

Arthritis & Rheumatology

AN OFFICIAL JOURNAL OF THE AMERICAN COLLEGE OF RHEUMATOLOGY

ABSTRACT SUPPLEMENT

2018 ACR/ARHP Annual Meeting

October 19–24, 2018

Chicago, IL

AMERICAN COLLEGE
OF RHEUMATOLOGY
EDUCATION • TREATMENT • RESEARCH

WILEY

Accreditation Statement: The American College of Rheumatology is accredited by the Accreditation Council for Continuing Medical Education (ACCME) to provide continuing medical education for physicians.

Designation Statement: The ACR designates this live educational activity for a maximum of *53 AMA PRA Category 1 Credits™*. Physicians should claim only the credit commensurate with the extent of their participation in the activity.

International Physicians: International physicians who register as part of a group and require *AMA PRA Category 1 Credit(s)™* must provide the following information to your tour leader: full name, mailing address, telephone and fax numbers and e-mail address. The information will be used to verify your meeting attendance.

The American Medical Association has an agreement of mutual recognition of continuing medical education credit with the European Union of Medical Specialties. International physicians interested in converting *AMA PRA Category 1 Credit™* to EACCME credit should contact the UEMS.

Health Professionals: Participants may claim hours to receive a Certificate of Participation for an activity designated for *AMA PRA Category 1 Credit(s)™*. For non-CME sessions, attendees may also request a certificate of participation.

Disclosure Policy

As an educational provider accredited by the Accreditation Council for Continuing Medical Education, the American College of Rheumatology must ensure balance, independence, objectivity and scientific rigor in all its educational activities. Therefore, all those in a position to control content (e.g., speakers and moderators) participating in an ACR-sponsored activity are required to disclose to the planning committee and audience any financial or other relationships that occurred in the past 12 months. This includes the relationships of spouse/partners. If there are relationships that create a conflict of interest, these must be resolved in accordance with the ACR's CME Resolution of Conflict policy prior to the participation of the individual in the development or presentation of CME content. Relevant relationships include, but are not limited to:

None: Has no relevant financial relationship to disclose.

1. Stock, stock options or bond holdings in a for-profit corporation or self-directed pension plan;
2. Research grants;
3. Employment (full or part time);
4. Ownership or partnership;
5. Consulting fees or other remuneration;
6. Non-remunerative positions of influence, such as officer, board member, trustee or public spokesperson;
7. Receipt of royalties;
8. Speakers' bureau; or
9. Other.

Abstract author disclosures are published online. Any individual who refuses to disclose relevant financial relationships is ineligible to serve as a planning committee member, presenter or author of an ACR CME activity, and cannot have control of, or responsibility for, the development, management, presentation or evaluation of the CME activity.

Abstract Embargo Policy

Accepted abstracts are made available to the public online in advance of the meeting and are published in a special online supplement of our scientific journal, *Arthritis & Rheumatology*. Information contained in those abstracts may not be released until the abstracts appear online. Academic institutions, private organizations and companies with products whose value may be influenced by information contained in an abstract may issue a press release to coincide with the availability of an ACR abstract on the ACR/ARHP Annual Meeting Abstract website. However, the ACR continues to require that information that goes beyond that contained in the abstract (e.g., discussion of the abstract done as part of a scientific presentation or presentation of additional new information that will be available at the time of the meeting) is under embargo until **October 20, 2018 at 4:30 PM CT**.

Violation of this policy may result in the abstract being withdrawn from the meeting and other measures deemed appropriate. Authors are responsible for notifying financial and other sponsors about this policy. If you have questions about the ACR abstract embargo policy, please contact the

Annual Meeting abstract staff at
abstracts@rheumatology.org.

Media

Credentialed media press attend the Annual Meeting to cover stories for consumer, trade, and other media outlets and are easily identified by their black press ribbons. Media Press has access to all general sessions and limited access (at the discretion of speakers) to Meet the Professor and Workshop sessions. Media Press may use handheld audio recorders and still cameras (assuming that intellectual property copyrights are respected); moving video recording is also permitted with the advance permission of the presenter(s). This policy refers to credentialed members of the press only. No photos or video are allowed in the Poster Hall without prior permission from the poster presenter. **The exception to this policy is that no photos or video are allowed in the Exhibit Hall.** Press who would like general photos of the Exhibit Hall can obtain these after the meeting from the ACR. Attendees who have questions about the ACR's media policies should contact the ACR public relations department at pr@rheumatology.org.

Photographs and Video Recording Policy

As a courtesy to our presenters, ACR policy does not permit photographs or recordings during educational sessions, including poster sessions. The only exception to this is for registered media, who should review their registration materials for more information.

Abstract Reprint (Reproduction) Policy

Copyright law covers all Annual Meeting abstracts published by the American College of Rheumatology. All rights reserved. No abstracts may be reproduced in any form or by any means without the prior permission of the publisher, except as permitted under section 107 and 108 of the 1976 United States Copyright Act.

For the purposes of this statement, the term **ACR Abstracts** refers to all Annual Meeting abstracts as published in *Arthritis & Rheumatology* and posted online, including the abstracts accepted for presentation during ARHP sessions and the late-breaking category.

For the purposes of this statement, the term **ACR Posters** refers to the accepted abstract **POSTER PRESENTATIONS** as presented in the poster hall

during the Annual Meeting. **This does not include abstract text published in the online supplement of *Arthritis & Rheumatology*.** All **ACR Posters** are the property of the ACR and the presenting author and cannot be reproduced or distributed without written permission from the ACR and the presenting author.

- For the purposes of this statement, the term “reproduce” includes all forms of reproduction, including, but not limited to, print, electronic and photographed formats.
- For the purposes of this statement, the term “presenting author” refers to the author who is designated as the individual who will present the work during the ACR/ARHP Annual Meeting, as identified through the abstract submission process.

Approval Process for ACR Abstracts

- Excerpts or the entirety of **ACR Abstracts** may not be reproduced without the prior written permission of the publisher.
- Permission requests for abstract content and other permission inquiries should be addressed to:

Permissions Department

c/o John Wiley & Sons, Inc.
111 River Street
Hoboken, NJ 07030
Fax: 201-748-6008
wiley.com/go/permissions

- Commercial entities seeking permission to reprint must obtain all materials from the author and/or publisher John Wiley & Sons, Inc. The ACR cannot provide any materials.

Approval Process for ACR Posters

- Reprint requests for the actual poster abstract text published in the *Arthritis & Rheumatology* supplement are considered **ACR Abstracts** and must be submitted to Wiley (see approval process above).
- Requests to reproduce individual ACR posters, figures from ACR posters, or booklets of poster presentations (e.g., two or more) must be submitted via e-mail to abstractreprints@rheumatology.org.
- Poster reproduction requests must include the following:

- Abstract ID Number
- Abstract Title
- Presenting Author's Name
- A copy of Presenting Author's written

approval (Please Note: An e-mail approval from Presenting Author is acceptable)

Reproducing ACR Abstracts and Posters for Dissemination Prior to the Annual Meeting

- Requests to reproduce abstracts for dissemination prior to the Annual Meeting *will not be approved*.
- Per the ACR Embargo Policy (see above), academic institutions, private organizations, and companies with products whose value may be influenced by information contained in an abstract may issue a press release to coincide with the availability of an abstract online.
- Permission to issue a press release does not require ACR approval. However, it must comply with the ACR Embargo Policy; violation of this policy may result in the abstract being withdrawn from the meeting or other measures deemed appropriate.
- For more information regarding press releases, please contact the ACR public relations department at pr@rheumatology.org.

Reproducing ACR Abstracts and Posters for Dissemination During the Annual Meeting

Following approval (see approval process above), an exhibiting organization may:

- Following approval (see approval process above), an exhibiting organization may disseminate copies of individual ACR Abstracts from its exhibit space. Booklets of abstracts (e.g., two or more) may not be produced.
- Following approval, an exhibiting organization may disseminate information summaries (title/date/time/poster number) of ACR Abstracts from its exhibit space. Summaries may not reference company or product names. Requests for approval must be submitted in writing to abstractreprints@rheumatology.org.
- Presenting authors may disseminate individual copies of their ACR Poster during their assigned poster presentation time. Dissemination must be limited to the area

directly in front of their assigned poster space and may not interfere with other poster presentations.

- An electronic copy of the poster may be provided via a QR code generated by the presenter and included on the poster.

Reproducing ACR Abstracts and ACR Posters for Dissemination After the Annual Meeting **ACR Abstracts**

Following approval from Wiley (see approval process above), the ACR permits ACR Abstracts (i.e., all abstract content published in the online supplement) to be reprinted and disseminated following the Annual Meeting.

- Abstracts and booklets of abstracts (e.g., two or more) must include the following statement on the front of the abstract/booklet:
Abstract(s) reprinted from the ACR/ARHP Annual Meeting held October 19–24, 2018. The American College of Rheumatology does not guarantee, warrant, or endorse any commercial products or services. Reprinted by (insert name of supporting company).
- Booklets cannot contain corporate or product logos or any advertisements. No exceptions.

ACR Posters

Following approval from the presenting author and the ACR (see approval process above), copies of actual ACR poster presentations (i.e., images from the poster presentation hung in the poster hall) may be reproduced.

- Reprint requests for the actual poster abstract text published in the *Arthritis & Rheumatology* supplement are considered **ACR Abstracts** and must be submitted to Wiley (see approval process above).
- **IMPORTANT: The ACR does not retain and cannot provide poster presentation images.**
- The following statement must be listed under each Poster reprint:
Reprinted from the ACR/ARHP Annual Meeting held October 19–24, 2018. The American College of Rheumatology does not guarantee, warrant, or endorse any

commercial products or services. Reprinted by (insert name of supporting company).

Use of the ACR Name

The names, insignias, logos and acronyms of the ACR, the ARHP, and the Rheumatology Research Foundation are proprietary marks. Use of the names in any fashion, by any entity, for any purpose, is prohibited without the express written permission of the American College of Rheumatology.

Use of the ACR Disclosure Key

It is suggested when referencing disclosures in the reprints, that the ACR's disclosure key be added to provide adequate context for abstracts:

None: Has no relevant financial relationship to disclose.

1. Stock, stock options or bond holdings in a for-profit corporation or self-directed pension plan;
2. Research grants;
3. Employment (full or part time);
4. Ownership or partnership;
5. Consulting fees or other remuneration;

6. Non-remunerative positions of influence, such as officer, board member, trustee or public spokesperson;
7. Receipt of royalties;
8. Speakers' bureau; or
9. Other.

Use of the ACR Scientific Program Content

- Information displayed or presented at all sessions during the Annual Meeting is the property of the ACR or the presenter. Information may not be recorded, photographed, copied, photocopied, transferred to electronic format, reproduced or distributed without the prior written permission of the ACR and the presenter.
- Any use of the program content, which includes but is not limited to oral presentations, audiovisual materials used by speakers and program handouts, without the written consent of the ACR is prohibited.
- This policy applies before, during and after the meeting.
- The ACR will enforce its intellectual property rights and penalize those who infringe upon it.

Table of Contents

ACR/ARHP ABSTRACT SESSIONS

SUNDAY, OCTOBER 21, 2018

8:30 AM - 4:00 PM

ACR/ARHP Poster Session A
(#1-834)

11:00 AM - 12:30 PM

ACR Plenary Session I: Discovery 2018
(#835-839)

2:30 - 4:00 PM

ACR Concurrent Abstract Sessions
(#840–845) Cytokines and Cell Trafficking
(#846–850) Osteoarthritis and Joint Biology – Basic Science
(#851–856) Antiphospholipid Syndrome
(#857–862) Education
(#863–868) Imaging of Rheumatic Diseases I: MRI and CT
(#869–874) Metabolic and Crystal Arthropathies: Comorbidities and Outcomes
(#875–879) Muscle Biology, Myositis and Myopathies I: Biomarkers
(#880–885) Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes I: Other Co-Morbidities
(#886–891) Rheumatoid Arthritis – Treatments I: JAK Inhibitors
(#892–897) Spondyloarthritis Including Psoriatic Arthritis – Clinical I: Axial SpA Epidemiology
(#898–903) Systemic Sclerosis and Related Disorders – Clinical I: Clinical Trial Results & Insights
(#904–909) Vasculitis – ANCA-Associated

ARHP Concurrent Abstract Session
(#910–915) Epidemiology and Public Health – ACR/ARHP

4:30 - 6:00 PM

ACR Concurrent Abstract Session
(#916–921) Genetics, Genomics and Proteomics: Precision Medicine
(#922–927) Pediatric Rheumatology – Basic Science
(#928–933) Rheumatoid Arthritis – Etiology and Pathogenesis I
(#934–939) Systemic Lupus Erythematosus – Animal Models
(#940–945) Epidemiology and Public Health I: Morbidity and Mortality
(#946–951) Infection-related Rheumatic Disease

(#952–957) Osteoarthritis – Clinical
(#958–963) Rheumatoid Arthritis – Treatments II: Safety
(#964–969) Spondyloarthritis Including Psoriatic Arthritis – Clinical II: PsA Epidemiology
(#970–975) Systemic Lupus Erythematosus – Clinical I: Clinical Trials

ARHP Concurrent Abstract Session
(#976–981) Pediatric Rheumatology – ACR/ARHP

MONDAY, OCTOBER 22, 2018

8:30 AM - 4:00 PM

ACR/ARHP Poster Session B
(#982-1815)

11:00 AM - 12:30 PM

ACR Plenary Session II: Discovery 2018
(#1816-1821)
2:30 - 4:00 PM

ACR Concurrent Abstract Sessions
(#1822–1827) Rheumatoid Arthritis – Animal Models
(#1828–1833) Spondyloarthritis Including Psoriatic Arthritis – Basic Science
(#1834–1839) Fibromyalgia and Other Clinical Pain Syndromes
(#1840–1845) Healthcare Disparities in Rheumatology
(#1846–1851) Pediatric Rheumatology – Clinical I: Outcomes and Comorbidities
(#1852–1857) Reproductive Issues in Rheumatic Disorders
(#1858–1863) Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes II: Diagnosis and Prognosis I
(#1864–1869) Spondyloarthritis Including Psoriatic Arthritis – Clinical III: Treatment of Axial SpA
(#1870–1874) Edmond L. Dubois, MD Memorial Lecture: SLE–Clinical
(#1875–1880) Systemic Sclerosis and Related Disorders – Clinical II: Clinical Trial Results, Predictors, Design
(#1881–1886) Vasculitis I: Population-Based Studies

ACR/ARHP Combined Abstract Session
(#1887–1892) Health Services Research – ACR/ARHP I: Focus on Big Data
4:30 - 6:00 PM

ACR Concurrent Abstract Sessions
(#1893–1898) Systemic Lupus Erythematosus – Etiology and Pathogenesis I
(#1899–1904) Systemic Sclerosis and Related Disorders – Basic Science

(#1905–1910) Epidemiology and Public Health II: RA Risk: Education, Obesity, Smoking, or Biomarkers?
(#1911–1916) Miscellaneous Rheumatic and Inflammatory Diseases I: DADA2, Cardiac Sarcoid, Cancer Immunotherapy

(#1917–1922) Pain Mechanisms – Basic and Clinical Science

(#1923–1928) Patient Outcomes, Preferences, and Attitudes I: Beliefs and Behaviors

(#1929–1934) Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes III: Diagnosis and Prognosis II

(#1935–1940) Rheumatoid Arthritis – Treatments III: New Compounds and Biosimilars

(#1941–1945) Systemic Lupus Erythematosus – Clinical II: Renal and Neuropsychiatric Disease in SLE

ARHP Concurrent Abstract Session

(#1946–1951) ARHP I: Pain, Anxiety, and Depression

ACR/ARHP Combined Abstract Session

(#1952–1957) Orthopedics, Low Back Pain and Rehabilitation – ACR/ARHP

TUESDAY, OCTOBER 23, 2018

8:30 AM - 4:00 PM

ACR/ARHP Poster Session C

(#1958–2784)

11:00 AM - 12:30 PM

ACR Plenary Session III: Discovery 2018

(#2785–2790)

2:30 - 4:00 PM

ACR Concurrent Abstract Sessions

(#2791–2796) B Cell Biology and Targets in Autoimmune and Inflammatory Disease

(#2797–2801) T Cell Biology and Targets in Autoimmune and Inflammatory Disease

(#2802–2807) Epidemiology and Public Health III: SLE and Scleroderma, Big Data and Large Cohorts

(#2808–2813) Osteoporosis and Metabolic Bone Disease – Basic and Clinical Science

(#2814–2819) Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes IV: Cardiovascular Co-Morbidities

(#2820–2825) Rheumatoid Arthritis – Treatments IV: Strategy

(#2826–2831) Spondyloarthritis Including Psoriatic Arthritis – Clinical IV: Comorbid or Related Conditions

(#2832–2837) Systemic Lupus Erythematosus – Clinical III: Translational Aspects

(#2838–2843) Vasculitis II: Novel Diagnostics and Therapeutics

ARHP Concurrent Abstract Session

(#2844–2849) ARHP II: Clinical Aspects and Outcomes Research

4:30 - 6:00 PM

ACR Concurrent Abstract Sessions

(#2850–2855) Innate Immunity

(#2856–2861) Measures and Measurement of Healthcare Quality I: Quality Improvement in Rheumatoid Arthritis

(#2862–2867) Pediatric Rheumatology – Clinical II: Treatment Update

(#2868–2873) Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes V: Outcomes Measures

(#2874–2879) Rheumatoid Arthritis – Treatments V: Beyond Individual Compounds

(#2880–2885) Sjögren's Syndrome – Basic and Clinical Science

(#2886–2891) Spondyloarthritis Including Psoriatic Arthritis – Clinical V: Treatment of PsA and Peripheral SpA

(#2892–2897) Systemic Lupus Erythematosus – Clinical IV: Clinical Outcomes

WEDNESDAY, OCTOBER 24, 2018

9:00 AM - 10:30 AM

ACR Concurrent Abstract Sessions

(#2898–2903) Rheumatoid Arthritis – Etiology and Pathogenesis II

(#2904–2909) Imaging of Rheumatic Diseases II: Ultrasound

(#2910–2915) Patient Outcomes, Preferences, and Attitudes II: Patient-Reported Outcomes

(#2916–2921) Pediatric Rheumatology – Clinical III: Assessment Tools and Biomarkers

(#2922–2927) Spondyloarthritis Including Psoriatic Arthritis – Clinical VI: Imaging of Axial SpA

(#2928–2933) Systemic Lupus Erythematosus – Clinical V: Biomarkers, Criteria, and Outcomes

(#2934–2939) Systemic Sclerosis and Related Disorders – Clinical III: Cohort Studies, Biomarkers, & Response

ARHP Concurrent Abstract Session

(#2940–2945) ARHP III: Interventions and Self-Management

11:00 AM - 12:30 PM

ACR Concurrent Abstract Sessions

(#2946–2951) Systemic Lupus Erythematosus – Etiology and Pathogenesis II

(#2952–2957) Epidemiology and Public Health IV: Determinants and Consequences of Treatment
(#2958–2963) Measures and Measurement of Healthcare Quality II: Quality Improvement in SLE, Gout and JIA
(#2964–2969) Metabolic and Crystal Arthropathies – Basic Science and Imaging
(#2970–2975) Miscellaneous Rheumatic and Inflammatory Diseases II
(#2976–2981) Muscle Biology, Myositis and Myopathies II: Clinical and Miscellaneous Topics
(#2982–2987) Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes VI: Outcomes Reports
(#2988–2993) Vasculitis III: Clinical Subtypes and Outcomes

ACR/ARHP Combined Abstract Session

(#2994–2999) Health Services Research – ACR/ARHP II: Economic and Clinical Implications of Rheumatic Disease

ACR LATE-BREAKING

ABSTRACT SESSIONS

TUESDAY, OCTOBER 23, 2018

9:00 - 11:00 AM

ACR/ARHP Poster Session C

(#L01–L14) Late-Breaking Abstract Poster Session

4:00 – 6:00 PM

ACR Concurrent Abstract Session

(L15–L20) Late-Breaking Abstract Session

ACR/ARHP PATIENT PERSPECTIVES

SUNDAY, OCTOBER 21, 2018

ACR/ARHP Combined Session

12:00 - 2:00 PM

(#PP01–PP13) Patient Perspectives Poster Session

Profiling of B-Cell Related Factors and Its Decoy Receptors in Rheumatoid Arthritis: Potential Clues for Patient Stratification

Javier Rodríguez-Carrio^{1,2}, Mercedes Alperi-López³, Patricia López¹, Francisco Javier Ballina-García⁴ and Ana Suárez¹,
¹Area of Immunology, Department of Functional Biology, University of Oviedo, Oviedo, Spain, ²Instituto de Investigación Sanitaria del Principado de Asturias, Oviedo, Spain, ³Department of Rheumatology, Hospital Universitario Central de Asturias, Asturias, Spain, ⁴Department of Rheumatology, Hospital Universitario Central de Asturias, Oviedo, Spain

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: B Cell Biology and Targets in Autoimmune and Inflammatory Disease Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: B-cell over-activation plays a key role in the pathogenesis of rheumatoid arthritis (RA), thus being recognized as a therapeutic target. However, the activation of the B-cell compartment is under the control of a complex network of mediators, including ligands and receptors, expressed as membrane (m) and soluble (s) forms. The main aim of this study was to gain insight into the associations of B-cell related factors and its decoy receptors in RA, focusing on its clinical relevance.

Methods: serum levels of sBLyS, sAPRIL, sBCMA, sTACI, sBLyS-R (BR3), IFN α , MIP1 α , TNF α , IL-10, IFN γ and GM-CSF levels were measured by immunoassays in 104 RA patients (EULAR/ACR 2010 criteria) and 33 healthy controls (HC). The gene expression of IFI44, IFI44L, IFI6 and MX1 was measured in peripheral blood and averaged into an IFN score. The membrane BLyS (mBLyS) expression was assessed on B cells, monocytes (M ϕ), myeloid (mDC) dendritic cells and neutrophils (N ϕ) by flow cytometry in blood samples. A group of biological-naïve RA patients was prospectively followed for 3 months upon TNF α -blockade.

Results: RA patients exhibited increased sAPRIL ($p<0.001$) and sBCMA levels ($p=0.002$) than HC. sBLyS was higher in patients with very early RA (VERA, recruited at onset) compared to those with long-standing disease ($p=0.051$) and HC ($p=0.024$). No differences in sTACI and sBLyS-R were observed ($p=0.462$ and $p=0.507$). The sBLyS/sBLyS-R ratio was increased in VERA patients compared to HC and patients with established disease, where a positive correlation with DAS28 was noted ($r=0.298$, $p=0.008$). Moreover, increased sBLyS/sBLyS-R ratio at onset was associated with poor clinical response after 6 and 12 months (both $p<0.050$) in VERA patients. IFN score was negatively associated with sBLyS ($r=-0.463$, $p=0.031$) in VERA, whereas it was positively associated with sBLyS-R ($r=0.271$, $p=0.029$) and sTACI ($r=0.210$, $p=0.050$) in patients with established disease. mBLyS expression was increased on B cells, M ϕ , mDC (all $p<0.001$) and N ϕ ($p=0.014$) in RA, without differences by disease duration. An unsupervised cluster analysis based on sBLyS, sAPRIL, sBCMA, sTACI and sBLyS-R identified 2 clusters (I and II), cluster II being hallmarked by increased sAPRIL and sBCMA levels. Cluster II was overrepresented in RA compared to HC (32/104 vs 3/33, $p=0.015$). Cluster II RA patients showed increased prevalence of RF ($p=0.008$) and ACPA ($p=0.008$) positivity and were more likely treated with anti-TNF α agents ($p=0.020$) compared to their cluster I counterparts. Moreover, higher IFN α ($p=0.035$), TNF α ($p<0.001$), GM-CSF ($p<0.001$), IL-37 ($p=0.015$) levels and IFN score ($p=0.015$) were found in cluster II. Finally, increasing sBLyS ($p=0.043$) and sBCMA levels ($p=0.019$) were associated with poor clinical outcome upon TNF α -blockade.

Conclusion: Altered serum levels of B-cell factors are found in RA, with important differences between the very early and established stages. sAPRIL and sBCMA identify a subset of patients with a more severe disease, probably linked to a B-cell over-activation, and inadequate response to TNF α -blockade. A less efficient negative feedback from their decoy receptors may underlie these associations.

The Influence of Abatacept on Human B Cell Functions

Ming-Han Chen¹, Yen-Po Tsao², Chuen-Miin Leu³ and Chang Youh Tsai³, ¹Division of Allergy- Immunology- Rheumatology, Department of Medicine, Division of Allergy- Immunology- Rheumatology, Department of Medicine, Taipei Veterans General Hospital, Taipei, Taiwan, ²Division of Allergy- Immunology- Rheumatology, Department of Medicine, Taipei Veterans General Hospital, Taipei, Taiwan, ³National Yang-Ming University, Taipei, Taiwan

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: B Cell Biology and Targets in Autoimmune and Inflammatory Disease Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Cytotoxic T lymphocyte antigen-4 (CTLA-4) competes with CD28 for binding the CD80/CD86 on antigen presenting cells to inhibit further activation of T cells. Abatacept, a CTLA-4 fusion protein, has been used for rheumatoid arthritis (RA) treatment worldwide. The aim of this study was to test whether CTLA-4 regulates human B cell functions.

Methods: The influence of abatacept on B cell functions in both *in vitro* and *in vivo* conditions was assayed. Blood was taken from 30 patients with RA before and after abatacept treatment. RA disease activity was measured using the Disease Activity Score 28 using ESR (DAS28-ESR). Serum level of rheumatoid factor (RF), anti-cyclic citrullinated peptide antibody (ACPA), and anti-tetanus toxoid antibodies was measured by ELISA. The expression of CD80/CD86 on B cells was detected using immunofluorescent staining. Purified human B cells from healthy donors were treated by T-independent (TI) and T-dependent (TD) stimulation in the presence of abatacept and cell proliferation, cytokine production, plasma cell differentiation, and antibody production were measured.

Results: RA patients showed significant clinical improvement after 6 months of abatacept treatment and a decrease in mean DAS28-ESR score was found. Abatacept transiently reduced the level of CD80/CD86 on peripheral blood memory B cells. A decrease in serum RF level was observed in our RA patients during the 6 months of abatacept treatment. However, the serum level of ACPA and anti-tetanus toxoid antibodies were not influenced. In the *in vitro* assays, we observed that the CD80 and CD86 induced by T-independent (TI) but not T-dependent (TD) stimulation was significantly downregulated by abatacept at both the mRNA level and protein level. TI-induced TNF- α and IL-6 production by B cells was also reduced by abatacept. Neither TI nor TD-stimulated B cell proliferation was reduced by abatacept in ³H-thymidine incorporation assay. Finally, abatacept inhibited Daudi-B cell induced allogeneic T cell proliferation, indicating a significant blockade of T-B interaction by abatacept.

Conclusion: Abatacept may decrease RF level by blocking the interaction of CD28 with CD80/CD86, therefore preventing B cells from T cells' help for differentiation into plasma cells. Our results also demonstrate that abatacept may provoke a negative reverse signal to B cells to further regulate B cells activation.

Interferon-Alpha Disrupts DNA-Specific B Cell Tolerance in 3H9 Mice

Dario Ferri¹, Yuriy Baglaenko², Ariana Karanxha¹, Kieran Manion¹, Carolina Grajales¹ and Joan E. Wither¹, ¹Genetics and Development, Krembil Research Institute, University Health Network, Toronto, ON, Canada, ²Department of Biomedical Informatics, Brigham Women's Hospital, Harvard Medical School, Boston, MA

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: B Cell Biology and Targets in Autoimmune and Inflammatory Disease Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: A central mediator of Systemic Lupus Erythematosus (SLE) pathogenesis is interferon-alpha (IFN α), which is elevated in the serum of SLE patients. IFN α has been shown to enhance B cell signaling and promote survival. It also plays a major role in the induction of B cell activating factor (BAFF). While past studies have explored the effects BAFF on B cell tolerance, little work has focused on how IFN α itself directly affects this process. We hypothesize that elevated levels of IFN α directly contribute to the breach of B cell tolerance in SLE. To address this question, we have obtained an adenoviral vector encoding mouse IFN α (mDEF201), which we are using to induce sustained elevation of serum IFN α in a mouse model of B cell tolerance (3H9).

Methods: 6-8 week old 3H9 transgenic mice, which contain a knock-in Ig heavy chain derived from a DNA-specific hybridoma, were injected IV with 10⁷ PFU of Ad-mIFN α (mDEF201) or Ad-dI70-3 (empty vector). At 2 weeks post-treatment immune cell populations in the spleen and bone marrow were examined by flow cytometry, and anti-DNA antibody production was measured by ELISA. Serum levels of IFN α and BAFF were quantified by ELISA and IFN-induced gene expression was assessed by qRT-PCR.

Results: Mice administered with mDEF201 showed elevation of serum IFN α from 48h to 2 weeks post infection. At 2 weeks post infection, the mRNA expression of several IFN-inducible genes, but not BAFF, was also elevated in infected mice. There was only a 0.5 fold increase in BAFF expression at the protein level. mDEF201 infection resulted in a marked increase in the level of anti-ss/dsDNA IgM^a autoantibodies (OD450 PBS=0.32, Ad-di70-3=0.29, mDEF201=1.46 for ssDNA, and PBS=0.13, Ad-di70-3=0.10, mDEF201=0.56 for dsDNA, $p<0.0001$) signifying a potential breach of B cell tolerance. Consistent with this idea, mDEF201 infected mice displayed altered B cell activation and homeostasis, with a significant increase in the frequency of CD86⁺ B cells as well as total number of mature B cells. mDEF201 infection also resulted in increased frequency of plasmablasts, CD138⁺ plasma cells and IgM^a/IgG2^a germinal center (GC) B cells. Despite the increase in IgG2^a GC B cells, anti-ss/dsDNA IgG2^a antibodies were not increased with elevated IFN α at 2 weeks post infection. To assess the effect of IFN α on B cell anergy we examined the Ig λ 1⁺ population, a well characterized dsDNA-specific anergic B cell population in 3H9 mice. Ig λ 1⁺ B cells also displayed increased activation (CD86⁺) and entry into germinal centers; however, anti-ss/dsDNA Ig λ 1⁺ levels were not increased. Infection with mDEF201 resulted in a mild increase in T cell activation (CD69⁺); although, no difference was seen in the total number of T follicular helper cells.

Conclusion: Taken together, these data suggest that IFN α may be a major contributing factor in breaches of B cell tolerance in SLE not only through the induction of BAFF, but also through direct effects on autoreactive B cells. Elevation of IFN α may promote the activation and differentiation of autoreactive B cells towards an antibody producing state; however, in the absence of other immune defects, some peripheral tolerance mechanisms seem to remain partially intact preventing a whole-cell breach of tolerance.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: B Cell Biology and Targets in Autoimmune and Inflammatory Disease Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: IgG Fc-glycans affect IgG function and are altered in autoimmune diseases and autoantibodies. Anti-histidyl tRNA synthetase autoantibodies (anti-Jo1) are frequent in myositis associated with interstitial lung disease (ILD). We tested if total IgG Fc-glycans from Jo1⁺ versus Jo1⁻ myositis patients and anti-Jo1-IgG showed characteristic differences, and if particular Fc-glycan features could be associated with specific clinical manifestations.

Methods: Total IgG was isolated by affinity purification from serum of 44 myositis patients (19 Jo1⁺ and 25 Jo1⁻) and 24 age/sex matched healthy controls (HC). Anti-Jo1-IgG was further purified from eleven patients using a recombinant Jo1-coupled affinity column. A shotgun proteomics approach was used to profile serum-derived IgG-Fc-glycans and IgG-chain distributions. Uni- and multivariate statistics were used to find characteristics and correlate data with clinical information.

Results: A high abundance of agalactosylated IgG₁ Fc-glycans was observed in myositis patients compared to HC. Using intra-individual normalization of the main agalactosylated glycan (FA2) of IgG₁ vs FA2-IgG₂, myositis and HC were distinguished with an area under the curve (AUC) of 79±6%. For Jo1⁺ the AUCs went up to 88±6%. Bisected and afucosylated Fc-glycans were significantly lower in Jo1⁺ compared to Jo1⁻ patients. Anti-Jo1 IgG contained even lower abundance of bisected, afucosylated and galactosylated forms compared to matched total IgG. ASS and ILD diagnosis correlated with the Jo1⁺ characteristic Fc-glycan features via multivariate analysis.

Conclusion: The anti-Jo1⁺ patient IgG Fc-glycan profile contains phenotype specific features which may underlie the pathogenic role of Jo1 autoantibodies.

Session Title: B Cell Biology and Targets in Autoimmune and Inflammatory Disease Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Autoimmunity and more broadly non-communicable diseases develop with the imbalance between anti- and pro-inflammatory immune cell subsets, leading to an uncontrolled and damaging inflammation. Evidences have shown that short chain fatty acids promote anti-inflammatory regulatory T cell protecting from type 1 diabetes, colitis and allergies in mice. In the present study, we investigated the benefits of short chain fatty acid acetate extend to other immune cells involved in tolerance, the regulatory B cells (Breg).

Methods: For this purpose, we assessed the effect of acetate on Breg *in vitro* and *in vivo* through oral supplementation or intraperitoneal injections. The functions of acetate-induced Bregs were assessed i) *in vitro* using co-culture with naïve T cells to assess Th17 differentiation ii) *in vivo* with adoptive transfer of acetate-stimulated B cells in a model of collagen antibody-induced arthritis (CAIA). In addition, the effect of acetate was also evaluated on B cells from human samples.

Results: We showed that both *in vivo* and *in vitro* acetate promoted Breg differentiation from B1a cells but not from B2 cells in mice. Acetate-induced Breg cells could protect from collagen antibody-induced arthritis development when adoptively transferred. These effects were neither through specific G-protein receptor activation nor HDAC inhibition but by inducing metabolic changes particularly in B1a cells by fueling TCA cycle. Similarly, we found that acetate also promotes human Breg cells through metabolic changes.

Conclusion: This work suggest that acetate might be a promising therapeutic approach to restore Breg population in autoimmune diseases such as Rheumatoid Arthritis in which they are defective.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: B Cell Biology and Targets in Autoimmune and Inflammatory Disease Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic rheumatic diseases are characterized by abnormal B cell activation with autoantibody production and hypergammaglobulinemia. The autoantigen Ro52/SSA, also denoted TRIM21, is a major autoantigen in Sjögren's syndrome and systemic lupus erythematosus. Interestingly, Trim21-deficient mice develop systemic autoimmunity with B cell-related features such as autoantibodies, hypergammaglobulinemia and glomerulonephritis following tissue injury. The mechanisms by which Trim21 deficiency leads to enhanced B cell activation and antibody production are not well understood, and to further elucidate the role of Trim21 in systemic autoimmunity we investigated the B cell phenotype of Trim21^{-/-} mice.

Methods: Littermate C57BL/6J Trim21^{+/+} and Trim21^{-/-} mice were immunized with antigens eliciting thymus-dependent or thymus-independent B cell responses: nitrophenol-coupled ovalbumin (NP-OVA), lipopolysaccharide (NP-LPS) and ficoll (NP-ficoll). Anti-NP-IgM and IgG antibody titers were measured by ELISA, and B cell subpopulations were assessed by flow cytometry. CD19⁺ splenic cells from naïve mice were sorted and stimulated with anti-IgM antibodies, and proliferation was estimated by H³-thymidine incorporation and Ki67 expression. CD19⁺CD21⁺CD23^{high} follicular B cells were isolated from naïve mice and subjected to RNA extraction and microarray analysis.

Results: Higher specific IgG and IgM antibody titers were detected in Trim21^{-/-} mice compared to wild-type littermates upon immunization with NP-OVA and NP-ficoll. Consistent with these observations, NP-OVA-immunized Trim21^{-/-} mice had higher frequencies of splenic follicular (CD19⁺CD21⁺CD23^{high}) cells and bone marrow plasma (CD19⁺CD138⁺) cells. B cell receptor-specific stimulation of naïve splenic B cells *in vitro* resulted in significantly higher proliferation of Trim21^{-/-} cells. We also observed that splenic follicular B cells were more frequent already in naïve Trim21^{-/-} mice. Transcriptome analysis of these cells revealed differential regulation of genes associated with B cell differentiation, proliferation and metabolism.

Conclusion: Our findings reveal a link between the rheumatic autoantigen Ro52/Trim21 and increased antibody production associated with expansion of follicular B cells, suggesting a potential role for this autoantigen in the pathogenesis of systemic autoimmunity.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: B Cell Biology and Targets in Autoimmune and Inflammatory Disease Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Primary Sjögren's syndrome (pSS) is a chronic auto-immune disorder characterized by lymphocytic infiltrates and destruction of the salivary glands. Chronic B cell activation, the secretion of autoantibodies and the critical role of BAFF have been demonstrated. However, mechanisms leading to B cells dysregulation remain partially understood. The objective of this study was to establish transcriptomic maps of the B cells sorted from the salivary glands and from blood in pSS patients and controls.

Methods: Patients had pSS according to 2016 EULAR/ACR criteria and controls had sicca symptoms without any antibodies and with normal salivary gland biopsy. B cells were sorted from salivary gland biopsies and from blood. Total RNASeq profiling was performed using MiSeq (Illumina). Statistical analysis (DESeq2) identified differentially expressed genes between pSS and controls in B cells sorted from salivary glands (9 pSS patients and 4 controls), from blood (16 pSS patients and 7 controls); and between B cells sorted from salivary glands and blood in the same patients (4 pSS patients). Functional enrichment analysis was performed using Ingenuity Pathway Analysis software.

Results: The pSS vs controls comparison in B cells sorted from salivary glands identified up-regulated genes involved in activation of B cells including CD48, CD22 and CD40. TLR10, which is involved in innate immunity was also up-regulated in pSS. The analysis of the non-coding expressed RNAs showed an up-regulation of Mir155 which is essential for B cell differentiation and antibody production (**Table 1A**).

In blood B cells, TLR7 and the downstream signaling molecule IRF7 were up-regulated in pSS. Additionally, IL-6 which is involved in B cells growth was up-regulated (**Table 1B**). Enrichment analysis highlighted EIF2 signaling pathway, interferon (IFN) signaling pathway and role of JAK in IFN signaling (**Table 2**).

The paired comparison between B cells from salivary glands and from blood identified up-regulated genes including CD138, a plasma cell marker, IL-6, TLR5 and IFN induced genes (**Table 1C**). As non-coding RNA, Mir155 was also up-regulated.

The confirmation by qPCR method of these results is ongoing.

Conclusion: This study allowed to explore the mechanisms that support B cell activation in pSS focusing on tissue resident and circulating cells. Our data confirmed the B cell activation and differentiation through several markers including CD40, CD22, CD48, CD138 and highlighted the role of innate immunity with the TLRs and key pathways including IFN and JAK signaling. Precise understanding of these dysregulation should offer development of new targeted therapeutic perspectives for patients.

Table 1A, 1B and 1C: Selection of genes differentially expressed between pSS and controls in B cells sorted from salivary gland biopsy (**1A**), blood (**1B**) and between salivary glands and blood B cells from the same pSS patients (**1C**)

	Gene Symbol	log2 fold-change	p-value
1A	Salivary B cells (pSS vs controls)		
	CD48	2.59	0.009
	CD22	2.29	0.048
	CD40	2.64	0.017
	TLR10	5.67	0.002
	Mir155HG	4.94	0.002
1B	Blood B cells (pSS vs controls)		
	TLR7	1.40	0.008
	IRF7	0.76	0.041
	IL-6	1.54	0.006
1C	Salivary vs blood B cells in pSS		
	CD138	6.92	9.63e-05
	IL-6	3.05	0.004

Session Date: Sunday, October 21, 2018

Session Title: B Cell Biology and Targets in Autoimmune and Inflammatory Disease Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The immunological hallmark of rheumatoid arthritis (RA) is autoreactivity to citrullinated proteins and rheumatoid factor activity. Hence, the adaptive immune system and B cells are postulated to be central in RA pathogenesis, yet possible underlying B cell baseline autoreactivity defects have not been studied. Here, we use next generation sequencing (NGS) to study overall B cell repertoire shifts in RA patients compared to healthy individuals, as well as in ACPA specific B-cell populations.

Methods: Peripheral blood B cell receptor (BCR) repertoires were investigated in 13 seropositive RA patients and six age-matched healthy blood donors using PCR multiplex amplicon libraries with a molecular barcode strategy and the Illumina MiSeq platform to generate full variable region coverage. Citrullinated vimentin (Cit-Vim, aa 59-74) and citrullinated fibrinogen (Cit-Fib, aa a566-580) positive B cells were sorted using antigen-tetramers based on a scaffold with grafted RA peptides into the sunflower trypsin inhibitor-1, SFTI-1. Sequences were filtered using pRESTO, annotated by IMGT and Change-O. Filtering of 14×10^6 transcript reads generated 587 000 unique antibody V-regions. Genomic DNA was used to analyze recombination frequency in out-of-frame (OOF) sequences. Analysis of variable gene frequency was performed by Chi-square with Yates correction.

Results: Several significant shifts in the RA B cell repertoire could be observed. RA-derived circulating B cells had increased class-switching to IgG3 and IgG4 but lower IgA. Strikingly, there was a significantly higher frequency of VH with low somatic hypermutation (SHM) level in RA-derived B cells (<5 mutations, $p < 0.0001$ 14.7% vs 8.7). This was seen in all sequences, IgM and class-switched, but especially prominent in IgG1 rearrangements (9.6% vs 18.8% low mutation, $p < 0.0001$ OR=2.2 CI:2.0-2.35). Yet, IgG1 displayed evidence of stronger antigen selection pressure as compared to controls (5.5% vs 3.7%, $p < 0.0001$ OR=1.5 CI: 1.3-1.7) suggesting that an increased IgG1 class-switching of unmutated BCR may initiate further B cells selection. Recombination of VH4 sequences were higher in RA and there was a general RA VH4 bias that was enriched in Cit-Vim and Cit-Fib positive cells, although class-switched Cit-Fib had a VH1, VH3 profile. Furthermore, VH N-linked glycosylation sites accumulated with SHM and were increased in RA (IgG > 15 mutations, $p < 0.0001$, 17.2% vs 13.8%), primarily driven by IgG1, and further elevated in Cit-Vim and Cit-Fib populations (19.3%, 32.2%). BCR carrying the autoreactivity-associated VH4-34 gene with a germline-encoded N-glyc site were also enriched in RA and tetramer-sorted populations, especially in IgMs.

Conclusion: We found significant distortions in the B cell populations in seropositive RA compared to controls, especially within IgG1. Many findings were further enriched in the citrulline specific B cells suggesting correlation with ACPA autoreactivity. Overall, the differences may partly be explained by a strong ongoing B cell response but could also reflect baseline shifts and elevated natural autoreactivity as an underlying mechanism in the RA pathogenesis.

Session Date: Sunday, October 21, 2018

Session Title: B Cell Biology and Targets in Autoimmune and Inflammatory Disease Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The functional duality of B cells is central to balance immune homeostasis by regulating or promoting the immune response. However, the mechanisms by which the cytokine environment is involved in B-cell fate decisions leading to distinct B-cell functions are largely unknown.

Methods: We designed an *in vitro* approach to understand how extracellular components participate in human B-cell functional plasticity, and how this network might be involved in autoimmune diseases. Two activated T cell subsets ($CD4^+CD45RA^+$ (T_{RA}) and $CD4^+CD45RO^+$ (T_{RO}) T cells) were used to expose a common pool of B cells to distinct microenvironments. We showed that the same B-cell population could experience two possible opposite evolutions, to either helper or suppressor functions, in a flexible manner. These cells were thus referred to as effector B cells (Eff B) or suppressor B cells (Supp B). We analyzed the nature of those distinct bystander signals to assess the different functional cytokine clusters linked to phenotypic changes in B cells and explored the influence of those cytokine patterns in 179 Patients with systemic autoimmune diseases (SADs) and 48 healthy volunteers included in the PRECISESADS project [RA (n=44), SLE (n=45), systemic sclerosis (n=46), and Sjogren's syndrome (SjS, n=44)].

Results: We showed that distinct cytokine modules were involved in the modulation of B-cell functions. The identification of functional cytokine modules showed that the suppressive function of B cells was associated with Th2-related cytokines (IL-13, IL-5, IL-9 and IL-10) while the effector module, headed by IL-6 and CXCL10, also included CXCL1 and IL-8. Finally, we observed a common last cluster of cytokines that we considered to be a master modulator group able to control each cytokine network. This module included TNF- α , IFN- γ , IL-2 and IL-21. The key players of the effector module consisting of IL-6 and CXCL10 were over-represented in the four SADs, underlining a common key pathogenic cytokine network. We then wanted to address whether the analysis of the two different clusters of patients could be linked to biological activities and/or clinical manifestations. The measure of anti-nuclear antigen autoAb in patients delimited a more autoreactive pattern in the disconnected SLE patients cluster, demonstrating a significant increase in anti-DNA Ab and anti-SSA-52KD Ab. We, next confirmed a selective increase in systemic autoreactivity in disconnected SjS patients cluster with the upregulation of anti-SSB Ab and the increase of rheumatoid factors in disconnected RA patients. Finally, we underlined a major increase of extra-glandular clinical manifestations in the disconnected SjS patients group depicting a strong systemic activity of the disease. We also observed in SLE patients that the appearance of clinical symptoms of nephritic disorders during the course of the disease was significantly higher in the disconnected cluster.

Conclusion: Our experimental and translational approach identified subgroups of SADs patients, particularly distinguished by an effector B-cell signature.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: B Cell Biology and Targets in Autoimmune and Inflammatory Disease Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid Arthritis (RA) is a disease characterized by chronic inflammation of the synovial tissue in joints. It is driven by highly activated B cells. Synovial cells, primarily Fibroblast like synoviocytes (FLS) play an important role in activating these B cells. It was previously shown, that FLS upregulate CD40L under pro-inflammatory conditions (other abstract). In order to investigate the interactions responsible for B cell activation, a co-culture model was established with RAFLS and SF from Osteoarthritis (OA) patients.

Methods: IgD+ B cells were isolated from human peripheral blood by MACS and co-cultured w/o SFs in medium only, in the presence of CpG, IFN-gamma, TNF-alpha or both, respectively. B cell subpopulations, survival and proliferation were determined by FACS. IgG and IgM were measured by ELISA. Images of co-cultures were produced by immunocytochemistry.

Results: B cell survival is increased in co-culture after 6 days without additional stimulation (RAFLS: +20.65% +/-1.27%; OAFLS: +14.53% +/- 5.54% compared to B cell control) Proliferation of B cells is already increased after 3 hours of co-culture without additional stimulation (RASf: +13.48% +/- 2.16%; OASF: +13.02% +/- 1.16% compared to B cell control). Without additional stimulation IgD+ B cells are reduced in FLS co-culture after 6 days (RAFLS: -26.2% +/- 12.8%; OAFLS: -23.1 +/- 5.5% compared to B cell control). With IFN-gamma, the reduction of IgD+ B cells is even more pronounced (RAFLS: -44.6% +/- 4.7%; OAFLS: -33.6% +/- 9.2% compared to B cell control). The proportion of CD138+ B cells is increased after 6 days in co-culture (RAFLS: from 0.37% to 14.8% +/- 0.9%; OAFLS: from 0.37% to 15% +/- 2.9%) IgM could only be measured in considerable amounts in the supernatant after stimulation with CpG and exclusively in the co-cultures (RAFLS: from: 6.7 ng/mL +/- 0.95 ng/mL to 517.5 ng/mL +/- 228.4 ng/mL; OAFLS: from: 5.9 ng/mL +/-

0.3 ng/mL to 189.6 ng/ml \pm 204.4 ng/ml) IgG could not be detected in the supernatant above baseline levels. However, immunofluorescence staining showed IgG positive B cells in the co-cultures.

Conclusion: FLS are capable of inducing CSR in naïve B cells, probably through CD40L upregulated under pro-inflammatory conditions (shown in other abstract), but they do not supply enough stimulation to drive the B cells to immunoglobulin secretion. TLR stimuli (or hypothetically BCR stimuli) are required for Ig release.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: B Cell Biology and Targets in Autoimmune and Inflammatory Disease Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) associated anti-citrullinated protein autoantibodies (ACPA) bind a wide range of citrullinated proteins with high cross-reactivity. Recent findings suggest that certain, but not all, ACPA may have pathogenic properties. Citrullination occurs during physiological processes such as apoptosis, neutrophil extracellular trap (NET) formation and histone modifications, yet little is known about the interaction of ACPA with these antigens. Since uncleared apoptotic cells and NET products have been postulated to be central sources of autoantigen and immunostimulation in autoimmune disease, we sought to determine the anti-nuclear and anti-neutrophil ACPA reactivity.

Methods: We screened a total of 11 recombinant single B-cell isolated RA monoclonal human ACPA-IgG, derived from different cellular origin and compartments, for binding to full-length citrullinated nuclear antigens including histones and hnRNPs by ELISA. All ACPA mAbs have previously been confirmed anti-CCP2 reactive, with specific and extensive cit-peptide reactivity demonstrated by ELISA and antigen-arrays. ACPA apoptotic cell binding was determined by flow cytometry and immunoprecipitation. Immunofluorescence was utilized for primary human neutrophil and the Ecom-G murine neutrophil systems. ACPA binding to Ecom-G cells was also evaluated with flow cytometry. Anti-nuclear antibody reactivity (ANA) was evaluated with standard HEp-2 tests. CRISPR-Cas9 technology was used to generate peptidylarginine deiminase type 4 (PAD4) KO neutrophils and chlor-amidine (Cl-A) was used as pharmacological inhibition of PAD enzymes.

Results: We could observe that a subset of three monoclonal ACPA (37CEPT2C04, 37CEPT1G09, 1325:01B09) had high ANA reactivity and high binding to apoptotic cells. This did to some extent correlate with ELISA reactivity patterns to full-length citrullinated histones, but less so to citrullinated hnRNPs. Indeed, immunoprecipitations from apoptotic cell lysates revealed citrullinated histones as primary targets. One of the ACPA (1325:01B09) had a high capacity to induce IL-8 release from human peripheral mononuclear cells in plate-bound immune complexes with citrullinated histones. Importantly, all the anti-nuclear ACPA mAbs bound strongly to activated murine and human neutrophils and NETs. However, we also found two mAbs (1325:01C03 and BVCA1) in a second NET-reactive ACPA subset with contrasting perinuclear neutrophil binding and cross-reactivity patterns more towards the cytoplasmic antigens vimentin and alpha-enolase. Notably, CRISPR-Cas9 KO studies and pharmacological PAD inhibition showed that the cytoplasmic NET binding was fully dependent on PAD4 while the nuclear and histone mediated NET-reactivity was independent of PAD4.

Conclusion: When investigating monoclonal ACPA, we identified distinct subsets based on binding to neutrophils and NETs with either a nuclear pattern or a cytoplasmic perinuclear pattern. Importantly, only the cytoplasmic anti-neutrophil ACPA binding was PAD4 dependent. This may have important functional impact and provide insights in RA pathogenesis.

Session Title: B Cell Biology and Targets in Autoimmune and Inflammatory Disease Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Protein phosphatase 2A (PP2A) is a serine/threonine phosphatase ubiquitously expressed in eukaryotic cells. PP2A levels and activity are increased in T cells from patients with systemic lupus erythematosus and account for certain aspects of their aberrant function. We asked whether PP2A is similarly involved in the control of B cell function in lupus.

Methods: To understand the contribution of PP2A to B cell function, we generated a Cd19^{Cre}Ppp2r1a^{flox/flox} (*flox/flox*) mouse which lacks functional PP2A specifically in B cells along with Cd19^{Cre}Ppp2r1a^{WT/WT} (*control*) mice. B cells were isolated from lupus-prone *Mrl.lpr*, *SLE1.2.3* and *B6.lpr* mice to study the activity and protein levels of PP2A. Flow cytometry was performed in peripheral blood mononuclear cells of 15 patients with systemic lupus erythematosus and age, sex and race-matched healthy controls to measure the level of catalytic subunit of PP2A.

Results: We found that *in vitro* activated B cells by CpG, anti-IgM and anti-CD40 display increased PP2A activity. *Flox/flox* mice displayed decreased spontaneous germinal center B cells and decreased serum immunoglobulin levels compared to control mice. Immunization of *flox/flox* mice with sheep red blood cells resulted in decreased germinal center formation and immunization with T-dependent and T-independent antigens resulted in impaired antigen specific immunoglobulin production. *In vitro* stimulation of *flox/flox* B cells with anti-CD40/IL-4 and CpG/IL-4 similarly resulted in decreased immunoglobulin production. B cells from lupus-prone mice showed increased levels of PP2A and PP2A activity. B cells from patients with systemic lupus erythematosus expressed increased levels of PP2A.

Conclusion: Our results demonstrate that PP2A is required for optimal B cell function and contributes to increased B cell activity in systemic autoimmunity.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: B Cell Biology and Targets in Autoimmune and Inflammatory Disease Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with ANCA vasculitis and anti-glomerular basement membrane (GBM) nephritis (Goodpasture's Disease) develop pathogenic autoantibodies (autoAb) that destroy the microvasculature in lungs and kidneys. A substantial subset of patients develops double-positive (DP) ANCA+ anti-GBM+ autoAb and a clinical overlap syndrome. A recent analysis of a large patient cohort suggests that clinical relapse is particularly likely in the surviving DP patients with anti-PR3 ANCA. Little is known about the sequence and structure of autoAb of either specificity or about the relationship between ANCA and anti-GBM autoAb in DP patients. To gain insight into the origins of human anti-PR3 DP autoAb, we took advantage of the HuHSC-NSG model in which conditioned immunodeficient NOD-scid-gamma (NSG) mice are injected with human hematopoietic stem cells (HSC) to reconstitute a human immune system *in vivo*.

Methods: We measured binding to purified native human PR3 in two panels of HuHSC-NSG-derived human antibodies: 1) Six clonally unrelated human anti-GBM monoclonal antibodies (mAb) previously generated from collagen-immunized HuHSC-NSG mice and selected for binding to the non-collagenous domain-1 of the alpha3 chain of collagen IV, the antigen targeted by pathogenic anti-GBM autoAb; and, 2) Serum from a cohort of HuHSC-NSG mice (n=29) 4-6 months post engraftment and 1-3 months post aspiration of vehicle (saline) or crystalline silica, the environmental exposure most compellingly linked to human autoimmunity including ANCA vasculitis. Results using ELISA are reported as mean sample OD after subtraction of mean OD on diluent-coated plates.

Results: Two human anti-GBM mAb bound to PR3 (ODs = 0.618 and 0.455; positive control ANCA+ patients' plasma IgG diluted 1:50 mean OD = 1.376). PR3 binding did not reflect broad polyreactivity, as neither mAb bound to MPO or Hep-2 cells. Low level anti-PR3 activity (mean OD = 0.084, diluted 1:50) was detected among human antibodies in the blood of a subset of silica-exposed HuHSC-NSG subjects derived from the same HSC unit.

Conclusion: Detection of both anti-GBM and anti-PR3 specificities in individual human mAb confirms that a single immunoglobulin can bind both autoantigens and that anti-GBM and anti-PR3 autoAb can share genetic origins. Prior sequence analysis of the human mAb revealed uncommon motifs that favor autoreactivity and are typically selected against in the immune repertoire. Our findings in humanized immune system mice suggest that genetics of the HSC donor and permissive environmental exposures may facilitate their expression. Sequence analysis of single-positive anti-PR3 and patients' pathogenic autoAb will provide further insight into their genetic relationship and immune regulation, as well as potential novel targets for therapy.

Session Title: B Cell Biology and Targets in Autoimmune and Inflammatory Disease Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The presence of serum IgG anti-citrullinated protein autoantibodies (ACPA) in rheumatoid arthritis (RA), is associated with more aggressive disease progression. Although ACPA have been suggested to be important in the pathogenesis, the mechanisms and pathogenic targets are still poorly described. ACPA multi-reactivity to synthetically citrullinated peptides have been reported, yet how this corresponds to ACPA full-length protein targeting have not previously been explored. Here we used a novel protein array approach to investigate the citrulline reactivity broadness of three single-cell derived ACPA monoclonal antibodies (mAbs) compared to polyclonal IgG anti-CCP2.

Methods: The macroarray platform (hEXselect, Engine) consists of 20 776 *E.coli* on-array expressed protein fragments from 6 909 genes with between 1-37 fragments for each gene. All originating from human fetal brain cDNA, cloned into an IPTG inducible vector with N-terminal RGS-His6-Tag as expression control. The array was enzymatically citrullinated with rabbit PAD. Duplicated spotting and alkaline phosphatase conjugated anti-human IgG (Fc) with AttoPhos substrate enabled reliable spectral fluorescent intensity detection that were scored from 0-3 using a grid based analyzing software. Binding of two recombinant ACPA mAbs derived from RA synovial plasma cells (1325:01B09 and 1325:04C03) and one mAb derived from tetramer sorted blood memory cells (37CEPT2C04) were evaluated. The technology was validated with ELISA and Western blot using individually expressed selected protein fragments.

Results: Purified polyclonal IgG anti-CCP2 from ACPA+ RA patients contained, as expected, reactivity to a range of citrullinated full-length proteins and protein fragments (674 total hits, 154 with visual scoring 3). However, interestingly, the individually analyzed monoclonal ACPA also displayed reactivity to a large number of citrullinated targets. While some shared targets were identified, also unique mAb-specific antibody targets were detected. The ACPA mAb 1325:01B09 reacted to in total 1790 citrullinated protein fragments (1328 mAb-unique; 190 with visual scoring 3), 1325:04C03 reacted to 408 (115 mAb-unique; 42 with visual scoring 3), and 37CEPT2C04 reacted to 792 (487 mAb-unique; 118 with visual scoring 3). Reactivity to native unmodified proteins were limited (53, 19, or 22 hits, respectively). Among the identified proteins were known targets e.g. Cit-vimentin, Cit-hnRNPs, and Cit-histones, as well as less studied RA autoimmunity targets e.g. Cit-40S ribosomal proteins.

Conclusion: All investigated monoclonal ACPA were multi-reactive to citrullinated protein targets to a much larger extent than previously described and bound hundreds of full-length proteins and protein fragments. Nevertheless, ACPA mAbs demonstrate individual distinct binding patterns. Further studies on how ACPA bind to proteins in cells during physiological citrullination and the clinical relevance of ACPA multi-reactivity will be of importance.

Session Title: B Cell Biology and Targets in Autoimmune and Inflammatory Disease Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Abnormal expression of the tyrosine kinase ZAP-70 by tumoral B cells in chronic lymphocytic leukemia (CLL) is associated with B cell receptor (BCR) hypersignalling and autoimmune cytopenia (AIC), mostly induced by polyclonal IgG from non-tumoral B cells. We previously shown that ZAP-70 is also expressed by residual non tumoral B cells in CLL and associated with AIC occurrence. We therefore hypothesized that ZAP-70 expression in non tumoral B cells could generally predispose to tolerance breakdown.

Methods: Ig heavy and light chain were amplified from FACS-sorted non tumoral mature switched ZAP-70⁺ B cells of CLL patients with AIC, for production of recombinant antibodies (rAb). Reactivity of these rAb was tested in ELISA and on HEp-2 cells. A knock in *Zap-70⁺/Mb1-Cre⁺* mouse model (KI ZAP) was generated to conditionally express ZAP-70 in B cells since proB stage, to study functional consequences of ZAP-70 expression in B cells *in vivo*. *Zap-70⁺/Mb1-Cre⁻* mice were used as controls (CTRL).

Results: Among the 13 rAb produced to date from 5 different patients, 2 (15,5%) have an antinuclear autoreactivity and two others (15,5%) were polyreactive (DNA, lipopolysaccharide, insulin), compared respectively to 6% and 4,3% of control B cells. Compared to CTRL, microarrays revealed that KI ZAP mice were significantly enriched in circulating IgG and IgM autoantibodies against various antigens (mainly nuclear). These mice had reduced apoptosis rates of proB, preB and immatures B cells, enrichment in marginal zone (p=0.01) and reduction in B1a B cells (p=0.008). In the other part, KI ZAP mice had persistent hypogammaglobulinemia since 16 weeks-old (p=0.003 for IgG and p=0.03 for IgM), together with a reduction in matures naive, matures switched as well as in germinal center B cells (p=0.001, p=0.002 and p<0.001 respectively) and a trend was observed for plasma cells (p=0.07). After immunization by ovalbumin + Freund's adjuvant, a reduced production of specific IgG and IgM was observed (p=0.01 and p=0.03 respectively). KI ZAP B cells shown increased spontaneous activation and proliferation levels holding after BCR stimulation, as well as an increased intracellular calcic flow. Preliminary data suggested a reduced SYK phosphorylation after BCR stimulation in KI ZAP B cells compared to CTRL.

Conclusion: We report for the first time that non tumoral ZAP-70⁺ B cells could be enriching in autoreactive cells *in vitro* and that ZAP-70 expression in B cells is associated *in vivo* with medullar selective advantage, enrichment in circulating autoreactive Ig and potential autoreactive B cells (marginal zone) with reduced immunoregulatory B cells (B1a). This expression is also associated with partial block in B cells peripheral development, but with a conversely early increased activation and proliferation status. ZAP-70 could interfere early with SYK leading to an altered BCR signaling responsible for defect in normal B maturation promoting emergence of autoreactive B cells. Mechanistic role of ZAP-70 in BCR signaling has to be further analyzed but our data open new opportunities involving ZAP-70 in the understanding of B cell development and physiopathology of tolerance breakdown.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: B Cell Biology and Targets in Autoimmune and Inflammatory Disease Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Autoantibodies against citrullinated proteins are found in 64-89% of rheumatoid arthritis (RA) patients, with a specificity of 88-99%. While citrullinated vimentin, fibrin and histone have been implicated as targets of autoantibody reactivity, new targets, such as Tenascin-C, continue to be uncovered. To this end, we performed an unbiased epitope-level characterization of autoantibodies from RA serum samples using a high density peptide microarray.

Methods: Our high-density peptide array, comprised of over 4.6M peptides, contains the entire annotated human proteome from the UNIPROT database. The 20,188 unique proteins were represented as overlapping 16-mer peptides. In addition to native peptide sequences, sequences containing arginine residues were replaced with citrulline and lysine residues were replaced with homo-citrulline to provide a comprehensive screen against all possible epitopes. We analyzed IgG antibodies for 27 serum samples (9 control, 9 RA DMARDS responders and 9 RA DMARDS non-responders).

Results: Autoantibody reactivity was seen ubiquitously in all RA serum samples, with citrullinated peptides being the most prevalent over homocitrullinated and native peptide sequences. Hierarchical clustering revealed strong autoantibody reactivity against citrullinated peptides in almost all (8/9) RA DMARDS non-responder and 4/9 RA DMARDS responder samples. Within this group of RA samples with high reactivity, identical immunodominant epitopes were observed in 959

proteins. Within the 959 proteins, which included previously known targets such as vimentin, fibrin and type II collagen, over half have not been previously associated with RA. These include proteins such as PATE4 and NENF.

Conclusion: Using high-density peptide arrays, antibody reactivity was observed against citrullinated proteins that have not been previously associated with RA. These protein targets may further contribute to our understanding of the role of autoantibodies in RA pathophysiology.

Session Title: B Cell Biology and Targets in Autoimmune and Inflammatory Disease Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Rituximab is used for the treatment of juvenile dermatomyositis (JDM) with variable success. Some of this variability is presumed to be related to the effectiveness of tissue B cell depletion. Forming new B cells requires B cell receptor recombination and the formation of KREC. The KREC does not replicate with B cell divisions. The recombination site on chromosomal DNA is known as the joining code (JC). The ratio of JC: KREC determined by qRT-PCR estimates the number of B cell divisions that have occurred in a B cell population. BAFF is a cytokine produced by activated macrophages and dendritic cell to promote B cell survival and proliferation. We hypothesized that Rituximab treated JDM who have near complete tissue B cell depletion will have a low JC to KRECs ratio and increased soluble BAFF level, which is associated with a more effective response to Rituximab.

Gender	Race	HLA	Medication	Age at 1st Ritux	No of Ritux doses	Disease Manifestations	Oligoclonal B cell expansion	B cell depletion	Response	Relapse

9	F	W	P155/140+	CYC, IVIG, MTX, MMF, HCQ, steroid	15.9 yr	4	S only	No	Yes	n/a

F = Female, M = Male, W = White, H = Hispanic, B = Black, yr = years, m = months, S = Skin, Mu = Muscle, Cyc = Cyclosporine, MMF = mycophenolate mofetil (cellcept), IVIG = Intravenous Immunoglobulin, MTX = methotrexate, HCQ = hydroxychloroquine, Ritux=Rituximab

Methods: This is an IRB approved, retrospective pilot study conducted at Lurie Children's Hospital. We included 9 JDM patients (mean age 12.5 ± 2.2 years). Their demographics are presented in Table 1. We measured JC and KREC qRT-PCR from serial PBMC stored (-80°C) in the CureJM Center Repository. BAFF level was measured using Mesoscale® technology. We defined oligoclonal B cell expansion as a JC:KRECs ratio of 8 or more before Rituximab therapy. A JC:KREC ratio of 2.5 or less on the first detectable sample post-Rituximab was considered as an evidence of good B cell depletion. A good response to therapy was defined as improvement of the Disease Activity Score (DAS) by at least 2 points on two consecutive visits. This study is supported by a grant from CARRA.

Results: 6 out of 9 JDM had evidence of oligoclonal B cell expansion prior to Rituximab use. Of those 6 subjects, 4 had good B cell depletion and responded well to Rituximab therapy. On the other hand, 1 out of 2 subjects with poor B cells depletion had a lack of response to Rituximab. All JDM without oligoclonal B cell expansion had a poor response to Rituximab therapy (Table 1). Although serum BAFF level increased in almost all subjects after Rituximab therapy, subjects with poor B cell depletion appeared to have only a minor increase (Fig 1).

Conclusion: Children with JDM who demonstrate oligoclonal B cell expansion prior to the use of Rituximab have a more favorable outcome. If this finding is confirmed, KREC PCR may serve as a selection criterion for Rituximab therapy. BAFF levels increase after Rituximab therapy, which may contribute to disease flare and may provide a therapeutic target. Limitations of this pilot study include the low numbers of subjects, which requires validation in additional cohorts.

Cytoplasmic FOXO1 Identifies Novel Disease-Activity Associated B Cell Subsets in SLE

Molly Hritzo¹ and Amit Golding², ¹Microbiology and Molecular Immunology, University of Maryland School of Medicine, Baltimore, MD, ²10 South Pine Street, Baltimore VA/VAMHCS AND University of Maryland School of Medicine, Baltimore, MD

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: B Cell Biology and Targets in Autoimmune and Inflammatory Disease Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: A key integrator of external stimuli in lymphocytes, Forkhead box protein O1 (FOXO1) is a highly attractive factor to study in SLE because it is central to B cell activation/maturation and integration of metabolic and inflammatory stimuli. When active, it remains in the nucleus, but upon Akt phosphorylation downstream of T or B Cell Receptor signaling, FOXO1 is inactivated and shuttles to the cytoplasm, linking FOXO1 localization to function. In SLE, both T and B cells are hyperactive, and respond more quickly and strongly to antigen, producing a disproportionate

inflammatory response. Thus, we hypothesized that SLE lymphocytes would have altered FOXO1 localization, reflecting altered lymphocyte activation.

Methods: To address this hypothesis, we first developed a method of examining dynamic native FOXO1 localization in human peripheral lymphocyte subsets using imaging flow cytometry (IFC). IFC combines the quantitative power of flow cytometry with the qualitative images of microscopy and can be performed with many fewer cells than are needed for the more traditional methods. We demonstrated that we can visualize native FOXO1 and detect significant kinetic differences in localization within user-defined subsets of primary peripheral human T and B cells. We then used IFC to compare FOXO1 localization in SLE and healthy donor lymphocytes.

Results: Most T and B cell subsets demonstrated nuclear FOXO1 localization in both healthy controls and individuals with SLE. However, FOXO1 was significantly more cytoplasmic in SLE in atypical memory IgD-CD27- B cells (see representative figure below). Cytoplasmic-predominant FOXO1 (CytoFox) B cells were significantly increased in SLE patients as compared to healthy controls, and the levels of CytoFox B cells correlated positively with SLE disease activity. The highest abundance of CytoFox B cells was observed in African American females with SLEDAI ≥ 6 and elevated anti-dsDNA Antibodies or lupus nephritis. The phenotype of CytoFox B cells in SLE included relatively low CD20 expression and high granularity/side scatter.

Conclusion: We report, here, on dramatic cytoplasmic localization of FOXO1 in IgD-CD27-(atypical memory) B cells. So-called “Double Negative” (DN) B cells have previously been shown to be increased in SLE and enriched in autoreactive clones. As FOXO1 phosphorylation downstream of B cell receptor-dependent signaling is required for nuclear exclusion, CytoFox B cells likely represent a high state of B cell activation with excess signaling and/or loss of phosphatase activity. We hypothesize that CytoFox B cells in lupus represent a novel biomarker for the expansion of pathologic, autoreactive B cells which may provide new insights into the pathophysiology of SLE.

Session Title: B Cell Biology and Targets in Autoimmune and Inflammatory Disease Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Anti-citrullinated protein antibodies (ACPA) have proven highly useful as biomarkers in rheumatoid arthritis (RA) and appear to be important to disease pathogenesis. Nevertheless, the relationship between progressive B cell receptor (*IGH*, *IGK*, and *IGL*) gene somatic hypermutation (SHM) and citrullinated protein antigen specificity in RA B cells remains only poorly understood. In this investigation, we aimed to characterize citrullinated peptide reactivity as a function of heavy and light chain SHM events using a panel of citrullinated autoantigen-specific RA B cells.

Methods: Three subjects from the University of Minnesota ACPA⁺ RA cohort gave consent for the study of peripheral blood B cell receptor antigen specificity. Citrullinated filaggrin peptide (CFC1) and citrullinated a-enolase peptide (CEP-1) tetramer-bound B cells were subjected to flow cytometric cell sorting and single-cell *IGH*, *IGK*, and *IGL* gene sequencing. BCR genes demonstrating related V-(D)-J region gene usage and conserved junction structures were compared using the PHYLP/DNApars algorithm and B cell lineage relationships (clades) were characterized. BCR gene sequences were also expressed as recombinant monoclonal antibodies (mAbs) for direct evaluation of citrullinated antigen binding by ELISA.

Results: Paired heavy and light chain *Ig* gene sequences were obtained at a single time point from subjects RA14 (n = 9) and RA62 (n = 10). Additionally, 86 paired nucleotide sequences were obtained from subject RA37 at three separate time points. Parsimonious clustering of related immunoglobulin gene nucleotide sequences revealed that 52 of these 105 B cells (50%) arose within 9 unique clades as a consequence of clonal expansion and progressive SHM. The frequency of clade membership by citrullinated peptide tetramer-bound B cells in each subject varied from 44% to 89% ($\chi^2 = 7.0$, P-value = 0.030). The distribution of clade membership by CEP-1 tetramer-bound B cells in subject RA37 also varied significantly across time ($\chi^2 = 25.9$, P-value = 0.011). In ELISA, 9 of 20 recombinant human mAbs (45%) generated from a sample of these BCR sequences proved capable of binding to at least one citrullinated antigen, and all 9 of these citrullinated peptide-binding mAbs derived from a highly mutated clade-associated B cell. Citrulline-dependent cross-reactivity (*citrulline multispecificity*) extending beyond the citrullinated peptides used for B cell capture was observed in all clade-derived mAbs tested.

Conclusion: Our findings suggest that the acquisition of broad ACPA specificity in RA arises from a restricted repertoire of continuously evolving citrulline-multispecific B cell clades.

Session Title: B Cell Biology and Targets in Autoimmune and Inflammatory Disease Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Polymorphisms of the transcription factors Ikaros (IKZF1) and Aiolos (IKZF3), which are essential for the maturation, differentiation and survival of B cells, have been linked to systemic autoimmunity. The Cereblon modulator CC-220, known to induce the degradation of Ikaros and Aiolos, is being explored as a therapeutic option in Systemic Lupus Erythematosus (SLE). The involvement of IKZF1 and 3 in other autoimmune diseases is poorly known, and their effects on B cell activation and differentiation in the context of autoimmunity have been only partially described. Aim of this study was to evaluate the expression of IKZF1 and IKZF3 in the salivary glands (SGs) of patients with Sjogren's syndrome (SS) and the effects of CC-220 on the TLR7-mediated activation and plasmablast differentiation of B cells isolated from patients with Sjogren and SLE.

Methods: SG biopsies of patients with SS (n=29) and sicca controls (n=11) were analysed by immunohistochemistry for IKZF1 and IKZF3 expression using a semi-quantitative (SQ) score (0-3, based on number of positive cells) to quantify expression. Sequential sections were stained for B and T cells, and patients were classified into Ectopic Lymphoid Structures (ELS) positive and negative. CD19⁺ B cells were isolated from the peripheral blood of patients with SLE (n=16) and Sjogren's (n=4), triggered with TLR7 ligand Resiquimod +/- IFN α , with or without CC-220 (1, 10, 100 nM). After 5 days, cells were analysed by FACS, IgG and IgM measured by ELISA and ANA by immunofluorescence. In parallel experiments, SLE B cells (n=7) were differentiated into plasmablasts in vitro by stimulation with IL-2, IL-10, IL-15, CD40L & Resiquimod for 5 days and analysed as above.

Results: Ikaros expression was significantly higher in the SGs of SS patients vs sicca controls ($p < 0.05$), while aiolos was expressed at similar levels. SS patients with ectopic lymphoid structure (ELS) had significantly higher scores than ELS negative for both IKZF1 ($p = 0.041$) and IKZF3 ($p = 0.016$). CC-220 significantly inhibited the TLR7 and IFN α -mediated production of IgM and IgG from B cells from SLE and Sjogren's patients, in a dose dependent manner, inhibited the production of anti-nuclear antibodies, and significantly reduced the number of CD27⁺ memory B cells. CC-220 significantly inhibited in vitro differentiation of plasmablasts (CD19⁺CD20⁻CD27^{hi}CD38^{hi}) from SLE B cells, while leaving IgD⁺ naive B cells unaffected.

Conclusion: This study shows that Ikaros and Aiolos expression in the salivary glands of patients with Sjogren's syndrome is associated with the presence of ectopic lymphoid structures. CC-220, a cereblon modulator which induces IKZF1/3 degradation, reduced B cell activation and autoantibody production triggered by TLR-7 and IFN- α , and inhibited the differentiation of SLE B cells into plasmablasts. Our work further confirms the relevance of Ikaros and Aiolos in SLE, and suggests that they might be useful therapeutic targets in B cell driven systemic autoimmune diseases, such as Sjogren's.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: B Cell Biology and Targets in Autoimmune and Inflammatory Disease Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Sjogren's syndrome (SS) is a common systemic autoimmune disease characterized with aberrant B cells activation. B cells play a key role in the pathogenesis of SS, however, the abnormal B cell activation in SS is partially understood.

Methods: We performed whole transcriptome sequencing of B cells from 3 SS patients and 3 matched Healthy controls (HC). We then confirmed the differential gene expressions in 40 SS patients and 40 HC by quantitative PCR and Western-blot. We further transfected with siRNA targeting candidate genes into B cells and stimulated B cells with anti-IgM or CpG to measure the proliferation potential and immunoglobulins secretion. We also explored TLR9 signaling to identify the potential molecular mechanism of B cell hyperactivation in SS.

Results: We identified 51 up-regulated and 22 down-regulated differentially expression genes in B cells from SS patients. We confirmed the RNA and protein level of EPSTI1(Epithelial Stromal Interaction 1) in B cells from 40 SS patients was significantly higher than those from 40 HCs. Comparing with control B cells, EPSTI1-siencing B cells stimulated with CpG (but not anti-IgM) were proliferated less and produced lower level of IgG. We observed the level of p-p65, but not pJNK and (p38MAPK), were decreased in EPSTI1-siencing B cells stimulated with CpG. Consistently, we also found the level of p-p65 was significantly higher in B cells from SS patients than those from HC. Finally, the level of I κ Ba, a key regulator of p65, was significantly up-regulated in EPSTI1-siencing B cells and B cells from HC.

Conclusion: Elevated EPSTI1 expression in B cells from SS patients promoted TLR9 signaling activation and contributed to the abnormal B cells activation. Mechanistically, EPSTI1 stimulated the phosphorylation of p65, which was likely through the interaction and degradation of I κ Ba.

Session Title: B Cell Biology and Targets in Autoimmune and Inflammatory Disease Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) associated anti-citrullinated protein autoantibodies (ACPA) develop before RA diagnosis, at which point a wide range of citrullinated proteins have been shown to be targeted based on different peptide assays. Intriguingly, ACPAs have been found to be multi-reactive even on monoclonal level. We set out to study the breadth of that multireactivity and try to determine what the antibodies recognize, as recent findings suggest that certain, but not all, ACPA may have pathogenic properties.

Methods: We screened 6 different monoclonal ACPAs, originating from 3 different patients, 4 were derived from synovial fluid plasma cells and 2 were derived from peptide-tetramer captured B cells from peripheral blood. All ACPA mAbs have confirmed anti-CCP2 reactivity and have demonstrated multi-citrulline-peptide reactivity by ELISA. A custom-made peptide array (NimbleGen, Roche) was designed with 16aa peptides derived from 1610 extracellular matrix- or RA associated- proteins. Peptides containing either an arginine or lysine were synthesized in pairs with a modified version containing either a citrulline or a homocitrulline in the respective position. Altogether >53,000 citrullinated peptides, >49,000 carbamylated peptides and >70,000 native peptides were included. Monoclonal antibodies were run on the array at a concentration of 1ug/ml, while serum and synovial fluid were diluted 1/100.

Results: The monoclonal ACPAs consistently displayed low reactivity (<0.06%) to unmodified peptides, while all 6 reacted to 1,000s (3.4-9.4%) of the citrullinated peptides. Intriguingly, 3 out of the 6 ACPAs also reacted with the carbamylated peptides to a similar broad extent (2.2-4.5% of the peptides). Based on the sequences from the positive peptides we could create LOGOs of the preferred amino acids. Intriguingly, two dominating aa-patterns were identified and only minor contributions from the flanking sequences were observed.

Serum and synovial fluid (SF) from the same patient as the synovial plasma cell-derived ACPAs were also assessed at both the time point of the cell draw and a 10-year follow-up. The SF samples displayed a robust citrulline-reactivity with only 10% divergence between the two samples taken 10 years apart. In contrast, the homocitrulline reactivity was significantly altered between the two time points as approximately 50% of the signals were lost at follow-up in both SF and peripheral blood.

Conclusion: An ACPA serum response is a hallmark of seropositive RA and develops early, often before clinical symptoms. Our study of monoclonal ACPAs generated from established RA implicates that a truly broad citrulline-reactivity is found also on individual immunoglobulin level and may be the result of multiple antigen encounters which have selected for very focused citrulline-recognition with only modest contribution from flanking amino acids. This citrulline autoimmunity appears robust with minimal changes over time, while that was less true for the homocitrulline response.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: B Cell Biology and Targets in Autoimmune and Inflammatory Disease Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The field of autoimmunity may benefit from the knowledge gained by studying immune checkpoint inhibitors (ICIs). These agents have shown enormous efficacy in oncology by (re)activating T-cells to assault cancer cells, but come at the cost of immune-related adverse events (irAEs). Since ICI's mode of action is not antigen-specific, we hypothesized that tolerance may be broken not only to tumor antigens but also to autoantigens, leading to the formation of autoantibodies. Therefore, we investigated whether patient treated with ICIs develop autoantibodies, and whether this trait is associated irAEs and ICI efficacy.

Methods: In pre- and post-treatment sera of 133 ipilimumab (anti-CTLA4)-treated melanoma patients, we determined 23 common clinical autoantibodies associated with autoimmune diseases (Figure 1). The association between autoantibody development and irAEs (under ipilimumab or subsequent anti-PD-1 therapy), best overall response, and overall survival was investigated.

Results: Autoantibodies developed in 19.2% (19/99) of pre-treatment autoantibody-negative patients ($p < 0.0001$; Figure 1). A non-significant association was observed between development of any autoantibodies and any irAEs: 5/19 (26.3%) patients that developed any autoantibodies had irAEs, versus 46/80 (57.5%) patients that did not develop autoantibodies (OR: 2.92 [95% CI: 0.85 to 10.01]). Predominantly anti-TPO (4.8%, 6/125) and anti-TG antibodies (6.0%, 8/132) developed ($p = 0.03$ and $p = 0.008$, respectively). Patients with anti-thyroid antibodies after ipilimumab had significantly more thyroid dysfunction under subsequent anti-PD-1 therapy: 7/11 (63.6%) patients with anti-thyroid antibodies after ipilimumab developed thyroid dysfunction under anti-PD-1, versus 7/49 (14.3%) patients without antibodies (OR: 9.96 [95% CI: 1.94 to 51.1]). For most other autoantibodies, including RA-associated antibodies, post-treatment positivity increased only marginally and was not associated with occurrence of irAEs in the organ system related to the autoantibody specificity. Becoming autoantibody positive showed a trend towards better overall survival (HR for all-cause death: 0.66 [95% CI: 0.34 to 1.26]; Figure 2) and therapy response (OR: 2.64 [95% CI: 0.85 to 8.16]).

Figure 1. Heatmap of antibody positivity pre- and post-ipilimumab treatment. Not shown: all patients were anti-ENA negative at baseline, while at follow-up, two patients became anti-ENA positive, specifically anti-SSA positive.

Figure 2: Overall survival for baseline autoantibody negative patients that developed any autoantibodies ("Converted to positive") compared to those that did not develop any autoantibodies ("Stayed autoantibody negative"). Numbers below the graph indicate the number of patients at risk within each group.

Conclusion: Breaking of humoral tolerance as measured by development of autoantibodies is relatively common under treatment with ipilimumab and holds promise as a marker of ICI toxicity and efficacy. The nature of the autoantigens towards which tolerance is broken is not reflected in the phenotype of the irAEs.

Session Title: B Cell Biology and Targets in Autoimmune and Inflammatory Disease Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: While the role of Rituximab (RTX) in controlling the clinical manifestations of Rheumatoid Arthritis (RA) and Systemic Lupus Erythematosus (SLE) has been documented, the mechanisms underlying the interplay between B-cell depletion and pro-inflammatory status leading to clinical response remain unknown. This translational multicenter study explored changes in serologic variables following B-lymphocyte depletion by *in vivo* Rituximab (RTX) treatment in Systemic Lupus Erythematosus (SLE) and Rheumatoid Arthritis (RA) patients and investigated RTX *in vitro* effects on the activity of other immune cells and on the vascular endothelium.

Methods: Sixteen SLE patients and 16 RA patients treated with RTX were enrolled. Changes in circulating inflammatory mediators, oxidative stress markers, and NETosis-derived products were evaluated at baseline and after 3 months. Serum miRNomes were identified using next-generation sequencing miRNA assay, and RTX-induced changes were delineated. Purified lymphocytes from RA and SLE patients were treated *in vitro* with RTX for 24h and B-cell depletion and inflammatory profile were evaluated by flow cytometry and RT-PCR respectively. Serum from RA and SLE patients at baseline and after RTX therapy were further added to HUVECs, monocytes, and neutrophils purified from healthy donors and activity profiles were evaluated.

Results: *In vivo* treatment of SLE and RA patients with RTX caused a significant decrease of disease activity along with a prominent alteration in circulating biomolecules related to inflammation, oxidative stress and NETosis. Reversion in altered expression of miRNAs regulating those molecules was also noticed. The *in vitro* treatment of SLE and RA purified lymphocytes with RTX significantly decreased the percentage of B lymphocytes, and was also effective in reducing the levels of a cytokine panel integrated by IL-1 β , IL-6, IFN- γ and TNF- α . Likewise, the treatment of HUVECs, monocytes and neutrophils -isolated from healthy donors- with serum of SLE and RA patients after 3 months of RTX therapy, prevented the overexpression of pro-thrombotic and pro-inflammatory markers induced by the serum of those patients before RTX therapy, and avoided the induction of NETosis in neutrophils.

Conclusion: 1. The role of B cells in autoimmunity is not confined to the production of auto-antibodies, also playing important roles in shaping the outcome of pathological immune responses. 2. RTX induced an early re-assessment of the pro-inflammatory status in RA and SLE patients, involving a re-establishment of the homeostatic equilibrium in the immune system and the vascular wall, thus paving the way to more tailored therapeutic approaches.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: B Cell Biology and Targets in Autoimmune and Inflammatory Disease Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: To investigate whether there is a direct relation between expanded proportions of Th17-effector memory (Th_{EM}17) cells and diminished proportions of regulatory B-cells (Bregs) in peripheral blood of granulomatosis with polyangiitis (GPA) patients.

Methods: Frequencies of both Bregs and Th_{EM}17-cells were determined by FACS in blood samples from 42 GPA-patients in remission and 18 matched healthy controls (HCs). Breg frequency was defined as the percentage of CD24^{hi}CD38^{hi} cells within the CD19⁺ population. Th_{EM}17-cell frequency was defined as the percentage of CCR6⁺CXCR3⁺CCR4⁺ cells within the CD3⁺CD4⁺CD45RO⁺CCR7⁺ population. In addition, CD3⁺CD4⁺ Th-cells were sorted from 9 GPA-patients and co-cultured with either total B-cells or with a Breg-depleted cell fraction. Cultured cells were stimulated with Staphylococcus Enterotoxin B (SEB) and CpG-oligodeoxynucleotides (CpG-ODN). Frequencies of Th17- (IL-17⁺) and Th1-cells (IFN γ ⁺) were determined at baseline and day 5 upon restimulation with PMA and Ca²⁺ ionophore.

Results: In remission GPA-patients, the Breg frequency was lower ($p < 0.05$), whereas the Th_{EM}17-cell frequency was increased ($p < 0.001$) compared to HCs. In remission GPA-patients the circulating Breg frequency correlated negatively with circulating Th_{EM}17-cell frequency ($r = -0.371$; $p = 0.007$). The co-culture experiments revealed a significant increase in the frequency of IL-17⁺ Th-cells in Breg-depleted samples (median:3%; range:1-7.5%) compared to undepleted samples ($p = 0.002$; undepleted samples median:2.1%; range:0.9-6.4%), whereas a trend towards a decrease in the frequency of IFN γ ⁺ Th-cells in Breg-depleted cultures was observed ($p = 0.08$; undepleted median:11.8%; range:2.8-21% vs. Breg-depleted median:12.2%; range:2.6-17.6%).

Conclusion: Bregs modulate Th_{EM}17 responses in AAV-patients. Future studies should elaborate on clinical and therapeutic implications of the Breg-Th17 interaction in GPA patients.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: B Cell Biology and Targets in Autoimmune and Inflammatory Disease Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is an autoimmune disease affecting 1% of the worldwide population and characterized by synovial hypertrophy and chronic joint inflammation. In recent work, it has been shown that release of catecholamines by the sympathetic nervous system (SNS) modulates development and course of arthritis. In this context, we were able to show that catecholamines increase the production of the anti-inflammatory cytokine IL-10, which can ameliorate joint inflammation. In the current study, we investigated whether regulatory B cells have enzymes for catecholamine biosynthesis and adrenergic receptors to determine if autocrine mechanisms could contribute to controlling regulatory B cell function.

Methods: In *in vitro* experiments on IgM/CpG-activated murine primary B cells, the basics for the mechanism(s) of increased regulatory B cell function and its targeted influence were investigated. Tyrosine hydroxylase (TH) as well as the expression of adrenergic receptors were analyzed in naïve (0h) or IgM/CpG activated B cells after 24h and 48h by FACS, Western Blot and qRT-PCR. For analysis of IL-10 production released IL-10 from inactivated and activated B cells were quantified in supernatant of B cell cultures by ELISA or directly in B cells by intracellular FACS staining.

Results: Here, we demonstrated that tyrosine hydroxylase (TH), the rate limiting enzyme of catecholamine biosynthesis are strongly expressed by splenic mouse B cells after activation with the BCR/TLR9 stimulus IgM/CpG. Analysis of B cells by FACS showed a raised expression of tyrosine hydroxylase with duration of IgM/CpG activation (0h vs. 24h, $n = 12$, $p^{***} < 0.0001$; 0h vs. 48h, $n = 12$, $p^{***} < 0.0001$; 24h vs. 48h, $n = 12$, $p^{**} = 0.0091$). A sign that catecholamines are not only provided by the sympathetic nervous system, but also produced by B cells. Furthermore, qRT-PCR and FACS showed that all adrenergic receptors (ADR) determined (ADR α 1a, ADR α 1b, ADR α 2b, ADR β 1 and ADR β 2) are expressed on the surface of IgM/CpG-activated B cells ($n = 12$). The number of TH⁺ cells, as determined by FACS correlates with the expression of ADR α 1a ($r = 0.575$, $p = 0.2$, $n = 6$), ADR α 2b ($r = 0.582$, $p = 0.046$, $n = 12$), and ADR β 2 ($r = 0.742$, $p = 0.006$, $n = 12$) ADR β 1 ($r = 0.575$, $p = 0.2$, $n = 6$). After activation with IgM/CpG B cells produce IL-10 as determined by ELISA ($n = 6$, $p^{***} < 0.0001$) and FACS ($n = 5$, $p^{***} < 0.0001$) and the production can be increased by addition of isoproterenol, a ADR-

beta agonist (n=12, p**=0,006), an effect that was blocked by nadolol (n=12, p*=0,0293). FACS analysis showed that IL-10 was mainly produced by TH+ B cells (n=6, p***<0,0001; TH+:23%, IL-10+:1,68% TH+IL-10+:2,13%; 99,3% of IL-10+ cells are TH+).

Conclusion: In conclusion, our data suggest that IgM/CpG-induced expression of TH in murine, primary B cells is associated with an increase in IL-10 mediated by stimulation of betaAR adrenergic receptors. This might point to an autocrine mechanism to control regulatory B cells, which could be exploited for therapeutic purposes in RA.

Session Title: B Cell Biology and Targets in Autoimmune and Inflammatory Disease Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Proteomics is becoming an increasingly powerful tool to study autoantibodies. Current bottom-up approaches are yielding a plethora of knowledge about public clonotypes and clonal turnover. However, reports using top-down proteomics are scarce and the advantages of not using digestions to increase the complexity of already complex mixtures are enormous. *De novo* top-down sequencing approaches, however, are extremely difficult. To overcome these limitations, we have coupled antibody sequencing from single B cells with targeted top-down MS for analysis and quantification of antibodies in autoimmune patient serum.

Methods: Fully human recombinant monoclonal antibodies were generated from single B cells. Antibody secreting cells (ASCs), sorted 7 days after vaccination of an SLE patient, have specificities to the vaccine antigen, but SLE patients also have persistent ASCs with auto-specificities which we have detected using this methodology. After identifying monoclonal specificities of interest, we then applied top-down proteomics to search for this antibody clone of known heavy and light chain sequences in longitudinal serum samples from the same donor. The detected ion intensities of known masses were used for quantitation. This allows us to directly link the presence of a specific antibody-producing B cell with a specific monoclonal antibody in the polyclonal serum antibody pool.

Results: An anti-Sm monoclonal was characterized from an SLE donor with high (>mg/ml) levels of anti-Sm. This particular antibody was isolated from an ASC following vaccination with the influenza vaccine. Although this antibody does not bind to influenza virus, it binds to both SmB' (1.5 nM affinity) and SmD (2.6 nM affinity). The serum of the donor was also carefully analyzed over a three-year period and this patient's antibody response to Sm affinity matured, increasing in overall affinity in each year. In order to determine whether this antibody was present in the serum during these three years we purified IgG from the donor's serum using protein A, and applied the polyclonal IgG to an Ultra High-pressure Liquid Chromatography-High Resolution Mass Spectrometry system for top-down proteomics analysis. We determined that the antibody is present in the serum in the year the ASC was isolated, as well as the years before and after.

Conclusion: Our results demonstrate the ability of top-down proteomics, coupled with single cell sequencing of monoclonal antibodies, to perform targeted analysis of specific serum autoantibody clones over time. In this particular SLE patient, we characterized an anti-Sm monoclonal antibody from a single B cell and determined that this antibody is present in the serum over a period of at least three years. Although clonal turnover may produce new predominant clones over a period of months, this technique shows that particular antibody clones are still present for extended periods of time (years). Overall, using single cell sequencing to enable "targeted" top-down proteomics, is a potent method for analyzing single monoclonal antibody specificities in the serum.

Session Title: B Cell Biology and Targets in Autoimmune and Inflammatory Disease Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Rho GTPases, such as RhoA, are emerging as important regulators of lymphocyte biology owing to their ability to be rapidly activated downstream of a broad range of signals. Two of the major effectors of RhoA signaling are the Rho Kinases (ROCKs), ROCK1 and ROCK2, a pair of serine-threonine kinases that have been previously implicated in the control of cell adhesion, migration, proliferation/survival, and gene expression. Despite the fundamental reliance of T and B cells on these processes, the precise involvement of the ROCKs in lymphocyte biology is yet to be elucidated. Our laboratory previously identified a role for ROCK2 in the differentiation of T_H17 cells through the phosphorylation of IRF4. This ROCK2-pIRF4 pathway drives the production of key effector cytokines, such as IL-21, and is deregulated in several autoimmune models. While previous studies have focused on the role of ROCK2 in the T cell compartment, ROCK2 is expressed in other immune cell types, including B cells, leading us to hypothesize that ROCK2 may play a broad role in immunoregulation and T-B collaborations.

Methods: To assess the role of B-cell ROCK2 in T cell-dependent responses, WT mice or mice with B cell-specific deletion of ROCK2 were immunized with a T-dependent antigen and differentiation of germinal center (GC) B cells and plasmablasts/plasma cells (PB/PCs) was monitored by FACS. The molecular mechanisms employed by ROCK2 to promote B cell differentiation was further examined by FACS-sorting B cell populations from spleens of immunized mice followed by qPCR and immunoblot analyses. Total and antigen-specific antibody responses were assessed by ELISA.

Results: We found that ROCK2 is activated in GC B cells and in PB/PCs following immunization and that ROCK2 activity is also induced *in vitro* upon stimulation with T-cell derived signals such as aCD40 and IL-21. Mice with B cell-specific deletion of ROCK2 exhibited no abnormalities in their mature B cell compartments at baseline, yet showed marked decreases in total and antigen-specific antibody titers in response to immunization with a TD antigen. These decreased humoral responses corresponded with diminished germinal center formation and maintenance following antigen challenge. Residual germinal centers in ROCK2-deficient mice revealed skewed frequencies of GC subpopulations, reduced proliferation, and attenuated class switching to IgG1.

Conclusion: Our study demonstrates that ROCK2 is activated in B cells following immunization with a TD antigen and is required for optimal GC maintenance and function. These findings thus uncover a previously unknown B cell-intrinsic role for ROCK2 in promoting humoral responses and further support the notion that targeting ROCK2 activity may provide therapeutic benefit for the treatment of diseases marked by aberrant B cell responses.

CD70-Mediated CD27 Downregulation Contributed to Regulatory B10 Cell Impairment in Rheumatoid Arthritis

Lianjie Shi¹, Fanlei Hu², Rong Mu³ and Zhan-Guo Li⁴, ¹Peking University International Hospital, Beijing, China, ²Peking University People's Hospital, Beijing, China, ³Peking University People's Hospital, Beijing, China, ⁴Peking University People's Hospital, Beijing, China

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: B Cell Biology and Targets in Autoimmune and Inflammatory Disease Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Impaired function of regulatory B10 cells has been shown in autoimmune diseases. However, the underlying mechanism is still obscure. In the present study, we investigated the potential contribution of CD70-CD27 interaction to B10 cell impairment in rheumatoid arthritis.

Methods: A total of 120 RA patients and 73 healthy controls were enrolled in our study. CD19⁺CD24^{hi}CD27⁺ regulatory B10 cells and CD19⁺IL-10⁺ B cells in PBMCs were assessed by flow cytometry. CD70, CD27, IL-10, TNF- α , IL-1 β , IL-6, IFN- γ and IL-17 was evaluated by qPCR. PBMCs from healthy controls were pretreated with or without anti-CD70 antibody before anti-CD3 plus anti-CD28 antibodies treatment. Soluble CD27 and IL-10 in sera and supernatants was detected by ELISA. CD70 expression on CD4⁺ T and CD19⁺ B cells were assessed by flow cytometry in RA and healthy controls.

Results: The frequencies of CD19⁺CD24^{hi}CD27⁺ regulatory B10 cells were decreased and their IL-10-producing competency was impaired in patients with RA. The impairment of CD19⁺CD24^{hi}CD27⁺ B10 cells was partially attributed to the decreased expression of CD27 induced by upregulated CD70 on CD19⁺ B cells and CD4⁺ T cells. The frequencies of CD19⁺CD24^{hi}CD27⁺ regulatory B10 cells could be restored after blocking CD70-CD27 interaction by anti-CD70 antibody. Furthermore, CD70-CD27 interaction significantly elevated the IL-10 expression accompanied and compensated for the number decreasing of CD19⁺CD24^{hi}CD27⁺ B cells.

Conclusion: CD70-CD27 interaction may play a critical role in the numerical and functional impairment of regulatory B10 cells, thus contributing to RA pathogenesis.

CD21^{lo} Cells Are Increased in Patients with Systemic Sclerosis and May be Associated with Interstitial Lung Disease

Erin Wilfong¹, Katherine Vowell², Leslie Crofford³ and Peggy Kendall¹, ¹Department of Medicine, Division of Allergy, Pulmonary, and Critical Care Medicine, Vanderbilt University, Nashville, TN, ²Division of Rheumatology and Immunology, Vanderbilt University, Nashville, TN, ³Division of Rheumatology and Immunology, Vanderbilt University Medical Center, Nashville, TN

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: B Cell Biology and Targets in Autoimmune and Inflammatory Disease Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic sclerosis (SSc) is a severe systemic disease characterized by fibrosis of the skin and visceral organs. While the exact pathogenesis of SSc is incompletely understood, there is increasing evidence that B cells and autoantibodies may play a role. Several autoimmune-prone B cell subsets have been previously described in other autoimmune conditions including subsets with low CD21 expression (CD21^{lo}), high expression of CD19 (CD19^{hi}), high expression of CD24 and CD38 (CD24^{hi}CD38^{hi}), and high expression of IgD with low expression of IgM (B_{ND} cells). We describe preliminary investigations to the presence of these subsets in SSc.

Methods: Cryopreserved peripheral blood mononuclear cells (PBMCs) were stored as part of the MYSTIC cohort (VUMC IRB141415). Detailed clinical phenotyping was performed at the time of patient enrollment. PBMCs were thawed and subjected to fluorescence flow cytometry to investigate B cell phenotypes in patients with SSc (n=11) versus healthy controls (n=5). Data was analyzed with biaxial gating and the multi-dimensional unsupervised analysis tool viSNE, which displays single cells on a 2D 'map' based on their phenotypic similarity to each other in high dimensional space. Cell frequencies were compared using Mann-Whitney tests.

Results: Biaxial gating revealed that SSc patients had a significantly higher proportion of CD21^{lo} cells relative to healthy controls (Figure 1). There was no difference in the frequency of CD19^{hi}, B_{ND}, or CD24^{hi}CD38^{hi} cells. Subgroup analysis revealed patients with SSc associated ILD (SSc-ILD) had a higher frequency of CD21^{lo} cells relative to patients without

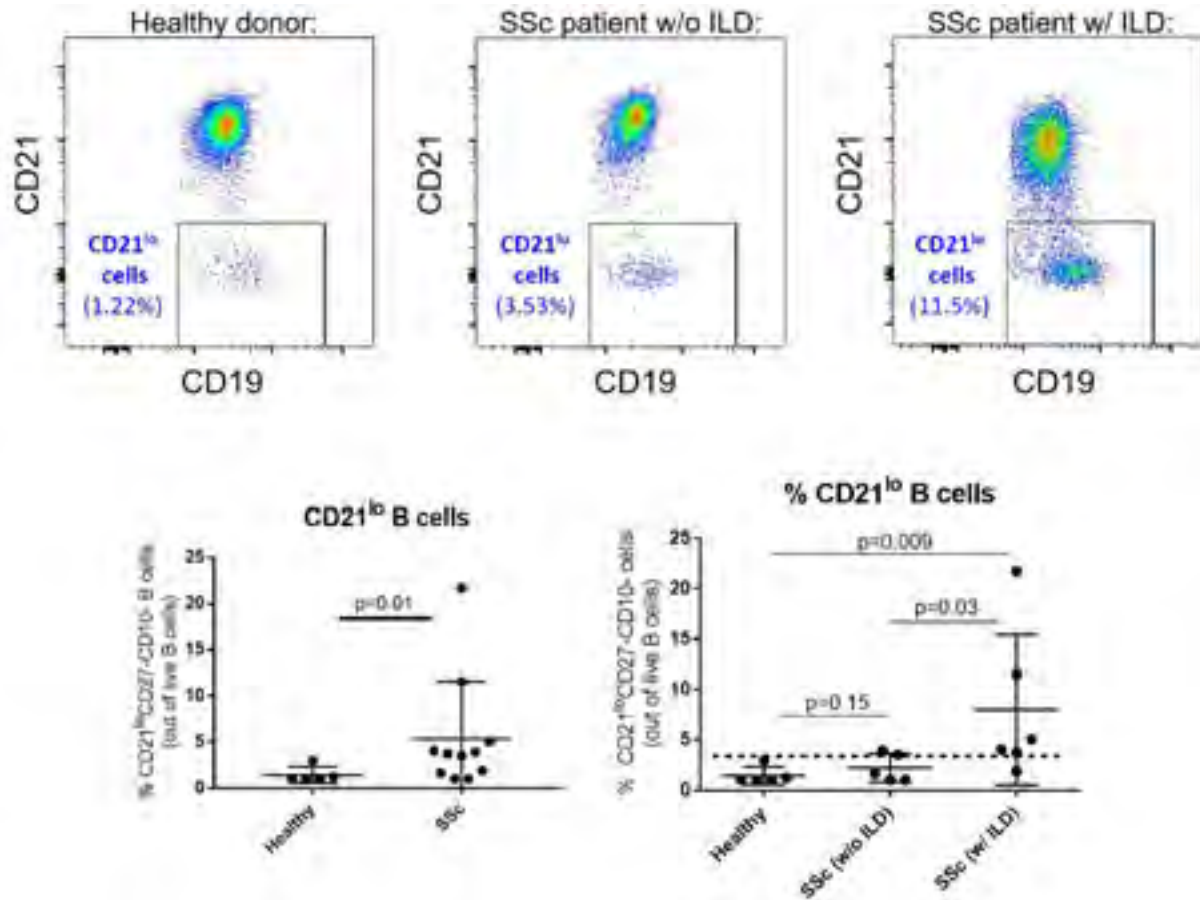

Figure 1. Biaxial gating of CD21^{lo} cells in SSc patients and healthy controls

ILD (mean frequency 7.99% vs. 2.23%, $p=0.03$). Further analysis of the data—using viSNE—confirmed that CD21^{lo} B cells were increased in SSc-ILD patients compared to SSc without ILD ($p=0.03$) (Island 1, Figure 2). viSNE analysis also revealed a population of CD24+IgM- memory B cells (Island 2) that were underrepresented in SSc patients without ILD ($p=0.03$).

Conclusion: Preliminary studies indicate that certain populations of B cells may be associated with SSc-ILD compared to SSc patients without ILD and healthy controls. These findings need to be validated in the larger MYSTIC cohort.

Ritchlin¹, ¹Division of Allergy/Immunology and Rheumatology and Center for Musculoskeletal Research, School of Medicine and Dentistry, University of Rochester Medical School, Rochester, New York, USA, Rochester, NY, ²Division of Allergy, Immunology and Rheumatology and Center for Musculoskeletal Research School of Medicine and Dentistry, University of Rochester, Rochester, New York, USA, Rochester, NY

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Animal Models Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Pathologic bone resorption in rheumatoid arthritis (RA) is mediated by multinucleated osteoclasts (OC) at the bone-pannus junction. OC differentiation (OCgenesis) is dependent on a number of signals that promote cell fusion, formation of specific organelles and the development of a ruffled border. Dendritic Cell-Specific Transmembrane Protein (DC-STAMP), is upregulated in monocytes at early stages of OCgenesis and is required for cell-cell fusion. DC-STAMP^{-/-} mice develop mild osteopetrosis, due to the presence of mononuclear OC with limited capacity to resorb bone. The role of DC-STAMP in the induction of joint inflammation and pathologic bone resorption has not been examined. Therefore, we determine whether the absence of DC-STAMP ameliorates joint inflammation and bone damage in the TNF transgenic murine arthritis model.

Methods: Four experimental groups of 7-month old C57BL/6, DC-STAMP^{-/-}, TNF-Tg and DC-STAMP^{-/-} x TNF-Tg mice were generated. The presence of arthritis was determined by visual examination along with recording of grip strength, and ankle width. We analyzed the impact of DCSTAMP deficiency on bone architecture with mCT-scan analysis. The extent of tibial bone resorption was determined by the area occupied by OC in bone sections. Serum cytokines were quantitated by

multiplex assay and the accumulation of inflammatory cells in bone sections was quantitated by immunofluorescence microscopy.

Results: DC-STAMP^{-/-} x TNF-Tg mice had a 2.5-fold decrease in ankle thickness from week 28 to 49 of age, compared to age-matched TNF-Tg mice ($p < 0.0001$), and was comparable to that of C57BL/6 and DC-STAMP^{-/-} mice. Notably, DC-STAMP^{-/-} x TNF Tg mice had a significantly smaller TRAP⁺ area in the tibia, compared to the TRAP⁺ area in the tibia of TNF-Tg mice (1.05 ± 0.1 vs 17.3 ± 0.6 , $p = 0.0001$). Consistent with the reduction in OC in the tibia, we found a four-fold reduction in bone resorption by OCs in DCSTAMP^{-/-} x TNF-Tg mice, compared to TNF-Tg mice (0.053 ± 0.05 vs 0.21 ± 0.005 , $p = 0.002$). Accumulation of inflammatory cells in the synovia and systemic levels of proinflammatory molecules were markedly reduced in DC-STAMP^{-/-} x TNF-Tg mice (IL- α : 80 pg/ml, 3-fold decrease, $p = 0.001$; TNF- α : 20 pg/ml, 30-fold decrease, $p = 0.04$ and MCP1: 56 pg/ml, 3-fold decrease, $p = 0.04$). In contrast, macrophage infiltration was abundant in the synovial tissue from TNF-Tg mice and correlated with the significantly higher levels of MCP1 (170 pg/ml), a chemokine that attracts macrophages into inflamed tissues.

Conclusion: In addition to the well-known role of DC-STAMP in cell-cell fusion, we found that it is required for progressive development of synovitis and joint damage in the setting of TNF mediated arthritis. Apparently, DC-STAMP modulates synovitis and joint damage through regulation of signaling events that promote differentiation and activation of monocytes and possibly other immune cells.

T Cell-Intrinsic Nod2 Protects Against Th17-Mediated Autoimmune Arthritis in SKG Mice

Ruth Napier¹, Ellen Lee¹, Emily Vance¹, Paige Snow², Clare Dawson³, Kimberly Samson⁴, Amy Moran⁵, Michael Davey⁶, Shimon Sakaguchi⁷ and Holly Rosenzweig¹, ¹Molecular Microbiology and Immunology, Oregon Health & Science University, Portland, OR, ²Molecular Microbiology and Immunology, VA Portland Health Care System, Portland, OR, ³Portland VA, PORTLAND, OR, ⁴Oregon Health & Science University, Portland, OR, ⁵Cell, Developmental, and Cancer Biology, Oregon Health & Science University, Portland, OR, ⁶VA Portland Health Care System, Portland, OR, ⁷Osaka University, Osaka, Japan

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Animal Models Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Nucleotide-binding oligomerization domain-containing protein 2 (Nod2) is an innate immune receptor known primarily for its role in host protection against bacterial infections. Intriguingly, Nod2 also appears to have a role outside of infection, as a single point mutation in this molecule leads to 100% incidence of arthritis in Blau Syndrome. Although the contribution of autoreactive CD4⁺ T cells to autoimmune arthritis is appreciated, the molecules that regulate their development and propagation remain unknown. Here we sought to elucidate the role of Nod2 in the generation of autoreactive CD4⁺ T cells using SKG mice, which are genetically predisposed to arthritis.

Methods: SKG and Nod2^{-/-}SKG mice housed under specific pathogen-free conditions were i.p. injected with zymosan (1.5 mg) at 6-8 wk age, clinically monitored for arthritis and analyzed histologically for joint pathology. CD4⁺ T cells from ankle-draining lymph nodes of naïve or zymosan treated mice were stimulated *in vitro* with PMA/io and production of pro-inflammatory cytokines was quantified by ICS and flow cytometry. IL-17 concentration in synovial fluid was determined by ELISA. The role of IL-17 in disease was assessed by *in vivo* neutralization with anti-IL-17A monoclonal antibody. T regulatory (Treg) cell (CD4⁺CD25⁺Foxp3⁺) frequency and ability to suppress T effector (CD4⁺CD25⁻) cell proliferation was determined by Treg suppression assays and flow cytometry. For adoptive T cell transfers, splenic CD4⁺T cells (4×10^6) purified from naïve mice by magnetic positive selection were injected i.v. into lymphopenic Nude (*nu/nu*) recipients who were injected 24h later with zymosan. Experiments were performed three independent times ($n = 5-6$ mice/genotype) and data were analyzed using non-parametric statistics.

Results: Nod2^{-/-} SKG mice developed markedly worse arthritis following zymosan injection that coincided with increased numbers of pro-inflammatory Th17 (CD4⁺IL-17⁺) cells in the ankle-draining lymph nodes and elevated IL-17 protein levels in joint synovial fluid. The increase in Th17 cell frequency was likely not due to compromised Treg responses as the frequency and suppressive capacity of Tregs was not affected by Nod2 deletion. Neutralization of IL-17A *in vivo*

attenuated arthritis in Nod2^{-/-} SKG mice suggesting Nod2 is a negative regulator of IL-17. Importantly, CD4⁺ T cells from naïve Nod2^{-/-}SKG mice had a fundamental capacity to produce more IL-17 and had enhanced ability to passively transfer arthritis to T cell-deplete nude recipients.

Conclusion: These data uncover a previously unappreciated role for T cell-intrinsic Nod2 as an endogenous negative regulator of the Th17 response and the arthritogenicity of CD4⁺ T cells on a single cell level. Understanding how Nod2 participates in immune tolerance mechanisms could illuminate protective mechanisms in arthritis that may be exploited for the future development of novel treatments.

Card9 Is a Critical Regulator of Autoimmune Arthritis in SKG Mice

Ruth Napier¹, Ellen Lee¹, Emily Vance¹, Kimberly Samson², Paige Snow³, Shimon Sakaguchi⁴ and Holly Rosenzweig¹,
¹Molecular Microbiology and Immunology, Oregon Health & Science University, Portland, OR, ²Oregon Health & Science University, Portland, OR, ³Molecular Microbiology and Immunology, VA Portland Health Care System, Portland, OR, ⁴Osaka University, Osaka, Japan

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Animal Models Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Caspase recruitment domain-containing protein 9 (Card9) is a C-type lectin receptor known for its function in protection against fungal infection and association with human diseases including ankylosing spondylitis and inflammatory bowel disease. Recently, polymorphisms in Card9 were linked to the pathogenesis of a prevalent type of autoimmune arthritis, Rheumatoid arthritis (RA). Here we sought to investigate the role of Card9 in the pathogenesis of arthritis using the genetically susceptible strain of mice (SKG) that develop a T cell-mediated arthritis in response to microbial triggers. Understanding how Card9 affects the pathogenesis of T cell-mediated arthritis will contribute to our understanding of the etiology of RA and development of future therapeutics.

Methods: SKG and Card9^{-/-}SKG mice housed under specific pathogen-free conditions were intraperitoneally injected with zymosan (1.5 mg) at 6-8 wk age, clinically monitored for arthritis, and analyzed histologically for joint pathology. CD4⁺ T cells from ankle-draining (popliteal) lymph nodes were stimulated *in vitro* with PMA/ionomycin and production of pro-inflammatory cytokines was quantified by intracellular cytokine staining and flow cytometry. For adoptive T cell transfers, splenic CD4⁺ T cells (4x10⁶) purified from naïve mice by magnetic positive selection were intravenously injected into lymphopenic nude (*nu/nu*) recipients who were injected 24h later with zymosan. Three independent experiments were performed (n=5-6 mice/genotype), and data analyzed using non-parametric statistics.

Results: To investigate the role of Card9 in arthritis we created Card9-deficient SKG (Card9^{-/-} SKG) mice. In stark contrast to SKG mice that develop chronic arthritis following zymosan injection, Card9^{-/-}SKG mice developed no detectable arthritis. Further examination of the popliteal lymph nodes showed reduced numbers of CD4⁺, CD8⁺, and CD4⁺CD8⁺T cells and decreased total numbers of pro-inflammatory CD4⁺ T effector cells including; Th17, Th1, and Th22. Although Card9^{-/-}SKG had reduced T cell responses and no arthritis there was still a substantial induction in Th17, Th22, and Th1 responses relative to naïve SKG and Card9^{-/-}SKG mice. Furthermore, Card9-deficiency did not affect the arthritogenic capacity of SKG T cells as adoptive transfer of CD4⁺ T cells from naïve Card9^{-/-}SKG or naïve SKG mice into T cell-deplete nude recipients resulted in equal levels of arthritis. These data indicate that Card9 expression is required for the development of arthritis in SKG mice but not for the induction of a pro-inflammatory T effector response.

Conclusion: These findings identify Card9 as an essential mediator of arthritis induced by environmental microbial β -glucans (zymosan) in SKG mice and imply that Card9 positively regulates the magnitude of pathogenic T cell responses and ankle/joint inflammation in SKG mice. Understanding the immunological mechanism by which Card9 controls arthritis will contribute to our understanding of how the environment influences development of autoimmunity in genetically predisposed individuals.

Microbiome-Driven Aberration of Hematopoietic Stem Cell Development Facilitates Immune Deregulation on the Onset of Collagen-Induced Arthritis in Mice

Peiqing Yang¹, Lingchong Su¹, Yanhong Li¹, Yi Liu² and **Yubin Luo**³, ¹West China Hospital, Sichuan University, Chengdu, China, ²Department of Rheumatology and Immunology, West China Hospital, Sichuan University, Chengdu, Sichuan, China, Chengdu, China, ³Department of Rheumatology & Immunology, West China Hospital, Sichuan University, Chengdu, China

SESSION INFORMATION

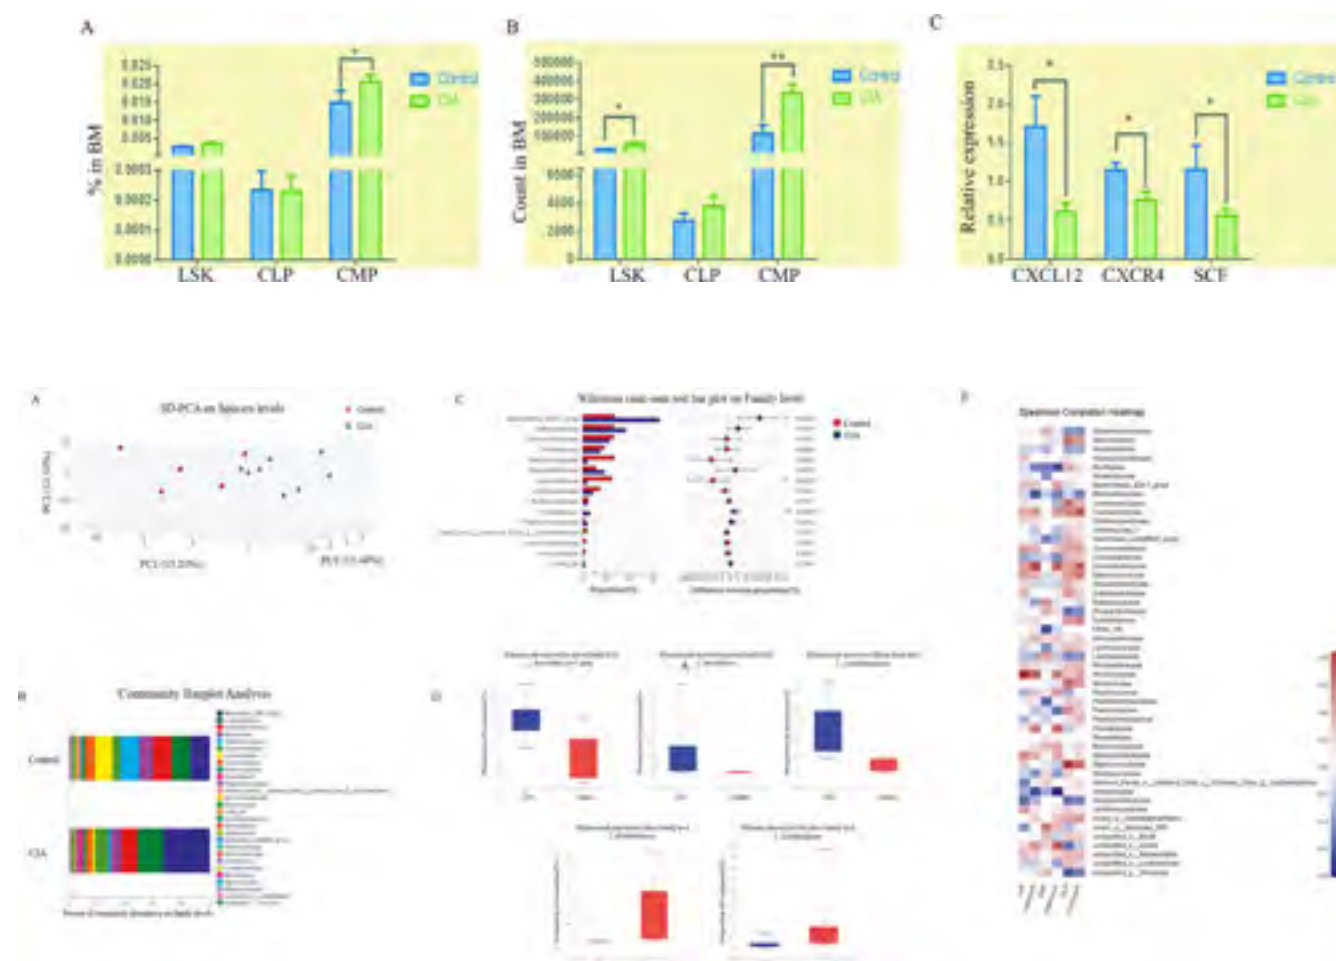

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Animal Models Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Increasing studies indicate that immune deregulation occurs prior to symptom in Rheumatoid arthritis (RA). Hematopoietic stem cell (HSC) gives rise to multipotent progenitors differentiating to lymphoid and myeloid immune cells. The turbulence of HSC development, precisely regulated by bone niche markers, may be the radical factor causing immune deregulation during RA progression. Gut microbiome (GM) is reported to implicate into RA and specific bacteria are known to influence immune cells and HSC⁺'s development. However, whether GM alteration is causation or consequence of RA is still unclear. In this study, we test whether GM affects RA development via regulating HSC⁺'s development in BM at the early stage of arthritis.

Methods: Collagen induced arthritis (CIA) in mice was applied in this study. HSC, common lymphoid progenitor (CLP) and common myeloid progenitor (CMP) in bone marrow were stained with Lineage, Sca-1, c-kit and CD127 cell surface markers and detected by flow cytometry on day 14 after the first immunization. Total numbers of stem cells and progenitors were monitored using beads. Stools were collected and the composition of the intestinal bacterial flora was detected by 16S rRNA sequencing. RT-PCR analysis was used to detect the genes expression of bone niche marker including CXCL12, CXCL4 and SCF.

Results: The percentages of hematopoietic stem cell (LSK, Lin⁻Sca-1⁺c-Kit⁺) and CLP was not altered in CIA mice, whereas the total number of LSK was significantly increased compared with control mice. In contrast, the frequency and number of CMP were significantly enhanced in CIA mice (Fig 1A and B). The gene expressions of SCF, CXCL12 and CXCR4 in CIA mice were significantly lower than that of control. Additionally, the gut microbial communities in cecum of CIA mice was remarkably altered at the species and family level (Fig 2A and B). Analyses of the microbiota at the family level indicated an increase of *Bacteroidales*, *Prevotellaceae*, *Corynebacteriaceae* and a decrease of *Lactobacillaceae* and *Bifidobacteriaceae*(Fig 2C-D). Interestingly, *Prevotellaceae* was positively correlated with both LSK and CMP count. *Corynebacteriaceae* also showed highly positive correlation with LSK, CMP and CLP count. In contrast, *Bifidobacteriaceae* was negatively correlated with LSK count. No significant correlation was found between *Bacteroidales*/*Lactobacillaceae* and HSC and progenitors (Fig 2E).

Conclusion: The increase of HSC count and its differentiation toward CMP occurs in bone marrow at the early stage of CIA mice, which is closely associated with GM alteration.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Animal Models Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is an inflammatory disease of the joints associated with cardiovascular disease, which accounts for 40% of RA mortality. Macrophages are implicated in pathology of both RA and atherosclerosis, however it remains unknown if shared immune mechanisms are involved at both sites of disease. To investigate this, KRN Ag⁷ mice which develop spontaneous arthritis and atherosclerosis were used to monitor changes in the cellular composition of the synovium and aorta during development of disease. To further characterize the role of monocyte and macrophage populations, CCR2^{-/-} mice, which have reduced Ly6c^{hi} monocytes and impaired macrophage recruitment, were crossed with KRN Ag⁷ mice to create KRN Ag⁷ CCR2^{-/-}.

Methods: KRN Ag⁷, C57Bl/6, and KRN Ag⁷ CCR2^{-/-} mice were bred in house and euthanized at desired timepoints from 1 - 24 months. Ankles and aortas were collected and single cell suspensions were prepared. Cell suspensions were stained with an antibody cocktail designed to identify monocyte and macrophage populations which were analyzed by flow cytometry. Statistical analysis was carried out in Flowjo v9 and Prism7. Statistical significance was defined at $P \leq 0.05$.

Results: KRN Ag⁷ mice developed arthropathy from birth. Flow cytometric analysis of synovial immune cell populations in KRN Ag⁷ mice from 1-24months identified two phases of disease. From 1-3 months, an inflammatory phenotype is characterized by significant increases in monocytes, eosinophils, and neutrophils and a decrease in dendritic cells, compared to C57Bl/6. During an erosive phase from 6-24months levels of these populations trended towards C57Bl/6 levels, but remained significantly different. Macrophage populations MHCII⁻CX3CR1⁺ and MHCII⁺CX3CR1⁻ were associated with the inflammation phase and were significantly increased and decreased respectively compared to C57Bl/6. KRN Ag⁷ CCR2^{-/-} mice developed comparable arthropathy to KRN Ag⁷ mice from birth, although levels of total CD11b⁺ cells, neutrophils and monocytes were all significantly lower in KRN Ag⁷ CCR2^{-/-} synovium than in KRN Ag⁷. Composition of the macrophage compartment of KRN Ag⁷ and KRN Ag⁷ CCR2^{-/-} mice displayed similar trends including an increased and decreased proportions of MHCII⁻CX3CR1⁺ and MHCII⁺CX3CR1⁻ macrophages. Cell populations isolated from the

aorta of KRN Ag⁷ CCR2^{-/-} mice displayed a striking inflammatory phenotype from 1 month, comprising more total CD11b⁺ cells, neutrophils, and decreased dendritic cells than both KRN Ag⁷ and C57Bl/6 controls. KRN Ag⁷ CCR2^{-/-} aorta also had a significant increase in monocytes, although levels of macrophages were comparable to those of C57Bl/6 controls. All trends were maintained at 3 months.

Conclusion: These findings suggest CCR2 is not essential for the development of inflammatory arthritis in KRN Ag⁷ mice, but does affect cell burden. Surprisingly, aorta tissue from KRN Ag⁷ CCR2^{-/-} mice developed a more striking inflammatory phenotype than KRN Ag⁷. Taken together these findings indicate distinct inflammatory mechanisms are involved in arthritis and concomitant atherosclerosis, and neither process is dependent on CCR2.

The Pleiotropic Effects of TAM Signaling on Inflammatory Arthritis in Mice Using Kbxn Serum Transfer Induced Arthritis

Anna B Montgomery¹, Salina Dominguez², Maximilian Mayr³ and Harris Perlman³, ¹Division of Rheumatology, Northwestern University Feinberg School of Medicine, Chicago, IL, ²Department of Medicine Division of Rheumatology, Northwestern University Feinberg School of Medicine, Chicago, IL, ³Northwestern University Feinberg School of Medicine, Chicago, IL

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Animal Models Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: TAM receptors are a small family of receptor tyrosine kinases comprising Tyro-3, Axl and Mer, which are activated by GAS6 and Protein-S. TAM signaling is involved in phagocytosis, apoptosis, efferocytosis, and leukocyte stabilization and adhesion, and thus has been implicated in inflammatory disease. In fact, our findings from a previous study show apoptosis of neutrophils in the murine joint during inflammatory arthritis induces polarization of synovial macrophages, a key effector cell in arthritis. These data strongly suggest TAM signaling is involved in inflammatory arthritis in mice. However, TAM signaling can also induce immunoregulatory effects via inhibition of TLR signaling and blockade of the cytokine cascade. To that end, we used a number of genetic mouse models lacking TAM receptors Tyro3, Axl and Mer, or GAS6 to investigate the disparate functionalities of TAM signaling in inflammation using the KBxN model of inflammatory arthritis.

Methods: Female GAS6^{-/-}, Tyro-3^{-/-}, Mer^{-/-}Axl^{-/-} and C57Bl/6 mice were bred in house until 8-10 weeks of age. Serum transfer induced arthritis was induced in mice using intravenous administration of KBxN sera at a dose of 85µl/20g. Inflammatory arthritis was monitored and scored for severity from day 0-21 or until all mice had 0 clinical score of disease. Clinical score was measured by scoring each distal joint from 0-3 based on inflammation, and summed to give a maximum clinical score of 12 per mouse. Mean clinical scores of N=4 mice in each treatment group were compared using GraphPad Prism. Differences were considered significant if $P \leq 0.05$.

Results: Tyro-3^{-/-} mice developed less severe inflammatory arthritis than C57Bl/6 controls. Mean clinical score in Tyro-3^{-/-} was less than that of C57Bl/6 controls from day 7 until day 14 although this did not reach statistical significance. Both groups had resolved all inflammation by day 21. Mer^{-/-}Axl^{-/-} mice also had reduced mean clinical score compared to C57Bl/6 controls which was statistically significant from day 11-23 ($P < 0.05$). Inflammation in the Mer^{-/-}Axl^{-/-} group resolved more quickly at day 21 vs day 25. Conversely, the Gas6^{-/-} group had increased disease compared to control mice from day 2 until day 11, which became statistically significant at peak disease on day 7 ($P < 0.05$).

Conclusion: These findings demonstrate the pro-inflammatory effects of Tyro-3, Mer and Axl. In these models Tyro3 deletion inhibited early stage disease, whereas MerAxl deletion resulted in faster disease resolution, thus indicating these receptors induce different downstream effects. Meanwhile, loss of GAS6 in these studies resulted in significantly increased inflammatory arthritis, suggesting GAS6 induces an anti-inflammatory or modulatory effect. Previous studies have shown TAM signaling causes both pro-inflammatory effects and induces a negative feedback loop to reduce inflammation via blockade of TLR signaling. The findings presented here indicate that TAM receptors Tyro-3, Mer and Axl have direct pro-inflammatory functions, whilst specific ligation of GAS6 is required to activate the anti-inflammatory negative feedback process.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Animal Models Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Interleukin-2-inducible T-cell Kinase (ITK) and Bruton's tyrosine kinase (BTK) are critical for B cells and T cells activation, and dysregulation of this process has been known to cause various immune-related diseases. Overexpression or hyperactivation of ITK/BTK has been shown to cause various autoimmune diseases. Existing BTK inhibitors has low clinical efficacy, which creates huge demands for treatment with higher efficacy. Thus, ITK and BTK dual target inhibitors may have synergistic therapeutic efficacy for the treatment of autoimmune diseases, including rheumatoid arthritis (RA). Therefore, we developed a novel ITK and BTK dual target inhibitor (DWP213388), which demonstrates higher pharmacological efficacy than existing selective BTK inhibitor.

Methods: Inhibition of ITK and BTK enzyme activity and selectivity against Cys-family kinase group were evaluated by biochemical assay. Target occupancy in human T and B cells (Jurkat/Ramos) was measured by quantifying unbound ITK or BTK in ELISA-based assay using biotinylated-DWP213388, which binds to free active site of target following DWP213388 pre-incubation. Cellular assays for TCR or BCR stimulation-dependent activation and cytokine secretion were determined in human peripheral blood mononuclear cells (hPBMC). The efficacy of DWP213388 was investigated in collagen-induced arthritis (CIA) models in mouse and rat, in comparison with selective BTK inhibitor. To measure BTK occupancy, mouse spleen was extracted 2 hours and 24 hours after oral administration of DWP213388.

Results: We developed a novel, potent dual target inhibitor, DWP213388, with ITK IC₅₀ value of 1.4 nM and BTK IC₅₀ value of 0.7 nM. More importantly, this compound is highly selective against ITK and BTK, yet has low affinity toward EGFR. DWP213388 potently occupied both of its targets at low concentration (ITK EC₅₀ value of 4.3 nM and BTK IC₅₀ value of 2.2 nM), which shows successful inhibition of TCR/BCR-dependent CD69 expression in T cells (54.4% inhibition at 100 nM) and B cells (58.2% inhibition at 10 nM). Unlike other selective BTK inhibitors, DWP213388 has an inhibitory effect on IL-17 production by Th17 (IC₅₀=29.1 nM). In mouse CIA model, treatment of DWP213388 improved arthritis in a dose-dependent manner, and the inhibitory effect was more potent than selective BTK inhibitor. In addition, histological damages in ankle and knee were markedly improved in mouse CIA model. The ED₅₀ value of DWP213388 is 0.38 mg/kg in mouse CIA model. Oral administration of DWP213388 at 1 mg/kg dose showed BTK occupancy in mouse splenocytes at 2 and 24 hours as 86% and 55%, respectively. BTK occupancy in mouse splenocytes shows strong correlation with the efficacy in mouse CIA model.

Conclusion: We developed a novel, highly potent, and selective covalent inhibitor of ITK and BTK, DWP213388. We demonstrated that DWP213388 has potent in vitro and in vivo pharmacological activities compared to existing selective BTK inhibitor without affecting EGFR. These results suggest that DWP213388 may serve as a next generation therapeutic agent for autoimmune diseases, including RA.

Pre-Clinical Clonally-Expanded aggrecan⁸⁹⁻¹⁰³-Specific CD4⁺ T Cells Are a Target for Autoimmune Arthritis Prevention

Pascale Wehr¹, Hendrik Nel¹, Soi Cheng Law¹, Diahann Jansen¹, Nicole La Gruta², Hugh Reid², Jamie Rossjohn² and Ranjeny Thomas¹, ¹University of Queensland Diamantina Institute, Translational Research Institute, Woolloongabba, Australia, ²Infection and Immunity Program, Biomedicine Discovery Institute and Department of Biochemistry and Molecular Biology, Monash University, Clayton, Australia

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Animal Models Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: In the pre-clinical rheumatoid arthritis (RA) prodrome, autoantibodies and transient symptoms may develop. Pre-clinical autoantibody development suggests concomitant expansion of autoantigen-specific CD4⁺ follicular helper T cells (T_{FH}). A biased T cell receptor (TCR) repertoire in the joints of recent-onset RA patients suggests clonal expansion in early RA. Antigen-specific CD4⁺ T cells were clonally expanded at onset of murine collagen-induced arthritis. To model the pathogenetic role played by autoantigen-specific CD4⁺ T cells before and after autoantibody development, we longitudinally assessed the frequency, phenotype and clonotypic composition of the dominant aggrecan⁸⁹⁻¹⁰³ epitope-specific CD4⁺ T cell repertoire in proteoglycan-induced arthritis (PGIA). We aimed to elucidate how and when autoantigen-specific CD4⁺ T cells contribute to arthritis progression.

Methods: PGIA was induced in BALB/cAnNCrI and BALB/c FoxP3-GFP mice by intraperitoneal injection (prime and two booster injections) of recombinant G1 epitope of human proteoglycan (rhG1-PG) emulsified in DDA adjuvant. MHC class II (I-A^d)-aggrecan⁸⁹⁻¹⁰³ tetramers and single-cell multiplex-nested PCR-TCR sequencing was used to study splenic aggrecan⁸⁹⁻¹⁰³-specific CD4⁺ T cells before and after onset of PGIA. Quantitative and phenotypic analysis of aggrecan⁸⁹⁻¹⁰³-specific CD4⁺ T cells was assessed by flow cytometry, based on the expression of CD44, CD62L, FoxP3, CXCR5 and PD1 and index sorting in TCR sequencing experiments. ELISA measured anti-human PG-specific antibodies.

Results: Splenic aggrecan⁸⁹⁻¹⁰³-specific CD4⁺ T cells expanded in the prodrome before the detection of autoantibodies or persistent disease activity. Aggrecan⁸⁹⁻¹⁰³-specific CD4⁺ T cells shifted from naïve to activated effector memory (T_{EM}) and T_{FH}, associated with a loss of aggrecan⁸⁹⁻¹⁰³-specific FoxP3⁺ Treg. CD4⁺ TCR β-chain variable genes (TRBV)13-1⁺, 13-2⁺ and 2⁺ aggrecan⁸⁹⁻¹⁰³-specific T_{EM} and T_{FH} cells clonally expanded in the prodromal period during transient joint inflammation. After clonotype depletion with anti-TRBV13 mAb, disease onset was delayed, autoantibody titres reduced and arthritis attenuated. Three public TRBV13⁺ clonotypes were shared between mice and between different BALB/c strains. All public clonotypes had conserved amino acid residues arising from convergent recombination, supporting selection of TCR for antigen recognition.

Conclusion: Antigen-specific public clonotypes expand during the prodromal period, prior to development of autoantibodies. Therefore longitudinal antigen-specific TCR repertoire analysis prior to high titre autoantibody development may identify expanding autoreactive CD4⁺ T cell clones in individuals at risk of RA.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Animal Models Poster
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Mesenchymal stemcells (MSCs) are creating promising new options for autoimmune disorders. MSCs utilize multiple mechanisms to modulate immune cells, and extracellular vesicles (EVs) have recently been

recognized as important intercellular mediators, in this study we tested whether EVs derived from allogeneic MSCs would have therapeutic potential in comparison with their parent cells in murine collagen-induced arthritis model.

Methods: At the time of primary immunization with type II collagen, DBA/1 mice were systemically infused with PBS (sham), EVs derived from 1×10^6 allogeneic BMMSCs, and 1×10^6 allogeneic bone marrow MSCs (BMMSCs) as control. Therapeutic efficacy was determined by arthritis activity, joint histology, and CT imaging. Serum cytokine level, as well as T cell phenotypes in blood, spleen and draining lymph nodes were analyzed. Naïve CD4⁺ T cells were isolated and co-cultured with BMMSCs or EVs to assess activation and differentiation.

Results: EVs outperformed BMMSCs in three aspects: clinically, EVs treated mice had delayed onset and milder arthritis score; histologically, with decreased joint inflammation, pannus formation, collagen disruption, IL-17+ cells infiltration, as well as CT visual score; and immunologically, with lower serum IL-6 and IL-17, as well as decreased Th17 and activated CD4⁺ T cells in the circulation and lymphoid organs. When co-cultured in vitro and compared with BMMSCs, EVs decreased Ca²⁺ release upon CD3/28 stimulation and greatly suppressed naïve T cells activation, and suppressed Th17 differentiation.

Conclusion: Collectively, these data demonstrated the outstanding therapeutic efficacy of EVs derived from allogeneic MSCs, and provided a new strategy for stem cell-based immunotherapy.

IFN Regulatory Factor 3 but Not IFN Regulatory Factor 7 Contributes to Bone Erosion in Collagen Induced Arthritis

Susan Sweeney¹, David L. Boyle², Yuya Fujita³, Anthony Bui⁴, Gary S. Firestein² and Maripat Corr⁵, ¹Lilly Research Laboratories, Eli Lilly, San Diego, CA, ²Medicine, University of California San Diego, La Jolla, CA, ³Medicine, University of California San Diego, La Jolla, CA, ⁴Medicine, University of California San Diego, San Diego, CA, ⁵University of California San Diego, La Jolla, CA

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Animal Models Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Type I interferons and their mRNA signatures have become prominent in biomarkers of autoimmune and autoinflammatory disease activity. Two master regulators of type I interferon have emerged: interferon

regulatory factor (IRF) 3 and 7. These transcription factors are differentially expressed in immune cells. Prior studies using the K/BxN serum transfer model demonstrated that the *Irf7*^{-/-} mice had increased swelling and the *Irf3*^{-/-} mice had reduced swelling compared to their C57BL/6 WT counterparts. Here we used the collagen induced arthritis (CIA) model to examine the roles of IRF3 and IRF7 in developing arthritis in a model dependent on the adaptive immune system.

Methods: *Irf7*^{-/-} and *Irf3*^{-/-} mice were backcrossed on to the DBA/1J background. To induce arthritis we gave an initial immunization sc with 100mg bovine type II collagen (bCII) in complete Freund's adjuvant with 5mg/mL mycobacterial extract (Chondrex) and then a boost on day 21 with bCII in IFA. In confirmatory experiments bCII was injected in CFA with 2mg/ml M. Tb extract and then to synchronize arthritis 5mg of lipopolysaccharide was injected on day 28. Hind paws prepared for histology or microCT on Day 35 or 40. Sera tested by ELISA for IL-6 and anti-mouse collagen antibodies. Synovial tissues were frozen and mRNA harvested and qPCR performed.

Results: In the CIA model, DBA.Irf7 mice had greater ankle swelling ($P<0.0001$; $F(2, 2095) = 27.51$), than DBA.Irf3 and WT mice, and DBA.Irf3 mice had with lower clinical scores ($P<0.0001$; $F(2, 1302) = 35.85$). There was no difference anti-mouse collagen type II (mCII) antibody levels or serum IL-6 between the groups. Strikingly there was minimal inflammation, bone erosion and cartilage damage in the DBA.Irf3 compared to the other groups ($P=0.036$; $F(2, 27) = 3.978$). In a second protocol adapted to increase arthritis severity using an injection of LPS on day 28. Using this protocol DBA.Irf3 ($p<0.0001$; $F(1, 962) = 24.33$) and DBA.Irf7 ($P<0.001$, $F(1, 731) = 99.74$) mice had decreased joint scores compared to WT DBA mice. DBA.Irf3 and DBA.Irf7 mice had the same levels of anti-mCII antibodies as WT. In the DBA.Irf3 male mice there was no significant difference in the cortical bone fraction (% BA/TA; 68.05 ± 2.56 vs. 70.05 ± 0.30 , $p>0.05$) compared to WT, but there was a significantly lower trabecular bone volume fraction than WT as assessed by microCT (% BV/TV; 15.72 ± 1.24 vs. 29.82 ± 1.37 ; $p<0.05$). Joint extracts were prepared and gene expression was determined by qPCR. Interferon β and associated transcripts (*Cxcl10*, *Ccl5*) were reduced in the synovial tissues DBA.Irf3, but not the DBA.Irf7 mice ($p < 0.05$). *Mmp3*, *Mmp9*, *Mmp13*, *Rank* and *Opg* mRNA were increased in the DBA.Irf3 mice and Cathepsin K mRNA was decreased. There was no significant difference in RANKL.

Conclusion: IRF7 deficiency had an impact on swelling but minimal impact on histologic bone damage in the CIA model. In contrast IRF3 deficiency was markedly protective of bone erosion and was associated with a decline in IFN β and cathepsin K mRNA.

TAS5315, a Novel Bruton's Tyrosine Kinase Inhibitor, Improves Bone Strength in Mouse Model for Rheumatoid Arthritis

Ryuusuke Kaneko, Fumihito Hosoi, Satoru Iguchi, Hiroaki Hayashi, Yohei Yoshiga, Yoshinori Nakachi, Daichi Akasaka, Kenji Tanaka, Teruhiro Utsugi, Eiji Sasaki and Yoshikazu Iwasawa, TAIHO PHARMACEUTICAL CO., LTD., Tsukuba, Japan

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Animal Models Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The erosions of bone and cartilage are a cardinal feature of rheumatoid arthritis (RA) and associated with disease severity and poor functional outcome. Although several anti-inflammatory drugs for treatment of RA improve symptoms of articular inflammation and bone erosion, unfortunately they do not have a powerful potency against repair of existing bone erosion. Bruton's tyrosine kinase (BTK), which is expressed in immune cells and mature osteoclasts, is reported to be a key molecule in inflammatory response and bone resorption. Thus, targeting BTK may be efficacious against not only inflammation but also bone erosion through direct regulation of activation of effector cells such as B cells, macrophages and osteoclasts in RA.

Previously, we evaluated the effect of TAS5315, a novel BTK inhibitor, on bone damage in an established mouse collagen-induced arthritis (CIA) by micro-CT analysis, and revealed that TAS5315 improves bone erosion in a mouse CIA.

However, it remained uncertain whether TAS5315 improves the bone quality.

In this study, we assessed mechanical bone strength of the tibia in a mouse CIA for the purpose of examining whether TAS5315 improves bone quality as well as bone erosion.

Methods: Kinase selectivity of TAS5315 was assessed by available kinase assay panels. The BioMAP Diversity PLUS panels were used to determine the profile of TAS5315 in primary human cell systems. The effects of TAS5315 on osteoclasts were

assessed by examining phosphorylation of BTK, osteoclast *differentiation and bone resorptions*. TAS5315 were orally administrated once a day for 14 or 21 consecutive days in an established mouse CIA model. Bone mineral density (BMD) and bone erosion were assessed using micro-CT analysis. The mechanical strength of the tibia was evaluated by a three-point bending test of the tibial diaphysis and a compression test of proximal metaphysis using a material-testing machine.

Results: TAS5315 selectively inhibited the enzyme activity of BTK and had less off target inhibition against other kinases. In BioMAP Systems, TAS5315 decreased the production of IgG and the expression of cytokines (TNF α , IL-8, IL-17A, IL-6, IL-17F and IL-2) and increased the expression of IL-10. TAS5315 also inhibited RANKL and M-CFS-induced phosphorylation of BTK, and bone resorbing activity in osteoclasts.

In an established mouse CIA model, TAS5315 significantly ameliorated paw swelling and pathological features at a dose of 0.1 mg/kg. TAS5315 also showed repair of BMD by time-dependent micro-CT analysis. The mechanical strength tests of tibia were performed in an established mouse CIA model. Whereas the mechanical strength of tibia was decreased in CIA model mice compared to normal mice, TAS5315 led to recovery of the decreased parameters of mechanical strength of tibia.

These data suggests that TAS5315 indicated more potent efficacy on joint damage as well as inflammation, and improved bone quality as well as bone erosion in mouse model for RA through direct inhibitory effects against osteoclasts function.

Conclusion: Our study demonstrates that TAS5315 would be an ideal RA therapeutic agent that could improve bone destruction as well as inflammation.

Modulation of Autoimmune Arthritis By Protein Tyrosine Phosphatase SHP-1

Adrienn Markovics¹, Andrew B Nesterovitch², Katalin Mikecz¹, Tibor A. Rauch¹, Daniel M. Tóth¹ and Tibor T. Glant¹,
¹Department of Orthopedic Surgery, Rush University Medical Center, Chicago, IL, ²Department of Dermatology, Rush University Medical Center, Chicago, IL

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Animal Models Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The protein tyrosine phosphatase termed Src homology region 2 domain-containing phosphatase-1 (SHP-1) is known to exert negative regulatory effects on immune cell signaling. Mice with mutations in the Shp1 gene display inflammatory skin disease and autoimmune features, but no arthritis.

The objective of this study is to explore the role of SHP-1 in arthritis using cartilage proteoglycan (PG)-induced arthritis (PGIA), an autoimmune model of rheumatoid arthritis (RA). We generated Shp1 transgenic (Shp1-Tg) mice overexpressing this phosphatase to study the impact of SHP-1 overexpression on arthritis susceptibility and adaptive immune responses.

Methods: Wild-type (WT) and Shp1-Tg mice were immunized with cartilage PG in adjuvant, and arthritis symptoms were monitored. Tyrosine phosphatase activity, T-cell and B-cell proliferation and activation in response to polyclonal stimulation as well as global protein tyrosine phosphorylation (pTyr) levels were measured in spleen cells from WT and Shp1-Tg mice using cell proliferation and enzyme activity assays, flow cytometry, and Western blot. Statistical analysis was carried out employing GraphPad Prism 7.

Results: Interestingly, while all of the WT mice developed arthritis after PG immunization, none of the Shp1-Tg mice developed disease (n=13-16 mice per genotype). Shp1-Tg spleen cells showed 7-fold higher tyrosine phosphatase activity than WT cells. In response to polyclonal stimulation, T and B cells from Shp1-Tg mice proliferated less well and expressed significantly lower levels of activation markers than those from WT mice. Global pTyr levels were also lower in T and B cells from Shp1-Tg mice than in cells from WT animals.

Conclusion: Resistance to autoimmune arthritis in Shp1-Tg mice is likely due to impaired T- and B-cell responses to PG immunization. Reduced T- and B-cell activation and resistance to arthritis in the presence of SHP-1 overexpression seem to result from the impairment of tyrosine phosphorylation (deactivation) of key T-cell and B-cell signaling proteins, due to the overwhelming tyrosine phosphatase activity of the enzyme in Shp1-Tg mice. Our study is the first to investigate the role of SHP-1 in autoimmune arthritis. Further experiments with the animal model may identify a therapeutic target for the treatment of human autoimmune arthritis such as RA.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Animal Models Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid Arthritis (RA) is a highly prevalent autoimmune disease affecting ~1% of the world population and can lead to permanent joint damage and severe disability. Although current biologics improve disease, they do not cure or even lead to long-term remission. DNase II is an enzyme that degrades endosomal DNA. When DNaseII^{-/-} mice are crossed to mice that lack the Type 1 Interferon Receptor (IFNAR) to create double knockouts (DKO), the DKO develop a rheumatoid arthritis (RA)-like disease including ACPA antibodies in the serum. The arthritis is dependent on activation of the cGAS-STING pathway, likely caused by leakage of DNA from the endosome into the cytosol. Since we synthesized a novel antimalarial like drug (X6) that was effective in the inhibition of cGAS in mice in vivo, we tested the effects of X6 on arthritis and serology in the DNaseII/IFNAR DKO mouse model of RA.

Methods: DNaseII DKO mice were treated orally with either Splenda alone or X6 in Splenda at 25mg/kg/day (n=6) from 2 to 6 months of age. Anti-Citrullinated Protein/Peptide Antibodies (ACPA) were quantified with ELISA kit (IMMUNOSCAN CCPlus kit from Euro Diagnostica), except that Alkaline Phosphatase-conjugated goat antibody against mouse immunoglobulin (IgM) was used as the detection antibody. RF IgG/IgM and total IgG/IgM were quantified by in house ELISAs. Swelling of the forelimb and hindlimb joints was inspected manually and scored blindly. Cytokines in the synovial tissues were quantified by qPCR.

Results: ACPA is a highly specific and sensitive serologic biomarker of RA. There was increased IgM-ACPA expression in IFNAR^{-/-}/DNaseII^{-/-} (DKO) mice compared to IFNAR^{-/-}/DNaseII^{+/+} (WT) and IFNAR^{-/-}/DNaseII^{+/-} (Het) mice (Fig. 1A). X6 treatment statistically significantly reduced IgM-ACPA compared to untreated controls (p<0.01, Fig. 1A). X6 treatment reduced IgM-RF although these values did not reach statistical significance. Total IgM and IgG were significantly elevated in DKO mice compared to DNaseII WT and Het mice (Fig. 1B and 1C). X6 treatment statistically significantly decreased total IgM (p<0.01, Fig. 1B) and total IgG (p<0.01, Fig. 1C) compared to untreated controls. Tumor Necrosis Factor (TNF)

Figure 1. Drug X6 treatment decreased the IgM-ACPA(1A), total IgM(1B) and total IgG(1C) production in the serum of DNaseII/IFNAR DKO mice

is the key cytokine implicated in the pathogenesis of arthritis in DKO mice. X6 treatment reduced mRNA expression of TNF although reduction did not reach statistical significance. Clinically, X6 treatment did not significantly reduce the arthritis score and joint thickness.

Conclusion: Our studies demonstrate that X6 was highly effective in reducing the elevated arthritis-relevant serology that includes ACPA and total immunoglobulins. While clinical arthritis did not change significantly at 25 mg/kg/day, higher drug doses may be beneficial. Differential impact of X6 on the cGAS-STING versus the TLR pathways may also be relevant for future exploration.

Session Title: Rheumatoid Arthritis – Animal Models Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Despite enormous efforts to develop new therapeutic strategies for treatment of rheumatoid arthritis (RA), the large number of non responding patients to currently available drugs underlies the unmet need to identify new therapeutic targets. Certain CD4⁺T cell subsets, especially Th17 cells, have been shown to be major drivers of inflammation in patients with RA. The expression of their key transcription factors is controlled by histone modifications which includes acetylation of *lysine residues* mediated by histone deacetylases (HDAC). Indeed, pan HDAC inhibitors have been shown to be a potential therapeutic strategy. However, major side effects limited the clinical use and underline the need of more specific HDAC inhibitors. We therefore addressed the individual role of HDAC1 on the development of collagen-induced arthritis model (CIA).

Methods: Mice with a T cell specific deletion of HDAC1 (HDAC1 cKO) were generated by using the CD4Cre/LoxP system. Collagen induced arthritis (CIA) was induced at week 8. Animals were scored for paw swelling and grip strength. After 10 weeks, mice were sacrificed and paraffin sections of the affected joints were analysed for histomorphologic signs of inflammation, cartilage and bone destruction. Anti-CII antibody levels were determined by ELISA. Serum samples were analysed for various cytokines by multiplex assays. CCR6 expression in CD4 T cells was analysed by flow cytometry.

Results: To address potential effects of HDAC1 in the pathogenesis of RA, CIA was induced in *HDAC1cKO* mice and *WT* mice. Surprisingly *HDAC1cKO* mice were completely protected from the development of arthritis. In line with the clinical data, histological analysis revealed no signs of inflammation, no bone erosion and no osteoclasts in the joints of *HDAC1cKO* mice. Anti-CII antibodies, including total IgG and IgG2c were detected in *HDAC1cKO* and *WT* mice. Surprisingly, IL-17 was significantly decreased in the serum of *HDAC1 cKO* mice as compared to *WT* mice, suggesting a role of HDAC1 in the development of Th17 cells. To see whether HDAC1 is involved in the regulation of the chemokine receptor 6 (CCR6), the main marker of Th17 cells, we compared the upregulation of CCR6 in CD4⁺ T cells from *WT* and *HDAC1cKO* mice. Indeed, CCR6 could not be upregulated in CD4⁺ T cells from *HDAC1cKO* mice upon IL-6 *in vitro*. These data support the role of HDAC1 in the regulation of CCR6, an important chemokine receptor, which is necessary for the migration of pathogenic Th17 cells and therefore for the development of arthritis.

Conclusion: Our data show the importance of HDAC1 as a key immune regulator in the pathogenesis of T cell driven collagen induced arthritis. Therefore, it might be considered as an interesting novel therapeutic target in RA.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Animal Models Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Broad-spectrum histone deacetylase inhibitors are well known for immunomodulatory functions. However, due to their toxicity, HDAC subtype specific inhibition has been proposed as therapeutic strategy for treatment of autoimmune diseases. Herein, we introduce CKD-506, a potent and selective HDAC6 inhibitor, as an immunomodulatory agent for treatment of rheumatoid arthritis.

Methods: The selectivity and potency of CKD-506 were determined by enzyme assay. Adjuvant- (AIA) induced arthritis animal model was used to evaluate its *in vivo* efficacy. Peripheral blood mononuclear cells (PBMCs) and fibroblast-like synoviocytes (FLS) from rheumatoid arthritis (RA) patients were used for *ex vivo* studies. Macrophage cells with HDAC6 overexpression were used for mechanism studies.

Results: CKD-506 showed potent and selective inhibitory activity on HDAC6 with an IC₅₀ of 5 nM in enzyme assay and induced tubulin acetylation in human PBMCs and rat lymphocytes. In AIA model, CKD-506 strongly inhibited arthritis score as well as serum anti-CCP level. Interestingly, CKD-506 exhibited strong synergistic efficacy with MTX in rat AIA model. In *ex vivo* study with RA patients' samples, CKD-506 inhibited secretion of inflammatory cytokines and chemokines such as TNFα and CXCL10 but induced IL-10 secretion. Moreover, the induced regulatory T cells of RA patients, which had been differentiated in the presence of CKD-506, significantly inhibited the proliferation of effector T cells. In mechanism studies, HDAC6 overexpression induced the expression of various inflammation mediators such as cytokines, chemokines and adhesion molecules from macrophages but CKD-506 inhibited HDAC6-mediated inflammatory responses of macrophage in a dose dependent manner. CKD-506 with MTX exhibited better anti-inflammatory effect on macrophages with HDAC6 overexpression.

Conclusion: CKD-506 exhibited strong efficacy in *ex vivo* studies with RA patients' samples as well as *in vivo* rat AIA model. CKD-506 is a first-in-class HDAC6 inhibitor for treatment of rheumatoid arthritis. (Current status: in preparation of Phase IIa for moderate to severe RA patients in EU).

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Animal Models Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Emerging evidence suggests that the lungs may be an initiating site of autoimmunity leading to RA with organic inhalant exposures such as those from cigarette smoking acting as a trigger. To study the impact of organic inhalant exposures in RA pathogenesis, we previously developed a novel mouse model by exposing mice with collagen induced arthritis to repeated organic dust extract (ODE). Our objective in the present study was to evaluate autoantibody responses and tissue expression of extracellular matrix proteins (ECM) that have been implicated in RA pathogenesis and that may be involved in articular and lung responses in this model.

Methods: Male DBA/1J mice were injected with chicken collagen type II with Freund's complete adjuvant (CIA) or saline on day 1 and 21. ODE or saline was instilled by intranasal inhalation daily for 5 weeks. Groups are identified as: 1) Saline, 2) ODE, 3) CIA, and 4) ODE + CIA. Anti-citrullinated protein antibody (ACPA) and IgG antibody to malondialdehyde-acetaldehyde (MAA) were measured in serum. Synovial and lung tissues were collected and stained for the presence of MAA, collagen II, fibronectin and vimentin. Confocal microscopy was used to assess tissue expression of ECM and MAA. Coloc 2 plugin (ImageJ) was used to quantify correlations between the tissue expression of ECM and MAA.

Results: Serum ACPA concentrations were significantly increased ($p < 0.05$) in mice treated with ODE + CIA compared to all other treatment groups. Anti-MAA levels were increased in the ODE exposed mice compared to Saline or CIA ($p < 0.0001$) and decreased with the addition of ODE + CIA ($p < 0.02$). ECM and MAA expression mean pixel density in lung and joint tissues are shown in the Table 1. Paralleling enhanced arthritis and attenuated lung disease previously reported in ODE + CIA, differential colocalization of MAA with both collagen II and vimentin was observed in both synovium and lung ($p < 0.001$) in ODE + CIA (Figure 1). In contrast, fibronectin + MAA colocalization was similarly predominate in the lung in all groups.

Conclusion: Increased ACPA and decreased anti-MAA levels in the ODE + CIA treated group suggests a shift in the immune response with dual exposures. Likewise, ECM protein expression was markedly altered between synovium and lung in the combined ODE + CIA model. Our study importantly characterizes alterations in immune responses and ECM proteins that may explain the compartmentalized response of increase in inflammatory arthritis with the simultaneous attenuation of pulmonary disease previously observed in CIA mice exposed to ODE.

Figure 1. Correlation coefficients between Extracellular matrix proteins and MAA in saline, CIA, ODE, and ODE + CIA treated mice (A) Collagen II + MAA antibody (B) Fibronectin + MAA antibody (C) Vimentin + MAA antibody. Collagen + MAA significantly decreased in lung tissue for all groups (* $p < 0.001$), significantly increased in the lung for all groups (# $p < 0.001$). Vimentin + MAA significantly decreased in the lung for all groups (* $p < 0.001$).

Analysis of the Role of ROR γ t+Foxp3+ T Regulatory 17 (Tr17) Cells in Murine Autoimmune Arthritis Model

Kotona Furuyama¹, Yuya Kondo¹, Masaru Shimizu², Iizuka Akira¹, Masahiro Yokosawa¹, Seiji Segawa¹, Hiroto Tsuboi¹, Isao Matsumoto¹ and Takayuki Sumida¹, ¹Department of Internal Medicine, Faculty of Medicine, University of Tsukuba, Tsukuba, Japan, ²Internal Medicine, Department of Internal Medicine, Faculty of Medicine, University of Tsukuba, Tsukuba, Japan

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Animal Models Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: ROR γ ⁺Foxp3⁺ regulatory T (Treg) cells, designated as Tr17 is one of the new subset of Treg cells, having the potential to regulate the development of experimental autoimmune encephalomyelitis (EAE) through a specific repression of Th17 mediated inflammation. The function of Tr17 remain unclear in the development of other autoimmune diseases such as collagen induced arthritis (CIA). To clarify the role of ROR γ ⁺Foxp3⁺ Tr17 in the development CIA.

Methods: 1) Lymphocytes in draining lymph node were harvested from C57BL/6 mice on 10 days after immunization of type II collagen (CII) emulsified with complete Freund's adjuvant. The expression of ROR γ t in Foxp3⁺Treg cells was analyzed by flow cytometry and compared them with lymphocytes of non-immunized mice. 2) At 10 days after CII immunization, C-chemokine receptor type 6 (CCR6), CD25, cytotoxic T-lymphocyte antigen 4 (CTLA-4), and Glucocorticoid-induced TNF-receptor (GITR) expression on Tr17, ROR γ t Treg cells, and ROR γ ⁺ T cells (Th17) in lymph node were analyzed by flow cytometry. 3) Lymphocytes in draining lymph node were harvested from Foxp3^{IREs-gfp} reporter mice on 10 days after first CII immunization. CD4⁺GFP⁺ Treg and CD4⁺GFP⁺ T cells were isolated and stimulated with PMA and Ionomycin *in vitro*. The expression of IL-10 and IL-17 in ROR γ ⁺GFP⁺ Tr17 cells was analyzed by flow cytometry and compared with that in ROR γ t GFP⁺ cells or ROR γ ⁺GFP⁺ cells. 4) After the induction of CIA, lymphocytes in inflamed ankle joints and draining lymph node were harvested from Foxp3^{IREs-gfp} reporter mice. The expression of CCR6, CD25, and CTLA-4 were analyzed in ROR γ ⁺GFP⁺ cells, ROR γ t GFP⁺ cells or ROR γ ⁺GFP⁺ cells by flow cytometry.

Results: 1) ROR γ ⁺Foxp3⁺ Tr17 cells in draining lymph nodes were significantly increased in CII-immunized mice compared with non-immunized mice. 2) CCR6 and CD25 expression was elevated on Tr17 cells compared with ROR γ t Treg cells and Th17 cells and CTLA-4 and GITR expression was also up-regulated on Tr17 cells compared with ROR γ t Treg cells. 3) IL-10 producing cells were increased in Tr17 cells compared with ROR γ t Treg cells (33.2 \pm 2.95, $p < 0.001$). On the other hand, IL-17 producing cells were decreased in Tr17 cells in spite of the high expression of ROR γ t compared with ROR γ ⁺Th17 cells (9.57 \pm 1.25, $p = 0.002$) (Figure). 4) CCR6⁺Treg cells were increased in inflamed ankle joints compared with draining lymph node after the induction of CIA. CD25 expression was elevated on joint infiltrating CCR6⁺Treg cells compared with CCR6⁺ Treg cells. There was no difference of CTLA-4 expression between CCR6⁺ and CCR6⁺Treg cells in inflamed joints.

Conclusion: Tr17 cells were increased in the course of CIA and might preferentially infiltrate into inflamed joints. Moreover, Tr17 cells had the potential to regulate the development of CIA through the high expression of suppressive molecules such as IL-10 and CTLA-4 in inflamed joints.

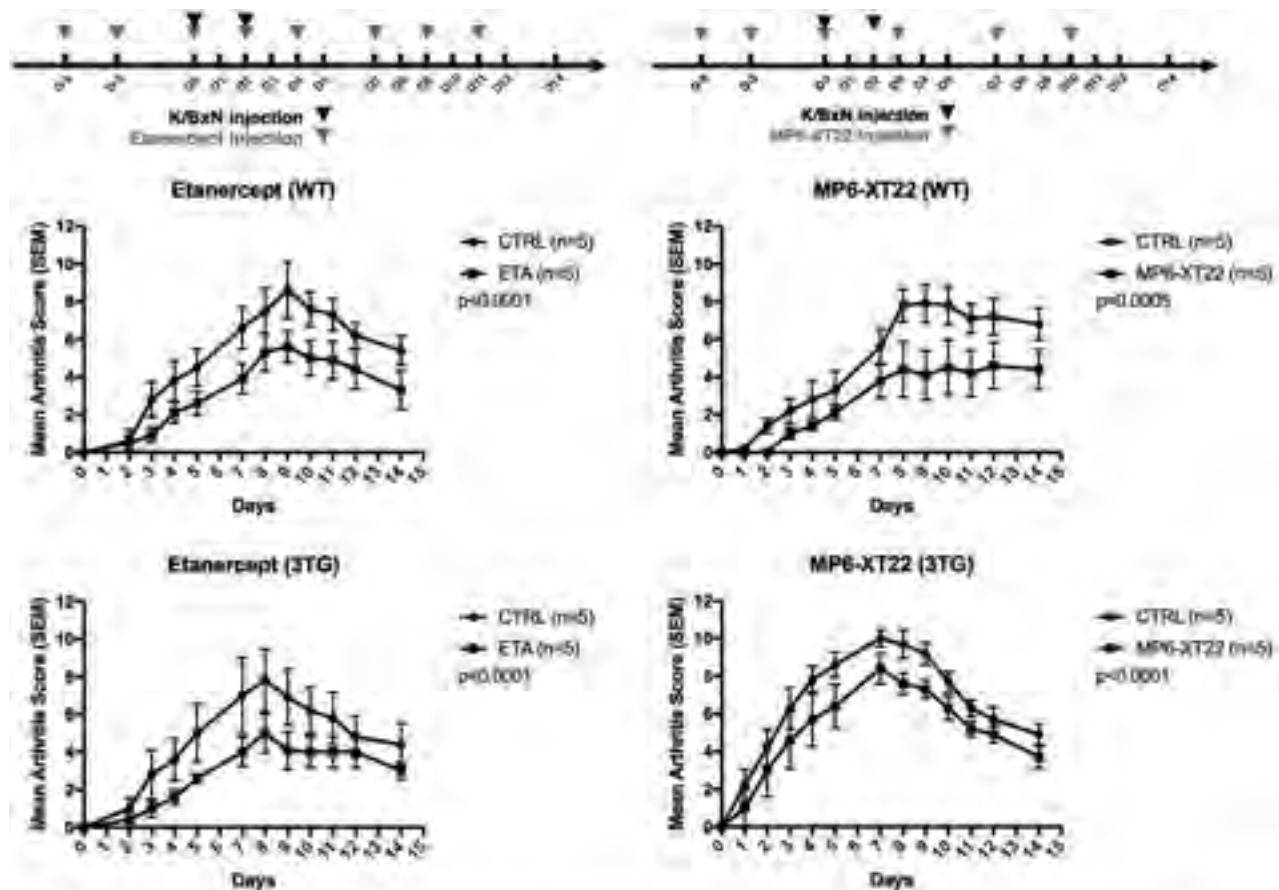

Figure 1: Evolution of K/BxN serum arthritis-induced clinical scores in WT (n=10) and 3TG (n=10) mice over time. K/BxN serum was injected I.P. on days 0 and 2. Etanercept (ETA) or MP6-XT22 were injected (10 mg/kg) I.P. on days -5, -3, then every 2 or 3 days.

Background/Purpose: Anti-TNF agents are widely used in rheumatoid arthritis (RA). Their effect on inflammation results from the neutralization of soluble TNF (sTNF), but also supposedly from the induction of reverse signaling through their binding to membrane TNF (tmTNF). Despite possible clinical relevance, reverse signaling has been described only *in vitro* but has not been proven *in vivo*.

Methods: Triple transgenic mouse model (3TG), KO for TNFR1 / TNFR2 and KI for tmTNF, thus secreting no sTNF was developed. To analyze reverse signaling, mice were injected either with etanercept (ETA), an anti-mouse TNF antibody (MP6-XT22, rat IgG1) or an anti-human IL17 antibody (secukinumab, SEC) as a control. Daily clinical evaluation of K/BxN serum induced-arthritis was performed in 3TG as well as WT mice. Polarization of bone marrow-derived macrophages (BMDM) from non-arthritic WT and 3TG mice under the action of anti-TNF *in vitro* was evaluated by RT-qPCR and flow cytometry.

Results: *In vivo*, the administration of anti-TNF (ETA or MP6-XT22) decreased arthritic scores in WT mice ($p=0.005$) as well as in 3TG mice ($p<0.001$), unlike SEC which had no effect, proving that anti-TNF binding of tmTNF decreased arthritis (fig. 1). *In vitro* effect of anti-TNF on BMDM from WT as well as 3TG mice induced a decrease in the expression of genes specific of inflammatory macrophages, and an increase in the expression of genes specific of alternative macrophages. This suggested a switch in macrophage polarization as a probable mechanism for modulation of inflammation during K/BxN serum-induced arthritis.

Conclusion: Our work provides *in vivo* evidence for the involvement of reverse signaling in the anti-TNF-mediated modulation of arthritis. Reverse signaling is expected to result in the modulation of macrophage polarization from an inflammatory to an alternative functional phenotype in arthritic mice. Our data prompt us to consider new interpretation of the effects of anti-TNF in the treatment of RA.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Animal Models Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: SKG mice, which are rheumatoid arthritis (RA) model, develop not only arthritis but interstitial lung disease (ILD) resembling RA-ILD. Myeloid-derived suppressor cells (MDSCs) are heterogeneous immature myeloid cells with suppressive functions. We previously reported that tofacitinib, which is JAK inhibitor, facilitates the expansion of MDSCs and ameliorates arthritis in SKG mice. The purpose of this study is to elucidate the effect of tofacitinib on ILD in SKG mice.

Methods: SKG mice were induced ILD by Zymosan A (ZyA) injection. Four weeks after the ZyA-injection, tofacitinib (20 mg/kg) or DMSO was intraperitoneally injected three times per week for eight weeks. We evaluated lung infiltrating cells by flow cytometry, and severity of ILD by HE staining. DC generation, T-cell proliferation and Th17 cell differentiation assays were performed in vitro.

Results: Tofacitinib significantly suppressed the progression of ILD compared to control. Flow cytometry revealed that tofacitinib significantly increased MDSCs and suppressed Th17 cells, group 1 innate lymphoid cells (ILC1s), and GM-CSF⁺ILCs in vivo. Tofacitinib suppressed the Th17 cell differentiation and increased MDSCs expansion in vitro. MDSCs expanded in the inflamed lungs also suppressed T cell proliferation and Th17 cell differentiation ex vivo.

Discussion: To our knowledge, this is the first report to show that tofacitinib is effective for RA-ILD model. Tofacitinib not only directly but also indirectly suppress the pathogenic lymphocytes by facilitating the expansion of MDSCs. These results indicate a potential therapeutic effect of tofacitinib for RA-ILD.

Conclusion: Tofacitinib facilitates the expansion of MDSCs and suppresses Th17 cells, which in turn suppress the progression of ILD in SKG mice.

Figure: Tofacitinib suppressed the progression of ILD and facilitated the expansion of MDSCs in the lung

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Animal Models Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Aberrantly higher expression of long non-coding RNAs (lncRNAs) in synovial fibroblasts (SFs) plays pathogenic roles in rheumatoid joint. Studying the effects on knocking down lncRNAs expression in arthritis models would contribute to the development of lncRNAs-related therapeutics in rheumatoid arthritis (RA). We examined whether intra-articularly (i.a.) delivering the lentivirus (LV)-based CRISPR interference (CRISPRi) targeting H19, an oncofetal lncRNA involved in tumor metastasis, in SFs can ameliorate experimental arthritis.

Methods: H19 expression levels were examined by quantitative real-time PCR (qRT-PCR) in mononuclear cells (MNCs) from RA before and after receiving a TNF blockade therapy and osteoarthritis (OA) patients. Synovial tissues were from arthritis patients and an experimental model, collagen-induced arthritis (CIA). SFs were purified from patients, and normal human SFs were obtained commercially. Single guide RNA oligonucleotides that directing Cas9 to target sites were designed according to available algorithms. A 1.9 kb stuffer was removed from LV plasmid pAll-dCAS9-KRAB.pPuro for cloning, and created single guide RNA vectors were transiently transfected into 293T cells to obtain recombinant LV vectors. SFs were transduced with LVCRISPRi-H19 under polybrene, followed by selection with puromycin incubation to produce stable H19-silenced transfectants. Cell lysates were subjected to immunoblot with anti-EZH2, anti-pGSK-3 β (a Wnt signaling) and anti-Snail. Cell invasion was assayed by Transwells with membrane coated with Matrigel. Supernatant IL-6 was quantified by ELISA. Arthritis indexes and histological scores were evaluated in CIA joints receiving LVCRISPRi-H19 or LVCRISPRi-GFP (negative control) injection, and synovial H19 expression was examined by qRT-PCR.

Results: Synovial tissues, SFs and MNCs from RA had higher H19 expression as compared with OA patients. RA MNCs had lower H19 expression after a TNF blockade injection. H19 and EZH2 levels were up-regulated in normal SFs in the presence of TNF in vitro. Lower EZH2, pGSK-3 β and Snail expression was found in H19-silenced SF transfectants. LVCRISPRi-H19-injected CIA joints with lower synovial H19 expression had reduced arthritis indexes and histological scores.

Conclusion: Our results demonstrate that a TNF-mediated lncRNA pathway with H19-EZH2-Wnt signaling-Snail axis might exist in RASFs, and i.a. delivering CRISPRi targeting lncRNA H19 in SFs could ameliorates experimental arthritis.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

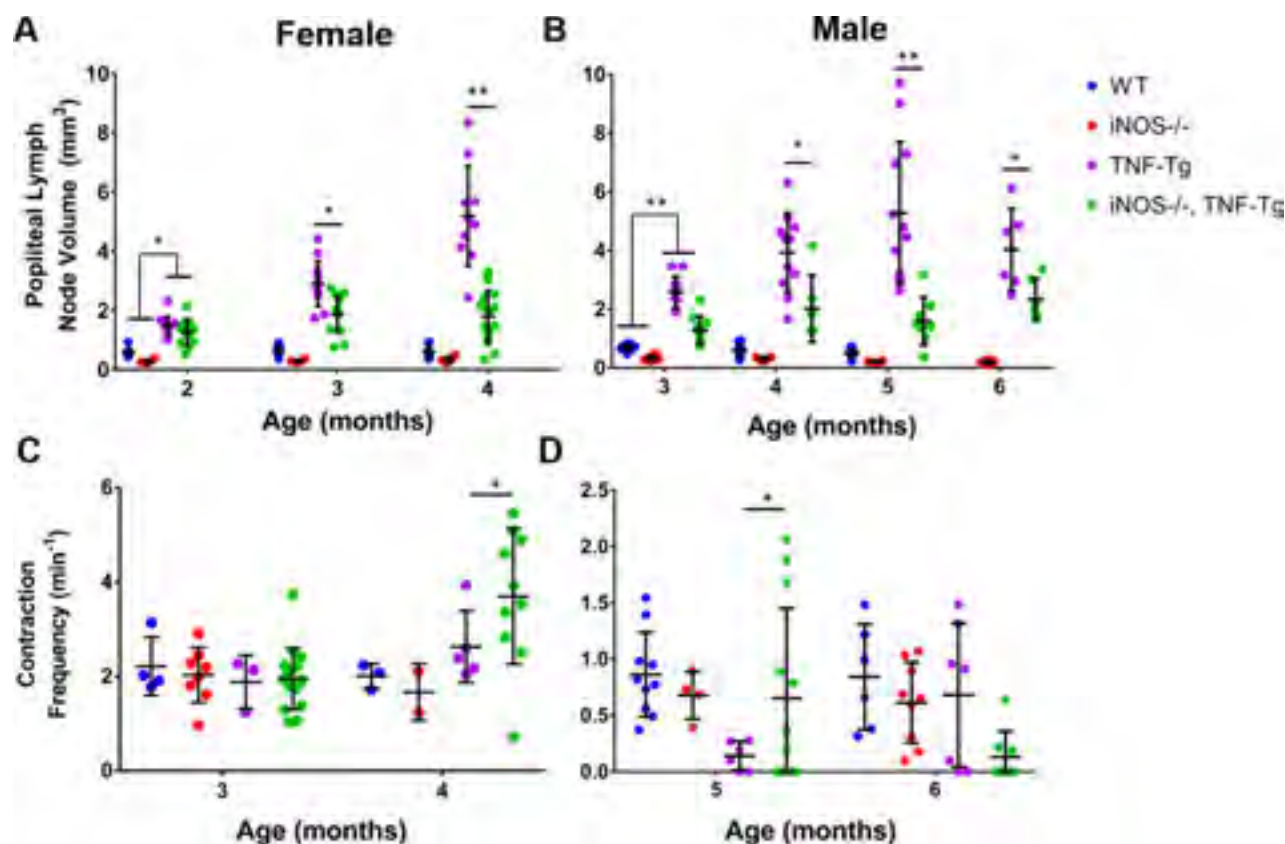

Session Title: Rheumatoid Arthritis – Animal Models Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Recent studies in the TNF-Tg mouse model of rheumatoid arthritis (RA) demonstrated a critical role of lymphatic vessel (LV) function in joint homeostasis and arthritis progression, as loss of LV contractions promotes synovitis and erosions due to decrease drainage of joint inflammation. The joint draining lymph nodes (LN) were also found to be a biomarker of arthritic progression, as they expand in volume during the onset of arthritis. It is also known that macrophages and lymphatic endothelial cells express inducible nitric oxide synthase (iNOS), which disrupts LV contractions and transport of immune cells to the draining LNs. Lastly, pharmacological inhibition of iNOS transiently recovers LV contractions in TNF-Tg mice, and maintains flow in the LVs and LNs, which correlates with reduced synovitis and bone damage in inflamed joints. Therefore, we hypothesized that global genetic ablation of iNOS prevents expansion of draining LN, maintains LV contractions, and ameliorates synovitis in TNF-Tgmice.

Methods: Male and female $iNOS^{-/-}$ x TNF-Tg mice and control littermates ($iNOS^{-/-}$, TNF-Tg, and WT; n=4-12 per group) were examine for LN volume, LV contraction frequency and synovitis. Since stark sexual dimorphism exists in TNF-Tg mice, female LN volume and LV contraction frequency were measured at 2, 3 and 4 months of age via 3D ultrasound;

while male LN volume was determined at 3, 4, 5 and 6 months. Knees were harvested for histology after the last ultrasound.

Results: No differences were seen in LN volume at the earliest time points in both sexes between TNF-Tg and iNOS^{-/-} x TNF-Tg (Figure A, Female 2mo: 1.6 ± 0.4 vs 1.4 ± 0.5 mm³; B, Male 3mo: 2.5 ± 0.6 vs 1.2 ± 0.6 mm³), however these were all significantly increase from their sex-aged matched WT and iNOS^{-/-} counterparts (WT and iNOS pooled data, Female 2mo: 0.6 ± 0.2 mm³, $p < 0.05$; Male 3mo: 0.6 ± 0.2 mm³, $p < 0.05$). Importantly, both female and male iNOS^{-/-} x TNF-Tg LNs were significantly decreased at 4 and 5 months of age compared to their TNF-Tg littermates, respectively (Female 4mo: 6.3 ± 1.9 vs 1.9 ± 0.9 , $p < 0.05$; Male 5mo: 5.3 ± 2.4 vs 1.6 ± 0.8 mm³, $p < 0.05$). LV contraction frequency was also increased at these timepoints for iNOS^{-/-} x TNF-Tg compared to TNF-Tg (Figure C, Female 4mo: 3.2 ± 1.4 vs 2.5 ± 1 contractions/min, $p < 0.05$; D, Male 5mo: 0.6 ± 0.7 vs 0.1 ± 0.1 contractions/min, $p < 0.05$). Lastly, female iNOS^{-/-} x TNF-Tg contain significantly fewer cells within their synovium compared to TNF-Tg counterparts ($1.3 \times 10^4 \pm 5.2 \times 10^3$ vs $2.6 \times 10^4 \pm 5.2 \times 10^3$).

