI-2). By comparison, the frequency of anti-NT5c1A in the non-sIBM control group was 9% (specificity 0.91). Of note, 12/60 (20.0%) of systemic lupus erythematosus (SLE) patients were positive for anti-NT5c1A. Furthermore, the two IIM comparator groups (which did not include sIBM) showed 4/40 (10.0%) and 5/104 (4.9%)

positivity for anti-NT5c1A. Review of ANA results for anti-NT5c1A positive (n=34) and anti-NT5c1A negative sera (n=37) indicated that there was no consistent IIF staining pattern associated with anti-NT5c1A positive sera, regardless of disease.

Conclusion: The sensitivity and specificity of anti-NT5c1A for IBM was 0.63 and 0.91, respectively. Therefore, a normal anti-NT5c1A test does not rule out sIBM (moderate sensitivity) whilst a positive test may be helpful with the canonical features of sIBM to support the diagnosis (high specificity). The clinical significance of anti-NT5c1A in SLE requires further study. Anti-NT5c1A antibodies were not associated with a specific IIF staining pattern, hence screening using HEp-2 substrate is unlikely to be a useful predictor for the presence of these autoantibodies.

Session Title: Muscle Biology, Myositis and Myopathies Poster II: Basic and Translational Science

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: There is a lack of standardized methodology for assessing whole body MRI (WBMRI) in idiopathic inflammatory myopathy (IIM) patients. This leads to difficulty in comparing results across studies and combining data in meta-analysis. The goal of this study was to develop a new standardized assessment tool to characterize WBMRI findings in IIM patients.

Methods: Thirty patients with probable or definite Bohan and Peter juvenile or adult dermatomyositis (JDM, DM) or juvenile or adult polymyositis (JPM, PM) or definite IBM by Grigg's criteria underwent WBMRI, including T1, T2, and STIRMRI sequences. A tool was developed to record scores for these patients based on consensus opinion among radiologists with expertise in musculoskeletal assessment and rheumatologists with myositis expertise. Images were scored in a blinded manner across 34 compartments (Fig. 1) by 3-4 radiologists without an expertise in musculoskeletal disease. Each compartment was assessed for abnormal findings in muscle, subcutaneous tissue, and myofascia. The intensity of muscle signal abnormality (STIR intensity score), extent of muscle inflammation (STIR involvement score) and fatty infiltration (T1 fatty infiltration score) were scored using a 0-3-point scale. The presence of fasciitis and subcutaneous tissue signal intensity (Skin/SC T2 signal) and muscle atrophy (T1 atrophy) were evaluated on a binary scale (0=negative; 1=positive signal abnormality).

Clinical assessments included physician global disease activity visual analogue scale (PGA), the Myositis Disease Activity Assessment tool (MDAAT) and manual muscle testing (MMT). Interrater reliability was assessed by intra-class coefficient. Correlations were assessed by Spearman correlation coefficient.

Results: Patients included 12 JDM, 2 JPM, 9 DM, 4 PM, and 3 IBM. Most patients were female (80%) and 25 patients (83%) were non-Hispanic Caucasians, 3 (10%) were non-Hispanic African-Americans, and 2 (7%) had Hispanic ethnicity. The median age at the time of MRI was 26 years (IQR: 12 – 55), and the median duration between IIM diagnosis and MRI was 12.7 months (IQR: 6.7 – 23.3). There was fair to excellent agreement for 29/34 compartments (ICC>0.40). Among all IIM patients, PGA correlated with adjusted global total muscle and total disease WBMRI scores ($r_s=-0.525$, $P=0.005$ and $r_s=-0.500$, $P=0.008$, respectively). Adjusted global total muscle and total disease scores also had significant

correlations with MMT ($r_s=-0.399, P=0.032$ and $r_s=-0.388, P=0.038$, respectively). There were no significant correlations between MDAAT cutaneous disease activity and WBMRI fasciitis or subcutaneous edema scores.

Conclusion: WBMRI correlated well with physician assessment of disease activity and MMT. This assessment tool offers a reliable semi-quantitative assessment of MRI findings in IIM patients.

Quantitative High Throughput Screening of Small Molecules to Inhibit Interferon-Stimulated Major Histocompatibility Complex Class I in Myositis Muscle

Travis Kinder, Patricia Dranchak and James Inglese, National Center for Advancing Translational Sciences, National Institutes of Health, Rockville, MD

Session Information

Session Date: Monday, October 22, 2018

Session Title: Muscle Biology, Myositis and Myopathies Poster II: Basic and Translational Science

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Common molecular and histological features of idiopathic inflammatory myopathies (myositis) include activation of the type 1 interferon (IFN) response and aberrant expression of major histocompatibility complex (MHC) classes I and II in myofibers. The IFN response correlates with myositis disease activity, and IFN is known to up-regulate MHC in muscle. MHC is directly involved in autoimmune attack by presenting self-antigens to T cells, and certain of its alleles (human leukocyte antigens (HLAs)) confer susceptibility to myositis. These molecules are not expressed in healthy myofibers, and over-expression of MHC class I in mouse muscle recapitulates many characteristics of myositis including inflammation, atrophy, and ER stress. Here we report the development of a series of cell-based assays for quantitative high throughput screening (qHTS) for small molecule inhibitors of IFN-stimulated MHC class I expression in muscle.

Methods: The primary screen involves immunofluorescence of HLA-ABC in immortalized human myoblasts stimulated with IFN-beta and treated with large and diverse chemical libraries containing approved, well-characterized, or novel compounds, and then analyzed by laser cytometry and high content imaging. Active molecules displaying concentration-response profiles for inhibition of HLA-ABC expression will be validated in primary myoblasts from myositis patients by both immunofluorescence and RT-qPCR of several HLA genes. In addition, we are developing a CRISPR/Cas9 genome-edited myoblast with reporter genes inserted into the endogenous HLA loci to measure its expression level.

Results:: We have developed both high throughput RT-qPCR and immunofluorescence assays for HLA-ABC in immortalized human myoblasts, have measured concentration-response profiles for IFN-beta, and are currently screening chemical libraries. We sequenced the HLA loci of this cell line, designed guide RNAs, and are optimizing Cas9 transfections to create a reporter gene edited cell line.

Conclusion: These efforts will be the first application of qHTS technology with a chemical genomics approach to interrogating the IFN-MHC response in myositis muscle.

Session Title: Muscle Biology, Myositis and Myopathies Poster II: Basic and Translational Science

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The HMG-Cr form of Necrotizing Myopathy (NM) is a relatively newly recognized entity within the constellation of pediatric inflammatory myopathies. The purpose of this study is to assess peripheral blood mononuclear cells (PBMCs) from 2 children with NM, one with documented IgG antibody to HMG-Cr, for their pattern of gene dysregulation, compared with JDM and control PBMCs, using RNASeq.

Methods: After obtaining the appropriate informed consent, the following were enrolled in the CureJM Juvenile Myositis Registry: 4 girls with JDM (mean age 12.4±4.6 SD years), 2 girls with NM, (mean age 7.5± 8.8 years) and 4 controls (mean age 8.5± 4.4 years); all participants were White/Hispanic. Sera for all current Myositis Specific Antibody as well as SRP and SAE antibody was tested by Oklahoma Research Labs. They were also tested for SAE and HMG-Cr antibody by RND labs (Culver, Ca.). RNASeq libraries were generated from PBMC RNA using the Clontech stranded high input ribosomal depletion total RNA kits. The samples were sequenced on an Illumina HiSeq2500 or HiSeq3000 in paired-end mode. Sequence reads were aligned to the reference genome GRCh38 by STAR. Read count normalization and differential expression analysis were performed by DESeq2.

