Results: In total, 255 and 142 new patients attended the UA and PC-strategy clinic, respectively, for the first time. Of the initial patients, 29/255 (11%) vs 13/142 (9%) patients stopped prematurely clinical follow-up and 6/255 (2%) vs 11/142 (8%) patients died. Finally, 126 and 86 patients had a follow-up assessment between 9-15 months after inclusion. Diagnosis of gout was further confirmed by ACR/EULAR classification criteria for 122/126 (97%) patients in the UA-strategy vs 51/86 (59%) patients in the PC-strategy ($p < 0.001$), respectively. In the UA-strategy 105/126 (83%) patients compared to 63/86 (74%) patients in the PC-strategy ($p = 0.10$), reached the threshold of ≤ 0.36 mmol/L and 58/126 (46%) vs 31/86 (36%) patients ($p = 0.15$) were free of flares (table 1). In the UA-strategy 76/126 (60%) patients were on allopurinol mono therapy compared to 63/86 (73%) in those receiving the PC-strategy ($p = 0.05$). 2MoA therapy was significantly more frequent in the UA-strategy ($n = 21$ (17%) vs $n = 1$ (1%), $p < 0.001$), yet the number of registered adverse events was not different ($n = 25$ (20%) vs $n = 20$ (23%), $p = 0.55$). After adjustment for baseline confounders, the UA-strategy had a slightly higher but non-significant chance to reach sUA ≤ 0.36 mmol/L and to be free of flares, but required significantly more therapy intensification.

Conclusion: A strict UA-strategy resulted in a non-significant higher proportion of patients reaching the UA target (≤ 0.36 mmol/L) and free of flares. This was accomplished with significant more therapy intensification from allopurinol monotherapy to 2MoA therapy, without a significant difference in adverse events.

Table 1: Uni- and multivariable logistic regression analyses for co-primary and secondary outcomes in patients with gout disease undergoing two different treatment strategies

	UA-strategy (n=126)	PC-strategy (n=86)	Univariate (n=212)		Multivariable (n=207)	
	N (%)	N (%)	Odds ratio	95% CI	Odds ratio	95% CI
Co-primary						
sUA ≤ 0.36 mmol/L	105 (83.3)	63 (74.1)	1.75	0.89-3.43	1.65	0.77-3.56
Free of flares	58 (46.0)	31 (36.0)	1.51	0.86-2.66	1.61	0.83-3.10
Secondary						
sUA ≤ 0.30 mmol/L	83 (65.9)	44 (51.8)	1.80	1.03-3.16	1.97	1.00-3.85
Adverse events	25 (19.8)	20 (23.3)	0.82	0.42-1.59	1.04	0.49-2.21
Allopurinol monotherapy	76 (60.3)	63 (73.3)	0.56	0.31-1.01	0.40	0.20-0.82

Multivariable model includes treatment strategy (center), age, gender, estimated glomerular filtration rate (eGFR), use of diuretics, presence of tophi, and baseline serum uric acid. sUA = serum uric acid, UA-strategy= uric acid strategy, PC-strategy= patient-centred strategy.

Abstract Number: 2242

Cardiovascular Outcomes of Treatment with Febuxostat and Allopurinol in Gout Patients with Kidney Disease

William B. White¹ and Lhanoo Gunawardhana², ¹Cardiology, University of Connecticut School of Medicine, Farmington, CT, ²Takeda Pharmaceuticals International, Deerfield, IL

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Metabolic and Crystal Arthropathies – Basic and Clinical Science Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The Cardiovascular Safety of Febuxostat and Allopurinol in Patients with Gout and Cardiovascular Comorbidities (CARES) trial demonstrated that major cardiovascular (CV) outcomes on febuxostat versus allopurinol in patients with gout and CV disease were comparable but that rates of CV mortality were higher on febuxostat. We evaluated the CV outcomes in those patients with chronic kidney disease (CKD) according to the need for up-titration of dose aimed at achieving serum urate (sUA) levels < 6 mg/dL.

Methods: Fifty-three percent of the study population in CARES (n = 3267) had moderately impaired kidney function (CKD 3, estimated creatinine clearance (eCRCL) < 60 ml/min and ≥ 30 ml/min). Febuxostat patients received 40 mg daily, increased to 80 mg at Week 4 if the sUA was ≥ 6.0mg/dL at Week 2, regardless of kidney function. Allopurinol patients received 200 mg to 400 mg for CKD 3, or 300 mg to 600 mg when the eCRCL was ≥ 60 ml/min, increased in 100 mg increments each month until the sUA was < 6.0mg/dL. The rates of the primary composite endpoint and its 4 components were analyzed according to final dose requirements in patients with CKD 3.

Results: There were 1636 CKD 3 patients randomized to febuxostat and 1631 to allopurinol in CARES. In these patients, the final dose of febuxostat was 40 mg in 59% and 80 mg in 41% whereas the final dose of allopurinol was 200 mg in 41%, 300 mg in 28%, and 400 mg in 31% of patients. At baseline, CKD 3 patients who required up-titration of dose to achieve serum urate levels < 6 mg/dL for both febuxostat and allopurinol were slightly younger, had greater serum urate levels and higher rates of tophi and higher rates of congestive heart failure compared to those patients not requiring up-titration of dose (p < 0.05) (**Table 1**). In patients with CKD 3, higher proportions of patients in the febuxostat group achieved the targets of < 6 and < 5 mg/dL compared to allopurinol at most time points during the trial and the incidence of gout flares was comparable for the 2 treatment arms (febuxostat, 47.9% and allopurinol 43.9%, overall). The incidence of CV events was greater in the patients who required higher doses and was driven by CV mortality rates; however, these results were similar for both febuxostat and allopurinol (**Table 2**).

Conclusion: CV event rates, driven by CV mortality, were greater in patients with moderately impaired kidney function who required up-titration of both febuxostat and allopurinol. However, these findings occurred in association with greater gout and CV disease burden, particularly heart failure, a comorbidity linked to increases in subsequent CV mortality.

Table 1. Baseline characteristics of CKD 3 patients requiring dose increase versus those who did not

Characteristic	Patients requiring dose increase		Patients not requiring dose increase

Sex Difference of the Association between Serum Urate and Blood Pressure in Young Adults

Angelo Gaffo¹, Elizabeth J. Rahn², Tanja Dudenbostel¹, Amy S. Mudano¹, Peng Li³, David T. Redden³, Stephanie Biggers¹, Phillip J. Foster², Paul M. Muntner⁴, Suzanne Oparil⁵, David A. Calhoun⁵ and Kenneth Saag¹, ¹University of Alabama at Birmingham, Birmingham, AL, ²Department of Medicine, Division of Immunology and Rheumatology, University of Alabama at Birmingham, Birmingham, AL, ³Department of Biostatistics, University of Alabama at Birmingham, Birmingham, AL, ⁴Department of Epidemiology, University of Alabama at Birmingham, Birmingham, AL, ⁵Department of Medicine, Division of Cardiovascular Disease, University of Alabama at Birmingham, Birmingham, AL

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Metabolic and Crystal Arthropathies – Basic and Clinical Science Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Serum urate (sUA) has been associated with blood pressure in most but not all studies. This study aims to test whether there are sex differences in the association between sUA and systolic blood pressure (SBP) in young adults.

Methods: This is a cross sectional analysis using baseline data from young adults with normal renal function participating in a clinical trial. Men and women ages 18-40 years were eligible if they had SBP ≥ 140 mm Hg or diastolic blood pressure ≥ 90 mm Hg and sUA > 5.0 mg/dL for men and > 4.0 mg/dL for women. Multiple linear regression analysis was used to evaluate the association between sUA and SBP (measured with in-office sphygmomanometer), controlling for age, sex and race. The potential sex difference was tested with a sex-by-sUA interaction term in the regression model.

Results: The mean age of the 99 participants was 27.6 ± 6.9 years; 37.4% were female, and 40.4% were African American. After controlling for age, sex and race, SBP was significantly associated with sUA ($p=0.019$). The results also suggested a statistically significant sex difference in the association ($p=0.026$). Specifically, a one unit increase in sUA was associated with 6.8 mm Hg higher SBP in women, but only 0.2 mm Hg in men (Figure). No statistically significant race effect was detected.

Conclusion: Higher sUA was associated with higher SBP in women but not in men. This association was present at ranges of sUA below the threshold of hyperuricemia (6.8 mg/dL). Whether an interaction between sUA and hormonal factors can account for this differential effect of sex on SBP in young adults should be explored further.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Metabolic and Crystal Arthropathies – Basic and Clinical Science Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Gout flares are a major cause of morbidity and are an important outcome in clinical studies. Significant limitations for timely flare ascertainment exist, and while technology has promise to capture flares passively, optimal methods to do so are uncertain. We examined the feasibility, preference, and satisfaction of an interactive voice response [IVR] system versus a smartphone mobile application [RheumPRO; Birmingham, AL] to capture gout flares between study visits.

Methods: Gout patients were randomized to IVR vs. RheumPRO for flare capture and crossed over to the other technology at 3 months. Study inclusion criteria: physician diagnosed gout, hyperuricemia (serum urate level ≥ 6.8 mg/dl), self-report of ≥ 2 flares in the previous 6 months, and smartphone ownership. Participants reported flare status via weekly scheduled RheumPRO interactions or IVR calls. At 3 (crossover) and 6 months (end of study), participants completed satisfaction/feasibility surveys. Feasibility was ascertained via response rate (adherence) to RheumPRO interactions or IVR calls. Satisfaction was assessed using dichotomous preference questions and a Likert scale question on ease of use (range 0 to 10; very easy to very difficult). Descriptive statistics characterized differences between methods.

Results: Of 44 participants enrolled, 38 completed both study arms. Participants were predominantly men (87%), had a mean (\pm SD) age of 50 (± 15) years, and most (87%) were on urate lowering therapy at enrollment. At study completion, 28 (74%) preferred RheumPRO, 3 (8%) preferred IVR and 7 (18%) had no preference. Adherence with both methods did not differ at 80%. Measures of feasibility and satisfaction for each method are shown in Table 1.

Table 1

	IVR	RheumPRO	p-value
<i>Gout Flares</i>			
Weeks with a flare (per pt)	2.6 (± 2.5)	3.4 (± 3.3)	0.27
Mean (\pm SD)			
Total flare weeks (% of study time with flares)	27%	35%	0.02
Feasibility (Adherence) (weekly response to interactions or calls)	80.6% ($\pm 21.3\%$)	80.1% ($\pm 24.6\%$)	0.94
Mean % (\pm SD)			
<i>Technology Satisfaction Measures</i>			
Ease of use (0-10; very easy to very difficult)	1.63 (± 2.5)	0.58 (± 1.12)	0.02
Mean (\pm SD)			
Disrupted activity (i.e. intrusiveness), %	18.4%	2.6%	0.06
Ability to respond to interactions or calls, %	72.8%	94.7%	0.01
Preference of reporting via device/call compared clinic visit, %	86.5%	92.1%	0.48
Satisfaction with frequency of contact, %	89.5%	89.5%	1.00
Willing to use in future, %	89.5%	97.3%	0.36

Conclusion: Both a smartphone App and IVR were found to be equally feasible technologies and reasonably accepted to capture gout flares. More patients preferred the RheumPRO App, which detected more flares, and found it easier to use

and more convenient than an automated call system. Each technology may offer variable benefits for feasible gout flare assessment in future clinical studies.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Metabolic and Crystal Arthropathies – Basic and Clinical Science Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Lubricin/proteoglycan-4 (PRG4) is a mucinous glycoprotein secreted by synovial fibroblast and superficial zone chondrocytes. PRG4 has a multifaceted homeostatic role in the joint including boundary lubrication, friction lowering of apposed cartilage surfaces and prevention of synovial overgrowth. PRG4 is abundant in the synovial fluid (SF) and its levels are reduced in SF from patients with inflammatory arthropathies. Therapeutically, the recombinant and native form of PRG4 has been shown to exhibit a disease-modifying effect in pre-clinical osteoarthritis (OA) models. We recently showed that rhPRG4 reduces phagocytosis of MSU-crystals, activation of chemokines and cytokines, NLRP3 expression, generation of mature IL-1 β , and NF κ B nuclear translocation. The objective of this study was to further evaluate role of Lubricin/PRG4 in NLRP3 inflammasome activation, ASC recruitment and speck formation in MSU-crystal stimulation in THP-1 macrophages and wild-type and Prg4 knock-out macrophages.

Methods: We evaluated the impact of recombinant human PRG4 (rhPRG4) on MSU-induced release, secretion and expression of interleukin-1 beta (IL-1 β), NLRP3 induction, caspase-1 activation by ELISA, immunohistochemistry, and Western-blot analysis in MSU-stimulated THP-1 cell and MSU-stimulated peritoneal macrophages (PEM) and bone marrow derived macrophages (BMDPs) from wildtype and Prg4 knock-out (KO) mice. We also evaluated the role of rhPRG4 in the expression of the NLRP3 inflammasome components using qPCR, immunohistochemistry and western-blot analysis. Immunohistochemistry experiments were performed to evaluate if rhPRG4 inhibited ASC speck formation and oligomerization. Colocalization of rhodamine rhPRG4 and NLRP3, ASC was evaluated in MSU-stimulated THP-1 cells.

Results: rhPRG4 inhibited the expression of NALP3, PYCARD, Caspase-1 and IL-18 in MSU-stimulated THP-1 cell using immunohistochemistry, western blot analysis and qPCR in a dose dependent manner. rhPRG4 inhibited the formation of ASC speck, a critical marker of NLRP3 inflammasome assembly, in MSU-stimulated cells. PEM from Prg4 $-/-$ mice showed increased NLRP3 induction, caspase-1 activation and conversion of pro-IL-1 β to mature IL-1 β compared to wild-type mice. Colocalization of rhodamine rhPRG4 in MSU-stimulated THP-1 cells showed colocalization with NLRP3 but not ASC.

Conclusion: Our findings advance our current understanding of the complex anti-inflammatory mechanisms of PRG4 in gout. One of the rhPRG4's anti-inflammatory mechanism may be due to targeting the NALP3 inflammasome assembly. This work is supported by P20GM104937 (AMR and GDT) and Arthritis Foundation Grant (AMR).

Insulin: Genetic and Physiological Influences on Human Uric Acid Homeostasis

David B. Mount¹, Tony R. Merriman² and Asim Mandal¹, ¹Renal Division, Brigham and Women's Hospital, Harvard Medical School, Boston, MA, ²University of Otago, Dunedin, New Zealand

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Metabolic and Crystal Arthropathies – Basic and Clinical Science Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Insulin plays a key role in the genesis of hyperuricemia. In particular, hyperinsulinemia in metabolic syndrome is inversely correlated with urinary uric acid (UA) excretion and insulin infusion in humans also reduces urinary fractional excretion of UA.

Methods: An existing GWAS cohort was analyzed, testing for association between genetic variants in the insulin and insulin receptor genes with serum UA (SUA). HEK 293T cells, human PTC5 proximal tubule cells, and *Xenopus* oocytes were probed with antibodies to UA transporters, the insulin receptor, downstream kinases, and the relevant phosphokinases. ¹⁴C-UA transport was assayed in these human cell lines and in oocytes expressing individual transporters.

Results: Variants in the human insulin and insulin receptor genes demonstrated significance for association with variation in SUA, at $p < 10^{-4}$ and $p < 10^{-7}$, respectively. HEK293T and PTC5 proximal tubular cells express several endogenous UA transporter proteins, including GLUT9, OAT10, and URAT1. Insulin activates PI3 kinase/Akt and MEK/ERK signaling pathways through the insulin receptor in HEK 293T and PTC5 cells, as detected with phosphokinase antibodies, with activation of endogenous ¹⁴C-UA transport. The stimulatory effect of insulin on UA uptake is abrogated by uricosurics and by inhibition of protein tyrosine kinase (genistein), PI3 kinase (LY295002), and MEK/ERK (PD98059). UA transport mediated by GLUT9a, GLUT9b, OAT10, OAT3, OAT1, NPT1 and ABCG2, when expressed separately in *Xenopus* oocytes, is also activated by insulin, with equivalent activation of signaling pathways and differential effects of signaling inhibitors on insulin-stimulated UA transport. Insulin has no effect on URAT1, OAT4, and the SMCT1/2 nicotinate transporters, when expressed in oocytes. GLUT9a is the basolateral exit pathway in reabsorption of filtered UA by the proximal tubule; given much greater absolute UA transport rates mediated by GLUT9 isoforms in oocytes, much of the anti-uricosuric effect of in vivo insulin infusion is likely due to activation of GLUT9a.

Conclusion: Variation in the human insulin and insulin receptor genes affects SUA. Insulin and associated signaling pathways also activate multiple UA transporters, indicating a pivotal physiological role for insulin in UA homeostasis. We postulate that basolateral GLUT9a in the proximal tubule is the dominant post-translational target of insulin in the regulation of renal UA transport.

Predictors of End-Stage Renal Disease (ESRD) in Gout Patients and General Population (GP) Controls – a Role for Interstitial Nephritis, Urate Nephropathy?

Martin Joelsson¹, Lennart Jacobsson¹ and Mats Dehlin², ¹Dept of Rheumatology and Inflammation Research, Sahlgrenska Academy, University of Gothenburg, Sweden, Gothenburg, Sweden, ²Department of Rheumatology and Inflammation Research, Sahlgrenska Academy, University of Gothenburg, Sweden, Gothenburg, Sweden

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Metabolic and Crystal Arthropathies – Basic and Clinical Science Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Decreased renal excretion of urate is an established risk factor for hyperuricemia, whereas it is less clear if hyperuricemia or gout predict impaired kidney function. Aims were to; 1) Determine if gout predicted ESRD and what the predictors for ESRD were in gout and control subjects separately, 2) describe the underlying kidney diagnoses for ESRD.

Methods: All patients aged ≥ 18 with a visit to physician with a gout diagnosis (ICD-10) between 2002 and 2012 in the Western Sweden Health Care Region (WSHCR) were individually matched with 5 general population controls (GP) by age, sex, county and year of gout diagnosis. In all subjects, for the two years preceding the gout diagnosis, visits to physician with the following diagnoses (ICD10) were identified: atrial fibrillation (AF), diabetes (DM), glomerulonephritis (GN), heart failure (HF), hypertension (HT), ischemic heart disease (IHD), and tubulointerstitial nephritis (TIN). Follow-up started Jan 1st 2002 or at the date of first visit with a gout diagnosis thereafter and ended at the first of ESRD diagnosis, death, or end of study (31st of December 2012). ESRD was defined as first kidney transplantation or start of dialysis during follow-up. Multivariable Cox-regression models with ESRD as outcome were used to examine gout as a predictor and individual predictors in the gout and control cohorts separately. In addition descriptive information on underlying kidney disease diagnoses for ESRD are shown.

Results: We identified 28304 patients with a diagnosis of gout and 135287 GP. In gout patients and GP 0.76% (mean follow-up: 3.92 yrs) and 0.12% (mean follow-up: 4.35 yrs) developed ESRD, respectively. Gout was associated with an increased risk for ESRD (HR 7.2; 95% Confidence Interval (CI) 6.0 to 8.6) compared to GP controls. The HRs for risk factors for ESRD were similar between gout and GP with the exception of male sex and age that decreased the risk in patients with gout (Table 1). Interestingly, when identifying causes to ESRD we found that GN and TIN were significantly more common in gout patients compared to GP controls, 21.6 vs 11.9% ($p=0.005$) and 8.4 vs 3.6% ($p=0.052$) respectively. Diabetic nephropathy was slightly more common in GP controls compared to gout patients, 20.7 vs 18.7% ($p=0.59$).

Conclusion: ESRD is much more common in gout patients compared to GP, with a similar pattern of predictors, with the exception of age and sex. Interestingly, TIN was much more frequent in gout patients both overall and as a cause of ESRD, which may reflect presence of urate nephropathy.

Table 1

	Gout cases, n=28304	Gout hazard ratio (SD)	General population controls, n=135287	General population controls, hazard ratio (SD)

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: During a gout flare monosodium urate (MSU) crystals induce, in the presence of a secondary stimulus, acute joint inflammation characterized by the recruitment of predominantly neutrophils. These neutrophils release chemokines and inflammatory mediators, further amplifying the inflammation. IL37 emerges as a fundamental inhibitor of the innate immune response and inhibits MSU-crystal induced inflammation in cell lines and murine models of gout. To further elucidate the role of IL37 in gout, we examined DNA of people with gout for genetic variations in *IL37* and assessed the functional consequences of these mutations.

Methods: Exons of the *IL37* gene were sequenced using Molecular Inversion Probes (MIPs) in 677 people with crystal-proven gout. The frequency of rare genetic variants in *IL37* was compared to a cohort of 469 healthy controls and a cluster analysis was performed.

Neutrophils were isolated from healthy Dutch donors, pretreated with IL37, a genetic variant of IL37 or IL37Fc (the tail region of an antibody to IL37) and stimulated with opsonized MSU crystals. Reactive oxygen species (ROS) and IL8 production were measured.