Conclusion: These data indicate an iNOS independent phase of LN expansion precedes an iNOS dependent phase, and that pharmacological inhibition of iNOS may ameliorate RA progression by preventing the full expansion of the LN while increasing LV function, which would increase inflammatory cells egress from the synovium.

Session Title: Rheumatoid Arthritis – Animal Models Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Type I interferons (IFN-I) can be both anti- and pro-inflammatory. Among them, IFN- α inhibits normal Th17 differentiation, whereas it is pathogenic in lupus. The role of IFN-I is controversial in rheumatoid arthritis (RA) and experimental models. An IFN-I signature has been reported in RA patients, the significance of which is unclear. In mice, IFN-I enhance or inhibit arthritis development according to IFN subtype, arthritis model and kinetics. We aimed to evaluate the therapeutic effect of IFN- α in collagen-induced arthritis (CIA) and its relation with regulatory T lymphocytes (Treg) in RA patients, where Treg are functionally deficient.

Methods: CIA was induced by 2 immunizations with collagen/CFA. Disease development was studied in conditional transgenic mice over-expressing mouse IFN- α 1 and non-transgenic littermates after cessation of doxycycline administration (Tet-off system). Arthritis was followed by clinical evaluation. Inflammation/bone destruction were estimated by histology. Pain was followed by Von Frey tests. Plasma cytokines/anti-collagen antibodies were measured by Luminex/ELISA. Leukocytes sub-populations and Th polarization were analyzed by flow cytometry. Osteoclasts were prepared from the bone marrow (BM) after culture with M-CSF/RANKL. CD4⁺CD25⁺ Treg and CD4⁺CD25⁻ effector T cells (Teff) were purified by magnetic sorting. ATPase activity was determined in vitro. Treg inhibition of Teff activation was measured by flow cytometry/ELISA. The in vivo therapeutic capacity of purified Treg was estimated by adoptive transfer. Blood Treg (CD4⁺FoxP3⁺CD25⁺CD127^{low}) and suppressive phenotype (CD39 expression) were analyzed by flow cytometry in RA patients before and 3 months after anti-IL-6-receptor therapy. Plasma IFN- α concentrations were measured by digital ELISA.

Results: IFN- α 1 induction by doxycycline cessation before the first or even between both immunizations resulted in CIA protection/lower pain in transgenic mice. Anti-collagen antibody and IL-6 productions were lower in IFN- α 1⁺ mice.

Protected mice show decreased polarization to Th17 and increased polarization to Th2 and IFN- γ -positive Th1/NK cells. CIA protection in IFN- α 1-overexpressing mice was associated with lower osteoclastogenesis and osteoclast activity, altered BM-B cells, increased BM-CD86⁺ neutrophils, and particularly expansion of Treg with higher CD39/CTLA-4 expression, higher ATPase activity and higher suppressive capacity on Teff. Importantly, adoptive transfer of these Treg purified from CIA-IFN- α 1⁺ mice impaired CIA development in recipients in comparison to Treg purified from CIA-IFN- α 1⁻ mice. In RA patients, therapy blocking IL-6 signalling was associated with increased IFN- α plasma concentrations and in vivo expansion of Treg after 3 months, with increased CD39 expression. Most importantly, blood IFN- α and Treg frequencies were correlated in these patients. Thus, results in CIA mimic thus these obtained in RA patients.

Conclusion: IFN- α 1 protects against inflammatory arthritis, even in mice already seropositive, clarifying its role and showing its potent modulatory or therapeutic effect. In RA patients, IFN- α might serve as a biomarker in response to treatment.

Cyclin-Dependent Kinase 4/6 Inhibitor: A Promising Development Candidate Targeting Synovial Hypertrophy for Rheumatoid Arthritis Treatment

Shunsuke Tsujimoto, Kyohei Horie, Toshiya Mashiko, Johji Nomura and Tsunefumi Kobayashi, Teijin Institute for Bio-medical Research, TEIJIN PHARMA LIMITED, Tokyo, Japan

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Animal Models Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The pathogenesis of rheumatoid arthritis (RA) is characterized by the infiltration of immune cells into the synovial tissues and the hypertrophy of synovial fibroblasts, resulting in the destruction of bone and joint. Given the pathogenesis, the ideal therapeutic strategy for RA is to target both immune cells/pro-inflammatory cytokines and synovial fibroblasts. However, there is no drug targeting the latter, whereas anti-immune cell/cytokine drugs such as methotrexate, biologics and JAK inhibitors are the mainstay in the current treatment of RA. To date we found Compound X, a highly selective and potent inhibitor against cyclin-dependent kinase (CDK) 4/6, which is a key regulator of cell cycle. Compound X inhibits the proliferation and matrix metalloproteinase 3 (MMP-3) secretion in synovial fibroblasts from RA patients, and the progression of arthritis in adjuvant-induced arthritic rats. To determine the potential of CDK4/6 inhibitor targeting the hypertrophy of synovial fibroblasts, as development candidate for RA treatment, we examined the efficacy of Compound X using preclinical animal models.

Methods: To examine the effects of Compound X on arthritis, collagen-induced arthritis (CIA) was used. To induce arthritis, DBA/1 mice were administered twice with intradermal injection of type II collagen at the tail root on Day0 and 3. Compound X was orally administered twice daily for 19 days. To examine the effect of Compound X on arthritis after the activation of immune system, anti-type II collagen antibody-induced arthritis (CAIA) model was used. DBA/1 mice were intraperitoneally injected with anti-type II collagen antibody on Day0 and LPS on Day3. Compound X was orally administered twice daily for 18 days. Arthritic score over time, serum MMP-3 level and bone destruction were examined in CIA and CAIA mice. In addition, MMP-3 expression in the joint and anti-type II collagen IgG level were examined in CIA mice.

Results: CIA mice developed the arthritis and showed gradual increase in arthritic score. Compound X significantly suppressed the progression of arthritis in a dose-dependent manner. Serum MMP-3 level in CIA mice was increased compared with Intact animals, which is consistent with MMP-3 expression in the joint. Compound X suppressed serum MMP-3 level and tissue expression. CIA mice with Compound X had lower incidence of bone destruction than CIA mice. Compound X did not reduce type II collagen IgG level, suggesting that Compound X has no impact on the immune system. Consistent with this, Compound X also suppressed the progression of arthritis in CAIA mice without immunization. Bone erosion score was reduced by Compound X, and correlated to arthritic score.

Conclusion: Compound X suppressed RA-related events such as the progression of the arthritis, increased serum MMP-3 and bone destruction. These results suggest that CDK4/6 inhibitor can be the first-in-class drug which targets the hypertrophy of synovial fibroblasts.

In a Macaque Model of RA By Immunization with Citrullinated Peptides, the Valine in the 11 Position of the DRB1 Molecule Has Greater Impacts on T-Cell Response to Citrullinated Peptides Than the 70-74 Position in the Shared Epitope

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Animal Models Poster

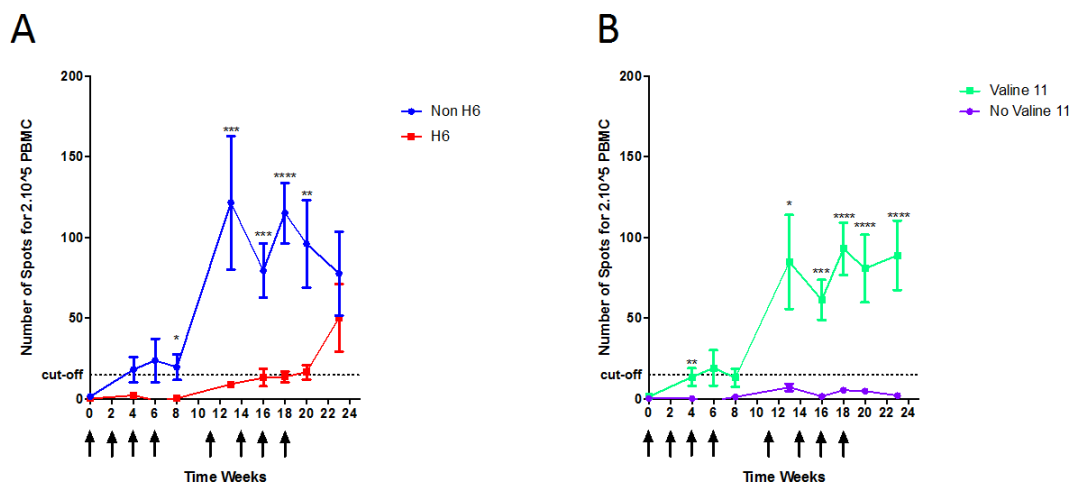

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Among genetic risk factors of RA, HLA class II molecules confers the highest risk of ACPA positive RA. The shared epitope (SE) hypothesis that initially involved positions 70 to 74 on the HLA molecule has been recently challenged by the influence of other positions such as the valine 11 position. The presence of the SE is thought to influence presentation of citrullinated peptides (Cit-P) by antigen presenting cells to T cells. Study of T-cell response in patients with various HLADRB1 haplotype is challenging. Rodent models lack the expression of the equivalent of the DRB1 molecule and transgenic mice for the SE have led to controversial results. Certain macaques express DRB1 molecules in a similar fashion compared to humans. They are thus a great tool to analyze the effect of the HLA molecule on T cell response to Cit-P. In these macaques, we previously demonstrated that immunization with Cit-P and an intra-articular boost are able to induce aspecific T-cell anti-Cit-P response independent of the SE epitope and amonoarthritis (Bitoun et al. Frontiers Immunol 2017).

Methods: We selected two macaque haplotypes to have the greatest difference in the risk induced by the HLADRB1. The H6 haplotype has a similar sequence to the human RA risk-conferring HLADRB1*01:01 and displays QRRAA in the 70 to 74 positions and a F in the 11 position. The H3 haplotype is the closest to RA protective haplotypes HLA-DRB1 04:02 and 13:01 and expresses DRRAS (70-74 positions) but a V in position 11. Two groups of six animals were immunized with four Cit-P: vimentin (59–71) and (66–78), fibrinogen α (79–91) and aggrecan (89–103). These peptides were selected based on their ability to induce an anti-citrullinated T-cell response in RA patients carrying the SE. T-cell response was assessed using Interferon γ ELISPOT. Timepoints were compared using Mann Whitney tests.

Results: After a prime and 7 boosts, we obtained a detectable anti-citrullinated T cell response in only 7 out of twelve animals. The analysis dividing animals according to the presence of the SE motif (H6 in macaques) show a significantly

diminished T-cell response in H6 macaques (FigureA). This was contradictory with the common description of higher T cell response in patients carrying the SE. When we reanalyzed the data based on the presence or not of a V in position 11, we found that this valine in position 11 was strongly associated with the presence of a T-cell response against citrullinated peptides, whatever the 70-74 sequence was (Figure B).

Conclusion: As recently described in humans for association to RA and anti-CCP positivity, T-cell response to Cit-P in macaques is more influenced by the presence of a valine at position 11 in the HLA-DRB1 than with the presence of the QRRAA 70-74 SE. The respective influence of the V in position 11 and the 70-74 QRRAA sequence should be studied regarding a better binding and presentation of Cit-P.

Adipose Derived Stem Cell Suppressed Synovial Inflammation and Repaired Cartilage Destruction in Rheumatoid Arthritis Model Mice

Tadashi Okano¹, Kentaro Inui², Hideki Ueyama³, Kumi Orita³, Tatsuya Koike⁴ and Hiroaki Nakamura², ¹Orthopedic Surgery, Osaka City University Graduate School of Medicine, Osaka, Japan, ²Orthopaedic Surgery, Osaka City University Graduate School of Medicine, Osaka, Japan, ³Osaka City University Graduate School of Medicine, Osaka, Japan, ⁴Center for Senile Degenerative Disorders, Osaka City University Graduate School of Medicine, Osaka, Japan

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Animal Models Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Adipose derived stem cell (ADSC) is one of the stem cells produced by adipose tissue which can be collected easily and in large quantities. It has been reported the anti-inflammatory effect of ADSC in some disease models. However, the effect of ADSC for synovitis such as rheumatoid arthritis (RA) is unknown. The aim of this study is to investigate the effects of ADSC for intra-articular synovitis and cartilage degeneration in SKG/Jcl mice in vivo and the effects of ADSC for synovial fibroblast in vitro.

Methods: SKG/Jcl mice which developed auto-immune arthritis by adjuvant stimulation were used as RA animal model. In vivo, the intra-articular injections of ADSC or PBS were performed to the bilateral knee of SKG mice with arthritis. The knee joint was histologically assessed with synovitis score and Mankin score at week 2 after ADSC injection. In vitro, the anti-inflammatory effect of ADSC for stimulated human synovial fibroblast was analyzed by real-time RT-PCR.

Results: In vivo, the synovitis score and Mankin score were significantly lower in ADSC group (synovitis score 2.0 ± 0.7 vs 6.0 ± 1.6 , $p < 0.01$ and Mankin score 2.2 ± 0.8 vs 4.9 ± 0.8 , $p < 0.01$) (Figure 1). Surprisingly, the cartilage degeneration was repaired in ADSC group (Figure 2). As a comparison, glucocorticoid injection suppressed the synovial inflammation but cartilage degeneration was not improved (Figure 2). In vitro, the expression of tumor necrosis factor-stimulated gene-6 (TSG-6), the anti-inflammatory cytokine, was significantly higher in ADSC than in synovial cell ($p < 0.01$). The inflammatory cytokine levels in stimulated synovial cell were significantly decreased by ADSC treatment ($p < 0.01$).

Figure 1. The anti-inflammatory effects of intra-articular ADSC injection.

The H-E stain of knee joint in SKG/Jcl mice (a) and PBS treated SKG/Jcl mice after induction of synovitis (b). The synovial proliferation was suppressed in ADSC treated SKG/Jcl mice after induction of synovitis (c). The Safranin-O stain in SKG/Jcl mice without synovitis (d), PBS treated SKG/Jcl mice (e) and ADSC treated SKG/Jcl mice (f) after induction of synovitis. The cartilage staining was reduced in SKG/Jcl mice with inflammatory synovitis (yellow arrows).

Figure 2. Cartilage repair in ADSC group

Conclusion: This is the first report to show the anti-inflammatory effect of ADSC for synovitis in RA animal model. ADSC can be collected with a minimally invasive technique more easily than other mesenchymal stem cells. ADSC might have potential to be one of the RA treatment and repair cartilage degeneration.

Comparison of Metabolic Changes in Osteoarthritis and Rheumatoid Arthritis Mouse Models

Marie-Lisa Hülser¹, Hani Manfred Sauermilch¹, Carina Schreyäck¹, Yubin Luo², Aline Bozec², Georg Schett³, Ulf Müller-Ladner⁴ and Elena Neumann¹, ¹Dept. of Rheumatology and Clinical Immunology, Campus Kerckhoff, Justus-Liebig-University Gießen, Germany, Bad Nauheim, Germany, ²University of Erlangen-Nürnberg, Department Clinic of Medicine 3 - Immunology and Rheumatology, Erlangen, Germany, Erlangen, Germany, ³Friedrich-Alexander-Universität Erlangen, Nürnberg und Universitätsklinikum Erlangen, Erlangen, Germany, ⁴Dept. of Rheumatology and Clinical Immunology, Campus Kerckhoff, Justus-Liebig-University Giessen, Germany, Bad Nauheim, Germany

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Animal Models Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Adipocytokines are bioactive factors produced mainly by adipose tissue. They not only regulate energy homeostasis, but also influence immune responses. Osteoarthritis (OA) is one of the most common degenerative joint diseases whereas rheumatoid arthritis (RA) is a chronic autoimmune joint disease. Therefore, an obesity model (High-fat diet, HFD) was combined with a model for OA (DMM, destabilization of the medial meniscus) or a model for RA (collagen induced arthritis, CIA) to evaluate the role of the adipokines adiponectin, leptin and visfatin in these settings. This work evaluates the influence of different adipokines and obesity on OA compared to RA regarding systemic vs. local effects at different time points.

Methods: The OA model was performed in C57Bl/6 mice fed with HFD or ND (normal diet) prior to OA induction. The RA model was performed in DBA/1Rj mice fed with the same diets. Mice were sacrificed and analyzed 4, 6 and 8 weeks (OA model) or 4, 5.5 and 7 weeks (RA model) after induction of RA/OA. For systemic analysis, sera were evaluated for the adipokines adiponectin, leptin and visfatin and inflammatory markers. Diet induced systemic changes were analyzed using a fatty liver score and evaluation of crown-like structures (CLS) in adipose tissue. Histological scoring for OA and a clinical score for RA was performed. Immunohistochemical stainings of OA joints were performed to evaluate local adipokines and the producing cell types.

Results: All three models in the respective combinations were successful, represented by histological destruction of the joints and increased fatty liver score (C57Bl/6) or bodyweight (DBA/1Rj). The number of CLS were significantly higher comparing HFD (0.2 ± 0.1553 , $n=7$) with ND (5.219 ± 0.9831 , $n=8$) in C57Bl/6 mice and fatty-liver score was significantly higher in HFD compared to ND in C57Bl/6 but not in DBA/1Rj. Leptin was significantly induced by HFD in both mouse strains, this effect could be annulled by leptin reducing effects of the CIA model. DMM reduced systemic leptin but with much weaker effect. HFD, DMM or the combination of both did not show significant effects on serum levels of adiponectin, visfatin or IL-6. However, in DBA/1Rj mice CRP was significantly induced by CIA. Local adipokine distribution in the joints after DMM surgery was independent from systemic metabolism parameters.

Conclusion: Our data show that similar to observations in humans, OA is deteriorated by HFD which correlates mainly with the bodyweight. This phenomenon was not visible in our RA model. CIA and DMM both decreased systemic leptin, which was much more effective in CIA suggesting an inflammation-dependent mechanism. Interestingly, in OA the local adipokine expression was independent from systemic adipokine levels.

Repository Corticotropin Injection (H.P. Acthar® Gel) Inhibits Bone Degradation in Rat Adjuvant-Induced Arthritis Model

Dale Wright, Ben Zweifel, Steve Settle and Rick Fitch, Pharmacology, Mallinckrodt Pharmaceuticals, Hazelwood, MO

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Animal Models Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Repository corticotropin injection (RCI: H.P. Acthar® gel) contains a purified porcine pituitary ACTH-analogue, and is an FDA-approved treatment for short-term adjunctive therapy of acute episode or exacerbation in rheumatic disorders. It has been suggested that ACTH modulates the immune response via binding to melanocortin receptors (MC1R to MC5R). These receptors are expressed on a number of cells including immune cells and bone cells, and have been shown to modulate several immuneresponses. This study was designed to investigate the effects of RCI treatment compared to prednisolone with regard to arthritis disease attenuation and boneprotection.

Methods: Ratadjuvant-induced arthritis (AIA) model was used to determine efficacy in the subacute inflammation setting. Disease was induced by an injection of alipoidal amine in Freund's complete adjuvant (FCA) on day 0. The AIA rats were treated with either vehicle, prednisolone (5 mg/kg) or RCI (40, 160, 400 IU/kg) every other day by subcutaneous injection beginning on the day of disease induction and continuing for 15 days (8 total doses). Disease progression was monitored on days 7-14 by measuring both paw diameter and body weight. Inflammation and bone damage were evaluated histologically at the end of the study.

Results: Treatment with RCI showed significant and dose responsive inhibition of disease induction as determined by evaluation of ankle diameter (area under the curve (AUC) inhibition of 44%, 74%, 94% for 40 IU/kg, 160 IU/kg and 400

IU/kg, respectively) whereas prednisolone reduced swelling by 33%. Microscopic examination of the ankle joints showed that RCI significantly inhibited total histopathology sum score by 64% and 85% at 160 IU/kg and 400 IU/kg, respectively, while treatment with prednisolone resulted in 33% inhibition, which was not significantly different from the controls. Furthermore, RCI inhibited inflammation-related bone resorption and reduced the number of osteoclasts in the inflamed joint. Interestingly, prednisolone significantly reduced the number of osteoclasts but did not show a significant benefit on joint damage as evaluated by bone resorption and cartilage damage.

Conclusion: RCI treatment significantly inhibited the development of disease in rat AIA, whereas prednisolone treatment alone only showed a minor benefit. Furthermore, there was a significant reduction in the number of osteoclasts following RCI treatment. These findings support the use of RCI for treatment of rheumatoid arthritis and suggest a potential bone sparing effect.

Histopathology Scoring

Treatment	Inflammation	Pannus	Cartilage Damage	Bone Resorption	Periosteal Bone Formation	Osteoclast Numbers

Liang¹, ¹Division of Hematology/Oncology, Rhode Island Hospital, Providence, RI, ²Division of Rheumatology, Rhode Island Hospital/The Warren Alpert School of Medicine of Brown University, Providence, RI, ³Division of Rheumatology, Rhode Island Hospital, Providence, RI

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Animal Models Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The SH2-containing inositol-5'-phosphatase-1 (SHIP1) controls PI3K initiated signaling by limiting membrane recruitment and activation of AKT. SHIP1 knockout in mice leads to an increase of myeloid-derived suppressor cells (MDSCs) as well as the regulatory T-cells (T_{reg}), both are important autoimmune regulators. MDSCs are blood cells of myeloid origin that are able to suppress T cell responses. A recent study suggests that MDSCs play a critical role in the regulation of collagen-induced arthritis (CIA) in mice, where the MDSCs suppress disease progression by inhibiting the immune response of CD4⁺ T cells. Although, an increased MDSCs seems to have suppressive effect on RA progression, the exact role of SHIP1 in the differentiation/expansion of MDSCs in RA remains unknown. Therefore, the objective of this project is to determine the role of SHIP1 in initiation and progression of RA. Our long-term goal is to develop novel strategies for the treatment of inflammatory arthritis diseases.

Methods: A specific SHIP1 inhibitor 3a-aminocholestane (3AC)-injected DBA mice were compared to vehicle-injected mice during Collagen-induced Arthritis (CIA) development. The development and severity of arthritis was assed using scoring system, histological analysis and X-ray imaging. We examined the effect of 3AC on the population of MDSCs and T cells obtained from peripheral blood, spleen, and bone marrow during CIA development through flow cytometry analysis.

Results: We found a delay of CIA onset and significant decrease in the progression of disease, compared with vehicle-injected mice. However, we also found that early suppressive effect on incidence and severity of CIA by 3AC disappeared around day 65. Additionally, there was significant reduction in 3AC-induced expansion of MDSC from day 43 to 63, while the number of T cells in peripheral blood of 3AC-treated mice was recovered to control levels. Histologic examinations of

Figure 1. X-ray analysis to examine the erosion and destruction of bone. Untreated (A and B), vehicle-injected (C and D), and 3AC injected (E and F) mice at day 45. Equivalent X-ray images at day 70 (G-L). Triplicate experiments.

the joints from the CIA mice treated with 3AC showed no evidence of erosive arthritis, whereas the joints from mice treated with vehicle showed markedly erosive changes (Figure 1).

Conclusion: Our results suggest that SHIP1 inhibitor maintains the immunoregulatory microenvironment through an increase of regulatory myeloid (MDSCs) and T-cells (Treg). Further, pre-treatment of 3AC inhibits early onset of arthritis, and although this effect was limited and disappeared at later stage of the disease. SHIP1 inhibition was able to protect mice from severe bone destruction which it could be observed at late stage CIA.

Singh¹ and Salahuddin Ahmed^{2,3}, ¹Washington State University, Department of Pharmaceutical Sciences, College of Pharmacy, Spokane, WA, ²Department of Pharmaceutical Sciences, Washington State University, College of Pharmacy, Spokane, WA, ³Division of Rheumatology, University of Washington, Division of Rheumatology, School of Medicine, Seattle, WA

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Animal Models Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Syndecans are cell-surface heparan sulfate proteoglycans (HSPGs) that modulate the receptor/ligand binding of chemokines, cytokines, and growth factors in order to facilitate cellular signaling. Two extracellular sulfatase enzymes, namely Sulf-1 and Sulf-2, cleave 6-O-sulfates to dynamically edit the sulfation pattern of syndecans and other membrane-bound HSPGs in response to the microenvironment. However, the role of syndecans and sulfatases in inflammatory condition such as rheumatoid arthritis (RA) remains poorly understood.

Methods: Sulf-1, Sulf-2, and syndecans expression were evaluated in de-identified synovial tissues (ST) and isolated synovial fibroblasts (SFs) from RA and non-diseased (NL) donors under the IRB approved protocol, and in the rat adjuvant-induced arthritis (AIA) model of RA. Effect of TNF- α or IL-1 β on the expression of Sulf-1, Sulf-2, and

syndecans in RASFs was determined. The effect of OKN-007, a known Sulf-2 inhibitor, on TNF- α -induced IL-6 and IL-8 production in RASFs was determined using an ELISA assay. The role of nuclear factor- κ B (NF- κ B) and mitogen-activated protein kinases (MAPKs) in TNF- α -induced Sulf-1 and Sulf-2 expression was evaluated using known chemical inhibitors. Statistical value of $p < 0.05$ was considered significant.

Results: Human RASTs showed an increased expression of Sulf-1 and Sulf-2 protein compared to the NLSTs, which also correlated with a selective increase in syndecan-2 expression in RASTs ($p < 0.05$; $n = 5$). Furthermore, Sulf-1 and Sulf-2 expression in the joints of AIA rats showed a concerted increase with the disease severity, where their expression increased around day 8 (onset of arthritis) and peaked around day 18 (established arthritis) in AIA, and concomitantly correlated with a robust expression in syndecan-2 ($p < 0.01$ for day 18; $n = 5$). Stimulation of RASFs with TNF- α (0.1-20 ng/mL) or IL-1 β (0.1-10 ng/mL) showed a dose-dependent increase in Sulf-1 and Sulf-2 expression that increased to >2 -fold when compared to the non-stimulated samples. Evaluation of the signaling pathways using chemical inhibitors showed that among the inhibitors tested, the inhibitor of TAK1 (5Z-7-oxozeanone) and NF- κ B (PDTC) were most effective in inhibiting TNF- α -induced Sulf-1 and Sulf-2 expression. Furthermore, pretreatment of RASFs with Sulf-2 inhibitor (OKN-007; 40-200 μ M) reduced TNF- α -induced IL-6 and IL-8 production by $\sim 50\%$ and $\sim 20\%$, respectively, suggesting its anti-inflammatory potential in RA. However, we did not observe a significant reduction in TNF- α -induced MAPKs (ERK, JNK, or p38) by OKN-007, suggesting that TNF- α induces Sulf-1 and Sulf-2 expression in RASF potentially via TAK1-NF- κ B pathway.

Conclusion: Our preliminary findings suggest that the Sulf-1 and Sulf-2 expression is increased in RASTs and in rat AIA, and may potentially play an important role in modulating cytokine signaling. Understanding their role in HSPG processing may help elucidate the pathology of aggressive RASFs and may direct our studies towards targeted drug design for treatment of RA.

Session Title: Rheumatoid Arthritis – Animal Models Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The mechanistic target of rapamycin (mTOR) pathway and glutamine metabolism are activated cooperatively in the differentiation and the activation of inflammatory immune cells such as effector lymphocytes and M1 macrophages. Myeloid-derived suppressor cells (MDSCs) are an immature myeloid cell population with immunosuppressive ability. The promotion of the expansion and immunosuppressive ability of MDSCs by mTOR inhibition has been reported. The aim of this study is to elucidate the effect of combined inhibition of mTOR and glutamine metabolism on immune cells and therapeutic effect in a mouse model of rheumatoid arthritis.

Methods: The proliferation of CD4⁺ T cells treated with four patterns of drugs; 1) DMSO (control), 2) rapamycin (Rapa), 3) 6-Diazo-5-oxo-L-norleucine (DON; a glutamine antagonist), or 4) the combination of rapamycin and DON (Rapa+DON), were assessed by CFSE-dilution assay. The differentiation of CD4⁺ T cells and bone marrow cells from untreated Balb/c mice were analyzed by flow cytometry. Immunosuppressive ability of *in vitro* generated-MDSCs were assessed by co-culture with CFSE-labeled CD4⁺ T cells. The four patterns of drugs were administered intraperitoneally to arthritic SKG mice and splenocytes were analyzed by flow cytometry.

Results: Rapamycin and DON synergistically inhibited the CD4⁺ T cell proliferation and both of them inhibited the Th17 cell differentiation *in vitro*. DON significantly suppressed the differentiation of dendritic cells and macrophages, and increased the proportions of MDSCs *in vitro*. Most of *in vitro* generated-MDSCs treated with rapamycin or DON were Ly6G⁺ granulocytic (G)-MDSCs. On the other hand, *in vitro*-generated G-MDSCs treated with rapamycin suppressed the proliferation of CD4⁺ T cells more strongly than G-MDSCs treated without rapamycin. The combination of rapamycin and

DON synergistically suppressed arthritis in SKG mice *in vivo* (see Figure). The number of CD4⁺ T cells in splenocytes was the most suppressed in the combination therapy group and the proportions of Th17 cells were suppressed in rapamycin, DON, or the combination therapy groups.

Conclusion: The combination of rapamycin and DON synergistically ameliorated arthritis in SKG mice possibly through suppressing CD4⁺ T cell proliferation and Th17 differentiation.

Session Title: Rheumatoid Arthritis – Animal Models Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Periodontal disease (PD) is the chronic inflammatory disease caused by the infection of periodontal pathogenic bacteria, *Porphyromonas gingivalis* (Pg). Pg infection is known as a major pathogenic factor of some systemic diseases including rheumatoid arthritis (RA). Our group established b-galcan (laminarin, LA) induced RA model mouse with Pg infection (Pg-RA mouse) by using SKG mouse. Pg-RA mouse showed severe arthritis and joint destruction like human RA compared with RA mouse. The cause of exacerbation of joint destruction by Pg infection was the activation of osteoclastogenesis (OCD) in Pg-RA mouse with the elevation of ACPA, IL-6, and MMP-3 in serum (Clin Exp Immunol. 2016 Nov; 186 (2):177-189.). Immune complex (IC) is also important in the activation of OCD. However, the involvement of IC derived from citrullinated protein (CP) in the progression of OCD is unclear. It is also unclear that the involvement of Pg pathogenic factors even if there are some enzymes possessed by Pg such as peptidyl arginine diamidase (PAD) and gingipain. In this study, the involvement of Pg which is a major source of endogenous CP in bacteria in the synthesis of IC in the periodontal tissue and joint tissue was determined. The localization and effect of ACPA in the progression of RA in model mouse were also analyzed by using a ACPA monoclonal antibody generated from RA patients B cell (CCP1-Ab).

Methods: In order to induce periodontal bone loss in SKG mouse, Pg was diluted into 2% *carboxyl methyl cellulose* (CMC, 10f8 CFU/50 ml) and also infected into mouse oral cavity twice a week for 2 weeks with the placement of 5-0 silk thread around the maxillary second molar. As a control, CMC was only applied into oral cavity. At the same time for induction of RA, the single i.p. injection of LA was performed. In order to measure the amount of CP and ACPA, mouse was received adaptive transferred CCP-Ab1 (Arthritis Rheumatol. 2015 May; 67(8):2020-31.). Then, the tissue homogenates of periodontal tissue, joint tissue, spleen and serum were determined by ELISA. The immune fluorescence microscopic analysis was also performed to determine the localization of ACPA and IC in periodontal tissue. In order to determine the effect of ACPA in the activation of OCD, bone marrow mononuclear cell (BMC) was cultured with sRANKL and M-CSF in the presence or absence of CCP-Ab1 and analyzed by TRAP staining and by CellInsight CX-5 HCS Platform for quantitative analysis of osteoclast. mRNA expression of OCD related genes in BMC was determined by quantitative RT-PCR.

Results and Conclusion: The distributions of ACPA in periodontal tissue, joint tissue, and spleen were observed in Pg infected periodontitis mouse by ELISA. IC was also generated in Pg infected periodontitis mouse compared with healthy mouse. The adaptive transfer of CCP1-Ab resulted in the elevation of AS compared with the that of control IgG. OCD was activated in the presence of CCP1-Ab compared with control antibody. mRNA expression of OCD related gene (*traf6*, *nfatc1*, *Oscar*, *dc-stamp*, *mmp-9*, and *catK*) in BMC was induced by CCP1-Ab. The possibility of the involvement of IC from ACPA and CP generated by Pg in periodontal tissue for the progression of bone resorption was observed in Pg-RA mouse.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Animal Models Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The IL-23/IL-17A immune pathway is important for the progression of T cell-mediated arthritis. However, it is not known where IL-23R⁺ T cells locate during the different stages of arthritis and which IL-23R⁺ T cells drive joint inflammation. We aimed to identify IL-23R⁺ T cells in the secondary lymphoid organs during the development and progression of antigen-induced arthritis (AIA). Furthermore, we studied which IL-23R⁺ T cells drive full-blown AIA.

Methods: To induce AIA, IL-23R^{+/+} (WT), heterozygous IL-23R^{+/-GFP}, and IL-23R^{GFP/GFP} (IL-23RKO) mice were immunized with methylated bovine serum albumin (mBSA) in Complete Freund's Adjuvant. After 7 days mice were injected in the knee joints with mBSA. Mice were macroscopically scored at different time points and knees were used for histological analysis of the joints. The spleen, inguinal and popliteal lymph nodes (LN) were collected and analyzed for the expression of GFP⁺/IL-23R⁺ T cells. To study which T cells drive AIA, CCR6⁺CD4⁺ T cells and $\gamma\delta$ T cells from CFA/mBSA immunized WT mice were adoptively transferred into IL-23RKO recipient mice prior to AIA induction and disease severity was assessed at the peak of AIA.

Results: AIA disease progression was mainly driven by the IL-23R pathway since IL-23RKO mice had significantly lower arthritis scores and less bone damage. Furthermore, the fraction and total CD4⁺ and TCR $\gamma\delta$ ⁺ cell counts were lower in IL-23RKO joints at day 4 of AIA. *In vitro*, cells of IL-23RKO mice produced less IL-17A. Heterozygous IL-23R reporter mice had similar disease scores to WT mice, indicating that half of the receptor expression is sufficient to drive disease. Flow cytometric analysis of GFP/IL-23R in T cells of naïve and arthritic IL-23R reporter mice revealed that a fraction of CCR6⁺CD4⁺ T cells and $\gamma\delta$ T cells, but not CD8⁺ T cells, expressed IL-23R in the lymphoid tissues. Already one day after arthritis induction, the fraction IL-23R⁺ CCR6⁺CD4⁺ T cells was increased in the draining LNs from the joints. The fraction of these IL-23R⁺ T cells decreased gradually during the progression of disease, possibly due to their migration towards the synovium. Adoptively transferred CCR6⁺CD4⁺ T cells, but not $\gamma\delta$ T cells, were able

Conclusion: The IL-23R signaling pathway is essential for full-blown AIA. CCR6⁺CD4⁺ T cells and $\gamma\delta$ T cells, but not CD8⁺ T cells, express IL-23R during naïve and inflammatory conditions. Interestingly, adoptive transfer of CCR6⁺CD4⁺ T cells but not $\gamma\delta$ T cells, can rescue arthritis in IL-23R deficient mice.

TNF- α Blockade Incompletely Reverses Inflammatory Pulmonary Pathology in the TNF-Transgenic Mouse Model of Rheumatoid Arthritis

Emily Wu¹, Richard Bell², Edward Schwarz³ and Homaira Rahimi⁴, ¹Department of Immunology, Microbiology, and Virology, University of Rochester, Rochester, NY, ²Center for Musculoskeletal Research, University of Rochester, Rochester, NY, ³Orthopediatrics, University of Rochester, Rochester, NY, ⁴Rheumatology, University of Rochester/Golisano Children's Hosp, Rochester, NY

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Animal Models Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Interstitial lung disease (ILD) is a significant contributor to rheumatoid arthritis (RA) mortality, yet its pathogenesis remains enigmatic. One hypothesis is that initial inflammatory RA-ILD pathology occurs secondary to systemic inflammation, prior to transitioning to irreversible fibrotic lung disease. This idea is supported by the TNF-transgenic (TNF-Tg) mouse model of RA, which manifests a purely inflammatory pulmonary pathology of interstitial infiltrate, perivascular inflammation, vascular occlusion, and follicle formation. While anti-TNF agents are largely effective for arthritis, some reports have found them to be ineffective, and possibly detrimental, to patients with RA-ILD. Here, we tested the hypothesis that pre-fibrotic inflammatory ILD is reversible by treating established ILD in TNF-Tg mice.

Methods: TNF-Tg mice underwent in vivo micro-computed tomography (μ CT) to establish baseline ILD. Once they achieved a minimum lung tissue volume of 400 mm³, mice (n=6) were randomized to 6-weeks of treatment with anti-TNF or Placebo (10 mg/kg/wk i.p.). Body weight, grip strength, and knee ultrasound were measured bi-weekly. Terminal outcomes included lung μ CT, histology, and flow cytometry.

Results: Anti-TNF treated mice recovered their body weight, grip strength and had resolution of their arthritis. Further, they demonstrated a dramatic yet incomplete amelioration of lung pathology. Total lung tissue volume was significantly reduced vs. placebo (302.25 \pm 38.40 mm³ vs. 471.53 \pm 27.13 mm³; p<0.0001) (Fig. 1). Histologic analysis corroborated this finding, with marked decreases in interstitial infiltrate, perivascular inflammation, and vascular occlusion in anti-TNF treated lungs. In contrast, prominent follicle-like structures remained (Fig. 2A-C). Flow cytometry identified a novel CD11b^{int}/CD11c⁻ population, which declined with a concomitant increase in a CD11b^{hi}/CD11c^{hi} cDC2-like population in placebo treated lungs, and reverted to WT in the anti-TNF treated lungs (Fig. 2D-F).

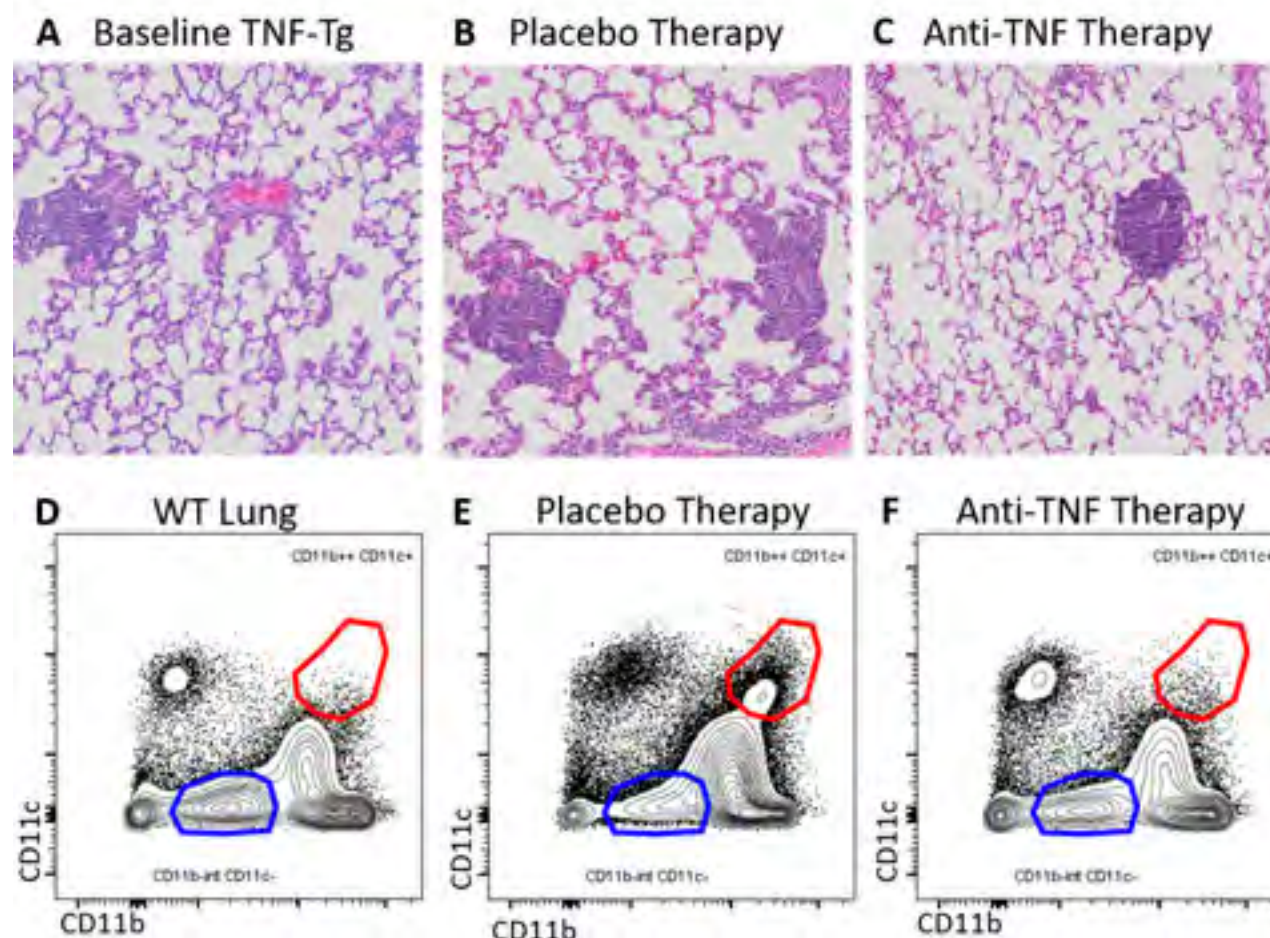

Figure 2

Conclusion: Our results demonstrate that a purely inflammatory RA-ILD is largely resolved with anti-TNF therapy, supporting the hypothesis that the inflammatory phase of ILD is potentially reversible. Interestingly, the follicle-like structures in the pulmonary tissue were not cleared by anti-TNF therapy, and a novel cell population was identified in TNF-Tg mice lungs that was no longer present after anti-TNF therapy. Further research is needed to investigate the role of the follicle-like structures and to characterize this novel cell population.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Animal Models Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Several studies have demonstrated that Magnesium (Mg) has a key role in the immune responses. Our previous studies showed that a short-term low Mg diet was significantly protective in mice with Collagen-Induced Arthritis (CIA) arthritis decreasing disease severity and preserving normal joints' architecture without any erosive changes. Spleen from these mice had reduced levels of Th17 cells and increased numbers of CD4+FoxP3+ Treg cells. Given the strong relationship between Tregs, Th17 cell and the gut microbiota we examined the effect of different Mg diets on the intestinal microbiota of arthritic mice.

Methods: Mice were placed either on a low (50 ppm), regular (500 ppm) or high Mg diet (2800 ppm) 22 days before the induction of CIA, and discontinued three days after the induction. The diets were then converted into a regular Mg diet that was continued until the end of the arthritis experiment. Fecal samples were collected before starting the Mg diets (day 0), after 22 days of diet and at the end of the arthritis scoring period (day 56); Fecal genomic DNA was extracted and expression of the commensal bacteria *Bacteroides fragilis* (BFR), *Bifidobacterium* (Bfd), clostridium cluster IV (sg-Clep), *Clostridium coccoides* group (g-Ccoc), *Clostridium Perfringens* (Closp), *Lactobacillus* (Lact) and Segmented filamentous bacteria (SFB) determined by qPCR by amplifying 16S rRNA genes and normalizing for Eubacteria. Splenocytes were used for flow cytometry quantification of Th17 and CD4+FoxP3+ Tregs.

Results: There were no significant group differences in the baseline levels of microbiota before starting the diets. At the end of the arthritis experiment (day 56) the low and high Mg diet groups had significantly lower levels of SFB ($p=0.04$ and $p=0.05$, respectively; unpaired t-test; $n=5/\text{group}$), compared with the regular Mg diet (500ppm) group. These results correlated with decreased numbers of Th17 cells in low Mg treated mice. The low Mg diet group also had significantly increased levels of BFR ($p=0.05$; unpaired t-test, $n=5/\text{group}$) and increased numbers of CD4+FoxP3+ Treg cells. BFR has been shown to promote differentiation and increased suppressive activity of CD4+FoxP3+ Treg cells.

Conclusion: This study describes for the first time that alterations in dietary Mg may affect the status of the gut microbiome and those changes correlate with numbers of Tregs and Th17 cells. These results suggest that changes in dietary Mg may affect arthritis by inducing changes in the microbiome and in pathogenic and protective T cell subsets.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Animal Models Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Ongoing studies in rheumatoid arthritis (RA) implicate intestinal dysbiosis of bacteria as a contributing factor, though the mechanism(s) by which bacteria influence disease is not known. Our recent studies using the murine collagen-induced arthritis (CIA) model of inflammatory arthritis demonstrated a role of intestinal bacteria in influencing autoantibody pathogenicity through modulation of autoantibody glycosylation. As bacterial metabolites are potent immune modulators, we profiled intestinal metabolites generated during CIA to identify potential mediators of antibody glycosylation. We identified the bacteria-produced metabolite indole as significantly correlating with the development of disease. In this study, we aimed to further investigate the role of indole for antibody glycosylation during the development of CIA.

Methods: We utilized the murine collagen-induced arthritis (CIA) model in which mice are immunized with bovine type II collagen on days 0 and 21. To reduce the effect of microbe-produced metabolites during disease, we administered broad-spectrum antibiotics in the drinking water starting at day 21, which reduces intestinal bacteria >90% and CIA severity >95%. Indole was then added to this water at a concentration of 1 μM . Cecal contents with tissue were evaluated by LC-MS and 16S rRNA sequencing of bacteria. Cells in Peyer's patches, mesenteric LNs, and spleens evaluated by flow cytometry and qPCR. Serum antibodies were measured by ELISA. For ex vivo stimulation of B cells with indole, splenic B cells were negatively sorted 10 days following CII-immunization and differentiated in culture with LPS \pm indole. After 24 hours, RNA was isolated from cells and gene expression determined by qPCR.

Results: Profiling the metabolome during CIA identified the indole pathway as significantly altered and correlating with disease severity in CIA. Indole also correlated with the significant expansion of bacteria known to produce indole in the development of CIA. In mice protected from CIA by antibiotic administration (CIA+Abx) indole levels were significantly reduced ($P<0.0001$). Mice with CIA compared to CIA+Abx demonstrated significantly increased expression of β 1,4-galactosyltransferase 1 (GalT) and β -galactoside α 2, 6-sialyltransferase 1 (St6gal1), two enzymes important in mediating pathogenic antibody glycosylation. Administration of indole to mice with CIA+Abx resulted in significantly reversing the

protective effects of antibiotics both on disease severity and expression of GalT and St6Gal1. Treatment of CII-primed B cells with indole ex vivo also resulted in a significant induction of expression of these enzymes.

Conclusion: Our data demonstrate that the bacteria-produced metabolite indole significantly drives the development of CIA. While the glycosylation status of antibodies from mice in our treatment groups needs to be confirmed, these results strongly suggest that the mechanism is via induction of B cell glycosylation enzymes that modulate autoantibody effector function towards a proinflammatory profile. Targeting this pathway has potential clinical implications in treating and/or preventing RA.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Animal Models Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Paraoxonase 1 (PON1) is an HDL-associated protein, which hydrolyzes biologically active oxidized phospholipids and prevents oxidation of lipids in LDL and HDL. Increased lipid peroxidation and oxidative stress have been implicated in the pathogenesis of rheumatoid arthritis (RA), and we previously reported decreased inflammatory arthritis activity in PON1 transgenic (Tg) mice in 2 RA mouse models. The current work evaluated mechanisms for decreased inflammatory arthritis in PON1Tg mice using the K/BxN serum transfer model of RA.

Methods: The K/BxN serum transfer-induced arthritis model (STIA) was used in B6 mice homozygous for the PON1 human transgene [PON1Tg] and wild type littermate control mice [WT] (n= 10 per group). Non-STIA PON1Tg (n= 9) and WT (n=10) mice were also evaluated. Liquid chromatography–electrospray ionization, tandem mass spectroscopy was performed for a panel of 13 circulating bioactive lipid mediators (BLM) including TXB2, 6tl 2epi LTB4, LTB4, 15d-D12,14 PGJ2, 13 HODE, 9 HODE, 17S-HDHA, 15 HETE, 14 S-HDHA, 11 HETE, 12 HETE, 5 HETE, and 5-oxoETE. Next-generation RNA sequencing analysis was done on liver tissue. Histopathologic scoring of arthritic hind limbs was performed by a blinded reviewer as were the prior clinical arthritis activity scores.

Results: Marked reduction in histologic damage was observed in PON1Tg compared to WT mice (p values<0.0002; see Table) consistent with decreases in clinical arthritis scores. WT mice had significant increases in the majority of BLMs (11/13) after arthritis induction, however, PON1Tg mice did not have similar increases, and had significantly lower levels of 9/13 BLMs post-arthritis induction compared to WT mice (Table). Significant correlations were evident between lower levels of BLMs and lower clinical and histologic scores (r values = 0.5 - 0.8, p values < 0.05) for 10/13 BLMs. The hepatic glutathione metabolism pathway was 14-fold upregulated in PON1Tg mice versus WT mice after arthritis induction, controlling for baseline (non-arthritic) expression differences in PON1Tg and WT mice (Bonferroni p value < 1.5E-04). Increased expression of 7/8 genes in this pathway was significantly associated with decreases in circulating BLMs (r values = -0.5 - 0.8, p values <0.05; correlations of raw gene expression counts/various BLMs). Upregulation of GSTM3 (glutathione S-transferase mu 3) was highly correlated with both lower histologic damage scores (r = -0.8 - 0.9, p values <0.05) as well as trended with decreased clinical arthritis scores (r = -0.6, p = 0.09).

Conclusion: Overexpression of the human PON1 transgene in the KBxN STIA model of RA suppressed inflammatory arthritis, which correlated with upregulation of the hepatic glutathione pathway and reduction of circulating BLMs. Further investigation of these findings is warranted to evaluate potentially novel therapeutic targets for treatment of RA.

Session Title: Rheumatoid Arthritis – Etiology and Pathogenesis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Anti-citrullinated protein antibodies (ACPA) and inflammation characterized by neutrophil extracellular trap (NET)osis have been detected at mucosal sites such as the lung and periodontium in individuals at-risk for RA. We postulated that the intestine is an additional site for inflammation and ACPA generation in subjects at-risk for future RA.

Methods: Stool was collected from 16 healthy controls, 13 subjects with early RA (eRA) (<1 year), and 34 subjects at-risk for the future development of RA. At-risk subjects included individuals without inflammatory arthritis at or prior to the study visit and were first-degree relatives (FDRs) of RA probands (10 serum CCP+ and 9 CCP-) or non-FDRs who were

CCP+ (N=15). Stool was tested by ELISA for CCP3 IgA, total IgA, myeloperoxidase (MPO)-DNANET remnants, and calprotectin. Isotype-specific antibody coating of stool bacteria was determined by flow cytometry. The murine collagen-induced arthritis (CIA) model was treated with broad-spectrum antibiotics after induction of disease (day 21) to interrogate the microbiome's role in stimulating intestinal inflammation and autoantibodies. Antibodies to collagen (CII) were measured by ELISA, and tissue neutrophils were assessed by flow cytometry.

Results: Stool IgA CCP3 was detected in 30% of at-risk subjects and 38% of eRA, and was significantly increased in serum CCP3 IgG+FDRs, while those in the eRA group demonstrated significantly increased IgA-coating of bacteria in the stool samples compared to the other groups (Table 1). Neutrophil-driven mucosal inflammation was present in at-risk subjects, reflected by high calprotectin and NET-remnant levels. MPO-containing NET remnants, which are reported to be induced by bacteria, significantly positively correlated with stool IgA CCP3 ($r=0.3$, $P=0.004$). In mice with CIA, antibiotic treatment significantly reduced disease severity >95%, neutrophil recruitment to the intestine, and mucosal anti-CII IgA. Mucosal anti-CII IgA significantly correlated with serum anti-CII IgG ($r=0.33$, $P=0.03$).

Conclusion: These data implicate a role of intestinal microbiota and inflammation in the induction of mucosal ACPA in at-risk subjects and anti-CII antibodies in CIA. Local neutrophil-associated inflammation strongly correlates with the generation of ACPA IgA in the intestine of at-risk subjects. In eRA, IgA coating of bacteria is increased, suggesting that the earlier generation of intestinal ACPA may lead to increased targeting of specific bacteria. The CIA model confirms the necessity of bacteria in driving the mucosal autoantibody response as mice depleted of bacteria using antibiotics resulted in reduced neutrophils and autoantibodies. While more specific mechanisms need to be defined, we propose that intestinal mucosal responses in at-risk individuals are significantly involved in the progression towards RA in a subset of individuals.

Table 1. Results of stool testing in study groups

Study Group	Stool CCP3 IgA (U/ml)	ACPA Index (U/ml CCP3 IgA ÷ U/ml total IgA)	IgA Coated Bacteria (% of total)	MPO-DNA complex (U/ml)	Fecal Calprotectin (mg/kg)
Healthy controls	301 ± 68	0.25 ± 0.03	9.1 ± 3.2	6,042 ± 639	115 ± 68
Serum CCP+ IgG FDR	1256 ± 627*	1.25 ± 0.50*	8.8 ± 2.0	12,342 ± 2,567	334 ± 139
Serum CCP- IgG FDR	530 ± 211	0.40 ± 0.16	4.8 ± 2.2	13,545 ± 3,214*	833 ± 395*
Serum CCP+ IgG non-FDR	344 ± 63	0.35 ± 0.06	5.6 ± 1.0	8,848 ± 2,184	311 ± 84
eRA	720 ± 249	0.41 ± 0.13	20.4 ± 6.5*	13,159 ± 2,899*	278 ± 160

Session Title: Rheumatoid Arthritis – Etiology and Pathogenesis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Cardiovascular (CV) disease is the most common cause of morbidity and mortality in patients with rheumatoid arthritis (RA) [1, 2]. Traditional CV risk factors and chronic inflammation do not fully explain the increased CV predisposition observed in patients with RA [3]. In this regard, cumulative knowledge suggests that genetic factors may play a relevant role in this phenomenon [4]. To shed light onto the genetic background influencing the development of CV disease in patients with RA, we performed a genome-wide association study (GWAS) in a cohort of Spanish patients diagnosed with this condition.

Methods: After quality control filters, 2,989 Spanish patients with RA who fulfilled the 2010 American College of Rheumatology classification criteria [5] were analyzed. In addition, data on subclinical atherosclerosis, obtained by carotid ultrasonography (by assessment of carotid intima-media thickness-cIMT-and presence/absence of carotid plaques), was available for 1,355 of these patients.

Results: rs116199914 was identified as an intergenic variant associated with cIMT values at the genome-wide level of significance (minor allele (G): $\beta=0.142$, $P=1.86E-08$). In addition, suggestive signals of potential relevance were observed when both the presence/absence of CV events and subclinical atherosclerosis were evaluated, although none of them reached the genome-wide level of significance. Finally, a molecular pathway enrichment and a predictive protein-protein relationship analyses, including these suggestive GWAS signals, revealed a potential functional enrichment of the collagen biosynthesis network regarding the presence/absence of carotid plaques (GO:0032964, $P=0.0497$).

Conclusion: Our study suggests that the rs116199914 genetic variant is implicated in the increased CV risk observed in Spanish patients with RA.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Etiology and Pathogenesis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Disease clustering suggests a possible environmental cause. Rheumatoidarthritis (RA) is an autoimmune disease that may be triggered by environmental factors such as viruses. Influenza is a common viral infection worldwide. There is a laboratory confirmation that similar inflammatory cytokines and cells are involved in the pathogenesis of influenza and RA. Also, in subjects without RA, the presence of antibodies to influenza in recently exposed to influenza individuals is associated with the presence of rheumatoid factor. We estimated the distribution of early incident inflammatory arthritis over time. We examined whether and to what extent seasonal variations in influenza may be associated with inflammatory arthritis first symptom onset.

Methods: Canadian Early Arthritis Cohort (CATCH) is a prospective observational cohort study of adults with early (≤ 12 months) incident inflammatory arthritis. We included patients enrolled from January 2007 till January 2017. We used patient-reported date of first symptom onset as a proxy measure of IA onset in our study, and estimated the seasonal distribution of inflammatory arthritis (IA) onset for 10 years of observations. Influenza time series was based on laboratory confirmed influenza A & B retrieved from the Canadian Flu Watch surveillance program initiated in 2010. Bivariate analysis of influenza and IA was performed for 2010-2016 period using cross-correlations with different time lags, and time series Poisson regression with smoothing function to remove seasonality and long-term patterns in the exposure and outcome series. Both IA and influenza were recorded as monthly total frequencies.

Fig. 1. Average onset of inflammatory arthritis aggregated by season, 2006-2016

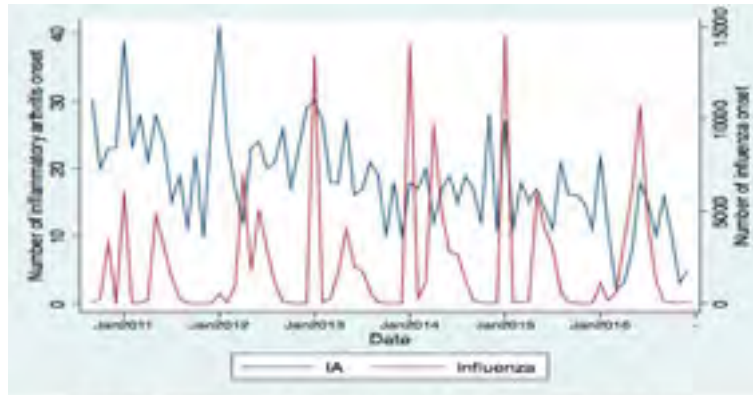

Fig. 2. Time series of inflammatory arthritis and influenza, 2010-2016

Results: 2519 patients with IA were included, 88% had confirmed RA. More IA onsets occurred in January though the difference between months was not significant. There were significantly more IA onsets in winter compared to other seasons (Figure 1). Bivariate time series analysis of IA and influenza revealed similar high-level patterns in the onsets in January (Figure 2). We found that influenza weakly correlated with IA onset. We estimated that every influenza onset was associated with on average 0.0023 % increase in IA onset ($p=0.04$).

Conclusion: Patient-reported IA symptom onset occurs more frequently in winter, when the immune system is more susceptible to infections. Peak periods of influenza outbreaks in Canada over 6 years were very weakly associated with an increase in IA onset.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Etiology and Pathogenesis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Malondialdehyde-acetaldehyde adducts (MAA) are products of oxidative stress that modify self-proteins and stimulate potent cellular and humoral immune responses. We have previously demonstrated that MAA adducts are present in lung and joint tissues from rheumatoid arthritis (RA) patients and colocalize with citrullinated

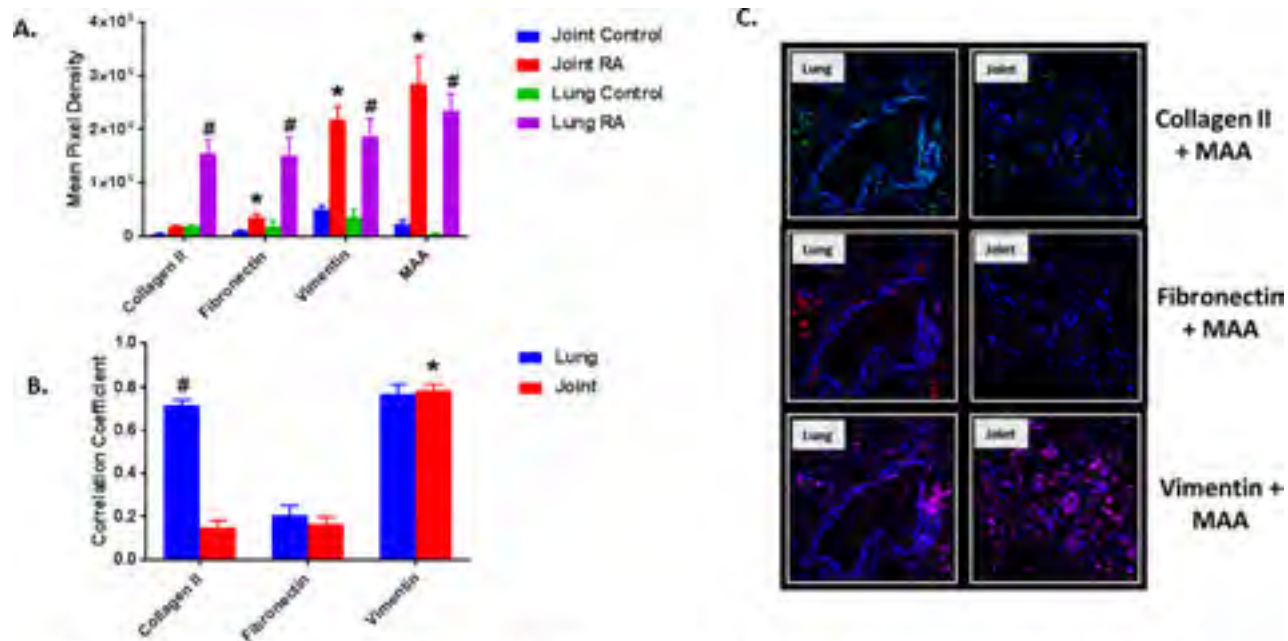

Figure 1 (A) Mean pixel density of malondialdehyde-acetaldehyde adducts (MAA) and extracellular matrix proteins in rheumatoid arthritis (RA) synovium and Lung compared to controls. (B) Correlation coefficients between Lung and joint tissue co-stained with MAA and Collagen II, Fibronectin, and Vimentin. (C) Representative lung RA-ILD and RA synovial tissue sections are depicted (blue = MAA, green = Collagen II, red = Fibronectin, purple = Vimentin).

proteins. Moreover, anti-MAA antibodies are associated with higher RA disease activity and extra articular features including interstitial lung disease (ILD). However, the adducted protein(s) driving these immune responses are unknown. Implicated as pathogenic target autoantigens; we characterized extracellular matrix (ECM) protein and MAA expression in RA lung and joint tissues.

Methods: Paraffin embedded joint tissues from osteoarthritis (OA) and RA patients (n=5 each) were stained for MAA, vimentin, fibronectin, and collagen II. Similarly, we stained non-paired lung tissues from subjects with RA-ILD and controls (n=3 each). Tissues were assessed with confocal microscopy and staining patterns were quantified using Zen and image J software. Co-localization of ECM proteins with MAA was determined using the Fiji plugin, Coloc2. Pearson's correlation coefficients were calculated and compared between disease groups for lung and synovium.

Results: MAA, vimentin, and fibronectin expression (but not collagen II) were all significantly higher in joint tissues from RA compared to OA patients (*P<0.001) **Fig 1A**. Colocalization of MAA with vimentin was significantly greater than that observed with other ECM proteins in RA synovium (*P<0.001) **Fig 1B/C**. In lung tissues, all 3 ECM proteins and MAA were all significantly increased in RA-ILD vs. normal controls (#P<0.03) **Fig 1A**. Colocalization of MAA with the ECM proteins (Collagen II and Vimentin) was increased in RA-ILD lung tissue. Similar to RA joint tissues, colocalization with MAA and vimentin was observed (R=0.77). However, collagen II was significantly increased (#P<0.001) in the lung compared to the joint **Fig 1B/C**.

Conclusion: Enhanced colocalization of critically important ECM proteins with MAA in diseased tissues, in addition to prior observations of increased anti-MAA antibody responses in RA, suggests a mechanistic role of MAA in RA synovial and lung disease. Moreover, these results suggest that interactions between MAA and ECM proteins are tissue dependent with MAA modification of vimentin potentially shared between the lung and synovium, while MAA modification of collagen may be more lung predominant.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Etiology and Pathogenesis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: There is a strong genetic association between RA and human leukocyte antigen (HLA) regions, particularly HLA-DRB1 alleles with the shared epitope (SE). SE alleles are associated with seropositivity, erosions and higher disease activity (DA) in RA. We evaluated the association between SE alleles and multiple poor prognostic factors (PPFs) of seropositive (anti-citrullinated protein antibody and/or RF) and erosive RA, and changes in DA.

Methods: We analyzed patients (pts) enrolled in a large sequential RA registry started in 2003; most had established RA and annual clinical evaluations. Pts with baseline (BL) data on SE status were included. A commercially available kit was used for HLA genotyping. HLA-DRB1 serotypes were assessed from DNA sequences using allele-specific polymerase chain reaction methods and categorized as pts with 0, 1 or 2 SE alleles. Association of multiple PPFs and SE status was evaluated using multinomial logistic models; association between change in DA and SE status was analyzed using linear regression models with age, sex, disease duration (DD), co-morbidities and biologic DMARDs as covariates.

Results: Of 689 pts with RA, 0, 1 and 2 SE alleles were reported in 241 (35.0%), 275 (40.0%) and 173 (25.1%) pts, respectively. At BL, pts with SE alleles (vs 0) were more likely to have PPFs and had longer DD and higher DA (Table 1). Odds ratio (OR) for seropositive erosive RA in pts with 2 and 1 SE alleles (vs 0) was 5.44 (95% CI 2.39, 12.39) and 2.87 (1.32, 6.23; Fig), respectively. OR for double seropositivity in pts with 2 and 1 SE alleles (vs 0) was 4.27 (95% CI 2.51, 7.28) and 2.56 (1.66, 3.94), respectively. In total, 551 pts had DA measures at BL and 1 year. After controlling for BL covariates, pts with SE (vs 0 SE) had a mean increase in DAS28 (CRP) of 0.24 ($p=0.031$), CDAI of 2.71 ($p=0.027$) and SDAI of 3.25 ($p=0.013$; Table 2).

Conclusion: Pts with SE alleles are more likely to have multiple PPFs; pts with 2 SE alleles are 5 times more likely to be seropositive with erosive RA and 4 times more likely to be double positive. Pts with SE alleles also had an increase in DA over time with standard-of-care treatment.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Etiology and Pathogenesis Poster I

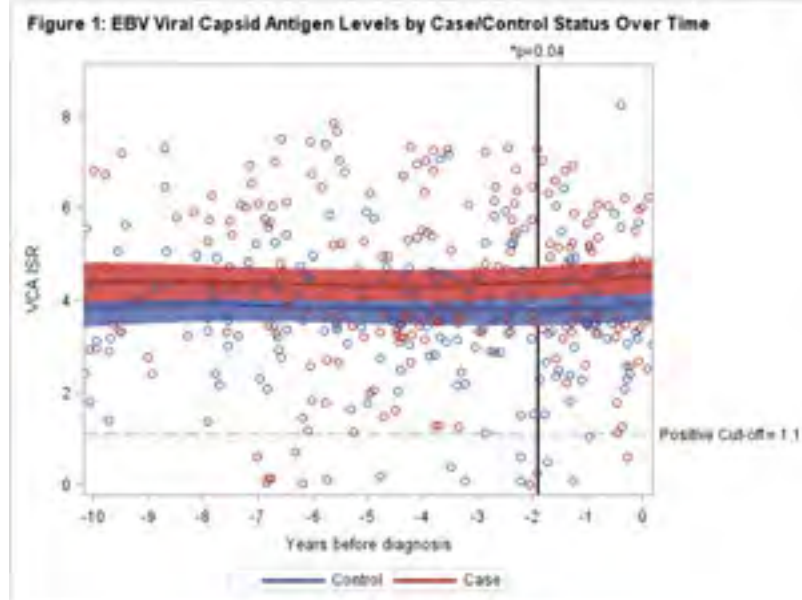

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: EBV infects B cells and is associated with several autoimmune diseases, including RA. Prior studies have shown that patients with active RA have altered immune responses to EBV, including elevated anti-viral capsid antigen (VCA) antibodies that indicate recent reactivation. We hypothesized that the abnormal response to EBV occurs in the preclinical period and contributes to the initial development of autoimmunity in subjects who develop RA.

Methods: Serum from military subjects who developed RA (n=83) and controls matched for age, race, sex, region, and timing of blood draw (n=83) was obtained from Department of Defense Serum Repository as previously described (1). All RA subjects met 1987 ACR revised criteria for RA or were diagnosed by a board-certified rheumatologist. Sera were tested for anti-EBNA-1 IgG (2), anti-VCA IgG (Wampole, Cranbury, NJ), and anti-CCP3.1 and RF IgM (both Inova, San Diego, CA) by ELISA. Statistical analysis was by Chi-square, t-test, and ANOVA. A mixed model compared EBV levels at one-year intervals followed by 1 month intervals to identify the time when levels differed significantly between cases and

Fig 1. Mixed model analysis of VCA levels between cases and controls for 10 years before diagnosis of RA. VCA shows significant divergence between cases and controls at -1 year and 11 months (1.9 years) prior to RA diagnosis [Cases: mean[SE] = 4.41(0.18) and Controls: mean[SE] = 3.81(0.18)]

	RA Case	Control	p value

†Average of repeated measures per individual (n=83 RA cases and n=83 controls)

controls ($P < 0.05$). Multiple comparison adjustment with a step down Holm-simulated method was used to control the family-wise type I error rate.

Results: Levels of VCA and EBNA-1 antibodies were significantly higher in RA cases vs controls over all visits, most notably in the pre-diagnosis period (Table 1). Analysis of EBV antibody levels in the 10 years prior to diagnosis showed VCA diverged 1.9 years before onset RA compared to controls (Fig 1), and EBNA-1 diverged at 3.5 years.

Conclusion: An altered immune response to EBV characterized by relatively elevated EBNA-1 and VCA antibodies is seen in pre-clinical RA. Elevated anti-VCA antibodies suggests that viral reactivation may contribute to the future development of RA. Further studies are needed to assess the complex lifecycle of EBV and immune regulation of viral infection in the pre-clinical period and the role in promoting RA-related autoantibody and classified disease development.

Circular RNAs Expression Profile in Chinese Rheumatoid Arthritis Patients at Different Disease Activity

Huan Liu, Qibing Xie and Geng Yin, Department of Rheumatology and Immunology, West China Hospital, Sichuan University, Chengdu, China

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Etiology and Pathogenesis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is an autoimmune-mediated chronic inflammatory joint disease, that is still no clear pathogenesis for patients to be cured in a timely manner. Circular RNAs (circRNAs) have been recently

Spearman correlation test of clinical variables and confirmed circRNAs from RA patients at different disease activity

	ESR	CRP	RF	Anti-CCP	HAQ	Pain_VAS	DAS28	CDAI	SDAI
CircRNA_02235	.004	-.309**	-.092	-.080	-.230*	.283**	-.363**	-.299**	-.350**
CircRNA_19131	-.159	-.407**	-.008	-.040	-.434**	.470**	-.501**	-.514**	-.542**
CircRNA_29264	-.073	-.332**	.001	.002	-.326**	.340**	.439**	-.397**	-.422**

Note: ESR: Erythrocyte sedimentation rate; CRP: C-reactive protein; RF: Rheumatoid factor; Anti-CCP: Anti-cyclic citrullinated peptide antibody; HAQ: Health assessment questionnaire; Pain_VAS: Visual analogue scale pain score; DAS28: Disease activity score in 28 joints; CDAI: Clinical disease activity index; SDAI: Simplified disease activity index

* $P < 0.05$, ** $P < 0.01$

identified as non coding RNAs in most common model organisms and show potential as gene regulators. Here, we profiled the circRNAs expression of RA at different disease activity to improve our understanding of RA pathogenesis.

Methods: Expression profiling was performed by high throughput sequencing using whole blood RNA samples obtained from 12 RA patients. In each group there were 3 patients at low, moderate, high disease activity, respectively, as well as 3 healthy controls. Quantitative real time reverse-transcription polymerase chain reaction (qRT-PCR) was used to identify the differential circRNAs. Spearman correlation test assessed the correlation of circRNAs and clinical variables.

Results: Compared to health controls, a total of 155 circRNAs and 161 circRNAs were significantly upregulated and downregulated, respectively, in RA patients. qRT-PCR detection showed that the expression levels of downregulated circRNA_29264 (hsa_circ_0007889), upregulated circRNA_19131 (hsa_circ_0003123) decreased as the disease activity increased, upregulated circRNA_02235 was higher in remission than other disease activities. The correlation test showed the negative correlation among three circRNAs and C-reactive protein (CRP), health assessment questionnaire (HAQ), VAS pain score, disease activity score in 28 joints (DAS28), clinical disease activity index (CDAI) and simplified disease activity index (SDAI), respectively.

Conclusion: This work illustrates that circRNAs dysregulation may play a role in RA pathogenesis, and three key circRNAs show promise as candidate biomarkers for development of RA.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Etiology and Pathogenesis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The Dual specificity protein phosphatase 22 (*DUSP22*) gene is aberrantly methylated in mononuclear cells in RA, and it has been associated with erosive disease. Increased serum IL-6 and phosphorylated STAT3 levels, which are negatively regulated by *DUSP22*, have been found in T cells of patients with anti-citrullinated peptide autoantibody (ACPA)-negative RA. Pathogenic mechanisms underlying different serotypes in RA are poorly understood. Here, we aim to determine whether plasma nuclear circulating cell-free DNA (ccfDNA) can be used to study DNA methylation of *DUSP22* and whether it is associated with serotype and other clinical features of RA.

Methods: This is an exploratory study in which we recruited 21 patients who satisfied the ACR criteria for RA. They were further classified in 14 seropositive (ACPA+ and/or RF+), and 7 seronegative patients (ACPA- and RF-). DNA was extracted from isolated plasma, bisulfite converted and pyrosequenced to determine DNA methylation levels in the promoter region of *DUSP22*. Statistical analysis was carried out to determine whether *DUSP22* DNA methylation in plasma correlated with serotype, index disease activity (CDAI), Simple Erosive Narrowing Score (SENS), Visual Analogue Scale (VAS), neuropathic pain (IDpain), Toronto Clinical Neuropathy Score (TCNS), Neuropathy Symptom Score (NSS), treatment (DMARDs, anti-TNF alpha), and disease duration. Variables were also analyzed by serotype status and the groups were compared using non-parametric tests.

Results: Hypomethylation of the *DUSP22* promoter was correlated with an increase in SENS ($p=0.02$), and NSS ($p=0.03$) in all RA patients. We found that *DUSP22* DNA methylation did not vary for the different treatment groups. While no statistically significant difference was determined in the DNA methylation of *DUSP22* between seronegative and seropositive patients, hypomethylation of *DUSP22* in seropositives was negatively and significantly correlated with years of disease ($p=0.002$), SENS ($p=0.04$), and NSS ($p=0.002$). We also found seronegative there was only significantly correlated with NSS ($p=0.017$).

Conclusion: While our study has a small samples size, it is the first study to demonstrate that DNA methylation can be measured in ccfDNA of RA patients. We also found that hypomethylation of *DUSP22* was correlated with erosive disease, disease duration and neuropathic pain in seropositive patients, and only with neuropathic symptoms in seronegative patients.

Elevated Oxylipin Profile in Autoantibody-Positive Individuals at-Risk of Developing Rheumatoid Arthritis

Vidyanand Anaparti¹, Irene Smolik², Tanja Winter³, Xiaobo Meng⁴, Harold Aukema³ and Hani El-Gabalawy⁴, ¹Internal Medicine, University of Manitoba, Winnipeg, MB, Canada, ²Arthritis Center, University of Manitoba, Winnipeg, MB, Canada, ³Food and Nutritional Sciences, University of Manitoba, Winnipeg, MB, Canada, ⁴University of Manitoba, Winnipeg, MB, Canada

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Etiology and Pathogenesis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Preclinical phase of rheumatoid arthritis (RA) is characterized by presence of autoantibodies, including anti-citrullinated protein antibodies (ACPA), years before disease onset. Epidemiological observations suggest that high levels of total ω-3 fatty acids are significantly associated with lowering RA transition rate in autoantibody-positive individuals [1]. Fatty acids (FA) and their oxygenated eicosanoid metabolites (oxylipins) regulate systemic inflammatory

responses and pro-inflammatory gene expression leading to orchestration of chronic inflammatory cascade[2]. Over the last 15 years, we longitudinally followed genetically-susceptible Indigenous North American (INA) population with a disproportionately high RA risk (~2-3fold) and increased autoantibody prevalence. In this study, we examined the circulating levels of FA and their oxylipins in RA patients and their asymptomatic ACPA+ and ACPA- first-degree relatives (FDR) from this cohort to understand the role of these metabolites in preclinical RA pathogenesis.

Methods: Gas chromatography (GC) was used for FA estimation in serum samples from age-matched ACPA+ RA patients (N=10), ACPA- FDR (N=10), and ACPA+ FDR (N=53). Oxylipins were extracted and quantified using high performance liquid chromatography – tandem mass spectrometry (HPLC/MS/MS).

Results: We observed an overall increase in unsaturated and ω -6 FA levels in all the study subjects. The ω -3 index (% EPA + DHA) in these individuals was ~5-6% of total FA suggesting an intermediate risk category for coronary heart disease and inflammation. No significant differences were observed in circulating FA levels between RA patients and ACPA- FDRs. Serum eicosanoid profiling identified enrichment of 41 oxylipins (out of 77 mapped metabolites) in ACPA+ FDR compared to RA patients and ACPA- FDR (Mann-Whitney U test). Of these, 9-HODE and 13-HODE were significantly elevated in ACPA+ FDR compared to ACPA- FDR (~55-fold and ~41-fold respectively; $P < 0.0000000001$) and RA patients (~32-fold and ~22-fold respectively; $P < 0.0000000001$). While usage of NSAIDs had no effect on total oxylipin levels, samples stored at -20°C for >5yrs demonstrated significant oxylipin enrichment (*** $P=0.0006$). After correcting for duration of storage effects, we still observed an elevated oxylipin profile in ACPA+ FDR compared to other groups.

Conclusion: Our study demonstrates a distinct FA and oxylipin profile in asymptomatic ACPA+ FDR of INA RA patients and suggests that changes in the specific eicosanoids and their oxygenated metabolites are involved in the development of ACPA and/or the transition to clinically imminent RA in ACPA+ individuals.

Whole Blood Targeted Bisulfite Pyrosequencing Identifies Differentially Methylated Regions within Major Histocompatibility Complex (MHC) of Patients with Rheumatoid Arthritis

Vidyanand Anaparti¹, Irene Smolik², Praseon Agarwal³, Neeloffer Mookherjee¹ and Hani El-Gabalawy⁴, ¹Internal Medicine, University of Manitoba, Winnipeg, MB, Canada, ²Food and Nutritional Sciences, University of Manitoba, Winnipeg, MB, Canada, ³Physiology and Pathophysiology, University of Manitoba, Winnipeg, MB, Canada, ⁴University of Manitoba, Winnipeg, MB, Canada

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Etiology and Pathogenesis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Human major histocompatibility complex (MHC) is strongly associated with rheumatoid arthritis (RA) pathogenesis. Epigenome-wide association study by Liu et al showed that differential DNA methylation within the MHC region can mediate RA genetic risk and contribute significantly to disease susceptibility [1]. Our study objective was to validate Liu et al study findings in an independent study cohort genetically predisposed for developing clinically imminent RA. Therefore, we sequenced MHC-specific methylated CpGs in autoantibody-positive RA patients and matched disease-free healthy controls from a high-risk indigenous North American (INA) population.

Methods: DNA was isolated from whole blood (WB) samples and targeted bisulfite pyrosequencing was used to profile methylated CpGs. Differentially methylated CpG loci (DMLs) were mapped and gene-annotated using R package. mRNA expression of identified genes with multiple DMLs was verified using quantitative real-time PCR (qPCR) in an independent cohort of RA patients and HCs.

Results: We identified 74 uniquely methylated CpG sites within the MHC region that were differentially methylated in the WB of RA patients ($q < 0.05$), compared to HCs. Of these, 36 DMLs were located on 19 genes. IPA network analyses showed these genes regulate NF- κ B complex and processes involved in antigen presentation, immune cell crosstalk and inflammation in autoimmunity and insulin-dependent diabetes mellitus. By qPCR, we also demonstrated a deregulated expression of mRNAs corresponding to *C6ORF10*, *TNXB* and *HCG18*.

Conclusion: Our results demonstrate presence of specific differentially methylated loci within the genomic region encompassing MHC region in whole blood DNA of indigenous RA patients. While some of these genes (*C6ORF10* and *TNXB*) confirm the findings of previous publication, we believe they might be involved in RA pathogenesis in high-risk INA individuals.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Etiology and Pathogenesis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: In neutrophils, peptidylarginine deiminase 4 (PAD4) citrullinates histones allowing chromatin unraveling and neutrophil extracellular trap (NET) formation. NETs are increased and display proteins targeted by autoantibodies in rheumatoid arthritis. Interestingly, antibodies against citrullinated histones are among the first autoantibodies detected in rheumatoid arthritis. Thus, PAD4 may contribute to the development of rheumatoid arthritis by inducing NETs and ultimately autoantibodies. Murine studies have demonstrated that PAD4-deficient mice have reduced NETosis, autoantibodies, and inflammatory arthritis, but the effects of a loss of PAD4 in humans is unknown. Recently it has been shown that the G allele of single nucleotide polymorphism (SNP) rs2240335 in *PADI4* is associated with decreased expression of PAD4 in human neutrophils in healthy Caucasians. The purpose of this study is to determine if the G allele of rs2240335 correlates with reduced NETs and autoantibodies against citrullinated histones in humans, similar to the PAD4 knockout studies in mice.

Methods: DNA, plasma, and serum from subjects with rheumatoid arthritis, both anti-cyclic citrullinated peptide (CCP) antibody negative (n=44) and positive (n=71), and controls (n=28) were obtained from our biorepository. Subjects were ~90% Caucasian. DNA was genotyped at rs2240335. Plasma from controls homozygous at rs2240335 was subjected to an enzyme linked immunosorbent assay (ELISA) to quantify circulating NETs. Serum from rheumatoid arthritis subjects homozygous at rs2240335 was subjected to ELISA to quantify IgG that binds native histones and histones *in vitro* citrullinated with human PAD4. Results were compared between genotypes using a student's t test and verified by a permutation routine.

Results: The concentration of circulating NETs is significantly lower in controls homozygous for the G allele at rs2240335 compared to homozygotes for the T allele ($p=0.027$). In CCP+ rheumatoid arthritis subjects, there was no significant difference in anti-native and anti-citrullinated histone H1, H2A, H2B, H3, and H4 antibody levels between genotypes. However, for CCP- rheumatoid arthritis subjects, anti-citrullinated histone H2B ($p=0.036$) and H3 ($p=0.0041$) and anti-native histone H2A ($p=0.0064$), H2B ($p=0.0073$), and H3 ($p=0.030$) antibody levels were decreased in subjects with the GG genotype.

Conclusion: Similar to studies in PAD4-deficient mice, the G allele of SNP rs2240335, which has been shown to be associated with reduced PAD4 expression in human neutrophils, correlates with reduced NETosis in controls and reduced anti-histone antibodies in CCP- rheumatoid arthritis. Further studies are needed to determine if this allele is associated with rheumatoid arthritis risk in Caucasians.

Decreased B Cell Ataxia-Telangiectasia Mutated Expression and Receptor Diversity Identify a Subset of Rheumatoid Arthritis Patients with Increased Joint Erosion Prevalence

Kofi Mensah¹, Jean-Nicolas Schickel², Isabel Isnardi² and Eric Meffre², ¹Section of Rheumatology, Yale University School of Medicine, New Haven, CT, ²Department of Immunobiology, Yale University School of Medicine, New Haven, CT

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Etiology and Pathogenesis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: A skewed B cell receptor (BCR) repertoire was observed in some RA patients. In these patients, BCR κ light chains contain a higher percentage of downstream V κ and upstream J κ gene segments rather than the broader utilization of V κ -J κ gene segments seen in healthy donor (HD) controls. How this BCR phenotype occurs and whether it relates to erosive disease is unclear.

Methods: Peripheral blood B cells were obtained from 40 seropositive RA patients meeting ACR classification criteria. V κ and J κ gene segment usage was determined by PCR and allowed patients to be separated into two groups. Erosive disease prevalence was compared between the groups. Gene microarray was done on B cells from each group to determine candidate genes for further investigation and we developed *in vitro* and *in vivo* models based on this to investigate mechanisms for the observed differences.

Results: We identified a subgroup of RA patients whom we call group I in which BCR κ light chains contain a higher percentage of downstream V κ and upstream J κ gene segments compared to HD controls suggesting abnormalities in RAG-mediated BCR V(D)J rearrangement. BCRs in a second subgroup, group II, had broader utilization of V κ -J κ gene segments similar to that of HD. B cell gene array showed decreased ataxia-telangiectasia mutated (*ATM*) in group I vs group II. *ATM* is a key regulator of DNA double-strand break repair, RAG expression, and BCR κ locus allelic exclusion during RAG-induced V(D)J rearrangement. Intriguingly, group I RA patients had a higher prevalence of erosive disease despite no differences in age, disease duration, RF, or ACPA titers between the groups. To determine if lack of functional *ATM* independent of other RA disease factors could explain the increased erosive prevalence in group I, we pharmacologically inhibited *ATM* *in vitro* in HD control B cells and found increased pro-osteoclastogenic B cell *RANKL*, *IL6* and *TNF* expression and decreased anti-osteoclastogenic *OPG* and anti-inflammatory *IL10* expression. To determine if decreased B cell *ATM* expression in the absence of RA disease could account for the skewed BCR V κ -J κ segment usage in RA group I, we examined B cells from ataxia-telangiectasia (A-T) patients lacking *ATM*. BCRs from A-T patients showed the same skewed V κ -J κ gene segment usage seen in group I RA patients. We utilized the NSG “humanized” mouse model transplanted with non-RA human hematopoietic stem cells to examine developing human bone marrow B cells undergoing V(D)J recombination. *ATM* inhibition led to an increased immature B cell CD69⁺CXCR4⁺ phenotype indicative of retention in the bone marrow and an increased proportion of BCRs expressing λ light chains with evidence of κ chain deletion.

Conclusion: We have identified a novel way of subgrouping RA patients. Group I RA patients lack broad BCR V κ -J κ gene segment utilization, which can be explained by relatively insufficient B cell *ATM* expression. Lack of sufficient functional B cell *ATM* can also explain the increased erosive disease prevalence in group I compared to group II RA patients. Thus, subgrouping RA patients in the manner presented here has important implications for diagnosis, prognosis and treatment.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Etiology and Pathogenesis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Seropositivity for anti-citrullinated protein antibodies (ACPA) and rheumatoid factor (RF) is a hallmark of RA and can be present years before clinical onset has become apparent. Environmental factors, including smoking and chronic inflamed mucosal tissues of the lungs, gastro-intestinal tract or oral cavity (i.e. the periodontium), are suggested to contribute to initiation of these autoantibodies. While it is known that the inflamed periodontium contains citrullinated proteins and peptides, only Harvey et al. (2013) showed that IgG ACPA is indeed present in the periodontal exudate (n=9). As the IgA isotype is specific for mucosal immunity, we assessed in patients with and without RA whether IgA RF and IgA ACPA are present gingivocrevicular fluid (GCF), the periodontal inflammatory exudate.

Methods: RA patients fulfilling the ACR/EULAR 2010 classification criteria were recruited at the Rheumatology department of the Dr. Sardjito General Hospital, Yogyakarta, Indonesia. Patients without RA (non-RA) were recruited from the Oral Surgery department of the same hospital. Patients with diabetes or cardiovascular disease were excluded. Periodontitis was defined as periodontal inflamed surface area (PISA)>130 mm² (Leira et al. 2017). RF and ACPA were determined by ELISA in serum (IgM RF, IgA RF, IgG ACPA, IgA ACPA) and GCF (IgA RF, IgA ACPA). In addition, total IgA and IgG were determined in GCF. IgA ACPA seropositivity and IgA RF- and IgA ACPA positivity in GCF were defined as >mean+2SD of healthy controls (non-RA patients, never smokers, no periodontitis, n=88).

Results: In non-RA patients (n=151), PISA was correlated with total IgG and IgA in GCF (p<0.0001). IgA RF and IgA ACPA were present in GCF and correlated with total IgA in GCF (p<0.05 and p<0.01 respectively). In contrast to RA patients (n=72), IgA RF and IgA ACPA in GCF of non-RA patients were not correlated with IgA RF or IgA ACPA in serum. In non-RA patients, IgA ACPA positivity in GCF was more frequent in ever smokers (18%) than in never smokers (9.8%), the same held for presence or absence of periodontitis (18 and 9.3% IgA ACPA positivity in GCF respectively). Moreover, in non-RA patients PISA was correlated with IgA ACPA in serum (p<0.01) and GCF (p=0.05).

Conclusion: In non-RA patients, RA-associated autoantibodies are present in GCF, and are presumably the result of local formation due to periodontitis. Local production of autoantibodies may contribute to onset of RA.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Etiology and Pathogenesis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Arthralgia in patients who are seropositive for rheumatoid factor (RF) and anti-citrullinated protein antibodies (ACPA) is a precursor to rheumatoid arthritis (RA) in some but not all patients. The factors which influence progression and outcomes in these patients remain to be fully defined. The aim of this study was to evaluate outcome and prognostic factors in a consecutive cohort of patients with seropositive arthralgia undergoing arthroscopy.

Methods: We performed a prospective study of consecutive patients seropositive for RF and/or ACPA, with arthralgia, presenting to our outpatient clinic. Demographic and clinical measures were collected and synovial biopsy was performed by needle arthroscopy to score macroscopic and microscopic changes. The degree of synovitis and vascularity were recorded on a 0–100-mm visual analog scale, and chondroscopy on a semi-quantitative scale from 0–3. Patients were then followed up at 3 monthly intervals and the time of diagnosis recorded. Mann-Whitney U test was used to compare groups. Spearman's Rank Correlation Coefficient was used to assess for associations between biometrics and demographic and clinical markers. GraphPad Prism Version 7 and IBM SPSS Statistics Version 24 were used for data analysis.

Results: 33 patients were recruited. Mean (SD) age was 54 (12) years. 22 (67%) were female. 27 (82%) were positive for RF and 30 (91%) for ACPA with 24 (73%) dual positive. Mean (SD) follow-up was 29 (10) months. Baseline characteristics are shown in Table 1. Final diagnosis was RA in 24 (73%), psoriatic arthritis in 2 (6%), connective tissue disease in 1 (3%), calcium pyrophosphate arthritis in 1 (3%), and remained seropositive arthralgia in 5 (15%). Baseline CRP was significantly higher in patients who developed rheumatoid arthritis than those who remained seropositive arthralgia, mean (SD) 9.63 (16.63) vs 1.40 (0.55) mg/dL ($p=0.005$). CRP was elevated in 9/24 RA patients (range 1–64 mg/dL), and 0/5 who remained seropositive arthralgia (range 1–2 mg/dL). Macroscopic synovitis and vascularity were both significantly higher in those who developed RA than in those who remained arthralgia only, mean (SD) 60 (25) vs 28 (13) mm ($p=0.009$) and mean (SD) 56 (26) vs 26 (13) mm ($p=0.012$) respectively. Baseline DAS28-CRP, tender joint count, swollen joint count, and patient global assessment were not different between the groups. Baseline synovial cell immunophenotyping did not predict final diagnosis.

Conclusion: The majority of seropositive arthralgia patients developed RA. Elevated baseline CRP and macroscopic synovitis and vascularity scores at arthroscopy predict the future development of RA.

Table 1. Baseline Characteristics of 33 Patients with Seropositive Arthralgia

Age, years	54 (12)
Sex, female, n (%)	22 (67%)
Tender Joint Count	3 (6)
Swollen Joint Count	0 (0)
Patient Global Assessment (mm)	47 (28)
DAS28-CRP	3.42 (1.34)
Arthroscopic synovitis (mm)	56 (26)
Arthroscopic vascularity (mm)	53 (26)

Data expressed as mean (SD) unless otherwise specified.

Additive Effects of Functional Rheumatoid Arthritis (RA) LBH Risk Alleles on LBH Gene Transcription

Gyrid Nygaard, Deepa Hammaker, David L. Boyle and Gary S. Firestein, Medicine, University of California San Diego, La Jolla, CA

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Etiology and Pathogenesis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: *LBH* (Limb-bud and heart development gene) is dysregulated in RA, with a SNP associated with increased RA risk located in an upstream enhancer. This mutation decreases *LBH* gene transcription in FLS and *Lbh* deficiency in the passive K/BxN arthritis model increases disease severity. To understand the functional significance of *LBH* SNPs, we investigated the individual and combined effects of additional SNPs on *LBH* regulation.

Methods: FLS cultures were established from RA synovium obtained at the time of arthroplasty. Search of UCSC Genome Browser, NCBI dbSNP database and NIH GWAS Catalog identified two new *LBH*-associated SNPs, SNP1 and SNP2, that are modestly protective in RA. The two SNP1 (rs7579944) and SNP2 (rs1355208) are 300 bp apart in an intergenic region 9371 and 9071 bp upstream of the *LBH* TSS, respectively. Genomic DNA containing individual or combined RA Risk (Ref1 and -2) or RA Protective SNP1 and -2 alleles of *LBH* were cloned into minimal promoter pGL4.23-luciferase constructs. For luciferase assays, the control plasmids and single or combined Refs and SNPs plasmids (Ref1, SNP1, Ref2, SNP2, Ref1/Ref2 and SNP1/SNP2) were co-transfected into cultured RA FLS by nucleofection. Firefly luciferase activity was normalized to *Renilla*. Samples with minimal luciferase expression due to inadequate transfection efficiency were eliminated from the analysis.

Results: Transfection of FLS with 5 of the 6 constructs increased transcriptional activity of the minimal promoter by 2.2-2.6 fold, with no significant differences between Ref1, SNP1, Ref2, SNP2, or SNP1/SNP2 from each other. Surprisingly, the increase in luciferase activity was significantly less with risk-associated Ref1/Ref2 combination compared with the protective SNP1/SNP2 construct (1.8 ± 0.2 fold compared with 2.3 ± 0.2 fold of the minimal promoter, $p=0.0096$, $n=7$). This pattern remained the same after stimulation with TGF β 1 (1 ng/ml, 18 hr) or IL-1 β (2 ng/ml, 18 hr), even though these cytokines decrease the *LBH* gene expression in RA FLS. The NIH LDlink analysis tool showed that SNP1 and SNP2 have high linkage disequilibrium ($D>0.99$), with 44% of the population having the combined Refs and 39.7% having the combined RA protective SNPs.

Conclusion: The combination of two RA Risk *LBH*-associated SNPs significantly decreased transcriptional activity compared to the individual SNPs or combination of the two corresponding protective alleles. These results correlate with the protective effect of *LBH* in arthritis and suggest that the mechanism of RA protection with the combination SNP1/SNP2 is higher *LBH* transcription compared with the risk alleles. Therefore the genetic risk conferred by individual *LBH* alleles is additive and underscores the importance of their combinatorial contributions to RA susceptibility.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Etiology and Pathogenesis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: To describe the fecal microbiome profile in RA patients and analyze the mechanisms involved in the pathogenesis of RA

Methods: Design: Controlled, observational, cross-sectional study of established RA cohort.

Patients: Forty consecutive RA patients (ACR/EULAR 2010 criteria) >16 years, selected from a prospective inception cohort (diagnosis of RA between 2007-2011) and 40 sex-age matched healthy controls. Subjects with antibiotics, probiotics, initiation of a new therapy in the previous 3 months or other autoimmune diseases were excluded. Protocol: Cases and

controls were evaluated by a rheumatologist. Clinical data of disease activity were collected during the follow-up and analytical values were determined. Fecal samples were frozen within 24 hours of collection. All participants signed informed consent.

Main outcome: *Fecal samples exam.* Microbial DNA was extracted from fecal samples using QIAamp DNA stool Mini kit. The concentration and quality of DNA was determined by Nanodrop. **Secondary outcome:** Average DAS28-ESR during the follow-up, HAQ, RF, ACPA and erosive status. **Other variables:** Demographic, clinical-analytical and therapies (DMARDs).

Statistical analysis: Analysis of microbiota profile: UniFracPCoA(Principal Coordinate Analysis) was performed with the abundance data of operational taxonomic units (OTU) by means of the variance-covariance matrix implemented in Quantitative Insights Into Microbial Ecology(QIIME). The relative abundance of each OTU (taxa) was compared using a Wilcoxon test. The variations of abundance and diversity were compared by statistical analysis of an ANOSIM pathway with PAST and the differences were with $P < 0.05$. The calculation of α and β -diversity was carried out using QIIME.

Results: Most of subjects were women (75%) with a mean age of 59 years. In RA patients, the average DAS28 was 3.6 (table 1). β -diversity data showed that patients tend to differ from healthy subjects according to their microbiota ($p = 0.07$). Patients with RA exhibited decreased gut microbiome diversity compared with controls, although was not statistically significant. Regarding in species richness, the analysis suggested an increase of the *Collinsella aerofaciens* species and enterococcus genera in patients compared with controls. Likewise, an increase of arginine deaminase activity was observed, which belonged, in approximately 90%, to the RA genes of the genus *Collinsella*. Also, we observed a decrease in other bacterial lineages. On the other hand, RA patients showed an altered metabolic capacity for the transport of zinc and copper in comparison with controls.

Conclusion: These observations suggest a dysbiosis in RA patients, resulting from the abundance of certain bacterial (i.e. *Collinsella*) and decrease of other bacterial lineages. These alterations could influence in a significant way, by enzymatic or metabolic mechanisms, in the perpetuation of the autoimmunity of the disease.

Table 1.

VARIABLE	RA n=40	Control n=40	P - VALUE

The Risk of Developing Rheumatoid Arthritis Based on HLA-DQ Genotypes

Sami B. Kanaan¹, Oyku Sensoy² and J. Lee Nelson³, ¹Clinical Research Division, Fred Hutchinson Cancer Research Center, SEATTLE, WA, ²Clinical Research Division, Fred Hutchinson Cancer Research Center, seattle, WA, ³Fred Hutchinson Cancer Research Center, Seattle, WA

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Etiology and Pathogenesis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The strongest genetic risk for rheumatoid arthritis (RA) is contributed from the HLA region. RA-risk associated *HLA-DRB1* alleles including *04:01/4/5/8, *01:01, *10:01, and *14:02 code for the ‘Shared Epitope’ (SE) motif of the DRβ1 third hypervariable region. In an individual’s genotype, different combinations of SE and non-SE alleles contribute differently to RA-risk, as has been delineated in a table of Odds Ratios (OR) in a prior publication (1). Other studies have pointed to the importance in RA of specific *DQA1-DQB1* allele combinations in linkage disequilibrium (LD) with SE alleles that have been referred to as DQ5.1, DQ7.3, and DQ8 (2, 3). Interestingly, these particular DQ molecules, but not other DQs or DRs, bind certain peptides involved in autoantibody-positive RA (3). In the current study we investigated RA risk according to the DQ genotype and evaluated combinations of DQ molecules for hierarchy in RA risk.

Methods: 314 RA patients meeting 1988 ACR criteria and 316 controls from Washington State (USA) and the surrounding area were genotyped for *DRB1-DQA1-DQB1* haplotypes. *DQA1* and *DQB1* combinations were classified into 10 groups based on functional relevance and most frequent LD with *DRB1*: DQ5.1 (LD: *DRB1**01), DQ5.2/3 (LD: *DRB1**14 and *16), DQ6.1/2 (LD: *DRB1**15), DQ6.3/4/5/9 (LD: *DRB1**13, RA protective), DQ2 (LD: *DRB1**03 and *07, both RA protective), DQ7.3 (LD: *DRB1**04), DQ7.5/6 (LD: *DRB1**11 and *12), DQ8 (LD: *DRB1**04), DQ9 (LD: *DRB1**07 and *09), and DQ4 (LD: *DRB1**08). ORs for RA-risk were calculated for 48 of 55 possible combinations accounting for 97% of subjects.

Results: The genotypic OR [and 95% confidence intervals] for developing RA based on DQ ranged from 24.9 [4.63–259.0] to 0.16 [0.04–0.64]. The risk was generally significant when an individual carried simultaneously 2 of the 3 DQs in linkage with the SE (DQ5.1, DQ7.3 and DQ8), and was alleviated when the second DQ was no longer of those 3. DQ2 provided significant protection when combined with itself, DQ6.3/4/5/9, or DQ7.5/6, which are in linkage with *DRB1* alleles previously associated with protection against RA.

Conclusion: The risk of developing RA is influenced by both *HLA-DQ* alleles in the genotype. ORs varied according to particular combinations of DQ molecules. These observations considered along with recognition that HLA molecules present peptides derived from other (self) HLA molecules point to likely functional significance of *HLA-DQ* molecules in RA risk.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Etiology and Pathogenesis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Anti-citrullinated protein antibodies (ACPA) are predictive markers with pathological effects in rheumatoid arthritis (RA) development. Previous studies of ACPA-positive patients with musculo skeletal complaints (mainly arthralgia), but no arthritis, have shown increased risk for arthritis onset. However, these studies used clinical definition of arthritis, but did not exclude those subjects with ultrasound-detected subclinical arthritis. We aimed therefore to investigate risk factors for developing arthritis in ACPA-positive subjects with musculoskeletal complaints in the absence of any clinical and ultrasound signs of arthritis.

Methods: Patients presenting with musculoskeletal complaints and positive Anti-citrullinated protein antibody (ACPA) test in primary care were referred to the Rheumatology Clinic at Karolinska Hospital. Patients lacking arthritis by clinical and ultrasound examination (defined as synovial hypertrophy with Doppler activity) were recruited into the Risk-RA research program. A total of 66 subjects included between years 2015 up to December 2016 were analysed in this study. Blood samples from inclusion have been analysed for thirteen ACPA reactivities (citrullinated peptides from fillagrin, fibrinogen, alfa-enolase, vimentin, histones) using microarray based on ImmunoCap ISAC. DNA samples have been analysed for HLA-SE risk gene using DRlow-resolution kit (2-digit).

Results: A high proportion of the Risk-RA subjects, 41% (27 out of 66), developed clinical and/or ultrasound-detected arthritis during a median follow up of 8 months while 59% (39 out of 66) subjects didn't developed arthritis during a median follow up of 25 months.

No differences in characteristics at inclusion were observed between subjects developing and those not developing clinical and/or ultrasound-detected arthritis (table 1). Interestingly, subjects developing arthritis had higher concentration of anti-CCP and number of tender joints as compared to those not developing arthritis, but the difference did not reach statistically significance.

In contrast, subjects developing arthritis had a higher number of ACPA-reactivities (mean 6) than those not developing arthritis (mean 3, t test, $p < 0.05$). A significant difference in occurrence of a HLA-SE risk-gene was detected with subjects developing arthritis being more often carrier of such risk-gene (86%) as compared to those not developing arthritis (56%, chi-square test, $p < 0.05$). Cox proportional hazards regression accounting for the time of follow-up showed a HR for arthritis development of 1.1 for every increase in number of ACPA reactivities (95% CI 0.99-1.2, $p = 0.07$) and 4.9 (95% CI 1.5-16, $p = 0.01$) for HLA-SE carriers.

Conclusion: Subjects with ACPA-positive musculoskeletal complaints lacking any clinical and ultrasound signs of arthritis are at high risk to develop arthritis, especially among carriers of HLA-SE risk-gene. Table 1.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Etiology and Pathogenesis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: 1) To test the relationship among ACPAs and levels of adipocytokines and atherosclerosis in RA patients. 2) To analyze the effects of ACPAs on the AT function: adipocyte differentiation, macrophage polarization and lipid accumulation, and 3) To evaluate the effects tocilizumab (TCZ) or infliximab (IFX) on the metabolic alterations induced by ACPAs on AT.

Methods: Human study: 75 RA patients and 40 healthy donors were included. Serum levels of adipocytokines were evaluated. Carotid intima media thickness (CMIT) was evaluated as atherosclerosis marker. **In vitro studies:** IgG-ACPAs were isolated from serum of RA patients. 3T3-L1 cells were treated with IgG-NHS or IgG-ACPAs alone or in combination with IFX or TCZ during several stages of the adipocyte differentiation. M0 macrophages were treated with IgG-NHS or IgG-ACPAs alone or in combination with IFX or TCZ. **Ex vivo experiments:** Subcutaneous AT samples were obtained from 8 obese patients through bariatric surgery. AT samples were treated *ex vivo* with IgG-NHS or IgG-ACPAs alone or in combination with bDMARDs. Protein and gene expression of molecules involved in adipogenesis, inflammation, insulin signaling and lipid accumulation was analyzed.

Results: RA patients had elevated levels of leptin/adiponectin ratio, visfatin and inflammatory markers in serum. These alterations were associated with the ACPAs levels. Disease activity and CMIT were associated with ACPAs, leptin/adiponectin ratio, levels of visfatin and inflammatory markers. IgG-ACPAs induced M1 polarization state and impaired insulin signaling in M0 macrophages. 3T3-L1 fibroblast treated with IgG-ACPAs at day 0 showed an impaired adipocyte differentiation. Genes involved in insulin signaling were reduced. Treatment with IFX and TCZ restore adipocyte differentiation and improved insulin signaling. In human AT, the treatment with IgG-ACPAs increased the inflammation, accompanied by a downregulation of genes involved in lipid accumulation, adipogenesis and insulin signaling. bDMARDs reverted inflammatory and metabolic alterations on human AT explants.

Conclusion: 1) ACPAs are related to high levels of adipocytokines in RA patients, suggesting its action on AT dysfunction, contributing to the increased CVD risk. 2) In vitro, ACPAs impairs AT function, acting in both, macrophages and adipocytes, inducing inflammation, impairing adipogenesis and lipid accumulation, and favoring an IR state. 3) TCZ and IFX might reverse the metabolic alterations induced in AT by ACPAs. 4) Targeting these autoantibodies would be an excellent therapeutic strategy to restore AT function and reduce the CVD related to RA. Funded by ISCIII(PI17/01316, CP15/00158 and RIER RD16/0012/0015) co-funded with FEDER.

Age Dependent Effects of Cholesterol and Smoking on the Risk of Rheumatoid Arthritis in Women – Results from a Nested Case Control Study

Carl Turesson^{1,2}, Ulf Bergström¹, Jan-Ake Nilsson^{1,2} and Lennart Jacobsson³, ¹Rheumatology, Department of Clinical Sciences, Malmö, Lund University, Malmö, Sweden, ²Department of Rheumatology, Skane University Hospital, Malmö, Sweden, ³Dept of Rheumatology and Inflammation Research, Sahlgrenska Academy, University of Gothenburg, Sweden, Gothenburg, Sweden

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Etiology and Pathogenesis Poster I

Table 1. Demographics and smoking history in women with incident RA, by age at inclusion in the PMP

	All	Lowest age tertile (29-48 years)	Middle age tertile (49-54 years)	Oldest age tertile (55-57 years)
n	139	48	47	44
Age at inclusion (years); mean (SD)	49.3 (7.5)	40.8 (6.0)	51.7 (3.2)	56.1 (0.3)
Time from inclusion to RA diagnosis (years); Median (IQR)	11 (7-17)	12 (8-19)	12 (7-15)	9 (6-13)
Current smoker	46 %	54 %	51 %	33 %

Table 2. Predictors of RA, by age at screening in pre-RA cases and matched controls. Bivariate conditional logistic regression

Age tertile	29-48 years	49-54 years	55-57 years
	OR (95 % CI)	OR (95 % CI)	OR (95 % CI)
Total cholesterol (per SD)	1.56 (1.00-2.42)	1.95 (1.36-3.02)	1.30 (0.90-2.06)
Body mass index (per SD)	1.00 (0.76-1.30)	0.91 (0.68-1.36)	1.07 (0.68-1.68)
Current smoking at screening	2.29 (1.07-4.98)	2.11 (0.94-4.89)	0.98 (0.41-2.32)

Standard deviation (SD): body mass index 3.1 kg/m²; Total cholesterol 1.1 mmol/l

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Smoking is an established risk factor for rheumatoid arthritis (RA). A positive association between body mass index (BMI) and the risk of RA in women has been reported from several studies, but not from surveys of Scandinavian populations. Finally, a high serum cholesterol has been shown to predict RA in women, but not in men, possibly due to hormone related exposures. The objective of this study was to investigate the impact of described RA predictors in women in different age groups.

Methods: A total of 10902 women from a defined catchment area were included in a Preventive Medicine Program (PMP). Height and weight were measured as part of the health survey, and fasting blood samples were obtained. Serum total cholesterol (TC) was assessed by an enzymatic routine method. From this population, we identified individuals who developed RA after inclusion by linking the PMP register to the local community based RA register and to local and national patient administrative databases. In a structured review of the medical records, patients were classified according to the 1987 ACR criteria for RA. Four controls for each validated case, matched for sex, year of birth and year of screening, who were alive and free of RA when the index person was diagnosed with RA, were selected from the PMP register. The impact of TC, BMI and smoking on the risk of RA was examined in conditional logistic regression models, stratified by age (tertile).

Results: 139 women were diagnosed with RA and fulfilled the ACR criteria after inclusion in the PMP. These pre-RA cases were compared to 556 matched controls. There was a significant positive association between TC and subsequent development of RA in the two younger age groups, but not in the oldest group (Table). Current smoking was associated with a significantly increased risk of RA in the youngest age group (women aged 29-48 years), whereas there was no association among those aged above 55. BMI did not predict RA in either of the subgroups.

Conclusion: High cholesterol levels and smoking predict RA in an age dependent manner. The greater impact of these factors on the future risk of RA in younger women suggests that hormone related mechanisms contribute to the underlying pathways.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Etiology and Pathogenesis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is an autoimmune inflammatory disease that mainly affects synovial joints. Most research on RA has focused on cytokines as main effectors in disease progression however, cell-cell communication involves a much broader scope of responses. Cells can release additionally extracellular vesicles (EVs) and an important role of these EVs has been postulated as important communicators between resident and inflammatory cells [1]. B-cells also release EVs that contain the B-cell receptor on their surface which is an immunoglobulin that binds and presents antigens to T-cells [2]. The presence of IgM-RF in seropositive RA patients clearly points to a role of B-cells and plasma cells in the pathogenesis of this disease. In this study we investigate the presence of RF-IgM on circulating EVs and the relation to the severity of RA.

Methods: EVs were isolated from platelet-free plasma of 41 RA patients and 24 healthy controls (HC) by size exclusion chromatography. We quantified the particle and protein concentration, using NanoSight particle tracking analysis and micro-BCA. Tender (TJC) and swollen joints (SJC) were assessed by physicians and the global patient visual analogue score (VAS) was determined by the patient. IgM-RF, erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP) levels were determined by standard laboratory blood tests in our hospital. Disease activity score (DAS28) was calculated.

Results: RA and HC pEVs were not different in particle size, protein content and particle concentration (115nm, 49fg, 3.5×10^{10} and 108nm, 45fg, 3.8×10^{10} , respectively). Between seronegative (RA-) and seropositive (RA+) patients, particle size, protein content per particle and amount of particles of pEVs were not statistically different (116nm, 39fg, 5.4×10^{10} and 114nm, 58fg, 1.8×10^{10} , respectively). In plasma of 28 out of 41 RA patients IgM-RF was detectable, and in 13 out of these 28 RA+ IgM-RF was also detected on their isolated pEVs (RF⁺pEVs). In RA- patients we did not find any RF present on pEVs. When comparing disease parameters we found no differences between RA+ and RA- patients, except for increased ESR levels in RA+ patients. However, RA+ patients with RF⁺pEVs showed significant higher levels of CRP and ESR and also VAS and DAS28 were significant increased compared to RA+ patients without RF⁺pEVs.

Conclusion: This study shows for the first time the presence of IgM-RF on pEVs in a subset of RA+ patients with a more severe disease. The presence of RF⁺pEVs may point to a higher B-cell involvement in the disease process in these patients.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Rheumatoid Arthritis – Etiology and Pathogenesis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Genome-wide association studies (GWAS) have to date identified over 100 genomic loci at which single nucleotide polymorphisms (SNPs) confer an increased risk of developing rheumatoid arthritis (RA). These loci are enriched for lymphocyte-specific enhancer elements, consistent with a regulatory function of many causal variant(s). Epigenetic modifications have also been strongly implicated in RA pathogenesis, potentially impacting cell phenotype through altered gene expression. Here, we investigate the role of DNA methylation as a mediator of RA genetic risk.

Methods: CD4⁺ T- and B-lymphocytes were isolated by positive selection from fresh peripheral blood of drug-naïve patients attending an early arthritis clinic. Paired CD4⁺ T-lymphocyte-specific DNA and RNA were extracted from 43 RA and 60 disease control patients, respectively, and equivalent material from B-lymphocytes of 46 RA and 73 controls. Comparator groups were matched for age, sex, and acute phase response. Genotyping was performed using the Illumina Infinium Human CoreExome-24 array, and DNA methylation at >850,000 CpG sites quantified with the Illumina MethylationEPIC array. Gene expression profiling was measured using the Illumina Human HT-12 v4 BeadChip. Having first mapped genome-wide methylation quantitative trait loci (mQTLs) in *cis* (<1Mb), we focussed our analysis on known RA risk loci, and integrated paired normalised gene expression measurements for transcripts within 500kb of index CpGs. Finally, we performed an analysis of mQTLs acting in *trans*, seeking interactions between genotype and disease diagnosis to highlight RA-specific effects.

Results: CD4⁺ T lymphocyte *cis*-mQTLs colocalised with 30 independent ($r^2 < 0.8$) RA-associated SNPs, whilst in B lymphocytes such mQTL effects were present at 31 RA SNPs. A high proportion of these variants (>80%) appeared to function as *cis*-mQTLs in both cell types. CpG sites subject to *cis* effects at risk loci were depleted in regions associated with cell type-specific repressed chromatin marks, with enrichment at enhancer regions and those flanking transcription start sites suggesting active roles in transcriptional regulation. Linear regression identified putative regulatory effects of these CpG sites on gene expression, and causal inference testing highlighted genes for which risk SNPs most likely modulate gene expression via CpG methylation. Such effects, robust to false discovery rate, were particularly prevalent in CD4⁺ T lymphocytes, implicating *ANKRD55*, *ORMDL3*, and *FCRL3* amongst others as causal genes in this cell type. Similar effects were less robust in B-lymphocytes, albeit potentially implicating genes including *CCR6*. Our analysis of mQTLs acting in *trans* identified inter-chromosomal SNP-CpG associations, also revealing instances of differential effect sizes in RA patients and controls.

Conclusion: Here we demonstrate the utility of DNA methylation profiling as a tool for the prioritization of candidate genes following GWAS studies in RA, and highlight an important mechanism through which genetic variants may contribute to altered lymphocyte phenotype. The functional roles of highlighted genes in CD4⁺ T cells during RA pathogenesis await clarification.

Session Date: Sunday, October 21, 2018

Session Title: Systemic Lupus Erythematosus – Etiology and Pathogenesis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Previous studies have suggested links between air pollution (particularly PM_{2.5}) and serum antibodies related to rheumatic diseases. No one has yet examined anti-nuclear antibody (ANA) positivity and ultrafine particles (UFP), or ozone (O₃), both of which can trigger systemic immune system activation.

Methods: Our analyses were based within the CARTaGENE cohort, 20,000 general population subjects drawn from the province of Quebec, Canada. We determined baseline ANA positivity on a random sample of these. Exposure to air pollutants were assigned by linking subjects' residential postal codes with estimated levels (determined by hybrid approaches including satellite imagery and modelling). We performed multivariable logistic regression models for the outcome of positive ANA, assessing for independent effects of UFP (available for Montreal only) and O₃ in separate models, adjusting for age, sex, smoking, and self-reported ancestry. As a sensitivity analysis, a final multipollutant model included both variables together with ambient PM_{2.5} variable (estimated using hybrid approaches including satellite imagery).

Results: ANA positivity at a titre of at least 1: 160 occurred in 713 (20%) of 3,578 randomly selected patients tested. The ANA positive subjects were more likely than ANA negative subjects to be female (63%, versus 49%) while average age (55.4 versus 54.0) and percent never-smokers (37% versus 40%) were similar. There was a trend for higher average UFP: exposure for ANA positive subjects (24606.28 particles / cm³, standard deviation, SD 4978.62) versus ANA negative (24328.35, SD 5075.62), while average ozone levels were very similar (22.5 versus 22.6 µg/m³). The multivariable model for UFP showed a trend to higher levels in the ANA positive group (1.008, 0.982, 1.034) while in the multivariable model for O₃ the OR was very close to the null value (0.996, 95% CI 0.965, 1.029). The multipollutant model results were very similar. In all models, risk factors for ANA positivity included older age and female sex, with trends for lower ANA positivity in French Canadians.

Conclusion: We saw a non-significant trend towards higher UFP levels in ANA positive versus negative subjects, while O₃ levels seemed very similar in the two groups. Expected trends for more ANA positivity with older age and female sex was seen. Further study of UFP levels with a larger sample size in in progress.

Pollution variables and ANA positivity: Odds ratios with 95% confidence intervals

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Lupus Erythematosus – Etiology and Pathogenesis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Deoxyribonuclease 1-like-3 (DNase1L3) belongs to Deoxyribonuclease 1 (DNase1) family. This nuclease originally identified as one of apoptosis- and necrosis-related endonucleases that fragmentates intranucleosomal DNA. Unlike DNase1, DNase1L3 is able to digest protein-associated DNA in addition to naked DNA. Hence, DNase1L3 can degrade nucleosomal DNA more efficiently than DNase1, which is resistant to DNase1 because of the surrounding DNA-binding proteins such as histones. Mutations of *DNase1L3* gene that cause loss of function have been reported in murine models of systemic lupus erythematosus (SLE) and familial SLE with an autosomal recessive pattern of inheritance. A recent report showed that DNase1L3-deficient mice also developed features of SLE. In addition, several genetic variants of *DNase1L3* are associated with disease susceptibility to systemic sclerosis and hypocomplementemic urticarial vasculitis syndrome. The role of DNase1L3 in human immune systems is largely unknown. We aimed to clarify the expression and function of DNase1L3 in human immune cells.

Methods: We analyzed expression levels of DNase1L3 mRNA in each subset of human peripheral white blood cells, monocyte-derived dendritic cells and monocyte-derived macrophages. The effects of various stimuli on expression levels of DNase1L3 were tested in human immune cells. Nuclease activities of DNase1L3 was examined using various forms of DNA. We also analyzed the effect of secreted DNase1L3 on type 1 interferon production in plasmacytoid dendritic cells (pDCs) mediated by extracellular human DNA. Concentration of DNase1L3 in sera of systemic lupus erythematosus (SLE) patients was also measured.

Results: At steady states, pDCs expressed the highest levels of DNase1L3. In monocyte-derived cells, monocyte-derived dendritic cells (MoDCs) differentiated with interleukin (IL)-4 and granulocyte monocyte colony-stimulating factor (GM-CSF) showed markedly high expression of DNase1L3 mRNA in comparison with MoDCs differentiated with interferon-alpha (IFN α) and GM-CSF. Additionally, IL-4, not IL-13, induced expression of DNase1L3 mRNA in monocytes and monocyte-derived macrophages. As downstream of IL-4 signaling, insulin receptor substrate 2 and extracellular signal-regulated kinase 1/2 were required for the induction of DNase1L3 mRNA expression. DNase1L3 protein was distributed in the cytosol but not in the nucleus and could be secreted into the culture supernatant. The secreted DNase1L3 protein could digest not only naked DNA but also lipid-DNA complexes and protein-DNA complexes, which were only partially digested by DNase1. DNase1L3 could inhibit IFN α secretion from pDCs induced by apoptotic blebs more efficiently than DNase1. We developed enzyme-linked immunosorbent assay of DNase1L3 and identified co-relation between serum DNase1L3 and serum complement 4 in patients with systemic lupus erythematosus.

Conclusion: DNase1L3 is secreted by innate immune cells and may play a critical role in the tissue homeostasis by degrading self-DNA associated with various types of cell death.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Lupus Erythematosus – Etiology and Pathogenesis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: SLE is characterized by persistently high type I IFN activity. Plasmacytoid dendritic cells (pDCs) produce large amounts of IFNs in viral infections in response to nucleic acids and they have therefore been postulated to be the main source of type I IFNs in SLE. However, the precise role of pDCs in autoimmunity still remains unclear. The aim of this study was to investigate the source of type I IFN in patients with established SLE and preclinical autoimmunity.

Methods: Patients with SLE meeting 2012 ACR/SLICC criteria and healthy donors were recruited alongside therapy-naïve individuals presenting with ANA and 1 clinical symptom (At-Risk). IFN activity was evaluated by a score of IFN-responsive genes in the peripheral blood using TaqMan. pDCs were immunophenotyped and studied *in vitro* for production of cytokines and induction of T cell responses using flow cytometry. pDCs were sorted and sequenced using high-sensitive RNA sequencing. IFN expression was visualised in skin biopsies using *in situ* hybridisation. Keratinocytes were isolated from fresh skin biopsies and cultured *in vitro*; IFN production was measured by qPCR and ELISA.

Results: Most of SLE and At-Risk patients had increased IFN activity, which correlated with disease activity. In contrast, circulating pDCs were decreased in both SLE and At-Risk patients and their numbers did not correlate with any clinical features or IFN status. *In vitro* stimulation with TLR9 or TLR7 agonists revealed that pDCs from SLE and At-Risk patients could not produce IFN- α and TNF- α . In addition, they induced significantly less T cell activation and proliferation compared to pDCs from healthy donors. RNA-seq data analysis showed an upregulation of IFN-responsive genes in most of the SLE and At-Risk pDCs as well as pathways related to immune regulation and senescence but not transcripts of any IFN subtypes. Phenotypically, SLE pDCs were characterised by increased telomeric erosion. *In situ* hybridization revealed high IFN expression in the epidermis but not in lymphocyte-infiltrating areas of lesional biopsies from SLE patients. High expression of IFN was also observed in epidermis of At-Risk individuals without any signs of cutaneous inflammation. *In vitro* stimulation of freshly isolated keratinocytes from these also showed a notable increase in IFN production.

Conclusion: In SLE, non-haematopoietic tissue resident cells are a dominant source of IFN and this is present prior to clinically overt disease. Meanwhile, the professional IFN-producing pDCs have lost their immunogenic properties. These findings suggest an important role for tissue resident cells in autoimmunity and may facilitate novel therapeutic interventions.

Session Date: Sunday, October 21, 2018

Session Title: Systemic Lupus Erythematosus – Etiology and Pathogenesis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Title: Lupus Nephritis Serum Induces Neutrophil Chemotaxis towards Glomerular Endothelial Cells In Vitro :

Background/Purpose: Systemic lupus erythematosus (SLE) is a chronic inflammatory disease associated with endothelial cell dysfunction (ECD), a key modulator of proliferative renal disease through upregulation of adhesion molecules, release of inflammatory chemokines, and ingress of neutrophils into glomerular tissue. Understanding how ECD processes lead to neutrophil influx across the endothelium is essential to finding therapeutic targets for SLE. Our previous studies showed that lupus serum induces neutrophil adhesion to glomerular endothelial cells. The aim of this study is to uncover the functional ability of SLE serum from patients with active disease to induce chemotaxis of neutrophils towards glomerular endothelial cells.

Methods: SLE patients meeting ACR criteria had serum collected and stored at -80°C during paired visits with lower and higher activity by SLE Disease Activity Index (SLEDAI) score. 15 SLE patients (5 SLE only, 5 SLE with hypertension (HTN), and 5 SLE lupus nephritis (LN) with HTN) and 10 healthy controls (5 with and 5 without HTN) were examined. To assess the functional ability of SLE serum to induce neutrophil chemotaxis, primary Human Renal Glomerular

Figure 1. SLE serum increases neutrophil migration, which is enhanced with HTN and LN, along with disease activity in LN HTN cohorts. Number of neutrophils migrated towards CM from HRGECs treated with control (A), SLE (A,B,C), SLE HTN (B,C), or SLE LN HTN (B,C) serum. * $p \leq 0.05$, ** $p \leq 0.01$, as estimated using student's t test.

Endothelial Cells (HRGECs) were cultured in 10% SLE serum (or control serum) for 3 hours and washed, then conditioned media (CM) was collected. Neutrophils collected from healthy donors and stained with CalceinAM were then allowed to migrate through a transwell towards the CM for 1 hour. Migration towards CM was calculated as cells that migrated into the receiving wells based on fluorescence intensity. Groups were compared using student's test.

Results: SLEDAI scores from lower and higher activity paired visits were 0-6 and 4-14 (always ≥ 4 points higher than the inactive visit). HRGECs treated with SLE serum and HTN serum (SLE and control aggregated) induced significantly greater neutrophil chemotaxis than control serum ($p=0.027$) (Figure 1A) and non-HTN serum (not shown, $p=1.8 \times 10^{-7}$), respectively. HRGECs treated with SLE HTN serum and SLE LN HTN serum significantly promoted neutrophil migration compared to SLE serum (Figure 1B, $p=0.0007$, $p=4.173 \times 10^{-9}$) with only SLE LN HTN showing significant differences between inactive and active disease (Figure 1C, $p=0.001$).

Conclusion: This study suggests that circulating factors in SLE serum induce expression of mediators by glomerular endothelial cells that promote neutrophil migration, furthering our understanding of how ECD processes lead to renal inflammation in SLE. Furthermore, hypertension may be an independent and synergistic mediator of ECD induced by circulating factors in SLE.

Session Title: Systemic Lupus Erythematosus – Etiology and Pathogenesis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The endothelium is a key element in the regulation of vascular homeostasis and its alteration is a precursor of vascular disease. Considering SLE is a systemic autoimmune disease with potentiated extensive vascular lesions, such as skin vessels, renal glomeruli, the cardiovascular system, brain, lung alveoli, and gastrointestinal tract

vessels. We aimed to assess serum levels of endothelial function related biomarkers including Ang1, Ang2, adam13, VEGF, Tie-2 and thrombomodulin in patients with systemic lupus erythematosus (SLE) and elucidate its correlation with clinical features, laboratory parameters, and the overall disease activity.

Methods: Disease activities were evaluated by SLE disease activity index (SLEDAI). Patient characteristics were obtained by retrospective chart review. Laboratory investigations included complete blood count, urine analysis, 24-h total urinary protein, assay of serum creatinine, ANA, anti-DNA, complement component C3, C4. Six biomarkers associated with endothelial function were tested through enzyme-linked immunosorbent assay (ELISA) measurement.

Results: This study comprised 80 children and adolescents with SLE. Serum levels of VEGF and Tie-2 were significantly increased in active SLE patients when compared with inactive SLE patients ($p < 0.05$). Angiopoietin-2 and Tie-2 serum levels were significantly increased in patients with low complement levels ($P < 0.05$). Although serum levels of Angiopoietin-1 and -2 were higher in active SLE patients when compared with inactive SLE patients, the difference did not reach statistical significance. While levels of VEGF, angiopoietin-2, and Tie-2 show no differences between patients with and without renal involvement ($p > 0.05$), serum angiopoietin-1 levels was negatively associated with neurological involvement ($P < 0.05$). Additionally, SLEDAI score positively associated with thrombomodulin levels ($P < 0.05$); and negatively associated with VW factor levels ($P < 0.05$). SLEDAI score positively correlated to serum levels of VEGF, Angiopoietin-2, and Tie-2 ($P > 0.05$) without statistical significance.

Conclusion: These six serum markers may be relevant to SLE pathogenesis. Its serum level seems to be potent biomarker for SLE activity as well as organ involvement. These biomarkers may be beneficial in disease monitoring and planning of future therapy.

Session Title: Systemic Lupus Erythematosus – Etiology and Pathogenesis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The MHC class I-related chain A (MICA) is a major ligand for the NKG2D receptor of NK and CD8 T cells. MICA expression at the cell surface is triggered by environmental stressors and label malfunctioning cells for their recognition by cytotoxic cells, which is followed by activation of programmed death in the MICA-labeled cells and their subsequent clearance by the immune system. Alterations in this recognition and also abnormal NK functions have been associated to defective apoptosis in SLE. The disruption of the MICA expression pathway is a major immune escape strategy of virus-infected or transformed cells to avoid immune surveillance. MICA can be shed from the cell surface and act as a soluble decoy receptor (sMICA) for cytotoxic cells. Our objective was to study circulating sMICA levels in relationship with innate molecular processes and clinical features in a cohort of patients with lupus.

Methods: 36 patients diagnosed with SLE and 13 healthy controls were recruited for a cross-sectional study. Circulating mononuclear cells were characterized by flow cytometry, and individual populations of monocytes, T and B lymphocytes were purified with magnetic bead sorting (Miltenyi MACS) for gene expression studies. A commercial ELISA (Diacalone) was used for detection of sMICA. Data are shown as median (CI95). The statistical analysis was done with non-parametric tests. An alpha value of 5% was considered significant.

Results: Globally, no differences in sMICA levels were found between patients and controls. However, in the lupus cohort, sMICA correlated with BILAG (p 0.428, p 0.023) and with SLEDAI scores (p 0.378, p 0.047). Interestingly, the up-regulation of sMICA was inversely associated to circulating NK counts (p 0.07), which were significantly lower in patients than in controls, and further decreased during active disease (p 0.01). Levels of sMICA were particularly high in patients

with active nephritis [aLN: 6.0 ng/ml (4.23-7.74), iLN 3.36 ng/ml (2.23-4.67) (p 0.029 vs aLN), healthy controls 3.0 ng/ml (1.66 - 4.39) (p 0.012 vs aLN)]. Furthermore, sMICA correlated with proteinuria (ρ 0.52, p 0.004) and with plasma creatinine (p 0.421, p 0.026). On the other hand, no association was observed with dsDNA antibodies or with complement levels. As regards activation of mononuclear cell subpopulations, sMICA levels were associated with the up-regulation of TLR2 (p 0.002) and TLR4 (p 0.003) in T lymphocytes, as well as with the transcripts of the interferon sensitive genes IFIT1 (p 0.035) and HERC5 (p 0.018) in these cells. An inverse association between sMICA and MICA gene expression levels in B lymphocytes approached significance (p 0.08).

Conclusion: Our data support an impairment in NK functions in active lupus, and a tight association between kidney flares and the up-regulation of sMICA. This molecule could come either from the innate activation of kidney cells or from PBMCs shedding. Disruption of the MICA pathway could account for a complement-unrelated process of damage in SLE.

Session Title: Systemic Lupus Erythematosus – Etiology and Pathogenesis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is multisystem disorder that is caused by tissue damage resulting from antibody and complement-fixing immune complex deposition. Lupus nephritis (LN) is frequent complication and one of the most serious manifestations of SLE. The alteration of the structural protein in podocytes is known as a mechanism of proteinuria in LN. The signaling lymphocyte activation molecule family (the SLAM family) of type I transmembrane receptors consists of nine related members of the immunoglobulin superfamily and has been reported to mediate important regulatory signals between immune cells through their homophilic and heterophilic interactions (Nat Rev Immunol. 2003 Oct;3(10):813-21). The 1q23 region on human chromosome 1 including the SLAMF cluster of genes, containing SLAMF6 has been identified as a lupus susceptibility locus (Nat Rev Rheumatol. 2010 Jun;6(6):348-57). It has been shown that the expression of signaling lymphocyte activation molecule family 6 (SLAMF6) is enhanced in CD4⁺T cells of SLE patients and is involved in IL-17 production (J Immunol 2012; 188:1206-1212). We sought to examine the functional role of SLAMF6 in lupus podocytes.

Methods: We evaluated the co-expression of nephrin, a podocyte marker and SLAMF6 in kidney of normal controls and LN patients, also in B6 and MRL/*lpr* mice at the age of 8wk and 16wk by immunofluorescence analysis. We also examined nephrin positive SLAMF6 expression in isolated podocytes from B6 and MRL/*lpr* kidneys. Then, we analyzed the expression of SLAMF6 in CD4⁺T cells of isolated kidney and spleen in B6 and MRL/*lpr* mice. We treated human podocytes with IgG from healthy individuals and LN patients for 24 h and 48h and analyzed the expression of SLAMF6 by real-time PCR.

Results: In the histopathology, the expression of SLAMF6 was increased in nephrin positive area in LN patients and MRL/*lpr* mice compared to control. Although the expression of nephrin in MRL/*lpr* mice kidney at 16 wk old decreased compared to B6 mice at same age, the expression of SLAMF6 in podocytes increased in diseased MRL/*lpr* mice compared to B6 mice. Similarly, the expression of SLAMF6 in CD4⁺T cells increased in diseased MRL/*lpr* mice kidney and spleen compared to B6 mice. The level of SLAMF6 mRNA elevated in human podocytes exposed to LN-derived IgG.

Conclusion: The expression of SLAMF6 is enhanced in LN podocytes, suggesting that the possibility of cooperating with CD4⁺T cells contributing to its dysfunction. Further examination is needed to investigate in detail how SLAMF6 is involved in the development of LN in the future.

The Liver X Receptor Modulates Inflammatory Cytokines Based on Lxr α Polymorphism in Monocyte-Derived Macrophages and Patients with Systemic Lupus Erythematosus

Chang-Hee Suh¹, Wook-Young Baek², Hyoun-Ah Kim³ and Ju-Yang Jung², ¹Rheumatology, Ajou University School of Medicine, Suwon, Korea, Republic of (South), ²Ajou University School of Medicine, Suwon, Korea, Republic of (South), ³Department of Rheumatology, Ajou University School of Medicine, Suwon, Korea, Republic of (South)

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Lupus Erythematosus – Etiology and Pathogenesis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Liver X receptors (LXRs) have emerged as important regulators of inflammatory gene expression. Previously, we had reported that an LXR α gene promoter polymorphism (-1830 T>C) is associated with systemic lupus erythematosus (SLE). Therefore, we assessed cytokine expression in relation to LXR α polymorphism in monocyte-derived macrophages and peripheral blood mononuclear cells (PBMC) from patients with SLE.

Methods: Macrophages were obtained after 72 hours of culture of human monocytes supplemented with phorbol 12-myristate 13-acetate. Cells were transfected with LXR α promoter constructs. Additionally, PBMC-derived macrophages from the patients with SLE were evaluated for pro-inflammatory cytokines in relation to the genotypes of LXR α -1830 T>C.

Results: The expression of LXR α was increased in macrophages; levels of pro-inflammatory cytokines, such as IL-1 β and TNF- α , were decreased with increased expression of LXR α . Production of pro-inflammatory cytokines varied depending on the expression of LXR α -1830 T>C genotype. In particular, decreased LXR α expression with increased pro-inflammatory cytokine expression was observed in monocyte-derived macrophages transfected with the TC genotype of LXR α -1830 T>C compared to those in cells transfected with the TT genotype. To verify the involvement of TLR in the expression of pro-inflammatory cytokines according to LXR α -1830 T>C genotype, various TLR agonists were treated in monocyte-derived macrophages transfected with the LXR α -1830 T>C. The levels of pro-inflammatory cytokines were further increased in TC genotype-transfected cells compared to those in TT genotype-transfected cells with treatment of TLR7 and TLR9 agonist. Pro-inflammatory cytokine levels were significantly decreased in TC genotype-transfected cells after treatment with TLR7 or TLR9 inhibitors. These results are consistent with those of an *ex vivo* study on PBMCs from patients with SLE with respect to the TC and TT genotypes of LXR α -1830.

Conclusion: These data suggest that expression levels of LXR α , according to LXR α -1830 T>C genotype, may contribute to the inflammatory response by induction of inflammatory cytokines in SLE.

Enhanced IFN- α Production By Plasmacytoid Dendritic Cells Is Associated with Increased Toll-like Receptor 7 Retention in the Lysosomes and Exposure to Type I IFN in Systemic Lupus Erythematosus

Goh Murayama¹, Asako Chiba², Ayako Makiyama², Ken Yamaji¹, Naoto Tamura¹ and Sachiko Miyake², ¹Internal Medicine and Rheumatology, Juntendo University School of Medicine, Tokyo, Japan, ²Immunology, Juntendo University School of Medicine, Tokyo, Japan

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Lupus Erythematosus – Etiology and Pathogenesis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Type I interferon (IFN) appears to contribute to the development of systemic lupus erythematosus (SLE). Overexpression of type I IFN regulated genes has been reported in patients with SLE. Although plasmacytoid dendritic cells (pDCs) is a major source of type I IFN including IFN- α and IFN- β , previous reports showed that IFN- α production by pDCs stimulated with a Toll-like receptor (TLR) 9 agonist or viruses was not increased in SLE compared to healthy controls (HC). In this study, we investigated another endosomal TLR-signaling pathway in SLE and the effect of type I IFN on TLR pathways.

Methods: Blood samples were obtained from HC and patients with SLE diagnosed according to the systemic lupus international collaborating clinics classification criteria for systemic lupus erythematosus. Peripheral blood mononuclear cells (PBMCs) from SLE patients and HC were stimulated with a TLR9 agonist, CpG-A oligodeoxynucleotides -2216 (CpG-A ODN), or a TLR7 agonist, imiquimod. The proportion of IFN- α producing -pDCs was investigated by intracellular cytokine staining and flow cytometry. PBMCs were pretreated with IFN- α or IFN- β for 24 hours, and then IFN- α and IFN- β production by pDCs was assessed. Localization of TLR7 in cellular compartments in pDCs was investigated with or without pretreatment with IFN- α or IFN- β .

Results: As previously reported, the level of IFN- α production by pDCs stimulated with CpG-A ODN was reduced in SLE compared with HC. However, the proportion of IFN- α producing pDCs stimulated with imiquimod was significantly increased in SLE patients. The percentage of IFN- α producing pDCs stimulated with imiquimod was positively correlated with SLE disease activity index (SLEDAI) score, and the proportion of IFN- α producing pDCs stimulated with CpG-A ODN was negatively correlated with SLEDAI. Exposure to Type I IFN enhanced IFN- α production of TLR7-stimulated pDCs, but reduced that of pDCs activated with CpG-A ODN. TLR7 localization was increased in late endosome/lysosome compartments in pDCs from SLE patients. TLR7 localization was increased in late endosome/lysosome compartments of pDCs treated with either IFN- α or IFN- β both in HC and SLE.

Conclusion: IFN- α production by pDCs was increased upon stimulation with a TLR7 agonist in SLE patients. We found more TLR7 localization in late endosome/lysosome in lupus pDCs. Because IFN- α production requires TLR trafficking to lysosome-related organelle, enhanced IFN- α production by pDCs was partially due to TLR7 retention in the lysosomes in SLE. We also demonstrated that pretreatment with type I IFN enhanced IFN- α production by a TLR7 agonist-stimulated pDCs. In animal models of lupus, the role of TLR9 pathway in the pathogenesis is unclear but several reports indicated that TLR7 pathway is involved in the progression of autoimmune responses. Our study also indicates the importance of TLR7 pathway in SLE.

Session Date: Sunday, October 21, 2018

Session Title: Systemic Lupus Erythematosus – Etiology and Pathogenesis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Currently, little is known about what distinguishes asymptomatic Anti-Nuclear Antibody (ANA) positive individuals (ANA⁺NS) who will progress to Systemic Lupus Erythematosus (SLE) from those who will not. Preliminary data from our laboratory indicates that pro-inflammatory cytokines are increased in SLE but not in ANA⁺ NS. This finding suggests that the development of SLE is characterized by a change in the ability of the autoimmune response to elicit inflammation. Microparticles (MPs) are one of the sources of nuclear antigens in SLE. Previous studies have found increased levels of MP complexed with IgG (MP-ICs) in SLE as compared to healthy controls (HC) and have shown that these MP-ICs constitute a strong pro-inflammatory stimulus. In this study, we examined if ANA⁺NS individuals have MP-ICs to determine whether the lack of inflammation in these individuals results from the absence, or change in character, of their immune complexes.

Methods: Flow cytometry was used to examine the type, nucleic acid content, and IgG binding of peripheral blood Annexin V⁺ MPs in ANA⁻HC (n=7), ANA⁺NS (≥1:160 by IF, n=11), symptomatic ANA⁺ individuals lacking sufficient classification criteria for a connective tissue disease diagnosis (UCTD, n=17) and SLE patients (n=10, classified according to the 1997 American College of Rheumatology criteria). MP nucleic acid content was determined by staining with Syto13 which detects DNA and RNA. Eleven specific ANAs were detected using the Bioplex 2200 ANA Screen. The expression levels of five IFN- α induced genes were measured and summed to generate an IFN5 score.

Results: Consistent with previous studies, SLE patients had increased levels of MP-ICs (Figure 1A) that contained higher levels of nucleic acids (Figure 1B), as compared to ANA⁻ HC. Surprisingly, ANA⁺NS and UCTD patients had similar elevations in the amount of IgG coating their MPs to those seen in SLE (Figure 1A) and in a subset of these individuals the MP nucleic acid content was also higher than ANA⁻ HC (Figure 1B). There was a non-statistically significant trend to higher MP-ICs in ANA⁺ NS and UCTD individuals with specific ANAs and to higher IFN5 scores in those UCTD individuals with elevated Syto13⁺ MPs.

Conclusion: MPs appear to be a source of autoantigen in ANA⁺NS individuals. The results suggest that the differences in elaboration of pro-inflammatory factors between ANA⁺NS individuals and SLE patients do not result from a lack of immune complexes.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Lupus Erythematosus – Etiology and Pathogenesis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Myeloid-derived suppressor cells (MDSCs) are major T cell suppressors, and their dysfunction has been implicated in the pathophysiology of autoimmune diseases. MDSCs suppress T cells using multiple co-receptors including the DC-HIL receptor, which has been shown to be a major receptor in monocytic MDSCs (M-MDSCs). We previously showed that DC-HIL⁺ M-MDSCs from patients with psoriasis are expanded and functionally deficient, thus enhancing autoreactivity. However, the function of MDSCs in cutaneous lupus erythematosus (CLE) is poorly understood. We hypothesized that DC-HIL⁺ M-MDSCs are elevated in the peripheral blood and lesional skin of patients with CLE.

Methods: All patients were recruited through the UT Southwestern Cutaneous Lupus Registry. PBMCs from 20 CLE patients and 16 age- and gender-matched healthy controls were analyzed using flow cytometry. M-MDSCs were identified by the phenotype of CD14⁺ HLA-DR^{neg/low}. To investigate the suppressor function of M-MDSCs, freshly isolated autologous M-MDSCs and T cells were co-cultured at varying ratios. T cell function was measured by secretion of IFN- γ by ELISA. Anti-DC-HIL mAb (50 $\mu\text{g/mL}$) was added to the 1:1 co-culture to study the role of the DC-HIL receptor. Immunohistochemical staining of five CLE lesional skin biopsies and three control skin biopsies using anti-DC-HIL antibodies was performed to study the population of MDSCs in skin tissue.

Results: CLE patients had significantly higher %M-MDSCs amongst PBMCs (2.3% (IQR: 1.2%-4.2%)) compared to controls (0.5% (0.1%-1.1%)) ($p=0.0005$). Percent DC-HIL⁺ M-MDSCs amongst PBMCs was also elevated in CLE patients (0.22% (0.06%-0.67%)) compared to healthy controls (0.04% (0.01%-0.1%)) ($p=0.003$). MDSCs isolated from PBMCs of three additional CLE patients suppressed activated autologous T cells in a dose-dependent manner. Addition of anti-DC-HIL monoclonal antibody partially reversed the suppressor function, indicating that DC-HIL is a receptor involved in MDSC-mediated T-cell suppression in CLE. Compared with normal skin, CLE skin had increased DC-HIL⁺ cells ($p=0.04$), particularly at the dermal-epidermal junction. DC-HIL⁺ cells were in close proximity to CD3⁺ T cells at the dermal-epidermal junction, perifollicular, and perivascular areas.

Conclusion: In summary, DC-HIL⁺ M-MDSCs are expanded in CLE blood and skin, and display immunosuppressive properties. Their up-regulation in CLE blood may represent the body's response to limiting disease severity, since most patients had mild disease activity. Further studies are needed to discern whether these cells help contain the immune dysregulation to skin, since few CLE patients progress to SLE.

Glycosphingolipids and Proteins in Urine Exosomes: Potential Biomarkers of Lupus Nephritis

Tamara K. Nowling¹, Jessalyn Rodgers¹, Jim C. Oates², Michael Janech³ and Richard Drake⁴, ¹Medicine/Rheumatology, Medical University of South Carolina, Charleston, SC, ²Division of Rheumatology & Immunology, Department of Medicine, Medical University of South Carolina, Charleston, SC, ³Medicine/Nephrology, Medical University of South Carolina, Charleston, SC, ⁴Pharmacology, Medical University of South Carolina, Charleston, SC

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Lupus Erythematosus – Etiology and Pathogenesis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Exosomes, extracellular vesicles that are abundant in human urine and contain proteins from renal cells, are a potential source of biomarkers of renal disease in LN patients. We previously demonstrated that levels of Glycosphingolipids (GSL) glucosylceramide (GlcCer) and lactosylceramide (LacCer), and expression of a neuraminidase (NEU1) that mediates GSL catabolism, are elevated in the urine of human patients with nephritis compared to controls. Based on these results we hypothesized that lipids and proteins in the GSL catabolic pathway in urine exosomes could be used as biomarkers of therapeutic response and/or disease flare in LN patients.

Methods: Lipids and proteins were analyzed by mass spectrometry in exosome fractions isolated from urine in 1) a pilot study of lupus nephritis (LN) patients during quiescent disease (non-flare) and renal flare, and in non-nephritis lupus patients; and 2) LN patients that failed to respond or had a complete response to mycophenolate mofetil (MMF) treatment.

Results: In the LN flare versus non-flare versus non-nephritis pilot study, differences in GSL (GlcCers and LacCers) levels were observed among the three sets of samples. Differences in phospholipids were also observed. Proteomics results identified several abundant and known urine biomarkers for LN albumin and serotransferrin in the samples from LN patients. Additional known urine biomarkers in the LN samples included complement factors, anti-trypsin, and alpha-2-HS-glycoprotein/fetuin-A. Novel proteins that were differentially abundant (either higher or lower) in LN samples compared to non-nephritis lupus samples and/or in flare compared to non-flare samples also were identified and included lysosomal protective protein (cathepsin A), a co-factor for NEU1. In the treatment response study, significant differences in GlcCer levels in exosomes isolated from pooled urine samples collected at baseline (prior to MMF treatment) were observed between LN patients that responded compared to those that did not respond to therapy. These results are being validated in a cohort of MMF responder (30) and non-responder (30) LN patients using exosomes isolated from individual urine samples taken at baseline and at 3-, 6-, and 12-months post-treatment. Additional lipids and proteins that are differentially abundant in these urine exosome samples between responders and non-responders are being identified and validated.

Conclusion: Preliminary data suggest that lipid and protein molecules in urine exosomes may serve as early markers of disease flare and/or response to therapy in LN patients and may enhance the predictive power of current models of response to therapy.

Regulation of Monocyte Function By Epstein Barr Virus Interleukin-10 (vIL10) in Systemic Lupus Erythematosus

Neelakshi R. Jog¹, Eliza Chakravarty¹, Joel M. Guthridge¹ and Judith A. James^{2,3}, ¹Arthritis and Clinical Immunology, Oklahoma Medical Research Foundation, Oklahoma City, OK, ²Arthritis & Clinical Immunology, Oklahoma Medical Research Foundation, Oklahoma City, OK, ³Department of Pathology, University of Oklahoma Health Sciences Center, Oklahoma City, OK

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Lupus Erythematosus – Etiology and Pathogenesis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic Lupus Erythematosus (SLE) is a systemic autoimmune disease characterized by periods of elevated and suppressed disease activity. Epstein Barr Virus (EBV) has been associated with SLE. EBV maintains latency in infected B cells and shows intermittent reactivation. Elevated concentrations of EBV Early Antigen (EA) IgG, a measure of viral reactivation, increase the probability of transitioning to SLE in unaffected family members, which underscores the importance of EBV reactivation in SLE autoimmune responses. Viral IL10 (vIL10), an EBV lytic protein, is a homolog of interleukin 10. Monocytes are one of the first cells to respond following infection and dysregulation of monocytes plays a dynamic role in the systemic autoimmune response in SLE. However, the effects of vIL-10 on monocyte function in the context of increased human or cellular IL10 (hIL10) have not been examined. In this study we examine whether vIL10 has similar inhibitory effects on monocytes as hIL10.

Methods: Plasma from 20 SLE patients (10 European American and 10 African American) with varying disease activity and 19 age, race and sex matched healthy unrelated controls were concentrated and vIL10 detected by western blotting. The band intensities were normalized to pooled sera from infectious mononucleosis patients. Plasma IL10 levels were measured by xMAP assays. Monocytes were enriched from peripheral blood mononuclear cells from healthy donors. STAT phosphorylation, cytokine secretion and expression of cell surface markers were determined by flow cytometry. Gene expression was by quantitative PCR.

Results: SLE patients had significantly higher levels of plasma vIL10 (8516 ± 3291 ; 6509 ± 1953 , $p=0.03$), and significantly higher levels of hIL10. No correlation was observed between vIL10 and hIL10. To determine the functional consequences of increased vIL10 in the presence of high levels of endogenous cellular IL10, we performed in vitro stimulation of monocytes with hIL10 in the presence or absence of vIL10. As expected, hIL10 induced phosphorylated STAT3 (pSTAT3), which is required for anti-inflammatory gene expression induced by IL10, while vIL-10 induced significantly lower pSTAT3. The presence of vIL10 reduced hIL10 induced pSTAT3 in a dose dependent manner, suggesting that vIL10 can act as a competitive inhibitor of hIL10 activity. vIL10 increased pro-inflammatory gene expression, but was unable to downregulate IL10R1 gene expression. However, neutralizing antibody to IL10R1 reduced pSTAT3 and inhibited upregulation CD163 induced by both hIL10 and vIL10, suggesting that vIL10 signals through IL10R1. We did not see any significant differences between the frequency of cells positive for intracellular hIL10 in monocytes stimulated with hIL10 or vIL10.

Conclusion: Lupus patients have increased levels of plasma vIL-10, possibly due to increased EBV reactivation. vIL10 signals through IL10R1 and can suppress hIL10 induced STAT3 phosphorylation. Suppression of hIL10 induced anti-inflammatory genes by vIL10, together with an increase in inflammatory gene expression may overcome the anti-inflammatory effect of IL10 and exacerbate autoimmune responses in SLE.

Session Title: Systemic Lupus Erythematosus – Etiology and Pathogenesis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is a chronic debilitating autoimmune disease that primarily afflicts women in the childbearing years. Female hormones especially estrogen are implicated in the pathogenesis of disease, however the precise molecular mechanisms regulated by estrogen in immune cells are not well understood. We previously identified novel roles for the multifunctional protein serine/arginine-rich splicing factor 1 (SRSF1) in T cells. We

showed that SRSF1 promotes expression of the CD3zeta signaling gene and activates IL-2 production in normal T cells. T cell specific *Srsf1*-conditional knockout mice exhibit defects in T cell function and develop autoimmune disease. SRSF1 expression levels are decreased in T cells from SLE patients, and associate with severe disease activity. Importantly, overexpression of SRSF1 into SLE T cells rescues IL-2 production. These results imply that the SRSF1 is an important molecule in T cells and immune-mediated disease. However, not much is known about the regulation of SRSF1, and if hormones may contribute to its expression.

Methods: Peripheral blood was collected from healthy women in the follicular phase of the menstrual cycle. T cells were isolated by negative selection from peripheral blood. T cells were cultured (in RPMI without phenol red supplemented with charcoal-stripped serum), with increasing concentrations (0, 1nM, 10nM, 100nM) of beta-estradiol for 18 – 24 hours. To assess mRNA stability, transcription was blocked with actinomycin D, cells collected at 0, 0.5, 1, 1.5 and 2 hours, and *Srsf1* expression assessed by RT-qPCR. To assess posttranslational protein degradation mechanisms, the proteasome inhibitor MG132 or the lysosome inhibitor Bafilomycin A1 were added to cultures followed by western blots for SRSF1. The *Srsf1* promoter was cloned into a pGL3-luciferase plasmid. T cells were transfected by electroporation and luciferase activity measured by a luminometer.

Results: Exposure to estrogen led to a dose dependent increase in *Srsf1* mRNA expression, but decreased protein levels in T cells. This discrepancy between mRNA and protein levels suggests that estrogen controls SRSF1 at transcriptional and post-transcriptional levels and may upregulate transcriptional activity of its promoter but downregulate protein levels via mRNA decay, translation or protein degradation. Accordingly, estrogen increased luciferase activity of the *Srsf1* promoter-luciferase construct indicating that estrogen activates *Srsf1* transcription. Estrogen did not affect mRNA stability, however protein analyses showed that the proteasome is involved in the degradation of SRSF1. In silico analysis revealed microRNA (miR) target sites within the *Srsf1* 3' UTR, of which miR-21-5p, miR-27, and miR-200b-3p are known to be regulated by estrogen and to be dysregulated in SLE.

Conclusion: Our results suggest that estrogen can modulate the expression of SRSF1 via transcriptional and posttranscriptional mechanisms in human T lymphocytes, thus revealing a potential molecular link between hormones, immune cells and autoimmune disease.

Session Date: Sunday, October 21, 2018

Session Title: Systemic Lupus Erythematosus – Etiology and Pathogenesis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: We have previously shown that DN T cells are expanded in both lupus-prone mice and patients with SLE and we have demonstrated that this population is an essential component of the immunopathogenesis of the disease. It still remains unknown whether the DN T cell pool consists of functionally heterogeneous subpopulations. In this study we ask whether DN T cells comprise distinct functional subsets.

Methods: Flow cytometry analysis was applied for the expression of cytokines, chemokine receptors, and T cell receptor (TCR) repertoire etc. IL-17-GFP B6 mice were crossed to MPL/lpr mice for 8 generations to generate IL-17-GFP MPL/lpr mice which were used to track IL-17⁺ DN T cells *in vivo* and sort IL-17⁺ DN T cells *ex vivo*. Cytokine capture assay was applied for *ex vivo* isolation of either IL-17⁺ or IL-10⁺ DN T cells. Metabolism-associated gene expression was quantified by RT-qPCR. Peripheral blood T cells from either healthy subjects or patients with SLE were assessed by flow cytometry analysis.

Results: Two distinct DN T populations were identified in both mice and humans based on the expression of two cytokines, IL-17 and IL-10. As expected, IL-17⁺ DN T cells were significantly increased in aging MRL/lpr mice (20 wks old) compared to either age matched control MRL/mpj mice or young MRL/lpr mice (12 wks old), a finding which is consistent with our previous report that DN T cells contribute to lupus pathogenesis by producing IL-17. Interestingly, the numbers of IL-10⁺ DN T cells in aging (20 wks old) mice were reduced compared to young (12 wks old) MRL/lpr mice. Flow cytometry analysis revealed that the predominant chemokine receptors expressed on IL-17⁺ and IL-10⁺ DN T cells were different. Higher levels of CCR6 expression were observed only on IL-17⁺ DN T cells and especially in those infiltrating the kidneys (64±11.4% in kidneys vs 19.3 ± 5.6% in spleens) but CCR4 expression was restricted on IL-10⁺ DN T cells. Furthermore, different TCR V beta repertoire usage (V β 5, 6, 8.1/8.2, 12) was observed in IL-17⁺ DN T cells while V β 14 and 15 were noted on IL-10⁺ DN T cells. Finally, different expression levels of metabolic genes were recorded between IL-17⁺ vs IL-10⁺ DN T cells. Consistently, increased percentage of IL-17⁺ DN T cells (7.0 ± 5.4% vs 4.1 ± 2.6 %) and reduced IL-10⁺ DN T cells (0.49 ± 0.65% vs 7.5 ± 1.6%) were observed in the peripheral blood from the subjects with SLE compared to healthy subjects.

Conclusion: We present evidence that two distinct subsets exist within the DN T cell population in lupus prone mice and patients with SLE. The ratio of IL-17⁺/10⁺ DN T cells increases as the disease progresses in MRL/lpr mice. The two subsets appear to utilize different TCR repertoire and express different cytokine receptors and metabolic enzyme patterns. We propose that the ratio between the two subsets represents a valid disease biomarker and particularly of impeding kidney involvement.

Identification of a Gut Pathobiont Immunostimulatory Lipoglycan Antigen Linked to Lupus Nephritis

Gregg Silverman¹, Nicolas Gisch², Aidana Omarbekova³ and Doua F. Azzouz⁴, ¹Department of Medicine, New York University School of Medicine, New York, NY, ²Research Center Borstel, Schleswig-Holstein, Germany, ³New York University School of Medicine, New York, NY, ⁴Medicine, New York University School of Medicine, New York, NY

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Lupus Erythematosus – Etiology and Pathogenesis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: A transmissible agent has long been suspected in SLE. In a discovery cohort we found that, compared with healthy subjects, Lupus patients had a five-fold overall mean greater representation of the *Ruminococcus gnavus* species of the Lachnospiraceae family of anaerobic gram-positive cocci. Many SLE patients also displayed biomarkers of increased gut permeability that has been associated with bacterial translocation. In a patient, the relative fecal *R. gnavus* abundance directly correlated with serum levels of IgG anti-*R. gnavus* antibodies. This anti-bacterial immune response had features indicative of molecular mimicry with anti-native DNA antibodies, which are direct contributors to the pathogenesis of Lupus nephritis (LN). We therefore sought to isolate and characterize the responsible strain-associated antigen in the *R. gnavus* candidate pathobiont.

Methods: A panel of strains of the Lachnospiraceae family, and other anaerobic commensals, were evaluated by immunoblot, bead-based Luminex assay, as well as direct and competition ELISA. To isolate lipoconjugates from the candidate Gram-positive bacterial commensal strain, we applied a validated extraction protocol using a butanol separation with fractionation after passage over Hydrophobic Interaction Chromatography (HIC). Fractions were then evaluated for immunoreactivity and capacity to stimulate a human TLR2- transfected HEK reporter gene system.

Results: In an assay with a cutoff based on the mean+2SD of 55 healthy controls, we found that one of 8 independent *R. gnavus* isolates, which we termed RG2, displayed high level serum IgG reactivity with 30 of 50 active LN patients and only 4 of 36 patients without active renal disease (P<0.001 by *t* test). Fractionation of the RG2 extract by chromatography enabled the isolation of a lipoglycan, which by high-resolution NMR spectroscopy showed the presence of repetitive oligosaccharide building blocks. Sera from LN patients also displayed strong IgG reactivity with the lipoglycan, which was inhibitable by the nuclease-treated RG2 extract. In side-by-side analyses the lipoglycan had the same oligomeric immunoblot banding pattern of the parental bacterial extract, and in a HEK transfected reporter cell system displayed strong dose-dependent (range 2 to 2000 ng/ml) NFκB activation, compared to nonstimulated conditions. This activity was significantly inhibited by an anti-huTLR2 mAb at 10 ug/ml (P=0.006) but not isotype control. Further analyses of the exact

carbohydrate content, as well as the overall size and detailed structure of the isolated lipoglycan, are currently under study by NMR, MS, and GC/MS.

Conclusion: We have identified a gut commensal strain-associated cell wall lipoglycan, which appears to represent an immunodominant antigen in a candidate pathobiont implicated in the pathogenesis of LN. Moreover, the TLR2-activation potential of the lipoglycan pool may be due to the presence of lipopeptides, which will require further investigation. Our findings suggest a pathway by which continuous translocation of a bacterial mimic of DNA with innate immunostimulatory properties may contribute to the pathogenesis of LN.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Lupus Erythematosus – Etiology and Pathogenesis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Two major therapies for cutaneous lupus erythematosus (CLE) are the antimalarials, hydroxychloroquine (HCQ) and quinacrine (QC). HCQ is often the first-line therapy for CLE, but only half of patients show a response to it. While some of the patients that do not initially respond to HCQ benefit from the addition of QC, there is a subset of patients that are refractory to both antimalarials. Refractoriness poses a huge challenge because these patients will often continue to have active disease when they are initially started on antimalarials. To better characterize these refractory patients, we investigated the immunologic characteristics of patients that respond to antimalarials versus those that do not.

Methods: CLE patients were classified as HCQ-responders, HCQ/QC-responders, or HCQ/QC-nonresponders. Immunohistochemistry was used to characterize the inflammatory cell composition and cytokine expression in lesional skin biopsies from patients. Total RNA was extracted from these biopsies to analyze specific gene signatures. The patient's CLASI score – a measure of disease activity – at the time of the biopsy was also determined.

Results: Immunohistochemistry showed that myeloid dendritic cells (mDCs) were significantly higher in HCQ/QC-responders compared to HCQ-responders and HCQ/QC-nonresponders, while plasmacytoid dendritic cells, neutrophils, macrophages, and autoreactive T cells did not differ significantly among the three groups. The HCQ/QC-nonresponder group was distinct from the other groups in that their CLASI scores did correlate positively with the number of macrophages ($p < 0.05$, Figure 1). Staining also showed that IL-22 expression was significantly higher in HCQ/QC-nonresponders versus the HCQ- or HCQ/QC-responders while IL-17 expression was not significantly different between the responders and nonresponders. Analyzing their RNA expression demonstrated a high type I IFN signature (LY6E, OAS1, ISG15, MX1) in HCQ-responders but a low type I IFN signature and higher TNF-alpha expression in both HCQ/QC-nonresponders and HCQ/QC-responders.

Conclusion: An increased number of mDCs may contribute to HCQ-refractoriness and predict a better response to treatment with both HCQ and QC but do not contribute to HCQ/QC-refractoriness. The significant correlation between macrophages and CLASI scores in the HCQ/QC-nonresponders, a finding not seen in either HCQ or HCQ/QC-responders, may also indicate that macrophages are more involved in antimalarial-refractory skin disease. The difference between the responders and nonresponders is further confirmed by the cytokine staining and mRNA expression. Our data is an initial step in determining the activation pathways that account for the lack of response to antimalarials.

Highly Elevated Levels of Anti-Mitochondrial Antibodies in Systemic Lupus Erythematosus and Rheumatoid Arthritis

Richard Moore¹ and Christian Lood², ¹Division of Rheumatology, University of Washington, Seattle, WA, ²Department of Medicine, Division of Rheumatology, University of Washington, Seattle, WA

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Lupus Erythematosus – Etiology and Pathogenesis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: We recently described the phenomenon in systemic lupus erythematosus (SLE) in which mitochondria are extruded into the extracellular space during formation of neutrophil extracellular traps (NETs). NET formation has been demonstrated to be inflammatory and immunogenic, possibly including mitochondria. While poorly characterized, it is known that in both SLE and rheumatoid arthritis (RA) a small subset of patients are positive for anti-mitochondrial antibodies (AMAs). Frustratingly, current mitochondrial isolation techniques produce mitochondria that are wrapped in nuclear DNA (nuDNA), blurring the distinction of AMAs and anti-dsDNA antibodies, commonly seen in SLE. Here, we aim to perfect mitochondrial isolation, characterize the targets of AMAs, and determine their clinical implications in RA and SLE.

Methods: Mitochondria from HepG2 cells isolated by Dounce homogenization and subsequent DNase treatment were tested for nuDNA contamination by quantitative PCR (qPCR) of 16S rRNA and 18S rRNA genes and organelle purity by fluorescence-activated cell sorting (FACS). Isolated mitochondria were used to test sera from healthy individuals (HC, n=17), SLE patients (n=44), and RA patients (n=101) for anti-mitochondrial IgG antibodies via FACS and western blot (WB) methods. Finally, sera were tested for presence of AMA by immunocytochemistry using a HepG2 cell line with GFP-tagged mitochondria.

Results: Our mitochondrial isolation technique yielded over a 1,000-fold reduction in nuDNA over standard techniques, reducing the possibility of anti-dsDNA antibodies binding to residual nuDNA on the mitochondrial surface. Further, we did not observe any binding of propidium iodide, an impermeable DNA-binding dye, or anti-dsDNA antibodies, to the isolated mitochondria. Similarly, this technique produced particles that were 99.1% positive for mitochondria markers MitoView and MitoTracker. Using this ultrapure isolate, we found that SLE and RA patients had significantly elevated reactivity against isolated mitochondria compared to HC ($p < 0.0001$, 727 vs 333 MFI and 680 vs 400 MFI, respectively). Levels of AMAs were particularly elevated in patients with severe disease, including erosive disease (RA, $p = 0.01$) and nephritis (SLE, $p = 0.02$). AMA reactivity was confirmed with ICC using HepG2 cells with GFP-tagged mitochondria. Lastly, we found mitochondrial proteins near band sizes 15, 30, 35, 45, and 75kDa that were consistently labeled by SLE sera, indicating an unequal antigenicity between mitochondrial proteins.

Conclusion: Here, we introduce a highly effective method of mitochondrial isolation in which both nuDNA and non-mitochondrial organelle contamination are reduced to insignificant levels compared to previous methods. Subsets of SLE and RA patients have been reported to have AMAs, but they have not been well-characterized. In this study, we show a

tremendous increase in AMAs in SLE and RA patients and we illuminate that these AMAs target only a subset of mitochondrial proteins. Little is known about AMA targets, and it is expected that their identification will open new avenues for SLE and RA monitoring, stratification, treatment and prevention.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Lupus Erythematosus – Etiology and Pathogenesis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Apolipoprotein L1 (APOL1) risk variants (RV), G1 and G2, associate with CKD in African Americans (AA) and are evolutionarily preserved due to improved infectious resistance. Interferons (IFN) in SLE, have been shown to increase APOL1 expression and RV toxicity in endothelial cells and podocytes. Though RV homozygotes with SLE nephritis demonstrate advanced renal progression, associations with renal histopathologies have not been validated in SLE.

Methods: Herein, this cohort study tested the hypothesis that RV homozygosity (RV/RV) associates with specific clinical and biopsy features compared to reference allele (G0) homozygosity (G0/G0) or RV heterozygosity (RV/G0). Whole blood DNA for genotyping, kidney biopsy slides, and clinical reports from 77 AA SLE patients with biopsy-proven nephritis reviewed for: biopsy class, activity index (AI), chronicity index (CI) and clinical features across APOL1 genotype. RV-attributed mitochondrial morphology, was assessed on electron microscopy (EM) images. Analysis was confirmed by two blinded pathologists. As proof of concept, primary endothelial cells across genotype were given IFN to over-express APOL1, and features on EM were compared.

Results: The G0/G0, RV/G0, and RV/RV groups comprised 35%, 52%, and 12% of the cohort. There were no genotype differences in SLE history or demographics. Compared to G0/G0, and RV/G0 groups, the RV/RV had higher urine protein to creatinine ratios (uPCR) and creatinine (Cr) at biopsy (mean uPCR: 2.5; 2.7; 4.3 mg/L p=0.06 and Cr: 1.3; 1.03; 2.3 mg/dL p=0.01 respectively). Adjusting for dsDNA, AI, CI, and percent sclerotic glomeruli, the RVs independently associated with proteinuria at biopsy (OR=2.1, p=0.05). Paradoxically, the G0/G0 and RV/G0 vs the RV/RV group displayed higher AI and CI with a trend toward higher dsDNAs at biopsy (G0/G0 or RV/G0: AI: 5.3/24; CI: 2.6/12 dsDNA: 447 vs RV/RV: AI: 1.2/24; CI: 1.3/12; dsDNA: 69, p=AI: 0.004; CI: 0.01; dsDNA: 0.1). In 30% of the RV/RV cases, the reading pathologist commented that clinical severity was out of proportion to the biopsy lesion. The RV associated with ESRD in 7.9%, 3.9%, and 20% of the G0/G0, RV/G0, and RV/RV cases (OR: 5.7; p=0.03). On EM, RVs associated with mitochondrial condensation (mitochondrial area: G0/G0: 0.17; RV/G0: 0.09; RV/RV: 0.06 μm^2 ; p<0.01); this result was recapitulated in our cell culture model. IFN-treated endothelial cells increased APOL1 expression 18 fold across genotypes (p<0.01). Compared to G0/G0 and RV/G0 cells, RV/RV cells had mitochondrial areas: G0/G0: 0.08; RV/G0: 0.07; RV/RV: 0.04 μm^2 ; (p<0.01).

Conclusion: In this SLE cohort, APOL1 RVs associated with poorer prognosticators, initial proteinuria and creatinine, and ultimately progressive nephritis. These features were paradoxically out of proportion to the SLE lesion on biopsy. The literature supports RV-conferred podocyte and endothelial cell mitochondrial defects owing to a mitophagy deficiency. As evidenced by EM images from both SLE patient biopsies and primary cell cultures, these genes may confer intrinsic renal pathology. Consequently, traditional scoring of histopathologic severity may underestimate injury that associates with RV alleles.

Sex-Specific Expression of CXorf21 Provide Molecular Explanation for the Fundamental Difference in Male and Female Immune Response: An Explanation for Female-Bias SLE Pathogenesis

R. Hal Scofield¹, Valerie M Harris², Biji T. Kurien³ and Kristi A. Koelsch⁴, ¹Medicine, University of Oklahoma Health Sciences Center, Oklahoma City, OK, ²Oklahoma Medical Research Foundation, Oklahoma City, OK, ³University of Oklahoma Health Sciences Center, Oklahoma City, OK, ⁴Section of Endocrinology and Diabetes, University of Oklahoma Health Sciences Center, Oklahoma City, OK

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Lupus Erythematosus – Etiology and Pathogenesis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is complex autoimmune disorders characterized by B cell hyperactivity resulting in autoantibody and cytokine production. Approximately 90% of patients are female. We have produced data an X-chromosome gene dose effect increases susceptibility. Therefore, our objective is to functionally describe an X-linked protein which escapes X-inactivation, Chromosome X open reading frame 21 (*CXorf21*), to uncover any role this protein may have in the pathogenesis or susceptibility to SLE. Publicly available data predict CXorf21 is a dehydrogenase/reductase expressed almost exclusively in monocytes, B cells, and and other antigen-presenting cells. Additional studies show that CXorf21, a SLE risk allele, directly interacts with another SS/SLE-associated risk allele, *Slc15a4*. SLC15a4, a lysosomal proton-oligopeptide co-transporter, is necessary for endolysosomal antigen processing, TLR7- and NOD1-mediated cytokine as well as antibody production in dendritic cells and B cells.

Methods: We used quantitative real-time PCR, Western blot protein analysis, Bio-plex cytokine immunoassay, and pHrodo™ assay, as well as, *in vitro* CRISPR-Cas9 knockdown experiments to examine the role of CXorf21 in monocytes and B cell immunity.

Results: Our data show that CXorf21 basal gene and protein expression is elevated in female primary monocytes and B cells compared to male cells. We also found CXorf21 mRNA expression was higher in both male and female SLE-affected EBV-transformed B cells and female primary Sjogren's Syndrome patient's PBMC subsets compared to healthy male controls. Additionally, we found that following activation by TLR7 (Imiquimod) and NOD1 (iE-DAP) agonists *CXorf21*, *IFN-alpha*, and *NFkappaB* expression increases, in addition to an increase IL-6 and TNF-alpha cytokine production. This response is exaggerated in a female-specific manner. Successful knockdown of CXorf21, using CXorf21-specific gRNA (CRISPR-Cas9), abrogated both the expression levels and cytokine response in the female samples, but had not affect in male subjects. pHrodo™ lysosomal pH experiments revealed that knockdown of CXorf21 protein in healthy female monocytes resulted in an increased lysosomal pH. As result of the increase from acidic to a more alkaline lysosomal environment in the female samples (auto)antigen processing is perceived to be disrupted.

Conclusion: CXorf21 is over-expressed in female immune cells compared to male cells and is involved in a sex-dependent dimorphic response to activation through TLR7 and NOD1. We propose that CXorf21 via interaction with the lysosome proton cotransporter, SLC15a4, maintains the lysosomal pH gradient necessary for monocyte and B cell immune response. Thus, sexual dimorphic expression of CXorf21, based on escape of X chromosome inactivation, skews (auto)antigen processing and immune response by women compared to men. CXorf21 may be a major contributor to TLR7 disease pathogenesis, and sex bias of the diseases based on an X chromosome dosage effect.

Session Date: Sunday, October 21, 2018

Session Title: Systemic Lupus Erythematosus – Etiology and Pathogenesis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Recent studies have identified distinct changes in cellular miRNA (miR) expression associated with systemic lupus erythematosus (SLE). We have previously shown that toll-like receptor TLR7 and TLR8 are significantly up-regulated in PBMCs of SLE patients. TLR7 and TLR8 bind to single-stranded RNA of viral origin to stimulate innate inflammatory responses. We have demonstrated that EV-encapsulated miR-21 induces both TLR8-mediated cytokine signaling and EV secretion in vitro. In another recent publication from our group, we also discovered that high mobility group box (HMGB)1 is a substrate for transglutaminase-2-mediated autoantigen complex formation and HMGB1 complexes are significantly up-regulated in both extracellular plasma and PBMCs of SLE patients. The objective of this study was to identify miR and other small RNA signatures that may be used as diagnostic biomarkers and potential therapeutic targets to limit either HMGB1 or TLR-induced inflammatory response in SLE.

Methods: Our pilot cohort consisted of four active female SLE patients meeting the revised criteria of the American College of Rheumatology and three age/sex matched healthy controls. Active disease was defined as a SLEDAI > 4 at the time of sample collection. Plasma-derived EVs were isolated by ultracentrifugation and small RNA libraries were prepared for RNA-sequencing (RNAseq). Global small RNA reads were analyzed and cross-referenced with a sequencing database (miR-Base) of known miRs. RNAseq reads with more or less than a 2-fold change when comparing healthy to SLE were characterized and considered statistically significant if $p < 0.05$.

Results: Analysis of our RNAseq data resulted in a large collection of statistically significant small RNA reads (< 25nt) that were up or down-regulated in SLE patients relative to healthy controls; 77% of these RNA reads were unique non-coding RNA sequences that did not align with a database of known miRs, which suggests that many of the SLE-associated small RNAs in EVs are long non-coding RNA (lncRNA), piwi interacting RNA (piRNA), or novel/undiscovered miRs. Conversely, 23% of the reads correlated with miRBase-aligned sequences for known miRs. Since our database analysis found that there are 47 predicted miRs targeting the 5030nt long mRNA sequence for HMGB1 and there are 121 known miRs predicted to target HMGB1, we cross-referenced our results to identify miRs that may inhibit its expression that were down-regulated in the plasma-derived EVs of SLE patients. Our analysis revealed that miR-142-3p, a previously characterized negative regulator of HMGB1, was down regulated over 15-fold in EVs from SLE patients when compared to healthy controls. In examining the dataset for miRs that may bind HMGB1 to facilitate EV trafficking, we found that let-7b-5p was up-regulated in SLE EVs more than 4-fold.

Conclusion: Our data demonstrate unique EV-derived small RNA signatures that may be targeted therapeutically or used as diagnostic biomarkers for SLE. Also, these results identify HMGB1-associated miRs that are dysregulated in SLE and a collection of miRs that may function as TLR7/8 agonists. Future studies will expand our cohort and validate miRs of interest in the context of HMGB1 and TLR7/8.

Session Title: Systemic Lupus Erythematosus – Etiology and Pathogenesis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: One hallmark of the autoimmune disease Systemic lupus erythematosus (SLE) is the presence of antinuclear antibodies (ANAs). While the specificities and levels can indicate characteristics of SLE status, many individuals acquire ANAs either years prior to clinical diagnosis of SLE or fail to develop any further symptoms. At present, the mechanisms controlling further autoimmune progression in ANA+ healthy individuals remain unknown.

Methods: To ascertain potential differences in immune cell populations and/or their transcriptional state, we performed single cell RNA-seq on peripheral blood mononuclear cells from 30 patients, including African and European American individuals which were healthy ANA+ individuals with no other SLE criteria (n=10), active SLE patients (n=10), and healthy controls (n=10) with no autoantibodies. Transcriptomes were analyzed using canonical correlation analysis, followed cell population identification and by tSNE cluster visualization and differential gene expression within each cell population was assessed.

Results: Distinct cell population clusters could be identified for each of the disease classifications. EA ANA+ individuals showed an increase in the number of NK cells relative to SLE and healthy individuals while, in contrast, AA ANA+ individuals had lower numbers of NK cells. Specific populations of B cells could be identified for each disease classification in both AA and EA patients. For EA patients, stress response related genes such as *JUN* and *PPP1R15A* were upregulated in ANA+-specific B cells while SLE-specific B cells were marked by upregulation of pro-survival/proliferation genes such as *TCL1A*, *PCDH9* and *RALGPS2*. AA SLE patients demonstrated a proportional enrichment of plasma cells relative to both ANA+ and healthy individuals while *FCRL5*, a marker of dysfunctional B cells, was increased in SLE memory B cells. Overall, AA ANA+ cell populations showed an upregulation in a number of heat shock genes in ANA+ (*HSPA6*, *HSPA1A*, *DNAJB1*). Comparison of a list of candidate regulatory factors demonstrated dysregulation of several genes, including an upregulation of *TGFB* across all AA ANA+ cell clusters and a similar increase in CD46 in EA ANA+ clusters.

Conclusion: These data indicate that substantial transcriptional and cell population differences exist among immune cells from ANA+, SLE, and healthy individuals, including an apparent activated stress response programs in the cells from ANA+ individuals. Our results suggest that cells from ANA+ individuals may be actively regulating a response to autoantigen stimulation, whereas an exhaustion of that response may allow for transition to SLE.