Results: The MSAs of the 4 JDM were: p155/140=3; negative=1; the entire group was negative for SAE and SRP antibodies. Of the NM group, one was positive for IgG antibody to HMG-Cr. Cluster analysis of the RNAseq data suggests three distinct JDM subgroups (2 JDM each), with the two NM patients (one HMGCr +) which had very similar expression patterns. Overall, these 6 myositis transcriptome patterns were quite different from the 4 controls. One of the two groups of JDM was more similar to the controls (termed normal-like JDM). Using DESeq, we identified 209 genes that were differentially expressed in both HMGCr-normal-like JDM comparison and HMGCr-control comparison (False Discovery Rate (FDR) < 0.15). Pathway analysis by WebGestalt revealed several enriched pathways including neutrophil degranulation (29 genes, FDR<0.00001); innate immune system (46 genes, FDR<1.6*E-8), Toll-like receptors cascades (11 genes, FDR=0.0023), complement and coagulation cascades (6 genes, FDR=0.048), which play a role in autoimmune disease. Of note, several genes with critical roles in T-cell receptor signaling (i.e., CD3D, CD8A, ICOS, ITK) were consistently down-regulated in the 2 NM children. Using weighted correlation network analysis, we identified 156 genes that were highly connected with the HMG-Cr gene. WebGestalt shows that this gene network is enriched in circadian clock/NAD metabolism and degradation of beta-catenin by the destruction complex.

Conclusion: Specific patterns of gene dysregulation determined by RNASeq appear to characterize PBMCs from these children with necrotizing myopathy. There is wide variation in gene dysregulation in PBMCs compared to JDM, revealing some shared modes of muscle destruction. When serological diagnosis is not established, characterization of the patient's RNASeq pattern, using PBMCs, may be helpful in assessing necrotizing myopathy.

Session Information

Session Date: Monday, October 22, 2018

Session Title: Muscle Biology, Myositis and Myopathies Poster II: Basic and Translational Science

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: CD146 is a transmembrane glycoprotein belonging to the immunoglobulin superfamily, acts as an adhesion molecule for the maintenance of cell monolayer. Human endothelial cells constitutively express CD146 which is involved in angiogenesis and inflammation. Recently, we established a sandwich ELISA for detecting soluble CD146 (sCD146) in human serum and reported presence of elevated level of sCD146 in patients with Behcet's disease and systemic sclerosis.

Figure 1. Serum levels of soluble CD146 (sCD146) in patients with Dermatomyositis (DM) or Polymyositis (PM) and healthy controls (HC)

However, an association of sCD146 with PM/DM remains unknown. The aims of this study are to examine serum levels of sCD146 in patients with PM/DM and their association with clinical features and to clarify the mechanism of the difference in levels of sCD146.

Methods: Serum levels of sCD146 were quantified in 102 patients with PM/DM who visited our hospital from January 2001 to 2017 and compared with those of 22 healthy controls (HC). Recombinant CD146 protein was used to obtain a standard curve to measure quantity of sCD146. We also established another ELISA for detecting autoantibody against CD146 by using human recombinant CD146 protein.

Results: Serum levels of sCD146 were higher in the PM/DM subset than in HC but not statistically significant difference. Especially, the levels of sCD146 was significantly higher ($P < 0.01$) at mean 12.2 ng/mL in the PM subset, as compared to the DM subset or HC (Figure 1). Inverse correlations were observed between the levels of sCD146 and those of C-reactive protein in the PM/DM subset, and between the levels of sCD146 and those of creatine kinase in the PM subset. The levels of sCD146 were significantly higher ($P < 0.05$) in the patients with anti-ARS antibody than in patients with anti-TIF1-gamma antibody. There was no correlation between the levels of sCD146 and other clinical features such as complication of interstitial lung disease or malignancy. We hypothesized the existence of CD146 autoantibody in patients with DM and its involvement in the mechanism of the difference in the levels of sCD146. We measured serum CD146 autoantibody by established ELISA and found out the presence of serum CD146 autoantibody in PM/DM and significant high levels ($P < 0.05$) in the DM subset at 2 folds higher than mean level of the PM subset. These findings suggested the presence of CD146 autoantibodies could make disturbance to detect sCD146 in DM. Additionally, the levels of CD146 autoantibody showed a significant correlation with disease activity in patients with DM.

Conclusion: We identified higher levels of sCD146 in patients with PM than DM, and higher levels of CD146 autoantibody in DM than PM. CD146 could be one of the key factors involved in the pathophysiology of PM/DM.

Session Title: Muscle Biology, Myositis and Myopathies Poster II: Basic and Translational Science

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The Idiopathic Inflammatory Myopathies (IIM) are the largest number of acquired and potentially treatable muscle disorders. Nevertheless, there are currently no FDA or EMA-approved medications apart from corticosteroids, and the mortality and morbidity of these diseases pairs the ones of rheumatoid arthritis in the pre-biologic era. In the last 10 years, interest has been raised about the roles of dendritic cells (DCs) in the pathogenesis of IIM. In this pilot study, we aim to apply previously validated approach of multi-channel confocal microscopy using fluorescent antibodies for identification and characterization of DC populations in biopsies of patients with Dermatomyositis (DM) and Inclusion Body Myositis (IBM).

Methods: This study was performed with deidentified samples from patients with IIM. This study was approved by the University of Chicago institutional IRB. A total of 3 DM and 3 IBM samples were stained for myeloid dendritic cells (mDCs) with BDCA1 and CD11c; plasmacytoid DCs (pDCs) with BDCA 2 and CD123; and cell nuclei with DAPI (Hoechst 33342). These slides were imaged with the SP8 3D 3-color STED laser scanning confocal microscope with time gating at a magnification of 630x, using a pixel size of 1024x1024 and 12 bit depth. Single fluorochrome controls were utilized to ensure no cross-bleeding was present in between fluorescent channels. Given the large amount of tissue, pertaining to each biopsy, and to minimize potential bias, we performed a random acquisition protocol by means of tiling. Using a mechanized stage, the entire tissue section of interest was mapped, automatically segmented into Regions of Interest (ROIs), corresponding to individual High Power Fields (HPFs), and acquired by random means. An average of 50

ROIs per biopsy was acquired in this manner. In addition, manual imaging was performed for areas of significant inflammation, identified during the above process. The resulting image data was reviewed and manually analyzed for number of DCs by a blinded observer (IBV) using Fiji Software. Mann-Whitney U test was used to calculate statistical significance for all analyses.

Results: Subjects with IBM and DM had high counts of mDCs, particularly in DM, with an average of 14 mDCs in DM and 7 mDCs in IBM per biopsy. The difference between DM and IBM in regards to mDCs was decreased after normalization, maybe reflecting the rich inflammatory milieu of DM, in comparison to IBM. The counts of pDCs were also high in both diseases, and significantly higher compared to the ones of mDCs in IBM ($p=.02$), even when normalized by cell density ($p=.032$).

Conclusion: Our findings challenge the classic correlation between DM, IBM, pDCs and mDCs. This pilot study illustrates the complexity behind the cellular drives of IIM in regards to DCs. Priorly established patterns of inflammation used to describe these diseases must be revisited, as new therapeutic targets are urged in IIM.

Session Title: Muscle Biology, Myositis and Myopathies Poster II: Basic and Translational Science

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Idiopathic Inflammatory Myopathy (IIM) is a group of autoimmune diseases characterized by immune-mediated injury to skeletal muscle, including polymyositis (PM) and dermatomyositis (DM). Recent studies have shown that IIM patients exhibit a type I interferon (IFN) signature, which is also present in systemic lupus erythematosus (SLE) (1). Low density granulocytes (LDG) have been identified as an important source of IFN production in SLE patients (2). Given the importance of IFN in the pathogenesis of SLE, DM, and PM, we hypothesized that LDG numbers would be increased in patients with IIM.