For the validation of genetic variants, a total of 2202 clinically-ascertained gout cases and 2295 controls (further stratified into 424 hyperuricemic ($\geq 0.41\text{mmol/L}$) controls) of European and NZ Māori and Pacific (Polynesian) ancestry were utilized. Taqman[®] genotyping was carried out, followed by multivariate-adjusted association analysis with gout as the outcome.

Results: MIP-sequencing identified 4 non-synonymous rare variants in exon 5 of *IL37* in 6 gout patients, whereas none were detected in the healthy controls (fisher's exact test; $p=0.043$). Two variants (p.H172HX; p.N182S), present in two individuals, were observed in the Exome Aggregation Consortium database; the private variants (p.A144P; p.C181*) were not. Cluster analysis showed the rare variants in *IL37* significantly cluster ($p=5.71 \times 10^{-5}$).

To elucidate the effect of mutations in *IL37*, a recombinant protein was produced based on the p.C181* mutation. *In vitro*, full length IL37(46-218) significantly decreased ROS and IL8 production. The IL37 mutant demonstrated diminished anti-inflammatory effects compared to the full-length protein.

In our validation cohort, the *rs752113534* variant (p.N182S) was monomorphic in people of European ancestry, but the minor G-allele exhibited a frequency of 0.05 in people of Eastern and Western Polynesian ancestry. A meta-analysis of people of Eastern and Western Polynesian ancestry showed a significant association of the G-allele with gout risk using hyperuricemic controls ($\text{OR}=1.81$, $P_{\text{OR}}=0.03$). As a potential therapeutic, IL37Fc was tested *in vitro* and strongly inhibited ROS and IL8 production.

Conclusion: Rare genetic variants in *IL37* clustering in exon 5 were found in people with gout. One of these *IL37* mutants demonstrated a loss of the anti-inflammatory function *in vitro*. Moreover, the association of *IL37* rare variant *rs752113534* in prevalent gout in people of Polynesian ancestry supports a role for IL37 in an inflammatory pathway leading to gout in the presence of hyperuricemia. Furthermore, IL37Fc was identified as a potential new therapeutic in the treatment of gout.

Not Just a Swollen Big Toe: Increasing All-Cause Hospitalizations in Patients with Gout in the United States: 1993–2014

Gurkirpal Singh¹ and Alka Mithal², ¹Stanford University School of Medicine, Woodside, CA, ²ICORE, Woodside, CA

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Metabolic and Crystal Arthropathies – Basic and Clinical Science Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Gout is a disorder of uric acid metabolism and often presents as acute severe joint pain. However, several recent studies have highlighted systemic complications of associated hyperuricemia in patients with gout, including possible increased risk of renal and cardiovascular comorbidities. We studied all-cause hospitalizations in patients with gout in the United States (US) from 1993 to 2014.

Methods: The Nationwide Inpatient Sample (NIS) is a stratified random sample of all US community hospitals. It is the only US national hospital database with information on all patients, regardless of payer, including persons covered by Medicare, Medicaid, private insurance, and the uninsured. We examined all inpatient hospitalizations in NIS from 1993 to 2014 with a primary or secondary diagnosis of gout, and compared them to total all-cause US hospitalizations during the same period. US population estimates and projections for the resident US population were obtained from the US Census Bureau.

Results: There were 789.8 million all-cause hospitalizations in 6.4 billion person-years of observation from 1993 to 2014 (123.4 hospitalizations per 1,000 person-years). During this time-period, 9,741,598 hospitalizations occurred in patients with gout (152.2 per 100,000 person-years). All-cause US hospitalizations increased from 33.7 million in 1993 to 35.4 million in 2014, an increase of 4.8% over 22 years. All-cause hospitalizations in gout patients have increased from 167,441 in 1993 (64.2 per 100,000 person-year) to 854,475 in 2014 (267.9 per 100,000 person-years, a dramatic increase of over 410% ($p<0.0001$)). In 2014, hospitalizations in gout patients accounted for over 4.6 million hospital days at a total national cost of over US \$42.6 billion.

Conclusion: All-cause hospitalizations in patients with gout in the US have significantly increased by 410% in the last 22 years, almost hundred-fold of the 4.8% increase in US population all-cause hospitalization rate in the same time-period. This calls for an increase need for identification and management of serious co-morbid conditions in patients with gout.

Mitigation of Inflammation Induced By Monosodium Urate Crystals in Mice By Treatment with Svp-Rapamycin

Pallavi Kolte, Robert LaMothe, Joseph Ferrari, Sheldon Leung, Wesley DeHaan, Earl Sands and Takashi Kei Kishimoto, Selecta Biosciences, Watertown, MA

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Metabolic and Crystal Arthropathies – Basic and Clinical Science Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Initiation of urate-lowering therapies is typically associated with an increase in gout flares due to mobilization of pro-inflammatory urate crystals. SEL-212 is a novel combination product consisting of pegadricase (also known as pegsiticase), a pegylated uricase, co-administered with synthetic vaccine particles encapsulating rapamycin (SVP-R) being developed for the treatment of chronic severe gout. Data from the ongoing open-label Phase 2 multidose study of SEL-212 indicate that SVP-R mitigates the formation of anti-drug antibodies (ADAs) against pegadricase, enabling monthly dosing and sustained control of serum uric acid (sUA) levels in most patients. Despite rapid and sustained reduction of sUA, patients treated with SEL-212 experienced a low rate of flares. Here we evaluated in animal studies whether SVP-R might have a beneficial effect on reducing inflammation induced by monosodium urate crystals (MSU) in addition to its effects on mitigating the formation of ADAs.

Methods: MSU-induced inflammation was investigated in an air pouch model in C57Bl/6 mice. An air pouch was generated on the dorsal aspect of a mouse by injecting sterile air on d0 and d3. Mice were treated intravenously with placebo or SVP-R on d7. MSU crystals were injected in the air pouch on d8 and mice were sacrificed 5 hours after MSU injection. Air pouch exudate was analyzed for cellularity and interleukin-1 β (IL-1 β) levels as markers of inflammation.

Results: Injection of MSU crystals into the air pouch of a mouse has been previously shown to induce an acute inflammatory response characterized by expression of IL-1 β and an influx of neutrophils. Intravenous administration of SVP-Rapamycin reduced the generation of IL-1 β in the air pouch exudate by four-fold (from 131.5 pg/ml to 30.5 pg/ml) and the number of Ly6G+CD11b+ neutrophils by five-fold (from 0.5×10^6 cells/ml to 0.1×10^6 cells/ml).

Conclusion: SVP-R has been shown to mitigate the formation of ADAs to biologic therapies by inducing tolerogenic dendritic cells and antigen-specific regulatory T cells. Here we demonstrate that SVP-R also attenuates inflammatory responses induced by MSU crystals and mediated by innate immune cells. These results may explain why gout patients treated with pegadricase in combination with SVP-R experience an unexpectedly low rate of gout flares.

Calcific Tendonitis of the Rotator Cuff: Do We Need Steroid Injection after Ultrasound Guided Percutaneous Lavage? Results of a 12-Months Double-Blind Randomized Controlled Study

Christelle Darrieutort-Laffite¹, Stéphane Varin², Guillaume Coiffier³, Jean-David Albert³, Gregoire Cormier² and **Benoit Le Goff**¹, ¹Rheumatology, Nantes University Hospital, Nantes, France, ²Rheumatology, La Roche-Sur-Yon Hospital, La Roche-Sur-Yon, France, ³Rheumatology, Rennes University Hospital, Rennes, France

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Metabolic and Crystal Arthropathies – Basic and Clinical Science Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Rotator cuff calcific tendinopathy is a common condition causing up to 20% of the painful shoulder. Ultrasound-guided percutaneous lavage (UGPL) is indicated after failure of conservative treatments. Steroids injections in the subacromial bursa (SAB) are usually performed after the lavage to prevent the pain induced by the procedure. However, some suggested that this injection could prevent the inflammatory reaction leading to the disappearance of the calcific deposit. Moreover, its efficacy to prevent post-procedure pain has never been demonstrated. The purpose of the study was to evaluate the effect of a steroid injection in the SAB after UGPL on the pain and the radiographic evolution of the calcification.

Methods: This was a multicentric prospective double-blind randomized controlled study. We included patients with shoulder pain for more than 3 months and a type A or B calcification > 5 mm on X-Ray. Patients were treated with UGPL and, at the end of the procedure, they received a blind injection of either 2 mL of methylprednisolone acetate or 2 mL of serum saline (placebo group). The primary outcome was the maximal VAS pain (0-100) the first week following UGPL. Secondary outcomes were the evolution of VAS pain at 7 days, 6 weeks, 3 months, 6 months and 12 months and the radiographic changes of the calcification during the follow-up.

Results: We included 132 patients: mean age was 49.8 (+/-9.7) years and 89 were females (67.4%). Mean size of the calcification was 1.5 cm (+/- 0.5) and calcifications mainly involved the supraspinatus (86%). Backflow of calcific material was obtained in 107 patients (81.1%). Maximum pain during the first week following UGPL was 71.5 [CI95%:63.9-79.20] in the serum saline group versus 59.8 [CI95%:52.2-67.41] in the steroid group with a mean difference of 11.7 [CI95%:3.7-19.7]. More patients in the placebo group needed to take NSAID (12.1% versus 6.1%) and paracetamol (16.7% versus 9.1%) during the first week. VAS pain during activities decreased significantly more in the steroid group compared to the placebo between the baseline and 3 months while VAS pain was similar at 6 and 12 months (Figure 1). At 12 months, no difference was found in the radiographic evolution: 61.9% of the patients treated with steroid and 65% treated with placebo had more than 50% of resorption of their calcification and complete disappearance of the calcification was obtained in 46% of the steroid group versus 40% of the placebo group.

Conclusion: Our study shows that steroid injection in the SAB leads to a significant decrease of maximal pain during the following week. This treatment also decreases significantly the pain during the 3 first months after UGPL. Importantly, we

found no difference between the 2 groups in the radiographic evolution of the calcification at 12 months. Overall, steroids injections in the SAB can be recommended after UGPL.

Serum Urate Ant Its Clearance in Patients with Chronic Kidney Disease Under Peritoneal Dialysis

Claudia Diez¹, Javier Pérez-Contreras^{1,2} and **Mariano Andrés**^{1,3}, ¹Departamento de Medicina Clínica, Universidad Miguel Hernández, Alicante, Spain, ²Servicio de Nefrología, Hospital General Universitario de Alicante-ISABIAL, Alicante, Spain, ³Sección de Reumatología, Hospital General Universitario de Alicante-ISABIAL, Alicante, Spain

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Metabolic and Crystal Arthropathies – Basic and Clinical Science Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Hyperuricemia and gout are common in patients with chronic kidney disease (CKD), some ultimately requiring replacement therapy. Serum urate (SU) levels appear to achieve proper control under hemodialysis [1], making urate-lowering drugs (ULD) unnecessary in this setting. Scant data is available for peritoneal dialysis (PD). The aim of the present study was to assess SU levels and urate clearance in patients with CKD under PD.

Methods: A cross-sectional, monocentric study was performed, enrolling all twenty subjects followed in a PD unit during the study period (2018 Jan-Feb). Treatment modalities employed were continuous ambulatory peritoneal dialysis (CAPD) [n=6]; night intermittent peritoneal dialysis (NIPD) [n=3]; and continuous cyclic peritoneal dialysis (CCPD) [n=11]. Blood, 24h urine and dialysis fluid tests were requested in order to measure SU levels (primary outcome variable) and to estimate urate clearance (total, renal, and peritoneal) and residual kidney function (RKF), according to current guidelines [2]. Hyperuricemia was considered as SU >6.8mg/dl. Demographic, clinical and PD-related variables were also collected to assess factors associated with being on SU target (<6.0 mg/dl). For outcome variables, 95% confidence intervals (95%CI) were estimated, and non-parametric tests (Mann-Whitney U's, Kruskal-Wallis, chi-square, and Fisher's exact) were used to evaluate associations.

Results: Median (IQR) age was 53.5 years (42.3-63.3), being 65% men. Sixty-five percent were on furosemide, and median RKF was 4.7 ml/min/1.73m² (2.1-5.8). Half of subjects were hyperuricemic before initiating PD, only three (15%) reported gout. Urate-lowering drugs (ULD) were currently used in nine patients (45%), mostly allopurinol (n=8, at 100-150 mg/d), febuxostat in one (40 mg/d). In the sample, median SU levels were 5.4 mg/dl [95%CI 4.8-6.0], being 90% <6.8 mg/dl, and 80% <6.0 mg/dl. SU levels did not statistically varied according to the use of ULD (5.6 vs 4.2 mg/dl respectively, p=0.056). Median peritoneal urate clearance was 3.0 ml/min/1.73m² [95%CI 2.5-3.5], that accounted for 71.4% of total urate clearance (4.2 ml/min/1.73m², 95%CI 3.6-4.6). Explanatory variables that significantly associated with a SU on target were peritoneal urate clearance (3.2 vs 2.0 ml/min/1.73m², p=0.006), RKF (4.0 vs 6.4 ml/min/1.73m², p=0.032), and the use of CCPD modality (100% vs 0%, p=0.008). CCPD modality also showed significantly higher peritoneal urate clearance compared to CAPD and NIPD (3.7, 2.7, and 1.3 ml/min/1.73m², respectively, p=0.011).

Conclusion: Most CKD patients under PD showed SU levels on target, suggesting that PD is effective for hyperuricemia management. ULDs appear then unnecessary in this setting. The CCPD modality showed the best results in terms of urate levels and its clearance, finding that may be of interest for CKD patients with gout.

Session Date: Tuesday, October 23, 2018

Session Title: Metabolic and Crystal Arthropathies – Basic and Clinical Science Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: A recent US Medicaid study found that in addition to certain races (Asians and Blacks), older age, female sex, chronic kidney disease (CKD), and initial allopurinol dose >100 mg/day are associated with a higher risk of hospitalized allopurinol-associated severe cutaneous adverse reactions (AASCARs) (*Ann Rheum Dis* 2018). We aimed to replicate these findings in a general population database from another country (Canada) and expand our investigation for an independent role of cardiovascular disease (CVD) on the risk of AASCARs.

Methods: We used Population Data BC, a population-based administrative database that covers the entire general population of British Columbia, Canada, to identify incident allopurinol users between 1999 and 2012. We examined the risk of hospitalized AASCARs according to purported key risk factors and used Poisson regression models to calculate relative risks (RR), adjusting for purported risk factors for AASCARs (**Table**).

Results: Among 451,897 allopurinol initiators, we documented 110 hospitalized AASCAR cases (mean age, 62 years; 71% male) during a mean follow-up of 3 months. The risk of hospitalized AASCARs was apparent within 10 days of allopurinol initiation, peaked around one month after initiation, and declined progressively thereafter, reaching its nadir at the end of the third month (**Figure**). Of the 110 cases, 10 (9%) died during hospitalization. The overall risk of hospitalized AASCARs was 1 out of 1185 allopurinol initiators (**Table**). Female sex, older age (>60 years), CKD, and initial allopurinol dose (>100mg/day) were independently associated with a 2.6-, 1.5-, 1.7-, and 2.8-fold higher risk of AASCARs, respectively (**Table**). CVD was associated with a 2.5 higher risk of AASCARs after adjusting for other risk factors (RR, 2.45; 95% CI, 1.59 to 3.77), whereas diuretic use, a previously suspected risk factor, was not (RR, 1.05; 95% CI, 0.69 to 1.60) (**Table**).

Conclusion: This general population-based cohort study confirms the independent role of older age, female sex, CKD, and initial allopurinol dose (>100 mg/day) in predicting a higher risk of AASCARs. Furthermore, having CVD is also strongly

associated with an increased risk of AASCARs, independent of these risk factors. These factors should be considered when initiating allopurinol to help prevent this extremely severe and potentially fatal adverse reaction.

Table 1 Risk of Hospitalized Allopurinol-Associated Severe Cutaneous Adverse Reactions According to Purported Risk Factors

Risk Factor	Allopurinol Initiators, N (%)	Hospitalized SCARs, N	Risk of Hospitalized AASCARs (/1000 persons)	Age-, Sex-Adjusted Relative Risk	Multivariable Relative Risk

Update of SEL-212 Phase 2 Clinical Data in Symptomatic Gout Patients: Svp-Rapamycin Combined with Pegadricase Mitigates Immunogenicity and Enables Sustained Reduction of Serum Uric Acid Levels, Low Rate of Gout Flares and Monthly Dosing

Earl Sands¹, Alan J. Kivitz², Wesley DeHaan¹, Lloyd Johnston¹ and Takashi Kei Kishimoto¹, ¹Selecta Biosciences, Watertown, MA, ²Altoona Center for Clinical Research, Duncansville, PA

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Metabolic and Crystal Arthropathies – Basic and Clinical Science Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Pegylated uricases are promising therapies for the treatment of severe chronic gout, but are limited by their immunogenicity. We have previously shown that synthetic vaccine particles encapsulating rapamycin (SVP-R) co-administered with pegadricase (also known as pegsiticase) prevented the formation of ADAs in a dose-dependent manner. A Phase 1 study of SEL-212, a novel combination product consisting of pegadricase and SVP-R, demonstrated sustained control of serum uric acid (sUA) for at least 30 days after a single dose. Here we report data on the safety, tolerability, and effects on sUA, ADAs, and gout flares of repeated monthly doses of SEL-212 in symptomatic gout patients treated with 0.125 or 0.15 mg/kg SVP-R in combination with 0.2 or 0.4 mg/kg pegadricase.

Methods: Patients with symptomatic gout (≥1 tophus, gout flare within 6 months, and/or gouty arthropathy) and elevated sUA (sUA≥6 mg/dL) were enrolled in SEL-212 treatment cohorts. Patients reported here received three monthly doses of

SEL-212 (0.2mg/kg or 0.4mg/kg pegadricase combined with 0.125 or 0.15 mg/kg SVP-R) followed by two monthly doses of pegadricase alone. Safety, tolerability, sUA, and ADAs were monitored, and clinical data were collected.

Results: As of 1 June 2018, 143 patients had been dosed in the Phase 2 study. Approximately 81% of evaluable patients receiving 0.125 or 0.15mg/kg SVP-R administered with either 0.2 or 0.4 mg/kg pegadricase maintained serum uric acid levels substantially below 6 mg/dl at week 12 after three monthly doses of SEL-212. The sustained reduction of sUA correlated with low or no ADAs. SEL-212 was generally well tolerated and associated with a low rate of gout flare rates. Thirty-three percent of evaluable patients treated with 0.125-0.15mg/kg SVP-R, and only 27% of all current patients in the SEL-212 Phase 2 trial, experienced gout flares after initiation of first treatment with continued reduction of gout flare rates over months two through five. This low rate of gout flares appears to be in contrast with higher incidence of gout flares reported in clinical trials involving other urate lowering therapies.

Conclusion: SEL-212 has been well-tolerated, showing substantially reduced immunogenicity, sustained control of sUA, and low rate of gout flares with repeated monthly dosing.

Increased Cost Burden in an Early Diagnosed Cohort of Uncontrolled Versus Controlled Gout: Analysis of a Large US Payer Database

Brian LaMoreaux¹, Megan Francis-Sedlak² and Robert J Holt², ¹Horizon Pharma USA, Inc, Lake Forest, IL, ²Horizon Pharma USA, Inc., Lake Forest, IL

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Metabolic and Crystal Arthropathies – Basic and Clinical Science Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Gout is a progressive systemic inflammatory disease that is widely prevalent, estimated to effect 3.9% or 8.3 million people of the United State (US) population. The underlying pathogenic feature of gout is hyperuricemia, and appropriate management of gout requires achieving uric acid levels at a minimum of <6 mg/dL to mobilize and clear deposited urate. Uncontrolled gout patients who fail to reach serum uric acid(sUA) level goals do worse in terms of clinical outcomes including gout flares and resolution of visible tophi. Herein, we quantify the cost burden for uncontrolled versus controlled gout patients from a large US payer de-identified database.

Methods: A retrospective review of Humana Healthcare data from 2007 to 2016 in private pay and medicare patients was performed for patients with gout diagnosis codes (ICD9/10) to identify patients with at least 1 gout diagnosis (N=539,802) and 90 days of continuous urate-lowering therapy within 1 year of diagnosis. Two cohorts of patients were categorized according to their sUA levels after at least 90 days of gout therapy: sUA<6.0 mg/dL(controlled) and sUA ≥8 mg/dL (uncontrolled). Patients must have had more than 1 serum uric acid test to be included.