Session Title: Systemic Sclerosis and Related Disorders – Basic Science Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Figure 1

Figure 2

Background/Purpose: Systemic sclerosis (SSc) is an autoimmune disease characterized by skin and lung fibrosis. Over 90% of patients with SSc are positive for autoantibodies. In addition, serum B cell activating factor (BAFF) level is correlated with SSc severity and activity. Thus, B cells are considered to play a pathogenic role in SSc. However, there are two opposing subsets: regulatory B cells (Bregs) and effector B cells (Beffs). IL-10-producing Bregs negatively regulate the immune response, while IL-6-producing Beffs positively regulate. Therefore, a protocol that selectively depletes Beffs would represent a potent therapy for SSc. The aim of this study was to investigate the roles of Bregs and Beffs in SSc, and to provide a scientific basis for developing a new treatment strategy targeting B cells.

Figure 3

Methods: The bleomycin-induced scleroderma model was induced in the mice with a B cell-specific deficiency in IL-6 or IL-10. We also examined whether BAFF regulates cytokine-producing B cells and its effects on scleroderma model.

Results: Serum IL-6 levels gradually increased with the development of fibrosis in bleomycin-induced scleroderma mice, while serum IL-10 levels did not. IL-6-producing Beffs increased in Spleen and the inflamed skin of scleroderma model. The skin and lung fibrosis was attenuated in B cell-specific IL-6-deficient mice, whereas B cell-specific IL-10-deficient mice showed more severe fibrosis. BAFF stimulation increased Beffs and decreased Bregs. By contrast, BAFF antagonist (BAFFR-Fc) increased Bregs and decreased Beffs (Fig 1). Furthermore, BAFF antagonist attenuated skin and lung fibrosis in scleroderma model via modulating the regulatory and effector B-cell balance (Fig 2).

Conclusion: The current study indicates that Beffs play a pathogenic role in scleroderma model while Bregs play a protective role (Fig 3). BAFF inhibition is a potential therapeutic strategy for SSc via alteration of B cell balance.

Session Title: Systemic Sclerosis and Related Disorders – Basic Science Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The T β RII Δ k-fib transgenic (TG) mouse model of scleroderma carries a fibroblast-specific TGF β receptor II mutation resulting in balanced up-regulation of TGF β signalling and replicates key fibrotic and vasculopathic features of scleroderma, including susceptibility to lung fibrosis and pulmonary hypertension. This study examines evidence of PPAR pathway perturbation in whole tissue or explanted cells from adult or neonatal TG mice compared with wildtype (WT) littermates. Lanifibranor (formerly known as IVA337) is a new chemical entity that activates all PPAR isoforms and is undergoing clinical trials in scleroderma at present.

Methods: Gene expression differences between whole skin biopsies, fibroblasts or aortic smooth muscle cells (aSMCs) from T β RII Δ k-fib and WT littermate mice (n=3 each group) were quantified using MouseRef-8v1.1 expression BeadChips (Illumina, USA). In total, 42 microarray gene expression profiles were analysed. After normalisation (global; Bioconductor Lumi), the genes were ranked according to differential expression. Data were expressed as pairwise analysis comparing the mean expression of two groups (t test), with FDR correction for multiple testing (number of tests/rank of p value). The PPAR pathway gene list obtained from http://software.broadinstitute.org/gsea/msigdb/cards/KEGG_PPAR_SIGNALING_PATHWAY was cross-referenced with each microarray. Within the GSEA cohort of genes the number with significant differential expression or a trend to difference (P<0.10) in analysis was determined. A total list of 12800 genes were tested.

Results: The genes within the PPAR pathway showing either significant difference (p<0.05) or trend of difference are summarised in Table 1 below. Overall, 11 genes showed significant difference between WT and TG explant cells and 82% (n=9) were reduced in the TG cells. 25 genes showed a trend of difference in ≥ 1 of the test substrates and the majority, 18 (72%), were down-regulated in TG mice. This suggested down-regulation of the PPAR pathway in the T β RII Δ k-fib mouse model. As shown in Table 1, there were most differences for the aSMCs and this is notable as the altered phenotype of these in culture is likely to reflect an altered in vivo environment, with elevated TGF β activity in the vessel wall rather than intrinsic SMC abnormalities; the SMC do not express the transgene.

Conclusion: As expected, whole tissue is less informative than explanted cells with whole skin showing no significantly differentially expressed genes. These results are not indicative of highly dysregulated PPAR pathway expression, although overall there is a signal that the PPAR pathway, assessed by GSEA, may be reduced in TG mice. This trend is seen most often in aSMC explant culture. This mouse model provides a potential platform for in vivo experiments to provide mechanistic support for trials of lanifibranor in scleroderma.

Epigenetic Changes in Dermal Fibroblasts By Inhibition of DOT1L Affect Cell Proliferation and Cell Cycle, but Have No Direct Effects on Collagen Deposition in in Vitro and In Vivo models of Fibrosis

Nathalie Berghen^{1,2}, Jonathan Cremer³, Ellen de Langhe^{1,2} and Rik Lories^{1,2}, ¹Skeletal Biology and Engineering Research Center, KU Leuven, Leuven, Belgium, ²Rheumatology, UZ Leuven, Leuven, Belgium, ³Translational Research in GastroIntestinal Disorders, KU Leuven, Leuven, Belgium

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Sclerosis and Related Disorders – Basic Science Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Fibrosis is a key feature of systemic sclerosis, a devastating disease that is not well understood. The role of epigenetic factors in the pathophysiology is increasingly explored. Histone modifications such as histone methylation are dynamic epigenetic events that regulate signaling pathways and cellular processes. DOT1L is the unique H3K79-methyltransferase and methylates histone 3 at the Lysine residue at position 79. Inhibition of DOT1L in cartilage and bone has cell-type specific effects on Wnt-signaling, a pathway suggested to play an important role in fibrosis. We aim to study the role of DOT1L in fibrosis using different *in vitro* and *in vivo* models.

Methods: Primary cell cultures of healthy human dermal fibroblasts (breast and abdomen) were treated with DOT1L-inhibitor EPZ-5676 or vehicle for 14 days and stimulated with TGF- β after starvation. Smooth muscle alpha 2 actin (ACTA2) gene expression was measured by RT-qPCR. Western Blot was performed for dimethylated H3K79. Picrosirius Red staining measured collagen deposition. Proliferation was analyzed with 5-Bromo-2'-deoxy-uridine (BrdU) labeling. Flow cytometry was done using Propidium Iodide to analyze the cell cycle phases. Col1a2;Cre-ERT²;DOT1L^{fl/fl} mice (tamoxifen-inducible fibroblast specific DOT1L knockout mice) were injected subcutaneously with bleomycin (0.1mg) or vehicle (5 days/week, 4 weeks). Injected skin was analyzed by OH-proline assay for collagen content, and by histology for dermal thickness.

Results: The DOT1L-inhibitor EPZ-5676 reduced H3K79 dimethylation in all samples. DOT1L inhibition had a differential effect on ACTA2 expression: in breast dermal fibroblasts the increase of ACTA2 after TGF- β stimulation was reduced, while in abdominal dermal fibroblasts the increase of ACTA2 was more pronounced. After 48 hours of TGF- β , collagen deposition was higher in DOT1L-inhibitor exposed fibroblasts. After 72 hours of TGF- β stimulation however, collagen deposition was comparable between control and DOT1L inhibition. BrdU labeling assay showed more fibroblast proliferation with inhibition of DOT1L. Analysis of the cell cycle using flow cytometry revealed that DOT1L inhibition increased the proportion of cells in the G1/G0 phase, with fewer cells in S and M/G2 phase. *In vivo*, subcutaneous bleomycin increased dermal thickness and skin collagen content in mice. No difference was observed between mice with a conditional fibroblast-specific deletion of DOT1L or wild type mice.

Conclusion: In an *in vitro* model of fibrosis, the induction of ACTA2 with TGF- β in DOT1L-inhibited primary human dermal fibroblasts was dependent on the site of origin of the fibroblasts. DOT1L inhibition resulted in a more rapid increase in collagen deposition, but this did not result in detectable differences in collagen deposition at the end point of the experiments. DOT1L inhibition increased fibroblast proliferation but also led to a higher proportion of cells in the G0/G1 phase. In an *in vivo* murine model of skin fibrosis, no difference in bleomycin-induced skin thickness and collagen content was found when the DOT1L gene was deleted in fibroblasts.

Antifibrotic Regulation By Response Gene to Complement 32 Protein

Sergei Atamas, Violeta Rus, Virginia Lockett, Horea Rus and Irina Luzina, University of Maryland School of Medicine, Baltimore, MD

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Sclerosis and Related Disorders – Basic Science Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Pulmonary fibrosis is a serious problem in patients with scleroderma lung disease (SLD). Better therapies for pulmonary fibrosis are urgently needed. Identification of new therapeutic targets guides the development of innovative therapies for patients with pulmonary fibrosis. Previous research suggested that a protein termed Response Gene to Complement 32 (RGC-32) is involved in kidney fibrosis, but RGC-32 involvement in SLD or other forms of pulmonary fibrosis has not been explored in depth.

Methods: The levels of RGC-32 mRNA and protein in human lung tissues were studied by RNA-Seq, qRT-PCR, and Western blotting. A chronic bleomycin exposure model of pulmonary fibrosis was used to assess the effects of RGC-32 gene deficiency on collagen accumulation in the lungs *in vivo*. Experiments in primary human lung fibroblast cultures were used to investigate the effect of plasmid-based RGC-32 gene delivery on TGF- β -induced upregulation of collagen mRNA and protein.

Results: The RNA-Seq data suggested and qRT-PCR confirmed a significant decline in the levels of RGC-32 mRNA in the lung tissues of patients with SLD and idiopathic pulmonary fibrosis (IPF) compared with lung tissues from healthy controls. Similarly, RGC-32 protein levels were significantly decreased in SLD and IPF lung tissues based on western blotting analyses. These observations contrasted previous reports about RGC-32 involvement in several non-fibrotic diseases as well as in kidney fibrosis, all of which implicated elevated levels of RGC-32 in disease mechanisms. In an attempt to explain the striking difference between the commonly observed elevation of RGC-32 level in a variety of diseases and the observed decline in pulmonary RGC-32 mRNA and protein in patients with SLD and IPF, the possibility was considered that the decrease in RGC-32 in pulmonary fibrosis might be part of a failing protective feedback loop in which lower RGC-32 levels represent the organism's attempt to attenuate profibrotic signaling. To assess this possibility, germline-deficient (RGC-32^{-/-}) mice were challenged with bleomycin. The expectation was that if RGC-32 is a profibrotic mediator as suggested by the studies of kidney fibrosis, then RGC-32^{-/-} mice would be protected from bleomycin-induced fibrosis compared with their wild-type RGC-32^{+/+} strain background controls. However, RGC-32^{-/-} mice were not only not protected from fibrosis, but accumulated significantly more collagen in response to bleomycin challenge, indicating that RGC-32 acts protectively against fibrosis in the lungs. Further supporting this notion, overexpression of RGC-32 attenuated TGF- β -induced upregulation of collagen in primary human lung fibroblast cultures.

Conclusion: These combined data from human patients, the animal model, and cultured primary fibroblasts indicate that RGC-32 protects from fibrosis in the lung and that its loss in patients with SLD and IPF allows for a more severe fibrosis. Therapeutic restoration of pulmonary RGC-32 levels may be beneficial for patients with pulmonary fibrosis.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Sclerosis and Related Disorders – Basic Science Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: CTLA4-Ig interacts with the cell surface costimulatory molecule CD86 and can downregulate the target cell activation [1]. Circulating fibrocytes (CFs) express markers of both hematopoietic cells (CD45, MHC class II) and stromal cells (collagen I and III), together with the chemokine receptors, which regulate their migration into inflammatory lesions (CXCR4, CCR2, CCR7) [2]. CFs can migrate into systemic sclerosis (SSc)-affected tissues and can differentiate into fibroblasts/myofibroblasts [2]. Skin fibroblasts (SFs) are involved in the excessive production of extracellular matrix (ECM) proteins which characterizes fibrosis in SSc [3].

The aim of the study was to compare CD86 expression on CFs, SFs and human macrophages (M) from SSc patients and to study the effects of CTLA4-Ig/CD86 interaction on SSc cultured CFs and SFs.

Methods: Peripheral blood CFs and M together with SFs were obtained from 8 “limited” cutaneous SSc patients (treated only with vasodilators, mainly cyclic prostanoids), after patient informed consent and local Ethics Committee approval for skin biopsies.

CFs and M were characterized by fluorescence-activated cell sorter analysis (FACS), for CD45, collagen type I (COL I), CXCR4, CD14, CD86, and HLA-DRII expression. After 8 days (T8) of culture, CFs were treated for 3 hrs and SFs were treated for 24 and 48 hrs, in the absence or in the presence of CTLA4-Ig (10, 50, 100 and 500 micrograms/ml).

Quantitative real-time polymerase chain reaction (qRT-PCR) for CD86 on CFs, SFs and M were performed. In addition, after CTLA4-Ig treatment, qRT-PCR for CD86, COL I, IL1beta, TGFbeta, α phaSMA, S100A4, CXCR2, CXCR4, CD11a was performed. The statistical analysis was carried out by the nonparametric Mann-Whitney U test.

Results: At gene level, SSc M highly expressed CD86 molecule. Notably, T8-cultured SSc CFs showed significantly higher CD86 gene expression, compared to SSc M ($p<0.05$). On the contrary, SSc SFs showed a very low CD86 gene expression, compared to both M and CFs (both $p<0.01$). After 3 hrs-CTLA4-Ig treatments, qRT-PCR of SSc CFs showed α phaSMA, COL I and CD11a gene expression significantly decreased ($p<0.01$, $p<0.05$ and $p<0.05$ respectively), whereas S100A4 gene expression resulted significantly increased ($p<0.01$), compared to untreated cells (CNT). CD86 and CXCR4 gene expression resulted decreased (not significantly) only after treatment with CTLA4-Ig 500 micrograms/ml. Otherwise, SSc CFs did not show any significant variations in TGFbeta, IL1beta and CXCR2 gene expressions, compared to CNT. SSc SFs treated with CTLA4-Ig did not show any significant modulation in the gene expression levels of CD86, compared to CNT.

Conclusion: In conclusion, CD86 expression on M and CFs in SSc patients might support their earlier and intensive activation in this disease when compared to resident SFs in the same patients. Therefore, SSc CFs seem to be more responsive to CTLA4-Ig treatment than SFs, thus a new therapeutic option for abatacept in SSc treatment should be taken into consideration based on its possible anti-fibrotic effect.

Identifying Matricellular Protein CYR61 As a Potential Anti-Fibrotic and Pro-Angiogenic Mediator in Scleroderma

Pei-Suen Tsou¹, Dinesh Khanna² and Amr H Sawalha¹, ¹Division of Rheumatology, University of Michigan, Ann Arbor, MI, ² Division of Rheumatology, University of Michigan Scleroderma Program, Ann Arbor, MI

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Sclerosis and Related Disorders – Basic Science Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Vascular abnormalities represent a fundamental event in the pathogenesis of scleroderma (SSc) in that endothelial cell (EC) damage triggers a self-fueling process ending in pathological tissue fibrosis. In our previous study we identified CYR61 as a histone deacetylase 5-target gene in SSc ECs, and further confirmed its role in impaired angiogenesis in SSc. As CYR61 is also involved in fibrosis, we hypothesize that CYR61 is beneficial for SSc through its anti-fibrotic and pro-angiogenic properties. In this study, we examined the anti-fibrotic role of CYR61 in SSc fibroblasts, and also dissected the mechanism of its pro-angiogenic property in SSc ECs.

Methods: Dermal ECs and fibroblasts were isolated from biopsies from healthy subjects or patients with diffuse cutaneous SSc. CYR61 was determined by qPCR and ELISA. CYR61 was overexpressed using a CYR61 vector. Angiogenesis was assessed by an *in vitro* Matrigel tube formation assay. The scratch wound assay and gel contraction assay were used to evaluate fibroblast function. Cell proliferation was assessed by ki67 immunofluorescence, while superoxide production was measured using dihydroethidium. Cell senescence was analyzed by measuring p21. A t-test was used to compare differences between groups, and a p-value of <0.05 was considered significant.

Results: In both SSc ECs and fibroblasts, CYR61 levels were significantly lower compared to control cells. In SSc ECs, overexpression of CYR61 was accompanied with elevation of *NOS3* as well as increased secretion of CYR61 and VEGF. The cell surface receptor for CYR61 on ECs, integrin $\alpha v\beta 3$, was significantly elevated on SSc ECs. The proangiogenic properties of CYR61 was blocked by neutralizing antibodies for $\alpha v\beta 3$, as well as inhibitors for AMPK or AKT/NO signaling pathways. In SSc fibroblasts, overexpression of CYR61 led to significant decrease in profibrotic genes including *COL1A1* and *ACTA2* while increasing anti-fibrotic *PPARG*. CYR61 overexpression also resulted in increased secretion of matrix degrading MMP1 and 3, as well as pro-angiogenic VEGF. The anti-fibrotic effect of CYR61 was further demonstrated by delay in wound healing and inhibition of gel contraction. CYR61 led to early superoxide production followed by decrease in cell proliferation and cell senescence in SSc fibroblasts.

Conclusion: In this study we showed that deficiency in CYR61 potentially contributes to impaired angiogenesis and enhanced fibrosis in SSc ECs and fibroblasts. CYR61 overexpression in SSc ECs led to increase excretion of CYR61, which through binding to $\alpha\text{v}\beta 3$, activates the AMPK/AKT pathways to promote angiogenesis. CYR61 also induced pro-angiogenic VEGF expression to further increase its pro-angiogenic potential. In addition, CYR61-overexpressed SSc fibroblasts were converted from extracellular matrix-producing myofibroblasts into extracellular matrix-degrading senescent cells. Moreover, the ability of CYR61 to increase VEGF secretion in fibroblasts may modulate angiogenesis in SSc ECs. Taken all together, our data supports the beneficial role of CYR61 in SSc and warrants the use of CYR61 mimetics as a therapeutic option.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Sclerosis and Related Disorders – Basic Science Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Multiple organ fibrosis, a hallmark of systemic sclerosis (SSc), remains poorly understood. Recent GWAS have uncovered consistent genetic linkage between TNFAIP3, encoding the ubiquitin-editing enzyme A20, and fibrotic SSc phenotypes. A20 has been previously implicated in negative regulation of innate immune cell activity, and hypomorphic variants are linked with autoimmunity in SLE, RA, IBD and Behcet syndrome. In view of its potential importance in SSc, we sought to characterize the regulation and role of A20 in the context of fibrosis and SSc pathogenesis.

Methods: We evaluated A20 expression in skin and lung biopsies from patients with SSc, and examined the effect of A20 gain- and loss-of-function in explanted human and mouse fibroblasts. Moreover, we generated transgenic mice with partial or fibroblast-specific deletion of A20, and analysed the effect on experimentally-induced fibrosis and associated transcriptome changes by RNA seq.

Results: Unbiased transcriptome analysis of SSc skin and lung biopsies revealed significantly decreased A20 levels and **robust anti-correlation with fibrotic TGF- β signaling ($r=-0.84$, $p<0.005$)**. Lesional skin myofibroblasts in SSc showed a notable absence of A20 expression. In vitro, A20 expression was markedly reduced in fibroblasts treated with TGF- β . Moreover, TGF- β abrogated the stimulation of A20 elicited by TLR4. Remarkably, ectopic A20 in skin and lung fibroblasts abrogated profibrotic responses and disrupted Smad signalling, and prevented myofibroblast differentiation in mesenchymal progenitor cells. Conversely, reduced A20 activity was associated with enhanced magnitude of fibrotic responses. A20 haploinsufficient mice, which show a partial reduction of A20 levels comparable to individuals harbouring A20 risk alleles, showed augmented bleomycin-induced skin and lung fibrosis, **increased tissue levels of F4/80, procollagen I and ASMA, and transcriptome signatures with altered fibrotic and inflammatory gene expression**.

Conclusion: We uncover a novel role for the SSc risk gene A20 as a fundamental checkpoint in modulating fibroblast activity and differentiation. Reduced A20 renders fibroblasts and transgenic mice susceptible to fibrosis. These observations suggest that reduced A20 in SSc patients carrying TNFAIP3 risk variants may underlie unchecked fibroblast activation and contribute to the pathogenesis of multiple organ fibrosis.

Session Title: Systemic Sclerosis and Related Disorders – Basic Science Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Synchronous fibrosis in systemic sclerosis (SSc) leads to failure of the skin, lungs and other organs, and has no effective treatments. Myofibroblast activation underlies fibrosis in different organs, but the pathogenesis of fibrosis and the key extracellular cues driving the process remains poorly understood. Multiple intracellular pathways are triggered by cytokines and chemokines implicated in SSc. Of special interest is IL-6, which activates JAK/STAT signaling. A recent multi-ethnic GWAS identified strong associations of JAK-STAT variants with SSc. In order to illuminate the mechanisms linking these risk genes with disease pathogenesis, we investigated the IL6/JAK/STAT axis in SSc, and the effect of tofacitinib, a JAK/STAT inhibitor, in preclinical model of organ fibrosis.

Methods: We measured JAK/STAT expression and activity in SSc skin biopsies by immunohistochemistry and by unbiased transcriptome profiling. We defined a tofacitinib gene signature, and measured its activity in SSc. The effects of tofacitinib treatment were determined in explanted fibroblasts, and in a preclinical model of multiple organ fibrosis.

Results: We measured JAK/STAT expression and activity in SSc skin biopsies by immunohistochemistry and by unbiased transcriptome profiling. We defined a tofacitinib gene signature, and measured its activity in SSc. The effects of tofacitinib treatment were determined in explanted fibroblasts, and in a preclinical model of multiple organ fibrosis.

RESULTS: Expression of both phospho-JAK2 and phospho-STAT3 was significantly elevated in SSc skin biopsies (n=19) compared to matched healthy controls (n=10) (p<0.0001). Moreover, activated JAK/STAT expression showed significant negative correlation with pulmonary function (r=-0.48, p<0.01). We next analyzed gene expression signatures in transcriptome datasets comprised of 84 SSc and 12 healthy control skin biopsies, that clustered SSc biopsies into four distinct subsets. We found a significant correlation of the IL6/JAK/STAT signature (63 genes) with the inflammatory intrinsic subset, accounting for 40% of all SSc biopsies. The strength of an experimentally-derived “tofacitinib gene signature” of 39 genes was significantly reduced (p<0.001) in the same SSc biopsies, and was negatively correlated with TNF α and IFN α pathway scores. In fibroblasts, tofacitinib effectively inhibited induction of inflammatory and fibrotic genes induced by IL-6. Notably, tofacitinib treatment resulted in dramatic attenuation of bleomycin-induced skin and lung fibrosis in mice.

Conclusion: The JAK/STAT signaling pathway is markedly activated in a subset of SSc patients, and appears to contribute to disease progression. Blocking JAK/STAT activity with tofacitinib abrogates core fibrotic responses in fibroblasts, and prevents multiple organ fibrosis in mice. These results are the first to demonstrate that in SSc patients with genomic evidence of enhanced JAK/STAT pathway activity in target organs, tofacitinib treatment might be effective in slowing or reversing fibrosis.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Sclerosis and Related Disorders – Basic Science Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Persistent myofibroblast activation underlies unresolving multi-organ fibrosis in systemic sclerosis (SSc). We had shown that fibrosis is associated with reduced expression of NAD-dependent sirtuins (SIRT) 1 and 3. The activity of SIRT is determined by availability of NAD^+ , which in turn is regulated by CD38, the main NAD-consuming enzyme. We had shown that during chronological aging, up-regulation of CD38 drives cellular NAD^+ consumption, resulting in reduced SIRT activity, mitochondrial dysfunction, cellular metabolic collapse and senescence. We sought to test the hypothesis that biological aging is accelerated in SSc, and causes NAD^+ depletion and metabolic imbalance contributing to cellular senescence and fibrosis. We also hypothesize restoring NAD^+ homeostasis will prevent fibrosis in mouse model.

Methods: Expression and regulation of NAD^+ metabolic pathway enzymes and fibrotic pathway genes was examined in human and mouse SSc transcriptomes, tissue biopsies, and explanted fibroblasts. Cellular senescence was investigated by immunostaining. Fibrosis and inflammation induced by chronic subcutaneous bleomycin were examined in aged mice treated with the orally available NAD^+ precursor nicotinamide riboside (NR), and a novel potent and selective CD38 inhibitor (78c).

Results: The number of p16-positive senescent cells was elevated in SSc skin biopsies. Moreover, levels of CD38 transcript and protein were increased in SSc skin biopsies as well as explanted skin fibroblasts compared to matched controls. CD38 expression was also elevated in skin from mice with fibrosis. Notably, CD38 levels showed strong correlation with the TGF- β signature ($p < 0.0001$, $r = 0.42$) as well as Modified Rodnan skin score ($p < 0.003$, $r = 0.34$), while an anti-correlation with SIRT activity was observed. Overexpressing CD38 lowered cellular SIRT activity and augmented, while CD38 inhibition diminished, fibrotic responses in cultured fibroblasts. NR alone, or combined with the CD38 inhibitor 78c, abrogated TGF- β -mediated fibrotic responses and Smad-dependent transcriptional activity in fibroblasts. Treatment of aged mice with 78c alone, or combined with NR supplementation, attenuated fibrosis and inflammation in the skin and lungs. These anti-fibrotic effects were correlated with increased tissue levels of NAD^+ .

Conclusion: Expression of CD38 and other NAD-consuming enzymes is elevated in fibrotic skin. Elevated CD38 potentially causes cellular NAD^+ depletion and reduced SIRT activity with protein hyperacetylation. SIRT dysfunction in turn contributes to persistent fibroblast activation and senescence underlying unresolving fibrosis (Fig.1). Restoring NAD^+ homeostasis through CD38 inhibition and NR supplementation ameliorated fibrosis in mouse models and could represent a novel strategy for the treatment of SSc.

An Orally Available Highly Selective 5-Hydroxytryptamine 2B Receptor Antagonist Ameliorating Pulmonary and Dermal Fibrosis in Preclinical Models of Systemic Sclerosis

Christina Wenglén¹, Helena Arozenius², Lars Pettersson² and Gunilla Ekström¹, ¹R&D, AnaMar AB, Lund, Sweden, ²AnaMar AB, Lund, Sweden

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Sclerosis and Related Disorders – Basic Science Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Serotonin or 5-hydroxytryptamine (5-HT) is well known as a stimulator of tissue fibrosis and a significant role of peripheral 5-HT_{2B} receptors in fibrosis has been suggested with the receptor being upregulated in fibrotic tissues. In addition, agonism of the 5-HT_{2B} receptor has been implicated in human tissue fibrosis caused by drugs known to activate the receptor. Pharmacologic inhibition of 5-HT_{2B} receptor signalling consequently represents a promising treatment strategy for fibrotic disorders including systemic sclerosis. 5-HT is released from platelets activated due to vascular damage, one of the first pathological events in systemic sclerosis. The local 5-HT concentration is increased and leads to activation of 5-HT_{2B} receptors on e.g. fibroblasts. This results in progression of myofibroblast differentiation leading to excessive extracellular matrix synthesis and eventually fibrosis. The objective of the present study was to evaluate a novel highly selective orally available 5-HT_{2B} receptor antagonist for its ability to reduce pulmonary and dermal fibrosis in the sclerodermatous chronic graft-versus-host disease model and dermal fibrosis in the tight-skin-1 model of systemic sclerosis.

Methods: The murine sclerodermatous chronic graft-versus-host disease (cGvHD) model was used to evaluate anti-fibrotic effects after therapeutic dosing of the 5-HT_{2B} receptor antagonist, AM1476. The compound was orally administered at 1, 10 and 30 mg/kg b.i.d. from day 21, several days after the first clinical signs of cGvHD, to day 49. Dermal thickness, myofibroblast counts, collagen production and number of phosphorylated Smad3 positive cells were used to evaluate dermal fibrosis. Effects on pulmonary fibrosis were measured using hydroxyproline content, Sirius Red staining and Ashcroft score. The tight-skin-1 model was used to evaluate anti-fibrotic effects after therapeutic treatment. AM1476 was orally administered at 10 mg/kg, b.i.d. from week 5 to week 10. Hypodermal thickening, myofibroblast counts and hydroxyproline content in skin biopsies were evaluated at the end of the treatment period.

Results: The 5-HT_{2B} receptor antagonist AM1476, significantly reduced all measured dermal and pulmonary fibrosis readouts in the cGvHD model using an oral therapeutic treatment approach. Therapeutic treatment of dermal fibrosis in the tight-skin model effectively and significantly reduced hypodermal thickening, number of myofibroblast and hydroxyproline content.

Conclusion: Inhibition of 5-HT_{2B} receptor activity resulted in pronounced anti-fibrotic effects in both pulmonary and dermal fibrotic tissues. The highly selective 5-HT_{2B} receptor antagonist AM1476 represents a promising drug candidate for treatment of fibrotic conditions and is currently in development for systemic sclerosis.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Sclerosis and Related Disorders – Basic Science Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Uncontrolled activation of fibroblasts releasing large amounts of extracellular matrix proteins is a key feature of systemic sclerosis (SSc). The nuclear receptor coactivators (NCOA) are named after their role as coactivators for nuclear hormone receptors, but are indeed modulating a large number of signaling pathways. In this study, we aimed to analyze whether targeting of NCOA3 may ameliorate fibrosis in preclinical models of SSc.

Methods: Fibroblasts were exposed to chronically high levels of TGF- β to mimic the situation in fibrotic diseases. The expression of different transcriptional cofactors in response to TGF- β stimulation was analyzed by quantitative real-time PCR. Protein levels were analyzed by Western Blot. Knockdown of NCOA3 was achieved via transfection with siRNA *in vitro*. For knockdown of NCOA3 *in vivo*, siRNA was premixed with atelocollagen for stabilization and injected subcutaneously at the site of bleomycin injections. Additionally, NCOA3 was targeted with the SRC3 inhibitor-2 (SI-2) in different murine models. The interaction of NCOA3 and TGF- β /SMAD signaling was analyzed by SMAD-responsive reporter as well as CoIP assays.

Results: SiRNA-mediated knockdown of NCOA3 strongly decreased the pro-fibrotic effects of TGF- β , with significant reductions in collagen protein, in the mRNA levels of *COL1A1* and *ACTA2* as well as significant decreases in the prototypical TGF- β target genes *PAIL* and *CTGF*. Knockdown of NCOA3 also ameliorated fibrosis in the bleomycin-induced dermal fibrosis model of SSc, with reductions of dermal thickening, of myofibroblast counts and of hydroxyproline content. Furthermore, pharmacological targeting of NCOA3 by the inhibitor SI-2 was able to ameliorate fibrosis in bleomycin-induced pulmonary fibrosis and in dermal fibrosis induced by overexpression of constitutively active TGF- β receptor type I (TBRI^{act}). Mechanistically, NCOA3 directly interacts with SMAD3 to promote TGF- β /SMAD3 signaling as shown by reporter studies and CoIP assays.

When we analyzed the expression levels of NCOA3 in SSc and in matched healthy individuals, we observed a modest, but statistically significant downregulation of NCOA3 expression, a phenotype that persisted also in cultured SSc fibroblasts. Stimulation of normal fibroblasts with chronically high levels of TGF- β also decreased the mRNA and protein levels of NCOA3. Given the profibrotic effects of NCOA3, the downregulation of NCOA3 in fibrotic SSc skin may be an endogenous regulatory attempt to counteract the increased activity of TGF- β /SMAD3 signaling.

Conclusion: We demonstrate in our study that inhibition of NCOA3 has profound anti-fibrotic effects and serves as a coactivator for the profibrotic effects of TGF- β /SMAD. Antagonizing NCOA3 augments an endogenous regulatory loop to reduce persistent fibroblast activation and tissue fibrosis in SSc.

Session Title: Systemic Sclerosis and Related Disorders – Basic Science Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Scleroderma is a multisystem connective tissue disease characterized by extensive tissue fibrosis and its three prominent cardinal features are vasculopathy, excessive collagen deposition and immunological abnormalities. Metformin (MET) has anti-inflammatory and anti-fibrotic effects. Therefore, we investigated the potential effect of metformin on fibrosis in a murine model bleomycin (BLM) of scleroderma.

Methods: A total of 50 mice were randomly divided into 5 group: MET treatment groups (200mg/kg, 100mg/kg, 50mg/kg), model group and control group. Scleroderma was induced in C57BL mice by subcutaneous injections of BLM daily, after 2 hours interval, different dose MET was intraperitoneally injected, while control group received with normal saline at corresponding time point. At the end of the fourth week, all mice were sacrificed and spleen tissues were collected for flow cytometry analysis. The skin samples were harvested for immunohistochemistry and quantify biological parameters (hydroxyproline content and RT-PCR).

Results: MET treatments markedly alleviated histopathological changes (dermal thickness and collagen deposition) and hydroxyproline contents compared with model group ($P < 0.05$). The abnormal differentiation of Th17 cells, Th1 cells, Th2 cells and follicular helper T (Tfh) cells was significantly inhibited by MET ($P < 0.05$), while the proliferation of Treg cells were upregulated ($P < 0.05$). Moreover, the expression levels of specific cytokines and transcriptions factors related to Th17 cells changed: interleukin-17A (IL-17A) and retinoic-acid-receptor related orphan receptors gamma t (ROR γ t) were decreased whereas fork head box protein 3 (Foxp3) was increased partly in a dose-depend manner. In addition, MET treatment inhibited spleen germinal center B cells formation ($P < 0.01$).

Conclusion: Our results indicate that MET can effectively alleviate the fibrotic disorders by modulating the balance between Treg cells and effector T cells and germinal center B cells formation.

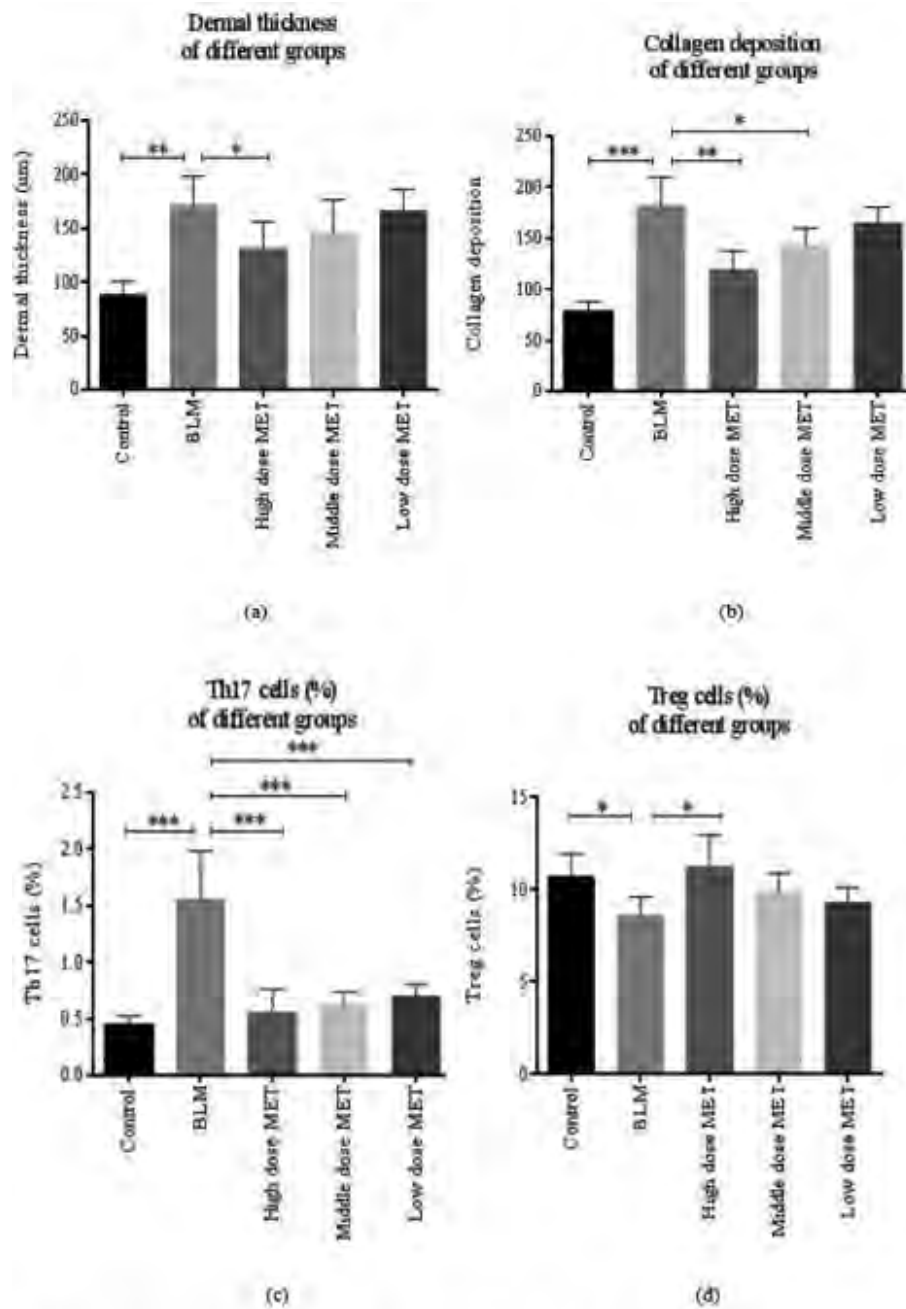

Figure legends. Therapeutic effects of metformin in BLM-treated mice. Scleroderma was induced in C57BL mice. Metformin (50mg/kg, 100mg/kg, 200mg/kg) was intraperitoneally injections in a 28 days. Mice were sacrificed in the end of the fourth weeks. Quantitative analysis of dermal thickness and collagen deposition in skin tissues

Ritchlin², Homaira Rahimi⁴ and Edward Schwarz⁵, ¹Center for Musculoskeletal Research, University of Rochester, Rochester, NY, ²Division of Allergy/Immunology and Rheumatology and Center for Musculoskeletal Research, School of Medicine and Dentistry, University of Rochester Medical School, Rochester, New York, USA, Rochester, NY, ³Division of Allergy, Immunology and Rheumatology and Center for Musculoskeletal Research School of Medicine and Dentistry, University of Rochester, Rochester, New York, USA, Rochester, NY, ⁴Rheumatology, University of Rochester/Golisano Children's Hosp, Rochester, NY, ⁵Orthopediatrics, University of Rochester, Rochester, NY

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Sclerosis and Related Disorders – Basic Science Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Cardiopulmonary disease is a severe comorbidity in many connective tissue diseases (CTD). Rheumatoid arthritis, systemic sclerosis, and systemic lupus patients are all at increased risk of pulmonary complications and mortality secondary to these complications. Specifically, pulmonary arteriole vasculopathy can lead to right ventricle hypertrophy and eventually, right heart failure. Recently, TNF transgenic (TNF-Tg) mice with inflammatory erosive arthritis was described to have inflammatory interstitial lung disease with significant arteriole thickening, concomitant with right ventricle hypertrophy. However, the source of the pathogenic TNF in this model remains unknown. Thus, we performed adoptive transfer experiments to test the hypothesis that non-hematopoietic derived TNF mediates pulmonary vasculopathy in the setting of inflammatory arthritis.

Methods: Female TNF-Tg and WT littermates were treated with a 10 Gy split dose at 6 weeks of age, and syngeneic TNF-Tg or WT bone marrow was transferred back into the irradiated mice. Following bone marrow reconstitution, the mice were euthanized at 4-5 months of age for histology of the hearts and lungs. Histomorphometry was performed to assess, right ventricular (RV) area, lung cellular area, and pulmonary arteriole thickness.

Figure 1

Figure 2

Results: Representative images (Figure 1A-E) of the hearts show an increase in RV area (Arrows) in the TNF-Tg and the TNF-Tg donor into TNF-Tg recipients (TNF-Tg → TNF-Tg) compared to the WT mice (5.4 ± 1.2 and 3.7 ± 0.6 vs 2.0 ± 0.6 mm², $p < 0.05$). However, the WT recipient of TNF-Tg bone marrow (TNF-Tg → WT) showed no signs of ventricular hypertrophy. In contrast, the TNF-Tg recipient of WT bone marrow (WT → TNF-Tg) displayed increased RV area compared to the TNF-Tg → WT mice (4.8 ± 1.1 vs 1.3 ± 0.1 mm³, $p < 0.05$). The lung cellular infiltrate is also reduced in the TNF-Tg → WT compared to the WT → TNF-Tg (Arrows, Figure 2 A-C, 6.8 ± 0.2 vs 12.5 ± 1.3 %, $p < 0.05$), as well as the pulmonary arteriole thickness (Arrows, Figure 2 D-E, 29.5 ± 8.4 vs 38.3 ± 14.2 μm, $p < 0.05$).

Conclusion: We have previously described significant cardiopulmonary disease in the TNF-Tg mouse. Here, we interrogated the role of the non-hematopoietic derived TNF to drive cardiopulmonary pathology associated with connective tissue disorders. These data suggest a critical role of tissue resident cells and their inflammatory profile in the development of vasculopathy and pulmonary hypertension.

M10, a Small Fragment of the Hepatocyte Growth Factor Receptor, Attenuates Fibrotic Changes in a Murine Model of Scleroderma Lung Disease and in Human Lung Fibroblasts

Tanjina Akter¹, Ilia Atanelishvili¹, Atsushi Noguchi², Galina S. Bogatkevich¹ and Rick Silver³, ¹Division of Rheumatology and Immunology, Department of Medicine, Medical University of South Carolina, Charleston, SC, ²Division of Rheumatology, Endocrinology and Nephrology, Hokkaido University Graduate School of Medicine, Sapporo, Japan, ³Rheumatology, Medical University of SC, Charleston, SC

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Sclerosis and Related Disorders – Basic Science Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Interstitial lung disease (ILD) is the major cause of mortality among scleroderma (systemic sclerosis, SSc) patients. Extracellular matrix (ECM) deposition is a hallmark of this and other fibrotic lung diseases. TGFβ plays a crucial role in ECM gene expression via regulation of Ca²⁺/calmodulin-dependent protein kinases and matrix

metalloproteinases (MMPs). We recently demonstrated that M10 peptide, naturally derived from the cytosolic fragment of the hepatocyte growth factor receptor, blocks the TGF β -mediated canonical pathway via interaction with SMAD2 and reduces fibrosis *in vivo*. In this study, we investigate the efficacy of M10 in the regulation of intracellular Ca²⁺ levels, ECM proteins, and in the bleomycin-induced therapeutic mouse model of SSc-ILD.

Methods: Lung fibroblasts were derived from lung tissues of SSc patients and from matched normal lungs obtained at autopsy. Antifibrotic *in vivo* effects of M10 (10 mg/kg, intraperitoneal, every 48h) were studied in the bleomycin-induced therapeutic mouse model of SSc-ILD. Ca²⁺ was measured by FLIPR Tetra cellular screening system equipped with Molecular Devices ScreenWorks® software. Expression levels of collagen, connective tissue growth factor (CTGF, CCN2), fibronectin and tenascin were measured by immunoblotting and real-time PCR. Expression levels of matrix metalloproteinases (MMPs) were determined by human MMP antibody array. Statistical analysis was performed using GraphPad Prism 7 software.

Results: In both normal lung fibroblasts and SSc-ILD lung fibroblasts, an acute increase of intracellular Ca²⁺ was observed 15 sec following TGF β administration, with a second peak of delayed Ca²⁺ efflux at 60 sec. A high level of Ca²⁺ was maintained throughout the 10 min of the cellular screening process. In the presence of M10 peptide, TGF β -mediated Ca²⁺ was significantly ($p < 0.001$) reduced in both acute and delayed states maintaining overall lower amplitude. M10 peptide suppressed TGF β -mediated mRNA and protein expression of collagen I, CCN2, fibronectin, and tenascin. M10 peptide significantly induced the expression of MMP-10 in normal lung fibroblasts, whereas M10 peptide inhibited MMP-3 in SSc-ILD lung fibroblasts. In the bleomycin-induced therapeutic mouse model of SSc-ILD, M10 noticeably reduced collagen in lung parenchyma. A semi-quantitative evaluation of histopathology using the Ashcroft scale demonstrated a significant decrease in bleomycin-induced fibrosis in M10-treated mice as compared to mice treated with control (scrambled) peptide.

Conclusion: M10 peptide reduces ECM proteins, inhibits TGF β -mediated Ca²⁺ efflux and regulates MMPs demonstrating strong antifibrotic effects *in vitro* and *in vivo* in an animal model of lung fibrosis and should be considered as a potential therapeutic agent for systemic sclerosis and other fibrosing diseases.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Sclerosis and Related Disorders – Basic Science Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The etiology and pathogenesis of SSc are poorly understood; however, an increasing body of evidence supports an early inflammatory phase that precedes, and may precipitate, fibrosis. Circulating monocytes are likely to play a role in the progression of SSc because they produce inflammatory cytokines, including interferon, that have previously been identified in SSc patients. Moreover, monocytes are precursors of macrophages that can reorganize the extracellular matrix (ECM), resulting in end-organ fibrosis.

Methods: We sequenced RNA from classical and nonclassical monocytes obtained from whole blood of patients enrolled in the Prospective Registry of Early Systemic Sclerosis (PRESS) cohort at one of 11 United States Scleroderma Centers and compared them with age-, sex-, and ethnicity-matched controls. The PRESS cohort includes patients with early (< 2 years' duration since first non-Raynaud symptom attributed to SSc) diffuse cutaneous SSc (swollen hands or sclerodactyly and at least one of the following: anti-topoisomerase I or anti-RNA polymerase III serum autoantibodies; proximal skin involvement; tendon friction rubs). Patients were 73% women, 67% white, and mean (SD) age was 51y (12); healthy

controls were 73% women, 67% white, and mean (SD) age was 52y (13). Skin biopsies collected through the Northwestern Scleroderma Patient Registry were used to examine gene expression in dermal myeloid cells.

Results: Based on RNA sequencing data from classical monocytes, we define three sub-groups of patients who are robustly delineated by upregulation of distinct functional pathways. Group 1 was defined by an interferon signature, group 2 exhibited marked increase in pro-inflammatory chemokines including CCL2 and proliferation markers, and group 3 samples upregulated genes associated with TGF β signaling and ECM remodeling. These sub-groups were recapitulated in nonclassical monocytes, although not all the same genes were up-regulated. Additionally, we found that expression of genes associated with monocyte maturation from classical to nonclassical phenotype differed in these three patient groups. Finally, we examined gene expression in myeloid cells isolated from the fibrotic skin of SSc patients and healthy control participants. Genes associated with patient groups 1 and 3 were generally more upregulated in patients than genes from group 2. This result bolsters previous findings regarding the importance of interferon and TGF β signaling in SSc skin disease and illustrates a relationship between disease-specific gene expression during maturation from blood-borne monocytes to tissue-resident myeloid cells.

Conclusion: Our study confirms the role of monocytes in SSc pathogenesis through the dysregulation of genes that have been previously reported in SSc patients. Future studies will integrate longitudinal data in order to determine whether the gene expression that defined patient groups in our study is stable over time and whether it predicts patient response to specific therapies.

Session Title: Systemic Sclerosis and Related Disorders – Basic Science Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic sclerosis (SSc) is a connective tissue disorder that is characterized by fibrosis and vascular damage in the skin and other visceral organs, with an autoimmune background. One of the cause of vasculopathy is thought to be the repair dysfunction of damaged vessels. Actually, endothelial progenitor cells in peripheral blood mononuclear cells (PBMCs) of SSc were reported to be reduced. However, the mechanism of these reduction is unclear. Recent studies have indicated that B cells play critical roles in systemic autoimmunity and disease expression through various functions such as activation of other immune cells in addition to autoantibody production. Several studies have also shown that B cells activated in SSc produce IL-6, which induces fibrosis. Indeed, Rituximab (RTX), a B cell depleting antibody, or Tocilizumab (TCZ), anti-IL-6 receptor (IL-6R) antibody, can ameliorate many autoimmune diseases including SSc. Here, we focused on the relationships between endothelial colony forming cells (ECFCs), and autoantigen-reactive B cells in SSc.

Methods: In SSc patients treated with RTX, TCZ, or oral steroid, we analyzed nailfold capillary changes over time. We also compared the number of ECFCs in PBMCs before and one year after treatment. In mouse study, we assessed the relationship between Topo I reactive B cells and ECFCs with or without contact, using topo I and complete Freund's adjuvant-induced SSc model mice (Topo I model). We also analyzed activated signaling pathway after contact with Topo I reactive B cells and ECFCs. Finally, the effect of B cell depletion treatment or anti-IL-6R antibody treatment to vasculopathy and ECFCs in Topo I model mice was assessed.

Results: Both B cell depletion treatment and anti-IL-6R antibody treatment improved ulcer healing, promoting neovascularization. The number of ECFCs in PBMCs of SSc patients, which was reduced before treatment, increased after one year of RTX treatment or TCZ treatment. In particular, the number of ECFCs after RTX treatment increased as many as healthy controls. In Topo I model mice, the number of ECFCs was reduced compared with controls. The experiment with recombinant cytokines or neutralizing antibody revealed that this reduction of ECFCs is caused by cytokines such as IL-6, TNF- α , CCL3, and CCL4 from Topo I reactive B cells, which were activated by direct interaction with ECFCs. In contrast, IL-10 production, which promotes colony formation of ECFCs, from Topo I reactive B cells was reduced compared with Topo I non-reactive B cells. This direct interaction activates B cell receptor (BCR) pathway such as SYK, BTK, PLC γ 2, TRAF6, and NF- κ B. In Topo I reactive B cells, IL-6-JAK2-STAT3 pathway is also activated. These results suggest that activated both BCR pathway and IL-6-JAK2-STAT3 pathway are crucial in activation of Topo I reactive B cells and suppression of ECFCs. Finally, both B cell depletion and anti-IL-6R antibody treatment also increased ECFCs, suppressing vasculopathy in Topo I model mice.

Conclusion: Decreased number of ECFCs is closely related to vasculopathy of SSc. Autoreactive B cells, these signaling pathways, cytokines, and drugs which can increase ECFCs can be novel therapeutic targets in vasculopathy of SSc.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Sclerosis and Related Disorders – Basic Science Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Though transforming growth factor- β (TGF- β) plays a fundamental role in the pathogenesis of SSc, the mechanism by which TGF- β signaling acts in SSc remains largely unclear. The aim of this study is to clarify the underlying mechanism of TGF- β signaling over-activation in SSc, especially epigenetic manners.

Methods: Twenty SSc patients and twenty-one age, gender-matched healthy individuals were enrolled in this study. Luciferase analysis was used to evaluate the binding capacity of miRNA-3606-3p to TGFBR2. Western blot and qPCR were used to detect the expression of miRNA, TGFBR2, p-SMAD2/3 and collagen.

Results: Transcription level of *TGFBR2* was increased in both SSc skin samples and fibroblasts (**Fig. 1A and 1B**). In contrast, miR-3606-3p, a predicted miRNA of TGFBR2, was downregulated in SSc fibroblasts and skin tissues (**Fig. 1C and 1D**).

Based on the above findings, we then determined whether *TGFBR2* is the direct target for miR-3606-3p. Three *TGFBR2* 3'-UTR wild type-containing binding sites (site 1, site 2 and site 3) of miR-3606-3p were subcloned into the pmirGLO vector, and co-transfected with a luciferase construct containing miR-3606-3p mimics into primary dermal fibroblast cells. As illustrated in **Fig. 1E**, the relative luciferase activity was only significantly decreased in the *TGFBR2* 3'-UTR wildtype site 3 group, whereas there was no significant difference in the *TGFBR2* 3'-UTR wild type site 1 or site 2 group, suggesting that miR-3606-3p may selectively bind to the sequence containing site 3 of the *TGFBR2* 3'-UTR. Furthermore, overexpression of miR-3606-3p significantly diminished the level of *TGFBR2* mRNA (**Fig. 1F**) and TGFBR2 protein (**Fig. 1G**).

Next, we examined whether the repression of TGFBR2 mediated by miR-3606-3p would disrupt TGF- β /Smad signaling in fibroblasts. Western blot analysis showed that the transfection of primary fibroblast cells with miR-3606-3p mimics significantly reduced the protein levels of type I collagen and p-SMAD2/3 (**Fig. 1H**). We then analyzed the expression of type I collagen and p-SMAD2/3 in response to *TGFBR2* downregulation in the fibroblasts. Interestingly, siRNA-induced *TGFBR2* downregulation revealed similar results to those obtained via miR-3606-3p overexpression in the fibroblasts (**Fig. 1I**).

Conclusion: Our findings demonstrated that increased TGFBR2 could be responsible for the hyperactive TGF- β signaling observed in SSc. We identified a pivotal role for miR-3606-3p in SSc, which inhibits TGF- β signaling, at least partly, through TGFBR2 repression. The results suggest that the regulation of miR-3606-3p/TGFBR2 could be a promising therapeutic strategy for treatment of fibrosis.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Sclerosis and Related Disorders – Basic Science Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Prolyl-tRNA synthetase (PRS), a member of aminoacyl tRNA synthetases (ARS), is an enzyme that conjugates amino acid proline to its tRNA to generate prolyl-tRNA to be used in protein synthesis. Since proline is one of major components of collagen, we hypothesized that suppression of PRS would down-regulate collagen synthesis, which could be beneficial in fibrosis. Systemic sclerosis (SSc) is an autoimmune disease that is characterized by progressive thickening of skin, caused by excessive accumulation of collagen.

Methods: Inhibitory activity of DWN12088 against PRS was assessed by aminoacylation assay. Fibroblasts were treated with DWN12088 either before or after treatment of transforming growth factor beta (TGF β), and then collagen and pro-fibrotic markers were assessed using western blot. 3D skin organoid was constructed using systemic sclerosis patient-derived dermal fibroblast and keratinocyte. For in vivo study, constructed patient-derived 3D skin organoid was engrafted to SCID mouse using tie-over dressing. After 2 weeks administration of DWN12088, degree of dermal thickness and collagen I (Col I) expression were determined by histological analysis.

Results: To validate our hypothesis, we investigated the expression levels of pro-fibrotic markers by overexpression or knockdown of PRS in vitro. We showed that PRS is closely related to the expression of Col I and alpha smooth muscle actin (α SMA). Interestingly, PRS protein expression is significantly increased in lung tissue of idiopathic pulmonary fibrosis (IPF) patients. We developed a novel selective inhibitor of PRS, DWN12088, which has IC₅₀ value of 74 nM against PRS. DWN12088 reduced TGF β -induced Col I and pro-fibrotic marker expression in various cell-lines and primary fibroblasts. This suggests that PRS may be a critical contributor of excessive accumulation of collagen, a main pathological hallmark of fibrosis. Using systemic sclerosis patient-derived dermal fibroblast, we developed 3D skin organoid in order to investigate efficacy of DWN12088. In this model, DWN12088 successfully decreased skin thickness, Col I, and α SMA. In a mouse xenograft model using the patient-derived 3D skin organoid, treatment of 10 mg/kg DWN12088 also showed decrease in skin thickness and collagen expression compared to control group.

Conclusion: PRS is an enzyme required during protein translation involving proline amino acid. In fibrotic condition, we observed that PRS is overexpressed, which may be responsible for over-production of collagen. Inhibition of PRS successfully inhibited formation of collagen and expression of pro-fibrotic markers in various cellular systems, systemic sclerosis patient-derived skin organoid model, and its mouse xenograft model. Therefore, DWN12088, a novel PRS inhibitor, may serve as a potential therapeutic agent in systemic sclerosis and other fibrotic diseases.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Sclerosis and Related Disorders – Basic Science Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic sclerosis (SSc) is a complex multi-system autoimmune disease characterized by immune dysregulation, vasculopathy, and organ fibrosis. Skin fibrosis causes high morbidity and impaired quality of life in affected individuals. In this study, we identified genes that may be involved in the development of dermal fibrosis mediated by TGF- β in human skin maintained in organ culture.

Methods: To identify new genes regulated by TGF- β in human skin, we performed high-throughput RNA sequencing using ex vivo human skin samples treated with TGF- β or a vehicle control. We identified genes whose expression is altered in

human skin treated with TGF- β . Of these genes, COL22A1 showed the highest level of differential expression. The expression levels of COL22A1 and its time-dependent changes were evaluated using real-time PCR and immunoblotting (IB) in *ex vivo* human skin tissues and *in vitro* in normal human dermal fibroblasts. To investigate which TGF- β signaling cascades are involved in the induction of COL22A1 expression, normal skin fibroblasts were cultured with TGF- β in combination with specific inhibitors. Since COL22A1 was an early response gene, we sought to assess its role in the TGF- β -mediated response, thus normal skin fibroblasts were transfected with COL22A1 siRNA and then stimulated with TGF- β . Furthermore, we compared mRNA and protein levels of COL22A1 in skin fibroblasts from control donors and patients with the diffuse cutaneous form of SSc by using real-time PCR and IB.

Results: COL22A1 was most differentially expressed and its levels were significantly increased by TGF- β *ex vivo* and *in vitro*. TGF- β caused a significant increase in the expression levels of COL22A1 at earlier time points than other fibrosis associated genes. Further, TGF- β -induced COL22A1 expression was abrogated by ALK5 and MEK inhibition. Silencing of COL22A1 significantly reduced TGF- β -induced ACTA2 expression. Dermal fibroblasts from patients with diffuse cutaneous SSc showed significantly increased expression levels of COL22A1 compared with normal skin fibroblasts.

Conclusion: In conclusion, our findings suggest that the increased expression of COL22A1 is associated with the pathogenesis of fibrosis in SSc, and that the regulation of COL22A1 expression may have important implications for skin fibrosis. These results contribute novel insights into genes regulated under pro-fibrotic conditions in human skin, providing direct relevance to human dermal fibrosis.

Abstract Number: 130

The Role of Cofilin, an Actin Associated Protein, in Activation of Systemic Sclerosis Vascular Smooth Muscle Cells

Shadia Nada, Bashar Kahaleh and **Nezam Altorok**, Medicine/Rheumatology, University of Toledo, Toledo, OH

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Sclerosis and Related Disorders – Basic Science Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic sclerosis (SSc) is an autoimmune connective tissue disease characterized by activation of the immune system, vascular dysfunction and tissue fibrosis. Vascular dysfunction in SSc is one of the most prominent features of the disease that generally manifest as Raynaud's phenomenon and vascular wall proliferation resulting in progressive fibro-proliferative vasculopathy seen in all involved organs. There is evidence for increased vascular smooth muscle cell (vSMC) proliferation, migration and resistance to apoptosis in SSc. In this study, we wished to understand the role of cofilin signaling pathways involvement in SSc-vSMC dysfunction. Cofilin is a member of the actin associated proteins that accelerates actin depolymerization at pointed ends and severs long actin filaments. It plays a crucial role in cell migration by promoting the rapid turnover of actin filaments through severing filamentous actin (F-actin) and depolymerizing actin filaments from the pointed end. Cofilin is inactivated by phosphorylation through LIM-Kinases (LIMK), and activated by dephosphorylation mediated by Slingshot phosphatases (SSH-1).

Methods: We isolated vSMC from 4mm punch skin biopsies from 3 patients with diffuse cutaneous SSc (dcSSc) and 3 healthy controls. We examined the expression levels of P-cofilin, total cofilin, P-LIMK and Total LIMK by western blot analysis. We used insulin at a concentration of 5nM, which activates LIMK by phosphorylation, to evaluate the effect of cofilin on vSMC migration that was examined by the scratch test assay.

Results: We demonstrate significant increase in SSc-vSMC migration compared to control cells that was noted at 2 hours and continued for 48 hours, with an average increase migration of 2.1 fold at 24 hours. The expression ratio of P-cofilin to total cofilin was 3.7 and 0.3 in control-vSMC and SSc-vSMC, respectively ($P < 0.01$). We also noted decreased ratio of phosphorylation of LIMK in SSc-vSMC (0.21) compared to control vSMC (0.55, $P < 0.01$). The addition of insulin increased the ratio of phosphorylation of LIMK by 2 folds at 24 hours, which was associated with 6 fold increase in phosphorylation of cofilin. Moreover, *in vitro* treatment of vSMC with insulin decreased SSc-vSMC migration potential and reverted SSc-vSMC migration to a pattern similar to control vSMC.

Conclusion: We provide an experimental evidence for the role of cofilin in increased migration of SSc-vSMC, which contribute to the abnormal phenotype of SSc-vSMC. We report *activation* of cofilin in SSc-vSMC as shown by decrease P-

cofilin in association with inactivation of LIMK by decreased P-LIMK levels in the cells. Furthermore, the addition of insulin activates LIMK by phosphorylation, which in turn inactivates cofilin. Indeed, the addition of insulin to SSc-vSMC cultures resulted in reduced SSc-vSMC migration to a level comparable to control vSMC migration rate.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Systemic Sclerosis and Related Disorders – Basic Science Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Microvascular rarefaction and tissue fibrosis are the hallmarks of Systemic Sclerosis (SSc). CD248, also known as endosialin, is a transmembrane glycoprotein expressed on key effector cells within the stroma of fibrotic tissue, including pericytes and fibroblast (FBs). The functional role of CD248 during fibrotic process is largely unknown, although it has been reported that in the experimental models of liver and kidney fibrosis, CD248^{-/-} mice are protected from myofibroblast accumulation and capillary rarefaction, probably inhibiting pericytes differentiation toward α SMA⁺ myofibroblasts. On these bases, CD248 may be considered an attractive therapeutic target in the pathologic processes in which vascular damage and fibrosis are strongly joined, as observed in SSc. The aim of this work was to investigate the expression of CD248 isoforms, in dermal fibroblasts and evaluate the functional contribute of this molecule to exacerbate the microvascular damage during SSc.

Methods: After ethical approval, skin biopsies were collected from SSc-patients and healthy controls (HC). CD248 expression was investigated in the skin and in cultured FBs before and after TGF β treatment, by immunohistochemistry, qRT-PCR and western-blot. Additionally, we assessed the role of CD248 expression on angiogenesis by employing endothelial cel/SSc-FBs organotypic cocultures where FBs were treated or not with lentiviral induced CD248 short-hairpin RNAs delivery.

Results: CD248 expression was increased in perivascular cells and fibroblasts in SSc-skin. We identified 2 different isoforms of CD248 molecule, one short isoform, which has been generally correlated with the activated status of CD248, and one long isoform. Both the isoforms were significantly increased in SSc-FBs compared to HC-FBs, with the short isoform was not expressed at all in HC-cells. TGF β treatment of SSc-FBs induced a significant increase of CD248 expression. Functionally, SSc-FBs, SSc-FBs, overexpressing CD248, suppressed angiogenesis in the organotypic model and, after silencing this molecule, the angiogenic phenotype was rescued.

Conclusion: The over-expression of short isoform of CD248, increased after TGF β treatment, may play a role in fibrotic process by modulating the molecular pathways leading to dermal FBs differentiation toward myofibroblast, responsible of the impaired extracellular matrix production and interfering with endothelial cells tube formation. The CD248 silencing may prevent these angiogenic alterations. Future study, targeting CD248, may open new therapeutic strategy to inhibit both myofibroblasts generation and microvascular damage.

Session Title: Systemic Sclerosis and Related Disorders – Basic Science Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Alternatively activated macrophages expressing CD206 are believed to promote fibrosis in a range of disorders including systemic sclerosis (SSc). Novel therapeutic peptides (RP) which enter the cell by binding CD206 may selectively inhibit this population of cells. We investigated the potential for RP peptides to suppress fibrosis in experimental mice and in model systems using SSc derived macrophages. sCD206 and CD206 cell surface expression were evaluated as biomarkers in SSc.

Methods: RP therapeutic peptides 10mg/kg were administered by twice daily subcutaneous injection during dermal and lung bleomycin fibrosis models, in wild type C57BL/6 female mice (n=10 mice per group). SSc macrophage viability was assayed by Presto Blue assay. SSc macrophage-fibroblast cross-talk was modelled using transfer of media followed by qPCR for collagen I. sCD206 was assayed by ELISA in plasma (n=40 healthy control (HC) and 40 diffuse SSc) and blister fluid (BF) (n=12 HC and 13 SSc). SSc monocyte-derived macrophages (n=17 SSc & 9 HC) were profiled by flow cytometry for CD206 (M2) and P2X7 (ATP receptor) expression, and by qPCR for arginase (M2) and IFN γ (M1).

Results: In mouse models, RP peptides inhibited both the dermal and lung fibrosis induced by bleomycin, and reduced plasma cytokines to basal levels (skin model; dermal thickness in controls 343, bleo 402, bleo +RP 345 μ m, $p<0.0009$, plasma IL-6 in bleo 101 pg/ml, bleo+RP 24, $p<0.00018$, plasma IL12p40 bleo 38, bleo+RP 0, $p<0.15\times10^{-7}$) (lung model; Ashcroft score bleomycin 5.8, bleo+RP 2.8, $p<0.0024$, plasma IL6 bleo 58, bleo+RP 7 $p<0.0005$, IL12p40 bleo 152, bleo+RP0, $p<0.00014$).

As a biomarker, sCD206 was elevated in SSc plasma (SSc median 683, HC 583 pg/ml, $p<0.024$), and BF (SSc median sCD206 42, HC 31 pg/ml, $p<0.041$). Both CD206 and P2X₇ were highly expressed by SSc macrophages (mean fluorescence SSc, 776.1 SD=409.1, 724.4 SD=455.3 vs HC 632.2 SD=73.7, 472.9 SD=25.4), correlating with modified Rodnan skin score ($p<0.05$, $r=0.51$). Double positive P2X₇ and CD206 cells were seen in a subgroup with higher skin scores. SSc macrophages had elevated arginase:IFN γ ratio (11.4 vs 5.9, $p=0.03$).

RP therapeutic peptides suppressed viability in SSc macrophage cultures with raised arginase:IFN γ ratio >8 , but had no effect on macrophages with lower arginase:IFN γ . Treatment of SSc macrophages with RP832c, as the lead candidate, effectively abolished macrophage-fibroblast cross-talk, reducing collagen I to basal levels (collagen I, basal 2830, TGF β stimulated 3026, SSc macrophage media treated 4186, RP832c 10 μ M macrophage media 3519, RP832c 100 μ M macrophage media 2475, relative expression to TBP, $p<0.0039$).

Conclusion: These data confirm the presence of activated CD206 positive macrophages in SSc, and demonstrate the potential for these cells to directly stimulate fibroblasts, inducing collagen I. Furthermore, the RP peptides suppress fibrosis and cytokines in mouse models and selectively inhibit highly activated SSc macrophages. RP832c, the lead compound, blocked SSc macrophage-fibroblast cross-talk and will be developed as a GLP therapeutic for clinical trials.

Session Date: Sunday, October 21, 2018

Session Title: T Cell Biology and Targets in Autoimmune and Inflammatory Disease Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: OX40 (TNFRSF4, CD134) is a costimulatory receptor member of the NGFR/TNFR superfamily expressed predominantly on activated T lymphocytes. Ligation of OX40 by its ligand OX40L (TNFSF4, CD252) leads to enhanced T cell survival, proliferation, and effector function. Blocking the OX40/OX40L pathway is therefore highly attractive to treat a broad range of T cell-mediated autoimmune diseases. While several OX40 agonist antibodies are in clinical development for cancer, generation of a true OX40 antagonist is challenging. The studies presented herein characterize the preclinical profile, mechanism of action, and immunomodulatory capabilities of GBR 830.

Methods: T cell proliferation assay (inhibition or agonism); NFκB reporter cell assay; xenogeneic human graft versus host disease model in SCID mice; cynomolgus monkey T cell-dependent antigen response (T-DAR) model; and in vitro antigen reactivation model.

Results: GBR 830, a humanized IgG1 anti-OX40 antibody, recognizes the cysteine-rich domain 2 of OX40 that overlaps the binding region to OX40L. Consequently, GBR 830 blocks the binding of OX40L to OX40 and inhibits OX40L-mediated inhibition of T cell proliferation and NFκB signaling. In contrast to all other anti-OX40 antibodies tested, GBR 830 did not reveal any residual agonism even in a sensitive experimental setup. In a xenogeneic graft versus host disease model using immunodeficient mice reconstituted with human peripheral blood mononuclear cells, GBR 830 suppressed T helper cell-mediated responses. In a cynomolgus monkey T-DAR model to keyhole limpet hemocyanin, GBR 830 demonstrated a profound inhibitory effect on memory response but not on primary antibody response. In vitro vaccine (tetanus toxoid) or autoantigen reactivation assays showed that GBR 830 can inhibit memory T cell reactivation.

Conclusion: Overall, these data suggest that GBR 830 has immunomodulatory capabilities in T helper cell-mediated responses, applicable to a broad range of autoimmune pathologies. Accordingly, GBR 830 demonstrated positive results in a phase 2a clinical study in patients with moderate-to-severe atopic dermatitis (NCT02683928) and has the potential to address unmet medical needs in autoimmune and inflammatory diseases.

Session Title: T Cell Biology and Targets in Autoimmune and Inflammatory Disease Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: For rheumatoid arthritis (RA), as with many other rheumatic diseases, the importance of determining which therapy will work best, early in disease, to prevent further progression, is an important area of research. Progress in treatment response has been limited, possibly due to the complex interplay between various cell types. As such, specific T-cell signatures, determined by single cell RNA-Seq (scRNA-Seq), could be predictive of future response to treatments such as anti-TNF biologic therapies. Our aim was therefore to determine the optimal study design and to assess the potential of scRNA-Seq to identify T-cell signatures under resting and stimulated conditions to inform future studies.

Methods: Primary CD4⁺ T-cells were either stimulated using anti-CD3/CD28 beads or subjected to the same conditions without stimulation for 4 hours. Single cells were isolated using the 10X Genomics Chromium Controller with a target recovery of 6000 cells. Each scRNA-Seq library was sequenced on 4 Illumina HiSeq 4000 lanes (~200K reads/cell) and processed using the cellranger pipeline. Further quality control and cluster analysis was performed using Seurat.

Results: For the unstimulated sample 5,586 cells were recovered and after quality control and filtering, 5,387 cells remained. Similarly, for the stimulated sample, 4,621 cells were recovered and 4,473 remained. This resulted in an average of 1,094 and 1,456 genes per cell. Similar clusters were seen after downsampling the stimulated dataset to 1 lane (~379M reads, ~82K reads/cell), suggesting that CD4⁺ T-cells are defined by large gene expression changes rather than subtle variations, consistent with protein expression data. Cluster exploration allowed the identification of several typical CD4⁺ T-cell populations, including naïve, helper and regulatory. Furthermore, alignment of the two conditions in Seurat, identified classical and non-classical markers of activation, such as CD69, CCR7, MYC and PIM3. Finally, the relative cluster location and the expression of indicative markers suggested evidence of a progression from a naïve cell state to an 'active' effector state.

Conclusion: This data has provided important insights into future study design and confirmed the potential of scRNA-Seq to identify T-cell signatures. Importantly, despite obvious expression changes, cluster identity was maintained between stimulatory conditions. This implies it is possible to directly compare scRNA-Seq expression profiles between patient samples showing different disease activity without confounding the conclusions and enable the use of scRNA-Seq to investigate its predictive potential in RA treatment response. We are therefore in the process of expanding this work to study patient samples and different cell types. For example we have already generated similar data for monocytes on 3 RA samples and 3 healthy samples.

Session Date: Sunday, October 21, 2018

Session Title: T Cell Biology and Targets in Autoimmune and Inflammatory Disease Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic sclerosis (SSc) is an autoimmune disease characterised by excessive fibrosis of skin and internal organs, and vascular dysfunction. Association of T and B cell subsets have been reported in SSc, however there is lack of systematic studies of functional relations between immune cell subsets in this disease. This lack of mechanistic knowledge hampers targeted intervention.

In the current study we ought to determine differential immune cell composition and heterogeneity in peripheral blood of SSc patients and its impact on disease severity and progression.

Methods: Mononuclear cells from blood of SSc patients with interstitial lung disease (ILD, n=10) or No ILD (n=10) and healthy controls (n=10) were analysed by mass cytometry using a 36 marker (cell-surface and intracellular) panel to aid in identification of major PBMC lineages including T cells, B cells, monocytes and NK cells and their subsets. Transcriptome analysis (m-RNA sequencing) was performed on sorted T and B cell subsets. Unsupervised clustering of mass cytometry data was performed using in-house developed analysis software MARVIS. This software combines dimension reduction and

clustering steps to identify all possible cellular subsets. Further, custom R scripts helped in identifying nodes that were differentially expressed between the study groups and also phenotype of these nodes.

Results: Unsupervised clustering performed revealed significant differences in the frequencies of T cell and B cell subsets. Most strikingly we identify a 3 fold decrease in frequencies of Va7.2+ CD161+ mucosal associated invariant T cells (MAIT) in SSc patients and 2 fold increase in total B cells, particularly CD19+ CD27- naive cells. A subset of memory CD8+ T cell, expressing CXCR3 was found to be increased in SSc patients as compared to healthy controls. Transcriptome analysis of sorted B cell and T cell subsets showed decrease in genes related to survival and increased expression of apoptotic genes in CD4,CD8 T and MAIT cells from SSc patients. Genes related to exhaustion and leukocyte migration were highly expressed in T cells from patients.

Conclusion: This study provides an in depth analysis of systemic immune composition in SSc with the potential to delineate mechanisms of pathogenesis and identify diagnostic and/or therapeutic targets. This is the first demonstration of altered frequencies of T cell subsets, particularly MAIT cells, in systemic sclerosis and also outlines exhaustive nature of these cells in the periphery of systemic sclerosis patients.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: T Cell Biology and Targets in Autoimmune and Inflammatory Disease Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: CD28 and Inducible T-cell Costimulator (ICOS) are two related costimulatory molecules within the immunoglobulin superfamily (IgSF) expressed on T cells and interacting with CD80/CD86 and ICOS ligand (ICOSL), respectively. Both play critical roles in T cell activation and adaptive immunity, but when dysregulated can contribute to autoimmunity. We used our proprietary platform to create a variant Ig domain (vIgDTM), an engineered version of ICOSL capable of binding both ICOS and CD28 and blocking the interaction of these costimulatory molecules with their respective receptors. This ICOSL vIgD was fused to a human Fc lacking effector function (i.e. FcR binding and complement fixation) to create the therapeutic candidate ALPN-101, which has previously been shown to have potent immunosuppressive activity *in vitro*. We report here *in vivo* activity data in mouse models of autoimmune disease supporting the potent immunosuppressive activity of ALPN-101.

Methods: ALPN-101 was evaluated for immunosuppressive activity in multiple mouse models, including the collagen-induced arthritis (CIA) model with either prophylactic or therapeutic dosing. ALPN-101 was dosed a maximum of 4 times either prior to or just after disease onset. Comparator molecules were administered at molar equivalent doses in regimens matching ALPN-101.

Results: ALPN-101, when given either prophylactically or therapeutically, significantly attenuated disease activity in the collagen-induced arthritis model. ALPN-101 mediated significant disease reduction in CIA, matching or exceeding CD28-only or ICOS-only inhibitors. Similar effects were observed in additional disease models.

Conclusion: Efficacy *in vivo* of ALPN-101 is superior to wild-type ICOSL domains or CD28-only inhibitors. The increased efficacy of ALPN-101 was made possible by engineering the wild-type ICOSL IgSF to create a vIgD with altered affinity between ICOSL and ICOS and through specifically-directed alterations in ICOSL/CD28 binding. Preclinical development of ALPN-101 is underway to support clinical studies of this potentially first-in-class dual ICOS and CD28 inhibitor.

Autoantibody-Inducing CD4 T (aiCD4 T) Cells Which Induce Systemic Lupus Erythematosus (SLE) Contain Follicular Helper T Cell in Addition to the Major IL-21-Producing CXCR5-ICOS^{hi}PD1^{hi} Population: Self-Organized Criticality Theory As the Cause of SLE

Ken Tsumiyama and Shunichi Shiozawa, Institute for Rheumatic Diseases, Nagahama, Japan

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: T Cell Biology and Targets in Autoimmune and Inflammatory Disease Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: We have shown that repeated immunization with antigen induces systemic lupus erythematosus (SLE) in the mice otherwise not prone to spontaneous autoimmune diseases. We found that overstimulation of CD4 T cells led to the development of autoantibody-inducing CD4 T (aiCD4 T) cell which had undergone *de novo* T cell receptor (TCR) revision, capable of inducing variety of autoantibodies and stimulating CD8 T cells, driving them to become cytotoxic T lymphocyte (CTL). These CTLs then matured through antigen cross-presentation in dendritic cell (DC), after which they caused tissue injury identical to SLE. We have proposed Self-Organized Criticality Theory, explaining that systemic autoimmunity would be an inevitable consequence of over-stimulating host's immune system by repeated immunization with antigen to levels that surpass system's self-organized criticality. Since the aiCD4 T cell appeared to be included in CD45RB^{lo}122^{lo} CD4 T cell subset, we here further dissected the phenotype of the aiCD4 T cell by pursuing this subset, and found that aiCD4 T cells include not only follicular helper T (Tfh) cell but also IL-21-producing CXCR5⁺ICOS^{hi}PD-1^{hi} cell, and this subset seemed to be responsible for the induction of SLE.

Methods: BALB/c mice were repeatedly immunized with ovalbumin (OVA) and SLE was induced. CD45RB^{hi} or CD45RB^{lo} CD4 T cells in spleen of these mice were studied the expression of cell surface marker using flow cytometry. Splenic CD45RB^{hi} or CD45RB^{lo} CD4 T cells were also magnetically isolated and stimulated by anti-CD3 and anti-CD28 antibodies *in vitro*. After stimulation, IL-21 in culture supernatant were detected using ELISA. IL-21-producing CD4 T cell was also detected using flow cytometry.

Results: After repeated immunization with OVA, the CXCR5⁺PD-1^{hi} Tfh cell was significantly increased. A unique CXCR5⁺PD-1^{hi} CD4 T cell subset was also increased in the OVA-immunized mice. These subsets were, however, absent in the CD45RB^{hi} subset. The expression of ICOS was equally high in both subsets as compared with conventional CXCR5⁺PD-1⁻ CD4 T cells, however, the expression of Bcl-6 was lower in the CXCR5⁺ICOS^{hi}PD-1^{hi} CD4 T cells as compared with Tfh cells. The amount of IL-21 produced from CD45RB^{lo} CD4 T cell of OVA-immunized mice was significantly high as compared with CD45RB^{hi} CD4 T cell of OVA-immunized mice or whole CD4 T cell of control mice. IL-21-producing CD4 T cell was also significantly increased within CD45RB^{lo} subset after repeated immunization with OVA. We also found that CXCR5⁺PD-1^{hi} CD4 T cells produced much more IL-21 as compared with Tfh cells after repeated immunization with OVA.

Conclusion: The CXCR5⁺ICOS^{hi}PD-1^{hi} CD4 T cells that produce IL-21 were significantly increased in addition to Tfh cells in the mice repeatedly immunized with OVA. This novel CXCR5⁺ICOS^{hi}PD-1^{hi} CD4 T cells may behave as aiCD4 T cells, and drive B cells and CD8 T cells to induce a variety of autoantibodies and lupus tissue injuries by producing massive IL-21.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: T Cell Biology and Targets in Autoimmune and Inflammatory Disease Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: IgG4-related disease (IgG4-RD) is a novel disease entity characterized by the infiltration of IgG4-secreting plasmablasts (PBs) and the generation of germinal centers in various affected organs. Several CD4+ T cell subsets including follicular helper T cells (Tfh), Th2 cells and Th1 (cytotoxic) cells have thus far been shown to be involved in the pathogenesis of IgG4-RD. Given the classic tenet that Th1 and Th2 are mutually exclusive, the above findings seem apparently contradictory and the underlying mechanism of this disease remain largely enigmatic. Here, we have thoroughly investigated the role of each CD4+ T cell subsets in patients with IgG4-RD.

Methods: Peripheral blood (PB) mononuclear cells were obtained from 21 patients with IgG4-RD and 10 healthy controls (HC). The phenotype of CD4+ T cells was analyzed by a flow cytometry. CD4+ T cells were categorized as Th1, Th2, Th17, Th1/17, Tfh1, Tfh2, Tfh17, and respective activated populations by expression of CXCR5, CXCR3, CCR6 and PD-1. The frequency of SLAMF7+ (cytotoxic CD4+) cells was also evaluated among CD4+ T cells subsets. The proportion of CD4+ T cell subsets relative to whole CD4+ T cells in patients with IgG4-RD was compared with that in HC. Moreover, the number of CD4+ T cell subsets was assessed for correlation with the titers of serum IgG4.

Results: The patients with IgG4-RD enrolled in this study were aged 66 ± 11 years and their titers of serum IgG4 were 372 ± 336 mg/dl. The frequency of Th1, Tfh1, Tfh2, and respective activated populations in patients with IgG4-RD patients was significantly increased compared with that in HC. Positive correlations were noted between the number of activated Tfh2 cells and the titer of serum IgG4 ($r=0.46$, $p=0.03$), while no correlations were observed between the number of any other activated subsets and the titer of serum IgG4, suggesting a critical role of this subset in generating IgG4-producing PBs. Notably, SLAMF7+ cells were almost exclusively observed in activated subsets of Th1 and Tfh1 cells in patients with IgG4-RD. This trend was more noticeable in patients with IgG4-RD than in HC. Moreover, the expression levels of SLAMF7 in activated Tfh1 cells were much higher than that in non-activated Tfh1 cells in patients with IgG4-RD ($13.99 \pm 5.59\%$ vs $0.81 \pm 0.56\%$, $p<0.0001$). Intriguingly enough, positive correlations were noted between the number of SLAMF7+ activated Tfh1 cells and the titer of serum IgG4 ($r=0.45$, $p=0.039$), while no correlations were observed between that of SLAMF+ activated Th1 cells and serum IgG4 ($r=0.11$, $p=0.63$).

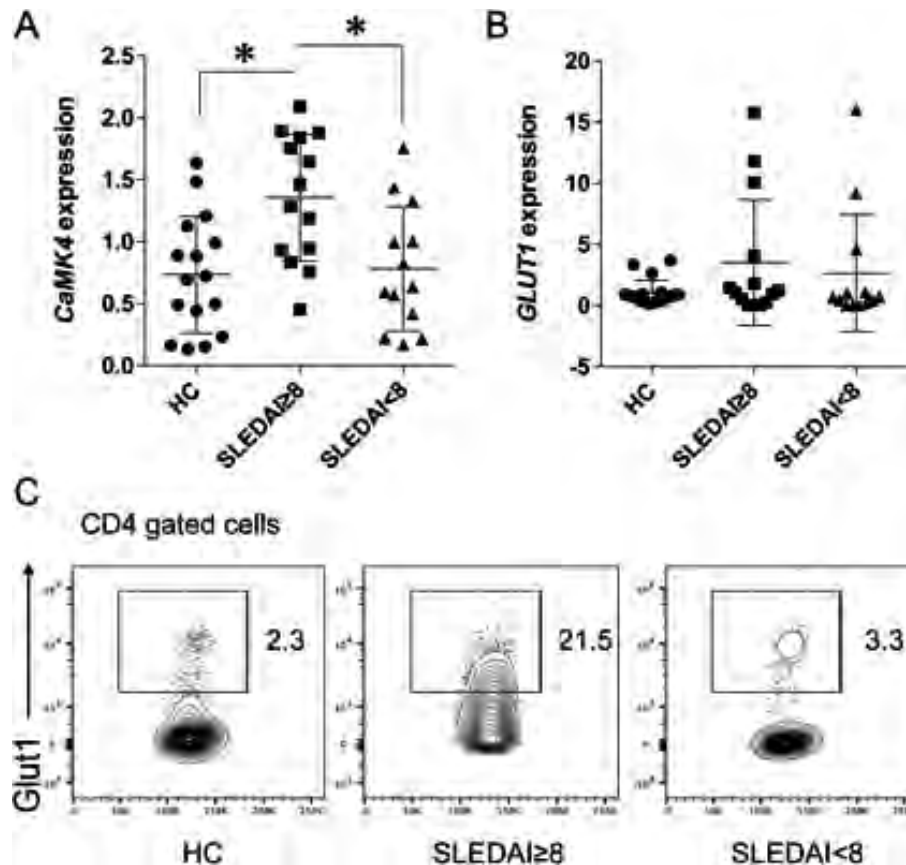

Conclusion: Together, these suggest that activated Tfh2 cells and SLAMF7+ activated Tfh1 cells were involved with the pathogenesis of IgG4-RD via generating IgG4-producing PBs, while Th1 cells, especially SLAMF7+ cells, contribute to another pathologic processes in this disease via antibody-independent mechanisms such as the production of cytokines and cytotoxic molecules. These results might reconcile the previous contradictory findings and expand our knowledge of this novel disease entity.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: T Cell Biology and Targets in Autoimmune and Inflammatory Disease Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Glycolysis is critical for T-cell effector functions, and increased glycolysis leads to autoimmunity. APT production by effector T cells is dependent on the mitochondria-independent glycolysis system. In addition, the expression of GLUT1, a major glucose transporter, is enhanced upon the activation of T cells.

We sought to clarify the significance of immunometabolism in the pathological condition of systemic lupus erythematosus (SLE) and to determine the effect of calcium/calmodulin-dependent protein kinase 4 (CaMK4) on T-cell metabolism.

Methods: We performed metabolomic profiling using capillary electrophoresis mass spectrometry in naive T cells from MRL/lpr mice treated with anti-CD3/28 antibodies in the absence or presence of a CaMK4 inhibitor (KN-93). We examined the expression of GLUT1 and CaMK4 in CD4⁺ T cells from healthy controls (HCs: n=34), patients with inactive SLE (n=18), and patients with active SLE (n=24) by flow cytometry and quantitative PCR. We performed in vitro experiments to determine the effect of KN-93 on the expression of GLUT1 during Th17 differentiation in T cells from SLE patients.

Results: CaMK4 inhibition significantly decreased the levels of glycolytic intermediates such as G6P, F6P, F1, 6DP, pyruvate, and lactate, whereas it did not affect the levels of the pentose phosphate pathway intermediates such as 6-PG, Ru5P, R5P and PRPP. As shown in Figure A, the mRNA expression of *CAMK4* in CD4⁺ T cells was significantly higher in the active SLE patients (SLEDAI ≥ 8) compared to the HCs and the inactive SLE patients (SLEDAI < 8). Although there was no significant difference in the gene expression of *GLUT1* among these three groups (Fig. B), the surface expression of GLUT1 was the highest in the SLE patients with SLEDAI ≥ 8 among the HCs and SLE patients (Fig. C). A functional analysis revealed that CaMK4 inhibition decreased the expression of GLUT1 during Th17 cell differentiation, followed by a reduction of IL-17 production.

Conclusion: Our results indicate that (1) the activity of CaMK4 could be responsible for glycolysis, which contributes to the production of IL-17, and (2) CaMK4 may contribute to an aberrant expression of GLUT1 in T cells from active SLE patients.

Inhibition of Cathepsin S Leads to Suppression of SS-a/SS-B Specific T Cells from Patients with Primary Sjögren Syndrome

Patrick Hargreaves^{1,2}, Michel Theron¹, Fabrice Kolb¹, Marianne Manchester¹, Bernhard Reis¹, Andre Tiaden², Diego Kyburz² and **Tobias Manigold**², ¹Hoffmann La Roche, Basel, Switzerland, ²Rheumatology, University Hospital Basel, Basel, Switzerland

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: T Cell Biology and Targets in Autoimmune and Inflammatory Disease Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Primary Sjögren syndrome (pSS) is an autoimmune disease characterised by an infiltration of T and B cells into exocrine gland tissue and its subsequent destruction. Antigen presenting cells, including B cells, foster T cell activation and anti-SS-A/SS-B producing plasma cells, eventually leading to disease progression and systemic complications. Cathepsin S (CatS) is crucially involved in MHCII processing in pSS mouse models and patients. In this translational study we investigated the *ex vivo* effects of the CatS inhibitor RO5459072 in different bio-compartments, including specific T cells, of pSS patients and healthy controls.

Methods: *Ex vivo* CatS activity was assessed in different bio-compartments of 15 pSS patients and 13 healthy controls and in presence or absence of RO5459072 using commercial activity and quantification assays. In addition, antigen (5µg/mL SS-A, 5µg/mL SS-B, 5µg/mL Influenza H₃N₂; 2µg/mL Tetanus Toxoid and 100ng/mL SEB) specific T cell responses were examined using 2x10⁵PBMC/well IFN-g/IL-17 Dual ELISPOT (48h incubation) and 5x10⁴ PBMC/well BrdU proliferation assays after (72h incubation) in presence or absence of RO5459072.

Results: pSS patients showed significantly higher CatS activity in tear fluid than healthy controls (two-tailed t-test p<0.01). RO5459072 significantly suppressed CatS activity in tears of pSS patients (two-tailed t-test p<0.01). CatS inhibition also exerted a strong and dose-dependent suppression of T cell responses towards SS-A and SS-B antigen in *ex vivo* derived pSS patient cells in Elispot and BrdU assays (Table 1).

Conclusion: CatS activity in tear fluid seems to be a relevant biomarker for pSS disease activity. RO5459072 is a potent inhibitor of CatS and the pSS associated relevant antigen specific T cell responses.

Session Title: T Cell Biology and Targets in Autoimmune and Inflammatory Disease Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Lymphocyte activation gene 3 (LAG3) resembles CD4 and is a key checkpoint molecule leading to downregulation of T cell proliferation and antigen presentation via interactions with CD3 and MHC-II respectively. LAG3 is primarily expressed by activated T cells, regulatory T cells, and exhausted T cells. LAG3 plays an important role in maintaining immunological unresponsiveness to self-antigens. However, little is known about its pathogenetic role in autoimmune diseases, like rheumatoid arthritis (RA).

Methods: The plasma level of soluble (s) LAG3 was measured in 120 treatment naïve patients with early RA, with symptoms for an average of 3 months. This was done at baseline and after 12 months of treatment with either methotrexate + placebo or methotrexate + adalimumab. Treatment response was evaluated by DAS28CRP, total sharp score (TSS), erosion score (ES) and joint space narrowing (JSN). IgM-RF and anti-CCP status were also measured. Further, we examined paired plasma and synovial fluid samples from 38 RA patients with long standing disease (> 8 years) and plasma from healthy donors (HD, n=35). Human peripheral blood mononuclear cells (PBMCs) and synovial fluid mononuclear cells (SFMCs) were examined by flow cytometric analysis to characterize LAG3 and PD-1 expression on CD4+ T cells. Exhaustion status was assessed by IL-2 expression, after stimulation with CD3CD28 beads in a cell:bead ratio of 2:1 (suboptimal stimulation). Finally, SFMCs were stimulated with rhLAG3 for 48 hours.

Results: Plasma level of sLAG3 was increased in early RA patients (1725 ± 2285 pg/ml) vs HD (741 ± 381 pg/ml, $p < 0.001$). After 12 months of treatment, sLAG3 remains elevated compared with HD (1236 ± 1326 pg/ml, $p < 0.05$). The changes in sLAG3 were not affected by adding adalimumab to the methotrexate treatment. Baseline plasma levels of sLAG3 were strongly associated with autoantibody status, IgM-RF ($\rho = 0.38$, $p = 0.006$) and anti-CCP ($\rho = 0.38$, $p = 0.005$), but not to DAS28CRP, and inversely with CRP ($\rho = 0.38$, $p = 0.04$). Furthermore, baseline levels of sLAG3 were associated with progression in TSS after two years ($p < 0.05$) and changes in TSS (0-2 year) was also associated with change in sLAG3 ($\rho = 0.25$, $p < 0.05$). Highest levels of sLAG3 were observed in the synovial fluid from patients with chronic RA (3615 ± 2854 pg/ml), compared with plasma ($p < 0.001$). No correlation between sLAG3 in the two compartments was observed. Highest expression of LAG3 after suboptimal stimulation was observed in synovial IL-2-, FOXP3-, PD-1+, CD4+ T-cells. No biological effect was observed by addition of rhLAG3 to cultured PMBCs and SFMCs as assessed by production of TNFa, MCP-1 or IgM-RF.

Conclusion: sLAG3 in plasma is increased in early, untreated and longstanding RA despite a favorable response to intensive synovitis suppressive treatment. A high baseline sLAG3 level is associated autoantibody seropositivity and with radiographic progression at two years. These observations support that persistent CD4+ T cell activation is a key feature in the RA pathogenetic pathway.

Session Title: T Cell Biology and Targets in Autoimmune and Inflammatory Disease Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: RegulatoryT (Treg) cells, with the capacity to suppress immune responses, and effector T (Teff)cells, to promote inflammation, have been intensively studied in recent years. However, previous reports describing the respective changes of Treg and Teff, especially T helper 17 cells (Th17) in patients with systematic lupus erythematosus

(SLE) were controversial. Here, we investigated the changes of both the absolute number and percentage of CD4+CD25+Foxp3+Treg(CD4Treg) and effector cells on a large scale and further the role of low-dose interleukin-2 (IL-2) on these changes in SLE.

Methods: A total of 235 SLE patients (219 women and 16 men), with mean age of 37.80±14.00 years, and 90 healthy volunteers, matched for patients' age and gender, were enrolled. The absolute number and percentage of subpopulation of peripheral blood (PB) lymphocyte in these patients were measured by flow cytometry combined with internal microsphere standard. And low-dose IL-2 was used among 127 patients at a dosage of 50 WIU every day for five days. Immunological and clinical assessments were performed again.

Figure 1:

Results: As compared to healthy controls, the absolute number of CD4Treg were significantly decreased in SLE. The median ratios of Th17/Treg in patients were greatly higher than those of healthy volunteers [0.42(0.19, 0.88) vs. 0.21(0.15, 0.34), $P<0.001$], while there was not significantly different about Th17. Besides, Th1, Th2, CD8+T, B cells and their respective ratios to Treg were like that of Th17 as well. Moreover, CD4Treg cells were negatively correlated with ESR and SLEDAI score. While no obvious correlation was seen between Th17 cells and SLEDAI score. After IL-2 therapy in SLE, there was a four-fold increase in CD4Treg [43.73(24.08, 74.22) vs. 11.95(7.51, 20.34), $P<0.001$], whereas Th17 cells were increased slightly. The ratio of Th17/Treg was decreased significantly in patients with IL-2 treatment [0.19(0.09, 0.41) vs. 0.52(0.23, 0.95), $P<0.001$], tended to balance and had no difference with healthy individual ($P=0.275$). Similarly, there were same trends in Th1, Th2, CD8+T, B and NK cells.

Conclusion: The reduction of CD4Tregs, rather than the elevation of effector cells, contributes to the imbalance of Teff/Treg, indicating that SLE is an autoimmune disease triggered by the defect of immunotolerance. More importantly, although low-dose IL-2 might promote the proliferation of various lymphocyte subpopulation, it mainly modulated the abundance and immunosuppression activity of Tregs, which effectively induced autoimmune tolerance and further improved clinical symptoms.

Session Title: T Cell Biology and Targets in Autoimmune and Inflammatory Disease Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Th17, a subset of CD4⁺ helper T cells, provides protection against pathogens and malignancies, but also promotes immune-mediated-inflammation in a range of disorders including psoriasis, psoriatic arthritis, and axial spondyloarthritis. In our analysis of high throughput transcriptomic data, we identified *aquaporin 3 (AQP3)* as a novel gene in the promotion of Th17 differentiation and pathogenicity. *AQP3* encodes for a water channel protein highly expressed in the kidney and keratinocytes. Interestingly elevated AQP3 expression is reported in inflamed skin of patients with atopic dermatitis. Elevated *AQP3* was recently reported in a murine model of psoriasiform dermatitis but its importance in human psoriasis has not been examined. We investigated AQP3 expression in human psoriatic skin and analyzed the expression of AQP3 in human CD4⁺ T cells following cytokine exposure.

Methods: To validate our initial *in silico* findings, we conducted *in vitro* experiments with human naive T cells. To investigate key inducers of *AQP3* in CD4⁺ lymphocytes, we cultured naïve CD4⁺ T cells in the presence of IL1B, IL6, TGFβ1, and IL23, alone, or in combination, and monitored *IL17A*, *IL17F*, and *AQP3* mRNA expression levels by qPCR. We also analyzed AQP3 mRNA and protein levels in lesional and non-lesional skin from psoriasis patients compared to skin from healthy controls.

Results: We found that *AQP3* expression at 72 hours increased more than 7-fold in naive CD4⁺ T cells when cultured in the presence of Th17 differentiating conditions and correlated with IL-17A and IL-17F expression. When CD4⁺ lymphocytes were cultured in the presence of IL1B, IL6, and TGFβ1 or TGFβ3, a 5-fold increase in *AQP3* was observed, but no increased expression was noted when cells were cultured with the individual cytokines. Interestingly, IL23 dramatically increased AQP3 expression in naive CD4⁺ T cells (more than 15-fold) when combined with IL1B, IL6, and TGFβ1, but failed to do so when added alone. We also noted elevated mRNA (2.3 fold) and protein expression levels of *AQP3* in lesional psoriatic skin compared to non-lesional skin (figure 1). Expression levels were highest in the epidermis but also noted in cells infiltrating the dermis.

Conclusion: Expression of *AQP3* was elevated in Th17 cells compared to naive CD4⁺ T cells. IL23 greatly augmented *AQP3* expression in CD4⁺ T cells in the presence of IL1B, IL6, and TGFβ1. In addition, AQP3 protein expression is increased in the cells infiltrating the dermis and keratinocytes in psoriasis, a Th17-related disorder. These data suggest that AQP3 may be a cellular marker of a pathogenic Th17 subset and may provide insights into disease pathogenesis with the potential to serve as a therapeutic target.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: T Cell Biology and Targets in Autoimmune and Inflammatory Disease Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is a common autoimmune disease characterized by chronic joint inflammation, synovial hyperplasia and progressive destruction of cartilage and bone. T follicular helper (Tfh) cells, a CD4⁺ T cell subset, predominantly located in lymphoid follicles, regulate B cell survival and antibody production in germinal centers. Our previous studies have showed that circulating Tfh cells were significantly increased in active RA

patients, correlated with their anti-CCP antibody titer and disease activity. Here, we further investigated the role of Tfh cells in RA pathogenesis in mice with collagen-induced arthritis (CIA) and also examined the therapeutic effect of a small molecule inhibitor (SMI-Tfh) which selectively blocks the Tfh cell signature transcription factor Bcl-6.

Methods: CIA model was induced by administering chicken type II collagen in twenty-four DBA/1 mice. The joints were observed for score of swelling of paws and ankles. Disease progression was monitored daily and recorded by arthritis severity scores weekly. Following the onset of clinical arthritis, mice were treated with SMI-Tfh. Blood, spleen, and affected paws were collected at the end of the study. Pathological changes were examined by staining of tissue sections with hematoxylin and eosin. Immunofluorescent histochemistry (IHC) staining and flow cytometry analysis were performed to identify Tfh cells ($CD4^+CXCR5^+ICOS^+$) in spleen, paw, and blood. IHC results were analyzed by Image J and flow cytometry results were analyzed by FlowJo software. Statistical analysis was carried out using GraphPad Prism software and the significance was evaluated by t test.

Results: Our results showed paw-swelling onset between days 21-28 and with peak on day 42 after initial immunization in DBA/1 mice. Compared with the ankles of control mice, the joints of CIA mice had increased inflammatory cells in the synovial tissues and destruction of articular cartilage. Tfh cells ($CD4^+CXCR5^+ICOS^+$) were observed in the blood and the germinal centers of the spleen of CIA mice. Mice treated with SMI-Tfh had significantly reduced paw swelling. SMI-Tfh was nontoxic at the tested dose (50mg/kg). SMI-Tfh treatment also reduced inflammatory cell and Tfh cell infiltration in inflamed joints, and significantly inhibited the numbers of Tfh cells in the blood and in the germinal centers of spleen ($p<0.01$) in CIA mouse.

Conclusion: Tfh cells originating from splenic lymphoid follicles may contribute to the circulating Tfh cells in the peripheral blood in RA and play an important role in the development of active RA. The small molecule inhibitor SMI-Tfh selectively inhibits Tfh cells in the spleen and in the inflamed joints. It appears to decrease severity in inflammatory arthritis, and may be useful as a new and additional therapeutic modality for RA.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: T Cell Biology and Targets in Autoimmune and Inflammatory Disease Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Despite improvement in treatment of rheumatoid arthritis (RA) over the past decades, insufficient treatment response and treatment resistance in many patients demonstrate the need to develop new therapeutic strategies. Chronic synovial inflammation could be suppressed by targeting activation of RA synovial fibroblasts (RASf) by for example IL-17A-producing CCR6⁺ T helper memory (memTh) cells. Previously, we have shown that dexamethasone (DEX) combined with the active vitamin D metabolite 1,25(OH)₂D₃ reduces pathogenicity of memTh cells. Therefore, we here studied the additive effect of 1,25(OH)₂D₃ and DEX on suppressing the pro-inflammatory loop between RASf and CCR6⁺ memTh cells and explored potential therapeutic applications.

Methods: CCR6⁺ memTh cells from PBMC of healthy donors or treatment-naïve early RA patients were cultured alone or with RASf from established RA patients for three days and treated with or without 1,25(OH)₂D₃, DEX or etanercept. Treatment effects were assessed using ELISA and flow cytometry.

Results: CCR6⁺ memTh produces less of the pro-inflammatory cytokines IL-17A, IL-22 and IFN γ upon exposure to 1,25(OH)₂D₃, and to a lesser extent by DEX. TNF α was only inhibited by the combination of 1,25(OH)₂D₃ and DEX. In contrast, in RASf cultures DEX was the strongest inhibitor of IL-6, IL-8 and tissue-destructive enzymes. As a result, 1,25

(OH)₂D₃ and DEX additively inhibited inflammatory mediators in CCR6+ memTh-RASF co-cultures. Interestingly, low doses of mainly DEX, but also 1,25(OH)₂D₃, combined with etanercept better suppressed synovial inflammation in this co-culture model compared to etanercept alone.

Conclusion: This study suggests that 1,25(OH)₂D₃ and DEX additively inhibit synovial inflammation through targeting different pro-inflammatory mechanisms. Furthermore, low doses of DEX and 1,25(OH)₂D₃ enhance the effect of TNF α blockade in inhibiting RASF activation, providing a basis to improve RA treatment.

Session Title: T Cell Biology and Targets in Autoimmune and Inflammatory Disease Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Mesenchymal stromal cells (MSCs) are progenitor cells with suppressive capacities that have fueled ample translation for the treatment of immune mediated diseases including Graft versus Host Disease (GVHD), one of the human indications with regulatory approval. Paracrine effects of the MSC secretome contribute to these actions, but recent evidence suggests that cell-to-cell transfer of MSC mitochondria to different tissues (MitoT) exerts significant regenerative and restoring effects. We hypothesized that MitoT would also encompass immunocompetent cells, and provide the first evidence herein of MitoT to T cells, relating it to a novel immune reprogramming mechanism of MSC therapy, tested both *in-vitro* and *in-vivo*, in an animal model of GVHD.

Methods: MitoT was assessed by flow cytometry, qPCR and confocal microscopy of human mononuclear cells (PBMCs) previously co-cultured in vitro with mitotracker (mitochondrial stained) umbilical cord MSCs at different ratios and conditions. To assess the direct functional impact of MitoT we employed the artificial transfer of MSC-derived mitochondria ("Mitoception")¹ to PBMCs. Mitotracker-positive (Mito+) acceptor cells were sorted for further testing and compared to Mitotracker-negative (Mito-) sorted cells. Experimental readouts included target cell phenotype and function, immune-related gene expression by RNA sequencing and qPCR, and metabolic "Seahorse" analysis of OXPHOS and glycolytic functions. *In vivo* effects were tested in a humanized xenogenic model of GVHD in NSG immunodeficient mice.

Results: Dose-dependent MitoT was observed from MSCs to T and B lymphocytes, NK and Dendritic cells (100%), reaching 60%-90% in CD3+CD4+ cells according to their state of activation. Transfer was independent of proinflammatory MSC pre-treatment, inhibition of gap junctions, hemi-channels or nanotubule formation. The suppression of MitoT at 4°C and the detection of human-specific mitochondrial genes (qPCR) in murine MSC-cocultured lymphoid cells confirmed the mediation of an energy dependent process, not attributable to cell fusion.

Genetic analysis showed most significant changes of mRNA expression in Treg activation pathways, including FOXP3, IL2RA, CTLA4, TGF β and Runx1. Indeed, naïve Mito+ sorted T cells were driven towards a CD127^{low}, CD25⁺ FoxP3⁺ (Treg) functionally proven suppressor phenotype as opposed to Mito- cells (fold change of 14) (p<0.01). Preliminary metabolic analysis of MitoT+ PBMCs displayed a 50% increase in the Glycolytic/OXPHOS ratio, which is a hallmark of T cell activation.

In vivo testing of xeno-GVHD induced by human Mito+ cells as compared to non-treated cells, showed significant improvement in weight loss (p<0.05), gut (p<0.05) and liver (p<0.01) tissue damage, organ infiltrating CD4⁺, CD8⁺ (p<0.05) and IFN γ ⁺ cells (p<0.0001) as well as survival (p<0.05).

Conclusion: These findings present the first evidence of MitoT from MSC to T-lymphocytes and immune cell subpopulations, pointing to a new level of complexity of the immunoregulatory role of MSCs, widening the horizon of their clinical applications.

Session Date: Sunday, October 21, 2018

Session Title: T Cell Biology and Targets in Autoimmune and Inflammatory Disease Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: B and T cells contribute to tissue injury in rheumatoid arthritis (RA). Rituximab (RTX), an anti-CD20 monoclonal antibody, is used for the treatment of RA and results in rapid B-cell depletion. However, the therapeutic effect of RTX may not be entirely contingent on depletion of B cells; rather, we hypothesized a contributing factor is the dampening of their interplay with the T-cell drivers of their maturation in secondary lymphoid organs. The latter follicular helper T (Tfh) cells are represented in the blood as a circulating (cTfh) pool. Thus, we examined effects of RTX on cTfh cells in RA patients treated either for the first time (“naïve”) or on maintenance therapy (*i.e.*; received at least once prior; “maintenance”).

Methods: Blood was drawn from 5 naïve and 11 maintenance patients prior to the first infusion, at 2 weeks (prior to 2nd infusion, if given) and 12 weeks. Peripheral blood mononuclear cells were stained with antibodies conjugated with fluorochromes for flow cytometry—CD4, CD3, CD45RA, CXCR5, PD-1, ICOS, CCR7, CD127, CD25, TCR β , CD19, IgD, CD38, CD27, PSGL-1, CD138, and CD5—to determine naïve, activated, and memory CD4 T cells, cTfh and cTfh subsets (cTfh1, cTfh2, cTfh17) and conventional CD4 T helper cell subsets (Th1, Th2, Th17). Naïve and memory B cells, and plasma cells were also enumerated. Data were analyzed using FlowJo® software. Plasma was assessed for anti-citrullinated peptide antibody (IgG) titers (ACPA) using QuantaLite® ELISA kit. Disease activity (DA) was determined by chart review.

Results: Naïve compared to maintenance patients had more cTfh cells (CXCR5⁺PD-1^{hi}ICOS^{hi}; $5.65 \pm 0.68\%$ vs. $2.67 \pm 0.36\%$; among CD4 T cells), with a significant linear relationship between the percentage of cTfh and that of CD19⁺ B cells (Pearson’s correlation coefficient 0.52); more cTfh17 cells (CXCR3⁻CCR6⁺; $29.5 \pm 2.79\%$ vs. $21.42 \pm 1.16\%$; within the CD4⁺CD45RA⁻CXCR5⁺ population); and more PD-1^{lo} memory cTfh17 cells ($35.42 \pm 3.32\%$ vs. $21.88 \pm 1.27\%$), although their percentages and ACPA titers did not change over the course of therapy. Th17 cells were differentiated from cTfh17 cells by their expression of CXCR5⁻ rather than CXCR5⁺. Naïve compared to maintenance patients also had more Th17 cells (CD4⁺CXCR5⁻CXCR3⁻CCR6⁺; $19.35 \pm 1.54\%$ vs. $14.27 \pm 1.08\%$), in both the PD-1^{hi} effector ($16.38 \pm 1.82\%$ vs. $11.89 \pm 0.87\%$) and PD-1^{lo} memory subsets ($20.77 \pm 1.72\%$ vs. $13.91 \pm 1.07\%$). All naïve patients had moderate-to-high DA at baseline as compared to only 27% of maintenance patients; post-RTX, all naïve patients had either low DA or clinical remission as compared to 82% of the maintenance patients.

Conclusion: We found a higher percentage of cTfh cells in naïve compared to maintenance RA patients treated with RTX, consistent with prior studies showing that B-cell help is needed for Tfh-cell development. We also found a higher frequency of cTfh17 and Th17 cells in naïve compared to maintenance patients and correspondingly higher DA at baseline in naïve patients, suggesting that B-cell depletion results in reduced cTfh and Th17 cells, as DA improves. Future studies are needed to better understand these cTfh subsets and their correlation to B-cell depletion and DA in RA, as well as their potential as therapeutic targets.

High Level of CD38 Expression in SLE CD8 T Cells Dictates Decreased Cytotoxicity

Eri Katsuyama, Abel Suarez-Fueyo, Sean Bradley, Michihito Kono, Lama Mulki, Vasileios C. Kyttaris and George C Tsokos, Rheumatology, Department of Medicine, Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA, Boston, MA

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: T Cell Biology and Targets in Autoimmune and Inflammatory Disease Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: CD38 is an ectonucleotidase that has the ability to degrade nicotinamide adenine dinucleotide (NAD). The percentage of CD38 expressing CD8 T cells are increased in patients with SLE in whom cytotoxic responses are known to be decreased. We sought to determine whether CD38 is responsible for the decreased cytotoxicity in T cells from patients with SLE.

Methods: We used sorted human primary CD8 T cells, TALL-104 and CRISPR-generated CD38 knock out Jurkat cells. Electroporation was performed using Amaxa. Cells were stimulated with anti-CD3/CD28 or P815 cells. Degranulation and cytotoxicity were assayed by flow cytometry (FCM). Expression of cytolytic molecules (granzymeB, perforin and IFN-g) and the transcription factors Eomes, T-bet and EZH2 were measured by FCM and qPCR. NAD production and protein acetylation were measured using colorimetric or Western blot techniques.

Results: Compared with CD38^{low}, CD38^{high}CD8 T cells displayed lower cytotoxicity as determined by the expression of CD107a, granzymeB, perforin and IFN-g. In addition, CD38^{high}CD8 T cells showed lower cytotoxicity against P815 cells. Eomes and T-bet, which regulate cytotoxic function of CD8 T cells, were decreased in CD38^{high}CD8 T cells, while EZH2 levels were increased. EZH2 known to repress Eomes and T-bet has been reported to have a higher suppressive capacity and stability when acetylated. SIRT1 is a NAD-dependent deacetylase and controls EZH2 acetylation. Consequent upon lower production of NAD, the levels of proteins acetylated on lysine residues increased in CD38^{high}CD8 T cells. Lower deacetylation activity of SIRT1 may cause higher acetylation of EZH2 and suppression of Eomes and T-bet in CD38^{high}CD8 T cells. Finally, overexpression of CD38 in CD38^{low}CD8 T cells or TALL-104 cells increased acetylated protein and decreased degranulation and cytotoxicity against P815 cells, which indicates that CD38 may reprogram cytotoxicity in CD8 T cells.

Normal: CD38^{low}→NAD[↑]→SIRT1 activity (deacetylase)[↑]→EZH2[↓]→Eomes, T-bet[↑]→Cytotoxicity[↑]

SLE: CD38^{high}→NAD[↓]→SIRT1 activity (deacetylase)[↓]→EZH2[↑]→Eomes, T-bet[↓]→Cytotoxicity[↓]

Conclusion: We present novel evidence that CD38^{high}CD8 T cells which are expanded in patients with SLE display decreased cytotoxicity. CD38 causes decreased NAD levels, higher acetylation of EZH2 and subsequent decrease of the cytotoxicity-linked transcription factors, Eomes and T-bet. Our data document the role of CD38 in the control of the cytotoxic response of CD8T cells and provide a molecular explanation for the known decreased cytotoxic responses in patients with SLE.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: T Cell Biology and Targets in Autoimmune and Inflammatory Disease Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Functionality and immune-phenotypes of the human CD4⁺ T-cell compartment in Behcet's disease (BD) are under-investigated, but several lines of evidence point to its relevance in the pathogenesis and progression of the disease. We aimed to apply an unbiased single cell approach to dissect the immune-phenotype of CD4⁺ T cells in prototypical BD in order to identify cell populations of potential pathobiological relevance.

Methods: We determined single cell expression levels of CD3, CD4, CD8, CD127, CD25, CD45RA, CCR7, FoxP3, HELIOS, Ki76, HLA-DR, CD38, CD39 in PBMC by flow cytometry and computed the representation of all possible cell populations within CD4⁺ starting populations in PBMC from healthy (HD, n=25), BD (n=13), and diseased subjects with non-BD auto-immune uveitis (n=11, VKH, Sarcoidosis, and HLA-B27 associated uveitis). BD subjects met ISG criteria and were Arab or Chinese. 62% had pan-uveitis, 23% major vascular disease, and 7% parenchymal CNS disease. 46% were HLA-B51 carriers.

Results: Computation of all populations defined by 8 markers (CD127, CD25, CD45RA, CCR7, FoxP3, HELIOS, Ki67, HLA-DR) within the CD4⁺ T cell compartment yielded a total of 6,560 cell populations per subject out of which 45 reached significance ($p < 0.000001$) differentiating 3 groups (BD, non-BD uveitis, and HD). All of these populations comprised sub-types of the human regulatory T (Treg) cell compartment with strong predominance of non-proliferating, non-activated, FoxP3⁺Helios⁺ Treg carrying central-memory phenotypes (CD45RA⁻, CCR7⁺). 2-group testing of BD vs non-BD revealed 43 distinct cell populations at a significance level of $p \leq 0.002$ representing CD25⁺ non-Treg; comparison of BD vs HD uncovered 58 populations at significance level of $p \leq 0.0001$ representing FoxP3⁺Helios⁺ subpopulations, and non-BD vs HD identified 61 populations at $p \leq 0.001$, comprising CD25⁺CD127^{+/+} FoxP3^{+/+}, but consistently HELIOS⁻, presumably non-Treg populations. A separate analysis using 6 marker combinations (CD38, CD39, CD226, TIGIT, CD45RA, CCR7) within the CD3⁺CD4⁺CD8⁻CD127⁻CD25⁺ compartment which contains most human Treg, showed 48 populations ($p \leq 0.0001$) in 3-way comparison (BD, non-BD uveitis, and HD) pointing to high significance of TIGIT and CD226, and 18 populations with differential expression of CD39⁺ between BD and non-BD diseases subjects. TIGIT and CD226 co-expressing Treg (CD127⁻CD25⁺) subpopulations also reached significance ($p \leq 0.02$) in a longitudinal analysis of 7 BD subjects in active vs inactive disease states, as did 56 out of 6,560 populations within total CD4⁺CD3⁺ cells, mostly representing non-Treg cells in active disease.

Conclusion: Differential expression of CD4⁺ Treg and non-Treg cells shapes the immune-phenotype of BD vs HD and non-BD autoimmune diseases that have phenotypic overlap with BD (uveitis). Populations within the HELIOS⁺FOXP3⁺ compartment of non-activated, non-proliferating Treg had the highest significance when differentiating BD from HD, suggesting relevance of a true Treg phenotype. Non-Treg CD25⁺ cell populations seem more indicative of BD vs non-BD uveitic disease as well as of clinically active BD while populations with high CD39 expression may indicate non-BD states.

Session Date: Sunday, October 21, 2018

Session Title: T Cell Biology and Targets in Autoimmune and Inflammatory Disease Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: In systemic lupus erythematosus (SLE), the dysregulated production of autoantibodies is a consequence of disrupted T cell homeostasis. Programmed death-1 (PD-1), a negative regulator in T cells, limits certain T cell-mediated immune responses. Increased PD-1 expression on T cells inhibits cell activation and proliferation and its blockade reinstates immune cell function. Our laboratory has shown that attenuated, but not absent, PD-1 signaling enables CD4⁺ regulatory T cells (T_{reg}) to survive and suppress helper T cells T_h and B cells. Gene array data have shown that attenuated PD-1 expression in T_{reg} down-regulates several members of the TNF receptor family, including OX40L. It has been reported that OX40L is up-regulated in immune cells from patients with autoimmune disease by promoting follicular helper and effector memory T cells, and suppressing T_{reg} proliferation. We hypothesize that one mechanism by which PD-1 sustains T_{reg} proliferation and suppressive function is by reducing OX40L expression on T_{reg}.

Methods: We treated lupus-prone BWF₁ mice with a neutralizing Ab against PD-1 or control isotype-matched IgG intraperitoneally. OX40L, Foxp3 and PD-1 expression on T_{reg} from the spleens was measured by flow cytometry. T_{reg} were cocultured with unmanipulated CD4⁺CD25⁻ T_h and B cells, and cell proliferation/apoptosis of T_{reg}, T_h and B cells was measured with CFSE/Annexin V by flow cytometry. Cytokine production namely IFN γ (T_{h1}), IL-4 (T_{h2}), IL-17a (T_{h17}) and TGF- β (T_{reg}), and anti-dsDNA (B cells) in the culture media were measured by ELISA. To test the plasticity of these T_{reg}, we treated T_{reg} with agonistic vs antagonistic OX40L Ab *in vitro*, and set up the coculture experiments and determined cell proliferation and cytokine production as described above.

Results: OX40L expression was lower in PD1^{lo}T_{reg} from anti-PD1-treated mice when compared to PD1^{hi}T_{reg} from controls. OX40L^{hi}T_{reg}, irrespective to its Foxp3 expression, lost its ability to suppress T_h and B proliferation. PD1^{lo}T_{reg} treated with agonistic OX40L had attenuated suppressive function: there was decreased production of TGF- β , increased proliferation of T_h (T_{h1} predominant) and increased anti-DNA production. These T_{reg} also had increased apoptosis. Treating PD1^{hi}T_{reg} with antagonistic OX40L could not restore the suppressivity in T_{reg}.

Conclusion: Effective induction of T_{reg} is associated with low expression of PD-1, which permits cells to survive and perform cell suppressive function. Attenuated PD-1 expression in T_{reg} reduces OX40L expression on T_{reg}, which helps restore the suppressive capacity and proliferation of T_{reg}. Increased OX40L expression overrides PD-1 signaling to deactivate and induce apoptosis in Foxp3⁺T_{reg}, but reduced OX40L expression cannot recover T_{reg} suppressivity when PD-1 signal is high. The suppressive function induced by low PD-1 expression is influenced by the intensity of OX40L expression. PD-1 and OX40L signaling most likely crosstalk to regulate the suppressive capacity and survival of T_{reg} to achieve peripheral tolerance in SLE.

Session Date: Sunday, October 21, 2018

Session Title: T Cell Biology and Targets in Autoimmune and Inflammatory Disease Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: T-cell resilience is critical to the immune pathogenesis of human autoimmune arthritis. Autophagy is essential for memory T cell generation and is associated with pathogenesis in rheumatoid arthritis (RA). We have previously described that CD4⁺ T cells in patients with RA have an increased level of autophagy compared to their healthy controls. Here, we sought to explore at epigenetic and transcriptional levels the concept of persisting increased autophagy as the consequence of "autophagic memory", as one of the mechanisms conferring resilience to pathogenic T cells, in particular to a subset of CD4⁺ T cells (CPL: Circulating Pathogenic-like Lymphocytes), which are significantly more represented in patients with active arthritis and patients resistant to therapy with biologics.

Methods: Autophagy was assessed in CD4⁺ T cell subsets from autoimmune arthritis patients and healthy subjects using flow cytometry. RNA sequencing and methylation array analysis to understand the molecular mechanism of autophagic memory. Transcription-factor gene regulatory network analysis was built to identify key regulators. qPCR was used to confirm the gene expression level of key regulators.

Results: We demonstrated "Autophagic memory" as elevated autophagy levels in CD4⁺ memory T cells compared to CD4⁺ naive T cells and in Jurkat Human T cell line trained with starvation stress. We then showed increased levels of autophagy in pathogenic CD4⁺ T cells subsets from autoimmune arthritis patients. Using RNA-sequencing, transcription factor gene regulatory network and methylation analyses we identified MYC as a key regulator of autophagic memory. We validated MYC levels using qPCR and further demonstrated that inhibiting MYC increased autophagy.

Conclusion: The present study proposes the novel concept of autophagic memory and suggests that autophagic memory confers metabolic advantage to pathogenic T cells from RA and supports its resilience and long term survival. Particularly, suppression of MYC imparted the heightened autophagy levels in pathogenic T cells. These studies have a direct translational valency as they identify autophagy and its metabolic controllers as a novel therapeutic target.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: T Cell Biology and Targets in Autoimmune and Inflammatory Disease Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Polymorphonuclear neutrophils (PMN) are abundant and activated in rheumatoid arthritis (RA) joints. In addition to their pro-inflammatory role, PMN exert immunoregulatory functions and may thus affect T-cell responses. Regulatory T lymphocytes (Treg) play a key role in the control of autoimmunity but they are functionally deficient in RA. Very few data are available on Treg-PMN communication in normal conditions, and even less during inflammation, especially in RA. The aim of this study was to analyze the mechanisms controlling the interaction between Tregs and PMNs and the consequences on their activity.

Methods: Splenic Treg and bone marrow PMN (C57BL/6 mice) were purified by magnetic sorting. Treg and PMN of healthy donors and RA patients were freshly isolated by magnetic sorting from peripheral blood. Co-cultures were unstimulated or exposed to anti-CD3/anti-CD28 antibodies and/or LPS. CD4⁺FoxP3⁺ Treg (mouse and human), Ly6G⁺ (mouse) and CD66b⁺ (human) PMN were identified by flow cytometry. Cell activation was studied using antibodies against CD39, CD25, CTLA-4 (Treg) and CD11b (PMN). Treg maintenance was evaluated as the frequency of FoxP3 expression among CD4⁺ cells, and cell proliferation by CFSE staining followed by flow cytometry analysis. In some case, co-cultures were performed using Transwell (0.4 mm). Cytokine levels were quantified in culture supernatants by ELISA. Collagen-induced arthritis (CIA) was induced by immunization with type II collagen in complete Freund's adjuvant.

Results: Without stimulation of both Treg and PMN from naive mice, no effect on any cell type was observed in co-culture. In contrast, co-culture of activated Treg with activated PMN resulted in Treg proliferation and increased maintenance of FoxP3 expression, with higher CTLA4 but lower CD39 expression, sustained PMN activation evidenced by CD11b up-regulation, and higher secretion of MIP-2, IL-6 and IL-17 but not IFN- γ in naive mice. All these effects were lost in transwell experiments or when blocking JAK signalling. Nevertheless, transfer of supernatants from LPS-activated PMN also partly increases Treg maintenance. Most importantly, PMN sustain Treg suppressive effect on effector T cells (CD4⁺FoxP3⁻) proliferation. Similar results were observed in co-cultures of activated Treg/PMN isolated from CIA mice, although in vitro activation of PMN is not required. Likewise, human Treg-PMN co-cultures led to enhanced Treg maintenance with higher expression of CTLA4/CD25 in a cell contact-dependent manner in both healthy donors and RA patients. Secretion of IL-8 and IL-10 was enhanced in co-cultures.

Conclusion: Our results reveal the existence of a link between Treg and PMN, mainly leading to an activation of both cell types in normal or inflammatory conditions. Although cell contacts are clearly required, soluble mediators are also involved and probably as a second signal. Whether these synergistic interactions lead to a global suppressive or inflammatory milieu with functional modulation of either partner needs to be clarified, especially in RA patients.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: T Cell Biology and Targets in Autoimmune and Inflammatory Disease Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: To explore the role of Vδ2 t cells in the pathogenesis of rheumatoid arthritis (rA)

Methods: Sixty-eight patients with RA, 21 patients with osteoarthritis and 21 healthy controls were enrolled in the study. All patients with RA fulfilled the 2010 American College of Rheumatology/European League Against Rheumatism criteria for RA. Peripheral Vδ2T population, chemokine receptor expression and proinflammatory cytokine secretion were quantified by flow cytometry. The infiltration of Vδ2 T cells within the synovium was examined by immunohistochemistry and flow cytometry. The effect of tumour necrosis factor (TNF)-α and interleukin (IL)-6 on Vδ2 T migration was determined by flow cytometry and transwell migration assay.

Results: Peripheral Vδ2T cells, but not Vδ1 T cells, were significantly lower in patients with RA, which was negatively correlated with disease activity gauged by Disease Activity Score in 28 joints. Vδ2 T cells from RA accumulated in the synovium and produced high levels of proinflammatory cytokines including interferon-γ and IL-17. Phenotypically, Vδ2 T cells from RA showed elevated chemotaxis potential and expressed high levels of chemokine receptors CCR5 and CXCR3, which was driven by increased serum TNF-α through nuclear factor kappa B signalling. In vivo, TNF-α neutralising therapy dramatically downregulated CCR5 and CXCR3 on Vδ2 T cells and repopulated the peripheral Vδ2 T cells in patients with RA

Conclusion: High levels of TNF-α promoted CCR5 and CXCR3 expression in Vδ2 T cells from RA, which potentially infiltrated into the synovium and played crucial roles in the pathogenesis of RA. Targeting Vδ2 T cells might be a potential approach for RA.

Epigenetic Editing of FOXP3 in Human T Cells Is Sufficient to Induce Overexpression and Create a Regulatory T Cell Phenotype in Vitro

Christopher Dunn¹, Cassandra Velasco¹, Madison Andrews², Alexander Rivas³ and Matlock A. Jeffries⁴, ¹Rheumatology, Immunology, and Allergy, University of Oklahoma Health Sciences Center, Oklahoma City, OK, ²Oklahoma Medical Research Foundation, Oklahoma City, OK, ³University of Arkansas for Medical Sciences, Little Rock, AR, ⁴Arthritis and Clinical Immunology, Oklahoma Medical Research Foundation, Oklahoma City, OK

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: T Cell Biology and Targets in Autoimmune and Inflammatory Disease Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Defects in the number and function of naturally-occurring regulatory T cells (Tregs) have been identified in a variety of autoimmune diseases. The development of Tregs is marked by a variety of epigenetic modifications, most closely associated with demethylation of the *FOXP3* gene. Transfection of T cells with *FOXP3* transgenes has resulted in conversion to a Treg phenotype; however, the effects on cellular function of direct epigenetic editing of *FOXP3* has not yet been evaluated.

Figure 1

Methods: Guide RNA (gRNA) sequences targeting the human *FOXP3* promoter, TSDR, and CNS1 region were designed. An epigenetic editing SUNTAG (dCas9 + TET1) construct was used to demethylate genomic regions. Constructs containing dCas9 + TET1 + guide RNA sequences + fluorescent reporter were transfected by electroporation into Jurkat cells and cultured for 24 hours, then enriched by flow sorting. *FOXP3* and *CTLA4* gene expression was determined by qPCR and *FOXP3-TSDR* DNA methylation quantified by bisulfite pyrosequencing 3 days after transfection. Primary CD4+ T cells were isolated from human peripheral blood, stained with CellTrace reagent and combined with *FOXP3* epigenetically-edited Jurkat cells in a 1:1 ratio and stimulated with anti-CD3/anti-CD28 beads and 30U/mL rhIL-2 for 5 days. Suppression of T cell division was determined by flow cytometry.

Results: Epigenetic editing constructs targeting the *FOXP3* TSDR reduced DNA methylation (TSDR region, transfected: $55\% \pm 2$ mean \pm SEM vs. vehicle: 91 ± 3 , $p=8E-5$) (Figure 1), whereas constructs targeting the promoter and CNS1 did not reduce TSDR methylation. All gRNAs increased *FOXP3* expression (TSDR-targeted vehicle: 0.7 ± 0.2 , dC9-TET1+TSDR gRNA 230 ± 10 relative units vs. GAPDH, $p<0.0001$) (promoter-targeted: vehicle: 0.7 ± 0.2 , dC9-TET1+Prom. gRNA 120 ± 20 , $p=0.02$), (CNS1-targeted vehicle: 0.7 ± 0.2 , dC9-TET1 +CNS2 gRNA 59 ± 10 , $p=0.001$) (Figure 1). Furthermore, epigenetic editing of *FOXP3* resulted in increased expression of the Treg-related gene *CTLA4* (*FOXP3* prom.-targeted non-significant, dC9-TET1+*FOXP3* TSDR gRNA 6.4 ± 0.6 vs. vehicle: 1.6 ± 0.4 , $p=0.003$; dC9-TET1+*FOXP3*+CNS1 gRNA: 3.9 ± 5 vs. vehicle: 0.8 ± 0.3 , $p=0.009$). Epigenetically edited cells resulted in suppression of naïve T-cell proliferation by 20-30% (dC9+TET1+prom. gRNA=29% avg. suppression, $p=2E-5$, dC9+TET1+TSDR gRNA=20% avg. suppression, $p=0.008$, dC9+TET1+CNS1 gRNA=28% avg. suppression, $p=3E-5$, all vs. dC9+TET1-gRNA) (Figure 1).

Conclusion: Epigenetic editing of *FOXP3* using a dCas9-TET1 construct induces DNA demethylation, overexpression, and a regulatory T cell phenotype. Our data are intriguing but need confirmation, particularly to clarify the persistence of induced DNA methylation changes and resistance to phenotype switching. If confirmed, this approach has the potential to significantly improve upon current methods of T-reg generation.

Veale³ and Ursula Fearon¹, ¹Molecular Rheumatology, School of Medicine, Trinity Biomedical Sciences Institute, Trinity College Dublin, Dublin, Ireland, ²Department of Rheumatology, Tallaght Hospital, Dublin, Ireland, ³Centre for Arthritis and Rheumatic Diseases, Dublin Academic Medical Centre, University College Dublin, Dublin, Ireland

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: T Cell Biology and Targets in Autoimmune and Inflammatory Disease Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Genetic and functional studies strongly support the role of T-cells in PsA pathophysiology. Effective targeting of T-cells requires a detailed understanding of their phenotypic and functional characteristics at the site of

inflammation. This study aims to understand the different components of T-cell responses in the PsA synovium compared to the peripheral blood and investigate the effects of targeting broader pro-inflammatory signalling pathways by interfering with phosphodiesterase 4 (PDE4).

Methods: PsA Synovial tissue cell suspensions, matched synovial fluid mononuclear cells (SFMC) and PsA peripheral blood mononuclear cells (PBMC) were stimulated with PMA and ionomycin in the presence of Brefeldin A and analysed for CD4, CD8, CD161, IL-17A, IFN γ , GM-CSF and TNF α expression by flow cytometry. PsA synovial cell suspensions were cultured in the presence of PDE4 inhibitor, Rolipram (10 μ M) for 8hr followed by analysis of intracellular cytokines. Polyfunctional cytokine expression was determined by SPICE analysis. The effect of Rolipram treatment on the spontaneous secretion of IL-6, IL-8, MCP-1, IL-1 β , RANTES, MMP-1 and MMP-3 was quantified by ELISA. Explants were also embedded in matrigel over a time-course of 1-21 days and synovial outgrowths assessed.

Results: PsA synovial infiltrating T-cells had increased frequencies of CD4 T helper subsets; Th1 ($p<0.05$), Th17 and exTh17 ($p<0.05$) compared to the peripheral blood. The production of GM-CSF, IL-17A and IFN γ , but not TNF α , was also higher in the synovial tissue compared to peripheral blood ($p<0.05$). Strikingly, polyfunctional cells co-expressing GM-CSF, TNF, IL17A and/or IFN- γ were significantly increased in the CD4, CD8, Th1, Th17 and exTh17 compartment of synovial T-cells. Analysis of disease activity revealed that polyfunctional cytokine expressing T-cells ($p<0.01$, $r=0.89$) and not monofunctional synovial T-cells ($p=0.267$, $r=-0.05$) are important to disease progression. Moreover, we revealed that PDE4 blockade can suppress the frequencies of these polyfunctional GM-CSF⁺TNF α ⁺IL-17A⁺ and/or IFN- γ ⁺ in CD8, CD4, Th1, Th17 and exTh17 cells (all $p<0.05$). Finally, using whole tissue synovial explants, which closely reflect the *in-vivo* inflamed microenvironment of the joint, we demonstrate that PDE4 blockade also inhibits the secretion of pro-inflammatory mediators and synovial invasiveness ($p<0.05$).

Conclusion: Immunophenotypic analysis of the synovial tissue of PsA patients shows accumulation of Th1, Th17 and exTh17 cells, with a specific increase in polyfunctional cells co-expressing GM-CSF⁺TNF α ⁺IL-17A⁺ and/or IFN- γ ⁺, exerting pleiotropic effects and disease progression. Neutralisation of these polyfunctional T-cells and synovial invasiveness by PDE4 may therefore produce optimal inhibition of pro-inflammatory signalling responses in the PsA synovium.

Abstract Number: 156

Assessing the Role of Ascvd Score in Primary Thrombosis Prophylaxis Strategy Among Asymptomatic Antiphospholipid Antibody Carriers

Yu Zuo¹, Akriithi Udupa², Jennifer Fan¹, Una E. Makris¹, David Karp^{1,3} and Yu-min Shen¹, ¹University of Texas Southwestern Medical Center, Dallas, TX, ²Internal Medicine, University of Texas Southwestern Medical Center, Dallas, TX, ³Internal Medicine/Division of Rheumatic Diseases, University of Texas Southwestern Medical Center, Dallas, TX

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Antiphospholipid Syndrome Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Primary thrombosis prophylaxis among asymptomatic antiphospholipid antibody (aPL) carriers is challenging. The presence of aPL does not always lead to thromboembolic events. Additional factors are needed to potentiate thrombus formation. A risk stratification tool to guide primary thrombosis prophylaxis among aPL positive carriers does not yet exist. Our study aims to evaluate the role of ASCVD score in primary thrombosis prophylaxis among asymptomatic aPL carriers.

Methods: This study included a convenience cohort of 198 persistent aPL positive patients who attended clinic at University of Texas Southwestern Medical Center. All patients had persistent high titer (≥ 99 percentiles) aPL. LA was tested by dilute Russell's viper venom time, partial thromboplastin time-LA and silica clotting time, with appropriate cut-offs established in the laboratory. ASCVD is calculated based on patients' age, total cholesterol, HDL, most recently documented systolic blood pressure, diabetes status, and smoking status. Pearson Chi-squared analysis was used to determine the association between increased ASCVD >10 and various thromboembolic events. Non-parametric comparison of ASCVD as a continuous variable was performed among different groups.

Results: Of the 198 aPL positive patients, 38 (19.2%) patients had arterial thrombosis, 72 (36.3%) had venous thrombosis, 7 had both arterial and venous thrombosis, and 95 (48.0%) were asymptomatic. Significantly higher 10-year CVD risk was

seen among aPL patients with arterial thrombosis compared to asymptomatic carriers ($P<0.0001$). When comparing thrombotic APS patients to asymptomatic aPL positive carriers, 10-year CVD risk $>7.5\%$ ($OR=2.202$, 95% CI 1.043–4.556, $P=0.042$) and 10-year CVD risk $>10\%$ ($OR=2.321$, 95% CI 1.089–5.153, $P=0.029$) were significantly associated with arterial thrombosis but not venous thrombosis or any thrombosis. There were no significant CVD risk differences observed between aPL patients with venous thrombosis/or any thrombosis and asymptomatic carriers.

Conclusion: Increased 10 year cardiovascular disease risk determined by ASCVD among aPL positive patients is significantly associated with arterial thrombosis but not venous thrombosis. Since the protective effect of aspirin against incident thrombosis in all aPL carriers is not supported by randomized controlled data, our result suggests that ASCVD may be useful in identifying a subgroup of aPL carriers who benefit from aspirin.

Abstract Number: 157

Identifying Additional Risk Factors Associated with Thrombosis and Pregnancy Morbidity in a Unique Cohort of Antiphospholipid Antibody Positive Chinese Patients

Yu Zuo¹, Chun Li², Song Zhang³, Una Makris¹, David Karp⁴ and Zhan-Guo Li⁵, ¹University of Texas Southwestern Medical Center, Dallas, TX, ²Peking University People's Hospital, Beijing, China, ³University of Texas Southwestern Medical Center, Dallas, TX, ⁴Rheumatology, UT Southwestern Med Ctr, Dallas, TX, ⁵Rheum/Immunology, Peking University People's Hospital, Beijing, China

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Antiphospholipid Syndrome Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Risk stratification of asymptomatic aPL carriers is difficult. Our objective was to identify additional clinical and epidemiological predictors of arterial thrombosis, venous thrombosis, and pregnancy morbidities in a large cohort of Chinese aPL carriers.

Methods: This cohort included 297 consecutive persistent aPL positive patients who attended the rheumatology clinic at Peking University People's Hospital. Among those, 85 had arterial thrombosis, 76 had venous thrombosis, and 34 experienced APS related pregnancy morbidities. 143 patients had at least one persistent positive aPL without any other criteria APS manifestations and were defined as aPL positive control patients. When assessing risk factors associated with pregnancy morbidities, only reproductive age (age <45) female controls were used. Pearson Chi-squared analysis and multivariable logistic regression were used to evaluate correlation between different risk factors and clinical manifestations.

Results: When comparing to asymptomatic aPL positive controls, additional risk factors associated with arterial thrombosis included: hypertension ($OR=2.368$, 95% CI 1.249 – 4.491, $P=0.0083$), smoking ($OR=6.137$, 95% CI 2.408 – 15.637, $P=0.0001$), and the presence of underlying autoimmune disease ($OR=4.401$, 95% CI 2.387– 8.113, $P<0.0001$). Additional risks associated with venous thrombosis included: smoking ($OR=4.594$, 95%CI 1.681 – 12.553, $P=0.029$) and the presence of underlying autoimmune disease ($OR=6.33$, 95%CI 3.355 – 11.94, $P<0.0001$). The presence of underlying autoimmune disease ($OR=3.301$, 95%CI 1.407 – 7.744, $P=0.0061$) is the only additional risk which demonstrated a significant association with pregnancy morbidity. A high frequency of thrombocytopenia and hypocomplementemia were observed in all +aPLs patients.

Conclusion: Hypertension is a potential predictor for arterial thrombosis. Smoking and the presence of underlying autoimmune disease are potential predictors for both arterial and venous thrombosis among aPL carriers. The presence of underlying autoimmune disease is an additional risk for APS related pregnancy morbidities in +aPL Chinese patients. This is the largest cross sectional comparison between Chinese APS patients and asymptomatic aPL carriers where we are able to identify additional risk factors for thromboembolic events and pregnancy morbidities. Our data may help physicians to risk stratify aPLs positive Asian patients.

Incidence and Prevalence of Antiphospholipid Syndrome in a Health Management Organization (HMO): A 15-Year Study

Aurelia Luissi¹, Marina Scolnik² and Enrique R Soriano³, ¹Rheumatology Unit, Internal Medicine Service, Hospital Italiano de Buenos Aires, Capital Federal, Argentina, ²Rheumatology Unit, Internal Medicine Service, Hospital Italiano Buenos Aires, Argentina, Buenos Aires, Argentina, ³Rheumatology Unit, Internal Medicine Service, Hospital Italiano de Buenos Aires, CABA, Argentina

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Antiphospholipid Syndrome Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Antiphospholipid Syndrome (APS) is an unusual disease and there are scarce epidemiological data. Our objective was to assess incidence and prevalence rates of APS using data from a tertiary university hospital-based health management organization (HMO) in Latin America.

Methods: Different methods were used to ensure complete APS cases ascertainment: (a) patients with diagnosis of APS, recurrent abortions and/or fetal death in HMO electronic medical records, (b) patients with a Lupus anticoagulant, IgG/IgM anticardiolipin and/or IgG/IgM β 2glycoprotein positive test in laboratory database, (c) patients included in the Institutional Registry of Thromboembolic Disease of our hospital. Electronical medical records of all cases retrieved by these ascertainment methods were reviewed and definite APS was diagnosed if 2006 modified Sapporo Criteria were fulfilled. Possible APS was diagnosed if diagnosed by an experienced rheumatologist (in spite of absence of a second antibody determination). Global, age-specific, and sex-specific incidence and prevalence rates were calculated for members of the HMO. For the incidence study members with continuous affiliation ≥ 1 year from January 2000 to January 2015 were followed until he/she voluntarily left the HMO, APS was diagnosed, death, or study finalization. Prevalence was calculated on January 1st 2015.

Results: 53 incident cases of APS were identified during the study period. Patients' characteristics are shown in table 1. A total of 349,775 persons contributed a total of 2,073,438 person-years. Incidence rates are reported as cases per 100,000 person-years (py): APS overall incidence rate was 2.6 (95% CI 1.9-3.2), 2.9 (95% CI 2.0-3.9) and 2.0 (95% CI 1.1-3.0) in women and men respectively. In our population, age-specific incidence and prevalence rates in female patients peaked in the third decades of life and in male they peaked in the sixth decades. On January 1st 2015, 55 APS prevalent cases were identified from a denominator population of 135,750 HMO members. Prevalence rate was 40.5 per 100,000 persons (95% CI 29.8-51.2). LA was the most frequent antibody (71.7%); thrombotic events were more frequent than obstetric ones and only 2 women had both (5.6%).

Conclusion: Incidence and prevalence rates were similar of previous reports. Incidence and prevalence rates in women were higher in the young population, associated with obstetric morbidity.

Table 1. APS Incident cases characteristics

	APS patients(n=53)
Female, n (% , 95% CI)	36 (67.9 ,53.9-79.3)
Mean age at diagnosis, years (DS)	55.9 (17.1)
Mean age at first event, years (DS)	52.6 (17.5)
Global Incidence per 100,000 patients-year (% , 95% CI)	2.6 (1.9-3.2)
Definite cases (fulfilment of Sapporo criteria), n (%)	50 (94.3)
Probable cases, n (%)	3 (5.7)
Lupus anticoagulant +, n (% , 95% CI)	38 (71.7, 57.8-82.4)

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Antiphospholipid Syndrome Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The antiphospholipid syndrome (APS) is defined by vascular thrombosis or pregnancy morbidity in the presence of persistently circulating antiphospholipid antibodies (aPL). Those positive for multiple types of aPL have greatest future thrombotic risk. Little is known regarding testing patterns in a population-based sample and whether testing for aPL is done in accordance with the revised Sydney recommendations. We characterized patterns of aPL testing in a large general population sample.

Methods: We performed a retrospective analysis using TruvenHealth MarketScan® Research Databases, that integrate de-identified patient health data (contributed by large employers, managed care organizations, hospitals, EMR providers, Medicare and Medicaid) including laboratory results on a subset (over 1 million). We used MarketScan lab data from 2010-2015 to identify individuals tested for lupus anticoagulant (LA), anti-cardiolipin(aCL), and anti-beta2-glycoprotein1 (aGP1) antibodies. All subjects were required to be at least 18 years old, having continuous eligibility for medical benefits at least 12 months before and 3 months following the first aPL test.

Results: We identified 33,456 individuals who had had at least one aPL test performed. The distribution of testing is shown in Figure 1. In these 33, 456 individuals, only 6,391 (19%) had been tested for all three tests (LA, aCL, aGP1). Of those 33,456 tested at least once, 5786 (17.3%) were positive for at least one test and 255 of these 5,786 (10.6%) had a confirmatory second finding.

18,370 individuals had one or more LA test, among which 1,291 (7%) were positive initially. Among these 1,291 initially positive, only 996 (77%) were known to have been retested ≥12 weeks later.

24,964 individuals had one or more aCL test, among whom 3,753 (15%) were positive initially. Of those 3,753 initially positive, only 1,707 (45%) were re-tested ≥12 weeks.

11,456 individuals had one or more aGP1 test, among whom 1,304 (11%) were positive initially. Of those 1,304 initially positive, only 537 (41%) were re-tested ≥12 weeks.

Conclusion: In this retrospective claims analysis, and applying revised Sydney criteria for APS diagnosis, we determined that confirmatory aPL testing was performed ≥12 weeks in 77%,45%, and 41% of initially positive LA, aCL, and aGP1, respectively. In addition, in those individuals who had been tested at least once for any aPL, only 6,391 had been tested for all 3 aPL. These findings highlight that aPL testing may often be incompletely performed. Limitations of these analyses include the possibility that testing was done outside the window for which we had data. Further characterization of testing

patterns in individuals with known thrombotic events, pregnancy morbidity, systemic lupus, and other high-risk conditions is warranted and may help to inform local diagnostic practices.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Antiphospholipid Syndrome Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: APS ACTION Registry was created to study the natural course of disease over 10 years in persistently antiphospholipid antibody (aPL) positive patients with or without systemic autoimmune diseases. The objective of this analysis was to describe the new pregnancy outcomes of the aPL-positive patients since the inception of the registry.

Methods: A web-based data capture system is used to store patient demographics, history, and medications. The inclusion criteria are positive aPL, based on the laboratory section of the Updated Sapporo APS Classification Criteria, tested at least twice within one year prior to enrollment. Patients are followed every 12±3 months with clinical data and blood collection. For this descriptive analysis, we identified patients who were recorded as “pregnant” during the prospective follow-up; new “aPL-related pregnancy morbidity” was defined as: a) live birth with small-for-gestational-age (SGA) infant with/without preeclampsia (PEC); b) preterm live birth (PTLB) ≤ 34th week of gestation due to PEC or eclampsia; or c) fetal death ≥ 10th week of gestation. Categorical variables were analyzed using chi-square test or Fisher’s exact test, and continuous variables using Student’s t-test or ANOVA.

Results: Since the inception of the registry in 2012, 55 pregnancies were recorded in 42 aPL-positive patients. Three pregnancies, ongoing at the time of data lock, were excluded. Of 40 patients included (mean maternal age: 32.9 ± 5.2 y; primary aPL/APS: 30 [75%]; systemic lupus erythematosus [SLE]: 10 [25%]), 10 (25%) did not fulfill clinical APS classification criteria, 5 (13%) had obstetric APS (OAPS), 12 (30%) thrombotic APS (TAPS), and 13 (33%) OAPS+TAPS. Pregnancy outcomes (Table) were not different between patients with or without TAPS, with and without OAPS, with or without APS, and with OAPS and with TAPS with one exception: term live birth occurred in 12/34 (35%) of pregnancies of patients with history of TAPS compared to 12/18 (67%) of pregnancies of patients without history of TAPS (*p*: 0.03). The analysis of all the pregnancy morbidity combined showed no significant difference between the groups. Forty-four of 52 (85%) pregnancies were treated with low dose aspirin (LDA) and/or low-molecular weight heparin (LMWH) (37 with LDA+LMWH): 5/52 (10%) due to OAPS only (LDA+LMWH: 5); 14/52 (27%) TAPS only (LDA+LMWH: 12); 16/52 (31%) OAPS and TAPS (LDA+LMWH: 13); and 9/52 (17%) despite no APS classification (LDA+LMWH: 7). Medications were not different among patients with different new pregnancy outcomes.

Conclusion: In our multi-center international prospective aPL-positive cohort, after excluding one-fourth of pregnancies complicated by pre-embryonic or embryonic losses before 10 weeks of gestation: a) five of 39 (13%) resulted in fetal deaths; and b) 34 of 39 (87%) resulted in live birth, while 12 of 39 (31%) patients had “aPL-related pregnancy morbidity”. SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Antiphospholipid Syndrome Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: APS ACTION Registry was created to study long-term outcomes in persistently antiphospholipid antibody (aPL)-positive patients with/without other systemic autoimmune diseases (SAIDx). The primary objective of this analysis was to report the baseline demographic, clinical, and laboratory characteristics of aPL-positive patients enrolled since 2012. Secondly, we analyzed the association between aPL-profiles and aPL-related events at baseline.

Methods: A web-based data capture system is used to store patient demographics and aPL-related medical history. Inclusion criteria are positive aPL, based on the Updated Sapporo APS Classification Criteria, tested at least twice within one year prior to enrollment (IgA aCL/aβ₂GPI included whenever available). Patients are followed every 12±3 months with clinical data and blood collection. For this analysis, aCL and aβ₂GPI IgG/M/A positivity was defined as a titer of ≥40 U, based on local enrollment tests, and criteria and non-criteria (NC) aPL manifestations were retrieved (Table). To test the association between aPL profiles and clinical outcomes, we used chi-square test or Fisher's exact test for categorical variables.

Results: As of 12/2017, 714 patients were enrolled from 26 centers worldwide (mean age at entry: 45 ± 13y; female: 530 [74%]; white: 460 [64%]; and other SAIDx: 257 [36%]). Historically, 161 (23%) had aPL-positivity without APS; 393 (55%) thrombotic APS (TAPS); 66 (9%) obstetric APS (OAPS); and 94 (13%) TAPS+OAPS. 48% and 63% of TAPS patients had arterial and venous thrombosis, respectively (14% both); 1% had catastrophic APS. 81 of 161 (50%) and 263 of 553 (48%) of patients without and with clinical APS classification, respectively, had ≥1 NC aPL manifestation. Livedo (p=0.002) and skin ulcers (p=0.047) were more frequent in patients with TAPS+OAPS and TAPS (with/without OAPS), respectively (vs aPL-positive patients without APS). Based on inclusion aPL, 585 (82%) patients were tested for all three aPL; 222/585 (38%) were triple aPL-positive. Thrombosis, pregnancy morbidity, and NC aPL manifestation rates were similar across different aPL profiles except (Table): a) ≥3 consecutive (pre)embryonic losses and cardiac valve disease

differed when compared between triple-, double-, and single aPL-positive patients; and b) livedo was higher in isolated LA-positive patients compared to triple aPL-positive patients.

Conclusion: In our international aPL-positive cohort, at baseline: a) one-fourth of patients do not fulfill clinical APS classification criteria; b) almost half have at least one non-criteria aPL manifestation; c) livedo and skin ulcers are more common in thrombotic APS patients; and d) there is no association between the aPL-related criteria events and aPL profile. Future prospective registry analysis, accounting for potential confounders and using standardized core laboratory aPL test results, will help clarify aPL risk profiles.

Baseline Clinical Characteristics of 714 Patients Included in AntiPhospholipid Syndrome Alliance for Clinical Trials and International Networking (APS ACTION) Clinical Database and Repository (“Registry”) Between 2012-2018, by Antiphospholipid Antibody (aPL) Profile

Baseline Clinical Characteristics	P ¹	LA only Positivity (134)	Triple* aPL Positivity (222)	Double* aPL Positivity (176)	Single* aPL Positivity (179)	P ²

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Antiphospholipid Syndrome Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Figure: Increased mTOR Activity Suggested by the S6RP Staining (arrows) in the Central Skin Biopsy (A) of an Antiphospholipid Antibody-positive SLE Patient with Livedo, Compared to the Lesional Skin Biopsy (B) in the same patient (no similar mTOR activity was observed in the central [C] or lesional [D] skin biopsies of the aPL-negative SLE patient with livedo).

Background/Purpose: Endothelial proliferation is a key finding in antiphospholipid antibody (aPL)-positive patients with microthrombosis. The mTOR pathway plays a role in the endothelial proliferation leading to aPL-related nephropathy; however the role of mTOR pathway is not well determined in patients with livedo, which is purple discoloration of the skin due to reactive dilation of peripheral dermal venules triggered by reduced blood flow in the center. Thus, our primary objective was to investigate mTOR pathway activation in the skin biopsies of aPL-positive patients with livedo reticularis/racemosa; secondly, we investigated mTOR activation in peripheral blood mononuclear cells (PBMC).

Methods: This ongoing cross-sectional study includes patients with livedo reticularis/racemosa: a) those with persistent aPL-positivity (LA, aCL IgG/M ≥ 40 U, and/or α_2 GPIIgG/M ≥ 40 U) with/without systemic lupus erythematosus (SLE); and b) aPL-negative SLE patients as a control group. We collect demographics and aPL-related history. We perform two 5-mm skin biopsies on each patient, one from the erythematous-violaceous (lesional) and the second from a non-violaceous area (central). Specimens are stained for phosphorylated S6 ribosomal protein (P-S6RP) as a marker of mTOR complex-1 activity;,. We also collect PBMCs from aPL-positive patients to examine mTOR expression in monocytes assessed by flow cytometry. Unstimulated and lipopolysaccharide (LPS)-stimulated measurements are used to calculate the fold change in mTOR activation. Mann-Whitney-U test is used to compare the fold change between aPL-positive patients and sex- and age-matched healthy controls.

Results: As of May 2018, three aPL-positive SLE patients (all female and Caucasian; mean age: 40 ± 11.2 y; and 2 met APS clinical classification criteria) and one aPL-negative SLE control were enrolled. In all aPL-positive patients, but not in aPL-negative SLE control, there was increased mTOR activity in the non-violaceous area (central) of the skin (epidermis), compared to erythematous-violaceous (lesional) skin (Figure). Unstimulated, LPS-stimulated, and fold change mTOR measurements were not different in monocytes of aPL-positive patients, compared to the healthy control group (p: 0.57, p: 0.73, and p: 0.56, respectively).

Conclusion: Based on the preliminary results of our ongoing study, we found increased mTOR activity in the center of livedoid lesions of aPL-positive patients with SLE, compared to an aPL-negative SLE patient. However, there was no systemic mTOR activation in monocytes. Given the vascular stenosis occurring in arterioles located in the center leading to livedo at the periphery, our findings are consistent with the pathophysiology of livedoid lesions. Further analysis with increased number of patients will determine the clinical relevance of our findings.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Antiphospholipid Syndrome Poster

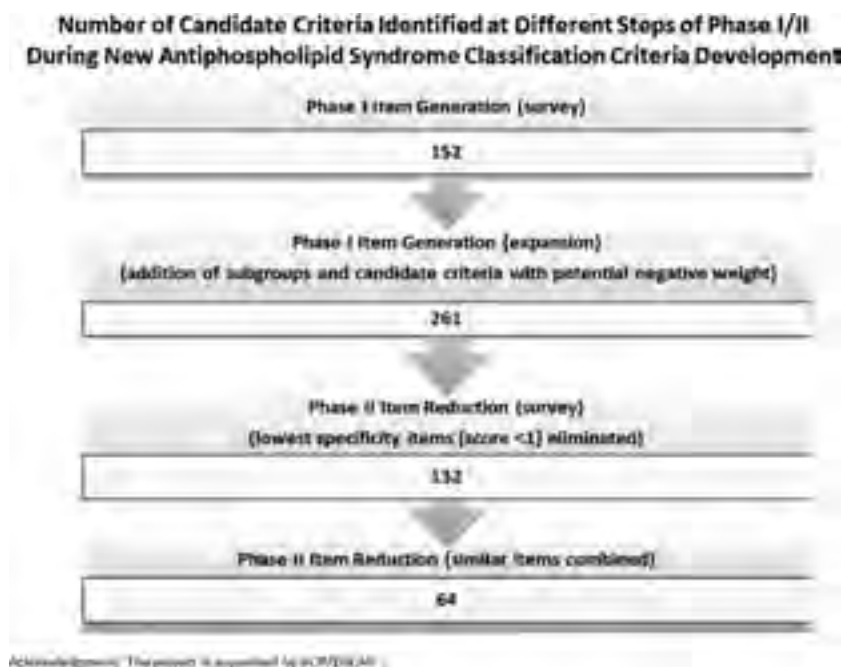

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: An international multidisciplinary effort has been initiated to develop new rigorous, consensus-based criteria to identify patients with high likelihood of having APS. The methodological approach includes both expert-based and data-driven methods, and four phases: item generation (I); item reduction (II); item weighting and threshold identification (III); and classification criteria refinement and validation (IV). We have previously reported Phase I results (Barbhuiya M, et al. *Lupus* 2016;25[SupplS]:11); here we report our Phase II "Item Reduction" survey results. The aim of Phase II is to reduce the 261 Phase I items to approximately 20 items, considered to be the most important features distinguishing APS from other conditions.

Methods: 61 international physician-scientists experienced in APS were e-mailed a survey to rank each item generated in Phase I on a Likert scale (-5 to +5), with (-5) **extremely strongly against APS, i.e., more likely related to another disease entity; (0) not for or against APS; and (+5) extremely likely APS**. Experts were asked to "consider two patients who are exactly the same except that one has the clinical feature presented and the other does not. Please rate each feature in terms of how strong this feature is in differentiating APS from other similar conditions, i.e., specific for APS." An article reference library (n: 26), including mostly aPL/APS-related systemic reviews and meta-analyses, was provided. Mean survey scores for each item (\pm SD) were calculated. Items were ranked from highest to lowest mean score, and highest scoring items were grouped based on independent logical domains.

Results: Phase II survey response rate was 71%. Of 43 responders, 22 were rheumatologists, four hematologists, four nephrologists/cardiologists/neurologists/vascular specialists, four internists, three clinical immunologists, three pediatric rheumatologists, two pediatric hematologists, and one obstetrician. Mean item scores ranged from -2.29 to 4.65; items of

low specificity (score less than 1) were eliminated. The higher specificity items (n=132) were organized into seven clinical (cardiopulmonary, dermatologic, hematologic, neurologic, obstetric, renal/abdominal, and vascular), two laboratory (antiphospholipid antibody [aPL] ELISA and lupus anticoagulant), and one pathologic domains. Items overlapping or describing similar concepts were combined (n=64) (Figure).

Conclusion: Sixty-four candidate criteria identified using the Phase II item reduction survey will be further reduced and refined based on the ongoing project to develop new APS classification criteria, with the goal of better standardizing patients for APS research.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Antiphospholipid Syndrome Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Correct interpretation of lupus anticoagulant (LA) tests is crucial for diagnosis of antiphospholipid syndrome (APS). However, testing patients during vitamin K antagonist (VKA) or other anticoagulant treatment remains a contentious issue and has been discouraged by official guidelines because of interpretational problems affecting the mixing test.

Methods: We enrolled 60 patients who met one of the following inclusion criteria: 1) Fulfilled the diagnosis of thrombotic APS defined as per Sidney criteria; 2) Patients with thrombosis and suspected APS not completely fulfilling the laboratory criteria, as follows: a) and inconstant previous LA positivity; and/or b) low-medium titers aPL (defined as levels of aCL IgG/IgM or anti- β 2GPI IgG/IgM 10-30GPL/MPL aPL) with no LA positivity. aPL testing was performed in a blind fashion in 4 centers undergoing periodic external quality assessment.

Results: The mean age at was 50 years old (SD ± 11) (F:M71,7% : 28,3%). Forty-three patients (72%) had a confirmed diagnosis of thrombotic APS (arterial 58%; venous 56%), and 17 patients presented with thrombosis and inconstant LA positivity (N. 7; 41%) and/or with low-medium titers (N. 10;59%). Categorical agreement for LA among the centers, as expressed by Cohen's kappa coefficients, ranged between 0.41 and 0.60 (corresponding to moderate agreement). The correlation among quantitative results at the 4 sites for aPS/PT IgG was strong (Cohen's kappa coefficients=0.81–1. Spearman rho 0.84). We observed 27 (45 % of the total) cases (15/20, 75% patients on VKA) in which LA results were discordant (as defined by lack of agreement in ≥ 3 laboratories) or inconclusive. Conversely, in those cases, we observed a good correlation for aPS/PT IgG testing (Cohen's kappa coefficients=0.81–1, Spearman rho 0.86). aPS/PT testing showed an overall agreement of 83% (up to 90% in patients receiving VKA), providing an overall increase in test reproducibility of + 28% when compared to LA, becoming even more evident (+65%) when analyzing patients on VKA.

Conclusion: Despite the progress in the standardization of aPL testing, we observed up to 45% of discrepant results for LA, even higher in patients on VKA. Our findings highlight that some discordances in the reliability of LA testing still exist. The introduction of aPS/PT antibody testing into the diagnostic process of APS might represent a further diagnostic tool, especially when LA is not available or the results are uncertain.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Antiphospholipid Syndrome Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Antiphospholipid syndrome (APS) mainly affects women who are of child-bearing age. We aimed to describe the clinical and immunological features of APS patients diagnosed after the age of 60.

Methods: The Elderly-Phospholipid study is a national, multicenter, retrospective study involving all APS (2006 revised Sapporo criteria) patients followed in 5 French tertiary university centers including 4 national referral centres for lupus and APS. The clinical and serologic features of patients in whom APS was diagnosed after the age of 60 were analyzed and compared to APS patients included in the Euro-Phospholipid cohort.

Results: Sixty-one patients (40 women (65.6%); 68.2 ± 7 years at diagnosis) were included in the Elderly-Phospholipid study. 70.4% of the patients had primary APS. Stroke was the most common manifestation at diagnosis (36.1%) and during follow

up (9.8%). Lupus anticoagulant (LA), aCL and a β 2GPI antibodies were detected in 70.5%, 67.7% and 60.6% of patients, respectively. 37.7% patients were triple-positive for aPL antibodies. All patients were treated with antithrombotic treatment including antiplatelet agents (29.5%) and/or oral anticoagulants (82%). Over a 5.3 \pm 3.8 years follow-up, only 5 (8.2%) patients, all receiving oral anticoagulants, developed major bleeding. The mortality rate was 11.5% with a mean age at death of 77.2 \pm 6 years. The most common causes of death were infection, haemorrhage and malignancy. As compared to Euro-Phospholipid APS patients who had a mean age of 34 \pm 13 years at the onset of the disease, patients in the Elderly-Phospholipid study were more frequently male ($p<0.01$) and had a higher frequency of primary APS ($p<0.01$), stroke ($p<0.0001$) and LA ($p<0.05$).

Conclusion: Older patients with late APS onset have a distinct disease profile, with a higher frequency of LA antibody and arterial thrombosis.

Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Antiphospholipid Syndrome (APS) is characterized by thrombotic events mediated by antiphospholipid antibodies (aPL). Most patients have primary APS (PAPS), while a significant minority has SLE (Ann. Rheum. Dis. 74, 1011). Although PAPS affects 0.5% of the population (Thrombosis Res. 151, S43), it may be underdiagnosed in the absence of SLE. Thus, we evaluated aPL testing in non-SLE patients with deep venous thrombosis (DVT), pulmonary embolism (PE), and stroke or transient ischemic attack (S/TIA).

Methods: 1835 patients were evaluated for PAPS at our Institution between 2010 and 2018: 513 were diagnosed with PE, 583 with DVT, and 739 with S/TIA. Lupus anticoagulants were assessed by hexagonal phase phospholipid neutralization assay (HPPNA) and diluted Russell viper venom test (DRVVT) using Stago protocols (Parsippany, NJ, USA). Platelet neutralization procedure (PNP) was performed, as earlier described (*Am. J. Clin. Pathol.* 79, 678). IgG and IgM antibodies to $\beta 2$ -glycoprotein 1 ($\alpha 2$ -IgG, $\alpha 2$ -IgM) and cardiolipin (aCL-IgG, aCL-IgM) were measured in house while IgA isotypes ($\alpha 2$ -IgA, aCL-IgA) were tested by LabCorp (Burlington, NC). Sensitivities, specificities, positive (PPV) and negative predictive values (NPV) were assessed by 2-tailed χ^2 tests using GraphPad software.

Results: In patients with PE, HPPNA was the most sensitive individual test for detecting APS (from 349/513 tested, 144/349 resulted in positive HPPNA (41%). 50/513 patients were assessed with all 9 tests; 30/50 had at least one positive result (sensitivity: 60%; $p < 0.0001$ relative to HPPNA). In patients with DVT, HPPNA was also most sensitive for detecting APS (from 485/583, 216/485 resulted in positive HPPNA (45%), $p < 0.01$ relative to all other individual tests). 47/583 patients were assessed with all 9 tests; 36/47 had at least one positive test (sensitivity: 76.6%; $p < 0.0001$ relative to HPPNA). In 739 patients with S/TIA, PNP was the most sensitive individual test for detecting APS (from 81/739, 26/81 resulted in positive PNP (32%). 54/739 patients were evaluated with all 9 tests; 39/54 had at least one positive test (sensitivity: 72%; $p < 0.0001$ relative to PNP). When combining patients with DVT, PE, and S/TIA (Table 1), the complete 9-test panel yielded the greatest sensitivity for detecting APS (105/151, 69.5%) relative to the most sensitive individual test, HPPNA (382/1060, 36%; $p < 0.0001$). The 9-test panel had similar specificity and PPV but markedly higher NPV at 46% over any individual test ($p < 0.0001$).

Conclusion: This study indicates that a 9-test aPL panel has superior sensitivity for detecting PAPS in patients with DVT, PE, or Stroke/TIA. However, the complete panel was only performed in 151 of 1835 patients with thrombotic events. These findings have major implications for diagnosis of PAPS patients who need lifelong anticoagulation for preventing potentially fatal thrombotic events.

Session Date: Sunday, October 21, 2018

Session Title: Antiphospholipid Syndrome Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: After an initial thromboembolic event (TE), several studies reported that patients with antiphospholipid syndrome (APS) manifest a high-risk for recurrent TE. A systematic review found that antiphospholipid antibody (aPL) positivity in patients with a first venous TE (VTE) predicted an increased risk of recurrent VTE, but the strength of the association was uncertain because of low quality studies. Few studies report on recurrent TE after a first arterial TE (ATE). We performed a systematic review to determine if the risk for recurrence was comparable between VTE and ATE in patients with APS.

Methods: We used the systematic review methodology developed by Cochrane and the Evidence-based Practice Centers and EPPI-Reviewer 4 software. The population of interest was APS patients who had a single VTE or ATE. Outcomes included recurrent VTE, ATE, and death. Studies that did not distinguish patients based on an initial VTE or ATE were excluded. Risk of bias was formally assessed. Aggregate recurrence rates were estimated using meta-analysis. Statistical heterogeneity of pooled analysis was assessed using the chi-squared and the I² statistics. A weighted 24-month rate was estimated using OpenMeta software.

Results: Table 1 demonstrates the number of articles. For patients with initial VTE, 10 studies described 257 patients on anticoagulation and 572 patients who had discontinued anticoagulation. For patients with initial ATE, 4 studies described 405 patients on anticoagulation and 370 patients who had discontinued anticoagulation. Patients with initial VTE who stopped anticoagulation were generally not treated with aspirin, whereas patients with an initial ATE who stopped anticoagulation took aspirin. Table 2 provides 2-year risk estimates of recurrent TE following an initial VTE or ATE. Limitations of studies included heterogeneous criteria for positive aPL definition and APS diagnosis, varying study designs (randomized trials vs. cohort studies), and small sample sizes. In addition, only 3 studies provided information about the same patients while taking anticoagulation as well as after stopping anticoagulation.

Conclusion: Compared to APS patients with an initial VTE, APS patients with an initial ATE have a higher risk for recurrent TE while taking anticoagulation, similar to the rate while not taking anticoagulation. Due to the limitations of literature, however, it is difficult to accurately estimate and compare recurrence rates for APS patients with different thrombotic phenotypes. Future studies need to clearly distinguish between different thrombotic manifestations of APS.

Table 1: The Number of Articles Identified at Each Stage of the Systematic Review

	VTE	ATE
# after the first search	3,137	1,694
# after the exclusion based on title and abstract screening	90	137
# after the exclusion based on full review	6	4
# after the inclusion of new studies based on manual review	13	5
# included in the final analysis	10	4

VTE: venous thromboembolism; ATE: arterial thromboembolism

Table 2: Overall Risk Estimates of Recurrent Thromboembolism (TE) in APS Patients Following an Initial Venous TE (VTE) and Arterial TE (ATE), Stratified by Long-term Anticoagulation (95% Confidence Interval)*

	VTE	ATE
On Anticoagulation	0.045 (0.020-0.070)	0.187 (0.101 – 0.274)
	13 Events in 257 Patients	81 Events in 405 Patients
No Anticoagulation (c/s antiplatelet Rx)	0.167 (0.085-0.250)	0.168 (0.129 – 0.206)
	105 Events in 572 Patients	62 Events in 370 Patients

* Results are provided as proportions and total number of events, and represent the rates over 24 months

Session Title: Antiphospholipid Syndrome Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Reliable biomarkers for risk stratification in Antiphospholipid Syndrome (APS) are still lacking. Anti-high-density lipoproteins antibodies (anti-HDL) showed promising results in predicting the development of cardiovascular disease in autoimmune conditions. Nevertheless, the association between anti-HDL and clinical features of APS remains unclear.

Methods: This cross-sectional study included 60 thrombotic APS patients and 20 healthy donors(HDs). Clinical data were retrospectively collected (Figure 1). Serum levels of total IgG, IgG anti-HDL antibodies and complete aPL profile were assessed, including lupus anticoagulant, anti-cardiolipin, anti- β 2glycoproteinI, and anti-phosphatidylserine/prothrombin antibodies.

Patients Characteristics	APS patients (n=50)	HDs (n=20)
Female sex, n (%)	43 (71.9)	25 (75)
Age (mean, S.D.), years	50±10.6	45.1±11.6
Primary APS patients, n (%)	43 (71.9)	0 (0)
Concomitant diagnosis of SLE, n (%)	17 (28.3)	-
Disease duration since APS diagnosis (mean, S.D.), years	11.7±7.5	-
Thrombosis, n (%)	60 (100)	0 (0)
Venous thrombosis, n (%)	57 (61)	-
Arterial thrombosis, n (%)	20 (30)	-
Pregnancy morbidity, n (%)	1 (1.6)	0 (0)
Arterial hypertension, n (%)	22 (36.6)	1 (5)
Hyperlipemia, n (%)	19 (31.6)	0 (0)
Smoking, n (%)	5 (8.3)	2 (10)
LA, n (%)	14 (56.6)	0 (0)
aCL-IgG/IgM, n (%)	22 (36.6)	0 (0)
Anti-B2GPI-IgG/IgM, n (%)	22 (36.6)	0 (0)
aPS/PT-IgG/IgM, n (%)	29 (48.3)	0 (0)
Triple aPL positivity, n (%)	15 (25)	-
GAPSS (mean, S.D.)	12.3±5.5	-
Total cholesterol levels (mean, S.D.), mg/dl	187.4±51	145±32.2
LDL-cholesterol levels (mean, S.D.), mg/dl	84±9.1	72±15.8
Triglycerides levels (mean, S.D.), mg/dl	38.7±28.6	104±26.2
CRP levels (mean, S.D.), mg/dl	0.4±0.2	0.2±0.2
Statins, n (%)	20 (33)	0 (0)
Anti-thrombotic drugs, n (%)	19 (31.6)	1 (5)
HCQ, n (%)	15 (25)	0 (0)
Anticoagulant agents, n (%)	33 (55)	0 (0)
Antithrombotic agents, n (%)	36 (60)	0 (0)

APS means Antiphospholipid Syndrome; HDs, healthy donors; SLE, systemic lupus erythematosus; LA, lupus anticoagulant; aCL, anti-cardiolipin antibodies; anti-B2GPI, anti-B2 glycoprotein I antibodies; aPS/PT, antiphosphatidylserine/prothrombin antibodies; aPL, anti-phospholipid antibodies; GAPSS, Global Antiphospholipid Score; HDL, high-density lipoproteins; CRP, C-reactive protein; HCQ, hydroxychloroquine

Results: 43 patients (72%) were primary APS and 17 patients (28%) had a concomitant diagnosis of autoimmune disease. Thirty APS patients (50%) presented previous arterial events and 37 (61%) venous events. Higher levels of IgG anti-HDL were found in APS patients compared to HDs [mean 46 (\pm 70) vs. 14 (\pm 13)AU, respectively; $p < 0.001$], even after correcting for total IgG levels [mean 13 (\pm 16) vs. 4.6 (\pm 5), respectively; $p < 0.001$]. No association with traditional cardiovascular risk factors, except for smoking habit ($p < 0.0001$) was found. No differences in anti-HDL levels were observed between patients with primary APS and those with a concomitant autoimmune disease ($p > 0.050$). Patients who experienced at least one arterial event had significantly higher levels of anti-HDL antibodies when compared to patients with history of venous thrombosis [mean 53 (SD \pm 94) vs. mean 34 (SD \pm 29), respectively; $p = 0.046$] (Figure 2). This difference became stronger when adjusting for total IgG levels [anti-HDL/IgG: mean 13.1 (SD \pm 16.7) vs. mean 9.5 (SD \pm 6.6); $p = 0.007$]. In addition, patients tested positive for aPS/PT (IgG/IgM) antibodies had significantly higher levels of anti-HDL antibodies [mean 53.1 (SD \pm 81.1) vs. mean 20.7 (SD \pm 17.6), $p = 0.045$]. The levels of IgG anti-HDL antibodies were not influenced by pharmacological treatments (all $p > 0.050$).

Conclusion: Our study demonstrates that thrombotic APS patients have higher levels of IgG anti-HDL antibodies, supporting the emerging role of these autoantibodies in APS setting. Moreover, our findings suggest that anti-HDL represent a promising tool for risk management and assessment and a potential biomarker for lipid dysfunction and arterial thrombotic events.

Session Date: Sunday, October 21, 2018

Session Title: Antiphospholipid Syndrome Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Antiphospholipid syndrome (APS) is associated with several patterns of renal involvement. Among them, antiphospholipid nephropathy (APSN) is a rare but specific pattern resulting from microvascular lesions. APSN prognosis, outside lupus nephritis, is unknown. We aimed to describe the renal, vascular and general prognosis of patients with APSN.

Methods: We performed a retrospective multicenter study on patients with antiphospholipid antibodies associated with APSN lesions, and no other nephropathy. Patients were identified through a national call for medical reports. End-stage renal disease (ESRD)-free survival, thrombosis recurrence-free survival and overall survival were assessed. Factors associated with estimated glomerular filtration rate (eGFR) change were also analysed.

Results: Twenty-five patients were included : 18 (72%) women, median age 38.8 (24.6-68.7) years. Seventeen (68%) had APS according to revised Sapporo criteria, 22 (88%) with lupus anticoagulant, 14 (56%) with triple positivity. Median blood pressure was 132 (110-214) / 79.5 (60-124) mmHg, median eGFR was 47.8 (5.8-103) mL/min/1.73m², median proteinuria was 0.95 (0.14-5) g/day. On renal biopsy 13 (52%) had glomerular thrombotic microangiopathy, 17 (68%) fibrous intimal hyperplasia and 3 (12%) focal cortical atrophy. Moderate to severe interstitial fibrosis ($\geq 25\%$) was observed in 11 (44%) patients. Three patients developed ESRD after a median follow-up of 4.4 (0.4-38.3) years. ESRD-free survival at 5 years was 82.3% (IC95% 65.5%-100%). Two other patients presented a 30% decrease in eGFR. No factor was significantly associated with annual change in eGFR. However patients with interstitial fibrosis ($\geq 25\%$) seemed to have steeper eGFR decline (-0.08 (-4.42;7.005) ; 3.03 (-18.23;14.05) ; $p=0.06$). Thrombosis recurrence-free survival was 96% at 5 years (IC95% 88.7%-100%), 74% at 10 years (IC95% 51%-100%). One patient died during follow-up. Overall survival was 100% at 5 years and 90% at 10 years (IC95% 73%-100%).

Conclusion: The renal prognosis of isolated APSN is poor in this young population. Up to 20% of patients developed ESRD at 5 years. Severe lesions of renal fibrosis suggest a late diagnosis. The early detection of renal features could improve prognosis with the possibility of evaluating the efficacy of anti-proliferative treatments in APSN.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Antiphospholipid Syndrome Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Deep vein thrombosis (DVT) is frequent and potentially life threatening disease with tendency to reoccur. Anticoagulant treatment of the first episode of DVT usually lasts 3 months. Antiphospholipid syndrome (APS) is an important cause of DVT. However, the APS can be confirmed only 24 weeks after DVT according to the current APS classification criteria. Thus, undiagnosed APS patients, who cease anticoagulant therapy after 3 months, might be exposed to a greater risk for recurrent venous thromboembolism. Studies evaluating the significance of positive antiphospholipid antibody (aPL) test in the acute phase of DVT are lacking. We aimed to evaluate whether positive aPL test at the time of acute DVT diagnosis is predictive of APS.

Methods: Patients with acute DVT, confirmed by compression ultrasound, were included into a 24-month prospective study. All patients were given anticoagulants. aCL IgG/IgM and anti-β2GPI IgG/IgM/IgA antibodies were determined by our in-house ELISA at inclusion and then every 4 weeks for the first 24 weeks. The last aPL measurement was performed 24 months after inclusion into the study. APS was confirmed if a patient tested positive (medium or high positive aCL and/or presence of anti-β2GPI) 12 and 24 weeks after DVT. Lupus anticoagulants (LA) were tested after cessation of anticoagulation.

Results: 196 patients (111 male, 85 female, age 54±2 years) included in the study had aPL titer assessed at least 5 times. Ultimately, 20/196 (10.2%) patients fulfilled APS classification criteria. Among these, 15/20 (75%) patients had medium or high titer aPL at the time of acute DVT (1 of whom had double positive aPL and 2 of them had multiple positive aPL at first aPL determination). Two patients (10%) had low positive aCL IgG and one had low titer aCL IgM. Two patients (10%) were negative for aPL, but had later fulfilled APS criteria due to positive LA. APS was not established in 176/196 (89.7%) patients. Among these, 146/176 (83%) patients were negative for aPL at inclusion, while 30/176 (17%) had low titer aCL IgM or aCL IgG. Altogether, diagnostically important aCL IgG/IgM and/or anti-β2GPI titer at the time of acute DVT had 83% specificity and 90.5% sensitivity for APS. Isolated low titer aCL IgG were more frequent in patients with APS than in patients without APS ($\chi^2=125.6$; $p<0.001$). Completely negative aCL IgG/IgM and anti-β2GPI in the acute phase of DVT had a negative predictive value of 98.6%.