Methods: Healthy donors (HD) and patients with undifferentiated connective tissue disease (UCTD) were enrolled in the Hospital for Special Surgery UCTD Registry. SLE patients were enrolled in the FLARE lupus registry, and all met at least 4 of 11 ACR classification criteria for SLE. Myositis subjects in the present study were enrolled in the Hospital for Special Surgery Myositis Registry. All patients with IIM either 1) met Bohan and Peter criteria for probable or definite PM or DM, or 2) met Bohan and Peter criteria for possible PM/DM and were positive for a myositis-specific or myositis-associated antibody. PBMC were isolated from whole blood using Ficoll density centrifugation, then stained and fixed with paraformaldehyde until analyzed by flow cytometry. Cells were stained with antibodies against CD16, CD15, CD14, CD64, and CD56. LDGs were identified as cells in the PBMC fraction staining CD15hi/CD14lo. Differences between groups were analyzed using 2-tailed Student's T tests. No correction for multiple comparisons was made in this exploratory analysis.

Results: 18 patients with IIM (10 DM/8 PM), 14 healthy donors, 3 SLE patients, and 4 patients with UCTD were evaluated. The mean proportion of LDGs in IIM was numerically greater than HD, but the difference did not reach statistical significance (all presented as mean +/- standard error: 4.13% +/- 1.61 vs 0.91% +/- 0.27, $p=0.104$). However, when PM and DM patients were compared to HD in a subgroup analysis, DM patients had a significant elevation of LDGs (4.22% +/- 1.75, $p=0.045$). There was no significant correlation between strength as assessed by manual muscle testing (MMT8), or with creatine kinase levels. In accordance w/ prior studies, LDGs in SLE were elevated relative to HD (14.48% +/- 11.67, $p=0.015$), while the level in UCTD was closer to HD (0.61% +/- 0.14, $p=0.558$).

Conclusion: We did not find an increase in LDGs in PBMC of patients with IIM relative to HD, though a subgroup analysis showed DM patients exhibit a significant elevation of LDGs. Our study may not have had sufficient power to distinguish a difference in IIM patients relative to HD in the aggregate, possibly due to the heterogeneity and complexity of IIM patients. LDGs may be of importance in subgroups of IIM patients.

Session Title: Muscle Biology, Myositis and Myopathies Poster II: Basic and Translational Science

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: To investigate the expression of autophagy marker LC3, localization of macrophages and accumulation of misfolded proteins in myofibres of immune-mediated necrotizing myopathy (IMNM) muscle biopsies.

Methods: The analysis was made on muscle sections of 12 IMNM, 12 Dermatomyositis (DM), 5 Polymyositis (PM), 8 sporadic Inclusion Body Myositis (sIBM) patients and 6 healthy, age-matched controls immuno labelled with anti: - autophagy markers LC3b, -ubiquitin, - SQSTM1/p62, -TDP-43 (TAR DNA binding protein), -SMI31, -C5b-9, -CD68, - NCAM (neural cell adhesion molecule), -MHC I (major histocompatibility complex-I), -MHC II.

Results: In IMNM, inflammation was mild compared with DM, PM, sIBM; sporadic endomysial and/or perivascular inflammatory cells were CD68+ macrophages. The number of myofibres containing LC3b was statistically higher in IMNM and IBMs rather than in DM and PM.

In IMNM, LC3b was mainly located in regenerating myofibres, CD56 + and was associated with MHC-II⁺ vesicles. In sIBM, a high number of LC3b was found in vacuolated myofibers, whereas CD56+ myofibers appeared less pronounced. SMI31 and p62 aggregates were significantly higher in sIBM rather than in the other IIMs, even if, also in IMNM they accumulated in non-necrotic myofibres, the latter colocalizing with LC3 as small puncta in IMNM myofibres and large vacuoles in sIBM myofibres. However, the highest number of ubiquitin⁺ myofibres was revealed in IMNM.

Conclusion: These findings suggest an involvement of cellular clearance systems in the pathophysiology of IMNM, like that of sIBM. LC3b⁺ puncta in regenerating myofibres can be considered a peculiar biomarker in IMNM. Further studies of larger patients' cohorts are needed to better define IMNM.

Session Information

Session Date: Monday, October 22, 2018

Session Title: Osteoarthritis – Clinical Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Cumulative evidence suggests central sensitization contributes to a neuropathic-like phenotype in a subset of patients with knee osteoarthritis (OA). Using a variety of validated neuropathic pain (NP) questionnaires in musculoskeletal patient cohorts, factors including gender, body mass index, and depression, insomnia and pain catastrophizing have been associated with neuropathic symptoms. In the current study, the modified pain Detect Questionnaire (mPDQ) was administered to subjects enrolled in the Osteoarthritis Initiative (OAI), a well-established, longitudinal knee OA cohort, with the aim of further exploring the prevalence and correlates of NP specific to knee OA. A better understanding of the factors associated with NP in knee OA can help identify affected patients who may benefit from alternative treatment approaches that target NP pathways.

Methods: The mPDQ was administered to 699 subjects enrolled in the Baltimore OAI cohort during their scheduled 72-month follow up visit. Standard demographic, clinical, and radiographic data were collected as per the OAI study protocol. The presence of NP was determined using a previously defined mPDQ cut-point. Correlates of NP were evaluated through univariate analysis and logistic regression, and included factors relating to demographics, knee OA symptom severity, markers of chronic pain and pain intensity, psychological factors, functional disability, medical comorbidities and concurrent medication usage.

Results: Of the 699 subjects in the cohort, 476 were eligible for the analysis; 99 (21%) subjects were found to have NP symptoms (mPDQ score ≥ 13). Knee Injury and Osteoarthritis (KOOS) pain score, The Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) total score, WOMAC physical function score, Von Korff pain score (VKP) and the Late Life Disability Instrument (LLDI) - limitation dimension were shown to be different between patients with and without NP ($p < 0.01$). Independent correlates ($p < 0.01$) of NP were: WOMAC total score (OR=1.93), coping strategies - pain catastrophizing subscale (OR=1.23), VKP (OR=1.06), WOMAC physical function score (OR=1.02) and LLDI – limitation dimension (OR=0.98). Multivariate modelling found WOMAC total score (OR=2.07, $p=0.018$), coping strategies – pain catastrophizing subscale (OR=1.22, $p=0.035$) and VKP (OR=1.07, $p < 0.001$) to be significant predictors of NP.

Conclusion: Similar to other studies, a subset of the Baltimore OAI knee OA cohort had a NP phenotype, which was associated with more pain catastrophizing and greater symptom burden. This study additionally found that a NP phenotype was associated with greater disability. Further studies are needed to determine if treatment targeted to the NP phenotype reduces knee OA symptom severity and functional impairment in affected individuals.

Session Date: Monday, October 22, 2018

Session Title: Osteoarthritis – Clinical Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Inflammation plays a pathogenetic role in OA, and catabolic cytokines including IL-1 β potentiate joint space narrowing. Elevated serum urate (sUA) levels promote crystal-induced stimulation of inflammasome IL-1 β production, potentially contributing to OA incidence and/or progression. Additionally, intraarticular urate concentrations associate with radiographic knee OA (RKO) severity. However, there is limited research on associations of asymptomatic hyperuricemia (AH) and knee OA outcomes. Therefore, we sought to examine the association of AH with RKO and symptomatic RKO (sRKO) using the National Health and Nutrition Examination Survey III (NHANES III), a large nationally representative survey. We also examined whether body mass index (BMI) modifies the association between AH and RKO.

Methods: NHANES III was a cross-sectional health examination survey conducted between 1988 and 1994. It used a multistage, stratified probability cluster design to select a representative sample of noninstitutionalized civilian in the US, and included data on sUA, gout, clinical and radiographic knee OA. We analyzed data (n=2213) for adults over age 60, excluding individuals with self-reported gout. Hyperuricemia was defined as serum urate > 6.8, mg/dL. One non-weight bearing AP knee X-ray was performed with RKO defined as KL grade \geq 2, and sRKO as RKO plus pain in the affected joint on most days for the prior 6 weeks. Wald chi-square tests were used to examine differences in proportions between different study characteristics. Multivariate log binomial models were used to examine the association between AH and knee OA outcomes and estimate prevalence ratios (PRs) and 95% confidence intervals (CIs).