Results: The controlled gout group (sUA<6 mg/dL)included 5,473 patients and the uncontrolled gout group (sUA≥8 mg/dL) had 1,358 patients. The two groups were comparable in terms of demographic features, though the controlled group was slightly younger with an adjusted mean age of 72.5 years compared to mean age of 69.1 in the uncontrolled patients. Costs were higher among the patients in the uncontrolled gout group (**figure 1**). Among total costs, the controlled group mean/patient/year was \$14,892 as compared to the uncontrolled gout patients of \$23,339 (p<0.0001). The cost difference was primarily driven by increased hospital costs within the refractory group, where the cost was \$7,255/patient/year greater than the controlled group (p<0.0001, **figure 1**).

Conclusion: Accepted guidelines for gout management recommend treating to uric acid levels of <6 mg/dL for all patients and <5 mg/dL for tophaceous or symptomatic patients. This analysis sought to quantify costs associated with uncontrolled hyperuricemia (≥8 mg/dL) in early diagnosed gout patients, and found that uncontrolled gout patients had significantly higher per-patient mean total costs and costs from hospitalizations. This disparity may likely be greater in patients with long-standing gout. This finding suggests an increased financial burden associated with uncontrolled gout, and warrants further study.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster III: Sarcoid, Inflammatory Eye Disease, and Autoinflammatory Disease

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: NMOSD are autoimmune disorders characterized by optic neuritis (ON), longitudinal extensive transverse myelitis (LETM), and other clinical features. Aquaporin 4 antibodies (AQP4 Ab) have enhanced diagnostic

accuracy of NMOSD. We aimed to characterize the clinical features, diagnostic laboratory and imaging studies of NMOSD in our Afro-Caribbean patient population to identify associated autoimmune disorders.

Methods: Retrospective chart review of patients ≥ 18 years of age, with a diagnosis of multiple sclerosis, optic neuritis, acute transverse myelitis and NMOSD at 2 urban hospitals from 1/2005 to 4/2017. Demographics, clinical presentation, laboratory, imaging and treatment data were collected to confirm NMOSD as per International Panel for NMOSD Diagnosis. Imaging studies were reviewed for NMOSD details by a Neuro-radiologist.

Results: Of the 1,227 charts reviewed, 39 patients (3.17%) met criteria for NMOSD. Of those 82.1% had positive AQP4 Abs., 87.2% were women, 84.6% were Blacks, and 38.7% had another autoimmune disease, with SLE being the most common (66.7%). ANA and anti-dsDNA were positive in 41.7% and 21.4% of the patients respectively. Motor weakness (55.3%) and visual changes (35.9%) were the most common presenting symptoms. In brain-MRI 62.8% of patients had non-specific white matter lesions, followed by T2 hyperintense lesions in optic nerve (37.1%), spindle like hemispheric lesions (34.3%), and dorsal medulla lesions (34.3%). Spine MRI revealed LETM in 48.6%, and gadolinium enhancement in 68.6% of the cases. Initial therapy included pulse CS in 53.5% followed by pulse CS-plasma exchange(PLEX) (23.1%) and pulse CS-PLEX-IVIG (7.7%). Maintenance therapy included CS in 38.5%, followed by CS-AZA (17.9%) and CS-MMF (10.3%). Four cases received Rituximab after initial therapy. 89.4% of the patients had follow-up imaging. Among the 7 cases of AQP4 negative NMOSD patients, M:F ratio was 2:5, and only 14.3% had other autoimmune diseases, tended to have a lower disability score when compared to AQP4 positive patients, and 50% had optic nerve involvement.

Conclusion: NMOSD prevalence in our population was higher (3.2% vs. 1.5%) than previously reported among patients with suspected inflammatory demyelinating disease. Black middle age women were most frequently affected. SLE was the most prevalent rheumatic disease present prior to NMOSD diagnosis in the majority of the cases. AQP4 seronegative cases had higher male ratio, less association with autoimmune diseases, lower disability scale score and less abnormalities on MRI except for optic nerve involvement.

Ong⁴, ¹Centre of Rheumatology and Connective Tissue Diseases, University College London, London, United Kingdom, ²Department of Rheumatology, Royal Free Hospital, London, United Kingdom, ³UCL Division of Medicine, Royal Free Campus, London, United Kingdom, ⁴Division of Medicine, University College London, London, United Kingdom

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster III: Sarcoid, Inflammatory Eye Disease, and Autoinflammatory Disease

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Lung involvement is common in both sarcoidosis (up to 90%) and autoimmune rheumatic diseases (ARDs). Case reports have suggested distinct clinical manifestations when sarcoidosis is diagnosed with other ARDs. However clinical and serological manifestations have not been described in larger cohorts.

Methods: A retrospective medical chart review of patients attending our centre with a diagnosis of sarcoidosis and ARD. ARD was classified as systemic sclerosis (SSc), lupus, myositis or inflammatory arthritis (IA). Organ manifestations were further classified into sarcoid or ARD as the main pathology. Comparison was made between the SSc/sarcoid cohort and other ARD/sarcoid cohort. Statistical analysis of organ involvement was performed using Fisher exact test.

Results: 61 patients (17 males) with overlap sarcoid and ARD were identified, with 5 patients having more than one ARD diagnosis. The mean time lag between sarcoid diagnosis to ARD diagnosis was 51 months (median 71 mths) (range -432 to 372 mths). Sarcoid predates diagnosis of ARD in 68.8% cases.

The majority of patients had an overlap diagnosis of SSc(n=22, 36.1%), of those 77.3% were limited SSc. In the SSc/sarcoid cohort, 92% patients were ANA positive, 35% Scl70 positive, and 21% ACA positive.

In the ARD/sarcoid cohort, the most frequent overlap diagnosis was IA (72%). 23% were ANA positive, 35.8% rheumatoid factor positive, and 30.8% anti-CCP positive.

The frequency of major organ involvement was statistically different for lung disease, arthritis and sarcoid-skin involvement between SSc/sarcoid and ARD/sarcoid cohorts. A trend of increased frequency of pulmonary hypertension in SSc/sarcoid cohort was observed (table 1).

Further evaluation of interstitial lung disease (ILD) highlighted, overall 32% was attributable to sarcoid, and 19% related to ARD. In the SSc/sarcoid cohort, 22% had features of sarcoid ILD (bronchovascular beading or pulmonary nodularity), 45.5% had ILD consistent with SSc (non-specific interstitial pneumonia (NSIP)). In contrast, 38% of the ARD/sarcoid cohort had sarcoid predominant ILD (peribronchovascular beading, pulmonary nodules, and cystic lung disease), and 5% had ARD ILD (NSIP-ILD, and organising pneumonia). Baseline FVC was not different between SSc/sarcoid and ARD/sarcoid ILD cohorts (91.6% and 86.2% respectively).

Conclusion: We report the largest cohort to date of patients with a concomitant diagnosis of sarcoidosis and ARD from a single centre cohort. Our data suggest that lung involvement in overlap SSc/sarcoid is less frequent than expected for each disease in isolation. The significant difference between arthritis between the SSc/sarcoid group and ARD/sarcoid group is likely due to the high proportion of IA in the latter group.

Our results highlight the importance of recognising concurrent sarcoidosis in multisystem ARD, especially as this may affect treatment and outcome.

Table 1 Frequency of key organ involvement for SSc/Sarcoid and ARD/Sarcoid

Organ involvement	SSc/Sarcoid (n)		ARD/Sarcoid (n)		Fisher exact test (p=)
	SSc	Sarcoid	ARD	Sarcoid	
hilar lymph node (LN)	0	14	0	25	1

Abstract Number: 2258

Defining Characteristics of Patients with Overlap between Sarcoidosis and Connective Tissue Diseases

Mugdha Agrawal and Colin Ligon, Department of Medicine; Division of Rheumatology, University of Pennsylvania, Philadelphia, PA

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster III: Sarcoid, Inflammatory Eye Disease, and Autoinflammatory Disease

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Sarcoidosis has been suggested to occur with connective tissue diseases (CTDs) more frequently than would be expected by chance, but the types, relative timing, and prognosis of the associated CTDs are not well-described. The objective of this study is to define relative timing of sarcoidosis with CTD to determine whether one could predispose to another. Our secondary objectives are patient demographics, medication triggers, antibody profiles and frequency of overlap with each CTD. We analyzed a large institutional retrospective cohort of patients with overlapping CTD and sarcoidosis, to identify and explore these features.

Methods: For this descriptive study using retrospective chart review we identified patients with a dual diagnosis of sarcoidosis and one of 6 other CTDs (RA, SLE, inflammatory myositis, SpA, SSc or Ss) seen within the Division of Rheumatology from October 2015 to October 2017 in our health system, using ICD-10 codes. These were manually validated by chart review. If patients did not have a diagnosis of CTD and/or sarcoidosis confirmed by Rheumatology or lacked data to validate both of these diagnoses by ACR classification, they were excluded.

Results: 66 charts matched our query and on individual review, 33 patients fulfilled our criteria. 70% of our patients were female and 64% were black. Mean age at diagnosis of CTD was 46 (SD 16.4) years and of sarcoidosis was 44 (14.4) years. There was no predisposition towards development of sarcoidosis or CTD first ($p=0.6$). 58% (19) of patients had RA, 15% (5) had SLE, 15% (5) SSc, 9% (3) SpA, and 3% (1) myositis. 12% (4) of patients had secondary Ss. Lung was the most common organ involved with sarcoidosis (88%); 58% of patients had Scadding stage I disease, and only 1 (3%) had stage IV disease. The odds of single organ sarcoidosis were not different whether the CTD or sarcoidosis was diagnosed first ($p=0.7$); the order of diagnosis did not predict sarcoidosis remission ($p=0.3$). There was a high prevalence of positive ANA throughout the cohort (73% of the 24 with available data). Of 29 patients with data, RF was present in 9 (45%) patients with RA, versus 1 (11%) of patients without RA ($p=0.1$). TNF-alpha inhibitor induced sarcoidosis developed in two patients with RA and one with SpA.

Conclusion: The timing of CTD and sarcoidosis development in this cohort does not argue for a strong effect of CTD predisposing to sarcoidosis or vice versa, and the clinical course of sarcoidosis is similar whether diagnosed before or after the CTD. RA was most commonly associated with sarcoidosis. A High prevalence of Scadding Stage I disease may point to a close link of sarcoidosis with inflammatory disease, as does a high prevalence of ANA and RF across the cohort. Further information from a case control study is needed to draw generalizable conclusions.

Disclosure: M. Agrawal, None; C. Ligon, None.

Session Date: Tuesday, October 23, 2018

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster III: Sarcoid, Inflammatory Eye Disease, and Autoinflammatory Disease

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Osseous manifestations of sarcoidosis are uncommon. We aimed to characterize clinical presentation, distribution of lesions, treatment, and outcomes of bone sarcoidosis.

Methods: A French retrospective multicenter study of patients with biopsy-proven sarcoidosis and osseous manifestations was analyzed. Inclusion criteria for sarcoidosis with bone involvement were 1) a biopsy-proven granuloma without caseous necrosis and either 2) bone clinical manifestations or 3) abnormal bone imaging. Musculoskeletal involvement with isolated joint or muscular manifestations was excluded. Sarcoidosis patients with bone involvement (patients) were compared to 264 age- and sex-matched patients with a biopsy-proven sarcoidosis and no bone manifestations (controls).

Results: In bone sarcoidosis group (n=88), the median age [IQR] at sarcoidosis diagnosis was 41 [34-51] years, and 44 (50%) patients were women. Forty two out of 88 (48%) patients had bone related symptoms, involving mainly axial (69%) and/or appendicular (58%) skeleton. On imaging, spine was the most commonly affected bone (52%), followed by pelvis (42%), hands (22%) and femur (19%). Bone biopsy showed granuloma without caseous necrosis in 17/25 (68%) patients. Compared to controls, bone sarcoidosis patients had higher rates of mediastinal (93% vs 47%, $P < 0.0001$) and extra-thoracic lymph node (66% vs 21%, $P < 0.0001$), and pulmonary (90% vs 65%, $P < 0.0001$) and cutaneous involvement (44% vs 23%, $P < 0.0001$). Gastro-intestinal involvement was less frequent in bone sarcoidosis group (1% vs 17%, $P < 0.0001$). Hypercalcemia was observed in 8.5% of patients compared to 2% of controls ($P=0.014$). Seven patients did not receive specific treatment for bone sarcoidosis. Glucocorticoid was used in 63/81 (78%) patients, alone in 44 patients, and associated with methotrexate in 13 patients or hydroxychloroquine in 6 patients. Rates of clinical and/or radiological response of bone sarcoidosis were 23/44 (52%), 9/13 (70%) and 4/6 (67%), respectively.

Conclusion: In patients with bone sarcoidosis, spine and pelvis were the most commonly affected bones. Patients with bone sarcoidosis compared to sarcoidosis patients with no bone involvement have higher rates of thoracic and extra-thoracic lymph node, pulmonary, cutaneous involvement and hypercalcemia. Most patients with bone sarcoidosis had a good response to glucocorticoids used alone or in association with methotrexate or hydroxychloroquine.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster III: Sarcoid, Inflammatory Eye Disease, and Autoinflammatory Disease

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Sarcoidosis, a systemic disease characterized by non-caseating granulomas within the affected organs. Less than 10% of cases manifest as musculoskeletal (MSK) involvement of joints, muscles and bone tissue. Common first line therapies for MSK sarcoidosis are NSAIDs and systemic steroids. Due to its rarity, studies assessing clinical presentation and therapeutic efficacy of disease modifying drugs are rare.

We aim to determine prevalence of MSK sarcoidosis at University of Iowa Hospitals and clinics, describe epidemiologic and clinical characteristics of MSK sarcoidosis and describe various therapeutic agents and their outcomes in our cohort.

Methods: We conducted an IRB-approved, retrospective electronic medical records (EMR) search using ICD-9 codes for sarcoidosis followed by review of individual records to identify patients with MSK sarcoidosis between January 1, 2000 and December 31, 2014.

MSK sarcoidosis cases were based on:

a. Lofgren syndrome, or : b. biopsy-proven sarcoidosis and chronic arthritis not attributed to other causes, or

c. biopsy-proven sarcoidosis of MSK tissue (bone, muscle). : Clinical data from the MSK sarcoid cases was then entered into a standardized questionnaire created in REDCap. Statistical analysis was done using REDCap.

Results: Among 1016 patients with sarcoidosis, 58 patients met the inclusion criteria, making the prevalence 5.70%. Epidemiological and clinical characteristics were as follows: Mean age (47.21 years); Female (74.14%); Caucasian (82.76%), African American (10.34%), Lofgren syndrome (46.55%), chronic arthritis (24.14%), osseous sarcoid (25.86%), myopathy (6.90%) (Figure 1). Most commonly involved sites in Lofgren syndrome was ankle (96.30%), in chronic arthritis

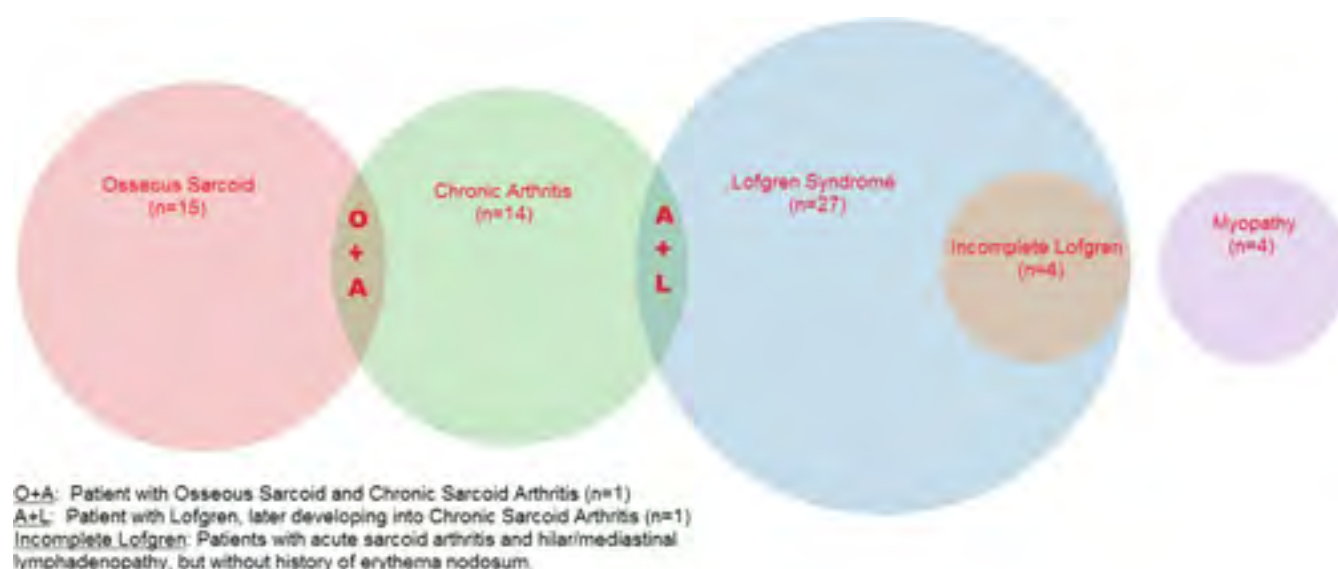

Figure 1. Venn diagram showing distribution of various MSK sarcoidosis manifestations in our cohort.

was finger joints (71.43%), in Osseous sarcoid was pelvis (53.33%), in Myopathy was proximal upper and lower extremity muscles.

Treatment was considered not necessary in 14.81% with Lofgren syndrome and 26.67% with osseous sarcoid. Most commonly used medication was prednisone (59.26% Lofgren, 57.14% chronic arthritis, 60% osseous, 75% myopathy). Methotrexate was the most commonly (25.86%) used DMARD. Biologics (anti-TNF agents) were used for chronic arthritis (n=1), osseous sarcoid (n=1) and myopathy (n=1).

Conclusion: To our knowledge, this is the largest case series describing all forms of MSK sarcoidosis in the US since 1984. MSK sarcoidosis appears to be seen in a small fraction of patients with sarcoidosis, with Lofgren syndrome being the most frequent and myopathy least frequent MSK manifestation. Ankle was most commonly involved in Lofgren and finger joints in chronic arthritis. Osseous sarcoid was seen most commonly in pelvis. Prednisone was most commonly used medication and methotrexate was the most commonly used DMARD across all forms of MSK sarcoidosis. Anti-TNF medications were used in a small minority of patients.

Long-term Outcome of Pulmonary Sarcoidosis: A Population-Based Cohort Study from 1976-2013

Background/Purpose: A hallmark of sarcoidosis is lung disease, which has variable expression. This study was undertaken to better understand the course of pulmonary sarcoidosis.

Methods: A cohort of 311 incident cases of pulmonary sarcoidosis in a geographically well-defined population from 1976-2013 was identified from the comprehensive medical record-linkage system. Diagnosis of sarcoidosis required physician

diagnosis supported by biopsy showing non-caseating granuloma, radiographic evidence of intrathoracic sarcoidosis and compatible clinical presentations without evidence of other granulomatous diseases. Medical records of the confirmed cases were reviewed from diagnosis to last follow-up. Data on stage of pulmonary sarcoidosis at diagnosis, serial pulmonary function tests (total lung capacity [TLC], forced vital capacity [FVC], forced expiratory volume in 1 second [FEV1] and diffusing capacity for carbon monoxide [DLCO]), requirement of oxygen therapy and treatment were abstracted. The cumulative incidence of chronic respiratory impairment (defined as FVC of <50%, DLCO of <40% or requirement to use oxygen supplementation) adjusted for the competing risk of death was estimated. Cox models were used to assess the association of stage of pulmonary sarcoidosis and treatment on the development of chronic respiratory impairment.

Results: The means of PFT measures at baseline in this cohort were 97.1%, 95.3%, 91.4% and 91.1% of predicted values for TLC, FVC, FEV1 and DLCO, respectively. At 5 years, the mean percentage predicted for TLC, FVC, FEV1 and DLCO declined by 1.6%, 3.5%, 4.3% and 3.1%, respectively. A total of 25 patients developed chronic respiratory impairment which corresponded to 10 year event rate of 4.4% (95% confidence interval [CI], 1.9%–6.9%) as demonstrated in figure 1. Stage of pulmonary sarcoidosis at diagnosis was a strong predictor for chronic respiratory impairment with hazard ratio (HR) compared with stage I of 5.29 (95% CI, 1.65–16.96) for stage II and 8.36 (95% CI, 26.3–26.52) for stage III and IV. Use of glucocorticoids and immunosuppressive agents was associated with a significantly increased risk of chronic respiratory impairment (HR 4.60; 95% CI, 1.94–10.88 and HR 5.13; 95% CI, 1.47–17.86, respectively). However, it is unlikely that treatment with glucocorticoids/immunosuppressive agents had a deteriorative effect on pulmonary function. It is more likely that use of these medications is simply an indicator of more severe disease.

Conclusion: Patients with pulmonary sarcoidosis have a good pulmonary prognosis with a low incidence of chronic respiratory impairment.