Conclusion: Here we show that in acute phase of DVT, positive medium or high titer aCL IgG/IgM or anti-β2GPI is suggestive of APS. In these patients continuation of anticoagulation beyond the initial 3 months should be considered. Patients with negative aPL in the acute phase of DVT do not need further aPL testing; however, LA should be determined. Low aPL titre at the time of acute DVT deems further testing imperative.

Flow Cytometric Assessment of the Mammalian Target of Rapamycin Pathway Using Antiphospholipid Syndrome As a Disease Model

Ariel Badger¹, Ecem Sevim², Oral Alpan³ and Doruk Erkan⁴, ¹O&O Alpan Medical Center, Fairfax, VA, ²Rheumatology, Hospital for Special Surgery, New York, NY, ³Allergy & Immunology, O&O Alpan Medical Center, Fairfax, VA, ⁴Rheumatology, Hospital for Special Surgery- Weill Cornell Medicine, New York, NY

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Antiphospholipid Syndrome Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The mammalian target of rapamycin (mTOR) is a component of MTOR complex-1 that, when activated by upstream molecule protein kinase B (AKT) and another cell signaling pathway mitogen activated protein kinase p38 (p38/MAPK), is responsible for protective autophagy, cell proliferation and growth, and protein synthesis. These independent signaling pathways cross-talk and regulate each other. The mTOR pathway is responsible for the endothelial proliferation leading to chronic renal vascular lesions in antiphospholipid antibody (aPL)-positive patients.

Firstly, our team developed a flow cytometry-based assay that assesses the basal and responsive mTOR phosphorylation in peripheral blood monocytes of patients in relation to the activation of AKT and p38/MAPK . Secondly, based on this assay, we evaluated three antiphospholipid syndrome (APS) patients.

Methods: We assayed unstimulated and lipopolysaccharide (LPS)-stimulated whole blood, 30 minutes at 37C, for peripheral blood classical monocyte (HLA-DR⁺⁺CD14⁺CD16⁻), phosphorylated mTOR/AKT, and p38/MAPK analysis. Unstimulated and stimulated levels of phosphorylated mTOR/AKT and p38/MAPK were reported as percent positives and median fluorescence intensities, and compared against each other. Three APS patients, identified according to the Updated Sapporo Classification Criteria, were assessed with the assay. The mean results were compared with three age- and gender-matched healthy volunteers by the Mann-Whitney U test.

Results: All patients were male (mean age: 51 ± 18.5) with no other systemic autoimmune diseases. Patient #1 had history of arterial thrombosis, autoimmune hemolytic anemia, thrombocytopenia, white matter changes, aPL nephropathy, and livedo reticularis (on aspirin [ASA], azathioprine, and low dose prednisone). Patient #2 had arterial thrombosis, transient ischemic attacks, and microthrombotic APS with peripheral cyanosis, diffuse alveolar hemorrhage, and livedoid vasculopathy (on ASA, hydroxychloroquine, atorvastatin, and low-molecular-weight-heparin). Patient #3 had microthrombotic APS with livedoid vasculopathy (on mycophenolate mofetil and warfarin). All three patients had high mTOR levels both at baseline and after stimulation when compared to healthy controls (p: 0.02 and p: 0.007, respectively), which was independent of AKT and p38/MAPK activation (p: 0.02 and p: 0.03, respectively) (Table).

Conclusion: We developed a flow cytometry-based assay that assesses the activation of mTOR and related proteins; our preliminary analysis of three APS patients demonstrates that mTOR pathway is activated independent of AKT and p38/MAPK. Further clinical studies will determine the clinical utility of this assay.

Table: Flow Cytometric Detection of mTOR, AKT, and p38/MAPK in Monocytes of APS Patients and Healthy Controls Before and After Lipopolysaccharide Stimulation

		Patient 1	Patient 2	Patient 3	Patient Mean	Control Mean	p

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Antiphospholipid Syndrome Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Recent evidence suggests that chemokines and miRNAs are involved in the pathogenesis of antiphospholipid syndrome (APS). However, the specific role of these molecules in both cumulative thrombotic damage and in risk of thrombosis is still not well understood. The aim of this study was to explore the association between autoimmunity related chemokines and miRNAs with cumulative organ damage as well as the clinical risk of thrombosis in patients with APS.

Methods: This cross-sectional study included patients with APS Sapporo/Sydney criteria from a single outpatient rheumatology clinic. Demographic, clinical and clinimetric data (DIAPS, Damage Index in patients with Thrombotic Antiphospholipid Syndrome; aGAPSS, adjusted Global Anti-Phospholipid Syndrome Score and SLEDAI, Systemic Lupus Erythematosus Disease Activity Index) were recorded. Serum samples were obtained in the same visit and levels of chemokines BLC (B lymphocyte chemoattractant), IP10 (IFN- γ -induced protein 10), MCP-1 (monocyte chemoattractant protein-1) and MIG (monokine-induced-by-IFN- γ) were measured by multiplex bead array technology (Luminex MAGPIX System). In addition, relative expression of miR-19, miR-20, miR-126, and miR-155 was measured by qPCR. Sera from healthy individuals were evaluated for reference. Normality analysis was performed with Kolmogorov-Smirnov test and comparisons were made with Mann-Whitney U test. Associations were evaluated with exact Fisher's test and Spearman rho coefficient. ROCs were used to investigate miRNAs cut-off points. IBM SPSS version 23.0 was used for calculations.

Results: Sixty five APS patients were included, mean age was 43 ± 14 years old, 73% were female and 53% primary APS. DIAPS correlates with number of thrombosis (0.381, $p=0.003$), anti-cardiolipin antibodies IgG (0.328, $p=0.030$), anti- β 2GPI IgG (0.366, $p=0.017$) and BLC (0.385, $p=0.015$). Anti-cardiolipin IgG (0.395, $p=0.010$) and BCL (0.359, $p=0.025$) also correlates with aGAPSS. SLEDAI correlates with miR-126 (0.637, $p=0.001$) in secondary APS. The tissue factor related miRNAs, miR-19 (AUC=0.812, $p<0.0001$) and miR-20 (0.834 $p<0.0001$) were able to differentiate patients from controls. Interestingly, $\text{miR-20} \leq 0.0198$ was associate to the presence of anticardiolipin ($p=0.048$) and a tendency of triple positivity ($p=0.093$) as well as recurrent thrombosis ($p=0.075$).

Conclusion: Our results suggest that BLC, miRNA-19 and miRNA-20 may be involved in the accrual damage in APS and risk of thrombosis. Wide and prospective studies to explore processes related to accumulation of chronic damage in APS are needed. The long time follow up for clinical end-points is the challenge for validating new potential circulating biological markers.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Antiphospholipid Syndrome Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Anti-phospholipid antibodies (aPL) are the biomarkers of anti-phospholipid syndrome (APS), a systemic autoimmune condition characterized by thrombosis and/or pregnancy morbidity (PM). The aim of this study was

to quantify the magnitude of the obstetric risk conveyed by criteria aPL, simultaneously assessing the efficacy of conventional treatment.

Methods: Data on 178 pregnancies in 60 women with persistent criteria aPL positivity (lupus anticoagulant, anti-cardiolipin and/or anti-b2GPI antibodies) were retrospectively collected (Table 1, Table 2). A weighted generalized estimating equations(GEE) model for repeated measures was applied to quantify the probability of PM conveyed by aPL, considering as covariates: number of positive aPL tests, low-dose aspirin (LDASA), low molecular weight heparin (LMWH) and their interaction; systemic autoimmune disease and age>35 years were inserted as confounders.

Results: Women with multiple aPL positivity had a probability of PM twice that of women with single aPL positivity. Women with single criteria aPL positivity had a probability of PM of 77%(95%CI 68-85), which raised to 86% (95%CI 76-93) in case of multiple aPL. Treatment with LDASA reduced the probability of PM to 29% (95%CI 11-57) in women with a single aPL test and to 44% (95%CI 17-75) in women with multiple positive tests. Among women with a single criteria aPL test receiving combo treatment, the probability of PM was 30% (95%CI 20-42). The association LDASA+LMWH reduced to 45% (95%CI 31-59) the probability of PM in women with multiple aPL tests.

Conclusion: This retrospective longitudinal cohort study showed that LDASA+LMWH allowed a significant decrease of PM in women with single but not multiple criteria aPL. Even though the association regimen led to a reduction of the probability of PM from 86% to 45% in patients with a high-risk aPL profile, it might be worth to add supplementary therapeutic tools.

Table 1.

	Criteria aPL (N of patients: 60)
Age at first conception, years	30.8 (5.78)
Systemic AD	28 (46.7%)
Organ-specific AD	11 (18.3%)
Pregnancy complications	16 (26.7%)
None	26 (43.3%)
≥ 3 PrL before 10 gw	10 (16.7%)
PrL after 10 gw	8 (13.3%)
Premature birth before 34 gw	
Thrombotic events	12 (20.0%)
Arterial	4 (6.7%)
Venous	7 (11.7%)
Arterial + venous	1 (1.6%)
LA	45 (75.0%)
aCL IgG/IgM	25 (41.7%)
anti-b2GPI IgG/IgM	30 (50.0%)
Number of positive aPL tests	
1	37 (61.7%)
2	6 (10.0%)
3	17 (28.3%)
aPL isotypes	
IgG	21 (60.0%)
IgM	9 (25.7%)
IgG + IgM	5 (14.3%)

Table 2.

	Criteria aPL (N of pregnancies: 178)
Pregnancy complications	
None	72 (40.5%)
≥ 3 PrL before 10 gw	68 (38.2%)
PrL after 10 gw	23 (12.9%)
Premature birth before 34 gw	15 (8.4%)
Treatments	
None	81 (45.5%)
LDASA [+ HCQ]	18 [8] (14.6%)
LDASA + LMWH [+ HCQ]	52 [14] (37.1%)
LMWH	4 (2.2%)
HCQ	1 (0.6%)

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Antiphospholipid Syndrome Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Long-term anticoagulation with vitamin K antagonists (VKAs) is the standard of care in thrombotic antiphospholipid syndrome (APS) but requires frequent monitoring and dose adjustment. Rivaroxaban, an orally active direct factor Xa inhibitor, provides more consistent anticoagulation but its use in APS is controversial.

Methods: This is a phase 3 non-inferiority open-label RCT. We randomly (1:1) assigned 190 patients with thrombotic APS (arterial or venous) receiving warfarin to receive either rivaroxaban (at a daily dose of 20 mg) or dose-adjusted acenocumarol (standard of care, normalized ratio (INR) 2-3 or 3.1 to 4.1 in those with recurrent thrombotic episodes). The per-protocol analysis was designed to determine the rivaroxaban noninferiority to warfarin for the primary endpoint of recurrent thrombosis. Secondary efficacy outcomes include time to thrombosis, type of recurrent events (arterial or venous), and overall causes of death. The primary safety outcome was major bleeding.

Results: In the primary analysis, thrombotic events occurred in 11 patients in the rivaroxaban group (11.6%; 4.59 patients-year) and in 6 patients in the VKAs group (6.3%; 2.26 patients-year) (hazard ratio, 1.93; 95% CI, 0.69 to 5.39; p=0.210). In the intention-to treat analysis, thrombotic events occurred in 12 patients in the rivaroxaban group (12.6%; 4.68 patients-year) and in 6 patients in the VKAs group (6.3%; 2.22 patients-year) (hazard ratio, 2.13; 95% CI, 0.77 to 5.88; p=0.144). In the per-protocol population and in the intention-to-treat population, patients in the rivaroxaban group had a higher rate of stroke (9 events (3.75 patient-year) and 10 events (3.90 patient-year), respectively, than those in the VKAs group (0 events) (hazard ratio in the rivaroxaban group, 16.16; 95% CI, 0.84 to 309.43; p=0.065, in the PP study and 20.04; 95% CI, 1.04 to 386.58; p=0.047 in the ITT study). Major and nonmajor clinically relevant bleeding occurred similarly in both groups (31.6% in the rivaroxaban and 26.3% in the VKAs), but with less intracranial hemorrhage and critically significant bleeding in the rivaroxaban group

Conclusion: In patients with APS, rivaroxaban could not demonstrate its noninferiority to VKAs for the prevention of recurrent thrombosis, and stroke occurred more frequently in the rivaroxaban group. There were no significant between-group difference in the risk of major bleeding, although critical bleeding occurred less frequently in the rivaroxaban (ClinicalTrials.gov number: 02926170)

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Education Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Traditionally, anatomy has been taught by dissection and textbooks of descriptive and topographic anatomy. Today, dissection is increasingly rare and emphasis is placed instead on peer examination with or without US, and CT or Magnetic Resonance Imaging-based images. Counter-current to this progressively technological evolution, the authors have developed a humanistic method of teaching and learning anatomy that involves self-examination and requires no technology. We have termed this deductive anatomy by self-examination (DASE) and it is based on inspection, palpation, and sensory input originating directly from the self-examined anatomical items.

Methods: The authors gave three DASE seminars at the 2018 PANLAR Meeting in Buenos Aires. Seminars were 1 hour and 45 minutes duration, were given in consecutive days, and each dealt with different anatomical regions. Seminar #1 dealt with the wrist and hand (5 exercises), #2 dealt with the elbow and shoulder (7 exercises) and #3 dealt with the lower extremity (6 exercises). At the end of each seminar participants were invited to complete an anonymous evaluation that included rating five characteristics of the seminar on a Likert scale as well as a global evaluation.

Results: Ninety of 100 (90%) participants evaluated seminar #1, 100 of 120 (83%) seminar #2, and 37 of 60 (62%) seminar #3. Graph 1 shows the global ratings per anatomical region by rheumatologists, unspecified professionals, and fellows. In all instances, the acceptance rate was over 80%. A strongly agree rating was given by 60 to 92% of participants in the lower extremity seminar, 52 to 78% in the shoulder and elbow seminar, and 43 to 68% in the hand and wrist seminar. Graph 2 depicts the individual questions asked, and the participants recommendation, per anatomic region. Once again, scores were uniformly greater than 80% acceptance on questions regarding attendee's satisfaction and the technique's relevance and applicability. There was the suggestion that movies be included to facilitate the performance of the exercises.

Conclusion: DASE was well received by a variety of participants. There were no differences in the evaluation scores according to the anatomical region or participants' level of training. The authors believe that DASE holds promise as a supporting method to the usual teaching of anatomy. Exercises are self-performed, may be repeated as needed, cause no embarrassment, and have no cost. Problems inherent to its N=1 nature may be solved by peer examination. DASE is now being assessed in medical students.

Graph 2: Overall ratings of the seminar

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Education Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Knowledge of musculoskeletal anatomy (MSA) is essential for physicians such as rheumatologists, orthopedic surgeons, physiatrists, generalists, and other professionals for whom a musculoskeletal-centered physical examination is a central component of their patient assessments. Teaching methods of MSA range from cadaver dissection to technology-heavy virtual anatomy. Large student classes, a shortage of instructors, and a dearth of available cadavers have shifted anatomical education from the former to the latter and other innovative methods. To these, we are adding deductive anatomy by self-examination (DASE), which is based on self-inspection, self-palpation, plus an additional channel the other ancillary methods lack, self-perception by the explored structure. The objective of this presentation is to introduce the concept of DASE and describe exercises using DASE that explore the upper and lower extremities.

Methods: DASE exercises follow a set pattern. 1. The targeted anatomical items involved are described. 2. The re-arrangement brought by the motion of the related joint(s) of the targeted items is hypothesized. 3. The targeted items are analyzed through inspection, palpation and the explored items perception during motion of one's own body part. 4. The new geometrical arrangement is understood. 5. The clinical applications of the exercise are correlated. Filmed exercises will be shown.

Results: Thirty-seven DASE exercises were designed by authors consensus. In the upper extremity, they included, as examples, the palpatory recognition of the lateral bands of the digital extensor mechanism, the action of interosseal and lumbrical muscles, a functional distinction of the flexor and the extensor wrist pulleys, and abstruse functions such as pronosupination and the external rotation of the humerus required for arm elevation. In the lower extremity, examples include the ischiotibial muscles and the hip abductors during ambulation, re-arrangement of items caused by knee flexion, and the co-ordination of leg muscles during ankle motion. The above exercises elucidate anatomic relationships during normal movement and help understand the deformities caused by joint, capsule, or tendon damage, some shoulder limitations, gait disorders, and more.

Conclusion: We propose DASE as an N=1 supplementary strategy to current teaching of MSA. DASE provides unlimited opportunities to reinforce knowledge at no cost, and the understanding of complex anatomical regions may be improved. Enthusiastic feedback obtained at recent seminars suggest the potential utility of DASE in medical school and postgraduate curricula at a time in which more active learning and teaching techniques are being encouraged and incorporated, but controlled studies of the educational outcomes and reproducibility will be needed.

Acknowledgement: We thank Fernando Peña for expert movies production.

Abstract Number: 177

A Needs Assessment to Inform Rheumatology Curriculum Re-Design for Internal Medicine Residents

David Leverenz¹, Amanda M. Eudy¹ and Lisa Criscione-Schreiber², ¹Department of Medicine, Division of Rheumatology and Immunology, Duke University, Durham, NC, ²Division of Rheumatology, Department of Medicine, Duke University, Durham, NC

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Education Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: In an effort to redesign our rheumatology curriculum for internal medicine (IM) residents, we sought to understand the correlations between IM resident in-training exam (ITE) scores, self-reported confidence, rheumatologists' perception of residents' proficiency, and diagnoses seen in rheumatology clinic.

Methods: All data was collected from a single academic medical center. We analyzed IM resident ITE scores on rheumatology-related educational objectives from 2010-2017. Objectives were divided into 10 categories defined by the ABIM Certification Examination Blueprint: RA, SpA, SLE, SSc, OA, crystalline arthritis, infectious arthritis, vasculitis, bone disease, and regional musculoskeletal. In spring 2018, we surveyed IM residents on their self-reported confidence and rheumatology fellows, faculty, and advanced practice providers (APPs) on their perceived proficiency of IM residents in these same 10 categories on a 10-point Likert scale. In addition, we tallied diagnoses seen by IM residents in rheumatology clinic from January-April 2018 in each of these categories. Pearson correlation coefficients were calculated between these measures.

Results: The average ITE score on rheumatology-related educational objectives was 66.3%. The lowest average score was in crystalline arthritis (55.9%) and the highest was in SLE (73.4%). Regarding survey data, everyone who received a survey responded (response rate 100%). The resident survey included 38 residents (17 interns, 21 upper-levels). The lowest average confidence was in vasculitis (3.68) and the highest was in OA (7.53). The rheumatologist survey included 22 respondents (7 fellows, 12 faculty, 3 APPs). The lowest average perceived proficiency was in SSc (3.80) and the highest was in OA (6.14). Of 143 diagnoses seen by IM residents in rheumatology clinic, the least common diagnosis category was infectious arthritis (n = 0) and the most common was RA (n = 40). There was a positive correlation between resident confidence and rheumatologists' perceived proficiency (r = 0.934, p < 0.001). In contrast, there was no statistically significant correlation between resident ITE scores and resident confidence (r = -0.474, p = 0.166), rheumatologist's perceived proficiency (r = -0.442, p = 0.201), or number of diagnoses seen in rheumatology clinic (r = -0.319, p = 0.369), all showing a trend towards a negative correlation. In particular, crystalline arthritis was second highest in resident confidence (6.95), third highest in perceived proficiency by rheumatologists (5.43), and the third most common diagnosis encountered by residents in rheumatology clinic (n = 16), though it had the lowest ITE scores.

Conclusion: IM resident confidence correlates with rheumatologists' perceptions of their proficiency in core rheumatology topics. However, ITE scores do not correlate with either of these measures. Thus, common diagnoses like crystalline arthritis and OA that are felt to be simple may be overlooked in IM resident education. When designing curricula, rheumatology educators should not rely on perceptions and instead must analyze objective assessments like the ITE to identify significant gaps in IM resident knowledge.

Abstract Number: 178

The Impact of a Novel Immune Related Adverse Event Tumor Board on Interprofessional Clinical Confidence and Collaboration

Cassandra Calabrese¹, Pauline Funchain², Pradnya D. Patil² and Leonard H. Calabrese³, ¹Rheumatic & Immunologic Disease, Cleveland Clinic Foundation, Cleveland, OH, ²Hematology Oncology, Cleveland Clinic Foundation, Cleveland, OH, ³Rheumatic & Immunologic Disease and Infectious Disease, Cleveland Clinic Foundation, Cleveland, OH

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Education Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The diagnosis and management of patients who develop immune related adverse events (irAEs) from checkpoint inhibitor therapy (ICI) requires multidisciplinary care and rheumatologists play an important role in their management¹. In September 2017 a new monthly conference was developed at our institution dedicated to the presentation and management of irAEs. This tumor board consists of clinicians from numerous departments with known interest and experience in irAEs. The goal is to discuss new and/or challenging cases of irAEs, review the extant literature and receive input on interprofessional management. On average, 6 cases are discussed at each conference. A survey was developed to assess its educational value to attendees and appraise its impact on confidence in managing irAEs.

Methods: In the 2nd quarter of 2018, an online survey was sent via e-mail to health care providers (HCPs) at the Cleveland Clinic. The survey population was made up of HCPs included on the monthly tumor board invitation. The survey questions aimed to assess the satisfaction with the educational value of this new conference, the perceived impact on irAE awareness, confidence level in diagnosing and management of irAEs, and perceived impact on patient care. Future educational needs were also assessed.

Results: The survey was sent to 37 HCPs with a response rate of 24/37 (65%). The majority of responders were oncologists followed by rheumatology HCPs (Table 1). 95.8% reported having seen a patient who developed an irAE from ICI with 29.2% seeing 1-2 patients per month. In terms of the clinical impact of this irAE tumor board, 66.7% reported a significant increase in their awareness of the scope and presentation of irAEs, and 41.7% reported significantly increased confidence in diagnosing and managing certain irAEs. Most (75%) felt that the conference format/content was superior to other conferences in terms of interest and practical content. When queried about what aspects they valued most, the most common response was the multidisciplinary nature of the conference.

Table 1. Tumor Board survey responses (N = 24)

Which advanced degree do you have?	DO/MD 83.3% NP 4.2% PA 0% RN 8.3% Other 4.2%
What type of medicine to you practice	Oncology 66.7% Rheumatology 12.5% Pulmonology 0% Gastroenterology 4.2% Hepatology 0% Endocrinology 4.2% Ophthalmology 0% Dermatology 4.2% Other 12.5%

How many years have you been practicing in your field?	< 5 years 33.3% 5-10years 29.2% > 10 years 37.5%
Have you seen patients who are treated with ICI and develop irAEs?	Yes 95.8% No 4.2%
Describe you primary role in irAEs from ICI	Prescriber/manager of ICI therapy 4.2% Management of irAEs 29.2% Both 54.2% Neither 12.5%
How many tumor board conferences have you attended	One 12.5% Two 16.7% Three or more 70.8%

Conclusion: irAEs are a new area of medicine that require multidisciplinary collaboration for investigation and optimal management. The multisystem involvement and autoimmune, inflammatory mechanisms of these complications makes rheumatologists valued, if not central, partners in both patient management and research. Novel venues for educational interchange are needed to further this evolving field. A regular conference solely dedicated to irAEs appears to have educational value as assessed by learner satisfaction and may increase skill and confidence in patient management.

Swimming Against the Stream- the Fishbowl Discussion Method As an Interactive Tool for Medical Conferences – Experiences from the 11. European Lupus Meeting

Johanna Mucke¹, Hans-Joachim Anders², Martin Aringer³, Dr. Gamal Chehab¹, Rebecca Fischer-Betz¹, Falk Hiepe⁴, Hannes-Martin Lorenz⁵, Andreas Schwarting⁶, Reinhard Voll⁷ and Matthias Schneider¹, ¹Policlinic for Rheumatology & Hiller Research Centre for Rheumatology, Heinrich-Heine-University Duesseldorf, Duesseldorf, Germany, ²Division of Nephrology, Medizinische Klinik und Poliklinik IV, Klinikum der Universität München, Munich, Germany, ³Medicine III, University Medical Center and Faculty of Medicine TU Dresden, Dresden, Germany, ⁴Charité University Medicine, Department of Medicine/Rheumatology and Clinical Immunology and German Rheumatism Research Centre Berlin (DRFZ), Berlin, Germany, ⁵Im Neuenheimer Feld 41, UNI-Klinikum Heidelberg, Medizinische Klinik, Heidelberg, Germany, ⁶Department of Internal Medicine, Rheumatology and Clinical Immunology, University Hospital Johannes-Gutenberg, Mainz, Germany, ⁷Clinic for Rheumatology and Clinical Immunology, University Medical Center Freiburg, Faculty of Medicine, University of Freiburg, Freiburg, Germany

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Education Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: A ubiquitous hierarchy pervades all levels of medicine. The high level of recognition and respect for experts and their opinions prevents exchange between the different levels of the hierarchy. Especially at medical conferences, discussions usually take place between experts, while patients, young doctors and students listen, and active participation often does not occur. The fishbowl method is an interactive and dynamic technique with a group of discussants sitting in an inner circle that contains an additional empty chair. Members from the auditorium can, at anytime, occupy the empty chair and join the discussion. It was our aim to introduce this method as an alternative to pure expert panels.

Methods: Ten discussion groups with different topics were formed in advance of the European Lupus Meeting 2018. The groups consisted of an SLE expert moderator, a SLE patient representative, a fellow in training and two international SLE experts. Each discussion lasted one hour and was protocolled on flipcharts by another fellow and a fourth SLE expert. The method was evaluated by participants and the auditorium in an online survey distributed via email after the conference among all attendees assessing feelings as active participants and opinions regarding the effectiveness of the method.

Results: A total of 169 attendees completed the online survey. 47 were members of the inner circle (8 moderators, 14 experts, 5 patient representatives, 20 fellows) and 122 were members of the audience. Only 15.5% had heard about the method before and 6.6% had participated in a fishbowl round before. 39 members of the audience participated actively, of whom the majority felt comfortable (28.7%) or even very comfortable (16.6%) with their role on the empty chair. 78.5% of all participants would recommend the method for future conferences. Levels of agreement regarding the effectiveness of the method are shown in Figure 1. Opinions did not differ between the inner circle and the audience.

Conclusion: The fishbowl discussions were overall excellently received and positively evaluated. Fishbowl provides a diverse and apparently effective method for scientific exchange. By reducing hierarchies and challenging traditions, active participation is facilitated and otherwise hesitant listeners can easily contribute to the discussion.

Back to Bedside Teaching: Completion of a Rheumatology Rotation Significantly Increases Internal Medicine Residents' Competency and Comfort with Comprehensive Knee Examinations

Alysia Kwiatkowski¹, Najia Shakoor², Joel A. Block², Augustine Manadan¹ and Sonali Khandelwal¹, ¹Rheumatology, Rush University Medical Center, Chicago, IL, ²Division of Rheumatology, Rush University Medical Center, Chicago, IL

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Education Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Prior studies have elucidated the lack of competency and confidence in musculoskeletal (MSK) examination skills amongst medical trainees. A variety of teaching modalities have been studied, including lecture or workshop-based and peer-to-peer training, however, there remains a dearth of literature regarding the effectiveness of traditional bedside teaching versus dedicated workshops. The aim of this study was to determine if incorporating a MSK workshop into a 2 week clinical rotation in rheumatology would be an effective means to increase internal medicine residents' competency and comfort with knee examinations when compared to the rotation alone.

Methods: Informed consent was obtained from all participants. Each block of resident rotations during a 6 month period was randomized to workshop plus rotation versus rotation alone; the number of residents assigned to rheumatology varied biweekly, yielding unequal group sizes. Participants were tested on their knee examination skills at the start of their rotation using an objective structured clinical examination (OSCE) administered by trained rheumatology faculty. Those

randomized to the intervention group were provided a 1-hour workshop consisting of a didactic presentation, video and hands on application of skills. Immediately following the rotation, all residents were retested using the OSCE. Residents were administered a pre and post rotation survey assessing to what degree the rotation was beneficial in enhancing their comfort with knee examination skills. Comfort and helpfulness were measured using a 5-point Likert scale (1: not comfortable and 5: very comfortable). Paired and independent samples t-tests were used for pre and post as well as between group comparisons.

Results: Twenty residents participated in the study (12 received the workshop). For the group as a whole, there were significant improvements in pre and post-test OSCE scores (pre-test mean = 6.3 ± 2.2 , post-test mean = 11.3 ± 1.4 , $p < 0.001$), showing improvements of close to 80%. Comfort with examination also significantly improved post rotation (pre-level mean = 2.6 ± 0.8 , post-level mean = 4.1 ± 0.7 , $p < 0.001$), moving overall from “somewhat uncomfortable” to “comfortable” ranges. Interestingly, there was no significant difference in the change in OSCE scores ($p = 0.140$) or levels of comfort ($p = 0.560$) between the group that received the workshop and the group that completed rotation alone. Ninety-five percent of residents found completion of the rotation to be helpful in improving examination skills (mean helpfulness = 4.5 ± 0.7). This did not differ between groups ($p = 0.560$).

Conclusion: This study provides evidence that completion of a rheumatology rotation results in substantial improvement in resident competency and comfort with comprehensive knee examinations. In an educational era emphasizing organized interactive learning, it is of interest that we were unable to demonstrate that provision of a focused workshop improved outcomes beyond the rotation itself. These findings highlight the continued value of bedside teaching and the effectiveness of the rheumatology elective in helping to bridge known gaps in MSK education.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Education Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Elective choice during residency is influenced by future career goals and perceived knowledge gaps. There is limited literature directly comparing elective exposures to outcomes on the American Board of Internal Medicine Certification Exam (ABIM-CE). Developing structured curricula within an elective experience has been shown to enhance ABIM-CE performance (Shanmugam et al, BMC Med Edu, 2012). Studies have shown outcomes on the in-training exam, a surrogate marker for the ABIM-CE, can be improved with conference attendance and self-directed reading. Comfort with managing specialty specific conditions after elective completion has not been well studied. The major aim of this study was to determine if completion of a 2 week rheumatology rotation improved residents' board preparedness and comfort with diagnosing and treating common rheumatologic diseases.

Methods: Informed consent was obtained from all participating residents. The curriculum was based equally on inpatient and outpatient experiences, with formal didactics. A 10 question pre-test using knowledge based multiple choice questions on a variety of rheumatologic principles was given at the start of the rotation. At rotation completion, a different 10 question post-test was administered. Residents completed a pre and post rotation survey assessing to what degree the rotation enhanced their board preparedness and comfort with diagnosing and treating rheumatologic conditions. Comfort was measured on a 5-point Likert scale (1: not comfortable and 5: very comfortable). Paired samples t-tests were used for pre and post comparisons and bivariate correlations were evaluated using Spearman's rho.

Results: Twenty residents participated in the study. There was no significant difference between individual pre and post rotation question test scores (pre-test mean = 8.1 ± 1.2 , post-test mean = 7.7 ± 1.2 , $p = 0.290$). Interestingly, comfort with board preparedness significantly improved (pre-level mean = 2.3 ± 1.2 , post-level mean = 3.5 ± 1.0 , $p < 0.001$), as did comfort with diagnosing (pre-level mean = 2.3 ± 1.2 , post-level mean = 3.5 ± 1.0 , $p < 0.001$) and treating (pre-level mean = 2.0 ± 0.9 ,

post-level mean = 3.7 ± 0.8 , $p < 0.001$) rheumatologic conditions (moving overall from “somewhat uncomfortable” to “comfortable” ranges). There was no correlation between composite test scores and comfort with board preparedness ($p = 0.280$). There was also no correlation between composite test scores and amount of independent reading time on rheumatology specific topics ($p = 0.718$).

Conclusion: This study shows that completion of a rheumatology elective greatly increases resident comfort with diagnosing and treating common rheumatologic conditions. Interestingly, while there was no improvement in ABIM style test scores, residents felt much more comfortable with the ABIM-CE after the rotation. The differences between subjective and objective findings warrant further investigation into the relationship between comfort and knowledge acquisition. Additionally, whether ABIM style questions truly capture clinically relevant knowledge or whether residents are not appropriately gauging board preparedness should be explored.

Needs Assessment of a Structured Program for Fellows As Teachers: Rheumatology Program Directors' Perspective

Pankti Reid¹, Eli Miloslavsky² and Anisha Dua³, ¹Internal Medicine, rheumatology, University of Chicago, Chicago, IL, ²Division of Rheumatology, Massachusetts General Hospital, Harvard Medical School, Boston, MA, ³Medicine, University of Chicago, Chicago, IL

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Education Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatology fellowship programs and program directors (PDs) are dedicated to didactic and clinical training of their fellows. Throughout fellowship training, fellows serve as teachers for residents, medical students, patients and families. However, structured teaching programs through which fellows themselves can acquire teaching skills are limited. Rheumatology program directors' interest in developing structured teaching programs has not been previously evaluated.

Methods: We conducted an in-person needs assessment of Rheumatology PDs attending the 2017 American College of Rheumatology national conference. The survey addressed questions regarding the availability of and interest in structured teaching programs for fellows.

Results: Fifty-seven of 94 Rheumatology PDs attending the meeting completed the survey (response rate 60.6%). The majority of PDs had >15 years of experience (38%) followed by 29% with 11-15 years of experience. Only 28% of programs required structured training in education and 33% of programs reported not having any structured training in teaching for their fellows. Over half of PDs (55%) reported that fellows are not trained in how to give feedback to medical students or residents, but almost all PDs (98.3%) believe that “fellows are a valuable resource for medical student/resident learning.” Additionally, majority of PDs (84%) agreed that [their] fellows could use additional instruction in teaching skills and 90% noted that this would be an asset to fellows for their future careers. Our survey also identified barriers to implementing teacher training programs as only 55.1% of PDs agreed that fellows have time for such programs and only 39.7% agreed that faculty have time to supervise fellow teaching.

Conclusion: This is the first evaluation of Rheumatology program directors' opinions regarding opportunities for their fellows to learn teaching and feedback skills. Less than a third of respondents reported having required structured training in education in their programs. PDs are interested in providing structured training opportunities on how to teach for fellows as they believe this will be an asset in their future careers. However, despite the need and interest in creating structured opportunities for teaching fellows how to teach, there are concerns about time available within the fellowship for fellows to receive this training, as well as time for faculty members to provide it. Future research based on this needs assessment should involve an efficient way to create a fellows-as-teachers curriculum.

Needs Assessment of a Structured Teaching Program for Fellows As Teachers: Rheumatology Fellows' Perspective

Pankti Reid¹, **Eli Miloslavsky**² and **Anisha Dua**³, ¹Internal Medicine, rheumatology, University of Chicago, Chicago, IL, ²Division of Rheumatology, Massachusetts General Hospital, Harvard Medical School, Boston, MA, ³Medicine, University of Chicago, Chicago, IL

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Education Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Fellows are expected to teach patients, trainees and colleagues, regardless of what type of practice they join. The Accreditation Council for Graduate Medical Education (ACGME) Internal Medicine subspecialty milestones reflect that graduating fellows demonstrate the ability to teach effectively.¹ Yet, fellows frequently learn how to teach during their training through trial and error or observation.² Rheumatology fellows' experience and attitudes regarding teaching and teacher training have not been previously assessed. We evaluated fellows' interest in and access to training in education during their fellowship.

Methods: An anonymous survey was administered during the Fellows education session at the 2017 American College of Rheumatology national conference. The survey assessed fellows' career plans, interest and confidence in teaching, as well as experience with training in education during fellowship.

Results: Of the 150 surveys distributed, 107 were returned (response rate 71%). Seventy percent of those surveyed were adult rheumatology fellows, 12% were in pediatric rheumatology; 25% were 1st year fellows and 67% were 2nd year fellows. About 75% fellows demonstrated interest in pursuing a career that would involve teaching: 50% in "private practice with academic affiliation or teaching role" and 25% in "clinical educators in an academic program." Regarding fellowship training, over half reported that their program did not provide structured training in education, but notably, about 49% of programs were reported to "offer direct observation and feedback of [fellow's] teaching ability by attending physicians." Almost all fellows (94%) agreed or strongly agreed with the statement "If I had more time, I would do more teaching" and 97% felt that their "Teaching skills can be improved." About 88% of fellows reported that "learning how to teach effectively will be valuable to [his/her] career" and about 80% of fellows "would be willing to participate in a program to improve [their] teaching skills if no additional years of training required." Finally, while the majority (84%) of fellows felt confident in their ability to teach Rheumatology to a medical student/resident, 36% did not feel confident in their ability to give feedback to students/residents.

Conclusion: This is the first national needs assessment of rheumatology fellows' attitudes regarding experience as teachers. The majority of fellows are interested in pursuing careers where teaching would be a vital part of their profession and most felt that their teaching skills could be improved. However, over half of fellowship programs do not provide structured training in education, demonstrating a gap between fellows' needs and fellowship resources. Our study suggests a significant need to develop programs aimed at enhancing fellows' teaching skills.

Development of Focused Musculoskeletal Ultrasound Training for Primary Care Providers to Facilitate the Diagnosis of Gout: Initial Steps in an Educational Needs Assessment

Gary A. Kunkel¹, Andrea Barker², Jeremy Timm^{3,4}, Curry L. Koenig⁵ and Michael J. Battistone⁶, ¹Division of Rheumatology, George Wahlen VA Medical Center/University of Utah, Salt Lake City, UT, ²Veterans Affairs Salt Lake City Health Care System and University of Utah School of Medicine, Salt Lake City, UT, ³Salt Lake City VA Medical Center, Salt Lake City, UT, ⁴Internal Medicine, University of Utah, Salt Lake City, UT, ⁵Rheumatology, Division of Rheumatology, University of Utah, Salt Lake City, UT, ⁶Division of Rheumatology, Salt Lake City VA and University of Utah, Salt Lake City, UT

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Education Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Gout is common in primary care settings, though establishing or excluding the diagnosis with confidence can be challenging, particularly if arthrocentesis is not feasible at the time. Musculoskeletal ultrasound (MSKUS) has emerged as a useful diagnostic tool, as identification of the double contour sign (DCS) is a rapid, relatively easy assessment that can help confirm the presence of gout. Although the practice of “point of care” ultrasound in several clinical conditions has expanded for some primary care providers (PCPs), the use of MSK US to specifically explore the diagnosis of gout remains largely associated with the subset of rheumatologists who have been trained in this technology. The purpose of our project was to contribute to a clinical and educational needs assessment, to inform the discussion and

Figure 1 – Description of Visits to the Rheumatology MSK US Clinic for the Evaluation of Gout

	Visits n (% of Total)	Time from Referral Request to Clinic Visit Average days [Range, SD]
Referral Request From		
Rheumatology Clinic	37 (71%)	31d [0 – 83, 23]
Primary Care Clinic	11 (21%)	24d [0 – 49, 15]
MSK Clinics	4 (8%)	26d [0 – 41, 14]
Primary Care Clinic Location		
Salt Lake City VA	29 (58%)	33d [0 – 83, 20]
Utah Community VA Clinics	16 (31%)	30d [0 – 69, 22]
Non-Utah Community VA Clinics	6 (12%)	15d [0 – 38, 13]
Total	52	29d [0 – 83, 21]

Figure 2 - Number of Patient Visits in the Rheumatology MSK US Clinic per Month

development of a potential training experience in MSK US for PCPs as well as health professions students and trainees at the Salt Lake City Veterans Affairs Medical Center (SLCVAMC) and University of Utah.

Methods: All consult requests and appointments in the SLCVAMC Rheumatology MSK US clinic from May 2016 to May 2018 were identified, and those specifically addressing the diagnosis of gout were reviewed. Quality indicators relevant to access to care, including the time from the consult request to the clinic visit were also collected, as well as the origin of the consult request (e.g., rheumatology clinic vs. primary care; rural primary care vs non-rural primary care).

Results: A total of 235 visits to the Rheumatology MSK US clinic were identified between May 2016 and May 2018; 52 (22%) of these included an evaluation for gout. Description of the gout MSK US visits is presented in Figure 1 and overall MSK US visits by type is presented in Figure 2. Out of the 52 patients for whom the visit included an evaluation for gout, 23 (44%) were confirmed.

Conclusion: Over 2 years, the availability in the MSK US clinic has been relatively unchanged, and is consistently near 30 days, a critical measure for VA health care systems. A substantial portion of these involves specific requests to consider the diagnosis of gout. As use of MSK US increases, there is likely to be a growing educational need within primary care. Rheumatologists should develop their role not only as content and technology experts in MSK US, but also as teachers for PCPs who are interested in learning how to perform and interpret this focused assessment to investigate the possibility of gout.

Evaluating Medical Student Confidence and Performance of the Pediatric Musculoskeletal Exam

Kimberly Hays¹, Natasha M. Ruth¹, Donna Kern², Paul J. Nietert³, Lutfiyya Muhammad³, Michele Knoll Friesinger⁴ and Patricia McBurney⁵, ¹Pediatric Rheumatology, Medical University of South Carolina, Charleston, SC, ²Family Medicine, Senior Associate Dean for Education, Medical University of South Carolina, Charleston, SC, ³Public Health Sciences, Medical University of South Carolina, Charleston, SC, ⁴Psychiatry and Behavioral Sciences, Assistant Dean for Assessment, Evaluation and Quality Improvement, Medical University of South Carolina, Charleston, SC, ⁵Pediatrics, Medical University of South Carolina, Charleston, SC

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Education Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Children commonly present with musculoskeletal complaints to primary care providers who work in a busy practice with diverse populations. Musculoskeletal complaints may result from mechanical causes including trauma or from inflammatory etiologies such as juvenile idiopathic arthritis. Pain may not be the presenting musculoskeletal complaint, which makes evaluation difficult. General knowledge of how to evaluate a patient with musculoskeletal complaints and how to do an appropriate musculoskeletal exam is necessary to effectively triage patients. However, many physicians report a lack of confidence and competence in the musculoskeletal examination due to limited training. Pediatric Gait, Arms, Legs, and Spine (pGALS) is a validated screening tool aimed at general practitioners to help discern normal from abnormal pediatric musculoskeletal findings. Its utilization at the medical student level has not been well described.

Methods: Graduating fourth year medical students were surveyed regarding their future specialty choice, confidence in pediatric exam skills (including the pediatric musculoskeletal exam), and the amount of pediatric musculoskeletal training they received in medical school. They performed a scored baseline pediatric musculoskeletal exam on a pediatric standardized patient presenting with chronic joint complaints consistent with juvenile idiopathic arthritis; the total score had a theoretic range from 0 to 42. Following the initial survey and baseline exam, they watched training videos in the pGALS assessment. After the pGALS intervention, they returned to complete a follow-up pediatric musculoskeletal exam and survey.

Results: 14 graduating medical students participated in the study. 11 planned to enter a pediatric residency. On the initial survey, participants were least confident in their pediatric musculoskeletal exam skills compared to all other pediatric exam skills. Prior to pGALS training, 21.4% of participants reported being confident or very confident in their pediatric

musculoskeletal exam skills, compared to 100% of participants reporting confidence after training ($p < 0.0001$). The average musculoskeletal exam score also increased significantly (pre: 22.1 ± 4.2 vs. post: 32.2 ± 4.9 , $p = 0.0001$). In regards to pediatric musculoskeletal training, there were no participants who felt that they received extensive education in the pediatric musculoskeletal exam. All participants desired additional training. 100% of participants felt that the pGALS training was beneficial to their education.

Conclusion: Graduating fourth year medical students may not be confident nor proficient at the pediatric musculoskeletal exam based on our analysis. While our study population was small, many of the student participants plan to enter pediatrics. Instruction in using a validated pediatric musculoskeletal screening tool, such as pGALS, may be a low cost and efficient way to improve medical student confidence and proficiency in the pediatric musculoskeletal exam. The information found from this study will be the basis for testing pGALS in a larger population at different centers.

Abstract Number: 186

The Accuracy and Potential Impact of a Diagnostic Decision Support System in Rare Disease Cases

Simon Ronicke^{1,2}, Martin C. Hirsch³, Ewelina Türk³, Katharina Larionov², Daphne Tientcheu² and Annette D. Wagner²,
¹Ada Health GmbH, Belrin, Germany, ²Nephrology, Medical School Hannover, Hannover, Germany, ³Ada Health GmbH, Berlin, Germany

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Education Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Diagnosis in rare diseases cases is often delayed by several years. Main factors for delayed diagnosis are believed to be lack of awareness and knowledge about rare diseases among health care professionals. Diagnostic decision support systems (DDSS) have the potential to enhance clinical diagnosis by assessing case data based on incorporated medical knowledge and by suggesting relevant differential diagnoses. DDSS can contribute to professional support and education by visualising medical information and reasoning. We report about the use of Ada/DX, a DDSS in development, in an outpatient clinic for rare inflammatory systemic diseases. Presenting preliminary results, we evaluate the system's diagnostic accuracy and assess the potential impact of this diagnostic and educational tool on the time to diagnosis.

Methods: This retrospective study is being conducted at the outpatient clinic for rare inflammatory systemic diseases at the Hannover Medical School, Germany. Ethical approval was obtained from the local ethics committee. To date, 82 (of a total 120) patient cases with confirmed diagnosis were included. The time of the visit of first documented symptoms and the time of diagnosis were identified. Time to diagnosis (TD) was calculated. Documented clinical evidence from the medical record was transferred to the DDSS and the disease suggestions in the DDSS were evaluated. Primary endpoint was the correctness of top disease suggestions for the visit of diagnosis. In these cases, secondary endpoints were the time to first correct top rare disease suggestion (T1R) and the time to first correct top 5 rare disease suggestion (T5R). The difference between TD and T1R and the difference between TD and T5R was calculated. Wilcoxon signed-rank test was conducted.

Results: On preliminary evaluation, primary accuracy of top suggestions of the DDSS at the time of diagnosis was 80.5% (71.9% to 89.1%, 95% CI). The table shows a comparison of the original time to diagnosis without the use of the DDSS and the time to correct disease suggestions with the use of the DDSS. (All times are expressed in months.)

	Mean	Std Dev	PCTL 25	PCTL 50	PCTL 75
Among all cases					
Time to diagnosis (TD) in medical record	57.8	84.2	2.3	18.0	74.5
Among cases with correct top suggestion at time of diagnosis					
Time to correct top rare disease suggestion (T1R)	25.0	50.6	0.0	3.0	21.0
Time to correct top 5 rare disease suggestion (T5R)	13.1	31.9	0.0	0.0	5.3
Time difference (TD - T1R)	29.6	70.5	0.0	1.0	19.3
Time difference (TD - T5R)	41.5	78.3	0.8	9.5	40.0

The Wilcoxon signed-rank test shows a significant difference for TD - T1R (z-score -5.37, $\alpha=0.05$, $p<0.001$) and TD - T5R (z-score -6.03, $\alpha=0.05$, $p<0.001$). Main reasons for incorrect DDSS disease suggestions were multi-morbidity (cases with multiple relevant diagnoses), atypical disease presentation and high level of case complexity.

Conclusion: The DDSS suggested the correct diseases based on information from the medical record in most of the analysed rare disease cases. The DDSS often suggested the correct diseases at times prior to the visit of diagnosis. DDSS could be used as educational tools that suggest relevant differential diagnoses in rare disease cases. They might help to reduce time to diagnosis and improve patient outcomes. Prospective research is needed to verify the results.

Abstract Number: 187

Participant-Reported Effect of an Indigenous Health Continuous Professional Development Education Initiative

Cheryl Barnabe¹, Raheem B Kherani², Tom Appleton³, Rita Henderson⁴ and Lynden Crowshoe⁴, ¹Medicine, University of Calgary, Calgary, AB, Canada, ²University of British Columbia, Richmond, BC, Canada, ³Medicine, The University of Western Ontario, LONDON, ON, Canada, ⁴Family Medicine, University of Calgary, Calgary, AB, Canada

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Education Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Arthritis conditions are highly prevalent in Indigenous populations in Canada and patients experience severe outcomes. Patients avoid specialty care health systems due to experiences of racism, stereotyping and culturally unsafe environments. The 'Educating for Equity' program was designed as a continuing medical education (CME) intervention to incorporate skill-based teaching to re-center relationships and engage patient social realities, and was adapted as an educational intervention for rheumatologists.

Methods: Following introductory exposure to Indigenous health competency training, a half-day interactive workshop was delivered to 9 rheumatologists who were recruited through the Canadian Rheumatology Association membership. This half-day workshop provided content knowledge and skill practice through role playing case studies with instantaneous feedback on performance. Participants completed a pre-workshop survey which was repeated 3 months following the workshop to identify the strategies they used to address social issues and enhance therapeutic relationships, as well as a 15 question Likert-scaled Social Cultural Confidence in Care Survey (SCCCS). They were asked about the perceived impact of the intervention on their practice.

Results: Prior to the workshop, strategies to address social issues were primarily to involve allied health staff or local primary care providers, with few offering they would ask patients about social situations themselves. Strategies they used to enhance the therapeutic relationship were being open, available, and flexible, encouraging family participation in decision making, and sharing expectations for treatment effects while working to reach common ground and earn trust. Following the workshop, they were more likely to focus on relationship building with patients and their families, had enhanced awareness and confidence to explore the context of patient social reality in decision making, were serving as advocates for access to treatment, enquired about residential school experiences and patient cultural practices, and had changed their practices to be more patient-centered, with attention paid to space and time in the care environment. They valued the developing community of practice and were motivated to learn more about Indigenous health. There was no statistical improvement in the SCCC ratings, but trends to improvement in rankings were noted in this small group. Interactive group discussion and role playing were reported as the most effective part of the intervention.

Conclusion: This CME intervention had beneficial impact on self-reported confidence and enhanced practice strategies to engage with Indigenous patients. The next phase will incorporate reinforcement of principles and skills while providing training in facilitation to expand the community of practice.

Disclosure: C. Barnabe, None; R. B. Kherani, None; T. Appleton, None; R. Henderson, None; L. Crowshoe, None.

Pediatric Trainee Confidence and Exposure to Rheumatology

Jessica Rutsky¹, Ann Salvator², Laura Ballenger³, Steven Cuff⁴ and Kyla Driest⁵, ¹Pediatrics, Nationwide Children's Hospital, Columbus, OH, ²Statistics, Nationwide Children's Hospital, Columbus, OH, ³Department of Rheumatology, Nationwide Children's Hospital, Columbus, OH, ⁴Sports Medicine, Nationwide Children's Hospital, Columbus, OH, ⁵Rheumatology, Nationwide Children's Hospital, Columbus, OH

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Education Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: A small number of previous studies show residents have low levels of confidence in rheumatologic and musculoskeletal (MSK) skills. The objective of this study was to evaluate pediatric trainee exposure to and confidence in Rheumatology skills at our institution.

Methods: Fourth year medical students applying for pediatric residency and pediatric residents from a single institution completed an anonymous survey to evaluate confidence in MSK history, physical exam, rheumatologic lab interpretation and exposure to MSK pathology. Confidence levels were measured as continuous variables on a scale from 0 to 100. Survey responses were compiled and summarized using frequency with percentages for categorical variables and means and standard deviations and medians with interquartile range (IQR) for continuous variables. Group comparisons between the rheumatology rotation and patients seen/evaluated with arthritis were assessed using two-sample t-tests or Wilcoxon rank sum or one-way ANOVA with post hoc Tukey adjustment for multiple comparisons. The rating of sufficient exposure of residents with confidence in MSK history, physical exam, lab interpretation and diagnosing arthritis was assessed with Spearman correlations for continuous variables. Two-sided p-values <0.05 were considered statistically significant.

Results: All 20 medical students responded to the survey. Student confidence performing the MSK exam (p=0.03) and perceived ability to diagnose arthritis (p=0.07) was positively correlated with an increased perceived exposure to MSK pathology. This association was moderate-strong via Spearman correlation (0.49 and 0.41, respectively).

Table 1: Medical student confidence comparisons

	Medical Student Confidence		
	MSK History	MSK Physical Exam	Diagnosing Arthritis
Rheumatology rotation			
Yes (n=5), mean ± sd	62 ± 21.95	56.93 ± 14.56	55 ± 12.51
No (n=15), mean ± sd	59.73 ± 13.84	52.8 ± 22.62	45.4 ± 11.44
p-value	0.46	0.66	0.33
Seen/evaluated arthritis patients			
No (n=10), mean ± sd	60.6 ± 14.03	61.1 ± 15.85	54.1 ± 13.07
Yes (n=9), mean ± sd	58.89 ± 18.53	48.67 ± 15.43	51.22 ± 13.59
p-value	1.0	0.12	0.81
Correlation exposure vs confidence			
Medical student sufficient exposure	0.22	0.49	0.41
p-value	0.35	0.03	0.07

Table 2: Resident confidence comparisons

	Resident Confidence			
	MSK History	MSK Physical Exam	Lab Interpretation	Diagnosing Arthritis
Seen/evaluated arthritis patients				
No (n=16)	66.25 ± 27.17	52.69 ± 29.45	32.06 ± 15.74	25.12 ± 21.56
Yes (n=47)	70.64 ± 19.09	61.42 ± 20.44	56.25 ± 18.73	50.96 ± 24.83
p-value	0.88	0.32	<0.0001	0.001
Training year				
1 (n=18)	66.78 ± 19.03	59.11 ± 22.52	40.94 ± 13.48	30.78 ± 15.93
2 (n=22)	70.73 ± 16.66	59.5 ± 20.02	50.95 ± 22.94	46.28 ± 25.63
3 (n=19)	70.53 ± 23.19	57.16 ± 26.87	52.79 ± 20.22	49.47 ± 29.47
p-value	0.34	0.88	0.05	0.08
Correlation exposure vs confidence				
Resident sufficient exposure	0.58	0.65	0.41	0.47
p-value	<0.0001	<0.0001	0.0009	0.0001

Of 160 residents surveyed, 63 responded. Resident confidence in interpreting rheumatologic labs and diagnosing arthritis was greater in residents who reported seeing/evaluating new-onset arthritis patients ($p<0.0001$ and $p=0.001$, respectively). Greater level of perceived exposure to MSK pathology was associated with an increased level of confidence obtaining MSK history ($p<0.0001$), performing MSK exam ($p<0.0001$), interpreting rheumatologic labs ($p=0.0009$), and diagnosing arthritis ($p<0.0001$).

25% of residents and 50% of medical students reported no contact with a newly diagnosed arthritis patient.

Conclusion: Lack of perceived trainee exposure to MSK topics correlates to less confidence in MSK skills. Yet, many trainees had never examined a new arthritis patient. Further studies are needed to investigate strategies to increase trainee exposure and confidence in MSK skills. Future studies should also evaluate trainee competence.

Abstract Number: 189

Evaluation of Rheumatology Lectures By Clinical Students in a Nigerian Medical School: Learning from the Learners

Akpabio Akpabio¹, Mayowa Owolabi², Victor Umoh³ and Olufemi Adelowo⁴, ¹Internal Medicine, University of Uyo Teaching Hospital, Uyo, Akwa Ibom State, Nigeria, Uyo, Nigeria, ²Department of Medicine, University College Hospital, Ibadan, Nigeria, Ibadan, Nigeria, ³Internal Medicine, University of Uyo Teaching Hospital, Uyo, Uyo, Nigeria, ⁴Arthrimed Specialist Clinic:The Arthritis Centre, Lagos, Nigeria

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Education Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: There is a disparity between the enormous burden and the knowledge of rheumatic disorders among doctors and this is partly traceable to inadequate undergraduate rheumatology training. The situation is worse in sub-saharan Africa and Nigeria in particular where only 10 out of 30 medical schools teach rheumatology. To bridge the gap, specialist rheumatology residents are increasingly being utilized. Currently, there is no known student-based evaluation of rheumatology teaching effectiveness in Nigeria.

This study aims to identify the most and least enjoyable lectures preferred by the students, the proportion of students able to identify rheumatic conditions after the lectures as well as evaluate rheumatology teaching effectiveness using the augmented Stanford Faculty Development Program Questionnaire (aSFDPQ).

Methods: All 134 4th to 6th year medical students in the University of Uyo medical School, South-south Nigeria were asked to evaluate their rheumatology lectures using a self-administered questionnaire that included the likert-scale (aSFDPQ) instrument. Each class received about 3 one hour long didactic lectures during their 16-week medicine rotation. Mann whitney U test was used for ordinal data with $p<0.05$.

Results: A 94% response rate was obtained from 126 participants. 78 were male (61.9%). 63 students (50%) chose rheumatoid arthritis (RA) as their best topic because it was well explained (52.4%). 42(33.3%) cited spondyloarthropathies (SpAs) as their worst topic because it was difficult(30.1%). Twenty six students (20.6%) identified a rheumatic condition before the lectures compared with 57 (45.2%) after the lectures representing an increase of 24.6% ($p=0.001$). The mean aSFDPO score was 3.76 ± 0.47 . Highest scoring domains were: learning climate (4.03) and teacher's attitude (4.0). The least domain was Evaluation(3.39). Mann Whitney U domain values ranged from (1647.5<U<1869.5), ($0.257 < p < 0.990$) with no significant differences by gender ($p=0.825$) or class($p=0.162$). The mean global teacher rating was 74.64 ± 13.65 (range 40-100).

Conclusion: Rheumatoid arthritis was most enjoyed while spondyloarthritis was least understood by our students. There was a 24.6% increase in the proportion of students able to identify rheumatic conditions after the lectures. Although global teacher rating was good (74.6%), resident teaching effectiveness was suboptimal as assessed by total aSFDPO score<4.0. There is an urgent need for formal pedagogic training to improve rheumatology teaching effectiveness in Nigeria.

Table 1: Teaching skill evaluation of Rheumatology Resident

S/N		No. of items	Mean	SD	Minimum	Maximum	p value

An Innovative Pilot Educational Program to Inform Rheumatology Fellows about the Population of the Bronx: Issues Affecting and Resources Available to the Community

Irene Blanco¹ and Heather Archer-Dyer², ¹Rheumatology, Albert Einstein College of Medicine, Bronx, NY, ²Albert Einstein College of Medicine, Bronx, NY

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Education Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: As noted in the 2015 ACR Workforce Study, few in the rheumatology identify as being from a community of color. Therefore, most rheumatologists do not have first-hand experience being part of these communities -- which are often those most affected by the rheumatic diseases. We therefore devised a community tour for our fellows to 1. better understand the community of patients they serve and 2. have an appreciation of the community resources available to the patients of the Bronx, NY.

Methods: In order to devise the tour, an assessment was done of the zip codes from patients seen in the Montefiore general arthritis clinic. We found that patients from across the borough were seen in clinic, therefore the decision was made to leave the neighborhoods where the clinics were located in order to bring the fellows to an area of the Bronx that they did not commonly visit. No traditional tourist sites were visited on the 3 hour tour. While on the tour, fellows learned about the history of the Bronx including several key events, such as the construction of the Cross Bronx Expressway, in addition to concepts such as "White Flight" and the discriminatory housing practice known as "Red-Lining." While on the tour the fellows visited 3 major community resources: Women's Housing and Economic Development Corporation (WHEDco); Institute for Family Health: Urban Horizons and Bronx Works. WHEDco provides award winning affordable housing, an Early Childhood Discovery Center, home-based childcare training institute and the Bronx Cook Space -- where street vendors can safely prepare food for purchase using shared industrial kitchen space. Institute for Family Health: Urban Horizons is a federally qualified health center that was created to address health disparities in innovative ways by

working with programs such as the CDC's REACH program. Bronx Works, located adjacent to housing court, offers in addition to eviction prevention and homelessness services, health insurance assistance, and youth programs.

Results: 5/7 fellows completed the post-tour survey. None of these 5 fellows had ever participated in something similar. 5/5 felt that the tour was: "Informative/Very Informative" and "Helpful/Very Helpful" All respondents "Recommend doing it next year" and felt that it "Enhanced their fellowship".

Conclusion: Most of the physicians that work for Montefiore do not live in the Bronx and many use public transit and local highways thus avoiding local streets and neighborhoods. This, in addition to the typical media portrayal of the Bronx, can lead to providers not engaging with the community outside of the clinical setting. This can also lead to the reinforcement of biases often faced by communities of color. By taking the fellows into the neighborhood and having them interact with community members it begins to give them a nuanced perspective of the patients they serve.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Education Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: A strong foundational knowledge in immunology is key to understanding complex rheumatologic disease processes. Indeed, an immunology curriculum delivered by Rheumatology training programs across Canada is required to meet the core competencies outlined by the regulatory college. With initial work completed by Mahendira *et al* (2015), a need for improving current immunology curricula was identified and high yield immunology teaching topics to be included in a national curriculum were established. In order to meet these needs, video illustration was chosen as a method of communicating complex immunological content to a geographically dispersed audience. Three short video clips were developed to highlight important immunology topics. The effectiveness of these videos in facilitating comprehension and knowledge acquisition amongst rheumatology trainees was assessed.

Methods: Immunology topics including "T cells", "Cytokines", and "Cytokine Receptors" were previously identified as essential to an immunology curriculum for Rheumatology trainees. Video content related to these topics was generated with the assistance of immunology, rheumatology, and medical education experts as well as a Biomedical Illustrator. The videos were piloted on adult rheumatology trainees, with pre- and post- video quizzes based on video content administered. To evaluate duration of knowledge retention, post- video quizzes were administered immediately after and six weeks following each video clip. The statistical significance of improvements in quiz performance was evaluated using paired t-testing. Qualitative feedback was also gathered to assess video content and design.

Results: Eight adult rheumatology trainees participated in video testing. The average pre test score for "T cells", "Cytokines" and "Cytokine Receptors" was 58.3% (+/- 36.5), 61.1% (+/- 19.7), and 38.9% (+/- 16.8), respectively. Immediate post test scores were significantly improved ($p < 0.05$) for "T cells" and "Cytokines" with averages of 90.3% (+/- 20.1) and 91.7% (+/- 15.4), respectively. Immediate post test scores for "Cytokine Receptors" were not significantly improved however scores did improve to meet departmental pass standards ($> 60\%$), with average post test scores being 62.5% (+/- 16.7). Six week post test scores continued to be above departmental pass standards for "T cells" and "Cytokines", with scores of 76.4% (+/- 16.2), 81.9% (+/- 10.2), respectively. Overall, video modules for "T cells" and "Cytokines" were well received with comments suggesting content was "easy to follow," "helpful," and a "great teaching resource." Post-test scores and qualitative data for "Cytokine Receptors" suggest the video was "too complex" and as such will be revised and re-piloted to better meet the needs of Rheumatology trainees.

Conclusion: Immunology video content is an effective tool for improving short term comprehension and knowledge retention amongst rheumatology trainees. We hope to continue to develop these educational deliverables, building an

Abstract Number: 192

Impact of Case-Based Simulation Training on the Confidence and Knowledge of Medical Residents to Perform Rheumatologic Procedures

Suraiya Afroz¹, Manideep Duttuluri², Rupa Iyengar¹ and Yousaf Ali³, ¹Internal Medicine, Mount Sinai St. Luke's-West Hospitals, New York, NY, ²Mount Sinai St. Luke's-West Hospitals, New York, NY, ³Medicine/Rheumatology, Icahn School of Medicine at Mount Sinai, New York, NY

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Education Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Simulation training is now widely used in various residency programs, especially in the field of critical care, to train and prepare residents for real life medical cases and procedures. Training in rheumatologic procedures such as arthrocentesis however, is a neglected part of many internal medicine residency programs. The purpose of this study was to explore the impact of simulation based training curriculum on the residents' confidence and knowledge to perform these procedures independently.

Methods: A case-based simulation training curriculum was developed in our internal medicine residency program based in an urban tertiary care center. The initial assessment consisted of surveying the participants' past experience with arthrocentesis and corticosteroid injections, current satisfaction with such training in their program and knowledge regarding the basic anatomical landmarks. Understanding the indications/contraindications of performing these procedures was also reviewed. The training sessions included faculty led, hands on, simulation based instruction using knee and shoulder anatomic models. The post-training questionnaire was provided to assess for any difference in outcome. Simulation models provided instant feedback by providing a sound when the needle was placed in the correct location. The training was not complete until all participants had located and inserted the needle in the appropriate location as verified by the auditory feedback.

Results: A total of 37 participants (54% men and 46% women), enrolled in the educational curriculum. 9 (24%) of the medical residents were Year-1, 13 (35%) Year-2, 12 (32%) Year-3; 3 participants were medical students and attending physicians. Among the medical residents, 28 (76%) participants were International Medical Graduates and 9 (24%) were American Medical Graduates. Analysis was completed using SAS 9.4 and paired t-test. Median post training satisfaction and confidence in the procedural skills were higher (p-value <0.05). There was also improvement in the mean post-training objective knowledge based questionnaire scores in 4 out of 8 areas (p-value <0.05). All 37 participants were interested in training in similar sessions in the future.

Conclusion: Simulation based training helps residents learn complex medical cases and practice invasive procedures in a safe environment. This study shows that use of knee and shoulder models to practice joint injections increases residents' confidence and satisfaction and improves their clinical skills. We feel that simulation based arthrocentesis training should be incorporated as part of the basic internal medicine curriculum.

Abstract Number: 193

Practice Improvement Using Virtual Online Training: A Novel App-Based Platform to Teach Clinical Reasoning in Rheumatology

Megan Lockwood¹, Jennifer Mandal², Sebastian Andreatta³ and Maria Dall'Era³, ¹Internal Medicine, University of California, San Francisco, San Francisco, CA, ²Rheumatology, University of California, San Francisco, San Francisco, CA, ³University of California, San Francisco, San Francisco, CA

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Education Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The demand for rheumatologists continues to increase due to the high prevalence of rheumatic disease in a growing population. As outlined in ACR's 2015 Workforce Study, recruitment of the future workforce is a critical part of strategies to address the predicted shortage. ACR has identified graduate medical education and early exposure at the medical student level as key parts of recruitment strategies. Yet, the diminished amount of time allotted to introduce and study rheumatic disease in the undergraduate medical curriculum stands at odds with this recommendation and may reduce the likelihood of attracting students to rheumatology. While there has been some attention paid at the graduate medical education level, little attention has been focused on the undergraduate level, particularly the pre-clinical years. We developed an interactive virtual patient platform that presents rheumatology case scenarios. Virtual patient platforms combine case-based learning with new technology and are increasingly used in medical school curricula as an engaging, interactive instructional strategy and assessment tool. Virtual patient platforms can, in theory, support learners' development of clinical reasoning skills across health professions, but few studies provide evidence to support these claims. The development of clinical reasoning skills is of particular importance in rheumatology given the complex nature of rheumatic disease and diversity of clinical presentations.

Methods: We created a simulation platform, "Practice Improvement using Virtual Online Training" (PIVOT), to present virtual cases of patients. During their rheumatology block, 150 second-year medical students used PIVOT to work through a case of a young woman presenting with fatigue, joint pain, and low-grade fever, ultimately diagnosed with lupus. The case content (which included videos of the patient interview, photographs of exam findings, and lab results) was released via the app over four days. Each day, students worked in teams to answer 2-3 open-text questions and received timely feedback from an expert rheumatologist. Students also used a "differential diagnosis slider" to demonstrate their clinical reasoning by ranking diagnoses in order of likelihood.

Results: Individual responses to surveys were analyzed to measure user satisfaction. Use of the differential diagnosis slider and justifications for laboratory studies throughout the case measured clinical reasoning. The educational features most valued by learners included emphasis on clinical decision-making, working within a team, directed expert feedback, and support in "bridging the gap" between the pre-clinical and clinical years.

Conclusion: This application recognizes the evolving, iterative process of developing a differential diagnosis and encourages learners to engage in repeated hypothesis generation and refinement. Tracking the use of the differential diagnosis slider measures valuable information about the development of critical reasoning skills. This platform can be adapted for different learner levels in various settings. The asynchronous, technology-driven framework reflects the way healthcare providers increasingly interact in practice.

A Survey on Gout-Related Knowledge Among Internal Medicine Residents

Sreelakshmi Panginikkod¹, Ahmad Raja², Ehsan Rajabirostami¹, Roshanak Habibi¹, Rasiya Hashim³, Sumia Matin Afridi⁴, Alvaro Altamirano Ufion⁵ and Venu Pararath Gopalakrishnan¹, ¹Internal Medicine, Presence Saint Francis Hospital, Evanston, IL, ²Presence Saint Francis Hospital, Evanston, IL, ³Presence Saint Joseph Hospital, Evanston, IL, ⁴Florida Hospital Orlando, Orlando, FL, ⁵Internal Medicine, Advocate Illinois Masonic Medical Center, Chicago, IL

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Education Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The prevalence of gout has risen in recent decades despite advancements in therapeutic options due to several reasons, including lack of adherence to treatment guidelines by physicians and patients' poor perception and adherence to therapy. We aim to assess the beliefs and knowledge of gout management in Internal Medicine residents, to investigate the gaps, so that education programs can target these gaps and address them in a comprehensive fashion.

Methods: A cross-section survey of Internal Medicine residents from three residency programs in Chicago was conducted using a 20-item questionnaire based on current ACR guidelines on gout management. Residents were considered to have

“good” knowledge if 70% of the questions are answered correctly. Survey performance was compared to respondent’s year in residency, information on guidelines, number of teaching sessions attended, and number of gout patients cared for. We obtained adjusted relative risks (RRs) of good knowledge by estimating a multivariable Poisson regression model with robust variance estimates, adjusted for covariates. Analyses were conducted using Stata, version 14.2.

Results: Of the original sample of 150 residents, 126 (84%) responded to the survey. Good knowledge was demonstrated by only 40% of the respondents. In our survey, two-third of the residents reported that their teaching on gout management is inadequate. For acute gout attacks, 70% of the respondents recognized the right therapeutic options. Only half of the residents knew the correct dose of colchicine and other half opted regimens accounting for higher dose of >2 mg/day. During an acute attack, urate-lowering therapy (ULT) was continued by approximately three-quarters (73%) of the residents. Half of the respondents (50%) were aware that anti-inflammatory prophylaxis (54% colchicine) was indicated while initiating ULT, but only one-third offered the prophylaxis for ≥8 weeks. Approximately 60% of residents reported that allopurinol is initially dosed according to the renal function, but only one third (33%) were aware that it must be titrated to the target serum urate level. Less than half (46%) considered the target serum urate level to be less than 6 mg/dl. In multivariable regression analysis, gout related knowledge was found to be higher among residents who attended more than 3 teaching sessions (RR-3.1; P=0.03; 95% CI, 1.09 to 10.9) and who read the guidelines (ACR/ACP/EULAR) on management (RR-1.8; P=0.04; 95% CI, 1.87 to 4.00).

Conclusion: Our study suggests that better dissemination of knowledge on gout management to Internal Medicine physicians in training is needed. We have identified several areas that should be focused: 1) avoidance of high-dose colchicine; 2) initiating anti-inflammatory prophylaxis while starting urate lowering therapy and its duration; 3) initial dosing of allopurinol 4) target serum urate level; and 4) the need to titrate allopurinol to target serum urate level. Education programs targeting these knowledge gaps may lead to better management practices of the upcoming physicians and help in reducing the prevalence of this burdensome disease.

A Two-Year Educational Initiative to Teach Rheumatology through Social Media: The Rheumatology Image of the Week Project (#RheumIOW)

Jeanne Gosselin¹ and Jonathan S. Hausmann², ¹Internal Medicine, Beth Israel Deaconess Medical Center, Boston, MA, ²Rheumatology, Boston Children’s Hospital / Beth Israel Deaconess Medical Center, Boston, MA

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Education Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: With 2 billion global active monthly users of Facebook and 330 million users of Twitter, social media platforms may be used to deliver educational content to today’s adult learner. The Rheumatology Image of the Week project (#RheumIOW) sought to leverage social media to disseminate educational micro-content about rheumatology topics. We recruited rheumatology Fellows-In-Training (FITs) to generate questions based on the ACR Image Library and shared these questions online. We previously showed FITs found question-generation to be a valuable educational experience and useful for learning rheumatology. In the present analysis, we explore the engagement of social media users with #RheumIOW during the two years of the project.

Methods: FITs created questions related to images from the ACR Image Library. Every Tuesday from August 2015-August 2017, one question, its accompanying image, and a link to the Image Library were shared via ACR accounts on Twitter, Facebook, and LinkedIn (Figure 1). Online engagement was measured using platform analytics.

Results: As of May 2018, ACR accounts on Twitter, Facebook and LinkedIn accounts had 15,800, 18,900, and 3,600 followers, respectively. Figure 2 shows clicks generated by platform over the two-year project period. There was a trend toward decreasing participation across all platforms over time with a decline of 40% in Facebook clicks, 59% in Twitter clicks, and 22% in LinkedIn clicks between the first and last six months of the project. Nevertheless, #RheumIOW posts had more engagement than most ACR posts during this time.

Conclusion: The #RheumIOW project sought to leverage social media to deliver educational micro-content on rheumatology topics. Our project was successful in engaging social media users to learn rheumatology and in driving users

to ACR's Image Library. Although ACR has similar numbers of followers on Twitter and Facebook, the latter generated 1.9 times more clicks for #RheumIOW posts. Facebook outperformed Twitter and LinkedIn in stimulating engagement with learners, which may help guide future educational projects. The decline in participation over time indicates that future educational interventions may be most effective when limited in duration. Educational outreach projects on social media may help to increase interest in rheumatology and could be used to recruit Millennials into the field.

Figure 1. #RheumIOWpost with question, associated image, and link to ACR Image Library.

Figure 2. Number of #RheumIOW clicks from August 2015 to August 2017.

Abstract Number: 196

Immunology and Immunopharmacology at Point of Care: A Quality Improvement Teaching Initiative for Rheumatology Fellows

Nina Kello¹ and Anne Davidson², ¹Rheumatology, Northwell Health, Donald and Barbara Zucker School of Medicine, Manhasset, NY, ²Feinstein Institute for Medical Research, Manhasset, NY

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Education Poster
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Immunology knowledge in the rheumatology community is important for a better understanding of disease pathogenesis and management, especially in an era of an expanding number of biologic therapies. Focus on immunology and immunopharmacology within rheumatology fellowship training programs varies depending on institution, as well as the involvement and availability of immunologists. The ACGME Program Requirements for Rheumatology requires “knowledge in pharmacokinetics, metabolism, adverse events, interactions, and relative costs of drug therapies used in the management of rheumatic diseases” and 5% of the rheumatology certification exam tests immunology and pharmacology. Immunology knowledge of rheumatology fellows and attendings has anecdotally been inadequate, though official data on immunology and immunopharmacology knowledge is lacking. We hypothesized that teaching and applying immunology in the clinic setting at “point of care” would promote a better understanding of immunopharmacology.

Methods: Over the course of 6 months, with the use of diagrams and flash cards, a brief (25min) tutorial covering the basic science behind a drug, followed by the pharmacology of said drug, was held at every fellow’s clinic by our immunologist and a senior fellow. Baseline immunology and immunopharmacology knowledge of the rheumatology fellows was determined with a pre-assessment test on the selected topic prior to each tutorial. The handouts were compiled into a book, which was available both in print and online and used on a regular basis when discussing patient management in clinic. The attending would initially model how to teach the material in a 3-5 minute format, and thereafter the fellow would use the same material to teach medical residents and students. A post-test assessment was performed 6 months after the lectures.

Results: Rheumatology fellows showed a significant improvement in test scores after our immunology tutorials, with pre-test scores ranging from 51-68% to post-test scores 82-95%. Post-test assessments not only evaluated improvement in knowledge, but also identified areas of weakness for repeat teaching.

Conclusion: Teaching immunology and immunopharmacology at “point of care” has proven to be an effective and well-liked tool to use in clinical practice among rheumatology fellows. Our innovative approach makes immunology clinically relevant and will indirectly improve patient care given better understanding of drug side effects and interactions. Our approach is interactive, convenient, time-efficient, flexible, easily updated, promotes the “fellow as teacher”, and can be used in the clinic even by programs with limited immunology expertise. We encourage application of this approach to future generations of rheumatology fellows within our fellowship program and beyond.

Abstract Number: 197

Improving Clinical Decisions for Gout Management: Effect of Online Case-Based Education

Nimish Mehta, Piyali Chatterjee-Shin and Karen Badal, Medscape, LLC, New York, NY

SESSION INFORMATION

Session Date: Sunday, October 21, 2018
Session Title: Education Poster
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Gout is a chronic condition with a considerable effect on patient health and quality of life. Despite the availability of multiple pharmacologic treatments and evidence-based management guidelines, treatment targets are often not achieved in patients with gout. A study was conducted to determine if online, case-based intervention could improve clinical decisions made by rheumatologists and PCPs regarding the management of patients with gout.

Methods: Educational design included 2 online, interactive, patient cases presented using a “test, then teach” approach to elicit cognitive dissonance, with evidence-based feedback provided following each learner response. Educational effectiveness was assessed with a repeated-pairs pre-/post-assessment study design with 3 case-based questions and 1 confidence question, in which each individual served as his/her own control. McNemar’s chi-squared test assessed differences from pre- to post-assessment. P values <.05 are statistically significant. Cramer’s V was used to calculate the effect size (<0.05 no effect; 0.06-0.15 noticeable effect; 0.16-0.26 considerable effect; >0.26 extensive effect). The activity launched 12/26/2017, with data collected through 1/18/2018.

Results: The analysis set consisted of responses from rheumatologists (n=73) and primary care physicians (PCPs, n=1053) who answered all assessment questions during the study period. Analysis of pre- vs post-intervention responses by demonstrated a significant improvement in overall competence of with considerable educational impact (rheumatologists: $V = .276$, $P < .0001$. PCPs: $V = .358$, $P < .0001$).

Average correct responses increase from 68% pre to 90% post education for rheumatologists, and 41% pre to 76% post for PCPs. Specific areas of improvement in clinical decisions include:

- Addition of allopurinol to colchicine in a patient with serum urate level of 9.2 mg/d
- Treatment with fixed-dose lesinurad/allopurinol combination therapy in a patient with adherence issues while maintaining target urate levels
- Switching from allopurinol to febuxostat in a patient with uncontrolled serum urate levels and hypersensitivity to allopurinol based on HLA-B*5801 positivity

Post-education, 18% of rheumatologists and 36% of PCPs were more confident in using a treat-to-target approach when prescribing urate-lowering therapy in gout.

Conclusion: This study demonstrated the success of online, interactive, case-based education on improving the evidence-based clinical decisions and confidence of rheumatologists and PCPs in selecting appropriate treatment for patients with gout using a treat-to-target approach.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Education Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Ultrasonography is an important modality to evaluate and diagnose a host of musculoskeletal and rheumatologic conditions. However, the interpretation of sonographic images is a challenging skill to acquire. Furthermore, there is a limited set of resources available to rheumatology fellows for self-study. To fill that gap, the investigators created a musculoskeletal ultrasound coloring book as an adjunct to didactic sessions, and assessed the utility of this book through a pragmatic randomized control trial.

Methods: The investigators prepared a coloring book using images obtained by scanning their own joints. Complete ultrasound scans of 10 joints were taken according to OMERACT protocols. Two sets of chapters were created: a 'control' chapter with faithful reproductions of the ultrasound images, and a 'coloring' chapter, with color inversions of black-and-white ultrasound images to enable participants to color in the spaces. Both have identical captions and interpretations underneath the images.

Participants were recruited from the University of Iowa Rheumatology Fellowship Program. All participants attended didactic hour-long weekly sessions and were administered four sets of distinct examinations: the pre-test, the immediate post-test, the 4-week post-test, and the 6-month post-test. Each participant was provided a copy of the modified coloring book which was composed of 5 randomly assigned 'control' chapters and 5 randomly assigned 'coloring' chapters. Participants were strongly encouraged to study the material prior to didactic sessions, follow along during sessions, and use the book chapters as resources thereafter. Test results were blinded to investigators until the end of the trial.

Results: 6 fellow physicians participated in 10 sessions each and appeared for each of the four 10-question exams. Therefore, the group had an overall total of 60 sessions, of which 30 were subject to intervention with the 'coloring' chapter and 30 were controls with the 'standard' chapter. The mean pre-test scores were 2.3 (SD = 1.9) for controls and 3.1 (SD = 1.4) for interventions. The mean post-test scores were 9.3 (SD=0.4) and 9.8 (SD=0.3) for controls and interventions, respectively. Mean 4-week post-test scores were 5.8 (SD=0.9) and 7.6 (SD=1.1), respectively, and 6-month post-test scores were 4.1 (SD=0.8) and 6.8 (SD=1.1), respectively. The differences between the pre-test, immediate post-test, and 4-week post-test scores were not statistically significant ($p=0.736$, $p=0.322$, and $p=0.210$, respectively). However, the difference between the mean 6-month post-test scores was statistically significant ($p=0.05$).

Conclusion: The musculoskeletal ultrasound coloring book is a useful adjunct to didactic sessions to promote six-month retention of sonoanatomy knowledge by fellow physicians. Further investigation is necessary to determine if this translates into greater fluency in interpretation of pathology, technique in obtaining images, and satisfaction. The investigators recommend implementation in multiple institutions to more definitively determine the utility of a musculoskeletal ultrasound coloring book as an adjunct to didactic sessions.

Abstract Number: 199

Evaluating the Perception Among Rheumatologists of Maintenance of Board Certification Programs in the United States

Amr H Sawalha and Patrick Coit, Division of Rheumatology, University of Michigan, Ann Arbor, MI

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Education Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: There continues to be a debate about the value and purpose of maintenance of certification programs (MOC) created by board-certifying organizations. Physicians, echoed by multiple societies including the American College of Rheumatology (ACR), have raised concerns questioning the recertification process. The goal of this survey study is to assess the impact, value, and purpose of maintenance of board certification in rheumatology.

Methods: A survey designed to assess the impact and perceived value of maintenance of board certification in rheumatology was sent via email to 3,107 rheumatologists within the US. The survey addressed issues related to how rheumatologists perceive negative and positive impacts of MOC, and how this program might affect various aspects related to rheumatology practice and patient access to care.

Results: A total of 515 rheumatologists completed the survey. With an estimated number of ~5,000 full-time practicing rheumatologists in the US, this sample size gives a margin of error of <5% with 95% confidence that the responses accurately reflect the views of rheumatologists. The majority (74.8%) did not think there is significant additional value in MOC, beyond what is already achieved from Continuing Medical Education, or that MOC is valuable in terms of improving patients care (63.5%). The majority felt that the primary reason for creating MOC is financial well-being of board certifying organizations (43.4%) or to satisfy administrative requirements in health systems (30%). Only 15.1% believed improving patient care was the primary reason for MOC. The majority of rheumatologists believed board certification should be a life-long credential (63.7%), and 75.2% favor a state legislation to remove MOC as a requirement for employment, insurance reimbursement, or securing clinical privileges. Notably, when asked about positive and negative impacts, the majority reported that MOC results in time away from providing patient care (74.6%), time away from family (74%), and psychological stress (69.7%). 65.6% perceived staying current with new knowledge as a positive impact of MOC. When asked about anticipated effects of requiring MOC, 77.7% reported physician burnout, 67.4% early physician retirement, and 63.9% anticipated an effect on reducing the overall number of practicing rheumatologist. Of interest, 58.9% believe board certification in rheumatology should be administered or overseen by other organizations such as the ACR. Of the respondents who reported participating in research activities, 39.6% believed MOC is adversely affecting their ability to perform research or research related activities.

Conclusion: The majority of rheumatologists in the US do not believe there is value for recertification and maintenance of certification in rheumatology. Negative impact was clearly more than any positive impact perceived. Importantly, there is evidence for lack of trust in board certifying organizations among rheumatologists, and the majority of rheumatologists believe MOC contributes to physician burnout, early retirement, and loss in the rheumatology work force. This is alarming given the current and predicted shortage in rheumatologists in the future.

Validation of the Ers-RA Risk Score in a Dutch Population

Milad Baniaamam¹ and Michael Nurmohamed², ¹Department of rheumatology, Amsterdam Rheumatology immunology Center | Reade and VU University Medical Center Amsterdam, Netherlands, Amsterdam, Netherlands, ²Rheumatology, VU University Medical Center, Amsterdam, Netherlands

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Epidemiology and Public Health Poster I: Rheumatoid Arthritis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The most frequent cause of death in patients with chronic rheumatoid arthritis(RA) is of cardiovascular (CV) origin. CV risk prediction scores in the normal population do not predict the CV risk in RA patients adequately due to the additional systemic inflammatory burden which is pathogenic for CV disease. Recently, Solomon et al developed the ERS-RA Risk Score, a newly and expanded CV risk score predicting the 10 year CV event risk in RA

Area Under the Curve	
Test Result Variable(s)	Area
ERS_RA_RISK_SCORE_70	0.04
ERS_RA_RISK_SCORE_80	0.05
ERS_RA_RISK_SCORE_90	0.05
ERS_RA_RISK_SCORE_100	0.05
ERS_RA_RISK_SCORE_110	0.04
ERS_RA_RISK_SCORE_120	0.03
ERS_RA_RISK_SCORE_130	0.03
ERS_RA_RISK_SCORE_CDAI>10	0.12

The test result variable(s):

ERS_RA_RISK_SCORE_70
ERS_RA_RISK_SCORE_80
ERS_RA_RISK_SCORE_90
ERS_RA_RISK_SCORE_100
ERS_RA_RISK_SCORE_110
ERS_RA_RISK_SCORE_120
ERS_RA_RISK_SCORE_130
ERS_RA_RISK_SCORE_CDAI>10

patients. This is based on a cohort from the Consortium of Rheumatology Researchers of North America registry. In this abstract we present the results of a validation test performed with the ERS-RA Risk Score in the Dutch CARRE study.

Objective: To perform a validation test of the ERS-RA Risk Score in the Dutch CARRE study.

Methods: We validated the ERS-RA Risk Score in the CARRE cohort by performing a ROC curve analysis. The CARRE study is a Dutch cohort study investigating CVD and its risk factors in RA-patients who have been followed prospectively for at least five years. RA patients registered at Reade (location Jan van Breemen institute in Amsterdam, the Netherlands) participated if they fulfilled the 1987 ACR classification criteria, were diagnosed between 1989 and 2001, and were aged between 50 and 75 years. In contrast to the cohort used in study of Solomon et al, the CARRE study used the HAQ instead of m-HAQ and the CARRE lacks the Predictor's Global Assessment to calculate the CDAI. However, to approximate the true outcome of the m-HAQ and the CDAI we conducted the following modifications of the CARRE cohort data. To calculate the CDAI we estimated the Predictor's Global Assessment as 70%, 80%, 100%, 110%, 120% and 130% of the Patient's Global Assessment. Furthermore, we approximated the m-HAQ score 50% lower than the HAQ score as described in a recent published article.

Results: The CARRE study included 352 RA patients with 60 CV events over a 10 year follow up period. The mean age was 63.3 years of which 121 (34%) male participants. The ROC curve analysis shows an area under the curve of 0.603-0.612 depending on the predicted Predictor's Global Assessment (see figure 1).

Figure 1. ROC curve analysis of the ERS-RA Risk score in the CARRE cohort with different approximated CDAI scores.

Conclusion: In conclusion, the ERS-RA Risk Score has a limited validity in the CARRE study, a Dutch RA cohort and can therefore not be used for risk prediction in Dutch RA patients.

Occupational Exposure to Coal and Silica Dust Is Associated with Elevated Risk of Rheumatoid Arthritis in Coal Mining Areas of US

Laura Trupin¹, Edward H. Yelin², Gabriela Schmajuk³ and Paul Blanc⁴, ¹University of California San Francisco, San Francisco, CA, ²Medicine/Rheumatology, University of California San Francisco, San Francisco, CA, ³San Francisco VA Medical Center, San Francisco, CA, ⁴Medicine, University of California San Francisco, San Francisco, CA

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Epidemiology and Public Health Poster I: Rheumatoid Arthritis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Exposure to inhaled mineral dust, particularly silica, has been associated with increased risk of RA and other autoimmune diseases. Coal mining leads to silica exposure, but the extent to which RA can be attributed to coal mining has not been estimated. We studied the association of RA with work-related coal and silica exposure in the Appalachian region of the US, given its geographic concentration of mining and data showing a high population prevalence of arthritis.

Methods: We conducted a random digit dial telephone survey within selected counties in the Appalachian region with the highest coal workers' pneumoconiosis mortality rates identified by NIOSH. Eligibility was limited to males, age ≥ 50 , with any work history. A brief structured telephone interview included demographics, occupational dust, work-related ergonomic exposures, and self-reported physician diagnoses of and treatment for arthritis, including RA. Only those reporting both a physician diagnosis of RA and glucocorticoid use for joint symptoms were considered to have RA for this analysis. We scored ergonomic exposures using a 13-item list of physical work hazards (e.g. lifting, bending, using power tools), each contributing 1 point. We used logistic regression analysis to estimate the risks of any arthritis and, separately, the subset meeting the study definition of RA associated with occupational coal dust and other occupational silica exposure, adjusting for high-levels of ergonomic exposure (≥ 11 items; 75th percentile), age, and smoking status (current/former/never). The models of RA risk exclude those reporting a diagnosis of arthritis who do not meet the study definition of RA.

Results: Among the 973 men, average age was 66 ± 10 years; 91% were white; 54% ever smokers. 266 (27%) reported coal mining work; 189 (19%) reported work-related silica exposure without coal mining. Arthritis was highly prevalent among the respondents, with 517 (53%) reporting a physician diagnosis of any arthritis and 112 (12%) RA. In the fully adjusted models (Table 1), coal mining was associated with elevated odds of both RA and any arthritis. Other silica exposure also increased the odds of any arthritis. Current smoking was associated with RA only.

Conclusion: In this population of older men living in areas in which coal mining and other occupational silica dust exposure is common, we found a high prevalence of self-reported arthritis, particularly of RA. While this study may overestimate the true prevalence of RA, the odds of any arthritis and RA associated with coal-mining remained markedly elevated after adjusting for ergonomic exposures and smoking. Given both the frequency of exposure and magnitude of risk, a substantial proportion of prevalent arthritis in this region may be attributable to occupational factors, a link that is not widely appreciated or acknowledged.

Table 1. Risk of arthritis associated with occupational coal dust and silica exposure among 973 men age ≥ 50 from US counties with high prevalence of coal mining.

	Model 1 (Adjusted for Age/Smoking)		Model 2 (Age/Smoking/Ergonomics)	
	All arthritis	RA	All arthritis	RA

Risk of Inflammatory Arthritis Development in the Family Members of Indigenous North American (INA) RA Patients

Stacy Tanner¹, Irene Smolik², Brenden Dufault³, Carol Hitchon³, David Robinson¹, Elizabeth Ferucci⁴ and Hani El-Gabalawy³, ¹Rheumatology, University of Manitoba, Winnipeg, MB, Canada, ²Arthritis Center, University of Manitoba, Winnipeg, MB, Canada, ³University of Manitoba, Winnipeg, MB, Canada, ⁴Alaska Native Medical Center, Anchorage, AK

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Epidemiology and Public Health Poster I: Rheumatoid Arthritis

Background/Purpose: INA populations have a high prevalence of seropositive RA, often with severe disease. The risk of RA in family members of RA patients, particularly first-degree relatives (FDR), is estimated to be up to 4 times that of the general population. We prospectively followed a cohort of unaffected family members of INA RA patients to determine the incidence of inflammatory arthritis (IA).

Methods: Family members of INA RA probands were recruited and followed longitudinally between 2005-2017. At baseline, participants were examined to confirm absence of synovitis and questionnaires regarding joint symptoms, lifestyle, and comorbidities were administered. Serum was tested for ACPA (anti-CCP3 ELISA) and IgM RF seropositivity. Seropositive individuals were re-evaluated annually and seronegative individuals every three years. Participants were instructed to contact the investigators if symptoms suggestive of IA occurred and were re-evaluated at that time. Diagnosis of IA required one or more swollen joints deemed to represent synovitis by a study rheumatologist. Individuals included in the analysis had a least two visits, 6 months or more apart. To calculate the incidence of IA, number of IA cases was used as the numerator, and total years of follow-up of the entire cohort served as the denominator.

Results: 374 family members (314 from Manitoba, 60 from Alaska) were enrolled. The majority (75%) were FDR. Total follow-up time for the cohort was 1,940 person-years. 18 (4.8%) people developed IA after a mean of 4.8 (IQR 3.6-6.1) years, and 15/18 (83%) met the 2010 ACR/EULAR criteria for RA. Baseline cohort characteristics are in Table 1. The rate of IA development was 9.2 cases per 1000 person years of follow-up (0.9% annually). 6/18 of the IA group was ACPA and RF seronegative at baseline with a median time to transition of 5.6 (± 1.1) years, whereas the 5/18 who were ACPA/RF positive at baseline developed IA after 3.2 (± 2.2) years (Table 2). Interestingly, 7/12 relatives who were ACPA/RF positive at baseline had not developed IA after being followed for a mean of 5.1 years (± 2.2), and many individuals who were seropositive at any given time subsequently became seronegative.

Conclusion: This prospective longitudinal cohort study of the relatives of INA RA patients is the first to establish the incidence of IA in this high-risk population. As expected, ACPA+/RF+ seropositivity is associated with the highest rates of IA development and shortest latency period. Importantly, the lack of IA development in the majority of seropositive individuals, including ACPA+/RF+, suggests the transition to clinically detectable disease relates to other unknown factors.

Abstract Number: 203

Meat Consumption and Risk of Rheumatoid Arthritis in Women: A Population-Based Cohort Study

Daniela Di Giuseppe¹, Lotta Ljung² and Bjorn Sundstrom², ¹Department of Medicine Solna, Karolinska Institutet, Stockholm, Sweden, ²Department of Public Health and Clinical Medicine/Rheumatology, Umea University, Umea, Sweden

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Epidemiology and Public Health Poster I: Rheumatoid Arthritis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Mixed results have been reported for the association between meat consumption and the risk of developing rheumatoid arthritis (RA). The aim of this study was to evaluate the association between red meat, particularly processed meat, and the risk of RA using data from a population-based cohort of women.

Methods: We prospectively followed 35,600 women aged 48-83 years from the Swedish Mammography Cohort (SMC), between 2003 and 2014. Meat consumption was assessed with a 96-item self-administered questionnaire in 1997. A corresponding questionnaire data from 1987 was available, enabling identification of long-term meat consumption. The relative risk (RR) of RA associated with meat consumption and its 95% confidence interval (CI) were estimated using Cox proportional hazard regression models. Multivariable models were adjusted for age, body mass index, educational level, physical activity, use of dietary supplements, energy intake, and smoking.

Results: During the 12 years of follow-up (381 456 person years), 368 new cases of rheumatoid arthritis were identified. Meat consumption was not associated with the development of RA in age-adjusted (RR=0.96 (95% CI: 0.69-1.32)) or multivariable adjusted (RR=1.08 (95%CI: 0.77-1.53)) models (**Table 1**). No association was observed either for consumption of type-specific meat, such as red meat (RR=1.08 (95% CI: 0.77-1.50)), processed meat (RR=0.84 (95% CI: 0.59-1.22)), or poultry (RR=0.88 (95% CI: 0.60-1.31)). , Women with a consistent long-term consumption of meat of >7 servings/week over a period of 10 years had no increased risk of RA, HR 1.19 (95% CI: 0.78-1.80), compared to women with a consistent consumption of <=4 servings/week.

Conclusion: In this large population-based cohort study, meat consumption, in total, by sub-types, or over time, was not associated with the risk of RA development in women.

Table 1. Relative risk of rheumatoid arthritis during follow-up (2003-14) of women in the Swedish Mammography Cohort by meat consumption in 1997.

Investigating Asthma, Allergic Disease, Passive Smoke Exposure, and Risk of Rheumatoid Arthritis

Vanessa L. Kronzer¹, Cynthia S. Crowson², Jeffrey A. Sparks³, Robert Vassallo⁴ and John M. Davis III⁵, ¹Internal Medicine, Mayo Clinic, Rochester, MN, ²Health Sciences Research, Mayo Clinic College of Medicine and Science, Rochester, MN, ³Division of Rheumatology, Immunology and Allergy, Brigham and Women's Hospital, Boston, MA, ⁴Pulmonary and Critical Care Medicine, Mayo Clinic, Rochester, MN, ⁵Division of Rheumatology, Mayo Clinic College of Medicine and Science, Rochester, MN

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Epidemiology and Public Health Poster I: Rheumatoid Arthritis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Several studies show an association between asthma and RA. However, none have controlled for allergic disease, urban environment, or passive smoke exposure. We aimed to determine the association of asthma, allergic disease, and passive smoke exposure with RA risk.

Methods: We performed a case-control study using a biobank at a single center, identifying cases of RA using a rules-based algorithm combining self-report with two diagnosis codes (PPV = 88%). We matched each case to three controls based on age, sex, and location of residence at index date of survey. Data on exposures were self-reported on biobank surveys. Unconditional logistic regression models calculated the relationship between each exposure and RA after adjusting for potential confounders.

Results: We identified 1,149 RA cases and 3,441 controls. Mean age at survey date was 62 years (SD 13), and 72% were female. Asthma was associated with RA even after adjusting for allergies, urban environment, and passive smoke exposure (Table 1). History of allergic disease was also associated with RA (Table 1). Passive home smoke exposure duration and pack-years were modestly associated with development of RA, but the association with passive work smoke exposure was not statistically significant (Table 1).

Conclusion: Asthma, allergic diseases, and passive smoke exposure at home may be associated with increased risk of developing RA. Future studies investigating the relationship between atopy and autoimmunity are needed.

Table 1. Association between asthma, allergy, passive smoke exposure and RA*

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Epidemiology and Public Health Poster I: Rheumatoid Arthritis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) develops insidiously, often over many years. Given that diet and obesity have been associated with increased RA risk, we investigated whether metabolomic profiling of plasma could identify novel biomarkers associated with risk of developing RA among women.

Methods: Incident RA cases with plasma samples drawn prior to disease onset in the Nurses' Health Study (NHS) and Nurses' Health Study II (NHSII) cohorts were matched to controls at a 1:2 ratio based on age, race, menopausal status, post-menopausal hormone use, as well as blood-draw variables: fasting status, time of day, and date of blood draw.

*Statistically significant ORs for identifying metabolites

RA: all rheumatoid RA; SP: seropositive RA; OR: odds ratio per standard deviation; P: p-value

Untargeted liquid chromatography tandem mass-spectrometry molecular profiling of plasma samples drawn prior to RA onset from incident cases and matched controls participating in NHS and NHSII were collected. The final sample after quality control filtering consisted of a total of 256 pre-RA cases and 511 matched controls, measured across 437 unique, known metabolites. Conditional logistic regression was used to assess the association between individual metabolites and risk of RA, with adjustment for BMI and smoking. Subgroup analyses were also performed among case-control matched groups with 1) seropositive RA cases, and 2) with RA cases whose plasma was drawn between 1-5 years prior to diagnosis. Multiple comparison adjustments were made using the number of effective tests.

Results: Top metabolites associated with increased risk of incident RA included C18:1 lysophospholipid (OR: 1.23, 95% CI: 1.05-1.45), and C22:0 lysophosphatidylserine isomer (OR: 1.22, 95% CI: 1.03-1.43). 4-acetamidobutanoic acid (OR: 0.78, 95% CI: 0.66-0.93) and N-acetyltryptophan (OR: 0.83, 95% CI: 0.70-0.98), as well as C5 (OR: 0.84, 95% CI: 0.71-0.995) and C5:1 carnitines (OR: 0.82, 95% CI: 0.69-0.96) were shown to have a protective effect against incident RA. Although these metabolites did not survive adjustment for multiple comparisons, they were found to be marginally significant and shared consistent directions of effect in the seropositive-only RA analyses. In the 1-5 year period prior to RA diagnosis, homoarginine was identified as a significant risk factor for incident RA in both the full group (OR: 1.77, 95% CI: 1.24-3.53) and in the seropositive-only (OR: 3.01, 95% CI: 1.30-6.96) analyses.

Conclusion: We have identified several metabolic markers of incident RA. Further replication in an independent cohort is ongoing to confirm our findings.

Liao³, ¹Division of Rheumatology, Immunology and Allergy, Brigham and Women's Hospital, Boston, MA, ²Rheumatology, Immunology, and Allergy, Brigham and Women's Hospital, Boston, MA, ³Brigham and Women's Hospital, Boston, MA, ⁴Research Computing, Partners HealthCare, Charlestown, MA, ⁵Harvard T.H. Chan School of Public Health, Boston, MA

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Epidemiology and Public Health Poster I: Rheumatoid Arthritis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Electronic medical records (EMRs) are increasingly being utilized for clinical research, where the phenotypes of interest are typically defined by algorithms. Almost a decade ago, a rheumatoid arthritis (RA) phenotype algorithm using codified and narrative data extracted from the EMR using natural language processing (NLP), was developed using machine learning approaches. The objective of this study was to evaluate the temporal portability of this algorithm, with the introduction of International Classification of Diseases (ICD), 10th revision codes, as well as a new EMR system (Epic) at our institution.

Methods: We studied subjects from the EMR of 2 large academic centers with ≥ 1 ICD9 RA code (714.x) or ICD10 RA code (M05.x, M06.x) and ≥ 2 clinical notes to create a database of all potential patients with RA ("RA Mart", n = 52,728). A random 100 subjects were selected from the RA Mart, and patients were classified as RA yes/no from medical record review to create the validation set. We first calculated the performance characteristics of using ≥ 2 RA ICD9 or ICD10 RA codes to define RA compared to RA classified from chart review. We then applied a previously published logistic regression algorithm for RA using ICD9 codes and data extracted using NLP from data fields specified in 2010. For example, this model would not include treatments approved after 2010. We then applied a modified algorithm incorporating ICD10 codes and additional medications to existing variable fields, e.g. number of RA ICD9 codes became number of ICD 9 or 10 RA codes. We compared performance characteristics of the original 2010 with the modified 2010 RA algorithm using the original published positive predictive value (PPV) as a benchmark.

Results: In the validation set, 41% of subjects were classified as RA. Among those with RA, mean age was 68, 76% female, and 59% were RF or anti-CCP positive; 7% of subjects only had ICD10 but not ICD9 codes. The PPV for

classifying RA using ≥ 2 ICD9 codes was 50%; and for using ≥ 2 ICD9 or ICD10 was 52% (Table). Using the exact data fields specified in the 2010 algorithm, we achieved a PPV of 93%. When the data fields were updated with new types of data, ICD10, new treatments, the PPV remained at 93%. In comparison, the published PPV of the algorithm was 94%, with a sensitivity of 63%.

Conclusion: We observed that an existing RA algorithm trained using machine learning approaches on EMR data was robust temporally, despite the introduction of new medical information which also updated the algorithm steps. At this time including ICD10 had a minimal impact on classification. The existing RA algorithm continued to perform significantly better than using ICD9 or ICD10 data alone at classifying RA.

Table. Performance characteristic of the published algorithm and modified algorithm to identify individuals with RA, as compared to codified data alone (n=100).

	≥ 2 ICD9 RA codes	≥ 2 ICD9 or ICD10 RA codes	Published algorithm	Modified algorithm
Sensitivity	0.80	0.93	0.68	0.66
Specificity	0.44	0.41	0.97	0.97
PPV	0.50	0.52	0.93	0.93

RA: rheumatoid arthritis

PPV: positive predictive value

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Epidemiology and Public Health Poster I: Rheumatoid Arthritis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Inflammation is an independent risk factor for cardiovascular (CV) risk in rheumatoid arthritis (RA). Paradoxically, potentially cardioprotective decreases in inflammation is associated with increased low-density lipoprotein cholesterol (LDL-C). Few studies exist as to how increased inflammation modulates lipid parameters. This study's objective was to examine changes between lipids and markers of myocardial injury among RA patients demonstrating increased inflammation.

Methods: We studied a longitudinal, large academic medical center-based RA cohort, examining annually-collected clinical data, CRP and blood samples among patients with an increase in C-reactive protein (CRP) ≥ 10 mg/L CRP between any two time points at least one year apart. The first time point was defined as the baseline. Subjects on statin therapy one year before baseline or during the one-year follow-up period were excluded. For all subjects, we measured routine lipids: total cholesterol (TC), high density lipoprotein cholesterol (HDL-C), LDL-C; advanced lipoprotein measures: apoA1, apoB, HDL cholesterol efflux capacity; myocardial injury markers: high sensitivity troponin T (hs-cTnT); myocardial strain: pro-BNP. The paired t-test was used to determine significant differences between baseline and follow-up.

Results: Among 1,443 unique RA patients we identified n=103 RA patients who experienced an ≥ 10 mg/L CRP increase in two consecutive years. Baseline characteristics of this cohort were as follows: mean age 59 years, 80% female, 72% positive for RF and/or anti-CCP antibodies; baseline treatment MTX 50.5%, tumor necrosis factor inhibitor 49.5%; a mean CRP increase of 35.9 mg/dL was found. On concurrent follow-up labs, TC, LDL-C, apoB and apoA1 were all significantly reduced (Table). HDL cholesterol efflux capacity was not significantly altered. Both biomarkers of myocardial strain and injury (pro-BNP, hs-cTnT) were significantly increased.

Conclusion: Among 103 RA patients experiencing significant increases in inflammation, markers of subclinical myocardial injury and strain were increased despite concurrent decreases in routine lipid levels, including ones predictive of reduced CV risk. These findings suggest that increases in inflammation in RA may promote subclinical cardiac damage and CV risk while other, accepted CV risk markers, i.e. LDL-C, may mislead clinicians in this setting.

Table. Lipid and myocardial biomarkers at baseline and follow-up after RA patients experienced increase in inflammation.

Biomarker	Baseline	Follow-up	p-value
Routine lipids, mean (SD)			
Total cholesterol (mg/dL)	192.1 (40.3)	177.0 (35.1)	<.0001
HDL-C (mg/dL)	59.1 (18.4)	57.0 (17.5)	0.2
LDL-C (mg/dL)	113.4 (32.4)	101.8 (29.2)	<.0001
Triglycerides (mg/dL)	112.1 (59.1)	101.1 (57.7)	0.003
Non-HDL (mg/dL)	133.0 (37.0)	120.0 (32.8)	<.0001
Total cholesterol/HDL-C	3.5 (1.1)	3.4 (1.7)	0.01
Advanced lipoprotein measures, mean (SD)			
apoA1 (mg/dL)	162.0 (34.6)	152.5 (33.3)	<.0001
apoB (mg/dL)	94.0 (24.0)	90.4 (23.2)	0.02
apoB/apoA1	0.60 (0.20)	0.62 (0.22)	0.3
HDL cholesterol efflux capacity	1.3 (0.40)	1.2 (0.40)	0.1
Markers of myocardial injury or strain			
Hs-cTnT (ng/mL)	8.3 (10.6)	9.8 (12.9)	0.0003
Pro-BNP (pg/mL)	197.4 (371.4)	298.9 (650.2)	0.001
Inflammatory markers and RA disease activity			
hsCRP (mg/L)	8.7 (14.7)	44.6 (47.7)	<.0001
RA Clinical Disease Activity Index (CDAI)	14.8 (12.5)	19.5 (17.0)	0.02

CDAI: ≤10, remission/low disease activity; >10 and ≤22, moderate disease activity; >22 high disease activity

Antibodies to Citrullinated Protein Antigens are Associated with Risk of Cardiovascular Disease in Community Dwelling Women: The Multi-Ethnic Study of Atherosclerosis

Background/Purpose: Risk for cardiovascular (CV) events in patients with RA is double what it is for the general population. Antibodies to citrullinated proteins (ACPA) are detectable years before RA onset and in some individuals who do not develop RA. It is not known whether ACPA, in the absence of clinical RA, is associated with CV events. Among men and women without RA in a multi-ethnic community dwelling population, we investigated associations between ACPA and incident CV events.

Methods: Among a randomly selected subset of 1617 participants in the Multi-Ethnic Study of Atherosclerosis (MESA), a prospective cohort study designed to determine risk factors and progression of subclinical and clinical cardiovascular disease, we measured ACPA using a multiplex array of 38 different individual ACPA. Each ACPA was defined as positive if > 95th percentile cut-off in MESA. The number of (+) ACPA were summed for each participant (range 0-38). We

*For every (+)ACPA, there was a 7% higher risk of MI and angina, and 4% higher risk of CV events in women.			
**Fully adjusted for age, race, diabetes, SBP, eGFR, HTN med use, current smoking, and IL-6			

examined the association of the number of ACPA with all-cause mortality, incident heart failure, angina, MI, and a composite of all CV events using Coxproportional hazards models and adjusting for covariates and tested for interaction by sex.

Results: Mean age was 65 years. The sample was 50% women, 40% Caucasian; and 31% had ≥ 1 (+) ACPA. Among ACPA(+) participants, the median number (+) was 2 (IQR 1-6). ACPA(+) and ACPA(-) participants were similar in age, gender, and race/ethnicity, but ACPA(+) participants had higher IL-6 concentrations. Associations between number of ACPA and incident CV events differed significantly by sex ($p_{\text{interaction}} < 0.05$). In women, but not men, higher number of (+) ACPA was significantly associated with risk of angina, MI, and CV events. No associations were observed among men.

Conclusion: In a community-living population without RA, higher number of ACPA was associated with incident angina, MI, and CV events in women, but not men. To better understand mechanisms, future studies are needed to determine whether ACPA are associated with subclinical CVD markers in people without RA, but with RA-related autoimmunity, and whether these associations differ by sex.

Development of an Algorithm for the Classification of Cardiovascular Comorbidity in Rheumatoid Arthritis: Data from the Ontario Best Practices Research Initiative

Background/Purpose: Cardiovascular disease (CVD) is increased in rheumatoid arthritis (RA). The ability to accurately identify CVD is important for primary and secondary prevention strategies. RA registries collect comorbidity data, but discordance between physician-reported and patient-reported CVD often exists. Therefore, we aimed to develop an algorithm for the classification of CVD in a representative RA registry.

Methods: Data were collected from the Ontario Best-practices Research Initiative (OBRI), a clinical registry of RA patients followed in routine care in Ontario, Canada. Clinical information, including patient medication profile, was obtained at registry entry, through physician visits and patient telephone interviews. Cardiovascular disease (CVD) was defined as having ≥ 1 of myocardial infarction (MI), coronary artery disease (CAD), cerebral vascular accident (CVA), including transient ischemic attack and stroke), or peripheral arterial disease (PAD).

Results: An algorithm for classifying CVD and CVD risk factors was developed including the 2033 subjects with baseline data (Figure 1). At cohort entry, the prevalence of CVD was 5.3% (n=108) and the majority had physician reported CAD/MI (n=96, 4.7%) with lower prevalence of CVA (0.5%) or PAD (0.1%). Seventeen subjects (15.7%) were not identified as having CVD by physician-report but were classified as having CVD upon medication review.

Conclusion: An algorithm for classification of CVD has been successfully developed in a representative RA registry. Validation based on chart review is underway in a subsample to verify the findings. The discrepancy between physician and

* MI: myocardial infarction; CAD: coronary artery disease; PAD: peripheral artery disease; CVA: cerebral vascular accident (including stroke and TIA).

** Clinical judgement is applied at this step. Information taken into account includes whether the patient is on anti-platelet agents, anti hypertensives, cholesterol control medications, or nitroglycerin's. For uncertain cases, a second reviewer's opinion is used.

patient-reported CVD highlights the importance of utilizing information from multiple sources when classifying comorbidities. The classification of CVD risk factors is also underway to further validate the algorithm.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Epidemiology and Public Health Poster I: Rheumatoid Arthritis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Prior studies observed better disease control, quality of life, and physical function among patients with rheumatoid arthritis (RA) who drink alcohol. These studies may suffer from reverse causality due to discontinuation of use over time among those with poor health. We assessed factors associated with changes in alcohol use over time and the effects of discontinuation on disease activity and mortality in a large RA registry.

Methods: RA participants in FORWARD, the National Data bank for Rheumatic Diseases, were asked about alcohol use on semi-annual surveys (any v. none). Our disease activity measure was the Patient Activity Scale2 (PAS2). Logistic regression models with generalized estimating equations assessed associations between patient factors and alcohol use at the time of the next questionnaire among those reporting current regular alcohol intake. Multivariable logistic regression and Cox proportional hazards models illustrated survival of alcohol use over time by disease activity categories and assessed the risk of discontinuation of alcohol use on subsequent worsening of disease activity (>0.5 standard deviation change) and mortality.

Results: In 121,280 observations (16,722 unique patients), alcohol users had lower PAS2 [β : -0.18 (-0.21, -0.15) $p < 0.001$]. Discontinuation of alcohol was common among drinkers (8.2% of observations). Higher disease activity was associated with future discontinuation of alcohol (Table, Figure). This was explained by other factors associated with discontinuation: older age, female sex, non-white race, obesity, comorbidity, work disability, low educational level and income, and poor physical/mental quality of life. Recent discontinuation (in prior 6 month interval) was not independently associated with a subsequent increase in PAS2 over the subsequent 6 months after adjustment [OR 1.03 (0.94, 1.13) $p = 0.58$]. Discontinuation was associated with a greater risk of death [HR 1.58 (1.25, 2.00) $p < 0.001$], but not independently of the above factors [HR 1.13 (0.86, 1.47) $p = 0.36$]. Sensitivity analyses limited only to moderate alcohol use were similar.

Conclusion: Higher disease activity, disability, comorbidity, and poor quality of life are associated with discontinuation of alcohol use in RA. Discontinuation of alcohol is not independently associated with worsening disease activity or greater mortality. These observations highlight a need to ensure that a behavioral exposure temporally precedes the outcome in epidemiologic studies and calls into question previously described benefits of alcohol consumption in RA.

Table: Associations between disease activity and discontinuation of alcohol use.

	Model 1 Odds of Discontinuation (N=7,937; Obs=52,345)		Model 2 Odds of Discontinuation (N=7,817; Obs=51,073)

Excess in Prevalence of Functional Disability in Patients with Rheumatoid Arthritis: Does Serologic Status Matter?

Elena Myasoedova¹, John M. Davis III¹, Sara J. Achenbach², Eric L. Matteson¹ and Cynthia S. Crowson², ¹Division of Rheumatology, Mayo Clinic College of Medicine and Science, Rochester, MN, ²Health Sciences Research, Mayo Clinic College of Medicine and Science, Rochester, MN

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Epidemiology and Public Health Poster I: Rheumatoid Arthritis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Despite the advances in treatment of rheumatoid arthritis (RA) over the recent decades, many patients with RA do not achieve remission or full physical functioning. Changing burden of functional disability (FD) in patients with RA has not been widely studied. We aimed to assess the prevalence of patient-reported FD in RA compared to subjects without RA over RA disease duration, age range and calendar time, and to define the effect of rheumatoid factor/ anti-cyclic citrullinated peptide (RF/CCP) positivity on the prevalence of FD in patients with RA.

Methods: This retrospective population-based cohort study included residents of a geographical area who met 1987 ACR criteria for RA in 1999-2013 and a cohort of subjects without RA from the same area matched by age and sex. Index date for each non-RA subject corresponded to incidence date of the matching patient with RA. Activities of Daily Living (ADL) were recorded annually over the past 20 years based on patient provided information about performing six ADLs without assistance including feeding oneself, dressing, using the toilet, bathing, walking and housekeeping. FD was defined as having difficulty with ≥ 1 of the six ADLs. Analyses were performed using age-, sex- and disease duration adjusted logistic regression models with random subject effects to account for multiple measures per patient.

Results: Five hundred eighty-six patients with RA (mean age 55 years, 70% females, 374 (64%) RF/CCP positive) and 531 non-RA subjects (mean age 56, 70% females) have completed 7,446 questionnaires (4,301 RA and 3,145 non-RA) from 1/5/1999 to 1/5/2018 on or following their RA incidence/index date. The prevalence of FD was significantly higher in the RA vs non-RA subjects, starting at RA incidence/index date (26% in RA vs 11% in non-RA subjects, $p < 0.001$), with persistent excess in prevalence over the entire follow-up time. Patients with RA compared to the non-RA subjects had at least a 15%-excess in the proportion of FD at any given age up to the 8-9th decade of life. The prevalence of FD overall was similar in RF/CCP positive vs negative patients with RA ($p = 0.67$). However, there was a significant interaction between RF/CCP positivity and disease duration ($p = 0.027$; Figure), suggesting that the prevalence of FD over disease duration is increasing in patients with RF/CCP and declining in those negative for RF/CCP.

Conclusion: Patients with RA have a significantly higher prevalence of FD over RA disease duration and across the age-range compared to their non-RA counterparts. RF/CCP positive patients are disadvantaged with an increasing burden of FD over their RA disease duration, while RF/CCP negative patients experience decline in FD, suggesting that additional vigilance and measures may be needed in management of patients with positive RF/CCP to help improve their FD profile.

Mortality and Causes of Death in Patients with Inflammatory Arthritis in Hong Kong over 20 Years

Tommy Tsang Cheung, Simon Man Fung Tsoi, Bernard Man Yung Cheung and Chak Sing Lau, Medicine, The University of Hong Kong, Hong Kong, Hong Kong

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Epidemiology and Public Health Poster I: Rheumatoid Arthritis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with inflammatory arthritis have a higher mortality than the general population due to increased risks of cardiovascular diseases, infection and cancer. As the treatment of inflammatory arthritis and its associated complications has improved significantly over the past decades, many studies have demonstrated a better survival in patients with inflammatory arthritis. However, it is unknown if the survival of patients with inflammatory arthritis in Hong Kong has also improved. Therefore, the aim of this study was to determine the trend in the mortality and the causes of death of different inflammatory arthritis in Hong Kong.

Methods: The Hong Kong Hospital Authority is the only public healthcare service provider in Hong Kong. The Clinical Data Analysis and Report System (CDARS) captures diagnosis, medication prescriptions, laboratory parameters for all patients. Patients with a diagnosis of rheumatoid arthritis, psoriatic arthritis or ankylosing spondylitis from 1997 to 2016 were included in this analysis.

Patient demographics and causes of death were obtained. Results were analysed by R version 3.4.3 with package “epitools” version 0.5-10. Mortality rate and standardised mortality ratio (SMR) for all-cause mortality and cause-specific mortality were estimated every 5 years. Age and gender adjustment was conducted using census statistics provided by the Census and Statistics Department. A linear poisson regression analysis was performed to evaluate the change in SMR over time.

Results: 15445, 2165 and 4488 patients with RA, PsA and AS were included in this analysis respectively. Characteristics of the patients were summarised in Table 1. The SMR of RA, PsA and AS dropped significantly over 20 years (Table 2). There was a significant decrease in cardiovascular death in patients with RA and AS (Table 3; $p < 0.001$). However, infection remained the leading cause of death and the mortality due to infection increased over the past 20 years.

Conclusion: The mortality in patients with inflammatory arthritis in Hong Kong decreased significantly over the past 20 years.

Table 1. Characteristics of patients included in this study (cut-off date: 31/12/2016)

	RA	PsA	AS
n	15445	2165	4488
Age	61.9±0.1	55.86±0.27	49.6±0.22
Male (%)	2952 (19.1%)	1221 (56.4%)	3580 (79.8%)
Female (%)	12493 (80.9%)	944 (43.6%)	908 (20.2%)
Male:Female ratio	1:4.23	1.29:1	3.94:1

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Epidemiology and Public Health Poster I: Rheumatoid Arthritis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is a known risk factor for the development of cardiovascular disease (CVD). However, the influence of RA on the prognosis after initial diagnosis and treatment for coronary artery disease (CAD) is unknown.

Objective: To examine the risk of major cardiovascular events (MACE) and all-cause mortality among RA and non-RA patients after referral to cardiac computed tomography (CCT) due to symptoms suggestive of CAD.

Methods: This was a follow-up study, using data from the Western Denmark Heart Registry [1] covering all diagnostic procedures in a catchment area with approximately 3.3 mill. inhabitants. The register provides information on clinical variables such as smoking, severity of stenosis and calcium score. Information on RA diagnosis and co-variables were identified through individual-level linkage of nationwide administrative registers. Outcome measures were *MACE alone* and a combined outcome (CO) including *MACE*, coronary artery bypass grafting, percutaneous coronary intervention, and *all-cause mortality*. Median time until events or censoring were 3.5 years (min/max: 0.0: 9.2).

In the studied region, RA-flares are controlled through escalation of disease modifying drugs and intra-articular or intramuscular glucocorticoid injections (GCI). Hence, the number of times a patient had received GCIs 3 years prior to the CCT were used as a surrogate marker of disease activity. Analyses were performed for overall RA and the serological subtypes: 'seropositive RA'(ICD-10: M05) and 'other RA'(ICD-10: M06).

Cox proportional hazard models were used to examine the association between RA and non-RA patients and the outcomes.

Results: *We included 42,257 patients, and identified 358 (0.8%) patients with RA. The incidence rate for revascularization, not related to the initial diagnosis, in RA and non-RA patients was 3.4 (95% CI 1.3-9.0) vs. 3.7 (95% CI 3.7-4.1)/1000 person-years. For both the CO and MACE an increased risk was seen in RA compared to non-RA (CO: hazard ratio (HR): 1.35 (95% CI: 0.93-1.96), MACE: HR 1.94 (95% CI: 1.18-3.19)). The risk was higher among patients who had received GCI more than one time during 3 years prior to the CT (CO: HR: 1.80 (95% CI: 1.1-3.0), MACE: HR 3.02 (95% CI: 1.62-5.65)) and in patients with sero-positive RA (CO: HR: 1.42 (95% CI: 0.93-2.16), MACE: HR: 2.45 (95% CI: 1.47-4.08)) (Fig.1).*

Conclusion: *We found a strong association between RA and cardiovascular events in the period after the initial diagnosis and treatment in this cohort of patients with a-priori risk of CAD referred for cardiac CT. These findings support that RA per se, but in particular, sero-positivity and inflammation related to flares increase the risk of CVD and mortality.*

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Epidemiology and Public Health Poster I: Rheumatoid Arthritis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Disease remission is considered an achievable target in a significant proportion of patients with rheumatoid arthritis (RA). Nevertheless, diseases flares, that significantly contributes to damage progression and disability, remain unpredictable. Thus, factors able to potentially interfere on disease activity should be considered and assessed. The aim of our study is to evaluate the influence of particulate matter (PM) on disease activity and general health (GH) in patients with RA.

Methods: All consecutive patients with RA (ACR/EULAR Criteria 2010) resident in Lombardy (Italy) were enrolled in this cross-sectional design study. In each patient Disease Activity Score on 28 joints (DAS28), Simple Disease Activity Index (SDAI) and General Health (GH) were assessed. Data on daily pollutants concentration levels (PM2.5 e PM10) were derived from the Local Environmental Protection Agency (ARPA Lombardia) website. Continuous variables are expressed as mean±SD. Categorical variables are presented as absolute numbers and frequencies. Multivariable linear regression models were used to test the associations between the daily PM10 and PM2.5 exposure and disease activity (DAS28, GH and SDAI). The variables, which were significant with simple regression analysis (p-

value <0.05), were considered for adjustment in the multivariate model. β coefficients were reported for 10 $\mu\text{g}/\text{m}^3$ increments of PM concentrations. All statistical analyses were performed using SAS 9.4 (SAS Institute, Cary, NC, USA).

Results: 235 patients were enrolled in the study (patients' characteristics: age at visit 57.5 ± 13.9 years, disease duration 16.1 ± 11.9 , female 77.87%, rheumatoid factor positivity 51.91%, anti-citrullinated protein antibody positivity 48.94%, radiographic damage 41.28%). Multivariable linear regression models were adjusted for radiographic damage (DAS28, SDAI and GH), disease duration (DAS28 and SDAI) and age (GH). Increases of PM2.5 and PM10 exposure (9 day before the visit) were significantly associated with worsening of DAS28, SDAI and GH (table 1).

Multivariable linear regression model

	PM exposure	β	SE	95% CI		p-value
DAS28	PM ₁₀ Day -9	0,1169	0,0524	0,0137	0,2201	0,0266
	PM2.5 Day -9	0,1402	0,0665	0,0092	0,2713	0,0361
SDAI	PM ₁₀ Day -9	0,9703	0,4418	0,0995	1,8412	0,0292
	PM2.5 Day -9	1,1988	0,5607	0,0935	2,3040	0,0337
GH	PM ₁₀ Day -9	2,0574	0,9346	0,2152	3,8997	0,0288
	PM2.5 Day -9	2,3624	1,1848	0,0270	4,6979	0,0474

Conclusion: In our cohort of RA patients, there was significant evidence of the harmful effect on RA activity related to PM2.5 and PM10 exposure. Nevertheless, the association between day-to-day PM changes and disease activity do not confirm causation. Further studied are required to evaluate the influence of air pollution on RA activity.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Epidemiology and Public Health Poster I: Rheumatoid Arthritis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Reported symptom onset and diagnosis debut in rheumatoid arthritis (RA) patients may be influenced by environmental factors, genetics and gene-environmental interactions, but also by cultural and socioeconomic differences. We have shown high burden of RA in younger women in our population surveys.^{1,2} We aimed to compare symptom onset and diagnosis debut in an Indian and a Dutch cohort.

Methods: METEOR, an international database capturing daily clinical practice, has registered RA patients using a comprehensive online case record form for over two decades. 3500 Indian patients were registered from 2007-2012. We randomly selected a retrospective, cross sectional sample of 500 subjects to contain 125 subjects in each of the four disease duration a-priori categories [0-2, 2-5, 5-10, >10 years]. Using similar methods, a Dutch cohort (500 out of 7899 patients, registered between 2000-2012) was selected. Between group differences were compared using Chi-square & Mann-Whitney tests, p-values <0.05 were considered statistically significant.

Results: 85% and 72.5% of patients in the Indian and Dutch cohort were women. The mean age (SD) at symptom onset and diagnosis debut was 39.8 (11.7) and 43.8 (12.1) years respectively in the Indian cohort; these were 52.7 (14.1) and 53.2 (13.9) years in the Dutch cohort (p <0.001). Figure 1 shows the proportion of patients at onset of symptoms as per age groups. Mean disease duration (years) at Meteor entry was not significantly different (Indian 7.4, Dutch 7.2). 33% Indian women and 11% Dutch women in the study data belonged to 16-40 years age group (p<0.05). Indian patients were more often active-severe. 84.2% and 65.2% Indian respectively were RF and ACPA positive: this was 65.1% and 64.4% in the Dutch cohort.

Conclusion: The earlier age at onset in the Indian compared to the Dutch cohort is strikingly significant and merits further research. It has several important implications which are not merely confined to socioeconomic and health care disparities in the study populations.

Acknowledgement: Sponsored by METEOR (The Netherlands) and Arthritis Research Care Foundation (Pune India).

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Epidemiology and Public Health Poster I: Rheumatoid Arthritis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Inflectra (infliximab) was the first biosimilar for inflammatory bowel disease and/or arthritis, approved by Health Canada on the belief that it is as safe and effective as its bio-originator Remicade. We assessed recent use of Inflectra versus Remicade (regardless of indication), within Canadian provincial publicly financed drug benefit programs.

Methods: We used aggregate claims data from the National Prescription Drug Utilization Information System (NPDUIS), for 2016. This contains public drug plans data from across Canada except Quebec. Aggregated data were obtained by province, sex, and age groups. We described patients for whom the public drug plan/program accepted at least part of 1 or more claims for Inflectra or Remicade, either towards a deductible (if applicable) or payment. We also calculated total number of claims and recorded amounts paid by the public drug plan (drug cost and pharmacy fees).

Results: In 2016, there were 218 beneficiaries with at least one Inflectra dispensation,, with a total of 856 claims approved. During this time, at least 12,912 individuals were dispensed Remicade, with a total of 80,862 approved claims. No other infliximab biosimilar was dispensed under public drug plans in 2016. Stratified information (sex, age group, province financing the claim) was available for 184 Inflectra and 12,904 Remicade users. Most patients were dispensed Inflectra in Ontario (146 /186, 79%) or in British Columbia (38/186, 21%). Excluding Quebec, other provinces with Inflectra dispensation were Alberta, Newfoundland and Labrador, New Brunswick, Saskatchewan, and Manitoba. There was a significantly higher proportion of seniors receiving Inflectra (71/184, 38%) versus Remicade (2362/12912, 18%) and more females (see Table).

The estimated total cost recorded according to public plans for Remicade in Canada (exclusive of Quebec) in 2016 was \$361,502,867 Canadian, representing an average cost per claim of Remicade of \$4,471 (versus Inflectra, \$1,934). If half of the Remicade claims had been Inflectra instead, the cost difference would have been over \$102.5 million. This does not consider undisclosed rebates/discounts which may have been in place.

The findings are limited in terms of our inability to stratify by indication. We were unable to establish if subjects were primarily new-users. No analyses of drug persistence (which may reflect safety and effectiveness) were done.

Conclusion: In 2016, there were 12,912 Remicade users and 218 Inflectra users in Canada, exclusive of Quebec; Remicade's recorded price tag was over \$361.5 million, not including rebates/discounts. Although cost savings of using biosimilars are potentially large, our estimates do not account for other considerations, such as safety and effectiveness, and rebates/discounts offered by drug companies.

Table

	Inflectra	Remicade
Number of beneficiaries	218	12,912
Number of accepted claims ^e	856	80,862
Program paid amount	\$1,655,245	\$361,502,867
Cost per claim	\$1,934	\$4,471

¹Division of Rheumatology, Department of Internal Medicine, Seoul National University Bundang Hospital, Gyeonggi-do, Korea, Republic of (South), ²Department of Internal Medicine, Chungbuk National University Hospital, Chungcheongbuk-do, Korea, Republic of (South), ³Seoul National University College of Medicine, Seoul, Korea, Republic of (South)

SESSION INFORMATION

Session Date: Sunday, October 21, 2018
Session Title: Epidemiology and Public Health Poster I: Rheumatoid Arthritis
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Increased prevalence of comorbidities in patients with rheumatoid arthritis (RA) compared to general population has been noted in several previous study. This study aims to systematically examine the effect of SES on the comorbidity distribution among Korean patients with RA.

Methods: A total of 1,088 (weighted n = 612,303) RA patients aged ≥ 19 years were selected from 2007-2015 Korea National Health and Nutrition Examination Survey which is a nation-wide survey annually conducted using questionnaires and medical examinations. Three components of SES including household equivalence income (below versus above median level), education (below versus above high school education), residence (rural versus urban) were stratified into low and high. The prevalence of the following comorbidities was compared between low and high group in terms of each component: stroke, myocardial infarction (MI), angina, hypertension, dyslipidemia (hypercholesterolemia and/or hypertriglyceridemia), diabetes, obesity, thyroid disease, osteoporosis, osteoarthritis, stress, depression, and suicide ideation.

Results: When stratified into low and high group of each SES component, patients of low income or low education were older and more comorbid than those of high income or high education, showing higher prevalence of stroke, MI, angina, hypertension, dyslipidemia, diabetes, osteoporosis, depression, and suicide ideation (all p-value < 0.05). To adjust confounding by age, we further stratified RA patients according to the median age value of 63 years. In the aged under the 63 years, low income was associated with depression, hypertension, diabetes, osteoarthritis, suicide ideation, obesity and hypertriglyceridemia (Figure 1) while the prevalence of these comorbidities was comparable in the aged above the 63 years. Low education showed a similar trend in the aged under the 63 years (Figure 2). In the aged above the 63 years,

Figure 1. Association between income level and comorbidities in RA patients

Figure 2. Association between education level and comorbidities in RA patients

low education was associated only with suicide ideation (p < 0.05).

Conclusion: Among Korean RA patients aged under the 63 years, higher prevalence of comorbidities was found in association with low income and/or low education. Recognizing the different prevalence of comorbidities by SES would be essential to provide optimal patient care and to improve the health outcome in patients with RA.

Risk of Serious Infection Associated with TNF Inhibitor Versus Triple Therapy in Rheumatoid Arthritis Patients

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Epidemiology and Public Health Poster I: Rheumatoid Arthritis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Treatment with tumor necrosis factor inhibitor (TNFi) with methotrexate or triple therapy (MTX, sulfasalazine, and sulfasalazine) is considered in patients with rheumatoid arthritis (RA) who have inadequate response to methotrexate (MTX) alone. One of the safety concerns of both these treatment strategies is serious infection. We compared the rate of serious infection among two treatment groups.

Methods: We used Truven Market Scan data (2003-2014) to conduct an observational cohort study among RA patients ≥ 18 years old with MTX prescription. We identified initiators of triple therapy when both HCQ and SSZ were newly added to MTX. TNFi initiators were identified when they newly started a TNFi in addition to MTX treatment. Index date was the first dispensing date of the last drug to complete triple therapy or a TNFi. We excluded patients with malignancy, dialysis, HIV, nursing home stay or hospitalized infection, and any prior use of study drugs except MTX during a 180-day baseline period before the index date. Outcome was defined as time to hospitalized bacterial or opportunistic infections based on inpatient diagnosis codes. In as-treated analysis, patients were followed from the day after index date until first of the following events: outcome occurrence, disenrollment, death, or drug switching or discontinuation. In an intention-to-treat (ITT) follow-up approach, we also followed patients until 180 days and 365 days after the index date without censoring on drug switching or discontinuation. For confounding adjustment, we used propensity score fine stratification weights that accounted for demographics, comorbidities, medication use, and healthcare utilization factors. A weighted Cox-proportional hazards model estimated the hazard ratio (HR) and 95% confidence interval (CI).

Results: We identified 45,305 TNFi initiators and 1,388 triple therapy initiators. Mean age was 53 (± 12) years in both groups. Patients in two treatment groups had similar baseline characteristics except that the TNFi group had more psoriasis and inflammatory bowel disease, underlying use of bisphosphonate, proton pump inhibitors, and more use of healthcare system. Two treatment groups had a similar incidence rate of outcome in as treated analysis (adjusted HR = 1.06, 95% CI 1.79-1.41). ITT analyses also showed consistent results (**Table**).

Conclusion: Among RA patients with inadequate response to MTX, the risk of serious infection was similar after starting a TNFi versus triple therapy adjusted for baseline confounding.

Table. Weighted incidence rates and HR of serious infections requiring hospitalization among patients who received combination therapy versus triple therapy

	TNFi + MTX					Triple therapy (reference group)			
	No. of patients	No. of outcome	Person-year	Incidence rate per 100 person-years (95% CI)	Weighted HR (95% CI)	No. of patients	No. of outcome	Person-year	Incidence rate per 100 person-years (95% CI)
As treated	45,305	2,124	72,246	2.93 (2.81, 3.06)	1.06 (0.79, 1.41)	1,388	47	1,671	2.81 (2.11, 3.74)
180 days ITT	45,305	686	20,449	3.35 (3.11, 3.61)	0.89 (0.59, 1.35)	1,388	23	611	3.76 (2.50, 5.66)
365 days ITT	45,305	1,165	37,635	3.09 (2.92, 3.27)	0.86 (0.63, 1.18)	1,388	40	1,106	3.62 (2.65, 4.93)

Impact of Rheumatoid Arthritis on Influenza-Related Complications: A Population Based Cohort Study

Preethi Gondi Kamma Venkatesh¹ and Xiang Zhu², ¹Internal Medicine, Florida Hospital, Orlando, FL, ²Florida Hospital, Orlando, FL

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Epidemiology and Public Health Poster I: Rheumatoid Arthritis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid Arthritis (RA) is associated with increased incidence of seasonal influenza and its complications. Population-based studies on outcomes are lacking. The aim of our study was to evaluate the impact of RA on in-hospital mortality, length of stay, and hospitalization costs in patients with influenza.

Methods: We examined National Inpatient Sample data from 2000-2012. We performed a case-control study in which we included all discharges with influenza as primary diagnosis and RA (ICD 9 coded as 714.xx) as secondary diagnosis as cases (discharges with any comorbidities were excluded); while those with influenza as primary diagnosis and no comorbidities including RA as controls. The main outcomes included in-hospital mortality, length of stay, and hospitalization costs to study the impact of RA on influenza patients.

Results: A total of 1097 discharges had influenza as the primary diagnosis for admission. A total of 543 patients had influenza with RA (study group), and 554 had influenza without RA (control group). (Table 1) Both the groups who had any comorbidities listed as a secondary diagnosis were excluded to exclude the impact of other comorbidities on outcomes. There was no difference in mortality in patients with influenza with or without RA (0.5% vs 0.2%, $P = .31$). However, patients with influenza and RA had increased length of hospital stay (3.8 vs 2.1 days, $P < .001$), and higher hospitalization costs (\$15,826 vs \$5,953, $P < .001$). On multivariate analysis, RA was independently associated with increased hospital stay and higher hospitalization costs; but not mortality.

Conclusion: RA appears to be associated with increased length of stay and hospitalization costs in patients with influenza.

Factor	Discharges of Influenza only(N=554)	Discharges of Influenza +RA(N=543)	P value
Age	44.5 (20.3)	67.6 (14.9)	< 0.001
Gender	241 (43.5)	125 (23.0)	<0.001
Male (%)			
Female (%)	313 (56.5)	418 (77.0)	
Length of stay (days)	2.1 (1.6)	3.8 (2.8)	<0.001
Total Charges (\$)	6263.2 (5952.8)	14137 (15826)	<0.001
Mortality (%)	1 (0.18)	3 (0.55)	0.306

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Epidemiology and Public Health Poster I: Rheumatoid Arthritis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Biosimilars intend to be as effective and safe as the originator product and would increase patients' access to biological agents. The decision for switching to a biosimilar is not always promoted by the physicians and, although there is emerging evidence from randomized controlled trials concerning this issue, data from real world clinical practice is still lacking.

Our objective was to learn about physicians' and patients' perspectives concerning biosimilars in the context of non-medical switch.

Methods: A standardized questionnaire was conducted aimed at physicians' perspectives and to patients who experienced a switch to a biosimilar.

Results: The survey was applied to 51 physicians (39% male), both residents and specialists of rheumatology (public and private practice). All of them considered themselves to be at least reasonably informed about the concept of biosimilar and more than half (n=31; 61%) were reasonably familiar with its prescription. Among the factors influencing biosimilars prescription, efficacy was considered the most relevant (reduction of symptoms n=16, 31%; disease progression n=9, 18%), followed by safety (n=16, 31%) and cost (n=12; 24%). Even though the large majority believes that prescription of these therapies will increase in the near future (especially in RA, PsA and AS), they would prescribe them as first, second or third line therapy in only 22, 24 and 29%, respectively. Almost half the physicians (n=25; 49%) had only a mild to moderate degree of confidence in the switching process. Globally, economic reasons were assumed to have determined the switching process (costs n=17, 33%; savings n=16, 31%).

Regarding the 22 patients who answered the telephone survey, most of them (n=15; 68.2%) claimed to have been at least 'reasonably' informed about biosimilars. Several health care providers were involved in this process. The patients' main worries about switching were safety (n=11; 50%) and efficacy (n=6; 27.3%). Most patients were at least moderately confident about biosimilars' efficacy and safety (50% and 36.4%, respectively). Nearly half of the patients (n=10) accepted the switch without apprehension while the other half (n=11) believed they had no other choice, and 50% (n=11) considered that the switch was made by economic reasons. Globally, most patients didn't change the degree of satisfaction after switching to the biosimilar.

Conclusion: In this case-study, physicians seem to still be cautious about biosimilar prescription, worrying particularly about their efficacy. On the other hand, patients do not seem to have changed their satisfaction with biological agents (before and after the switch), yet still worry mostly about the safety of biosimilars. Economic issues were the main reason to justify the switching process in both physicians' and patients' perspectives. However, switching should remain a case-by-case clinical decision made primarily by the physician and patient on an individual basis.

Distal Interphalangeal Joint Involvement and Its Association with Disease Activity in Rheumatoid Arthritis (RA): Analysis Based on a Nationwide RA Database in Japan

Tetsuji Sawada¹, Susumu Nishiyama², Mayu Tago³, Koichiro Tahara³, Eri Kato¹, Hiroaki Mori³, Haeru Hayashi³, Toshihiro Matsui⁴, Jinju Nishino⁵ and Shigeto Tohma⁶, ¹Rheumatology, Tokyo Medical University, Shinjuku Tokyo, Japan, ²Rheumatic Disease Center, Kurashiki Medical Center, Okayama, Japan, ³Rheumatology, Tokyo Medical University, Tokyo, Japan, ⁴National Hospital Organization Sagami Hospital, Clinical Research Center for Allergy and Rheumatology, Kanagawa, Japan, ⁵Department of Orthopaedic Surgery, Faculty of Medicine, The University of Tokyo, Tokyo, Japan, ⁶National Hospital Organization Tokyo National Hospital, Kiyose, Japan

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Epidemiology and Public Health Poster I: Rheumatoid Arthritis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Distal interphalangeal (DIP) joint arthropathy is characteristic of both psoriatic arthritis and osteoarthritis, but it has long been pointed out that DIP joints can also be affected in rheumatoid arthritis (RA) since the report by McCarty et al. (Arthritis Rheum 9(2):325,1966). However, the clinical significance of DIP joint involvement in RA has yet to be elucidated in detail. The aim of this study was to examine the frequency of DIP joint involvement in RA, and its relationship with RA disease activity, using the National Database of Rheumatic Diseases in Japan (*NinJa*).

Methods: We used data of patients with adult-onset RA registered in *NinJa* in 2016 whose affected joint distribution data were available (n=12413). The relationship between DIP joint involvement and age, sex, age at RA onset, disease duration, stage, class, pain visual analog scale (VAS) score, tender joint count (TJC), swollen joint count (SJC), disease activity score in 28 joints-C-reactive protein level (DAS28-CRP), modified Health Assessment Questionnaire (mHAQ), rheumatoid factor, and anti-cyclic citrullinated peptide (anti-CCP) antibody were analyzed.

Results: The number of RA patients who presented with DIP joint involvement (tenderness or swelling in the second to fourth DIP joints) was 257 (2.0%). The number (mean \pm standard deviation) of affected DIP joints was 2.6 ± 2.3 with median of 1. DIP involvement was not related to age, age at RA onset, disease duration, stage III-IV, class 3-4, mHAQ, presence of rheumatoid factor or that of anti-CCP antibody. On the other hand, DIP involvement was significantly more frequent in women than in men (91.0% versus 80.1%, $p < 0.01$). Furthermore, pain VAS, TJC, SJC, and DAS28-CRP were significantly higher in RA patients with DIP involvement than in those without it, indicating the association of DIP involvement with high RA disease activity. Categorizing RA disease activity based on DAS28-CRP scores also revealed that DIP involvement was significantly associated with higher frequency of moderate and high disease activity and with lower frequency of remission status. Regarding the involvement of other joints in the hand, the number of affected DIP joints was significantly correlated with those of the proximal interphalangeal (PIP) and metacarpophalangeal (MCP) joints with correlation coefficients of 0.24 and 0.14, respectively ($p < 0.01$).

Conclusion: We have demonstrated that DIP involvement was significantly associated with high disease activity in RA. It would thus be necessary to pay more attention to DIP joint involvement, albeit being observed infrequently, when evaluating disease activity in RA patients.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Epidemiology and Public Health Poster I: Rheumatoid Arthritis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoidarthritis (RA) is an autoimmune disease with a complex etiology. Infections are viewed as environmental triggers of RA.

Different viral exposures have been implicated in the etiology of RA via several mechanisms of immune activation, such as molecular mimicry. The purpose of this systematic review was to summarize the evidence relating to the association between putative viral exposures and RA.

Methods: A systematic literature search was conducted using MEDLINE-OVID, EMBASE-OVID, PUBMED and Cochrane library databases. Articles were included if they were case-controls, cross-sectional or cohort studies and were published in English.

Results: Of 6724 citations, 78 studies were selected for review, 48 were meta-analysed (Figure 1). Studies had poor quality. Based on the IgG antibodies and viral DNA, the odds of parvovirus B19 (PBV19) infection were increased in RA patients compared to controls (odds ratio (OR) (95%CI) = 1.77 (1.11; 2.80), $p=0.02$, OR (95% CI) =3.53 (1.00; 12.53), $p=0.05$ for PVB19 IgG and DNA, respectively) (Figure 2). For Epstein-Barr virus (EBV), patients with RA had not significant OR of anti-Epstein-Barrnuclear antigen (EBNA) (N=17 studies, OR (95% CI) = 1.05 (0.79; 1.39), $p=0.75$), but significant OR of anti-viral capsid antigen (VCA) (OR (95% CI) = 1.5(1.07; 2.10), $p=0.02$) and anti-early antigen (EA) (OR (95% CI) = 2.74 (1.27;5.94), $p=0.01$) (Figure 3). Cytomegalovirus (CMV) was not associated with RA (OR(95% CI) = 1.24 (0.78; 1.95), $p=0.36$). Chronic hepatitis B (HBV) was not associated with RA in 5 case-control (OR (95% CI) = 1.37 (0.83; 2.25, $p=0.22$) and 1 cohort studies (HR 1.09 (0.74, 1.63), $p>0.05$). Chronic hepatitis C (HCV) was associated with increased risk of RA in 7 case-control studies (OR (95% CI)= 2.82 (1.35; 5.90, $p=0.006$) and 1 cohort study (HR 2.03 (1.27, 3.22), $p<0.01$). There is a risk of persistent arthritis after Chikungunya fever (OR(95% CI) = 90 (15.2; 134.3)).

Conclusion: Studies about the risk of RA after viral exposures suffer from inconsistent methodological quality. There is a risk of RA after PBV19 infection and possibly HCV but not EBV or HBV. Chikungunya virus is associated with the persistent inflammatory arthritis.

Session Date: Sunday, October 21, 2018

Session Title: Epidemiology and Public Health Poster I: Rheumatoid Arthritis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The impact of concomitant comorbidities on RA outcomes is of high interest, and some evidence suggests that patients (pts) with RA and diabetes may have worse clinical outcomes and adverse events compared with pts with RA without diabetes. Therefore, we evaluated the effects of diabetes on change in HAQ score and infection in pts with RA, comparing those with diabetes to those without diabetes.

Methods: Using the ACR's Rheumatology Informatics System for Effectiveness (RISE) electronic health record-based registry, we identified pts with RA who had ≥ 1 rheumatologist visit with a valid HAQ measurement (index visit) in 2016. Eligible pts had ≥ 1 previous visit and a subsequent outcome visit with any HAQ measured at 12 months (± 3 months) after the index visit. Prior to the index visit, diabetes was identified based on ≥ 1 ICD-9 or ICD-10 diagnosis code, any medication for diabetes or elevated diabetes biomarkers (hemoglobin A_{1c}, random glucose). Mean HAQ change between the index and outcome visit was calculated based on HAQ categories at the index visit (0–0.5, 0.5–1 and 1–3). Generalized linear models were used to calculate the adjusted mean HAQ change controlling for potential confounders (e.g., demographics, conventional DMARDs, biologic DMARDs). First infection during follow-up was defined by ICD-9 or ICD-10 diagnosis codes or anti-infective medications. We calculated the incidence rate (IR) of

infections among pts with and without diabetes and compared hazard ratios (HR) using Cox regression adjusting for potential confounders.

Results: Among 457,950 pts in the 2016 RISE registry, there were 3897 pts with RA with diabetes and 18,689 without diabetes in the final cohort. Overall, the mean HAQ change between index and outcome visit was 0.03 in pts with diabetes and 0.002 in pts without diabetes ($p<0.01$). After stratifying on baseline HAQ and comparing with pts without diabetes, pts with diabetes and RA worsened more and improved less, depending on their baseline HAQ (Table 1). Among those with diabetes, we identified 935 infections, yielding an IR of 27.9 (95% CI: 26.2, 29.8) per 100 person years. For pts without diabetes, we identified 3989 infections with an IR of 24.4 (95% CI: 23.7, 25.2). After adjusting for potential confounders, the HR of infection among diabetes pts (HR: 1.09; 95% CI: 0.94, 1.26) was not significantly different to pts without diabetes.

Conclusion: Among pts with RA, those with diabetes had greater worsening, or less improvement, in their functional status. These results suggest additional interventions may be needed for pts with RA and diabetes to optimize this and other comorbidities.

Risk of Venous Thrombotic Events in Rheumatoid Arthritis Patients Initiating Tofacitinib or Adalimumab

Huifeng Yun, Fenglong Xie, Lang Chen and Jeffrey R. Curtis, University of Alabama at Birmingham, Birmingham, AL

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Epidemiology and Public Health Poster I: Rheumatoid Arthritis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Recent concern has been raised for a risk for venous thromboembolism (VTE) associated with janus kinase inhibitors among patients with RA who are already known to bear increased risk for VTE based on their underlying conditions. We evaluated the risk of VTE, defined as the composite of pulmonary embolism (PE) or deep vein thrombosis (DVT) among RA patients initiating tofacitinib (Tofa) compared to patients initiating adalimumab (ADA).

Methods: Using 2010-2015 US Market scan claims data, we conducted a retrospective cohort study among RA patients (identified based on ≥ 1 ICD-9 RA diagnosis codes initiating Tofa or ADA). Patients were not allowed to have used Tofa or ADA prior to the date of initiation (index date) using all available data. Eligible patients must have had ≥ 12 months (baseline) prior health plan enrollment. Patients with history of other autoimmune disease, advanced kidney or liver disease, malignancy, HIV, hepatitis B/C, or pregnancy during baseline were excluded. Follow-up started from the index date and ended at the earliest date of: VTE, death, loss of medical/pharmacy coverage, switch to other biologic, or drug discontinuation (with a 90 day extension). PE was identified using inpatient diagnosis codes plus outpatient anti-coagulant treatment within 0-60 days; DVT was identified using inpatient/outpatient diagnosis codes and medication use as above. We calculated incidence rates per 100 patient-years of VTE for each drug and compared VTE risks during follow-up using

Cox regression, adjusting for potential confounders including age, gender, history of VTE, comorbidities and concurrent medications. Several sensitivity analyses were conducted using different exclusion criteria and outcome definitions (such as using only inpatient diagnosis and anti-coagulant use within 60 days to define DVT occurrence).

Results: We identified 6,022 ADA initiators (4,798 PY) and 2,155 for Tofa (1,523 PY). During median (IQR) follow up of 0.5 (0.3, 1.0) years, we identified 20 VTE events among tofa users with an IR of 1.31 (95% CI: 0.80-2.03) and 40 VTE events among ADA users with an IR of 0.83 (95% CI: 0.60-1.14). After adjustment for potential cofounders, the hazard ratio of VTE for Tofa users was 1.07 (95% CI: 0.54-2.14) referent to ADA users. Sensitivity analyses using different exclusion criteria and outcome definitions had a large impact on the number of events and absolute incidence rates, but minimal effect on the adjusted hazard ratios comparing the two therapies. For an example, using an outcome definition of inpatient VTE events with anti-coagulation within 60 days, the IR rate associated with tofacitinib was 0.65/100PY (95% CI: 0.31, 1.20) with similar adjusted HR to the main analysis (1.02, 95% CI 0.40-2.62).

Conclusion: In this comparison of tofacitinib vs. adalimumab based on 60 VTE events, we observed comparable risk between these two RA treatments.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Epidemiology and Public Health Poster I: Rheumatoid Arthritis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Over the past two decades, major advances have been made in the treatment of RA, allowing disease remission to become an achievable goal. Although studies have looked at the trends in hospitalization for RA, contemporary data on the principal diagnoses that lead to hospitalizations and in-hospital mortality in RA are lacking. The objective of this study was to evaluate national trends in hospitalizations, underlying causes, and in-hospital mortality in RA over the past 15 years.

Methods: We used the National Inpatient Sample (NIS) from 2000-2014 to study the temporal trends in RA hospitalizations in the US. All hospitalized adults with RA (ICD9-CM 714.0 and 714.2) were included. We examined trends over time using linear regression in SAS version 9.3.

Results: Between 2000 and 2014, there were 183,983 hospitalizations with a principal discharge diagnosis of RA. The annual rates of hospitalization for principal diagnosis of RA decreased from 76.5 admissions per 1 million adults in 2000 to 30 in 2014 ($P < 0.0001$ for trend), an admission rate reduction of 61%. Although overall annual hospitalization rates declined in the US as well in this time frame- from 14.5% to 12% (rate reduction of 16%) - the decline was not as significant as in RA. In-hospital mortality declined from 0.70% of all hospitalizations in 2000 to 0.41% in 2014 ($P < 0.0001$ for trend). The mean (\pm SD) age of hospitalized RA patients remained largely stable, 62.7 (\pm 30.7) in 2000 and 61.9 (\pm 32.3) years in 2014. When RA was listed as a non-primary diagnosis, the most frequent principal diagnoses for admission remained diseases of the circulatory system over the entire study period. However, the rates of hospitalization for RA patients for circulatory or respiratory system diseases significantly declined between 2000 and 2014, whereas hospitalization for infectious disease causes significantly increased (Figure 1). The most common principal diagnosis leading to in-hospital mortality changed from diseases of the respiratory system in 2000 to infectious and parasitic diseases in 2014 (Figure 2).

Conclusion: Both hospitalization rates and in-hospital mortality rates in U.S. patients with RA have declined significantly over the past 15 years. Diseases of the circulatory system continue to be the principal diagnosis associated with hospitalizations whereas infectious diseases account for the hospitalizations resulting in highest in-hospital mortality in RA in recent years.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Epidemiology and Public Health Poster I: Rheumatoid Arthritis

Figure 1. Meta-analyses' estimates of population-based studies (PBS) and randomized controlled trials (RCT) on rheumatoid arthritis (RA) and osteoarthritis (OA) for the proportion of elderly people, mean age, standard deviation of age, and the proportion of women. CI, confidence interval.

Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Elderly people (as commonly defined by an age of ≥ 65 years) and women have been reported to be underrepresented in clinical trials of various medical specialties from past to present. However, it has not yet been quantitatively assessed in rheumatology. Rheumatoid arthritis (RA) and osteoarthritis (OA) are two of the most common chronic rheumatic diseases, major contributors to global disability, and both tend to occur predominantly in the elderly and in women. We assessed whether randomized controlled trials (RCT) in RA and OA include adequate proportions of elderly people and women comparable to data from population-based studies including registries (PBS).

Methods: Our systematic review and meta-analysis was registered with PROSPERO (www.crd.york.ac.uk/prospero/; identifier CRD42018085409). Four systematic searches in MEDLINE (PubMed), extended by a hand search, yielded RCT in RA and OA on any intervention published in 2016 and 2017 and PBS in RA and OA published between 2013 and 2017. Random effects meta-analyses estimated the pooled proportion of elderly people (aged ≥ 65 years), the mean age and standard deviation (SD), and the proportion of women stratified by disease (RA and OA) and study type (RCT and PBS). The proportion of elderly people was estimated if it could not be abstracted from the original manuscript. Heterogeneity was evaluated with Cochran's Q and the I^2 -statistic. Finally, estimates of RCT and PBS were subsequently compared with two-sample Z-Tests.

Results: 265 RCT including over 50,000 participants and 53 PBS including over 520,000 participants were finally deemed eligible, and 260 RCT and 52 PBS were included in quantitative syntheses (i.e., meta-analyses). Heterogeneity was considerable in all meta-analyses with I^2 values between 96% and 100%. In both RA and OA, RCT included less elderly people (RA -0.18 [95% confidence interval -0.22 to -0.13] $p < 0.001$; OA -0.20 [-0.30 to -0.09] $p < 0.001$) and had lower mean ages (RA -5.2 years [-6.8 to -3.5] $p < 0.001$; OA -4.7 years [-7.5 to -2.0] $p = 0.001$) and SD (RA -1.9 years [-2.6 to -1.3] $p < 0.001$; OA -2.7 years [-4.2 to -1.2] $p < 0.001$) than did PBS (Figure 1). Five RCT analyzed the influence of age on outcome with conflicting results. Proportions of women were similar in RCT compared to PBS in both RA and OA (RA 0.02 [-0.01 to 0.05] $p = 0.156$; OA -0.04 [-0.10 to 0.03] $p = 0.269$).

Conclusion: While women are adequately represented in RA and OA RCT, the elderly are significantly underrepresented. This undermines the applicability of trials' results to the general population. It is urgent to improve the inclusion of elderly people in clinical trials and study age as a determinant for outcome.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Epidemiology and Public Health Poster I: Rheumatoid Arthritis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Safety concerns have been raised regarding the risk of serious infections (SI) with the different available biologic disease-modifying anti-rheumatic drugs (bDMARDs). Little is known about the risk of SI in patients with rheumatoid arthritis (RA) treated with non-tumor-necrosis-factor-inhibitors (non-TNFi) bDMARDs. In RA patients treated in routine care with the three non-TNFi, abatacept, rituximab and tocilizumab, we aimed to estimate 1) crude and adjusted incidence rates (IR) and 2) relative risks (RR) of SI during the first year since treatment start.

Methods: Collaborative observational cohort study conducted in Denmark (DK) and Sweden (SE) in parallel. RA patients in DANBIO (DK) and ARTIS/SRQ (SE) who started a non-TNFi treatment between 2010-2015 were included and their clinical characteristics at baseline were identified. Baseline comorbidities, reimbursed/dispensed antibiotic prescriptions and incident SI (hospitalization listing infection as major cause of admission) were identified through linkage to National Patient Registries and Prescription Drug Registries. IR of SI/100 patient years (adjusted for age and sex) and rate ratios (as estimates of RR, adjusted for additional covariates) during the first year since treatment start were assessed by Poisson regression.

Results: 8,987 treatment episodes were identified (abatacept 2,725/rituximab 3,363/tocilizumab 2,899). Differences in baseline characteristics between the three drugs were observed (Table). During the first year since treatment start, 456 SI were identified. Age/sex-adjusted IRs for SI were numerically different across treatments in each country (abatacept/rituximab/tocilizumab for SE 6.0/6.4/4.7 and for DK 7.1/8.1/6.1, respectively), but the confidence intervals (CI) were wide. Differences in the 1-year adjusted between-drug comparisons (=RR) were observed, but with 1 included in the CIs (Table).

Table Baseline characteristics, IR and RR of RA patients starting non-TNFi stratified by drug and country

Variable	ABA, N=2725		RTX, N=3363		TCZ, N=2899	
Country	DK	SE	DK	SE	DK	SE
Treatment episodes, n	830	1895	718	2645	1098	1801

Abstract Number: 228

Widespread Chronic Use of Proton-Pump Inhibitors and Potential for Drug-Drug Interactions in Rheumatoid Arthritis and Lupus Patients

Daniel Keebler¹, Nicholas Jones¹ and Matthew McEnany², ¹Genentech, Inc., South San Francisco, CA, ²Genesis Research, Hoboken, NJ

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Epidemiology and Public Health Poster I: Rheumatoid Arthritis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Poor control of rheumatoid arthritis (RA) and systemic lupus erythematosus (SLE) can lead to the use of corticosteroids and non-steroidal anti-inflammatories (NSAIDs), which in turn can affect patients' gastric mucosa and contribute to gastroesophageal reflux disease (GERD). GERD may be treated with acid-reducing agents including proton pump inhibitors (PPIs); PPIs are known to interact with a variety of drugs, potentially including investigational therapies in clinical trials. The prevalence of chronic PPI use in RA and SLE patients is not well-known, and therefore the potential for widespread drug-drug interactions in these patients is not well-understood. A better understanding of the details of concomitant medication use in these patient populations could guide more effective therapies in the future. We investigated the prevalence and type of chronic PPI use in RA and SLE populations, with the aim of helping clinicians and investigators to make appropriate treatment decisions, and to highlight the importance of PPI polypharmacy in clinical trial design.

Methods: A retrospective analysis of medication use in RA and SLE patients from 2012-2015 was done using Truven MarketScan® Claims Databases. Algorithms from the literature were used to identify RA and lupus cases, and to stratify by disease severity/line of treatment; these were pressure-tested using sensitivity analyses. Omnibus tests for between-strata differences in PPI use according to disease severity/line of treatment were carried out, followed by pairwise comparisons (n=15 for RA; n=3 for lupus) using Fisher's exact test correction for multiple comparisons via false discovery rate (FDR).

Results: Roughly one-third of RA and lupus patients in a large claims database were chronic users of PPIs. For SLE patients, this proportion increased with our measure of disease severity. For RA patients, higher use was observed in TNF-IR and BIO-IR patients. Following significant results from our omnibus tests and FDR correction of pairwise comparisons, all but the following four remained significant for RA: csDMARD vs. bDMARD/JAKi; TNF-IR vs. no treatment; TNF-IR vs. multiple treatment; and BIO-IR vs. multiple treatment. For lupus, mild vs. moderate and mild vs. severe comparisons remained significant. Results are given in Table 1.

Conclusion: Chronic use of PPIs is widespread among RA and lupus patients in the Market Scan database. Because PPIs may interact with a number of other medications, providers who treat RA and lupus patients should take care to assess concomitant medication use in these patients, and researchers designing clinical trials should carefully assess the prevalence of PPI use in comparator versus treatment arms to ensure that results are not unduly influenced by PPI use. In each case, attention should be paid to the particular type of PPI used, as pharmacokinetic characteristics of each PPI vary.

Table 1. Chronic PPI Use Among RA and SLE Patients.

	Chronic PPI use (n, %)
RA	
csDMARD	14,056 (34)
bDMARD/JAKi	8,838 (34)
TNF-IR	304 (40)
BIO-IR	268 (50)
No treatment	3,244 (37)
Multiple treatments	120 (44)

Lupus

Mild (n=1,436)	427 (30)
Moderate (n=782)	334 (43)
Severe (n=6)	5 (83)

Disability Status, Mortality, and Leading Causes of Death in Seropositive Rheumatoid Arthritis Patients: A Population-Based Study in Korea

In Ah Choi¹, Jeong Seok Lee^{2,3} and Eun Young Lee², ¹Division of Rheumatology, Department of Internal Medicine, Chungbuk National University Hospital, Cheongju, Korea, Republic of (South), ²Division of Rheumatology, Department of Internal Medicine, Seoul National University Hospital, Seoul, Korea, Republic of (South), ³Graduate School of Medical Science and Engineering, Korea Advanced Institute of Science and Technology, Daejeon, Korea, Republic of (South)

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Epidemiology and Public Health Poster I: Rheumatoid Arthritis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is a chronic inflammatory disease that leads to functional disability and premature mortality. We aimed to identify the status of disability and mortality in patients newly diagnosed with seropositive RA who were followed up for up to 10 years, as compared with the general population in Korea.

Methods: We conducted a nationwide population-based study using a National Health Insurance Service-National Sample Cohort of a Korean population consisting of 1 million individuals who submitted medical care claims between 2002 and 2013. A RA diagnosis was defined as the diagnostic code for seropositive RA (*International Classification of Diseases* code M05) with the prescription of any disease-modifying anti-rheumatic drug (DMARD).

Results: The analysis included 1655 incident seropositive RA patients and 8275 non-RA controls, matched by age, sex, and income. In RA patients, the most commonly used DMARD was hydroxychloroquine (n=1180, 71.30%), followed by methotrexate (n=1150, 69.49%), leflunomide (n=434, 26.22%), sulfasalazine (n=598, 36.13%), and bucillamine (n=269, 16.25%). The most commonly used biologic DMARD was adalimumab (n=42, 2.54%), followed by etanercept (n=29, 1.75%), infliximab (n=14, 0.85%), and rituximab (n=8, 0.48%).

The disability rate in the first 10 years of the disease increased in RA patients compared with non-RA controls (odds ratio [OR] 2.27, 95% confidence interval [CI] 1.75–2.93, $p<0.0001$). The physical disability rate significantly increased (OR 3.81, 95% CI 2.80–5.18, $p<0.0001$). During the follow-up period, 88 RA patients (0.05%) and 200 non-RA controls (0.02%) developed disability regardless of cause and severity. Of these, 73 and 99 had physical disabilities (82.95% and 49.50% of all disabilities, respectively). The mortality rate in the first 10 years of the disease also significantly increased in the RA group compared with the non-RA controls (OR 1.33, 95% CI 1.05–1.69, $p=0.02$), especially in the death caused by infection (OR 4.39, 95% CI 1.59–12.12, $p<0.01$). During the follow-up period, 88 RA patients (0.05%) and 335 non-RA controls (0.04%) died. The main causes of death in the first 10 years of RA were malignancy (19.32%), cardiovascular disease (15.90%), RA itself (11.36%), and infection (7.95%). In the non-RA control group, the main causes of death were malignancy (36.41%), cardiovascular disease (21.50%), and respiratory disease (7.16%).

Conclusion: Seropositive RA patients had higher mortality and disability than the non-RA population in the first 10 years of the disease. Further study about the determinants of disability and mortality is needed.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Epidemiology and Public Health Poster I: Rheumatoid Arthritis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Inflammation seems to play a central role in the development of atherosclerosis and inflammatory diseases seem to promote progression of coronary artery disease (CAD). Rheumatoid arthritis (RA) is associated with increased mortality, and evidence exists of a strong association between RA and premature cardiac events. However, knowledge of the severity and pattern of coronary artery calcifications in RA patients is still sparse. The aim of this study was to examine the prevalence and severity of CAD in RA patients from a large-scale cohort with chest pain referred for CAD rule out.

Methods: This was a cross sectional study in 39,534 patients from the Western Denmark Heart Registry. For each individual, data included cardiac CTs (CCT) with a registration of up to 40 variables including level of stenosis and calcification. RA patients were identified through linkage with the Danish National Patient Registry. All analyses were performed for overall RA and the serological subtypes: 'sero-positive RA' and 'other RA'. In the studied region, RA-flares are controlled through escalation of disease modifying drugs and intra-articular or intramuscular glucocorticoid injections (GCI). The number of times a patient had received GCIs 3 years prior to the CCT was used as a surrogate marker for disease activity. The prevalence of having a coronary artery calcium score (CACS) > 0 among RA and non-RA patients was assessed by estimating odds ratios (OR) with [95% CI], adjusted for gender, age, Charlsons co-morbidity index, hypertension, lipid-lowering treatment, body mass index and smoking status.

Results: A total of 337 (0.9%) patients with RA were identified; 268 (79.5%) being sero-positive. Women accounted for 73.9% of the RA patients compared to 54.4% of the non-RA patients. Non-obstructive CAD was present in 35.6% of the RA patients vs. 31.7% of the non-RA patients, and 15.4% of the RA patients had a CACS > 400 vs. 10.1% in non-RA patients. OR for having a CACS > 0 was 1.17 [0.91-1.50] 95% CI for overall RA, 1.33 [1.00-1.77] for sero-positive RA and 0.72 [0.42-1.24] for other-RA. Patients who had received >1 GCI 3 years prior to the CCT had an OR at 1.49 [0.99-2.27] for having CACS > 0.

Conclusion: Based on data from a large CCT database, coronary artery calcifications are more frequent in RA patients with seropositive disease and high disease activity RA. In particular, the occurrence of severe calcifications is more frequent. These findings support the hypothesis that inflammatory disease may accelerate the atherosclerotic process leading to increased coronary artery calcification and risk of cardiac events.

Rates of Influenza Vaccination in a Cohort of Patients with Rheumatoid Arthritis and Psoriatic Arthritis

Andreea Coca¹, James Dolan² and Christopher T. Ritchlin², ¹University of Rochester Medical Center, Rochester, NY, ²University of Rochester, Rochester, NY

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Epidemiology and Public Health Poster I: Rheumatoid Arthritis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The infections complicating rheumatic diseases cause significant morbidity and mortality. Rheumatoid arthritis and psoriatic arthritis patients are at increased risk of infection due to their altered immune system superimposed over the immunosuppressive effects of the treatment. The Center for Disease Control and Prevention is recommending that any person with rheumatoid arthritis should receive annual influenza vaccination. Despite these endorsements, the uptake of influenza vaccination in rheumatoid arthritis patients is low, and the rates of influenza vaccinations for psoriatic arthritis are largely unknown. The overall objective of this study is to understand the vaccination rate in our cohort of rheumatoid arthritis and psoriatic arthritis, and compare it with the literature reported rates in these populations. We also aim to understand the barriers for non-vaccination in a small subset of patients.

Methods: All the patients from the Rheumatology clinic with a clinical diagnosis of either psoriatic arthritis or rheumatoid arthritis were included in the analysis. The data was collected by retrospective chart review for the last 2 influenza season. Vaccination status was verified based on the electronic medical record documentation. We offered the questionnaire to 35 consecutive patients with rheumatoid arthritis and 17 with psoriatic arthritis whose record of vaccination is No. If the answer was No, the patients were subsequently asked about reasons for non-vaccination.

Results: We identified 526 patients with a diagnosis of psoriatic arthritis. The average age was 55.7. The gender distribution was 49.4% male, 50.6% females. Out of the 526 psoriatic arthritis patients, only 52.7% of them were “ever” vaccinated. This includes any reported vaccination since 2001. However, only 28.9% were vaccinated in the last 2 flu seasons. The Rheumatology clinic follows a total of 1489 patients with a diagnosis of rheumatoid arthritis. This subset of patients was slightly older than the PsA cohort, mean age 62.5, with 54.9% being female. The “ever” vaccination rate in this cohort was 61.3%. The vaccination rate in the last 2 winter seasons was much lower, only 37.4%. We compared the vaccination rates in the clinic, with the literature-reported vaccination rates in rheumatoid arthritis population. There was no difference in the vaccination rates between the PsA and RA cohort, and also no statistical difference between the vaccination rates in the 2 cohorts, based on sex. Among individuals with RA who ever received vaccination for influenza, the proportion of individuals who received the vaccine in the last two years was smaller in those younger than 65 compared with those older than 65, 51.7% and 63.7%, respectively ($p=0.0001$). Among individuals with PsA who ever received vaccination for influenza, the proportion of individuals who received the vaccine in the last two years was much higher in those older than 65 compared with those younger than 65, 38.7% vs. 4.02% respectively ($p=0.0001$).

Conclusion: Our result indicate that the influenza vaccination rates in a cohort of PsA and RA patients are very low, less than half of them receiving the influenza vaccine.

Inpatient Mortality in Transition-Aged Youth with Rheumatic Disease: An Analysis of the National Inpatient Sample

Paul T. Jensen^{1,2,3}, Keumseok Koh², Rebecca Cash², Stacy P. Ardoin⁴ and Ayaz Hyder², ¹Pediatrics, Nationwide Children's Hospital, Columbus, OH, ²The Ohio State University College of Public Health, Columbus, OH, ³Internal Medicine, The Ohio State University Wexner Medical Center, Columbus, OH, ⁴The Ohio State University Wexner Medical Center, Columbus, OH

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Epidemiology and Public Health Poster I: Rheumatoid Arthritis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Transition from pediatric to adult care is seen as a vulnerable time for youth with chronic diseases. In patients with rheumatic disease, studies show high rates of loss to follow up and increased disease activity in young adults compared to adolescents. However, there are no mortality data on young adults with rheumatic diseases. In this study, we sought to assess whether transitional age is a risk factor for inpatient mortality.

Methods: We analyzed the 2012-2014 National Inpatient Sample database, a representative sample of all discharges in the United States produced by the Agency for Healthcare Research and Quality (AHRQ). Individuals with rheumatic diseases were identified by International Statistical Classification of Disease – 9 (ICD-9) codes at time of discharge. Youth were divided by age into three age groups: pre-transitional age (11-17), transitional age (18-24) and post transitional (25-31). We fitted univariable and multivariable logistic regression models to assess whether transitional age was a risk factor for inpatient mortality. We also assessed whether sex, underlying disease, socioeconomic status, insurance type, and psychiatric comorbidity were risk factors for inpatient death. Due to NIS restrictions on reporting data cells with fewer than 10 outcomes, specific diagnoses were combined to form the following categories: inflammatory arthritis, systemic lupus erythematosus (SLE), systemic sclerosis (SS), connective tissue diseases other than SLE or SS, systemic vasculitis, and periodic fever syndromes.

Results: There were 21,488,293 individual hospital discharges in the NIS data sets from 2012-2014. Of these, 30,269 met our inclusion criteria of diagnosis and age. There were 195 inpatient deaths (0.7%). The Odds ratio for inpatient death of an individual in the transitional age range was 1.18 compared to the pre transitional and post-transitional age ranges in the multivariable model ($p=0.3$). Black race (OR=1.4, $p=0.06$), male sex (1.75, $p<0.001$), and a diagnosis of systemic sclerosis (OR= 4.81, $p<0.001$) or vasculitis (OR= 2.85 $p<0.001$) were the greatest risk factors of inpatient mortality.

Conclusion: Transitional age was not a risk factor for inpatient mortality in this study. We did identify other risk factors for inpatient mortality other than age. Further studies are required to assess if there is an increased risk of mortality in outpatients of the transitional age group.

Figure 1: Parsimonious multivariable logistic regression model including all covariates significant at the $p=0.05$ level. Transition age was forced into the model despite being non-significant. White Race was the referent racial category.

TNF Inhibitors: Prevalence of Use and Predictors of Treatment Non-Persistence in the 2011-2016 Medicare Population

Nicholas S. Roetker, Yi Peng, Kimberly M. Nieman, Suying Li and David T. Gilbertson, Minneapolis Medical Research Foundation, Chronic Disease Research Group, Minneapolis, MN

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Epidemiology and Public Health Poster I: Rheumatoid Arthritis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Use of tumor necrosis factor inhibitor (TNFi) drugs is common among patients with rheumatic disease who do not respond to conventional therapies. The aims of this study were to (i) characterize the use of, and (ii) investigate factors associated with non-persistence to TNFis in a contemporary database of Medicare beneficiaries.

Methods: This study used claims data from 2010-2016 from a 20% Medicare sample. We identified all patients whose first (i.e., index) TNFi use occurred between 2011-2016 based on the presence of one or more Medicare Part D prescription or Part B injectable/IV drug claims for adalimumab, certolizumab pegol, etanercept, golimumab, or infliximab. To identify baseline covariates, we required that patients have Medicare Parts A/B and D coverage for a baseline period of at least one year prior to the index TNFi claim. Comorbid conditions were defined based on a diagnosis code in at least one inpatient or two outpatient claims separated by 30 days or more. We defined non-persistence as a gap in supply of the index TNFi of more than 180 days. Factors associated with the rate of non-persistence were assessed using multivariable Cox proportional hazards regression.

Figure. Hazard ratios (HR) and 95% confidence intervals (CI) for non-persistence to the index TNFi from a multivariable Cox regression model.

Results: We identified 15,622 patients initiating a TNFi from 2011-2016, with infliximab being the most common and golimumab the least common (**Table**). Mean age was 64 ± 13 years and 71% were female. History of rheumatoid arthritis (60%) was the most common TNFi indication, and 40% of patients had baseline concomitant use of each of conventional DMARDs and corticosteroids. Among 8,147 patients with rheumatoid arthritis and two or more TNFi claims, over a mean of 16.1 months of follow-up, we identified 2,937 (36%) patients who were non-persistent with the index TNFi. Female sex, chronic obstructive pulmonary disease, and hypertension were associated with a higher rate of non-persistence, and age 65-74 years and concomitant DMARD use were associated with a lower rate of non-persistence (**Figure**). In comparison to initiators of infliximab, rates of non-persistence were higher among initiators of adalimumab, certolizumab pegol, and etanercept, and lower among initiators of golimumab.

Table. Baseline characteristics of Medicare patients initiating a TNFi biologic medication.

Diabetes	1389 (30%)	396 (23%)	1000 (31%)	261 (26%)	1302 (26%)	4348 (28%)
Hypertension	2639 (57%)	1065 (62%)	1888 (59%)	649 (64%)	3062 (61%)	9303 (60%)

SD, standard deviation; DMARD, disease-modifying antirheumatic drug; TNFi, tumor necrosis factor inhibitor.

^aFrequencies shown in gray if disease not indicated for a specific TNFi drug.

Conclusion: TNFis are used among a diverse set of Medicare beneficiaries. In TNFi initiators with rheumatoid arthritis, there were differences in the rate of non-persistence by sex, age, co-medication, comorbid disease, and the type of TNFi. These findings suggest that there may be differences in the benefit and harm profiles (e.g., therapeutic response or adverse complications), or patient preferences in drug administration (e.g., once-monthly dosing for golimumab), between the TNFis.

Population-Based Estimates of Fatigue Prevalence Among Adults Aged >18 Years with and without Arthritis, United States, 2015-2016

Jennifer M. Hootman¹, Louise Murphy¹, Michael Boring¹ and Dana Guglielmo², ¹Arthritis Program, Centers for Disease Control and Prevention, Atlanta, GA, ²Oak Ridge Institute for Science and Education, Oak Ridge, TN

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Epidemiology and Public Health Poster I: Rheumatoid Arthritis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Fatigue is a common symptom among adults with arthritis and can severely impact quality-of life. This study's two objectives were to estimate the national prevalence of fatigue among US adults with and without arthritis and to describe differences in intensity, duration, sociodemographic and health-related characteristics in fatigue among adults with arthritis.