Results: Among US adults age 60 years and older, prevalence of AH was 17.9% (CI 15.3-20.5). AH prevalence was significantly greater among men vs women (24.5% vs. 13.3%, $p < 0.01$) and persons with obesity (BMI ≥ 30 kg/m²) vs persons without obesity (27.4% vs. 14.8%, $p < 0.01$). Prevalence of RKO was 37.7% (CI 35.0-40.3) and was significantly greater in women vs men (42.1% vs. 31.3%, $p = 0.01$). The prevalence of RKO was highest among subjects with greater age, obesity, non-Hispanic Black race, and less education. RKO prevalence among adults with AH was 44.0% vs 36.3% for those with normuricemia ($p = 0.056$). Importantly, sRKO was significantly higher in the AH group (17.4 vs 10.9%, $p = 0.04$). After adjusting for age, sex, race, and education, adults with AH were more likely to have RKO (PR = 1.26, 95% CI: 1.06, 1.36) and sRKO (PR = 1.69, 95% CI: 1.19, 2.42). These associations were observed for persons without obesity, but were severely attenuated among persons with obesity, suggesting that obesity status may modify the association between AH and knee OA.

Conclusion: We identified a greater prevalence of RKO among persons with AH, along with a greater prevalence of sRKO, suggesting urate may participate in OA pathogenesis. This association appeared to be modified by obesity status with non-obese adults (but not adults with obesity) reporting a greater prevalence of knee OA among participants with AH. Longitudinal studies are needed to verify these findings.

Increasing Oral Doses of GLPG1972 Administered Daily for 29 Days Show a Strong Target Engagement in Patients with Knee and/or Hip OA

Henri Deckx¹, Simon Hatch², Martine Robberechts¹, Sonia Dupont³, Julie Desrivot³, Hugh Coleman⁴, Staffan Larsson⁵, André Struglics⁵, Ellen van der Aar¹ and Ann Fieuw¹, ¹Galapagos NV, Mechelen, Belgium, ²Galapagos NV, Boston, MA, ³Galapagos SASU, Romainville, France, ⁴CRU, Covance, Daytona Beach, FL, ⁵Clinical Sciences, Lund University, Lund, Sweden

Session Information

Session Date: Monday, October 22, 2018

Session Title: Osteoarthritis – Clinical Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Osteoarthritis (OA) is characterized by structural changes of the joint, of which degradation of articular cartilage is one of the major signs¹. The main proteoglycan component of the extracellular matrix of articular cartilage is aggrecan. GLPG1972 as a potent and selective inhibitor of ADAMTS-5, a key aggrecan-cleaving enzyme involved in cartilage degradation, is being developed as a potential disease-modifying OA drug (DMOAD). Aggrecan cleavage by ADAMTS-5 results in release of N-terminal ARGS neoepitope fragments of which serum levels significantly decreased in healthy subjects treated with GLPG1972 during 14 days in a previous study².

The objective was to assess safety, tolerability, pharmacokinetics (PK) and pharmacodynamics (PD, i.e. serum ARGS-aggrecan levels) during and following administration of GLPG1972 in patients with knee and/or hip OA.

Methods: This was a single center, randomized, double-blind, placebo-controlled, age and gender stratified, ascending dose Phase Ib study, with three semi-sequential cohorts of 10 patients each, randomized to GLPG1972 or placebo in a 4:1 ratio. Doses tested were once daily 100, 200 or 300 mg given orally. Treatment duration was 29 days. Patients had follow-up visits 14 and 21 days after last dosing for additional PD assessments. Methods for PD have been described previously³.

Results: Thirty patients were included. Of these, 24 patients (M/F rate 8/16, 14 aged 50-64 and 10 aged 65-75) received GLPG1972. All adverse events (AE) were mild and transient. No serious AEs were reported during the study; one female patient in the 300-mg group was discontinued after 15 days of treatment due to drug-related elevated transaminase values which returned to normal 9 days after treatment discontinuation while her bilirubin levels remained normal. There were no overall trends in lab abnormalities over time or significant changes in vital signs, ECG and Holter parameters. Steady state in plasma exposure was reached after 3-5 days of dosing. Exposure increased dose-proportionally. Mean serum ARGS levels (SEM) decreased steadily over time in all patients receiving GLPG1972: -40% (2.9), -46% (4.5) and -53% (2.8) at day 15 compared to baseline in the 100, 200 and 300 mg group respectively. These levels remained stable until last dose on day 29, then consistently returned to pre-dose levels for all groups 14 and 21 days after last dose. Placebo group levels remained unchanged.

Conclusion: When administered daily for 29 days in patients with knee and/or hip OA, GLPG1972 at oral doses of 100, 200 and 300 mg q.d. was generally well tolerated and safe. Serum ARGS levels, as a marker for target engagement and potential proxy of cartilage degradation, showed a decrease over time up to 53% below baseline in the 300 mg group. These findings are consistent with what we observed in a previous study in healthy subjects² and reinforce the rationale for developing GLPG1972 as a DMOAD.

Flexion Contractures Are Associated with Worse Pain, Stiffness, and Function in Patients with Knee Osteoarthritis

T Mark Campbell¹, Marc Monsour² and Guy Trudel³, ¹Physical Medicine and Rehabilitation, Elisabeth Bruyere Hospital, Ottawa, ON, Canada, ²Medicine, University of Ottawa, Ottawa, ON, Canada, ³Medicine, The Ottawa Hospital Rehabilitation Centre, Ottawa, ON, Canada

Session Information

Session Date: Monday, October 22, 2018

Session Title: Osteoarthritis – Clinical Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Knee osteoarthritis (OA) causes pain, disability, and affects ~20% of the population in the United States [Wallace2017]. Knee flexion contractures (FCs) are limitations to knee extension [Campbell 2015]. Despite >1/3 of patients with knee OA having a FC [Ritter 2007], little is known regarding FC effect on their OA symptoms and function. Our objective was to determine if the presence and severity of a knee FC affected joint pain, stiffness and function in patients at risk of developing, or with knee OA.

Methods: Cross-sectional study using the Osteoarthritis Initiative (OAI) cohort divided into 3 subcohorts: those at risk of knee OA (n=3284), those with radiographic knee OA (n=1390), and controls (n=122). At enrollment, knee FCs were graded based on the loss of maximum knee extension ($\leq 5^\circ$ none, $6-14^\circ$ mild, $\geq 15^\circ$ moderate-to-severe). Pain was evaluated using the Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) pain subscale and the numeric

Figure 1: Outcome measures for OAI participants. (A) Pain outcomes as measured by WOMAC and NRS pain scales. (B) Stiffness as measured by WOMAC Stiffness subscale. (C) Disability outcomes measured using WOMAC Disability scale and 400m walk time. All outcomes show a dose-dependent worsening with increasing contracture severity. *p<0.05; **p<0.01; ***p<0.001.

Figure 2. Prevalence of knee flexion contracture, pain, knee dysfunction and stiffness in patients at-risk of OA and with OA. All outcomes were worse with dose-dependency on knee contracture severity and all were amplified in the OA subcohort compared to the at-risk subcohort. * $p < 0.05$; ** $p < 0.01$; *** $p < 0.001$; Δ =difference in outcome between no FC vs moderate to severe FC for at-risk (Δ^R) and OA (Δ^O) participants.

rating scale. Stiffness was evaluated using the WOMAC stiffness subscale. Function was evaluated using the WOMAC function subscale and 400m walk time. Between-group outcomes were compared using ANOVA with post-hoc testing corrected for multiple comparisons. Two-way ANOVA tested for knee FC interaction with subcohort grouping. Multiple linear regression tested for an independent association between knee FC and outcomes, correcting for age, sex, BMI, race, and radiographic severity.