Figure 1: Cumulative incidence of chronic respiratory impairment among 311 patients with pulmonary sarcoidosis

Increased Risk of Sarcoidosis among Patients with Celiac Disease: A Systematic Review and Meta-Analysis

Abstract:

Background/Purpose: Several epidemiologic studies have suggested that patients with celiac disease may have an increased risk of sarcoidosis but the results were inconsistent. This systematic review and meta-analysis was conducted with the aim to better characterize this risk by summarizing all available data

Methods: A literature review was performed using MEDLINE and EMBASE database from inception to April 2018 using the search strategy that included the terms for sarcoidosis and celiac disease. Cohort studies or case-control studies that compared the risk of sarcoidosis among patients with celiac disease versus individuals without celiac disease were included. For cohort studies, cases must be patients with celiac disease, comparators must be individuals without celiac disease and the outcome of interest must be incident sarcoidosis. For case-control studies, cases must be patients with sarcoidosis, controls must be individuals without sarcoidosis and the exposure of interest must be celiac disease. Point estimates and standard errors of the included studies were extracted and the pooled odds ratio (OR) and 95% confidence interval (CI) were calculated using a random-effect, generic inverse variance method of DerSimonian and Laird.

Results: Of 375 retrieved articles, a total of 4 studies (2 cohort studies and 2 case-control studies) with 693,639 participants met the eligibility criteria and were included into the meta-analysis. The risk of sarcoidosis among patients with celiac disease

was significantly higher than individuals without celiac disease with the pooled OR of 7.16 (95% CI, 1.48 – 34.56). The statistical heterogeneity of this study was high ($I^2=95\%$). The forest plot of this meta-analysis is shown as figure 1.

Conclusion: This systematic review and meta-analysis found a significantly higher risk of sarcoidosis among patients with celiac disease.

Session Information

Session Date: Tuesday, October 23, 2018
Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster III: Sarcoid, Inflammatory Eye Disease, and Autoinflammatory Disease
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: To analyse the correlation between Scadding radiological stages and the main phenotypic features at diagnosis (epidemiology, clinical patterns at presentation, extrathoracic disease and need for initial systemic therapy) in one of the largest cohorts of patients with sarcoidosis reported from Southern Europe.

Methods: The SARCOGEAS-Study Group was formed in 2015 including a multicenter database of consecutive patients diagnosed with sarcoidosis according to the WASOG 1999 criteria. Extrathoracic disease at diagnosis was defined according to the 2014 WASOG organ assessment instrument and the extrathoracic clusters proposed by Schupp et al.

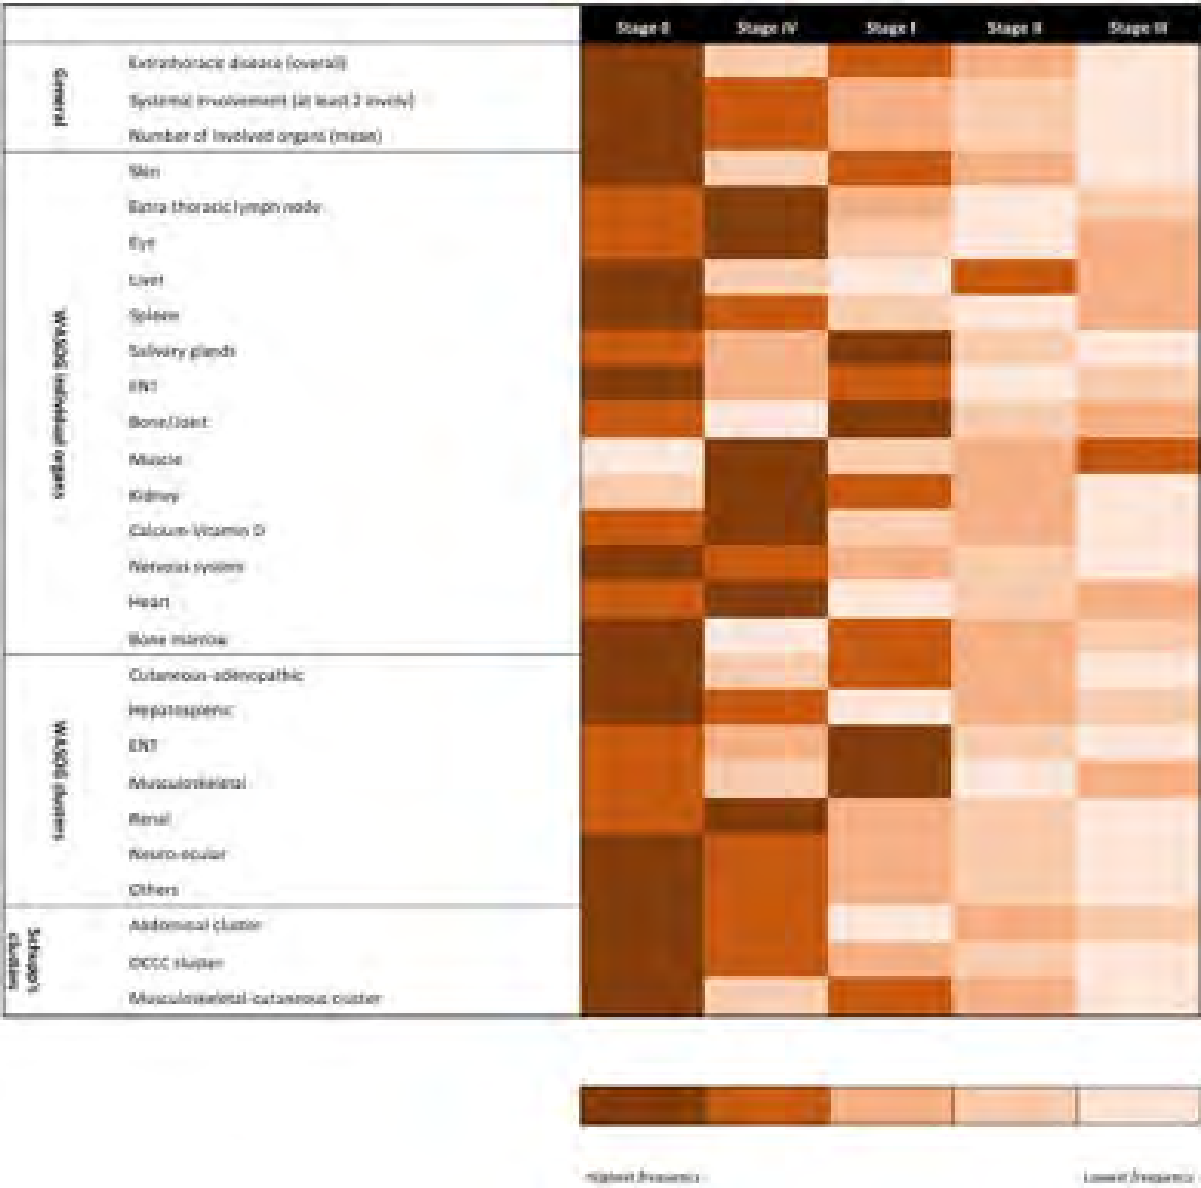

Figure 1.

Results: 1230 patients were finally analysed (712 women, mean age 47.3 yrs). Scadding radiologic stage at diagnosis consisted of stage 0 in 98 (8%) patients, stage I in 395 (32%), stage II in 500 (41%), stage III in 195 (16%) and stage IV in 42 (3%) patients. Epidemiologically, age at diagnosis was clearly linked with the Scadding stage, with younger mean ages being reported for stages I and II ($p=0.001$). With respect to extrathoracic disease, the highest frequencies of the organ-by-organ WASOG involvements are reported in stage 0 (skin, liver, spleen, ENT, nervous system and bone marrow), stage I (salivary glands, bone/joint) and stage IV (extra-thoracic lymph node, eye, kidney, calcium-vitamin D and heart) (**FIGURE 1**). The three SchappOs extrathoracic clusters are overrepresented in stage 0. Patients with stage IV had the highest frequencies of both need of and aggressiveness of therapy, while patients with stage I had the lowest frequencies. Pulmonary fibrosis was related to a higher mean age at diagnosis (55 vs 47 yrs, $p<0.001$), a higher mean number of extrathoracic organs involved (1.5 vs 1.1, $p=0.045$), a higher frequency of calcium/vitamin D WASOG involvement (17% vs 7%, $p=0.047$) and a higher frequency of need for therapy (81% vs 49%, $p<0.001$); no statistically-significant differences were found between the stages II and III.

Conclusion: We found a significant association between Scadding stages and sarcoidosis phenotype at the time of diagnosis, including epidemiological profile, extrathoracic involvement and initial therapeutic management. However, the key determinant in phenotyping the disease at diagnosis was the involvement of each organ more than the classification using the Scadding stages.

Methotrexate in the Treatment of Granulomatous Mastitis: A Retrospective Review of 19 Cases

Anna Postolova¹ and Mark C. Genovese², ¹Department of Medicine, Stanford University Medical Center, Palo Alto, CA, ²Department of Medicine, Stanford University, Palo Alto, CA

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster III: Sarcoid, Inflammatory Eye Disease, and Autoinflammatory Disease

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Granulomatous Mastitis is a rare, inflammatory disease of the breast. Presenting symptoms in the breast can be unilateral or bilateral pain, masses, skin induration, erythema, discharge, and abscess formation. Few patients experience self-limited disease over 1-2 years, while most have a longer relapsing course. Imaging modalities such as mammography, ultrasonography, and magnetic resonance imaging (MRI) help characterize lesions, but definitive diagnosis requires histologic examination of tissue via biopsy. Frequently used treatment modalities include antibiotics, prednisone, and surgery, which are often ineffective and fraught with recurrence rates of 50%. This study describes the largest granulomatous mastitis cohort to date in the Americas and Europe with an emphasis on the efficacy of methotrexate treatment.

Methods: Institutional Review Board (IRB) approval was obtained from Stanford University. The Stanford Translational Research Integrated Database Environment (STRIDE) was queried using the terms “granulomatous mastitis” and “rheumatology” and “methotrexate” or “prednisone” from 2006-2017. Inclusion criteria included histopathologically-established granulomatous mastitis patients who were evaluated, treated with methotrexate, and had at least one follow up appointment at the Stanford Immunology and Rheumatology Clinic. Retrospective chart review was performed including pertinent demographic, medical, clinical, and treatment information.

Results: Of the 70 patients identified using STRIDE, 19 met the inclusion criteria. All patients were female with an average age of 33.5 years at the time of presentation. Majority were Hispanic (57.9%), followed by Asian (21.1%), African American (10.5%), and Caucasian (10.5%). The average parity at presentation was 2 children with a latency between the last pregnancy and diagnosis of 29.4 months. Presenting symptoms were unilateral in 68.4% of patients and included breast pain/tenderness (68.4%), mass/lump (47.3%), swelling (21.1%), erythema (21.1%) and induration (15.8%). Most patients had prior unsuccessful treatments with antibiotics (84.2%), incision and drainage (42.1%), prednisone (36.8%), and surgical intervention (5.3%). After three and six months of methotrexate treatment, 89.5% and 94.4% of patients noted disease improvement, respectively. In patients who were compliant with prescribed methotrexate treatment for 12-15 months, 71% achieved disease remission and were disease free on follow up ranging from 1-5 years. The average methotrexate dose in the first 12 months of treatment was 18mg PO weekly. The most common reason for termination of treatment was disease remission.

Conclusion: Our center's experience demonstrates that granulomatous mastitis presents predominately in multiparous Hispanic females of childbearing age as unilateral, painful breast masses. Methotrexate is an effective treatment modality resulting in sustained disease remission in most patients who are compliant with therapy for at least one year.

Session Date: Tuesday, October 23, 2018

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster III: Sarcoid, Inflammatory Eye Disease, and Autoinflammatory Disease

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The diagnostic workup of uveitis is a challenge due to the wide range of diagnoses and the lack of a well-codified diagnostic procedure. Underlying causes are multiple and include 3 major etiological frameworks, i.e. pure ophthalmological entities, infectious diseases, and inflammatory diseases such as sarcoidosis. However, one third of uveitis is considered of undetermined origin or idiopathic. Lumbar puncture with analysis of cerebrospinal fluid (CSF) can be included in the diagnostic workup of uveitis, especially in intermediate and/or posterior uveitis. This study aimed to assess the diagnostic interest of determination of CD4/CD8 ratio in CSF for the etiological diagnosis of intermediate and/or posterior uveitis.

Methods: We prospectively included, from May 2016 to March 2018, patients referred to our department for the diagnostic workup of intermediate and/or posterior uveitis and who underwent lumbar puncture. Patients had a complete ophthalmological examination as well as a clinical and paraclinical examination for diagnostic purposes, and lymphocyte immunophenotyping using Transfix® was also performed on CSF. Etiological diagnoses were established according to international diagnostic criteria, including IWOS criteria for sarcoidosis. Diagnoses were made in a blind manner of Transfix® results.

Results: Fifty-two patients (men 44%, median age 50 years) were included. Features of uveitis were: anterior (60%), intermediate (58%), posterior (67%), and 19 (37%) had panuveitis. The diagnosis of defined, presumed or probable sarcoidosis was made in 29% of patients while 49% of cases remained of undetermined origin. Eleven patients had other diagnoses.

Lumbar puncture was considered contributive in 10 cases (19%). Increased CSF protein (>0.4 g/L) (median 0.68 g/L, range 0.22–1.96 g/L) and lymphocytic meningitis (median 76, range 45–83) were noted in 8 cases each, respectively. The median CD4/CD8 ratio in CSF in patients with definite sarcoidosis, presumed sarcoidosis and in those with uveitis of undetermined origin were 4.50 (1.78–5.94), 4.57 (2.12–5.84) and 2.83 (0.9–8.01) ($P=0.03$), respectively. ROC curve analysis showed that the CD4/CD8 ratio threshold with the best performance was >3.56 for the diagnostic of ocular sarcoidosis with a 66.7% sensitivity, a 76.9% specificity, a 62.6% positive predictive value and a 80% negative predictive value, and an area under the curve of 0.74 (0.56–0.92). A threshold of 1.73 had a 100% sensitivity but a poor specificity of 20%. By analogy with the cut-off used in bronchoalveolar lavage fluid, CD4/CD8 ratio >3.5 had a 66.7% sensitivity, a 73.1% specificity, a 58.8% positive predictive value and a 79.2% negative predictive value for the diagnostic of ocular sarcoidosis.

Conclusion: The determination of CD4/CD8 ratio in CSF can be useful in the etiological workup of patients with intermediate and/or posterior uveitis, since a CD4/CD8 ratio >3.5 in CSF is suggestive of ocular sarcoidosis. These findings need to be confirmed on a larger patient population.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster III: Sarcoid, Inflammatory Eye Disease, and Autoinflammatory Disease

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The diagnostic workup of uveitis is challenging, with 30 to 50% of cases remaining of undetermined etiology despite multiple investigations. Sarcoid granuloma-related increase of 1,25(OH)₂D levels could be helpful for the diagnosis of ocular sarcoidosis.

Methods: Monocentric retrospective cohort study of patients for whom serum 25(OH)D and 1,25(OH)₂D levels were measured during the etiologic workup of unexplained uveitis in a tertiary referral center. The diagnoses of uveitis' underlying diseases were established according to international diagnostic criteria.

Results: Fifty-nine patients were included. The diagnosis of defined, presumed or probable sarcoidosis was made in 37% of patients while 41% of cases remained of undetermined origin. The median serum levels of 25(OH)D in patients with ocular sarcoidosis and in those with uveitis due to another cause were 34.50 [21.2–40.8] and 43.20 [32.2–58.3] nmol/L ($P=0.02$), respectively. In the same subgroups of patients, the median serum levels of 1,25(OH)₂D were 132.4 [107.4–163.9] and 108.0 [84.30–130.5] pmol/l ($P=0.02$), and the median 1,25(OH)₂D/25(OH)D ratio was 4.17 [3.11–5.09] and 2.56 [1.54–3.37] ($P=0.0007$) respectively. A 1,25(OH)₂D/25(OH)D ratio >3.5 was associated with the diagnosis of sarcoidosis with a 68% sensitivity and a 78% specificity and, in univariate analysis, was associated with an abnormal chest CT-scan (OR=5.7,

P=0.003), granulomas on bronchial biopsy (OR=14.7, P=0.007) and bronchoalveolar lavage fluid lymphocytosis (OR=12.4, P=0.0006).

Conclusion: The measurement of serum 25(OH)D and 1,25(OH)₂D levels is a useful tool in the etiological workup of patients with unexplained uveitis, since a high 1,25(OH)₂D/25(OH)D ratio is suggestive of ocular sarcoidosis.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster III: Sarcoid, Inflammatory Eye Disease, and Autoinflammatory Disease

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Sarcoidosis is a multisystemic inflammatory disease of unknown origin characterized by non-caseating epithelioid granulomas that can affect any organ system. The three most frequency affected organs are lung, skin and eyes. Ocular involvement is the presenting symptom in approximately 20-30% and can involve any part of the eye and its adnexal tissues. Sarcoidosis may cause uveitis, conjunctivitis, episcleritis/scleritis, optical nerve disease and orbital inflammation. The aim of this study was to analyze the prevalence of ocular involvement in systemic sarcoidosis in the population of Cantabria (Spain), the clinical patterns and their correlation with the IWOS criteria.

Methods: Retrospective study of patients admitted to a single reference University Hospital between 2004 and 2017 with diagnosis of sarcoidosis. Clinical findings, demographics features, anatomic location and IWOS intraocular signs were recorded. We also collected serum angiotensin converting enzyme (ACE), liver enzyme test, chest radiography, chest computed tomography scan (CT), treatment and biopsy if it was performed.

Results: We included 262 patients with diagnosis of sarcoidosis. Most of the cases were women (59%) with a median age of 44 years. The most affected organ was lung (79%), followed by skin (25%) and eye (12.2%). Thirty-two patients had ocular symptoms due to sarcoid disease and 29 of them had uveitis. There were 27 patients (84.4%) who met one of the 4 IWOS ocular sarcoidosis diagnostic categories: 15 with definite (46.9%), 9 presumed (28.1%) and 3 with possible (9.4%) sarcoidosis. Five patients did not meet IWOS criteria. The most common ocular signs were bilaterality (55.2%), snowballs or strings of pearls (51.7%), mutton-fat KPs (31%), multiple chorioretinal peripheral lesions (20.7%) and periphlebitis (13.8%). ACE increase was observed in 23% of patients with ocular sarcoidosis with a median value of 75.9. Ninety three percent of patients received oral corticosteroids, 17 a conventional immunosuppressor and 5 a biological treatment.

Conclusion: The eye is the third organ of sarcoidosis involvement. Although there is no gold standard for diagnosing ocular sarcoidosis yet, IWOS signs can help clinicians suspect it. However, there seem to be some limitations.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster III: Sarcoid, Inflammatory Eye Disease, and Autoinflammatory Disease

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: To assess the efficacy of Tocilizumab (TCZ) in refractory thyroid associated orbitopathy (TAO) due to Grave's disease.

Methods: Multicenter study of 46 patients with TAO refractory to conventional immunosuppressive therapy.

Results: We studied 46 patients (85 eyes) (37 women/9 men); mean age at diagnosis 49.2 ± 11.8 years. Besides oral corticosteroids and before the onset of TCZ, patients had been treated with pulses of intravenous methylprednisolone (n=42), radioactive iodine (n=4), methotrexate (n=2) and other drugs (methimazole in 8 cases, leflunomide in 1, azathioprine in 1, selenium in 11). Urgent decompressive surgery had to be performed in 7 patients. According to the classification of severity of the EUGOGO group (European Group on Graves' Orbitopathy) using the clinical activity score (CAS), before TCZ onset patients whose data were available had severe (n=27 eyes) or moderate (n=34 eyes) disease. Moreover, patients presented exophthalmos (n=53 eyes), strabismus (n=37 eyes), muscle fibrosis (n=38 eyes) and dysthyroid optic neuropathy (n=10 eyes). TCZ was used in monotherapy (n=43) or combined with methotrexate (n=2) or azathioprine (n=1) at 8 mg/kg/iv/4 weeks (n=41) or 162 mg/sc/week (n=5). TCZ yielded rapid and maintained improvement in all ocular parameters as shown in Table 1. After a mean of 7.42 ± 6.41 months using TCZ and a mean follow-up of 16.47 ± 11.99 months, all patients experienced ocular improvement, with TCZ withdrawal in 28 cases due to complete remission (n=10), improvement (n=12) or stability of ocular inflammation (n=3), inefficacy (n=2) and total thyroidectomy (n=1). Only 5 relevant adverse effects were observed (neutropenia, external otitis, otitis media, costal osteitis and gingival hyperplasia, 1 each).

Conclusion: TCZ appears to be useful in TAO treatment.

Table. Improvement of ocular parameters with TCZ therapy. Data are expressed as mean±SD or median[IQR].