Methods: The National Health Interview Survey is an ongoing survey of the civilian, non-institutionalized population designed to gather nationally representative data on a variety of health topics. We analyzed 2015 and 2016 Adult Functioning and Disability Supplement data (sample sizes = 16,939 and 16,478, respectively). Doctor-diagnosed arthritis was defined as a "yes" to: "Have you ever been told by a doctor or other health care professional that you have arthritis, rheumatoid arthritis, gout, lupus or fibromyalgia?" The case finding question for fatigue was "In the past 3 months, how often did you feel very tired or exhausted?" (never, some days, most days, every day). Any fatigue was defined as positive answer some days, most days, or every day. Among those reporting any fatigue, intensity responses were a little, a lot, somewhere in between to "How would you describe the level of tiredness?" and duration responses were some of the day, most of the day, all day to "How long did it last?". Age-standardized prevalence (%) and 95% confidence intervals (CI) were calculated overall and by sociodemographic characteristics (age, sex, race/ethnicity, and education) and health-related characteristics (arthritis-attributable activity limitation (AAAL), self-rated health (excellent/very good, good, fair/poor), body mass index (BMI) (<25.0, 25.0-30 and 30.0+), number of co-morbid conditions, and physical activity level (inactive, insufficient, active). Analyses accounted for the complex survey design.

Results: Any fatigue was higher among adults with arthritis (80.4% CI 78.6-82.0) than without arthritis (60.8% CI 59.8-61.8; $p<0.01$). Adults with arthritis vs. no arthritis also reported significantly greater "fatigue on most days" (16.4%, CI=14.7-18.3 vs. 7.2%, CI=6.7-7.6) and "fatigue every day" (12.2%, CI=10.7-13.9 vs. 4.1%, CI=3.8-4.5). The highest prevalence of "fatigue every day" among adults with arthritis was observed for those with ≥ 3 co-morbid conditions (27.4%), reporting fair/poor health (25.9%) and being physically inactive (21.9%). "Fatigue every day" prevalence among adults with arthritis was significantly lower for those age 65+, college degree or higher, no AAAL, no co-morbid conditions, excellent/very good health, and physically active. Among adults with arthritis with any fatigue, 25.8% (CI=23.6-28.1) said their intensity was "a lot"; 24.1% (CI=21.9-26.5) reported a duration of "most of the day" and 12.4% (CI=10.7-14.4) "all of the day".

Conclusion: Among adults with arthritis about 4 in 5 report any fatigue, and among those 1 in four report intense ("a lot") fatigue and 1 in 3 report a duration of most or all of the day. Because pain is an important component of fatigue, exercise and self-management education interventions that lower pain levels may also improve fatigue.

Clinical Predictors and Risk of Methotrexate Induced Liver Fibrosis

Sarah Oberholtzer¹ and Lawrence Worobetz², ¹Department of Internal Medicine, University of Saskatchewan, Saskatoon, SK, Canada, ²Department of Internal Medicine, University of Saskatchewan Division of Gastroenterology, Saskatoon, SK, Canada

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Epidemiology and Public Health Poster I: Rheumatoid Arthritis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Methotrexate (MTX) is a highly effective therapy for patients with rheumatologic and dermatologic conditions. Its use infers significant reduction in morbidity and mortality; however, it has been associated with a range of liver related adverse events. The risk with current dosing remains unknown. The American College of Rheumatology and American Association of Dermatology guidelines identify alcohol use, diabetes, and obesity as risk factors for MTX-induced liver injury.

Methods: We aim to quantify the prevalence of liver fibrosis and its relationship to clinical features. This will include total lifetime dose and parameters associated with non-alcoholic fatty liver disease (NAFLD) including obesity and diabetes. We predict those with NAFLD will be at increased risk of liver injury while taking MTX. A retrospective cross sectional study was performed among patients with rheumatoid arthritis or psoriasis/psoriatic arthritis who were referred to hepatology between 2015-2018 for evaluation of liver injury in the setting of chronic MTX use. The primary outcome was the prevalence of liver fibrosis using Fibroscan ($\geq 6\text{kPa}$ = $\geq \text{F1}$ Fibrosis) or biopsy where available. Clinical predictive variables analyzed were demographics, co-morbidities, symptoms, physical exam findings, dose and duration of MTX use, laboratory values, and the controlled attenuation parameter (CAP) score, which is a method for measuring steatosis based on Fibroscan. Variables with a univariate $P < 0.2$ were included in a multivariable logistic regression model.

Results: 30% (11/37) of patients had RA and 70 % (26/37) had psoriasis. 38% (14/37) were determined to have liver fibrosis. Rates were much higher among those with psoriasis (11/14 patients). Clinical variables retained in the final regression model were weight, body mass index (BMI), CAP score, and the presence of NAFLD.

Conclusion: Early detection of liver toxicity ensures improved outcomes and prevents unnecessary cessation of methotrexate. Those with NAFLD have an increased risk of methotrexate hepatotoxicity. We recommend individuals with risk factors for metabolic syndrome be referred to hepatology and screened for NAFLD prior to initiation of methotrexate.

Hypogammaglobulinemia and Infection Risk in Patients Treated with Rituximab

Joana Caetano¹, Frederico Batista¹ and Jose Delgado Alves^{2,3}, ¹Department of Medicine IV, Systemic Immunomediated Diseases Unit, Fernando Fonseca Hospital, Amadora, Portugal, ²CEDOC/NOVA Medical School, Lisbon, Portugal, ³Department of Medicina IV, Systemic Immunomediated Diseases Unit, Fernando Fonseca Hospital, Amadora, Portugal

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Epidemiology and Public Health Poster I: Rheumatoid Arthritis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Rituximab (RTX) is an effective immunosuppressive therapy for many autoimmune diseases. Secondary hypogammaglobulinemia (hypoIg) can occur mainly after repeated cycles of RTX. The risk of infection in these patients has been shown to be higher in some studies, especially with secondary hypoIgM. Our objectives are to determine whether low IgG or IgM levels associate with infection in RTX treated patients.

Methods: Retrospective observational study of patients with autoimmune diseases from a single center, treated with RTX (2x1000mg 2 weeks apart) between 2010-2017. Patients that did not complete one full RTX cycle were excluded. Exposures were demographical characteristics; previous/concomitant immunosuppressants and peripheral B cell CD19+ count. Outcomes were serum Ig levels (IgM, IgG and IgA) at baseline and 4-6 months after each cycle, hypoIg and serious infections (defined as requiring hospitalization and/or intravenous treatment). Fisher exact test was used to compare dichotomous variables; Wilcoxon rank sum test to compare continuous variables with skewed distributions; logistic regression for normal distributed continuous variables.

Results: 41 patients were included with a median age of 50.9 years (IQR 37.4, 64.9); median number of cycles of 4. Most patients had systemic lupus erythematosus (36.6%), rheumatoid arthritis (14.6%) and myasthenia gravis (14.6%). During all treatment period 18 patients (43.9%) developed hypoIgG, 22 (53.7%) hypoIgM and none hypoIgA. Lower baseline IgG and IgM levels were associated with hypoIgG ($p < 0.001$) and hypoIgM ($p = 0.03$), respectively. Moreover, after each RTX cycle median IgM levels tend to decrease ($p < 0.001$ until the 3rd cycle), while median IgG levels tend to remain stable after the 1st cycle. Incidence of hypoIgG was lower in patients treated hydroxychloroquine (HCQ) ($p = 0.01$). Other immunosuppressive therapy and clinical characteristics did not associate with hypoIg. 13 patients had a serious infection (incidence rate of infection of 19.2/100 patients-year). Incidence of infection was higher in elderly patients ($p = 0.02$) and

lower in patients treated with HCQ ($p=0.02$), and did not associate with hypoIgG or hypoIgM. Lower median levels of IgG were associated with a higher incidence of infection after the 2nd ($p=0.03$) and the 3rd ($p=0.02$) cycles. Analyzing the variation of IgG levels between baseline and each cycle, there was a tendency towards the occurrence of infection in relation with a higher % of negative variation of IgG levels, especially after the 3rd cycle, although not statistically significant ($p=0.06$).

Conclusion: a higher incidence of serious infections did not associate with low absolute IgM or IgG titers, but with the percentage of reduction of IgG levels, and not IgM, from baseline and each treatment. This can have a clinical impact in the decision to stop RTX treatment based on safety. HCQ showed a protective role for infection in patients treated with RTX, which can be explored in larger prospective studies.

The Risk of Serious and Opportunistic Infections in Rheumatologic Patients on Interleukin Inhibitors: A Systematic Review and Meta-Analysis

Adam Berlinberg¹, Jawad Bilal², Abdullah Alhifany³, Warda Faridi⁴ and C. Kent Kwoh⁵, ¹Department of Internal Medicine, University of Arizona, Tucson, AZ, ²Internal Medicine, University of Arizona, Tucson, AZ, ³Department of Pharmacy, University of Arizona, Tucson, AZ, ⁴Department of Hematology/Oncology, University of Arizona, Tucson, AZ, ⁵Medicine, Division of Rheumatology, University of Arizona School of Medicine, University of Arizona Arthritis Center, Tucson, AZ

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Epidemiology and Public Health Poster I: Rheumatoid Arthritis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Interleukin (IL) inhibitors are increasingly being used for rheumatologic diseases. There are many controlled clinical trials assessing the efficacy of IL inhibitors, but there are few meta-analyses which have examined the pooled risk of infection with these drugs. Our objective was to assess the risk of serious infection and opportunistic infections in patients with rheumatologic diseases treated with IL inhibitor therapy (anakinra, brodalumab, canakinumab, secukinumab, tocilizumab, olokizumab, ixekizumab, ustekinumab, clazakizumab, and rilanocept).

Methods: Medline via Pubmed, Embase, conference proceedings from ASCO, AACR and ACR and reference lists from published systematic reviews related to rheumatologic diseases and interleukin inhibitors for were searched for RCTs using PICOS strategy. We extracted the incident data for serious infections and opportunistic infections. We conducted a fixed-effect meta-analysis via calculating a pooled odds ratio (Mantel-Haenszel methods with a continuity correction designed for sparse data) using STATA software version 14 (Stata Corp., College Station, Texas, USA). Heterogeneity was assessed using Q-statistic and quantified using I^2 statistic.

Results: The initial search of PubMed and Embase yielded 881 citations. We included 38 eligible RCTs that included 16,841 patients. We extracted data on serious infections (death or hospitalization), candidiasis, herpes zoster, and Pneumocystis carinii Pneumonia (PCP) as the main outcomes of interest. Serious infections were significantly more common with patients who received IL inhibitors compared to standard of care (OR 1.97, 95% CI 1.48-2.62) and the heterogeneity was minimal ($I^2 = 0\%$, $P = 0.99$). Moreover, we found that candidiasis also was significantly more common with patients who received IL inhibitors than standard of care (OR 5.41, 95% CI 2.04-14.33; $I^2 = 0\%$, $P = 0.99$). However, we found no significant difference between patients who received IL inhibitors or standard of care in terms of the risk of herpes zoster or PCP (OR 1.23, 95% CI 0.39-3.84; $I^2 = 0\%$, $p = 0.97$ and OR 0.99, 95% CI 0.10-9.65; $I^2 = 0\%$, $p = 0.70$, respectively). There was no increased incidence of secondary assessed opportunistic infections such as TB, non-TB mycobacterium, coccidioidomycosis, histoplasmosis, aspergillosis, cryptococcus, etc.

Conclusion: We found an increased risk of serious infections, and a significantly increased risk of candidiasis with the use of IL inhibitors, but there was no appreciable increase in the risk of herpes zoster or PCP. Other opportunistic infections were also found to have no appreciable increased risk. Patients and providers need to remain vigilant in recognizing the risk of serious and opportunistic infections with the use of IL inhibitors, and proper care must be taken to quickly identify and treat any infections as a result of IL inhibitor therapy.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Epidemiology and Public Health Poster I: Rheumatoid Arthritis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Tumor necrosis factor alpha (TNF α) inhibitor therapy in patients with rheumatologic disorders is well known to increase the risk of malignancy. While the individual trials report these incident side effects with Interleukin (IL) inhibitor therapy, the subject has not been systematically investigated.

Objective: To investigate the risk of malignancies in patients with rheumatic diseases treated with interleukin (IL) inhibitor therapies (Anakinra, brodalumab, canakinumab, secukinumab, tocilizumab, olokizumab, ixekizumab, ustekinumab, clazakizumab, and rilanocept).

Methods: Medline via Pubmed, Embase, conference proceedings from ASCO, AACR and ACR and reference lists from published systematic reviews related to rheumatologic diseases and interleukin inhibitors for were searched for RCTs using PICOS strategy. We extracted the incident data for malignancies. We conducted a fixed-effect meta-analysis via calculating a pooled odds ratio (Mantel-Haenszel methods with a continuity correction designed for sparse data) using STATA software version 14 (Stata Corp., College Station, Texas, USA). Heterogeneity was assessed using Q-statistic and quantified using I² statistic.

Results: After screening 881 studies, 16841 patients from 38 eligible studies were analyzed. We found no significant difference between patients who received IL-inhibitors or placebo in terms of the risk of malignancies (OR 1.07, 95% CI 0.708-1.63; I²= 9.9%, P = 0.32). We conducted a sensitivity analysis to examine the risk of malignancies based on individual IL-inhibitors. We found no significant difference in the occurrence of malignancies in patients who received anakinra, Ixekizumab, Rilanocept, Secukinumab, Tocilizumab or Ustekinumab versus placebo (OR 0.20, 95% CI 0.06-0.66; I²= 0%, P = 0.97), (OR 1.28, 95% CI 0.30-5.5; I²= 4.9%, P = 0.35), (OR 2.18, 95% CI 0.22-21.23; I²= 0%, P = 0.75), (OR 2.43, 95% CI 0.71-8.27; I²= 0%, P = 0.98), and (OR 1.46, 95% CI 0.72-2.97; I²= 44%, P = 0.13), and (OR 2.14, 95% CI 0.25-18.37; I²= 0%, P = 0.67) respectively.

Conclusion: IL inhibitors therapies appear safe with regards to risk of malignancies for a follow up duration of up to 52 weeks. Long term data is required from cancer survivors to further ensure the safety of IL inhibitor therapies.

Outcomes of Hospitalizations and the Temporal Trends in Mortality from Acute Myocardial Infarction in Patients with RA and FM during 2005 to 2015

Atefeh Vafa¹, Setri Fugar² and John P. Case^{3,4}, ¹Internal Medicine, John H. Stroger, Jr. Hospital of Cook County, Chicago, IL, ²Cardiology, Rush University Medical Center, Chicago, IL, ³Internal Medicine/Rheumatology, John H. Stroger, Jr. Hospital of Cook County, Chicago, IL, ⁴Internal Medicine, Chicago Medical School, North Chicago, IL

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Epidemiology and Public Health Poster I: Rheumatoid Arthritis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: RA is associated with an increased risk of coronary artery disease (CAD). This association is believed to be due to systemic inflammation and its role in atherogenesis. The non-inflammatory FM has also been reported as an independent risk factor for CAD. In this study, we evaluated the outcomes of patients hospitalized for acute myocardial infarction (AMI) in those with and without RA or FM in a nationally representative sample.

Methods: We used data from the National Inpatient Sample (NIS) for hospitalizations during the period 2005-2015 with adult AMI as the primary diagnosis and RA or FM as the secondary diagnosis using ICD-9 codes. The proportion who met ACR classification criteria cannot be determined with the NIS database. FM in the presence of immune-mediated or inflammatory rheumatic diseases was excluded. We used logistic regression to calculate the adjusted odds ratios for inpatient mortality from AMI with RA and with FM. We also investigated the unadjusted temporal trend of mortality rate in these groups and compared it to that of the general population.

Results: We identified a total of 1,363,041 AMI hospitalizations from 2005-2015 of which 18,383 (1%) had a diagnosis of RA and 8133 (0.6%) had a diagnosis of FM. Compared to patients without RA, hospitalized RA patients were older (70.4 vs. 67.4 years; $p < 0.01$) and predominantly female (62.8% vs. 39.1%; $p < 0.01$). Compared to patients without FM, FM patients were younger (63.9 vs. 67.4 years; $p < 0.01$) with an even higher proportion of females (81% vs. 39.1%; $p < 0.01$). After adjusting for age, gender, race, comorbidities and cardiac procedures, RA hospitalizations with AMI had similar adjusted inpatient mortality (aOR=0.94; 95% CI= 0.87-1.01; $p=0.14$) compared to non-RA hospitalizations while the adjusted odds-ratio for inpatient mortality due to AMI in FM hospitalizations was 0.67 (95% CI= 0.57-0.80; $p < 0.01$). The temporal trends of mortality rate (per 1,000 adults) in AMI hospitalizations in RA ($p=0.13$), FM ($p=0.02$) and the general population ($p < 0.01$) are shown in the figure.

Conclusion: Inpatient mortality in RA patients hospitalized for AMI was similar to that for non-RA patients even though the RA patients were older. The temporal trend of the unadjusted mortality rate in RA was similar to that of the general population and both were slightly decreasing. These findings may be related to strict cardiovascular risk factor modifications and in the case of RA, the availability of better DMARDs as well.

Compared to non-FM patients, patients with FM hospitalized for AMI had a lower inpatient mortality. The trend of AMI mortality rate in FM patients, however, was different from the other trends. Unlike that in RA or in general population, the AMI mortality rate in FM was increasing. This may be due to increased recognition of FM as a diagnostic entity or to the failure to recognize or treat CAD risk factors in the mostly female population.

Bi-Directional Associations between “Too Much Sitting” and Self-Reported Pain in Patients with Rheumatoid Arthritis

Ciara O'Brien¹, Joan L. Duda¹, Jet J.C.S. Veldhuijzen van Zanten^{1,2}, George S. Metsios^{2,3}, George D. Kitas^{1,2,4} and Sally A.M. Fenton^{1,2}, ¹School of Sport, Exercise and Rehabilitation Sciences, University of Birmingham, Birmingham, United Kingdom, ²Department of Rheumatology, Russells Hall Hospital, Dudley Group of Hospitals NHS Foundation Trust, Dudley, United Kingdom, ³Faculty of Education Health & Wellbeing, University of Wolverhampton, Walsall, United Kingdom, ⁴Arthritis Research UK Centre for Epidemiology, University of Manchester, Manchester, United Kingdom

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Epidemiology and Public Health Poster I – ARHP

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Epidemiological evidence indicates that sedentary behaviour, or “too much sitting”, is associated with poor health outcomes in the general population, including elevated systemic inflammation. In addition, regularly breaking up sitting with light-intensity physical activities - such as standing or walking (i.e., sedentary breaks), is proposed to confer positive effects on systemic inflammation, and the experience of bodily pain. Importantly, these relationships are observed to be independent of engagement in moderate-to-vigorous physical activity.

We propose sedentary behaviour may contribute to the progression of pertinent RA outcomes, and particularly those with an inflammatory origin (e.g., joint pain). However, these associations may be bi-directional in nature, and sedentary behaviour may represent a consequence, as well as a cause of RA outcomes. The aim of this study is therefore to explore potential bi-directional associations between sedentary behaviour patterns (sitting, standing, sedentary breaks), with self-reported pain in RA.

Methods: Patients with RA (n = 62, Mean age = 56 ± 13 years) were recruited to this study lasting 8-days. On Day 1, patients completed validated questionnaires to assess their experience of pain over the preceding 2-weeks (McGill Pain Questionnaire-Short Form). Following this, they were given an activPAL (accelerometer enabled posture sensor) to wear for the next 7-days to assess their sitting time (min/day), standing time (min/day) and frequency of sedentary breaks (number/day). On Day 8, participants completed the same pain questionnaire as on Day 1, but were asked to report their experience of pain over the previous 7-days.

Linear regressions examined the relationship between pain on Day 1 (independent variable) with sedentary behaviour patterns over the subsequent week (sitting, standing, sedentary breaks – dependent variables) [Model 1]. Next, the association between sedentary behaviour patterns (in the preceding 7-days - independent variables) and pain on Day 8 were investigated [Model 2]. Finally, to investigate directionality Model 2 was further adjusted for reported pain on Day 1 [Model 3].

Results: Pain on Day 1 significantly predicted time spent sitting in the subsequent 7-days (Model 1; $\beta = .27, p < .05$), but was not significantly linked to standing or sedentary breaks. Time spent sitting was significantly linked to the experience of pain on Day 8 (Model 2; $\beta = .26, p < .05$), but no relationships were demonstrated between standing and sedentary breaks with this outcome. The association between sitting time and pain on Day 8, was no longer significant following adjustment for baseline (Day 1) pain ($\beta = .06, p = .52$).

Conclusion: This is the first study to explore the potential bi-directional associations between sedentary behaviour patterns and pain in RA. Results suggest that sitting time may represent a consequence, rather than a cause of joint pain in these patients. However, the observed association between “too much sitting” throughout the week and subsequent pain (Day 8), may point to the potential of interventions targeting sitting time for minimising the risk of recurrent joint pain.

Is There a Relationship between Takotsubo Cardiomyopathy and Fibromyalgia? Insights from the National Inpatient Sample Database

Atefeh Vafa¹, Setri Fugar², Chimezie Mbachi¹, Alexis K Okoh³ and John P. Case⁴, ¹Internal Medicine, John H. Stroger, Jr. Hospital of Cook County, Chicago, IL, ²Cardiology, Rush University Medical Center, Chicago, IL, ³Cardiothoracic surgery,

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Fibromyalgia and Other Clinical Pain Syndromes Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Takotsubo cardiomyopathy (TCM) or stress cardiomyopathy is an unusual but potentially fatal type of acute cardiomyopathy characterized by transient regional left ventricular systolic dysfunction. It is suggested to be related to stress-induced catecholamine release and is more common in females. Fibromyalgia is also characterized by chronic pain believed to be related to chronic emotional and physical stress. The aim of this study is to determine whether the prevalence of patients with FM is higher among patients hospitalized with TCM compared to the estimated prevalence of FM in the general population and to investigate the characteristics and outcomes of patients hospitalized with TCM and FM compared to patients with TCM and no FM.

Methods: We used data from the National Inpatient Sample (NIS) for hospitalizations during the period 2005-2015 with TCM as a primary diagnosis and FM as a secondary diagnosis using ICD-9 codes. The proportion who met ACR classification criteria cannot be determined with the NIS database. We calculated the prevalence of FM in TCM hospitalizations and compared the characteristics and outcomes of TCM hospitalizations with FM and without FM using SPSS software. The prevalence of FM in the general adult population was obtained from Centers for Disease Control and Prevention (CDC) and is about 2%.

Results: We identified a total of 8,164 TCM hospitalizations from 2005-2015 of which 238 (2.9%) had a diagnosis of FM. FM hospitalizations with TCM were younger (63.0 vs 66.2; $p < 0.01$) and with a higher proportion of females (99.6% vs. 91.5%; $p < 0.01$) compared to patients without FM. Common comorbidities and cardiovascular risk factors such as DM, HTN, and tobacco use were similar in both groups, however, obesity was more common in patients with FM (12.6% vs 9.0%; $p = 0.05$).

Patients with TCM and FM also had higher rates of depression and drug use compared to those without FM. The rates of severe inpatient complications including cardiac shock and cardiac arrest were similar in both groups. One patient died in the FM group (0.4%) while 105 patients (1.3%) died in the non-FM group ($p = 0.2$). The findings are summarized in the table.

Conclusion: About 3 percent of TCM hospitalizations have FM. This is slightly higher than the estimated national prevalence of this disorder in the general population by the CDC. Patients with FM presenting with TCM are younger with even higher proportion of females compared to the ones without FM. Inpatient mortality due to TCM, however, was not statistically different between two groups.

Given the similar presumed etiologies in these disorders, this study suggests that FM may be a risk factor for TCM, however, further investigations are required to establish the possible association between FM and TCM.

Variables*	TCM with FM vs. TCM without FM
Mean age (years)	63.0 vs. 66.2 ($p < 0.01$)
Female percentage	99.6 vs. 91.5 ($p < 0.01$)
Hypertension (%)	64.7 vs. 63.4 ($p = 0.6$)
Diabetes mellitus (%)	13.9 vs. 16.9 ($p = 0.2$)
Obesity (%)	12.6 vs. 9.0 ($p = 0.05$)
Depression (%)	34.9 vs. 15.3 ($p < 0.01$)
Tobacco use (%)	18.9 vs. 15.8 ($p = 0.2$)
Drug use (%)	5.9 vs. 2.6 ($p < 0.01$)
Alcohol use (%)	2.5 vs. 3.5 ($p = 0.4$)
Cardiac shock	2.9 vs. 4.3 ($p = 0.3$)
Inpatient mortality (%)	0.4 vs. 1.3 ($p = 0.2$)
Mean length of stay (days)	3.5 vs. 3.7 ($p = 0.3$)
Mean total charges (\$)	38253.8 vs. 41130.6 ($p = 0.3$)

* Demographic, Clinical Characteristics, and outcomes of TCM hospitalizations in patients with FM and without FM

Abstract Number: 242

DHEA Deficiency in Fibromyalgia

Thomas Romano, Private Practice, Martins Ferry, OH

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Fibromyalgia and Other Clinical Pain Syndromes Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Fibromyalgia (FM) is a common condition but often difficult to treat. This may be because co-morbidities are unrecognized and pose an impediment to a successful therapeutic outcome. This study examined the presence of one such co-morbidity in such patients.

Methods: 108 consecutive female FM patients, mean age 48.87 years treated in a private community-based rheumatology practice were evaluated. All fulfilled ACR 1990 and 2010 FM criteria. All complained of fatigue and decreased stamina. Blood samples were obtained on the initial visit and sent to a reference lab for measurement of dehydroepiandrosterone sulfate (DHEA-S) levels.

Results: Of the 108 FM patients tested, 83 (77%) had low-for-age DHEA-S levels. 6 had no detectable DHEA-S. The levels ranged from 0 to 679 mcg/dl, with 75 having levels under 100 mcg/dl. The mean DHEA-S level for the 108 patients was 96.8 mcg/dl, much lower than the expected level of 150 mcg/dl.

Conclusion: DHEA deficiency is a common co-morbidity in FM and levels should be measured especially if fatigue and decreased stamina are prominent symptoms.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Fibromyalgia and Other Clinical Pain Syndromes Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Fibromyalgia Syndrome (FMS), characterized by widespread pain and fatigue, has frequently been associated with stress in various models, including workplace related stress. In the current study we have evaluated the prevalence of FMS symptoms among Israeli school teachers and have attempted to correlate such symptoms with work – related stress.

Methods: Individuals, all currently employed as school teachers in Israel, were recruited to the study. Participants were asked to answer a questionnaire evaluating symptoms of FMS, based on the current diagnostic criteria, which include the widespread pain index (WPI) and the symptom severity scale (SSS). Participants were further questioned regarding stressful experiences during their work and about post – traumatic symptoms as well as regarding work performance and motivation.

Results: 321 participants were recruited (79.4% female, 20.6 male). 30 individuals (9.3%) of the sample fulfilled current criteria for a diagnosis of FMS, with a rate of 11.4% among females and 1.5% among males. While specific symptoms such as fatigue and irritable bowel symptoms were negatively correlated with work performance, no significant difference was found between teachers with or without fibromyalgia regarding work attendance and performance. FMS symptoms were strongly correlated with work – related stress and were strongly correlated with Post Traumatic Stress Disorder

(PTSD) related symptoms. Motivation to work was significantly lower among teachers fulfilling FMS criteria, but other performance – related parameters did not differ between teachers fulfilling or not fulfilling FMS criteria.

Conclusion: Fibromyalgia symptoms are highly prevalent among Israeli school teachers, and may be related to stress encountered in the classroom. These results are relevant both for physicians treating individuals involved in educational careers as well as for educators and decision – makers involved in planning and managing educational strategies.

A Qualitative Study Mapping the Behaviour Change Techniques Used in a Practice-Based Fibromyalgia Self-Management Programme

Jennifer Pearson¹, Katie Whale², Nicola Walsh¹, Sandi Derham³, Julie Russell³ and Fiona Cramp¹, ¹Department of Allied Health Professionals, University of the West of England, Bristol, United Kingdom, ²Musculoskeletal Research Unit, University of Bristol, Bristol, United Kingdom, ³Rheumatology Therapy Outpatients, Royal United Hospital Bath, Bath, United Kingdom

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Fibromyalgia and Other Clinical Pain Syndromes Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Fibromyalgia (FM) is a complex long-term condition that affects up to 5.4% of the UK population. It is associated with chronic widespread pain, fatigue, stiffness, sleep problems, memory and concentration difficulties, and irritable bowel syndrome. FM can cause significant levels of disability, with individuals frequently using healthcare resources, and experiencing loss of work days. There is a lack of robust evidence for the effectiveness of pharmacological treatments for FM, with current guidelines all recommending non-pharmacological interventions. Allied Health Professionals at the Royal National Hospital for Rheumatic Diseases, Bath, UK, developed the manualised Fibromyalgia Self-Management Programme (FSMP); a non-pharmacological, multidisciplinary exercise and education group intervention. The main aims of the FSMP are to provide condition-specific, patient centred, education and exercise advice, supporting the development of core, self-management skills. The FSMP comprises 2.5 hour weekly sessions over six weeks or 4 hour weekly sessions over four weeks. Core components include education about FM, sleep hygiene, goal-setting, pacing, hydrotherapy, and dietary advice. As the FSMP was developed clinically there has been little opportunity for the clinical team to fully understand the mechanisms by which it is effective. To inform successful widespread implementation, this research aimed to map the FSMP to the Michie Behaviour Change Taxonomy (BCT) to determine the mechanisms that facilitate the patient's ability to self-manage FM.

Methods: Non-participatory observations were conducted of the four week and six week FSMP. Comprehensive field notes on the content of the course, therapist delivery, and any additional content not included in the manual were recorded. Subsequently, semi-structured interviews were conducted with both therapists (n=4) and patients (n=9). Observations and the review of the therapist manual data were deductively coded in NVIVO to the BCT using Framework Analysis. Interview data were analysed using Theoretical Thematic Analysis.

Results: Review of the course manual and session observations showed that the FSMP coded onto 12 of the 16 main areas of the taxonomy, encompassing 22 behaviour change techniques. Patient's interviews indicated that they had made substantial behaviour changes as a result of attending the course including; increased activity levels; pacing; better quality sleep and improved communication with family members. Patients reported positive changes to symptoms as a result of attending the course. Therapists highlighted four key challenges in delivering the course; fidelity between therapists; patient readiness and acceptance of FM; group management; and patient fatigue while attending the programme.

Conclusion: The FSMP uses a range of behaviour change techniques. Patients who attended the course made changes to their behaviour, which enabled them to manage their symptoms of FM more effectively.

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Fibromyalgia and Other Clinical Pain Syndromes Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Small fiber neuropathy is often a challenging clinical problem; patients with small fiber sensory neuropathy commonly have severe complaints but only minimal objective abnormalities on examination. Because it affects mainly small, unmyelinated nerve fibers, standard electrophysiological testing is often normal, and skin biopsy was proven to be diagnostic with sensitivity in 88% of cases in one study. The purpose of this study is to assess the effectiveness of IVIG in the treatment of SFN in patients with Fibromyalgia both subjectively (patient reported improvement in symptoms) and objectively by measuring nerve fiber density through skin biopsy before and after 6 months of treatment.

Methods: Our study is an interventional open labelled treatment trial, involving 7 patients diagnosed with Fibromyalgia according to ACR criteria and had symptoms of SFN (ranging from chronic extremity pain, numbness or tingling) All the 7 patients were diagnosed by Small fiber neuropathy after undergoing a 3 mm punch skin biopsy (1 on the thigh and one on the lower leg, as approved by the American Academy of Neurology) and the decrease in nerve fiber density was used for diagnosis of SFN) All patients after being diagnosed with SFN on skin biopsy got 6 months of weight based IVIG treatment (2gm/kg). Objective effectiveness of IVIG therapy was assessed by a repeat post treatment biopsy after completing the 6 months of treatment. Subjective effectiveness was assessed by patient-filled FIQR questionnaires before and after treatment.

Patient demographics:

Age groups	42-68	
Male: Female ratio	1:6	
Prevalence of Fibromyalgia	7 of 7 patients	100%
Prevalence of Rheumatoid	3 of 7 patients	42.86%
Prevalence of Sjogren's disease	4 of 7 patients	57.14%
Prevalence of Sarcoidosis	1 of 7 patients	14.29%
Prevalence of vitamin D deficiency	3 of 7 patients	42.86%

Results: Revised Fibromyalgia Impact Questionnaire (FIQR) results before and after treatment:

Patient	FIQR score before treatment	FIQR score after treatment	Magnitude of improvement change
1	85	27	58
2	70	48	22
3	27	0	27
4	64	41	23
5	83	58	25
6	23.6	9.3	14.3
7	78	71	7

Nerve fiber diameter on skin Biopsy before and after treatment:

Pt	Pretreatment upper thigh nerve fiber diameter	Post-treatment upper thigh nerve fiber diameter	Magnitude of change in upper thigh nerve diameter	Pretreatment lower leg nerve fiber diameter	Post-treatment lower leg nerve fiber diameter	Magnitude of change in lower leg nerve diameter	Net change of nerve fiber diameter
1	3.9 mm	9.3 mm	+5.4 mm	5.3 mm	12.4 mm	+7.1 mm	+12.5 mm
2	5.0 mm	3.5 mm	-1.5 mm	0.4 mm	1.6 mm	+1.2 mm	-0.3 mm
3	3.6 mm	11 mm	+7.4 mm	0.4 mm	0.8 mm	+0.4 mm	+7.8 mm
4	4.3 mm	9.5 mm	+5.2 mm	0.3 mm	0.0 mm	-0.3 mm	+4.9 mm
5	2.6 mm	4.9 mm	+2.3 mm	1.2 mm	6.8 mm	+5.6 mm	+7.9 mm
6	4.6 mm	9.9 mm	+5.3 mm	5.5 mm	4.3 mm	-1.2 mm	+4.1 mm
7	3.0 mm	3.6 mm	+0.6 mm	1.5 mm	4.5 mm	+3 mm	+3.6 mm

Mean improvement changes of FIQR score is 25, mean improvement of upper thigh nerve diameter is 3.5 mm, and mean improvement of lower leg nerve diameter is 5.7 mm.

Conclusion: As shown in our study, IVIG has been proven to be very effective in improving SFN on both the clinical and the pathophysiologic levels and should be considered for the routine management of this underdiagnosed, yet very troublesome and crippling disease. Larger scale studies are definitely needed to confirm these results and facilitate the wider use of IVIG in treatment.

Factors Associated with Disability in a Prospective Cohort of Complex Regional Pain Syndrome Type 1

Einer Sanchez Prado¹, Alvaro Ruta¹, Jessica Torres Chichande¹, Facundo Salvatori¹, Sebastian Magri² and Rodrigo García Salinas³, ¹Rheumatology, Hospital Italiano de La Plata, La Plata, Argentina, ²Section of Rheumatology, Hospital Italiano de La Plata, La Plata, Argentina, ³Rheumatology Section, Hospital Italiano de La Plata, La Plata, Argentina

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Fibromyalgia and Other Clinical Pain Syndromes Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Complex regional pain syndrome (CRPS) is a form of chronic pain that usually affects an arm or a leg. CRPS typically develops after an injury, a surgery, a stroke or a heart attack. The pain is out of proportion to the severity of the initial injury. CRPS is uncommon, and its cause isn't clearly understood.

Methods: To estimate the percentage of patients with CRPS who develop disability and its associated factors. **Consecutive** patients older than 18 years old whose met Budapest criteria for CRPS type 1 were included. Demographic variables, time of follow-up, main cause of the disease and location, time between trauma and starting treatment were recorded from the electronic clinical history (ECH). Previous immobilization, type were recorded. of treatment, response to it and clinical manifestations. Disability was defined when there was a change in work activity.

Results: 98 patients were included with at least one year of follow up, 65.3% were women. The median age is 54 years (45-61), presented the following clinical patterns: pain 69.7%, inflammation 39.7%, dysautonomic phenomena 33.6% and motor alterations 21.4%. The main cause that triggered the SDRC was fracture in 60.2%, followed by 15.3% in contusion and 14.2% in soft tissue trauma, of which 66% corresponds to upper limb and 37% to lower limb. With respect to the diagnosis, a 3-step scintigraphy compatible with CRPS was obtained in 70.4% of the cases. In the radiographic evaluation, patchy osteopenia was the predominant pattern in 28.5% of the cases. Regarding the treatment, it was distributed: 74.4% received immobilization indication. 56% of patients received oral bisphosphonate and 32% EV. It was also found that 60% of patients used vitamin D and calcium, NSAIDs in 30%, corticosteroids in 23.4% and 29.5% of adjuvant medication during the course of the disease. 66.3% of patients performed rehabilitation as part of their treatment. 67.3% had some response to treatment and 50% had a good response to treatment. The prevalence of disability was 60%. In the univariate analysis, this was associated with: Precise indication of rehabilitation (0.001), Greater use of NSAIDs (p: 0.004) positivity in bone scintigraphy (0.044), dysautonomic phenomena (0.025), and negatively with good response to treatment (p: 0.000). In the logistic regression analysis using disability as a dependent variable, we found a significant and independent association with indication of rehabilitation (OR: 4.3 CI: 1.3-14) and response to treatment (OR: 0.078 CI: 0.023-0, 2).

Conclusion: 60% of the patients developed disability in their follow-up, they were associated independently with the indication of rehabilitation and in a negative way with a good response to treatment.

Fibromyalgia Patients Often Receive Several Rheumatic Disease Diagnoses

Robert S. Katz¹ and Jessica L. Polyak², ¹Rush University Medical Center, Chicago, IL, ²Rheumatology Associates S.C., Chicago, IL

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Fibromyalgia and Other Clinical Pain Syndromes Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: In a written office questionnaire, we asked patients the number of rheumatic disease diagnoses they had been given. We also asked about the length of time from the start of symptoms to receive a rheumatic disease diagnosis, how many doctors were seen, and whether the patient agrees with the current rheumatic disease diagnosis.

Methods: Patients were given an in-office questionnaire, which listed the following rheumatic disease diagnoses. They checked diagnoses that they had received by clinicians.

Results: We asked 155 Fibromyalgia patients and 106 non fibromyalgia rheumatic disease controls, how many diagnosis¹ they have previously been given. The mean age was 52.45 years for fibromyalgia patients and 50.39 years for non FMS rheumatic disease controls.

Conclusion: Fibromyalgia patients receive multiple rheumatic disease diagnoses more often than other rheumatic disease patients. Fibromyalgia can be difficult to diagnose as patients often report widespread pain and subjective joint swelling, yet the clinician does not find synovitis on exam. The use of the 2011 published ACR criteria sheet developed for the diagnosis may assist the clinician and the patient in making the diagnosis of fibromyalgia. Having at least 12 points on this 31-point scale suggests the likelihood of the patient having fibromyalgia.

		FMS (N=191)	Non-FMS (N=130)	Two- sided P- value
Number of Diagnoses	0 [n (%)]	27 (14.1)	25 (19.2)	0.0060*

The Emotional Quotient in Fibromyalgia Patients Is Similar to Rheumatic Disease Controls

Robert S. Katz¹ and Jessica L. Polyak², ¹Rush University Medical Center, Chicago, IL, ²Rheumatology Associates S.C., Chicago, IL

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Fibromyalgia and Other Clinical Pain Syndromes Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: There is IQ, the intelligence quotient, and EQ, the emotional quotient. EQ refers to emotional intelligence or the emotional intelligence quotient, the ability to use emotional information to guide thinking and behavior. It also refers to the ability to adjust emotions to achieve one's goals.

We wondered whether patients with fibromyalgia might have a poor emotional quotient and not be able to handle their symptoms well. We administered an in-office questionnaire to evaluate EQ.

Methods: We administered an in-office questionnaire to patients with fibromyalgia and non-fibromyalgia rheumatic disease controls. Included were 10 questions, each graded 0-4, regarding social/emotional awareness. We compared the results from patients with fibromyalgia syndrome meeting the 2010 ACR criteria for the diagnosis and those with other rheumatic diseases.

Results: There were 160 females and 31 males in the fibromyalgia syndrome group, and 82 females and 48 males in the non-fibromyalgia rheumatic disease patient group. The mean age of the fibromyalgia patients was 52.45 years for females and 50.39 years for males. The mean age of the patients with other rheumatic disease was 55.23 years for females and 54.02 years for males. 66.5% of the FMS patients and 57.7% of the no-FMS patients were married. The mean HAQ scores in FMS patients was 3.1 and in non-FMS rheumatic disease patients was 1.7 (p 0.001). Patients with FMS had an emotional quotient scale of 33.0 compared with 32.0 for rheumatic disease controls, p 0.84. There was no statistically significant difference between the two groups.

Conclusion: There was not a statistically significant difference between patients with fibromyalgia and non-FMS rheumatic disease patients with regard to their emotional quotient or social/emotional awareness. It does not appear from the results of this study, that fibromyalgia patients are less equipped to handle their symptoms. Rather, their symptoms may overwhelm them because of the intensity, and not necessarily from an inability to cope with them emotionally.

Abstract Number: 249

Patients with Fibromyalgia May be Fearful of Developing Dementia Despite Lack of Concrete Evidence of Cognitive Decline

Robert S. Katz¹ and Frank Leavitt², ¹Rheumatology, Rush University Medical Center, Chicago, IL, ²Rush University Medical Center, Chicago, IL

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Fibromyalgia and Other Clinical Pain Syndromes Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Core features of cognitive dysfunction in fibromyalgia are memory loss and disturbance in mental clarity. The present study examines if disturbance in mental clarity, a core feature of fibromyalgia, shapes the fear of falling prey to Alzheimer's in rheumatic disease groups with and without fibromyalgia.

Methods: The self administered form of the new ACR criteria for fibromyalgia along with the Mental Clutter Scale were administered to 246 consecutive patients at a single office site. Scores on the new ACR criteria of ≥ 12 formed the fibromyalgia group. Scores ≥ 4 defined disturbance in mental clarity. Risk of Alzheimer's disease, as judged by the patient, was measured on a 0 to 100 chance scale.

Results: Perception of risk substantially increased with sharp reductions in mental clarity often referred to as brain fog, with risk increasing from 18.7 ± 20.7 to 46.2 ± 20.6 $p < 0.01$ in the fibromyalgia group, and from 22.0 ± 23.2 to 41.1 ± 25.3 , $p < 0.01$ in controls. The percentage of people who perceived high risk was significantly higher among fibromyalgia patients (40.6% vs. 19.3%, $p < 0.01$). The age of risk perception was very similar in the two groups (fibromyalgia 47.4 ± 9.9 vs. 49.6 ± 9.8 , $p = .38$).

Conclusion: Fear among people with fibromyalgia that Alzheimer's will strike them is often presumed to be due to the development of memory problems in their young years. This is the first known evidence of an association between perceived risk of Alzheimer's disease in fibromyalgia and poor mental clarity, a core component of cognitive dysfunction in fibromyalgia. At the average age of 47, the risk views of the fibromyalgia group will be a costly burden in the years to come. Yet, there is no evidence that the cognitive problems of fibromyalgia transition to Alzheimer's later in life. A better understanding of the cognitive problems of fibromyalgia among clinicians would be an important advance.

Fibromyalgia Patients Do Not Appear to Obsess about Their Symptoms Compared with Other Rheumatic Disease Patients

Robert S. Katz¹ and Jessica L. Polyak², ¹Rush University Medical Center, Chicago, IL, ²Rheumatology Associates S.C., Chicago, IL

SESSION INFORMATION

Session Date: Sunday, October 21, 2018

Session Title: Fibromyalgia and Other Clinical Pain Syndromes Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: We wanted to know if fibromyalgia patients tend to obsess about their symptoms, and whether this might aggravate the complaints that they experience. We administered an obsessive-compulsive disease scale (1-3 for each question), as part of a questionnaire to patients in an office rheumatology practice.

Methods: Patients in an office rheumatology practice were given a questionnaire, which included a scale of obsessive-compulsive symptoms. The obsessive-compulsive questions were the following (each question 1-3):

1. I am worried about dirt, germs, and viruses.
2. I wash my hands very often or in a special way to be sure that I am not dirty or contaminated.
3. I must check the stove or other electrical appliances that I have locked the door, to make sure that things have not disappeared.
4. I get a compelling urge to put my things in a special order.
5. Do you have unwanted ideas, images, or impulses that seem silly, nasty or horrible?
6. Do you persistently engage in actions or behaviors that you feel compelled to do, but seem to make little sense and are unrewarding?

Results: There were 160 females and 31 males in the fibromyalgia syndrome group, and 82 females and 48 males in the non-fibromyalgia rheumatic disease patient group. The mean age of the fibromyalgia patients was 52.45 years for females and 50.39 years for males. The mean age of the patients with other rheumatic disease was 55.23 years for females and 54.02 years for males. 66.5% of the FMS patients and 57.7% of the no-FMS patients were married. The mean HAQ scores in FMS patients was 3.1 and in non-FMS rheumatic disease patients was 1.7 ($p = 0.001$). Fibromyalgia syndrome (FMS) patients met the 2010 ACR criteria for the diagnosis.

The obsessive-compulsive scale symptom total was 15.7 in FMS patients and 15.7 in non FMS rheumatic disease patients. $p = 0.84$. The results were not statistically significant.

Conclusion: Patients with fibromyalgia do not appear to be more obsessive-compulsive compared to rheumatic disease controls. Though fibromyalgia patients often have intense subjective symptoms, they do not appear to become more obsessive about their health problems, compared to non FMS rheumatic disease patients.

Using the Stroop Word Naming Test and the Mental Clutter Scale in Fibromyalgia Patients to Evaluate the Symptoms of Fibrofog in Office Testing of Cognitive Complaints

Robert S. Katz¹, Lauren Kwan², Josephine Anilao², Elizabeth Mitchell² and Jessica L. Polyak², ¹Rush University Medical Center, Chicago, IL, ²Rheumatology Associates S.C., Chicago, IL

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Fibromyalgia and Other Clinical Pain Syndromes Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: We have found that the Stroop word naming test is useful in evaluating fibromyalgia patients with cognitive symptoms, especially in those describing word retrieval problems. It is possible that the slower processing of information may disturb the synchrony of neural circuits and lead to some of the symptoms of cognitive dysfunction in fibromyalgia patients. The Mental Clutter Scale is also valuable in the assessment of cognitive problems.

Methods: We administered the Stroop word naming test and the Mental Clutter Scale to rheumatic disease patients in a rheumatology office practice.

Results: There were 28 patients (27 females and 1 male), in the fibromyalgia syndrome group, and 42 (28 females and 14 males), in the non-fibromyalgia rheumatic disease patient group. The mean age of the fibromyalgia patients was 50.66 years for females and 45 years for males. The mean age of the patients with other rheumatic disease was 53.14 years for females and 48.86 years for males. Fibromyalgia syndrome (FMS) patients met the 2010 ACR criteria for the diagnosis. The mental clutter score in those with fibromyalgia was 3.8 ± 2.2 and was 2.2 ± 1.6 in patients with other rheumatic diseases, $p < 0.001$

Conclusion: Fibromyalgia patients have an abnormal Stroop word naming speed. The test is simple to administer. When attempting to evaluate patients with cognitive dysfunction, it can be a helpful test to screen for fibrofog. This test, in addition to the Mental Clutter Scale, can be given in the office, and can help to evaluate patients who are concerned about cognitive dysfunction.

One theory based on the abnormal Stroop test is that fibromyalgia patients appear to be “a beat behind” in their cognitive functioning. Perhaps, when they are sitting at a group meeting, they are not quite following the content because of a slowing of some neural circuits.

Publication Bias Regarding Scientific Studies about Fibromyalgia

Robert S. Katz¹, Lauren Kwan² and Frank Leavitt¹, ¹Rush University Medical Center, Chicago, IL, ²Rheumatology Associates S.C., Chicago, IL

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Fibromyalgia and Other Clinical Pain Syndromes Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: It is estimated that approximately 5 million people in the United States suffer from Fibromyalgia. That's compared to 1.3 million adults with rheumatoid arthritis and about 250,000 with systemic lupus.

Methods: We reviewed six major rheumatology journals over a two-year period to assess the number of articles written regarding rheumatoid arthritis, lupus, osteoarthritis, ankylosing spondylitis, and psoriatic arthritis. The journals reviewed were Arthritis and Rheumatology; The Annals of Rheumatic Disease; The Journal of Clinical Rheumatology; Nature Reviews of Rheumatology; Arthritis Care and Research; and Seminars in Arthritis and Rheumatism.

Results: We found the number of publications for rheumatoid arthritis, lupus, osteoarthritis, psoriatic arthritis, ankylosing spondylitis, and fibromyalgia as the following:

Conclusion: Research papers regarding lupus appeared 13 times more often in these six rheumatology journals compared with fibromyalgia articles. Rheumatoid arthritis studies were 26 times more frequently included, compared to articles on fibromyalgia, in these journals.

Publication bias could have critical adverse consequences for the 5 million people in the United States that carry the diagnosis of fibromyalgia.

Journal editors need to carefully consider the origins of this bias, the damaging effects on treatment advances for patients who carry the diagnosis, and ways of ameliorating this situation.

Publication bias limits the amount of literature on fibromyalgia that clinicians can use to synthesize and learn from. It can also distort the importance of the disease entity in the mind of the reader.

Chi squared test of equal proportions between all groups

The FREQ Procedure

disease	Frequency	Percent
AS	141	5.35
FMS	20	0.76
H	1318	50.00
LUPUS	268	10.17
OA	299	11.34
PSA	66	2.50
RA	524	19.83
Total	2636	100.0

Chi-Square Test for Equal Proportions	
Chi-Square	3199.7109
DF	6
Pr > ChiSq	<.0001

Sample Size = 2636

Chi squared test of equal proportions between LUPUS and FMS

The FREQ Procedure

disease	Frequency	Percent
FMS	20	8.94
LUPUS	268	93.06
Total	288	100.0

Chi-Square Test for Equal Proportions	
Chi-Square	213.1536
DF	1
Pr > ChiSq	<.0001

Sample Size = 288

Chi-squared test of equal proportions between RA and FMS

The FREQ Procedure

diagnosis	Frequency	Percent
FMS	20	3.68
RA	524	96.32
Total	544	100.0

Chi-Square Test for Equal Proportions	
Chi-Square	166.9417
DF	1
Pr > ChiSq	<.0001

Sample Size = 544

Articles on lupus, with a prevalence of less than 300,000, appeared in these rheumatology journals 13 times compared with articles about fibromyalgia, with a prevalence of 5 million. It is likely that manuscripts of fibromyalgia face greater publication hurdles than other rheumatic diseases.

Abstract Number: 253

Fibromyalgia Patients Are Frequently Thought to be Challenging to Treat- Are They?

Robert S. Katz¹ and Lauren Kwan², ¹Rush University Medical Center, Chicago, IL, ²Rheumatology Associates S.C., Chicago, IL

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Fibromyalgia and Other Clinical Pain Syndromes Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Fibromyalgia patients can be time consuming to treat and difficult to manage. Especially challenging fibromyalgia patients tend to have many symptoms, ask many questions, are sometimes non-believing in their diagnosis. Some call this group 'catastrophizers'. We evaluated the difficulty of caring for fibromyalgia patients in a rheumatology office practice.

Methods: A rheumatologist and a rheumatology nurse both independently assessed the perceived difficulty of taking care of individual fibromyalgia patients. The difficulty of caring for each patient was discussed between the doctor and the rheumatology nurse until there was an agreement. Each patient met the 2010 ACR criteria for the diagnosis. Patients were rated on a scale of one through three to indicate how challenging and exhausting they were to treat. (1 = easy; 2= moderate; 3 = difficult) Factors considered included the patient's attitude and needs, the difficulty to treat, time spent compared with treating other rheumatic disease patients, and, in general, how challenging they were as patients.

Results: 350 fibromyalgia patients followed in a rheumatology office practice were evaluated. 132 (37.7%) patients were judged to be in Category One, easy to care for. 170 (48.6%) patients were considered to be in Category Two, moderately challenging for the rheumatologist and nurse. 48 (13.7%) patients were judged to be in Category Three, especially difficult to care for.

Conclusion: Most fibromyalgia patients (86.3%) were rated by the rheumatologist and nurse as moderate or easy to care for. These patients appreciated the care given and the expertise, and were willing to consider lifestyle changes and medication.

Only 13.7% of the fibromyalgia patients in this office practice were considered to be exhausting and especially challenging to care for.

Fibromyalgia patients have an undeserved reputation for being extremely difficult to care for. The majority are not.

Session Title: Fibromyalgia and Other Clinical Pain Syndromes Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Previously we investigated the lack of alordotic curve in the cervical spine seen on lateral view x-rays in patients with fibromyalgia compared with patients without fibromyalgia. One hypothesis is that the muscle pressure is increased in fibromyalgia, and that this can lead to straightening of the neck. We evaluated these changes in the lumbar spine.

Folded F	60	18	1.31	0.5401

*Two sample t-test to compare:
L-1 L-5 Cobb Angle between FMS & Non-FMS*

group	Method	N	Mean	Std Dev	Std Err	Minimum	Maximum
FMS		61	22.3574	10.3996	1.3315	4.0000	48.0000
NOFMS		19	29.2105	6.0218	1.3820	15.0000	38.0000
Diff (1-2)	Heteroscedastic		-6.8531		1.0191		

Method	P-value
Heteroscedastic	0.0001

Equality of Variances				
Method	Num DF	Den DF	F Value	Pr > F
Folded F	60	18	2.08	0.0125

Methods: Patients with and without fibromyalgia who had x-rays of the lumbar spine had a measurement of the Cobb angle between the top of L1 to the bottom of L4 and the top of L1 to the bottom of L5.

Results: There were 61 patients (55 females and 6 males), in the fibromyalgia syndrome group, and 19 (11 females and 8 males), in the non-fibromyalgia rheumatic disease patient group. The mean age of the fibromyalgia patients was 47.90 years for females and 44.66 years for males. The mean age of the patients with other rheumatic disease was 60.72 years for females and 46.62 years for males. Fibromyalgia syndrome (FMS) patients met the 2010 ACR criteria for the diagnosis.

Conclusion: Fibromyalgia patients have a straight lumbar spine when compared to controls without fibromyalgia. A straight lumbar spine, in addition to a straight cervical spine, which has previously been reported, suggests increased muscle tension in fibromyalgia patients. Elevated muscle pressure may be the cause of pain in patients with fibromyalgia, and clinicians can use the straight cervical spine and straight lumbar spine as additional support for the diagnosis of fibromyalgia. A straight lumbar spine may also be a window into the etiology of fibromyalgia.

Abstract Number: 255

Interpretation of Proverbs Compared with the Mental Clutter Scale in Fibromyalgia Patients Demonstrates Intact Intellectual Ability Despite the Symptoms of Fibrofog

Robert S. Katz¹ and Lauren Kwan², ¹Rush University Medical Center, Chicago, IL, ²Rheumatology Associates S.C., Chicago, IL

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Fibromyalgia and Other Clinical Pain Syndromes Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Fibromyalgia patients frequently have cognitive dysfunction (fibrofog). We compared cognitive ability using an interpretation of proverbs with reported poor mental clarity and other fibrofog symptoms.

Methods: Patients meeting the 2010 ACR criteria for fibromyalgia and rheumatic disease controls were given 10 proverbs to interpret. The proverbs were listed on a form, and five potential explanations were given the patients. Patients circled the correct response.

Table: List the proverbs: :

1. The pen is mightier than the sword.
2. People who live in glass houses should not throw stones.
3. Birds of a feather flock together.
4. There is no such thing as a free lunch.
5. The squeaky wheel gets the grease.
6. Too many cooks spoil the broth.

7. Necessity is the mother of invention.
8. A chain is only as strong as its weakest link.
9. You can lead a horse to water, but cannot make it drink.
10. Keep your friends close and your enemies closer.

Results: 109 fibromyalgia patients (mean age 50 y.o.) and 157 rheumatic disease control patients (mean age 53.5 y.o.) were given the list of the 10 proverbs. The fibromyalgia patients scored 73% of the answers correct. The rheumatic disease control patients scored 71% of the answers correct. There was no statistical difference between the two groups. On the mental clutter scale, the mean score for Fibromyalgia patients was 3.8 ± 2.2 ; and the mean score for rheumatic disease patients was 2.2 ± 1.6 , $p < 0.001$. A mental clutter score of 3.8 is an abnormal score and is associated with brain fog.

Conclusion: Proverb interpretation requires the ability to think abstractly and is often impaired in the early stages of dementia.

There was no relationship between the mental clutter scores and cognitive ability based on the interpretation of proverbs. This suggests that while fibromyalgia patients report a lack of mental clarity and other fibrofog symptoms, their intellectual function appears to be intact, and this likely reassures them that they are not developing dementia. Even with the difficulties they experience regarding memory, concentration, and mental foginess, fibromyalgia patients do not appear to be developing dementia.

Abstract Number: 256

The Effectiveness of Medications for Fibromyalgia Based on Patient Experiences

Robert S. Katz, Rush University Medical Center, Chicago, IL

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Fibromyalgia and Other Clinical Pain Syndromes Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: We asked patients with fibromyalgia to rank the effectiveness of medications they have tried.

Methods: In a rheumatology office practice, 95 patients (mean age 50.5) who met the 2010 ACR criteria for fibromyalgia (88 females and seven males) completed an in-office questionnaire regarding the effectiveness of various medications used to treat fibromyalgia. The medications included pregabalin, gabapentin, duloxetine, various muscle relaxants, sleep aids, stimulants, pain medications, and nonsteroidal anti-inflammatory medicines. Patients rated the medications on a 1 to 4 scale from not helpful to very helpful.

Results: See tables

Conclusion: There were much higher effectiveness results for pain medications, sleeping aids, stimulants, muscle relaxants, and anti-inflammatory drugs than for pregabalin and duloxetine, which are both FDA-approved medications. Fibromyalgia patients in this office survey concluded that the FDA approved medications for fibromyalgia were ineffective compared with other medications tried for this disorder.

Medications	Patient	Mean VAS (1-3)
Pain Medications	70	2.814
Sleeping Aids	72	2.778
ADD Medications	34	2.647
Stimulants	35	2.486
Muscle Relaxers	78	2.436
NSAIDs	81	2.304
Pregabalin	43	1.256
Duloxetine	44	1.023
Gabapentin	30	0.733

Session Date: Sunday, October 21, 2018

Session Title: Fibromyalgia and Other Clinical Pain Syndromes Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Fibromyalgia (FM) has been reported in up to 5% of adult population and its treatment still represents a challenge. In Argentina, there are few records describing the different aspects of FM patients. Therefore, the aim of the study was to describe the frequency of FM patients consults in daily practice and to analyze these patient characteristics.

Methods: Multicenter, observational, cross-sectional study that included a total of 759 patients with FM (ACR 1990 and/or ACR 2010 criteria). The number of consultations performed from January to June of 2017 (both the total consultations and those of patients with FM) was recorded. For each patient with FM, we collected the following data: age, gender, health insurance provider, whether it was the first time consulting a physician, professional who referred the patient, duration of FM, presence of concomitant autoimmune disease, comorbidities and treatment. **Statistical analysis:** Descriptive analyses of the clinical characteristics were performed, using absolute numbers and proportions for categorical variables, and means and medians, standard deviation (SD) and interquartile range (IQR) for numerical variables. Frequency of FM consultations with the corresponding 95% confidence interval was determined. We compared demographic and disease characteristics according to health insurance provider, public care and presence of comorbidities by means of chi-square or T-student test.

Results: A total of 759 patients (12 children) from 15 rheumatology centers were included. According to the complete registries from 6 centers, from a total of 7350 visits in a 6-month period, the frequency of FM patients consults was 10.4% (CI95 9.7-11.1). Out of 747 adult patients, 95% were women, median age 52 (SD 12.6), 9% were consulting for the first time and 78% had a health insurance. Median duration of FM was 24 months (IQR 10-48). Most patients resulted from referrals from General Practice (54%) and Traumatology (28%). About 28% of the patients have a concomitant autoimmune disease, being RA and Hypothyroidism present in more than 30% of the cases. Hypertension and Osteoarthritis were the most frequent comorbidities reported. Most patients (96%) were on pharmacological treatment (80% Pregabalin). The most frequent non-pharmacological treatments were kinesiotherapy (40%) and physical activity (27%). Patients from the public health system (36%) showed higher probability of being referred by other specialists (69 vs 48%, $p<0.001$), longer duration of FM (55 vs 32 months, $p<0.0001$) and less number of doctors previously consulted (2 vs 3, $p<0.0001$). Out of 12 pediatric patients (all referred by other specialists), 11 were girls, mean age 13 (SD 3). Median duration of symptoms was 10 months (ICQ 7-48); 75% were treated with NSAIDs and 25% with Pregabalin; 92% were on kinesiotherapy and 85% on psychotherapy.

Conclusion: Until the date, this is the largest Argentine registry of FM patients, including a large number of patients (both adult and pediatric) and many participating centers. We believe that this registry could provide evidence-based socio-demographic data, useful not only for clinical trials but also to improve treatment strategies in FM.

Abstract Number: 258

Association of Sudoscan Values with Disease Duration in Female Patients with Fibromyalgia

Kyung Min Ko and Su-Jin Moon, Bucheon St. Mary's Hospital, Division of rheumatology, Department of Internal Medicine, College of Medicine, The Catholic University of Korea, Bucheon, Korea, Republic of (South)

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Fibromyalgia and Other Clinical Pain Syndromes Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Fibromyalgia is characterized by chronic widespread pain. The patients with fibromyalgia complain of symptoms such as fatigue, sleep disturbance and intermittent palpitation, suggesting the potential contribution of autonomic dysfunction in the pathogenesis of the disease. Although dysfunction of autonomic nervous system is common in fibromyalgia patients, there is still a lack of simple methods for the assessment of autonomic dysfunction in the disease. Assessment of sudomotor function has been recently proposed to explore peripheral autonomic sympathetic function. In the present study, we investigated the sudomotor function by using a rapid, objective and non-invasive method in female patients with fibromyalgia.

Methods: Cross-sectional study included 23 female patients with fibromyalgia (mean age 51.1 ± 8.5 , disease duration 13.6 ± 14.7 months) and 29 age-matched healthy controls (HC) subjects. Electrochemical skin conductance (ESC) of hand and feet were measured with the SUDOSCAN (Impeto Medical, France). Fibromyalgia severity was assessed by fibromyalgia impact questionnaire (FIQ) and pain visual analogue scale (VAS). Toronto clinical neuropathy score (TCNS) was applied

in the enrolled subjects. During the sudomotor test, patients were asked to place their bare hands and feet on large electrodes. The test took 2~3 min to carry out without pain.

Results: Hand (58.8 ± 16.9 microSiemens (μS) vs. 64.9 ± 11.7 μS) and feet ESC values (65.8 ± 12.2 μS vs. 69.3 ± 9.4 μS) tended to be lower in female patients with fibromyalgia, compared to those of HC subjects, although the differences were not statistically significant. TCNS in fibromyalgia patients was significantly higher than HC subjects (7.4 ± 2.1 vs. 1.4 ± 0.9 , respectively). There was no association between the hand or feet ESC values and FIQ, pain VAS, TCNS, or body mass index. Interestingly, there were significant negative correlation between fibromyalgia duration and ESC values of hand and feet (spearman's correlation coefficient ; -0.523 and -0.635, respectively).

Conclusion: Our study identified that this quick and non-invasive method to assess sudomotor function might represent the pathologic changes of autonomic nervous system in female patients with fibromyalgia. Further longitudinal study with a larger number of participants is needed to elucidate the clinical significance of hand and feet ESC values in the disease.

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Fibromyalgia and Other Clinical Pain Syndromes Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Chronic diseases involve cognitive aspects. Attention deficit hyperactivity disorder (ADHD) is a chronic condition, marked by persistent inattention, impaired concentration, hyperactivity, impulsivity, emotional lability, anxiety and disorganized behavior. Fibromyalgia (FM) includes a range of symptoms affecting memory, attention and concentration. High rates of comorbidity between ADHD and FM have been reported, as well as some evidence that patients with both conditions experience heightened symptom severity. In addition, recent studies suggest that vitamin D deficiency is associated with cognitive impairment.

Methods: Consecutive patients, older than 18 years, with diagnosis of fibromyalgia (2010 ACR criteria) seen at the outpatient Rheumatology Unit between May 2016 and April 2017, were included. During the inclusion visit the following data were collected: Revised Fibromyalgia Impact Questionnaire (FIQ-R), HAQ-A (Health Auto Questionnaire-simplified, Argentine validation); pain (Visual Analogue Scale, VAS), fatigue (VAS) and serum 25 -hydroxyvitamin D (25(OH)D) level. During the Neurology visit, the following tests were performed: Conners Continuous Performance Test II (CPT II), Wender-Utah Rating Scale (WURS) and Structured Clinical Interview for Personality Disorders (SCID-II). Descriptive statistics were calculated. Correlations were calculated between CPT II and pain, fatigue, FIQ-R, HAQ-A and 25(OH)D, using Spearman's test.

Results: 37 patients with FM were included. Patients' characteristics are shown in table 1. 73% (n=27) of the patients tested positive for adult ADHD. In 40.7% (11/27) of them, the diagnosis had been missed in childhood. Participants with both FM and a positive adult ADHD screening test did not score significantly higher on the FIQ-R (54.9 , $SD= 16.3$ vs 48.8 , $SD= 11.3$; $p= 0.3320$) and did not have lower vitamin D levels (27.4 ng/ml, $SD= 13.1$ vs 36.7 ng/ml, $SD= 9.6$; $p= 0.1050$). There was a very good positive correlation between ADHD and fatigue ($r= -0.9607$; $p= 0.0086$). No association was found between ADHD and severity of perceived cognitive symptoms ($p= 0.673$). There was no correlation with pain ($r= 0.1688$ $p=0.3325$), HAQ-A ($r= 0.1340$; $p= 0.4429$) or vitamin D level ($r= -0.3211$; $p=0.1176$). No correlation was observed between vitamin D levels and FIQ-R ($r= -0.1848$; $p= 0.3662$). The most frequent personality disorders found were narcissism (32,4%) and obsessive-compulsive disorder (32,4%).

Conclusion: The co-occurrence of adult ADHD in FM was highly prevalent. The diagnosis had been often overlooked in childhood. ADHD was associated with fatigue but not with pain, disease impact or functional capacity. Vitamin D levels were not associated with disease impact or dyscognition. Patients with FM should be assessed for the presence of adult ADHD. More investigations are needed to understand the impact of cognitive disorders in FM.

Table 1.

Characteristics	n= 37
Female, n (%)	34 (92)
Age (years), mean (SD)	58.5 (13.4)
Time from diagnosis (years), mean (SD)	3.9 (3.9)
HAQ-A, mean (SD)	0.74 (0.52)
Pain (VAS, 0-100), mean (SD)	68.6 (22.8)
Fatigue (VAS, 0-100), mean (SD)	72.2 (27.2)
FIQ-R, mean (SD)	53.4 (15.2)
25(OH)D, ng/ml, mean (SD)	29.9 (12.5)
Cognitive complaint, n (%)	25 (67.6)

Outcome Expectations and Fibromyalgia: Perceived Benefits of Exercise Are Associated with Self-Efficacy and Physical Performance

Gerald Chi¹, Jolanta Marszalek², Lori Lyn Price^{3,4}, Raveendhara R. Bannuru² and Chenchen Wang², ¹Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA, ²Division of Rheumatology, Center for Complementary and Integrative Medicine, Tufts Medical Center, Boston, MA, ³Tufts Clinical and Translational Science Institute, Tufts University, Boston, MA, ⁴Institute for Clinical Research and Health Policy Studies, Tufts Medical Center, Boston, MA

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Fibromyalgia and Other Clinical Pain Syndromes Poster – ARHP

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Outcome expectancy is recognized as a determinant of exercise engagement and adherence. Higher outcome expectations for exercise (OEE) have been shown to correlate with greater motivation to exercise in patients with osteoarthritis. However, little is known about which factors may influence OEE in fibromyalgia. This is the first study to examine the associations between baseline OEE and demographic, physical and psychosocial variables in patients with fibromyalgia.

Methods: This study is a cross-sectional, secondary analysis of data obtained at baseline evaluation from a single-center, 52-week, randomized comparative effectiveness trial of Tai Chi versus aerobic exercise for participants with fibromyalgia (n=226). Baseline measures included demographics, physical performance, outcome expectancy, self-efficacy, anxiety, depression, stress, social support, and pain coping. OEE was assessed with the 9-item Outcome Expectations for Exercise Scale, where a higher value indicates stronger expectation for a positive outcome. Independent t-test and chi-square test were used to determine the relationship between participant characteristics and high OEE (\geq median of 3.9). Statistical significance was set at $p < 0.05$.

Results: Participants had a mean age of 51.8 years and body mass index of 30.0 kg/m², 92.5% were female, 61.1% were white, and 36.0% possessed at least college-level education. Compared to the lower OEE group, individuals with a higher OEE were more likely to have a greater self-efficacy (5.7 ± 2.2 vs. 4.8 ± 2.0 ; $P=0.001$) and physical performance as assessed by 6-minute walk distance (meters) (423.8 ± 85.8 vs. 382.2 ± 77.6 ; $P<0.001$) or SF-36 physical component (31.8 ± 7.0 vs. 29.6 ± 8.0 ; $P=0.029$). There were no other significant associations.

Conclusion: Our study found that higher OEE was significantly associated with greater self-efficacy and physical performance. Future longitudinal research should explore how these relationships affect long-term exercise engagement for patients with fibromyalgia.

Mindfulness Is Associated with Sleep Quality Among Patients with Fibromyalgia

Michelle Park¹, Yuan Zhang², Lori Lyn Price^{3,4}, Raveendhara R. Bannuru¹ and Chenchen Wang¹, ¹Division of Rheumatology, Center for Complementary and Integrative Medicine, Tufts Medical Center, Boston, MA, ²Susan and Alan Solomont School of Nursing, University of Massachusetts Lowell, Lowell, MA, ³Institute for Clinical Research and Health Policy Studies, Tufts Medical Center, Boston, MA, ⁴Tufts Clinical and Translational Science Institute, Tufts University, Boston, MA

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Fibromyalgia and Other Clinical Pain Syndromes Poster – ARHP

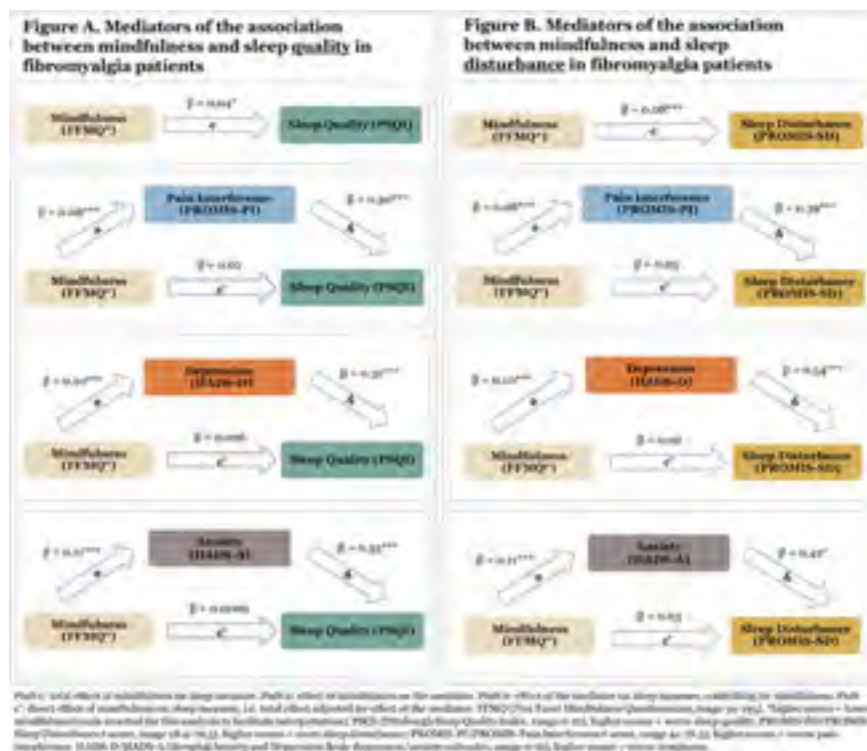

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Poor and disturbed sleep is an important disabling feature of fibromyalgia. Previous studies suggest higher mindfulness may be associated with better sleep quality in people with chronic health problems. However, the role of mindfulness in sleep problems in fibromyalgia remains understudied. We examine the relationships between mindfulness and sleep, psychological health, and pain interference in fibromyalgia patients.

Methods: A cross-sectional analysis of baseline data from a randomized controlled trial in fibromyalgia patients was performed. Measures included mindfulness (Five Facet Mindfulness Questionnaire), sleep quality (Pittsburgh Sleep Quality Index), sleep disturbance (PROMIS Sleep Disturbance), pain interference (PROMIS Pain Interference), anxiety, and depression (Hospital Anxiety and Depression Scale). Pearson correlations were used to examine associations among mindfulness, sleep quality, sleep disturbance, anxiety, depression, and pain interference. Mediation analysis was conducted to assess whether anxiety, depression, and pain interference mediated the association between mindfulness and sleep quality, and the association between mindfulness and sleep disturbance.

Results: A total of 177 patients with fibromyalgia were included (93% female, mean age: 52±12 years, 59% white, BMI: 30±7 kg/m²). Higher mindfulness in patients was associated with better sleep quality ($r = -0.23$, $p = 0.002$) as well as less sleep disturbance ($r = -0.24$, $p = 0.002$), pain interference ($r = -0.31$, $p < 0.0001$), anxiety ($r = -0.58$, $p < 0.0001$), and depression ($r = -0.54$, $p < 0.0001$). In addition, pain interference, depression, and anxiety mediated the association between mindfulness and sleep quality (**Figure A**), and the association between mindfulness and sleep disturbance (**Figure B**).

Conclusion: Higher mindfulness is associated with better sleep quality and less sleep disturbance, pain interference, anxiety, and depression in people with fibromyalgia. Further, higher mindfulness has a significant indirect effect on better sleep in fibromyalgia patients by way of lowering pain interference, depression, and anxiety.

Abstract Number: 262

Shedding Light on Fibromyalgia: Emotional Regulation Processes and Executive Functions Join Together

Marta Redondo¹, Almudena Trucharte Martinez², Gabriela Castillo Parra² and Leticia Leon³, ¹Health Sciences, Universidad Camilo Jose Cela, Madrid, Spain, ²Universidad Camilo Jose Cela, Madrid, Spain, ³Instituto de Investigación Sanitaria San Carlos (IdISSC), Madrid, Spain

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Fibromyalgia and Other Clinical Pain Syndromes Poster – ARHP

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Fibromyalgia (FM) is characterized mainly by the presence of generalized pain accompanied by emotional and cognitive symptoms. The evidence shows that in order to face the emotional consequences of pain, there must be an adequate capacity for self-regulation that is, in part, mediated by executive functions. However, this relationship between the emotional and the cognitive has been scarce studied in FM patients, whose shows a deficit in the use of emotional regulation strategies and executive functions. The purpose of the study was to compare the emotional regulation processes between FM and healthy subjects, and also to explore the relationship between emotional regulation and the processes of executive functions within FM patients.

Methods: 55 FM patients who satisfy the ACR criteria were included, and a healthy group matched by age and sex was also recruited. Both groups completed the Difficulties in Emotional Regulation Scale (DERS). Comparison of the groups was performed by the Student's t-test. For the second purpose of the study, 30 women in the FM group completed the measure of planning and monitoring with the Map of the Zoo (BADS: Behavioural Assessment of the Dysexecutive Syndrome the Map of the Zoo test). For the second purpose, a Spearman's Rho was carried out.

Results: The results found statistically significant differences in all the scales of the DERS ($p < .01$), showing that FM patients had greater difficulties in the emotional regulation process in comparison with a control group. The result of explore the relationship between executive function and emotional regulation showed a negative correlation between the emotional lack of control scale and the total score in formulating ($\rho = -.43$, $p = .04$) and the total score of planning (formulating and executing a plan) ($\rho = -.47$, $p = .03$), and between the interference emotional scale and the formulating ($\rho = -.45$, $p = .04$) and the total score of planning ($\rho = -.44$, $p = .04$).

Conclusion: The results of the present study indicate that, although FM patients do not differ from the control group in the attention or awareness given to their emotional states, they are not able to implement other strategies to regulate that emotional state. Moreover, these problems in the use of emotional strategies could be due to difficulties in the executive processes. Therefore, cognitive function impaired could potentiate alterations in psychological processes, so specific interventions could be designed in order to improve executive function and increasing the use of strategies for emotional regulation.

Abstract Number: 263

Racial Disparities in Total Knee Replacement Failure Are Not Explained By Poverty

Anne R. Bass¹, Jackie Szymonifka², Lisa A. Mandl¹, Bella Y. Mehta³, Emily Ying Lai², Stephen Lyman¹, Michael L. Parks¹, Serene Z. Mirza², Shirin A. Dey² and Susan M. Goodman², ¹Hospital for Special Surgery/Weill Cornell Medicine, New York, NY, ²Hospital for Special Surgery, New York, NY, ³Hospital for Special Surgery/Weill Cornell Medicine/Mailman School of Public Health, New York, NY

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Healthcare Disparities in Rheumatology Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: U.S. blacks have a higher risk of revision total knee replacement (TKR) than whites, but whether this is mediated by poverty is unknown. The goal of this study was to evaluate racial disparities in TKR failure and determine whether community poverty modifies this risk.

Methods: All black and white NewYork (NY) State residents enrolled in a prospective single-institution TKR registry 2007-2011 were included. Institutional registry patients were linked to the NY Statewide Planning and Research Cooperative System (SPARCS) database (1/1/07-12/31/14) to capture patients who underwent revision TKR at another institution, and the reasons for revision. Patients were linked by geocoded addresses to their residential census tract (CT). Cox regression was used to assess predictors of TKR revision. Next, multivariable logistic regression was used to analyze predictors of TKR failure, defined in two ways: 1. TKR revision in NY State 2 years or less after the initial surgery or; 2. KOOS Quality of Life (QOL) that worsened or improved less than or equal to 7.5 points, or HSS Satisfaction Survey QOL rating of no improvement or worsening 2 years after surgery. Logistic regression was used to estimate the interaction between percent of the CT under the poverty line (CT poverty) and race on TKR failure.

Results: 4529 TKR in 4263 patients were included in the study. 137 (3.0%) required TKR revision, and 330 (17%) experienced TKR failure. Mean age was 68.0 ± 9.8 , 64.1% were female, 8.4% black. Cases came from 1687 unique census tracts and mean CT poverty was $7.7\% \pm 8.1\%$ (a poverty area is defined as 20% or higher). Median follow-up in SPARCS was 63 months. TKR revisions occurred a median of 15.3 months [IQR 8.0- 28.1] after the index surgery. Causes of TKR revision were septic in 26 (19%) and aseptic in 111 (81%) including mechanical failure (n=104, 75.9%), fracture (n=5, 3.7%), other causes (n=2, 1.5%). Compared to aseptic revisions, septic revision cases were older (67.5 vs. 62.4 years, $p=0.028$), had lower volume surgeons ($p=0.019$), and a shorter time to revision (6.3 vs. 17.6 months; $p=0.018$). In multivariable analysis, factors influencing the risk of TKR revision were younger age (HR 0.80 per 5 years; 95% CI 0.74 - 0.86) and disruption of the operative wound during the index surgery admission (HR 8.05; 95% CI 1.12 - 57.7). Three hundred thirty out of 1943 (17%) cases resulted in TKR failure at 2 years. In univariate analysis, risk factors for TKR failure included race, diabetes, and upper respiratory tract infection during the index surgery admission, TKR laterality, patient expectations score, and CT poverty, but in multivariable analysis only black race remained statistically significant (OR 2.18; 95% CI 1.26 - 3.79). There was no interaction between CT poverty and race on the risk of TKR failure.

Conclusion: Blacks are at higher risk than whites of TKR failure, defined as no improvement after TKR or the need for revision, and community level poverty does not modify this risk.

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Adverse childhood experiences (ACEs) such as abuse, neglect and domestic violence are associated with poor adult health status and immune dysregulation. The extent and impact of ACEs on patients with existing autoimmune disease are not known. We compared prevalence of ACE in SLE patients with the general population and investigated relationships between ACEs and health status in SLE patients.

Methods: Data derive from the California Lupus Epidemiology Study (CLUES), a diverse population based cohort of individuals with SLE. Participants completed the ACE questionnaire, a validated 10 item survey covering 3 domains (abuse, neglect and household challenges). We estimated prevalence of ACE in 270 CLUES participants compared to the general population using 2015 California Behavioral Risk Factor Surveillance System data (1:1 matching by county, age, sex and race/ethnicity). We examined 5 patient-reported outcomes (SLE activity, damage, depression, physical function and quality of life) and 3 physician-assessed measures (SLE disease activity, damage and severity indices). SLE outcomes were compared across ACE levels (0, 1, 2-3, ≥ 4) and domains using multivariable linear regression controlling for age, sex, race/ethnicity, disease onset <18 years, and education level. Domain effects were estimated in separate models. Statistical significance was $p < 0.05$.

Results: ACE levels and domains were similar for SLE patients and the general population. Six in 10 individuals (63.3%) with SLE reported ≥ 1 ACE and 19.3% had ≥ 4 ACEs. Nonzero ACE levels were more common ($>58\%$) in women, Latino and African American participants, those who did not graduate college and those with lupus nephritis. In adjusted models, higher overall ACE score was associated with greater patient-reported SLE activity and damage, higher levels of depressive symptoms, poorer physical function and quality of life, though not all measures reached statistical significance (Table 1). ACE levels did not predict worse physician-assessed SLE activity, damage or severity (Table 2). The results for all 3 ACE domains paralleled results for ACE score levels with worse patient-reported, but not physician-assessed outcomes.

SLAQ - Systemic Lupus Activity Questionnaire; BILD - Brief Index of Lupus Damage; PHQ - Patient Health Questionnaire depression scale; PROMIS PF - Patient-Reported Outcomes Measurement Information System Physical Function; SF36 - Short Form-36 Physical Component Score; Quality of Life; SLEDAI - Systemic Lupus Erythematosus Disease Activity Index; SDI - Systemic Lupus Collaborating Clinics Damage Index; LSI - Lupus Severity Index.
Cells are means (95% confidence interval).
¹Adjusted for age, sex, race/ethnicity, disease onset <18 years, education level. (Domain effects estimated in separate models, with ACE0 as reference group).
* $p < 0.05$.

Conclusion: ACEs were equally common among CLUES cohort and the general population. Accumulation of adverse experiences was associated with poorer patient-reported health measures, but not physician-assessed outcomes, in adulthood. Results reinforce the need to prevent ACEs and promote resilience when a history of ACE is ascertained.

Session Date: Sunday, October 21, 2018

Session Title: Healthcare Disparities in Rheumatology Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: There is a lack of population-based statistics on utilization and costs of direct healthcare of systemic lupus erythematosus (SLE) in the US, which disproportionately impacts blacks. Data are limited to those from databases, such as Medicaid and commercial claims, which cannot validate SLE diagnoses on a larger scale. To overcome these limitations, we utilized a population-based registry to evaluate healthcare utilization and direct costs in SLE. **Methods:** The Georgia Lupus Registry is a Centers for Disease Control and Prevention-funded population-based registry of validated SLE patients in Atlanta, GA, from 2002–04. The state privacy exemption for public health surveillance allowed diagnoses to be validated without consent on a population level, using ≥ 4 ACR criteria or 3 ACR criteria with a final diagnosis of SLE by a board-certified rheumatologist. Validated incident patients were matched with the state Hospital Discharge Database from 2000–13, which captured all hospital and emergency room (ER) admissions. Direct costs were reported according to the latest Medicare reimbursement rates, regardless of insurance or lack thereof. Patients were censored at

All calculations from SLE diagnosis through 2015 or death. ACR renal criterion captured during the first year after SLE diagnosis. Charges are inflation adjusted to 2015 US\$.
SLE, Systemic Lupus Erythematosus.

death. **Results:** Of 336 incident patients, 86.9% were female, 73.8% black, 22.9% white and 58.9% unmarried; 246 (73.2%) were admitted to hospital and 257 (76.5%) to the ER (Table 1). Patients admitted to the ER and hospital were significantly more likely to be black and have serositis. Hospitalized patients were also more likely to have a renal disorder and meet a greater number of ACR criteria (Table 1). Overall, 1255 hospitalizations had a total cost of \$56,365,119 (Table 2). The hospitalization rate was higher in blacks and those with renal disorders. Charges per hospitalization were higher in whites compared with blacks and in those with renal involvement. Length of stay per admission was similar across all groups (6–8 days) (Table 2). There were 2004 ER admissions with a total cost of \$4,818,097. The ER admission rate was highest in the blacks and those with renal involvement. Charges per ER admission were similar by sex and in those with renal involvement, but were higher in whites compared with blacks (Table 2).

Conclusion: SLE has significant healthcare utilization and cost burden. A large proportion of patients are admitted to the ER or hospital. Blacks and those with early renal involvement have a higher rate of hospital and ER admissions. Despite having fewer hospital and ER admissions, whites incurred higher charges per admission than blacks. Further study of factors that drive healthcare utilization and cost is needed.

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Healthcare Disparities in Rheumatology Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) presents heterogeneously and can be difficult to diagnose. Once diagnosed, prompt evaluation and treatment by a specialist can prevent morbidity. Few studies have systematically quantified delays in diagnosis and access to specialty care in SLE. Using a large cohort of individuals with confirmed SLE, we aimed to characterize patient-perceived delays in diagnosis and access to specialty care at SLE onset.

Methods: Data were derived from the California Lupus Epidemiology Study (CLUES), a population-based, longitudinal, multi-ethnic cohort of patients with SLE. Data were collected via annual telephone interviews and in-person clinical visits. Questions included time from onset of symptoms to seeing a doctor and to diagnosis of SLE, the number of doctors seen before SLE diagnosis, specialty of diagnosing physician, specialty of doctor giving incorrect diagnosis, and the time until first visit with a specialist (rheumatologist or nephrologist) if not initially diagnosed by one. We examined the relationships between these variables and race/ethnicity, poverty (<125% of federal poverty level; FPL), education (\leq high school, vocational/trade schooling, college, postgraduate), and self-assessed health literacy (adequate vs. limited, using a validated 4-item scale), testing the differences with chi-square tests.

Results: This study included 417 patients, 90% female with a mean age of 47 ± 14 years. 90% met $\geq 4/11$ ACR criteria for SLE; the balance had a physician diagnosis of SLE and/or lupus nephritis. The racial/ethnic distribution was 31% Caucasian, 35% Asian, 23% Hispanic and 11% African-American. Twenty-two percent had an education level \leq high school, 19% were $>125\%$ FPL, and 40% with low health literacy. Time from symptom onset to seeing a doctor varied, with 65% seen in < 6 months, 12% in 6-12 months, 7% in 1-2 years and 16% waiting >2 years. Time from symptom onset to receiving a diagnosis also varied, with 48% of participants waiting >6 months. 39% of patients received an incorrect initial diagnosis, most commonly from primary care physicians. There were no significant differences for any of these outcomes by race, education, health literacy or poverty level. For patients who were initially diagnosed with SLE by a non-specialist, racial/ethnic minorities and those with a high school education or less were more likely to wait longer than 3 months for a referral (both $p = 0.03$). Compared with those with less education, patients with higher levels of education saw more doctors before receiving a correct diagnosis (mean=2.1 vs 2.6; $p=0.02$).

Conclusion: Overall approximately half of this study's patients waited >6 months to receive a diagnosis of SLE, and 39% received an incorrect initial diagnosis. Access to specialty care varied significantly, with racial/ethnic minorities, and those with low education waiting longer to see a specialist. Those with a higher education level saw more doctors prior to receiving a diagnosis, which could potentially be explained by greater access to healthcare in general. This study suggests that efforts to decrease diagnostic delays and errors, particularly among at-risk populations with SLE, are warranted.

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Healthcare Disparities in Rheumatology Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Medication access and adherence are important issues in determining patient outcomes. We investigated sociodemographic factors and disparities associated with prescription medication access in a population-based cohort of lupus patients and controls.

Methods: Detailed data on prescription access and sociodemographics were collected at the MILES baseline visit by structured interview. We compared access between cases and frequency-matched controls (using chi-squared tests) and examined factors associated with access in separate multivariable logistic regression models.

Results: 654 participants (462 SLE cases, 192 controls) completed the MILES Cohort baseline visit; 584 (89.3%) female, 288 (44%) black, and mean age 53 years. SLE patients were significantly more likely than controls to report the following in the preceding 12 months to save money: skipping doses, taking less medicine, delaying filling prescriptions and asking their doctor for a lower cost medication (Table 1).

Table 1. Self-reported prescription access within the preceding 12 months in SLE cases compared to frequency-matched controls.

Questionnaire Item	SLE cases (n=462) n (%)	Controls (n=192) n (%)	p-value
Unable to get Rx's doctor felt necessary?	56 (12.1)	18 (9.4)	NS
Skipped med doses to save money?	62 (13.4)	12 (6.3)	0.008
Taken less medicine to save money?	70 (15.2)	11 (5.7)	0.001
Delayed filling a Rx to save money?	75 (16.2)	17 (8.9)	0.013
Asked doctor for lower cost medication to save money?	110 (23.8)	30 (15.6)	0.02
Bought Rx from another country to save money?	5 (1.08)	2 (1.04)	NS
Used alternative therapies to save money?	38 (8.2)	11 (5.7)	NS

NS=not significant

Based on multivariable models (Figure 1), having SLE was associated with several types of limitations in medication access, after adjusting for sex, race, age, insurance status, and income level. Household income below the US median was also associated with limitations in medication access, whereas private insurance was generally associated with improved access. Black persons were less likely to ask their doctor for lower cost alternatives.

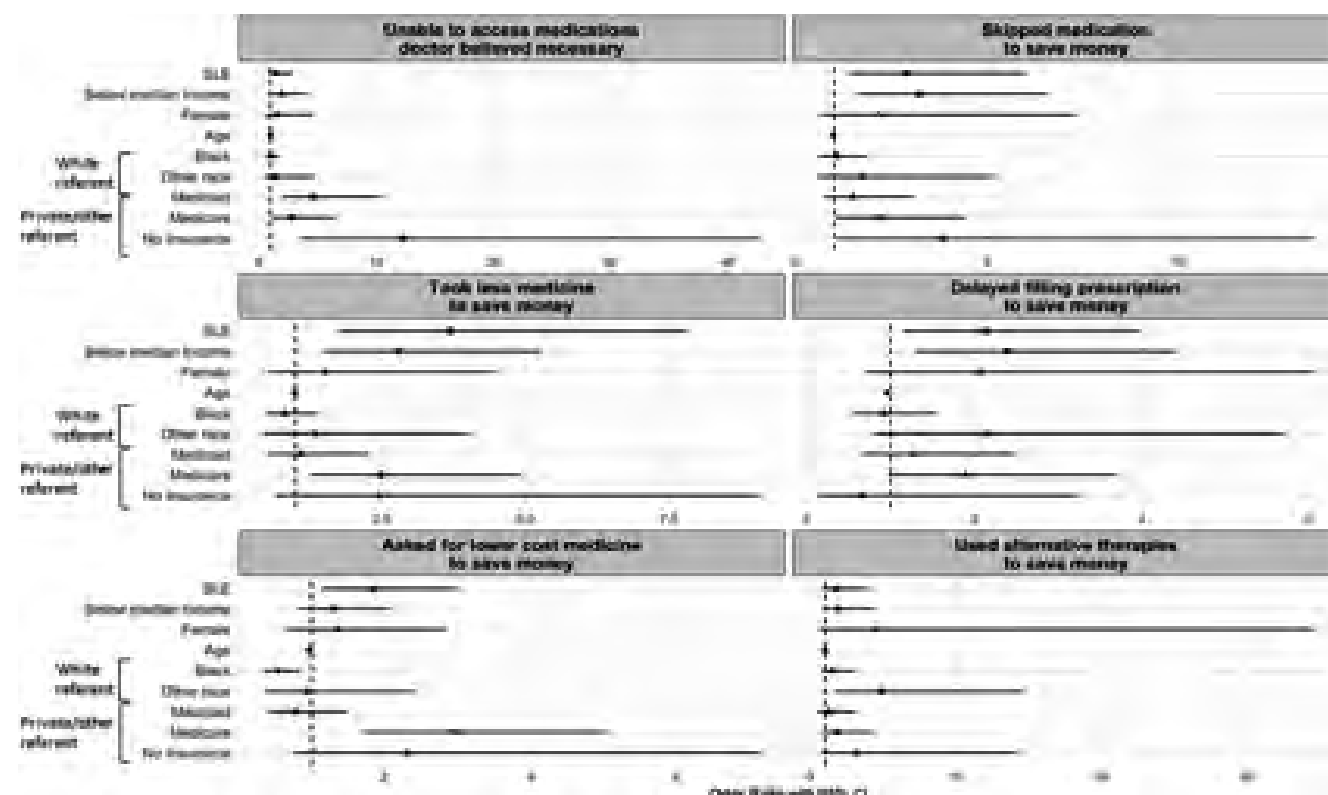

Figure 1. Forest plots from a series of multivariable models of factors associated with aspects of prescription medication access and adherence. Squares represent positive odds ratios (ORs), circles negative ORs, triangles not significant ORs; horizontal lines represent 95% CIs.

Conclusion: SLE patients were more likely than controls from the general population to experience limitations in prescription medication access, and less than 1 in 4 patients asked providers for lower cost medications. Further, disparities in access were found in association with income, race and insurance status. Consideration of medication costs in patient decision making could provide a meaningful avenue for improving patient access and adherence to medications.

The Effect of Renaming Gout to Urate Crystal Arthritis on Illness and Treatment Perceptions in Māori (the Indigenous People of Aotearoa/New Zealand)

Nicola Dalbeth¹, Meihana Douglas¹, Kate MacKrell¹, Leanne Te Karu², Maria Kleinstäuber¹ and Keith Petrie¹, ¹University of Auckland, Auckland, New Zealand, ²Ngā Kaitiaki o Te Puna Rongoā o Aotearoa, Taupō, New Zealand

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Healthcare Disparities in Rheumatology Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Recent research has suggested that renaming gout to a pathophysiological illness label (urate crystal arthritis) avoids inaccurate lay perceptions of gout and promotes more effective management strategies. In Aotearoa/New Zealand, Māori (indigenous New Zealanders) have high prevalence of gout, with early onset and severe disease. It is unknown how a change in illness label would impact on indigenous New Zealanders who are disproportionately affected by gout. The aim of this study was to examine the effect of changing the illness label of gout on the perceptions of the disease and its management in Māori in Aotearoa/New Zealand.

Methods: Supermarket shoppers in rural and urban locations with large Māori communities were recruited into a study examining the perceptions of different types of arthritis. Participants were randomised 1:1 to complete a questionnaire examining the perception of the same disease description labelled as either 'gout' or 'urate crystal arthritis' (UCA). Participants rated likely causal factors for the disease, illness perceptions and the usefulness of various management strategies using Likert scales. Differences between the two illness labels were tested using independent sample t-tests.

Results: Completed questionnaires were available from 172 Māori participants. The gout-labelled illness was most likely to be viewed as caused by diet ($P=0.003$), whereas the UCA-labelled illness was most likely to be viewed as caused by aging ($P=0.001$). 'UCA' was seen as having a wider range of factors as responsible for the illness, with stress or worry, hereditary factors, chance and pollution more likely to be viewed as causes of 'UCA'. 'Gout' was less likely to be viewed as having a chronic timeline than 'UCA' (mean (SD) for 'Gout' 6.9 (2.8) and for 'UCA' 7.9 (2.4), $P=0.013$). 'Gout' was also viewed as better understood than 'UCA' (mean (SD) for 'Gout' 6.3 (3.1) and for 'UCA' 4.4 (3.3), $P=0.001$). Other illness perceptions did not differ between the illness label groups. Changing to a healthier diet was perceived as more helpful for 'Gout' compared to 'UCA' (mean (SD) for 'Gout' 8.5 (2.3) and for 'UCA' 7.3 (2.7), $P=0.003$). Participants also viewed stopping or restricting alcohol use as more helpful for 'Gout' than 'UCA' (mean (SD) for 'Gout' 8.1 (2.8) and for 'UCA' 7.0 (3.1), $P=0.017$). There were no differences between 'Gout' and 'UCA' in perceptions that adopting regular exercise, losing weight or taking long-term medications would be helpful for managing the illness ($P>0.23$ for all).

Conclusion: In an indigenous population that is disproportionately affected by gout, causal beliefs and management strategies for a gout-labelled illness are consistent with widely-held lay beliefs that gout is a disease caused by self-inflicted dietary excess. Renaming gout to urate crystal arthritis promotes more complex causal beliefs, a longer timeline for the disease, and is likely to avoid perceptions that dietary modification and alcohol restriction are the main strategies for effective management.

Adverse Event Reporting Rates and Placebo/Standard-of-Care-Arm American College of Rheumatology Responses Vary By Region in Rheumatoid Arthritis Trials

Katie Tuckwell, Edmond Teng, Jenny Chia, Daisy Lee, Joshua Galanter, Jodie Peake and Daniel Keebler, Genentech, Inc., South San Francisco, CA

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Healthcare Disparities in Rheumatology Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Clinical trials are becoming increasingly globalized, with more representation from Asia, Latin America, and the Russian Federation and Eastern Europe (RFEE).¹ Adverse event (AE) reporting rates and placebo (or standard-of-care arm) responses may differ by geographic region and level of economic development²⁻⁴; efficacy and safety may not be generalizable across regions. This potential heterogeneity and its implications for rheumatoid arthritis (RA) trials have not been studied in detail. The current study assessed potential regional differences in rates of ACR response and AE reporting using patient-level data (PLD) from RA trials in the TransCelerate initiative.⁵

Methods: We obtained PLD for all 17 RA trials available through TransCelerate as of August 2017 and analyzed data from 7 trials for which geographic information was available (NCT01198002, NCT01202760, NCT01202773, NCT01404585, NCT00605735, NCT00048581, NCT00647270). We grouped patients by region and evaluated differences in demographics, AE reporting rates, and ACR response. After a significant omnibus chi-square test result, pairwise comparisons were made between regions using Fisher exact test, with false discovery rate (FDR) correction for multiple comparisons. All patients were included in analyses of AE reporting. Only patients with data sufficient to calculate ACR scores were included in analyses of ACR response. Demographics for patients in each region are shown in the Table.

Results: The lowest rates of AE reporting and ACR50 response were seen in RFEE. The highest rate of ACR20 response was seen in Asia. After FDR correction, significantly lower 12-week and 52-week AE reporting rates were seen in RFEE than in Asia, Latin America, and the United States. Only the ACR50 response difference between RFEE and Latin America survived FDR correction; however, ACR20 rates in Asia remained significantly higher than in RFEE and the United States (Table).

Table. Regional Variations in Patient Demographics and Efficacy and Safety in Placebo/Standard-of-Care Arms of Clinical Trials in RA

Patient numbers and demographics	US	Latin America	Asia	RFEE
AE analysis, n	369	167	164	213
ACR response analysis, n	268	132	107	160
Female, %	81	89	88	81
Median age, years (SD; range)	55 (11; 21-78)	51 (12; 22-76)	52 (12; 18-83)	51 (12; 25-79)
Proportions of patients attaining ACR50/20 response at 12 weeks and/or reporting ≥1 AE at 12 and 52 weeks				
Patients, %	US	Latin America	Asia	RFEE
ACR50 response	6	9a	7	1
ACR20 response	17	24	29a b	15
AE at 12 weeks	53a	49a	51a	22
AE at 52 weeks	68a	58a b	65a	39

^a*p* < 0.05 vs RFEE. ^b*p* < 0.05 vs US. All *p* values corrected for multiple comparisons.

Conclusion: Patient-level data from placebo arms in the TransCelerate initiative revealed significant regional differences in AE reporting rates and ACR50/ACR20 response rates. Differences in Latin America, RFEE, and Asia were especially notable; future patient populations from these regions may show distinct efficacy/safety profiles regardless of treatment. Given the ongoing globalization of clinical trials, country- and region-specific treatment patterns, patient populations, and safety issues should be explored to avoid misguided inferences across regions. Capping recruitment by region to balance these factors may be warranted. *References:* 1. Drain PK et al. *Nat Rev Drug Discov.* 2014;13:166-7. 2. Abstract Number: 270

Gaps in Knowledge about the Ontario Trillium Drug Program

Ambika Gupta¹, Heather Khey Beldman², Caroline Avern³ and Henry Avern³, ¹Internal Medicine, Queen's University, Kingston, ON, Canada, ²Department of Family Medicine, Queen's University, Kingston, ON, Canada, ³Private Practice, Kingston, ON, Canada

Session Information**Session Date:** Sunday, October 21, 2018**Session Title:** Healthcare Disparities in Rheumatology Poster**Session Type:** ACR Poster Session A**Session Time:** 9:00AM-11:00AM

Background/Purpose: Medication costs for patients with a rheumatic disease can add up as they may be on numerous and/or costly medications including anti-inflammatory medications, disease-modifying anti rheumatic drugs and/or biologic medications. The number of biologic medications available to treat rheumatic diseases has steadily increased over the last decade. Biologic medications generally cost over 10,000 Canadian dollars annually. In Ontario, Canada, the Trillium Drug Program (TDP) funds patients who approximately spend greater than 4% of their after-tax household income on prescription drugs. From 2005 to 2015, the TDP has increased its coverage of medications that cost greater than \$10,000 annually, from 20 to 124 medications, respectively.¹ However, the gaps in knowledge about the TDP is not clear among resident physicians and patients. The purpose of the study was to determine what resident physicians and patients know about the TDP.

Methods: This research survey project was approved by the Queen's University Health Sciences & Affiliated Teaching Hospitals Research Ethics Board. Qualtrics survey software was used to distribute anonymous questionnaires to Queen's University residents (family medicine and core internal medicine) and patients at a private rheumatology clinic. Two types of patient surveys were completed: a general patient questionnaire and a specific questionnaire for patients on expensive biologic medications.

Results: 50/55 residents have heard of the TDP but only 11/50 residents know how a patient would apply for it. The general patient survey revealed that 18/27 patients have heard of the TDP but only 2/18 patients know how to apply for it. Of these two patients, one patient has applied. The other patient did not think that they would qualify for it and so has not applied. The survey of patients on expensive medications revealed that 3/7 patients have a private drug plan and 6/7 patients have heard of the TDP. All six of these patients have heard of this program through a healthcare professional. 5/6 of the patients know how to apply for the TDP. 4 of these 5 patients has applied to the TDP and one has not as they do not think they need it.

Conclusion: The survey results reveal that resident physicians and patients generally do not know how to apply to the TDP, although they have heard of the program. On the other hand, the patients who are on expensive medications generally do know how to apply to the TDP and have done so. This is likely due to guidance by a healthcare professional. Due to these gaps in knowledge about the TDP, we have created an information sheet to educate patients about the TDP.

Abstract Number: 271

Health Care Disparities for Infectious and Non-Infectious Uveitis in the US

Krati Chauhan¹, Steven Scaife² and James T. Rosenbaum³, ¹Internal Medicine, Southern Illinois University School of Medicine, Springfield, IL, ²Center for clinical research, Southern Illinois University- School of Medicine, Springfield, IL, ³Ophthalmology, Oregon Health & Science University and Legacy Devers Eye Institute, Portland, OR

Session Information**Session Date:** Sunday, October 21, 2018**Session Title:** Healthcare Disparities in Rheumatology Poster**Session Type:** ACR Poster Session A**Session Time:** 9:00AM-11:00AM

Background/Purpose: Autoimmune disease like systemic lupus erythematosus and rheumatoid arthritis are influenced by health care disparities due to race, income, sex and age. Uveitis is a frequent association with rheumatic diseases including ankylosing spondylitis, Behcet's disease, and juvenile idiopathic arthritis. There is lack of national data regarding how health care disparities influence uveitis. The primary aim of our study is to compare the effect of race, income and insurance status in patients with infectious and non-infectious uveitis.

Methods: We used the National Inpatient Sample (NIS) for the years 2002-2013. We used ICD-9 codes to identify infectious, noninfectious uveitis cases and ocular complications. We collected information on patient's age, sex, race,

income quartile of median household income for patients' zip code and payer status. A multivariate logistic regression model was run to predict odds of developing infectious uveitis, non-infectious uveitis and ocular complications, adjusted for age, sex, race, income quartile of median household income for patient's zip code and payer status. To assess the effect of income irrespective of race, we ran a logistic regression model, excluding African Americans. Statistical analysis was done using SAS version 9.4.

Results: There were a total of 94,143,978 discharges, which included 15,296 total cases of uveitis, 4,538 cases of infectious uveitis and 10,758 cases of non-infectious uveitis. For a multivariate model odds of African Americans having infectious uveitis are five times: (OR = 5.37, 95% CI: 4.95-5.82) and having non-infectious uveitis are one and half times as compared to Caucasians: (OR = 1.43, 95% CI: 1.35-1.52). Odds of Medicare (OR = 2.21, 95% CI= 1.35-3.62) and Medicaid (OR = 1.7, 95% CI = 1.04-2.85) patients having complications from infectious uveitis are double and 1.7 times as compared to those with private insurance. Odds of Medicare (OR = 2.01, 95% CI= 1.46-2.71) and Medicaid (OR = 2.18, 95% CI = 1.51-3.16) patients having complications from non-infectious uveitis are double as compared to those with private insurance.

After excluding African Americans, patients with median household income for patient's zip code of \$ < 38,999 have 1.5 times odds of having infectious uveitis: (OR=1.54, 95% CI=1.38-1.71), as compared to those with median household income > \$63,000. Medicare patients have 1.6 times the odds (OR = 1.6, 95% CI= 0.83-3.06) and Medicaid patients double (OR = 2.05, 95% CI = 1.05-4) the odds having ocular complications from infectious uveitis. And Medicare patients have 1.7 times the odds (OR = 1.7, 95% CI= 1.21-2.46) and Medicaid patients double (OR = 2.35, 95% CI = 1.54-3.58) the odds having ocular complications from non-infectious uveitis as compared to those with private insurance.

Conclusion: African Americans have higher odds of developing infectious and non-infectious uveitis. Medicare and Medicaid patient have higher odds of developing complications from infectious and non-infectious uveitis. Uveitis should be added to the list of immune-mediated diseases which are affected by health care disparities. These disparities cannot be completely explained on the basis of racial or genetic factors.

Ethnic Disparities in Lupus Nephritis Outcomes in the Inland Empire: Findings from the Southern California Lupus Registry

Kristal Choi¹, Arezoo Haghshenas², Abigail Benitez³, Lorena Salto¹, Karina Torralba⁴ and Vaneet K. Sandhu², ¹Loma Linda University, Loma Linda, CA, ²Division of Rheumatology, Loma Linda University, Loma Linda, CA, ³Rheumatology, Loma Linda University, Loma Linda, CA, ⁴Loma Linda University Medical Center, Loma Linda, CA

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Healthcare Disparities in Rheumatology Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Loma Linda University Health (LLUH) serves Riverside and San Bernardino County, which are the two largest counties by geographic size in California and make up the Inland Empire of Southern California. This underserved region of California comprises 50% Hispanic, 31.8% White, 8.7% Black, and 6.6% Asian/Pacific Islander (PI)

Figure 1: UPC Trend Over 12 Months in Different Ethnicities

residents. Prior studies have established differences in the incidence, clinical manifestations, and treatment response of SLE among ethnic groups. Of particular note are Hispanics, who have demonstrated greater prevalence of renal involvement and better response to certain therapies. However, the majority of these studies were conducted in Latin America and few have focused exclusively on lupus nephritis (LN). The objective of our study was to evaluate therapy management and response differences between LN patients of different ethnic backgrounds in the Inland Empire.

Methods: Data was obtained from the Southern California Lupus Registry (SCOLR), a registry that enrolled SLE patients June 2016 to June 2018 at LLUH. All LN patients were screened for inclusion. Exclusion criteria included patients with renal transplant and unknown LN class. Information obtained from the medical record included demographics, LN class, medications used, and the Systemic Lupus Erythematosus Disease Activity Index 2000 (SLEDAI-2K) and urine protein-to-creatinine ratio (UPC) at baseline, 6 months, and 12 months. Simple descriptive statistical analyses were calculated to determine if observed differences were statistically significant, and a p-value ≤ 0.05 was considered significant.

Results: Thirty-five patients with LN were identified, of which there were 3 (8.6%) White, 18 (51.4%) Hispanic, 6 (17.1%) Asian/PI, and 8 (22.9%) Black. Baseline, 6 month, and 12 month SLEDAI were significantly lower in the Asian/PI cohort when compared to the other ethnic groups. In contrast, there was a trend towards higher baseline, 6 month, and 12 month SLEDAI and proteinuria levels in Hispanics when compared to the other ethnic groups (Figure 1). No significant association was found between change (between baseline and 6 months) in SLEDAI and ethnicity. All White patients had SLEDAI improvement over 6 months, while the majority of Asian/PI, Black, and Hispanic patients had no change or worsened disease activity. No association was found between medication type and ethnicity or between medication type and change in SLEDAI.

Conclusion: Asian/PI patients have significantly less disease activity whereas Hispanic patients trend towards greater disease activity than their counterparts. This study is the first endeavor to evaluate therapy management and response differences between LN patients of different ethnic backgrounds in Southern California. Further studies with greater power are needed to validate these findings.

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Healthcare Disparities in Rheumatology Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The incidence of systemic lupus erythematosus (SLE) varies significantly across patients from different racial/ethnic backgrounds, and is highest in non-Caucasian populations. In addition, poverty has been associated with increased SLE severity and mortality, independent of race/ethnicity. How the incidence of SLE varies by income level, the main determinant of poverty, is unknown.

Methods: Using OptumLabs Data Warehouse, a large administrative database of commercially insured and Medicare Advantage beneficiaries, we identified adults with newly diagnosed SLE (ascertained using three ICD-9/10 codes at least 30 days apart) from 2013-2017. Patients had at least two years of enrollment prior to SLE diagnosis. Patients of ≥ 65 years were excluded due to difficulty in estimating income after retirement. Income was based predominately on self-report or when data were missing, derived rulesets were used. Income was missing in 5% of the sample. We estimated the incidence rate (IR) of SLE per 100,000 person-years stratified by income and racial/ethnic categories with age- and sex-adjusted adjustment to the 2010 US total population aged 18-64 years.

Results: We identified 2810 patients with newly diagnosed SLE. The average age (SD) was 44.9 (12.5), 62% of the patients were Caucasian, 16% Black, 15% Hispanic, 7% Asian/other, and 88% were female. The overall age-, sex- and race/ethnicity-adjusted IR was 3.4 (95% confidence interval: 3.3-3.5) per 100,000. SLE incidence was 8 times higher among women (9.1) than men (1.2). The incidence rate among Blacks was twice as high as that of Caucasians, and was moderately higher in Hispanic and Asian/other compared to Caucasians. SLE incidence was 12% higher in those with <\$40,000 household income than those with ≥\$40,000 income. Caucasians with <\$40,000 income had 20% higher SLE incidence than those with ≥\$40,000 income, but there was no evidence of a differential income effect among minorities.

Conclusion: The incidence of SLE is highest among Blacks, and Hispanics. Lower income is associated with higher incidence of SLE in Caucasians; this differential effect of income on disease incidence was not seen in minorities.

Table. Incidence Rates of SLE per 100,000 person years according to income

Income	Overall	Caucasian	Black	Hispanic	Asian/Other
<\$40,000	4.4	3.9	6.0	5.7	3.9
\$40000 - \$99,000	3.8	3.3	6.0	5.7	3.4
\$100,000+	3.8	3.2	5.9	5.4	3.8
Unknown	1.7	1.5	3.3	2.4	1.3
OVERALL	3.4	2.9	5.1	2.4	3.1

Abstract Number: 274

Socioeconomic Disparities in Disease Activity in Patients with Rheumatoid Arthritis

Lei Zhu¹, Evelyn Talbott² and Larry W. Moreland¹, ¹Division of Rheumatology and Clinical Immunology, Division of Rheumatology, University of Pittsburgh, Pittsburgh, PA, ²Epidemiology, University of Pittsburgh, Pittsburgh, PA

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Healthcare Disparities in Rheumatology Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: To develop a methodology for well-defined rheumatoid arthritis (RA) measurement as an outcome and provide a clear definition of social determinants related to disease activity. We then examine the association between racial and social factors and risk of higher RA disease activity among RA patients.

Methods: The patients studied were from the University of Pittsburgh's Rheumatoid Arthritis Comparative Effectiveness Research (RACER) registry. Since February 2010, RACER has enrolled patients older than 18 years who have been diagnosed with RA by a rheumatologist. The registry had data to enable generating Disease Activity-C Reactive Protein (DAS28-CRP) for patients' each visit. We conducted across-sectional study using the baseline data. Evaluation for difference between dichotomous variables of outcome (high vs. low DAS28-CRP) was done using Chi-square or Fisher exact tests. Comparisons of continuous variables were performed using t-test or the Wilcoxon test. The multiple logistic regression models were then constructed and adjusted for confounders selected by backwards selection and consideration of clinically relevant covariates.

Results: A total of 729 patients with information available on both baseline DAS28-CRP and a majority of social factors' were included for the analyses. The mean age was 59.5(SD=12.7) years, 78% were female, and median RA disease duration was 9.8 (IQR: 3.7, 19.1) years. 45% of patients had high DAS (N=326), about 64% had less than a college degree, 24% had annual income <\$25K, and 67% were not-working. High RA disease activity group patients were more likely to be black, smokers, with a higher BMI, lower education level, not working. They were also less likely to be married, with a lower annual income, with abnormal CRP and longer disease duration. For the multiple logistic regression model adjusted for selected confounders, we found that having higher BMI, annual income below \$25K, and being not working were statistically significantly associated with increases risk of higher RA activity (Table 2).

Conclusion: The objective of this study is to utilize the well-defined RA cohort to estimate whether there are differences in RA disease activity at baseline for different social and racial factors groups. Our results indicate that significant

differences in RA disease activity by social and racial groups may be a reflection of lack of early care and delay in seeking treatment, leading to a more serious and debilitating disease outcome. Outreach into the community at all levels addressing the need for early RA detection and treatment will be needed.

Abstract Number: 275

Health Equity: Access to Rituximab for Patients Comparing Variable Access in a Single Rheumatology Clinic

Raymond Chu¹, Catherine Mallon¹, Jan Willem Cohen Tervaert¹ and Elaine Yacyshyn², ¹University of Alberta, Edmonton, AB, Canada, ²Medicine, University of Alberta, Edmonton, AB, Canada

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Healthcare Disparities in Rheumatology Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The purpose of our study is to investigate the difference in time to access of rituximab therapy between patients with rheumatoid arthritis (RA) compared to patients with other autoimmune diseases.

Methods: A retrospective chart review was performed on 236 patients under the care of rheumatologists out of the University of Alberta, who had received rituximab from October 2012 to October 2017. Data extracted included the method of drug coverage, the date determining when a patient would require rituximab for treatment and the date of first infusion. A Cuzick's test of trend was performed on three groups. The first group includes patients with autoimmune disease (not RA) receiving coverage through the Short Term Exceptional Drug Therapy (STEDT) program, Alberta's publicly funded special access program for high cost drugs. The second group includes patients with autoimmune disease (not RA) who receive non-STEDT funding, encompassing compassionate care and insurance. The third group includes RA patients followed by the Rheumatoid Arthritis Pharmacovigilance Program and Outcomes Research in New Therapies (RAPPORT) clinic at the University of Alberta whom all receive non-STEDT funding. Analysis was conducted using STATA 13.

Results: Of the 236 patients, 154 patients were identified as having RA and followed by the RAPPORT clinic. Eighty-two patients were identified as having other autoimmune diseases (vasculitis, dermatomyositis, systemic lupus erythematosus, myositis, sarcoidosis, Sjogren's and ankylosing spondylitis). Of these 82 patients, 54 had their rituximab covered through Alberta's STEDT program and 28 patients received coverage from non-STEDT programs. The median time to access was 36 days (QR: 25, 53) for RAPPORT patients, 30 days (QR: 17, 44) for STEDT patients with other autoimmune diseases and 45.5 days (QR: 33, 63) for non-STEDT patients with other autoimmune diseases. The Cuzick's test revealed a statistically significant trend between groups (p-value = 0.004).

Conclusion: Our analysis concludes that public funding through the STEDT program, allows quicker access to rituximab compared to alternative sources of funding including compassionate care and insurance. RA patients who also receive non-STEDT coverage also receive rituximab more quickly, having the benefit of a dedicated clinic familiar with drug application processes. The result of this study indicates evidence of medication health economic disparity between access for patients with different conditions. This is concerning for patients who require medications quickly, for disease control, such as vasculitis patients, who appear to have less equity in access to rituximab. Further analysis is necessary to determine causes for this disparity and expedite access.

Abstract Number: 276

Gender Differences in TNFi Treatment Adherence and Response in As Patients: A Prospective Longitudinal Cohort Study

S. Hoekstra¹, Tamara Rusman², Michael T. Nurmohamed³, Christiaan van Denderen⁴ and Irene van der Horst-Bruinsma⁵, ¹Rheumatology, VU University Medical Center, Amsterdam, Netherlands, ²Rheumatology, VU University medical centre, Amsterdam, Netherlands, ³Rheumatology, Amsterdam Rheumatology and immunology Center, VU University Medical

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Healthcare Disparities in Rheumatology Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Despite several observations of gender differences in TNF inhibitor (TNFi) treatment response and adherence in ankylosing spondylitis (AS) patients, limited studies were conducted. Our aim is to assess gender differences in TNFi treatment adherence and response in a longitudinal cohort study over a 10-year follow-up period in AS patients.

Methods: AS patients (fulfilling the modified New York Criteria) treated consecutively with TNFi were included in a prospective, observational cohort. Data were collected at baseline, screening, 3 and 6 months and thereafter every 6 months on demographics, lifestyle factors, inflammatory markers (C-reactive Protein (CRP)) and disease specific parameters (Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), Ankylosing Spondylitis Disease Activity Score (ASDAS), Bath Ankylosing Spondylitis Metrology Index (BASMI)). TNFi response was defined by BASDAI50% response criteria (50% of the initial score or improvement of >2 points) and ASDAS response criteria (improvement of >1.1 points). Kaplan Meier Survival curves and Generalized Estimating Equations (GEE)-analyses were performed.

Results: In total 359 AS patients (33.4% females) were included with a mean follow-up of 5.1 years. Women showed a significant lower follow-up duration than men, 4.5 vs. 5.4 years. Patients who were lost to follow-up, were mostly still treated. Overall, females showed significantly higher disease activity scores, BASDAI (0.57 points) (figure 1) and ASDAS (0.27 points), compared to males over the entire follow-up period. According to both the BASDAI and the ASDAS response criteria, females had an overall significantly lower percentage of responders compared with males. In the secondary outcomes, females showed only a clinically relevant lower BASMI (higher mobility) than males (0.23 points).

Conclusion: Female AS patients showed a significantly lower follow-up duration, a lower improvement and a lower clinical response to TNFi according to the BASDAI and ASDAS response criteria.

Abstract Number: 277

Outcomes of Telemedicine for Rheumatoid Arthritis in the Alaska Native Population

Elizabeth Ferucci¹, Tammy Choromanski¹, Gretchen Day² and Sarah Freeman³, ¹Division of Community Health Services, Alaska Native Tribal Health Consortium, Anchorage, AK, ²Clinical and Research Services, Alaska Native Tribal Health Consortium, Anchorage, AK, ³Telehealth, Alaska Native Tribal Health Consortium, Anchorage, AK

Session Information**Session Date:** Sunday, October 21, 2018**Session Title:** Healthcare Disparities in Rheumatology Poster**Session Type:** ACR Poster Session A**Session Time:** 9:00AM-11:00AM

Background/Purpose: In rheumatoid arthritis (RA), access to a rheumatologist is associated with improved quality of care and outcomes. Telemedicine has been proposed as a solution to the problem of limited access to rheumatologists given the workforce shortage and concentration of rheumatologists in urban areas. Rheumatology care using live video telemedicine has been implemented within the Alaska Tribal Health System. The purpose of this analysis is to evaluate the impact of telemedicine follow-up for RA on disease activity and functional status.

Methods: Study participants with a diagnosis of RA were recruited when seeing a rheumatologist, either in-person or by telemedicine. At the study visit, participants completed the Routine Assessment of Patient Index Data 3 (RAPID3) and a telemedicine perception survey and agreed to medical record review for disease characteristics and measures of quality and access to care. Participants also agreed to telephone contact at 6 and 12 months for follow-up surveys and RAPID3. This analysis describes the results as of the 6-month follow-up RAPID3.

Results: To date, 81 participants have completed the 6-month follow-up (41 telemedicine and 40 in-person). Demographics, disease characteristics and baseline RAPID3 and functional status were similar across groups. The telemedicine group had a higher mean number of rheumatologist visits in the preceding year (3.2 vs. 2.1, $p=0.002$). At the 6-month follow-up, the mean RAPID3 was lower in the in-person group (3.2 vs. 4.0, $p=0.04$), with no difference in functional status between groups. The change in RAPID3 and functional status over 6 months were no different in the telemedicine vs. in-person group. In multivariate linear regression, no factors (demographics, smoking status, disease characteristics, telemedicine vs. in-person group) were associated with change in RAPID3, but a worsening of functional status was more likely in smokers ($p=0.009$). The percent in low disease activity or remission at 6 months was low (16%) and did not differ by group. Multivariate logistic regression did not identify any factors associated with low disease activity or remission, although there was a non-significant trend toward lower odds of low disease activity or remission with a higher rheumatic disease comorbidity index ($p=0.079$).

Conclusion: Telemedicine can improve access to care in patients with RA. In this study, there was lower disease activity at 6 months in RA patients seen in-person compared to by telemedicine, but it was not significant in multivariate analyses. Based on this study to date, no significant differences are identified between telemedicine and in-person care on short-term outcomes in RA.

Abstract Number: 278

The Effect of Patient, Prescriber and Region on the Initiation of First Biologic for Rheumatoid Arthritis: A Longitudinal Population Study

Mark Tatangelo¹, George A. Tomlinson², Michael Paterson³, Nick Bansback⁴, Tara Gomes¹, Alex Kopp³, Vandana Ahluwalia⁵ and Claire Bombardier⁶, ¹University of Toronto, Toronto, ON, Canada, ²Medicine, Mount Sinai Hospital, Toronto, ON, Canada, ³Institute for Clinical Evaluative Sciences, Toronto, ON, Canada, ⁴St Paul's Hospital, Centre for Health Evaluation and Outcomes Sciences, Vancouver, BC, Canada, ⁵Ontario Rheumatology Association, Brampton, ON, Canada, ⁶Toronto General Hospital Research Institute, University Health Network, Toronto, ON, Canada

Session Information**Session Date:** Sunday, October 21, 2018**Session Title:** Healthcare Disparities in Rheumatology Poster**Session Type:** ACR Poster Session A**Session Time:** 9:00AM-11:00AM

Background/Purpose: Prescribing the first biologic for rheumatoid arthritis is an important decision for physicians, payers, and patients with costs and clinical implications. Our aim was to describe disparities in access to the first biologic prescribed to patients with rheumatoid arthritis in a single payer health care system (no insurance confounders) to explain the relative contributions of patient, prescriber and geographic region characteristics to receipt of first biologic.

Methods: Our study design is a population retrospective administrative data-based population study conducted in Ontario Canada. We used a time-series analysis to describe trends in rheumatologist preference and nested Cox proportional hazards models with random effects and time varying exposures to adjust for patient, physician and geographic area

characteristics. Patients had an incident RA diagnosis between 2001 to 2015 after 66 years of age in Ontario Canada and received at least one csDMARD or biologic. The main exposure was time from the first csDMARD prescription to the outcome of first biologic prescription, adjusted for patient, prescriber and geographic area variables. Patient covariates were age, sex, disease duration, socioeconomic status, distance to care and supply of care in the patient's area of residence. Prescriber covariates were year of graduation, specialty of practice, and the supply of rheumatologic care in the patient's geographic region. Patients were censored at death, move out of province or end of study follow-up.

Results: A total of 17,672 patients met the study inclusion criteria accruing 82,445.79 patient-years of follow up. Variables significantly associated with delayed receipt of first biologic medication, were older age, sex (male)(HR=0.76), lower socioeconomic status (HR=0.92), greater distance to nearest rheumatologist (HR=0.95). Rheumatologist preference for and use of biologics increased 2.5-fold in the study time period but have not kept pace with the number of new active RA patients (3 fold). Geographic area level differences in time to prescriptions of first biologic exists and widens over time with about a 10% difference from highest to lowest prescribing regions 2 years after first csDMARD prescription (Figure 1). Prescriber preference (after adjustment for patient and physician covariates) accounted for 65% of prescription variation while differences between the regions themselves contributed 4.6% to the overall prescription variation.

Conclusion: From a direct measurement of the total Provincial population of RA patients with identical medication coverage, variation in time to receipt of first biologic exist after adjusting for individual level patient, prescriber, and geographic area covariates. These findings illustrate systemic gaps in care and the influence of physician preferences that could be further optimized to improve patient outcomes.

Abstract Number: 279

Variations and Disparities in Healthcare Teams Among Individuals with Lupus

R. Paola Daly, Roushanac Partovi and Patricia Davidson, Lupus Foundation of America, Washington, DC

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Healthcare Disparities in Rheumatology Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Given the systemic and complex nature of lupus, individuals with lupus are often cared for by a multi-disciplinary team, each provider playing a unique role in lupus treatment, maintenance, or preventive healthcare. The purpose of this study is to analyze the composition of healthcare teams for individuals with lupus across demographic variables.

Methods: This cross-sectional study draws from an online national needs assessment survey conducted between December 2015 and January 2016 among 3,022 adults who self-reported a lupus diagnosis. Respondents identified the type of healthcare providers who cared for their lupus and also the one provider who primarily treated their lupus. Multiple

logistic regression models were conducted to assess the association between self-reported demographic information and treatment team composition.

Results: The majority of respondents (Table 1) had a rheumatologist primarily treating their lupus (78.6%), while a lower percentage reported a primary care provider (PCP) or nephrologist as their primary doctor for lupus (12.9% and 3.3%, respectively). Specific care team compositions emerged when analyzing what provider is primarily responsible for treating the individual's lupus (Table 2). Groups with higher odds of having a rheumatologist in charge of their lupus care included: African Americans, females, and individuals with moderate or severe symptoms. Groups reporting higher odds of having a PCP in charge of their lupus care included rural respondents and respondents with public insurance. The analysis revealed that individuals whose symptoms were moderate to life threatening, who had public insurance and who were under 65 had higher odds of having a PCP on their treatment team. Significantly lower odds of having a PCP on the treatment team were observed among African American and Asian respondents.

Conclusion: The study supports exploring whether rural respondents and individuals with public insurance are experiencing barriers to accessing specialty care. The study also highlights disparities among some minorities who are less likely to have a primary care provider on their care team. Considering the complexity of lupus and its comorbidities, ensuring access to both specialty and primary care is essential.

Disclosure: The Lupus Foundation of America received funding from UCB Pharma to support study data collection.

Be Fierce. Take Control.TM an Evidence-Based Digital Lupus Awareness and Education Campaign for Young Minority Women at Risk for Lupus

R. Paola Daly¹, Nicole Wanty², Maggie Maloney¹, Stacey Boyd³, Karin Tse¹ and Karen Goldstein⁴, ¹Lupus Foundation of America, Washington, DC, ²KDH Research & Communication, Atlanta, GA, ³American College of Rheumatology, Atlanta, GA, ⁴Ogilvy, Washington, DC

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Healthcare Disparities in Rheumatology Poster – ARHP

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Lupus is a complex, chronic autoimmune disease that has significantly higher prevalence and incidence among minority women.[i] In an effort to reduce the time to diagnosis for populations with highest risk, ACR and the Lupus Foundation of America created a digital awareness and education campaign, *Be Fierce. Take Control.*, intended for African American and Latino women ages 18-25 who may be experiencing lupus symptoms to raise their awareness of lupus and provide evidence-based information on what to do next.

Methods: Formative research was conducted via web-based focus groups with 60 individuals meeting intended audience criteria to gather information on help and information seeking behavior, attitudes towards health care, and appropriateness of culturally relevant language. Using this information, a digital campaign involving mobile ads, videos and articles all directing to a campaign website was developed and tested for cultural relevancy, health literacy, scientific accuracy, and general appeal. Testing was completed using user panels, as well as a rigorous review and approval process by two lupus clinician/researchers. Campaign assets were finalized using feedback, and the campaign was launched in June 2017. Following the first year of launch, user testing was conducted with 10 individuals in the intended audience to provide detailed information on how users navigated the campaign website in order to improve user experience.

Results: The website received a total 114,866 page views in the first year. The majority of visitors read the home page, followed by a page providing reliable resources of next steps to take if lupus symptoms are suspected. 72% of visitors who responded to a helpfulness poll present on each page indicated that the web-content was helpful. User testing post-launch revealed 9 out of 10 users could describe lupus as an autoimmune disease after reviewing the site, and 7 out of 10 users had a better understanding of lupus and would be comfortable enough to approach a doctor about potential lupus symptoms. New updates were released in May 2018 based on these results. In addition, a series of lupus articles were released through a paid media partnership with A Plus media, receiving 345,145 views in the first three months. The partnership also included development and promotion of a video featuring NY Sharks women's football team, depicting the theme of being fierce in their lives with an underlying message on taking control of your health. The video gained

attention from celebrity influencers, generating over 2 million views with nearly a third of its YouTube viewers watching the entire video.

Conclusion: *Be Fierce. Take Control.* provides an example of a well-designed, culturally competent online resource to increase awareness and knowledge of lupus symptoms in African American and Latino women ages 18-25 who may be experiencing lupus symptoms. This is the first digital-only lupus campaign targeted to this audience, highlighting the importance of rigorous testing to ensure cultural relevance in health communication campaigns.

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Healthcare Disparities in Rheumatology Poster – ARHP

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: African Americans (AA) with lupus experience severe manifestations and outcomes, and a long journey to diagnosis and care. We developed and tested evidence-based, culturally appropriate, scalable lupus education modules, one targeting the diverse AA community and one targeting primary care providers (PCPs). This curriculum was designed to disseminate lupus-related education, reduce stigma, and promote healthcare-seeking norms.

Methods: Rheumatology, public health and behavioral health experts from 2 academic institutions in Boston and Chicago developed 2 learning modules. The first was a didactic and participatory community-based curriculum for Popular Opinion Leaders (POLs). Based on a CDC model, POLs are community leaders trained to disseminate information through their social networks. The goal was to provide predominately AA POLs with lupus education and dissemination materials to improve awareness and promote positive health-seeking behaviors in their communities. The second included videos geared towards PCPs using motivational interviewing principles to improve culturally competent provider communication skills. To prepare both modules, we conducted a literature review on lupus disparities, racial discrimination and social determinants of health. We engaged key academic and community-based AA stakeholders and experts in an iterative process regarding curriculum content, cultural competency, dissemination materials and implementation strategies. POL and physician modules and materials were piloted and reviewed by POLs in Boston and Chicago and by key community stakeholders. Central themes from curriculum feedback were extracted after review of detailed notes.

Results: The community-based POL curriculum included lupus education, POL model principles, community research methods, and dissemination strategies. The POL training was delivered in Boston (N=18) and Chicago (N=19) in four 2-3 hour sessions. Materials included slide presentations, videos, role-plays, data monitoring exercises, and palm cards to facilitate dissemination. Multiple themes from community feedback were extracted (**Table**). The provider curriculum included video web-based modules using actors with scripted scenarios, and “do over” patient-doctor scenarios to demonstrate flawed interactions and subsequent improvement, supplemented by didactic materials. Physician modules were reviewed by the POLs and stakeholders for feedback and were approved for CME credit.

Conclusion: We utilized an interdisciplinary approach involving community-based and academic stakeholders to develop educational modules specific for the AA community. We incorporated nuanced and diverse feedback from community members in 2 cities to develop this tool. Our next step is to facilitate national dissemination.

Table. Key Themes from Popular Opine Leader and Community Stakeholder Curriculum Feedback

	POL Curriculum	Health Provider Video	Dissemination Materials
Popular Opinion Leaders (POL) participating in pilot in Boston (N=18) and in Chicago (N=19)	Theme 1: Development of an “African-American” Specific Model -Concerns about meaning of a targeted “African American (AA) POL model” in setting of significant heterogeneity of the black community by culture, religion, language and socioeconomic status	Theme 1: Hair Loss as a Culturally Significant Symptom of Lupus -Important for providers to understand relevance of hair when treating African American lupus patients-Hair loss may not be most important symptom for all AA patients, need to consider pain, fatigue and kidney problems	Theme 1: Palm Cards as a Dissemination Tool -Palm card with information about lupus symptoms and contact information for Lupus Foundation of America (LFA) and Lupus Society of Illinois (LSI) was well received-Palm card needs more facts about lupus including an explanation that lupus is not contagious, especially in cases of discoid lupus, so that strangers would feel more comfortable talking with them
	Theme 2: Curriculum Content and Presentation -Need more information about clinical trials; Boston or Chicago specific lupus research, choosing a rheumatologist, environmental risk-factors, medications and how they work for different people/ co-morbidities, mental health and lupus -Pictorials, videos and other interactive methods were most effective learning tools	Theme 2: Perceived Discrimination -Discrimination is not always the main issue for AA lupus patients. Some doctors just don’t know enough about lupus and recognizing signs/symptoms-Important to highlight specific discrimination faced by female patients in medical system; providers are dismissive about their pain and equate fatigue with laziness -Female patients often feel more comfortable seeing female providers because they can better relate to their experience	Theme 2: Creating Materials for a Wider Audience - Need more information appropriate for school-aged children and families. - Need to engage men - Need dissemination materials in other languages (e.g. Spanish, Portuguese, French)
	Theme 3: Evaluation Methods -POLs reported feeling flustered and/or overwhelmed by multiple-choice format of pre/post-tests; were reluctant to hand in forms; key points should be clearly presented in slides -Other POLs reported test questions were too easy	Theme 3: Patient-Provider Communication -Providers need to build rapport and address patient’s concerns -Providers should be encouraged to be more open and candid with their patients about clinical tests, results and treatment o Individuals felt that meaning and significance of test results aren’t explained o Individuals felt side effects from medications were not appreciated and contributed to more problems	
Community Stakeholders with experience with academic-community partnerships (N=3)	Theme 1: Tailoring Curriculum to Target City -Importance of including city-specific information in curriculum content o Local statistics regarding demographics and lupus prevalence o Relevant research studies including clinical trials particularly involving local city	Theme 1: Patient Rights -Video highlights patients need to know that they have options when seeing a rheumatologist -It is important that patients have access to information about the treating physician - Partnerships between physicians and patients are important to highlight	Theme 1: Dissemination Tracking -Emphasis on working with the LFA and LSI to track effectiveness of dissemination by measuring changes in call volume and documenting callers who reference the palm cards
	Theme 2: Perception of Research -Include information about perception of research and clinical trials within the community	Theme 2: Cultural humility -The viewer should recognize that physicians should treat patients with empathy	Theme 2: Palm Card Content -Materials should include all available lupus related resources locally -Palm cards depicting AA families are more appealing to different audiences
		Theme 3: Colorism concept -In addition to attention on hair, need to consider incorporating this concept in future modules Theme 4: Diagnosis delays Video addresses a poor patient-doctor encounter but not delays to diagnosis that AA patients with lupus face Theme 5:Language-related feedback Language thought to be clear and easy to understand. Feedback that AA should not be described as “minorities” and term replaced with “underrepresented population”

The Utility of Positive ANA Referrals at the University of Chicago

Veena Patel¹ and Anisha Dua², ¹University of Chicago, Chicago, IL, ²Section of Rheumatology, University of Chicago, Chicago, IL

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Health Services Research Poster I – ACR/ARHP

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 9:00AM-11:00AM

Background/Purpose: The ANA test is nonspecific and can be difficult to interpret without understanding the limitations of the test. Referrals to Rheumatology for positive ANA is a common practice that may lead to unnecessary resource utilization and contribute to delays in patients seeing a rheumatologist. At the University of Chicago, the current wait time for a new patient visit is over 60 days. The aim of this project is to evaluate the quality of our ANA referrals by analyzing how often these patients are diagnosed with an ANA-associated rheumatic disease (AARD) and the associated healthcare expenditures.

Methods: Charts were reviewed for patients referred to the University of Chicago outpatient rheumatology clinic over a 6-month period (April 2017-September 2017) with “positive ANA” as the reason for referral, or if “positive ANA” was a listed problem in the initial Rheumatology note’s plan. Demographic data, referral information, relevant rheumatologic labs and imaging were recorded. Patients’ final diagnoses were organized into the following categories: AARD, possible AARD (ongoing work-up at time of review) or no AARD. Positive predictive value for AARD was calculated using the total number of ANA referrals and the number of referrals diagnosed with AARD. Costs of lab tests and imaging were estimated using the Healthcare Bluebook and lab testing websites.

Results: Eighty-three patients referred for positive ANA were evaluated. The majority of patients were female (64/83,77%). Most patients were either Caucasian (36/83, 43%) or African American (36/83, 43%) with an average age of 40 years (range 19-85 years).

The majority of referrals were internal from University of Chicago providers (58/83,70%). Of these referrals, 50% came from primary care clinics. The six most common reasons for ordering an ANA were: joint pain, fatigue, neuropathy, rash, headache and interstitial lung disease. During initial rheumatologic visit, a total of 234 lab tests were ordered, with an

Lab Test	# of positive results/# total tests ordered (%)
ANA	4/4 (80%)
dsDNA	1/19 (0.5%)
C3/C4	5 (low C4)/39 (13%)
RNP/Smith	3/36 (8%)
SSA/SSB	3/39 (8%)
RF	1/14 (7%)
anti-CCP	0/14 (0%)
ANCA	0/4 (0%)
aPL	0/4 (0%)
ESR	0/22 (0%)
CRP	1/24 (4%)
ACE	0/3 (0%)
Scl-70	1/6 (17%)
Quantitative Igs	0/5 (0%)

Table 1. ACE= angiotensin converting enzyme

estimated cost of \$23,592. A total of 41 joint x-rays were ordered, with an estimated cost of \$3,731. Table 1 shows the most common lab tests ordered and the number of positive tests. The majority of tests were unremarkable. AARD was diagnosed in 5 patients (2 SS, 1 overlap CTD, 2 UCTD). Possible AARD included 7/83 (8%) patients and 71/83 (85%) had no systemic AARD. The positive predictive value (PPV) for AARD was 5.7%.

Conclusion: Our review shows that the PPV of diagnosing AARD in our system is very low and ANA referrals are contributing to unnecessary cost, resource use, and longer wait times for our clinic. As many referrals are internal, the next step of this project will be a multifold intervention including an educational component for primary providers and creating a decision-making support tool in our electronic medical record with the goal of improving the quality of referrals and creating more space for urgent patients to be seen.

Abstract Number: 283

Benefits Accrued through the Implementation of Telerheumatology Services

Alexander Peck¹, Anita Pender² and C. Kent Kwoh³, ¹Division of Internal Medicine, University of Arizona College of Medicine, Tucson, AZ, ²Division of Rheumatology, Southern Arizona VA Health Care System, Tucson, AZ, ³Medicine, Division of Rheumatology, University of Arizona School of Medicine, University of Arizona Arthritis Center, Tucson, AZ

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Health Services Research Poster I – ACR/ARHP

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 9:00AM-11:00AM

Background/Purpose: Telerheumatology services were developed at the Southern Arizona VA Health Care System (SAVAHCS) to provide specialty care to remote Community Based Outpatient Clinics (CBOCs). The aims of this study were to examine the potential benefits of this telerheumatology program.

Methods: As part of a quality improvement initiative, we performed a review of the patients seen in the SAVAHCS' weekly telerheumatology clinics in Sierra Vista, Casa Grande, and Yuma, AZ from 2015 to 2017. At each of the CBOCs, we use high level audio-video technology to obtain the patient's history in an in-person visit, direct nurses on appropriate musculoskeletal exams, assist in making diagnoses, and, ultimately, carry out the patient's treatment plan. The nurses received training on recognizing common rheumatologic disorders and performing a focused musculoskeletal exam. We calculated the following: the miles saved based on an estimate of the distance that patients did not need to travel as a result of the telerheumatology visit; miles saved based on round trip miles from the patient's CBOC clinic to the SAVAHCS (i.e. 70 miles one way for both Casa Grande and Sierra Vista CBOCs and 240 miles one way for Yuma CBOC); and estimates of direct cost savings were generated using the reimbursement rate for beneficiary travel (0.415/mile).

We also evaluated the number of encounters and unique patients for the most common rheumatologic diagnoses by CBOC site and by year.

Results: Table 1 summarizes the total number of patient encounters, miles saved, and travel dollars saved by CBOC site and year.

Table 2 summarizes the number of unique rheumatologic diagnoses in each CBOC site and year. A patient may have more than one rheumatologic diagnosis associated with each visit.

Table 1: Summary of number of visits, miles saved and travel dollars saved by clinic site

Site	Year	Total # visits	Total Miles Saved	Travel Dollars Saved
Casa Grande, AZ	2015	22	3,080	\$1,278
	2016	32	4,480	\$1,859
	2017	46	6,440	\$2,673
Sierra Vista, AZ	2015	33	4,620	\$1,917
	2016	37	5,180	\$2,150
	2017	48	6,720	\$2,789
Yuma, AZ	2017	23	11,040	\$4,582
Total 2015-2017		233	41,840	\$17,364

Table 2: Summary of Rheumatologic Diagnosis Codes per year per site

Clinic Site	Sierra Vista			Casa Grande			Yuma	Total
Year	2015	2016	2017	2015	2016	2017	2017	
Rheumatologic Diagnosis								
Rheumatoid Arthritis	1	4	6		1	7	3	22
Osteoporosis	6	5	6			5	1	23
Osteoarthritis	2	2	6				1	11
Gout	3	3	2			2	2	12
Pseudogout	3							3
Psoriatic Arthritis	1	1	2				3	7
Polymyalgia Rheumatica	3	2				1	1	7
Giant Cell Arteritis	1	1	4					6
SLE/Discoid Lupus	1	2	2	1	1			7
Sjogren's/Sicca Syndrome	1	1	3		1	1		7
De Quervain's Tenosynovitis		1						1
Fibromyalgia/Chronic Pain Syndrome		2				2	1	5
Inflammatory Bowel Disease			1			1		2
Ankylosing Spondylitis			1			2	1	4
Sarcoidosis						1	1	2
Unspecified Joint Pain	4	5	10	2	2	4	6	33
Totals	26	29	43	3	5	26	20	152

Of note, the total number of rheumatologic diagnoses in Sierra Vista increased from 26 diagnostic codes in 2015 to 43 diagnostic codes in 2017. In Casa Grande, the number of rheumatologic diagnostic codes increased from 3 in 2015 to 26 in 2017.

Conclusion: Our telerheumatology program has demonstrated a year-to-year increase in the use of the provided services, based on the increase in patient visits and diagnostic codes. Overall, telerheumatology shows excellent potential in increasing access to underserved populations by decreasing travel-related costs, as well as decreasing the time and distance traveled to appointments.

Mosher⁵ and Diane Lacaille⁶, ¹Rheumatology Department, CHRU Nancy, Vandoeuvre-lès-Nancy, France, ²Université de Lorraine, EA4360, APEMAC, Nancy, France, ³Arthritis Research Canada, Richmond, BC, Canada, ⁴Rheumatology, Arthritis Research Canada, Richmond, BC, Canada, ⁵Med, University of Calgary, Calgary, AB, Canada, ⁶Arthritis Research Canada/University of British Columbia, Medicine/Rheumatology, Richmond, BC, Canada

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Health Services Research Poster I – ACR/ARHP

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 9:00AM-11:00AM

Background/Purpose: To understand the challenges that people with osteoarthritis (OA) experience at work due to their condition, for the purpose of adapting to OA the content of Making It Work™, an online self-management program supporting workers with inflammatory arthritis (IA) to remain employed and lead healthy and productive lives at work.

Methods: Eight focus groups were conducted with 34 workers with OA (1 group with hand OA, 1 hip, 2 knee, and 4 multi-joint OA). Patients were recruited through arthritis consumer organizations, a teacher's benefit plan, and outpatient arthritis clinics. Eligibility criteria included, being currently employed, age 18–70 years, having been diagnosed with OA by a physician and reporting being affected by OA at work. Focus group were conducted using a standardized interview guide, led by an experienced facilitator and transcribed verbatim. Transcripts were analyzed independently by 2 researchers. A thematic analysis followed a general inductive approach to identify problems and organize them into topics and broad categories.

Results: The sample included 34 patients (mean age 55 years; OA duration: 8.2 yrs), working in education (n=23); health care (n=6); business (n=2); office/ clerical (n=3). Analysis revealed 4 main categories of problems or challenges:

1. Impact of OA : current symptoms (pain, psychological symptoms, fatigue due to constant pain and need for planning), impact of OA (functional limitations, interpersonal relationships, e.g., lack of understanding or fear of annoying others, reduced self-confidence, reduced social participation) and evolution of symptoms (variability, unpredictability).
2. Barriers to cope with OA: physical environment, lack of effective treatment, difficulty adapting having OA, other impacts (financial consequences, comorbidity).
3. Difficulties at work: impact of OA at work, e.g., safety issues, barriers at work [job characteristics (e.g., time constraints), job environment (e.g., limited work space or poor equipment), lack of support, reluctance to disclose (due to fear of stigmatization), difficulty commuting].
4. Adaptations to work done by patients without requesting job accommodations: modifying movement, activities or position, and planning work differently to avoid pain, addressing mobility and commuting issues (e.g finding parking close to work).

Conclusion: The study identified challenging issues meaningful to individuals working with OA. Though issues are similar to those described by IA patients, they are described differently, and their respective importance differs. Findings will be useful to vocational counsellors and other health professionals helping people with OA deal with employment issues related to their arthritis, and to people developing employment health services for arthritis.

Abstract Number: 285

Inflammatory Bowel Disease Is Associated with a Substantial Economic Burden in Patients with Psoriatic Arthritis and in Patients with Ankylosing Spondylitis

Martin J. Bergman¹, Patrick Zueger², Jinlin Song³, Irina Pivneva⁴, Keith A. Betts³ and Avani D. Joshi⁵, ¹Drexel University College of Medicine, Philadelphia, PA, ²AbbVie Inc., North Chicago, IL, ³Analysis Group, Inc., Los Angeles, CA, ⁴Analysis Group, Inc., Montreal, QC, Canada, ⁵AbbVie, Inc., North Chicago, IL

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Health Services Research Poster I – ACR/ARHP

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 9:00AM-11:00AM

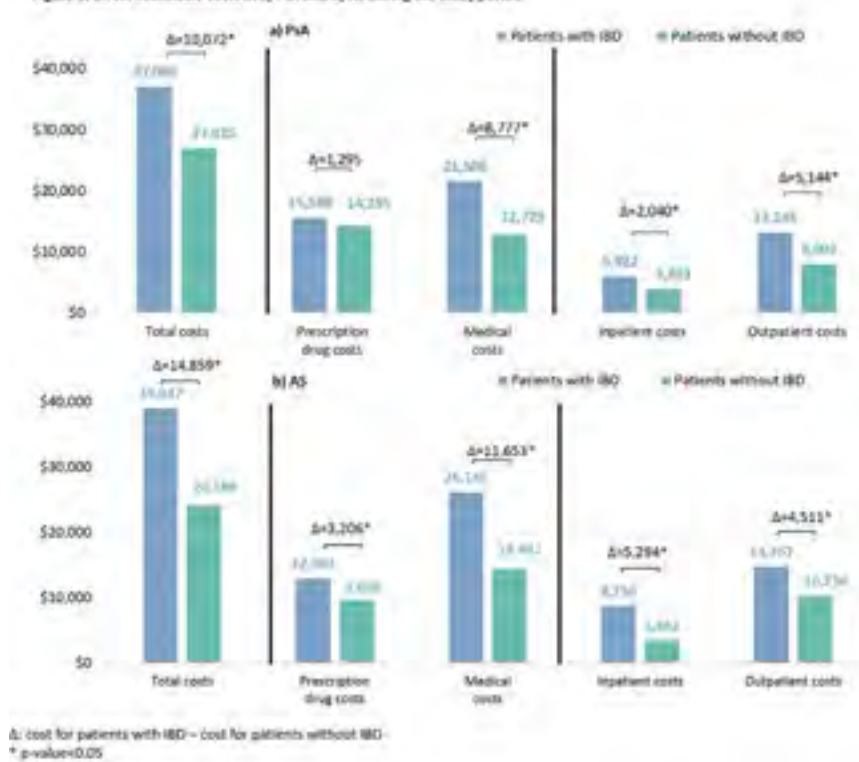

Background/Purpose: Psoriatic arthritis (PsA) and ankylosing spondylitis (AS) belong to a group of inflammatory arthritides known to share similar extra-articular manifestations, such as inflammatory bowel disease (IBD). Though, IBD, PsA, and AS individually present significant economic burden, it is not clear whether there is an incremental economic burden associated with IBD among patients with PsA or AS. This study aims to describe the prevalence and incidence of IBD and quantify the healthcare resource utilization (HRU) and direct healthcare costs associated with IBD among patients with PsA and AS.

Methods: Adult patients with ≥ 2 claims for PsA or AS were selected from a large US claims database (Q12007–Q32016). Prevalence and incidence of IBD, including Crohn's disease (CD), ulcerative colitis (UC), and IBD-related gastrointestinal (GI) disturbances (gastroenteritis/colitis/gastritis) were assessed during the 1-year period following the initial claim for PsA/AS (i.e., study period) in PsA patients and AS patients separately. Prevalence and incidence for each individual condition were also reported. HRU and costs (2017 US\$) were assessed during this period and compared between patients with (cases) and without (controls) IBD. Cases and controls were required not to have any IBD diagnosis during the 1-year period before their first claim for PsA/AS and were matched 1:1 on age, sex, region of residence, health plan type, index year, and employment status. The comparison of HRU and costs were conducted using Wilcoxon signed-rank test.

Results: We identified 22,205 PsA and 9,980 AS patients. IBD prevalence was 3.8% (CD: 1.0%; UC: 0.9%; GI disturbances: 2.5%) in PsA patients and 8.5% (3.8%; 2.7%; 4.2%) in AS patients. IBD incidence was 2.5% (0.4%; 0.3%; 2.0%) in PsA and 4.1% (1.0%; 0.8%; 2.9%) in AS. There were 464 PsA and 314 AS patients with IBD who were matched 1:1 with PsA and AS patients without IBD during the study period.

Patients with IBD had significantly higher HRU, including more outpatient (OP), emergency room, and inpatient (IP) visits, more IBD-related procedures (e.g., gastro-related endoscopy, abdominal/bowel imaging), and more corticosteroid use. In PsA, the mean annual total costs were \$37,086 for patients with IBD, 27% higher than for patients without IBD ($p < 0.001$; Figure 1); in AS, the costs were \$39,047 for patients with IBD, 38% higher than for patients without IBD

Figure 1. Direct healthcare costs in a) PsA and b) AS during the study period

($p < 0.001$). The difference in total costs was largely driven by the difference in medical costs (PsA: 87%; AS: 78%). Of the medical cost difference, 23% and 59% were accounted for by the differences in IP and OP costs, respectively, in PsA patients, while the percentages were 45% and 39% in AS patients.

Conclusion: IBD prevalence and incidence were 3.8% and 2.5% in PsA and 8.5% and 4.1% in AS, respectively. In both PsA and AS, IBD was associated with substantial economic burden, including higher HRU and healthcare costs.

Abstract Number: 286

The Prevalence and Treatment Patterns of Women of Childbearing Age with Rheumatic Diseases

Edward Lee¹, Robert Suruki², Brian Carpenter³, Ty Harkness³, Daniel Luk⁴ and Mohamed Yassine¹, ¹UCB Pharma, Smyrna, GA, ²UCB Pharma, Raleigh, NC, ³Charles River Associates, New York, NY, ⁴Charles River Associates, Boston, MA

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Health Services Research Poster I – ACR/ARHP

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 9:00AM-11:00AM

Background/Purpose: Emerging data on exposure of infants to therapeutics through placental transfer and breastmilk could impact the management of women of childbearing age (WoCBA) with rheumatic diseases (RD; including rheumatoid arthritis [RA], psoriatic arthritis [PsA] and ankylosing spondylitis [AS]). This descriptive study assessed differences in treatment patterns of patients (pts) with RD between WoCBA and comparator groups.

Methods: IMS PharMetrics claims were used to identify pts continuously enrolled between Jan 2014–Dec 2015 with: ≥ 2 RD diagnosis codes and ≥ 1 RD diagnosis or ≥ 1 RD medication claim between Jan–Dec 2015 (measurement period). Age/gender at the start of the measurement period were used to allocate pts to the following cohorts: WoCBA (aged 18–44

years), Women (45–65), Men (18–44), and Men (45–65). Outcomes assessed in the measurement period included % biologics utilization and treatment changes (discontinuation [≥ 60 -day gap with no additional biologic claims]; switch [initiation of new biologic within 60 days]; re-initiation of the same or new biologic [after gap ≥ 60 days]).

Results: Of the WoCBA pts analyzed, 15,999 had RA, 2,682 PsA and 1,153 AS. Biologic utilization among WoCBA pts with RD was lower compared with men in the same age group. Use of methotrexate was similar between genders for RA and PsA pts, but higher for WoCBA than for men with AS (**Figure A**). Across RD pt cohorts on biologic therapy, WoCBA had the highest proportion of new and reinitiating pts, and the lowest proportion of continuing pts (**Figure B**). Similarly, across RD indications, the WoCBA pt group on biologic therapy had one of the highest numbers of Switch, Reinitiate (new), and Discontinue events, compared to all other groups.

Conclusion: Despite the importance of disease control prior to, during and after pregnancy, trends show lower rates of biologic use in WoCBA pts. Further exploration is needed to better understand how treatment patterns among WoCBA pts are impacting their disease outcome and how to best optimize care.

The study was funded by UCB Pharma, conducted by Charles River Associates, medical writing by Julia Bárdos, Costello Medical, UK. We thank the patients, their caregivers and the investigators who contributed.

Comparison of Real-World Costs between Patients with Rheumatoid Arthritis Treated with Subcutaneously-Administered Biologics Previously Treated with Another Biologic

Jennie H. Best¹, Paul Juneau² and Amanda Kong², ¹Genentech, Inc., South San Francisco, CA, ²IBM Watson Health, Bethesda, MD

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Health Services Research Poster I – ACR/ARHP

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 9:00AM-11:00AM

Background/Purpose: To compare real-world healthcare costs between patients with rheumatoid arthritis (RA) who were treated with subcutaneously (SC) administered biologics after previously using at least one other biologic agent.

Methods: Using the Truven Health MarketScan® Commercial and Medicare Supplemental data, adult RA patients initiating one of six SC biologics between January 1, 2014 and June 30, 2016 were identified. Episodes (patients could contribute more than one) of treatment were captured, starting with initiation of index SC biologic and ending with end of data, end of continuous enrollment, switch to new biologic, or gap of 90+ days without index medication. Per-month biologic costs and RA-related healthcare costs (defined as claims with an RA diagnosis code or drug code for RA medication) were measured during the variable-length episodes. Generalized estimating equations models (accounting for multiple episodes per person) were used to compare costs between biologic agents by year of initiation, adjusting for baseline demographics and clinical characteristics.

Results: The sample comprised 10,464 episodes (from 8,418 patients). Biologics and number of episodes, by year of initiation 2014, 2015, 2016, were: tocilizumab—758, 557, 279; abatacept—970, 754, 453; adalimumab—1327, 1070, 526; etanercept—968, 888, 461; certolizumab—360, 330, 174; golimumab—284, 196, 109. Biologic costs accounted for 91-95% of total RA-related costs. Mean adjusted per month biologic costs, by year of initiation—2014, 2015, 2016—were: tocilizumab—\$2900, \$2765, \$3065; abatacept—\$3219, \$3534, \$4510; adalimumab—\$3478, \$4609, \$5145; etanercept—\$3129, \$4222, \$4154; certolizumab—\$4196, \$4697, \$5780; golimumab—\$3237, \$3513, \$4335. Tocilizumab per month costs were significantly lower ($p < 0.05$) than abatacept (2015, 2016), adalimumab (2015, 2016), etanercept (2015, 2016), certolizumab (2014, 2015, 2016), and golimumab (2016).

Conclusion: Among RA patients treated with SC biologics after using at least one other biologic, patients treated with tocilizumab generally had lower real-world costs than those treated with other SC therapies.

Burden of Illness of Treating Patients with Pemphigus vulgaris

Jennie H. Best, Margaret Michalska and Ibrahim Abbass, Genentech, Inc., South San Francisco, CA

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Health Services Research Poster I – ACR/ARHP

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 9:00AM-11:00AM

Background/Purpose: Pemphigus vulgaris (PV) is a rare autoimmune disorder that affects the skin and mucous membranes. Many patients with PV suffer from serious infections, and though rare, mortality is associated with complications of treatment of PV, including corticosteroids. This study aimed to estimate the burden of illness in patients with PV in the US.

Methods: A retrospective cohort of patients with a new diagnosis of PV was identified from the Truven Health Marketscan US commercial claims database between January 1, 2009 and September 30, 2016. Newly diagnosed PV patients were defined by one inpatient diagnosis or two outpatient diagnoses of Pemphigus NOS/PV ((PV), ICD-9/10 694.4/L10.0)) during the study period and no PV diagnosis in prior 12 months. One-year healthcare resource use and costs were calculated, and the most prevalent comorbidities in the PV population are described.

Results: A cohort of 631 PV patients was identified. The mean age of the cohort was 50 (SD=11) years and 55% were female. During the baseline period, the most frequently reported comorbidities were opportunistic infections (62.8%), hypertension (23.3%), and type 2 diabetes (12.8%); 58.3% of patients were prescribed corticosteroids. During the first-year after diagnosis of PV, outpatient visits were the most frequently reported resource use (mean=19.5; SD=17.5); mean length of inpatient stays, for patients with hospitalization, was 12.0 (SD=21) and mean ER visits were 0.33 (SD=0.8). Mean total costs in the year prior to diagnosis were \$16,420 (SD: \$39,781), comprised of pharmacy (\$2,500; SD=\$4,993), inpatient (\$5,423; SD=\$27,618), and outpatient (\$8,498; SD=\$17,121). Mean total costs during first year after diagnosis were \$30,742 (SD=\$69,875). Total costs were comprised of pharmacy (\$3,558; SD=8,858), inpatient (\$5,623; SD=\$18,108), and outpatient (\$21,561; SD=\$59,785). The mean cost [SD] of outpatient services during the first year after diagnosis was: durable medical equipment (\$1,107 [\$2,319]), evaluation and management (\$2,105 [\$2,386]), unclassified (\$8,717 [\$41,132]), imaging (\$1,454 [\$3,066]), other outpatient services (\$14,207 [\$48,573]), procedures (\$4,713 [\$17,383]), and tests (\$1,590 [\$2,604]).

Conclusion: Patients diagnosed with PV have high a comorbidity burden, particularly opportunistic infections. Healthcare costs almost doubled in the year following the diagnosis of PV compared to one year prior to diagnosis of PV.

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Health Services Research Poster I – ACR/ARHP

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 9:00AM-11:00AM

Background/Purpose: Real-world data on adherence to TNF α inhibitors in patients with RA are missing from many regions, including the Middle East. This study evaluated the real-world 1- and 5-year adherence to etanercept (ETN) among Iraqi patients with RA.

Methods: This observational, retrospective study assessed patient data entered in the National Center of Rheumatology in Iraq database during the period May 2012 – May 2017. Individuals aged >18 years, with a diagnosis of RA, and who required treatment with ETN, with or without MTX, were identified and included in the analysis. Those previously treated with a different biologic or who were enrolled in a randomized clinical trial were excluded. Adherence was assessed for 1- and 5-year periods, with 1-year adherence defined as 7 consecutive patient visits. Demographics, Disease Activity Score 28 (DAS28), Clinical Disease Activity Index (CDAI) scores, and adverse events (AEs) data were also collected. Editorial support was provided by Charlene Rivera, PhD, and Vojislav Pejovic, PhD, of Engage Scientific Solutions and was funded by Pfizer.

Results: In total, data from 1293 individuals were collected. Approximately half (51.7%, n=668) were treated concomitantly with MTX and 40.4% were taking prednisolone. At baseline, the mean (\pm standard deviation) disease duration was 10.0 \pm 8.3 years, and mean CDAI and DAS28 scores were 27.6 \pm 13.0 and 5.7 \pm 2.0, respectively. The adherence to treatment at 1 year was 86.5% (n=1119) for all patients and 85.5% (n=571) for those also receiving MTX. Among patients who discontinued treatment at 1 year, 75.2% (n=112) did not specify a reason, 20.8% (n=31) reported lack of efficacy, and 4.0% (n=6) reported side effects as reasons for discontinuation. Patients who discontinued treatment at 1 year due to side effects or other unspecified reasons had significantly improved CDAI and DAS28 scores at the last follow-up visit compared with baseline scores (16.3 and 19.9 vs 26.3 and 26.3 for CDAI, respectively; 4.5 and 4.8 vs 5.4 and 5.5 for DAS28, respectively; p \leq 0.001). The adherence at 5 years was 61.3% (50.4% for patients treated concomitantly with

MTX). Among patients who discontinued treatment at 5 years, 84.6% did not specify a reason, 12.2% reported lack of efficacy, and 3.2% reported side effects as reasons for discontinuation. Average CDAI and DAS28 scores significantly decreased at the last follow-up visit compared with baseline among patients still on treatment at 5 years (19.9 vs 26.6 and 4.7 vs 5.6, respectively; $p=0.001$).

Conclusion: A majority of real-world Iraqi patients with RA were adherent to ETN treatment after 5 years. Furthermore, most patients tolerated treatment with ETN and had significant improvements in treatment scores at 5 years. Adherence was higher among patients in the total population compared with the subset receiving concomitant MTX.

Session Date: Sunday, October 21, 2018

Session Title: Health Services Research Poster I – ACR/ARHP

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 9:00AM-11:00AM

Background/Purpose: SLE patients frequent the emergency department (ED) irrespective of their access to care, which raises concerns regarding the quality of care in the ambulatory setting. We investigated the characteristics and patterns of ED utilization among MILES Cohort participants to identify opportunities to improve quality of care in SLE.

Methods: Data were derived from the baseline visit of MILES, a longitudinal, population-based cohort of SLE patients and controls in southeastern Michigan. Frequency of ED utilization in the preceding 12 months was categorized as none, 1-2 visits, or 3 or more visits. We used stratified multivariable ordered logistic regression to evaluate factors associated with increasing frequency of ED utilization. Variables determined *a priori* to be important, or with p -values <0.1 in univariate analysis, were included in multivariable models (listed in Table 2).

Figure 1: ED utilization in the preceding 12 months among MILES Cohort participants

Current opioid use, n (%)	143 (31.0)	15 (7.8)	<0.001
Satisfaction with life score, mean (SD)	30.8 (8.1)	23.0 (7.7)	0.001

*VAS=visual analog pain scale

Results: Characteristics of the MILES Cohort participants (462 SLE patients and 192 controls) at baseline visit is summarized in Table 1. ED utilization grouped by frequency is shown in Figure 1, where SLE patients reported a total of 572 ED encounters and controls a total of 113 ED encounters. SLE patients reported higher pain scores and pain catastrophizing scores compared to controls, and more reported current opioid use ($p<0.001$). In stratified multivariable ordered logistic analysis, increasing frequency of ED utilization among SLE patients was associated with black race [OR 1.53(95% CI 1.01-2.31)], Medicaid coverage [2.35 (1.28-4.33)], and current opioid use [2.19(1.41-3.42)]. Among controls, black race [2.33 (1.08-5.03)] and higher pain catastrophizing scores [1.06 (1.00-1.12)] were associated with increasing frequency of ED utilization.

Conclusion: Factors associated with increasing frequency of ED utilization among SLE patients differ from those among controls from the general population. Although SLE patients experience high pain burden, only current opioid use is associated with frequent ED utilization. Opioid therapy is associated with high morbidity and mortality, and further study aimed at understanding opioid prescribing practices for SLE patients who frequent the ED is warranted to identify opportunities to improve quality of care.

Factors Associated with High-Dose Corticosteroid Use in SLE Patients Post Initiation of SLE Therapy

Krista Schroeder¹, Steve Gelwicks¹, **Jim Paik**² and Robert W. Hoffman¹, ¹Eli Lilly and Company, Indianapolis, IN, ²HEOR, Eli Lilly and Company, Indianapolis, IN

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Health Services Research Poster I – ACR/ARHP

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) therapies include non-steroidal anti-inflammatory drugs, antimalarials, systemic immunosuppressants, and biologics with corticosteroids as necessary. The majority of these current therapies are only partially effective in disease control. Despite treatment, patients may experience flares of disease activity, which can lead to progressive end-organ damage. Severe flares may require intensive immunosuppression, including with high-dose corticosteroids, with risk including end-organ damage. The objective was to understand the unmet need in SLE by quantifying use of high-dose (≥ 40 mg/day) corticosteroids and determining factors associated with its use.

Methods: This study utilized the Truven Marketscan® commercial claims database. Patients were indexed on first use of antimalarial, oral immunosuppressant or biologic during 2012-2013 (first use determined based on no claims for the 3 drug classes during the 1-year pre-index). Included patients had 2 recorded SLE diagnoses, were 18-50 years of age and had continuous medical and prescription enrollment from baseline through the 2-year follow-up. Patients with other pre-specified autoimmune disorders or cancers during the study period (baseline through follow-up) were excluded. During follow-up, fill of at least 1 high-dose corticosteroid prescription was assessed and associative logistic regression modeling performed.

Results: 1,401 patients (93% female; mean age 38.4 years) met the study criteria; 79% were indexed on an antimalarial, 15% on an oral immunosuppressive, 1% on a biologic and 5% on a combination of at least 2 of the aforementioned classes. 16% patients received a diagnosis code for nephritis or chronic kidney disease (CKD), 3% for myocarditis or pericarditis, and 13% for thrombocytopenia or leukopenia. During baseline, 56% of patients had at least 1 visit to a rheumatologist and 13% filled at least 1 high-dose corticosteroid prescription. During follow-up, 22% of patients had at least 1 high-dose corticosteroid prescription. Factors significantly associated ($p<0.05$) with high-dose corticosteroids during follow-up included: baseline rheumatologist visit ($OR=0.62$; 95% $CI=0.47-0.82$), number of SLE medication classes received during follow-up ($OR=1.85$, 95% $CI=1.36-2.51$), receipt of high dose corticosteroid during baseline ($OR=5.21$, 95% $CI=3.60-7.53$), nephritis or CKD ($OR=1.85$, 95% $CI=1.29-2.64$), myocarditis/pericarditis ($OR=3.38$, 95% $CI=1.75-6.55$), and thrombocytopenia/leukopenia ($OR=1.70$, 95% $CI=1.17-2.48$).

Conclusion: A number of baseline factors were associated with high-dose corticosteroid treatment during the follow-up period; one notable factor is the high percentage of patients using high-dose corticosteroids (≥ 40 mg/day). This indicates that important subsets of patients experience inadequate disease control with current therapies. This study reveals high-dose corticosteroid use is prevalent in SLE management broadly, underscoring the unmet need in this population.

Session Date: Sunday, October 21, 2018

Session Title: Health Services Research Poster I – ACR/ARHP

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 9:00AM-11:00AM

Background/Purpose: The Veterans Health Administration health system represents the largest integrated healthcare system in the U.S. and maintains robust administrative and clinical data that can facilitate outcomes research of chronic diseases. Our objective was to compare the ability of a combination of available Veterans Affairs (VA) data sources to define a national cohort of rheumatoid arthritis (RA) patients and validate these potential cohorts using the Veterans Affairs Rheumatoid Arthritis (VARA) Registry.

Methods: We queried national VA data in the Corporate Data Warehouse within the VA Informatics and Computing Infrastructure from 2000 through April 1, 2018. We collected outpatient and inpatient diagnostic codes, diagnostic codes from non-VA providers, outpatient medications and IV infusions, non-VA medications, provider specialty, autoantibody status, and corresponding dates. We tested the performance of administrative-based algorithms with varying requirements for RA classification. We characterized cohort membership by DMARD use and autoantibody status, and then calculated the sensitivity of each algorithm in VARA where all participants (n= 2640) fulfilled 1987 ACR RA Criteria.

Results: Using an RA algorithm based only on diagnostic codes, we identified 121,946 unique patients in the VA (Table 1). More stringent algorithms requiring rheumatologist diagnosis, DMARD use, exclusion of other rheumatic diseases, and/or incorporating autoantibody results reduced the cohort size (60,845 in the most stringent algorithm). The application of additional criteria had a limited impact on the sensitivity, with the most stringent algorithm identifying 94.5% of VARA participants. The proportion receiving a DMARD consistently increased with more restrictive algorithms in the national cohort (Table 2). The most restrictive algorithm yielded 97.6% with DMARD use (69.3% for MTX). Similarly, autoantibody positivity increased with greater stringency of the algorithm with a frequency of anti-CCP positivity ranging from 56.1% in criteria using only diagnostic codes to 64.6%.

Conclusion: Administrative-based algorithms are highly sensitive for defining a national cohort of VA patients with RA. The characteristics of this newly assembled national cohort reflect those of an established RA registry with respect to DMARD use, suggesting reasonable specificity. Greater autoantibody positivity in VARA registry may be due to channeling of seropositive subjects into registry participation.

Temporal Trends and Factors Associated with Bisphosphonate Drug Holidays

Jeffrey R. Curtis¹, Rui Chen¹, Tarun Arora¹, Shanette Daigle¹, Robert Matthews¹, Huifeng Yun¹, Nicole Wright², Ayesha Jaleel³, Elizabeth Delzell⁴ and Kenneth Saag⁵, ¹University of Alabama at Birmingham, Birmingham, AL, ²Epidemiology, University of Alabama at Birmingham, Birmingham, AL, ³University of Alabama at Birmingham, Birmingham, AL, ⁴Retired - University of Alabama at Birmingham, Birmingham, AL, ⁵UAB, Birmingham, AL

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Health Services Research Poster I – ACR/ARHP

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 9:00AM-11:00AM

Background/Purpose: Safety concerns related to osteoporosis (OP) medication use and temporary or permanent cessation of bisphosphonate therapy (e.g. ‘drug holidays’) have generated appreciable attention in the lay media and medical community. We examined trends and factors associated with BP drug holidays.

Methods: We assembled a cohort of women (‘OP cohort’) who had osteoporosis as diagnosed by a physician, fragility fracture, or were treated with any OP therapy using 2009-2015 Medicare data (100% sample). Women with Paget’s or malignancy were excluded. Use of any OP therapy was examined in 6 month calendar time intervals during which women had to remain alive with full medical & pharmacy coverage. We identified the subgroup of women (‘long term BP user cohort’) who had initiated BP therapy and were $\geq 80\%$ adherent with any BP for ≥ 3 years. Women were considered to

have taken a BP holiday if they had a gap in BP use > 12 months. We examined patterns of BP drug holidays over time, stratified in 6 month intervals and by cumulative duration of BP drug use.

Results: From a source population of more than 3 million women with osteoporosis, declining trends in use of all OP therapies were observed. Overall oral BP use fell by more than 50% from 2010 to 2014, although declines plateaued between 2012 and 2104. A total of 160,369 long-term BP users were identified, with mean (SD) age of 78.5 (7.5) years; 71% used alendronate and 51% used alendronate exclusively. Of these, 58,046 (36.2%) women had a BP drug holiday of >12 months. Approximately 10% of long term BP users discontinued each 6 month interval, reaching a peak in 2012 and continuing in a stable fashion thereafter (Figure). The timing of BP drug holidays peaked at a cumulative duration of 5-5.5 years of BP exposure. Numerous factors differed significantly between women taking drug holidays and those who did not including age, fragility fracture, and recent DXA.

Conclusion: Long term cessation of bisphosphonate therapy after 3-5 years of prior use has become increasingly common in the U.S. The impact on fracture risk and the optimal timing to restart remains of high importance.

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Health Services Research Poster I – ACR/ARHP

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 9:00AM-11:00AM

Background/Purpose: Early referral to rheumatology of persons with suspected inflammatory rheumatic disease is associated with better outcomes. Persons with undiagnosed rheumatic disease may directly consult a physical therapist (PT) in the Canadian private sector without physician referral.

Our objectives were: : 1) To investigate whether PTs can correctly identify new-onset inflammatory arthritis and differentiate between these cases and other musculoskeletal problems;
 2) To assess whether PTs are aware that persons with new-onset inflammatory arthritis should be seen promptly by a rheumatologist.

Methods: We sent a questionnaire to PTs in two Canadian provinces (Quebec and Alberta, where PTs are permitted to refer patients directly to medical specialists) describing four case scenarios (new-onset rheumatoid arthritis - RA; knee osteoarthritis - OA; new-onset ankylosing spondylitis - AS; and low back pain- LBP). Participants were asked to identify

probable diagnoses, and indicate their plan of action. Questionnaires were sent via professional licensing bodies and associations and completed through an online platform.

Results: There were 303 PTs who responded to the survey (290 in Quebec and 13 in Alberta). Most PTs (67.6%) were between 18 and 45 years of age, 77.9% were female and 76.4% had more than 5 years experience. The proportions who correctly identified each of the four cases were: 87.7, 82.8, 73.4, 100% respectively for RA, OA, AS, and LBP. The majority (77%) of respondents who correctly identified the case as RA/inflammatory arthritis indicated that it was very important or extremely important to refer to a rheumatologist. Similarly, 70.4% of those who correctly identified the case of AS/inflammatory arthritis said it was very important or extremely important to refer the patient to a rheumatologist. Of those who correctly identified the case of OA, 29.9% said that it was very or extremely important to do so. For the case of LBP, only 0.5% said that it was at least very important to refer to a rheumatologist. In terms of comfort level to refer to a specialist, the majority of respondents (63.1%) felt extremely or quite comfortable.

Conclusion: The majority of PTs correctly diagnosed the clinical cases and were aware of the importance of prompt referral to rheumatology of patients with suspected inflammatory disease. Most indicated that it was not very important to refer those with OA and the overwhelming majority would not refer those with LBP. The implications are that many PTs can distinguish between those with inflammatory and noninflammatory conditions and appropriately refer suspected inflammatory arthritis to rheumatology.

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Health Services Research Poster I – ACR/ARHP

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 9:00AM-11:00AM

Background/Purpose: Smoking remains the leading preventable cause of US mortality and predicts higher incidence, greater severity, and reduced treatment response in many rheumatologic conditions. Despite increased risk, few scalable rheumatology clinic interventions exist to support cessation; yet, all states have free tobacco quit lines. Our objective was to examine the impact of our 90-second electronic health record (EHR)-supported staff tobacco cessation protocol on state quit line referral rates in a community rheumatology clinic.

Methods: Using a pre-post implementation design, we implemented and evaluated our EHR-supported staff tobacco cessation protocol called Quit Connect with medical assistants at a community rheumatology practice between May 2015 and April 2018. The protocol included electronic health record prompts to *Ask* (assess smoking status and 30-day readiness to quit or cut back), *Advise* to quit and electronically *Connect* those willing to receive quit line support. Data sources included manually abstracted baseline data and post-implementation EHR protocol documentation. Clinic staff received a one-hour training session on the protocol components and monthly feedback on their fidelity. The effectiveness of the implementation was examined through manually abstracted EHR data using standardized manuals to determine delivery protocol components per patient visit (e.g. advice given, follow-up offered and quit line referrals). Post-implementation quit line referrals were compared to abstracted baseline rates using odds ratios (OR) with 95% confidence intervals.

Results: At baseline (n=100 visits with active smokers), tobacco use discussion was documented by providers 26% of the time. In 17% of these visits, cutting back or quitting was advised. Follow-up or referral to the quit line was never documented, although at three visits (3%), primary care follow up was advised.

Post-implementation, tobacco status was recorded at 5031 of 5117 visits (98%). Readiness to quit was asked at 595 of 607 visits (98%) with smokers. Among those asked, 129 (22%) expressed readiness to quit. Compared to baseline, where 3% (3/100) were recommended any follow up, post-intervention, 31% of smokers who were ready to quit (40/129) were offered referral to the quit line (OR 14.5, 95% CI 4.3-48.6, $p < 0.0001$). Of these, 93% (37/40; 28% of ready smokers) accepted referral. Challenges included >50% turnover of staff. Despite this, usual clinic and float staff were able to implement this protocol.

Conclusion: We demonstrated that Quit Connect, our 90-second staff tobacco cessation protocol, resulted in a 14-fold increase in referrals to the quit line in a community rheumatology clinic. Nearly one in four patients were ready to quit. Engaging staff to implement the protocol resulted in improved referral rates despite high staff turnover. Future studies should investigate scaling cessation protocols with rheumatology staff in diverse clinics to leverage free, state quit lines.