Results: Participants with knee FC tended to be older males with larger BMI and worse radiographic severity (all $p < 0.001$; Table 1). They reported worse knee pain, stiffness and function (all scales $p < 0.001$; Figure 1). Knee FC showed a severity-dependent association with WOMAC pain ($p = 0.020$), WOMAC stiffness ($p = 0.006$) and 400m walk time ($p < 0.001$), with the magnitude increase being greater in the OA group versus those at risk of OA (Figure 2). This association was maintained following multiple linear regression ($p < 0.001$).

Conclusion: Knee FC was associated with pain, stiffness, and dysfunction in participants at risk of, and with knee OA in a FC severity-dependent manner. These associations were strongest in those with knee OA. Measuring knee extension should be a routine component of the clinical assessment. Addressing FC in clinical care may lead to better OA outcomes.

The Association of Microbial Translocation and WOMAC Function in Patients with Knee Osteoarthritis

Sunghye Kim¹, Richard Loeser², Dennis Ang³ and Stephen P. Messier⁴, ¹Medicine, Wake Forest School of Medicine, Winston Salem, NC, ²Thurston Arthritis Research Center, University of North Carolina at Chapel Hill, Chapel Hill, NC, ³Wake Forest University School of Medicine, Winston-Salem, NC, ⁴Department of Health and Exerc, Wake Forest University, Winston-Salem, NC

Session Information

Session Date: Monday, October 22, 2018

Session Title: Osteoarthritis – Clinical Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Osteoarthritis (OA) affects 33.6% of population ≥ 65 . Knee OA (KOA) is the most prevalent OA and it is one of five leading causes of disability of non-institutionalized adults. Aging and excessive body mass are the two strongest risk factor for KOA. Biomechanical theory suggests that increase in axial load would promote degeneration in cartilage. However, it is undermined by the fact that even OA of non weight bearing joint such as carpometacarpal joint of the thumb is associated with obesity. Both obesity and aging, risk factors for OA are associated with low grade inflammation. Microbial translocation (MT) is defined as the passage of both viable and nonviable microbial products such as LPS across an anatomically intact intestinal barrier. A higher burden of microbial translocation with aging is reported both in animal and human studies. Obesity is also known to be associated with increased MT. Recently, MT is thought to be the source of low grade inflammation in obesity and aging, and it is possible that MT activates innate immunity which in turn causes the low grade inflammation seen in OA.

Methods: The Intensive Diet and Exercise for Arthritis (IDEA) study is a prospective, randomized controlled trial of 454 overweight and obese older adults with tibiofemoral osteoarthritis. Two subgroups were selected from IDEA study ($n=22$ each): a group that showed radiographic progression (≥ 0.7 mm decrease in joint space width, JSW) and age, gender, and BMI matched group who did not progress (≤ 0.35 mm decrease in JSW). Stored baseline blood samples were analyzed for markers of MT: lipoprotein binding protein-1 (LBP-1) and soluble cluster of differentiation 14 (sCD14). Multivariate analyses were performed to examine the association with baseline MT and KOA progression as well as the OA outcomes using Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC).

Results: The mean age was 66 (SD 5.3), 68% female, and mean BMI was 30.5 (SD 4.6). There was no association between baseline MT translocation and OA progression. However in multivariate analysis baseline Scd14 is positively associated functional limitation for 18 months WOMAC function measure (coefficient 0.37, $p=0.03$) after controlling for age, weight, randomization group.

Conclusion: In this secondary analysis of IDEA study, a microbial translocation marker at baseline is predictive of 18 months functional outcome. Future study to explore the mechanisms of this association is warranted.

e: NP vs. Both progression	5.32						
f: No rKOA vs. rKOA progression	0.75		k	h			kh
g: No pain vs. pain progression	4.25				kh		kh
h: NP vs. Any progression	1.55				kh	h	kh

Abbreviations: rKOA=radiographic knee OA; NP=non-progressors by pain or rKOA; Both=progressors by both pain and rKOA.
*All variables: Function includes gait/stride strength, walk time, self-reported function; SES includes education, marital status, employment; Health includes comorbidities and family history; Medic includes medications for pain, cardiovascular disease, and NSAID use; Genetics includes T-type from a recent genome (RAD 2775517); Note that clustering and k-means hierarchical methods did not result in significant clusters.

Session Title: Osteoarthritis – Clinical Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Knee osteoarthritis (KOA) is a heterogeneous condition characterized by changes in a variety of joint tissues and driven by a number of different potential mechanisms. The purpose of this study was to explore machine learning approaches to phenotyping in KOA in order to better define the progression phenotype(s) that may be more responsive to interventions.

Methods: We focused on identifying baseline differences in the Johnston County OA Project (T1) between 1) knees with and without prevalent radiographic KOA (rKOA, Kellgren-Lawrence grade [KLG] 2 or more, “OA”), and 2) those that did or did not have worsening KLG and/or symptoms (progression) at follow-up. The dataset included observations on 741 participants with 78 baseline variables selected to represent clinically relevant characteristics of this sample. Both k-means and hierarchical clustering methods were applied to identify important subgroups of observations within the dataset. Two high-dimension low-sample size (HDLSS) methods were used: SigClust, to assess statistical significance of clusters and 2) DiProPerm, a projection and permutation-based approach, to compare groups (e.g., prevalent rKOA vs. no OA, progression vs non-progression) by testing equality of distributions (by z-score) over all variables. Given multiple comparisons, a z-score of at least 2 (p value<0.05) was considered statistically significant.

Results: When considering all observations and all variables simultaneously, significant differences were observed for 5 comparisons (Table 1, hypotheses “OA”, a, d, e, and g). Both-means and hierarchical clustering methods identified clusters with greater significance than using all the observations, suggesting the existence of groups of observations where the difference between progressors and non-progressors is enhanced. For example, when focusing on the genetic data, both clustering methods identified different clusters of observations using SigClust (p<0.01), and further showed that when observations were clustered according to the genetic variables, there were stronger results for hypothesised (rKOA only vs. both radiographic and symptomatic progression). Statistically significant clusters were also identified when clustering was based on physical function, socioeconomic status, health, and medication variables. Clustering on all variables resulted in significant clusters only under hierarchical methods.

Conclusion: These innovative methods provide a way to assess numerous variables of different types and scalings simultaneously in relation to KOA prevalence and progression and could be used for assessing other outcomes of interest. Such methodology could identify both known and novel KOA phenotypes, potentially improving patient selection for specific interventions and providing insight into pathophysiology this heterogeneous condition.

The Role of Personality in Patients with Knee Osteoarthritis

Mengyu Zhou¹, Raveendhara R. Bannuru², Lori Lyn Price³, Michelle Park² and Chenchen Wang², ¹Department of Medicine, Tufts Medical Center, Boston, MA, ²Division of Rheumatology, Center for Complementary and Integrative Medicine, Tufts Medical Center, Boston, MA, ³Institute for Clinical Research and Health Policy Studies, Tufts Medical Center, Boston, MA

Session Information

Session Date: Monday, October 22, 2018

Session Title: Osteoarthritis – Clinical Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Kneeosteoarthritis (OA) is a leading cause of disability and no effective disease-modifying treatment currently exists. Identifying factors associated with clinical outcomes may help to better understand the disease and provide insight for new treatment. Previous studies have found that personality, the multifaceted characteristics underlying a person's affect, cognition, and behavior, may influence OA impact. The aim of the study was to clarify whether personality dimensions are associated with pain, function, psychosocial health, self-efficacy, and outcome expectations among patients with knee OA.