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster III: Sarcoid, Inflammatory Eye Disease, and Autoinflammatory Disease

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Retinal vasculitis is a serious complication of uveitis due to Behcet's disease (BD). The treatment is based on corticosteroids, conventional immunosuppressants (IS) and anti-TNF- α drugs in refractory cases. We assess the short and long-term efficacy of Infliximab (IFX) in refractory retinal vasculitis of BD.

Methods: Multicenter study of 72 patients with retinal vasculitis of BD refractory to corticosteroids and at least 1 IS. Diagnosis of retinal vasculitis was realized with fluorescein angiography. We compared the efficacy of IFX between at baseline visit, and the 1st week, 3, 6 months and 1, 2, 3, 4, 5 and 6 years.

Results: We studied 72 patients/129 affected eyes (40 σ /32 φ) with a mean age of 39.65 \pm 9.75 years. HLA-B51 was positive in 63%. Before IFX onset, patients had received: oral prednisone (n=70), methylprednisolone bolus (n=28), CyA (n=56), AZA (n=43), MTX(n=34) and other conventional immunosuppressants (n=22). IFX was administered as monotherapy in 17 patients and in the remaining 55, combined with conventional immunosuppressants.

IFX was administered as follows: 3 mg/kg/4w (n=1), 3mg/kg/8w (n=4), 4 mg/kg/4w (n=1), 5 mg/kg/4w (n=12), 5 mg/kg/6w (n=16), 5mg/kg/8w (n=37) y 5.5 mg/kg/8w (n=1).

Following IFX onset, an improvement in retinal vasculitis was observed, as well as in the rest of the ocular parameters. This enhancement was maintained (**TABLE**).

After a mean follow-up of 26.58 \pm 22.10 months, IFX was discontinued in 44 patients: remission(n=15), insufficient response (n=16), preference of another route of administration (n=8), pregnancy (n=1) and side effects (n=4; 1 miliary tuberculosis, 3 local reactions).

Conclusion: IFX seems an effective and safe short and long-term treatment in retinal vasculitis of BD.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster III: Sarcoid, Inflammatory Eye Disease, and Autoinflammatory Disease

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Cystoid macular edema (CME) is the main cause of irreversible visual loss in patients with uveitis. Our aim objective was to determine the efficacy of Tocilizumab (TCZ) in Immunomediated Inflammatory Diseases (IMIDs) with EMQ and to compare with Anti-TNF drugs in refractory patients to conventional immunosuppressive therapy.

Methods: We set up a multicenter study of patients with refractory CME to traditional treatment with glucocorticoids and at least 1 conventional immunosuppressant. All patients presented OCT> 300μ at the study onset. The main objective was the improvement of macular thickness. Results were expressed as mean±S.D. for variables with a normal distribution, or as median [IQR] [25th, 75th] for those not normally distributed. The Wilcoxon signed-rank test was used to compare continuous variables and Student's t-test was used to compare both groups.

Results: We studied 59 patients (87 affected eyes). Causes of uveitis were: Behcet's disease (n=41), Birdshot's retinochoroidopathy (n=4), Juvenile Idiopathic Arthritis (n=9), Sarcoidosis (n=1) and idiopathic (n=4). 25 patients were treated with TCZ as follows: 8 mg/kg/4 weeks (n=24) and 162 mg s.c./2 weeks (n=1). Anti-TNF-α therapy was used in the remaining 34 as follows: IFX (n=12) (5 mg/kg 0, 2 y 6 weeks and then every 4-8 weeks) y ADA (n=22) (40mg/s.c./2 weeks).

No statistically differences were observed at baseline in both groups (TCZ vs. Anti-TNF-α) in sex (σ/9; 8/17 vs. 15/19; p=0.34), mean age (35.6±18.9 vs. 40.0±9.1; p=0.25), and macular thickness (470.6±159.7 vs. 451.4±128.8; p=0.57). However, we found significant differences in the number of previous biological drugs (1 [1-2] vs. 0 [0]; p<0.01) and in the duration of uveitis before biological therapy onset (112[24-198] vs. 36 [15-82]; p=0.04). Regarding main objective, we observed a rapid and sustained improvement in macular thickness after 1 year of follow-up in both groups, without objectifying significant differences between them (TABLE).

Conclusion: Regardless of the EIIM that causes uveitis, both therapies seem effective in CME refractory to conventional therapy. TCZ is also effective in anti-TNF failure.

Session Date: Tuesday, October 23, 2018

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster III: Sarcoid, Inflammatory Eye Disease, and Autoinflammatory Disease

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: To evaluate the long-term safety and efficacy of adalimumab in patients with non-infectious intermediate, posterior, or panuveitis, by immunosuppressant (IMM) use.

Methods: Adult patients who completed or had a treatment failure in the VISUAL I/II trials were eligible to enter the Phase III open-label extension study, VISUAL III. Patients received adalimumab 40 mg every other week in VISUAL III, and interim follow-up data were collected through Weeks 0 to 78. Efficacy measures assessed included proportion of patients with: no active inflammatory lesions in both eyes; anterior chamber (AC) cell grade ≤0.5+ in both eyes; vitreous haze (VH) grade ≤0.5+ in both eyes; quiescence (defined as no active inflammatory lesions AND AC cell grade ≤0.5+ AND VH grade ≤0.5+); and steroid-free quiescence. Mean steroid dose and mean best corrected visual acuity (BCVA) were also assessed. Missing data were imputed using non-responder imputation for categorical endpoints, last observation carried forward for continuous variables, and as-observed for steroid dose. Efficacy was analyzed by IMM (methotrexate, cyclosporine, mycophenolate mofetil, or azathioprine) use. Adverse events (AEs) were reported from first adalimumab dose in VISUAL III through interim cut-off date of Oct 31, 2016, with analysis by IMM use.

Results: Of 371 patients included in the intent-to-treat analysis, 117 (31.5%) were using IMM at VISUAL III baseline (BL) and 30 (8.1%) started IMM during VISUAL III. The proportion of patients with quiescence improved over time irrespective of IMM use; compared with Week 0, 95% confidence intervals were non-overlapping at most time points (Figure). Numeric improvements were achieved in steroid-free quiescence, steroid dose reduction, and BCVA, with no difference by IMM use. No new safety signals were detected through 130 weeks of treatment and AE rates were generally

Figure: Proportion of patients in quiescence by IMM use in VISUAL III

consistent with previous VISUAL trials; some AEs, notably serious infections and malignancies, were slightly higher with concomitant IMM use.

Conclusion: Exploratory analyses from the VISUAL III trial demonstrated that efficacy in adalimumab-treated patients was sustained or improved through 78 weeks of treatment, irrespective of IMM use. AE rates were consistent with previous VISUAL trials, although numerically higher rates for a subset of AEs were observed in patients taking IMM.

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster III: Sarcoid, Inflammatory Eye Disease, and Autoinflammatory Disease

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Uveitis is the most common inflammatory eye disease and is frequently associated with secondary systemic autoimmune diseases (SSAID) excluding infection in 40-55% of cases. This analysis was undertaken to assess the

Table 1. Demographics and Overall Prevalence of Systemic Disorders in Uveitis patients.

Demographics (n=1096)	
Gender	
Female	734 (67%)
Male	362 (33%)
Age	
18-29	133 (12%)
30-39	165 (15%)
40-49	194 (18%)
50-59	222 (20%)
60-69	229 (21%)
≥ 70	153 (14%)
Smoking	
Non-smoker	688 (63%)
Smoker (Current or previous)	408 (37%)
Associated Systemic Diseases (n=434)	
Infectious Causes	238 (22%)
Non-Specific	165 (69%)
Bacterial	10 (4%)
Viral	15 (6%)
Fungal	5 (2%)
Parasitic (Toxoplasmosis)	43 (18%)
Auto-immune Systemic Disorders	184 (17%)
Connective tissue disease	82 (44%)
Sarcoidosis	48 (26%)
Spondyloarthrides	18 (10%)
Reactive Arthritis	6
Ankylosing Spondylitis	3
Psoriatic Arthritis	2
Crohn disease	3
Ulcerative Colitis	4
Systemic Lupus Erythematosus	6 (3%)
Sjogren's syndrome	5 (3%)
Vasculitis	17 (9%)
Behcet syndrome	3 (0.5%)
Multiple Sclerosis	5 (3%)
Malignancy	12 (1%)

diagnostic prevalence of patients of these disorders in patients with uveitis being evaluated by ophthalmology in a tertiary referral center.

Methods: Patients aged 18 years and older with uveitis, diagnosed and followed by ophthalmology from January 2013 to March 2018 were identified. By using the patient cohort explorer, an online visit processing tool, a search for diagnostic codes for uveitis (91 separate ICD-9 and ICD-10 codes) was performed. Individual searches for commonly associated SSAID were further done using ICD-9 and 10 codes to sub-categorize these patients. The search results were cross-referenced by running three additional data searches including medications administration, laboratory and imaging evaluation, and referral to rheumatology. Diagnostic prevalence was calculated and compared to historical data.

Results: There was a total of 1096 patient with uveitis. The majority of patients were female(67%). There was a high prevalence of smoking (37%) and the prevalence of uveitis increased with each decade of life. Only 17% of the cases had a concomitant diagnosis or evaluation for a SSAID, 22% had a diagnosis of an underlying infectious cause and only 1% due to malignancy. Table 1 shows the demographic data and relative frequency of prevalence in these disorders. Non-specific connective tissue disease was the most common diagnosis in SSAID, followed by sarcoidosis and vasculitis. Seronegative spondyloarthritides were only diagnosed in 18 patients (1.6%). HLA-B27 was only checked in 67 patients (6.1%) with 50% being positive.

Conclusion: Evaluation for and prevalence of systemic disease associated with uveitis was significantly lower (17%) than what was expected historically(40-55%). Even though this data is limited by the lack of individual review, the data obtained showed similar results through 4 different algorithmic searches. Smoking, a known risk factor for inflammation, was found at a higher prevalence than the general population, and there was an increase in the prevalence of uveitis with older age till 70 years. These data suggest that, despite overwhelming evidence, patients with uveitis may not be adequately evaluated for these systemic diseases. Strategies to improve education and perhaps targeted diagnostic algorithms may improve the detection of secondary systemic diseases.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster III: Sarcoid, Inflammatory Eye Disease, and Autoinflammatory Disease

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: In uveitis rapid and effective remission-inducing therapy is mandatory to avoid irreversible structural and functional damage. Our aim was to evaluate the efficacy and safety of high-dose intravenous methylprednisolone (IVMP) pulse therapy in abroad spectrum of uveitis.

Methods: Multicentre study of 120 patients (190 eyes) with severe ocular inflammation who received IVMP. The underlying diseases were: Idiopathic (n=34), VogtKoyanagy Harada (28), Behcet disease (19), Sarcoidosis (6), Multifocal Choroidopathy (4), Birdshot chorioretinopathy (2), Acute posterior multifocal placoid pigment epitheliopathy (1), Granulomatosis with polyangiitis (2), Aortitis (1), Rheumatoid arthritis (2), Axial Spondylitis (6), Psoriatic arthritis (2), Juvenile Idiopathic Arthritis (1), Eales Disease (1), Sympathetic Ophthalmia (3), Multiple Sclerosis (2), Relapsing Polychondritis (1), Cogan's synd. (1), Sjögren synd. (2), Crohn's disease (1) and Reactive arthritis (1). The inflammatory ocular patterns were: panuveitis (62), posterior uveitis (PU) (29), intermediate uveitis (IU) (3), anterior uveitis (AU) (12), AU and PU (2), AU and IU (1), IU and PU (1), exudative retinal detachment (4), retinal vasculitis (2), pseudotumor (1), scleritis (2) and sclero-uveitis (1). Bilateral ocular involvement was observed in 70 patients. Patients were assessed at basal visit and day 2-5, 7, 15 and 30 after IVMP.

The main outcome variable was best corrected visual acuity (BCVA), the degree of inflammation of the anterior chamber and vitreous, and macular thickness (macular edema defined by OCT >300 µm). The results are expressed as mean ±SD for normally distributed variables, or as median [interquartile range] when are not. Comparison of continuous variables was performed using the Wilcoxon test.

Results: We studied 70 ♀/ 50 ♂; mean age 42 ±14.46 years. IVMP dose ranged from 40-1000mg/day for 3-5 consecutive days. All of them had active intraocular inflammation. Prior to IVMP, cycloplegic and corticosteroid eye drops were used in all cases. Improvement was faster among patients with inflammation in anterior chamber and vitritis than in BCVA, CME, retinitis and retinal vasculitis (TABLE 1). Total remission was achieved in 17.5% of the 120 patients after IVMP. In 118 of the patients continued with oral corticosteroids and 4 received an intraocular dose of corticosteroids. The following conventional immunosuppressive drugs were added: Methotrexate (50), Cyclosporine A (47), Azathioprine (37) and others (5). In a few cases even biological therapy (61) was administered afterwards. In general, acute respiratory infection was the side-effect most frequent.

Conclusion: High-dose IVMP pulse therapy is beneficial in the prompt control of severe uveitis and it is well tolerated. TABLE 1.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster III: Sarcoid, Inflammatory Eye Disease, and Autoinflammatory Disease

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Cystoid macular edema (CME) represents the leading cause of blindness in uveitis of different immune mediated diseases (IMD). Our aim was to evaluate the efficacy of Tocilizumab (TCZ) in different IMD with refractory CME to other immunosuppressive drug.

Methods: Multicentre study of 24 patients with CME due to uveitis of different IMD refractory to traditional treatment with systemic corticosteroids and at least one conventional immunosuppressive drug including in most cases biological therapy (n=21). CME was defined by (OCT >300 µm). We studied CME with TCZ in 4 different IMD: juvenile idiopathic arthritis (JiA), Behcet's disease (BD), Birdshot retinochoroidopathy (BR) and idiopathic.

The main outcome was the improvement of macular thickness. Other variables assessed were inflammation of the anterior chamber and vitreous and best corrected visual acuity (BCVA).

Results: We studied 16 ♀/8 ♂, mean age 35.2±19.3 years. The associated diseases were: JiA (n=9), BD (n=7), BR(n=4) and idiopathic (n=4). The ocular patterns were: panuveitis (9), anterior uveitis (6), posterior uveitis (5) and intermediate uveitis (4). Most patients had bilateral involvement (22). The biological therapy used before the administration of TCZ were infliximab (8), adalimumab (18), etanercept (2), golimumab (2), rituximab (2), abatacept (3), anakinra (1) and daclizumab (1). TCZ administration schedule was 8 mg/kg/4 weeks iv. (n=23) or every 2 weeks (n=1). TCZ was used in monotherapy (12) or combined with conventional immunosuppressive drugs (12). OCT values improved considerably in 12 months: in JiA from 340.6 ± 134.1 µm to 252.5 ± 30 µm, in BD from 375.1 ± 117 µm to 235 ± 7.1 µm, in BR from 550.7 ± 214.4 µm to 295.5 ± 43.2 µm and in idiopathic from 515 ± 219.6 µm to 208.3 ± 46.7 µm (**FIGURE**). Inflammation in anterior chamber and vitritis and BCVA also improved in the 4 subtypes. No major side effects were observed, so no patient had to stop treatment.

Conclusion: TCZ seems a rapid effective treatment in severe and refractory uveitic CME, regardless of the underlying IMD.

Autoimmune Encephalitis with Concomitant Systemic Rheumatologic Auto-Antibodies

Nicole Droz¹, Alexander Rae-Grant² and Rula A Hajj-Ali³, ¹Rheumatology, Cleveland Clinic Foundation, Cleveland, OH, ²Neurology, Cleveland Clinic Foundation, Cleveland, OH, ³Rheumatic and Immunologic Disease, Cleveland Clinic Foundation, Cleveland, OH

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster III: Sarcoid, Inflammatory Eye Disease, and Autoinflammatory Disease

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Autoimmune encephalitis (AE) is a rapidly progressive encephalopathy presenting with neurologic and psychiatric manifestations and is often associated with antibodies targeting neuronal cell-surface or synaptic proteins. Current diagnostic approaches require exclusion of alternative etiologies, including rheumatologic causes such as SLE, SS or vasculitis. Little is known about presentation or outcomes of patients with AE and concomitant systemic rheumatologic auto-antibodies who do not meet classification criteria for rheumatic disease.

We hypothesize that patients with AE and concomitant systemic rheumatologic auto-antibodies have improved disability and mortality as compared to patients without.

Methods: Patients were retrospectively identified for inclusion into the study if they had been diagnosed with AE by a board-certified neurologist at our institution between 2003 and 2018.

Patients were defined as having positive systemic auto-antibodies if they had positive laboratory results for ANA, SSA, SSB, DsDNA, SCL70, Histone, RNP, centromere, chromatin or ANCA by western blot or ELISA.

Baseline demographics, disease characteristics, neuronal specific autoantibodies, disability measured by modified Rankin scale (MRS) and mortality were compared between groups.

Results: 122 patients were identified for inclusion. 98 patients were negative for systemic rheumatologic auto-antibodies, and 24 were positive. Baseline demographics were similar between groups. Patients presented clinically with symptoms of lethargy or coma, seizures and/or dementia but this was not different between groups. MRI abnormalities were most frequently seen in subcortical or deep regions on T2/FLAIR imaging. Many neuronal specific auto-antibodies were identified, but patients in the positive systemic autoantibody group were more likely to have GAD65abs related to AE as compared to patients without (33.3% vs 9.2% respectively) (Table 1). The most commonly occurring systemic rheumatologic auto-antibody was ANA (15/24 patients), followed by SSA (6/24) and DsDNA (4/24) (Table 2). No patients had or developed a concomitant rheumatic disease over the mean length of follow up of 92 weeks. Treatment did not differ between groups. MRS was not different at baseline or at discharge between groups (Table 1). Kaplan-Meier survival curves for both patient populations revealed no significant difference in the survival rates between groups.

Conclusion: In patients with AE, concomitant systemic antibody positivity does not confer an improved prognosis. No patients developed a systemic rheumatic disease over the length of follow up.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster III: Sarcoid, Inflammatory Eye Disease, and Autoinflammatory Disease

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Deficiency of adenosine deaminase 2 (DADA2) is an autosomal recessive condition characterized by recurrent fevers, early-onset ischemic strokes, livedo racemosa, polyarteritis nodosa, portal hypertension, immune deficiencies, and cytopenias. Additionally, several patients with DADA2 have had hemorrhagic strokes. DADA2 is caused by biallelic loss-of-function mutations in the *ADA2* gene (formerly known as *CECR1*), resulting in very low ADA2 levels in the blood, vasculopathy, and M1 skewing of macrophage differentiation. The use of tumor necrosis factor (TNF) inhibitors has significantly reduced the risk of recurrent stroke. In this abstract, we report two TNF-inhibitor naïve cases who cumulatively developed three spontaneous hemorrhagic strokes on no anticoagulants/antiplatelets. Additionally, we examine the safety of anticoagulants/antiplatelets in patients with DADA2.

Methods: A single center study evaluated 24 patients who had biallelic germline mutations in the *ADA2* gene. Patients were subdivided into those with a history of hemorrhagic stroke versus those without. We then identified the patients with hemorrhagic strokes on no anticoagulant/antiplatelet treatment, ASA alone, and other anticoagulants/antiplatelets versus patients without hemorrhagic stroke on no anticoagulant/antiplatelet treatment, ASA alone, and other anticoagulants/antiplatelets. None of the patients had been on TNF inhibitors at the time of the analysis. The primary outcome measure was to determine occurrence of hemorrhagic strokes in patients with DADA2 and if there is increased risk on anticoagulant/antiplatelet treatment.

Results: Among the 24 patients, 6 (25%) had hemorrhagic strokes and of those 1 was on ASA alone, 3 were on anticoagulants/antiplatelets, and 2 were on no anticoagulants/antiplatelets. The remaining 18 patients did not have a hemorrhagic stroke and of those, 8 were on ASA alone, 3 were on anticoagulants/antiplatelets, and 7 were on no anticoagulants/antiplatelets. The probability of a hemorrhagic stroke following anticoagulant/antiplatelet therapy is 4/13 (31%) while the probability of a hemorrhagic stroke following no such therapy is 2/11 (18%). A Fisher's exact test showed a p-value of 0.6494 (NS). The prevalence of patients with hemorrhagic strokes on ASA alone, no anticoagulant/antiplatelets, and on anticoagulants/antiplatelets were 1:6, 2:6, 3:6 respectively. A Fisher's exact test showed a p-value of 0.263 (NS).

Conclusion: In patients with DADA2, we have shown that there is a strong baseline risk of hemorrhagic strokes as evidenced by the two patients who cumulatively suffered three hemorrhagic strokes on no anticoagulant or antiplatelet treatment. The risk of hemorrhagic stroke was not significantly increased on anticoagulants/antiplatelet agents possibly due to the small sample size. However, given the baseline risk of hemorrhagic stroke in DADA2, and the (non-significant) increase in that risk on anticoagulants and antiplatelet agents, such agents should probably not be used in DADA2 except under extraordinary circumstances.