Session Title: Health Services Research Poster I – ACR/ARHP

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 9:00AM-11:00AM

Background/Purpose: Quality standards recommend an annual review by a multidisciplinary team (MDT) for all patients with rheumatoid arthritis (RA); however, this is based on expert opinion.

Methods: Single centre randomised single-blind controlled trial of MDT vs. routine rheumatologist review in established RA.

Primary outcome: Minimal clinically important difference (MCID) in quality of life (QOL) (increase in European QOL-5-Dimension-3-Level Singapore (EQ5D-SG) index by 0.1) at 6 months.

Secondary outcomes: Change in EQ5D-SG, pain, disease activity score in 28 joints (DAS28), physical function (modified Health Assessment Questionnaire, mHAQ), coping, self-efficacy (Rheumatoid Arthritis Self-Efficacy scale, RASE), Medication Adherence Report Scale (MARS), Disease Specific Knowledge (DSK) and physical activity.

Adult patients with RA were randomly assigned to a single visit to a 6-member MDT (rheumatologist, nurse, medical social worker, physiotherapist, occupational therapist and podiatrist) or usual care. MDT providers prescribed disease modifying anti-rheumatic drugs (DMARD) and counselled patients with respect to managing flares, medication adherence, coping, joint protection, exercise, footwear. Data were collected by face-to-face questionnaires, review of medical records and joint counts by a standardised blinded assessor at 0, 3 and 6 months. Paired and between-group t test with Bonferroni-Holm correction for multiple testing and logistic regression were used.

Results: 140 (power 95%, 10% attrition) patients (86.3% female, 53.4% Chinese, age 54.4 ± 12.7 years) were recruited. There were fewer females and seropositive patients in MDT (Table 1). The median (IQR) disease duration was 5.5 (2.4, 11.0) years and DAS28 was 2.87 (2.08, 3.66). There was more DMARD escalation in MDT (34.4% vs. 19.4%), and the mean patient experience score (1-10) was higher (8.9 ± 1.0 vs. 8.4 ± 1.0 , $p = 0.009$).

123 patients completed the study. 40.6% (MDT) vs. 34.3% patients achieved an MCID in EQ5D-SG, OR 1.3 (0.6, 2.7). Among the secondary outcomes, there were significant within group improvements in RASE and coping in the MDT arm, but not in the control arm (Table 2).

Conclusion: A single visit to a MDT in stable patients with established RA and low disease activity failed to achieve a MCID in EQ5D-SG index but did achieve small but significant improvements in coping and self-efficacy. Patients valued the MDT experience. Recommendation of MDT care needs to balance resource use with marginally improved outcomes.

Table 1: Baseline Characteristics

Hospitalization Rates Among Patients with Polymyalgia Rheumatica: A Population-Based Study from 1995-2017

Shafay Raheel¹, Cynthia S. Crowson², Sara J. Achenbach² and Eric L. Matteson³, ¹St. Joseph's Hospital, Chicago, IL, ²Health Sciences Research, Mayo Clinic College of Medicine and Science, Rochester, MN, ³Division of Rheumatology, Mayo Clinic College of Medicine and Science, Rochester, MN

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Health Services Research Poster I – ACR/ARHP

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 9:00AM-11:00AM

Background/Purpose: The study purpose was to determine whether patients with polymyalgia rheumatica (PMR) are at greater risk for all-cause hospitalizations compared to the general population.

Methods: The study cohorts included all incident cases of PMR in a geographically-defined area diagnosed between 1995 and 2014 and non-PMR subjects from the same underlying population with similar age, sex and calendar year of index. Patients were followed until death, migration, last contact or June 30, 2017. Discharge diagnoses were grouped together using Clinical Classification Software (CCS). Readmission was defined as a hospital admission date within 30 days of a prior discharge date. Person-year methods and rate ratios (RR) from Poisson regression models were used to compare hospitalization rates between the groups. Generalized linear models were used to analyze the length of stay (LOS).

Results: A total of 463 PMR and 459 non-PMR subjects (64% female; mean age 74.1 years for both) were followed for medians of 8.4 and 7.4 years, respectively.

The patients with PMR had 1398 hospitalizations and the non-PMR patients had 1207 hospitalizations. Both groups had similar rates of all-cause hospitalizations [rate ratio (RR) 1.03; 95% confidence interval (CI): 0.95–1.11]. The rate ratio of hospitalizations for PMR compared to non-PMR remained relatively stable over time except for marginally higher rate ratios in the 1995-1999 (RR 1.40; 95% CI: 1.01-1.96) and 2010-2017 (RR 1.17; 95% CI: 1.05-1.31) time period (Figure). The rate of hospitalization remained stable across disease duration. There were no significant differences in hospitalizations according to discharge diagnosis groupings for patients with PMR vs non-PMR. The average length of stay was 4.4 and 4.7 days, respectively, among the PMR and non-PMR hospitalizations ($p=0.16$). Readmission rates were similar among the PMR subjects with 215 readmissions (20% of 1063 subsequent hospitalizations) compared to the non-PMR subjects with 214 readmissions (24% of 904 subsequent hospitalizations; $p=0.07$).

Figure. Age and sex adjusted hospitalization rates across calendar year among patients with incidence PMR in Olmsted County (solid line) and age- and sex-matched comparators (dashed line)

Conclusion: In this analysis of all-cause hospitalizations in a population-based cohort, patients with PMR did not have higher hospitalization rates compared to the general population.

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Health Services Research Poster I – ACR/ARHP

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 9:00AM-11:00AM

Background/Purpose: Infections are associated with significant morbidity and mortality in systemic lupus erythematosus (SLE). Clinical outcomes of SLE patients hospitalized is variable due to variable demographic distribution. Sepsis is defined as life-threatening organ dysfunction caused by a dysregulated host response to infection with significant increase in inpatient mortality. Data describing clinical outcomes and factors associated with poor outcomes of patients with sepsis with SLE is limited in current literature. Our objective is to evaluate factors affecting mortality in patients with sepsis and underlying SLE.

Methods: We used the National Inpatient Sample (NIS) available through Healthcare Cost and Utilization Project (HCUP) to estimate the number of hospitalizations for sepsis among adult patients with SLE in the US from 2010-2014. ICD-9 CM codes were used to identify the population. Logistic regression analysis was used to identify independent associations of in-hospital mortality. We described the associations as patient factors and hospital factors.

Results: We identified 35475 hospitalizations for sepsis with secondary diagnosis of SLE using NIS database from 2010-2014. There were 3557 inpatient deaths during these hospitalizations. Mean age of patients admitted with sepsis and SLE was 54.145 years. Analysis of the population with inpatient mortality, suggested increased odds of mortality with age, location & size of hospital and number of associated comorbidities. Odds of mortality were noted to decrease with female sex and insurance status, as reported in Table 1.

Conclusion: This study suggests increased risk of inpatient mortality in males, with increasing age and increase in number of comorbidities. Previous studies have shown similar results. Urban and large hospitals were found to be associated with higher mortality. This may represent higher likelihood of patients with comorbidities like SLE being referred or transferred to larger urban hospitals. Serious infections continue to be an important source of mortality in SLE. And factors affecting the mortality can guide us to implement guidelines for prevention and management of infections including but not limited to vaccinations, especially in high risk subgroup including males, older population with SLE and patients with multiple comorbidities.

Session Date: Sunday, October 21, 2018

Session Title: Health Services Research Poster I – ACR/ARHP

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with SLE often require additional medical management outside of the outpatient setting from ED visits to hospital admissions. Previous studies in the general population showed that those who frequently visit the ED mostly do so over a limited time period(<12 months); however, a subgroup are persistent frequent ED users over years. We examined whether persistent and limited ED utilization in SLE patients are associated with patient characteristics, SLE history, long term opioid therapy (LTOT), and general health status.

Figure: Proportion of ED encounter in each encounter category group at discharge from either the ED or after ED-initiated hospitalization among SLE patients who frequented the ED between 2013-2016

Table: Factors associated with persistently frequent ED use compared to limited frequent ED use

Variable	OR (95% CI)	p-value
Age	1.00 (0.96-1.03)	0.870
Female	1.61 (0.39-6.54)	0.508
Race		
African American	Reference	
Caucasian	0.22 (0.07-0.75)	0.015†
Hispanic/Latino	0.46 (0.15-1.38)	0.165
Insurance		
Medicaid	Reference	
Medicare	13.84 (3.14-61.05)	0.001†
Private/Commercial	1.48 (0.50-4.38)	0.481
Area of Deprivation Index	1.01 (0.97-1.05)	0.687
Depression	1.74 (0.60-5.070)	0.306
Number of co-morbidities	0.77 (0.55-1.08)	0.135
Long-term opioid therapy	3.16 (1.04-9.64)	0.043†
Other DMARD	0.39 (0.16-0.95)	0.038†

Other DMARD=disease modifying antirheumatic drug (exclude HCQ)

†statistically significant with p-values<0.05

Methods: We conducted a retrospective study of SLE patients who frequented the ED for ≥ 3 visits in a calendar year from 2013-2016. Limited use was defined as meeting criteria for frequent ED use for 1 out of the 4 years. Persistent users met these criteria for at least 2 out of the 4 years, consecutive or non-consecutive during the study period. Patient demographics, medical history, and ED encounter information were collected through in-depth electronic health record review. Each ED encounter was categorized into the following groups; SLE-, infection-, pain-related, or “other”. Multivariate logistic regression was used to evaluate factors associated with frequent ED utilization.

Results: We identified 52 limited users who had 335 ED encounters, and 77 persistent users who had 1143 encounters; average age 41.5 (SD 15.6), 116(90%) female, 76 (58%) with Medicaid insurance coverage, and 77 (60%) African American, 27 (21%) Caucasian, and 25 (19%) Hispanic/Latino. Persistent users had more than twice the average number of ED visits (mean 14.8, SD 8.8) compared to limited users (mean 6.4, SD 2.0), and had more ED-initiated hospitalizations(49% vs 40%, respectively). Pain-related ED visits were more common among persistent users (32%)than limited users (18%) (see Figure). In multivariate analysis, persistently frequent ED users were more likely to be African American, have Medicare insurance coverage and be on LTOT, but less likely to be on other DMARD, than their respective counterparts who are limited frequent ED users (see Table).

Conclusion: Among SLE patients who persistently frequent the ED, pain is a major cause for both ED utilization and ED-initiated hospitalizations. This group of SLE patients who account for a high volume of healthcare resource utilization may be amenable to targeted interventions to improve pain management and care coordination in the outpatient setting. Further research is needed to improve quality of care and reduce healthcare resource utilization among SLE patients who frequently utilize the ED.

Built-in-Electronic-Medical-Record Disease Activity Calculators and Treat-to-Target in Rheumatoid Arthritis

Arundathi Jayatilleke¹ and Scott Pompa², ¹Department of Rheumatology, Drexel Rheumatology, Philadelphia, PA, ²Rheumatology, Drexel Rheumatology, Philadelphia, PA

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Health Services Research Poster I – ACR/ARHP

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is a chronic inflammatory arthritis that, if undertreated, can lead to cumulative damage and disability. The goal of treatment is to achieve the lowest possible disease activity. The current recommendations from ACR is to adopt a “treat to target” strategy (1). In order to quantify disease activity and monitor it over time, disease activity score calculators (DAC) were developed.

Table 1 Disease Activity CDAI	Step up therapy	No change therapy	Step down therapy	Most Common Added Medication Class	RTF (mo)	ATF (mo)	Fellow	Junior faculty	Senior faculty
Remission 33	-	27 (81%)	6	-	3.7 ⁵	4	14 (42%)	18 (54%)	1 (3%)
Low 74	14 (19%)	58 (78%)	2	6 42% cDMARDs	3	4.8 ²	23 (31%)	43 (58%)	8 (11%)
Moderate 75*	46 (61%)	23 (31%)	6	19 41% bDMARDs	2	2.8	27 (36%)	46 (61%)	2 (3%)
High 22	21 (95%)	-	-	14 67% bDMARDs	1.7	2.89	15 (68%)	6 (28%)	1 (4%)
204 Encounters									
Table 2 DAS CRP									
Remission 17	3 (18%)	12 (70%)	2 (12%)						
Low 3	2 (67%)	1 (33%)	-						
Moderate 5	5 (100%)	-	-						
High 2	2 (100%)	-	-						
27 encounters									
Table 3 Reference CDAI Calculated Value									
Disease activity (DA)		Calculated CDAI value							
Remission		≤2.8							
Low		2.9-10							
Moderate		11-22							
High		>22							

DAC were validated, incorporating subjective and objective data such as: patient pain level, patient perception of disease activity (PtGA), provider perception of disease activity based on history and exam (PrGA), the swollen joint count(SJC), the tender joint count (TJC) and timely laboratory values. In a treat-to-target strategy, treatment is adjusted in accordance with disease activity scores to achieve remission (2).

The Clinical Disease Activity Index (CDAI), Disease Activity Score 28 (DAS 28), and DAS28-CRP are three methods that incorporate subjective and objective data. The result is classified into 4 groups: remission, low disease, moderate disease, and high disease activity. Adjustment of therapy may entail changing one anti-rheumatic drug to another, the addition of a new drug or the maintenance of current regimen.

Methods: Our study employs a before-after design, retrospectively examining the adoption of EMR-DAC, of patients >18 years of age, with an ICD9/10 code of RA, seen 18 months before and after introduction of the EMR-DAC in 3/2015 within the Drexel Rheumatology practices. We hypothesized that provider documentation of disease activity would increase after DAC were built into the EMR. We hypothesized that calculation of an objective score would lead to a higher rate of medication changes and decreased time to first biologic.

Results: Of the 900 patients seen in Drexel Rheumatology practice from 3/2015 to 9/2016, 23% had a CDAI documented. Preliminary CDAI data showed that of the 97 patients with moderate or high disease activity, 61% and 95% respectively had a change in therapy. In the DAS 28-CRP study group, 100% of the patients with moderate to high disease activity were started on additional therapy, with 75% prescribed or recommended a bDMARD and prednisone. 67% of the low disease activity patients were started on additional medications.

Conclusion: Our preliminary results show a low adoption rate of DACs, with CDAI being the most commonly used. Our data show DAC values do correlate with overall changes inpatient care in our practice and suggest that providers are incorporating the values in implementing a treat-to-target strategy.

Rheumatology Clinic Staff Needs for Partnering to Improve Blood Pressure and Tobacco Risk Management

Michelle Tong¹, Laura Block², Andrea Gilmore-Bykovsky², Edmond Ramly³ and **Christie M. Bartels**⁴, ¹Biomedical Engineering, University of Wisconsin - Madison, Madison, WI, ²University of Wisconsin School of Nursing, Madison, WI, ³Department of Family Medicine, University of Wisconsin School of Medicine and Public Health, Madison, WI, ⁴Rheumatology/Medicine, University of Wisconsin - Madison, Madison, WI

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Health Services Research Poster I – ACR/ARHP

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with rheumatologic conditions are at a higher risk of cardiovascular disease (CVD) than peers. High blood pressure (BP) and tobacco use exacerbate CVD risk, yet many times these risk factors are unaddressed in patients in rheumatology clinics. We interviewed rheumatology clinic staff to identify facilitators and barriers to addressing high BP and tobacco to inform the development and dissemination of tailored CVD risk management protocols in specialty clinics.

Methods: Medical assistants, nurses, and scheduling staff from four adult rheumatology clinics in two health systems were interviewed by two expert facilitators in seven 60 minute focus groups (n=23 BP and n=14 tobacco group participants). We analyzed transcripts using qualitative content analysis with NVivo 11 software.

Results: We found systems- (Table 1) and person-level (Table 2) facilitators and barriers to addressing BP and tobacco. Across both health systems, rheumatology clinic staff's usual practices followed three process steps: (1) identify high BP or tobacco use, (2) follow-up within the clinic, and (3) follow-up across settings (i.e. with primary care and community resources). Focus groups identified the two key barriers as (1) lack of a system for follow-up, both within the specialty clinic and across settings, and (2) staff needs for talking points during patient interactions to address high BP and tobacco. Fragmented staff to provider communication and role perceptions were also reported as contributing to these barriers.

Conclusion: Our study identified addressable gaps in rheumatology staff's current processes for addressing high BP and tobacco including both risk identification and facilitating management. Future work should support systems of follow-up, talking points for staff discussions, and or improve staff and provider collaboration on CVD preventive care.

Table 1. Systems-level barriers and facilitators for blood pressure (BP) & tobacco (TOB) care

THEME	ILLUSTRATION
<i>Step 1. Identification of High BP or Tobacco Use</i>	
Standard check-in routine, time constraints	BP: "I mean <u>we barely have time</u> to get patients in... and then sometimes the providers come in when we're still rooming."
<i>Step 2. Follow-Up Within Specialty Clinic</i>	
No standard follow-up	BP: " <u>There is no system</u> thing that everybody does... they have come back and were like, 'Hey, did we ever recheck that blood pressure?' I noticed it was really high.' 'Well that was like 2 hours ago, and I didn't know that you wanted me to.'"
Physical reminders helped with BP rechecks	BP: "We give our providers stickers, so if it's a high blood pressure, we could write it on the stickers. <u>I don't know that we always do though.</u> "
EHR structure did not support nuance of cutting back.	
Educational materials provided	TOB: "When you give them this packet of [tobacco cessation] paperwork, it's kind of like <u>'Well, we care a little, but we don't have time to fully follow-up.'</u> "
Provider conversations rare	
<i>Step 3. Follow-Up Across Settings</i>	
No standard process for communication with primary care	TOB: "I usually just say, 'Do you want any information on quitting?'... And there's been people who have said yes, <u>but if it's in a specialty department where their PCP isn't there, it never gets addressed.</u> "

Table 2. Person-level barriers for specialty blood pressure (BP) and tobacco (TOB) care

THEME	ILLUSTRATION
<i>Provider</i>	
Providers' perception of roles and responsibilities for BP and tobacco management varied	BP: "But then a lot of times they are like, <u>'That's not my area, primary can take care of that.'</u> "

Table . (Cont'd)

THEME	ILLUSTRATION
<i>Nurse or medical assistant</i>	
Knowledge gaps about BP guidelines and tobacco treatments	BP: "Well they just start asking questions. <u>I'm not the doctor, so I don't feel like I... just try to down play it.</u> "
Staff verbiage needs about BP and tobacco management	TOB: " <u>I don't have the verbiage</u> to continue...Even when I tried to say, 'Are you interested? I have a card' ...I don't know where to go with it."
<i>Patient</i>	
Knowledge levels varied less knowledgeable about tobacco resources	BP: "[Patients] ask, ' <u>Well, what should [my BP] be?</u> ' I hear that all the time."
Patients appeared indifferent talking about BP and resistant during conversations about tobacco	TOB: "I've had, ' <u>Don't ask me that ever again</u> '...about if they're a smoker."

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Imaging of Rheumatic Diseases Poster I: MRI

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The RAMRIS scoring system is used to quantify synovitis, tenosynovitis, bone marrow edema (BME), bone erosions and joint space narrowing (JSN) on MRI examinations of the wrist and hand in clinical trials in RA. We explored methods to combine the MRI features into valid, responsive and feasible scores for a) *inflammation* and b) *joint damage*.

Methods: We analyzed baseline and 12-month MRI data (wrist and MCP 2-5) from the ARCTIC trial (derivation cohort, n=195, all fulfilling 2010 RA criteria) to assess five different approaches to the development of combined scores: **1) Unweighted summation:** RAMRIS synovitis, tenosynovitis and BME were summarized to an inflammation score. Erosions and JSN were summarized to a damage score. **2) Normalized summation:** Each component was transformed to the same scale before summation. **3) Weighted summation:** We divided each component into three joint, tendon or bone areas, which were individually weighted and summarized. Weights were calculated conditioned to give the highest standardized response mean (SRM) to the resulting score. **4) Adjusted weighted summation:** Weights from approach 3) were adjusted based on clinical experience and feasibility concerns (e.g. only whole numbers as adjustment weights). **5) Single site weighted summation:** As in 3, but weights calculated for each individual bone, joint and tendon. The combined scores were tested in pooled data from the CIMESTRA and OPERA trials (validation cohort, n=194, all fulfilling 1987 RA criteria, baseline and 12-month data for wrist and MCP 2-5). Validity was examined by assessing correlations to imaging, clinical and biochemical measures. Responsiveness was tested by calculating the SRM of the resulting combined score, and the relative efficiency using the score obtained by unweighted summation as reference.

Results: Patient characteristics, as well as baseline and follow-up RAMRIS scores were comparable between trials. Validity: All the combined scores were significantly correlated to other imaging, clinical and biochemical measures (**table 1**, all patients). Responsiveness: Inflammation scores combined by method 2, 3 and 4 had significantly higher responsiveness

compared to unweighted summation. For the damage score, there was a trend towards higher responsiveness for method 4 (figure 1, data from OPERA and CIMESTRA).

Table 1a: Spearman correlations of Combined Inflammation Scores to other disease measures (all patients)										
	DAS28	TJC28	SwC28	PGA	PhGA	CRP	ESR*	PFTS*†	USPD*	USBM*
1. Unweighted Summation	0.32	0.14	0.42	0.12	0.32	0.40	0.24	-0.26	0.49	0.54
2. Normalized Summation	0.36	0.18	0.46	0.14	0.35	0.43	0.24	-0.25	0.52	0.55
3. Weighted Summation	0.27	0.13	0.44	0.11	0.29	0.33	0.17	-0.29	0.47	0.52
4. Adjusted Weighted Summation	0.30	0.15	0.42	0.11	0.31	0.37	0.19	-0.28	0.50	0.54
5. Single Site Weighted Summation	0.29	0.14	0.45	0.11	0.29	0.32	0.21	-0.26	0.46	0.48

Table 1b: Spearman correlations of Combined Joint Damage Scores to radiographic outcomes (all patients)			
	vdHQS Erosions	vdHQS JSN	vdHQS Total
1. Unweighted Summation	0.43	0.33	0.40
2. Normalized Summation	0.41	0.32	0.38
3. Weighted Summation	0.41	0.34	0.40
4. Adjusted Weighted Summation	0.43	0.33	0.40
5. Single Site Weighted Summation	0.42	0.37	0.43

*ARCTIC only. Abbreviations: DAS28= Disease Activity Score, 28 joints. TJC28= Tender Joint Count, 28 joints. SwC28= Swollen Joint Count, 28 joints. PGA/PhGA= Patient's/Physician's Global Assessment. PFTS= PROMIS T-score. USPD= Ultrasound Power Doppler. USBM= Ultrasound B-Mode. vdHQS= van der Heijde Sharp Score † Negative correlation due to inverse scale of PROMIS T-score. Radiographic outcomes measured by vdHQS including hands, wrists and feet. All coefficients significant at the 0.05 level.

Conclusion: Combined RAMRIS scores assessing inflammation and damage with weighting of the individual components and adjustment for face validity and feasibility displayed the highest responsiveness. The discriminative properties of the proposed combined scores need to be tested in placebo-controlled clinical trials.

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Imaging of Rheumatic Diseases Poster I: MRI

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The aim of the study was to evaluate a simplified version of the Rheumatoid Arthritis Magnetic Resonance Imaging Score (RAMRIS) to five joints of the hand (RAMRIS-5) in patients with early rheumatoid arthritis (RA) before and after the initiation of a methotrexate (MTX) therapy using high-resolution, 3 Tesla (T), magnetic resonance imaging (MRI).

Methods: 28 RA patients according to 2010 ACR/EULAR criteria (Ø 56.8 years (range 39 - 74), seropositive, disease duration < 6 months (range 2 – 23 weeks) were prospectively assessed with baseline investigation including clinical assessment (DAS-28 and CRP) and 3T MRI of the clinical dominant hand, as well as 3 and 6 months after starting MTX therapy. MRI-scans were analysed according to RAMRIS and the simplified RAMRIS-5 (Figure-1).

Results: DAS-28, CRP, RAMRIS and RAMRIS-5 decreased significantly after initiation of a MTX therapy. There was a strong correlation between RAMRIS-5 and RAMRIS at baseline ($r=0.838$; $p<0.001$) and follow-up (3 months: $r=0.876$; $p<0.001$; 6 months: $r=0.897$; $p<0.001$).

Conclusion: 3T MRI based RAMRIS-5, a simplified and resource-saving RAMRIS score is a suitable tool to show changes in early RA and may be used for diagnosis and therapy monitoring in follow-up evaluations.

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Imaging of Rheumatic Diseases Poster I: MRI

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: To investigate the local inflammatory activity of the synovium by using dynamic magnetic resonance imaging (MRI) and cartilage biochemical composition of the MCP-joints 2 and 3 by using Delayed Gadolinium-Enhanced MRI (dGEMRIC) in patients with early rheumatoid Arthritis (eRA) treated with methotrexate.

Methods: MCP joints 2 and 3 of 28 patients with early RA (disease duration ≤ 6 months) were examined prior to methotrexate (baseline) as well as 3 and 6 months after the therapy-initiation. MRI perfusion parameters and dGEMRIC index were calculated. OMERACT RA MRI score (RAMRIS), including synovitis, bone marrow edema (BME) and erosion subscores, and clinical parameters (CRP and DAS28) were registered at all of the time points.

Results: Local perfusion in dynamic MRI decreased significantly after initiation of methotrexate-therapy and correlates significantly with the DAS28 improvement after 3 months ($p < 0.05$). The extent of local inflammation significantly correlated with dGEMRIC values at all of the time points evaluated ($p < 0.05$). Local inflammation and cartilage composite measurements showed significant correlation with BME subscore after 3 months and with RAMRIS and erosion subscore in the after 6 months ($p < 0.05$).

Conclusion: In patients with eRA, synovial local hyperperfusion measured by dynamic MRI correlated significantly with the local cartilage compositional and decreased significantly 3 and 6 months after initiating of methotrexate-therapy. Dynamic MRI seems to be a useful parameter for assessing therapy-success, since DAS28 and RAMRIS showed significant correlations. This is the first study showing that methotrexate is able to delay cartilage loss and underlines the priority of early treatment.

Figure 1: Overlay of native T1 image of digitus 2 and 3 with a color-coded map of dynamic MRI from blue - low perfusion to red - high perfusion of MCP D2 and D3. Picture A demonstrates the perfusion of MCP joints at baseline MRI prior to MTX therapy, while pictures B and C show the perfusion 3 and 6 months after MTX therapy. In this example, we found higher perfusion after 3 and 6 months compared to baseline MRI for both MCP joints.

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Imaging of Rheumatic Diseases Poster I: MRI

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The aim of the study was to evaluate a simplified version of the OMERACT Psoriasis Arthritis Magnetic Resonance Imaging Score (PsAMRIS) to seven regions of the clinically dominant hand in patients with psoriasis arthritis (PsA) before and after treatment escalation to biological Disease-Modifying Antirheumatic Drugs (bDMARDs) using high resolution, 3 Tesla (T) MRI.

Methods: 18 patients with PsA according to the CASPAR classification criteria (\bar{x} 47 years \pm 16) who qualified for bDMARD therapy due to inadequate Methotrexate (MTX) treatment, were prospectively assessed by both baseline investigation and 6 months after therapy escalation including clinical examination (CRP and DAS 28) and 3T MRI of the clinically dominant hand. Scans were analyzed by two independent experts (PS/CS) using the OMERACT PsAMRIS and the simplified PsAMRIS-7 which includes all distal interphalangeal joints (DIP), proximal interphalangeal joint (PIP) and metacarpophalangeal joint (MCP) of the index (PIP and MCP II).

Results: On average, PsAMRIS rating lasts 312 seconds (s; SD= 40.9); PsAMRIS-7 scoring was 116 s (SD=20.9), on average. We found no correlation between DAS28 and / or CRP to PsAMRIS ($r=-0.044$ / $r=-0.23$) or PsAMRIS-7 ($r=-0.094$ / $r=-0.13$). In contrast, there was a strong correlation between OMERACT PsAMRIS and the simplified PsAMRIS-7 at baseline ($r=0.871$; $p<0.01$) and after six months ($r=0.907$; $p<0.01$).

Conclusion: The simplified PsAMRIS-7, using 3T MRI, is a time and resource saving shortened version of the OMERACT PsAMRIS and a reliable tool for detecting morphological changes in PsA. Hence, the shortened PsAMRIS-7 may have the potential to apply in diagnosis and therapy monitoring of PsA patients. Therefore PsAMRIS-7 needs to be investigated in larger clinical studies.

The Role of Inflammation in the Evolution of MRI Erosions in the Feet of Patients with Early RA

Hanyan Zou¹, Karen A. Beattie², Saara Totterman³, George Ioannidis¹ and Maggie Larche^{2,4}, ¹McMaster University, Hamilton, ON, Canada, ²Medicine, McMaster University, Hamilton, ON, Canada, ³Qmetrics Technologies, Pittsford, NY, ⁴St Joseph's Healthcare Hamilton, Hamilton, ON, Canada

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Imaging of Rheumatic Diseases Poster I: MRI

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with aggressive RA develop early structural damage. As persistent inflammation is associated with bone erosions, assessing inflammatory activity may be key in treatment decision-making to slow or prevent further damage. This study aimed to determine the impact of inflammation on US and changes in erosions on MRI in early RA.

Methods: Patients with RA (ACR criteria, treatment naïve, symptom duration <2 years) were recruited and treated as per standard of care. The 2nd- 5th metatarsophalangeal joints (MTPJs) were imaged using US (Esaote MyLab70) at study entry, 6 weeks, 3-, 6- and 12-months follow-up. MTPJs were semi-quantitatively graded for synovial thickening (ST) and power Doppler (PD) (0-3, 3=severe inflammation). The most clinically symptomatic foot at baseline was imaged using a 1.0T peripheral MRI (GE Medical) at baseline, 12-months, and at a 24-49 months follow-up. MRI erosions were semi-quantitatively graded using the OMERACT-RAMRIS system (grade 0-10) for the metatarsal heads and phalanx bases. We characterized the number of MTPJs with low (grade <2) or high (grade ≥2) ST or PD during the majority of the first 12 months, and the number of erosions that were unchanged, improved or worsened by grade ≥1 over the follow-up.

Results: Forty-one patients were included [n=33 female, mean (SD) age=51.6 (10.3) years]. Of 32 patients with follow-up MRIs, total erosion score decreased (improved erosions) in 17 patients and increased (worsened) in 18. Ten patients had a simultaneous improvement and worsening of erosions in different MTPJs. At baseline, 12- and ≥24-months, 299, 308 and 242 metatarsal heads and phalanx bases were graded on MRI. Approximately 40% of joints had a grade ≥1 erosion at each visit, and 5-7% had grade ≥2 erosions. Of all baseline erosions, 28% improved and 27% worsened after 12-months; 40% improved and 29% worsened from baseline to post-24 months. Most changes were by grade 1, and the largest change was by grade 2. Joints with persistently low ST scores had more frequent erosion healing and fewer worsened erosions than joints with persistently high ST (Table 1). MTPJs with persistently high ST had more erosions that worsened than improved after 12 months, but approximately the same number had improved and worsened erosions after ≥24 months. Persistently high PD and erosion progression occurred very infrequently. Six patients were not treated with DMARDs or biologics throughout the study duration. Four of these patients had persistently high ST, of whom 3 had worsened total erosion scores.

Conclusion: Our findings suggested that more erosions worsened in joints with persistent severe inflammation than joints with low inflammation in early RA. The value of US inflammation for predicting erosion progression warrants further investigation, especially in populations with greater disease activity.

Table 1: MTPJs with persistently low or high inflammation during the first 12 months, and the progression of their MRI erosions after 12 months and after 24-49 months.

		MRI erosion BL to 12 months				MRI erosion BL to post-24 months

Tenosynovitis on MRI of Bilateral Hands and Its Concordance with Joint Swelling/Tenderness in Patients with Early Rheumatoid Arthritis

Ying-Qian Mo¹, Ze-Hong Yang², Jun-Wei Wang¹, Xin-Yun Du¹, Yan-Hui Xu¹, Kui-Min Yang¹, Guang-Zi Shi², Jun Shen² and Lie Dai¹, ¹Department of Rheumatology, Sun Yat-Sen Memorial Hospital, Sun Yat-Sen University, Guangzhou, China, ²Department of Radiology, Sun Yat-Sen Memorial Hospital, Sun Yat-Sen University, Guangzhou, China

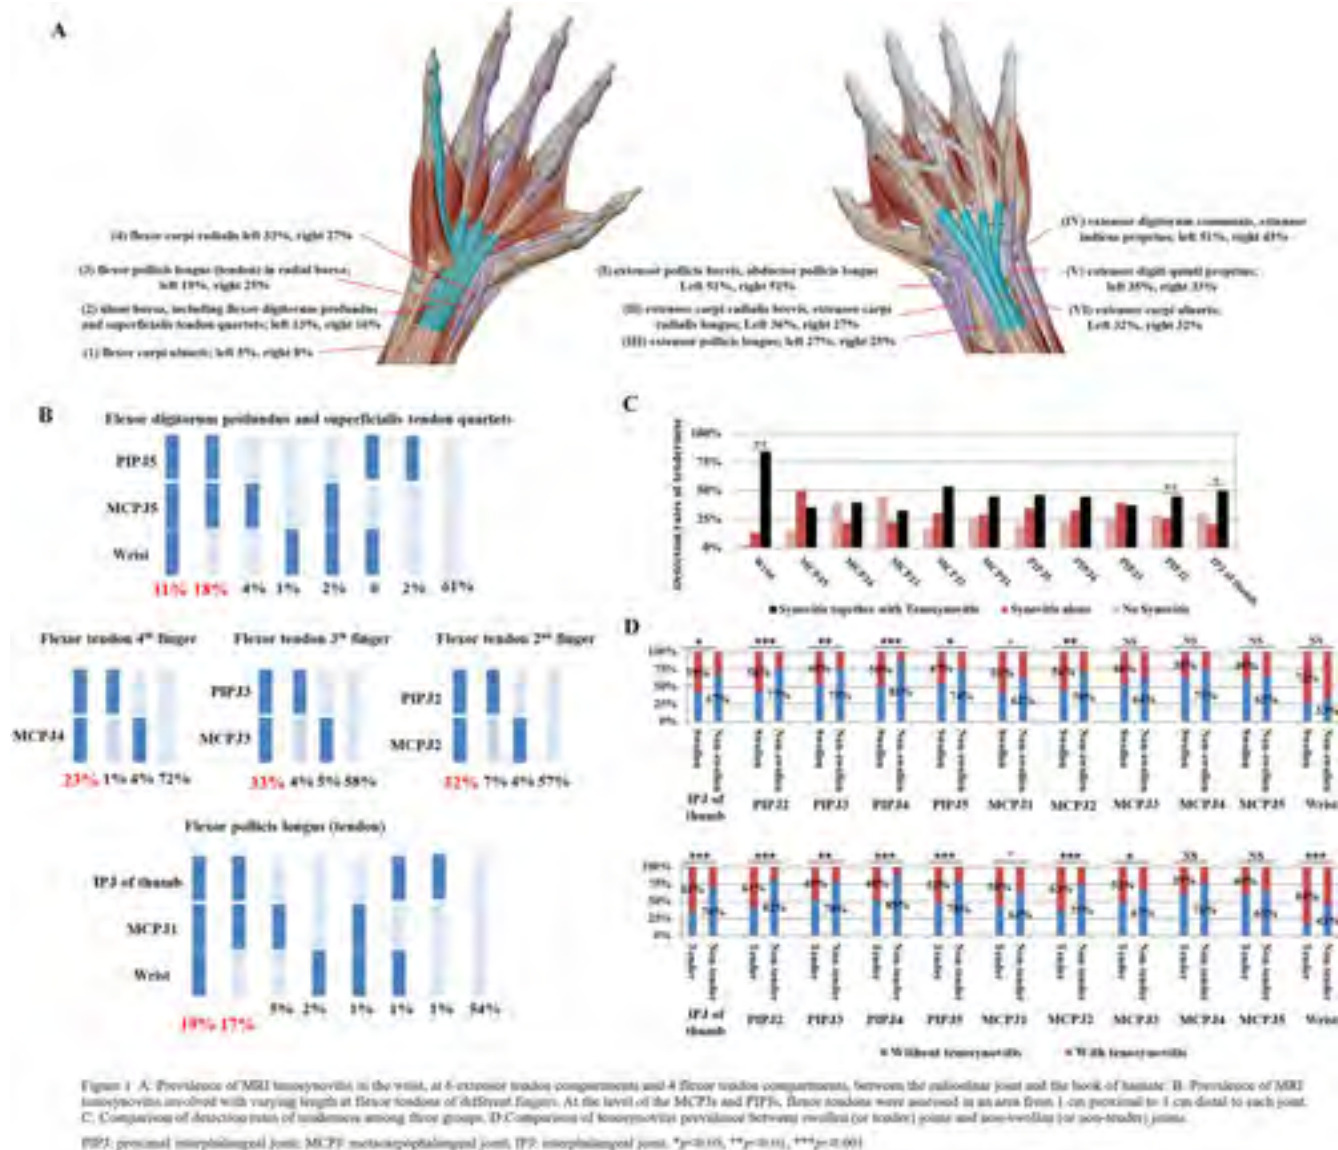

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Imaging of Rheumatic Diseases Poster I: MRI

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The updated recommendations of Rheumatoid Arthritis Magnetic Resonance Imaging Scoring (RAMRIS) System in 2017 firstly recommended tenosynovitis with a standard score. However, there is no study on the novel score of tenosynovitis using bilateral-hands MRI and no data of MRI tenosynovitis on proximal interphalangeal joints (PIPs) either.

Objective: To explore the distribution of MRI tenosynovitis among bilateral hands and its concordance with joint swelling/tenderness in early RA patients.

Methods: Early active RA patients (DAS28-CRP ≥ 2.6 and disease duration ≥ 1 year) were recruited in our hospital during October, 2011 to March, 2018. Bilateral hands (including PIPJs, MCPJs and wrists) of each patient were scanned simultaneously on 3.0T whole-body MRI system with an 8-channel sense head coil. MRI tenosynovitis and synovitis were scored based on RAMRIS 2017. Clinical data were collected simultaneously.

Results:

- Among 75 patients recruited, the median age was 45 years old with 71% female. The median disease duration was 7 months and 85% had bony erosions.
- MRI tenosynovitis was detected in 84% of patients. Tenosynovitis in extensors occurred in 72% of wrists, which were higher than tenosynovitis in flexors (52%), of which the most frequent tenosynovitis was detected in extensor pollicis brevis, abductor pollicis longus (figure 1A). Tenosynovitis occurred alone or together with synovitis. For wrists, interphalangeal joints (IPJ) of thumb and PIPJ2, joints with both synovitis and tenosynovitis showed higher rates of tenderness than those joints with synovitis alone ($p < 0.05$, figure 1C).
- For PIPJ2-5 and IPJ of thumb, the prevalence of synovitis in swollen (or tender) joints were significantly higher than those in non-swollen (or non-tender) joints (all $p < 0.05$, figure 1D). Multivariate Logistic regression analyses

showed MRI tenosynovitis score was an independent risk factor respectively for swelling (or tenderness) of PIPJ2, PIPJ4, PIPJ5; tenderness of MCPJ1~4 and IPJ of thumb (OR 1.859~3.414, all $p<0.05$).

4. Tender wrists showed more tendon sheaths with tenosynovitis than non-tender wrists (3.6±3.1 vs. 2.3±2.9, $p=0.007$). ROC analyses showed that when there were ≥3 tendon sheaths with tenosynovitis, tenderness occurred in the wrist with 54% of sensitivity and 66% of specificity (AUC: 0.647, 95% CI: 0.559-0.735, $p=0.002$). Tenosynovitis score of flexor carpi radialis tendon was an independent risk factor for tenderness of wrists (OR 2.050, 95% CI: 1.103-3.812, $p=0.023$).

Conclusion: This study first reports distribution of MRI tenosynovitis among bilateral hands including PIPJs, and tenosynovitis score was an independent risk factor for tenderness of wrist, certain MCPJs or PIPJs.

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Wrist joint between radio-ulna and first carpal row; scaphoid and triquetrum bones stabilize the central carpal column and support the flexion-extension or abduction-adduction movements¹. Rheumatoid arthritis (RA) chronic disease affects the hand-wrist small joints, causing disability. Magnetic resonance imaging (MRI) is the most sensitive diagnosis and disease follow-up method (96%)², that can demonstrates lesions since initial RA phases. Objective: Identify by MRI the most affected wrist bones in 3 different RA clinical phases.

Methods: Exploratory, non-blinded cohort; from Hospital “Dr. José E. González” since Nov. 2016-Feb. 2017, (approved by Ethics and Research Committees); 60 patients assessed by rheumatologists (ACR-EULAR 2010 criteria), were divided into 3 groups: Clinically Suspicious Arthralgia (CSA), 23 (38%); Early RA (ERA), 22 (37%) and RA 15 (25%); accepted to perform MRI 1.5T, dominant hand, simple T1, T1-gadolinium and STIR (coronal and axial sections) sequences; images were assessed by experimented radiologist

Results: Female was predominant with 83% (50); mean age 42 (19-70 years); we evaluated by OMERACT-RAMIRS 1,731 wrist sites of bones and joints, obtaining lesions (synovitis, erosions, osteitis) in 56% (964); synovitis was the most prevalent 46% (445) and Triquetrum bone the most affected in all 3 groups: CSA, 87% (20/23), ERA, 91% (20/22) and RA, 93% (14/15), see Table and Figure

Conclusion: The predominant Triquetral synovitis, could suggest us, be the first morphological site to be considered in the RA evaluation when it is clinically suspected; however further longitudinal studies are needed to conclude it

CSA (n=23)	Synovitis n (%)	Erosions n (%)	Osteitis n (%)
Triquetrum	20 (87)	21 (91)	2 (9)
Lunate	11 (48)	22 (96)	2 (9)
Capitate	10 (44)	21 (91)	4 (17)

Session Title: Imaging of Rheumatic Diseases Poster I: MRI

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Early diagnosis of RA and effective monitoring of disease activity are important for treatment decision-making. Early treatment strategies can be effective in preventing the development of erosive disease. The primary method of assessing disease activity with physical examination of swollen and tender joints has low accuracy and reliability but remains the cornerstone of assessment despite new imaging modalities. This study examines early RA disease activity in feet with clinical assessment and its correlation with findings on US and MRI, the latter being the reference standard.

Methods: Treatment naive patients with early RA (ACR criteria, <2 years of symptom duration) were recruited. The most clinically symptomatic foot was assessed for swelling and tenderness in the metatarsophalangeal joints (MTPJ) 2-5. The same foot was imaged by US (Esaote MyLab70, 6-18 MHz linear array probe) and a peripheral MRI (1.0 Tesla, GE Medical). US images were semi-quantitatively graded for synovial thickening (0-3) and Power Doppler (PD) (0-3), representing hypervascularization by the rheumatologist who performed clinical assessments. Based on OMERACT RA MRI scoring criteria, a radiologist blinded to clinical and US results semi-quantitatively graded MTPJ 2-5 for bone marrow edema (BME) (grade 0-3 per metatarsal head and phalanx base, max=24) and synovitis (grade 0-3 per MTPJ, max=12).

Results: Included in the analyses were 39 patients; 33 female (84.6%), mean (SD) symptom duration 12.2 months (10.9), 18 anti-CCP positive (46.2%), and 15 RF positive (38.5%). Mean CRP and ESR levels were 18.9 mg/L (30.7) and 28.4 mm/hr (22.4), respectively. Of the 31 swollen MTP joints, 81% had synovial thickening on US, and of these joints, 44% showed PD and 64% had synovitis or BME grade ≥ 2 on MRI. Of 125 MTP joints assessed as not swollen, 41% (51 joints) were found to have synovial thickening on US with 22% also showing PD and 38% with synovitis or BME grade ≥ 2 . Of the 39 patients, 18 had ≥ 1 swollen joint and, of this subset, 94% had synovial thickening, with 41% showing PD and 57% having synovitis or BME grade ≥ 2 . Of the 21 patients without swelling, 86% (18 patients) had synovial thickening in ≥ 1 joint, with 28% showing PD and 40% having synovitis or BME grade ≥ 2 .

Conclusion: In examining patients with early RA, joints with synovial thickening and PD on US are also found to have inflammation on MRI. Making treatment decisions based solely on clinical presentation might result in under treatment of a fairly high proportion of patients with sub-clinical inflammation. These findings are suggestive that US with evidence of synovial thickening and PD may be helpful as an adjunct to clinical examination in assessing disease activity.

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Imaging of Rheumatic Diseases Poster I: MRI

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The identification of erosions plays a critical role in the management of RA, as the presence of erosions denotes more aggressive disease requiring more aggressive treatment. MRI can be used to visualize and monitor erosion progression in RA, and is often used as a gold standard in research. While the clinical significance of grade 1 erosions remains unknown, so too does the trajectory of these erosions over time. This study examined the course of grade 1 erosions (involving 1-10% of bone on MRI) in the feet of newly diagnosed RA patients after two or more years of treatment.

Methods: Patients newly diagnosed with RA (treatment-naïve, ACR criteria) were recruited. Participants were assessed at baseline, 1-year, and ≥ 2 years (24-49 months) after diagnosis. The most clinically symptomatic foot chosen at baseline was scanned using a 1.0T peripheral MRI at each visit. A radiologist, blinded to clinical results, semi-quantitatively scored erosions in the metatarsal head and the base of the phalanges of each of MTPs 2-4 (grade 0-10) according to OMERACT-RAMRIS criteria. All patients were treated as per standard of care, and therapy received after baseline assessment was noted. The location of each erosion was noted to ensure that changes over time corresponded to the original erosion. Erosions were compared after one year and ≥ 2 years and categorized as unchanged, worsened or improved. New erosions were also noted.

Results: This study included 41 patients [n=33 females, mean (SD) age 51.9 (10.3) years]. The baseline MRI found at least one grade ≥ 1 erosion in 35 of 41 patients (85%), in 103 MTP joint bones. The majority of the erosions were grade 1 [n=89 (86%)] at baseline. Comparing grade 1 erosions one year later, 20 (19%) had resolved, 77 (75%) remained unchanged, 6 (6%) had progressed, and there were 20 new grade 1 erosions. Comparing baseline grade 1 erosions to ≥ 2 years later, 16 (16%) had resolved, 87 (84%) remained stable, 0 had progressed, and there were 10 new grade 1 erosions. Of note, only one erosion progressed by more than 1 grade within a follow-up period (grade 1 to grade 3 after 1 year). In terms of treatment, by their final assessment, 6 patients had received no DMARDs/biologics, 20 were on a single DMARD, 8 on combination DMARDs, and 7 on biologic or biologic/DMARD combination. There was no consistent relationship identified between the type of therapy and the improvement, stability, or progression of erosions.

Conclusion: Grade 1 erosions on MRI are common in the MTP joints of early RA patients. The majority of erosions appear to resolve or remain stable following two or more years of treatment. This suggests that early standard treatment may be sufficient to manage small erosions. There does not appear to be any consistent relationship between change in these small erosions and the type of RA treatment chosen. The clinical relevance of these erosions remains unknown.

Magnetic Resonance Imaging of the Cervical Spine in Patients with Rheumatoid Arthritis and Ankylosing Spondylitis Presenting with Chronic Neck Pain – a Systematic Comparison of Clinical Assessments

Xenofon Baraliakos¹, Mina Soltani², Parham Damirchi², Uta Kiltz³ and Jürgen Braun¹, ¹Ruhr-University Bochum, Herne, Germany, ²Rheumazentrum Ruhrgebiet, Herne, Germany, ³Rheumatology, Rheumazentrum Ruhrgebiet, Herne, and Ruhr University Bochum, Herne, Germany

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Imaging of Rheumatic Diseases Poster I: MRI

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Despite the differences in pathogenesis, neck pain associated with functional limitation of the cervical spine is a frequent clinical symptom of patients with rheumatoid arthritis (RA) and ankylosing spondylitis (AS). Here we compare inflammatory and structural findings obtained by magnetic resonance imaging (MRI) in patients with RA and AS who present with chronic neck pain.

Methods: A total of 107 patients (59 RA with 295 and 48 AS with 240 vertebral segments) were consecutively included if they had chronic neck pain (duration >3 months). All patients had clinical examinations for neck function and mobility, were asked to fill in disease specific questionnaires, also had laboratory examinations (CRP, ESR) and MRI of the cervical spine (CS) using contrast-enhanced MRI sequences (T1 pre- and post-Gadolinium, sagittal and axial images). An experienced rheumatologist examined all patients blinded to diagnosis and MR images. In addition, two experienced readers blinded to patients' diagnosis and clinical assessments evaluated the MRIs by describing the anatomical structures of the CS (vertebral body, intervertebral disc, facet joints) and the pattern of inflammatory activity in the bone marrow (vertebral edges vs. vertebral endplates).

Results: The RA group included more females (66.1%) and older patients (58.6 ± 11.4 years) in comparison to AS (68.8% males, mean age 47.9 ± 13.1 years), while there were no differences in the duration of neck pain. AS patients reported higher mean levels of neck pain on a 0-10 numerical rating scale (5.0 ± 3.6) as compared to RA patients (3.0 ± 3.1) ($p=0.003$), while the Northwick pain questionnaire didn't reveal any differences. There were numerically more patients with AS (n=11, 22.9%) than RA (n=9, 15.3%) ($p=0.166$) with bone marrow edema (BME) at the vertebral edges. The majority of lesions was located in the lower CS. In contrast, more patients with RA (n=18, 30.5%) than AS (n=3, 6.3%) had erosive osteochondrosis with endplate BME ($p=0.002$). Atlantoaxial synovitis was found in only 1 patient with RA (1.7%), while inflammatory changes around the dens axis were found in 2 (3.4%) and atlantodental synovitis in 5 (8.5%) RA patients but not in AS patients. In comparison, erosive changes in the dens axis region were found in 3 RA (5.1%) vs. 2 AS (4.1%) patients. No major differences related to the presence of facet joint osteoarthritis was found (78% in RA vs. 65% in AS). The prevalence of facet joint osteoarthritis was the only imaging finding correlating with clinical symptoms: $r=0.259$ ($p=0.049$) for RA and $r=0.416$ ($p=0.003$) for AS, respectively. Similarly, only facet joint osteoarthritis correlated with restriction of cervical rotation in patients with AS ($r=0.471$, $p=0.001$).

Conclusion: Both BME and chronic changes of the lower part of the CS but not of the atlantoaxial region are seen in patients with RA and AS who present with chronic neck pain. The pattern of BME involvement in patients with RA vs.

AS was different. Facet joint osteoarthritis was the only imaging finding that correlated with the magnitude of neck pain, in AS it also correlated with impaired cervical rotation.

Session Title: Imaging of Rheumatic Diseases Poster I: MRI

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Few studies showed signs of inflammation at the MRI of the sacroiliac joints (SIJ) or spine in only 30% of the non-radiographic axial spondyloarthritis (nr-axSpA) patients ⁽¹⁾. Aims: 1) to evaluate inflammation at the MRI of the SIJ/ spine in TNF naïve nr-axSpA patients 2) consistency in case of absence of inflammation after 6 months and 3) evaluate gender differences

Methods: Consecutive patients with inflammatory back pain who were either HLA-B27 positive with ≥ 1 SpA-feature or HLA-B27 negative with ≥ 2 SpA-features, with high disease activity (BASDAI ≥ 4), had an MRI of the SIJ and spine. In case of absence of inflammation, the MRI was repeated after six months. MRI images were scored according to the Spondyloarthritis Research Consortium of Canada (SPARCC spine, range 0-108; SPARCC SIJ, range 0-72) method

Results: Included were 70 patients, of whom 37 (53%) females. Half of the patients (36/69, 52.2%) showed signs of inflammation on the first MRI: 27/69 patients (39.1%) at the SIJ, 14/46 patients (30.4%) at the spine and 4 patients (5.8%) on both sites and one patient missed the baseline MRI. Males had more often a positive MRI compared to females 62.5% vs. 43.2%. Patients with a positive MRI showed a median SPARCC score for SIJ of 8.0 (IQR: 1.8-23.5, higher in females) and for spine 6.5 (IQR: 2.8-10.8, higher in males). Only 4/33 patients (12.1%) showed a positive MRI after six months.

Conclusion: Fifty percent of the patients with nr-axSpA and high disease activity showed inflammatory lesions at the MRI of the SIJ and/or spine, which occurred more often in males compared to females. In most cases (87.9%) a MRI without inflammatory lesions remained negative after 6 months, indicating that a second MRI after a short period is not valuable.

Do Musculoskeletal Ultrasound and Magnetic Resonance Imaging Identify Synovitis and Tenosynovitis at the Same Joints and Tendons? – a Comparative Study in Patients Presenting with Early Arthritis and Clinically Suspect Arthralgia

Aleid C. Boer¹, Sarah Ohrndorf², Debbie M. Boeters¹, Robin M ten Brinck¹, Gerd R. Burmester², Marion Kortekaas¹ and Annette H.M. van der Helm-van Mil^{1,3}, ¹Department of Rheumatology, Leiden University Medical Center, Leiden,

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Imaging of Rheumatic Diseases Poster I: MRI

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: In the diagnostic process of RA, the use of advanced imaging techniques like musculoskeletal ultrasound (US) and magnetic resonance imaging (MRI) has been recommended. Unfortunately, research on its comparability is scarce. Therefore we aimed to compare findings of synovitis and tenosynovitis by US with MRI on joint- and tendon-levels in patients presenting with early inflammatory arthritis (IA) and clinically suspect arthralgia (CSA).

Methods: Seventy patients newly presenting to the rheumatology outpatient clinic (40 with recent-onset CSA, 30 with IA) underwent US and MRI of MCPs, wrist and MTPs at the same day. Grey-scale (GS) and power Doppler (PD) synovitis were scored according to Szkudlarek *et al* (combining synovial effusion and hypertrophy) and tenosynovitis by GS/PDUS was scored according to the OMERACT definition. Static images were also re-scored for GS synovitis according to the recently published EULAR/OMERACT score (considering synovial hypertrophy regardless of the presence of effusion) by two readers (ICC 0.92). MRI scans were scored according to the RAMRIS method. All scores ranged from 0-3. Analyses were performed on joint/tendon level. Synovitis and tenosynovitis scores were compared and test characteristics determined with MRI as reference. Cut-off for dichotomization were scores ≥ 1 and ≥ 2 for US and ≥ 1 for MRI.

Results: Compared to MRI, GSUS synovitis according to the EULAR/OMERACT (US cut-off ≥ 1) had a sensitivity ranging from 27-75% for the different locations (MCP, wrist, MTP joints) and a specificity of 80-98%. For the method according to Szkudlarek *et al* the sensitivity was between 68-91% and specificity 52-70%. When a US cut-off ≥ 2 was used, the sensitivity and specificity were 6-23% and 99-100%, respectively for the 'EULAR/OMERACT method' and 39-64% and 92-97% for the 'Szkudlarek method'. Synovitis by PDUS had a sensitivity of 30-54% and specificity of 97-99%. The sensitivity to detect tenosynovitis by GSUS ranged between 42-65% and the specificity 81-92%. For tenosynovitis by PDUS the sensitivity ranged between 16-35% and the specificity from 98-100%.

Conclusion: Ultrasound is less sensitive to detect synovitis and tenosynovitis compared to MRI in early arthritis and arthralgia. The high specificity implies that there were few 'false positive' results. The new EULAR/OMERACT method had a higher specificity than the method according to Szkudlarek *et al*, with MRI as a reference. Thus current data showed that MRI is more sensitive for the early detection of synovitis and tenosynovitis. However, US is more readily available to rheumatologists in many countries, it is inexpensive and logistically easier to arrange.

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Imaging of Rheumatic Diseases Poster I: MRI

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Enthesitis is a key feature in spondyloarthritis (SpA). MRI allows sensitive visualization of enthesal inflammation and damage, but no validated, internationally accepted MRI scoring systems exist. The objective of this study was to develop and perform preliminary validation of a novel OMERACT MRI scoring system for assessing ankle enthesitis in SpA patients.

Methods: A systematic literature review (SLR) of MRI studies on enthesitis in SpA identified key inflammatory and structural pathologies. Accordingly, pathologies to score and definitions of these were agreed by consensus within the OMERACT MRI in arthritis working group, followed by 3 internet-based multireader scoring exercises, with calibration sessions in between. In Exercise 1 the Achilles tendon and plantar fascia entheses in 10 ankle MRIs (sagittal T1-weighted (T1W) and sagittal and axial fat suppressed T2W images) were scored by 15 readers with varying expertise in ankle MRI. Each enthesis was assessed for peritendon hypersignal, intratendinous hypersignal, enthesal bone marrow edema, retrocalcaneal bursitis, tendon thickening, bone spur and erosion. Each parameter was scored 0-3 (no, mild, moderate, severe). After a calibration session leading to minor modifications, and development of reader rules, Exercise 2 comprised scoring of 16 ankle MRIs (specifications as above), by 15 readers. In Exercise 3, ankle MRIs (sagittal fat-suppressed T2W) of 21 patients before and after biological therapy were scored for the inflammatory variables by 10 readers, blinded to chronological order. Inter-reader agreement was calculated using single measure, two-way random effects, absolute agreement intraclass correlation coefficients (ICCs) for sum scores of inflammatory and structural lesions (patient level), and Cohen's kappa for scores at lesion level.

Results: Exercise 1: Mean pairwise inter-reader ICCs were 0.40 and 0.41 for inflammatory and structural variables, respectively. Exercise 2: Mean pairwise inter-reader ICCs were 0.64 (Range: 0.17 – 0.93) for inflammatory variables, while 0.45 (Range 0.08 – 0.91) for structural variables. Exercise 3: The mean pairwise inter-reader ICC for inflammatory variables was 0.81 (Range: 0.57 – 0.95) for baseline scores and 0.81 (Range: 0.57 – 0.92) for change scores. Table 1 shows ICCs and kappas for all readers and for 4 preselected readers (the participating radiologist and the 3 rheumatologists with highest interreader agreement in Exercise 2).

Conclusion: Initial steps in developing an OMERACT MRI enthesitis scoring system at the ankle have been performed, and good reliability (particularly for inflammatory variables) has been demonstrated.

Table 1: Inter-reader agreement on patient level (ICC for inflammation sum scores) and lesion level (kappa for inflammatory parameters) on baseline and change score in Exercise 3

		All readers together			Radiologist + Best 3 from Exercise 2		
		Mean	Median	Range	Mean	Median	Range
Patient level (ICC)							
Sum score of all parameters	Baseline	0.81	0.83	0.57 - 0.95	0.91	0.91	0.90 – 0.94
	Change	0.80	0.82	0.57 – 0.92	0.85	0.84	0.79 – 0.91
Lesion level (kappa values)

Session Date: Sunday, October 21, 2018

Session Title: Imaging of Rheumatic Diseases Poster I: MRI

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Evaluation of disease activity and treatment response in peripheral spondyloarthritis (pSpA) is currently based upon clinical findings, laboratory tests and ultrasound examination. Whole-body magnetic resonance imaging (WB MRI) is a relatively new imaging technique that could offer additional information regarding the inflammatory status of joints, entheses and soft tissues. The objective of this study is to determine A) the value of WB MRI, performed at baseline, in relation to clinical remission in pSpA and B) the value of subclinical inflammation, detected by WB MRI, at time of clinical remission in predicting flare after treatment withdrawal in pSpA.

Methods: Clinical REmission in peripheral SPondyloArthritis (CRESPA) is a placebo-controlled trial of golimumab treatment in 60 early (symptom duration < 12 weeks) pSpA patients (pts). All pts underwent a modified WB MRI at baseline and at the time of clinical remission when treatment was withdrawn. The WB MRI was performed by scanning multiple locations individually (using different coils) in order to investigate SpA-specific locations in detail. Several anatomical sites of pelvis and lower limbs were evaluated for bone marrow edema (BME), synovitis and soft tissue inflammation (STI) by 3 readers, giving a score of 0 (no abnormalities), 1 (mild), 2 (moderate) or 3 (severe). For each site a mean of the scores of the 3 readers was calculated. For each patient at each time point, we calculated a sum score for synovitis, STI and BME separately adjacent to a total sum score. Changes scores are baseline minus remission sum scores.

Results: Pts reaching remission had lower baseline MRI synovitis (3,0 vs. 3,6), STI (2,1 vs. 2,2), BME (1,8 vs. 2,9) and total sum scores (7,0 vs. 8,7) than the non-remission group. However, these differences lacked statistical significance. At the time of clinical remission 10/45 (22%) and 11/45 (24%) pts had residual talocrural and subtalar synovitis respectively. However, there was no statistically significant difference between patients who relapsed after treatment withdrawal and those who remained in remission concerning synovitis sum scores ($p = 0.497$) as well as BME sum scores ($p = 0.741$) and STI sum scores ($p = 0.131$) at time of clinical remission (Table 1).

Table 1: BME, synovitis and STI presence in early pSpA pts who relapsed and did not relapse after stopping golimumab therapy

	Patients relapsed (n=20)	Patients not relapsed (n=25)
BME at baseline	1.9 (± 2.4)	2.0 (± 2.4)
BME at follow-up	1.3 (± 1.1)	1.4 (± 1.9)
Synovitis at baseline	2.4 (± 2.9)	3.6 (± 3.9)
Synovitis at follow-up	1.2 (± 1.4)	1.4 (± 1.4)
STI at baseline	1.9 (± 2.4)	2.3 (± 2.3)
STI at follow-up	0.9 (± 0.7)	1.1 (± 1.1)

Conclusion: There was no significant difference in inflammatory burden on baseline WB MRI between patients going into remission and those with ongoing disease activity. At remission, a substantial part of the participants showed residual ankle synovitis on MRI. However, residual inflammatory lesions detected by MRI did not differ significantly between patients who relapsed after treatment withdrawal and those in ongoing remission.

Session Date: Sunday, October 21, 2018

Session Title: Imaging of Rheumatic Diseases Poster I: MRI

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Axial Spondyloarthritis (AxSpA) encompasses both non-radiographic (nr-AxSpA) as well as radiographic ankylosing spondylitis (AS) which displays structural changes at the sacro-iliac joint (SIJ). Phase 2 and 3 clinical trials are currently ongoing requiring imaging-based eligibility of subjects based on the protocol specific target population for the type of disease (nr-AxSpA vs. AS). The currently accepted modified New York (mNY) criterion includes a radiographic assessment of the SI joint. In clinical trials the subjects deemed locally to be good candidates either for an AS or an nr-AxSpA trial have an SIJ X-ray examination read centrally to determine eligibility (mNY+ for AS and mNY- for nr-AxSpA). For nr-AxSpA trials, an MRI examination of the SIJ is also obtained to confirm inflammation per ASAS/OMERACT guidelines; mNY- with positive MRI (MRI+) subjects are deemed eligible for these trials. Therefore, for prospective trial design it is important to understand the percentages of subjects likely to be deemed eligible by central imaging review and how many subjects will screen-fail for either AS (mNY+) or nr-AxSpA (mNY-).

Methods: A total of 4782 subjects from seven trials were assessed for mNY +/- and/or MRI +/- . 2 studies (n=1419) had both an AS or and nr-AxSpA cohort and subjects were recruited according to mNY+ (for AS cohort) or mNY-/MRI+ (for nr-AxSpA cohort). 3 studies (n=821) had mNY+ as the imaging inclusion criteria and 2 studies (n=2496) had mNY- / MRI+ as the imaging inclusion criteria. The read model was either a single or double read. Percentage of subjects deemed either eligible for AS (mNY+) or nr-AxSpA (mNY-/MRI+) was calculated. We also calculated the percentage of subjects who were mNY- / MRI- or MRI+.

Results: As shown in Table 1, for AS studies requiring an mNY+ radiograph, 52.6% were eligible and 47.2% were ineligible. For nr-AxSpA studies which required a mNY- radiograph, 70.9% were eligible and 29% were ineligible. Further, when nr-AxSpA mNY- subjects were assessed for MRI positivity per ASAS/OMERACT guidelines, 39.7% were MRI+ (eligible) and 60.3% were MRI- (ineligible).

Table 1:

Type of AxSpA Population	Radiographic Inclusion Criteria	Total # Analyzed	# mNY+ (%)	# mNY- (%)
AS	mNY+	2240	1180 (52.6%)	1058 (47.2%)
nr-AxSpA	mNY-	3915	1134 (29%)	2778 (70.9%)
Distribution of nr-AxSpA subjects (mNY-) into MRI +/-				
	MRI Inclusion Criteria	Total # analyzed	MRI+	MRI-
nr-AxSpA	MRI+	2635	1046 (39.7%)	61 (60.3%)

Conclusion: The screen failure rate was high for both AS (47.2%) and nr-AxSpA (29%) studies. Further, not all mNY- subjects initially categorized as nr-AxSpA were MRI+; 60.3% of the mNY- pool did not qualify per the ASAS/OMERACT criteria for inflammation of the SIJ. Given that MRI positivity is increasingly being used to enroll "true" non-radiographic axial SpA subjects the failure rate is noteworthy. Overall, the data suggests that not all subjects screened locally will qualify to enter the trial when the radiographic criteria are applied centrally. This is due partly to the deliberate lack of clinical observations during central review of the SIJ imaging. In conclusion, these rates should be taken into consideration during prospective AS and nr-AxSpA trial design.

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Imaging of Rheumatic Diseases Poster I: MRI

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Biomarker science has advanced to aid in distinguishing between different forms of arthritis: inflammatory arthritides such as rheumatoid arthritis (RA) and psoriatic arthritis (PsA) and OA. Biomarkers are also used to assess disease activity. Diagnostic serum biomarkers such as rheumatoid factor (RF) and cyclic-citrullinated peptide (CCP) and assays of disease activity such as C-reactive protein (CRP), and multi-biomarker assays have utility but lack complete sensitivity and specificity. Increasingly quantitative imaging biomarkers may fill an important gap in disease identification and assessment.

Objectives: 1) To investigate the association between imaging measures of inflammation in the synovium of the knee joint and systemic levels of CRP in patients with RA, PsA and OA. 2) Investigate how imaging and clinical markers correlate to IL-6 levels from joint fluid in different patient cohorts.

Methods: 38 patients with a flare of pain in the knee were recruited. 12 were diagnosed with RF positive (+) RA, 6 with RF negative (-) RA, 6 PsA, and 14 OA, according to ACR/EULAR criteria. CRP in blood and IL-6 levels from joint fluid were determined. Patients underwent MRI, including Dynamic Contrast Enhanced (DCE)-MRI exam prior to an ultrasound-guided arthrocentesis. MRI were scored for synovitis [1] and DCE-MRI were quantified using Dynamic Enhanced MRI Quantification (DEMRIQ) method, extracting the volume of enhancing voxels (Nvoxel), Initial Rate of Enhancement (IRE), Maximum Enhancement (ME). Inflammation was quantified as IRExNvoxels and MExNvoxels [2]. Correlation between all clinical scores and all imaging parameters was done using Spearman rho, with significance levels of $p < 0.05$.

Results: The imaging markers of perfusion in the synovium of the knee (MExNvoxels and IRExNvoxels) were the only imaging measures, which showed a very high association with CRP in both RF+ RA ($r = 0.92 / 0.97$, $p < 0.05$) and PsA patients ($0.93 / 0.99$, $p < 0.05$), whereas all other imaging markers of inflammation showed no statistical association with blood levels of CRP in these diseases. We found no association between CRP and any imaging assessed scores of inflammation in either RF- RA or OA. In addition, only RF+ RA patients showed a positive moderate to high association between MExNvoxels and IL-6 ($r = 0.66$, $p < 0.05$) in the knee joint aspirate.

Conclusion: Quantitative imaging and blood biomarkers of inflammation, such as DCE-MRI parameters and CRP, appear to relate differently to each other in the four most common knee arthritic diseases, RF + RA, RF- RA, PsA and OA. DCE-MRI may have specific utility in differentiating these conditions and their disease activity.

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Imaging of Rheumatic Diseases Poster I: MRI

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Polymyalgia rheumatica (PMR) is a common inflammatory disease of the elderly. In the absence of a diagnostic test its differential diagnosis which is mainly based on clinical expertise, elevation of C-reactive protein and exclusion of other diseases can be challenging. Extracapsular inflammation in the pelvic and the shoulder girdle has recently been highlighted by studies using FDG-PET/CT and MRI. Based on our observations in the last years we have developed a scoring system for pelvic girdle MRI scans concentrating on characteristic findings in PMR and, thus, evaluated its use as a diagnostic test.

Methods: A total of 120 pelvic contrast enhanced MRI scans of patients with pelvic girdle pain was available. While 40 patients had PMR diagnosed by an expert rheumatologist, 80 were found to have other inflammatory or non-inflammatory causes of pain. Three radiologists fully blinded to the clinical diagnosis scored peritendinous contrast enhancement at 19 predefined sites: 9 tendinous sites bilaterally and the most caudal perispinous area of the lumbar spine. Five different patterns of involvement were evaluated. Inter- and intraobserver agreements were assessed by intraclass correlation coefficients (ICC).

Results: There were 55% and 62.5% females in the PMR and the control group, respectively. Their mean age was 64.2 ± 8.8 years, with no difference between groups. The interobserver ICC with 0.76 and the intraobserver ICC with 0.88-0.91 for the assessment of single sites were excellent. In the PMR group, 13.4 ± 2.7 sites were affected, but only 4 ± 2.3 in controls. Mostly bilateral peritendinitis at the proximal M. rectus femoris and the origins of M. adductor longus were the hallmark of pelvic involvement in PMR (Figure). A bilateral affection of these two sites discriminated patients with PMR from controls with a sensitivity of 100% and a specificity of 95%. If at least 4 sites including one of those two were bilaterally affected the specificity even improved to 97.5% without reducing sensitivity, this pattern performed best.

Conclusion: The MRI findings described here were found to be very characteristic and even specific for PMR. Thus, we think that contrast enhanced pelvic MRI is a valid imaging tool for diagnosing PMR. These results need to be confirmed in larger prospective studies.

Figure. Illustration of extracapsular inflammation in 19 predefined sites in PMR (left) and controls (right) superimposed on X-ray. The upper semicircle represents colour encoded relative frequency at individual site, the lower semicircle colour encoded and numeric frequency of bilateral affection.

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Imaging of Rheumatic Diseases Poster I: MRI

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Magnetic resonance imaging (MRI) has been used as a non-invasive tool to aid diagnosis and monitor disease activity in the idiopathic inflammatory myopathies (IIMs). Recent research has focused on whether radiological features may help subtype a patient with IIM, as this can be difficult to determine clinically and false negative results may occur with muscle biopsy. Herein, we describe the MRI findings in patients with IIM and identify radiological patterns that may discriminate between the subtypes of polymyositis (PM), dermatomyositis (DM), inclusion body myositis (IBM) and necrotising autoimmune myopathy (NAM).

Methods: We retrospectively reviewed 114 lower-limb MRIs performed on 66 patients with IIM and 10 patients with non-inflammatory muscle histology (non-IIM) between 2009 and 2017 at the Royal Adelaide Hospital. Three patients did not satisfy EULAR/ACR criteria for IIM due to either normal creatinine kinase (CK) or strength, but had convincing clinical and histological features. A number of patients (n = 28) had serial images performed. Two musculoskeletal radiologists (SP, NB) independently quantified the degree of muscle oedema (MO), fatty replacement (MFR) and atrophy (MA). Clinical information was prospectively recorded. Ordinal logistic regression was performed analysing radiological grades for each IIM subtype. Spearman correlations were performed to evaluate associations between radiological grades and clinical parameters. Fisher's exact test was used to analyse categorical data. Grades were compared between time points using the Wilcoxon signed rank test.

Results: There was low inter-rater reliability ($\kappa < 0.60$) between radiologists for numerous muscular compartments and, as such, a finding was only considered convincing if it was statistically significant for both radiologists. Pelvic and adductor MO, MFR and MA and posterior thigh MA significantly increased the likelihood of NAM. Anterior thigh MA and MFR significantly increased the likelihood of IBM. Pelvic MO decreased the likelihood of PM. Radiological changes (MO, MFR or MA) in adductors, anterior thighs or posterior thighs significantly reduced the likelihood of a non-IIM diagnosis. Measures of disease activity by visual analogue scale, muscle strength and CK did not correlate with radiological muscle oedema. Follow up scans were performed at a median of 370 days (IQR 217-528 days) and the most striking observation was of stability in radiological grades in many muscular compartments. A significant increase in MA and MFR grades were observed in the anterior thigh and anterior lower limbs, due to progression in a minority of patients.

Conclusion: MRI patterns help discriminate between IIM subtypes. The observed stability over time in MA and MFR in multiple muscle compartments is reassuring and may reflect that these patients were treated intensively with suppression of inflammation, such that further muscle damage was not detected. Clinical disease activity assessments do not seem to reflect the degree of radiological muscle inflammation and, as such, MRI may be a useful adjunct for monitoring disease activity in clinical practice.

Development of a Magnetic Resonance Imaging Atlas for the Classification of Osteoarthritis of the First Metatarsophalangeal Joint

Shannon Munteanu, Karl Landorf, Jade Tan, Maria Auhl, Jamie Allan, Andrew Buldt and Hylton B. Menz, School of Allied Health, La Trobe University, Bundoora, Australia

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Imaging of Rheumatic Diseases Poster I – ARHP

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Osteoarthritis (OA) of the first metatarsophalangeal joint (MTPJ) of the foot is the most common form of foot OA. The condition is typically evaluated using plain film radiographs, however magnetic resonance imaging (MRI) may provide more detailed insights into the disease process. Therefore, the purpose of this study was to develop a standardised atlas of MRI features of first MTPJ OA and assess its reliability.

Methods: We selected representative images covering the spectrum of OA severity from a database of first MTPJ OA for the following features: osteophytes (dorsal and plantar metatarsal head and dorsal proximal phalanx), joint space narrowing (first MTPJ and first metatarsal-sesamoid joint), bone marrow lesions (first metatarsal, proximal phalanx and sesamoids), cysts (first metatarsal and proximal phalanx), effusion (dorsal and plantar), capsular thickening (dorsal and plantar) and cartilage loss. Thirty cases were then independently scored with the atlas by two raters (SEM and HBM) to determine inter-rater reliability. Statistical analysis was conducted using percentage agreement and Gwet's AC1 modification of the weighted kappa statistic (K_w) and were interpreted using the cut-offs proposed by Cohen (0-0.20 slight, 0.21-0.40 fair, 0.41-0.60 moderate, 0.61-0.80 substantial, 0.81-1.00 almost perfect). An *a priori* decision was made to exclude any observations with $K_w < 0.40$ from the atlas. Reliability of a combined score summing all observations was also assessed using the intra-class correlation coefficient (ICC).

Results: An example MRI from a participant with first MTPJ OA is shown in the figure, and inter-rater reliability results are presented in the table. Percentage agreement ranged from 57 to 96%, and K_w scores ranged from 0.13 to 0.91. Of the 15 features documented with the atlas, 14 (93%) demonstrated acceptable reliability. Only plantar capsular thickening did not reach the reliability threshold, with a K_w of 0.13. The ICC for the combined score was 0.89 (95% CI 0.78 – 0.95), and after excluding plantar capsular thickening, the ICC was 0.90 (95% CI 0.80 – 0.95).

Conclusion: With the exception of first MTPJ plantar capsular thickening, MRI features of first MTPJ OA can be reliably documented using our standardised atlas. The use of this atlas will assist in documenting the severity of first MTPJOA for epidemiological studies and for evaluating the effects of treatment in clinical trials.

Figure. Example MRI of first MTPJ OA, demonstrating osteophytes (OP), cyst (C) and bone marrow lesion (BML).

Table. Reliability results.

Variable	% agreement	Gwet's AC1 K_w	Interpretation
Osteophytes, dorsal metatarsal head ¹	91	0.72 (0.53 – 0.91)	Substantial
Osteophytes, plantar metatarsal head ¹	94	0.81 (0.68 – 0.94)	Almost perfect
Osteophytes, dorsal proximal phalanx ¹	86	0.54 (0.24 – 0.84)	Moderate
Joint space narrowing, 1st MTPJ ¹	95	0.88 (0.82 – 0.94)	Almost perfect
Joint space narrowing, 1st metatarsal-sesamoid ²	80	0.60 (0.30 – 0.91)	Moderate
Bone marrow lesions, metatarsal ³	96	0.87 (0.80 – 0.94)	Almost perfect
Bone marrow lesions, proximal phalanx ³	96	0.87 (0.76 – 0.98)	Almost perfect
Bone marrow lesions, sesamoids ²	67	0.40 (0.03 – 0.77)	Fair
Cysts, metatarsal ²	90	0.81 (0.58 – 1.00)	Almost perfect
Cysts, proximal phalanx ²	93	0.91 (0.78 – 1.00)	Almost perfect
Effusion – dorsal ²	83	0.76 (0.53 – 0.99)	Substantial
Effusion – plantar ²	80	0.67 (0.39 – 0.95)	Substantial
Thickening – dorsal ²	70	0.40 (0.05 – 0.75)	Fair
Thickening – plantar ²	57	0.13 (-0.24 – 0.51)	Slight
Cartilage loss ²	80	0.60 (0.29 – 0.91)	Moderate

In Rheumatoid Arthritis All Disease Activities Are Not Created Equal

Keith Knapp¹ and Gary Craig², ¹Discus Analytics LLC, Spokane, WA, ²Discus Analytics LLC., Spokane, WA

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Measures and Measurement of Healthcare Quality Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Multiple composite RA disease activity (DA) metrics are approved for use; each reflect different aspects of disease. Many use similar measurements but their values are handled with different weighting, specifically the RAPID3(R3) measures patient functional capacity rather than clinical measures of inflammation. Despite their use varying by problem it has long been realized that these metrics are not perfectly comparable. Further it is important to understand the impact of each and to select usage appropriately. In this study we analyze scores from multiple DA metrics for concordance within each DA state: high, moderate (mod), low and remission (rem).

Methods: Pts > 18 years and clinically diagnosed with RA in the JointMan database between 1 Jan 2009 and 4 Mar 2018 were included. Encounters for the Pts having DAS28, CDAI, RAPID3 scores and swollen joint counts (sjc) were selected and further filtered into four cohorts, high, mod, low, and rem. Each cohort contained only encounters where the patient was in its named DA state using all metrics. Encounters where a patient was in two or more named DA states were excluded. All DA scores and the sjc were normalized to Z-Scores on which was performed an analysis of variance. A Tukey HSD post-hoc analysis compared the individual cohort results.

Results: 4996 pts over 33,551 encounters were initially included, only 17.8% (5996 encounters) had DA state agreement (1470 high, 1785 moderate, 620 low, 2121 remission). The F values for each DA cohort were: High 461.9, Mod 1638, Low 2457, Rem 4824 and all had a P-value < 10^{-16} . All four scores compared had significantly different means at all disease activity states. The difference in means between SJC and R3 (0.945) at the remission state was particularly noteworthy.

Conclusion: Our results(especially with the meager 17.8% DA state concordance) suggest potential for wide variance in assessing DA state even with closely related measures. This may confuse clinical assessment & understanding of medication responses. Further, the discrepancy between SJC, a measure commonly used at office visits by clinicians to consider medication changes, and the functional measure R3, is concerning given the widespread use of R3 as a reporting metric. Prudence should be used when reporting DA scores and states.

Disclosure: K. Knapp, Discus Analytics, 1, 2, 3; G. Craig, Premera/Blue Cross, Celgen, Genentech, Lilly, Novartis, 5, Discus Analytics LLC, 4, Abbvie, BMS, Celgene, Genentech, Novartis, Lilly, UCB, 8.

Swollen Joint Count Vs. RAPID3: Why a Discrepancy in Remission State?

Gary Craig¹ and Keith Knapp², ¹Discus Analytics LLC., Spokane, WA, ²Discus Analytics LLC, Spokane, WA

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Measures and Measurement of Healthcare Quality Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: RA patients (pts) often have multiple comorbidities, and with multiple disease activity (DA) metrics available selecting an appropriate metric is vital. It remains an outstanding question as to how much non-inflammatory disease impacts the composite DA metrics, further increasing the need to understand the impact of each metric. A companion study to this suggested a significant difference between between RAPID3(R3) and the swollen joint count (SJC). In this study we compare the DA scores at each DA state for RA patients without Fibromyalgia, re-examined the SJC/R3 relationship, and subsequently factored in damage.

Methods: Pts > 18 years and diagnosed with RA in the JointMan database between 1 Jan 2009 and 4 Mar 2018 were initially included. Pts having a diagnosis of Fibromyalgia were subsequently excluded. Encounters for the Pts having DAS28, CDAI, and RAPID3 scores were selected and further filtered into four cohorts, high, moderate (mod), low, and remission (rem). Each cohort contained only encounters where the patient was in its named DA state using all three metrics. Encounters where a pt was in two or more named DA states were excluded. All DA scores and the SJC were normalized to Z-Scores on which was performed an analysis of variance. A subsequent ANOVA sensitivity analysis with pain scores and counts of decreased range of motion and deformed joints was also completed. A Tukey HSD post-hoc calculation compared the individual DA results.

Results: 4659 pts over 31,383 encounters were initially included, only 18.2% (5709 encounters) had DA state agreement (1300 high, 1690 moderate, 616 low, 2103 remission). The F values for each DA cohort were: 441.4 high, 1469 mod, 2326 low, 4392 rem and all had a P-value < 10^{-16} . In the main analysis, for the pair-wise comparisons of each metric to the others, virtually all pairs had significantly different means at each disease activity state. The difference in means between SJC and R3 was 0.96 in high and 0.91 in remission. In the sensitivity analysis the difference in means between SJC and DAS28 was 0.05 in high and 0.42 in remission. Similarly the differences in means between composite scores and joints with deformities or decreased range of motion was also significant (P-value = 0).

Conclusion: When controlling for fibromyalgia patients, each metric and its DA state is consistently different from other metrics at the same DA state. The exception of SJC/DAS28 scores was not surprising as SJC trends closest to DAS28 scores than other metrics. The SJC/DAS28 pair had a high concordance of means in the high DA state. A disparity between SJC/R3 in remission exists when excluding FM and is not resolved when considering the potential RA related joint damage that might adversely affect the function scores of R3. This raises concern that R3 values at remission may unduly represent functional impairment from concordant non-RA musculoskeletal diseases.

Session Date: Sunday, October 21, 2018

Session Title: Measures and Measurement of Healthcare Quality Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Despite significant interest in using health information technology (IT) to improve processes of care such as documentation of disease activity in RA, few studies have evaluated the impact of process improvements on actual health outcomes. In this study, we assessed whether 2 health-IT initiatives that improved collection and documentation of RA disease activity scores in a large academic rheumatology clinic resulted in concomitant improvements in clinical outcomes over time.

Methods: We examined 2 initiatives designed to facilitate Clinical Disease Activity Index (CDAI) documentation: 1) a monthly peer report of physician Os performance on CDAI documentation, and 2) introduction of an electronic health record (EHR) SmartForm with an embedded CDAI calculator to make collection and tracking of disease activity scores more efficient. All adult RA patients with ³ 2 encounters in our rheumatology clinic with ³ 1 CDAI documented (64% of all RA encounters) between 1/2013 - 10/2017 were included. Data derived from our EHR data warehouse included demographics, encounter dates, and CDAI scores. We compared mean CDAI 12 months pre- and post-the peer reporting initiative and 19 months pre- and post- the SmartForm initiative with t-tests. Paired t-tests were performed on a subgroup of patients with ³ 1 CDAI pre- and post- each initiative to assess whether there was significant change in CDAI over time for the same patient. The proportion of visits with a low/remission CDAI (CDAI²10) each month were examined using a control chart.

Results: We included 920 RA patients with 7171 encounters over 5 years. 82% were female; mean age was 57±16, 50% identified as non-White, and 13% preferred a language other than English (e.g. Chinese or Spanish). Mean CDAI was stable pre- and post- the peer reporting initiative (12.4) and increased slightly after the SmartForm initiative (from 11.3 to 13.4, p<0.05). Paired t-test detected small disease activity improvements after the peer reporting initiative (n=237, mean CDAI from 12.0 to 10.7, p<0.05) but worse scores after the SmartForm initiative (n=341, mean CDAI from 11.2 to 12.7, p<0.05). Though these changes were statistically significant, they did not exceed the minimally clinically important

difference thresholds for CDAI. The overall proportion of visits with a CDAI in the low/remission category increased from 42 to 46% during the study period (Figure).

Conclusion: Although 2 quality improvement initiatives resulted in sustained improvements in disease activity score documentation, we did not see parallel gains in actual CDAI scores. These findings demonstrate that recording CDAI scores is not sufficient to improve disease activity without a comprehensive treat-to-target program. Additional efforts are underway in our health system to build a health-IT intervention to support providers and patients in improving RA outcomes.

Session Date: Sunday, October 21, 2018

Session Title: Measures and Measurement of Healthcare Quality Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Regular assessment of disease activity is a fundamental part of high quality RA care. Customization of electronic health records (EHRs) can facilitate the systematic collection of disease activity scores as part of a treat-to-target approach to RA treatment. We aimed to evaluate the overall impact of 3 health IT initiatives at the point of care on documentation of RA disease activity scores in an academic rheumatology clinic.

Methods: We studied 3 initiatives designed to facilitate documentation of a validated RA measure, the Clinical Disease Activity Index (CDAI), over a 5-year period (see Figure): 1) an Epic flowsheet to input and track scores using structured fields, 2) peer reporting of provider performance on their individual proportion of RA visits with documented CDAI, and 3) an Epic SmartForm that included a CDAI calculator alongside workflow changes to optimize CDAI documentation. The study included all adult RA patients with ³ 2 visits in a rheumatology clinic at a tertiary care center between June 2012-October 2017. Clinical data were retrieved from the EHR data warehouse. Interrupted time-series (ITS) analysis was used to assess whether the proportion of visits with a CDAI documented in the EHR changed following implementation of each initiative. Provider surveys assessing satisfaction with CDAI documentation workflows (1-10 scale) and time spent documenting disease activity were administered immediately before and 24 months after the third initiative.

Figure: Interrupted time series (ITS) analysis with each dot representing mean proportion of disease activity scores recorded in the electronic health record during two-week time periods. Vertical lines indicate onset of three health IT quality improvement initiatives.

Results: We included data from 995 unique patients with 8,040 encounters. Mean (SD) age was 58.9(16) years, 82% were female, and 66% were non-Hispanic White. Over 60 months, overall documentation of CDAI scores increased from 0% to 64%. After introduction of the flowsheet, ITS analysis showed an immediate increase in documentation(28.1%, $p<0.05$) (Figure), followed by a steady rise (1.4% increase per 2-week period, $p<0.05$). Documentation remained stable after peer performance reporting. The SmartForm was associated with a small immediate decrease (-7.8%, $p<0.05$), followed by a rise back to near pre-intervention levels. Provider satisfaction with documentation increased (from 5.4 ± 2.5 to 7.5 ± 1.4) after SmartForm implementation and average time for RA disease activity documentation decreased (from 6.5 ± 5.3 to 3.2 ± 1.9 minutes).

Conclusion: Introducing an EHR flowsheet improved documentation of CDAI, and additional culture and workflow changes maintained these gains. This study illustrates how EHR optimizations evolve in stages, with an initial focus on health IT and subsequent attentions to workflows and provider satisfaction. Overall, modifications to the EHR, culture, and workflows proved to be an effective method of driving increased documentation of disease activity without compromising provider satisfaction.

Abstract Number: 325

A Comparison of RADAIS and RAPID3 Disease Measures

Ryan Jessee, Amanda M. Eudy and Megan E. B. Clowse, Department of Medicine, Division of Rheumatology and Immunology, Duke University, Durham, NC

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Measures and Measurement of Healthcare Quality Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Treat to target has been shown to improve outcomes in multiple rheumatology diseases although relies on accurate disease measures. Our academic clinic routinely measures RAPID-3 in all patients at clinic check-in. However, a previous survey of our providers found a low confidence in the accuracy of RAPID-3, often attributed to comorbidities. Therefore, we examined whether RADAIS-5, which includes questions that our providers felt were more specific for inflammatory arthritis activity, would be a more reliable measure of RA and more accurately predict medication changes in clinic.

Methods: We performed a cross-sectional study over a 4-month time period involving 100 randomly selected rheumatology clinic patients. Patients completed a RADAIS-5 and RAPID-3 questionnaire at the beginning of routine clinical visits. Therapy changes, comorbidities (osteoarthritis, fibromyalgia/chronic pain, and mood disorders), and diagnosis were recorded. Pearson correlation coefficients were calculated between RADAIS-5 and RAPID-3, and differences in disease activity scores by co-morbidities and diagnosis were estimated by t-tests.

Results: Inflammatory arthritis (IA), which included RA, PsA, IBD-related arthritis, and ReA, was the most common diagnosis ($n=45$). Both RADAIS-5 and RAPID-3 were highly correlated across diagnoses and comorbidities ($p<0.001$ for all,

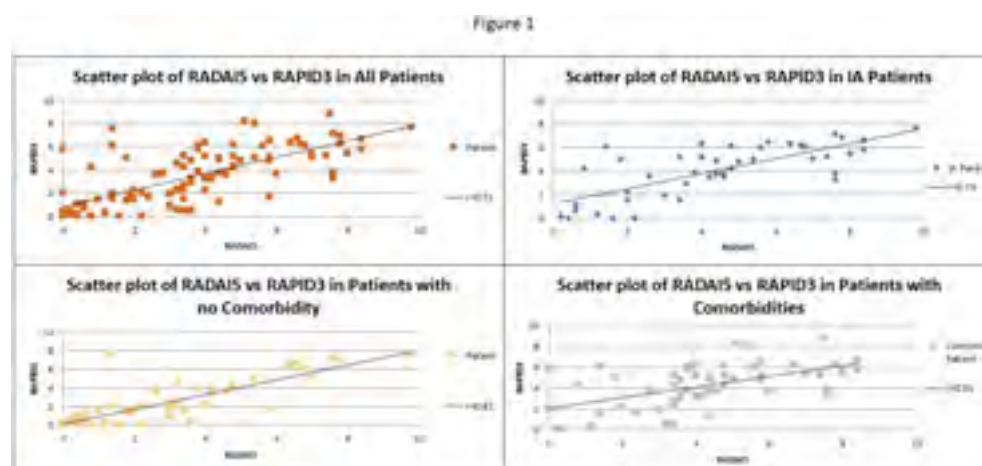

Figure 2

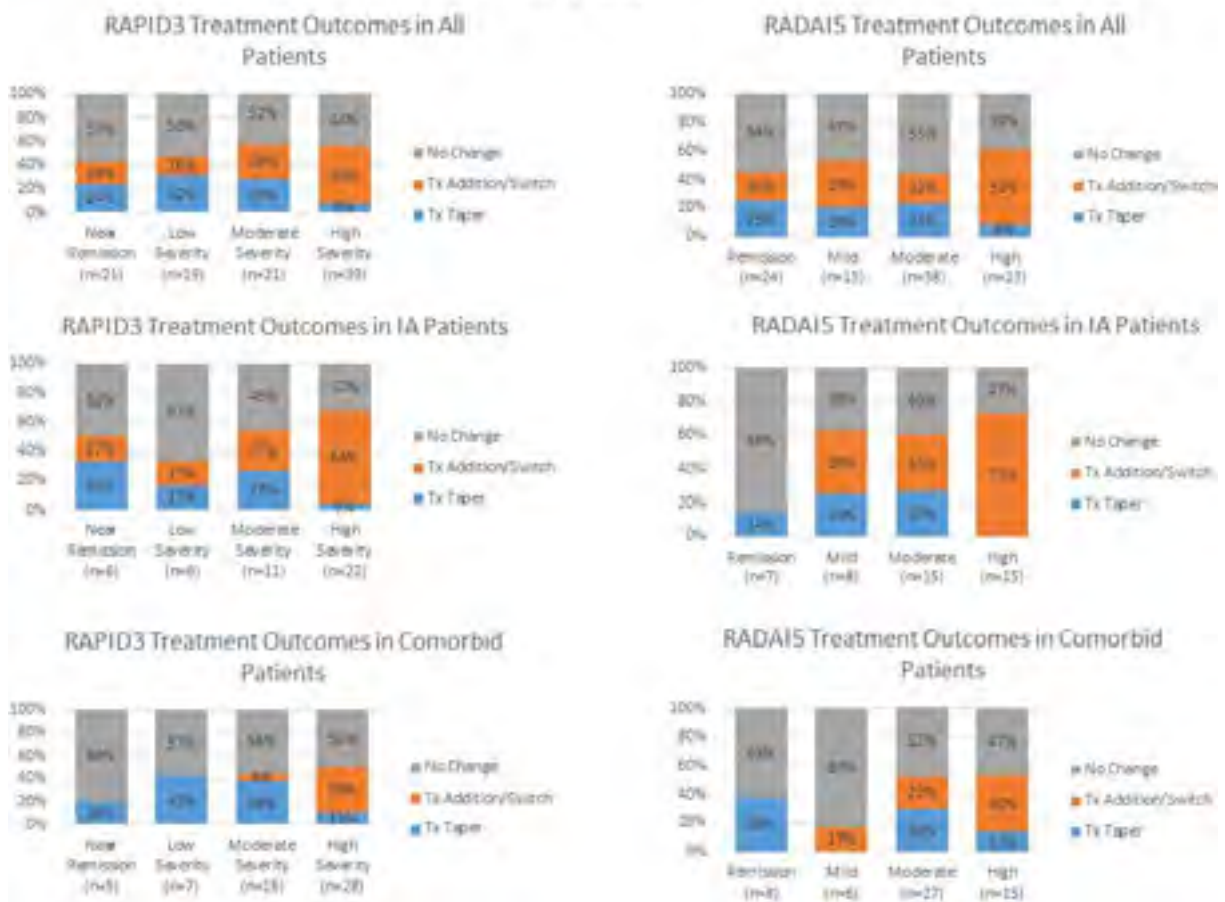

Figure 1). Comorbidities of OA, FM, and mood disorders uniformly resulted in higher disease activity measures ($p=0.01$). Across both measures, patients in remission had more medication tapering and patients with high disease activity had more treatment escalation ($p=0.1$), with this trend continuing when examining IA patients and comorbid patients (Figure 2). However, for patients with intermediate disease activity there was not a clear trend of management, and neither disease activity measure appeared to more accurately reflect medication change in these patients.

Conclusion: Our study confirms a high degree of correlation between RADAIS-5 and RAPID-3 across rheumatologic patients, although this relationship is weakened in patients with comorbid OA, FM, or mood disorders. Having one of these comorbid conditions clearly resulted in higher disability on both of the patient-reported measures. Based on the medication changes in this study, it does not appear that either measure provides clear guidance for patients with intermediate disease activity measurements. In order to improve patient care by incorporating patient-reported measures, additional work identifying approaches to decrease confounding by comorbid disease is essential.

Implementation of a Treat-to-Target Quality Improvement Program for Rheumatoid Arthritis Management Using Real-Time Patient Reported Outcome Measures

Malka Forman¹, Cianna Leatherwood², Chang Xu¹, Eunji Ko¹, Bing Lu³, Maura D. Iversen⁴, Daniel Solomon² and Sonali Desai², ¹Brigham and Women's Hospital, Boston, MA, ²Division of Rheumatology, Immunology and Allergy, Brigham and Women's Hospital, Boston, MA, ³Division of Rheumatology, Immunology and Allergy, Brigham & Women's Hospital, Harvard Medical School, Boston, MA, ⁴Division of Rheumatology, Immunology and Allergy, Brigham and Women's Hospital and Harvard Medical School, Boston, MA

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Measures and Measurement of Healthcare Quality Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Changing clinical practice patterns and incorporation patient-reported outcome measures (PROMs) for disease activity assessment into routine workflow is challenging. We sought to integrate a treat-to-target (TTT) approach for medication optimization for patients with RA in our practice through: 1) a reliable system to collect disease activity scores (PROMs) using iPads in the waiting room, 2) a multidisciplinary learning collaborative (LC) for providers focused on TTT, and 3) incorporation of patient perspectives on shared decision making (SDM) and treatment satisfaction.

Methods: At an academic medical center rheumatology clinic, patients completed a Routine Assessment of Patient Index Data 3 (RAPID3) survey via an online patient portal or an iPad. RAPID3 scores were uploaded to patient charts and were available for physicians to review during the visit. Rheumatologists were non-randomly allocated to either intervention (N=8) or control (N=13) groups. Intervention physicians attended monthly LC sessions between August 2017-June 2018 to discuss and develop TTT practices to use during visits with RA patients. Physician visit notes were retrospectively examined by 2 researchers to identify patients with medication changes and to calculate a “TTT score”. Mean TTT scores between intervention and control rheumatologists were evaluated using T-test. Phone calls were made to patients of physicians in the intervention group following a medication change to measure treatment satisfaction using the Treatment Satisfaction Questionnaire for Medication (TSQM) and use of SDM through the 9-item Shared Decision Making Questionnaire (SDM-Q-9). The TSQM and SDM-Q-9 questionnaires are both on 100 point scales and higher numbers reflect positive scores.

Figure: Comparison of Intervention Physician vs. Control Physician Cumulative Treat-to-Target Score Over Time

Results: From May 2017-April 2018, 2656 RA patients completed RAPID3 surveys with an average completion rate of 70%. Mean TTT scores among the intervention group rheumatologists were 9% higher than those in the control group (43% vs. 34%, $p=0.0042$) (Figure). 72 phone calls were completed to patients of rheumatologists in the intervention group with median[IQR] TSQM score components of 75[58, 92] (effectiveness), 92[83,100] (side effects), 100[89, 100] (convenience), and 83 [67, 100] (global satisfaction), and median[IQR] SDM-Q-9 score of 96[87, 00].

Conclusion: The results of this non-randomized, quality improvement study show feasibility and utility of electronic PROMs collection methods and real-time integration of PROMs survey scores into the electronic medical record. It also demonstrates the ability of a learning collaborative model to impact TTT practices within a large academic medical practice, as the non-randomized fashion mimics “real-world” experience.

Session Date: Sunday, October 21, 2018

Session Title: Measures and Measurement of Healthcare Quality Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The patient global assessment (PtGA) is a core domain used in RA composite disease activity (CDA) measures for trials and treat-to-target paradigms. The PtGA is asked differently, either referring to the patient's global health or condition (PtGA-GH), or to their arthritis disease activity (PtGA-AR). Objectives of this study were to assess agreement between PtGA-GH vs. PtGA-AR ratings and between CDA indices calculated using both versions of the PtGA.

Methods: We included patients enrolled in the Canadian Early Inflammatory Arthritis Cohort (CATCH) study between 2011 and 2017 who met 1987 or 2010 ACR/EULAR criteria for RA and simultaneously completed both PtGA-GH and PtGA-AR using a 10 cm VAS (scored 0-10) at baseline, 6- and 12-months of follow-up. Descriptive statistics were used to summarize baseline cohort characteristics, PtGA ratings and CDA indices with differences compared using Wilcoxon-sign rank tests and chi-square tests. Agreement was assessed using intraclass correlation coefficients (ICC) for continuous measures and weighted kappa coefficients for categorical measures. Stratified analyses were also performed by age (older >65) and sex.

Results: Of 571 early RA patients who completed both PtGAs, 71% were female, 83% were white, 17% were current smokers, 17% were erosive, and 60% had completed high-school. Baseline mean(sd) age was 55(15), symptom duration was 5(3) months and comorbid conditions were 2(2). Agreement between PGA ratings, composite CDA measures and classification of remission using both PtGA-GH and PtGA-AR are summarized in Table 1. Mean(sd) PtGA-GH ratings were only marginally higher than PtGA-AR ratings and agreement was high between PtGA ratings at baseline and over the first year follow up (all ICCs > 0.8). Agreement in CDA scores calculated with either PtGA was even higher at baseline and over time (all ICCs > 0.95). There was also high concordance in classification of remission using either PtGA at all time points (all Kappa's > 0.85). Results of stratified analyses showed that relative to men, women tended to report slightly higher differences in PtGA-GH vs. PtGA-AR (all p's >0.0001) but overall agreement in PGA ratings, CDA scores and classification of remission was very high and similar in both sexes. Age stratified analyses, which reflects the comorbidities that increase with age, were similar to those in the whole sample.

Conclusion: Results from this large sample of early RA patients followed in a longitudinal study in typical practice settings, showed patients rated their PtGA-GH marginally higher their PtGA-AR, but this difference had minimal impact on composite disease activity indices and classifications of remission commonly used in patient care. These findings suggest common composite measures of RA disease activity can be calculated using either the PtGA-GH or PtGA-AR.

Table 1: Agreement PtGA Indices

Variable	Baseline PtGA - GH	PtGA - AR	6-months PtGA - GH	PtGA - AR	12-months PtGA - GH	PtGA - AR
Patient Global Assessment (0-10)

Implementation of Systemic Lupus Erythematosus Disease Activity Index (SLEDAI) Documentation in Systemic Lupus Erythematosus (SLE) Patients at an Academic Medical Center

Sarah H. Chung¹, Hsin-Hsuan Juo², Jenna Thomason¹ and Alison Bays³, ¹Division of Rheumatology, University of Washington, Seattle, WA, ²Rheumatology, University of Washington, Seattle, WA, ³Rheumatology, University of Washington, Seattle, WA

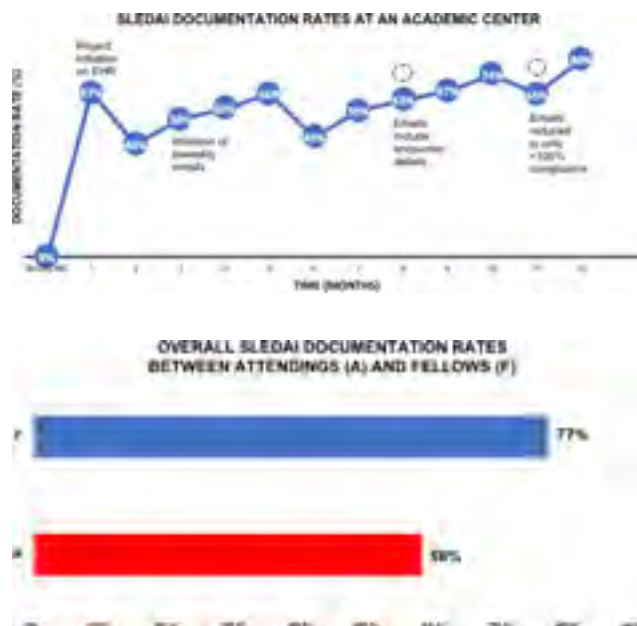

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Measures and Measurement of Healthcare Quality Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The 2008 European League Against Rheumatism (EULAR) Task Force on SLE management encourages the use of at least one of the SLE disease indices for the monitoring of disease activity. SLEDAI documentation is crucial to obtain for purposes of clinically meaningful translational and basic science research. This study aimed to 1) identify baseline SLEDAI documentation rates in an academic setting 2) determine if biweekly email feedback would improve documentation rates and 3) ascertain perceived barriers to documentation.

Methods: Chart review of all SLE encounters over a one-month period was performed at an academic center to ascertain a baseline SLEDAI documentation rate. Physicians were then instructed to document SLEDAI scores into a designated section of the electronic health record (EHR) at month 1. Chart review was repeated continuously for each provider over the next 12 months. Personalized SLEDAI documentation rates were emailed to each provider biweekly. Two Plan-Do-Study-Act (PDSA) cycles were performed over the 12-month period. Physicians completed a survey regarding documentation barriers at the close of the study.

Results: 704 SLE encounters were reviewed for this study. Pre-intervention, baseline SLEDAI documentation rates were 0%. Following the introduction of a designated section for documentation within the EHR, rates increased to 67%. After the initiation of personalized biweekly emails, collective documentation rates increased to 80% by 12 months. Rates continued to increase after emails included encounter details (PDSA 1), and after email frequency was reduced to contact only those providers who did not meet 100% compliance (PDSA 2). Fellows (77%) had higher documentation rates compared to attending physicians (58%) throughout the study. Survey results revealed that the majority of physicians (65%) believed SLEDAI documentation improved patient care, though 40% of physicians cited such documentation as a burden. Major barriers to documentation were cited to be forgetfulness and lack of time.

Conclusion: This quality improvement study demonstrates that a biweekly email feedback intervention increased SLEDAI documentation rates at an academic center, with higher documentation rates seen with rheumatology fellows. Additionally, physicians did perceive that increased documentation directly improved patient care. Major barriers to documentation were reported to be forgetfulness and lack of time.

Use of Inter-Professional Collaboration to Improve Adherence to American College of Rheumatology Recommendations for Use of Disease Activity Measures

Elisheva Weinberger¹, Douglas Einstadter² and Marina Magrey¹, ¹Rheumatology, Case Western Reserve University at MetroHealth Medical Center, Cleveland, OH, ²Case Western Reserve University at MetroHealth Medical Center, Cleveland, OH

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Measures and Measurement of Healthcare Quality Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: “Treat to target” is the goal of therapy in the treatment of Rheumatoid Arthritis (RA) based on the 2015 American College of Rheumatology (ACR) guidelines. Disease specific patient-reported outcome measures are a critical component of patient care to assess disease activity and function. The ACR recommends that disease activity measurement be performed in the majority of encounters for RA patients. This can be difficult to achieve in a busy Rheumatology practice. We hypothesized that using a collaborative and team-based approach would help us collect these data more effectively.

Methods: Beginning in September 2016, we trained the medical assistants in the Rheumatology clinic at the MetroHealth Medical Center on the administration and collection of RAPID3 questionnaires for all patients with RA seen for an office visit. To evaluate the effectiveness of this educational intervention, we retrospectively abstracted data from the medical record (Epic) for all patients with a problem list diagnosis of Rheumatoid Arthritis and who were seen for an office visit in the Rheumatology clinic between January 1, 2015 and December 31, 2017. We calculated the percentage of visits in which a RAPID3 was collected. We then compared pre-intervention to post-intervention results, using Chi-square analysis to determine statistical significance.

Results: Between January 1, 2015 and December 31, 2017, there were a total of 4485 visits for persons with a diagnosis of RA (1552 visits in 2015, 1590 in 2016 and 1333 in 2017). Prior to the intervention, 17.8% of patient visits (474/2663) included a RAPID3. After initiation of the intervention, the percentage of visits with a RAPID3 increased rapidly (Figure 1) and overall post-intervention, 45.7% of visits (832/1822) for RA patients had a RAPID3 recorded (p-value < 0.001 for pre- to post-intervention comparison).

Conclusion: The use of inter-professional collaboration is an effective way to improve adherence to ACR recommendations and provide high-quality care for patients with RA. A similar strategy to what we employed in our clinic could easily be implemented in other busy Rheumatology practices.

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Measures and Measurement of Healthcare Quality Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: A substantial amount of patients with chronic low back pain (CLBP) have axial spondyloarthritis (axSpA), but early recognition of these patients is difficult for general practitioners (GPs). As a result, several referral strategies have been developed to help physicians identify patients at risk for axSpA within the large group of CLBP patients. Most referral strategies were developed in secondary care patients. The only referral strategy that was developed and validated in primary low back patients is the CaFaSpA strategy. After model development and validation it is important to perform an impact analysis before implementation in daily clinical practice. The purpose of this study is to assess the impact of using a referral strategy on patient outcomes in young primary care patients with CLBP at risk for axSpA.

Methods: A clustered randomized controlled trial was performed in a primary care setting (ClinicalTrials.gov Identifier: NCT01944163). Each cluster contained the general practices from a single primary care practice and their included patients. Clusters were randomized to either the intervention (use of CaFaSpA referral strategy) or the control group

(usual care). Primary outcome was disability caused by CLBP, measured with the Roland Morris Disability Questionnaire (RMDQ) at baseline and 4 months. A linear mixed-effects model was used to analyze mean change in RMDQ score.

Results: In total 679 patients were included within 93 GP clusters. Sixty-four percent of our study population were female and mean age was 36 years. Median RMDQ score at baseline was 8 (IQR4-12) in both groups. Compared to baseline, mean RMDQ score decreased by 0.74 points at 4 months (intervention) and by 0.46 points (control)(**Figure 1**). This decrease did not significantly differ between groups($p=0.50$).

Conclusion: Although the CaFaSpA referral strategy can be used as a screening tool to identify axSpA patients but this strategy did not have an early impact on disability caused by CLBP.

Figure 1. Estimated mean RMDQ scores over time for the overall intervention and usual care group. Bars indicate 95% confidence intervals for the mean estimates.

Development and Implementation of a Patient-Reported Outcomes Measurement Information System (MyRheum)

Chad Deal¹, Abby Abelson², Leonard H. Calabrese³, Greg Strnad⁴, Irene Katzan⁴ and M. Elaine Husni⁵, ¹Cleveland Clinic, Shaker Heights, OH, ²Department of Rheumatologic & Immunologic Disease, Cleveland Clinic, Cleveland, OH, ³Rheumatology, Cleveland Clinic, Cleveland, OH, ⁴Cleveland Clinic, Cleveland, OH, ⁵Orthopedic and Rheumatologic Institute, Cleveland Clinic, Cleveland, OH

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Measures and Measurement of Healthcare Quality Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: There is a growing recognition of the potential value for measuring patient-reported outcomes (PROs) in patients with rheumatologic conditions. PROs measured at point of care can enhance shared decision making and facilitate treatment decisions, although the ability to collect and report PROs in real time is challenging because of technology and workflow barriers. Clinical disease activity measures are important for making treatment decisions in RA but do not measure patient domains of health important to patients. The Patient-Reported Outcomes Measurement Information System (PROMIS) measures patient status for different domains in people with a wide range of diseases and scores are standardized to the US general population.

We assessed the feasibility, patient/provider compliance and utility of electronically collecting PROs in patients in a large tertiary care rheumatology practice using PROMIS Global Health (GH), PHQ9, RAPID3 or SLAQ, the PROMIS domains: pain interference, fatigue and physical function, and a review of systems (ROS).

Methods: PROs are administered on a tablet at the patient's visit or through the patient portal (MyChart, Epic Systems) prior to their appointment through the Knowledge Program (Cleveland Clinic, Cleveland OH), an electronic platform that is integrated within the Epic electronic health record (EHR). PROMIS domains are administered using computer adaptive testing and scores are standardized on a T scale with a mean of 50 and SD of 10. Results are displayed within the EHR at

the time of the visit. The ROS is administered at every visit. PHQ9, if normal, is administered yearly and the remaining scales are completed at least 3 months apart.

Results: Since operational (8/2016–1/2018) MyRheum has administered 100,687 questionnaires in 29,238 patients at 53,608 visits (~30% using MyChart). More than 40,000 PROMIS GH and 50,000 RAPID3 scales have been collected. PROMIS GH physical and mental health summary scores were compared across 10 Cleveland Clinic disease areas (n=276,182). Mean PROMIS physical health summary score of rheumatology patients was 42.5, worse than all disease areas (mean score range 41.1 - 49.2) except neurology. Mean mental health summary scores of rheumatology patients was 47.4, which fell in the middle of the range of mean scores of the disease areas (39.6 to 50.3). Patient completion rates averaged 71% for 2017 with a small gradual decline over time. Nearly 1/3 were collected at home prior to the visit using My Chart.

Conclusion: The MyRheum system was successfully deployed in a tertiary care system with 27 rheumatologists in 10 locations. Cross departmental comparisons of diseases showed rheumatology patients had the second lowest self-reported physical health demonstrating the impact of our diseases and the need to measure PROs that assess this domain. The decline in participation requires further analysis. The creation of this large PRO biomarker databank demonstrates its practicality and provides a powerful platform for clinical care, research and value-based healthcare initiatives.

Session Date: Sunday, October 21, 2018

Session Title: Measures and Measurement of Healthcare Quality Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: HAQ-Di is broadly used to measure disability in RA, its assessment might influence taking decision process. However, it cannot differentiate disability related to arthritis, accrual damage, age, personal behaviors or comorbidities. We aimed to determine factors related to disability in a non-rheumatic population and evaluate its contributing factors.

Methods: We ask outpatients attendees of clinical specialties or first contact physician to fill out the HAQ-Di and have and structured interview during their scheduled visit. Those older than 18 years who signed informed consent were included. Participants with any musculoskeletal disease, chronic pain, neurological or psychiatric condition, use of drugs that impaired mobility or mental status, as well as illness in terminal stage were excluded. Demographic variables, formal education, exercise, and the Charlson index were recorded. Pearson's correlation, chi square, Mann-Whitney-U or t-test were performed as appropriate. Contribution of each factor to the predicted disability was determined by forward stepwise multivariate regression modelling.

Results: A total of 1,506 subjects were included, their mean age was 54.7±15.8 years, 17% were younger than 40 years, 65% between 40 and 70 years, and 18% older than 70 years. One fourth were ever smokers, 40.7% female, BMI was 27.1±4.4 Kg/m², Charlson index 1.5±1.7, HAQ-Di was 0.17±0.45 for the whole population; 25.1% declared some disability (HAQ-Di value >0). HAQ-Di values above 0.1 started at the 55 years subjects and increase to 1.3 at 90 years; it was higher in women than in men (0.25±0.54 versus 0.12±0.37; p <0.001). HAQ-Di showed correlation with age r=0.47 (p<0.001), and Charlson index, r=0.52 (p<0.001). Subjects with less than 10 years of formal education had a higher HAQ-Di, 0.52±0.73, compared with those with >10 years, 0.09±0.3 (p<0.001). Those who practice exercise on daily basis had a HAQ-Di of 0.09±0.32, those who did not any exercise had 0.45±0.69 (p<0.001). A regression model including standardized age (mean age value=0.17), sex (1=man), diagnosis of hypertension (1=yes) and diabetes (1=yes) explained the 25% of the HAQ-Di and predicted a HAQ score of 0.45.

Conclusion: One fourth of outpatients attending a general Hospital had disability. The main determinant is the age, but there is a significant contribution of comorbidity, high blood pressure and diabetes. Moreover, those who practice exercise

on daily basis and those with higher education had the lowest HAQ-Di scores. We suggest that when HAQ-Di must be used in the RA population, they must be adjusted by age, sex and comorbidity.

Variable	Coefficient B	Standard error	t value	P value
Constant	0.17	0.02	9.5	<0.001

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Measures and Measurement of Healthcare Quality Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Assessment of patient-reported outcomes (PROs) at clinic visits has emerged as an important component to determine disease activity in Rheumatoid Arthritis(RA). However, paper-based distribution, scoring and documentation on PROs is time-consuming and prone to human error. Modern electronic health record (EHR) systems allow for automatic integration of PRO data captured on tablets in the waiting room. Distribution, scoring, analysis and documentation of PRO questionnaires can be automated, thereby increasing the time a provider can spend with each patient.

Session Title: Measures and Measurement of Healthcare Quality Poster I

Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Patient-reported outcome measures (PROMs) are accepted modalities of gathering patient self-report of their health status in the realms of physical, mental and social well-being. PROMs are endorsed as metrics of quality of care. With the widespread implementation of electronic medical record (EMR) in the United States, PROM can be captured electronically. At the academic center, EMR in use is Epic® software which interfaces with the Patient-Reported Outcomes Measures System –PROMIS®. In a satellite clinic at UM rheumatology, the providers (n = 3) collectively opted to integrate PROMIS short form questionnaires [Adult Physical Function (PF) and Pain Intensity (PI)] into the EMR. However, the data collection of PROM via patient portals was low (5-10%). Our project aimed to examine collection rate of PROMs using portable devices (Tablets) at the time of check-in the clinic.

Methods: Between July 1, 2016, and March 31, 2018, patients seeking care at one rheumatology satellite clinic completed PROMIS® questionnaires (PF and PI), before the clinic visit. One week before the visit patients received a reminder on the EMR portal to complete the surveys. For patients who did not access questionnaire on the portal, they were able to complete at the time of appointment check-in on an Android-based Tablet. Those patients who could not complete by either portal or Tablet were assisted by a medical assistant (MA) using the office computer. The results were available on the EMR to the providers at the point of care.

Results: Of the total patients seen in rheumatology clinic, 87.2% completed the PROMIS® questionnaires, of which 82.4% used Tablets at check-in, 14.1% completed at home (portal), and 3.4% were assisted on a clinic desktop computer to complete the questionnaire (Table 1).

Conclusion: Use of tablets or other modalities in the clinic at check-in is associated with a high rate of PROMIS® questionnaire completion by patients. The routine use of PROM data collection at check-in may encourage patients to complete PROMIS® questionnaires on EMR portal accessed at home. Around 13% of patients did not complete questionnaires due to various reasons – lack of portal access, limited tablet availability at check-in, time constraints for MAs in a busy clinic, and rarely, patient refusal to complete. Given the increased acceptance, the routine of PROM data in the clinic using a tablet with EMR integration should be explored as a preferred modality.

Table 1: PROMIS® questionnaire completion rates

Quarter (year)	Total patients seen	Total N	Total %	Completed Questionnaires

Session Date: Sunday, October 21, 2018

Session Title: Measures and Measurement of Healthcare Quality Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Table 1. Summarized characteristics of included studies by instrument.

Instrument	Number of Studies Included	Languages (number of studies)*	Cosmin Rating	Translation	Cultural Adaptation	Cross-Cultural Validity
HAQ-DI	29 included studies	20 languages: Arabic (3), Bengali, British English, Chinese, Danish, Dutch, Estonian, French, Italian, Japanese, Korean, Malay, Marathi, Persian (3), Portuguese, Spanish(4), Swedish, Swiss German, Thai(2), and Turkish(2).	Poor: 21, Fair: 6, Good: 2	27	26	1
MDHAQ, MHAQ, HAQII	8 included studies	8 languages: Arabic, Chinese, Dutch, Finnish, Hindi, Korean, Spanish, and Swedish.	Poor: 3, Fair: 4, Good: 1	7	4	1
PROMIS	2 included studies	1 language: Dutch (2)	Poor: 1, Good: 1	1	1	1

* in parenthesis is the number of studies per language, if greater than one. This includes dialects.

Background/Purpose: Functional Status Assessment Measures (FSAMs) are important outcome measures in Rheumatoid Arthritis (RA) as poor function is a predictor for mortality and associated with lower quality of life and work disability. FSAMs inform assessment and treatment as part of guideline-based care. The Health Assessment Questionnaire (HAQ) and its derivatives are standardized and validated FSAMs commonly used in RA. More recently the Patient-Reported Outcomes Measurement Information System (PROMIS) has been developed and includes FSAMs. The HAQ and PROMIS measures were developed and validated in English, but have been translated and culturally adapted for use in other countries. Our objective was to conduct a systematic review of the cross-cultural validity of FSAMs for RA including HAQ and HAQ-derived measures as well as PROMIS measures.

Methods: Four electronic medical databases (MEDLINE, EMBASE, Cochrane Library and CINHALL) were searched in accordance with a published strategy from the Consensus-based Standards for the selection of health Measurement Instruments (COSMIN) group. The references of each included article were then manually searched for additional relevant studies. Included studies were evaluated using the COSMIN tool for cross-cultural validity and were scored as excellent, good, fair or poor.

Results: Of 58 papers identified, by our search strategy and 3 identified by manual search, 39 were included: 29 described the translation, cultural adaptation or cross-cultural validity of the HAQ-DI, 8 other HAQ derivatives, and 2 the PROMIS measures, representing 22 languages (Table). Of the 39 papers reviewed, 35 described translation, 31 described cultural adaptation, and only 3, examined cross-cultural validity of translated versions. There was generally poor adherence to proposed guidelines for cross-cultural adaptations of measures. No studies were rated as excellent by the COSMIN tool, only 4 studies were rated as good, 10 were rated fair, and 25 were rated as poor. Two studies that looked at cross-cultural validity noted differential item functioning (DIF) between Dutch and US populations for the HAQ-II and PROMIS measures and a third study found DIF between Turkish and UK populations on the HAQ.

Conclusion: FSAMs have been widely used both in their validated English form and in many translated forms. This review highlights a paucity of data on the cross-cultural validity of FSAMs and the mostly poor or fair quality methods by which they were translated and adapted. This needs to be considered when using these measures for multinational clinical trials and for day-to-day use in practice.

Physical Activity Monitors: New Tool to Assess Improvement in Myositis

Rohit Aggarwal¹, Chester V. Oddis², Siamak Moghadam-Kia³, Diane Koontz⁴, Nicole Marie Neiman³ and Bonny Rockette-Wagner⁵, ¹Division of Rheumatology and Clinical Immunology, Department of Medicine, University of Pittsburgh/University of Pittsburgh Medical Center, Pittsburgh, PA, ²Division of Rheumatology and Clinical Immunology, Department of Medicine, University of Pittsburgh/University of Pittsburgh Medical Center, Pittsburgh, PA, ³Rheumatology, University of Pittsburgh, Pittsburgh, PA, ⁴Internal Medicine Division of Rheumatology, University of Pittsburgh, Pittsburgh, PA, ⁵University of Pittsburgh, Pittsburgh, PA

Session Information**Session Date:** Sunday, October 21, 2018**Session Title:** Measures and Measurement of Healthcare Quality Poster I**Session Type:** ACR Poster Session A**Session Time:** 9:00AM-11:00AM

Background/Purpose: Physical activity monitors (PAM) are increasing being used to objectively quantify free-living movement in clinical research, especially musculoskeletal diseases. Given that patients with idiopathic inflammatory myopathies (IIM) have proximal muscle weakness which affects mobility, PAM may be a helpful tool for clinical assessment. We examined the validity, reliability and responsiveness of the activity measures obtained from a research grade PAM, Actigraph, as an outcome measures in IIM.

Methods: The 6 validated myositis core set measures (CSM; manual muscle testing [MMT], physician global disease activity [MD global], patient global disease activity [Pt. global], extra-muscular global disease activity [Ex-muscular global], HAQ and muscle enzymes) and 3 functional measures (six-minute walk [6MWD], timed up-and-go [TUG] and sit-to-stand tests [STS]) and Patient-Reported Outcome (PRO) Measurement Information System physical function short form (PROMIS-PF) were completed on outpatients with IIM [DM, PM, necrotizing myopathy (NM) or anti-synthetase syndrome] at baseline, 3 and 6 months. Patient were instructed to wear, Actigraph, a PAM device, on the waist for 7 consecutive days monthly for 6 months, and PAM measures including average of daily step count (controlled for length of time the device was worn) and average of maximum step counts in a minute (surrogate measure for speed of walking), were assessed. Pearson correlations were used for cross-sectional analysis with $\rho > 0.5$ considered strong, 0.35-0.5 moderate, and 0.2-0.35 weak correlation. We examined the test-retest reliability as well as responsiveness. Mixed liner model was used for longitudinal analysis and validation against all CSMs.

Results: Fifty patients [mean age, 53.6 (± 14.6); 30 females/20 males] were studied. Eleven of 50 had PM, 27 had DM, 7 had NM and 4 had anti-synthetase syndrome. Cross-sectional results at baseline showed Actigraph maximum steps per minute had moderate to strong correlation with MD global, MMT, Pt-global, HAQ and Ex-muscular global, whereas average daily steps showed moderate to strong correlation with MD global, Pt-global and HAQ. Both measures of actigraph showed significant longitudinal association with MD global, MMT, pt. global and HAQ demonstrating construct validity for the measure, whereas muscle enzyme and Ex-muscular global didn't show significant results (Table 1). There was significant association of both Actigraph measures with functional tests and patient reported outcomes (Table 1). Both measures increased significantly in patients with improvement and remained stable for patients with stable disease over 0, 3, and 6 months, demonstrating responsiveness and test-retest reliability of the measures.

Conclusion: Actigraph's average daily steps and maximum steps per minute both showed good construct validity, reliable and responsive longitudinally.

Abstract Number: 337

Does a Best Practice Alert Improve RA Patient Referral to Preventative Cardiology?

Savanna Smoker¹, Ellen Romich², Amy Nowacki³ and M. Elaine Husni⁴, ¹Case Western Reserve University, Cleveland, OH, ²Cleveland Clinic Lerner College of Medicine of Case Western Reserve University, Cleveland, OH, ³Quantitative Health Sciences, Cleveland Clinic, Cleveland, OH, ⁴Rheumatology, Cleveland Clinic, Cleveland, OH

Session Information**Session Date:** Sunday, October 21, 2018**Session Title:** Measures and Measurement of Healthcare Quality Poster I**Session Type:** ACR Poster Session A**Session Time:** 9:00AM-11:00AM

Background/Purpose: RA patients are at about 50% increased risk of cardiovascular disease (CVD)¹. Despite this risk, numerous studies show inadequate cardiovascular risk assessment of these patients. Preventive cardiology focuses on reducing CVD risk factors through a multidimensional approach that uses nutrition, exercise, and pharmacologic intervention. This study assesses referral rates of RA patients seen in outpatient rheumatology clinic and referred to the preventive cardiology department through the use of an electronic health record (EHR)based best practice alert (BPA).

Figure 1. Referral rate to preventive cardiology from rheumatology clinics with and without electronic best practice alert from 2009-2016. The predicted referral rate with 95% confidence interval (blue) is shown with overlay of the observed referral rate for each year.

Methods: This retrospective cohort study compares referral rates to preventive cardiology with and without a BPA for RA patients with visits to rheumatology clinics on main and satellite campuses in a tertiary care system. The main campus uses a BPA that is triggered at least once a year for patients with a diagnosis code of RA, while the satellite campuses did not institute a BPA (usual care) for RA patients. Only patients with referral eligible visits (no referral in past 12 months) were included each year for analysis. Patients with a CVD diagnosis were excluded. The referral rate from when the BPA was implemented in 2009 to 2016 was determined for each year as the number of patients with referral divided by the number of patients with at least one referral eligible visit. A Poisson regression was conducted to examine the number of preventive cardiology referrals performed by campus locations with and without the BPA as a function of year.

Results: Overall, 12,916 RA patients (age: 55.3 (SD=15.0); 77.2% female) were seen across 90,810 clinical visits from 2009-2016. There were 2,714 (21%) main campus patients and 10,202(79%) satellite patients. The difference in referral rates between the main campus(with BPA) and satellite group (without BPA) was statistically significant($p<0.0001$). The main campus rate ranged from 2.2% to 5.4% with an average of 4.1% (Figure 1). The satellite referral rate ranged from 0% to 0.1% (Figure 1).

Conclusion: The EHR-based BPA was modestly effective in improving referral rates for RA patients to preventive cardiology compared to usual care. A multimodality approach is needed to further improve CVD risk factor management for RA patients. Future interventions such as laboratory focused BPAs assessing lipid profiles, interdisciplinary clinics between rheumatology and cardiology, and increased education targeted to physicians and patients to promote CVD risk management in RA should be explored.

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Measures and Measurement of Healthcare Quality Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is a significant and well-established risk factor for atherosclerotic cardiovascular disease (ASCVD). Cardiovascular risk stratification is often left to the primary care provider (PCP), who may not be aware of the increased risk, leaving risk inadequately addressed. We aimed to increase documentation and identification of RA patients' ASCVD risk through the use of an automated phrase in an urban fellows' clinic.

Methods: RA patients were seen at a large public hospital serving a predominantly black underserved population. Providers imported an automated phrase into clinic notes for RA patients. The phrase included the 2013 American College of Cardiology/American Heart Association ASCVD 10-year risk score, along with associated risk factors. We compared demographic data, RA disease characteristics, ASCVD risk factors, and documentation of risk factors between the 8-week period before implementation (control) and the 8-week period after (study). All patients with a diagnosis of RA were included. Documentation of ASCVD risk was compared using chi-squared testing.

Results: A total of 343 RA patient encounters were reviewed (164 in study, 179 in control; 278 patients total). There were no differences between the study and control groups in terms of baseline demographics, RA characteristics, or ASCVD risk factors (Table 1). The automated phrase was used in 93 (56.7%) patient encounters during the study period. ASCVD risk score calculation was attempted in 71 (54.2%) study visits vs. 5 (3.4%) controls ($p < 0.0001$), and was successful in 47 (35.0%) study visits vs. 4 (2.7%) controls ($p < 0.001$). Tobacco use was documented in 99 (60.4%) study visits, vs. 38 (21.2%) controls ($p < 0.0001$). CDAI (clinical disease activity index) scores were documented in 109 (66.5%) study visits vs. 85 (47.5%) controls ($p = 0.005$). Documentation of diabetes status and smoking cessation interventions were not different between the two groups (Table 2).

Table 1: Demographic Data and Disease Characteristics Contributing to ASCVD Risk

	Study (n=127)	Control (n=151)	p value
Age – years	55.7 ± 13.6	58.5 ± 12.3	0.07

Table . (Cont'd)

	Study (n=127)	Control (n=151)	p value
CDAI			
Mean \pm SD	10.6 \pm 11.7	12.4 \pm 12.9	0.41
CDAI $\geq 10^+$	26 (36.1)	29 (50.9)	0.13
Use of prednisone			
Current use – no. (%)	88 (69.3)	108 (71.5)	0.68
Current dose – mg/day	4.7 \pm 5.3	4.3 \pm 4.3	0.45
Dose ≥ 8 mg/day – no. (%)	27 (21.3)	21 (13.9)	0.11

Values are depicted as number (%) of individuals unless otherwise specified.

Plus-minus values are means \pm SD.

P values were calculated using two-sided T test for comparison of means and chi-squared testing for comparison of proportions.

Duplicate patient encounters were excluded from analysis.

* : Denominators include patients with a successfully calculated ASCVD 10-yr risk score calculation only (n = 39 for study and n= 4 for control).

^ : Denominators include patients with pre-existing ASCVD only (n=8 for study and n=16 for control).

+ : Denominators include patients with a calculated CDAI only (n= 72 in study and n= 57 in control).

Table 2: Implementation of the use of an automated phrase and documentation of ASCVD risk

	Study (n=164)	Control (n=179)	p value¶
Use of automated phrase – no. (%)	93 (56.7%)	0 (N/A)	N/A
ASCVD risk score documentation *			
Attempted – no. (%)	71 (54.2)	5 (3.4)	<0.0001
Calculated – no. (%)	47 (35.9)	4 (2.7)	<0.0001
Diabetes documentation			
Diabetes documented – no. (%)	33 (76.7)	27 (73)	0.362
Tobacco use documentation#			
Documented (all) – no. (%)	99 (60.4)	38 (21.2)	<0.0001
Documented (smokers)# – no. (%)	28 (77.8)	13 (50.0)	0.023
Intervention (smokers)# – no. (%)	16 (44.4)	7 (26.9)	0.416
CDAI documentation – no. (%)	109 (66.5)	85 (47.5)	0.005

Values are depicted as number (%) of patient encounters unless otherwise specified.

Documentation encounters included 278 patients; 4 patients were seen 3 times, 57 patients were seen twice, and the remaining patients were seen once.

¶ P values were calculated with chi-squared testing.

* : Denominators include patients eligible for ASCVD 10-yr risk score calculation only (patients ≥ 40 and ≤ 79 years and without pre-existing ASCVD; n = 131 for study and n=146 for control).

: Denominators differ from the totals, and include smokers only (n=36 in study and n=26 in control)

Conclusion: ASCVD risk factors were identified in our predominantly black RA population, including uncontrolled hypertension, high mean BMI, high disease activity, and high prednisone use. The use of an automated phrase increased ASCVD risk score, tobacco use, and CDAI score documentation. Although the majority of patients were seen by a PCP within the past 6 months, statins were under-prescribed, and a significant proportion of blood pressures were not at goal. PCPs may underestimate the increased ASCVD risk in RA. Further interventions are needed to increase awareness among PCPs using a multi-disciplinary approach.

Documenting Bone Health for Veterans with Rheumatoid Arthritis in an Outpatient Academic Clinic

Brittany Ahmed¹, **Rabih Nayfe**², **Akrithi Udupa**³, **Una E. Makris**⁴, **Rashmi Arora**^{1,5} and **Swathi Reddy**^{1,5}, ¹UT Southwestern Medical Center, Dallas, TX, ²Department of Medicine, UT Southwestern Medical Center, Dallas, TX, ³Internal Medicine, University of Texas Southwestern Medical Center, Dallas, TX, ⁴UT Southwestern Medical Center and Dallas VA, Dallas, TX, ⁵Dallas VA Medical Center, Dallas, TX

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Measures and Measurement of Healthcare Quality Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) increases the risk of bone density abnormalities such as osteoporosis, predisposing patients to fragility fractures and subsequent morbidity. Osteoporotic fractures incur an economic burden

Image 1: Intervention: "Bone health" prompt in the Rheumatoid arthritis office visit template.

The image shows a digital medical template for a Rheumatoid Arthritis (RA) office visit. It features several sections:

- Assessment:** A large text area for clinical notes.
- Bone Health:** A section with checkboxes for:
 - ☐ Normal Bone Density
 - ☐ Osteopenia
 - ☐ Osteoporosis
 - ☐ Last Exam
 - ☐ High Fracture
 - ☐ Disseminated
 - ☐ No Assessment
- Plan:** A large text area for treatment plans.
- Review checkboxes:** At the bottom, there are checkboxes for "Review this case only in" and "Review this document in", each followed by a text field for specifying the location.

Figure 1: Three-month documentation rate of bone health among fellows and residents pre- and post-intervention. Each bar represents data in n=50 patients.

reaching nearly \$17 billion annually. Consequently, rheumatologists should assess and manage bone health more attentively. Bone density assessment in RA patients is not always evaluated in routine clinical practice despite guidelines suggesting its importance. We have noted that trainees in the rheumatology clinic are not routinely documenting or managing bone health in our patients. The aim of this quality improvement project was to increase documentation of bone health in RA patients seen by residents and fellows in a high volume VA Medical Center outpatient rheumatology clinic from the baseline 3 month average of 58% to 70% (stretch goal 80%) during the time period of February to April 2018.

Methods: Pre-intervention documentation rate of bone health was measured by reviewing 50 fellows' and 50 residents' rheumatology RA clinic visit notes between August and October 2017 at a VA center serving a large metropolitan area. Patients seen by the authors were excluded. Intervention: In December 2018, a "Bone Health" prompt was added to the RA note template, reminding physicians to document bone health status, FRAX score, and recommendations (Image 1). In order to facilitate the intervention, fellows were educated about the importance of bone health documentation and informed about the QI project at a Grand Rounds conference. Additionally, flyers reminding all residents and fellows about the template were posted in exam rooms at the VA. Post-intervention data were collected between February and April 2018, using the same process.

Results: The pre-intervention documentation rate among both 1st and 2nd year rheumatology fellows and residents (Internal Medicine, PM&R) was 58%. The post-intervention rate improved among both fellows and residents to 82% and 70% respectively (n=50 patients per subgroup), meeting the set goal of our project (Fig 1).

Conclusion: Adding a "Bone Health" prompt to the RA office visit template improves the documentation rate of bone health, as shown by improvement in the post-intervention chart review. Fellows had a greater documentation rate in their post-intervention results than did residents, potentially due to more frequent exposure to this topic. In the future, we plan to analyze if the increased documentation rate translated into improved rates of guideline concordant management of decreased bone density in this vulnerable population.

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Measures and Measurement of Healthcare Quality Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Proteinuria and urinary casts are good indicators of lupus nephritis (LN) yet six different LN guidelines recommend kidney biopsy to confirm LN. Therefore, kidney biopsy remains the gold standard for diagnosing LN and initiating therapy. Recent studies report an average wait time to see a specialist of 50 days which can delay biopsy and therapy in LN. There is limited information on wait times for confirming diagnosis and starting therapy in LN patients. We aimed to examine time to biopsy and therapy in LN patients and compare over two decades. We hypothesized that time to biopsy has not changed but therapy choices would differ in the decade after ALMS trial.

Methods: Our cohort study identified all incident LN patients with initial kidney biopsy from 1997-2017 at an academic center. Sociodemographics and reported details on the first biopsy in LN patients were abstracted from a comprehensive native kidney biopsy database. Biopsy reports were reviewed for LN class and chronicity as per International Society of Nephrology guidelines. Time to biopsy and therapy were defined as time from nephrology referral until biopsy, and time from biopsy until start or change in therapy respectively. Further, for two decades we compared change in time to biopsy over 1997-2007 vs. 2007-2017, rate of hospitalization while awaiting biopsy, and type of therapy initiated.

Results: Among 175 incident LN patients with initial native kidney biopsies, 79% were female, 72% White with median age of 24 years (2-77 years). Median times to biopsy and therapy were 52 days (24-155 days) and 7 days (0-18 days) respectively. 13% of the patients were hospitalized during the wait period. Over two decades, there was no significant change in time to biopsy (Fig 1) or hospitalization rates. Univariate and multivariate analyses showed 4 times higher odds of starting MMF in LN patients in the latter decade (OR 3.5, CI 1.2,10.8 p=0.02). Type of therapy was independent of race, proliferative LN and chronicity (Table 1). Limitations include examining only LN patients with kidney biopsy, and no data on LN patients on MMF without biopsy.

Conclusion: This is among the first studies to report wait times for diagnosing and starting therapy in LN (~60 days) with no improvement in the latter decade despite increased use of MMF after 2007. Observing wait times to undergo biopsy as a major barrier in provision of efficient care to LN patients we recommend system improvement strategies such as establishing multidisciplinary clinics. Future work will examine improvement in time to biopsy after establishing a multidisciplinary LN clinic.

Table 1. Odds of Mycophenolate Therapy Choice using Logistic Multivariate Regression Model

Variables	Multivariate OR (95% CI)	p-value
Biopsy after 2007	3.50 (1.20,10.80)	0.02
Gender (Female)	0.43 (0.11, 1.50)	0.20
Lupus Duration >5 years	0.08 (0.01, 0.76)	0.03
Race (White vs non-White)	1.24 (0.36, 4.73)	0.74
LN (Proliferative vs non-proliferative)*	0.44 (0.13, 1.38)	0.17
Chronicity Present	0.67 (0.21,2.13)	0.49

* LN proliferative includes class 3,4 while non-proliferative includes classes 1,2,5

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Measures and Measurement of Healthcare Quality Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Total management including reconstructive joint surgery and rehabilitation should be needed for further improvements of physical function for long-standing RA patients. It is very important to set treatment goal for

those management. The purpose of this study is to set treatment target using Timed Up and Go test (TUG) in relation to achievement of HAQ-DI remission ($\text{HAQ-DI} < 0.5$) with joint surgery in lower limbs.

Methods: Multicenter prospective observational cohort study was conducted among patients who underwent elective joint surgery for RA from April 2012 to March 2016 (Study registration: UMIN000012649). In this study, we collected data at baseline and at 6 or 12 months after the surgery. These data were as follow; age, sex, disease duration, drug therapies, and disease activity (DAS), TUG, and patient-reported outcome [HAQ-DI, EQ-5D (QOL), patient's global assessment (PtGA) and BDI-II (depression)]. Correlation between TUG and other variables were determined. Association between TUG and achievement of HAQ remission and cut-off values for HAQ remission were also determined using logistic regression analysis with adjustment of age and sex and ROC curve, respectively.

Results: Totally, 139 patients with elective joint surgery in lower limbs were analyzed. Mean age, disease duration, HAQ-DI and TUG were 65.4 years, 17.5 years, 1.022, and 12.7 seconds, respectively. Elective joint surgeries were total hip arthroplasty; 10.1%, total knee arthroplasty; 33.8%, total ankle arthroplasty or ankle fixation; 10.1%, and forefoot arthroplasty; 46.0%. The surgeries can significantly improve the outcome measures, including TUG, DAS, PtGA, pain, EQ-5D and BDI-II other than HAQ-DI. In this study, 45 of 139 patients (32.4%) had HAQ remission status at baseline. 18 of 94 patients (19.1%) who had $\text{HAQ-DI} > 0.5$ can achieve HAQ remission with the surgery. Notably, TUG at last observation was significantly associated with achievement of HAQ remission even after adjustment for age, sex, and DAS (1 second increasing of TUG, OR: 0.72, 95% CI: 0.53-0.97). The adjusted-TUG at last observation of patients with achievement of HAQ remission was 9.2 second (95% CI: 5.6-12.8) (Fig.1). Cut-off of TUG at observation for achievement of HAQ remission was 9.2 second based on ROC analysis (Fig.2). Importantly, We confirmed significant more improving of EQ-5D, HAQ-DI and TUG in patients who achieved TUG 9.2 second at last observation than in patients who did not (Fig.3).

Fig.2

Fig.3

Conclusion: TUG was significantly associated with patient reported outcomes, HAQ-DI and EQ-5D. The cut-off values of TUG (9.2 seconds) should be important to achieve good QOL and physical function for patients with joint surgery in lower limbs and could be suitable target for surgical procedure.

Optimizing the Dataset to Collect from Patients to Accurately Predict Their Status Prior to the Clinic Visit

Eric Newman¹, Elizabeth Thomas², Andrea Berger³ and H. Lester Kirchner³, ¹Department of Rheumatology, Geisinger Medical Center, Danville, PA, ²Rheumatology, Geisinger Medical Center, Danville, PA, ³Geisinger Medical Center, Danville, PA

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Measures and Measurement of Healthcare Quality Poster I

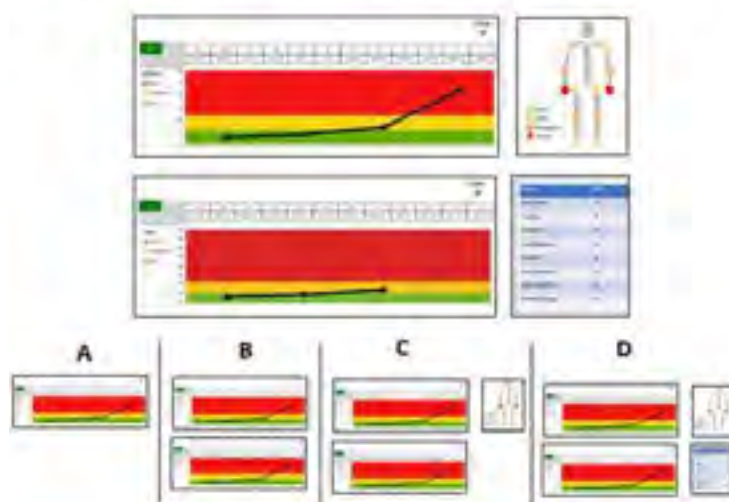

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Understanding a patient's status before entering the exam room, or accurately tracking status between visits, is vital to creating more efficient ways to apply patient care. We studied which patient-derived dataset resulted in the most accurate diagnosis for common clinical scenarios encountered in rheumatoid arthritis (RA) management.

Methods: 3 clinical cases were created for 4 RA scenarios: Acute Flare-RA, Chronic Active-RA, Acute Flare-Not RA, and Chronic Active-Not RA. To see which data most accurately predicted the clinical scenario, 4 datasets were developed (Figure 1): Dataset A (RAPID3), B (RAPID3 + CDAI), C (RAPID3 + CDAI + Homunculus), and D (RAPID3 + CDAI + Homunculus + Events). CDAI included only values from previous office visits, so the dataset could be derived without physician input. 12 rheumatologists were given randomly assembled packets with 48 cases (3 cases x 4 scenarios x 4 datasets). For each case, the rheumatologist decided which of the 4 RA scenarios the dataset represented, as well as how confident they were in their decision (10-point Likert scale). Comparisons were tested using a Generalized Estimating Equation for logistic regression. Post-hoc comparisons were tested for each incremental amount of data.

Figure 1: Datasets* Presented for Each Case Scenario; A = RAPID3; B = RAPID3 + CDAI; C = RAPID3 + CDAI + Homunculus; D = RAPID3 + CDAI + Homunculus + Events.

(*RAPID3 is a patient derived measure of disease activity, CDAI is a composite measure from patient and rheumatologist, Homunculus is a patient derived measure of severity of joint pain by location, and Events are important items that occurred since last visit, such as a new illness or symptom).

Table 1. Rheumatoid Arthritis and Doing Poorly - Correct Etiology by Clinical Phenotype for 4 Datasets. (Optimal Dataset shaded in green)

All Phenotypes	Dataset			
Response	A	B	C	D
Incorrect	135 (93.8%)	59 (41.0%)	20 (13.9%)	15 (10.4%)
Correct	9 (6.2%)	85 (59.0%)	124 (86.1%)	129 (89.6%)
Total	144	144	144	144
RA – Acute Flare	Dataset			
Response	A	B	C	D
Incorrect	31 (86.1%)	80 (83.3%)	10 (27.8%)	10 (27.8%)
Correct	5 (13.9%)	6 (16.7%)	26 (72.2%)	26 (72.2%)
Total	36	36	36	36
RA – Chronic Active	Dataset			
Response	A	B	C	D
Incorrect	32 (88.9%)	3 (8.3%)	2 (5.6%)	2 (5.6%)
Correct	4 (11.1%)	33 (91.7%)	34 (94.4%)	34 (94.4%)
Total	36	36	36	36
Not-RA – Acute	Dataset			
Response	A	B	C	D
Incorrect	36 (100%)	25 (69.4%)	7 (19.4%)	0 (0%)
Correct	0 (0%)	11 (30.6%)	29 (80.6%)	36 (100%)
Total	36	36	36	36
Not-RA – Chronic Active	Dataset			
Response	A	B	C	D
Incorrect	36 (100%)	1 (2.8%)	1 (2.8%)	1 (2.8%)
Correct	0 (0%)	35 (97.2%)	25 (69.7%)	35 (97.2%)
Total	36	36	36	36

Results: Across all scenarios (Table 1), there was an increase in percent correct as more clinical data was presented ($p<0.0001$). Post-hoc analysis showed improvement in % correct moving from dataset A to B (6.2% vs. 59.0%, $p<0.0001$) and B to C (59.0% vs. 86.1%, $p<0.0001$), but not C to D (86.1% vs. 89.6%, $p=0.4575$). Analysis of specific scenarios showed that dataset C was optimal for Acute Flare–RA and Acute Flare–Not RA. Dataset B was optimal for Chronic Active – RA and Chronic Active – Not RA. Level of confidence was high (8/10) and did not vary by dataset - indicating confidence in decision making regardless of the decision.

Conclusion: To our knowledge, this is the first study that shows the optimal data set to collect from patients between visits or before a visit to accurately diagnose the common clinical scenarios that affect patients with RA. The combination of RAPID3 (historical and current) + CDAI(historical) + pain Homunculus gave the greatest diagnostic accuracy across all clinical phenotypes. These results can inform the design of data collection systems that improve rheumatology efficiency, by empowering the rheumatologist before the visit, and driving return visits based on patient need rather than an arbitrary interval.

Low Rates of Immunizations in Cohort of Immunocompromised Patients in an Academic Rheumatology Practice

Dmitriy Cherny¹, Najia Shakoor², Todd Beck³ and Sonali Khandelwal⁴, ¹Internal Medicine, Rush University Medical Center, Chicago, IL, ²Division of Rheumatology, Rush University Medical Center, Chicago, IL, ³Bioinformatics, Rush University Medical Center, Chicago, IL, ⁴Rheumatology, Rush University Medical Center, Chicago, IL

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Measures and Measurement of Healthcare Quality Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with rheumatologic disorders often require immunosuppression (e.g. DMARDs, biologics, or high doses of prednisone). These patients are at increased risk for infections. While live vaccines are contraindicated in the immunosuppressed, 2018 CDC guidelines support inactivated vaccine administration [1]. Despite recommendations for immunization [2], there is lack of evidence on whether vaccination rates are optimal. The purpose of this study was to investigate the rates of influenza, pneumococcal, and tetanus/diphtheria/pertussis (Tdap) vaccination in immunosuppressed individuals with rheumatologic disorders seen from 2012-2017 at a large academic rheumatology clinic.

Methods: Patients seen at a large urban academic medical center's rheumatology clinic between 2012-2017 were included if they had a diagnosis of rheumatoid arthritis (RA), systemic lupus erythematosus (SLE), or vasculitis in addition to any of the following: prednisone ≥ 20 mg/day, a DMARD (except hydroxychloroquine), and/or a biologic agent. Deceased patients were excluded. Immunizations, medications, and comorbidities were recorded. Vaccination administration for Prevnar, Pneumovax, Influenza, or Tdap was assessed. Chi squared tests evaluated immunization patterns based on various factors including sex, comorbidities, physician experience level (< 10 years, ≥ 10 years), diagnosis, and age group (< 65 years, ≥ 65 years).

Results: Of 2366 patients reviewed, 1239 met inclusion/exclusion criteria. Results are shown in the Table. Vaccination rates were below 50% (except for receipt of flu vaccine once during the study period). More patients aged ≥ 65 years received Prevnar/Pneumovax than those < 65 years of age. Patients with SLE had higher rates of immunization versus those with RA or vasculitis. Presence of cardiopulmonary comorbidities generally increased rates. No significant difference was found in rates based on ethnicity, sex, non-cardiopulmonary comorbidities, or physician experience.

Conclusion: Infections contribute to morbidity and mortality for immunosuppressed patients, and guidelines recommend vaccination. The above results show strikingly low vaccination rates in this vulnerable population. Other risk factors for infection, including older age and cardiopulmonary comorbidities, were associated with higher vaccination rates. Rheumatologists may not be considering vaccination during their busy clinical practice. Education and quality improvement initiatives are needed to improve vaccination rates in Rheumatology clinics.

Use of Lean Six-Sigma Methodologies to Improve Pneumococcal Vaccination Rates Among Immunocompromised Veterans with Rheumatologic Diseases: A Quality Improvement Project

Melissa Swee¹, Jaime Wilson² and Bharat Kumar³, ¹Transplant Nephrology, University of Iowa, Iowa City, IA, ²Iowa City Veterans Affairs Medical Center, Iowa City, IA, ³Internal Medicine-Division of Immunology, University of Iowa, Iowa City, IA

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Measures and Measurement of Healthcare Quality Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Pneumonia is a leading cause of morbidity and mortality in the United States among immunocompromised individuals with rheumatologic diseases. Despite the publication of Advisory Committee on Immunization Practices (ACIP) guidelines for pneumococcal vaccinations addressing the specific needs of this population, implementation of these guidelines has been inconsistent. At one Midwestern VA Rheumatology Clinic, pneumococcal vaccination rates were determined to be as low as 3%. From January to June 2018, we used Lean Six Sigma methodologies to improve the current process surrounding pneumococcal vaccination in the Rheumatology Clinic.

Methods: Current processes and improvement targets for pneumococcal vaccine administration were explored using Lean-six sigma methods: 1) interdisciplinary process mapping; 2) process maps analysis, Voice of the Customer (VOC), and brainstorming for value and flow analyses; 3) value stream maps and pilot testing utilizing PDSA (Plan-Do-Study-Act) cycles; and 4) post-implementation control and sustainability planning. The interprofessional team consisted of a nurse and physician leader, a physician champion, and clinic management. The first set of PDSA cycles involved educating providers and posting the ACIP guidelines in each patient room. The second set of PDSA cycles involved bundling and relocating supplies to a more convenient location. Outcome measures were defined as time required to administer vaccine and percentage of eligible patients who are up-to-date with pneumococcal vaccination. Balancing measures included total time spent in clinic and vaccine adverse reactions.

Results: Process mapping revealed eight barriers. Process redesign resulted in elimination of five of these barriers through workflow simplification. A nurse alert step was added to further improve efficiency. The VOC indicated value in the delivery of high quality care and improving vaccination rates, but without spending excess time in the vaccine administration workflow. Interim results show improvement in outcome measures, including reduced time required for vaccine administration from 15 to 7 minutes, and increased percentage of patients appropriately immunized from 3% to 21%. Vaccine administration added fewer than 15 minutes to total appointment time and no adverse reactions occurred.

Conclusion: A bundle of quality improvement efforts utilizing lean six sigma methodologies increased the pneumococcal vaccination rate from 3% to 21% and reduced the time required for vaccination from 15 to 7 minutes. Elements of the bundle included: (1) clinician education, (2) posting of an easy-to-read version of the guidelines for vaccine administration, (3) simplification of workflow for administration of pneumococcal vaccines, and (4) integration and bundling of supplies necessary for vaccination. This bundle can be replicated at other sites using similar methodologies. The investigators intend on continuing through more iterations of these PDSA Cycles to achieve a goal of at least 70% appropriate pneumococcal vaccination among immunocompromised patients at the Iowa City VA Rheumatology Clinic.

Session Information

Session Date: Sunday, October 21, 2018

Session Time: 9:00AM-11:00AM

We used a Key Driver Diagram to define our leading factors and guide our change ideas, and an aim statement and data management plan to guide the work and data collection. Our run chart captures biweekly change and demonstrates improvement over time.

The average number of patients scheduled within 30 days of referral over the first four months compared to the subsequent five months represents a **131% increase**. Our run chart shows a shift demonstrating non-random variation and improvement in our outcome measure. We have continuously met and exceeded goal of 85% since December 2017.

By investing time in creative problem-solving, streamlining, and clear communication, and by facilitating staff empowerment and ownership, this project achieved remarkable gains in patient access and care delivery. This result is a process that can be transferred to other settings, and holds great value given the universal challenges of supply/demand.

Pankti Reid¹ and Reem Jan², ¹Internal Medicine, rheumatology, University of Chicago, Chicago, IL, ²Medicine, Rheumatology, University of Chicago, Chicago, IL

Session Information**Session Date:** Sunday, October 21, 2018**Session Title:** Measures and Measurement of Healthcare Quality Poster I**Session Type:** ACR Poster Session A**Session Time:** 9:00AM-11:00AM

Background/Purpose: The growing use of cancer immunotherapy and checkpoint inhibitors has led to a steep rise in immune-related adverse events (irAEs). Despite expanding research efforts, definitive methods of predicting irAE onset or severity and reliable therapeutic approaches beyond steroids are lacking. Evaluation and management of irAEs requires a multidisciplinary approach. At the University of Chicago, we have developed a dedicated irAE pilot clinic with the aim to facilitate diagnosis and management for irAE patients in a timely fashion.

Methods: The pilot clinic was run by Rheumatology over seven months with one hour per week dedicated to new or follow up irAE patient visits. No limit was placed on organ involvement so a wide breadth of complications was observed and treated. The indications for referral included: irAE refractory to steroids with possible need for steroid sparing immunosuppression (IS), high severity irAE needing early steroid-sparing agent, and concern for any Rheumatologic irAE. Referrals were placed through an order in our electronic medical record system. Physicians were informed about the irAE clinic through multiple presentations at Hematology-Oncology grand rounds and fellow rounds and Internal Medicine conferences. In addition to the primary irAE clinic, we have developed a network of specified “point person” physicians within various medical subspecialties (Hepatology, Dermatology, Pulmonary, Nephrology, Neurology) to coordinate diagnostic procedures and discuss therapeutic options in each case.

Results: A total of fifteen new patients were evaluated; eight of these required more than one follow up. Oncologists referred twelve patients and three were new referrals after hospital discharge. Most of the patients were seen for possible Rheumatologic irAE (40%). About 33% were seen for irAE refractory to steroids and 27% for high severity irAE requiring Rheumatology assistance for steroid-sparing IS. Malignancy history ranged from melanoma, non-small cell lung cancer to gynecologic tumors. Patients were able to be seen within an average of 7 days (0-19 days) and 93% of the Oncologists noted utilization of and followed Rheumatology recommendations in patient's care. Of the evaluated patients, 3 were ruled out for irAE. The irAEs diagnosed included the following: 2 arthritis, 1 vasculitis, 1 myocarditis, 1 dermatitis, 3 pneumonitis, 2 hepatitis and 2 neurologic. Of those with irAEs diagnosed, 8 had serologies checked and all had some antibody positivity (5 of 8 with ANA >1:160, 2 with RF positive (1 also with CCP positive), 1 ANCA positive). The patient with dermatitis had eosinophilia on differential and 40% of patients with diagnoses of irAE had lymphopenia on their differential (patient without irAE did not have abnormality on differential).

Conclusion: A dedicated irAE clinic can help Oncologists streamline care of their high risk patients resulting in more efficient and effective care for challenging cases. In addition, creation of an irAE clinic cohort allows for trends to be identified such as the development of lymphopenia in association with irAE, serological findings, and which steroid-sparing strategies are most effective.

Effectiveness of a Biopsychosocial Exercise Approach in Rheumatic Diseases

Edibe Ünal¹, Gamze Arın², Nur Banu Karaca³, Fatma Birgül Oflaz², Aykut Özcadırcı², Abdulsamet Erden⁴, Berkan Armağan⁴, Yavuz Yakut⁵ and Sule Apras Bilgen⁴, ¹Department of Physiotherapy and Rehabilitation, Hacettepe University Faculty of Health Sciences, Ankara, Turkey, ²Department of Physical Therapy and Rehabilitation, Hacettepe University Faculty of Health Sciences, Ankara, Turkey, ³Department of Physical Therapy and Rehabilitation, Hacettepe University Faculty of Health Sciences, Ankara, Turkey, ⁴Rheumatology Division, Hacettepe University Faculty of Medicine, Ankara, Turkey, ⁵Department of Physiotherapy and Rehabilitation, Hasan Kalyoncu University Faculty of Health Sciences, Ankara, Turkey

Session Information**Session Date:** Sunday, October 21, 2018**Session Title:** Measures and Measurements of Healthcare Quality Poster – ARHP**Session Type:** ACR Poster Session A**Session Time:** 9:00AM-11:00AM

Background/Purpose: The trend towards biopsychosocial approaches is increasing today and studies on psychosocial effects of exercise are limited in the literature. There is a need for framed exercise programs to assess clinical effectiveness of biopsychosocial approaches. There is a specific approach named as Cognitive Exercise Therapy Approach (the authors request that the abbreviation stays as “BETY” as the original in Turkish), which has newly developed its biopsychosocial

assessment scale. The purpose of this study is to investigate the effectiveness of BETY in rheumatic patients comparing to a control group.

Methods: Twenty-nine patients with rheumatic diseases were included in this study. Patients were divided into two groups; BETY group (n=14) and control group (n=15). BETY Scale for biopsychosocial status, Hospital Anxiety and Depression (HADS) for depression and anxiety, Health Assessment Questionnaire (HAQ) for daily living activity evaluation were used pre- and post-treatment. BETY approach is performed in a period of one hour, 3 times a week for 12 weeks and includes clinical pilates exercises, dance therapy-authentic movement and pain management information. The control group did not take any exercise treatment.

Results: Mean age of the BETY group and control group was $48,86 \pm 8$ and $40,47 \pm 10,97$ respectively. There were significant improvements in BETY scale and HADS anxiety and depression scores in BETY group ($p < 0.05$). Although HADS depression score was changed ($p < 0.05$), no changes were recorded in control group in other parameters ($p > 0.05$) (Table.1.). There wasn't any change in the HAQ scores of both groups ($p > 0.05$).

Table 1. Comparison between two groups.

	BETY Group (n=14)			Control Group (n=15)			Between groups
	Age	BMI		Age	BMI		
	48,86±8	25,68±3,19		40,47±10,97	26,49±4,89		
	Before Median (25th-75th)	After Median (25th-75th)	p	Before Median (25th-75th)	After Median (25th-75th)	p	p
BETY Score	60 (47,25-82)	39 (30,75-48,75)	0,013	62 (54-78)	61 (47-76)	0,409	0,347
HAQ	9 (4,75-14,75)	4 (2,5-10)	0,068	13 (6-20)	11 (1-16)	0,624	0,363
HADS-A	9,5 (6,75-12,75)	5 (1,5-5)	0,002	10 (5-12)	10 (7-12)	0,778	0,001
HADS-D	8 (5-10)	4 (1,5-5)	0,014	10 (9-12)	9 (4-11)	0,014	0,235

Conclusion: BETY program was effective on anxiety, depression and biopsychosocial status of patients. This study is important in demonstrating the effectiveness of a framed biopsychosocial exercise approach. More detailed studies are needed in several patient groups.

Session Title: Measures and Measurements of Healthcare Quality Poster – ARHP

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Helplessness is a relevant construct in systemic lupus erythematosus (SLE), an unpredictable chronic illness with no known cure characterized by relapsing and remitting features. However, no measure of helplessness has been validated in this population. The Arthritis Helplessness Index (AHI) is a 15-item self-report measure developed to assess perceptions of helplessness in coping with rheumatoid arthritis (RA). Since its development, the measure has been widely used across rheumatologic contexts and adapted into several variants. A single-factor total score, a bi-factor 7-item Internality and 5-item Helplessness version, and a 5-item Helplessness short-form have been proposed in the literature for RA patients. One potential challenge with using the AHI has been that multiple variants of the measure exist. Moreover, lack of a formal evaluation of the psychometric properties of the measure in SLE had precluded identification of the optimal form of the measure for this patient population. The present study examined the structural validity, reliability, and convergent validity of the Arthritis Helplessness Index in a sample of patients with SLE.

Methods: Patients with SLE ($N = 136$) receiving medical care at a private hospital completed the AHI and other self-report measures. The structural validity of the AHI was examined using confirmatory factor analysis. Internal consistency reliability was evaluated with Cronbach's coefficient alpha. Pearson product-moment correlations were used to examine convergent validity with measures of depression, anxiety, and mastery.

Results: The five-item AHI-Helplessness measure demonstrated a tenable factor structure ($CFI = 0.98$, $RMSEA = 0.06$, $SRMR = 0.04$). Internal consistency reliability was fair ($\alpha = 0.69$). Convergent validity was evidenced via significant correlations with measures of depression, anxiety, and mastery.

Conclusion: The results of the present study suggest that the 5-item AHI-Helplessness scale is a reliable and valid one-factor measure of helplessness for patients with SLE. Moreover, the results suggest that the 15-item AHI total score and 7-item AHI-Internality subscale should not be used in patients with SLE given the lack of structural validity.

Session Title: Measures and Measurements of Healthcare Quality Poster – ARHP

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: We have recently validated the Quality of Life-Rheumatoid Arthritis Scale (QOL-RA). Redundancy between questions N° 3 and N° 6 was observed, and it was influenced by age and disease duration. For this reason, with the author's permission, we have changed these questions and developed a new version of Spanish QOL-RA. The aim of our study was to validate this Spanish version in patients with RA.

Methods: Across-sectional multicenter study was carried out. Patients ≥ 18 years old, with a diagnosis of RA according to ACR-EULAR 2010 criteria were included. Patients with difficulties in answering the questionnaire (illiterate, blind) and with decompensated comorbidities were excluded. Sociodemographic data, comorbidities, RA characteristics, disease activity current treatment were registered. Questionnaires were administered to assess quality of life by EQ-5D-3L and QOL-RA, functional capacity by HAQ-A and depression by PHQ-9. The time to complete and calculate both quality of life questionnaires was measured, and the difficulties that the patients presented to complete any item were recorded. The QOL-RA was re-administered in 20 patients to evaluate reproducibility. *Statistical analysis:* Student's T, ANOVA and χ^2 tests. Spearman correlation. Reliability by Cronbach's alpha. Reproducibility using ICC. QOL-RA linear tendency based on RA activity by multinomial logistic regression with completed factorial model. Multiple linear regression.

Results: 430 patients were included. 87.7% were females, with a median (m) age of 53.1 years (IQR 45-62) and m disease duration of 8.9 years (IQR 4-16). Disease activity by DAS28-ESR was m 2.9 (IQR 1.9-3.9). The median of QOL-RA was 6.6 (IQR 5.3-8) and it had a good correlation with EQ-5D-3L ($Rho: 0.6$), PHQ-9 ($Rho: -0.56$), HAQ-A ($Rho: -0.55$), CDAI ($Rho: -0.47$) and DAS28-ESR ($Rho: -0.4$). Worse QOL-RA was observed in current smokers (mean 6.1 ± 1.7 vs 6.6 ± 1.9 , $p = 0.016$), unemployed (mean 6.1 ± 1.8 vs 6.9 ± 1.8 , $p = 0.0001$), patients not doing physical activity (mean 6.3 ± 1.9 vs 7 ± 1.9 , $p = 0.0001$) and those with morning stiffness (mean 5.8 ± 1.9 vs 7.1 ± 1.7 , $p = 0.0001$). It showed very good reliability (0.97) and reproducibility (ICC = 0.96 IC 95% 0.90-0.99). Ceiling and floor effects were 2.8% and 0.7%, respectively. Only 0.9%

of the questionnaires presented at least one missing answer. There was no redundancy between questions. Patients with higher disease activity had a significant poorer quality of life. (Figure 1) In the multivariate analysis, using QOL-RA as dependent variable, adjusting by age, sex and disease duration, disability, disease activity, and the presence of depression were independently associated to worse quality of life.

Conclusion: This new version of QOL-RA demonstrated better construct validity, reproducibility and reliability compared to the original version and it was easy to complete and calculate.

Session Date: Sunday, October 21, 2018

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster I: Checkpoint Inhibitors, Retroperitoneal Fibrosis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Checkpoint immunotherapy has become the standard of care in treating advanced melanoma. These medications have been associated with immune-related adverse events (irAEs). Accurate methods of predicting and managing irAEs are still lacking. Here, we aim to identify clinical correlates of irAEs from patients with melanoma previously treated with immunotherapy.

Methods: We retrospectively reviewed electronic medical records of patients with melanoma who were seen at The University of Chicago Medical Center between 1/2011-1/2017 and were treated with immune checkpoint inhibitors (ICIs). Other inclusion criteria included the following: ≥18 years old, ICI administered at least once, received systemic corticosteroids(CS). Patients' irAEs were graded based on the National Cancer Institute's Common Terminology Criteria for Adverse Events. Patients were excluded if they had low grade (1 or 2) irAEs and if systemic CS were used for reasons other than irAE management. Wilcoxon Mann-Whitney test and Chi-squared test of association were used to compare quantitative and categorical data (respectively) between patients with irAEs and patients without irAEs.

	Checkpoint inhibitor + irAE (22)	Checkpoint inhibitor, no irAE (87)	P value
Gender: female: Male	8 (40%): 12 (60%)	27 (46.25%): 43 (53.75%)	0.613 ^{ns}

^{ns} Fisher's Chi-squared test of association

^{**} Wilcoxon Mann-Whitney test

Results: Twenty patients with grade 3 or higher irAEs were identified and compared with 80 patients who received ICI therapy but did not have any irAEs. The irAEs were as follows: 4 transaminitis, 4 dermatitis, 3 arthritis, 3 colitis, 2 neurologic, 2 thyroiditis, 1 myocarditis, and 1 pneumonitis. Some patients had more than one high grade irAE with second irAE including iritis, Guillain-Barre syndrome, pancreatitis and adrenalin sufficiency (AI). From start of ICI, the average days to first irAE occurrence was 121 days (7-378 days). The average days to irAE after cessation of ICI was 61 days (0-375 days), excluding an outlier of a late AI at 1316 days. There was no statistically significant difference between irAE and non-irAE patients in terms of gender, race, age at melanoma diagnosis, age at ICI therapy, or type of ICI used (p values 0.615, 0.193, 0.315, 0.458 and 0.569, respectively). There was a statistically significant difference in peripheral absolute lymphocyte count (ALC) between the two groups; while 60% of patients with irAEs had ALC abnormalities (lymphopenia defined as ALC<900/uL, lymphocytosis>3300/uL), only 28.7% of the group without irAEs had any peripheral ALC abnormalities. The 3 irAE patients with eosinophilia (>600/uL) had dermatitis.

Conclusion: This cohort evaluated patients with Melanoma treated with ICIs and found no significant demographic differences between those who developed a high grade irAE compared with those who did not. There was a significant difference in ALC, with those patients who developed irAEs demonstrating an abnormal ALC. More research is needed to further validate and elucidate this observed association between peripherally lymphocyte count and development of irAEs.

Session Date: Sunday, October 21, 2018

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster I: Checkpoint Inhibitors, Retroperitoneal Fibrosis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: To evaluate the prevalence and type of rheumatic immune-related adverse events (irAEs) in patients receiving programmed cell death protein-1 (PD-1) inhibitors.

Methods: This is a single-center prospective observational study including all cancer patients receiving PD-1 inhibitors between January 2016 and January 2018. Patients who experienced new-onset rheumatic irAEs were referred to the department of rheumatology by oncologists or hematologists for standardized clinical evaluation and management. Patients

were remitted when they identified new clinically important symptoms during routine care or during a clinical trial. In general terms, only those with complications of moderate-severe intensity or unremitting were referred to us. Patients with mild and transient arthralgias that resolved with non-steroid anti-inflammatory drugs (NSAIDs) were not referred for evaluation (the incidence of arthralgia secondary to nivolumab in phase III trials ranges from 5 to 16%). The study only included cases in which there was a clear temporal relationship with the onset of treatment and they did not have any previous rheumatic disease that could explain the symptoms.

Results: During the period analyzed, we evaluated a total of 11 patients. No patient had pre-existing rheumatic or autoimmune disease. In this period, a total of 220 patients were treated with PD1 inhibitors in our center; therefore, the estimated minimum prevalence of rheumatic IRAEs related to these therapies in our population was 5%. The rheumatic IRAEs evaluated included 5 cases of oligo- or polyarthritis, 1 with a polymyalgia rheumatica-type syndrome, 2 cases of immunotherapy-induced sicca syndrome, 1 patient with a paraneoplastic acral vascular syndrome (the diagnosis was established after excluding other causes of blue digit syndrome) and 2 patients who presented symptomatic inflammatory myositis with fasciitis in lower extremities. These 2 patients developed abruptly the same clinical picture, characterized by symmetrical painful swelling of the lower limbs with a progressive induration and thickening of the skin and soft tissues. In both cases, the clinic was established acutely after the first doses of the anti-PD-1 immunotherapy. MRI in these patients demonstrated the presence of myositis and fasciitis involving the muscles of the thighs and legs. The temporal relationship and the rapid improvement of symptoms after withdrawal of the drug support a casual relationship, expanding the clinical spectrum of rheumatic IRAEs related with these agents (*fasciitis with myositis syndrome*). The median time to IRAE after anti-PD1 exposure was 8 weeks (range: 2–24). In 5 patients, immunotherapy was discontinued (due to the adverse effect in three and cancer progression in two). In general terms the symptoms resolved completely with symptomatic treatment. Disease-modifying antirheumatic drugs were needed for 2 patients.

Conclusion: Rheumatic IRAEs should be kept in mind during the follow-up and evaluation of patients treated with PD-1 inhibitors. The concomitant development of symptomatic inflammatory myositis with fasciitis in lower extremities appears to be a new adverse effect of anti-PD-1 immunotherapy.

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster I: Checkpoint Inhibitors, Retroperitoneal Fibrosis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatic immune related adverse events (irAEs) from checkpoint inhibitor (ICI) therapy remain poorly understood. In our early experience with rheumatic irAEs we encountered patients presenting with polymyalgiarheumatica (PMR)-like clinical phenotypes. This entity has also been described in the literature. It is the purpose of this study to describe the cases of PMR-like syndrome secondary to ICI reported in the literature to date, and determine if they meet the 2012 EULAR/ACR criteria for PMR¹.

Methods: A systematic literature search was performed in PubMed andOvid Embase using the search terms: “polymyalgia rheumatica”[MESH] OR“polymyalgia rheumatic” AND “ immunotherapy” OR checkpoint inhibitor therapy”. We determined how many cases provided enough data to apply the EULAR/ACR criteria for PMR (age > 50, elevated ESR or CRP, and bilateral shoulder aching) and these cases were designated “A level”evidence. The remaining cases, with incomplete or insufficient data, were designated “B level” evidence.

Results: A total of 39 patients were included for analysis, including 6 cases from our center. Among these, 25 (64%) were designated A level. The remaining 14 (36%) were designated B level and thus censored from further evaluation. Within group A, 20 cases fulfilled complete EULAR/ACR criteria for a diagnosis of PMR. Three patients also met imaging

criteria. The main reason why patients did not meet criteria was because they had other joint involvement– most commonly knees, followed by elbows and hands. Two patients had low-positive rheumatoid factor. One case described a patient with RS3PE. In the whole group, the specific checkpoint inhibitor was reported in 24 cases. 7 were exposed to nivolumab, 4 to combination ipilimumab/nivolumab, 5 to pembrolizumab, 3 to ipilimumab and 5 to PD-1 or PD-L1 agents. Of note, 3 cases of giant cell arteritis have been described with ICI therapy: 2 in the setting of PMR and one isolated case.

Table. Cases from our irAE clinic

	sex	Tumor type	ICI	Age	Shoulder aching	Abnormal ESR/CRP	EMS > 45 min	Hip pain	Normal RF/ACPA	No other joints
1	M	RCC	Nivolumab	63	Y	N	Y	Y	Y	N
2	M	Melanoma	Ipi/nivo	69	Y	Y	Y	Y	Y	Y
3	M	Melanoma	Ipi/nivo	79	Y	Y	Y	Y	Y	Y
4	M	Melanoma	Pembro	57	Y	N	Y	Y	RF 35 IU/ml	N
5	M	Melanoma	Pembro	60	Y	Y	Y	Y	RF 45 IU/ml	N
6	M	Melanoma	Nivo	66	Y	Y	Y	Y	Y	N

Conclusion: In this combined analysis 36% of reported cases of PMR were based on incomplete reporting data making verification problematic. Of those with enough data for evaluation nearly 80% met current classification criteria for PMR. Among those with insufficient evidence atypical features (synovitis, positive serology) were present that may indicate an alternative inflammatory rheumatic manifestation of unclear nosology. Prospective registry-based studies with adequate assessment of data are urgently needed.

Session Date: Sunday, October 21, 2018

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster I: Checkpoint Inhibitors, Retroperitoneal Fibrosis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Immune checkpoint blockade therapy (ICTB) has shown remarkable benefit in different cancer types. Blockade of intrinsic down-regulators of immunity increases the activity of the immune system, which can lead to different immune-related adverse events. Our aim was to assess the immune-related adverse events in patients who received anti-cytotoxic T-lymphocyte antigen 4 (CTLA-4), anti-programmed cell death 1 (PD-1) or anti-programmed cell death ligand 1 (PD-L1). Our aim was to assess the incidence, treatment and evolution of immune-related adverse events due to ICTB.

Methods: We set up an observational study of patients treated with Nivolumab and Pembrolizumab (anti-PD1), Atezolizumab (anti-PD-L1) and Ipilimumab (anti-CTLA-4) for solid organ tumors. All these patients were followed in a single reference University Hospital from March-2015 up to May-2018.

The main outcome was to determinate the incidence of immune-related adverse events of ICTB. The secondary objective was to assess the frequency and management of the rheumatological side effects.

Results: We studied 102 patients (63♂/39♀) with a mean age of 60.6±9.7 with lung (n=63), gastric (n=3), bladder (n=1), kidney (n=11), melanoma (n=21) and colon cancer (n=3). Only 7 patients had a previous diagnosis of an immune-mediated

disease: psoriasis (n=2), psoriatic arthritis (n=1), systemic lupus erythematosus (n=1), spondyloarthritis (n=1), rheumatoid arthritis (n=1) and skin lupus (n=1).

ICTB was performed as follows: pembrolizumab (n=35), nivolumab (n=52), atezolizumab (n=10) and ipilimumab (n=5). After a median of 5 [2.5-10.5] months since the ICTB onset, we observed 87 (85.3%) patients with different autoimmune adverse effects (n=95), summarized in **TABLE**. ICTB discontinuation was required in 39 patients. 36 patients received specific treatment (prednisone, antihistamine, levothyroxine and thiamazol), obtaining a good response in 31 cases (79.5%). ICTB was reintroduced in 28 patients (71.8%) after resolution of the adverse event, with an appropriate tolerance in all cases. Rheumatological side effects were observed in 11 patients (10.8%): inflammatory arthralgia (n=6), arthritis (n=4), and aortitis (n=1). 7 of them required a temporary withdrawal of the immunotherapy, 3 were treated with NSAIDs and other 4 with oral prednisone (one of them also needed intraarticular corticosteroids). From the 7 patients with previous diagnosis of an immune-mediated disease, only 1 patient with psoriasis suffered a worsening of skin symptoms and other with psoriasis arthritis had a monoarthritis episode.

Conclusion: In our study, the majority of autoimmune side effects due to ICBT were gastrointestinal, thyroiditis and cutaneous. The prevalence of rheumatological adverse effects was slightly higher than in pivotal studies. Most of them were with PD-1/PD-L1.

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster I: Checkpoint Inhibitors, Retroperitoneal Fibrosis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Immune checkpoint inhibitors (ICIs) have led to improved outcomes in multiple cancers, but they are associated with immune-related adverse events (irAEs), including inflammatory arthritis. We report our single center experience with rheumatic irAEs.

Methods: Patients ≥18 years treated with an ICI at our institution from 2011-2018 and seen by rheumatology for evaluation of musculoskeletal symptoms following ICI were included. A rheumatologist evaluated all patients and confirmed the

diagnosis of irAE at the time of evaluation. Cases were reviewed by two rheumatologists to confirm the presence of a rheumatic irAE. Inflammatory arthritis was defined as joint pain with inflammatory features on history and physical exam without an alternative etiology. PMR was based on 2012 ACR/EULAR criteria. Patients with and without pre-existing rheumatic conditions were analyzed.