Methods: We performed a secondary analysis using baseline data from a randomized controlled comparative effectiveness trial between TaiChi and physical therapy for knee OA. Patients enrolled were 40 years or older and met American College of Rheumatology criteria for symptomatic knee OA with radiologic evidence. Personality was assessed using the NEO-Five Factor Inventory, a validated measure of five basic personality dimensions: agreeableness, conscientiousness, extraversion, neuroticism, and openness. Outcome measures included Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) pain and function scores, patients global assessment for OA severity, six-minute and twenty-meter walk tests, health-related quality of life, depression, self-efficacy, and outcome expectations for exercise. Pearson correlation analysis was performed to assess the associations between personality dimensions and health outcomes.

Results: There were 34 participants, 71% female, mean age years, body mass index 33 kg/m², 56% white, and mean duration of knee pain 11 years. Higher conscientiousness was associated with better outcome expectations and physical component of quality of life as well as marginally correlated with better self-efficacy. Both higher openness and extraversion were also associated with higher outcome expectations, and higher openness had significant correlation with better self-efficacy. Higher neuroticism marginally correlated with worse depression. Agreeableness was nonsignificantly associated with any outcome. None of the five personality dimensions were significantly associated with WOMAC pain and function, patients global assessment, walk test performance, or mental health (**Table 1**).

Conclusion: Personality significantly correlated with a variety of health outcomes including outcome expectations, physical component of quality of life, and self-efficacy, but was not associated with the level of pain or function in patients with knee OA. The results further elucidate characteristics of OA patients, and implicate that individualized interventions taking personality into consideration may promote well-being in patients with knee OA. Future longitudinal studies with a larger sample are warranted to further inform clinical practice.

Table 1. Associations Between Personality and Osteoarthritis Health Outcomes

Dependent Variable	Mean	Personality Dimension ^à Pearson's correlation coefficients (p-value)				
		Agreeableness	Conscientiousness	Extraversion	Openness	Neuroticism
WOMAC Pain Score [Range: 0-500]	257 ± 107	-0.15 (0.41)	0.01 (0.97)	0.05 (0.79)	-0.26 (0.17)	0.17 (0.37)
WOMAC Physical Function Score [Range: 0-1700]	911 ± 423	-0.13 (0.50)	0.10 (0.57)	0.07 (0.69)	-0.26 (0.17)	0.17 (0.38)
Patient's Global Assessment Score [Range: 0-10]	4.8 ± 2.2	0.05 (0.78)	0.21 (0.25)	0.05 (0.78)	-0.18 (0.34)	0.16 (0.39)
Six-Minute Walk Test (meters)	414 ± 100	-0.08 (0.67)	0.01 (0.95)	-0.07 (0.70)	0.27 (0.16)	0.01 (0.96)
Twenty-Meter Walk Test (seconds)	17.4 ± 3.7	0.02 (0.91)	-0.07 (0.72)	-0.02 (0.93)	-0.33 (0.08)	0.07 (0.71)
SF-36 Physical Component Score [Range: 0-100]	37.3 ± 8.2	0.03 (0.87)	0.38 (0.03)	0.00 (1.00)	0.27 (0.15)	-0.19 (0.31)

Session Date: Monday, October 22, 2018

Session Title: Osteoarthritis – Clinical Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Phenotype identification in knee osteoarthritis (KOA) population could be useful for predicting drug response, allowing personalized interventions. In order to optimize therapeutic outcome in KOA, we aimed to predict drug response of patients treated with COX-2 selective nonsteroidal anti-inflammatory drug Celecoxib (CLX) or pharmaceutical grade Chondroitin sulfate plus glucosamine hydrochloride (CS+GH) combining the analysis of multiple clinical variables and *omics* data.

Methods: A shotgun proteomic analysis by iTRAQ was performed on sera from 80 patients enrolled in the Multicentre Osteoarthritis inter Ventiontrial with Sysadoa (MOVES). Then, a panel of 10 serum proteins was qualified using ELISA Kits in the whole MOVES cohort (n=1043). Patients were classified as responders (R) and non-responders (NR), either to CLX or CS+GH according to the OMERACT-OARSI criteria and the WOMAC pain score recorded after 6 months of treatment. Logistic regression analyses, adjusted by significant confounder variables, were used to analyze the contribution of the measured proteins to our prediction models of drug response in KOA. Appropriate receiver-operating-characteristics (ROC) curves were also calculated.

Results: In the *discovery phase* of the study, the proteomic screening led to the identification of 83 proteins significantly altered at baseline in R compared to NR. Among the proteins presenting the highest iTRAQ ratios and exclusively altered in one of the therapeutic groups, we selected 4 proteins specific for CLX treatment and 6 proteins specific for CS+GH treatment for the development of the *validation* assays in a larger cohort of KOA patients (Fig. 1). In the *qualification phase*, the sensitivity and specificity of the validated proteins were tested in blind in the whole MOVES cohort at baseline. In the CLX group, an increased level of TSP1 was detected at baseline in R compared to NR (363,03ng/mL vs 331,95ng/mL; $p=0,041$). The inclusion in the regression model of 4 predictive variables (2 clinical and 2 analytical) and TSP1 as covariate revealed a specific interaction between response to CLX and baseline protein levels ($p=0,045$) thus increasing the predictive power of this model up to AUC=0,749 (Model 1, Fig. 1). In CS+GH group, ORM 2 levels were significantly higher in NR compared to R (261,6ug/mL vs 192,8 ug/mL; $p=0,042$). 5 clinical and 2 analytical parameters recorded at baseline significantly influence patients' response. The inclusion of ORM 2 as covariate revealed a specific interaction between response to CS+GH and baseline protein levels ($p=0,007$) thus increasing the power of our prediction model up to AUC=0,843 (Model 2, Fig.1).

Fig. 1: Predictive biomarkers development: from the discovery phase to clinical qualification.

Conclusion: Combining clinical and analytical parameters, we qualified 2 panels of biomarkers that could efficiently predict OA patients' response told with an accuracy of 74,9% or to CS+GH with an accuracy of 84,3%.

Session Information

Session Date: Monday, October 22, 2018

Session Title: Osteoarthritis – Clinical Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Accelerated knee osteoarthritis (AKOA) is a painful disorder and is associated with several risk factors and pre-radiographic structural features. While no single factor can accurately predict who is at risk for AKOA, it would be beneficial to recognize the combinations of factors that identify adults at risk for AKOA. We examined the benefit of adding magnetic resonance (MR)-based features to clinical and demographic characteristics for classifying adults who develop AKOA.

Methods: We conducted a case-control study using Osteoarthritis Initiative data from baseline and the first 4 annual visits. Eligible participants had no radiographic KOA in either knee at baseline (Kellgren-Lawrence [KL]<2). We classified 2 sex-matched groups: 1) AKOA: ≥ 1 knee developed advance-stage KOA (KL=3 or 4) within 48 months and 2) did not develop AKOA within 48 months. MR images were assessed at OAI baseline for 3 quantitative measures (effusion-synovitis volume, cartilage damage, and bone marrow lesion volume) and 9 semi-quantitative features (cruciate/collateral ligaments, extensor mechanism, gastrocnemius tendon, synovitis, medial/lateral meniscal pathology, medial/lateral meniscal effusion) that were read by two musculoskeletal radiologists. We performed 2 classification and regression tree (CART) analyses to determine classification rules and important variables for 1) a base model with baseline clinical (serum and radiographic measures) and demographic (age, sex, body mass index [BMI]) characteristics and 2) a combined model with baseline MR-based features in addition to the variables in the base model. Pruning and 10-fold cross-validation were performed to avoid overfitting.