Colchicine: An Effective Treatment Option for Unclassified Autoinflammatory Diseases in Children

Jasmin B. Kuemmerle-Deschner¹, Anna Lena Schock², Sandra Hansmann³ and Susanne Benseler⁴, ¹Department of Pediatrics, Division of Rheumatology, University Hospital Tuebingen, Germany, Tuebingen, Germany, ²Department of Pediatrics, Division of Rheumatology, University Hospital Tuebingen, Tuebingen, Germany, Tuebingen, Germany, ³Department of Pediatrics, Division of Pediatric Rheumatology, University Hospital Tuebingen, Tuebingen, Germany, Tuebingen, Germany, ⁴Rheumatology, Department of Paediatrics, Alberta Children's Hospital, University of Calgary, Alberta, Canada, Calgary, AB, Canada

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster III: Sarcoid, Inflammatory Eye Disease, and Autoinflammatory Disease

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Interleukin-1 (IL-1) inhibition was found to be an effective, yet very expensive treatment option for children with clinically and genetically defined autoinflammatory diseases (AID). However, patients suffering from unclassified AIDs with mild to moderate disease activity in the absence of a pathogenic mutation commonly have no access to these treatment options. The aim of this study was to explore the efficacy and safety of colchicine monotherapy in children with AIDs without pathogenic mutations.

Methods: A single center prospective cohort study of consecutive AID patients ages <18 years without pathogenic mutations, who were treated with colchicine monotherapy was conducted between January 2009 and February 2018. Patients were included, if they had mild to moderate clinical disease activity and raised inflammatory markers (CRP > 0.5mg/dl, SAA >10 mg/l). Patients were excluded, if they had intolerance to colchicine, elevated liver enzymes > 3x ULN, amyloidosis or other AID related organ damage. Baseline variables included demographics, clinical features, laboratory markers, flare details and overall disease activity. Primary outcome was treatment response at 6 month. Complete response was defined by Physician Global Assessment (PGA) VAS < 2 plus normal inflammatory markers (CRP, SAA), partial response was defined as PGA VAS ≥ 2 - ≤ 5 and low normal inflammatory markers (CRP < 5mg/dl, SAA < 50mg/l). Secondary outcomes included flare characteristics (intervals, duration), toxicity and dose adjustment.

Results: A total of 33 patients were included, 13 girls and 20 boys; median age at start of therapy was 3.8 years (0.8 – 12.6). Clinical diagnoses included PFAPA (14), mutation-negative FMF (9), CAPS with low-penetrance *NLRP3*-variants (8) (2 *V198M*, 6 *Q703K*) and unclassified AID (2). Overall, recurrent fever was the leading symptom, mostly associated with arthralgia and myalgia. On colchicine, the median disease activity decreased from 4 at baseline to 2 at 6 months, median SAA-levels dropped from 74.5 to 4.4 mg/l, CRP from 2.9 to 0.06 mg/dl. Flare frequency was significantly reduced, as was flare duration. Overall, 73% of children responded to Colchicine therapy, complete response was documented in 21%, partial response in 52% at 6 months. The colchicine dose was increased in 79% of children. At last follow-up, 67% had a sustained response to Colchicine. Adverse events included abdominal pain and diarrhea seen in 42%. These appeared to be dose dependent.

Conclusion: Colchicine was an effective and safe treatment option for children with mild to moderately active AIDs. Dose adjustments are frequently required. Gastro-intestinal side effects have to be closely monitored at higher doses.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster III: Sarcoid, Inflammatory Eye Disease, and Autoinflammatory Disease

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Cryopyrinopathies are autoinflammatory disorders (AID) caused by mutations of NLRP3 gene that lead to interleukin-1 (IL-1) overproduction with the clinical picture of periodic fever. Milder forms as Muckle-Wells syndrome (MWS) can run undiagnosed until adulthood when disease damage (deafness, amyloidosis) may be discovered. We present a observational study of a large family where MWS was diagnosed simultaneously in 4 generations (G). This provides us with the information on the long-term natural disease course followed by systematically documented response to IL-1 blockade.

Methods: Case histories were retrieved from medical records complemented by detailed questioning. Clinical suspicion of MWS was genetically confirmed (c.1322C>T). Patients were followed from the time of diagnosis at 3-monthly intervals by clinical examination, blood and urine tests, patient-reported Auto-Inflammatory Disease Activity Index (AIDAI) and once yearly Autoinflammatory Disease Damage Index (ADDI). Audiometry was performed initially and then in 6-12-monthly intervals. Results of the 2-year follow-up are presented.

Results: Two children in **GIV** (1.5 and 5 yrs old) presented in infancy with urticarial rash. Their inflammatory markers as well as general condition remained normal and they have not yet required therapy. All 5 affected individuals in **GIII** (21-33 yrs old) reported frequent attacks of fever, rash, conjunctivitis and arthralgia since pre-school age. They all had raised inflammatory markers and no organ involvement. All responded briskly to daily anakinra. **GII** has 3 siblings (45, 46, 53 yrs old) all affected (rash, conjunctivitis, arthritis, arthralgia, fever, headaches from pre-school age). Renal amyloidosis was confirmed as a cause of proteinuria and chronic renal failure in patient II/1. Variable degree of sensorineural hearing loss was found in 2 cases. Anakinra led to the rapid improvement of their laboratory activity as well as clinical symptoms. In patient II/1 hearing has remained stable as did his renal function. Audiometry improved by 10-20 dB after 2 years of therapy in patient II/3. Patient I/1 from **GI** died at 52 years from renal failure. The pre-treatment **AIDAI** ranged 20-77 points and normalised within 1-3 months in all patients and have remained so. The disease damage noticed in **GII** expressed by **ADDI** was 6 (II/1) and 1 (II/3) at the first visit and has remained stable within the follow-up.

Conclusion: Although untreated MWS carries high risk of renal and auditory damage, little is known about the timing of their evolution. The cross-sectional view of untreated disease in 11 patients with the same mutation provides valuable information. Absence of impaired hearing in individuals below 40 years has encouraged us to postpone onset of IL-1 blockade in the mildly affected children. On the other hand, renal amyloidosis progressed sub-clinically into significant functional impairment in one patient and was a cause of death in another one both in their early fifties. High level of awareness of AIDs and close collaboration between paediatric and adult specialists are the main pre-requisites to optimal management of these rare diseases.

Therapeutic Value of Canakinumab in Patients with Yao Syndrome

Qingping Yao, Rheumatology, Allergy and Immunology, Stony Brook University Hospital, Stony Brook, NY;
Rheumatology, Allergy, and Immunology, Stony Brook University School of Medicine, Stony Brook, NY

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster III: Sarcoid, Inflammatory Eye Disease, and Autoinflammatory Disease

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Yao syndrome (YAOS, OMIM 617321), formerly termed nucleotide-binding, oligomerization domain 2(*NOD2*)-associated autoinflammatory disease, is characterized by periodic fever, dermatitis, arthritis, and swelling of the distal extremities, as well as gastrointestinal and sicca-like symptoms. The disorder is associated with specific *NOD2* variants. YAOS is not uncommon, yet effective drugs remain limited due to its recent identification. This study aimed at examining the therapeutic utility of canakinumab, a monoclonal antibody against interleukin-1 β for the disease.

Methods: In this retrospective analysis of prospectively designed single center study approved by the Institutional Research Board, 6 adult Caucasian patients that were enrolled fulfilled the diagnostic criteria for YAOS as confirmed by molecular analysis. These patients naïve to biologics received subcutaneous injections of canakinumab 150 mg every 4 to 8 weeks for 2 to 12 months. The primary end point was the change of overall clinical response evaluated by patient's global assessment at week 1, 2, 3 and 4. Secondary end points included changes in each of the major signs and symptoms using modified Schnitzler activity score on a scale of 0-4. Inflammation markers and drug adverse reactions were recorded including routine laboratory tests.

Results: All 6 patients receiving canakinumab reported overall clinical improvement with a mean change of 78% as compared with that before the drug administration. Patients noted improvement from day 7 following the injection with peak effect around day 14 to 21, and the improvement generally lasted up to 4 weeks. Patients felt even more symptomatic relief with more drug dosing over time. The results of the constituent signs and symptoms at day 14 after the biologic administrations are summarized in Table 1, and there was 78% improvement in fever and approximately 70% in each of the other major phenotypes, such as rash, arthritis, sicca-like and gastrointestinal symptoms. Three out of the 6 patients had elevated inflammation markers that normalized after canakinumab. Adverse events were minimal, including minimally elevated liver enzymes in one patient.

Table 1 Demographics, Scores and Changes in Major Constituent Manifestations in YAO Syndrome Patients Receiving Canakinumab

Patient	Sex	Age at dx	Age at onset	Caucasian	CAN doses	Fever Score(B/A) Improvement %	Rash Score(B/A) Improvement %	Arthritis Score(B/A) Improvement %	GI Score(B/A) Improvement	Sicca Score(B/A) Improvement %	Overall clinical response Score(B/A) Improvement %
1	F	19	15	Yes	4	(4/0)100	(3/1)67	(4/2)50	(3.5/1)71	(2/0)100	(4/2)50
2	F	40	20	Yes	7	(4/0)100	(3/2)33	(3/1)67	(0/0)	(0/0)	(4/0)100
3	M	34	30	Yes	10	(3/1)67	(4/1)75	(4/1)75	(2/0)100	(3/1)67	(3/1)67
4	M	49	20	Yes	2	(2/0)100	(3/0)100	(3/0)100	(1/0)100	(4/0)100	(4/1)75
5	F	27	7	Yes	6	(3/2)33	(3/1)67	(4/1.5)63	(3/3) 0	(3/1)67	(4/1)75
6	F	49	30	Yes	7	(3/1)67	(1/0)100	(3.5/2.5)29	(3.5/1)71	(4/3)25	(4/2)50
Mean \pm SD						77.8 \pm 27.3	73.7 \pm 25.0	64.0 \pm 23.9	68.4 \pm 40.9	71.8 \pm 30.9	69.5 \pm 18.7

Note: Dx: diagnosis; CAN: Canakinumab; Scores are based upon a scale of 0-4 with 4 being the most severe; B/A: before and after Canakinumab injections; Improvement % is computed based upon the score changes before and after treatment divided by the scores before the treatment; SD: standard deviation.

Conclusion: In this study, canakinumab was effective in patients with YAOS, and thus clinical trial of canakinumab may be warranted as a therapeutic option for this disease.

Transcriptomic Analysis of Hidradenitis Suppurativa Skin Demonstrates Dysregulation of Antimicrobial Proteins and Inflammatory Pathways

Victoria Shanmugam¹, Derek Jones², Matthew Bendall³ and Keith Crandall⁴, ¹Rheumatology, The George Washington University, Washington, DC, ²The George Washington University, Washington, DC, ³Department of Microbiology, Immunology and Tropical Medicine, The George Washington University, Washington, DC, ⁴Department of Biology, The George Washington University, Washington, DC

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster III: Sarcoid, Inflammatory Eye Disease, and Autoinflammatory Disease

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Hidradenitis suppurativa (HS) is a chronic, recurrent, inflammatory disease of the apocrine sweat glands. The purpose of the current study was to identify transcripts and upstream regulators that are differentially expressed in HS skin specimens compared to normal skin harvested at abdominoplasty.

Methods: Surgical specimens from operative HS debridement (n=10, IRB 041408) and abdominoplasty (n=11, IRB101419) were collected. Total RNA was extracted, amplified, biotin-labeled, purified and hybridized to Illumina HumanHT-12 v4 Expression BeadChips and scanned using a HiScanSQ system (Illumina Inc., CA). Low-level analysis of raw BeadChip data was performed using the limma and beadarray packages. Differentially expressed genes were detected by fitting gene-wise linear models to the normalized expression data at a false discovery rate (FDR) of <0.05 and an absolute log2-fold change greater than or equal to $\text{abs}(\log_2\text{FC}) \geq 1.00$ (equivalent to 2.0 fold changes). Differentially expressed genes were modelled using Ingenuity Pathway Analysis (IPA, Ingenuity, Qiagen, CA) and upstream regulator analysis was performed.

Results: In the HS to normal control comparison, 436 genes were overexpressed and 363 genes were under-expressed. The top 25 differentially expressed genes are shown in **Figure 1**. Notably, Dermcidin antimicrobial protein normally found in human sweat was significantly downregulated in the HS specimens. Significant differential expression was observed in 30 canonical pathways in the HS samples based on a $-\log(\text{p-value})$ cut off of 1.3 and a Z-score activation prediction cut off of >2 or <-2 , (**Table 1**). Upstream regulator analysis identified interferon alpha (IFN- α), IFN- γ , lipopolysaccharide, tumor necrosis factor and oncostatin-M as the top five upstream regulators in the HS dataset compared to normal skin (**Table 2**).

Conclusion: Production of antimicrobial peptides is dysregulated in HS, and inflammatory pathways, particularly the interferon pathway and pathways of leukocyte activation are upregulated suggesting novel pathways that could be therapeutic targets for the management of this disease.

Figure 1. Differential gene expression in HS and normal tissue.

Table 1 Top 30 canonical pathways in HS

	Ingenuity Canonical Pathways	-log(p-value)	Ratio	z-score	Down-regulated	No change	Upregulated

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster III: Sarcoid, Inflammatory Eye Disease, and Autoinflammatory Disease

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Figure 1. Activity parameters at initial and final assessment

Parameter, Mean (SD)	Baseline	Final Assessment	p value
BASDAI	4.6 (2.9)	1.3 (0.6)	0.2
BASFI	5.65 (2.6)	0.65 (0.4)	<0.001
CRP (mg/dl)	2.95 (5.5)	0.60 (0.54)	0.005
ESR (mm/h)	24.8 (22.8)	12.4 (11.9)	0.044
Number of swollen joints	0.20 (0.42)	0	NS
Number of painful joints with palpation	2.6 (3.2)	1.0 (1.7)	0.4

Background/Purpose: SAPHO Syndrome is a chronic disease with bone, joint and skin involvement characterized by synovitis, acne, pustulosis, hyperostosis, osteitis. Treatment decisions of SAPHO syndrome are generally based on experts' opinions. Our aim is to evaluate treatment options and response of patients with SAPHO syndrome in the referral outpatient clinic

Methods: All patients with SAPHO syndrome diagnosed since February 2014 have been registered and monitored prospectively with a standard form. All patients met the Benhamou criteria (1) for SAPHO syndrome. At baseline and follow-up visits, patients were assessed regarding acute phase reactants, BASDAI, BASFI, number of swollen and tender joints (28 joints), patient global assessment (particularly assessed for skin and joint) and overall assessment of patient. Baseline and follow-up treatment choices were decided by expert opinions. There were 25 patients with SAPHO syndrome and 22 patients had complete demographic and treatment data, who were analyzed.

Results: Twenty-two patients (12 (54.5%) female) with SAPHO syndrome were evaluated. Mean age of diagnosis was 40.1 ± 13.2 , the mean follow-up duration was 17.6 ± 24.5 months. The evaluation of the disease activity at initial and final visits were shown in figure 1. Initial and maintenance treatment regimens were given in table 1. At baseline, distribution of each particular treatment choices were pamidronate in 10 patients (45.4%), methotrexate in 9 patients (40.9%), sulphasalazine in 6 patients (27.2%), corticosteroids in 3 patients (13.6%), cyclosporine, anti-TNF and surgery each in 1 particular patient (4.5%). During follow-up period, 3 patients (13.6%) were switched to anti-TNF treatments due to inefficacy of other treatments. At the final visit, all patients achieved remission according to physician assessment. We did not find any treatment-related side effects during follow-up period.

Conclusion: Randomized controlled trials have not been performed to evaluate treatment options for rare rheumatologic disorders such as SAPHO syndrome. In our case series, pamidronate seems to be an effective treatment option against both osteoarthritic and skin manifestations, on the other hand anti-TNF treatments should be kept in mind on the resistant patients.

Table 1 Distribution of drugs administered at baseline and for the maintenance

Treatment regimens	Initial regimen n (%)	Maintenance regimen n (%)
Pamidronate	9 (40.9)	10 (45.4)
Methotrexate	4 (18.1)	2 (9.0)
Methotrexate + sulphasalazine	4 (18.1)	3 (13.6)
Anti-TNF	1 (4.5)	3 (13.6)
Anti-TNF + methotrexate	0 (0)	1 (4.5)
Pamidronate and sulphasalazine	1 (4.5)	1 (4.5)
Sulphasalazine	1 (4.5)	1 (4.5)
Methotrexate + cyclosporine	1 (4.5)	0 (0)
Surgery without concomitant drug	1 (4.5)	1 (4.5)

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster III: Sarcoid, Inflammatory Eye Disease, and Autoinflammatory Disease

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Microparticles (MPs) are small membrane-bound vesicles that arise from activated and dying cells. Although the majority of MPs in the blood originate from platelets, all cells appear to be able to release MPs. Many studies have raised the implication of these MP in various processes: inflammation, thrombosis, angiogenesis. Previous studies reported inconsistent results in inflammatory rheumatic diseases. Studies have shown the correlation between the circulating MPs, platelet MPs and lymphocyte MPs in patients with spondyloarthritis (SpA) compared to control patients. For rheumatoid arthritis (RA), platelet MPs levels were correlated with DAS28. The aim of this study was to search a possible correlation between the disease activity and the pro-coagulant property of microparticles, potential indirect marker of inflammation.

Methods: The test used (STA Procoag PPL®) is a standardised automated test. Results are expressed as coagulation times (in seconds). It is a functional test that provides information on the procoagulant potential of microparticles. The microparticles supply the phospholipids expressed on their membrane surface and the test provides calcium and factor Xa necessary to initiate coagulation : the shorter the coagulation time the greater the procoagulant activity of the phospholipids being studied, suggesting a higher number of MP.

This is a prospective, single-center study, including 39 patients with spondyloarthritis (ASAS criteria), 37 with rheumatoid arthritis (ACR criteria) and 26 control patients (healthy subjects, osteoarthritis). All patients underwent STA Procoag PPL test, and we collected medical data : disease activity (BASDAI, BASFI, DAS28vs and DAS28crp and HAQ), biological inflammation (VS, CRP), duration of disease, and current treatment.

Results: The in vitro clotting time of serum of patients with spondyloarthritis and rheumatoid arthritis compared with controls was not significantly different ($p = 0.23$ and $p = 0.44$, respectively). Regarding the activity scores of inflammatory rheumatic disease: BASDAI and BASFI, DAS28esr, DAS28crp and HAQ for patients with RA, no correlation between these data and coagulation time was found; the same goes for biological inflammation (ESR, CRP), duration and type of treatment (Nonsteroidal anti-inflammatory drugs, DMARDs, biologics).

STA PPL	Controls (n=26)	SpA (n=39)	p	RA (n=37)	p
Mean \pm SD	62,70 \pm 11,58	66,48 \pm 12,77	$p = 0,23$	65,25 \pm 13,54	$P = 0,44$
BASDAI	$r=0,0602$ $p=0,72$		DAS28 esr	$r= 0,230$ $p=0,17$	
BASFI	$r=-0,125$ $p=0,45$		DAS28 crp	$r=0,151$ $p=0,37$	

Conclusion: In this study, there is neither difference in values of procoagulant activity of MPs between inflammatory rheumatic diseases and control subjects, nor correlation with their activity scores or biological inflammation.

Incidental Steroid Use May Worsen Outcomes in Patients with Heparin Induced Thrombocytopenia in the ICU Setting

Roy Souaid¹ and Connie Lu², ¹Internal medicine, Brown University, Providence, RI, ²Medical school, Brown university, Providence, RI

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster – ARHP

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Heparin induced thrombocytopenia (HIT) is the destruction of platelets in patients exposed to heparin products. While there are two types of HIT, the term is often used without modifier to refer to HIT Type II, which is immune-mediated and severe. Up to 5% of patients on unfractionated heparin and 1-2% of patients on low molecular weight heparin will develop HIT Type II, with 30-80% of them developing thrombotic sequelae. The gold standard for treatment is to stop heparin products and start a different anticoagulant. Although not explicitly indicated, steroids are often incidentally given to suppress the immune-mediated destruction of platelets. However, the impact of steroids on patient outcomes, such as length of stay, mortality, and adverse events like bleeding or thrombosis, is unclear. A literature review of steroid use patients with HIT in the ICU setting did not show any definitive studies looking at this association. We believe that investigating incidental steroid use in this patient population could clarify its role and impact and help us develop better guidelines for treatment.