Results: Twenty-nine patients were evaluated by rheumatology for suspected rheumatic irAEs. Eighteen had confirmed inflammatory arthritis (n=12) or PMR (n=6) (**Table 1**). Six had inflammatory joint pain but no evidence of synovitis by exam, imaging or synovial fluid. Five had an alternative etiology identified (gout, fracture, infectious arthritis). Patients with pre-existing rheumatic conditions (n=6) (**Table2**) developed a flare of their underlying disease a median of 12 weeks following ICI (range 1-43 weeks). The mean initial prednisone dose was 25mg/day (range15-40mg), with a mean duration of use of 37.4 weeks (range 17-57 weeks). One patient with PMR/RA required tocilizumab; one patient with PsA required MTX. Two patients discontinued ICI.

Ten patients without a pre-existing rheumatic condition developed inflammatory arthritis and two developed PMR a median of 36 weeks following ICI (range 9-160 weeks, p=0.0485 compared to patients with pre-existing conditions). Patients with PMR were treated with prednisone. Patients with inflammatory arthritis were treated with systemic or IA steroids and in 8 cases with DMARDs, including HCQ or SSZ. The mean initial prednisone dose was 31.1mg/day (range 6-60mg), with a mean duration of use of 26.6 weeks(range 3-82 weeks). ICIs were discontinued in 5 patients.

Conclusion: We report 18 patients with inflammatory arthritis or PMR after ICI treatment. Our work highlights the differences between patients with and without pre-existing rheumatic conditions and describes the successful use of non-biologic DMARDs as treatment. Further studies are needed to determine the incidence of rheumaticirAEs, to improve classification and to identify the most effective treatment.

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster I: Checkpoint Inhibitors, Retroperitoneal Fibrosis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Immune checkpoint inhibitors (ICI), an important type of cancer therapy, can cause adverse events through immune activation. Inflammatory arthritis (IA) due to ICI treatment is increasingly appreciated as prevalent and morbid, but genetic risk factors are not understood. In this pilot study, we aimed to evaluate the frequency of HLA class I and II alleles associated with traditional forms of inflammatory arthritis in a group of patients with ICI-induced IA as compared to population controls.

Methods: High resolution HLA typing was performed on 27 patients with ICI-induced IA and 726 controls who were prospective bone marrow donors at our institution. Genotyping at the shared epitope (SE) locus (HLA-DRB1) was also performed on 220 rheumatoid arthritis (RA) cases. Allele-positivity rates were compared using Fisher's exact test. The frequency of having at least one SE allele was compared between ICI-induced IA patients and both population and RA controls.

Results: The average age was 60.2 (SD 12.1) years and 12 patients (44.4%) were female. Patients were treated with ICIs targeting CTLA-4, PD-1, and/or PD-L1. Melanoma was the most common tumor type (N=9), followed by non-small cell lung cancer (N=6). Other tumor types were renal cell carcinoma, basal cell carcinoma, squamous cell carcinoma, Merkel cell carcinoma, mycosis fungoides, colon, endometrial, esophageal, and breast cancers. Of the included patients, 26 were of European descent and one was African-American. In the 26 patients of European descent, 16 (61.5%) had at least one SE allele, significantly different from the European descent bone marrow donor controls where 299 (41.2%) had at least one SE allele (OR=2.3, p=0.04). Of individual class I or II alleles, only the allele-positivity rate of DRB1*04:05 was statistically different between groups. There were trends toward higher allele-positivity rates for HLA A*03:01, B*52:01, and C*12:02 in ICI-induced IA (Table 1). The ICI-induced IA population did not differ significantly from RA cases of European descent in frequency of having at least one SE allele, but they were more likely to be negative for rheumatoid factor and anti-cyclic citrullinated peptide antibody (Table 2).

Conclusion: Patients with ICI-induced IA who were of European descent were more likely to have at least one shared epitope allele compared to bone marrow donor controls. Further statistically powered studies are warranted to establish whether immunogenetic framework modifies the risk of developing IA from ICI therapy.

Table 1: Comparison of allele-positivity rates for select HLA class I and II alleles and prevalence of having at least one SE allele in ICI-induced IA vs healthy control patients of European descent

HLA allele/s	Odds Ratio (95% CI) ICI-induced IA vs. controls	p-value*
A*03:01	2.2 (0.9, 5.1)	0.07
B*08:01	0.9 (0.3, 2.6)	0.56
B*15:01	2.2 (0.7, 5.9)	0.12

Immune Related Adverse Events from Immune Checkpoint Inhibitors: A Retrospective Analysis from 2004-2017 at the University of North Carolina at Chapel Hill

Rachel Romero¹, Todd Schwartz², Shruti Saxena Beem¹ and Rumei Ishizawa³, ¹Division of Rheumatology, Allergy and Immunology and the Thurston Arthritis Research Center, University of North Carolina at Chapel Hill, Chapel Hill, NC, ²Department of Biostatistics, Gillings School of Global Public Health, University of North Carolina at Chapel Hill, Chapel Hill, NC, ³Division of Rheumatology, Allergy, and Immunology and Thurston Arthritis Research Center, University of North Carolina at Chapel Hill, Chapel Hill, NC

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster I: Checkpoint Inhibitors, Retroperitoneal Fibrosis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Immune checkpoint inhibitors (ICI) targeting CTLA-4, such as ipilimumab (anti-CTLA4), or PD-1/PD-L1, such as nivolumab and pembrolizumab are increasingly utilized in a wide variety of malignancies including melanoma, head and neck tumors, and small and non-small cell lung cancers. By upregulating the immune system to prevent evasion and promote destruction of cancer cells, these ICI may cause immune related adverse events (irAEs) which mimic autoimmune diseases such as inflammatory arthritis (RA, SLE, PMR), inflammatory bowel diseases (UC, Crohn's), and psoriasis. We sought to gain a better understanding of the range of irAEs that occur from ICI use at our institution including the type, severity, timing from onset of therapy, management, and ultimately how these impact patient outcomes. Better understanding of the irAEs provides a unique opportunity to explore and understand the pathogenesis of autoimmune diseases.

Methods: We identified patients who have received ipilimumab, nivolumab and/or pembrolizumab at UNC between January 2004 through July 9, 2017. We investigated the number of patients started on each immunotherapy and for which indication. Through chart review, we further investigated each type and severity of irAEs, their timing, management, duration, management of cancer therapy and cancer response.

Results: Between January 2004 and July 2017, 116 patients received ipilimumab (most frequently for melanoma in 91.3% of patients), 231 patients received pembrolizumab, and 444 patients received nivolumab. Immune related adverse events occurred in 72.4% of patients who received ipilimumab (52.6% of these patients also received nivolumab either in combination or monotherapy). The most frequent irAE was rash (40.5%), colitis (32.8%), thyroid disease (23.3%), musculoskeletal (MSK) (13.8%), hepatitis (12%) and hypophysitis/adrenal insufficiency (12%). The MSK irAEs were mostly asymmetric medium-large joint arthritis, clinically similar to a seronegative spondyloarthritis variant (68.8%) or proximal myalgias similar to PMR. Treatment of the MSK irAEs consisted of NSAIDs, mild to moderate doses of prednisone, intra-articular steroids, colchicine, hydroxychloroquine, apremilast (in a patient with psoriasis), and one patient eventually required knee replacement. Biologics were more frequently utilized in the treatment of severe grade 3-4 colitis with infliximab 5 mg/kg or vedolizumab. Other irAEs less frequently seen were pneumonitis (4.3%), ophthalmologic (4.3%), severe refractory peripheral neuropathy (4.3%), renal (2.3%), pancreatitis (1.7%), and appendicitis (0.9%).

Conclusion: Our findings among patients treated with ipilimumab and nivolumab were in line with prior studies evaluating the irAE secondary to ICIs with skin and GI manifestations being most frequent. In addition, most patients with MSK

irAEs had asymmetric medium-large joint involvement mimicking a seronegative spondyloarthropathy. We are currently evaluating other subsets including patients who received nivolumab monotherapy or pembrolizumab.

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster I: Checkpoint Inhibitors, Retroperitoneal Fibrosis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The strategy of using monoclonal antibodies to inhibit checkpoints on T cells, and enhance T-cell activity against cancer cells has significantly improved the survival of patients with advanced malignancies, particularly using inhibitors of the checkpoints PD-1 and CTLA-4. Treatment can be complicated by inflammatory and immune-related adverse events (irAE). This large case series reports on eighteen patients' treated with checkpoint inhibitors at three sites in Sydney, Australia and the rheumatic irAE noted. The purpose of the case series is to add the Australian experience into the mix of this emerging clinical entity.

Methods: This study included 18 patients with advanced cancer (15 melanoma, 2 non-small cell lung cancer, 1 renal cell carcinoma) treated at Melanoma Institute Australia, Westmead Hospital or Royal North Shore Hospital, who were referred for rheumatological evaluation from 2013 to 2016. Data was collected retrospectively by medical chart review and examined for the nature of symptoms, time to onset of symptoms, duration of immunotherapy prior to onset of rheumatic irAE, management strategies and treatment outcomes.

Results: The patient characteristics, immunotherapy regimes and presentations are summarised in Table 1 below. Joints affected were mainly large joints associated with tenosynovitis and peri-articular symptoms. Time to onset of symptoms was variable. There were no sex differences. All of these patients had a negative rheumatoid factor (RF) and anti-cyclic citrullinated protein (anti-CCP) antibody. Most patients responded to NSAIDs or low dose prednisone and were able to remain on immunotherapy for their malignancy.

Conclusion: Immunotherapy has an important role in the treatment of advanced malignancies. In our study the rheumatic irAEs appear, in the majority, to be easily managed and patients can remain on treatment with their check point inhibitor. The underlying cause and pathogenesis of these adverse effects remains unknown. Interestingly, the grading systems or guidelines for classification of rheumatic irAEs are much less established than those for gastrointestinal or endocrine manifestations. There is limited experience in the management of rheumatic irAEs and no consensus guidelines on how best to manage these rheumatic irAEs. Progress is required on how to best classify, evaluate, stratify and manage these conditions.

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster I: Checkpoint Inhibitors, Retroperitoneal Fibrosis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Immune checkpoint inhibitor (ICI)-based combinations are showing encouraging results in acute myeloid leukemia (AML) and myelodysplastic syndrome (MDS) treatment; however, ICIs can cause immune-related adverse events, inflammation of one or few organs. Ten percent of AML or MDS patients receiving an ICI develop respiratory complications, one of life-threatening immune related adverse events (irAEs) induced by ICIs. Understanding the mechanism by which pneumonitis occurs is important in risk stratification and early detection, however, this information remains elusive.

Methods: We performed flow cytometry and T cell receptor (TCR) analysis of cells isolated from bronchial alveolar lavage (BAL) fluid and matched blood from seven AML or MDS patients, who received ICI therapy, developed respiratory symptoms, and underwent a standard-of-care bronchoscopy (hereafter, ICI group). In parallel, we collected 22 BAL and matched blood samples from AML or MDS patients who had never been received an ICI. Six of these patients were determined to have documented bacterial or fungal pneumonia, based on the independent review of two independent pulmonologists and an infectious disease specialist, and served as controls.

Results: The ICI group patients developed respiratory symptoms 42.6 ± 62.6 days (mean \pm SD) after the first infusion of an ICI. TCR analysis showed that BAL T cells from the ICI group were clonally expanded compared to control BAL T cells. Immuno phenotyping revealed that BAL CD8⁺ T cells in the ICI group were expanded (ICI vs. control, % within live lymphocytes, mean \pm SD, 24.1 ± 18.3 vs. 5.8 ± 1.2 , $P = 0.02$). These cells were most likely effector memory or terminally differentiated effector memory cells. Compared to BAL CD4⁺ T cells in controls, Th1.17 (CXCR3^{hi} CCR6^{hi}) CD4⁺ T cells, known to be implicated in autoimmune diseases, were expanded in the ICI group (% within live CD4⁺ T cells, 49.4 ± 19.5 vs. 16.8 ± 11.0 , $P = 0.03$). IL-17 producing CD4⁺ T cells were also expanded in BAL in the ICI group (% within non-regulatory CD4⁺ T cells, 15.4 ± 4.8 vs. 7.6 ± 2.8 , $P = 0.03$). Although statistical significance was not reached, Th17 cell-related cytokines were detected in BAL fluid in ICI group at a frequency similar to, or slightly greater than controls. Immunophenotypic characteristics of T cells in blood were comparable between the ICI group and control.

Conclusion: These results suggest that Th1.17 CD4⁺ T cells may play a central role in ICI-associated pneumonitis. Understanding the biology of the Th1.17 CD4⁺ T cell will provide us therapeutic targets and reliable biomarkers of ICI-associated pneumonitis. Furthermore, characterization of Th1.17 CD4⁺ T cells may offer better insights into pneumonitis secondary to the autoimmune diseases.

Session Date: Sunday, October 21, 2018

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster I: Checkpoint Inhibitors, Retroperitoneal Fibrosis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Checkpoint inhibitors (ICIs) are revolutionizing cancer treatment; however, ICI therapy is associated with immune-related adverse events (irAEs). irAEs can be life-threatening and/or severely impair quality of life, necessitating early termination of ICI treatment. Two percent of cancer patients who receive ICI treatment develop arthritis as an irAE (arthritis-irAE). Prompt diagnosis and early intervention are critical in the management of irAE; however, detailed characterization of immune cells in the inflamed tissues, the first step in elucidating the mechanisms of irAEs, is still lacking. Here, we characterize synovial immune cells isolated from patients with arthritis-irAE.

Methods: We analyzed synovial fluid from five patients with arthritis-irAE. As a control, we also analyzed one anonymous pediatric tonsil. We stained lymphoid immune cells with lineage-specific markers and measured effector cytokines in the CD4⁺ T cell populations.

Results: Arthritis developed an average of 270±375 days after the first ICI infusion. Two of the five patients developed arthritis after completion of ICI treatment. Arthritis was treated with systemic prednisone and/or local injection. Three patients achieved complete resolution of arthritis ("steroid responders") while two patients had suboptimal response and needed additional treatment ("steroid non-responders"). The most abundant lymphoid immune cells were CD4⁺ T cells (53.1±13.2% of live immune cells), followed by CD8⁺ T cells, NK cells, $\gamma\delta$ T cells, NK T cells, and B cells. Most CD8⁺ T cells were effector memory or terminally differentiated effector memory cells. All CD4⁺ T cell subsets were identified in the synovial fluid, including regulatory T cells (Treg), naïve T cells, Th1 (CXCR3^{hi} CCR6^{hi}), Th1.17 (CXCR3^{hi} CCR6^{hi}), Th17 (CXCR3^{lo} CCR6^{hi}), and follicular helper T cells (CXCR5⁺). Effector CD4⁺ T cell cytokines, including interferon gamma, IL-4, IL-17, and IL-21, were produced by both Tregs and non-Tregs. Interestingly, IL-17⁺ non-Treg cells were expanded in steroid non-responders compared to steroid responders, indicating that Th17 cells might play a critical role in persistent arthritis-irAE.

Conclusion: Our results suggest that arthritis-irAE can develop at any time during or after the ICI treatment. The observed expansion of IL-17⁺ non-Treg cells in synovial fluid from steroid non-responders suggests that Th17 cells might play a key role in the pathogenesis of arthritis-irAE. Understanding of Th17 CD4⁺ cell biology will provide therapeutic targets and reliable biomarkers for arthritis-irAEs.

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster I: Checkpoint Inhibitors, Retroperitoneal Fibrosis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Immune check point inhibitors (ICIs) targeting programmed cell death-1 (PD-1) and cytotoxic T-lymphocyte associated protein 4 (CTLA-4) have demonstrated improved survival for multiple cancers but have been associated with immune related adverse events (IRAEs). Granulomatosis have been rarely reported.

Methods: We described patients with granulomatous /sarcoid-like reactions among those receiving anti-PD-1(L1) antibody included in the prospective registry REISAMIC ("Registry of Severe Adverse Events of Immunomodulating Monoclonal Antibodies in Oncology") between June 2014 and December 2017.

Results: Out of 657 patients under ICIs, 7 cases (1%) developed sarcoid like reactions. ICI regimens included pembrolizumab (4 patients), nivolumab (3 patients) including one in association with ipilimumab, and one combined with an antiangiogenic tyrosine kinase inhibitor. Five patients had melanoma and 2 patients had renal cell carcinoma. Five patients had partial or complete response under immunotherapy while 2 patients had disease progression. Granulomatous reaction occurred at a median time of 4 months after beginning the ICI. None patient had preexisting sarcoidosis or autoimmune disease. Granulomatosis involved lymph nodes in 7 cases (including lung in 6 cases), skin in 3 cases, and uveitis in 1 case. Patients were often asymptomatic (mediastinal and hilar lymphadenopathy discovered on radiological evaluation). Three patients developed granulomatous lesions on scars. These clinical presentations were highly suggestive of sarcoidosis diagnosis, confirmed by histology (skin biopsy, pulmonary biopsy in 1 case each, ultra sounded guided endobrachial fine needle aspiration in 3 cases, mediastinoscopy in 1 case). All biopsies were performed in order to avoid cancer progression. No other alternative diagnosis was identified. Bronchoalveolar lavage revealed lymphocytic alveolitis in 2 patients. Pulmonary function tests, cardiac evaluation, and calcemia were normal. Angiotensin converting enzyme levels were in the normal range for 6 out of 6 patients. No patient needed corticosteroid treatment while 1 patient required hydroxychloroquine or cutaneous disease. Despite these IRAEs, immunotherapy was continued for 3 patients. Prognosis was good and lymphadenopathy and pulmonary infiltrate and skin granulomas improved in most cases particularly when ICI was stopped.

Conclusion: ICI induced sarcoidosis reactions are rare and most often benign.

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster I: Checkpoint Inhibitors, Retroperitoneal Fibrosis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Immune checkpoint inhibitors have been established as a novel standard treatment for various types of malignancies. However, these new class of drugs have led to increased immune-related adverse events (irAEs) including rheumatic manifestations.

The aim of this study was to determine the risk factors of irAEs in patients treated with anti-programmed death 1 antibody pembrolizumab.

Methods: A retrospective medical record review was performed to identify all patients who received at least one dose of pembrolizumab at Samsung Medical Center, Seoul, Korea between June 2015 and December 2017. Three hundred and ninety-one patients were identified. Multivariate logistic regression model was used to identify risk factors of irAEs.

Results: The median number of cycles of pembrolizumab was two (range, 1-36). The primary malignancies included in the study were lung cancer (n=211, 54.0%), melanoma (n=74, 18.9%), lymphoma (n=53, 13.6%) and others (n=53, 13.6%). Sixty-seven (17.1%) patients experienced clinically significant irAEs; most commonly dermatologic disorders (n=39, 10.0%), pneumonitis (n=11, 2.8%), musculoskeletal disorders (n=10, 2.6%), followed by endocrine disorders (n=7, 1.8%). Fourteen patients (3.6%) experienced serious irAEs (\geq grade 3). Most common serious irAEs were pneumonitis (n=9, 2.3%). There were 4 deaths associated with irAEs, all of which were due to pneumonitis. In univariate logistic regression analysis, body mass index, number of cycles and cumulative dose of pembrolizumab, and baseline neutrophil-lymphocyte ratio were the risk factors of irAEs in pembrolizumab-treated patients. Multivariate logistic regression analysis was performed with variables that were significant in univariate analysis. Higher body mass index and multiple cycles of pembrolizumab were associated with higher risk of irAEs (body mass index: odds ratio [OR] 1.080, 95% confidence interval [95% CI] 1.005-1.161, $P = 0.035$; pembrolizumab cycle: OR 1.153, 95% CI 1.087-1.224, $P < 0.001$). Low neutrophil-leukocyte ratio tended to increase irAE risk, but not statistically significant in multivariate analysis (OR 0.953, 95% CI 0.902-1.007, $P = 0.089$).

Conclusion: To our knowledge, this is the first study to explore the risk factor for irAE in patients undergoing modern cancer immunotherapy. Our study demonstrate that BMI is associated with an increased risk of irAEs in patients treated with pembrolizumab. Also, the number of cycles of pembrolizumab was a risk factor for the development of irAEs. Further studies to investigate the potential mechanisms by which obesity raises irAEs are needed.

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster I: Checkpoint Inhibitors, Retroperitoneal Fibrosis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Immune checkpoint inhibitors (ICI) targeting cytotoxic T lymphocyte antigen 4 (CTLA-4) and programmed cell death 1 (PD-1) and its ligand PD-L1 have had substantial success in treating a variety of cancers. However, immune-related adverse events (irAEs) do occur and can cause significant morbidity and mortality. Although autoimmune (AI) processes share features of irAEs, little research has been done regarding the association between AI serologies and the risk of irAEs. The objective of our review is to determine whether positive AI antibodies (with or without presence of rheumatologic disease) were associated with irAEs and to characterize the nature, severity, and consequences of these irAEs.

Methods: We retrospectively evaluated charts of patients (pts) treated with ICIs at the Ohio State University Comprehensive Cancer Center between 2009 and 2017 under an IRB approved protocol. Those who had known rheumatic antibody testing associated with common rheumatic pathologies before, during or after treatment with ICI were identified. We collected information on pt demographics, clinical and treatment history, and test results to identify exacerbations of existing rheumatologic disease and irAE events. See table 1.

Results: A total of 15 patients were included in this study and received the CTLA-4 inhibitor ipilimumab (Ipi) or anti-PD-1 treatment with nivolumab (nivo) or pembrolizumab (see Table 1). Many were positive for more than one auto-Ab during their treatment course. Twelve pts (80%) had an irAE after a median of 3 cycles and 58% of those patients had documented evidence of positive antibodies prior to the onset of toxicity. Treatment included NSAIDs, steroids, treatment delay, and treatment cessation. Only 4 patients had pre-existing rheumatic diseases; several developed AI irAEs (often multiple) including: arthralgias, hypophysitis, Hashimoto's, and colitis. The pre-existing rheumatic disease patients with melanoma on Ipi had flares of their disease requiring steroids and/or cessation of therapy. A total of 9 patients had Ab drawn before treatment with ICI: 4 positive, and 5 negative. One patient with SCC and pre-existing Lupus suffered respiratory failure and died. None of 5 patients with negative ab had known rheum disease and 4 out of these 5 patients did not have complications. See table 1.

Conclusion: This study adds to the current knowledge about pts with pre-existing rheumatic disease who are treated with ICI. In our study all 4 pts with prior rheum disease developed complications related to treatment.. The role of routine testing for rheumatologic antibodies in unselected patients remains unclear, however close surveillance of patients with pre-existing disease is certainly warranted. Whether a specific profile or pattern of autoantibodies may be useful in the diagnosis and evaluation of suspected irAE remains an area of active investigation.

Immune-Related Adverse Events in Cancer Immunotherapy: How Often Do We See Them?

Valeria Scaglioni¹, Marina Scolnik¹, Jose Maria Lastiri², Lorena Lupinacci² and Enrique R Soriano¹, ¹Rheumatology Unit, Internal Medicine Service. Hospital Italiano Buenos Aires. Argentina, Buenos Aires, Argentina, ²Oncology Service. Hospital Italiano Buenos Aires. Argentina, Buenos Aires, Argentina

Session Information**Session Date:** Sunday, October 21, 2018**Session Title:** Miscellaneous Rheumatic and Inflammatory Diseases Poster I: Checkpoint Inhibitors, Retroperitoneal Fibrosis**Session Type:** ACR Poster Session A**Session Time:** 9:00AM-11:00AM

Background/Purpose: Over the years there has been a huge effort to change the traditional way to treat cancer, that was previously based on chemotherapy and/or radiotherapy. Enhancing the immune system with immunotherapy, instead of suppressing it, has achieved impressive results in some tumors, mainly metastatic melanoma, and nowadays several other tumors are being treated with it. Along with better results regarding tumor control, several immune-mediated adverse events have emerged

Methods: We included retrospectively all patients diagnosed with cancer that received immunotherapy (check point inhibitors) as part of their treatment between January 2014 and June 2018. Immunotherapy includes: monoclonal antibody to CTLA4 ipilimumab, IgG4 programmed death 1 (PD-1) inhibitor antibody nivolumab and pembrolizumab. There were no patients receiving IgG4 programmed death 1 ligand (PDL-1) inhibitor antibody atezolizumab, avelumab or durvalumab. We reported all immune-mediated adverse event (IMAE), time to first IMAE, treatment received, response to treatment, discontinuation of immunotherapy and deaths.

Results: A total of 27 patients, (54.5% males) were included. Type of tumor, name of check point inhibitor received, type of IMAE, time to first IMAE, treatment and response are summarized in table 1. We observed a total of 11 (40.7%, CI 95% 23.2-60.9) IMAE. Incidence density rate was 120.9 (100 person-year). The most frequent were hematologic and dermatologic adverse events. Most of the IMAE were mild to moderate, 27.3% required treatment, with 66% of response. Among the rheumatologic related IMAE, there were only arthritis and Sicca syndrome, the last one being the most frequent and generally mild, with no need for treatment. 2 patients presented with arthritis, one of them required methotrexate because of persistent arthritis. No specific autoantibodies were found. Only 1 out of 5 patients with rheumatic IMAE was sent to a rheumatologist for treatment, all others were managed by oncologists. No patients were evaluated by a rheumatologist before started immunotherapy.

Conclusion: immune-mediated adverse events related to check point's inhibitors are a new entity and oncologist and rheumatologist must be aware of them. Rheumatic IMAE had a frequency of 27.3%, with Sicca syndrome and seronegative arthritis as the only manifestations in our cohort.

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster I: Checkpoint Inhibitors, Retroperitoneal Fibrosis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The clinical use of immune checkpoint inhibitors (ICI) has led to outstanding clinical outcomes in previously refractory cancers, but ICI have also been associated with off-target side effects collectively known as immune related adverse events (irAE). Any organ system can be affected by these events during or after cessation of these therapies. Although management of these adverse events with immunosuppression is usually successful, our understanding of the underlying pathophysiology is incomplete. Furthermore, our ability to predict which patients will develop irAE is limited. The purpose of this study was to identify predictive biomarkers of irAE in cancer patients initiating ICI.

Methods: Patients with advanced cancer scheduled to begin treatment with ICI were recruited from a tertiary care oncology centre. A detailed review of their electronic medical record was performed to record demographics, disease details, and treatment history (including drug names, start and stop dates, last dose, disease response). Serum was collected prior to initiating ICI therapy. Anti-nuclear antibodies (ANA) were detected using a common platform in the Mitogen Diagnostics Lab (Calgary, AB) and cytokines/chemokines were measured using a Human Cytokine/Chemokine 65-Plex panel (Eve Technologies, Calgary, Alberta). Subjects were followed prospectively and any irAE, defined by Common Terminology Criteria for Adverse Events (CTCAE), were recorded. Associations between clinical and serological biomarkers, and irAE were analyzed using *t* tests and ANOVA.

Results: A total of 26 patients with advanced cancer were enrolled in this study. The mean age was 60 years old and 9/26 (35%) were female. Cancer types included melanoma (n = 13), renal carcinoma (n = 7), non-small cell carcinoma (n = 2), ovarian cancer (n = 2), Merkel cell carcinoma (n = 1), anal carcinoma (n = 1). All patients received therapeutic blockade of either PD-1 (n = 22) or PD-L1 (n = 4). irAEs occurred in 15/26 (58%) of the patients as follows: dermatitis (n = 1), colitis (n = 3), hepatitis (n = 2), hypothyroidism (n = 6), pneumonitis (n = 2), and type 1 diabetes mellitus (n = 1). The distribution of irAE grades were as follows (CTCAE grade 1 irAEs were excluded): CTCAE grade 2 (n = 9) and CTCAE grade ≥ 3 (n = 6). While males developed more grade 2 irAEs (n = 8), females developed more severe grade 3 irAEs (n = 4). Tumor type and the presence of ANA were not found to predict the development of irAE. On the other hand, sCD40L (p = 0.0413), PDGF-A (p = 0.0215) and PDGF-B (p = 0.007) were significantly higher prior to initiating ICI in patients who developed irAE compared to those who did not.

Conclusion: These findings identify sCD40L, PDGF-A and PDGF-B as potential predictive biomarkers for the development of irAE in patients receiving ICI treatment for advanced cancer. Interestingly, although it has been shown that sCD40L is elevated in advanced cancers such as non-small cell lung cancer and also in various autoimmune disease, these data are the first to implicate it as a predictive biomarker for irAE development. The mechanisms by which these biomarkers participate in the onset of irAE needs to be explored.

Session Date: Sunday, October 21, 2018

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster I: Checkpoint Inhibitors, Retroperitoneal Fibrosis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: To analyze the clinical spectrum, laboratory characteristics, and outcomes of monoclonal gammopathy (MG) in patients with rheumatic diseases.

Methods: Screening for the presence of MG was performed in 872 in patients with rheumatic diseases from January 2010 to July 2017. A total of 41 patients were enrolled. Their clinical and biological features in addition to outcomes were described. For each patient with primary Sjögren syndrome (pSS), 2 age- and sex-matched pSS patients without MG were selected as controls. Risk factors for the presence of MG and malignant hematological neoplasias were assessed.

Results: MG was observed in patients with SS, rheumatoid arthritis, systemic lupus erythematosus, ankylosing spondylitis, primary biliary cirrhosis, polymyositis, hypomyopathic dermatomyositis, psoriatic arthritis, ANCA-associated vasculitis, polyarteritis nodosa, and polymyalgia rheumatic, with SS the most frequent type. Serum M protein was detected in 37 patients. The monoclonal bands identified in serum were 16 IgG (5 κ , 11 λ), 11 IgA (6 κ , 5 λ), 6 IgM (5 κ , 1 λ), and 4 free λ chains. M components were observed in urine in the other 4 patients. High ESR, albumin/globulin inversion, rheumatoid factor positivity, hypergammaglobulinemia, and hypocomplementemia were common features, presented in more than half of the 41 patients. Patients with pSS, when complicated with MG, showed a higher rate of abnormal urine NAG (71.4 vs 15.8%, $P = 0.025$), higher levels of ESR [55.0 (53.5) mm/h vs 21.0 (31.8) mm/h, $P = 0.001$], ESSDAI [26.0 (25.0) vs 12.0 (9.0), $P = 0.006$], and ClinESSDAI scores [24.0 (25.0) vs 10.5 (10.0), $P = 0.011$]. Multivariate analysis revealed that the disease activity, assessed by either ESSDAI [adjusted OR 1.127 (95%CI 1.015–1.251), $P = 0.025$] or ClinESSDAI [adjusted OR 1.121 (95%CI 1.011–1.242), $P = 0.030$], was the only independent risk factor for the presence of MG. During the follow-up, 2 patients had transient serum M protein, 2 had isotype switch, 1 progressed to multiple myeloma (MM), and another 2 experienced renal injuries attributed by monoclonal or polyclonal plasma cell interstitial infiltration. Seven (17.1%) of the 41 MG patients presented hematological neoplasias, 4 with MM, 2 with smoldering multiple myeloma, and 1 with B cell lymphoma of mucosa-associated lymphoid tissue (MALT) type. The presence of light-chain MG was associated with the development of MM [OR 17.5 (95%CI 1.551–197.435), $P = 0.041$], but not with an increased risk of lymphoma or SMM.

Conclusion: MG was observed in patients with various rheumatic disorders, with SS being the most common type. The presence of MG might be associated with higher disease activity. The development of hematological neoplasias including MM and lymphoma was seen in this setting. Therefore, we recommend the screening for MG and close monitoring for potential malignant transformation in patients with rheumatic diseases as needed.

Abstract Number: 366

Infectious Complications of Immunosuppressive Therapy in Patients with Common Variable Immunodeficiency (CVID) and Inflammatory Arthritis

Fatima Alduraibi¹, Monica Lawrence², Larry Borish² and Adam Carlson³, ¹Department of Medicine, University of Virginia Health System, Charlottesville, VA, ²Department of Medicine, Division of Allergy and Immunology, University of Virginia Health System, Charlottesville, VA, ³Department of Medicine, Division of Rheumatology, University of Virginia Health System, Charlottesville, VA

Session Information**Session Date:** Sunday, October 21, 2018**Session Title:** Miscellaneous Rheumatic and Inflammatory Diseases Poster I: Checkpoint Inhibitors, Retroperitoneal Fibrosis**Session Type:** ACR Poster Session A**Session Time:** 9:00AM-11:00AM

Background/Purpose: Common variable immunodeficiency (CVID) is one of the most common symptomatic primary immunodeficiency syndrome with an incidence of ~1 in 25,000 people. CVID is a heterogeneous collection of syndromes, which are all characterized by impaired B-cell differentiation, resulting in defective immunoglobulin production and an increased susceptibility to infection. Autoimmune conditions are common in CVID, and the prevalence of autoimmune-associated inflammatory arthritis in patients with CVID is estimated to be around 10%. This study aims to further delineate the features of autoimmune inflammatory arthritis in patients with CVID.

Methods: Using ICD-9 and ICD-10 diagnostic codes, we identified patients with CVID at the University of Virginia from 2007 to 2018. We then reviewed individual charts to identify the patients who met the Revised European Society for Immunodeficiency (ESID) criteria for CVID. From this cohort of patients, we identified those who met the criteria for any one among various autoimmune inflammatory arthropathies. We reviewed the charts of the patients who met all these criteria for details on the treatment and outcomes of both autoimmune inflammatory arthritis and CVID.

Results: A total of 95 patients met the strict criteria for CVID. Of these, six patients (6.31%) were found to have autoimmune inflammatory arthritis; four had rheumatoid arthritis (RA) and two had psoriatic arthritis (PsA). The male-to-female ratio was 1:1. All the patients were non-Hispanic and Caucasian. All the patients were non-Hispanic and Caucasian. The median time between the diagnoses of autoimmune arthritis (median age = 44.5 years) and CVID (median age = 52.5 years) was 129 months (10.7 years). Four patients (66.6%) were initially diagnosed with autoimmune arthritis and had rheumatoid arthritis. Of these, three patients were on methotrexate and two patients were managed with anti-TNF and abatacept. Five patients (83.3 %) received intravenous immunoglobulin (IVIG). Of all of the patients diagnosed with CVID and autoimmune arthritis, none developed a major infection (requiring a lengthy course of antibiotics or hospitalization) while on treatment. Two patients (33.3%) developed other autoimmune diseases, namely, autoimmune thrombocytopenia (ITP) and autoimmune thyroiditis.

Conclusion: Autoimmune inflammatory arthritis was present in 6.31% of the patients in our CVID cohort. Despite the majority of patients being on immunosuppressants and IVIG, none of them developed a major infection during the study. To our knowledge, this study is the first to address the risk of infection in patients with CVID who received immunosuppressants and IVIG. However, the conclusions were limited by the low sample size. Therefore, there is a need for a prospective longitudinal cohort study. Increased vigilance for autoimmune arthritis complications is important as survival outcomes are worse in CVID patients with non-infectious complications. Further evaluation of these patients to understand the mechanism underlying immune dysregulation is essential, as this may promote targeted therapies and improve clinical outcomes.

Abstract Number: 367

Incidence of Inflammatory Bowel Disease (IBD) Among Patients (Pts) with Other Chronic Inflammatory Diseases (CID) Treated with Interleukin-17a (IL-17a) or Phosphodiesterase 4 (PDE4) Inhibitors

Bruno Emond¹, Lorie A. Ellis², Soumya D Chakravarty³, Martin Ladouceur¹ and Patrick Lefebvre¹, ¹Analysis Group, Inc., Montréal, QC, Canada, ²Janssen Scientific Affairs, LLC, Horsham, PA, ³Janssen Scientific Affairs, LLC/Drexel University School of Medicine, Horsham/Phila, PA

Session Information**Session Date:** Sunday, October 21, 2018**Session Title:** Miscellaneous Rheumatic and Inflammatory Diseases Poster I: Checkpoint Inhibitors, Retroperitoneal Fibrosis**Session Type:** ACR Poster Session A**Session Time:** 9:00AM-11:00AM

Background/Purpose: IBD is often associated with other CID, such as rheumatoid arthritis (RA), psoriatic arthritis (PsA), ankylosing spondylitis (AS), and psoriasis (PsO). Newer biologic agents such as IL-17a inhibitors and small molecule inhibitors targeting PDE4 have been shown to be useful to treat PsA and PsO with both, and AS with the former. However, real-world evidence of IBD co-occurrence in pts with CID treated with IL-17a/PDE4 inhibitors is scarce. To compare the incidence of IBD (i.e., Crohn's disease and ulcerative colitis) between pts with CID not treated with a biologic agent and those treated with IL-17a/PDE4 inhibitors.

Methods: Adults with ≥ 2 claims with a diagnosis of either RA, PsA, AS, or PsO and ≥ 12 months of continuous health plan enrollment pre- (baseline period) and post-index date (random date among CID claims) were selected from the MarketScan® Research Database (1/2010-7/2017). Pts with cancer treated with rituximab or ofatumumab, with a transplant, or with ≥ 2 baseline claims with a diagnosis of IBD were excluded. The 1-year and 2-year incidence of IBD (defined as ≥ 2 IBD claims) was evaluated post-index among pts with no baseline claim for biologics and pts treated with IL-17a/PDE4 inhibitors during the baseline period. Comparison of IBD incidence between the two cohorts was done using a logistic regression model adjusting for baseline characteristics (including type of CID).

Results: In total, 424,767 pts were not treated with biologics (mean age: 54.4 years; 63.0% female) and 2,489 were treated with IL-17a/PDE4 inhibitors (mean age: 50.3 years; 54.6% female). The 1-year incidence was 0.7% in pts treated with IL-17a/PDE4 inhibitors and 0.5% in pts not treated with biologics (unadjusted odds ratio [OR]=1.54, P=0.0680). Among pts with ≥ 2 years post-index (nobiologics: n=208,853; IL-17a/PDE4-4: n=362), the 2-year incidence was 1.7% in pts treated with IL-17a/PDE4 inhibitors and 0.8% in pts not treated with biologics (unadjusted OR=2.16, P=0.0625). After adjustment, pts treated with IL-17a/PDE4 inhibitors were more likely to develop IBD than pts not treated with biologics at both 1 year (adjusted OR=1.77, P=0.0187) and 2 years (adjusted OR=2.29, P=0.0477). Similar trends were found when excluding pts with RA only (1-year incidence: adjusted OR=1.80, p=0.0161; 2-year incidence: adjusted OR=2.32, p=0.0438).

Conclusion: Higher IBD incidence was found in CID pts treated with IL-17a/PDE4 inhibitors compared to those not treated with biologics.

Synovial Analysis Using Leukocyte Esterase Reagent Strips

Samantha Rodriguez-Muguruza¹, Cristian Morales², Susana Malumbres², Alicia Martinez², Alejandro Olivé-Marqués³, Susana Holgado³, Maria Lourdes Mateo⁴ and Melania Martinez-Morillo⁵, ¹Rheumatology, Hospital Verge de la Cinta, Tarragona, Spain, ²Clinical Biochemistry Service, Germans Trias i Pujol Hospital, Barcelona, Spain, ³Rheumatology, Hospital Universitari Germans Trias i Pujol, Badalona, Spain, ⁴Rheumatology, Hospital Germans Trias i Pujol, Badalona, Spain, ⁵Rheumatology, Germans Trias i Pujol University Hospital, Barcelona, Spain

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster I: Checkpoint Inhibitors, Retroperitoneal Fibrosis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The analysis of synovial fluid (SF) is an important tool to study joint diseases. SF is classified into non-inflammatory, inflammatory and septic according to white blood cell (WBC) count. This classification is essential to start the diagnostic process, and to determine whether a rheumatologist evaluation is required. When SF is removed, the WBC decreases with time; an inflammatory liquid could become a false non-inflammatory one in hours. Reagent strip testing of urine is a validated tool to diagnose urinary tract infection, via the detection of leukocyte esterase activity. It has been used to analyze other biological fluids occasionally. SF test immediately performed after an arthrocentesis using reagent strips could have potential benefits as a screening tool.

Methods: Prospective study. We analyzed SF samples collected successively from patients in a tertiary university Hospital (November 2015 to April 2018). All samples were tested within 1 hour after their collection. We analyzed: Visual appearance, WBC (measured by manual leukocyte method), synovial glucose and total protein. Leukocyte esterase was measured by reagent strip test. It was recorded semiquantitatively as a number of plus signs (negative, 1+, 2+ or 3+) using standard color chart found on the container's label. The cut-off for the WBC by manual leukocyte counting over than 2000 cells/mm was used to differentiate between inflammatory and non-inflammatory specimens. We decided to classify as inflammatory SF the ones with 1+ or more in the leukocyte esterase pad. We compared the WBC (reference standard diagnostic test) with the presence of leukocyte esterase using the leukocyte esterase reagent.

Results: 303 joint fluid samples were analyzed. According to manual leukocyte counting 147 (48.5%) were non-inflammatory and 156 (51.5%) inflammatory. Of the inflammatory fluids: 144 (92.3%) were positive according to leukocyte esterase reagent. Of the mechanical fluids: 95 (65.5%) were negative according to leukocyte esterase reagent. The sensitivity and specificity of leukocyte esterase reagent was 92.3% and 64.6% respectively. The PPV was 73.5% and NPV was 88.8%. The 12 false-negative results (negative by leukocyte esterase reagent but more than 2 000 leukocytes/mm³)

showed a predominance of mononuclear cells (62.2%), the median WBC count was 4017.7/mm³ and median polymorphonuclear cells percentage was 33.5%, all cultures were negatives. For inflammatory fluids: semi-quantitative results (negative, 1+, 2+ and 3+) were significantly different regarding the mean WBC, mononuclear cells, polymorphonuclear cells count and glucose. We found 20 hemorrhagic SF; the presence of erythrocytes did not alter the results.

Conclusion: Our results demonstrate that leukocyte esterase reagent strips are a rapid, cheap, and sensitive tool to identify inflammatory SF. Leukocyte esterase reagent strips had an excellent sensitivity but a poor specificity, so they could be used as a screening tool in primary care practice or in rural or poor areas. A positive result indicates an inflammatory process, so the patient should be referred to a rheumatologist.

Abstract Number: 369

Association of Retroperitoneal Fibrosis with Malignancy and the Pathologic Features of Malignancy with Retroperitoneal Fibrosis

Sang Jin Lee¹, Eon Jeong Nam², Yeong Wook Song³ and Young Mo Kang⁴, ¹Internal medicine, Kyungpook National University Chilgok Hospital, Daegu, Korea, Republic of (South), ²Internal Medicine, Kyungpook National University Chilgok Hospital, Daegu, Korea, Republic of (South), ³Dept of Internal Medicine, Seoul National Univ, Seoul, Korea, Republic of (South), ⁴Dept of Internal Medicine, Kyungpook National Univ Hosp, Daegu, Korea, Republic of (South)

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster I: Checkpoint Inhibitors, Retroperitoneal Fibrosis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Retroperitoneal fibrosis (RPF) is a periaortic sclerotic disease that encases adjacent structures, particularly the ureters. Because it is unclear whether RPF is associated with malignancy, we examined standardized incidence ratios (SIRs) of cancers in patients with RPF compared with age- and sex-matched general population. Subsequently, pathological differences between malignancy with RPF and malignancy without RPF were investigated.

Methods: Medical records of 111 patients diagnosed as having RPF by computed tomography, positron emission tomography (PET), and/or histological evaluation were reviewed. Forty one cases of cancers, which were confirmed by biopsies, were identified in 35 patients with RPF. Cancer incidence rates were calculated and compared with that observed in the Korean general population, computing the standardized incidence ratios (SIRs), which were then stratified according to RPF-cancer intervals. Cancer specimens with RPF (n=3) and cancer specimens without RPF (n=15), which were controls for age, sex, and cancer stage, were examined for the expression of interleukin (IL)-4, IL-10, PD-1, PD-L1, and IgG4/IgG by immunohistochemistry (IHC).

Results: The mean \pm SD age at RPF diagnosis was 59.2 \pm 15.0 years, and 69.4% of the patients were male. Ninety two cases (82.9%) showed peri-aortitis, and 65 cases (58.6%) presented with hydronephrosis. The cancer SIR (95% confidence intervals) in patients with RPF relative to age- and sex-matched individuals in the general population was 3.18 (2.23-4.41) [2.65 (1.70 - 3.94) in men; 5.34 (2.76 - 9.32) in women]. The most frequent cancer was unspecified urinary organ cancers with SIR of 733 (238 - 1711). SIRs of multiple myeloma [27.6 (3.34 - 99.6)], renal cell cancers [9.53, (1.15-34.4)] and adenocarcinoma of unknown primary cancers [16.9, (2.05 - 61.1)] were also significantly higher than in the general population. When stratified by RPF-cancer intervals, SIR was 10.4 (6.59 - 15.60) within 1 year of RPF diagnosis, while no significant increase in SIR was found out of 1 year around RPF. IHC analysis showed that the expressions of IL-4 and IL-10 in cancer tissues with RPF were higher than those in cancer tissues without RPF. However, there are no differences in the expression of PD-1, PD-L1 and IgG4/IgG between cancer tissues with RPF and those without RPF.

Conclusion: RPF was strongly associated with cancers within 1 year of RPF diagnosis. Immune environment of cancer tissues with RPF is different from that without RPF. That may contribute to the occurrence of RPF.

Rituximab in Idiopathic Retroperitoneal Fibrosis

Veronika Boyeva¹, Hatim Alabsi², Michael Seidman³, Ryan Paterson⁴, Jason Kur⁵, Silvia Chang⁶, Luke Chen⁷ and Mollie Carruthers⁵, ¹Department of Medicine, University of British Columbia, Vancouver, BC, Canada, ²Department of Radiology, King Abdulaziz University, Jeddah, Saudi Arabia, ³Pathology and Laboratory Medicine, University of British Columbia, Vancouver, BC, Canada, ⁴Department of Urology, University of British Columbia, Vancouver, BC, Canada, ⁵Rheumatology, University of British Columbia, Vancouver, BC, Canada, ⁶Department of Radiology, University of British Columbia, Vancouver, BC, Canada, ⁷Department of Hematology, University of British Columbia, Vancouver, BC, Canada

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster I: Checkpoint Inhibitors, Retroperitoneal Fibrosis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Retroperitoneal fibrosis (RPF) is a rare disease characterized by the proliferation of fibrous tissue in the retroperitoneum, most commonly surrounding the aorta from the renal vessels to the branching of the iliac arteries. RPF has a number of etiologies, which include idiopathic, IgG4-related, infectious, malignant, and drug-induced. However, the majority of cases are of either idiopathic or IgG4-related disease. Recent studies on IgG4-related disease have shown rituximab to possibly be an effective treatment. However, the current first-line treatment for idiopathic RPF (iRPF) is glucocorticoid therapy. Relapse rates vary widely in the literature after discontinuation of treatment, and DMARDs remain poorly studied. We sought to evaluate the efficacy of rituximab in idiopathic RPF by quantifying changes in iRPF diameter on imaging pre- and post-rituximab therapy in ten iRPF patients as well as response by lab parameters.

Methods: This study was approved by the ethics review board at the University of British Columbia. All except one patient had histopathologic proof of their idiopathic RPF diagnosis. All patients had clinical and imaging features consistent with the diagnosis. All patients were previously treated with rituximab (1000mg) in two doses approximately 2 weeks apart. Pre- and post-therapy contrast enhanced cross-sectional abdomen and pelvis imaging were compared, of which 17 were CTs and one was an MRI. In all patients, the thickest portion of the peri-aortic disease was measured in the axial plane. The presence of acute and/or long standing unilateral or bilateral back pressure related renal findings were also documented (e.g. hydronephrosis, presence of stents, and renal atrophy). Details of clinical visits including patient demographics, symptoms, biopsies and laboratory evaluations were also collected pre- and post-therapy. Statistical analysis was performed using a Student's t-test. A probability of $p < 0.05$ was considered statistically significant.

Results: A comparison of pre and post-rituximab imaging studies were available in nine patients and revealed a statistically significant decrease in iRPF diameter following treatment with rituximab. The RPF diameter around the aorta before and after therapy decreased from a mean of 16.4 ± 4.9 cm to 10.8 ± 6.5 cm, respectively ($p=0.016$). The craniocaudal iRPF mean length decreased from 110.1 ± 42.6 to 94.0 ± 47.3 ($p=0.027$). The GFR increased from 62.1 ± 13.1 to 64.8 ± 15.6 , the creatinine decreased from $108.9 \mu\text{mol/L} \pm 17.1$ to 105.4 ± 20.2 , and the CRP decreased from $15.7 \text{ mg/dl} \pm 16.4$ to 4.3 ± 5.2 when comparing mean values before to after therapy, respectively, but non-significantly.

Conclusion: There were statistically significant improvements in iRPF diameter following treatment with rituximab. Rituximab requires further study to establish its role in treating idiopathic RPF.

Therapeutic Efficacy and Safety of Igaratimod in Treating Mild IgG4-Related Diseases

Wen Zhang¹ and Panpan Zhang², ¹Rheumatology, Peking Union Medical College Hospital, Beijing, China, ²Department of Rheumatology, Peking Union Medical College Hospital, Beijing, China

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster I: Checkpoint Inhibitors, Retroperitoneal Fibrosis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: To evaluate the therapeutic efficacy and safety of Iguratimod in the treatment of mild IgG4 related disease (IgG4-RD).

Methods: Thirty patients with newly diagnosed mild IgG4-RD were enrolled. One initial dose of diprospan, intramuscular injection, and Iguratimod, 25 mg, twice daily, at 0, 12 and 24 weeks, patients were followed up. Follow up indexes including physician global assessment (PGA), IgG4-RD responder index (IgG4-RD RI), serology and imaging, plasma cytokines and adverse drug effect. Flow cytometry technology was performed for the detection of T, B-cell subsets and plasma cells before and after treatment in patients.

Results: The ages of thirty-four patients with newly diagnosed mild IgG4-RD were 50.83 ± 10.24 years old, and disease duration was 31.5 (8-66) months. The ratio of male to female was 1:1. The IgG4-RD RI of patients assessed at 0 weeks was 10.47 ± 3.98 . There was a significant decrease of IgG4-RD RI in patients following up at 12 weeks and 24 weeks, which was 3.60 ± 2.44 , 3.13 ± 1.71 , $P < 0.0001$. Serum IgG and IgG4 levels at baseline were 22.16 ± 9.54 g/L and 12250(5568-15625) mg/L, respectively. The IgG level at week 12 and week 24 was 15.42 ± 6.15 g/L and 15.43 ± 5.93 g/L respectively, and the IgG4 level was 4725 (2738-8748) mg/L and 6020(2613-11450) mg/L, which showed significantly reduction of serum IgG and IgG4, P values were both < 0.0001 respectively. After treatment, CD3+CD8+ T cells, plasmablast/plasma cells (surface markers as CD19+CD24-CD38hi, CD19+CD27hiCD38hi, CD19+IgD-CD38hi), and CD19+IgD-CD38-CD27+ memory B cells all decreased significantly. The percentage of CD19+IgD+CD38+/- naïve B cells increased after treatment. there were no significance of CD4+CXCR5+ ICOS+ and CD4+CXCR5+PD-1+ TFH, CD19+ total B cells, CD19+CD24hiCD38hi regulatory B cells, CD138+CD38+ plasma cells, CD4+IFN- γ + Th1, CD4+IL17-A+ classical Th17 cells, CD4+ IL-17A+IFN- γ + Th1-like Th17 cells before and after treatment with Iguratimod. Of 30 patients, 23(76.7%) patients had complete remission of clinical symptoms, 3(10.0%) patients had partial remission, and 4 (13.3%) patients had no response to Iguratimod treatment. According to adverse drug reaction, 3 had oral ulcers, two had stomach discomfort, 1 had mild hair loss, and others were well tolerated and had no significant adverse drug reaction.

Conclusion: Iguratimod is effective for the treatment of mild IgG4-RD, it can improve the clinical symptoms of patients, reduce the serum IgG and IgG4 levels, and can also reduce the peripheral blood CD3+CD8+ T, especially plasmablasts/plasma cells, memory B cells, and up-regulate naïve B cells. Besides, Iguratimod can also reduce the plasma IFN- γ levels. So we recommend that it can be used as a first-line treatment for some patients with mild IgG4-RD.

Arterial Involvement in Erdheim-Chester Disease: A Retrospective Cohort Study

Michel Villatoro-Villar¹, Michael Bold², Kenneth J. Warrington³, Cynthia S. Crowson⁴, Gaurav Goyal⁵, Mithun Shah⁵, Ronald Go⁵ and Matthew J. Koster¹, ¹Rheumatology, Mayo Clinic, Rochester, MN, ²Radiology, Mayo Clinic, Rochester, MN, ³Rheumatology, Division of Rheumatology, Mayo Clinic College of Medicine, Rochester, MN, ⁴Department of Health Sciences Research, Mayo Clinic, Rochester, MN, ⁵Hematology, Mayo Clinic, Rochester, MN

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster I: Checkpoint Inhibitors, Retroperitoneal Fibrosis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Erdheim-Chester disease (ECD) is a rare histiocytosis of the "L" (Langerhans) group with multisystem involvement that can affect the large and medium sized arteries mimicking vasculitis. Aortic involvement is common but the frequency and outcome of aortic branch vessel abnormalities are less well described.

Methods: Patients diagnosed with ECD from January 1, 1998 to July 31, 2016 were retrospectively identified. Images containing information of arterial involvement within six months of diagnosis were considered baseline and compared to last follow-up studies. Two physicians independently reviewed the studies to evaluate for presence of abnormalities

attributable to ECD. Age and sex adjusted logistic regression models were used to examine associations between patient characteristics and vessel involvement at baseline.

Results: Among a cohort of 64 patients with ECD, 63 had baseline imaging of vascular structures. ECD involvement of at least one segment of the aorta was observed in 56%. Abnormalities were also observed in aortic arch branches (26%), visceral branch arteries (40%), iliofemoral arteries (31%), coronary (5%) and pulmonary (3%) arteries. Perinephric fibrosis was strongly associated with the identification of abnormalities in the thoracic aorta [OR 4.92 (1.54, 15.75); $p=0.007$], abdominal aorta [OR 7.57 (2.28, 25.07); $p=0.001$] and visceral branch arteries [OR 6.05 (1.52, 24.03); $p=0.01$] but not pelvic/lower extremity arteries.

A total of 47 patients had follow-up imaging of arterial structures. The majority of arterial segments affected at baseline did not have significant radiographic change during the follow-up evaluation. Partial response was observed in 11% of patients with baseline abnormalities seen in the infra-renal abdominal aorta and 6% of patients with baseline aortic arch, descending thoracic aorta, and supra-renal abdominal aorta involvement, respectively. The remainder of arterial segments had partial response detected at a frequency of less than 5%. Complete normalization of arterial abnormalities at follow-up was only observed in 9% or less of arterial segments involved at baseline. Development of arterial involvement after diagnosis in patients with normal baseline arteries was similarly infrequent but occurred most often in the pulmonary arteries (11%), celiac artery (9%), right iliac (7%), left iliac (7%) and right femoral (5%). Eight patients required intervention with arterial endovascular stenting or bypass. At last follow-up 12 (19%) patients were deceased. Of the 9 patients for which cause of death was known, only 3 patients died from cardiovascular causes.

Conclusion: Aortic and aortic branch vessel abnormalities are frequently observed in patients with ECD and are often asymptomatic. Partial and/or complete resolution of arterial findings is uncommon.

Session Title: Muscle Biology, Myositis and Myopathies Poster I: Clinical Features and Disease Course

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Muscle inflammation and weakness, subsequent atrophy and permanent muscle damage in idiopathic inflammatory myopathies (IIM) lead to impaired function, reduced muscle strength, endurance and aerobic capacity, decreasing quality of life. Data on the effectiveness of non-pharmacological care in IIM are limited due to heterogeneity of studied interventions/outcomes. The aim of our study was to minimize the limitations of available studies and to determine the effect of an intensive exercise program on muscle strength and endurance and the quality of life in cohorts with a substantial number of IIM patients.

Methods: All patients were non-selectively consecutively recruited into intervention (IG) and control (CG) group and they had impaired skeletal muscle strength. They fulfilled the Bohan and Peter 1975 diagnostic criteria. Patients from both groups received educational material for home exercises, but only the IG underwent a six-month intensive ADL (activities of daily living) and muscle strength exercise program with a subsequent six-month follow-up period. All patients were evaluated by a physician and physiotherapist blinded to intervention at 0, 3, 6 and 12 months. Patients also filled out

patient reported outcomes/questionnaires and provided blood for routine laboratory analysis and biobanking. Data analysis was performed between groups and within the group.

Results: In total 27 patients were included in the IG and 23 patients in the CG. Compared to the observed statistically significant deterioration in the CG over the period of 0-6 months, we found a statistically significant improvement in IG in objectively assessed muscle strength and endurance as well as in subjectively assessed functional abilities (HAQ) and depression (BDI-II). During the follow-up period, there was a significant deterioration or stagnation of the achieved results in the IG. However, improved functional abilities during the intervention period persisted in the IG even in the follow-up period. Only numerical improvements in the IG compared to numerical deterioration in CG, that did not achieve statistical significance, during the intervention period, were observed in some subjectively assessed patient reported outcomes assessing quality of life and fatigue.

Conclusion: Our program led to a significant improvement in the observed parameters that was clinically significant in a substantial proportion of patients (in the IG) and prevention of the expected worsening in muscle strength and endurance (observed in the CG).

Acknowledgments: The project was supported by AZV-16-33574A, SVV for FTVS UK 2019-260466, MHCR 023728

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Muscle Biology, Myositis and Myopathies Poster I: Clinical Features and Disease Course

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Nailfold videocapillaroscopy (NVC) is a non invasive and useful method to assess peripheral microvascular status and evaluate patients with connective tissue diseases (1). Microvascular involvement was clearly

described in systemic sclerosis (SSc) (2-4), but may be detected also in patients with dermatomyositis (DM) (5,6). Only few studies described the main NVC changes over time in this last clinical condition (5,6). The aim of this retrospective study was to compare the NVC findings between DM and SSc at first NVC, and to identify NVC changes in patients with DM during a 3 year follow-up.

Methods: Twenty-four DM (mean age 54 ± 15 SD years; disease duration 4 ± 5 years; 4 males and 20 females) and 24 SSc patients, matched for age and disease duration at first NVC were retrospectively evaluated. NVC was yearly performed by the same operator, and capillary parameters scored as reported in the literature (2-4). Clinical aspects and treatments were recorded. Non parametric test were used to carry out statistical analysis.

Results: Nineteen out of 24 DM patients (79%) showed a NVC “scleroderma-like pattern”. Comparing at baseline DM with SSc patients, the giant capillary and microhaemorrhage scores were significantly higher in SSc than in DM patients (1.42 ± 0.58 vs 1.00 ± 0.72 , $p=0.04$, and 1.00 ± 0.66 vs 0.67 ± 0.56 , $p=0.05$ respectively), while capillary density, ramification (abnormally shaped capillaries, expression of angiogenesis) and disorganization scores were higher in DM patients (1.54 ± 0.72 vs 1.12 ± 0.85 , $p=0.05$; 1.79 ± 1.02 vs 0.79 ± 1.02 , $p=0.002$; 1.67 ± 0.82 vs 0.83 ± 1.01 , $p=0.004$, respectively). Accordingly, the absolute number of ramified capillaries was significantly higher in DM patients (1.92 ± 1.06 vs 0.88 ± 1.08 , $p=0.002$), while the absolute capillary number was significantly higher in SSc patients (6.83 ± 2.18 vs 5.62 ± 1.95 , $p=0.05$) at baseline. No statistically significant variations of all the capillaroscopic scores were observed during the 3 year follow-up in DM patients. By comparing DM patients with or without anti-Jo-1 antibody positivity, no statistically significant differences of the scores of the main capillary parameters were observed at baseline between the groups. However, anti-Jo-1 positive patients showed a statistically significant decrease of capillary ramifications at T2 (score 1.4 ± 1.1 vs 2.6 ± 0.7 , $p=0.05$) and T3 (1.0 ± 0.0 vs 2.6 ± 0.5 , $p=0.03$), when compared with the anti-Jo-1 negative group.

Conclusion: This study demonstrates that DM and SSc display different capillaroscopic features. The capillaroscopic manifestations of DM persist in contrast to the progressive changes described in SSc patients (4), and the anti-Jo-1 positivity do not seem to modify the DM NVC pattern.

Only a Minor Proportion of Individuals with Anti-Aminoacyl-tRNA Synthetase Autoimmunity Presents with the Clinical Picture of “Antisynthetase-Syndrome”

Johannes Knitza, Hannah Schenker, Georg Schett and Jörg Distler, Department of Internal Medicine 3, Rheumatology and Immunology, Universitätsklinikum Erlangen, Erlangen, Germany

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Muscle Biology, Myositis and Myopathies Poster I: Clinical Features and Disease Course

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Antisynthetase Syndrome is a rare and severe autoimmune inflammatory disease that is associated with autoimmunity against aminoacyl-tRNA synthetase and clinical signs of arthritis, myositis and interstitial lung disease. The aim of this study was to test how many patients with positive anti-aminoacyl-tRNA synthetase autoimmunity present with clinical signs of Antisynthetase Syndrome.

Methods: In a first step, patients with unexplained musculoskeletal pain referred to the outpatient clinic of Department of Internal Medicine 3 of the University of Erlangen-Nuremberg were tested for anti-aminoacyl-tRNA synthetase autoantibodies Jo1, PL12, PL7, EJ and OJ using immunoblot technology. In a second step, patients tested positive for the respective autoantibodies were carefully examined for the presence of clinical signs of Antisynthetase Syndrome and followed up whether clinical changes of Antisynthetase Syndrome developed.

Results: 160 subjects with positive anti-aminoacyl-tRNA synthetase autoantibodies were identified. 50 subjects (31%) had reactivity against anti-Jo1, 38 against PL12 (24%), 29 against PL7 (18%), 23 (14%) against OJ and 9 (6%) against EJ. 11

(7%) subjects had reactivities against more than one aminoacyl-tRNA synthetase. Median age at onset was 51 years (20 to 81 years) and mean (SD) follow up was 82 (81) months. 27 (17%) of these subjects had clear evidence for Antisynthetase Syndrome presenting with at least one of the clinical triad findings of the syndrome: arthritis, myositis and interstitial lung disease. There was a clear preponderance of females (78%) developing Antisynthetase Syndrome. 8 patients (30% of those with clinical signs of Antisynthetase Syndrome) presented with arthritis, 23 (85%) had myositis and 16 (59%) exhibited interstitial lung disease. Arthritis presented in all cases as symmetrical polyarthritis; IgG-RF was positive in one third of the patients, while ACPA were tested negative. Radiographic erosions on plain radiographs were only observed in one patient. “Mechanic” hands and Raynaud syndrome were present in 2 (7%) and 7 (26%) patients with Antisynthetase Syndrome, respectively. Two patients with Antisynthetase Syndrome died due to their disease.

Conclusion: These results suggest that only a minority of individuals tested positive for anti-aminoacyl-tRNA synthetase autoantibodies develops Antisynthetase Syndrome. Individuals with positive autoimmunity but no clinical signs of Antisynthetase Syndrome may either represent pre-disease subjects, who may develop Antisynthetase Syndrome later in life or resemble “forme fruste” of the disease, presenting with only mild and unspecific musculoskeletal symptoms. Hence, further longitudinal observations are needed to determine the outcome of anti-aminoacyl-tRNA synthetase autoantibody carriers.

Session Title: Muscle Biology, Myositis and Myopathies Poster I: Clinical Features and Disease Course

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Antisynthetase Syndrome(AS) is a relatively rare autoimmune disease characterized by interstitial lung disease (ILD), myositis, inflammatory arthritis, Raynaud phenomenon, and mechanic’s hands. Eight autoantibodies (Ab) to aminoacyl-transfer-RNA synthetases have been described so far: Jo-1, PL-7, PL-12, EJ, OJ, YRS, KS, and Zo. The morbidity and mortality in AS is mainly related to the pulmonary complications. However, little has been reported about the prevalence of serositis (pleural and/or pericardial effusions) in AS other than small cohort studies (15-20 patients) and case reports. The purpose of our study was to determine the prevalence of serositis in AS, its clinical significance, and its association with specific AS Ab subtype(s).

Methods: Clinical data were obtained by retrospective review of electronic medical records from 2004 – 12/2017. AS required diagnosis by a rheumatologist, and patients had to have one of the following AS Ab: Jo-1, PL-7, PL-12, EJ, and OJ. Pleural effusions were qualified as trace, small, medium, or large, based on the findings on chest X-ray and thoracic CT scan. Pericardial effusions were classified as trace, small, medium, large, ortamponade, based on echocardiographic findings. Patients grouped by AS Ab type were compared using Pearson chi-square tests or Fisher exact tests. Size measures were evaluated using Kruskal-Wallis tests that evaluate each measure as an ordered factor. *For all measures, aP-value of < 0.05 was considered significant.*

Results: A total of 93 patients were included in this study. The mean age was 57.5years; 63% were female. The largest subset of patients had Jo-1 Ab (N=62).Pleural effusions were present in 44% of patients, 75% of which were bilateral. Out of 90 patients with complete data available, 42.2% had pleural effusion(s) and 47% had a pericardial effusion, 10% of which were moderate to large, and one patient had tamponade physiology. Jo-1 patients were significantly less likely to have pleural effusions when compared to patients with other Ab (P=0.005). PL-12 had a higher frequency of pleural effusions relative to Jo-1 and PL-7, as well as, compared to all other Ab combined. No statistical comparisons were made between PL-7, EJ, and OJ Ab due to small sample sizes. Alternate causes of serositis were ruled out in all but two patients, who were found to have lung malignancy.

Session Title: Muscle Biology, Myositis and Myopathies Poster I: Clinical Features and Disease Course

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Muscle ultrasound (MUS) offers a cost effective, accessible option for detection of muscle inflammation and atrophy in patients with Idiopathic Inflammatory Myopathies (IIM). The goal of this study was to compare several MUS parameters in patients with IIM vs. healthy controls (CON), to examine their correlates with measures of IIM disease activity and damage, and to compare the sensitivity and specificity of MUS to magnetic resonance imaging (MRI).

Methods: MUS of the right mid-rectus femoris (RF) using the Acuson Sequoia was performed in 26 IIM patients (PTS) meeting probable or definite Bohan and Peter criteria (20 with juvenile dermatomyositis [JDM], 2 DM, 2 juvenile polymyositis [PM], and 2 juvenile overlap myositis) and compared to 30 age-, gender- and race-matched controls (CON). MUS parameters of IIM patients, evaluated by digital image processing software within regions of interest identified by radiologists, were correlated (Spearman rank) with IIM disease activity and damage assessments and semi-quantitative MRI short tau inversion recovery (STIR) and T1 scores. The area under the receiver operating characteristic (ROC) was used to compare sensitivity and specificity of MUS to MRI.

Results: The median age at diagnosis of IIM was 12.8 years, 69% were female, 77% were Caucasian. The median age of CON was 14.5 years, with similar genders and races as PTS. Median MD Global Disease Activity was 4.0 cm (10 cm VAS) and MD Global Disease Damage was 1.8 cm. There was a significant increase in RF echogenicity [median 48.5 in PTS vs. 39.3 CON, p=0.0004], but decrease in RF area (median 9.0 PTS vs 10.6 CON, p=0.038), RF contracted area (median 7.9 PTS vs. 9.9 CON, p=0.005) and vascular power Doppler (median 4.0 PTS vs. 1.0 CON, p=0.032) in IIM vs. CON. Mean

echogenicity of MUS correlated with MD Global Activity (r_s 0.46, $p=0.04$) and inversely with proximal MMT (r_s -0.54, $p=0.01$). RF area inversely correlated with MD global activity (r_s -0.46, $p=0.04$) and correlated with proximal MMT (r_s 0.57, $p=0.009$). Contracted RF area inversely correlated with MD Global Activity (r_s -0.56, $p=0.009$) and correlated with proximal MMT (r_s 0.76, $p<0.0001$) and CMAS (r_s 0.80, $p<0.0001$). MUS echogenicity correlated with both STIR (r_s 0.44, $p=0.03$) and T1 MRI sequences (r_s 0.46, $p=0.02$). T1 MRI correlated with the difference in RF area between the contracted and resting states (r_s 0.67, $p=0.002$). Several MUS measures inversely correlated with muscle atrophy on T1 MRI, including vascular color Doppler (r_s -0.49, $p=0.01$), RF contracted mean AP area (r_s -0.57, $p=0.003$), and RF contracted area (r_s -0.43, $p=0.03$). The area under the curve by ROC analysis of MUS echogenicity vs. STIR MRI was 0.75, and using an average of STIR and T1 MRI, improved to 0.81.

Conclusion: Several MUS parameters of RF differed between IIM vs. CON, including increased echogenicity, decreased resting and contracted area, and decreased vascular power Doppler. MUS also had moderate to strong construct validity with IIM disease activity, strength and MRI measures. MUS echogenicity has strong sensitivity and specificity compared to MRI, and is a promising imaging modality for IIM patients.

Session Date: Sunday, October 21, 2018

Session Title: Muscle Biology, Myositis and Myopathies Poster I: Clinical Features and Disease Course

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Clinical manifestations of anti-synthetase syndrome (ASS) include fever, Raynaud phenomenon, mechanic's hands, inflammatory arthritis, myositis and interstitial lung disease (ILD). Pulmonary hypertension (PH), although not part of the syndrome, when present may indicate a poor prognosis and has not been well studied.

Methods: We conducted a retrospective chart review of patients with ASS with Jo-1, PL-7, PL-12, EJ and OJ antibodies between 2003 - 2017. ASS patients with PH were selected for further review. PH was diagnosed by right heart catheterization (RHC) in all patients with mean pulmonary arterial pressure (mPAP) ≥ 25 mmHg, and defined as severe if mPAP was ≥ 35 mmHg. Patients were classified as having pre-capillary PH if pulmonary capillary wedge pressure (PCWP) was ≤ 15 mmHg, post-capillary PH if PCWP was >15 mmHg, and combined pre- and post-capillary PH if PCWP was >15 mmHg with diastolic pressure gradient ≥ 7 mmHg and/or pulmonary vascular resistance (PVR) >3 Wood units. Patient

demographics, laboratory data, echocardiogram and RHC parameters, spirometry and DLCO were evaluated. Numerical variables were compared using Mann-Whitney test. Categorical variables were compared using either Pearson's chi-squared test or Fisher's exact test. Binary logistic regression analysis was used to identify factors associated with mortality. Survival function was estimated using the Kaplan-Meier method. A p-value of <0.05 was considered significant.

Results: We identified 177 patients with positive anti-Jo-1 antibody, and 36 patients with non-Jo-1 antibodies. Twenty-two (10.33%) had PH and the following antibodies: Jo-1 (18), PL-12 (2), EJ (1) and PL-7 (1). The median age was 51 years and the median follow-up duration was 6.89 years. The median duration from ASS onset to PH diagnosis was 36.17 months. Fifteen patients had pre-capillary PH, 3 had post-capillary PH and 4 had combined PH. Median forced vital capacity (FVC) at PH diagnosis was 48%, of which 3 patients had FVC \geq 70%. One patient had PH without ILD. Sixteen patients (72.7%) had severe PH. Sixteen out of 19 patients with pre-capillary PH were treated for pulmonary arterial hypertension and 9 of them received combination therapy. All 22 patients also received immunosuppressive therapy. Twelve patients (54.5%) died. Two patients with lung transplants survived. The deceased group had higher PVR ($p=0.024$) and higher rates of severe PH ($p=0.05$). Right ventricular dilation was associated with mortality ($p=0.046$). Survival was not affected by SS-A antibody positivity, presence of Raynaud phenomenon or pericardial effusion, New York Heart Association Functional Class, FVC at PH diagnosis, and duration from ASS onset to PH diagnosis. Survival analysis is shown in Figure 1.

Conclusion: PH is not uncommon in patients with ASS. Severity of PH at diagnosis was a predictor of mortality. Given this dismal prognosis, we recommend screening echocardiography in all ASS patients.

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Muscle Biology, Myositis and Myopathies Poster I: Clinical Features and Disease Course

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Idiopathic inflammatory myopathies (IIM) are heterogeneous disorders characterised by skeletal muscle weakness and muscle inflammation. IIM includes dermatomyositis (DM), polymyositis (PM), antisynthetase syndromes (ASS), scleromyositis (SCM), inclusion body myositis (IBM), immune-mediated necrotizing myopathies (IMNM) and Overlap Syndromes (OS). Previous population-based studies have demonstrated a higher risk of venous thromboembolism (VTE) in IIM patients compared to healthy controls. In these works, IIM were only divided in PM and DM and few risk factors of VTE have been highlighted. The purpose of this study was to identify the VTE specific risk factors in IIM and analyse VTE occurrence in more recently defined subtypes of IIM.

Methods: All adults with IIM hospitalized in Internal Medicine units from Eastern France between 2004 and 2018 were enrolled. Demographic, clinical and laboratory data were retrospectively collected from medical records. Mann-Whitney test and Chi-square test were used for comparison of continuous and discrete variables, respectively. We computed a multivariate model to determine factors associated with VTE using a Cox analysis. VTE-free survival analysis was performed using log-rank test.

Results: 203 patients (55 male, 148 female) were involved. The mean age at diagnosis was 51 years \pm 16. VTE occurred in 12% of cases, mostly within the first year of follow-up (31%). At VTE diagnosis, conditions such as immobilization (20%), infection (10%), malignancy (20%), active disease (31%), treatment by intravenous immunoglobulins (17%) or by glucocorticoids (55%) were observed. In univariate analysis, we found that patients with VTE experienced more dysphonia ($p=0.037$) and received a greater number of therapeutic lines ($p=0.035$) compared to patients without VTE. In multivariate analysis, significant risk factors were personal history of pulmonary embolism (HR 13, $p=0.023$), dysphonia (HR 99,

p=0,00005), elevated C-reactive protein (HR 5.1, p=0.0081) and number of therapeutic lines (HR 2.7, p=0.023). We compared VTE-free survival in all IIM subtypes within the five years after diagnosis: a particular subgroup including DM, PM, ASS, OS and IMNM (group 1) presented a higher risk than another including SCM, IBM and unspecified myositis (group 2) (HR 4.21, p=0,048).

Conclusion: Common but also unexpected risk factors were reported here. Elevated C-reactive protein confirmed the link between inflammation and thrombosis mechanisms. Dysphonia and the number of therapeutic lines reflected a more severe disease. Among IIM, only those in group 1 (DM, PM, ASS, OS and IMNM) were associated with an increased risk of VTE. The identification of these subtypes should alert to VTE risk and lead to early apply prophylactic measures.

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Muscle Biology, Myositis and Myopathies Poster I: Clinical Features and Disease Course

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Idiopathic inflammatory myopathies (IIM) are a group of systemic autoimmune diseases characterized by proximal muscle weakness, which is often assessed clinically using manual muscle testing (MMT). Studies have shown that patient's weight and examiner's experience and strength may play important roles in grading muscle strength with MMT. Therefore, more objective tools are required to quantify muscle strength in order to optimize treatment response in clinical trials and practice. Hand-held dynamometry (HHD) is a quantitative, inexpensive, compact device with reliability in several neuromuscular diseases. We aimed to assess reliability, validity and responsiveness of HHD in IIM.

Methods: The 6 validated myositis core set measures (CSM; manual muscle testing [MMT], physician global disease activity (MD-GDA), patient global disease activity (PT-GDA), extra-muscular global disease activity (EM-GDA), HAQ and muscle enzymes) and 3 functional measures (six-minute walk [6MWD], timed-up-and-go [TUG] and sit-to-stand tests [STS]) were completed on patients with IIM [DM, PM, necrotizing myopathy (NM) or anti-synthetase syndrome] at baseline, 3 and 6 months. At each visit strength was assessed using HHD (Micro FET2, Hoggan Health Industries, Draper, UT) on 3 consecutive attempts. HHD was validated and compared with MMT as well as other CSMs and functional tests. Spearman correlations were used with rho >0.5 considered strong, 0.35-0.5 moderate, and 0.2-0.35 weak. We examined the test-retest reliability as well as HHD responsiveness.

Results: Fifty patients [mean age, 53.6(±14.6); 30 females/20 males] were studied. Eleven of 50 had PM, 28 had DM, 7 had NM and 4 had anti-synthetase syndrome. HHD showed strong test-retest reliability (Rho: 0.96) and excellent internal consistency (Cronbach-α: 0.95). HHD correlated moderately with MMT score (R: 0.44, p=0.003). HHD showed moderate to strong correlation with muscle disease activity (R: -0.5, p: 0.0008) and MD-GDA (R: -0.4, p: 0.006), HAQ (R: -0.5, p: 0.0005), STS (R: 0.5, p: 0.0002), and 6MWD (R: 0.4, p: 0.005) (Table 1). Longitudinal change in HHD strongly correlated with total improvement score (R: -0.6, p=0.01) at 6 months. HHD scores changed significantly in physician-reported "moderately-better" and "a-little-better" groups (p=0.01) demonstrating responsiveness to change. HHD did not change longitudinally in patients who had stable disease demonstrating reliability. MMT and HHD showed similar correlations with the conventional CSM, however, effect size and standardized response mean (SRM) of HHD was higher than MMT (0.56 vs 0.20; 0.33 vs 0.20).

Conclusion: HHD demonstrates good test-retest reliability, construct validity and responsiveness in a large cohort of patients with IIM and a better effect size and SRM than MMT.
Table. Comparison of MMT and hand-held DM

	MMT		Hand-held DM	
	R	P value	R	P value

Session Date: Sunday, October 21, 2018

Session Title: Muscle Biology, Myositis and Myopathies Poster I: Clinical Features and Disease Course

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: To assess muscle function in myositis patients, clinicians typically use manual muscle testing (MMT), a measure of maximal isometric strength. However, patients with high baseline strength and/or mild muscle impairment often report functional changes undetected by MMT. We investigated whether quantifying muscle endurance using the Myositis Functional Index-2 would identify muscle impairment uncaptured by MMT.

Methods: We reviewed the records of myositis patients from a large single-center cohort who had at least one FI2 muscle endurance assessment (n=128, 226 patient-visits). Patients with dermatomyositis (DM; n=31) and polymyositis (PM; n=39) met Bohan and Peter criteria. Patients with inclusion body myositis (IBM; n=58) met 2011 European Neuromuscular Centre diagnostic criteria for probable or definite IBM. MMT strength data were converted to a 0-10 scale using standard Kendall conversion.

Results: Composite FI2 endurance scores were similar in patients with IBM, DM, and PM, although IBM patients had diminished strength (Figure 1). At the population level, muscle endurance correlated with and evolved very similarly to strength overtime, inversely to serum creatine kinase (Figure 2). However, in patients with normal or near-normal strength (mean MMT >9.75/10; n=62), FI2 scores were typically abnormal and highly variable (mean FI2, 5.6/10; interquartile range, 3.3-7.8/10), suggesting the presence of muscle impairment not reflected by MMT. In an illustrative case, a DM patient with high baseline strength complained of flaring muscle weakness which was reflected by FI2 but not MMT scores (Figure 3).

Conclusion: Muscle endurance testing may identify muscle impairment inadequately described by MMT, particularly in patients with high MMT scores.

Figure 1: Composite FI2 endurance and MMT strength scores in myositis patients.

Figure 2: MMT and FI2 scores evolved similarly over time, inversely to serum CK levels. Locally-weighted regression of all myositis patient data.

Figure 3: The evolution of MMT, FI2, and serum CK in a DM patient with a disease flare at month 7.

Session Date: Sunday, October 21, 2018

Session Title: Muscle Biology, Myositis and Myopathies Poster I: Clinical Features and Disease Course

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: There is currently no study in newly onset dermatomyositis (DM) regarding nailfold capillaroscopy (NC) findings, angiogenic cytokines, disease related clinical, laboratory and treatment features. Therefore, the aims of the present study were: (a) to analyze cross-sectionally and prospectively NC findings in newly onset-DM; (b) to correlate NC findings with serum angiogenic cytokines [angiogenin (ANG), vascular endothelial growth factor-1 (VEGF1)] and DM clinical and laboratory features.

Methods: Twenty-three patients with DM with less than 12 months of symptoms were included. All the patients met at least four of the five criteria of Bohan and Peter criteria, including classical cutaneous lesions (heliotrope rash and/or Gottron's papules) and the new European League Against Rheumatism / American College of Rheumatology (EULAR / ACR) classification criteria for DM. To assess serum cytokine levels, age, gender and ethnicity-matched 23 healthy volunteers were recruited as a control group. NC characteristics and DM activity parameters were analyzed. Additionally, 15 out of 23 patients were also assessed prospectively after a median duration of 3.21 years.

Results: A significantly higher serum ANG and VEGF1 levels ($P=0.017$ and $P<0.001$, respectively) were observed in DM patients compared to controls. Capillary density and avascular areas correlated positively ($r=0.6$; $P=0.016$) and negatively ($r=-0.59$; $P=0.019$) with serum level of ANG. Besides, capillary density correlated inversely with the number of enlarged ($r=-0.54$; $P=0.007$); giant capillaries ($r=-0.53$; $P=0.009$) and avascular areas ($r=-0.84$; $P<0.001$). The number of the enlarged capillaries correlated positively with patient ($r=0.49$; $P=0.016$) and physician VAS ($r=0.56$; $P=0.005$), presence of facial rash ($r=0.44$; $P=0.035$), giant capillaries ($r=0.76$; $P<0.001$) and microhemorrhages ($r=0.59$; $P=0.003$). Giant capillaries had positive correlation with physician ($r=0.50$; $P=0.014$) and cutaneous VAS ($r=0.42$; $P=0.046$), enlarged capillaries ($r=0.76$; $P<0.001$), avascular areas ($r=0.54$; $P=0.007$), microhemorrhages ($r=0.55$; $P=0.006$) and bushy capillaries ($r=0.42$; $P=0.044$) and negative with capillary density ($r=-0.53$; $P=0.009$). Microhemorrhages correlated positively with "V-neck" sign ($r=0.44$; $P=0.032$) and physician VAS ($r=0.48$; $P=0.02$). VEGF1 showed no relation to NC parameters neither with DM-related clinical and laboratory features. Longitudinally, all patients had major clinical response with significant improvement in the all NC parameters, except for enlarged and bushy capillaries.

Conclusion: The present data emphasize that NC may be a useful tool to assess disease activity in recently onset-DM and also reinforce the role of ANG in the angiogenesis process in this myopathy.

Session Title: Muscle Biology, Myositis and Myopathies Poster I: Clinical Features and Disease Course

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: To define the clinical phenotype of myositis patients with anti-U1- ribonucleoprotein (RNP) autoantibodies.

Methods: The clinical features of 20 anti-U1RNP-positive patients were assessed and compared to those of 132 antisynthetase syndrome (ASyS), 178 dermatomyositis (DM), and 135 immune-mediated necrotizing myopathy (IMNM) patients.

Results: Twenty (4.6%) of 437 patients tested were anti-U1-RNP-positive; these were younger (~37 years) and more likely to be black (60%) than ASyS, DM, or IMNM patients. Muscle weakness, arthritis, interstitial lung disease (ILD), and DM-specific skin features eventually developed in 80%, 60%, 45%, and 60% of anti-U1-RNP-positive patients, respectively. Four of 7 (57%) anti-U1-RNP-positive patients had a necrotizing muscle biopsy. ILD was more severe in anti-U1-RNP-positive patients than in DM or IMNM. Glomerulonephritis and pericarditis occurred in 25% and 40% of anti-U1-RNP-positive patients, respectively, but rarely in the other groups. Pulmonary hypertension (PH) developed in 25% of anti-U1-RNP-positive, 20% of ASyS, and in <3% of DM and IMNM patients. Interestingly, glomerulonephritis, pericarditis and PH only occurred in anti-U1- RNP-positive patients with co-existing anti-Ro52 autoantibodies.

Conclusion: Muscle weakness and arthritis are the most common clinical features in anti- U1-RNP-positive patients; when present, ILD is severe. Pericarditis, glomerulonephritis and PH are relatively common in anti-U1-RNP-positive patients, and only developed in those anti-U1-RNP-positive patients with co-existing anti-Ro52 autoantibodies.

Session Title: Muscle Biology, Myositis and Myopathies Poster I: Clinical Features and Disease Course

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Interstitial lung disease (ILD) is a significant cause of morbidity and mortality in connective tissue diseases (CTDs). The purpose of this study is to compare the prevalence, physiology, and radiographic findings in different CTDs to formulate rational screening/monitoring plans.

Methods: Patients diagnosed with dermatomyositis (DM), polymyositis (PM), anti-aminoacyl tRNA synthetase syndrome (ARS), limited cutaneous systemic sclerosis (lcSS), diffuse cutaneous systemic sclerosis (dcSS), or mixed connective tissue disease (MCTD) were identified from the MYSTIC cohort (VUMCIRB 141415); the presence of ILD was identified from chart abstraction. Radiographic patterns of ILD were ascertained from the initial CT scan. American Thoracic Society Criteria were used to grade severity by forced vital capacity (FVC) and diffusing lung capacity for carbon monoxide (DLCO) percentages; if multiple pulmonary function tests (PFTs) were available, the most severe value was used.

Results: Patient characteristics are shown in Table 1. Forty of 71 patients had ILD with the highest prevalence in dcSS (70%), ARS (64.2%), and lcSS (48%). Nonspecific interstitial pneumonia (NSIP) was the most common radiographic pattern (Table 2), but 27% of patients with lcSS had a usual interstitial pneumonia (UIP) pattern. Severe restriction was present in 43% of ARS patients and 33% of dcSS patients. Similarly, 86% of ARS patients and 66% of dcSS had severe

gas exchange deficits. Supplemental oxygen use was 35.7% in ARS and 20% in dcSS. Despite the high prevalence of ILD in lcSS, physiologic severity was less than ARS or dcSS. FVC was mildly restricted in 46% of lcSS cases; only one patient had severe restriction. Fifty four percent of lcSS patients had severe reduction in DLCO, but this is likely due to concomitant pulmonary hypertension. Overall, ILD in dcSS and ARS was much more severe than lcSS, DM, PM, or MCTD.

Conclusion: In our cohort, ARS and dcSS had similar prevalence and severity of ILD. While expert opinion promotes screening and monitoring for ILD in systemic sclerosis (SSc), there are currently no clear recommendations for ARS. This data indicates that screening CT/PFTs are indicated for ARS as well as SSc.

Session Title: Muscle Biology, Myositis and Myopathies Poster I: Clinical Features and Disease Course

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Idiopathic inflammatory myopathies (IIM) are characterized by inflammation and atrophy of skeletal muscles, pulmonary and articular involvement, which leads to functional impairment, reduced quality of life including sexual life. The aim of this study was to assess sexual functions/quality of life and pelvic floor function in female IIM patients compared to age-/sex-matched healthy controls (HC).

Methods: In total, 22 women with IIM [mean age: 55.1, disease duration: 7.9 years, dermatomyositis (DM, 8)/ polymyositis (PM, 10)/ necrotizing myopathy (IMNM, 3)/ inclusion body myositis (IBM, 1)], who fulfilled the Bohan/Peter 1975 criteria for DM/PM, and 22 healthy controls (mean age: 55.1 years) without rheumatic diseases filled in 12 well-established and validated questionnaires assessing sexual function/quality of life, pelvic floor function, fatigue, physical activity and depression. Data are presented as mean \pm SEM.

Results: Compared to HC, patients with IIM had significantly higher prevalence and greater severity of sexual dysfunction (FSFI, BISF-W: in all subscales as well as total scores), dysfunction of pelvic floor (PISQ-12), and worse sexual quality of life (SQoL-F) (table). Worse scores in IIM patients were associated with elevated muscle enzyme levels [lactate dehydrogenase: FSFI ($r=-0.524, p=0.0123$), BISFW ($r=-0.528, p=0.0115$)], greater fatigue [FIS: FSFI ($r=-0.434, p=0.0438$), BISF-W ($r=-0.488, p=0.0211$), SQoL-F ($r=-0.488, p=0.0070$), PISQ-12 ($r=0.643, p=0.0013$)], more severe depression [BDI-II: PISQ-12 ($r=0.474, p=0.0258$)], deteriorated quality of life [HAQ: PISQ-12 ($r=0.476, p=0.0252$)], and worse ability to perform physical activities [HAP: FSFI ($r=0.437, p=0.0417$), BISF-W ($r=0.451, p=0.0351$), PISQ-12 ($r=-0.494, p=0.0195$)].

Conclusion: Women with IIM reported significantly impaired sexual function, sexual quality of life and pelvic floor function than age-matched healthy controls. Worse scores in IIM were associated with disease activity, physical activity, fatigue, depression and quality of life.

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Muscle Biology, Myositis and Myopathies Poster I: Clinical Features and Disease Course

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Skeletal muscle, pulmonary and articular involvement in idiopathic inflammatory myopathies (IIM) limit the mobility/self-sufficiency of patients, and can have a negative impact on body composition. The aim of this study was to assess body composition and physical activity of IIM patients and healthy controls (HC).

Methods: 54 patients with IIM (45 females; mean age 57.7; disease duration 5.8 years; polymyositis (PM, 22) / dermatomyositis (DM, 25) / necrotizing myopathy (IMNM, 7)) and 54 age-/sex-matched HC (45 females, mean age 57.7) without rheumatic/tumor diseases were included. PM/DM patients fulfilled Bohan/Peter criteria for PM/DM. Anthropometric parameters and body composition were assessed (by densitometry: iDXA Lunar, and by bioelectric impedance: BIA2000-M), and physical activity was evaluated using Human Activity Profile (HAP) questionnaire. Routine biochemistry analysis was performed after 8 hours of fasting. Disease activity was evaluated by MITAX and MYOACT activity score. Muscle involvement was evaluated by manual muscle test (MMT-8) and functional index 2 (FI2). Data are presented as mean±SD.

Results: Compared to HC, patients with IIM had a trend towards significantly increased body fat % (BF%) as assessed by iDXA (39.9±7.1 vs. 42.4±7.1 %, p=0.077), but significantly decreased lean body mass (LBM) as assessed both by iDXA (45.6±8.1 vs. 40.6±7.2 kg, p=0.001) and BIA (52.6±8.8 vs. 48.7±9.0 kg, p=0.023), and increased extracellular mass/body cell mass (ECM/BCM) ratio (1.06±0.15 vs. 1.44±0.42, p<0.001). Higher ECM/BCM ratio reflects worse muscle predispositions for physical exercise, aerobic fitness/performance, and deteriorated nutritional status. Compared to HC, IIM patients had significantly lower bone mineral density (BMD: 1.2±0.1 vs. 1.1±0.1 g/cm², p<0.001). Disease duration negatively correlated with BMD (r=-0.392, p=0.004) and LBM-BIA (r=-0.272, p=0.047). Disease activity assessed by both MITAX and MYOACT positively correlated with LBM-BIA (MITAX: r=0.294, p=0.031; MYOACT: r=0.335, p=0.013) and LBM-DXA (MITAX: r=0.341, p=0.012; MYOACT: r=0.368, p=0.007), similarly as with basal metabolic rate (BMR; MITAX: r=0.336, p=0.014; MYOACT: r=0.351, p=0.010), and fat free mass (FFM; MITAX: r=0.338, p=0.014; MYOACT: r=0.356, p=0.009). CRP was positively associated with BF% assessed both by DEXA (r=0.276, p=0.035) and BIA (r=0.306, p=0.025). Higher BF%-DEXA was associated with worse physical endurance (FI2: r=-0.311, p=0.026) and worse ability to perform physical activity (HAP: r=-0.292, p=0.032). MMT-8 score negatively correlated with ECM/BCM ratio (r=-0.385, p=0.006).

Conclusion: Compared to healthy age-/sex-matched individuals we found significant negative changes in body composition of our IIM patients, which are associated with their disease activity and duration, inflammatory status, skeletal muscle involvement, and physical activity. These data could reflect their impaired nutritional status and predispositions for physical exercise, aerobic fitness and performance.

Session Title: Muscle Biology, Myositis and Myopathies Poster I: Clinical Features and Disease Course

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The association between inflammatory myositis and malignancy is well established, however, the risk of malignancy in aged patients is known to be similar with general populations. We aimed to analyze the incidence of malignancy in elderly patients with inflammatory myositis, and to estimate the increased risk of malignancy of these patients compared to knee OA patients in Korea.

Methods: Patients with polymyositis (PM) and dermatomyositis (DM) over the age of 50 were identified from Korean nationwide claims database from January 2012 to December 2014 with excluding the patients who had history of any malignancy for a year prior to enrollment. They were observed until any malignancy was newly diagnosed or up to end of the study, December 2015. The crude incidence rate (IR) of malignancies in PM and DM patients over 50 years of age was estimated and we calculated age- and sex-adjusted standardized incidence ratio (SIR) by dividing the observed number of malignancies in patients with PM or DM by expected number of malignancies which was drawn from the incidence rate of malignancy in knee OA patients for cumulative person-years (PYs).

Results: A total of 683 patients with PM and 502 patients with DM over 50 years old were included. In PM patients, 46 cases of solid malignancy (217.7/10,000 PYs) and 4 of hematologic malignancy (18.2/10,000 PYs) occurred during 2,113 and 2,195 PYs of follow-up. On the other hand, the number of 36 solid malignancies (238.0/10,000 PYs) and 7 hematologic malignancies (44.7/10,000 PYs) were identified for 1,512 and 1,565 PYs of observation in patients with DM. Compared to patients with knee OA aged over 50 (n=5,476,302), the risk of overall malignancy was increased in both PM and DM patients; SIR was 1.4 (95% CI 1.0-1.8) in PM patients and 1.8 (95% CI 1.3-2.4) in DM patients, respectively. The risk of solid malignancy was also significantly increased than expected in patients with PM (SIR 1.4, 95% CI 1.0-1.8) and DM (SIR 1.6, 95% CI 1.1-2.1). However, the risk of hematologic malignancy was significantly increased in patients with DM (SIR 9.0, 95% CI 2.3-15.6), but not in those with PM (SIR 3.3, 95% CI 0.1-6.6).

Conclusion: We figure out that even in the elderly patients, inflammatory myositis is associated with increased risk of both solid and hematologic malignancies.

Session Date: Sunday, October 21, 2018

Session Title: Muscle Biology, Myositis and Myopathies Poster I: Clinical Features and Disease Course

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Immune-mediated necrotising myopathy (IMNM) is characterised by paucity of inflammation on muscle biopsy and is associated with antibodies to signal recognition particle (SRP) and 3-hydroxy-3-methylglutaryl-

coenzyme A reductase (HMGCR). IMNM patients tend to be more refractory to conventional immunosuppressive therapies. Previous case series suggested that a more severe clinical course and greater resistance to treatment in anti-SRP myopathy compared to anti-HMGCR. Thus, we aimed to analyse disease characteristics and treatment responses in a single-centre IMNM cohort based on SRP or HMGCR antibody status.

Methods: All subjects with a diagnosis of IMNM from 2008 to 2017 were included in this retrospective study. Patient electronic records were reviewed and disease subgroups based on antibody status (anti-SRP and anti-HMGCR) were analysed.

Results:

Subgroup	HMGCR	SRP
Number of patients, n (%)	17 (61)	11 (39)
Female, n (%)	13 (76)	6 (55)
Median age at onset, years (Interquartile range)	62 (57 - 71)	52 (31 - 55)
Ethnicity, n (%)	White British 12 (70.6) African-Caribbean 2 (11.8) South Asian 2 (11.8) Chinese 1 (5.8)	African 8 (72.7) African-Caribbean 2 (18.2) White British 1 (9.1)
Median peak creatine kinase, units/L (Interquartile range)	7030 (4143 – 19114)	9750 (3237 – 19022)
Statin exposure, n (%)	14 (82)	1 (9)
Type 2 diabetes, n (%)	11 (65)	0 (0)
Cardiac involvement, n (%)	0/5 (0)	2/6 (33)
Malignancy, n (%)	2 (12)	1 (9)
Rituximab, n (%)	2 (12)	5 (46)

28 patients had a diagnosis of IMNM, of which 39% had anti-SRP and 61% had anti-HMGCR myopathy. SRP patients were predominantly of African or African-Caribbean descent (91%) with more ethnic heterogeneity observed in the HMGCR group. 82% of HMGCR patients were exposed to statins compared to 9% of SRP subjects. Six SRP patients underwent cardiac MRI with two patients demonstrating cardiac involvement whilst myocarditis was not identified in anti-HMGCR myopathy. Two HMGCR patients were identified with malignancies (follicular thyroid carcinoma and low-grade non-Hodgkin's lymphoma) and one SRP patient was identified with prostate adenocarcinoma.

11 HMGCR and 4 SRP patients were initiated on 'triple therapy' – pulsed intravenous methylprednisolone (IVMP) followed by high dose oral prednisolone, intravenous immunoglobulin (IVIg) and an immunosuppressant (methotrexate or azathioprine). The remainder were initially commenced on either IVMP/prednisolone or IVIg dependent on patient factors (e.g. diabetes).

46% of SRP patients received rituximab therapy (6 months to 9 years post symptom onset) compared to 12% of HMGCR patients (4 to 6 years post symptom onset). 3 SRP patients responded well to rituximab clinically and biochemically (the other 2 patients were followed-up in local hospitals after their first dose of rituximab).

Conclusion: There were distinct features in our IMNM cohort based on antibody profile. Anti-SRP myopathy disproportionately affected more African and African-Caribbean patients. This group tended to have higher creatine kinase levels and cardiac complications were present in some. Anti-SRP myopathy was associated with a failure to respond adequately to conventional therapies requiring the addition of rituximab more frequently and earlier in the disease course. There is heterogeneity in therapy choice depending on clinician experience and patient factors suggesting the need for further prospective studies and standardised protocols.

Risk Factors Associated with Mortality in Inflammatory Myositis: An Asian Perspective

Tyng Yu Chuah¹, Yu Heng Kwan², Nai Lee Lui³ and Warren Fong^{4,5,6}, ¹Department of Rheumatology and Immunology, Singapore General Hospital, Singapore, Singapore, ²Program in Health Services and Systems Research, Duke-NUS Medical School, Singapore, Singapore, ³Rheumatology and Immunology, Singapore General Hospital, Singapore, Singapore, ⁴Department of Rheumatology and Immunology, Singapore General Hospital, Singapore, Singapore, ⁵Department of Medicine, Yong Loo Lin School of Medicine, National University of Singapore, Singapore, Singapore, ⁶Duke-NUS Medical School, Singapore, Singapore

Session Information

Session Date: Sunday, October 21, 2018

Background/Purpose: Idiopathic inflammatory myopathies (IIM) are a heterogeneous group of autoimmune diseases with systemic involvement and excess mortality. We aim to describe the causes and evaluate predictors of mortality in patients at a tertiary-care academic medical institution in Singapore.

Methods: Medical records of patients newly diagnosed with IIM in the Department of Rheumatology and Immunology, Singapore General Hospital, between 2003-2017 were retrospectively reviewed. Patients recruited fulfilled the 2017 EULAR/ American College of Rheumatology (ACR) classification criteria[1] for polymyositis (PM), dermatomyositis (DM), immune-mediated necrotizing myopathy (IMNM) and amyopathic dermatomyositis (ADM). Demographics, disease manifestations and treatment for cases were collected using a standardized protocol. In-hospital cause of death was determined by two independent reviewers according to categories set apriori. Person-years follow-up was calculated from date of cohort entry to either death or censor date. Univariate Cox proportional hazard (PH) regression was used to examine the association between each variable and mortality. We included both variables that were reported to be associated with mortality in the literature or variables with $p < 0.1$ in the multivariate Cox regression model. We used the stepwise forward selection approach to select variables that were significant at $p < 0.05$.

Results: Of 100 patients (23% male, 76% Chinese), 58% and 40% fulfilled the definite and probable EULAR/ACR criteria for IIM respectively; 50% PM, 43% DM, 6% ADM and 1% juvenile myositis (Table 1). Mean age of diagnosis was 53.7 (SD 14.7) years, with 359.0 person-years follow-up from initial diagnosis. Of those who underwent a muscle biopsy (N=77), 99% had features consistent with that of an inflammatory myositis. 40% of all patients were positive for myositis-specific/associated antibodies. (Figure 1). Forty-one percent of all patients had interstitial lung disease (ILD). There were 26 deaths (26%), translating to mortality rate of 72.4 per 1000 patient years. 62% percent of deaths were due to infection (pneumonia [n=14], infective endocarditis [n=1], staphylococcus bacteraemia [n=1]), whilst 19% were due to ILD. In the multivariate analysis, Chinese ethnicity (HR 0.48 95% CI 0.24-0.96, $p = 0.039$) and male gender (HR 2.58 95% CI 1.22-5.50, $p = 0.014$) were independent predictors of mortality.

Conclusion: Pneumonia and ILD are the leading causes of death for IIM in this Asian cohort. Chinese and male gender were independent predictors of mortality.

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Immune-mediated necrotizing myopathies (IMNM) are a severe condition with early muscle damage attested by MRI of thigh muscles. Presence of damage in the other muscle groups, as well as the pattern and the severity of muscle damage in IMNM according to clinical and serological features remain to be clarified.

Methods: IMNM patients with a whole-body MRI (WB-MRI) (n=42) (anti-HMGCR, anti-SRP and seronegative) were included as well as 60 sIBM patients (as controls). Each muscle groups (n=55) were evaluated and fat replacement was estimated in T1 sequence using the Mercuri score (1= normal; 2= mild involvement, fat replacement <30%, 3=moderate involvement, 30-60%; 4=severe involvement, >60%). Overall lesion load was defined as the sum of all abnormal Mercuri scores (≥ 2) evaluated in each muscle groups (reported in percentage from minimum 0% to maximum 100%) and lesion load quotient was defined as the overall lesion load divided by disease duration (years) at WB-MRI. Multivariate analysis including MRI data but also age at first symptom, disease duration and treatment initiation delay were performed by principal component analysis (PCA) and hierarchical clustering analysis (HCA).

Results: IMNM patients (anti-HMGCR, n=25; anti-SRP, n=12 and seronegative, n=5) were aged 48.1 ± 15.8 years at WB-MRI and had a disease duration of 9.8 ± 8.1 years. Most severely affected muscle groups (mean Mercuri \pm SD) were located in the pelvifemoral (gluteus minimus: 2.71 ± 1.15 , gluteus medius: 2.6 ± 1.17 , great adductors: 2.55 ± 1.27 and perineal: 2.43 ± 1.42), lumbar (lumbar extensors: 2.19 ± 1.11) and to a lesser extent in the scapular region (subscapularis: 2.73 ± 1.16). Unsupervised analysis showed two subgroups of patients: one with a mild lesion load ($15 \pm 10\%$, n=32/42) and another with a severe lesion load ($60 \pm 10\%$, n=10/42; $p < 0.001$). In the first group, the mean disease duration before WB-MRI was 6.8 ± 6.0 years compare to 19.52 ± 5.7 years in the second ($p < 0.0001$). Correlational studies confirmed that disease duration was the most important predictor of muscle damage (e.g lumbar $r = 0.76$, and pelvifemoral muscle groups r ranging from 0.55 - 0.73 ; $p < 0.01$).

Nonetheless, multivariate analyses – adjusted for disease duration, age at first symptoms and treatment initiation delay - demonstrated a more severe involvement of the gluteus maximus ($p = 0.04$) and the great adductor ($p = 0.04$) in seropositive vs seronegative patients.

Overall lesion load quotient was similar in IMNM compared to IBM (14 ± 14.9 vs 9.4 ± 8 , $p = 0.3$), but muscle involvement pattern was different. Lesion load quotient was more severe in the trapezius ($p = 0.05$), infraspinatus ($p = 0.03$), psoas ($p = 0.0008$), iliac ($p = 0.0002$), longus adductor ($p = 0.01$) and pectinus ($p = 0.0003$) in IMNM compared to IBM.

Conclusion: IMNM is associated with a severe fatty replacement in the axial and pelvifemoral muscle groups. Disease duration and serological status are important predictor of muscle damage. IMNM and IBM patients seem to have comparable overall lesion load, but progression was more severe in some muscle groups.

Session Title: Muscle Biology, Myositis and Myopathies Poster I: Clinical Features and Disease Course

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Many inflammatory myositis patients experience relapse (relapse rate : 48~65%). Risk factors for relapse in inflammatory myositis remain uncertain. We investigate the relapse and related factors in patients with inflammatory myopathy.

Methods: Retrospectively, the patients who met the Bohan and Peter criteria for the diagnosis of dermatomyositis and polymyositis were collected in a tertiary hospital between Jan. 2005 to Dec. 2016. The relapse was defined as resuming glucocorticoid or dose up of glucocorticoid more than 50% due to myositis or skin aggravation after improvement of inflammatory myositis by initial treatment. We investigated factors associated with the relapse using Multivariate Cox proportional hazards models with backward elimination.

Results: We identified 138 patients (61 dermatomyositis, 3 inclusion body myositis, and 74 polymyositis), and high dose (1mg/kg) of glucocorticoid (median, 60mg [50.0-60.0], prednisolone equivalent) was given as an initial treatment for inflammatory myopathy. Glucocorticoid dose has been reduced less than 15 mg (prednisolone equivalent) until 5 months (median, [4-7]) after initial treatment. However, during glucocorticoid tapering, relapse occurred in 86 patients (62%) after 12 months (median, [7-25]) of initial treatment. Independent risk factors for relapse on multivariable analysis in the overall inflammatory myopathy patients included anti-Ro antibody positivity (adjusted HR 1.84, $p = 0.028$), elevated level of creatine kinase at 1 month after initial glucocorticoid treatment (adjusted HR 2.10, $p = 0.007$), administration of immunomodulators for maintenance (methotrexate, azathioprine, or cyclosporine; adjusted HR 0.41, $p = 0.003$).

Conclusion: Administration of immunomodulator for maintenance may help to reduce the risk of relapse in inflammatory myopathy.

Session Date: Sunday, October 21, 2018

Session Title: Muscle Biology, Myositis and Myopathies Poster I: Clinical Features and Disease Course

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Autoimmune myositis(AIM) is a constellation of rare chronic disease with progressive muscle weakness. Several autoantibodies are found to be highly correlated with IIM(myositis-associated autoantibodies, MAAs) or distinct clinical features amongIIM (myositis-specific autoantibodies, MSAs). In the current study, we evaluated autoantibody profiles using LIA and analyzed their association with clinical features among patients with autoimmune myositis in Korea.

Methods: Patients with idiopathic inflammatory myopathies were enrolled at seven tertiary care university medical centers. Autoantibodies were examined using EUROLINE assay (for 16 antigens including Mi-2alpha, Mi-2beta, TIF1gamma, MDA5, NXP2, SAE1, Ku, PM-Scl100,PM-Scl75, Jo-1, SRP, PL-7, PL-12, EJ, OJ, Ro-52). Data on history, physical findings, and laboratory investigations were obtained by retrospective medical record review.

Results: A total of ninety-three patients were enrolled. Seventy-two percent (n=67) was women, and mean age at the diagnosis was 50.7 +/- 13.5 year-old. Patients with PM, DM, ADM, and OM were 37 (39.8%), 48 (51.6%), 6 (6.5%), and 10 (10.8%), respectively. Anti-Ro52antibody was the most common antibodies, and anti-TIF1gamma antibody was the most common MSA (Table 1). Positive anti-TIF1gamma antibody was significantly associated with the presence of malignancy and absence of interstitial lung disease (ILD). ILD was observed among 42 patients (45.2 %) and of those ILD,anti-MDA5 antibody was associated with bronchiolitis obliterans organizing pneumonia/cryptogenic organizing pneumonia (BOOP/COP) and anti-synthetase antibodies were associated with nonspecific interstitial pneumonia (NSIP, Table 2).

Conclusion: Myositis-specific autoantibodies were related with clinical manifestations. Especially, anti-MDA5 and anti-synthetase were associated with BOOP/COP and NSIP, respectively.

Table 1. Autoantibody profiles

Antigen	N	% (of total 93)
Mi-2 alpha	7	7.5
Mi-2 beta	5	5.4
TIF1 gamma	15	16.1
MDA5	11	11.8
NXP2	1	1.1
SAE1	2	2.2
Ku	4	4.3
PM-Scl100	1	1.1
PM-Scl75	8	8.6
Jo-1	13	14
SRP	12	12.9
PL-7	4	4.3
PL-12	1	1.1
EJ	4	4.3
OJ	6	6.5
Ro-52	37	49.3

Table 2. Clinical features and autoantibodies

Clinical features	autoantibodies	odds ratio	95% confidence interval	P
Malignancy	Anti-TIF1gamma	43.4	7.7-245.5	<0.01
ILD	Anti-TIF1gamma	0.3	0.7-1.0	=<0.05
ii	Anti-synthetase antibodies*	7.6	2.5-22.9	<0.01
ILD-BOOP/COP	Anti-MDA5	7	1.8-27.1	<0.01
ILD-NSIP	Anti-synthetase antibodies*	3.5	1.3-9.8	<0.05

* anti-synthetase antibodies include antibodies against Jo-1, PL-7, PL-12, EJ, and OJ

Physical Activity Monitoring Using Wrist-Worn Accelerometer in the Assessment and Follow-up of Patients with Myositis

Océane Landon-Cardinal¹, Damien Bachasson², Perrine Guillaume¹, Mathieu Vautier¹, Nicolas Champtiaux¹, Baptiste Hervier¹, Aude Rigolet¹, Olivier Benveniste¹, Jean-Yves Hogrel² and Yves Allenbach¹, ¹Department of Internal Medicine and Clinical Immunology and Inflammation-Immunopathology-Biotherapy Department (I2B), Pitié-Salpêtrière University Hospital, Assistance Publique-Hôpitaux de Paris, East Paris Neuromuscular Diseases Reference Center, Paris, France, ²Institute of Myology, Pitié-Salpêtrière University Hospital, Paris, France

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Muscle Biology, Myositis and Myopathies Poster I: Clinical Features and Disease Course

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Wrist-worn accelerometers allow the objective estimation of physical activity (PA) in daily life. Recently, the ENMC workshop on outcome measures in myositis suggested to implement PA monitoring for improving patient follow-up. This study aimed to evaluate PA monitoring in the assessment of myositis patients in daily clinical practice.

Methods: Included patients had a diagnosis of dermatomyositis (DM), immune-mediated necrotizing myopathy (IMNM) or overlap myositis (OM). They either had a new-onset or relapsing myositis, a stable disease on maintenance therapy or were undergoing immunosuppressant tapering. Patients were evaluated at baseline and 6 months (M6). IMACS core-set measures, ACR/EULAR improvement score, muscle endurance testing, deltoid and psoas strength using hand-held dynamometry, 14-days raw acceleration data (expressed both as mean daily Euclidean norm minus 1 g (ENMO) and as standard deviations from healthy control Z-score), and quality of life (QoL) questionnaires were recorded. Relationships between variables were investigated using Spearman correlation coefficient (ρ) and random forest (RF) regressions.

Results: Fifty-five patients (16 OM, 27 IMNM and 12 DM) were included. At baseline, 67% had ENMO Z-score lower than 1 (mean Z-scores -1.09 ± 0.94). At M0, ENMO mainly correlated with manual muscle testing 8 (MMT8, $\rho=0.44$, $p<0.001$), creatinine level ($\rho=0.43$, $p<0.001$), HAQ ($\rho=-0.53$, $p<0.0001$), and SF-36-physical functioning ($\rho=0.40$, $p<0.01$). According to RF regressions, most important features associated with ENMO Z-scores were HAQ, SF-36-physical functioning/energy/pain and disease duration.

At M6, ENMO changes mainly correlated to changes in muscle enzymes ($\rho=-0.44$, $p<0.01$), MMT8 ($\rho=0.44$, $p<0.01$), and depression score ($\rho=-0.44$, $p=0.013$). According to the RF regression, most important features associated with ENMO changes were absolute change in MMT8, HAQ, SF-36-physical functioning, physician global assessment, and depression score.

ENMO changes were correlated with ACR/EULAR improvement score ($\rho=0.48$, $p<0.01$) and all patients, except one, achieving a major improvement had an absolute change of ENMO >5 mg/day. Yet, only 50% with moderate improvement (ACR/EULAR) had an improvement in ENMO and variable changes in ENMO were observed in patients with unchanged and minimally improved status.

Conclusion: PA levels were smaller in myositis patients at baseline compared to healthy controls and were correlated with MMT8 and QoL. Patients with major ACR/EULAR improvements at follow-up were associated with consistent changes in PA, while other displayed heterogeneous changes in PA.

In Patients with Suspected Idiopathic Inflammatory Myopathy, Does Pre-Biopsy Musculoskeletal MRI Result in Greater Yield of Diagnostic Biopsy Results? Summary of Data from a 10-Year Single Hospital Audit

Julia Murdoch¹, Merrilee Needham^{2,3} and Helen Keen^{3,4,5}, ¹Sir Charles Gairdner Hospital, Perth, Australia, ²Fiona Stanley Hospital, Perth, Australia, ³Murdoch University, Perth, Australia, ⁴Rheumatology, Fiona Stanley Hospital, Murdoch, Australia, ⁵University of Western Australia, Perth, Australia

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Muscle Biology, Myositis and Myopathies Poster I: Clinical Features and Disease Course

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The idiopathic inflammatory myopathies (IIM) constitute a potentially steroid-responsive group of conditions that must be differentiated from other causes of muscle weakness. Histopathology from muscle biopsy remains pivotal to diagnosis; however, muscle involvement in IIM is often patchy with associated risk of non-diagnostic biopsies. There has been mounting evidence for the use of magnetic resonance imaging (MRI) prior to biopsy to target biopsy site and improve diagnostic yield [1], though this is not routinely used. This single-centre 10-year clinical audit aimed to examine whether the use of MRI prior to muscle biopsy in patients with undifferentiated myopathy resulted in high rates of diagnostic results compared to selection of biopsy site based on clinical assessment of muscle involvement alone.

Methods: Patient admissions over a 10-year period with an ICD code of “myopathy” or “myositis” were extracted from the hospital iSOFT database and screened for eligibility. Each eligible case was assessed to determine (1) clinical localisation of muscle involvement (2) whether a musculoskeletal MRI was performed pre-biopsy (3) site of muscle biopsy (4) histopathology result (+/- electron microscopy/muscle markers) (5) congruence of muscle involvement by clinical assessment and selected biopsy site (6) congruence of muscle involvement on MRI and selected biopsy site.

Results: Forty-eight eligible cases were identified for inclusion in the study. Of these, 15 had musculoskeletal MRI performed prior to muscle biopsy and 33 did not. Of the patients who did not have an MRI, the biopsy was positive in 30 cases (91%) and negative in 3 (9%). In the patients who did undergo MRI, the result was positive in 12 (80%) and negative in 3 (20%). The selected biopsy site correlated with clinical sites of muscle involvement in 40 cases, 3 did not, and 5 lacked sufficient clinical documentation to determine this. Two of the three negative biopsies in the MRI group had been targeted appropriately; biopsy correlated to sites of involvement on MRI. One of these cases was ultimately given a clinical diagnosis of dermatomyositis.

Conclusion: Inflammatory myopathies are uncommon clinical conditions. Despite the limitations of a small sample size and retrospective analysis, our results suggest that clinical targeting for muscle biopsy site alone yields high rates of diagnostic results and doesn't support the use of MRI to target biopsy site. However the results are perhaps surprising, and therefore a prospective study would be of interest.

Abstract Number: 395

Systemic Lupus Erythematosus (SLE) with Inflammatory Myositis

Nicole Bitencourt, Elizabeth (Blair) Solow and Bonnie L. Bermas, Division of Rheumatic Diseases, UT Southwestern Medical Center, Dallas, TX

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Muscle Biology, Myositis and Myopathies Poster I: Clinical Features and Disease Course

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The goal of this study was to identify specific clinical features of patients with SLE who have inflammatory myositis.

Methods: A retrospective chart review was performed of patients seen in the rheumatology clinic at a single center safety net hospital over a period of 4 months and who had an encounter diagnosis of SLE by ICD-10 code [M32.x]. Diagnosis of SLE was confirmed by one author (NB) using 2015 ACR/SLICC criteria. Cases of inflammatory myositis were defined by either muscle biopsy or with CK elevation/muscle weakness with or without confirming muscle MRI consistent with myositis. Data on patient demographics, clinical and laboratory features were extracted. Chi-square was used to analyze clinical features.

Results: Of 354 patients with an encounter diagnosis of SLE, 30 (8.5%) were diagnosed with myositis. Most (93%) were women; 56% were African American and 43% Hispanic. Half were diagnosed with SLE and myositis simultaneously, 30% developed myositis after SLE diagnosis (mean 5.5 years later) and 20% were diagnosed with myositis prior to SLE (mean 10.9 years earlier). Patients fell into two clinical categories, those with features of systemic sclerosis (60%) and those

without (40%). Among those with features of systemic sclerosis, 9 of 18 met the 2013 ACR/EULAR classification criteria for systemic sclerosis, while 9 of 18 did not but scored 5 or more criteria points. SLE patients with co-existing features of systemic sclerosis were more likely to have Raynaud's phenomenon and interstitial lung disease ($p < 0.05$) (Table 1 and 2). Muscle biopsy was performed in 16 patients, with 12 biopsies among 11 patients available for review (one patient underwent two biopsies over 3 years). Non-specific inflammatory changes were the most commonly observed muscle biopsy feature, followed by tubuloreticular inclusions by electron microscopy (Table 3). Autoimmune necrotizing myopathy was described in 4 of 12 muscle biopsies, three of whom lacked features of systemic sclerosis.

Conclusion: In our cohort of SLE patients at a large safety net hospital, the diagnosis of co-existing myositis was seen in 8.5% of patients, most of whom had overlap features of systemic sclerosis.

phenotypic, physiologic, and radiologic features of this cohort and to identify important factors that may predict prognosis in terms of disease severity and outcomes.

Methods: A retrospective single center observational longitudinal study characterized clinical characteristics, lung function, HRCT findings, and outcomes of MDA5-positive patients referred to a tertiary hospital. Patients who met the following criteria were defined as severe ILD: (1) baseline FVC <50% with ILD as known cause; (2) oxygen use due to ILD; (3) lung transplant evaluation due to ILD; (4) respiratory failure requiring mechanical ventilation for ILD; (5) death due to ILD or MDA5 diagnosis. CT scans were reviewed by 2 radiologists to determine ILD pattern and a semi-quantitative CT severity score.

Results: Fifteen MDA5-positive cases were identified between 2007 to 2018; 4 (27%) had clinically amyopathic DM (CADM), 6 (40%) had vasculopathic skin lesions, and 3 (20%) had both CADM/vasculopathy. Seven subjects (47%) developed severe ILD, of which 3 died from hypoxemic respiratory failure and 1 from failure to thrive. Those with severe disease had lower FVC%, TLC%, DLCO%, and CT ILD score at baseline and 1 year of following up, and were more likely to have a cryptogenic organizing pattern on CT. Smoking history, myositis, oral ulcers, nasal congestion, pneumomediastinum, and higher levels of inflammatory markers were more likely to be found in the severe group, whereas Raynaud's phenomenon and non-specific interstitial pneumonia pattern on CT were more common in the mild/moderate group.

Conclusion: Our data supports that MDA5Ab-associated ILD seems to follow a bimodal pattern, which can be severe and/or progressive in a significant number of cases, but may be treatable and stabilized in certain patients. Although CADM and ulcerative and nodular lesions consistent with vasculopathy were found in equal frequency in the entire cohort and in

Session Title: Muscle Biology, Myositis and Myopathies Poster I: Clinical Features and Disease Course

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Myositis-specific autoantibodies (MSAs) have been shown to predict clinical features and have prognostic implications in patients with idiopathic inflammatory myopathies (IIMs), with anti-melanoma differentiation-associated gene 5 antibody (anti-MDA5 Ab) and anti-transcriptional intermediary factor antibody (anti-TIF1γAb) being associated with potential life-threatening complications. However, testing of autoantibodies in inflammatory myopathy is not routinely performed in Hong Kong due to its cost and limited availability. The aim of the study is to investigate the prevalence of MSAs and their associated complications.

Methods: A total of 201 consecutive patients with IIMs being followed up in the Rheumatology clinics of participating regional hospitals from July 2016 to January 2018 were recruited. Clinical characteristics, treatment history and disease

complications such as interstitial lung disease (ILD), rapidly progressive interstitial lung disease (RP-ILD) and malignancies were documented. Immunoblot assay was used to detect the presence of MSAs in all the participants.

Results: Out of the 201 patients with IIMs, 122 (60.7%) had dermatomyositis while 79 (39.3%) had polymyositis. Around 63.2% patients had at least one MSA positive. The most common MSAs were anti-MDA5 Ab (28, 13.9%) and anti-TIF1 γ Ab (28, 13.9%), followed by anti-Jo-1 Ab (25, 12.4%). Anti-MDA5 Ab was present exclusively in dermatomyositis and was strongly associated with digital ulcers, clinically amyopathic dermatomyositis (CADM) and RP-ILD (all $p < 0.001$). Anti-TIF1 γ Ab was strongly associated with refractory rash and malignancy (both $p < 0.001$). Anti-Jo-1 Ab was strongly associated with interstitial lung disease (ILD) ($p = 0.001$) and was negatively associated with malignancy ($p = 0.006$). Multivariate analysis showed that independent risk factors of development of RP-ILD included anti-MDA5 Ab positivity (OR 14.5, $p = 0.001$), CADM (OR 13.9, $p = 0.015$) and history of pulmonary tuberculosis (OR 12.2, $p = 0.026$). By Cox regression with adjustment of confounders, independent risk factors for malignancy included anti-TIF1 γ Ab positivity (HR 3.55, $p = 0.002$), dermatomyositis (HR 3.82, $p = 0.009$) and family history of cancer (HR 3.40, $p = 0.038$). In 45 newly diagnosed IIM patients, 32 (71.1%) had dermatomyositis and 13 (28.9%) had polymyositis. Kaplan Meier analysis showed that the 6-month mortality in patients with anti-MDA5 Ab was 47.5%, compared to 11.1% in those without anti-MDA5 Ab. Anti-MDA5 was associated with significantly lower survival ($p = 0.002$).

Conclusion: The local data on MSA profiles and their clinical associations were established. Anti-MDA5 Ab was associated with CADM, RP-ILD and poorer survival, while anti-TIF1 γ Ab was associated with malignancy in Hong Kong Chinese patients with IIMs, especially nasopharyngeal carcinoma. MSA testing enables early confirmation of these diseases with potentially life-threatening complications, and will have an important impact on the management of pulmonary disease and vigilance of malignancy screening.

Session Title: Muscle Biology, Myositis and Myopathies Poster – ARHP

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Poly- and dermatomyositis (PM/DM) are idiopathic inflammatory muscle diseases characterized by reduced muscle function. Oral glucocorticoids and DMARD's are the usual treatment options and physical exercise plays an important role in the treatment as well. Despite an often beneficial effect of treatment, most patients are left with sustained muscle impairment and reduced quality of life. It is not known how muscle impairment differ between patients with newly onset PM/DM and patients with established PM/DM. The aim of this study is to investigate muscle function as to maximal isometric strength (MVIC) and isometric muscular endurance (ME) in patients with newly onset, active and established PM/DM. A further aim is to investigate possible correlations between muscle function and health related quality of life (HRQoL).

Methods: All patients diagnosed with PM or DM ($n = 5$, all female) during 170901 and 180401 at Karolinska University hospital in Solna who met the inclusion criteria were asked to participate. Patients with established PM/DM ($n = 6$, all female) were identified through patient register at the same clinic, selected to match recent onset disease group as to age and gender. A dynamometer from Biodex was used to assess MVIC and ME starting with three warm-up 4-sec contractions followed by three similar maximal contractions, all with a 3-minute rest in-between. Thereafter six sets of twelve submaximal repetitions, starting on 20 % of MVIC and increasing by 10 %/set, finishing on 70 % of MVIC. Each set ended with a new maximal contraction registered as percentage of initial MVIC. The participants reported HRQoL using SF-36. Statistical significance was set to $p < 0.05$, Mann-Whitney U-test was used to compare groups and Spearman's rho for correlations.

Results: Median age for patients with recent onset PM/DM was 36 (min–max 19–64) years and for established disease 61 (42–66) years. Diagnosis duration was 4 (1–6) months and 126 (85–433) for the two groups, respectively. Patients with recent onset disease had a median MVIC of 73 (53–127) Nm and patients with established disease had 58 (41–82) Nm ($p=0.22$). ME were 83 (63–94) % and 91 (85–98) % for patients with recent onset disease and established PM/DM, respectively ($p=0.08$). The correlations between ME and General Health was ($r_s=0.54$, $CI=-0.08-0.87$) with correlations to Physical Function, Physical Role Function, and Social Function varying between ($r_s=0.40$, $CI=-0.26-0.81$) and ($r_s=0.48$, $CI=-0.17-0.84$). Correlations between MVIC and Vitality, Physical Role function, Emotional Function and Social Function varied between ($r_s=-0.49$, $CI=-0.84-0.16$) and ($r_s=-0.34$, $CI=-0.78-0.33$). Correlations to remaining domains were lower.

Conclusion: No significant differences were found between the groups regarding MVIC and ME. However, there was a trend towards reduced ME in patients with recent onset PM/DM compared to established disease. Correlations between muscle function and HRQoL were moderate at best. Further research is needed with more patients to reach statistical power and improved matching of patients and controls.

Session Date: Sunday, October 21, 2018

Session Title: Orthopedics, Low Back Pain and Rehabilitation Poster – ACR/ARHP

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 9:00AM-11:00AM

Background/Purpose: For patients undergoing total knee replacement (TKR) for osteoarthritis (OA), preoperative musculoskeletal (MSK) complaints in areas beyond the index knee are common; however, the risk for new MSK comorbidities after TKR is not well studied.

Methods: We used data from the Adding Value in Knee Arthroplasty (AViKA) prospective cohort study on patients undergoing elective TKR for OA at a tertiary academic center. Preoperative questionnaires included demographics, data for Charlson Comorbidity Index, Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) Pain and Function Scales, Mental Health Inventory-5 (MHI-5), Pain Catastrophizing Scale (PCS), and presence of MSK symptomatic areas by region (neck, hands/wrists/arms/shoulders, back, hips, non-index knee, and ankles/feet). Follow-up questionnaires including data on incident symptomatic areas were distributed at 3, 6, 12, 24, 36, and 48 months post-TKR. Cumulative incidence (number of new cases per number of subjects at risk) and incidence rates (number of new cases per person time) were calculated for each symptomatic area. We used Poisson regression models to identify factors associated with incident MSK symptomatic areas. Covariates with two-sided p -values < 0.05 , or incidence rate ratio (RR) < 0.8 , or $RR > 1.25$ in univariate analyses were incorporated in the final parsimonious models.

Results: Among 308 patients undergoing elective TKR for OA, 87% were younger than 75 years and 60% were female. One-quarter of subjects had at least one symptomatic area at baseline, and of those, non-index knee was the most common presurgical symptomatic area (10%). The cumulative incidence of any new MSK symptomatic area over 4 years was 45%, while the incidence rate was 192 per 1000 person-years (95% CI 153-242 per 1000 person-years). Cumulative incidence was highest for non-index knee (23%) and back (15%); incidence rates for non-index knee and back were 69 per 1000 person-years (95% CI 52-92 per 1000 person-years) and 53 per 1000 person-years (95% CI 38-74 per 1000 person-years) respectively. Based on the final Poisson model (Table), variables associated with developing an incident MSK symptomatic area after TKR included female sex (RR 1.51, 95% CI 1.13-2.04), body mass index ≥ 35 (RR 1.34, 95% CI 1.03-1.74), baseline index knee WOMAC function score ≥ 41 (RR 1.49, 95% CI 1.12-1.97), and symptoms consistent with anxiety/depression (MHI-5 < 68) (RR 1.41, 95% CI 1.10-1.82).

Conclusion: Incident MSK comorbidities, particularly in the non-index knee and back, will occur in roughly half of elective TKR recipients in the four years following TKR. Factors associated with incident MSK comorbidities include female sex,

obesity, worse baseline index knee functions cores, and anxiety/depression. Further study is needed to examine the long-term impact of these incident comorbidities on postoperative rehabilitation and quality of life.

Session Title: Orthopedics, Low Back Pain and Rehabilitation Poster – ACR/ARHP

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 9:00AM-11:00AM

Background/Purpose: To investigate the potential predictors of response to a single intra-articular injection of mannitol-modified cross-linked hyaluronic acid (HANOX-M-XL) in patients with first metatarsophalangeal joint osteoarthritis (FMP-OA).

Methods: Observational, single-arm, prospective multicentre trial, with a 3 month follow-up (N° EudraCT 2015-AO1904-45). Inclusion criteria: patients with symptomatic hallux rigidus, not relieved by analgesics and / or non-steroidal-anti-

inflammatory drugs (NSAIDs) and / or foot orthotic) with radiological evidence of FMP-OA (joint space narrowing and/or osteophyte). Main exclusion criteria: Patients with hallux valgus, microcrystalline or inflammatory arthritis, viscosupplementation of the target joint in the last 3 months, intra-articular corticosteroids in the previous month, planned surgery within the 3 months of follow-up. All patients received a single, imaging guided (ultrasonography or fluoroscopy), intra-articular injection, of 1 ml of HANOX-M-XL, in the FMP joint. Data obtained at baseline: age, sex, weight, height, symptoms duration, bilaterality, previous and current treatments for OA, concomitant therapies, patient self-assessment of pain (11-point numeric scale 0-10), Menz radiological classification (stage 1 to 4). Outcome measures: patient self-assessment of pain at day 90, patient's perception of effectiveness ((0=not effective to 3= very effective), changes in analgesic intake, safety. The primary endpoint was the pain variation between the date of injection and month 3. The secondary outcome measures were the patient assessment of effectiveness and the decrease in pain killer use. Predictors of efficacy were studied in uni-variate and multivariate analysis from the intent-to-treat (ITT) population.

Results: Sixty-five subjects(72.3% women, mean age 60, mean symptom duration 24.9 months) were included in the trial. Nine (13.5%) were lost to follow-up. X-ray grade was 1 in 28 patients, 2 in 29, 3 in 6. There was no statistically significant correlation between the radiological stage and the pain score at baseline ($p = 0.69$). At baseline and end-point, the average pain was respectively 6.5 ± 1.8 and 2.8 ± 2.3 . The pain score mean difference was highly significant (-3.1 ± 2.9 ; $p < 0.0001$). The average pain score at end-point was 2.0 ± 1.9 in X-ray stage 1, 3.1 ± 2.3 in stage 2 and 3.3 ± 2.4 in stage 3. The between-group difference was statistically significant ($p=0.001$). In multivariate analysis, pain decrease was unrelated to age, gender, disease duration, pain score at baseline, bilaterality, and imaging guidance but remained related to X-ray stage ($p=0.02$). Adverse events (AEs) were reported by 15 patients (22.7%). All were a transient increase of the big toe pain, that occurred within the very next hours after injection and lasted a few days. All AEs have been resolved in 3 to 7 days.

Conclusion: This prospective study, from the largest cohort ever published in FMP visco supplementation, showed that the clinical outcome of a single injection of 1 ml of HANOX-M-XL, performed under imaging guidance, was significantly better in patients with mild joint space narrowing. However the majority of patients with more advanced OA were also significantly improved.

Session Title: Orthopedics, Low Back Pain and Rehabilitation Poster – ACR/ARHP

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 9:00AM-11:00AM

Background/Purpose: An increasing number of total jointreplacement (TJR) procedures are performed as computer-assisted total joint replacement (CA-TJR). Effectiveness of computer-assisted total joint replacement (CA-TJR) compared to conventional TJR has been evaluated by multiple systematic reviews with conflicting results. We evaluated the quality of systematic reviews comparing CA-TJR to conventional TJR.

Methods: We searched MEDLINE, EMBASE, the Cochrane, and Epistemonikos to identify systematic reviews published through May 2017. One reviewer conducted title and abstract screening of all resulting citations. Full-text articles that met inclusion criteria were retrieved and assessed independently by two reviewers using the AMSTAR 2 tool (Sheet al., 2017). AMSTAR 2 has seven critical and 9 non-critical domains. Systematic reviews are rated as high (no critical or non-critical flaws), moderate (non-critical flaws only), low (1critical flaw), or critically low quality (>1 critical flaw).

Results: Of 384 citations originally identified, 38 systematic reviews were included (Figure 1). Based on the AMSTAR2 tool, 37 studies were rated critically low and one study was rated low. The low rating was due to failure in meeting AMSTAR 2 criteria on the following critical domains (Figure 2): 37 (89%) reviews did not report the protocol registration; 32 (84%) studies did not justify excluding individual studies; 27(68%) studies did not account for risk of bias in primary studies when interpreting the results; 20 (52%) failed to use comprehensive literature search strategy; 17 reviews with meta-analyses failed to justify the use of appropriate methods for statistical combination of results from

randomized controlled trials (48%) and non-randomized studies (44%), and 16 (42%)meta-analyses did not use satisfactory techniques to assess risk of bias of RCTs; and 16 (42%) studies failed to report publication bias. The non-critical weaknesses are shown in figure 3.

Conclusion: Despite the large number of published systematic reviews about the relative effectiveness of CA-TJR, quality of these reviews was critically low, thus significantly weakening the conclusions derived from these reviews.

Session Title: Orthopedics, Low Back Pain and Rehabilitation Poster – ACR/ARHP

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 9:00AM-11:00AM

Background/Purpose: This study was undertaken to identify preoperative physical performance factors predictive of stair climbing ability 1 month following total knee arthroplasty.

Methods: In this prospective cohort study, we assessed a total of 84 patients (8 males and 76 females; average age 72.0 ± 6.0 years) who underwent a primary unilateral total knee arthroplasty (TKA). Before and 1 month after TKA, patients completed physical performance tests including stair climbing test (SCT), 6-minute walk test (6MWT), timed up and go test (TUG), isometric knee flexor and extensor strength of the surgical and non-surgical knees, and instrumental gait analysis for spatiotemporal parameters. Self-reported disease-specific physical function measured by using the Western Ontario McMaster Universities Osteoarthritis Index (WOMAC) and self-reported quality of life measured by using Euro QOL five dimensions (EQ-5D) questionnaire.

Results: In the bivariate analyses, the postoperative SCT-ascent had a significant positive correlation with the SCT-ascent ($r=0.29$, $p=0.01$), SCT-descent ($r=0.28$, $p=0.01$), TUG ($r=0.37$, $p<0.01$), preoperative age ($r=0.25$, $p=0.02$), and a significant negative correlation with the preoperative 6MWT ($r=-0.33$, $p<0.01$), peak torque (PT) extensor of surgical knee ($r=-0.29$, $p=0.01$), PT flexor of surgical knee ($r=-0.26$, $p=0.02$), PT extensor of the non-surgical knee ($r=-0.26$, $p=0.02$), PT flexor of the nonsurgical knee ($r=-0.25$, $p=0.02$). The postoperative SCT-descent had a significant positive correlation with the SCT-ascent ($r=0.28$, $p=0.01$), SCT-descent ($r=0.40$, $p<0.01$), TUG ($r=0.38$, $p<0.01$), preoperative age ($r=0.27$, $p=0.01$), WOMAC function ($r=0.30$, $p<0.01$), and a significant negative correlation with 6-MWT ($r=-0.33$, $p<0.01$), PT extensor of surgical knee ($r=-0.23$, $p=0.04$), PT flexor of surgical knee ($r=-0.24$, $p=0.03$), PT extensor of the nonsurgical knee ($r=-0.25$, $p=0.03$), PT flexor of the nonsurgical knee ($r=-0.23$, $p=0.03$). In the linear regression analyses, the postoperative SCT-ascent had a significant positive correlation with the preoperative TUG ($\beta=0.28$, $p<0.01$), PT extensor of surgical knee ($\beta=-0.23$, $p=0.03$) and the postoperative SCT-descent had a significant positive correlation with preoperative SCT-descent ($r=0.28$, $p=0.01$), and the age ($\beta=0.20$, $p=0.04$).

Conclusion: This study demonstrated that preoperative physical function influenced on postoperative stair climbing ability 1 month after TKA. Using variables easily measured before surgery, it may be possible to predict with good accuracy for postoperative stair climbing ability. In addition, these results could be of importance in determining variable preoperative rehabilitation strategies to improve stair climbing ability, especially focusing on balance, endurance and strengthening exercises.

Comparison of Radial Extracorporeal Shock Wave Therapy and Traditional Physiotherapy in Rotator Cuff Calcific Tendinitis Treatment

Tomris Duymaz¹ and Dilsad Sindel², ¹Physiotherapy and Rehabilitation, Istanbul Bilgi University, Faculty of Health Sciences, Istanbul, Turkey, Istanbul, Turkey, ²Department of Physical Medicine and Rehabilitation, Istanbul University Istanbul Faculty of Medicine, Istanbul, Turkey

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Orthopedics, Low Back Pain and Rehabilitation Poster – ACR/ARHP

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 9:00AM-11:00AM

Background/Purpose: Radial Extracorporeal Shock Wave Therapy (rESWT) has more recently been used in the treatment of a number of musculoskeletal conditions. The purpose of this study is to investigate the efficacy of rESWT on pain, range of motion (ROM) and functionality besides conventional physiotherapy methods in the treatment of chronic rotator cuff calcific tendinitis (RCCT).

Methods: We studied 80 patients with chronic RCCT. The patients were randomly divided into 2 groups: rESWT group (n=40) treated with conventional physiotherapy and rESWT and control group (n=40) treated only with a conventional physiotherapy program. The traditional physiotherapy program included ultrasound, transcutaneous electrical nerve stimulation, shoulder joint ROM and stretching exercises, and ice applications. All patients received a total of 20 treatments for 4 weeks, 5 days a week. rESWT was applied once a week in total for 4 weeks. Before and after treatment, all patients were evaluated for age, height, weight, body mass index (BMI), pain intensity with a visual analogue scale, shoulder ROM and functional disability status with the shortened version of the Disabilities of the Arm, Shoulder and Hand questionnaire (QuickDASH). The SPSS 22.0 was used for the statistical analysis. A p value of <0.05 was considered statistically significant.

Results: The mean age of the participants was 53.29 ± 9.57 years and the mean BMI value was 26.09 ± 2.99 kg/m². Although all the parameters of the patients in both groups improved significantly, it was determined that patients in the rESWT group had a statistically significant improvement in pain, ROM and QuickDash scores ($p < 0.001$, $p < 0.001$, $p < 0.001$, respectively).

Conclusion: We assume that rESWT is an effective and noninvasive method of reducing pain and increasing ROM and functional status without the need for surgery.

McInnes^{5,6} and Matthias Schieker³, ¹Institute of Infection, Immunity and Inflammation, University of Glasgow, Glasgow, United Kingdom, ²Novartis Institutes for Biomedical Research, Basel, Switzerland, ³Novartis Institutes for Biomedical Research, Basel, Switzerland, ⁴Novartis Institutes for Biomedical Research, Basel, United Kingdom, ⁵University of Glasgow, Glasgow, United Kingdom, ⁶Institute of Infection, Immunity and Inflammation, University of Glasgow, Glasgow, Great Britain

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Orthopedics, Low Back Pain and Rehabilitation Poster – ACR/ARHP

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 9:00AM-11:00AM

Background/Purpose: Shoulder tendinopathy is a multi factorial disorder that accounts for a high proportion (approx. 30%) of referrals to orthopaedic surgeons. Experimental evidence points to the importance of the interleukin 17 (IL-17) cytokine family in the pathogenesis of several immune inflammatory diseases. Given our previous findings of a role for IL-17A in tissue remodeling events in tendinopathy we hypothesized that blockade of IL-17A may provide a therapy for tendinopathy.

Methods: We confirmed evidence of IL-17 family expression in supraspinatus tendinopathy and thereafter, explored mechanisms whereby IL-17A mediated inflammation and tissue remodelling in human tenocytes. Torn supraspinatus tendon (established pathology) and matched intact subscapularis tendon (representing ‘early pathology’) along with control biopsies were collected from patients undergoing shoulder surgery. In tendon biopsies, expression of IL-17A was assessed by qRT-PCR and immune histochemistry. In isolated tenocytes, effects of IL-17A blockade by secukinumab were assessed following IL-17A and TNF activation by whole transcriptome AmpliSeq or multiplex cytokine assays. Finally, we assessed the translational effects of IL-17A blockade on structure/function in a rat model of rotator cuff tendinopathy of the supraspinatus tendon using magnetic resonance imaging (MRI) and gait analysis.

Results: *IL-17A blockade reduces proinflammatory signature in human tenocytes.* Transcriptomic datasets showed the presence of the IL-17 family members IL-17A-E and receptors IL-17RA & IL-17RC throughout the spectrum of tendinopathy. Furthermore IL-17A significantly elevated production of the proinflammatory cytokines IL-6, IL-8, CXCL-1 and CCL-2 in tenocytes. Importantly, IL-17A blockade by secukinumab significantly reduced the expression of these proinflammatory cytokines.

IL-17A blockade significantly improves tendon structure and function in vivo. The pharmacological effects of IL-17A blockade on MRI/ gait abnormalities were assessed 4 weeks after the surgical induction of tendinopathy and following once weekly dosing of anti-IL-17A antibody. The induction of tendinopathy significantly increased the MRI T2 signal in tendinopathy and triggered gait abnormalities by significant alteration of front-hind ratios of footprint contact areas. IL-17A blockade normalized both, altered MRI T2 signals ($p < 0.01$, $n = 4$) and gait abnormalities ($p < 0.05$, $n = 8$).

Conclusion: Our study provides evidence that IL-17A operates as a cytokine modulator in human supraspinatus tendinopathy and that blockade significantly improves tendon structure and function in a rodent model of supraspinatus tendinopathy. Based on these results we have commenced a randomised multicenter trial of the effect of IL-17A blockade with secukinumab in patients with rotator cuff tendinopathy (NCT03344640).

Feasibility of Enabling Self-Management and Coping with Arthritic Pain Using Exercise (ESCAPE-Pain) Programme for Knee Osteoarthritis in Malaysia

Muhammad Kamil Che Hasan^{1,2}, Emma Stanmore² and Chris Todd², ¹Kulliyyah (Faculty) of Nursing, International Islamic University Malaysia (IIUM), Kuantan Pahang, Malaysia, ²Division of Nursing, Midwifery and Social Work, The University of Manchester, Manchester, United Kingdom

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Orthopedics, Low Back Pain and Rehabilitation Poster – ACR/ARHP

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 9:00AM-11:00AM

Background/Purpose: In Malaysia around one in ten older people are diagnosed with osteoarthritis (OA), with the knee being one of the most commonly affected areas. This can lead to functional limitations, impaired activities of daily living and reduced quality-of-life. Our systematic review of the literature concludes that a programme integrating exercise, education and active coping strategies, known as Enabling Self-management and Coping with Arthritic Pain using Exercise (ESCAPE-pain) provides the best evidence for implementation. Thus, this study aims to evaluate the feasibility of the ESCAPE-pain programme among patients with knee OA in the Malaysian healthcare context.

Methods: A pragmatic, feasibility randomised controlled trial (RCT) was conducted recruiting patients with knee osteoarthritis from two hospitals in Malaysia. Participants were randomised to receive ESCAPE-pain intervention plus usual care ($n = 36$) (intervention group) or usual care only ($n = 36$) (control group). Outcomes were measured for physical function (TUG), knee injury and osteoarthritis outcome scores (KOOS), mental wellbeing (Short-WEMWBS), exercise health beliefs and self-efficacy (ExBeliefs) and fear of falling (Short-FES-I) at baseline, six-week and after 12-week of intervention.

Results: There were no significant differences in baseline characteristics between the groups ($p > 0.05$). Recruitment rate showed 90.5% (72/105) and retention rate at 12-week was 87.5% (63/72). Attendance to intervention programme at ≥ 10 of 12 sessions was high (82.4%). Using modified intention-to-treat analysis, repeated measures ANOVA showed no significant changes ($p > 0.05$) for TUG or KOOS between intervention and control groups. However, better outcomes ($p < 0.05$) were reported after 12 weeks for health beliefs, mental wellbeing, and fear of falling among patients in intervention group. Satisfaction survey among participants revealed that the ESCAPE-pain programme is easy to follow, straightforward and tolerable for future implementation.

Conclusion: The findings of this study indicate that the ESCAPE-pain programme is feasible for patients with knee OA in Malaysia. As a feasibility study, this is not powered to detect significant differences on primary KOOS outcomes,

nonetheless participants reported positive views towards exercise with significant improvements in belief in performing activities, mental wellbeing and reduced fear of falling.

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Orthopedics, Low Back Pain and Rehabilitation Poster – ACR/ARHP

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 9:00AM-11:00AM

Background/Purpose: Fifty percent of people with anterior cruciate (ACL) injury develop knee osteoarthritis (OA) within 6-10 years, even with ligament reconstruction. Despite evidence that targeted exercise, appropriate physical activity and weight management effectively limit symptomatic knee OA, only 27% (62/233) of Australians and Americans with ACL reconstruction 1-5 years previously, remembered discussing OA risk with any health care professional (HCP). We conducted a survey to understand what Canadian sports orthopedic surgeons, primary care physicians (PCPs) and physiotherapists (PTs) managing non-elite athletes with ACL injury do or do not tell their patients about their OA risk.

Methods: We surveyed practicing sports orthopedic surgeons, PCPs and PTs who provide care to non-elite athletes with acute ACL injury.

The electronic survey was distributed through an e-blast and newsletter link by the Canadian Academy of Sport and Exercise Medicine (CASEM) (many members are PCPs with specialty training in sports) and the Sports and Orthopedic Divisions of the Canadian Physiotherapy Association. Orthopedic surgeons were contacted via telephone and or email and completed the survey via fax, mail or online. The survey included four sections: practitioner demographics; frequency and specific factors discussed; when post-injury risk factors are discussed; and, recommendations for how and with whom risk factors and their management should be discussed.

Results: There were 98 PCP, 263 PT, and 140 orthopedic surgeon respondents. All Canadian provinces and 2 of 3 territories were represented. Seventy-five or more of each provider group had greater than 5 years' experience treating people with ACL injury. Seventy to 77% of physicians reported that they always discussed OA risk but only 35% of PTs do (Table 1). All groups reported that patient activity level (i.e. activities perceived as detrimental to knee health), ACL re-injury and simultaneous injury to other structures in the knee were most often the reason for discussing OA risk. A high proportion of providers discussed OA risk as part of initial management with many fewer respondents reporting such discussions 3-6 months after injury. Despite a lower proportion of PTs reporting always discussing OA risk, 80% of the physicians and 99% of the PTs indicated that PTs were best suited to provide OA risk information.

Conclusion: These results suggest that there is communication gaps as HCPs, particularly PTs, who routinely manage people with ACL injury do not consistently discuss OA risk post injury. Discussions occur only early post injury when the focus is likely on ACL recovery. Subsequently, there is a lack of emphasis on managing OA risk at final follow-up, when it's likely most important. Educational strategies for health professionals are needed to develop care pathways inclusive of support for OA risk management post ACL injury.

Table 1:

	Primary Care Sports Physician (n=98) % (95% CI)	Physiotherapist (n=263) % (95% CI)	Orthopedic Surgeon (n=140) % (95% CI)

Digital Disruptive Technology for Rehabilitation Following Elective Surgery for Low Back Pain, Knee and Hip Osteoarthritis: A Systematic Review and Meta-Analysis

Xia Wang¹, Manuela Ferreira¹, David J. Hunter², Giovana Vesentini³ and Daniel Pozzobon¹, ¹Institute of Bone and Joint Research, University of Sydney, Sydney, Australia, ²Rheumatology, Institute of Bone and Joint Research, Kolling Institute, University of Sydney, Sydney, Australia, ³Department of Obstetrics and Gynecology, São Paulo State University, Sydney, Australia

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Orthopedics, Low Back Pain and Rehabilitation Poster – ACR/ARHP

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 9:00AM-11:00AM

Background/Purpose: The global uptake of digital health technologies in rehabilitation is increasing, but their effectiveness warrants further investigation. We aim to evaluate the effects of digital solutions used in musculoskeletal rehabilitation for people who underwent orthopaedic surgeries.

Methods: Six databases were searched from the earliest records to October 2017. Eligible studies were randomised controlled trials (RCT) that investigated the effectiveness of disruptive digital technology-based intervention, solo or in combination with other interventions, compared with a control group for people who underwent elective total knee/hip replacement (TKR/THR) or lumbar spinal surgeries. Two researchers independently reviewed the studies as per the Cochrane methodology for the systematic literature review. Study quality was assessed using the Physiotherapy Evidence Database (PEDro) scale (0-10). Trials deemed clinically homogeneous were grouped in meta-analyses. Meta-analyses were performed using random-effects model, and results expressed as mean differences (MD), or standardised MDs (SMD) with 95% confidence interval (CI). The primary outcomes included visual analogue scale (VAS) for pain and functional assessments: the timed up-and-go (TUG) and 6-minute walk test (6MWT).

Results: We identified 19 eligible RCTs with 15 trials (n=1706) for people who underwent TKR, 3 trials (n=383) for THR and 1 (n=60) for lumbar discectomy. There were 3 types of digital rehabilitation interventions involved in this review: telerehabilitation relying on either telephone counselling (8 trials, n=1130) or videoconferencing (4 trials, n=384), game-based therapy (5 trials, n=308) and software (3 trials, n=327). Seven studies were rated as good quality (a PEDro score of 7 or greater).

The pooled analysis of VAS pain data included 5 trials (n=438) assessing post TKR rehabilitation and 1 trial (n=60) assessing post lumbar discectomy rehabilitation. The results showed that, compared to usual care, disruptive technology-based interventions are more effective in reducing pain (MD = -0.19; 95% CI: -0.35, -0.02) for people undergoing TKR. Results of TUG were available from 2 trials (n=207) assessing post TKR rehabilitation and 1 trial (n=72) in THR. Compared to usual care, the intervention showed significant effects in TUG for people who underwent TKR (MD: -7.03;

95% CI: -11.18, -2.88). Pooled estimates from 2 trials (n=258) for people undergoing TKR showed the digital-enabled rehabilitation was not superior to usual care in the 6MWT (MD: -29.36; 95% CI: -65.71, 6.99).

Three trials for people who underwent TKR investigated patient compliance via exercise diaries, leaving inconclusive results. No difference in rates of hospital readmissions or treatment-related adverse events were observed.

Conclusion: There is moderate quality evidence that current digital-enabled rehabilitation shows small but significant effects over usual rehabilitation in reducing pain and improving mobility post TKR. No evidence was observed for people undergoing THR or lumbar spinal surgery rehabilitation. Digital rehabilitation is technically feasible, well-accepted and can be used safely in people undergoing musculoskeletal surgeries.

State or Trait: Pain Catastrophizing and Widespread Pain Following TKR and Their Associations with Pain Relief

Emma Lape¹, Faith Selzer^{1,2}, Jamie E. Collins^{3,4}, Elena Losina^{1,4} and Jeffrey N. Katz^{1,4}, ¹Orthopedic Surgery, Orthopedic and Arthritis Center for Outcomes Research, Brigham and Women's Hospital, Boston, MA, ²Department of Orthopedic Surgery, Harvard Medical School, Boston, MA, ³Department of Orthopedic Surgery, Orthopedic and Arthritis Center for Outcomes Research, Brigham and Women's Hospital, Boston, MA, ⁴Harvard Medical School, Boston, MA

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Orthopedics, Low Back Pain and Rehabilitation Poster – ACR/ARHP

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 9:00AM-11:00AM

Background/Purpose: Pain catastrophizing and widespreadpain (WP) —constructs reflecting cognitive processes during the pain experience—predictdisability, pain chronicity/severity, and lower quality of life in a range of conditions. Gaps remain in our understanding of the extent to which each is a stable(trait) or dynamic (state) variable. We assess a) the stability of pain catastrophizing and WP from before to after TKR and b) whether changes in these measures could be explained by changes in pain.

Methods: We used data from a prospective study of TKR recipients ages 40+. Questionnaires included a body pain diagram to assess WP, the Pain Catastrophizing Scale (PCS; 0-52, 52=worst), and WOMAC Pain (0-100,100=worst). To calculate WP score, we summed the number of body regions, excluding the index knee, in which a subject attested to pain in the past week(maximum=7).

We divided subjects into 3 WP groups (0 vs. 1-2 vs. ≥3pain regions) and into low and high PCS groups (≤16 vs. >16) at baseline and 12 months post-TKR. We assessed changes in group membership from baseline to 12 months. To assess whether changes in PCS and WP were associated with knee pain relief, we created 4 groups by amount of WOMAC pain improvement: <10,10-29, 30-49, ≥50. Changes in PCS score and WP were compared across these groups using ANOVA.

Results: 176 subjects completed the scales at baseline and 12 months; 64% were female, mean age was 66, and baseline median WOMAC pain was 40.

The number of subjects in the high PCS score group diminished from 45 (26%) pre- to 23 (13%) post-TKR. Mean PCS score diminished from 11 (SD:10) to 6 (SD: 8). The number of subjects in each WP group was similar pre- and 12months post-TKR. However, 73 subjects (41%) changed group and were similarly likely to worsen (55%) and to improve (45%). As Figure 1 depicts, most changes in PCS group were in the direction of improvement while, for WP group, similar proportions worsened and improved.

Improvements in PCS score were associated with WOMAC pain reductions. The group with most pain relief (≥ 50 points) had a greater mean improvement in PCS score (11 (SD:12)) than the group with least pain relief (4(SD: 12)) ($p = 0.02$). We did not find a statistically significant association between change in WP and change in WOMAC.

Conclusion: 71% of those with baseline high PCS improved sufficiently to join the low PCS group after TKR. PCS score improvements were associated with pain relief, suggesting that the present measure of catastrophizing reflects state-like aspects that diminish along with pain. In contrast, WP scores were as likely to increase as to decrease after TKR, regardless of knee pain relief. The findings urge caution in interpreting PCS and WP as trait measures in MSK pain research.

Figure 1. Percent of subjects changing PCS or WP group membership from baseline to 12 months

Session Date: Sunday, October 21, 2018

Session Title: Orthopedics, Low Back Pain and Rehabilitation Poster – ACR/ARHP

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 9:00AM-11:00AM

Background/Purpose: Tolperisone is a centrally-acting muscle relaxant being developed in the US as a treatment for acute and painful symptoms of neck and low back muscle spasms. Tolperisone historically has shown both muscle relaxant and analgesic effects without sedation in placebo-controlled and head-to-head clinical studies in Europe and Asia. The present study explores the impact of tolperisone on driving simulation endpoints, self-reported sleepiness, and cognition compared to placebo and cyclobenzaprine.

Methods: The study was a 3-way, randomized, blinded, crossover study assessing the safety and cognitive effects of tolperisone in 31 healthy volunteers. Treatment groups included 450 mg tolperisone administered three-times-a-day (150 mg TID), 30 mg cyclobenzaprine (10 mg TID), and placebo (TID). Participants spent the first three days of three consecutive weeks in the research unit. Dosing occurred in the morning (AM) and at midday (PM) on Days 1-3 and at bedtime on Days 1 and 2. Subjects were administered a digit symbol substitution test followed by 100 km (60 minute) of simulated driving on Day 1 one hour after their midday dose (at drug T_{max}), and again the morning of Day 2 (pre-dosing) to assess next day residual effects. They were also tested the morning of Day 3 (post-dose) to assess the drug at steady-state. Subjects returned to the clinic on Days 7 and 14 to repeat these procedures.

Results: For the primary endpoint of Standard Deviation of Lateral Position (SDLP) over 100-km of driving, tolperisone was no different than placebo, whereas cyclobenzaprine showed significant impairment ($p < 0.001$). Results from secondary endpoints, including cognitive test findings, support this conclusion.

The distribution of SDLP for the placebo and tolperisone test conditions showed symmetry around zero, while cyclobenzaprine was markedly different; a subset of subjects in this study had a level of impairment associated with increased crash risk, as demonstrated by SDLP values above 4.4 cm in this test paradigm (consistent with normative Blood Alcohol Concentration (BAC) levels of above 0.05%).

Secondary measures confirmed the finding of absence of sedation for tolperisone relative to placebo: Digit Symbol Coding Day 1 $p = 0.84$, Day 2 $p = 0.21$, Day 3 $p = 0.12$; and Karolinska Sleepiness Scale: Day 1 $p = 0.47$, Day 2 $p = 0.47$, and Day 3 $p = 0.49$. Additional measures of driving indicated no impairment for tolperisone versus placebo.

Of note in this study, patients taking cyclobenzaprine perceived a distinct lack of effect discrimination and reported feeling safe to drive on Days 2 and 3, while demonstrating impairment based on their SDLP and other secondary endpoint outcomes.

Conclusion: Tolperisone at a dose of 150 mg TID was found to have no impact, compared to placebo, on various measures of driving, self-reported sleepiness, and cognition, in contrast to the widely used muscle relaxant cyclobenzaprine at a dose of 10 mg TID. Because of its long half-life and anticholinergic activity, cyclobenzaprine is not recommended for use in the

elderly and has been associated with an increase in falls and injury. Data from this study confirms impairment in cognition and driving for healthy subjects taking cyclobenzaprine.

Experience of Finding Footwear and Factors Contributing to Footwear Choice in People with Gout

Angela Brenton-Rule¹, Nicola Dalbeth², Larry Edwards³ and Keith Rome⁴, ¹Podiatry, AUT University, Auckland, New Zealand, ²University of Auckland, Auckland, New Zealand, ³University of Florida at Gainesville, Gainesville, FL, ⁴School of Clinical Science, Health & Rehabilitation Research Institute, AUT University, Auckland, New Zealand

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Orthopedics, Low Back Pain and Rehabilitation Poster – ACR/ARHP

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 9:00AM-11:00AM

Background/Purpose: Gout frequently affects the foot, particularly the first metatarsophalangeal joint and Achilles tendon. People with gout commonly wear ill-fitting footwear that lacks cushioning and support, which may further contribute to foot pain and disability. Currently, there is limited understanding about the footwear experience in people with gout and what variables contribute to their footwear choice. The aim of this study was to understand footwear characteristics, experience of finding appropriate footwear, and factors contributing to decisions about footwear choice in people with gout.

Methods: We conducted a web-based survey of people visiting a gout patient education website. All survey participants self-reported a diagnosis of gout and were resident in the United States. The 14-item survey included questions to elicit demographic and clinical characteristics, type of footwear worn, level of difficulty in finding appropriate footwear, and factors contributing to choices about footwear.

Results: There were 83 survey respondents. Respondents were predominately European ethnicity (n=70, 84%), male (n=48, 58%), and aged between 46-75 years old (n=61, 73%). Thirty-nine percent (n=32) were newly diagnosed (<12 months), 43% (n=35) had gout for 1-10 years, and 19% (n=16) had disease for more than 10 years. Most respondents (81%) had experienced at least one flare in the past three months. Medications included non-steroidal anti-inflammatory drugs (n=24, 29%), allopurinol (n=34, 41%), colchicine (n=24, 29%), and corticosteroids (n=9, 11%). Gout flares in the feet were reported by 77 (93%) respondents, mostly in the big toe joint (n=59, 73%), and 73 (88%) reported current foot pain. Tophi affecting the feet were reported by 29 (35%) respondents. Questions about footwear were completed by 76 participants. The majority of respondents (n=49, 64%) reported that they had difficulty in finding footwear. Closed-in athletic shoes (n=66, 88%), sturdy walking shoes or boots (n=60, 79%), and casual closed-in slip-on shoes (n=48, 63%) were the most frequently worn footwear. Orthopaedic or customised shoes were worn least often (n=12, 16%). Comfort, fit, support, and ease to put on/off were the features most often rated as important or very important features when choosing footwear (Table).

Conclusion: For people with gout, foot involvement is almost universal, and difficulty finding suitable footwear is a common experience. Comfort, fit, support, and ease of donning shoes are the key features that people with gout consider important when choosing footwear.

Table: Features of importance in choosing footwear, n=76

Features	Not important	Slightly important	Important	Very important
Comfort	1 (1)	1 (1)	13 (17)	61 (80)
Style	8 (11)	30 (39)	28 (37)	10 (13)
Fit	0 (0)	1 (1)	22 (29)	53 (70)
Support	4 (5)	12 (16)	21 (28)	39 (51)

Kinesiophobia and Physical Function Among Adults with Knee Osteoarthritis: Before and after Strength Training Classes

Aileen Ledingham¹, Michael P. LaValley², Kristin Baker³ and Julie Keysor⁴, ¹Boston University, Boston, MA, ²Biostatistics, Boston University School of Public Health, Boston, MA, ³Franklin Pierce University, Rindge, NH, ⁴Physical Therapy, MGH Institute of Health Professions, Boston, MA

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Orthopedics, Low Back Pain and Rehabilitation Poster – ACR/ARHP

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 9:00AM-11:00AM

Background/Purpose: Approximately 14 million people in the United States have been clinically diagnosed with symptomatic knee OA. Rising from a chair, negotiating stairs and walking can be compromised. Exercise, a widely recommended firstline treatment to improve pain and daily function among adults with OA is underutilized. Thus, identifying factors that restrict movement and exercise among adults with knee OA is critical. Kinesiophobia, or fear of movement due to pain and potential physical harm, has been proposed to be an important factor restricting movement and willingness to perform exercise among adults with chronic pain, however its relationship with painful knee OA is not well understood. This study examined the relationship of kinesiophobia with commonly used knee osteoarthritis performance-based measures before and after an evidence-based exercise class.

Methods: We used secondary data analysis from a randomized controlled trial before and after a 6-week group strength training class that met twice weekly for 1 hour. Participants were ≥ 50 years with knee pain and self-reported doctor diagnosed knee OA. Kinesiophobia was measured using the 17-item Tampa Scale of Kinesiophobia (TSK). Performance measures included timed-up-and-go (TUG), sit-to-stand 5 and 10 repetitions, and negotiation of 10 steps. We measured quadriceps strength with isokinetic testing, and pain and function with the WOMAC. For data analysis we used simple linear regression with TSK, or change in the TSK, being the independent and performance measures, or their changes, as the dependent variable, and paired T-tests.

Results: 68 participants had baseline data of which 55 had after exercise class data. Higher TSK was associated with slower stair climb ($p=0.02$) and time in the 5 sit-to-stand ($p=0.03$) at baseline. TSK decreased after the exercise class (mean change -0.58) but did not attain statistical significance ($p=0.47$). Change in TSK was associated with change in self-reported physical function ($p=0.02$), but not with pain or physical performance measures.

Conclusion: Among this cohort of adults with knee osteoarthritis, kinesiophobia was associated with negotiating stairs and rising from a chair, two critically important functional activities commonly restricted by osteoarthritis. Future research addressing the impact of kinesiophobia and efficacy of interventions to modify said impact is warranted.

Table 1. Simple linear regression baseline variables

Session Date: Sunday, October 21, 2018

Session Title: Orthopedics, Low Back Pain and Rehabilitation Poster – ACR/ARHP

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 9:00AM-11:00AM

Background/Purpose: This trial assessed the efficacy of shoe-stiffening inserts for reducing pain associated with first metatarsophalangeal joint (MTPJ) osteoarthritis (OA).

Methods: One hundred participants (45 men 55 women, mean age 57.5, SD 10.3 years) with first MTPJ OA received rehabilitation therapy and were randomised to receive either (i) full-length carbon fibre shoe-stiffening inserts (Figure 1) (intervention group) or(ii) sham shoe inserts (control group). The primary outcome measure was the footpain domain of the Foot Health Status Questionnaire (FHSQ) assessed at 12 weeks. Secondary outcome measures included the function domain of the FHSQ, severity of first MTPJ pain, general health status, use of rescue medication and co-interventions, adverse events, physical activity levels and global change in symptoms ('moderately better' or above considered a successful outcome). FHSQ and global change in symptoms at 12 weeks are presented here. Multiple imputation was used to replace missing data. FHSQ pain scores were analysed using analysis of covariance with the intervention group and baseline scores entered as independent variables, and global change in symptoms was analysed using absolute and relative benefit, and number needed to treat.

Results: Data were available for 91 participants at week 4 and 85 participants at week 12. FHSQ pain scores improved in both groups. There was a statistically significant difference in FHSQ pain in favour of the intervention group at 12 weeks (adjusted mean difference 7.4 points, 95%confidence interval [95% CI] 1.3 – 13.5, p=0.018). See Figure 2. Participants in

Figure 1. Full-length carbon fibreshoe-stiffening insert.

the intervention group were also more likely to report that their pain was at least moderately better (successful treatment) at 12 weeks compared to the control group (61 versus 34%; absolute benefit increase 27% [95% CI 6 – 45], relative benefit increase 79% [95% CI 11 – 189]). The number needed to treat was 4 (95% CI 2 – 18).

Conclusion: Carbon fibre shoe stiffening inserts are effective at reducing pain in people with first MTPJ OA.

Figure 2. Foot Health Status Questionnaire(FHSQ) scores at baseline, week 4 and week 12 for the control and intervention groups. Higher scores indicate less foot pain.

S100A8 & S100A9: Alarmin Mediated Inflammation in Tendinopathy

Lindsay A N Crowe¹, Michael McLean², Emma Garcia-Melchor², Katharina Patommel², Susan M Kitson², James H Reilly³, Iain B. McInnes^{2,3}, Moeed Akbar² and Neal L Millar², ¹Institute of Infection, Immunity and Inflammation, University of Glasgow, Glasgow, United Kingdom, ²Institute of Infection, Immunity and Inflammation, University of Glasgow, Glasgow, United Kingdom, ³University of Glasgow, Glasgow, United Kingdom

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Orthopedics, Low Back Pain and Rehabilitation Poster – ACR/ARHP

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 9:00AM-11:00AM

Background/Purpose: Alarmins, also referred to as damage associated molecular patterns (DAMPs), are endogenous molecules mobilized in response to tissue damage and are known to activate the innate immune system in the early stages of disease. The molecular mechanisms that regulate inflammatory and remodelling pathways in tendinopathy are largely unknown therefore identifying early immune effectors is essential to understanding the pathology.

S100A8 and S100A9 are low molecular weight calcium binding proteins constitutively expressed by cells of myeloid origin. Under pathological conditions they are released in other cell types in response to environmental triggers and cellular damage. Based on our previous investigations highlighting tendinopathy as an alarmin mediated pathology we sought evidence of S100A8 & A9 expression in human tendinopathy and thereafter, to explore mechanisms whereby S100 proteins may regulate release of inflammatory mediators and matrix synthesis in human tenocytes.

Methods: Torn supraspinatus tendon (representing established pathology) and matched intact subscapularis tendon (representing ‘early pathology’) biopsies were collected from patients undergoing arthroscopic shoulder surgery. Control samples of healthy hamstring tendon were collected from patients undergoing anterior cruciate ligament (ACL) reconstruction. S100A8 & A9 expression was analyzed at transcript and protein level using quantitative RT-PCR and immunohistochemistry, respectively. Primary human tenocytes were cultured from hamstring tendon tissue obtained during hamstring tendon ACL reconstruction. The *in vitro* effect of recombinant human S100A8 & A9 on human tenocytes was measured using quantitative RT-PCR and release of inflammatory mediators was measured at a protein level by ELISA.

Results: Immunohistochemical staining of tendinopathic tissues indicated the presence of S100A8 and S100A9 in tendinopathy with early diseased tissue displaying a distinct increase in S100A8 and S100A9 expression compared with control and established pathology. These findings were mirrored by data obtained at transcript level from both early and late pathology. Treating tenocytes with exogenous S100A8 & A9 significantly increased protein release of IL-6, IL-8 and CCL2 and an induction of CCL20 and CXCL10 release was observed. However, no alterations in genes associated with matrix remodelling were observed at a transcript level.

Conclusion: We have confirmed the presence of S100A8 and S100A9 in tendinopathy and propose that S100A8 & A9 participate in early pathology by modulating the stromal microenvironment and influencing the inflammatory profile of tenocytes. S100A8 and S100A9 may participate in a positive feedback mechanism involving enhanced leukocyte recruitment and release of pro-inflammatory cytokines from tenocytes that perpetuates the inflammatory response within the tendon in the early stages of disease. This, in turn, may contribute aberrant matrix remodelling and support a detrimental transition from acute to chronic inflammation. Selectively targeting DAMP signalling in early disease provides scope for novel translational strategies in the management of tendon disorders.

Session Date: Sunday, October 21, 2018

Session Title: Orthopedics, Low Back Pain and Rehabilitation Poster – ACR/ARHP

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 9:00AM-11:00AM

Background/Purpose: There is increasing public health interest in the objective measurement of free-living physical activity in persons with arthritis, but research grade wearable monitors can be expensive. We therefore sought to examine the accuracy of the affordable personal monitor (Fitbit Flex) by comparing that output with data from the GT3X+

Table 1. Definitions of Fitbit Flex and ActiGraph GT3x+ Measured Activity Intensity Level

Physical Activity Intensity	Fitbit* (worn on non-dominant wrist)	ActiGraph** (worn on waist)
Light	Slightly Active (Activity between 1.5-3 METs)	Light 100-2019 cpm (counts per minute)
Moderate (bouted)	Fairly Active (Activity between 3-6 METs in at least 10 min bout)	Moderate 2020-5999 cpm in at least 10 min bout
Vigorous (bouted)	Very Active (Activity ≥6 METs or ≥145 steps/minute in at least 10 min bout)	Vigorous 6000 cpm and above in at least 10 min bout
MVPA (bouted)	Active Minutes (Fairly Active + Very Active Min ≥ 3 METs in at least 10 min bout)	MVPA (bouted) 2020 cpm and above in at least 10 min bout
Non-sedentary	Slightly Active + Fairly Active + Very Active	Light + Moderate (unbouted) + Vigorous (unbouted)

* Thresholds based on Fitbit MET minute calculations

** Thresholds based on vertical counts per minute (cpm) by TriAxio

† Pate, R. P., Barrigan, D., Gould, K. W., Moore, J. C., Telford, T., McDowell, M. Physical Activity in the United States measured by accelerometers. Medicine and Science in Sports and Exercise 2008;40(1):183-83.

accelerometer (amount of time spent in light, moderate, and vigorous PA) worn simultaneously for 7 days; high accuracy would support substitution with this less expensive personal activity monitor in future arthritis research.

Table 2. Comparison of Data from Fitbit Flex and ActiGraph GT3x+ Worn Simultaneously for Seven Days (N=226 days from 35 persons)

Physical Activity Intensity	Fitbit Obtained Data Mean \pm SD (min/day)	ActiGraph GT3x+ Obtained Data Mean \pm SD (min/day)	Difference (95% CI) (min/day)	Spearman correlation (95% CI)
Light	201.8 \pm 117.7	229.5 \pm 86.2	-27.7 (-51.3, -4.1)	0.52 (0.43, 0.62)
Moderate (bouted)	17.4 \pm 23.6	18.8 \pm 27.1	-1.3 (-4.9, 2.3)	0.47 (0.36, 0.58)
Vigorous (bouted)	20.8 \pm 27.7	0.2 \pm 1.7	20.6 (17.0, 24.2)	0.34 (0.01, 0.28)
MVPA (bouted)	28.2 \pm 42.4	19.7 \pm 27.5	8.5 (4.7, 22.2)	0.67 (0.56, 0.74)
Non-sedentary	240.0 \pm 133.5	278.4 \pm 91.1	-38.4 (-49.5, -19.2)	0.57 (0.47, 0.65)

Methods: Subjects (n=35) with chronic knee symptoms were recruited for a pilot intervention study using Fitbits to increase physical activity in employees with chronic knee symptoms at an urban insurance corporation. Subjects simultaneously wore for 7 days a Fitbit Flex (wrist-worn) and ActiGraph GT3x+ (waist-worn) as part of 12-week post-intervention follow-up evaluation. Fitbit Flex data was regularly stored on a research storage service (Fitabase) by participants. Correlation tables were constructed to examine the association between the amount of time spent in activity intensity categories (Light, Moderate, Vigorous, and Moderate/Vigorous – the last three categories in bouts of 10 min or more). Due to discrepancy in wear time (Fitbit worn for 24 hours/day, ActiGraph unit was not), sedentary minutes were not included for comparison. Comparisons were calculated by matching Fitabase data from calendar days Fitbit was worn with data from valid monitoring days (≥ 10 hours wear time) of the ActiGraph.

Results: Participants at baseline were primarily female (69%), Caucasian (57%), with mean age 52 years, BMI 32 kg/m². Table I provides an overview of the definitions and distinctions of each measured activity intensity level. Table 2 provides the comparison of data from Fitbit Flex and ActiGraph GT3x+, including Spearman correlations, within each of the activity intensity categories.

Conclusion: The individual intensity category correlations for the two devices are not strong. However, the bouted Moderate-Vigorous activity categories are moderately well correlated. One potential confounder includes the wrist vs waist location of the monitoring device during data collection. This moderate correlation of moderate/vigorous intensity between devices is reassuring to consumers/researchers using the Fitbit to track bouted higher intensity activities, but may not support substitution of the ActiGraph with the Fitbit in population studies that seek to accurately measure all levels of activity and sedentary time.

1-Year Outcomes from a Novel Physical Therapist-Administered Physical Activity Intervention after Total Knee Replacement: A Pilot Study

Meredith Christiansen¹, Louise Thoma², Hiral Master¹, Dana Mathews³, Laura Schmitt¹, Melissa Ziegler⁴ and Daniel White⁵, ¹Physical Therapy and Biomechanics and Movement Science, University of Delaware, Newark, DE, ²Physical Therapy, University of Delaware, Newark, DE, ³Physical Therapy, Biomechanics and Movement Science, University of Delaware, Newark, DE, ⁴Biostatistics Core, College of Health Sciences, University of Delaware, Newark, DE, ⁵Department of Physical Therapy, University of Delaware, Newark, DE

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Orthopedics, Low Back Pain and Rehabilitation Poster – ACR/ARHP

Background/Purpose: Physical activity (PA) does not increase after total knee replacement (TKR) despite improvements in pain and function. A potential solution to this problem is to deliver a PA intervention during outpatient physical therapy (PT) that uses activity trackers, i.e., Fitbits and steps goals. We previously reported the 6-month preliminary effectiveness of our randomized controlled pilot trial. The aim of this abstract was to report on the long-term preliminary effectiveness and retention of PA at the 1-year follow-up.

Methods: Patients undergoing outpatient PT after a unilateral TKR were randomized to a control or intervention group. Both groups received standard PT. The intervention group additionally received a Fitbit Zip, step goals during PT, and monthly phone calls after discharge (DC). A physical therapist created and progressed individualized weekly step goals from baseline to DC from PT. For 6 months (6m) after DC from PT, research assistants called participants once a month to progress the weekly step goal and encourage the participants to continue tracking their steps/day. After 6m, the PA intervention was discontinued and the Fitbit was returned. The primary outcome was PA, quantified as steps/day and minutes/week in MVPA measured with an ActigraphGT3X at DC, 6m, and 1-year. For this analysis, we compared PA between the control and intervention group at 1-year after PT discharge with at-test.

Results: Of the 43 people enrolled, to date 19 people have completed the 1-year follow-up (mean(SD) age = 67.0 (7.0) years, BMI = 31.5 (5.9) kg/m², 53.4% women, days from TKR to PT = 13.8 (21.3)). At 1-year, those in the intervention (n=9) walked 5719 (1757) steps/day and spent 122.3 (101.9) min/week in MVPA, whereas the control (n=10) group walked 3959 (2009) steps/day and spent 46.7 (73.4) min/week in MVPA (Figure 1). The intervention group accumulated 1,760 more steps/day (p=0.13) and spent 75.6(p=0.24) more minutes/week in MVPA at 1-year than the control group.

Figure 1. MVPA/week between groups & sample size at baseline, DC, 6m, 1-year

Figure 2. Steps/Day between groups & sample size at baseline, DC, 6m, 1-year

Conclusion: The preliminary results indicate a physical therapist-administered PA intervention may increase PA after TKR. At 1-year, the intervention approached clinically meaningful levels of PA for steps/day, i.e. walking close to 6,000 step/day which is a benchmark known to protect against the development of functional limitation, and spent close to 150 min/week in MVPA, which is recommended dose from the 2008 Physical Activity Guidelines for Americans.

The Association of Biomechanical Change and Pain Catastrophizing with the Chronic Low Back Pain

Elizabeth Salt¹, Amanda Wiggins², Mary Kay Rayens², Quenten Hooker³, Iman Shojaei⁴ and Babak Barzgari⁴, ¹University of Kentucky, Lexington, KY, ²College of Nursing, University of Kentucky, Lexington, KY, ³Washington University, St. Louis, MO, ⁴College of Engineering, Biomechanics, University of Kentucky, Lexington, KY

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Orthopedics, Low Back Pain and Rehabilitation Poster – ACR/ARHP

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 9:00AM-11:00AM

Background/Purpose: Low back pain (LBP) is commonly characterized by symptom duration. Acute LBP is defined as pain lasting < 3 months and chronic LBP is defined as “pain on at least half the days in the past 6 months”. Identifying mechanisms that discriminate chronic versus non-chronic is important to prevent transitions to chronic pain states, thus, improving the LBP prevalence, disability rates and health care costs.

Biomechanical changes are one potential mechanism; prior research suggests that persons with acute LBP use more pelvic rotation and less lumbar flexion or a *stiff* spine when compared to healthy controls. Pain catastrophizing, the exaggerated and negative orientation of pain, predicts disability among persons with acute and chronic LBP.