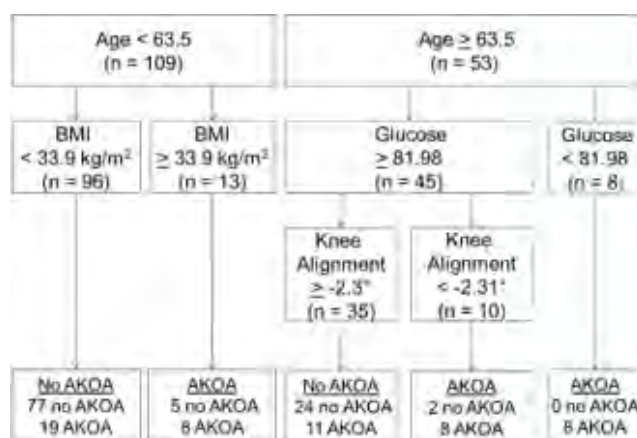

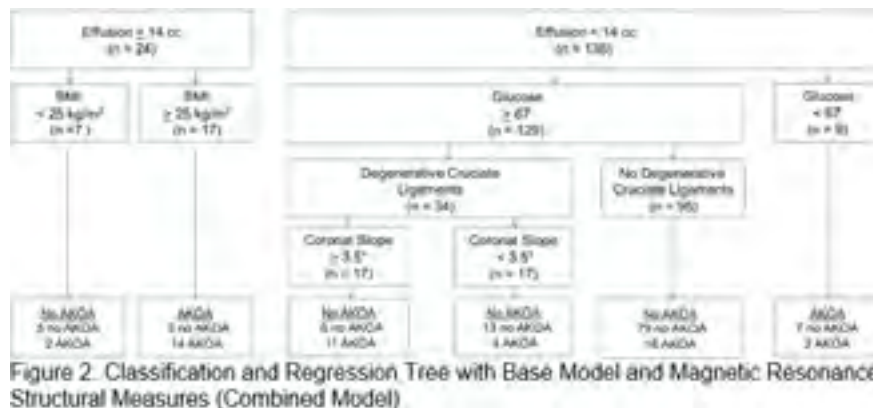

Figure 1. Classification and Regression Tree without Magnetic Resonance structural measures (Base Model)

Results: The most important variables for classifying individuals with incident AKOA in the base model (in order of importance) were age, serum glucose, and body mass index [BMI] (Figure 1). The most important variables in the combined model were effusion, serum glucose, presence of degenerative cruciate ligaments, and coronal tibial slope (Figure 2). The base model explained 31% of the variance, while the combined model explained 39% of the variance. Both the base and combined models offered good specificity (0.94 and 0.90) and moderate sensitivity (0.44 and 0.59, respectively).

Conclusion: MR-based features help classify adults who will develop AKOA; however, the cost of collecting standard MR-based features may outweigh the incremental improvement in classification in some settings.

Progression of Pain, Stiffness, Function Changes, and Ultrasound Detected Synovitis and Osteophyte Formation in Patients with Hand Osteoarthritis over Three Years

Olga Sleglova¹, Olga Ruzickova², Karel Pavelka¹ and Ladislav Šenolt¹, ¹Institute of Rheumatology, Department of Rheumatology, 1st Faculty of Medicine, Charles University, Prague, Czech Republic, Prague, Czech Republic, ²Institute of Rheumatology, Prague, Czech Republic, Prague, Czech Republic

Session Information

Session Date: Monday, October 22, 2018

Session Title: Osteoarthritis – Clinical Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Hand osteoarthritis (HOA) is a common and frequent cause of pain. HOA is a heterogeneous group of disorders with two main subsets including non-erosive and erosive disease. Few studies demonstrated inflammatory ultrasound changes and more severe clinical symptoms in patients with erosive compared with non-erosive disease, however the results are inconsistent. The aim of this study was to evaluate progression of pain, stiffness, physical impairment and ultrasound features in patients with erosive and non-erosive HOA in a three years longitudinal study.

Methods: Patients with symptomatic HOA fulfilling the American College of Rheumatology (ACR) criteria were included in this study. Joint pain and swelling were assessed. Pain, joint stiffness and disability were assessed by the Australian/Canadian OA hand index (AUSCAN). Radiographs of both hands were examined, and erosive disease was defined by at least one erosive interphalangeal joint. Synovial hypertrophy and power Doppler signal (PDS) were scored with ultrasound. Synovitis was graded on a scale of 0–3 and osteophytes were defined as cortical protrusions seen in two planes. Patients were examined at baseline and at the first, second and third year of follow up.

Results: Altogether, 97 patients (7 male) with symptomatic nodal HOA were included in this study and followed between April 2012 and January 2018. Out of these patients, 57 had erosive disease. The number of painful and clinically swollen

joints ($p<0.05$) was significantly higher in patients with erosive compared with non-erosive disease at baseline. The number of painful and clinically swollen joints fluctuate over the second and third year of follow up, but it still remains statistically higher ($p<0.01$) at the third year of follow up in patients with erosive disease.

According to the AUSCAN, patients with erosive disease had more pain ($p<0.05$) and stiffness ($p<0.01$) at baseline. Pain and stiffness, but not function, worsened in patients with erosive compared with non-erosive disease after second year ($p<0.01$). Pain ($p<0.01$), stiffness ($p<0.05$) and also function ($p<0.01$) worsened in patients with erosive disease at the third year of follow up.

US-detected pathologies such as gray-scale synovitis ($p<0.001$), intensity of PDS ($p<0.01$) and number of osteophytes ($p<0.01$) were significantly higher in patients with erosive disease at baseline. There were improvements in gray-scale synovitis total score and intensity of PDS in patients with non-erosive disease while patients with erosive disease worsened after the second and third year of follow up ($p<0.01$). The progression of US-determined osteophyte formation was observed in both groups after the second year of follow up but were significantly higher in patients with erosive than with non-erosive disease after the third year of follow up ($p<0.05$).

Conclusion: The findings of this study show that pain and number of clinically swollen joints associated with US-detected synovial changes and osteophyte formation is more severe in patients with erosive HOA than in patients with non-erosive disease. In addition, osteophyte formation is more likely to progress independent of synovial inflammation. Supported by the project MH 023728 and AZV 18-00542.

Treatment of Knee Osteoarthritis with SM04690 Improved WOMAC A1 “Pain on Walking” – Results from a 52-Week, Randomized, Double-Blind, Placebo-Controlled, Phase 2 Study of a Novel, Intra-Articular, Wnt Pathway Inhibitor

Jeyanesh Tambiah¹, Sarah Kennedy¹, Heli Ghandehari¹, Christopher Swearingen¹ and Marc C. Hochberg², ¹Samumed, LLC, San Diego, CA, ²University of Maryland School of Medicine, Baltimore, MD

Session Information

Session Date: Monday, October 22, 2018

Session Title: Osteoarthritis – Clinical Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Knee osteoarthritis (OA) is characterized by pain, functional limitation, and physical disability due to articular cartilage degradation and bone remodeling. Wnt signaling is involved in these cellular processes. SM04690, a small molecule, intra-articular (IA), Wnt pathway inhibitor, is in development for treatment of knee OA as a potential disease-modifying OA drug (DMOAD). A phase 2, multicenter, 52-week, randomized, double-blind, placebo (PBO)-controlled trial of SM04690 was conducted. Safety and efficacy outcomes including the Western Ontario and McMaster Universities Arthritis Index (WOMAC) were evaluated.

Methods: Subjects with ACR-defined knee OA, Kellgren-Lawrence (KL) grades 2-3, received a single 2 mL IA injection of SM04690 (0.03, 0.07 or 0.23 mg) or PBO in the target (most painful) knee. WOMAC was assessed at baseline and 4, 13, 26, 39 and 52 weeks post-injection. WOMAC question A1, (“how much pain have you had when walking on a flat surface?”), was analyzed as a post-hoc exploratory outcome. Analysis of covariance adjusted for baseline WOMAC A1 score in the intent-to-treat (ITT) population was conducted. Two subgroups identified in the primary analysis (Yazici Y et al., *Arthritis Rheumatol* 2017) were also explored: 1) subjects with unilateral symptomatic knee OA (pre-specified) and 2) subjects with unilateral symptomatic knee OA without widespread pain or comorbid symptoms (Widespread Pain Index ≤ 4 and Symptom Severity ≤ 2 [WP-], post-hoc).