Methods: We conducted a retrospective analysis using the MIMIC-III Critical Care Database. For our primary endpoint, we selected patients diagnosed with HIT using ICD-9 codes, filtered for earliest admission date and divided them into two groups for comparison: one group who received steroids, and the other group who did not receive steroids. Our sample is composed of 2,205 patients without incidental steroid use and 753 with incidental steroid use, with a total of 2,958. The chart was also abstracted for variables such as length of stay, admit type, mortality, and bleeding, as well as age (stratified by: neonate, 17-29, 30-49, 50-63, 64-75, 76+) and sex (male vs. female). Analysis was performed using chi-square test for categorical variables, Fisher's exact test for the admit type variable, and unpaired 2-sided t-test with unequal variances for the duration of stay variable

Results: Holding all other variables constant, we found that patients who were prescribed steroids had longer hospital stays by 6.5 days on average, when compared to patients who were not prescribed steroids ($p < 0.001$, 95% CI = 5.30 to 7.67). Moreover, patients who were prescribed steroids were almost twice as likely to experience mortality compared to those who were not prescribed steroids ($p < 0.001$, 95% CI = 1.63 to 2.45), and have increased odds of bleeding by 33% compared to those who were not given steroids ($p = 0.004$, 95% CI = 1.10 to 1.62).

Conclusion: This study represents the first attempt to discern the impact of steroid treatment on outcomes in patients with HIT Type II in the ICU setting. Given the results, it seems that steroid use is associated with worsened outcomes, such as longer length of stay, increased mortality, and increased bleeding. Although conventional wisdom has convinced us to give steroids in a large proportion of HIT cases, this study suggests that overall, steroid use in HIT patients may be more harmful than beneficial. We recommend that there be further investigation into the use of steroids in HIT, with demographic stratification, so that we can develop appropriate best practice guidelines for treatment.

Safety and Efficacy of Lenabasum in Refractory Skin-Predominant Dermatomyositis Subjects Treated on an Open-Label Extension of Trial JBT101-DM-001

Victoria P. Werth^{1,2}, David Pearson^{1,2}, Joyce Okawa^{1,2}, Rui Feng³, Josef Concha^{1,2}, Basil Patel^{1,2}, Emily Hejazi^{1,2}, Caitlin Cornwall⁴, Scott Constantine⁴ and Barbara White⁴, ¹University of Pennsylvania, Philadelphia, PA, ²Philadelphia Veterans Affairs Medical Center, Philadelphia, PA, ³University of Pennsylvania, Philadelphia, PA, ⁴Corbus Pharmaceuticals, Inc., Norwood, MA

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Muscle Biology, Myositis and Myopathies Poster III: Treatment and Classification Criteria

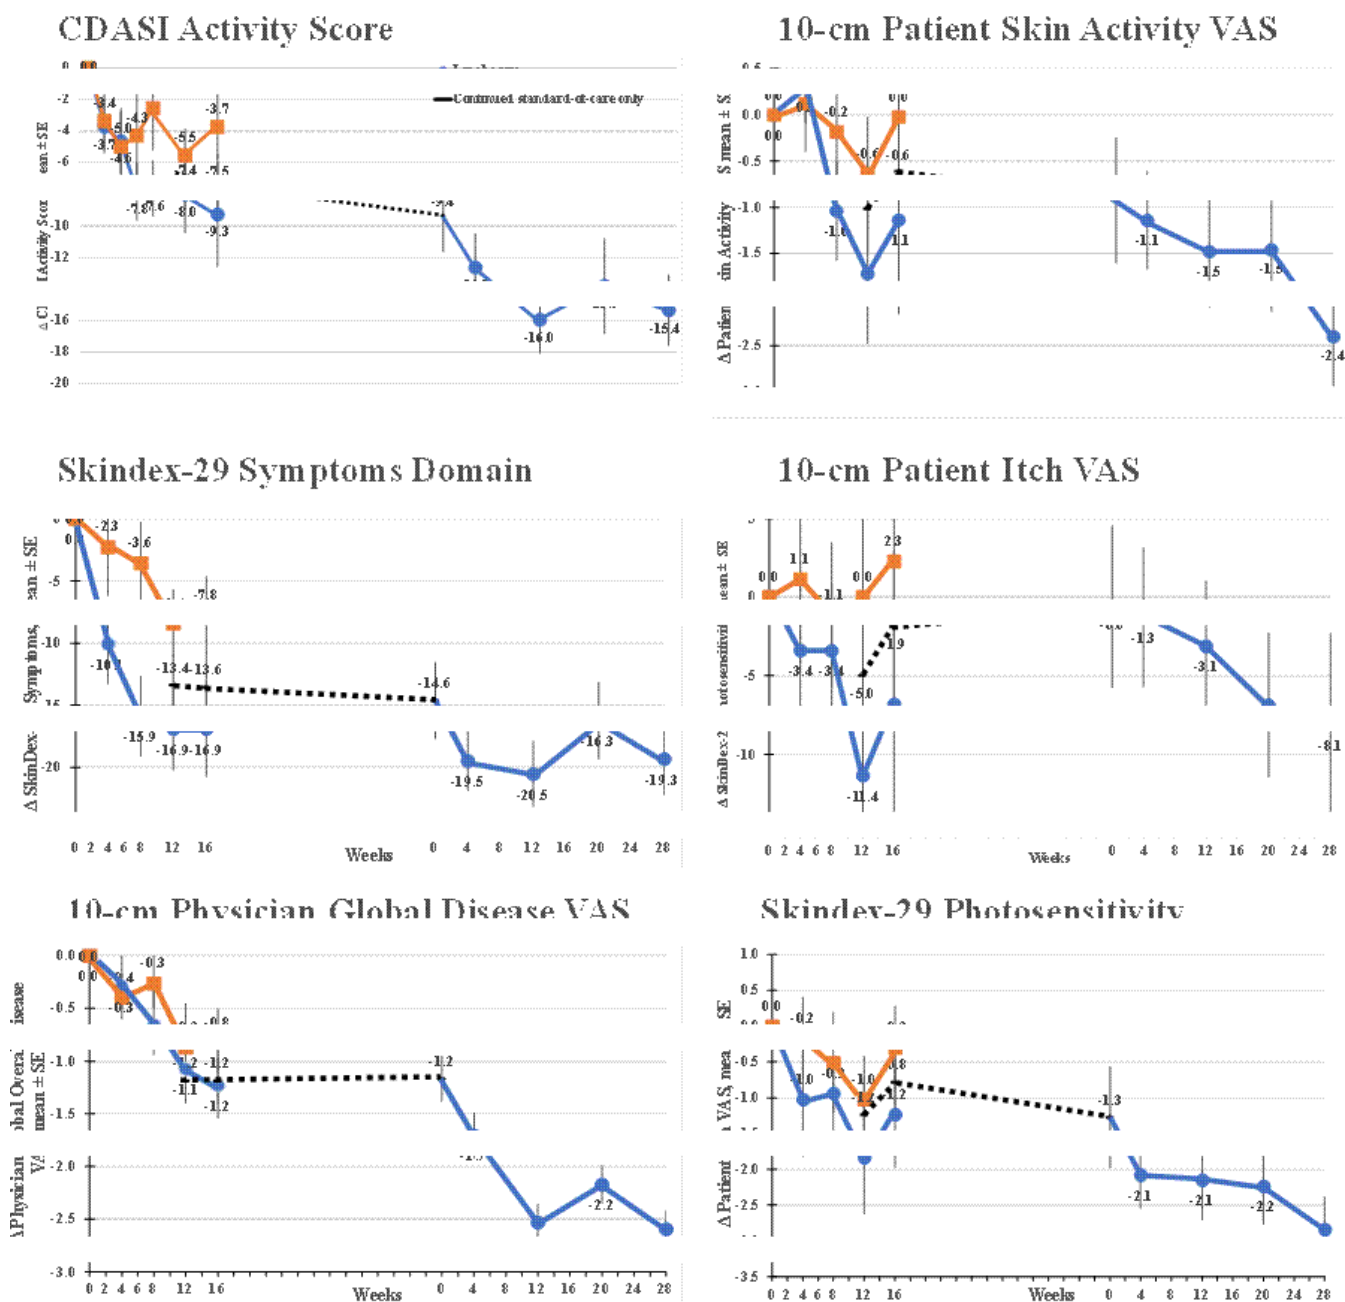

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Lenabasum is a synthetic, non-immunosuppressive, selective cannabinoid receptor type 2 agonist that activates resolution of innate immune responses. Lenabasum had acceptable safety and tolerability and improved efficacy outcomes in the double-blinded, randomized, placebo-controlled (DBPC) part A of Phase 2 trial JBT101-DM-001 (NCT02466243) in dermatomyositis(DM) subjects with refractory, skin-predominant involvement.

Figure 1. Change from Baseline in Selected Efficacy Outcomes in OLE of Phase 2 Trial JBT101-DM-001

Blue circle = lenabasum. Orange square = placebo. Black open circle = maintenance background treatment alone (no investigational product) before start of OLE. n = 21 in lenabasum group, n = 21 in placebo group. Time points are weeks 0, 4, 8, 12, 16, 20, 24, 28.

Objective: To provide long-term safety and efficacy data in DM subjects in study JBT101-DM-001.

Methods: Subjects who completed Part A were eligible to receive oral lenabasum 20 mg BID in an open-label extension (OLE) that assessed safety and efficacy at 4 weeks, then every 8 weeks.

Results: 20/22 (90.9%) eligible subjects received open-label lenabasum, following a mean interval of 31 weeks from end of Part A to start of OLE when they received only standard-of-care. 17/20 (85.0%) subjects were on stable baseline immunosuppressive drugs. At the time of data cut-off, no subjects had discontinued from the OLE, all completed Week 22 and 17 (85%) completed \geq Week 28. Adverse events (AEs, $n = 33$) occurred in 13/20 (65.0%) subjects, with 5/20 (25.0%) subjects having ≥ 1 AE (all mild) related to lenabasum. No subject had a serious or severe AEs. All subjects had AEs with maximum severity of mild (12/20, 60.0%) or moderate (1/20, 5.0%). The only AE that occurred in more than 1 subject was DM flare ($n = 2$, 10%); the last recorded CDASI activity score prior to flare was 14 points lower than baseline in 1 subject and 5 points higher than baseline in 1 subject. Mild dizziness occurred in 1 (5.0%) subject. Improvement was seen in multiple physician- and patient-reported efficacy outcomes including: CDASI activity score; physician VAS assessments of skin activity and extra-muscular disease; physician Likert assessments of global disease, skin disease, and extra-muscular disease; and patient VAS assessments of overall disease, skin disease, itch, pain, and several SkinDEX-29 and PROMIS-29 domain scores. Examples are shown in Figure 1. Mean (SD) changes at Week 28 from study start were: CDASI activity score = -15.4 (9.24) points, with 14/17 (82.3%) subjects achieving ≥ 10 -point improvement and 8/17 (47.1%) subjects achieving low disease activity with CDASI ≤ 14 ; 10-cm Physician Overall Disease VAS = -2.6 (1.90) points, with 14/17 (82.3%) subjects achieving ≥ 1 point and 20% improvement.

Conclusion: Lenabasum continues to have a favorable safety and tolerability profile in the OLE of the Phase 2 trial JBT101-DM-001 with no severe or serious AEs or study discontinuations related to lenabasum. The CDASI activity score and multiple other physician and patient-reported outcomes improved, although limitations of attributing efficacy to lenabasum in the setting of open-label dosing is acknowledged. These data support further testing of lenabasum for the treatment of DM.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Muscle Biology, Myositis and Myopathies Poster III: Treatment and Classification Criteria

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: We examined patients in a large juvenile dermatomyositis (JDM) registry for frequency of and factors associated with final corticosteroid discontinuation (Steroid DC), complete clinical response (CCR, clinically inactive disease for ≥ 6 continuous months on treatment), and remission (inactive disease for ≥ 6 continuous months off all treatment).

Table: Markov chain Monte Carlo Multivariable Weibull models of time to achieve final steroid discontinuation (DC), complete clinical response (CCR), and remission

Variables	Time to Final steroid DC		Time to CCR		Time to remission	
	Mean	SD	Mean	SD	Mean	SD
Shorter time to outcomes						
Anti-MDA5 autoantibodies	0.81	0.28				
South residential geoclimatic zone	0.71	0.24				
Northwest residential geoclimatic zone			1.35	0.29		
Anti-MJ (NXP2) autoantibodies			0.65	0.25		
Achievement of GS-DC					1.22	0.34
Age at first treatment <7 years old					0.97	0.25
Achievement of CCR					0.81	0.25
Longer time to outcomes						
GI, pulmonary or cardiac signs/symptoms	-0.81	0.17	-0.59	0.24	-0.59	0.23
Anti-p155/140 (TIF1) autoantibodies and any MAA	-0.77	0.35	-1.83	0.50		
Contracture	-0.58	0.19	-0.67	0.22		
Photosensitivity	-0.56	0.19			-0.5	0.22
Dysphonia			-1.21	0.27	-0.92	0.31
Southwest residential geoclimatic zone	-0.67	0.30				
Medication escalation within 18 months after initial treatment			-0.67	0.25		
Infection within 6 months of illness onset					-0.95	0.34
DIC	1401		944		890	

The higher absolute mean value indicates a stronger relative influence in the model. Mean values greater than zero indicate a shorter time to achieve the outcome, and mean values less than zero indicate a longer time to achieve the outcome. Only variables with parameter credible intervals that did not overlap zero were retained in the models. The multivariable models shown have the lowest DIC values. Variables without a mean and standard deviation number indicated were not significant and were not included in the model for that outcome.

Abbreviation: CCR, Complete clinical response; DC, Discontinuation; DIC, Deviance information criterion; GI, gastrointestinal; MAA, Myositis Associated Autoantibodies; MDA5, Melanoma Differentiation-Associated protein 5; NXP2, nuclear matrix protein 2; SD, Standard deviation; TIF1, transcriptional intermediary factor 1.

Methods: A retrospective review of illness outcomes was evaluated in 307 patients with probable or definite JDM with median follow-up duration of 43 months. The probability of achieving steroid DC, CCR, and remission were examined by Weibull time-to-event modeling. Significant univariable predictors were examined in multivariable time-to-event analysis using Markov chain Monte Carlo extension models. The conditional probability of each outcome was also evaluated using Bayesian network models.

Results: One-hundred-ninety-one of the 307 patients (62.2%) achieved at least one of the outcomes. By 60 months from treatment initiation, 57% of patients achieved steroid DC, 44% achieved CCR, and 31% achieved remission. Time to 50% probability of achieving steroid DC, CCR, and remission were 52, 69, and 92 months, respectively. The probability of CCR and remission were conditional. The probability of attaining CCR given steroid DC was 47%; when steroid DC was not attained, the probability of achieving CCR was 19%. When steroid DC and CCR were achieved, the probability of achieving remission was 66%. When steroid DC and CCR were not achieved, the probability of remission was 3.5%. Several factors were associated with longer times to achieve these outcomes in multivariable models. Gastrointestinal, pulmonary or cardiac symptoms were the only factors associated with longer times to achieve all three outcomes. Anti-p155/140 autoantibodies (Abs) with any myositis associated Abs and contractures were associated with longer times to steroid DC and CCR, photosensitivity with longer times to steroid DC and remission, and dysphonia with longer times to CCR and remission. A Southeast residential geoclimatic zone, medication escalation within 18 months of treatment initiation, and an infection within 6 months of illness onset were associated with longer times to achieve a single outcome. Anti-MDA5 Abs and a Southern residential geoclimatic zone were associated with shorter times to steroid DC. A Northwest residential geoclimatic zone and anti-MJ Abs were associated with shorter times to CCR. The achievement of steroid DC and CCR and younger age at first treatment were associated with shorter times to remission.

Conclusion: A large proportion of JDM patients achieve positive treatment responses, including steroid DC, CCR, and remission, although timelines for these important outcomes are relatively long. Factors associated with times to achieve these outcomes include selected clinical features, autoantibodies, and environmental factors.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Muscle Biology, Myositis and Myopathies Poster III: Treatment and Classification Criteria

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose : To assess the prevalence of myofascial inflammatory lesions visible by magnetic resonance imaging (MRI) and their changes after tocilizumab therapy in active polymyalgia rheumatica (PMR).

Methods: We conducted a post hoc analysis of data from the TENOR study (Devauchelle-Pensec V, et al Ann Rheum Dis. 2016; 75:1506-10). Inclusion criteria were PMR meeting Chuang's criteria, onset within the past 12 months, active disease defined as PMR-AS>10. 18 patients each received tocilizumab injections at weeks 0, 4, and 8. The shoulder and pelvic girdles were assessed at baseline then at weeks 2 and 12 using an MRI 3T Philips Achieva (Philips, Amsterdam, The Netherlands), with a 32-channel surface antenna. Three sequences were used: axial T1 turbo spin echo (TSE), axial T2 short tau inversion recovery (STIR), and coronal T2 STIR. Radiologists blinded to patient data assessed each muscle group for myositis and fasciitis on baseline, week-2, and week-12 MRIs. Myofascial lesions were defined as a high T2 STIR signal that was either diffuse within the muscle or formed a line surrounding the muscle. Reproducibility was estimated by having two radiologists assess the week-2 MRIs.

Results: For myofascial lesion detection, intraobserver reproducibility was almost perfect ($\kappa = 0.890$) and interobserver reproducibility was substantial ($\kappa = 0.758$). At baseline, all patients had at least one inflammatory myofascial lesion; sites involved were the shoulder in 10 (71.4%) patients, hip in 13 (86.7%), ischial tuberosity in 9 (60.0%), and pubic symphysis in 12 (80.0%). Sites involved at week 12 were the shoulder in 8 (53.3%) patients, hip in 5 (33.3%), ischial tuberosity in 1, and pubic symphysis in 3 (20.0%). At week 12, of 103 muscle groups studied in all, 43 (41.7%) had no inflammatory lesions, compared to 33 at baseline (Mac Nemar; $P < 0.001$) but some areas seemed to be more responsive to tocilizumab compared to other areas. Improvements were noted in 66 (64.1%) muscle groups, worsening in 2 (1.9%), no change in 35 (34.0%).

Conclusion: In addition to synovitis and bursitis, PMR causes myositis and fasciitis of the shoulder and pelvic girdles. Tocilizumab therapy improves the myofascial lesions, in addition to the clinical and laboratory features.

Abstract Number: 2287

Interim Results of an Open-Label Study Assessing Efficacy and Safety of Adrenocorticotrophic Hormone Gel for Treatment of Refractory Cutaneous Manifestations of Dermatomyositis

Anthony Fernandez, Dermatology and Pathology, Cleveland Clinic, Cleveland, OH

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Muscle Biology, Myositis and Myopathies Poster III: Treatment and Classification Criteria

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Cutaneous dermatomyositis (DM) is often refractory to multiple medications, suggesting better treatments are needed. Adrenocorticotrophic hormone gel is a repository corticotropin injection that is FDA-approved for DM, but little is known about its safety and efficacy for cutaneous DM manifestations. We are conducting an open-label study to assess efficacy and safety of repository corticotropin injection for treatment of refractory cutaneous DM. Here, interim results of this clinical trial are reported.

Methods: DM patients with \geq mild active cutaneous disease despite prior treatment with ≥ 2 systemic agents were eligible for inclusion. Pts were initiated on 80u repository corticotropin injection twice weekly for 24 weeks (6 months (mo)), with clinical evaluations at baseline, 1 mo, 3 mo, and 6 mo. Primary outcomes include decreases in Cutaneous Dermatomyositis Disease Area and Severity Index (CDASI) activity and Physician's Global Assessment (PGA) activity scores.

Results: Nine adults (8 females, 1 male) with DM (8 classic, 1 amyopathic), have been enrolled (average (avg) age 53.6 years (yrs)). On average, patients carried a diagnosis of DM for 5.2 yrs (median (med) 4 yrs) at time of study enrollment. Patients had been treated with an avg of 4.6 systemic medications (med 4) prior to study entry, and were being treated with an avg of 2.3 systemic medications (med 2) at time of study entry. Avg baseline CDASI activity score was 20.8 (med 19) and avg PGA activity score was 6/10 (med 6). In terms of patient assessments, baseline patient global skin (PGS) scores averaged 3.3/10 (med 3) and patient globalitch (PGI) scores averaged 6.4/10 (med 6). Six patients had a positive ANA (titer range= 1:160 to 1:1280, all speckled pattern). Eight patients had detectable myositis-associated autoantibodies (7 anti-transcriptional intermediary factor 1 gamma (TIF1 γ), 1 anti-small ubiquitin-like modifier activating enzyme (SAE) antibodies). All 9 patients completed ≥ 3 mos of treatment and 7 patients completed 6 mos of treatment at time of interim data analysis. At 3 mos, 7/9 patients had improved CDASI activity scores (average 15.3; med=13) and 8/9 had improved PGA activity scores (avg 7.7; med 8) (**Figure 1**). Additionally, 8/9 patients had improved PGS scores (avg 6.33; med 7) and PGI scores (avg 3.22; med 3) at 3 mos. At 6 mos, 7/7 patients had improved CDASI activity scores (avg decrease from baseline = 13.4) and PGA activity scores (avg improvement from baseline of 2.4 points). Furthermore, PGS scores improved in 6/7 patients and PGI scores improved in 5/7 patients at 6 mos. Adverse effects were mild in severity and no patient discontinued medication during the study period.