The aim of this study was to examine the association of lumbo-thoracic ratio (LTR), representing the level of stiffness of lumbar spine, with pain catastrophizing, assessing whether this association varies between individuals with chronic and non-chronic LBP at baseline, 2.5 and 6 months.

Methods: A sample of 29 adult patients with provider diagnosed acute LBP (<3 months) and telephone access completed questionnaires and biomechanical data at baseline, 2.5 and 6 months along with weekly questionnaires. The NIH Task Force of Research Standards for Chronic LBP's was used to classify participants as chronic vs. non-chronic.

Biomechanical measures. Participants completed trunk forward bending and backward return tasks at slow and fast self-selected paces. Lumbar flexion was calculated as the difference between the thoracic and pelvic rotations and was then used to calculate the LTR at that time instant as the ratio of lumbar flexion over thoracic rotation.

Pain catastrophizing measured with the *Pain Catastrophizing Scale* (PCS) (Cronbach's $\alpha=.94$; range: 0-52).

Analysis. Linear regression models were used to evaluate whether the association between PCS and LTR varied by chronic LBP status using an interaction term.

Results: At the 2.5 month follow-up, significant differences in the association of PCS with LTR of fast-paced tasks were identified between those with chronic and non-chronic LBP ($F=5.0$; $p=.04$ for both interaction terms); for those with chronic LBP, an increase in PCS was associated with an increase in LTR ($p=.006$), while among those without chronic LBP there was no association between PCS and LTR ($p=.23$). The association between PCS and LTR did not differ by chronic LBP status at baseline or 6 months; at each of these time points, regardless of chronic LBP status, there was a positive association between PCS and LTR of fast-paced tasks.

Conclusion: The relationship identified between PCS and LTR is a possible contributor to the development of chronic LBP.

Patient Reported Outcomes Pre and Post Intervention in Older Veterans with Chronic Back Pain

Rabih Nayfe¹, Matthieu Chansard², Linda S. Hynan³, Eric M. Mortensen⁴ and Una E. Makris⁵, ¹Department of Medicine, UT Southwestern Medical Center, Dallas, TX, ²Clinical Sciences, UT Southwestern Medical Center, Dallas, TX, ³Clinical Sciences, University of Texas Southwestern Medical Center, Dallas, TX, ⁴UT Southwestern Medical Center, Dallas, TX, ⁵UT Southwestern Medical Center and Dallas VA, Dallas, TX

Session Information

Session Date: Sunday, October 21, 2018

Background/Purpose: Chronic back pain is the second most common reason for a physician’s visit and results in significant physical and psychosocial consequences in older adults. Identifying appropriate and reliable patient reported outcome measures is critical for research and clinical purposes. The NIH’s Patient Reported Outcomes Measurement Information System (PROMIS) instruments provide robust patient reported outcome(PRO) measures; however, these have not been evaluated alongside “legacy”instruments in older adults with chronic back pain to expand our understanding of treatment response. In this pilot trial, we used epidural steroid injections(ESI) as a vehicle intervention to better understand our PRO. This study aims to evaluate whether legacy and/or PROMIS biopsychosocial measures change according to those who responded or were non-responders to ESI.

Table 1: Analysis of Variance (ANOVA) for PROMIS and Legacy Measures

Methods: We enrolled a convenience sample of older Veterans (age 60+) with chronic backpain with/without leg pain scheduled for lumbar ESI. Subjects completed “legacy” instruments and corresponding PROMIS computer adaptive test (CAT) item banks pre-and post-ESI in the following domains: pain interference, behavior and intensity; functional status; depression and anxiety; fatigue; sleep and social functioning. The effects of ESI on bio-psychosocial measures using legacy and PROMIS were assessed using a two-way analysis of variance (ANOVA) with one repeat factor (pre/post ESI) and one between factor (responder/non-responder). We defined responders vs non-responders to ESI based on the accepted minimally important significant difference for the Roland Morris Disability Questionnaire, used in back pain trials.

Results: Participants included 71 Veterans who were on average 67 years old, 94% men, 73% non-Hispanic white, 17% African American. Patients were obese with a mean BMI 32.25% reported multi-site pain and 59% were diagnosed with depression, anxiety and/or PTSD. The majority (69%) reported pain duration ≥ 5 years with 93% reporting associated radiculopathy. The time between pre and post ESI assessments ranged between 3-8 weeks (based on routine follow-up appointment). Two-way ANOVA results showed that ESI responders (compared to non-responders) reported significant improvement in several domains from legacy (pain interference and behavior, depression and fatigue) and PROMIS (fatigue and social) measures. Table 1 includes legacy and PROMIS mean values (+SD) as well as ANOVA results for the interaction and factor effects.

Conclusion: These results suggest that responders to ESI showed improvement in several domains, more commonly among legacy than PROMIS measures. Fatigue was the only variable that improved using both instruments. Further research in a larger and gender diverse sample is warranted to gain a better understanding of PRO that may improve in older adults with chronic back pain receiving ESI.

Abstract Number: 418

Dose-Response Relationship between Neuromuscular Electrical Stimulation and Muscle Function in Patients with Rheumatoid Arthritis

Gustavo J. Almeida¹, Samannaaz S. Khoja² and Sara R. Piva¹, ¹Physical Therapy, University of Pittsburgh, Pittsburgh, PA, ²Department of Physical Therapy, University of Pittsburgh, Pittsburgh, PA

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Orthopedics, Low Back Pain and Rehabilitation Poster – ACR/ARHP

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 9:00AM-11:00AM

Background/Purpose: Neuromuscular electrical stimulation (NMES) is a viable intervention to improve impaired muscle function of patients with rheumatoid arthritis (RA). However, there is limited evidence about dose-response of NMES to promote muscle function in these patients. The purpose of this study was to investigate the dose-response relationship between NMES and muscle function in patients with RA and to establish the minimal NMES intensity to promote improvements.

Methods: This was a secondary analysis of pre to post NMES intervention from a randomized study. Participants were adults diagnosed with RA. Participants underwent 36 NMES treatment sessions for the quadriceps muscles over 16 weeks. Muscle function was assessed pre- and post-intervention by the following 3 measures: quadriceps cross-sectional area and muscle quality were quantified using computed tomography, and strength via an isokinetic dynamometer. NMES intensity was calculated in percentage dividing NMES-elicited quadriceps muscle torque by maximum voluntary isometric contraction (MVIC). Improvements in muscle function were calculated using paired samples t-test. Dose-response relationship was determined using curve estimation regression statistics. The minimum NMES intensity was defined as the one sufficient to significantly improve all muscle function measures.

Results: Twenty-four subjects (48 legs) participated (75% female, 58[8] years old, and BMI of 32[7] kg/m²). Quadriceps cross-sectional area, muscle quality and strength improved pre-post intervention ($p < .001$) (Table 1). Associations between NMES and muscle quality ($r^2 = 0.20$) and strength ($r^2 = 0.23$) were significant, but between NMES and muscle cross-sectional area was not ($r^2 = 0.02$). The minimum NMES intensity necessary to improve all measures of muscle function ranged from 11% to 20% of MVIC (Table 2).

Conclusion: The minimum NMES intensity for significant gains in muscle function is around 15%. Larger NMES intensities may promote better muscle quality and strength in patients with RA.
Table 1: Muscle function pre and post NMES.

Variables	Baseline	Follow-up	Change	95% CI of Change
Quadriceps Cross-sectional Area (cm ²)	48.8 (8.5)	52.4 (8.5)	3.6 (2.8)	2.8; 4.4

Effect of Changes in Physical Activity on Cartilage Degradation in Knee Osteoarthritis

Gustavo J. Almeida¹, Charity Moore-Patterson¹, Clair N. Smith¹, Prakash Jayabalan² and Sara R. Piva¹, ¹Physical Therapy, University of Pittsburgh, Pittsburgh, PA, ²Shirley Ryan AbilityLab, Northwestern Feinberg School of Medicine, Chicago, IL

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Orthopedics, Low Back Pain and Rehabilitation Poster – ACR/ARHP

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 9:00AM-11:00AM

Background/Purpose: Guidelines recommend 150 minutes a week in moderate-intensity physical activity (PA) to improve health in knee osteoarthritis (KOA). Despite that, individuals with KOA do not engage in the recommended amount of PA and physicians refrain from prescribing the PA recommendations due to concerns that large amounts of PA may worsen KOA. Only few studies have investigated the effects of PA on cartilage health and this issue needs further clarification. Serum biomarkers have been validated to identify cartilage degradation. The aim of this study was to determine the associations between changes in PA and changes in concentration of a biomarker of cartilage degradation.

Methods: This is a secondary analysis from a randomized trial that compared the effects of an intensive exercise program (comprehensive behavioral intervention [CBI]) to a less intensive program (standard of care exercise [SCE]) on physical function and PA after total knee replacement. Subjects with available serum and PA measured at baseline and 3-month follow-up were included. Blood samples were collected in the morning after a 12-hour fasting. Samples were frozen for future analysis. Cartilage degradation was assessed by analyzing the concentration of cartilage oligomeric matrix protein (COMP) using standardized enzyme-linked immunosorbent assay (ELISA). Daily time in moderate PA was assessed using the Sensewear Armband activity monitor worn for 7 days. Pearson correlation coefficients were used to determine associations between changes in PA and changes in COMP.

Results: Data on 33 subjects were available and analyzed. Subjects were 67±6 years old, 67% female and 92% white, with BMI of 30±4 kg/m². They had mild pain on surgical (2±2) and non-surgical (3±3) knees, and moderate functional limitations (17.9±9.5) measured by the WOMAC (Western Ontario and McMaster Universities Osteoarthritis Index) physical function subscale. Demographics between CBI (n=14) and SCE (n=19) were similar at baseline. Forty three percent of the subjects in the CBI arm improved PA above the standard error of measurement (11 minutes of moderate PA per day) and experienced an increase in COMP (145±418 ng/ml), while only 26% of the subjects in the SCE improved PA and showed a slight decrease in COMP (-49±725 ng/ml), suggesting that perhaps more PA may increase cartilage degradation. However, upon further assessment of the direct associations between changes in PA and COMP, we observed negative associations between changes in PA and changes in COMP in the CBI (r=-.65; p=.012) and in the SCE (r=-.45; p=.056), indicating that individuals who increased PA actually had a decrease in COMP concentration.

Conclusion: These preliminary results indicate that moderate PA does not seem to contribute to cartilage degradation in individuals with KOA and strengthen to body of evidence in this area. In this study, individuals with KOA appear to

engage in activities of low impact such as brisk walk, which may not be detrimental to the knee joint. A larger study is warranted to validate our findings. Participation in moderate PA could be encouraged by physicians since its benefits outweigh the harms.

Session Information

Session Date: Sunday, October 21, 2018
Session Title: Osteoarthritis – Clinical Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: A subset of adults who develop knee osteoarthritis (KOA) quickly progress from no radiographic disease to advanced-stage disease often in ≤ 12 months. Adults with accelerated KOA (AKOA) have greater pain and disability than those with common KOA even prior to radiographic onset. AKOA may be a unique endotype of KOA consequent on specific pathologies, as opposed to rapid evolution of common KOA; however, this hypothesis is untested. Hence, we aimed to determine if incident AKOA is preceded and characterized by distinct pathologic changes (e.g., subchondral bone damage), destabilizing meniscal tears (e.g., root/anchor tears) or other secondary feature changes; such

as, diffuse meniscal pathology, greater quantitative changes in bone marrow lesions (BMLs) and articular cartilage than adults with common or no KOA.

Methods: We selected 3 sex-matched groups from the Osteoarthritis Initiative who had a knee without radiographic KOA at baseline (Kellgren-Lawrence [KL]<2): *AKOA* developed KL grade ≥ 3 ≤ 48 months, *common KOA* increased radiographic scoring ≤ 48 months without meeting AKOA criteria, and *no KOA* had the same KL grades at baseline and 48 months. Observation period was up to 2 years before and after an index visit, which was when the AKOA or common KOA criteria were met (no KOA index visit was matched to AKOA). Radiologists reported meniscal and other distinct pathological findings. We quantified BML volume and cartilage damage on magnetic resonance (MR) images. We performed linear mixed models –adjusting for sex and factors related to missing MR data.

Results: Overall the groups were predominantly female (63%), overweight, and 33% reported frequent knee pain within a year of baseline. At 1 year before the index visit, >75% of adults with AKOA had multiple meniscal regions affected (diffuse pathology; vs common KOA: OR=3.19, 95% CI=1.70 to 5.97). By the index visit, adults with AKOA were twice as likely to have distinct pathology than those with common KOA (OR=2.19, 95% CI=1.01, 4.77; Figure 1). The most common distinct pathology affected the subchondral bone (i.e., subchondral fracture, acute attrition), which was found in 12.3% of adults with AKOA, 0.8% with common KOA, and 1.6% with no KOA. Diffuse meniscal pathology was ubiquitous in AKOA; including 42% with a destabilizing meniscal tear (common KOA: 14%). These changes corresponded to larger BMLs and greater cartilage loss (Figure 1 and 2).

Conclusion: AKOA is characterized by destabilizing meniscal tears in a knee with greater pre-radiographic disease (e.g., diffuse meniscal pathology, large BMLs, greater cartilage loss)

Abstract Number: 421

What Do Patients with Osteoarthritis Think of Their Preoperative Education before Total Hip Replacement Surgery: Qualitative Study

Somayyeh Mohammadi¹, Wendy Watson², Brigita Grazys³, Marie Westby⁴ and William Miller⁵, ¹Department of Occupational Science and Occupational Science, University of British Columbia, Vancouver, BC, Canada, ²OASIS Program, Vancouver Coastal Health Authority, Vancouver, BC, Canada, ³Vancouver Coastal Health, Vancouver, BC, Canada, ⁴Centre for Hip Health and Mobility, Vancouver, BC, Canada, ⁵Department of Occupational Science and Occupational Therapy, University of British Columbia, Vancouver, BC, Canada

Session Information**Session Date:** Sunday, October 21, 2018**Session Title:** Osteoarthritis – Clinical Poster I**Session Type:** ACR Poster Session A**Session Time:** 9:00AM-11:00AM

Background/Purpose: Osteoarthritis (OA) is the most common joint disorder and one of the main causes of pain and disability in adults. The hip is one of the major joints affected by OA. OA of the hip can be observed in 7% to 27% of the population. When patients do not benefit from conservative treatments, Total Hip Replacement (THR) surgery is recommended. THR increases every year (> 50K in Canada in 2017). Providing preoperative education regarding THR decreases patients' anxiety and improves rehabilitation. So far, preoperative education is mostly developed based on clinicians' perspectives. Therefore, this study aimed to investigate patients' perspectives on the quality of current preoperative education and the educational gaps that they face.

Methods: In total, 46 patients with hip OA and 16 of their family caregivers/friends participated in in-person focus groups or telephone interviews. Patients answered questions regarding gaps in, and quality of, the preoperative education they received, the barriers to receiving preoperative education, and their main concerns before THR. Each focus group or interview was transcribed verbatim. The transcriptions were coded and analyzed using NVivo, is a software for analyzing qualitative research. To conduct the analyses and investigate the phenomenon that we were interested in (i.e., preoperative education), as patients and their family members experience it in their daily lives, the eidetic phenomenologic approach was used.

Results: Five themes were identified: 1) People learn in different ways: explains different methods participants use to gather information regarding THR, 2) Pre-op was useful but: provides information regarding patients' opinions on quality of preoperative education, 3) Never got a definitive answer: explains the educational gaps that exist in current preoperative education, 4) The biggest worry: indicates patients' concerns before THR and 5) Had to struggle to get the information: indicates barriers that patients face in receiving preoperative education.

Conclusion: These findings enhance our knowledge on the current educational gaps that patients experience and the reasons why some patients cannot receive preoperative education. These findings can be used to develop preoperative education that addresses patients' educational needs and facilitate their access to preoperative education.

Acknowledgment: We would also like to acknowledge Colleen O'Melinn and Halima Elmi for their contributions of recruitment, data collection and data analysis on this study.

Abstract Number: 422

Efficacy and Safety of a Fixed-Dose Combination of Nimesulide/Pantoprazole Compared with Naproxen/Esomeprazole for Pain Relief in Patients with Osteoarticular Diseases and Dyspeptic Symptoms

Eduardo de Almeida Macêdo¹, Henrique Pott Junior¹, Morton Scheinberg², Christina Ecclissato¹ and Roberto Bleuel Amazonas¹, ¹EMS Pharma Inc., Hortolândia, Brazil, ²AACD, São Paulo, Brazil

Session Information**Session Date:** Sunday, October 21, 2018**Session Title:** Osteoarthritis – Clinical Poster I**Session Type:** ACR Poster Session A**Session Time:** 9:00AM-11:00AM

Background/Purpose: NSAIDs are one of the most used drug classes in the world.¹ However, its use may be associated with potentially limiting adverse events (AEs), especially gastrointestinal toxicity.² Concomitant use of proton-pump inhibitors, including fixed-dose combination regimens, have emerged as an alternative to minimize gastrointestinal AEs.³ This study investigated the safety and efficacy of fixed-dose combination of naproxen/esomeprazole and nimesulide/pantoprazole to determine if both regimens are equally suited to relieve pain in patients with osteoarticular disease and dyspeptic symptoms.

Methods: This was a multi-center, randomized, double-blind, active-controlled, parallel-group, non-inferiority phase 3 study. Patients were assigned to receive either nimesulide/pantoprazole (100mg/20mg) twice daily or naproxen/esomeprazole (500mg/20mg) twice daily for 14 days. The primary endpoint was the mean change in modified Western Ontario and

McMaster Universities Osteoarthritis Index (WOMAC)⁴ pain subscale. Safety assessment was performed by the mean visual analog scale (VAS) of dyspeptic symptoms. This study is registered at ClinicalTrials.gov: NCT01670552.

Results: A total of 490 patients were enrolled and randomized (399 completed). The baseline characteristics are presented in Table 1. Mean changes in the modified WOMAC are presented in Table 2. The difference in mean change in the modified WOMAC after 7 days of treatment between the 2 groups was 2.33 mm (95% CI, -1.22 to 5.89 mm). After 14 days of therapy, the difference was 0.45 mm (95% CI, -3.29 to 4.19 mm). Overall frequencies of AEs were similar in the 2 groups.

Conclusion: The present study demonstrated non-inferiority of a 14-day regimen with a fixed-dose combination of nimesulide/pantoprazole compared to naproxen/esomeprazole for the treatment of osteoarticular pain. The results of the study show that the gastrointestinal adverse effects related to NSAID use may be reduced by the use of a fixed-dose combination of nimesulide/pantoprazole.

Session Title: Osteoarthritis – Clinical Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Degeneration of knee ligaments and tendons, which may be signs of joint instability and abnormal joint loading, may antedate the onset of radiographic accelerated knee osteoarthritis (AKOA) and contribute to prodromal joint symptoms that are common among adults with AKOA. We assessed whether adults with incident AKOA are more likely to have degenerative knee ligaments or tendons compared to adults with common or no KOA at timepoints prior to and after the onset of disease.

Methods: We classified 3 sex-matched groups of Osteoarthritis Initiative participants who had a knee without radiographic KOA at baseline (Kellgren-Lawrence [KL] < 2): 1) incident AKOA: ≥ 1 knee progressed to KL grade ≥ 3 within 48 months, 2) incident common KOA: ≥ 1 knee increased in radiographic scoring within 48 months but not meeting AKOA criteria, and 3) no KOA: both knees had the same KL grade at baseline and 48 months. The observation period included up to 2 years before and after when the accelerated or common KOA criteria were met (index visit; no KOA index visit was matched to AKOA). Two musculoskeletal radiologists read magnetic resonance images and reported degenerative signal changes for cruciate and collateral ligaments, extensor mechanism, and proximal gastrocnemius tendons. A degenerative appearance was defined as the presence of abnormal intrinsic high-signal intensity within the substance of the ligaments or tendon

without discrete tear. We used generalized linear mixed models with group (3 levels) and time (up to 5 levels) as independent variables.

Results: Table 1 provides the descriptive characteristics of each group. Regardless of time, adults with AKOA had twice the odds of having degenerative cruciate ligaments than those with no KOA (OR=2.10, 95% CI=1.18 to 3.74). A weaker association, which was not statistically significant, was found for those with AKOA versus those with common KOA (OR=1.73, 95% CI=0.99 to 3.02). Adults with common KOA had similar odds of having a degenerative cruciate ligament as those with no KOA (OR=1.21, 95% CI=0.68 to 2.17). Adults with accelerated or common KOA had twice the odds of having degenerative extensor mechanism than no KOA (OR=2.13 and 2.16, respectively). Collateral ligaments and proximal gastrocnemius tendons were not statistically significant.

Conclusion: Degenerative cruciate ligaments and extensor mechanism precede radiographic onset of AKOA. Hence, AKOA may be preceded by knee instability, which may help identify high-risk patients and novel prevention strategies.

Table 1. Descriptive Characteristics of those with Accelerated Knee Osteoarthritis (AKOA), Common Knee Osteoarthritis (KOA), or No KOA at Osteoarthritis Initiative Baseline

Variables (means, SD; except where noted)	AKOA (n=125)	Common KOA (n=125)	No KOA (n=125)
Females (n, %)	79 (63%)	79 (63%)	79 (63%)
Index knee KL Grade=0 (n, %)	42 (34%)	71 (57%)	92 (74%)
Patellofemoral Osteoarthritis (MR-based) (n, %)	88 (75%)	84 (69%)	80 (66%)
Frequent knee pain in past 12 months (n, %)	44 (35%)	49 (39%)	30 (24%)
Age (years)	62.5 (8.5)	58.4 (8.4)	57.3 (8.2)
Body mass index (kg/m ²)	29.7 (4.6)	28.1 (4.4)	26.9 (4.4)
Global impact rating (0 to 10; higher score=greater impact)	1.7 (1.9)	1.1 (1.5)	0.8 (1.1)
How many days limited activities in past 30 days (0 to 30)?	3.2 (7.3)	1.7 (4.8)	1.4 (4.3)
WOMAC pain (0 to 20; higher score=more pain)	2.3 (3.1)	1.8 (2.3)	1.6 (2.4)

Note: SD = standard deviation, KL = Kellgren-Lawrence, MR = Magnetic resonance

Table 2. Frequency of Degenerative Ligaments/Tendons Among Those with Accelerated Knee Osteoarthritis (AKOA), Common Knee Osteoarthritis (KOA), and No KOA

Frequency [n (%)]	Visit	AKOA	Common KOA	No KOA
Cruciate Ligaments	-2	39 (43)	14 (22)	25 (26)
Group effect (p = 0.03)	-1	50 (43)	34 (28)	30 (24)
Group*time Interaction (p = 0.24)	Index	49 (47)	35 (28)	30 (24)
	1	41 (51)	33 (31)	25 (26)
	2	17 (47)	27 (33)	11 (21)
Collateral Ligaments	-2	22 (24)	6 (9)	12 (13)

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Osteoarthritis – Clinical Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: We hypothesized that mechanical compression of the knee in rheumatoid arthritis(RA) and osteoarthritis (OA) would mobilize occult extractable fluid and improve arthrocentesis success.

Manual Compression

Mechanical Compression

Methods: 186 consecutive knees with grade II-III OA and 67 knees with RA were included. Conventional arthrocentesis was performed and success and volume (milliliters) determined; the needle was left intra-articularly, and mechanical compression was applied with an elastomeric knee brace. Arthrocentesis was then resumed until fluid return ceased. Fluid was characterized as to volume and cell counts.

Results: In the RA knee mechanical compression decreased failed diagnostic arthrocentesis from 56.7% (38/67) to 26.9% (18/67) (-47.4%, $p = 0.003$), and increased absolute arthrocentesis yield from 4.7 ± 10.3 ml to 9.8 ± 9.8 ml (108% increase, 95% CI -8.5 < -5.1 < -1.7 $p = 0.0038$). Total extractable fluid yield was 96% greater in RA (9.8 ± 9.8 ml) than OA (5.0 ± 9.4 ml, $p = 0.0008$), and occult extractable fluid was 77% greater in RA than OA (RA: 5.3 ± 8.7 ml, OA 3.0 ± 5.5 ml, $p = 0.046$). Large effusions (≥ 5 ml) in RA were associated with an increase in neutrophils in synovial fluid ($p = 0.04$) but not radiologic arthritis grade ($p = 0.87$). In contrast, in the OA knee large effusions were associated with more severe arthritis grade ($p = 0.0001$) but not synovial fluid neutrophil count ($p = 0.96$).

Conclusion: Mechanical compression improves the success of diagnostic and therapeutic knee arthrocentesis in both RA and OA. Large effusions in RA are associated with inflammatory synovial fluid but not arthritis grade; in contrast, large effusions in OA are associated with more severe arthritis grades.

Efficacy, Safety, and Tolerability of ONO-4474, an Orally Available Pan-Tropomyosin Receptor Kinase Inhibitor, in Japanese Patients with Moderate-to-Severe Osteoarthritis of the Knee: A Randomized, Placebo-Controlled, Double-Blind, Parallel-Group Comparative Study

Naoki Ishiguro¹, Shusuke Oyama², Ryunosuke Higashi³ and Kunio Yanagida⁴, ¹Orthopaedic Surgery, Nagoya University Graduate School of Medicine, Nagoya, Japan, ²Data Science, Ono Pharmaceutical Co., Ltd., Osaka, Japan, ³Translational Science, Translational Medicine Center, Ono Pharmaceutical Co., Ltd., Osaka, Japan, ⁴Translational Science, Translational Medicine Center, Ono Pharmaceutical Co., Ltd, Osaka, Japan

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Osteoarthritis – Clinical Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: ONO-4474 is an orally available, peripheral-specific, pan-tropomyosin receptor kinase (pan-Trk) inhibitor currently under development for treatment of musculoskeletal pain in OA patients. This study assessed the efficacy, safety, and tolerability of ONO-4474 in Japanese patients with OA of the knee with inadequate response to non-steroidal anti-inflammatory drugs (NSAIDs).

Methods: Male and female Japanese patients with moderate-to-severe OA of the knee and inadequate response to NSAIDs, who were aged 40 to <75 years with a body mass index between 18.5 and <39.0 kg/m² were recruited in this study. After a 14-day screening period, patients entered a 28-day, double-blind treatment period and were randomized to receive ONO-4474 200 mg/day (100 mg twice daily after meals) or placebo. Patients then entered a 14-day follow-up period. The primary efficacy endpoint was change in knee pain during walking, assessed over 24 hours, calculated as the difference in posterior mean of changes in VAS₂₄ scores from baseline versus placebo at Week 4. Other efficacy endpoints included WOMAC scores, Patients' Global Assessment (PGA) scores, and frequency of rescue treatment use. Safety endpoints were vital signs, 12-lead ECG, laboratory tests, neurological examinations, Columbia Suicide Severity Rating Scale (C-SSRS), and adverse events (AEs).

Results: The full analysis and safety analysis sets included 110 patients (ONO-4474 and placebo, both n = 55). The difference in posterior mean change in VAS₂₄ from baseline \pm posterior standard deviation (95% confidence interval [CI]) (ONO-4474 group – placebo group) was -5.8 ± 4.4 mm [$-14.3, 2.8$] at Week 4 and the posterior probability that the difference was less than 0 mm was 90.6%, indicating an improvement with ONO-4474 versus placebo. At Week 4, the difference for ONO-4474 versus placebo in the least-squares (LS) mean changes in WOMAC total and pain scores from baseline \pm standard error [95% CI] were -3.6 ± 3.5 mm [$-10.5, 3.3$] and -4.1 ± 3.8 mm [$-11.7, 3.5$]. The difference in the LS mean change of PGA from baseline \pm standard error [95% CI] was -6.4 ± 4.5 mm [$-15.4, 2.6$]. Fewer patients in the ONO-4474 group than the placebo group required rescue therapy. Treatment-emergent AEs (TEAEs) occurred in 41.8% of patients in the ONO-4474 group and 18.2% in the placebo group. The most common TEAE in the ONO-4474 group was myalgia (7.3%). In the ONO-4474 group, TEAEs related to the peripheral and central nervous system included dizziness and hypoaesthesia (3.6% each), and dysaesthesia, dysgeusia, feeling abnormal, skin warm, and hypoaesthesia oral (1.8% each), while TEAEs related to the musculoskeletal system included myalgia (7.3%), arthralgia (5.5%), and pain in extremity (1.8%). Four patients in the ONO-4474 group and one patient in the placebo group withdrew from treatment because of TEAEs, none of which were considered serious, and those patients recovered or were recovering after drug discontinuation. There were no clinically significant changes in vital signs, 12-lead ECG, laboratory tests, or C-SSRS scores.

Conclusion: ONO-4474 may be a tolerable and effective analgesic in patients with moderate-to-severe OA of the knee.

Session Title: Osteoarthritis – Clinical Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM The association of dietary patterns with knee symptoms and MRI detected structures in patients with knee osteoarthritis (OA)

Abstract

Background/Purpose: This study aimed to examine the cross-sectional and longitudinal associations of dietary patterns with knee symptoms and structures in knee OA patients.

Methods: Participants were from a subset of a randomised, placebo-controlled trial in Tasmania, who had symptomatic knee OA and vitamin D deficiency at baseline and received 50,000 IU vitamin D₃ (N= 129) or placebo (N= 132) monthly for 24 months (aged 63.0 ± 7.2 years). Baseline diet was assessed by the Anti-Cancer Council of Victoria food frequency questionnaire. At baseline and 24 months, knee symptoms were assessed using WOMAC index and knee structures using MRI. Factor analysis was used to identify dietary patterns. Each participant received a score for each dietary pattern, with a higher score indicating a greater intake of food composing that pattern. Associations between dietary pattern scores and knee OA outcomes were examined using multivariable linear regressions with adjustment for age, sex, BMI/change in BMI, treatment arm, total energy intake and physical activity.

Results: Three dietary patterns were identified: “western pattern”, characterised by high intakes of processed food, chips and wine, “vegetable and meat pattern”, characterised by high intakes of vegetables, red meat and beers, and “healthy pattern”, characterised by high intakes of vegetables, legumes, nuts, fish, fruits and whole grain. Participants with higher healthy pattern or vegetable and meat pattern scores had lower baseline WOMAC function scores (β : -54.0, 95% CI: -99.9 to -8.1 and -58.7, -10.9 to -0.8, respectively), and also had lower baseline total WOMAC scores (β : -69.4, 95% CI: -131.4 to -7.4 and -76.5, -144.7 to -8.3, respectively). Baseline western pattern scores were not associated with either total WOMAC or WOMAC function scores. Healthy pattern or vegetable and meat pattern scores were not associated in WOMAC scores over 24 months, but higher western pattern scores were associated with increased total WOMAC scores and WOMAC function scores (β : 118.4, 95% CI: 25.2 to 111.6 and 101.8, 36.2 to 167.4, respectively) over 24 months. In multivariable analyses, dietary patterns were not significantly associated with any knee structure cross-sectionally or longitudinally.

Conclusion: These results suggest that maintaining a healthy dietary pattern may have beneficial effects on knee function, whereas maintaining a western pattern may contribute to increased functional disability over time in knee OA patients. The evidence does not suggest that dietary patterns affect knee structure.

Figure 1. Rotated factor loading for the three dietary patterns.

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Osteoarthritis – Clinical Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Hylan G-F 20 is indicated for the treatment of pain in knee osteoarthritis (OA) in patients who failed to respond adequately to conservative nonpharmacologic therapy and simple analgesics. The 26-week efficacy and safety of 1 or 3 injections of hylan G-F 20 have been widely reported, but there is limited research focusing on the long-term effects. A systematic literature review (SLR) and meta-analysis were conducted to determine the 1-year efficacy and safety of hylan G-F 20 for knee OA.

Methods: A SLR was conducted by searching MEDLINE, Embase, and Cochrane CENTRAL and manual searching of relevant conference proceedings (published January 1, 1995 through May 4, 2017). Eligible studies were randomized controlled trials, non-randomized controlled trials, non-randomized non-controlled trials, and observational studies that investigated 1-year efficacy and safety of 1 or 3 injections of hylan G-F 20 for knee OA. Cohort analyses of both Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) Pain and Physical Function at 1 year were conducted for 1 or 3 injections of hylan G-F 20 using standardized mean change (SMC). Direct meta-analysis of WOMAC Pain and WOMAC Physical Function at 1 year were conducted for 1 injection of hylan G-F 20 vs. appropriate care (e.g. medications, education/counseling, weight loss, arthroscopy, etc.) or physical therapy using either reported or calculated endpoints or change from baseline values.

Results: The search retrieved 1,591 references; 22 met criteria for inclusion and were used to assess safety, 8 of which were included for efficacy analyses. Combined cohort analysis of 1 and 3 injections for WOMAC Pain at 1 year showed a decrease in SMC (95% confidence interval; p-value; I^2) of -0.89 (-1.15, -0.62; $p<0.0001$; 90.76%). Results of separate analyses for 1 and 3 injections were -1.17 (-1.86, -0.47; $p<0.001$; 96.87%) and -0.79 (-1.04, -0.53; $p<0.0001$; 81.35%), respectively. The cohort analysis results for WOMAC Physical Function at 1 year for combined, 1 injection, and 3 injections were -0.91 (-1.14, -0.67; $p<0.0001$; 88.14%), -1.03 (-1.60, -0.45; $p<0.001$; 95.78%), and -0.86 (-1.13, -0.58; $p<0.0001$; 83.39%), respectively. Comparative meta-analysis of 1 injection of hylan G-F 20 vs. appropriate care or physical therapy showed a mean difference (95% confidence interval; p-value; I^2) of -4.10 (-6.18, -2.02; $p<0.001$; 76.3%) for WOMAC Pain and -8.97 (-11.64, -6.31; $p<0.0001$; 0%) for WOMAC Physical Function at 1 year. Total adverse event (AE) rates at 1 year varied across the 22 studies, with 0-2% reported having serious/severe AEs, 3-19.6% for treatment-related AEs, 0.25-4.65% for drug discontinuation due to AEs, and 0-9.68% for withdrawals due to AE.

Conclusion: The evidence shows that both 1 and 3 injections of hylan G-F 20 are effective at reducing WOMAC Pain and Physical Function, with statistically significant improvements at 1 year compared to baseline and standard of care. Relatively low rates of AEs further strengthen the evidence in favor of using hylan G-F in knee OA. It is likely that additional research will continue to illustrate differences in long-term efficacy and safety between hylan G-F 20 and other comparators.

Session Date: Sunday, October 21, 2018

Session Title: Osteoarthritis – Clinical Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Current treatments for osteoarthritis (OA) are severely limited. Synovitis is prevalent in OA and is associated with pain. The slow-acting anti-rheumatic drug methotrexate (MTX) is the gold-standard treatment for synovitis in inflammatory arthritides. The primary aim of the PROMOTE trial was to determine the effectiveness of MTX versus placebo as an analgesic treatment for knee OA.

Methods: PROMOTE was a multi-centre, randomised, placebo-controlled trial with 12 months follow-up. Participants with symptomatic (visual analogue scale (VAS) pain $\geq 4/10$) and radiographic tibiofemoral knee OA, fulfilling clinical ACR criteria, were recruited across UK primary and secondary care. Participants were randomized on a 1:1 basis to MTX or placebo, in addition to ongoing usual care, with dose escalation from 10mg to 25mg over 8 weeks and maintenance at 25mg (or the highest tolerated dose) for the remainder of the study. The primary endpoint was average knee pain during the previous week (numerical rating scale [0-10], NRS) at 6-months. Secondary endpoints included WOMAC, quality-of-life and adverse events. Linear mixed models compared outcomes between groups on an intention-to-treat (ITT) basis. In a sub-study, contrast-enhanced MRI of the index knee was performed at baseline and 6 months.

Results: Of 207 patients screened, 155 participants (64% women, mean age 60.9 years, 50% K-L Grade 3-4) were randomized. Primary endpoint data at 6 months were available for 134 patients (86%); only ITT data are presented. At 6 months, average knee pain (as measured by NRS) was 6.2 in the placebo group and 5.1 in the MTX group, with a baseline adjusted treatment difference of -0.83 points (95% CI -1.55 to -0.10; $p=0.025$), equivalent to a standard effect size of 0.36. Statistically significant differences at 6 months were seen for WOMAC stiffness and physical function, but not pain. Treatment benefits were reduced by 12 months. 94 patients had analysable MRI data at baseline and 80 at 6 months; no change in synovial volume was found. Four serious adverse events were reported (MTX: 2 [not defined as possibly related], placebo: 2).

Conclusion: MTX added to usual care demonstrated significant reduction in knee OA pain at 6 months, and suggests improvements in WOMAC stiffness and function. Despite a moderate standard effect size, the treatment effect was smaller than thresholds considered clinically meaningful. Further analyses will explore predictors of response to understand if subsets with enhanced response can be identified.

We acknowledge Arthritis Research UK for funding support.

Table 1: Selected PROMOTE outcomes at baseline and 6 months follow-up (primary endpoint)

	Month	MTX		Placebo		Adjusted Difference at 6 months (95% CI)	p-value
		N	Mean (SD)	N	Mean (SD)

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Osteoarthritis – Clinical Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: New imaging biomarkers using supervised machine learning offer opportunities to demonstrate effects of potential DMOADs on joint structure in short, small trials based on superior reliability. MIV-711, a cathepsin K inhibitor, demonstrated substantial effects vs placebo on both joint bone area and cartilage thickness following 6 months' treatment. The Osteoarthritis Initiative (OAI) provides an opportunity to contextualize the short-term interventional trial data against a large prospective cohort.

Methods: In the MIV-711-201 study (ACR 2017, abstract 14L), patients with ACR knee OA, KL2-3 and pain ≥ 4 & <10 on 0-10 NRS were enrolled at 6 European sites and randomised to receive MIV-711 100mg or 200mg or matched

place boqd for 6 months. 244 participants were enrolled, 69% women, mean age 62, mean BMI ~32, (evaluable for imaging; 100mg n=72, 200mg n=71, placebo n=68). 3D bone area of the medial femoral condyle (MF) and cartilage thickness in the central medial femur (cMF) were measured using automated segmentation of MR images and active appearance modelling. Rates of change were compared against annual change from all knees with KL grade 0 (normal), 2 or 3 from the OAI cohort using the same method (n =2789, 1870, 918 for KL0,2,3; 3333 patients in total).

Results: In the MIV-711-201 quantitative MRI data, mean changes in MF bone area (mm²) were 13.4 (7.48, 19.28); 7.54 (-1.19, 16.27); 2.22 (-3.92, 8.37) for the placebo, 100mg and 200mg groups respectively (95% CI, Figure 1a). cMF cartilage thickness (mm) mean changes were -0.042 (0.001, -0.085), -0.008 (0.034, -0.051), -0.007 (0.044, -0.058) for the placebo, 100mg and 200mg respectively (95% CI, Figure 1b). These data are in good agreement with the corresponding published data based on manual segmentation. OAI MF bone area change (mm²) over 12 months was 4.26, 9.177, 20.09 (mm²) for KL0, 2 and 3 respectively (equates to 2.13, 4.59, 10.05 over 6 months assuming linear change, Figure 1c). OAI cMF cartilage change over 12 months was -0.005, -0.024, -0.060 (mm) for KL0, 2 and 3 respectively (equates to -0.0025, -0.012, -0.03 over 6 months assuming linear change, Figure 1d). The MIV-711 placebo group changes in bone and cartilage were similar to that expected for a group of KL3 knees (OAI). The MF bone area rate of change in the 200mg group was comparable to the rate found in OAI normal (KL 0) knees and both the 100mg and 200mg doses reduced cartilage loss area change by around 80% to a rate comparable to that seen in OAI normal knees.

Conclusion: This comparison strongly suggests that the 6-month MIV-711 treatment effects found on cartilage and bone measures has structural relevance when compared to the natural progression seen over 12 months in OAI KL3 patients. Should such beneficial structural effects be maintained over time, the already observed signals on clinical symptoms could become manifest clinical benefits.

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Osteoarthritis – Clinical Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: While intra-articular (i.a.) mineralization can be visualized on knee radiographs, the sensitivity of its identification is low with this modality, hampering efforts to understand its pathogenic role and consequences in knee OA. Computed tomography (CT) is highly sensitive for the detection and localization of i.a. mineralization. We report the prevalence of CT-detected i.a. mineralization in older adults with or at risk of knee OA.

Methods: Bilateral knee CT scans, PA knee radiographs and standard questionnaires to ascertain frequent knee pain are being obtained during the current study visit in the Multicenter Osteoarthritis (MOST) Study, a NIH-funded longitudinal cohort study of persons with or at risk of knee OA. Axial CT images with coronal and sagittal 2D reformats were scored by a musculoskeletal radiologist using an ordinal score (0-3) for degree of mineralization in each of the WOMBS subregions of cartilage and meniscus, as well as the soft tissue, capsule, and vasculature. A second MSK radiologist read a random sample of 50 subjects. Prevalence of i.a. mineralization was computed for the total

sample, and stratified by age, sex, and presence of frequent kneepain and radiographic knee OA (ROA) (Kellgren and Lawrence grade ≥ 2).

Results: To date, 150 subjects (300 knees) have been scored during the ongoing study visit (53% female, mean age 71, mean BMI 29.8). Overall, 9% of knees had chondrocalcinosis on radiograph, while CT-detected mineralization was present in 31% of knees in cartilage, meniscus, and/or capsule. The prevalence in specific locations was: 22% articular cartilage, 20% meniscal, and 12% capsular (Figure). 24% of knees without chondrocalcinosis on radiograph had articular cartilage and/or meniscal mineralization detected by CT. Of the knees with CT-detected articular cartilage mineralization, the majority had it present in 1-3 WORMS cartilage subregions (out of 14), and 63% also had meniscal mineralization. For the knees with meniscal mineralization, the majority had it in 5 or 6 WORMS meniscus subregions (out of 6), and 60% also had articular cartilage mineralization. Articular and meniscal mineralization increased with age, was similar among men and women, and was more prevalent in those with frequent knee pain and ROA (Figure). Capsular mineralization was similar across age and gender, but more prevalent in those with frequent knee pain and ROA. Overall, 47% of knees had vascular calcification, which increased with age and was more prevalent in men.

Conclusion: CT of the knee provides greater visualization of i.a. mineralization than radiographs, including locations within the hyaline articular cartilage, meniscus, and soft tissue, as well as its co-localization. These data will provide opportunity to evaluate the longitudinal relation of i.a. mineralization to adjacent articular tissue pathology and overall OA progression.

Session Date: Sunday, October 21, 2018

Session Title: Osteoarthritis – Clinical Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Individuals that develop accelerated knee osteoarthritis (AKOA) have more frequent knee pain, decreased physical function, and are more likely to receive a knee replacement when compared to adults with a gradual onset of knee osteoarthritis (OA). Therefore, developing prognostic tools that provide earlier signs of individuals at risk for the development of AKOA are needed to lessen the burden of this disease. The purpose of this analysis was to determine which pre-radiographic structural pathologies precede the development of AKOA.

Methods: The sample comprised participants from the Osteoarthritis Initiative (OAI) who had at least one radiographically normal knee at baseline (Kellgren-Lawrence [KL] grade ≤ 1). Participants were classified into 2 groups based on radiographic disease progression from baseline to 48 months: AKOA (KL grade change from ≤ 1 to ≥ 3) and No AKOA. Magnetic resonance images were assessed for the presence of 9 semi-quantitative structural pathologies and separated into tertiles for 3 quantitative pathologies at the OAI baseline (Table). For the quantitative pathologies, we converted the tertiles to a dichotomous variable to compare the worst tertile (i.e. largest bone marrow lesion and effusion, smallest cartilage damage index) to the combination of the other two tertiles. Logistic regressions were used to determine which pre-radiographic structural pathologies were more likely to antedate the development of AKOA compared to individuals not developing AKOA.

Results: Overall the groups were predominantly female (63%), overweight, and 33% reported frequent knee pain within a year of baseline. At the OAI baseline visit, degenerative cruciate ligaments (odds ratio [OR]=2.2, 95% confidence interval [CI]=1.3,3.5), infrapatellar synovitis (OR=2.0, 95%CI=1.2,3.2), medial meniscal pathology (OR=2.1, 95%CI=1.3,3.4), lateral meniscal pathology (OR=2.4, 95%CI=1.5,3.8) and larger quantitative knee effusion (OR=2.2, 95%CI=1.4,3.4) were more likely to antedate the development of AKOA when compared to those that did not develop AKOA (Table).

Table. Baseline Pre-Radiographic Structural Pathologies Associated with Accelerated Knee Osteoarthritis (OA) Over the Next 4 Years

Structural Pathologies			Group		Univariate Odds Ratio (95% CI)
			AKOA (n=113) n (%)	No AKOA (Reference, n=241) n (%)	
Semi-Quantitative	Degenerative Cruciate Ligaments ^a	Absence	66 (58%)	181 (75%)	Reference
		Presence	47 (42%)	60 (25%)	2.15 (1.34, 3.45)*
	Degenerative Collateral Ligaments ^a	Absence	86 (76%)	208 (86%)	Reference
		Presence	25 (22%)	33 (14%)	1.97 (0.95, 4.06)
	Degenerative Extensor Mechanism	Absence	64 (57%)	163 (68%)	Reference
		Presence	49 (43%)	78 (32%)	1.60 (1.01, 2.53)
	Degenerative Gastrocnemius/Tendon	Absence	64 (57%)	146 (61%)	Reference
		Presence	49 (43%)	95 (39%)	1.18 (0.75, 1.85)
	Infrapatellar Synovitis	Absence	63 (56%)	172 (71%)	Reference
		Presence	50 (44%)	69 (29%)	1.98 (1.24, 3.15)*
	Medial Meniscal Pathology	Absence	35 (31%)	118 (49%)	Reference
		Presence	78 (69%)	123 (51%)	2.14 (1.32, 3.43)*
Quantitative	Lateral Meniscal Pathology	Absence	64 (57%)	182 (76%)	Reference
		Presence	49 (43%)	59 (24%)	2.39 (1.47, 3.79)*
	Medial Meniscal Extrusion	Absence	90 (80%)	210 (87%)	Reference
		Presence	23 (20%)	31 (13%)	1.73 (0.98, 3.03)
	Lateral Meniscal Extrusion	Absence	109 (96%)	238 (99%)	Reference
		Presence	4 (4%)	3 (1%)	2.91 (0.54, 13.23)
	Effusion Volume ^a	Smallest	83 (74%)	176 (73%)	Reference
		Larger	30 (26%)	65 (27%)	2.18 (1.38, 3.43)*
	Bone Marrow Lesion Volume ^a	Smallest	78 (69%)	161 (67%)	Reference
		Larger	35 (31%)	80 (33%)	0.90 (0.58, 1.46)
	Cartilage Damage Index ^a	Larger	78 (70%)	153 (63%)	Reference
		Smallest	34 (30%)	88 (37%)	0.84 (0.52, 1.38)

*Statistically significant; $p \leq 0.004$. ^aComparing the worst tertile (i.e. largest effusion/bone marrow lesion, smallest CDI) to the other 2 tertiles.

^bAnterior and posterior cruciate ligaments were grouped together as there were too few to analyze separately.

^cMedial and lateral collateral ligaments were grouped together as there were too few to analyze separately.

Conclusion: The presence of early ligamentous degeneration, synovitis, meniscal pathology, and large effusion precedes the onset of AKOA and may be prognostic biomarkers.

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Osteoarthritis – Clinical Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Radiographic patellofemoral osteoarthritis (OA) is prevalent in approximately 25% of population-based samples and 39% of individuals with knee pain. Discordance between knee OA features and pain is common yet not well understood. It may in part be explained by mechanical factors, such as patellofemoral alignment or bony morphology, that could cause pain by altering joint load. It may also be due to factors that influence pain perception, such as psychosocial or central mechanisms. We aimed to compare within-person, between-knee alignment, morphology and presence of patellofemoral OA in individuals with unilateral frequent anterior knee pain, to determine if these variables explain pain discordance.

Methods: We evaluated a subsample from the Multicenter Osteoarthritis Study (MOST), a cohort of 3026 individuals aged 50–79 years who had, or were at risk of, knee OA at baseline. We identified individuals who presented at the 60-month clinic visit with discordant patellofemoral pain. We defined this as: (i) a response of ‘yes’ to the question “During the past 30 days, have you had pain, aching, or stiffness in your knee on most days?” for one knee, but ‘no’ to the same question regarding the contralateral knee; and (ii) this pain was reported to be isolated to the anterior knee region using a knee pain map. For those not meeting inclusion criteria at the 60-month visit, we also included participants who met the same criteria at 84-months.

We measured alignment and morphology using MR images (patellar tilt angle, bisect offset, sulcus angle, lateral trochlear inclination) and lateral radiographs (Insall-Salvati ratio). Patellofemoral OA was defined on lateral view radiographs as any osteophyte \geq grade 2, or joint space narrowing \geq 1 plus any osteophyte, sclerosis or cyst \geq 1.

We modelled the odds of having pain using conditional logistic regression, which enables within-person, between-knee comparisons. Within-person matched pairs (i.e. knees) removes the effect of person-level risk factors that may contribute to pain (e.g. age, sex, BMI, kinesiophobia, depression, genetics, and other known/ unknown factors) that could otherwise explain pain variability among people.

Results: Inclusion criteria were met in 136 participants, 115 with history of surgery/ injury data, 97 with bilateral radiographs and 71 with MR images. The mean age ($n=71$) was 69 (8) years, BMI 30.2 (5.3) kg/m², 47 (66%) women. Alignment and morphology measures did not differ between knees. Odds of having patellofemoral OA was significantly increased in knees with pain compared to those without (OR 6.6 [95% CI 1.5, 29.7], as was history of surgery or injury (OR 2.1 [1.2, 3.6]).

Conclusion: In individuals with unilateral frequent anterior knee pain, odds of having patellofemoral OA were higher in knees with pain than without. Alignment and morphology measures did not differ by knee. Dynamic alignment may be more relevant to pain outcomes.

Table. Odds of each exposure in knees with pain compared to knees without pain

	Crude Prevalence	Crude Odds Ratio (95% CI)	*Adjusted Odds Ratio (95% CI)
Structure variables			
PFROA ($n=97$)			
Painful	27 (28%)	7.50	6.63
Contralateral	14 (14%)	(1.72, 32.80)	(1.48, 29.69)

Table . (Cont'd)

	Crude Prevalence	Crude Odds Ratio (95% CI)	*Adjusted Odds Ratio (95% CI)
TFROA (n=97)			
Painful	44 (45%)	1.55	1.17
Contralateral	38 (39%)	(0.72, 3.30)	(0.49, 2.80)
Surg/inj (n=115)			
Painful	50 (44%)	2.05	
Contralateral	30 (26%)	(1.19, 3.55)	
Alignment/ morphology (n=71)			
Sulcus angle		1.03 (0.97, 1.09)	
Lateral trochlear inclination		1.02 (0.92, 1.13)	
Bisect offset x 100%		0.99 (0.94, 1.05)	
Patellar tilt angle		0.94 (0.86, 1.03)	
Insall Salvati ratio x 100%		0.95 (0.90, 1.00)	

* For PFROA, we included history of surgery or injury and TFROA as covariates; for TFROA, we included history of surgery or injury and PFROA.

Impact of Bariatric Surgery on Rheumatic Diseases: A Systematic Review and Meta-Analysis

Marie Moly¹, Bernard Combe¹, Thomas Barnetche², Claire Daien¹, Jacques Morel³, Cédric Lukas¹, Cécile Gaujoux-Viala⁴ and Charlotte Hua⁴, ¹Rheumatology, University Hospital Lapeyronie, Montpellier, Montpellier, France, ²Rheumatology, University Hospital Pellegrin, Bordeaux, Bordeaux, France, ³Department of Rheumatology, University Hospital Lapeyronie, Montpellier, Montpellier, France, ⁴Rheumatology, University Hospital Carémeau, Nîmes, Nîmes, France

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Osteoarthritis – Clinical Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Obesity increase the incidence of rheumatic diseases (1-3). Bariatric surgery (BS) improve obesity-related comorbidities (4). The aim of our study was to assess currently available literature the impact of BS on rheumatic disease such inflammatory rheumatic disease, gout, musculoskeletal disorder and surgical management of osteoarthritis.

Methods: We systematically searched literature (via Pubmed, Embase, Cochrane library and abstracts from recent ACR and EULAR congresses) for studies evaluating the effects of BS on rheumatic diseases. A meta-analysis was performed with Review Manager Software, with random effects models, whenever methodologically possible and relevant. Data were extracted by one investigator and independently checked by another.

Results: The literature search revealed 399 articles and abstracts of potential interest, and further examination resulted in 124 studies include in systematic review and 24 studies fulfilling required criteria for preplanned analyses regarding the impact of BS on rheumatic diseases. For musculoskeletal disorder, the mean difference between before and after BS was -468.14 (95% confidence interval[95% CI] -646.76 ; -289.51) for WOMAC function, -95.18 [-127.06 ; -63.29]for WOMAC pain, 30.45 [22.02 ; 38.87] for SF36 physical function, 22.91 [16.58; 29.24] for SF36 bodily pain (Figure 1). For surgical management of osteoarthritis incidence of reoperation, the Odd ratio (OR) was 1.41 [0.88;2.27] and for incidence of infection the OR was 0.91 [0.53;1.59]. For gout, the effect size was 0.83 [0.79;0.87] for hyperuricemia before and after, the mean difference between before and after BS was -1.45 [-1.95; -0.94] for uric acid (Figure 2).

Conclusion: This study supports the interest of BS in rheumatology, with improvement of function and pain in musculoskeletal disorders, decrease of acid uric level.

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Osteoarthritis – Clinical Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Bariatric surgery, the most effective treatment for losing weight and maintaining weight loss among morbidly obese persons, has been evolving as a treatment for morbidly obese patients with knee OA (KOA). The purpose of this study was to evaluate trends in the volume and distribution of surgical approaches, patient characteristics, and inpatient outcomes among persons with KOA undergoing bariatric surgery from 2005-2014.

Methods: We used the National Inpatient Sample data from 2005 to 2014 to identify bariatric procedure discharges with documented comorbid KOA. We abstracted hospital setting, procedure, demographic and clinical patient characteristics, and inpatient surgical outcomes from each discharge. We calculated descriptive characteristics and the Elixhauser Comorbidity Index, a comorbidity metric designed for use with administrative datasets. Inpatient outcomes included complication rates, length of stay (LOS), and costs. We examined temporal trends on distribution of surgery types, hospital and patient characteristics, and surgical outcomes using linear regression and the Cochran-Armitage test for trend.

Figure. Distribution of bariatric procedure types among persons with knee osteoarthritis undergoing bariatric surgery between 2005 and 2014. The bars represent the estimated volume of each type of bariatric surgery procedure, and the p-value was obtained for the total volume of procedures using linear regression.

Results: The national volume of persons with KOA undergoing bariatric surgery from 2005-2014 remained consistent at a total of about 3,300 procedures annually. The procedure distribution changed over time; the most commonly-performed procedure shifted from laparoscopic Roux-en-Y gastric bypass (RYGB) (65%) in 2005-2006 to laparoscopic sleeve gastrectomy (LSG) (58%) in 2013-2014 (Figure). The median age and Elixhauser Index increased from 46 to 50 years and 1.6 to 2.0, respectively. From 2005-2014, the median costs (2017 USD), adjusted for LOS, Elixhauser Index, hospital location and teaching status, and bed size, for laparoscopic RYGB and laparoscopic banding procedures decreased from \$15,100 to \$13,700 ($p<0.0001$) and \$14,100 to \$10,100 ($p=0.0001$), respectively, whereas the adjusted costs of open RYGB did not change significantly. The adjusted costs of LSG did not change significantly between 2011, when the procedure code was introduced, to 2014. Inpatient complication rates decreased significantly from 5.2% to 1.7%, and inpatient mortality remained at 0.0%-0.1%.

Conclusion: The volume of persons with KOA undergoing bariatric surgery remained unchanged from 2005-2014. Less invasive procedures, such as LSG, are utilized more frequently over time, likely leading to a decrease in inpatient complication rates associated with bariatric surgery. Decreases in the costs of older laparoscopic techniques (RYGB and banding) may be due to improved surgical technology, whereas the cost of open RYGB has not changed over the decade. There were no significant cost changes during the four-year period of evaluation for LSG, a relatively new procedure. Mortality rates remained low despite an increase in age and number of concomitant comorbidities.

Session Date: Sunday, October 21, 2018

Session Title: Osteoarthritis – Clinical Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: To determine whether frailty is associated with clinical outcomes 1-year after total hip or total knee replacement, (TKR and THR).

Methods: Community-dwelling patients ≥ 65 yo scheduled for elective TKR or THR were recruited from a musculoskeletal specialty hospital. Frailty was measured using validated criteria. A variety of instruments including Hip/Knee Injury and Osteoarthritis Outcome Score (HOOS/KOOS) and PROMIS-29 were administered pre-operatively and at 1-year. Preoperative dependence was measured with Katz ADL scores. Regression models were created by considering all variables which were significant at the 0.05 level in univariate models, and then performing backward selection to retain variables with 0.05 significance. Age and gender were forced in to all models.

Results: 740 subjects enrolled, 303 THR/437 TKR. Median age 72 years (range 65-94), 95.1% Caucasian, 63.5% female, 7.5% frail. 327 cases with 1 year data, (93% of eligible). There were no differences in percentage of frail and non-frail patients meeting OMERACT-OARSI responder criteria at 1-year, ($p=0.09$). In univariate analyses being frail was associated with worse HOOS/KOOS outcomes at 1-year in all subscales except HOOS pain; however, these relationships were no longer significant in multivariate analyses. Controlling for age, gender, and which joint was replaced, only pre-operative PROMIS-29 pain intensity predicted being an OMERACT-OARSI responder at 1-year, (OR 1.6; 95%CI 1.3-2.0). There were no predictors of being an OMERACT-OARSI responder in TKR. Interestingly, among THR, stronger baseline grip strength- a component of the frailty phenotype- was associated with decreased odds of being an OMERACT-OARSI responder, (OR 0.46; 0.23-0.93) and an increased likelihood of having worse HOOS pain at one year ($p=0.02$). Having fewer Katz ADL dependencies pre-operative strongly predicted better HOOS ADL scores at 1-year ($p<0.001$). No frailty components were associated with functional outcomes in TKR.

Conclusion: Frailty does not appear to be independently associated with 1-year outcomes in THR and TKR patients, although currently only a small absolute number of frail patients have completed 1-year follow-up. The finding that stronger grip strength is associated with worse outcomes is intriguing. Whether this reflects a ceiling effect of the OMERACT-OARSI responder criteria or is a clinically meaningful difference will be explored as the study progresses.

¹ p-values using Jonckheere-Terpstra (symptomatic) test

Background/Purpose: Sprifermin, a recombinant human fibroblast growth factor 18, is currently being investigated as a potential disease-modifying OA drug. Sprifermin treatment leads to a dose-dependent increase in femorotibial cartilage thickness, as well as medial and lateral compartment cartilage, over two years¹. The aim of this post-hoc analysis was to evaluate the potential effects of sprifermin on additional knee structural endpoints, based on semi-quantitative MRI assessment over 24 months.

¹Hochberg MC, et al. *Arthritis Rheumatol.* 2017; 69 (suppl 10).

Methods: Patients aged 40–85 years with symptomatic radiographic primary femorotibial OA according to ACR criteria, Kellgren-Lawrence Grade 2 or 3, and medial minimum joint space width ≥ 2.5 mm in the target knee were randomized (1:1:1:1) to receive double-blinded sprifermin (30 μ g or 100 μ g) or placebo, administered as three weekly intra-articular injections in 6- or 12-month cycles. 1.5 or 3 Tesla MRIs were acquired at baseline, 6, 12, 18 and 24-month follow-up visits using a standard protocol (NCT01033994).

MRIs were read using the Whole-Organ Magnetic Resonance Imaging Score (WORMS) system by three trained musculoskeletal radiologists at baseline, 12 and 24 months. Analyses of all sprifermin and placebo arms included multiple MRI-defined OA features and multi-dimensional assessments: (a) delta-subregional approach (the difference in the *number of subregions* with worsening as compared to improvement) and (b) delta-sum approach (absolute *scores of all subregions*). Analyses were performed on a whole knee level and separately for medial, lateral, and patellofemoral compartments. To test for potential dose-response effects, the Jonckheere-Terpstra (asymptotic) test was used. P-values were not adjusted for multiple testing.

Results: In total, 549 patients were included. A dose-dependent treatment effect for sprifermin on cartilage morphology (i.e., less worsening of cartilage damage) was observed for the entire knee from baseline to 24 months using both delta sum and delta subregion approaches (Table 1). For bone marrow lesions (BMLs), a dose-dependent treatment effect (improvement of BMLs) was observed from baseline to 24 months for the patello-femoral joint, using both delta sum and delta subregion approaches, but not in the other compartments (Table 2). No significant changes from baseline to 24 months were reported in Hoffa-synovitis, effusion-synovitis, menisci, or osteophytes.

Conclusion: Sprifermin has a positive effect on cartilage morphology based on semi-quantitative assessment, in addition to the previously reported effect on cartilage thickness based on 3D morphometry. Sprifermin was also associated with BML improvement in the patello-femoral joint. There were no significant effects associated with sprifermin on the other joint tissues assessed, and no additional safety concerns.

Abstract Number: 437

Does Reduction in Mechanical Knee Joint Loading Explain the Beneficial Effects of Weight Loss in Overweight or Obese Patients with Knee Osteoarthritis?

Dennis Ang¹, Daniel Beavers² and Stephen P. Messier³, ¹Wake Forest University School of Medicine, Winston-Salem, NC, ²Biostatistical Science, Wake Forest School of Medicine, WINSTON SALEM, NC, ³Department of Health and Exerc, Wake Forest University, Winston-Salem, NC

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Osteoarthritis – Clinical Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Knee osteoarthritis (KOA) is traditionally considered a local joint pathology. The effect of obesity on the pathogenesis of KOA is predominantly attributed to increase mechanical joint loading (local effect). Weight reduction, a well-established recommendation for overweight or obese patients with KOA, is hypothesized to improve OA symptoms via reduction in mechanical joint loading. We sought to confirm or refute the latter hypothesis.

Methods: This is a secondary data analysis of a previously completed 18-month randomized controlled trial in KOA that compared combination diet-induced weight loss plus exercise vs. diet only vs. exercise only. In this analysis, the primary outcomes were self-report measures on pain severity (WOMAC pain) and function (WOMAC function) at the end of the study (month-18). The primary independent variables were changes in weight (kg) and knee joint compressive force (N)

from baseline to month-6. Regression models were adjusted for gender, race, treatment group assignment, and baseline measures on BMI, number of comorbid illnesses, and SF36 mental component summary score (SF36 MCS).

Results: From the 454 subjects enrolled in the original study, 329 (72.4%) subjects had available baseline and follow-up WOMAC data. This cohort had the following baseline characteristics (mean \pm SD): age= 66 years \pm 6.3; BMI =33.5 \pm 3.6; weight (kg) = 92.7 \pm 14.5; 70% females; 85% Whites; SF36 MCS= 57.1 \pm 7.3; WOMAC pain (range 0-20) = 6.3 \pm 3.0; and WOMAC function (range 0-68) = 23.3 \pm 10.8. The mean changes (SD) in weight and knee joint compressive force from baseline to month 6 were -6.3 (6.7) kg and -60.2 (651) N, respectively.

After controlling for potential covariates, the change in weight (β coefficient= 0.06, $p=0.03$) from baseline to month-6 was a significant predictor of WOMAC pain at month-18. The change in knee joint compressive force was not ($p=0.68$). Additionally, the change in weight ($\beta= 0.29$, $p=0.001$) was a significant predictor of WOMAC function at month-18. Again, the change in knee joint compressive force was not ($p>0.10$).

Interestingly, gender, race, number of comorbid illnesses, and SF36 MCS were not significant in both multivariable models for WOMAC pain and function.

Conclusion: Weight loss was temporally associated with improvement in OA symptoms through mechanisms other than reduction in mechanical joint loading. Extra-articular mechanisms (e.g., peripheral inflammation from adipokines and central sensitization) of weight loss in KOA should be explored.

Session Title: Osteoarthritis – Clinical Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: To study structural and inflammatoryultrasound lesions in elderly subjects with hand osteoarthritis (HOA) as wellas in pain-free subjects with bony enlargements of finger joints.

Methods: Prospective study of 331 subjects [mean age 75.2 (\pm SD 7.2) years, 49.5%female], of the Bruneck Study cohort, recruited from the official population register by random sampling. Sixteen joints (wrist, CMC, MCP1-5, PIP1-5,DIP2-5) were clinically evaluated for the presence of bony enlargements, soft tissue swelling and tenderness. Ultrasound of the dorsal and palmar side of these joints was conducted using a GE Logic E ultrasound device. Osteophytes, synovial hypertrophy and/or joint effusion (SH/E), Power Doppler (PD), and erosions were subjectively graded from 0 to 3 in accordance with prior publications. The Health Assessment Questionnaire (HAQ), the Short Form Score for the Assessment and Quantification of Chronic Rheumatic Affections of the Hands (SF-SACRAH) and the Functional Index for Hand Osteoarthritis (FIHOA) were used to assess functional impairment of hands. We defined two groups according to the presence or absence of HOA: Group A were subjects fulfilling the ACRcriteria (n=89, 26.9%) whereas group B were individuals with bony enlargements at finger joints, but without any hand pain, aching, tenderness or soft tissue swelling (which are entry parameters for the ACR criteria). A global ultrasound sum score was calculated for each group by summing all semi quantitative scores of the investigated US abnormalities.

Results: Eighty-nine subjects (26.9%) fulfilled the ACR criteria for HOA, 176 subjects(53.2%) were in group B. Sixty-six patients (19.9%) did neither fulfill the definition of group A nor that of group B and were excluded. Osteophytes were the most common finding in both groups (n=89, 100% and n=175, 99%,respectively), whereas SH/E (n=83, 93% and n=119, 68%, respectively, p<0.001) and PD (n=29, 33% and n=23, 13%, respectively, p<0.001) were more frequent in group A as compared to group B. Erosions were the least common finding (n=15, 17% and n=24, 14%, respectively, p>0.2). Grade 2 or 3ultrasound changes were more frequently observed in group A than in group B(see Table 1). In group A, the SF-SACHRA correlated with the global SH/E (corr_{coeff}0.46,p<0.001) and the osteophyte score (corr_{coeff}0.27, p=0.036). The FIHOA score correlated with the osteophyte score (corr_{coeff}0.39,p=0.0028) as well as with the PD score (corr_{coeff}0.4, p<0.001).There was no association between ultrasound findings and the level of pain.

Conclusion: US-verified SH/E and PD were more common in patients with clinical HOA as compared to subjects with bony enlargement without pain. This indicates that inflammation might drive clinical symptoms in people with degenerative joint disease at hands. Whether US signs of structural changes and inflammation in a symptomatic subjects precedes clinical HOA needs to be investigated by future studies.

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Osteoarthritis – Clinical Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Figure 1. Human OA articular cartilage tissue explant cultures. Human OA articular cartilage explants were cultured for 20 days with weekly administration of Sprifermin or FGF18. (A) Metabolic activity was measured weekly by Molarblue, ALP (n=11). (B) and ProC2 (C), were measured in the conditioned medium collected weekly during culturing. Values are mean \pm SEM of 11 patients. Data from each patient were baseline corrected and normalized to placebo before patient data were combined.

Background/Purpose: Sprifermin, a truncated form of human fibroblast growth factor 18 (FGF18), is being investigated as a potential cartilage and disease-modifying OA drug. *In vitro*, Sprifermin induces chondrocyte proliferation and extracellular matrix (ECM) production. Here, we characterized the ECM remodeling of human knee OA articular cartilage in response to long-term Sprifermin treatment.

Methods: Full depth articular cartilage explants from OA patients ($n_{\text{patients}}=11$) were cultured for 70 days. Freshly prepared media with either Sprifermin (900, 450, 225 ng/mL), FGF18 (450 ng/mL), IGF-1 (100 ng/mL, positive control) or placebo formulation (negative control) was added once weekly ($n_{\text{explants/treatment/patient}}=2$). Metabolic activity was measured weekly by AlamarBlue. Biomarkers of ECM remodeling were quantified in conditioned media using well-described ELISAs; exProC2 reflecting type II collagen formation and exAGN1 reflecting aggrecanase-mediated aggrecan degradation. Data were baseline-corrected and normalized to placebo for each individual patient and reported as mean \pm standard errors of the mean (SEM).

Results: In human OA articular cartilage cultured *ex vivo*, the positive control IGF-1 induced ProC2 and increased metabolic activity in all patient explants as well. All investigated doses of Sprifermin and FGF18 continuously increased metabolic activity compared to placebo over the 70 days of treatment (fig. 1A). The aggrecan degradation biomarker exAGN1 was increased by the investigated doses of Sprifermin and FGF18 as compared to placebo (fig. 1B). exAGN1 release peaked at 21 and then gradually decreased in presence of Sprifermin and FGF18, indicating a shift of a catabolic to an anabolic phenotype as cause of treatment. Type II collagen formation, measured by exProC2, was initially (day 7-28) decreased by Sprifermin and FGF18 compared to placebo, but from day 35 to 70 exProC2 increased in a dose dependent manner, with sprifermin superior to FGF-18 (fig. 1C). The increase in exProC2 release from Sprifermin (900 ng/mL)-treated explants were 1.5-fold of placebo at day 49.

Conclusion: The data indicate that human knee OA articular cartilage explants increase their metabolic activity and formation of type II collagen in response to long-term treatment with Sprifermin and FGF18. The induction of cartilage formation is preceded by cartilage degradation, indicating that a catabolic process is needed to make room of proliferation of chondrocyte and renewal of cartilage (fig. 2).

Assessing Inappropriate Pain Management in Adults with Hip or Knee Osteoarthritis Treated with Different Opioid Intensity Regimens: Results from a Retrospective Database Analysis

Nathaniel P. Katz^{1,2}, Kavita Gandhi³, Wenhui Wei⁴, Ahong Huang⁵ and Li Wang⁶, ¹President, Analgesic Solutions, Natick, MA, ²Tufts University School of Medicine, Boston, MA, ³Director, Global Health Economics and Outcomes Research, Teva Pharmaceutical Industries, Frazer, PA, ⁴Senior Director, Health Economics and Outcomes Research (HEOR), Regeneron Pharmaceuticals, Inc., Tarrytown, NY, ⁵Project Manager, STATinMED Research, Dallas, TX, ⁶Senior Director, Analytic Research, STATinMED Research, Dallas, TX

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Osteoarthritis – Clinical Poster I

Session Type: ACR Poster Session A

Background/Purpose: Opioids are often prescribed for osteoarthritis (OA) pain management despite the need for balancing their risks and benefits. Since there are no standard criteria for defining inappropriate pain management (IPM), this study examined prevalence of potential criteria that may be indicative of IPM in OA patients (pts) treated with opioids.

Methods: Data were from a US employer-sponsored insurance claims database (2011-2016). Pts were community-dwelling adults (≥ 18 yr) diagnosed with hip/knee OA who filled an opioid prescription (index event) within 30 days of OA diagnosis; had continuous enrollment 6 months pre- and 12 months post-index; and no pre-index joint surgery. Opioid regimen intensity in the 3-month post-index period was defined by frequency (intermittent: ≤ 4 d/wk; daily: >4 d/wk), average daily dose in morphine milligram equivalents (MME: <50 MME/d=low, ≥ 50 MME/d=high), and short- or long-acting opioids (SAO, LAO), providing 6 increasing intensity regimens: intermittent-low-dose SAO, intermittent-high-dose SAO, daily-low-dose SAO, daily-high-dose SAO, LAO, and LAO+SAO. Potential IPM, defined based on existing literature and clinical input (Table 1), comprised 3 clinical categories (Opioid Use, Miscellaneous Drug Use, Medical Service Use). Descriptive analysis characterized prevalence of potential IPM over the 12-month post-index period.

Results: The study included 271,512 pts (61.5% knee; 11.1% hip; 27.4% both); mean age 59.8 yr; 62.7% women. IPM was observed in 52.6% of pts during the post-index period; 30.7% in Miscellaneous Drug Use, 27.7% in Opioid Use, and 14.4% in Medical Service Use. LAO+SAO had the highest IPM (85.4%); intermittent SAO regimens had the lowest (42.7%-44.7%; Table 2). IPM in the intermittent dose regimens was driven by Miscellaneous Drug Use; IPM in the higher intensity regimens was driven by Opioid Use. The top 2 IPM criteria in each clinical category were generally similar across opioid intensity regimens (Table 2).

<i>Clinical category/criterion</i>	<i>Definition</i>
<i>Opioid Use</i>	
Multiple opioids	≥ 4 prescriptions for unique opioids in any 90-day period
Early refills	≥ 1 opioid prescription fill when $>10\%$ of an existing prescription should have remained available
Excessive post-surgical opioid use	Opioid prescription fill >90 days after any OA surgery
Pre-surgical opioid use	Any opioid use within 60 days prior to joint surgery
Concomitant long-acting opioid use	≥ 2 occurrences during any ≥ 7 day period of overlapping prescription fills for unique long-acting opioids
History of substance abuse	Receives opioids despite history of substance abuse
Post-index opioid abuse	≥ 1 diagnoses of opioids abuse disorder (dependence/abuse) after receiving opioids
History of opioid abuse	≥ 1 diagnoses of pre-index opioid overdose
Opioid overdose	≥ 1 diagnoses of post index opioid overdose
<i>Miscellaneous Drug Use</i>	
Excessive muscle relaxant use	≥ 3 fills for unique muscle relaxants within any 90-day period among patients with comorbid chronic low back pain
Excessive non-opioid dose	Exposure to acetaminophen or aspirin >4 g/d, or ibuprofen >3.2 g/d
Multiple NSAIDs	≥ 2 NSAIDs used concomitantly except for cardiovascular aspirin (75-325mg/d)
NSAIDs despite contraindications	NSAIDs (single drug or combined with SAO) despite contraindications
NSAID adverse events	Gastrointestinal or cardiovascular events, renal failure, hepatotoxicity after NSAID use
Too many hyaluronic acid or corticosteroid injections	≥ 3 hyaluronic acid or corticosteroid injections in a 12-month period
<i>Medical Service Use</i>	
OA-related visits with multiple specialists	≥ 4 OA-related visits to pain medicine specialists, orthopedists, rheumatologists, anesthesiologists in any 90-day period
Excessive OA-related office visits	≥ 4 office visits with an OA diagnosis within a 90-day period
OA-related inpatient admissions	Any inpatient stay with an OA principal diagnosis without corresponding joint surgery
OA-related ED visits	An ED visit with a primary diagnosis for OA
Repeated OA-related joint surgeries	≥ 2 of the same OA procedures in a 90-day period

ED, emergency department; NSAID, nonsteroidal anti-inflammatory drug; OA, osteoarthritis

Conclusion: This study suggests potential criteria indicative of IPM were observed in the majority of OA pts treated with opioids. IPM generally increased with higher opioid intensity regimens; drivers of IPM differed between low and high intensity regimens. The study was limited by the data source and retrospective design such that it could not be determined if IPM resulted from the index opioid treatment regimen itself, patient/physician behavior, or other factors. Nevertheless, study findings reinforce physician need for evaluating pain management with opioids in OA pts individually to ensure optimal health outcomes.

Table 2. Adults in each opioid intensity regimen meeting any potential criterion of inappropriate pain management and top 2 criteria in each clinical category.

Opioid regimen	Any criterion, %	Opioid use		Miscellaneous drug use		Medical service use	
		Criterion	%	Criterion	%	Criterion	%
Intermittent low-dose SAG (n=145,425)	44.7	Any criterion	15.3	Any criterion	43.7	Any criterion	13.6
		Early refill	8.4	Too many hyaluronic acid/corticosteroid injections	22.3	OA-related visits with multiple specialists	9.3
		Pre-surgical use	6.9	NSAID adverse events	7.3	Excessive OA-related office visits	4.1
Intermittent high-dose SAG (n=44,669)	42.7	Any criterion	10.0	Any criterion	26.1	Any criterion	14.1
		Early refill	7.9	Too many hyaluronic acid/corticosteroid injections	18.6	OA-related visits with multiple specialists	10.3
		Pre-surgical use	6.9	NSAID adverse events	5.2	Excessive OA-related office visits	3.0
Daily low-dose SAG (n=41,178)	73.0	Any criterion	46.5	Any criterion	34.2	Any criterion	14.4
		Early refill	30.0	Too many hyaluronic acid/corticosteroid injections	23.9	OA-related visits with multiple specialists	8.6
		Excessive post-surgical opioid use	8.8	NSAID adverse events	8.6	Excessive OA-related office visits	6.3
Daily high-dose SAG (n=10,137)	81.8	Any criterion	68.0	Any criterion	36.2	Any criterion	19.0
		Early refill	41.0	Too many hyaluronic acid/corticosteroid injections	22.1	Excessive OA-related office visits	10.2
		Excessive post-surgical opioid use	13.0	NSAID adverse events	8.3	OA-related visits with multiple specialists	9.7
LAC (n=5,819)	66.9	Any criterion	40.4	Any criterion	30.9	Any criterion	16.1
		Early refill	27.0	Too many hyaluronic acid/corticosteroid injections	19.8	OA-related visits with multiple specialists	9.6
		Pre-surgical use	8.9	NSAID adverse events	3.3	Excessive OA-related office visits	6.9
LAC+SAG (n=13,673)	85.4	Any criterion	75.3	Any criterion	34.2	Any criterion	21.3
		Early refill	62.9	Too many hyaluronic acid/corticosteroid injections	20.0	OA-related visits with multiple specialists	11.5
		Multiple episodes	21.0	NSAID adverse events	8.5	Excessive OA-related office visits	10.6

LAC, long acting opioid; NSAID, nonsteroidal anti-inflammatory drug; OA, osteoarthritis; SAG, short acting opioid

The Presence of Neuropathic Pain Does Not Influence the Response to Hyaluronic Acid (HA) in Patients with Knee Osteoarthritis but HA Injections Modify Pain Phenotype

Evariste Tiendrebeogo¹, Thierry Conrozier², Xavier Chevalier³ and Florent Eymard⁴, ¹Rheumatology, APHP Henri Mondor Hospital, Creteil, France, ²Department of Rheumatology, Nord Franche-Comté Hospital, Belfort, France, ³Rheumatology, APHP Henri Mondor Hospital, Créteil, France, ⁴Department of Rheumatology, APHP Henri Mondor Hospital, Creteil, France

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Osteoarthritis – Clinical Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Twenty to forty percent of patients with symptomatic knee osteoarthritis (OA) described neuropathic pain (NP). Several studies have shown that hyaluronic acid (HA) is an effective treatment of pain-associated knee OA. However, the impact of NP in the response to HA in knee OA is unknown as well as the impact of HA injections on the neuropathic profile of pain.

Our main objective was to assess the effect of NP according to DN4 score (10 items; NP if DN4 \geq 4) in the response to HA in patient with moderate to severe symptomatic knee OA. Our secondary objectives were to assess the correlations between NP and baseline clinical and radiographic characteristics of knee OA patients and the effects of HA injections on NP.

Methods: We conducted a post-hoc analysis from the 2012 HAPPYVISC study, a multicenter randomized, double-blind, non-inferiority prospective trial comparing the efficacy of 3 weekly intra-articular injections of 2 different HA at 24 weeks. At baseline, demographic, anthropometric, clinical data (VAS Pain, WOMAC score, NP assessed by DN4, presence or lack of synovial effusion) radiologic data (OARSI score for joint space narrowing [JSN]) were recorded. The symptomatic effect of HA was assessed by PGA, WOMAC, DN4 and OMERACT-OARSI response. All patients from intention-to-treat population with fully available DN4 data were included. Mann-Whitney and chi-square tests and multivariate logistic regression analysis were used.

Results: 187 patients were included. As baseline characteristics and treatment effectiveness were similar between the 2 HA groups, their data were pooled. Mean age was 64.7, sex ratio was 0.8, mean BMI was 27.7 and mean disease duration was 46.5 months. At baseline, mean VAS pain, WOMAC pain, WOMAC function were respectively 5.8, 9.7 and 27.3. Intra-articular effusion was present in 59 patients (31.6%). 79 patients (42.2%) had a OARSI grade 3 JSN. NP was present in 20 patients (10.7%). Most common positive DN4 items were tingling (36.9) and burning (36.4%). NP was significantly associated with pain intensity according to WOMAC pain score ($p = 0.02$). A significant association between baseline burning and VAS pain intensity was also found ($p = 0.01$).

At 24 weeks, 132 patients (70.6%) were OMERACT-OARSI responders. We found a significant association between OMERACT-OARSI response and overweight, obesity, and OARSI grade ($p=0.01$; $p=0.0003$; $p=0.04$). The presence of NP according to DN4 score at baseline did not impact the rate of OMERACT-OARSI responders to HA ($p=0.32$). On the other hand, the prevalence of patients with NP decreased by 50% ($n=10$) at 24 weeks after HA injections and there was an improvement of more than 75% of absolute DN4 value in 64 patients (34.2%). Most improved DN4 items were itching (90%), hypoesthesia to pinprick (88%), and burning (50%).

Conclusion: NP is frequently described by symptomatic knee OA patients and is associated with pain severity. While NP does not influence HA response, AH reduces NP especially itching, sting hypoesthesia and burning.

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Osteoarthritis – Clinical Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Exercise, weight loss, simple analgesic medications and joint injections are effective non-surgical treatments for knee osteoarthritis (OA) to reduce pain and improve function. While these treatments are recommended in international guidelines and appropriate for virtually all patients, they are substantially under used. Furthermore, many patients receive opioid analgesia in place of recommended therapies. Reduced mobility due to knee OA increases risk for CV events, diabetes, and all-cause mortality; while opioid use for chronic non-cancer pain is associated with increased mortality without added therapeutic benefit. Currently, little is known about patient factors that influence use of recommended non-surgical OA care, as well as non-recommended care such as opioids, and thus which patients to target in implementation strategies.

Methods: Knee OA patients were assessed prior to orthopaedic surgical consultation using a standardized online questionnaire that assessed: sociodemographic factors (age, sex, education, income, employment, and Lubben social network score), medical comorbidities, OA disease severity (pain numeric rating scale, WOMAC pain scale, KOOS-physical function score, Gignac coping efficacy scale, and pain catastrophizing scale), and non-surgical therapies used (both

ever tried and currently using). Comprehensive non-surgical treatment was defined as use of analgesia (acetaminophen, NSAIDs or injection) *plus* exercise or physical therapy *plus* weight loss if BMI ≥ 25 kg/m². Multivariate logistic regression was used to assess the relationship between patient factors (sociodemographics, comorbidities, and OA severity) with lack of current use of comprehensive treatment, as well as with current use of opioid analgesia for knee OA.

Results: 2,220 patients were included: mean age 65.6 ± 9.1 years, 58.8% female, mean BMI 32.7 ± 6.6 kg/m², mean WOMAC pain $11.6/20 \pm 3.6$ and mean KOOS-PS $56.5/100 \pm 17.7$. 654 (29.5%) patients were currently using comprehensive treatment; 609 (27.4%) tried and stopped and 957 (43.1%) never used. 635 (28.6%) patients were currently using opioid analgesia for knee OA. In multivariate analysis, lack of use of comprehensive care was significantly associated with older age (OR 1.02, 95% CI 1.01-1.04), male sex (1.67, 1.34-2.08), high school education or less (1.25, 1.01 – 1.56; 1.82, 1.30-2.55), lower social support (0.97, 0.95-0.99), and higher BMI (1.03, 1.01-1.04). Use of opioids was significantly associated with comorbid hypertension (1.26, 1.01-1.59), depression (1.69, 1.30-2.20), other painful joints (1.27, 1.01-1.59), and worse physical function on the KOOS-PS (1.02, 1.01-1.03).

Conclusion: In a cohort with moderate-to-severe knee OA, less than one third were using comprehensive non-surgical OA treatment and over one quarter were using opioid analgesia. Sociodemographic factors including lower level of education and social support were associated with less uptake of comprehensive treatment, suggesting that clinicians should be aware of these barriers to care. Medical comorbidity and lower function, but not pain severity, were associated with opioid use, meriting further research to better understand opioid prescribing in OA.

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Osteoarthritis – Clinical Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Intra-articular (I/A) steroid injection is an effective treatment for alleviating symptoms in osteoarthritis (OA) of the hip but the impact of this treatment on imaging findings relevant to prognosis, such as bone marrow lesions (BML) on MRI, has not been reported. The OMERACTHip MRI Inflammation Scoring System (HIMRISS) is a validated method for semi-quantitative assessment of BML in hip OA¹. We aimed to assess the impact of I/A steroid on BML in a multi reader exercise of MRI scans from a prospective cohort.

Methods: We assessed MRI scans from both hips of 90 patients at baseline and 8 weeks after I/A steroid injection. In HIMRISS, BML is scored as 0/1 (absent/present) in 100 regions on a web-based grid overlay slice-by-slice on coronal hip MRI. T1/STIR sequences were read blinded to timepoint by 8 readers (2 radiology fellows, 3 rheumatologists, 3 MSK radiologists) after review of validated HIMRISS methodology and calibration tools and attaining pre-specified scoring proficiency for assessment of status and change scores (intra-class correlation coefficient (ICC) > 0.80) versus expert reader consensus scores. Readers each scored HIMRISS BML in all 360 hips.

Results: Subjects were 56% male, age 59±13 (mean±SD) years, symptom duration 4.4±4.5 years, K-L OA grade 1/2/3/4 in 20%/28%/34%/18%, 24% taking NSAID. Although mean change in femoral BML was small (potential range 0-100), a significant increase was noted after injection. Moreover, change in BML greater than smallest detectable change (SDC) was noted in 30-40% of cases among readers with worsening score being more frequent (mean 22.2%) than improvement (10.0%) (Figure). In univariate analysis, worsening of femoral BML by >SDC was associated with NSAID use (OR=3.78 (1.37 to 10.45), P=0.01) and this remained significant in multivariate analysis adjusted for age, gender, BML, baseline femoral BML score (OR=4.25 (1.31 to 13.83), P=0.02).

Conclusion: Following I/A steroid injection for hip OA, extent of BML is more likely to deteriorate than improve and deterioration may be associated with concomitant NSAID use.

Abstract Number: 444

Trajectories of Sport or Recreational Activities over Eight Years and Associated Factors in Persons at Risk for Knee Osteoarthritis

Alison H. Chang¹, Julia (Jungwha) Lee², Orit Almagor¹, Joan S. Chmiel³, Julie Szymaszek¹ and Leena Sharma⁴,

¹Northwestern University Feinberg School of Medicine, Chicago, IL, ²Department of Preventive Medicine, Biostatistics Collaboration Center, Northwestern University Feinberg School of Medicine, Chicago, IL, ³Preventive Medicine, Northwestern University Feinberg School of Medicine, Chicago, IL, ⁴Division of Rheumatology, Northwestern University Feinberg School of Medicine, Chicago, IL

Session Information

Session Date: Sunday, October 21, 2018

Background/Purpose: Participation in exercise, sport or recreational activities offers multiple health benefits, promotes wellbeing and weight management, and preserves function and quality of life. Staying physically active is important for persons at high risk for knee OA, but without radiographic disease, for helping to prevent the downward spiral of functional decline and disability onset associated with OA development and progression. Understanding how activity levels evolve over time and associated baseline modifiable factors will inform strategies for activity promotion. In persons at high risk for knee OA, we identified distinct trajectories of weekly hours spent in strenuous activities over 8 years and baseline factors associated with membership in each trajectory.

Methods: Weekly hours engaged in strenuous activities, such as jogging, swimming, cycling, singles tennis, aerobic dance, skiing (downhill or cross-country) or other similar activities were estimated using items in the PASE (Physical Activity Scale for the Elderly) questionnaire over 8 years. OAI Participants with KL 0 in both knees and with ≥ 3 time points of PASE data were included. We used latent mixture modeling with zero-inflated Poisson distribution to identify groups with a similar underlying trajectory of weekly hours spent in strenuous activities. Multinomial logistic regression was used to model associations of baseline predictors with membership in each trajectory. Multivariable models were created by including variables with $p \leq 0.20$ in the univariate model. Backward selection (removing variables with multivariable $p > 0.20$) was used to create final models.

Figure 1. Four distinct trajectories of weekly hours spent in strenuous sport or recreational activities over 8 years. 594 participants (49.8%) were in Group 1 (a persistently low group, blue line), 354 (29.7%) were in Group 2 (red line), 151 (12.7%) were in Group 3 (green line), and 95 (7.5%) were in Group 4 (a high group, orange line). The dots are actual hours at each time point; the solid lines are estimated hours across 8 years; the dotted lines are 95% confidence intervals.

Results: Among 1194 OAI participants [age: 58.4 (SD 8.9) years, BMI: 26.8 (4.5) kg/m², 58.4% women], we identified 4 distinct trajectories of weekly hours spent in strenuous activities (Figure 1). Nearly 50% of the participants reported zero hour and 30% reported 1-2 hours per week over 8 years. As shown in the table, being older, greater BMI, and more severe knee pain were each associated with reduced likelihood, and being a college graduate and having stronger knees with an increased likelihood of being in the high trajectory (Gr. 4 vs. 1). Depressive symptoms were associated with a reduced likelihood of being in Gr. 3 vs. 1 or Gr. 2 vs. 1 (Table).

Conclusion: In persons at high risk for knee OA, we identified 4 distinct trajectories of weekly hours spent in strenuous activities over 8 years. Reducing BMI, knee pain, and depressive symptoms and improving knee strength may potentially facilitate continued participation in exercise, sport, or recreational activities.

Table 1. Associations of baseline predictors (independent variables) with membership in each of the weekly hours spent in strenuous activities trajectory groups (reference group: membership in Group 1 – persistently low)

Multinomial logistic regression models results for relative risk ratios (95% confidence intervals)				
n = 1194				
Baseline predictors	Group 2 n = 354	Group 3 n = 151	Group 4 n = 95

Session Date: Sunday, October 21, 2018

Session Title: Osteoarthritis – Clinical Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: In osteoarthritis (OA), there are no therapeutics to prevent disease progression. Canakinumab, a monoclonal antibody targeting interleukin-1 β , reduced inflammation and cardiovascular events in the CANTOS trial (Ridker et al. 2017). CANTOS included 10,061 men and women with a history of myocardial infarction and high-sensitivity C-reactive protein (hsCRP) ≥ 2 mg/L who were randomized to placebo or one of three doses of canakinumab (50 mg, 150 mg, or 300 mg) given sc once every 3 months. Median follow-up was 3.7 years.

Methods: We conducted a post-hoc exploratory analysis of CANTOS data to evaluate potential effects of canakinumab on rates of OA-related adverse events (AE) and incident TKR/THR (ARGUS) in the full CANTOS cohort and in a subgroup with a medical history of OA. The high-level term Osteoarthropathy (OAP) was used to search the AE database, (no adjudication of OA was pursued). A time to event analysis was done for first occurrence of TKR/THR as well as for OAP-related AEs. The drug-treated groups were compared to placebo by two-sided log-rank test. Second, the analyses were repeated with pooled drug-treated groups and hazard ratios for pooled drug vs placebo computed by Cox proportional hazards regression (CPH).

Results: In all patients, incidence rates of TKR/THR were 1.41%, 0.88%, 0.66%, and 0.80% in the placebo and canakinumab 50 mg, 150 mg, and 300 mg groups, respectively. The relative risk reduction (RRR) for pooled treatment vs placebo was 45% computed by CPH, $p < 0.001$. For OA-related adverse events, comparable incidence rates were 7.0%, 5.2%, 5.1%, 6.0%, respectively. The RRR for pooled treatment vs. placebo was 23% computed by CPH, $p = 0.002$. In the subgroup of 1569 CANTOS participants with OAP at baseline, incidence rates of TKR/THR were 6.25% and 3.36% in the placebo and combined canakinumab groups respectively (RRR vs placebo 45%, $p < 0.013$, Figure 1). Incidence rates for OA-related adverse events were 20.7%, 16.6%, 12.4%, 15.0%, respectively (RRR vs. placebo across groups 31%, $p = 0.003$, Figure 2).

Conclusion: In an exploratory analysis of the CANTOS trial, canakinumab treatment was associated with reduced rates of THR/TKR and OA symptoms. Effects were most apparent among those with a prior history of OA. An additional responder analysis based on hsCRP lowering at 3 months is currently ongoing.

Session Date: Sunday, October 21, 2018

Session Title: Osteoarthritis – Clinical Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Male youth commonly participate in American football. Little data inform whether this is associated with knee pain or osteoarthritis (OA) later in life. We aimed to evaluate the relationship of football participation with these outcomes using data from the Osteoarthritis Initiative (OAI), hypothesizing that it is associated with a higher prevalence of knee pain, knee OA, and symptomatic knee OA.

Methods: This is a retrospective cross-sectional study of OAI participants with knee x-ray readings, symptom assessments, and completed surveys on lifetime physical activity. A modified version of the Historical Physical Activity Survey Instrument identified those who played football. Posterior-Anterior semi-flexed knee radiographs were scored for Kellgren-Lawrence (KL) grade (0-4). Radiographic OA (ROA) was defined as KL ≥ 2 . Frequent knee pain within a person required at least one knee to have frequent kneepain. Symptomatic radiographic OA (SOA) required that at least one knee had both ROA and frequent knee pain. Anyone with a total knee replacement was classified as having frequent knee pain, ROA, and SOA. Since 98% of the subjects who participated in football were men, we restricted this study to men only. Using logistic regression, we evaluated the association of any history of football participation during 2 age periods: ages 12 – 18 and over the participants' lifetime, with the prevalence of ROA, frequent knee pain, and SOA as the outcomes. Outcome Definitions. All outcomes were person-based definitions. Exposure Definitions. For the 12-18 age range and any history of American football participation, we looked at the exposure in two ways: (1) dichotomously (non-participants versus participants) and (2) 4 groups: non-participants and 3 levels of participation (low, medium, and high tertiles of football participation). The Cochran-Armitage trend test was used to evaluate for a dose response relationship. We performed analyses both unadjusted and adjusted for age, BMI, and history of knee injury.

Results: 1166 men were included with a mean age of 63.7 (SD 9.2) years and BMI of 28.6 (SD 4.2) kg/m². 31% (365/1166) played football at some time in their lives, 95% (346/365) played between 12-18 years old, with 65% (223/346) playing at least 5 years during that age range.

The ORs for SOA from lowest to highest football participation were 1.2, 1.5, and 2.2 respectively (p for trend = 0.004) (Table). Findings were similar for football from ages 12 –18 years and for outcomes of knee pain and ROA (Table).

Conclusion: This is the first large epidemiologic study to suggest that football participation, especially in the teen years, is detrimental to knee health, independent of knee injury. A limitation to this study is that the exposure of football was ascertained retrospectively. Prospective studies evaluating football players are warranted.

Table. Table of knee pain, knee OA, and symptomatic knee OA prevalence based on history of football participation status and associated odds ratios			
Football Time Period	Prev. of outcome	Unadjusted Odds Ratios	Adjusted Odds Ratios*
Any History of Football Participation			
Outcome of Frequent Knee Pain			
No (n = 801)	35.80%	Referent	Referent

Abstract Number: 447

Discriminating between Central & Peripheral Pain Sensitization Using a Slowly Repeated Evoked Pain Protocol

Manuel Romero¹, Stephen Bruehl², Gustavo A Reyes del Paso³ and Pablo De la Coba³, ¹University Hospital of Jaén, Jaén, Spain, ²Department of Anesthesiology, Vanderbilt University, Nashville, TN, ³Department of Psychology, University of Jaén, Jaén, Spain

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Pain Mechanisms – Basic and Clinical Science Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

- In a prior study, the response of pain sensitization by fibromyalgia (FM) patients to a protocol of Slowly Repeated Evoked Pain (SREP)* was strongly associated with clinical pain. However, this protocol needs further investigation regarding its underlying mechanisms and clinical usefulness.

* *SREP differs from Temporal Summation of Pain (TSP) in which the frequency of painful stimuli is usually around 0.33 Hz in TSP, whereas it is 10 times slower (0.03 Hz) in SREP.*

- This study explored the central vs. peripheral origin of the pain sensitivity observed in response to SREP protocol when this was applied to patients with chronic pain characterized by central sensitization (FM) vs. characterized by peripheral sensitization (rheumatoid arthritis, RA) vs. healthy controls (HC).

Methods:

- Fifty-nine patients with FM, 30 with RA, and 50 HC matched in socio-demographic variables participated in this study.
- Potential group differences of psychological factors were controlled: Clinical Pain (McGill Questionnaire), Anxiety and Depression (HADS), and Catastrophization (CSQ).
- Participants were instructed in the use of a Visual Analogue Scale (VAS) to assess the pain caused by a pressure algometer on the nail of the third finger.
- Threshold and tolerance were obtained to calculate the intensity of the pain stimulus individually for each participant. Then, a series of 9 pain stimuli of 5s duration and low-moderate intensity was applied at a 30s interval.
- SREP sensitization index was quantified as the difference in pain scores between the 9th and 1st painful stimuli.

Results:

- The repeated measures ANOVA showed a significant increase in subjective pain ratings of the SREP series exclusively for the FM group (see Figure).
- Logistic regressions revealed an acceptable diagnostic accuracy of SREP index to discriminate between FM & AR and FM & HC, but not between AR & HC (see Table).

Conclusion:

- SREP seems to be based on central processes rather than to be related to peripheral sensitization.
- SREP could be presented as a simple tool that would allow in a complementary way to explore the level of central pain sensitization in patients with chronic pain.
- Potential clinical utility of SREP warrants further investigation.

Tizanidine, a Frequently Used Muscle Relaxant, Is Associated with Severe Hypotension: Role of Cytochrome P450 1A2 Inhibition in Routine Clinical Practice

Sandip Chaugai¹, Alyson Dickson², Megan Shuey², QiPing Feng², Katherine Barker², James Luther², C. Michael Stein³ and Cecilia P. Chung³, ¹Medicine, Vanderbilt University Medical Center, Nashville, TN, ²Vanderbilt University Medical Center, Nashville, TN, ³Department of Medicine, Vanderbilt University Medical Center, Nashville, TN

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Pain Mechanisms – Basic and Clinical Science Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Tizanidine, a muscle relaxant widely used for musculoskeletal pain, can lower blood pressure and is metabolized by the cytochrome P450 1A2 (CYP1A2). As a result, strong CYP1A2 inhibitors raise plasma concentrations of tizanidine 10-33 fold, thus potentially increasing the risk of tizanidine side effects. Despite this concern, there is limited information about the clinical consequences of this drug-drug interaction in routine clinical practice. We tested the hypothesis that when used in combination with strong CYP1A2 inhibitors, tizanidine is associated with higher rates of severe hypotension than the active comparator, cyclobenzaprine.

Methods: In this retrospective cohort study in the de-identified electronic health record database at Vanderbilt University Medical Center, we studied patients 18 years of age or older who had received tizanidine or cyclobenzaprine concurrently with the strong CYP1A2 inhibitors ciprofloxacin or fluvoxamine. We extracted demographic variables (including age, race, and sex) and the specific CYP1A2 inhibitor drug, and we used ICD-9 codes, which were collapsed according to the categories described in the Charlson/Deyo modified score. The primary outcome was severe hypotension, defined as systolic blood pressure (SBP) ≤ 70 mm Hg. To examine the association between severe hypotension and the concurrent use of tizanidine and a strong CYP1A2 inhibitor, we built two multivariate logistic regression models: (1) adjusted for age, sex, and race; (2) adjusted by a logarithmically transformed propensity score, defined as the probability of assignment to tizanidine given demographics, Charlson score, specific strong CYP1A2 inhibitor, and current use of antihypertensives (by class).

Results: The cohort was comprised of 1,626 patients prescribed tizanidine and 5,012 prescribed cyclobenzaprine concurrently with a strong CYP1A2 inhibitor. Severe hypotension occurred more often in the tizanidine group [2.03% (n=33)] than the cyclobenzaprine group [1.28% (n=64)]; OR= 1.60, p=0.029. This difference remained statistically significant after adjustment for a log-transformed propensity score (OR= 1.57, p=0.049). The highest risk for severe hypotension was among patients receiving tizanidine and a strong CYP1A2 inhibitor who had a Charlson score of 3 or more [OR=10.60 (95% C.I. 4.19-26.81)] or who received three or more concurrent anti-hypertensives [OR=5.64 (95% C.I. 2.30-13.81)].

Table: Association between concurrent prescription of tizanidine and a CYP1A2 inhibitor and severe hypotension (SBP ≤ 70 mm Hg)

	Tizanidine (n=1,626)	Cyclobenzaprine (n=5,012)	p-value
Windows with event (SBP ≤ 70 mm Hg)	33	64	
Rate of Event (%)	2.03	1.28	0.032
Unadjusted Odds Ratio (95% CI)	1.60 (1.05, 2.45)	Reference	0.029
Adjusted Odds Ratio – adjusted for age, race, and sex	1.69 (1.08, 2.64)	Reference	0.021
Adjusted for logarithmically transformed PS	1.57 (1.0, 2.45)	Reference	0.049

Conclusion: Strong CYP1A2 inhibition increases the risk of severe hypotensive episodes associated with the use of tizanidine. Clinicians should avoid co-prescribing tizanidine with strong CYP1A2 inhibitors, particularly in patients with higher comorbidity indices and in those who receive three or more antihypertensive agents.

Pain Processing in Chronic Low Back Pain Individuals with or without Sick Leave

Aloma Feitosa¹, Liliansa Jorge², Liana Sanches², Eduardo Ferreira Borba³, Edson Amaro² and Ari Halpern^{1,2},
¹Rheumatology, Hospital das Clinicas HCFMUSP, Faculdade de Medicina, Universidade de Sao Paulo, SP, BR, Sao Paulo, Brazil, ²Instituto do Cérebro, Hospital Israelita Albert Einstein, Sao Paulo, Brazil, ³Rheumatology Division, Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Pain Mechanisms – Basic and Clinical Science Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Chronic low back pain (LBP) is one of the most common musculoskeletal complaints in industrialized societies. It affects 80% of the adult population at some time in their lives and chronic LBP (CLBP) remained one of the most common causes of disability among adults in the past 20 years. One of the reasons for relatively low impact of current available treatment is the lack of a better pathophysiologic understanding of CLBP, reflected in the inconsistent response to the commonly used drug and non-drug treatments. Pain definition *per se* is at the very basis of the problem, due to its complexity and subjective experience encompassing the interpretation of nociceptive stimuli influenced by many factors. Some of the CLBP characteristics are reflected in brain processes probed by functional magnetic resonance imaging (fMRI). With that in mind we performed a study comparing neuronal correlates between CLBP with or without sick-leave

Methods: Cross-sectional observational study comparing CLBP with or without sick leave with 74 volunteers divided into three groups: CLBP and sick leave [CLBP_L]; CLBP without sick leave [CLBP_NL]; controls without pain]. fMRI was used during performance of two paradigms: pain and attention.

Results: After acute painful stimulation (figure 1, 2), higher response at the anterior cingulate and superior frontal gyrus was observed in CLBP_NL vs. CLBP_L ($p < 0,001$) and at the frontal pole and paracingulate region, comparing control vs. CLBP_L ($p < 0,001$) showing a gradual modulation of these areas. We also observed a higher brain activity in the CLBP_NL compared to CLBP_L in superior frontal gyrus ($p = 0,047$).

Conclusion: Our results confirm and extend previous studies showing that chronic pain is associated with altered neuronal plasticity in brain areas that extend beyond somatosensory regions to include areas processing emotions. The lower activation of the superior frontal gyrus in the CLBP_L group in both tests (pain and attention) suggests a chronic preexisting activation in these areas. These results indicate that the modulation of acute pain and attention participates in the mechanism propagating chronic pain perception.

Injection Site Reaction Associated with Subcutaneous Biologic Agents and Methotrexate. Analysis from the Rhumadata® Clinical Database and Registry

Denis Choquette¹, Louis Bessette², Jacques Brown², Boulos Haraoui¹, Frédéric Massicotte¹, Jean-Pierre Pelletier¹, Jean-Pierre Raynauld¹, Marie-Anaïs Rémillard¹, Diane Sauvageau¹, Angèle Turcotte², Édith Villeneuve¹ and Louis Coupal¹,
¹Rheumatology, Institut de Recherche en Rhumatologie de Montréal (IRRM), Montréal, QC, Canada, ²Rheumatology, Centre de l'Ostéoporose et de Rhumatologie de Québec (CORQ), Québec, QC, Canada

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Pain Mechanisms – Basic and Clinical Science Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Injection Site Reaction (ISRs) are associated with the subcutaneous (SC) route of administration of all biologic agents, and 3% to 15% of patients reports it. ISRs include pain, itching, redness, swelling or a combination of any of those. Rhumadata® has collected the intensity of pain associated with SC injections. We report here the results and compare levels of pain across agents.

Methods: As part of the patient reported outcomes (PROs), one question on pain intensity was asked to patients exposed to SC methotrexate or a biologic agent administered with a device or a syringe. The same question was asked at all visits making multiple answers available for the same patient. The intensity of pain was described using the following scale: 1- none, 2- negligible, 3- mild, 4- moderate, 5- severe, 6- extremely severe and 7- intolerable. Pain levels associated with adalimumab (ADA), etanercept (ETA), certolizumab (CERTO), golimumab (GOLI), denosumab (DEN), abatacept (ABA), tocilizumab (TOCI) and methotrexate (MTX) are presented.

Results: A total of 12,843 injection pain assessments were extracted. 7,347, 2,117 and 3,319 were performed on patients with rheumatoid arthritis (RA), ankylosing spondylitis (AS) and psoriatic arthritis (PsA) respectively. Women represented 76%, 44% and 50% of these cohorts. Mean ages at treatment initiation were 53.0(SD=12.1), 41.6(12.4) and 48.7(11.6). Severe, very severe or intolerable pain was reported for 3.12%, 9.23% and 6.21% of SC injections performed on patients with RA, AS and PsA respectively. Multivariate logistic regression showed that women (OR=2.09, 95% CI=[1.42, 3.08]) were more likely to report severe, very severe or intolerable pain than men, as were patients with longer disease duration (OR=1.04, 95% CI=[1.02, 1.06]). Patients diagnosed later (Age at diagnosis OR=0.98, 95% CI=[0.97, 1.00]) were less likely to report high levels of pain. Subjects treated with ADA (OR=6.31, 95% CI=[3.13, 12.72]) and ETA (OR=4.37, 95% CI=[2.42, 7.90]) were more likely to report more pain than patients using MTX. Patients using CERTO (OR=0.26, 95% CI=[0.12, 0.54]) and GOLI (OR=0.11, 95% CI=[0.06, 0.23]) were less likely to report severe, very severe and intolerable pain than patients injected with ADA. Primary diagnosis (RA, AS and PsA) are similarly associated with reported pain levels. Stopping MTX or bDMARD treatment for an ISR-pain is extremely rare.

Conclusion: The intensity of pain associated with subcutaneous route of administration varies with gender, age (age at diagnosis and disease duration at injection) and administered medication.

Abstract Number: 451

The Frequency of Neuropathic Pain in Patients with Low Back Pain and the Relationship with Demographic Characteristics: A Cross-Sectional Study

Belgin Erhan, Kevser Gumussu, Belgin Kara, Gül Tuğba Bulut and Ebru Yılmaz Yalcinkaya, Physical Medicine and Rehabilitation, GOP Taksim Training and Research Hospital, Gaziosmanpasa, Turkey

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Pain Mechanisms – Basic and Clinical Science Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Low back pain (LBP) is one of the most challenging chronic pain conditions. The path physiology of LBP is complex and contains nociceptive and neuropathic pain (NP) pathways. NP may be associated with leg pain, sensory and motor deficits, disability and lower quality of life. The aim of this study was to evaluate the prevalence of NP in patients with LBP and the relationship of NP with demographic characteristics, body mass index (BMI) and pain duration.

Methods: 440 outpatient patients who applied to the PMR clinic of our research hospital with LBP from January 2017 to July 2017 were enrolled in the study. All the patients were evaluated with respect to NP. Data were collected using a structured questionnaire (demographics and LBP duration). Douleur Neuropathique 4 (DN4) questionnaire was used to identify NP. The main type of pain was recorded (tingling, numbness, burning etc.). Any difference in demographic characteristics or duration of pain were investigated between the patients with and without NP. Binary logistics regression modeling was used to obtain a subset of sociodemographic factors that were independently associated with NP. Data were analyzed using NCSS 10 (2015. Kaysville, Utah, USA).

Results: 193 (43, 9 %) of the 440 LBP patients had NP according to DN4 (score of $DN4 \geq 4$) (95% confidence interval 39%-49%). Mean age of the patients was 44.8 years (± 13.7 , min 18, max 85). 263 (59, 8%) of the patients were female. The median duration of LBP was 24 months (with extremes of 3 days and 30 years). 343 (77, 9%) of the patients had chronic LBP (more than 3 months). The average BMI was $27, 98 \pm 4, 54$. 275 patients (62,9%) were not officially employed (housewife, retired, student etc.), 35 patients (7,7%) were office holder, 130 patients (29,6%) were high-activity worker. The most common types of pain were numbness (62% of the patients with NP), and burning (21%). Gender distribution of the patients with and without NP was similar ($p=0,237$). The patients with NP were older ($p<0,001$), had higher BMI ($p=0,005$) and longer LBP duration ($p<0,001$) and had lower educational level ($p=0,018$). NP was significantly more common in unemployed patients and less common in high activity employees ($p=0,001$). Logistic regression analyses identified that high-active workers' risk of having NP was 1,76 times lesser than other groups (office workers, housewives and retired patients) ($p=0,039$, $OR(95\%CI)=1,76(1,03-3,02)$). Odds ratio of employment was not different in general ($p=0,099$). The predictive value of longer pain duration of having NP was close to significance ($p=0,056$).

Conclusion: In our group, nearly half of the patients with LBP had accompanied NP. NP was remarkably more common in patients with low socioeconomic status and patients who perform high levels of physical activity at workplace had interestingly lower NP scores compared to patients with less physically active lifestyles. Our results showing NP being more common in sedentary patients may suggest that emphasizing exercise training as a therapeutic intervention in LBP management could also be beneficial to NP also.

NP is associated with higher levels of pain and disability, clinicians should be mindful of NP management while LBP is being treated.

Session Title: Pain Mechanisms – Basic and Clinical Science Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: OA and RA are among the most common chronic painful rheumatic diseases. Appreciation of the role of pain sensitization in OA has revolutionized the management of chronic pain with neuroactive agents. By contrast, pain in RA has conventionally been considered to be “inflammatory”, with the belief that treatment with disease-modifying anti-rheumatic agents (DMARDs) aborts the painful experience. A number of patients with RA, however, continue to experience pain despite optimal control of inflammation. Thus, we aimed to test the hypothesis that pain in RA, similar to OA, includes signs of peripheral and central sensitization and neuropathic features.

Methods: After consent, patients with physician diagnosis of symptomatic OA of the hips and/or knees (VAS pain score at the sites $\geq 3/10$), active or DMARD-naïve RA (escalation or change in RA therapy, synovitis on physician exam at the reference clinic visit), and control (45 yrs or older, without pain ≥ 1 month, no arthritis or neuropathy or joint replacement history) were recruited and asked to fill a pain DETECT (PD-Q) questionnaire ¹. Quantitative sensory tests (QST) including pressure pain thresholds (PPT) using an algometer and temporal summation (TS) using von Frey monofilament (60 g), were performed on all subjects at right and left radial styloids, tibial tuberosities, and medial knees. Sensitization is present when there is low PPT using an algometer (peripheral= diseased site; central= no diseased site) and an increased in pain score after repeated controlled stimulation with von Frey monofilament (central) ². Demographic data, PD-Q scores and results from QST were compared between groups using analysis of variance (ANOVA). PD-Q scores were classified as ≤ 12 -unlikely neuropathic vs >12 -likely neuropathic. Correlations between PD-Q scores and QST results were analyzed using Spearman's rho.

Results: Participants included 25 OA, 20 RA, and 19 controls. Patients with OA were older and had higher BMI than RA and control subjects ($p < 0.001$). PD-Q scores were in the "likely neuropathic" range in 32% of OA and 40% of RA vs 0% of control subjects ($p < 0.001$). Both OA and RA had lower PPT vs control at all tested sites. OA and RA patients exhibited significantly higher TS vs control subjects. PD-Q final score and component questions were associated significantly with PPT ($\rho = -0.244$ to -0.448 , $p < 0.05$), but not to TS results.

Table: Demographic, clinical, and QST data of patients with symptomatic hip and/or knee OA, active or DMARD-naïve RA, and control subjects

Variable (s)	OA (n=25)	RA (n=20)	Control (n=19)	p all groups
Age	65.2 (10.2)	53.2 (10.7)	52.9 (10.4)	<0.001
BMI, kg/m ²	32.8 (9.6)	25.9 (7.0)	26.6 (4.3)	0.007
%Female patients	88%	65%	58%	0.063
Pain detect final score	8.6 (6.4)	11.9 (9.2)	1.4 (2.5)	<0.001
Likely neuropathic, % patients	32%	40%	0%	0.009
PPT Left radial styloid, lbf	4.5 (2.7)	4.0 (1.5)	5.6 (2.6)	0.121
PPT Right radial styloid, lbf	4.5 (2.8)	3.6 (1.4)	5.6 (2.4)	0.037
PPT Left medial knee joint, lbf	4.6 (2.8)	4.4 (2.7)	7.7 (3.3)	0.001
PPT Right medial knee joint, lbf	4.5 (2.8)	4.1 (2.4)	7.7 (3.2)	<0.001
PPT Left tibial tuberosity, lbf	5.2 (2.9)	5.4 (2.5)	8.9 (2.8)	<0.001
PPT Right tibial tuberosity, lbf	6.1 (3.6)	5.0 (2.7)	11.1 (9.9)	0.005
TS left radial styloid, % patients	68.0%	75.0%	57.9%	0.385
TS right radial styloid, % patients	76.0%	85.0%	42.1%	0.009
TS left tibial tuberosity, % patients	76.0%	60.0%	26.3%	0.004
TS right tibial tuberosity, % patients	68.0%	85.0%	36.8%	0.006

Data are reported in mean (standard deviation) unless specified. Abbreviation: lbf, pound-force.

Conclusion: Both OA and RA exhibited evidence of neuropathic features on a PD-Q questionnaire and peripheral and central sensitization on QST. To our knowledge, this is the first study evaluating sensitization in both OA and RA compared to control and demonstrating similar pain patterns and degrees of sensitization in both disease groups. The clinical and treatment implications of these findings warrant attention and further investigation.

Profound Changes in the NaV1.8 Nociceptive Innervation of the Murine Knee Joint after Destabilization of the Medial Meniscus

Alia Obeidat¹, Richard J. Miller², Rachel E. Miller³ and Anne-Marie Malfait⁴, ¹Rush University Medical Center, Chicago, IL, ²Pharmacology/Medical Humanities and Bioethics, Northwestern University, Chicago, IL, ³Biochemistry, Rush University Medical Center, Chicago, IL, ⁴Biochemistry & Rheumatology, Rush University Medical Center, Chicago, IL

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Pain Mechanisms – Basic and Clinical Science Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: We aimed to compare the nociceptive innervation of healthy and osteoarthritic mouse knees.

Methods: Destabilization of the medial meniscus (DMM) or sham surgery was performed in the right knee of 10-week old male C57BL/6 Na_v1.8-tdTomato mice. These mice express a bright red fluorescent tomato reporter in all neurons that express the voltage-gated sodium channel, Na_v1.8, which is expressed by approximately 75% of dorsal root ganglion (DRG) sensory neurons, including >90% of C-nociceptors (pain-sensing neurons) and C-low-threshold mechanoreceptors, as well as a lower percentage of A δ -nociceptors and A β afferents. Sixteen weeks after surgery, mice were perfused transcardially with paraformaldehyde, knees were collected, post fixed and decalcified (DMM, sham, and 26-week-old naïve mice, n=5/group). Twenty- μ m thick sections were cryosectioned and collected at mid-joint level. Na_v1.8-tdTomato signal was quantified using ImageJ. In order to confirm innervation patterns, we also used (1) Wild type C57BL/6 mice (n=3/group) immunostained for PGP9.5, and (2) C57BL/6-Pirt-GCaMP3 mice (n=3/group). These mice express the green fluorescent calcium indicator, GCaMP3, in ~90% of all sensory DRG neurons through the Pirt promoter.

Results: In 26-week old naïve knees, Na_v1.8 expressing sensory neurons were observed in the lateral synovium and insertions of the cruciate ligaments, while medial synovium showed less innervation. Sixteen weeks after DMM surgery, mice had severe OA joint damage (cartilage degeneration score = 12.8 ± 1.9 , compared to 0.4 ± 0.49 after sham surgery). DMM, but not sham-operated knees showed profound neuroanatomical changes in the nociceptive innervation. We detected an increase in Na_v1.8 innervation of the medial synovium compared to age-matched naïve and sham-operated controls. The lateral synovium and the cruciate ligaments showed no changes. We also observed changes in the subchondral bone (SCB) innervation of the tibia and femur in the medial compartment, characterized by the presence of channel-like structures containing Na_v1.8 expressing fibers pointing toward the calcified cartilage. These nerves were also observed to a lesser extent in sham and naïve knees. Finally, Na_v1.8 signal was detected in osteophytes. Findings in Pirt-GCaMP3 mice and PGP9.5 staining in WT mice confirmed the above findings.

Conclusion: The Na_v1.8 nociceptive innervation of the mouse knee profoundly changes at late stage experimental osteoarthritis, most notably an increase in the medial synovium and the presence of Na_v1.8 neurons in the SCB of the medial compartment. Ongoing studies are aimed at characterization of these nerves. The functional significance of these neuroanatomical changes associated with joint damage needs to be further investigated.

Effects of Prolonged Chemogenetic Inhibition of Nociceptors in a Murine Surgical Model of Osteoarthritis

Phuong B. Tran¹, Shingo Ishihara¹, Rachel E. Miller², Richard J. Miller³ and Anne-Marie Malfait⁴, ¹Internal Medicine, Rush University Medical Center, Chicago, IL, ²Rheumatology/Biochemistry, Rush University Medical Center, Chicago, IL, ³Pharmacology/Medical Humanities and Bioethics, Northwestern University, Chicago, IL, ⁴Biochemistry & Rheumatology, Rush University Medical Center, Chicago, IL

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Pain Mechanisms – Basic and Clinical Science Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The aim of this study was to investigate the effects of prolonged chemogenetic inhibition of Na_v1.8 nociceptors on pain-related behaviors and cellular changes in the dorsal root ganglia (DRG) in a murine model of OA. After destabilization of the medial meniscus (DMM), mice develop pain-related behaviors in association with progressive joint damage, including knee hyperalgesia and mechanical allodynia in the ipsilateral hindpaw. In addition, cellular changes occur in the DRG, including increased numbers of macrophages 8 and 16 weeks after DMM, compared to sham and naïve age-matched controls.

Chemogenetic silencing of nociceptors involves the use of Designer Receptors Exclusively Activated by Designer Drugs (DREADDs), also termed Pdi, genetically targeted to the Voltage-Gated Sodium Channel 1.8 (Na_v1.8). Na_v1.8 is expressed by the majority of nociceptors. Activation of Pdi with the synthetic chemical agonist clozapine N-oxide (CNO) inhibits the neuronal activity of these nociceptors (Miller RE et al, *Arthr Rheum* 2017).

Methods: CNO- or saline-loaded Alzet minipumps were implanted into the peritoneal cavity of 10-week old male Na_v1.8-Pdi C57BL/6 mice, which allows for chronic release of CNO or saline for up to 6 weeks. Three days after implantation, DMM surgery was performed on the right knees of these mice.

A blinded observer performed the following behavioral tests after surgery: Knee hyperalgesia was measured using a Pressure Application Measurement (PAM) device (Ugo Basile), and mechanical allodynia in the ipsilateral hind paw was measured using von Frey fibers and the up-down staircase technique. To assess cellular changes in the peripheral pain pathway, L4 DRG sections were immunostained with the macrophage marker, F4/80. The total number of macrophages per DRG section was quantified using ImageJ and normalized to the area of each DRG.

Results: Evaluation of knee hyperalgesia 2, 4 and 6 weeks after DMM surgery in saline (n=5) and CNO (n=11) implanted Nav1.8-Pdi mice revealed that CNO-implanted mice had significantly less knee hyperalgesia at 4 (p= 0.0004) and 6 (p= 0.01) weeks after DMM, compared to saline-implanted mice. Mechanical allodynia was assessed at 6 weeks after DMM surgery, and CNO-implanted mice had significantly less mechanical allodynia compared to saline-implanted mice (p= 0.03). Macrophage infiltration in the ipsilateral L4 DRG was significantly attenuated in CNO-implanted mice compared to vehicle controls (p=0.03).

Conclusion: The results showed that prolonged (*i.e.*, 6 weeks) chemogenetic inhibition of nociceptors in Nav1.8-Pdi mice significantly attenuated knee hyperalgesia and mechanical allodynia. In addition, prolonged chemogenetic inhibition also affected cellular changes in the DRGs, with fewer macrophages in CNO-implanted mice. This suggests that prolonged blockade of nociceptor activity can attenuate pain-related behaviors and influence cellular changes in the DRGs in murine OA. Histological assessment of the knee joints is ongoing.

Metabolic Syndrome and Trajectories of Pain Severity and Number of Painful Sites in Knee Osteoarthritis: Data from a 10.7-Year Prospective Study

Feng Pan¹, Jing Tian², Flavia Cicuttini³ and Graeme Jones⁴, ¹Musculoskeletal Unit, Menzies Institute for Medical Research, University of Tasmania, Hobart, Australia, ²Public health unit, Menzies Institute for Medical Research, University of Tasmania, Hobart, Australia, ³Department of Epidemiology and Preventive Medicine, Monash University, Melbourne, Australia, ⁴Menzies Institute for Medical Research, University of Tasmania, Hobart, Australia

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Pain Mechanisms – Basic and Clinical Science Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Metabolic syndrome (MetS) has been suggested as having a role in osteoarthritis (OA) pathogenesis. No study has assessed whether MetS and its components are associated with pain severity and number of painful sites (NPS) and their courses over time. We aimed to examine the association of MetS and its components with trajectories of pain severity and NPS in people with radiographic knee OA (ROA) over 10.7 years.

Methods: 1,099 participants (mean age 63 years) from a population-based older adult cohort study were recruited at baseline. 875, 768 and 563 participants attended years 2.6, 5.1 and 10.7 follow-up, respectively. Data were collected on demographic, psychological, lifestyle and comorbidities, blood pressure, glucose, triglycerides, and high-density lipoprotein (HDL) cholesterol. MetS was defined based on National Cholesterol Education Program-Adult Treatment Panel III criteria. ROA was assessed by X-ray. Knee pain was measured by Western Ontario and McMaster Universities Osteoarthritis Index pain questionnaire at each time-point. Presence/absence of pain at the neck, back, hands, shoulders, hips, knees and feet was collected by questionnaire at each time-point. Group-based trajectory modelling was applied to identify pain trajectories. Multi-nominal logistic regression was used for the analyses.

Results: 60% of participants had ROA and 32% had MetS at baseline. Three pain severity trajectories were identified in those with ROA: 'Marginal pain' (50%), 'Mild pain' (35%) and 'Moderate pain' (15%). Three NPS trajectories were identified: 'Low NPS' (10%), 'Medium NPS' (38%), and 'High NPS' (52%). In univariate analyses, MetS was associated with increased risk of both 'Mild pain' (relative risk: 1.47, 95%CI: 1.10–1.96) and 'Moderate pain' (2.22, 95%CI 1.54–3.20) relative to 'Marginal pain'. It was also associated with increased risk of both 'Medium NPS' (2.25, 1.11 to 4.54) and 'High NPS' (3.36, 1.70–6.63) compared to 'Low NPS'. In multivariable analyses, abdominal obesity was associated with increased risk of both 'Mild pain' (1.70, 1.17–2.49) and 'Moderate pain' (2.75, 1.63–4.64), and MetS and low HDL were associated with 'Moderate pain'. Abdominal obesity was the only component associated with increased risk of both 'Medium NPS' (2.82, 1.39–5.70) and 'High NPS' (3.60, 1.79–7.24), and MetS was only associated with increased risk of

'High NPS'. However, these associations became non-significant after further adjustment for body mass index, but hypertension became protective with 'Mild pain'.

Conclusion: MetS is predominantly associated with trajectories of pain severity and number of painful sites through abdominal obesity, suggesting that weight loss is the most important way of controlling OA pain.

Effect of Local and Systemic CCR2 Blockade on Knee Hyperalgesia in a Mouse Model of Osteoarthritis

Shingo Ishihara¹, Rachel E. Miller², Richard J. Miller³ and Anne-Marie Malfait⁴, ¹Internal Medicine, Rush University Medical Center, Chicago, IL, ²Biochemistry, Rush University Medical Center, Chicago, IL, ³Pharmacology/Medical Humanities and Bioethics, Northwestern University, Chicago, IL, ⁴Biochemistry & Rheumatology, Rush University Medical Center, Chicago, IL

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Pain Mechanisms – Basic and Clinical Science Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Surgical destabilization of the medial meniscus (DMM) in the mouse knee results in slowly progressive osteoarthritis (OA), characterized by moderate joint damage by week 8 and severe joint damage by week 16 after surgery. Progressive joint damage is associated with pain-related behaviors, including knee hyperalgesia and mechanical allodynia in the ipsilateral hindpaw (Miller RE et al. PNAS, 2012).

Knee hyperalgesia occurs in the early stages of experimental OA, week 2-8 after DMM surgery (Miller RE et al. Arthr Rheum 2017). We have previously shown that C-C Chemokine Receptor 2 (CCR2) signaling plays a key role in persistence of mechanical allodynia in this model, but has no effect on joint damage (Miller RE et al. PNAS, 2012). Here, we aimed to assess the effect of CCR2 blockade on knee hyperalgesia in the early phase of the disease.

Methods: DMM or sham surgery was performed on the right knee of 10-week old male C57BL/6 wild type (WT) or *Ccr2* null mice. Two, 4, and 8 weeks after surgery (n= 4-12/time point), knee hyperalgesia was measured by Pressure Application Measurement (PAM), as described (Miller RE et al. Arthr Rheum, 2017).

To study the effect of systemic pharmacological blockade of CCR2, CCR2 antagonist (5mg/kg) (CCR2RA, RS504393, Tocris) or vehicle control (100% DMSO₄) was injected intraperitoneally (i.p.), 4 or 8 weeks after surgery in WT mice. Knee hyperalgesia was assessed hourly for 3 hours after injection.

To study the effect of local CCR2 blockade in the knee, 5µL of CCR2RA (0.4mg/kg) (BMS CCR2 22, RD Systems) (n=4) or 5µL of vehicle control (50% EtOH) (n=3) were injected intra-articularly (IA) 7 weeks after DMM surgery in WT mice. Knee hyperalgesia was measured hourly for 4 hours.

In addition, MCP-1 (5µL of 100ng/µL), the ligand for CCR2, or vehicle control (5µL PBS in 0.1% BSA) were injected IA in the right knee of 10-week old naïve WT and *Ccr2* null mice (n=4/group), and knee hyperalgesia was assessed up to 24 hours after injection.

Results: WT mice developed knee hyperalgesia 2 weeks after DMM but not sham surgery, and this was maintained until week 8. In contrast, *Ccr2* null DMM mice were protected from hyperalgesia up to week 8 (p<0.0001 at week 2, 4, and 8). Systemically administered CCR2RA alleviated established hyperalgesia in WT mice, 4 and 8 weeks after DMM (p<0.0001 compared to vehicle). Likewise, IA injection of CCR2RA into the knee joint 7 weeks after DMM reversed hyperalgesia (p<0.05 compared to vehicle).

IA administration of MCP-1, but not vehicle, rapidly induced knee hyperalgesia in naïve WT mice (p<0.001 compared to vehicle control), but not in *Ccr2* null mice.

Conclusion: These findings suggest a role for MCP1-CCR2 signaling in the development of knee hyperalgesia after DMM surgery. Furthermore, the findings with IA injection of MCP-1 or CCR2RA suggest that the effect is mediated by CCR2 present in the intra-articular space and that CCR2 is important for early OA knee pain.

Neuropathic Pain in Patients with Knee Osteoarthritis (Preliminary Report)

Pinar Borman¹, Ferda Kaygisiz² and Aysegul Yaman³, ¹Department of Physical Medicine and Rehabilitation, University of Hacettepe Faculty of Medicine, Ankara, Turkey, ²Dept of PMR, Ankara Training and Research Hospital, Ankara, Turkey, ³Dept of PMR, University of Hacettepe Faculty of Medicine, Ankara, Turkey

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Pain Mechanisms – Basic and Clinical Science Poster – ARHP

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: There are limited studies in the literature indicating that neuropathic pain occurs in knee osteoarthritis (OA) (1). The aim of this cross sectional study was to evaluate frequency of neuropathic pain in knee OA patients and to determine the relation with disease variables.

Methods: Twenty knee OA patients who were not having any comorbid disease and/or using drugs that would cause neuropathy, were recruited to the study. Demographic properties (age, sex, disease duration) and clinical characteristics (functional status by WOMAC and pain intensity by VAS) recorded. The neuropathic property of knee pain was assessed by both LANSS and DN4 scales. Descriptive statistics was used for clinical variables and frequency of neuropathic pain. The difference of clinical variables between patients with and without neuropathic pain, were examined using t tests and chi square tests for continuous and categorical variables respectively. Correlation coefficients of clinical variables and neuropathic pain scores determined by LANSS and DN4, were analyzed with Spearman correlation analyses. The significance threshold was set as p values less than 0.05.

Results: Twenty knee OA patients (11 female, 9male) with a mean age of 55±18 years were included to the study. 11 patients (55%) were defined as having neuropathic pain depending on the LANSS (scores≥12) and DN4 (scores≥4) questionnaire scores. The mean scores of LANSS scale and DN4 were correlated with WOMAC scores

Conclusion: In conclusion neuropathic pain may be common in knee OA patients. Diagnosis and treatment of neuropathic pain are warranted in order to increase functional disability in patients suffering from knee OA.

Session Title: Pediatric Rheumatology – Clinical Poster I: Lupus, Sjögren's Disease, and Myositis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Different classification criteria for systemic lupus erythematosus (SLE) have been proposed over many years. The most widely used and accepted criteria have been the 1997 ACR criteria. In 2012, the SLICC criteria were published in an attempt to improve clinical relevance of SLE criteria and address concerns with the 1997 ACR

criteria. In 2017, a new candidate weighted criteria were proposed at the ACR meeting that included entry criteria. Our aim was to validate the 2012 SLICC criteria compared to 1997 ACR and 2017 weighted criteria for SLE in pediatric-onset SLE.

Methods: Retrospective chart review of patients with a clinical diagnosis of SLE diagnosed before the age of 19 years at our tertiary care center between 2002 and 2017. The ACR and SLICC classification criteria were applied to these patients. The 2017 weighted criteria were also applied for patients diagnosed after October 2014 as this was the date our laboratory began using the ANA Hep2 assay, which is an entry criterion for the new weighted criteria. We excluded patients diagnosed at another center and those for whom no records were available for review. All criteria sets were compared against a gold standard of physician diagnosis. Autoimmune controls were defined as patients who were referred for serologies positive for ANA but who did not fulfill criteria for diagnosis of SLE at the initial visit, or were diagnosed with another autoimmune disease.

Results: There were 150 patients (82% female) who were diagnosed with SLE over the past 15 years. The mean age at diagnosis was 13 ± 2.7 years, with 23% Asian, 28% Black, 26% White, and 26% Caucasian, and 23% Other; 24% also identified as Hispanic. The sensitivity for the 1997 ACR criteria was 90.3 (CI: 0.84-0.95) and specificity was 95.9 (CI: 0.90-0.99). The sensitivity for the 2012 SLICC criteria was 99.3 (CI: 0.96-0.99) and specificity was 95.7 (CI: 0.90-0.99). The 2017 weighted criteria did not produce significant results as the patient sample size compared was too small.

Conclusion: The 2012 SLICC criteria were more sensitive than, but with similar specificity as, the 1997 ACR criteria. These findings are comparable with the observed statistics seen in the adult population. Further patient samples are needed to determine the test characteristics for the new weighted candidate criteria.

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: There is a paucity of data regarding the early hospital readmission rates in newly diagnosed childhood lupus nephritis (cLN). We conducted a retrospective study to characterize the early hospital readmission rates in cLN and identify risk factors associated with these readmissions.

Methods: 76 cLN cases evaluated from 1/1/2008 to 4/2/2017 were included in the study. The readmission rate within 30 days following a hospitalization due to newly diagnosed cLN was calculated. The characteristics of the early readmitted cases were compared with those of whom were not early readmitted using chi-square, fisher exact test, independent t-test or Mann-Whitney U tests as appropriate; variables with a P-value <0.10 were included in a multivariable analysis using stepwise linear logistic regression.

Results: The 30-day readmission rate following hospitalization for cLN was 1 per 5.8 admissions (17.1%). Clinical characteristics of these cases are listed in tables 1, 2 and 3. Not receiving pulsed methylprednisolone (30.8% vs 3.2%, $p < 0.001$), stage 2 hypertension on day 1 (76.9% vs 41.3%, $p = 0.019$), higher white blood cell count on admission ($5.7 \times 10^3/\text{mm}^3$ vs $5.0 \times 10^3/\text{mm}^3$, $p = 0.022$) and at discharge ($13.7 \times 10^3/\text{mm}^3$ vs $8.8 \times 10^3/\text{mm}^3$, $p = 0.23$), diuretic treatment (69.2% vs 34.9%, $p = 0.021$), anti-hypertensives other than angiotensin-converting enzyme inhibitors (76.9% vs 49%, $p = 0.042$) and albumin infusions (46.2% vs 12.7%, $p = 0.004$) predicted early readmission in univariable analysis. In multivariable analysis the absence of treatment with pulsed methylprednisolone was a risk factor for early readmission (OR=21.4 (2.89-158.82) $p = 0.002$) whereas not receiving intravenous albumin had a protective effect (OR=0.12 (0.026-0.51) $p = 0.004$).

Conclusion: One in 5.8 children (17.1%) hospitalized for newly diagnosed cLN were readmitted within 30 days of discharge. Not receiving pulsed steroids and receiving intravenous albumin on admission increased the risk of hospital readmission in newly diagnosed cLN.

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Pediatric Rheumatology – Clinical Poster I: Lupus, Sjögren's Disease, and Myositis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: To examine immunomodulatory medication use for youth with systemic lupus erythematosus (SLE) during their first year of care.

Methods: We conducted a retrospective cohort study using administrative claims for 2000 to 2013 from Clinformatics™ DataMart (OptumInsight, Eden Prairie, MN) for youth ages 10-24 years with an incident diagnosis of SLE (≥ 3 International Classification of Diseases, Ninth Revision codes for SLE 710.0, each >30 days apart). We determined the proportion of subjects filling a prescription for an immunomodulatory medication, defined as hydroxychloroquine or an immunosuppressant (excluding glucocorticoids), within 3, 6, and 12 months after the first SLE diagnosis code (index date). We used a Cox proportional hazards regression model to examine associations between time to immunomodulatory prescription fill within 12 months and demographic and disease factors (age, race/ethnicity, household education level, region, history of seizures/stroke, history nephritis).

Results: We identified 650 youth with an incident diagnosis of SLE. In the 12 months following the index date, 511 (79%) of youth had a prescription fill for an immunomodulatory medication. For those with a prescription fill for hydroxychloroquine in the first year (n=457, 70%), 374 (58%) and 407 (63%) of youth filled the medication within 3 months and 6 months from the index date, respectively (Table). For those with a prescription fill for an immunosuppressant (n=221, 34%) in the first year, 114 (18%) and 162 (25%) of youth filled the medication within 3 months and 6 months from the index date, respectively (Table). Location in the Northeast region was significantly associated with a longer time to immunomodulatory prescription fill within 12 months, compared to location in the South (HR=0.69, 95% CI 0.50-0.94). There were no statistically significant associations for the other demographic and disease factors.

Conclusion: Among youth with newly-diagnosed SLE, hydroxychloroquine use is prevalent although not universal, and immunosuppressant use is notably low during the first year of care. As poorly controlled SLE disease activity can lead to organ damage, further work is needed to identify potential factors contributing to suboptimal immunomodulatory medication use in this population.

Table: Immunomodulatory Medication Use in Youth with Newly-Diagnosed SLE, N=650

Proportion with prescription fills after first SLE diagnosis code, n (%)	Within 3 months	Within 6 months	Within 1 year
Immunomodulatory medication (hydroxychloroquine or immunosuppressant)	428 (66)	460 (71)	511 (78)
Hydroxychloroquine	374 (58)	407 (63)	457 (70)
Immunosuppressant	114 (18)	162 (25)	221 (34)
Immunosuppressant medications include: mycophenolate mofetil, azathioprine, leflunomide, methotrexate, tacrolimus, and oral cyclophosphamide.

Session Date: Sunday, October 21, 2018

Session Title: Pediatric Rheumatology – Clinical Poster I: Lupus, Sjögren's Disease, and Myositis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Ofatumumab is a fully human anti-CD20 monoclonal antibody that has been approved for the treatment of chronic lymphocytic leukemia. It has been increasingly used in the treatment of autoimmune hemolytic anemia, rheumatoid arthritis, and nephrotic syndrome. There are limited case series reporting the off-label use of ofatumumab in SLE, with minimal data in childhood-onset SLE (cSLE). In majority of these reports, ofatumumab was used as alternative B-cell depletion therapy for patients who have become intolerant of rituximab due to development of severe infusion reactions. We describe our center's experience with the use of ofatumumab in cSLE patients who have become rituximab-intolerant.

Methods: A retrospective case series analysis of cSLE patients who met the ACR classification criteria for SLE and who received ofatumumab at our center was completed after IRB approval. Collected data include patient demographics, clinical presentation and course, medications, prior use of and reaction to rituximab, and response to ofatumumab therapy.

Results: Nine patients were included (females: 6, Hispanic ethnicity: 5, African-American: 3, Asian: 1). At the time of the first ofatumumab infusion, median age was 16 years (range: 11-18) and median disease duration was 39.6 months (16.2-139). All patients had received rituximab (median cumulative dose: 3g [0.5-9], median number of infusions received: 3 [0.5-13]) and developed severe infusion reactions precluding retreatment. Significant combination immunomodulatory therapy was also received pre-ofatumumab: plasmapheresis in 3 patients, cyclophosphamide in 2, IVIG in 3, mycophenolate mofetil in all 9, and cyclosporine in 1. Indications for ofatumumab included renal flare in 6 patients, extrarenal flare in 2, and both renal and extrarenal flare in 1. Ofatumumab (median cumulative dose: 1g [0.3-2.9], median number of infusions received: 2 [1-4]) was well-tolerated in all 9 patients. Within 6 months post-ofatumumab, partial renal response was achieved in 5 of 7 patients with renal flare. Clinical improvement was noted in all. B-cell depletion was achieved in 7 patients who were tested 3 months post-ofatumumab. In 5 patients tested, median B-cell repletion time was 6 months (range: 4-12). Three patients received a second course of ofatumumab within a median time of 18 months (5-19) due to disease flare. Two patients developed serious adverse events: 1 had septic shock 3.5 months after ofatumumab (only received one dose due to early B-cell depletion; also had significant prior immunomodulatory therapy) and 1 had an anaphylactic reaction after the third ofatumumab dose (previously also developed anaphylaxis after first rituximab infusion).

Conclusion: In this retrospective review we describe our center's experience with the use of ofatumumab in nine patients with childhood-onset SLE who had become intolerant of rituximab due to severe infusion reactions. Our patient outcomes

suggest that ofatumumab is a safe and well-tolerated alternative therapy to rituximab. Further studies in a larger cohort are warranted to determine long-term safety, efficacy, and the appropriate dosing regimen in cSLE patients.

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Pediatric Rheumatology – Clinical Poster I: Lupus, Sjögren's Disease, and Myositis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Corticosteroids (CS) are the mainstay of childhood-onset lupus (cSLE) and proliferative lupus nephritis (LN) therapy. However, there are no widely accepted CS dosing regimens for LN. We aim to identify the CS treatment approaches employed by providers for newly diagnosed pediatric proliferative LN in response to common and challenging clinical scenarios.

Methods: Pediatric rheumatologists and nephrologists attending the 2018 Childhood Arthritis and Rheumatology Research Alliance (CARRA) meeting participated in a working group addressing CS use in newly diagnosed pediatric LN. Participants responded to 3 scenarios in live polling and 12 questions of CS management in small groups. A post meeting survey was sent to each participant.

Results: In total, 51 physicians participated in the working group and 25 answered the survey. Of the 51 participants, 42 (82%) reported prednisone to be the oral CS of choice to treat newly diagnosed pediatric LN and 64.7% favored liquid prednisolone if swallowing pills is problematic. Once daily dosing was the preferred regimen (15/25, 60%) to help patients with adherence. Some (8/25, 32%) use a twice daily regimen for prednisone doses >2mg/kg/day or 60mg. A 3-4 times daily regimen was considered for hospitalized patients with severe disease manifestations by 6/25, 24%. Factors leading to the use of intravenous (IV) pulse methylprednisolone during the initial 12 months of therapy for proliferative LN are shown in Figure 1. Laboratory results prompting a CS dose change are shown in Table 1 (Panels A/B). Side effects such as weight

Panel A. Which laboratory results would cause you to start decreasing (or tapering) corticosteroids in your patient with proliferative LN?					
	Normal	>50% improvement	25-50% improvement	Any improvement	Not important for my decision
Complement C3 and C4	3 (12%)	5 (20%)	4 (16%)	9 (36%)	4 (16%)
Anti-dsDNA antibodies	2 (8%)	4 (16%)	4 (16%)	9 (36%)	8 (32%)
Proteinuria	0 (0%)	7 (28%)	7 (28%)	8 (32%)	3 (12%)
ESR	1 (4%)	2 (8%)	4 (16%)	8 (32%)	10 (40%)
Urinary cellular casts	3 (12%)	5 (20%)	1 (4%)	5 (20%)	11 (44%)

Panel B. Which changes in laboratory tests would cause you to increase corticosteroid doses in your patient with proliferative LN during the initial 12 months of therapy?					
	Newly abnormal	>50% worsening	25-50% worsening	Any worsening	Not important for my decision
Complement C3 and C4	4 (16%)	7 (28%)	10 (40%)	1 (4%)	3 (12%)
Anti-dsDNA antibodies	5 (20%)	3 (12%)	8 (32%)	1 (4%)	8 (32%)
Proteinuria	0 (0%)	10 (40%)	11 (44%)	2 (8%)	2 (8%)
ESR	2 (8%)	4 (16%)	4 (16%)	1 (4%)	14 (56%)
Urinary cellular casts	5 (20%)	3 (12%)	3 (12%)	9 (36%)	5 (20%)

gain (20/25, 80%), difficult to control blood pressure (19/25, 76%) or hyperglycemia (21/25, 84%) were reported as reasons to taper CS. In patients with inactive LN on mycophenolate mofetil, the extra-renal features that prompt an increase in CS are new/worsening neuropsychiatric disease (24/25, 96%), cardiac (23/25, 92%), or pulmonary involvement (23/25, 92%). In cases of non-adherence, all physicians would discuss reasons for non-adherence with 72% choosing to start/increase the frequency of IV steroids.

Conclusion: Prescribed CS dosing regimens vary widely in the U.S. when used for the treatment of children with proliferative LN. Decisions on initial CS dosing regimens and subsequent management strategies remain provider dependent.

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Pediatric Rheumatology – Clinical Poster I: Lupus, Sjögren's Disease, and Myositis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Outcomes for childhood-onset crescentic lupus nephritis are unclear. The revised classification system for lupus nephritis by the Renal Pathology Society clearly distinguishes between cellular, fibrocellular, and fibrous crescents. A revised activity index includes cellular and fibrocellular crescents and uses thresholds of 25% and 50% glomerular involvement to distinguish between mild, moderate, and severe. The revised chronicity index includes scores for <25%, 25-50% and >50% fibrous crescents.

Methods: The objective was to test the validity of the 25% and 50% thresholds for crescentic involvement in childhood-onset crescentic LN. We identified 69 patients in the Midwest Pediatric Nephrology Consortium's pediatric glomerulonephritis with crescents registry (21% of total). Enrollment in the retrospective IRB-approved registry includes patients <21 years old with >1 crescentic glomerulus on kidney biopsy from 15 centers from 2004-16 with at least 1 year of follow-up data. All biopsies sampled from >10 glomeruli. The primary outcome was end stage kidney disease (ESKD) at 1 year. Secondary outcomes included estimated glomerular filtration rate (eGFR) at 1 year and change in eGFR over time. Crescents were defined as cellular/fibrocellular or fibrous based on local pathologist.

Results: The median age at time of biopsy was 14.0 years (range 6-20) and median follow up was 3.0 years (range 1-11.3). A median of 27 glomeruli were sampled per biopsy (IQR 19-35). The median percentage of cellular crescents was 16.4% (IQR 10-38%, max 96%) and fibrous crescents was 0% (IQR 0-5%, max 56%). The cumulative incidence of ESKD was 1.5% at one year and 9% (n=6 patients) at last follow up. Median time to ESKD was 27.6 months (range 5-131). Outcomes stratified well by both percentage of cellular glomerular crescents and by percentage of fibrous crescents (Table 1). Median change in eGFR was +18mL/1.73m²/min (IQR -7 to +42) at 1 year and -3.1 mL/min/1.73m²/year (IQR -16 to +6) at latest follow-up. There were only three subjects with >25% fibrous crescents and only one with >50%.

Cellular crescents	#	Renal survival	eGFR at biopsy	Δ eGFR/yr	Follow-up (yr)
<25%	42	100%	67 (50-105)	+2.8	3.2
25-50%	15	93%	58 (46-81)	+4.5	2.7
>50%	11	82%	30 (19-51)	+8.8	1.8
Fibrous crescents	#	Renal survival	eGFR at 1year	Δ eGFR/yr	Follow-up (yr)
<25%	64	92%	92 (74-100)	+3.2	3.0
<10%	57	93%	93 (78-102)	+2.7	3.0
None	45	91%	92 (74-102)	+3.2	3.0
>1	23	91%	92 (81-100)	+2.8	2.8
>10%	10	80%	69 (28-91)	-2.4	3.8
>25%	3	67%	52 (26-79)	-15.4	2.3

Conclusion: We show utility for the thresholds for cellular crescents used in the 2018 revised NIH activity index in children with lupus nephritis. For fibrous crescents, thresholds of 10% and 25% better discriminate renal outcomes. We propose inclusion of a pediatric arm for future studies intended to generate evidence-based definitions for classification of lupus nephritis.

Session Title: Pediatric Rheumatology – Clinical Poster I: Lupus, Sjögren's Disease, and Myositis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Renal disease occurs in 50-70% of all childhood onset systemic lupus erythematosus (cSLE). The prevalence of LN is higher in children and the manifestations are usually more severe than the adult counterparts. Yet there are few reports on long term outcomes in cSLE patients with LN. This study aimed to study long-term outcomes in Chinese cSLE patients with biopsy proven LN.

Methods: We completed retrospective chart reviews of all patients diagnosed and followed with SLE and biopsy proven LN from Jan 2000 to Feb 2018 in 3 regional hospitals in Hong Kong. All the patients met either the ACR or SLICC classification criteria (after year 2012) for SLE. Patients with LN were classified according to WHO criteria or INS/RPS criteria (after year 2003). The outcomes including chronic kidney disease (CKD) stages, dialysis, renal transplant and death were retrieved from patient charts at 6 time points: the year of diagnosis (Y0), one year after diagnosis (Y1), Y5, Y10, Y15 and last follow up (Y last) of patients.

Results: Our cohort included 104 cSLE patients with biopsy proven LN (Table 1). Majority (85.6%) had LN diagnosed within 2 years of SLE diagnosis. Thirty-two patients had second renal biopsies. None of the Class V LN transformed to proliferative LN in their second renal biopsies and 9 (28.1%) transformed from non-proliferative to proliferative LN with a mean of 5.87 years from the 1st to 2nd renal biopsy. There were total 144 biopsies in the study cohort period. Cyclophosphamide (CYC) was used as induction therapy in 38/99 (38.38%) of proliferative LN (Class III/IV +/- V) episodes in 36 patients vs Mycophenolate mofetil (MMF) in 28/99 (28.3%) episodes in 28 patients. Three patients required transient dialysis during the course and none required long term dialysis. Two patients had renal transplant and 5 patients died. The outcomes of death and renal transplant are worst in patients with proliferative LN without using either CYC or MMF as induction therapy and are best in non-proliferative LN as expected (Table 2 and 3).

Conclusion: The renal outcome of LN in cSLE is suboptimal with close to 30% of patients have significant proteinuria and 18.2% have abnormal renal function (CKD stage 2 or above) at their last visit. Patients with non-proliferative LN have best outcomes followed by proliferative LN treated with CYC or MMF in the induction phase.

Table 1. Basic demographic and distribution of classes of LN

Feature	Value or count
Sex	
Male	Male 11 (10.6%)

Seasonal Variation in Cutaneous Flares for Pediatric Lupus

Tamara Tanner¹, Marija Dionizovik-Dimanovski², Dawn Wahezi³ and Tamar Rubinstein³, ¹Albert Einstein College of Medicine/ Children's Hospital at Montefiore, Albert Einstein College of Medicine/ Children's Hospital at Montefiore, Bronx, NY, ²Pediatric Rheumatology, Children's Hospital at Montefiore, Bronx, NY, ³Pediatric Rheumatology, Albert Einstein College of Medicine, Children's Hospital at Montefiore, Bronx, NY

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Pediatric Rheumatology – Clinical Poster I: Lupus, Sjögren's Disease, and Myositis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Exposure to sunlight has been proposed as a possible environmental trigger for lupus flares, particularly cutaneous disease. Contradictory findings exist regarding seasonal variation in cutaneous disease activity, with particular gaps in knowledge around pediatric and minority patient populations.

Our objectives for this study were to study the relationship between sun exposure and cutaneous lupus flares in a racially and ethnically diverse pediatric lupus population. Based on prior studies, we hypothesized that higher rates of cutaneous flares would be present in summer/fall compared to winter/spring seasons.

Methods: We retrospectively reviewed 12 years of data from patients enrolled in the Pediatric Einstein Lupus Cohort at the Children's Hospital at Montefiore from the Bronx, New York. We selected patients that had any history of mucocutaneous disease by indicated by BILAG scores of A-D, as opposed to E, at any point during follow up. We defined cutaneous flares by two methods: (1) mucocutaneous BILAG criteria A or B and (2) SLEDAI-2K inflammatory rash criteria. Chi-square tests were used to compare flare rates during summer/fall vs winter/spring and to compare flare rates during each season.

Results: We examined 320 visits for 90 individual patients. The average age of participants at included visits was 16.8 ± 3 years; 82% of patients were female; 52% were Hispanic and 43% Black. Among included visits, 33% had represented BILAG-mucocutaneous flares and 38% represented SLEDAI-rash flares. Total visits and flare visits were not evenly

Figure 1. Seasonal distribution of cutaneous flare visits and total visits in the Pediatric Einstein Lupus Cohort

distributed throughout the year; more total visits and more flare visits were observed during summer/fall (Figure 1). The rate of visits with BILAG-mucocutaneous flares was 37% in the summer/fall vs 27% in winter/spring ($p = 0.04$). The rate of visits with SLEDAI-rash flares was 43% in summer/fall vs 33% in winter/spring ($p = 0.05$) (Table 1). In contrast, there was no significant association between specific seasons and BILAG-mucocutaneous flares or SLEDAI-rash flares, though the highest flare rates were observed during fall (40%, 46% of visits, respectively).

Conclusion: Our results show a modestly increased rate of cutaneous flares during summer/fall months when compared with winter/spring months in a racially and ethnically diverse sample of children with SLE. More studies are needed to better understand the relationship between sun exposure and disease flare in minority race/ethnicities with pediatric lupus to inform disease activity prevention counseling.

Table 1. Rates of cutaneous flare in pediatric lupus patients

	Summer/Fall visits (N = 177)	Winter/Spring visits (N = 143)	p value:
Mucocutaneous flare visits by BILAG	66 (37%)	38 (27%)	0.04
Inflammatory rash flare by SLEDAI	76 (43%)	47 (33%)	0.05

Improving Pneumococcal Vaccination Rates in Childhood-Onset SLE Patients at a Large Tertiary Care Center: The Path to Creating a More Sustainable Model of Vaccination with the Help of EMR

Saimun Singla and Marietta M. De Guzman, Pediatric Immunology, Allergy and Rheumatology, Baylor College of Medicine, Texas Children's Hospital, Houston, TX

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Pediatric Rheumatology – Clinical Poster I: Lupus, Sjögren's Disease, and Myositis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: *Streptococcus pneumonia* is a leading cause of illness in children worldwide and can lead to death in those with an immune suppressed status. Given the pathophysiology of systemic lupus and therapies needed to induce and maintain remission, these patients are more susceptible to pneumococcal infections compared to healthy counterparts. As recommended by the CDC/HHS, a simple preventative measure by immunization with the pneumococcal polysaccharide vaccine (PPSV23) is key in risk reduction for this population. The purpose of this QI initiative was multidimensional: first to increase pneumococcal vaccination rates in childhood-onset systemic lupus erythematosus (cSLE) patients at our institution and second to examine the effectiveness of various interventions to ensure continued vaccination success.

Methods: Initial undertaking for this QI project was started in summer 2015 with utilization of a plan-do-study-act model. Baseline immunization rates of PPSV23 for eligible patients were assessed through chart review. These included all

children ≥ 2 to <18 years old with cSLE (with and without immunosuppression) and were evaluated in rheumatology clinics within 6 months of the initial cycle. Interventions included a presentation to rheumatology providers and nurses, pre-visit planning and placing paper reminders on clinic schedules. Various interventions were analyzed based on chart review and provider feedback, which led to identification of barriers to successful vaccination.

Results: The pre-intervention to post-intervention PPSV23 immunization rates for 111 eligible cSLE patients increased from 4.5% to 47.1% during a 27-week cycle. Out of the patients who did not receive PPSV23, the reason was unknown in 70.2%, declined in 10.8%, and due to lack of follow up in rheumatology clinic during cycle 1 in 18.9%. Of the patients with an unknown status, 52.5% did not receive the vaccination due to lack of vaccination reminder and 47.4% of providers deferred vaccination to the next visit due to lack of time. The reason for a lack of vaccination reminder included changing clinic schedules (i.e. clinic add-ons) in 65.8% and oversight in 34.1%. All providers specified that they needed reminders in the patient's EMR rather than on paper, as this would also circumvent changing clinic schedules. To date, the total number of cSLE patients at our institution is 548 (aged 2 years to 18 years old). Since initiation of this project, 60.4% of cSLE patients have received the PPSV23 vaccine.

Conclusion: Our study shows that the main barrier to cSLE patient's receiving PPSV23 vaccination is provider oversight, lack of clinic time, and/or ineffective reminders. To increase vaccination success, a best practice advisory (BPA) alert in each cSLE patient's EMR is being created. Ongoing work has centered on developing BPA parameters regarding variables such as PPSV23 vaccination status, age, and prior vaccination with the PCV13, a prerequisite to receiving the PPSV23. We hope this work will reduce vaccine preventable illnesses that would otherwise consume provider time, resources and unnecessary health care costs.

The Prevalence and Clinical Features of Co-Occurring Autoimmunity in Children with Systemic Lupus Erythematosus: The Childhood Arthritis and Rheumatology Research Alliance (CARRA) Legacy Registry

Ohoud ALAhmed¹, Vidya Sivaraman², Melissa Moore-Clingenpeel³, Stacy P. Ardoin⁴ and Sharon Bout-Tabaku⁵, ¹Pediatric Rheumatology, Nationwide Children's Hospital, Columbus, OH, ²Pediatrics, The Ohio State University, COLUMBUS, OH, ³Research, Nationwide Children's Hospital, Dublin, OH, ⁴Division of Rheumatology, Nationwide Children's Hospital, Columbus, OH, ⁵Rheumatology, Nationwide Children's Hospital, Columbus, OH

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Pediatric Rheumatology – Clinical Poster I: Lupus, Sjögren's Disease, and Myositis

Session Type: ACR Poster Session A

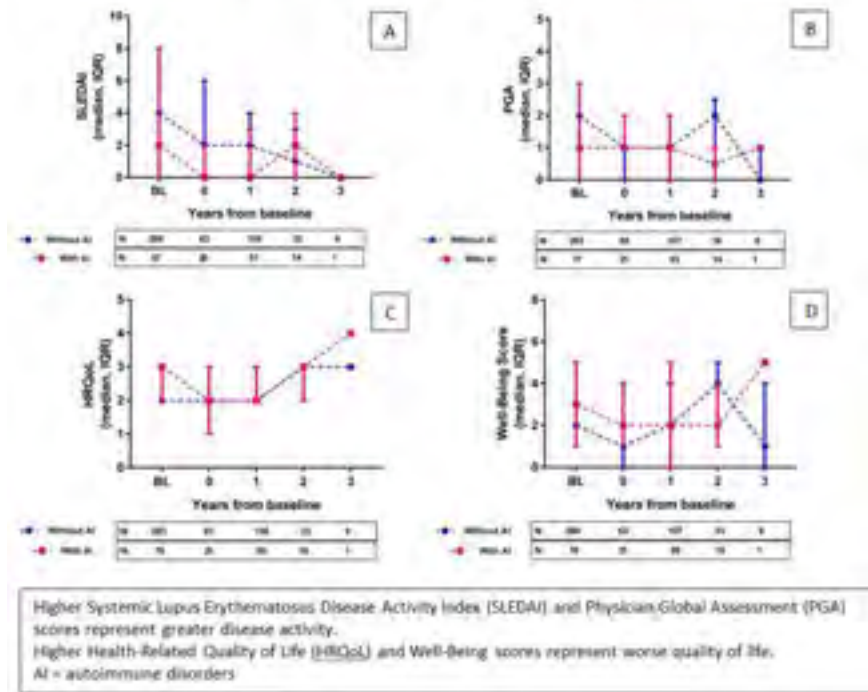

Session Time: 9:00AM-11:00AM

Background/Purpose: The co-occurrence of autoimmune disorders (AI) with systemic lupus erythematosus (SLE) in adults is associated with poor disease outcomes. We describe the co-occurrence of other AI in children with SLE (cSLE) and evaluate the relationship between comorbid AI and lupus disease outcomes using the Childhood Arthritis and Rheumatology Research Alliance (CARRA) Legacy Registry.

Methods: The CARRA Legacy Registry is a multicenter prospective, observational, longitudinal database of children with defined rheumatic conditions including SLE. Subjects were enrolled from May 2010 through July 2014 at anytime during their disease course and data were collected at 6-month interval follow up visits from 60 clinical sites in the US and Canada. 1285 subjects met the American College of Rheumatology (ACR) 1997 criteria for SLE. We defined comorbid AI as the presence of any of the following diseases: Hashimoto's thyroiditis, Celiac disease and type 1 diabetes mellitus. Disease outcomes were assessed by measures of disease activity and impact on quality of life (QoL). Comparisons by AI status were made using chi-square, Fisher's exact, two-sample t-tests, Wilcoxon rank sum tests, and mixed effects models as appropriate.

Results: Data on the co-occurrence of AI were available in 388 (30%), unknown in 31 (2%), and missing in 866 (67%) at the baseline visit. The prevalence of comorbid AI was 20% (n=79). When comparing subjects with AI (n=79) to those without AI (n=309), subjects with AI were significantly younger at onset of lupus and had more 1st degree relatives with AI (Table 1). Subjects without AI had significantly more renal disease at the time of enrollment. During follow up visits, the average Systemic Lupus Erythematosus Disease Activity Index (SLEDAI) score over time was significantly lower among subjects without AI. There were no significant differences over time in the Physician Global Assessment (PGA) level of

Figure 1: Disease activity and quality of life over time based on comorbid autoimmune disorders

disease activity by comorbid AI. Overall, there were no significant differences in the QoL measures or their trajectory over time based on the presence of comorbid AI (Figure 1).

Conclusion: Among children with SLE, the co-occurrence of another AI is associated with younger age at presentation, but is not associated with poor disease outcomes. Our study was limited by missing data on our variables of interest. Future plans include validating our results using the new prospectively collected CARRA Registry that has more complete data on comorbid AI and lupus disease outcomes.

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Pediatric Rheumatology – Clinical Poster I: Lupus, Sjögren's Disease, and Myositis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Discoid lupus erythematosus(DLE) is rare in children. Prior studies suggest 25-30% of children with skin-limited DLE are diagnosed with systemic lupus erythematosus (SLE) over time. Biomarkers and risk factors to identify those at highest risk are unknown. This multicenter, retrospective study aims to characterize baseline features and outcomes in pediatric patients with skin-limited DLE, as well as risk factors for the progression of DLE to SLE. Baseline characteristics of all patients with DLE and initial study findings are presented in this interim analysis.

Methods: Nine of 18 committed clinical sites, including pediatric dermatologists and rheumatologists, retrospectively reviewed all medical records of patients ≤ 18 years of age with clinical and/or histopathologic findings consistent with DLE. Baseline data were collected on all patients, including demographics, dates of DLE onset and diagnosis, distribution of DLE, and family history of SLE. For patients with skin-limited DLE, rates of progression to SLE based on American College of Rheumatology (ACR) and Systemic Lupus International Collaborating Clinics (SLICC) classification criteria were evaluated.

Results: Clinical records for 205 patients have been reviewed to date, with 50% of participating sites reporting. Baseline data are presented in Table 1. African-American females were most commonly affected. Median age at DLE diagnosis was 11.8 years, with median time from DLE onset to diagnosis of 0.5 years. Most patients (76%) had localized disease (i.e. head/neck only); 20% had a family history of SLE in a 1st degree relative. Most patients had skin-limited DLE at baseline, with only a minority exhibiting ≥ 4 ACR classification criteria (n = 56; 27%) or ≥ 4 SLICC classification criteria (n = 46; 22%). Initial treatments are presented in Table 2. Patients with skin-limited DLE and at least one follow-up visit (n=115) had median follow up of 3.1 years (range 0.1-12.5 years, 393 total patient-years). During this period, a minority met criteria for SLE diagnosis, utilizing ≥ 4 ACR classification criteria (n = 16; 14%) and ≥ 4 SLICC classification criteria (n = 24; 22%).

Conclusion: This study represents the largest investigation of pediatric DLE performed to date. Utilizing both ACR and SLICC classification criteria for SLE, most patients (>73%) presented with skin-limited DLE, with a low cumulative incidence of SLE using both ACR and SLICC classification criteria. Further analysis may help to determine risk factors for progression to SLE and inform the creation of consensus guidelines for treating children with DLE.

Clinical Characteristics and Treatment of 25 Children with Systemic Lupus Erythematosus Complicated with Thrombotic Microangiopathy in China

Ji Li, Pediatrics, Peking Union Medical College Hospital, Beijing, China

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Pediatric Rheumatology – Clinical Poster I: Lupus, Sjögren's Disease, and Myositis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Thrombotic microangiopathy (TTP) is a rare disease involving multiple organ systems. It is caused by extensive platelet thrombosis in the terminal arterioles and anterior capillaries, leading to clinical manifestations of microvascular hemolysis, thrombocytopenia, and organ dysfunction. Syndrome. TTP may be secondary to infection, malignancy, drugs, pregnancy, and autoimmune diseases. When TTP occurs in SLE patients, similar clinical symptoms may appear in TTP and SLE, and the symptoms in the early stages of the onset are lack of specificity, which mask each other and lead to delayed diagnosis. Although the incidence of SLE with TTP is not high, but the disease is serious, rapid progress, the fatality rate as high as 33.9-62.5%. This study investigated the clinical and laboratory characteristics, diagnosis, treatment, and prognosis of children with systemic lupus erythematosus (SLE) complicated with thrombotic microangiopathy (TTP).

Methods: Twenty-five children with SLE combined with TTP (SLE-TTP) were selected and their clinical symptoms, laboratory tests, renal pathological features, SLE disease activity indicators and treatment outcomes were analyzed retrospectively.

Results: 25 children with SLE-TTP, including 8 males (32%) and 17 females (68%). The onset age was 9-18 years, with a median age of 14 years. Among them, 9 cases were SLE first (25%), 1 case was TTP first (4%), and 15 cases were concurrent (60%). The mean SLE disease activity score (SLEDAI) was 22.4 points. Of the 25 children with SLE-TTP, all had thrombocytopenia, microvascular anemia, systemic symptoms in 21 cases (84%), cutaneous symptoms in 10 cases (40%), and digestive symptoms in 10 cases (40%). Nine cases had edema (36%), neurological symptoms in 9 cases (36%), respiratory symptoms in 6 cases (24%), joint pain in 5 cases (20%), and renal impairment in 19 cases (76%). Ten of these children completed a renal biopsy and found 8 pathological lesions of the kidney. Which type IV and TMA each accounted for 20% of renal pathological lesions. The most common treatment for children with SLE-TTP is immunosuppressive therapy with glucocorticoid pulse therapy (13 cases, 52%), followed by plasma exchange combined with glucocorticoid pulse therapy and immunosuppressive agents (10 cases, 40%). A total of 11 patients had plasma exchange (44%) with an average of 8.0 times. More than 80% of patients used plasma exchange and glucocorticoid therapy, and all patients achieved remission. Among the 25 cases, one case died (4%), and the remaining 15 cases (60%) were followed up at regular clinics without relapse.

Conclusion: SLE-TTP is often the first or concurrent SLE event, accompanied by middle-to-severe lupus activity. The main clinical manifestations of systemic symptoms in children with SLE-TTP included neurological symptoms, edema, and gastrointestinal symptoms. Renal pathology was mainly wolf kidney type IV or IV+TMA (40%). Severe SLE-TTP infection is an important risk factor for SLE-TTP. More than 92% of the patients were treated with immunosuppressants and glucocorticoids, and 40% of them needed plasmapheresis for effective remission.

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Pediatric Rheumatology – Clinical Poster I: Lupus, Sjögren's Disease, and Myositis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with childhood-onset(cSLE) are at significantly increased risk of death from cardiovascular disease when they reach early adulthood. The Atherosclerosis Prevention Pediatric Lupus Erythematosus (APPLE) trial was a randomized placebo-controlled trial evaluating the effect of atorvastatin on subclinical atherosclerosis over 3 years, as measured by carotid intima-media thickness (CIMT). Results showed a trend toward reduced CIMT progression in the atorvastatin treated group and that children with SLE have CIMT progression rates greater than children with familial hypercholesterolemia. Additional subgroup analyses showed that post pubertal children with elevated C-reactive protein benefited from statin therapy. Although traditional risk factors play an important role in atherosclerosis progression, they do not fully account for the increased risk seen in SLE and additional biomarkers are needed to identify high risk individuals. Since completion of the APPLE trial, pro-inflammatory high density lipoprotein function (piHDL) function has been identified as a biomarker predictive of both the presence and progression of subclinical atherosclerosis in adult women with SLE. Although higher levels of HDL cholesterol are generally considered to be protective against atherosclerosis, HDL may become inflammatory (piHDL) in the setting of chronic inflammation and promote LDL oxidation and atherosclerosis. This is the first study to evaluate piHDL function as a predictor of accelerated CIMT progression in cSLE.

Methods: Stored baseline plasma from the APPLE trial placebo group (n=94) was tested for piHDL function using a cell-free assay based on piHDL function. Plasma samples were stored at -80°C and had not been previously thawed. Baseline and last follow-up mean common CIMT measurements recorded in the APPLE trial were used to calculate the rate

of CIMT progression. Accelerated CIMT progression was defined as > 0.002 mm/year. Univariate logistic regression was performed to determine the association between baseline piHDL function and accelerated CIMT progression.

Results: The cohort was 87% female with a mean age of 15.7 years (standard deviation ± 2.4). The median piHDL function was 1.04 FU, interquartile range 0.49-2.08, similar to values seen in adult women with SLE. Univariate logistic regression showed that every one point increase in piHDL function was associated with a modest yet statistically significant 1.69-fold increased odds of accelerated mean-mean common CIMT progression (95% CI 1.08-2.65, $p = 0.22$).

Conclusion: piHDL may be a useful biomarker to aid in identifying cSLE patients at increased risk for atherosclerosis progression. Further study is underway to evaluate the predictive role of piHDL function as part of a biomarker panel in cSLE.

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Pediatric Rheumatology – Clinical Poster I: Lupus, Sjögren's Disease, and Myositis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The timing and etiology of diastolic impairment in pediatric-onset systemic lupus erythematosus (pSLE) are poorly understood, and the role of screening echocardiography remains unclear. We compared left ventricular diastolic function at pSLE diagnosis with controls and determined the prevalence of abnormal echocardiographic findings.

Methods: Echocardiograms of children with pSLE ages 5-18 years performed within 1 year of diagnosis and age- and sex-matched controls with structurally normal hearts (evaluated for benign murmurs or chest pain during the same period) were re-read by two blinded cardiologists. Baseline characteristics, SLE disease activity index (SLEDAI), and cardiovascular symptoms/signs were abstracted by chart review. Diastolic indices (E/A ratio, e' , E/e' , and isovolumetric relaxation time (IVRT)) were compared using linear mixed effects models adjusted for systemic hypertension. Other abnormalities, including pericardial effusion and valvular disease, were also evaluated. Pearson's correlation was used to identify factors associated with worse diastolic indices.

Results: 85 children with incident pSLE had baseline echocardiograms, of which 61% were for screening, 15% were for cardiovascular symptoms/signs, and 23% were for other indications. Median time from SLE diagnosis to echocardiogram was 6 days (interquartile range 1-70). Prior glucocorticoid exposure was minimal (Table 1). Diastolic indices were significantly worse in pSLE cases compared to controls (with lower E/A, lower e' , higher E/e' and longer IVRT) even after adjustment for hypertension (Table 2). 6 pSLE cases (7%) met cutoffs for abnormally low e' and 32 (47%) had prolonged IVRT, though none met international criteria for Grade I diastolic dysfunction. Mild to moderate pericardial effusions, aortic and mitral insufficiency were present in 15%, 17%, and 6% of all pSLE cases, respectively, including 8%, 15%, and 3% of asymptomatic pSLE cases ($n = 61$). SLE disease activity, but not presence of effusion, was correlated with worse E/e' ($p = 0.31$, $p = 0.02$), septal e' (-0.30 , $p < 0.01$), and IVRT (0.50 , $p < 0.01$).

Conclusion: Subclinical echocardiographic findings were prevalent in a group of children with incident SLE, with worse diastolic indices at diagnosis compared to peers without SLE, independent of long-term glucocorticoid use or hypertension.

Future longitudinal studies using echocardiography will determine whether these measures of diastolic function worsen over time and if they are prognostic of future cardiac complications.

Table 1. Baseline demographic and disease characteristics

	pSLE	Controls	p-value
	(N=85)	(N=85)	
Age, mean (SD)	14.6 (2.9)	14.6 (2.9)	-

Libman Sacks Endocarditis in Pediatric Systemic Lupus Erythematosus: Clinical Features and Complications

Marla Guzman, Meiqian Ma, B. Anne Eberhard and Joyce Hui-Yuen, Pediatric Rheumatology, Cohen Children's Medical Center, New Hyde Park, NY

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Pediatric Rheumatology – Clinical Poster I: Lupus, Sjögren's Disease, and Myositis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Libman-Sacks endocarditis (LSE) is a rare manifestation of pediatric-onset systemic lupus erythematosus (pSLE). It is difficult to differentiate LSE from infective endocarditis (IE) in immunosuppressed patients.

Data remain scarce on the diagnosis of LSE and disease course. We aim to describe the diagnosis, evaluation and management of endocarditis in pSLE.

Methods: A retrospective chart review was conducted of all patients who fulfilled ACR lupus classification criteria and were diagnosed with pSLE and either LSE or IE. Data were collected on demographics, laboratory results, echocardiogram findings, clinical features, and treatment. Descriptive statistics were used.

Results: We describe 6 patients (4 females) with pSLE and endocarditis, with a mean age at diagnosis of 11.6 +/- 3.3 years (Table 1). Three patients were White, 2 Black, and 1 Asian. The mean disease duration from pSLE diagnosis to diagnosed cardiac involvement was 1.4 +/- 2.8 years. Four patients had biopsy-proven lupus nephritis. All patients had positive serologies for ANA and anti-dsDNA antibodies. Five patients had anti-cardiolipin (aCL) antibodies at pSLE diagnosis and 3 had aCL antibodies at endocarditis diagnosis. Four patients were on treatment with steroids, 2 were on hydroxychloroquine, and 2 were treatment-naïve. One patient was treated with Cyclophosphamide, Rituximab, and plasmapheresis for pulmonary hemorrhage. The mean SLEDAI at diagnosis of endocarditis was 10.5 +/- 6.4. Two patients had baseline echocardiograms at the time of pSLE diagnosis; both were normal.

Two patients had LSE, with involvement of mitral and aortic valves on echocardiogram. Two patients had isolated IE without LSE, more commonly involving the tricuspid valve. Two patients were on antibiotics prior to obtaining blood cultures so overlying IE could not be ruled out. The only other concurrent clinical manifestation of lupus was arthritis in 2 patients. No patients had an increase or change in immunosuppression specifically for treatment of LSE. Five patients received prophylactic anti-coagulation. One patient was placed on subacute bacterial endocarditis prophylaxis. The most severe complications were pulmonary embolus (one definite, one possible), distal emboli and Roth spots (2 patients).

Conclusion: This is the largest case series of endocarditis in pSLE to date. Our data demonstrate endocarditis (LSE and/or IE) is more frequently diagnosed early in disease course, often in conjunction with other end-organ manifestations. As pSLE can have a more severe disease course than adult-onset SLE, our data suggest that endocarditis occurs in patients whose disease is either newly diagnosed or not well-controlled. Obtaining an echocardiogram at pSLE diagnosis with annual echocardiograms for surveillance may be useful. Anti-phospholipid antibodies play a role in LSE and should also be monitored.

A Weighty Diagnosis: Weight Change and Risk Factors in Early Juvenile Systemic Lupus Erythematosus

Erin Treemarcki¹, Jackie Szymonifka², Alexa Adams³, Nancy Pan⁴, Sarah Taber⁵ and Karen Onel⁵, ¹Hospital for Special Surgery Weill Cornell Medical College, New York, NY, ²Hospital for Special Surgery, New York, NY, ³Hospital for Special Surgery/Weill Cornell Medicine, New York, NY, ⁴Pediatric Rheumatology, Hospital for Special Surgery, New York, NY, ⁵Pediatric Rheumatology, Hospital for Special Surgery Weill Cornell Medical College, New York, NY

Session Information

Session Date: Sunday, October 21, 2018

Session Title: Pediatric Rheumatology – Clinical Poster I: Lupus, Sjögren's Disease, and Myositis

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: SLE is a chronic, multisystem autoimmune condition with multiple comorbidities due to inflammation and treatment, including metabolic syndrome, poor cardiac outcome, and poor quality of life. Obesity is more prevalent in children with jSLE compared to the general population. Obesity induces inflammation and independently contributes to lower functional status. Corticosteroid (CS) use is associated with weight gain. Obesity is also more prevalent in youths of lower socioeconomic status (SES). This study aims to retrospectively study weight change in an inception cohort of jSLE and potential contributors.

Methods: A retrospective chart review of jSLE was conducted at a single medical center. Inclusion criteria were an ICD-9 or ICD-10 diagnosis of jSLE prior to 18 years of age and multiple visits in the first year of jSLE. Baseline data included demographics and serologies. Variables collected from each visit included: time from diagnosis; age; weight, height, and BMI with percentiles and Z-scores; documentation of fatigue, gastrointestinal, psychiatric, or musculoskeletal symptoms; albumin; SLEDAI; and current medications with CS dose in mg/kg of prednisone. A mixed effect model was used to determine associations between BMI change and individual factors.

Results: Interim analysis included 16 patients, who were predominantly female, Hispanic, and on Medicaid (Table 1). Average age of diagnosis was 13.81 years. There was an average 0.064 ± 0.007 kg/m² increase in BMI per week ($p < 0.001$). Clinically, the number of obese and seriously obese patients increased from 25% to 43.75%. CS dose and SLEDAI were inversely associated with BMI ($p < 0.001$, $p = 0.017$). There was a trend towards association between higher BMI and fatigue ($p = 0.168$), gastrointestinal ($p = 0.074$), psychiatric ($p = 0.801$), and no musculoskeletal symptoms ($p = 0.403$).

Conclusion: There is a statistically significant trend towards increasing weight in the first year of jSLE and an increased rate of obesity. Increasing BMI was significantly associated with lower CS dose and SLEDAI and was associated with a more positive review of symptoms. Future study will expand this cohort, examine the impact of growth, and direct prospective studies.