Results: 455 subjects (mean age 60.3[\pm 8.7] years, BMI 29.9 [\pm 4.6] kg/m², female 58.9%, KL 3 [64.1%], unilateral symptomatic OA [36.0%]) were enrolled; 402 [88.4%] completed the study. No safety signals were observed. For WOMAC A1, in the ITT population, no statistically significant differences between treatment groups and PBO were seen, although the 0.07 mg dose demonstrated improvements compared with PBO at all time points (**Figure**). In unilateral symptomatic subjects, 0.07 mg showed significant improvements in WOMAC A1 compared with PBO at Weeks 39 (-1.2, 95% CI [-2.3, -0.0], $P=0.043$) and 52 (-1.1, 95% CI [-2.0, -0.1], $P=0.027$).

Improvement of SM04690 over Placebo

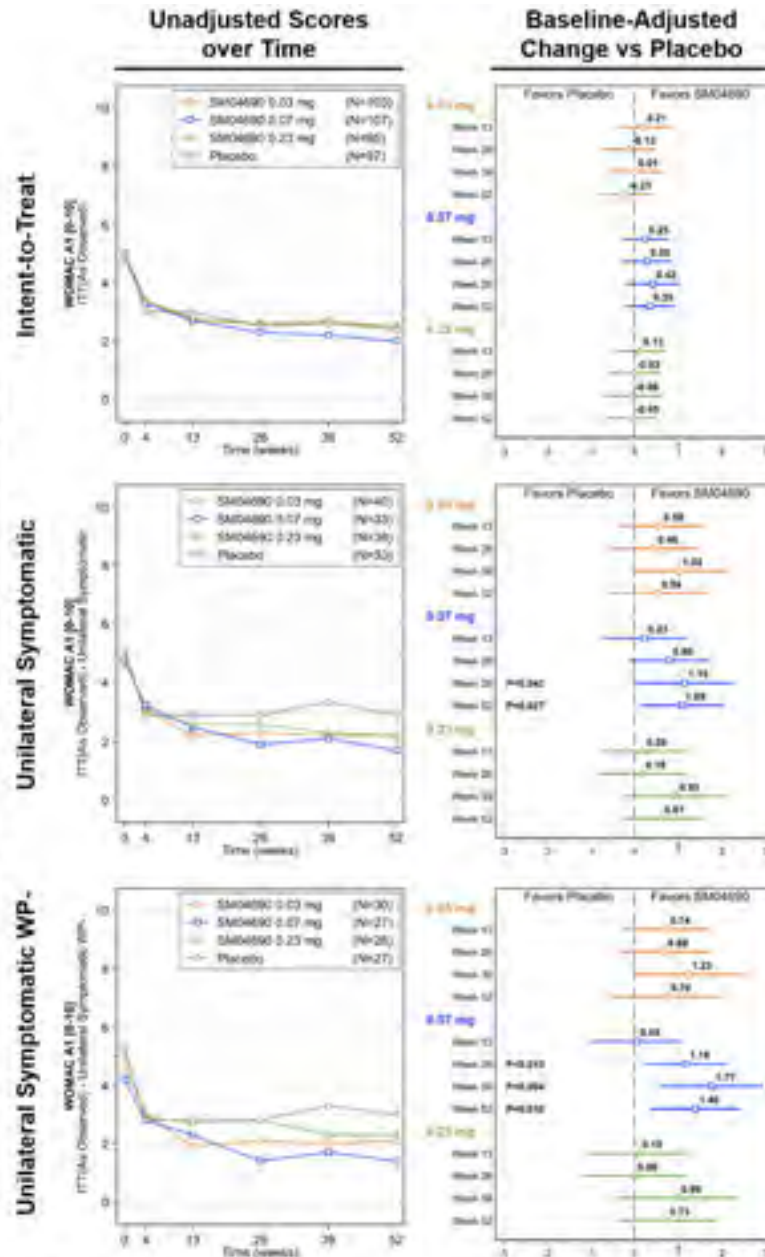

Figure. Change and Ladder plots depicting average WOMAC A1 improvement in SM04690 over placebo adjusted for baseline WOMAC A1.

*Minimal clinically important difference (MCID) defined as 10% of WOMAC A1, or 1 point.

In unilateral symptomatic WP- subjects, the 0.07 mg dose showed significant improvements in WOMAC A1 compared with PBO at Weeks 26 (-1.2, 95% CI [-2.1, -0.2], P=0.015), 39 (-1.8, 95% CI [-3.0, -0.6], P=0.004) and 52 (-1.4, 95% CI [-2.5, -0.4], P=0.010).

Conclusion: In this phase 2 study, improvements compared with PBO in WOMAC A1 were seen in clinically relevant unilateral symptomatic and unilateral symptomatic WP- subgroups. The improvements seen in this combined, multi-dimensional outcome of pain and function suggested SM04690 has a potential role in the treatment of signs and symptoms of knee OA.

Session Information

Session Date: Monday, October 22, 2018

Session Title: Osteoarthritis – Clinical Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Previous data showed that neutralization of granulocyte/monocyte colony stimulating factor (GM-CSF) rapidly abolished pain in an experimental OA model suggesting GM-CSF may be a promising therapeutic target in human OA (1).

Objective: Evaluate anti-GM-CSF GSK3196165 treatment on the signs and symptoms of hand OA.

Methods: Subjects with hand OA per ACR criteria, ≥ 2 swollen and tender IP joints in the same hand, hand pain ≥ 5 (numeric rating scale [NRS] 0-10, averaged over 7 days), signs of inflammatory changes by MRI and intolerance or unresponsiveness to NSAIDs, were randomized to 5 weekly SC doses of 180mg GSK3196165 or placebo (PBO), followed by 3 further doses every other week. Self-assessed 24h average and worst hand pain was recorded daily by electronic patient-reported outcome (ePRO) for the study duration. The primary outcome was ePRO change from baseline in average hand pain at Week 6. Secondary outcomes included safety, proportion of subjects showing 30% and 50% reductions in hand pain, change in Australian/Canadian Hand Osteoarthritis Index (AUSCAN) 3.1 NRS and changes in number of swollen and tender joints. Exploratory MRI endpoints included change in inflammatory and structural features.

Results: Of 44 treated subjects (91% women; mean age 58.8 years), 21/22 randomised to PBO and 20/22 to GSK3196165 completed the 12 week treatment period. Patient characteristics were well balanced between the groups. Measured GSK3196165 exposures were lower than anticipated from previous studies. Maximum pre-dose concentrations were achieved after 5 loading doses, but dropped significantly during every other week dosing.

Patients receiving GSK3196165 showed numerically larger reductions in hand pain than PBO at all time points, difference over PBO at W6: -0.36 (-1.31, 0.58; $p=0.442$), at W12: -0.89 (-2.06, 0.28; $p=0.132$); >2 points reduction from baseline seen from W8 to W12.

The proportion of subjects achieving 30% and 50% reductions of average hand pain was higher in the GSK3196165 group vs PBO at each assessment visit. At W12 the difference between GSK3196165 and PBO groups showing 30% reduction was 23% (odds ratio 3.2, 95% CI 0.86, 11.99; $p=0.083$) and for 50% reduction, was 27% (odds ratio 4.9, 95% CI 1.06, 22.59; $p=0.042$). AUSCAN pain (0-50) and function (0-90) showed difference vs PBO of -4.7 (-10.1, 0.6; $p=0.082$) and -8.2 (-19.1, 2.7; $p=0.136$) at W12 respectively. There was little difference from PBO on tender and swollen joints or MRI endpoints.

GSK3196165 was well tolerated. No serious infections or pulmonary events were observed. :