Conclusion: Our interim results suggest repository corticotropin injection is an effective, safe, and well-tolerated treatment for refractory cutaneous manifestations of dermatomyositis.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Muscle Biology, Myositis and Myopathies Poster III: Treatment and Classification Criteria

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Immune checkpoint inhibitors (ICIs) enhance the immune response against tumors but may also trigger immune-related adverse events (IRAEs). Myositis following receipt of ICIs is a rare IRAE. In prior studies, creatine kinase (CK) elevations occurred in just 0.2% of patients treated with avelumab, an anti-programmed death-ligand 1 antibody that has been effective against several solid tumor types. Since effective therapies for thymic epithelial tumors are lacking, we included patients with thymic malignancies in a phase I trial of avelumab administered at 10 or 20 mg/kg (NCT01772004).

Methods: Serum and peripheral blood mononuclear cells (PBMCs) were collected before and after avelumab therapy. Serum creatine kinase (CK) levels were monitored during the trial. Laboratory investigations included the assessment of thymoma- and myositis-associated autoantibodies as well as immunophenotyping of PBMCs by flow cytometry.

Results: Seven recurrent thymoma and 1 thymic carcinoma patients were enrolled. No patient had a history of autoimmunity or weakness and each had normal baseline CK levels. Four thymoma patients developed CK elevations (range 762 to 16,037 IU/L) and proximal weakness 7 to 35 days after avelumab administration consistent with ICI-associated myositis. CK levels normalized in all patients within weeks of starting immunosuppressive therapy. One patient with myositis also had myocarditis and a fifth patient without myositis developed enteritis. Four patients had preexisting muscle acetylcholine receptor (mAChR) autoantibodies and each developed CK elevations and weakness. No patient without mAChR autoantibodies developed myositis (100% vs. 0%; $p=0.029$). Electrophysiological studies revealed evidence of myasthenia gravis in just one patient. No patient sera were reactive for any of the 16 myositis autoantigens on EUROLINE Autoimmune Inflammatory Myopathies line blots (EUROIMMUN). Immunophenotyping of PBMCs collected prior to avelumab therapy showed that patients who developed either myositis or enteritis had lower B cell frequencies (0.19%, 0.12-0.73%; median, interquartile range) than those who did not (12.37%, 5.14-16.5%). The median B cell frequencies of 30 patients with non-thymic malignancies and 15 healthy controls were 8.3% (interquartile range 2.4-11.7%) and 16.3% (interquartile range 11.9-17.65%), respectively.

Conclusion: Myositis is a common IRAE in thymoma patients treated with avelumab. Preexisting mAChR autoantibodies may identify thymoma patients most at risk for developing this complication. Since mAChR autoantibodies are known to cause myasthenia but are not associated with myositis, we conclude that they are a marker of preexisting autoimmunity rather than the direct cause of muscle damage. B cell lymphopenia also appeared to be associated with myositis and enteritis in those treated with avelumab. Additional studies are needed to confirm these findings and to determine whether preexisting autoantibodies or immune cell subset dysregulation predicts which non-thymic tumor patients are at increased risk for IRAEs following treatment with avelumab or other immune checkpoint inhibitors.

Session Date: Tuesday, October 23, 2018

Session Title: Muscle Biology, Myositis and Myopathies Poster III: Treatment and Classification Criteria

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Granuloma in the muscle can be found in patients with myopathy. This finding has alternatively been interpreted as either sarcoid myopathy or other myositis subtype associated with granulomatosis. While the response of sarcoid myopathy to immunomodulatory therapy has been purported to be unpredictable, certain myositis subtypes have been linked to specific outcomes. Thus, we aimed at refining the predictive significance of granuloma in patients with myositis.

Methods: A group of 23 patients with myositis and granuloma on muscle biopsy (granuloma-myositis) from 8 centers (7 French and 1 Belgian), was analyzed and compared with a group of 23 patients without identified granuloma (control-myositis) randomly sampled in each centers.

Results: All but two granuloma-myositis patients had extra-muscular involvements, including sarcoid-like signs that were systematically absent in the control-myositis group, such as cutaneous granulomatosis (n=5) or ocular lesion (n=2). In addition, 52% of the granuloma-myositis patients group had biological signs of granulomatosis (i.e. hypercalcemia and/or increased angiotensin converting enzyme) vs. none in the control-myositis group. Hardly half (43%) of the granuloma-myositis patients matched the ENMC 2013 diagnostic criteria for inclusion-body myositis (sIBM, clinico-pathologically defined: n=3, clinically defined n=4 and probable n=3), which was more frequent as compared with the control-myositis group. In accordance with sIBM diagnosis, as compared with remaining granuloma-myositis, these patients were more frequently men, with a longer delay between onset and diagnosis of myositis, suggesting a slow progression of the disease. However, all of them had also extra muscular involvements that were compatible with systemic granulomatosis. All patients were treated with corticosteroids (n=22), methotrexate (n=19), mycophenolate mofetil (n=5), intravenous immunoglobulins (n=3), anti-TNF drug (n=3), hydroxychloroquine (n=2), cyclophosphamide (n=2) because of suspicion of muscle sarcoidosis. Despite a higher number of immunomodulatory treatments as compared with the control-myositis group and the rest of granuloma-myositis group, only 1 granuloma-myositis patients matching ENMC 2013 criteria for sIBM reached muscle improvement (p<0.05 vs. the other myositis groups). Aside one granuloma-myositis patient with anti-PM/Scl positive scleromyositis, the remaining 57% of granuloma-myositis patients did not match the criteria for a well-defined myositis subtype, suggesting pure sarcoidosis. The proportion of patients that reached the definition of muscle improvement at last follow-up in this group (69%) was not significantly different from the patients in the control-myositis group. In multivariate analysis, matching criteria for inclusion-body myositis was the sole feature independently associated with non-response to myopathy treatment in patients with granuloma-myositis (p=0.003).

Conclusion: Granuloma-myositis patients should be carefully screened for inclusion body myositis, which is a very frequent condition in these patients, with important consequences for their care.

Session Title: Muscle Biology, Myositis and Myopathies Poster III: Treatment and Classification Criteria

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Although HP Acthar gel is a purified, injectable formulation of full-length adrenocorticotrophic hormone approved by the FDA for use in myositis, peer-reviewed data is limited. We report long-term outcomes of myositis patients after 6 months of Acthar gel in an open-label pilot study.

Methods: Refractory myositis patients (6 DM, 4 PM) completing 6 months of treatment were included in the study. At the end of trial, 7 of 10 patients met criteria for response at 6 months with a significant reduction in prednisone dose. Post-trial follow-up period was 6 months with assessments at every 2 months which included collection of myositis core set measures (CSM) of disease activity [i.e. extra-muscular global disease activity (Ex-Musc global), physician global disease activity (MD-global), patient global disease activity (Pt-global), health assessment questionnaire (HAQ-DI), manual muscle testing (MMT), and muscle enzymes]. Treatment during the post-trial period was standard of care by the treating physician. ACR-EULAR myositis response criteria as well as the IMACS definition of improvement (DOI) were used to evaluate 12-month outcomes.

Results: 2 of 10 patients were lost to follow-up and 8 patients completed 6 months of post-trial visits. All patients continued their baseline immunosuppressive drugs and were off Acthar gel at the end of trial. Following discontinuation of Acthar gel, all patients had a slow clinical decline with an average time to flare of 4.3 months (median 5, range 0.5-7). Fifty percent of patients (n=4) were restarted on Acthar after an average of 10.3 months (6-13 months) with no other change in medications. The remaining patients who flared were managed by increasing prednisone doses. Patients had an average 41% increase in Ex-Musc global (median 20%, range 0-127%), 79% increase in MD-global (median 107%, range -100%-166%), 7% increase in HAQ-DI (median 0%, range -62% -576%), 0.6% increase in Pt-global (median 0%, range 16%-17%), and 3% decrease in MMT (median: -0.7%, range: -11 -4%) 6 months after Acthar discontinuation. Among 4 patients who restarted Acthar, one was lost to follow-up and 2 showed a partial clinical response in muscle strength and rash after 2 and 3 months and were subsequently treated with IVIG. One patient showed a complete response after restarting Acthar with increased muscle strength and rash resolution. Adverse events with Acthar use included dizziness, facial puffiness and upper respiratory tract infection.

Conclusion: Patients discontinuing Acthar after 6 months of clinical efficacy demonstrated a slow increase in disease activity, disability index, and decrease in muscle strength and had their first flare at 4 months after study drug discontinuation. There is need for a randomized, double-blind, placebo-controlled, clinical trial of Acthar in myositis patients.

Session Date: Tuesday, October 23, 2018

Session Title: Muscle Biology, Myositis and Myopathies Poster III: Treatment and Classification Criteria

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Autoantibodies targeting the Mi-2 (Mi-2a and Mi-2b) nuclear antigen in patients with dermatomyositis (DM) were first described in 1985. However, little is known about the phenotype and evolution of disease over time in these patients compared to anti-Mi2-negative DM patients. The objective of this project was to address the clinical features and the evolution of autoantibody titers over time in DM patients with anti-Mi2 autoantibodies compared to anti-Mi2-negative DM patients and other forms of myositis.

Methods: In this longitudinal cohort study, the prevalence and severity of clinical features at disease onset and during follow-up were compared between anti-Mi2-positive patients and patients with anti-Mi2-negative DM, the antisynthetase syndrome (AS), and immune-mediated necrotizing myopathy (IMNM). The evolution of the anti-Mi2 autoantibody titers were also studied in those patients with available longitudinal sera.

Results: Sixty-two anti-Mi2-positive DM, 160 anti-Mi2-negative DM, 168 AS, and 183 IMNM patients were included in this study. Anti-Mi2-positive patients had more severe proximal muscle weakness and increased muscle enzyme levels both at disease onset and during follow-up compared to anti-Mi2-negative DM (all $p < 0.001$) or AS patients (all $p < 0.01$). Anti-Mi2-positive DM patients were stronger compared to those with IMNM (all $p < 0.01$). Unlike those with IMNM, younger anti-Mi2-positive patients were stronger at disease onset compared to older anti-Mi2-positive patients ($p = 0.005$). Calcinosis and myalgia were less common in anti-Mi2-positive than in anti-Mi2-negative DM patients. Anti-Mi2-positive patients were generally responsive to first-line immunosuppressant treatment; after two years of follow-up, most of them had recovered full strength. Ninety-two percent (11/12) of anti-Mi2-positive patients had decreases in autoantibody titers during the first 3 years of follow-up; 25% (3/12) of them had normalization anti-Mi2 autoantibodies during follow-up.

Conclusion: Although anti-Mi2-positive DM patients are initially weaker than anti-Mi2-negative DM patients, both groups generally respond well to treatment with recovery of muscle strength. With treatment, anti-Mi2 autoantibody titers decrease and may even normalize.

Session Information**Session Date:** Tuesday, October 23, 2018**Session Title:** Muscle Biology, Myositis and Myopathies Poster III: Treatment and Classification Criteria**Session Type:** ACR Poster Session C**Session Time:** 9:00AM-11:00AM

Background/Purpose: Although concomitant infectious diseases are the predominant causes of death in patients with polymyositis (PM)/dermatomyositis (DM), intensive immunosuppressive treatment are necessary for severe cases. We have already reported that high initial dose of glucocorticoid and combination immunosuppressive therapy for induction therapy, and KL-6 levels at the baseline were independent risk factors for infection. Here we investigated the predictive risk factors for opportunistic infection during immunosuppressive treatment for PM/DM by assessing cytomegalovirus (CMV) antigen test as a barometer for immunocompromised status.

Methods: We retrospectively analyzed clinical features, laboratory data at baseline in the patients with PM/DM who had received initial treatment at six hospitals affiliated to Yokohama City University from 2003 to 2016. We also investigated initial therapeutic regimens and clinical outcomes including CMV antigenemia as a complication. We conducted univariate and multivariate analyses to extract risk factors for CMV antigenemia.

Results: One hundred sixty-eight (PM 42, DM 82, and clinically amyopathic DM (CADM) 44) were recruited. The mean age was 56 ± 16 years and 120 (71.4%) were female. As initial therapies, oral prednisolone (PSL) was prescribed in all patients. Methylprednisolone (mPSL) pulse, intravenous cyclophosphamide (IVCY), and oral calcineurin inhibitor therapies were performed in 93 (56%), 50 (30%) and 86 (51%), respectively. Forty patients (24%) received combination therapy with IVCY and a calcineurin inhibitor. Fifty-two patients (31%) had CMV antigenemia within 6 months from initiation of immunosuppressant. An univariate analysis showed complication of ILD, high activity of ILD such as high KL-6 and low PaCO₂ and strong immunosuppressive therapy tended to be positive CMV antigenemia (Table 1). There was no association between the cumulative PSL dose except within one month and CMV antigenemia. A multivariate logistic regression analyses revealed that low PaCO₂ ($p = 0.023$, OR 0.78) and old age ($p = 0.040$, OR 1.07) were independent risk factors for CMV antigenemia. Moreover, the patients with positive CMV antigenemia tended to infected which were needed antibiotic therapy with significant differences (OR 4.52, $p < 0.001$). There were no patients with organ dysfunction as CMV infection.

Conclusion: Although rapid and intensive therapies are required for PM/DM, appropriate monitoring, prophylaxis and early treatment for opportunistic infection are important, especially in patients who receive strong immunosuppressive therapy and who show low PaCO₂ level and old age at baseline.

Abstract Number: 2293

Subcutaneous Intravenous Immunoglobulins in Idiopathic Inflammatory Myopathies: Analysis of a Monocentric Cohort

Emanuele Calabresi¹, Simone Barsotti², Elisa Cioffi³, Alessandra Tripoli¹, Andrea Delle Sedie¹, Laura Bazzichi⁴, Ornella Mazzarella¹, Rossella Neri⁴ and Marta Mosca¹, ¹Rheumatology Unit, University of Pisa, Pisa, Italy, ²Department of Medical Biotechnologies, University of Siena, Siena, Italy, ³Rheumatology Unit, Rheumatology Unit, University of Pisa, Pisa, Italy, ⁴Rheumatology Unit, University of Pisa, PISA, Italy

Session Information**Session Date:** Tuesday, October 23, 2018**Session Title:** Muscle Biology, Myositis and Myopathies Poster III: Treatment and Classification Criteria**Session Type:** ACR Poster Session C**Session Time:** 9:00AM-11:00AM

Background/Purpose: Despite the absence of specific guidelines, the treatment with intravenous immunoglobulins (IvIg) is considered effective in patients with refractory idiopathic inflammatory myopathies (IIM). Recently, a new therapeutic approach with subcutaneous immunoglobulins (ScIg) has been proposed. The aim of our study is to evaluate efficacy and safety of ScIg in patients with IIM followed in a rheumatology unit.

Methods: 10 IIM patients (7 Female, mean age 64.4 ± 10.2 years) treated in our rheumatology unit with ScIg were enrolled. Six patients had PM and 3 DM (Bohan and Peter criteria) while 1 had IBM (Griggs criteria). The treatment scheme was 2g/kg/month divided in 4 weekly administrations at home. At baseline and after treatment the following data were

collected: myositis specific/associated autoantibodies; indications to the treatment (skin lesions, dysphagia, lung or muscular involvement) and clinical response according to the manual muscle test 8 (MMT8), creatine kinase (CK), physician and patients' disease activity visual analogue scale (ph-VAS and pt-VAS), and health assessment questionnaires (HAQ).

Results: Nine patients received ScIg after treatment with IvIg (mean 22 months of treatment) while one started ScIg directly for severe skin involvement. Five patients had Ro52 positivity, 1 Tif1 γ , 1 anti-Ku. The indication for the treatment was the presence of refractory disease in 8 patients. All of these patients were treated with high dose steroids and at least 2 immunosuppressant. In 2 patients the treatment was prescribed for recurrent infections during immunosuppressive treatment. In addition, 7 patients had severe dysphagia. Only 1 patient reported an adverse event (vomiting, headache) and stopped the treatment after the first month. In the other nine patients, the duration of the follow-up was 18 months (3-72). At the last evaluation, compared to the switch to ScIg, no statistically significant differences were identified in MMT8, CK, ph-VAS, pt-VAS and HAQ ($p=n.s.$). The mean daily steroid dose was reduced from 6.1 ± 4.2 to 3.7 ± 2.5 mg ($p=n.s.$). Dysphagia improved in 4/7 patients. The patient who started ScIg directly for refractory and severe skin involvement improved after 6 months of treatment. No disease flares were identified during the treatment.

Conclusion: Despite their high cost, ScIg confirmed similar efficacy compared to IvIg for the treatment of refractory IIM patients and may represent an alternative. The treatment may allow an improvement of the quality of life of the patients, reducing the necessity of hospitalization. Furthermore was safe and no serious adverse events were reported during the treatment. Additional data with longer follow-up are necessary to confirm our data in different subset of patients.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Muscle Biology, Myositis and Myopathies Poster III: Treatment and Classification Criteria

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: New 2016 EULAR/ACR classification criteria have been established for idiopathic inflammatory myopathies (IIM). The highest weighted score is associated with the presence of anti-Jo-1 antibody and dermatomyositis (DM) classic rashes (Gottron papules/sign and heliotrope rash). The aim of our study was to evaluate if the addition of other myositis specific antibodies (MSAs) and/or other DM rashes would improve the accuracy of the criteria.

Methods: A prospective, longitudinal IIM dataset from a single myositis center was evaluated using the 2016 EULAR/ACR criteria as well as the Bohan & Peter classification criteria. All variables required for both these criteria were ascertained at the patient's first visit and subsequently updated prospectively on follow up visits. Expert physician clinical diagnoses (RA, CVO) were used as the gold standard to evaluate the criteria and proposed modifications. The latter included a) all other MSAs with anti-Jo1, b) all other DM rashes with Gottron papules (i.e. shawl sign, V-neck, holster sign, malar rash not sparing nasolabial fold, mechanics hands, periorbital edema), c) both a& b. This ongoing project thus far only includes data collection for DM. Percent agreement between the criteria and its proposed modifications with expert physician diagnosis were evaluated along with sensitivity and specificity.

Results: 213 DM patients (70% female, 89% Caucasian) have been analyzed to date. 2016 EULAR/ACR and Bohan & Peter showed % agreement of 84.3% and 82.9%, respectively as compared to the expert physician diagnosis, with sensitivity and specificity of 95.3% and 34.2% for EULAR/ACR and 83.8% and 82.9% for Bohan & Peter. The low specificity of EULAR/ACR criteria was partially explained by high false positives, as the current criteria fail to differentiate between DM and amyopathic DM, whereas the expert physician assessment did. The specificity of EULAR/ACR criteria improves to 44.8% without loss of sensitivity, if amyopathic DM is included under DM in the gold standard (Table 1). With the inclusion of other MSAs, there is a small gain in sensitivity to 98.3%, however, there is a marked decrease in specificity and a mild reduction of %agreement (Table 1). Similarly, with modification of inclusion of other

DM rashes, the sensitivity increases to 97.7% at the cost of specificity and %agreement. Applying both other MSA and other rash modifications, the sensitivity increases to almost 99%, with a severe loss of specificity and %agreement.

Conclusion: Contrary to popular belief, addition of other MSAs or other DM rashes or both in the 2016 EULAR/ACR criteria did not improve the criteria. There is a small gain in sensitivity but a marked decrease in % agreement and specificity. Further analysis including PM, IBM and other muscle disease control subjects is required to provide conclusive answers.

Table 1

	Expert Physician Classification Positive	Expert Physician Classification Negative	Sensitivity	Specificity	% Agreement
EULAR/ACR Positive	173	16	95.6%	44.8%	88.5%
EULAR/ACR Negative	8	13			
Bohan & Peter Positive	148	5	84.1%	78.4%	85.3%

Classification of Idiopathic Inflammatory Myopathies: Assessment of 123 Patients According to 2017 Acr/EULAR Criteria Followed up By a Single Center from Turkey

Emin Oguz¹, Ezgi Sahin², Murat Erdugan¹, Bahar Artim-Esen¹, Ahmet Gül¹, Lale Ocal¹ and Murat Inanc³, ¹Department of Internal Medicine, Division of Rheumatology, Istanbul University, Istanbul Faculty of Medicine, Istanbul, Turkey, ²Department of Internal Medicine, Istanbul University, Istanbul Faculty of Medicine, Istanbul, Turkey, ³Department of Internal Medicine, Division of Rheumatology, Istanbul University, Istanbul Faculty of Medicine, Istanbul, Turkey

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Muscle Biology, Myositis and Myopathies Poster III: Treatment and Classification Criteria

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The aim of this study is to evaluate sensitivity, limitations and assessment of 2017 ACR/EULAR IIMs classification criteria (ACR/EULAR2017) in 123 patients with idiopathic inflammatory myopathy (IIM).

Methods: Demographic data, clinical and serological features of 123 patients with a clinical diagnosis of IIM fulfilling Bohan/Peter criteria and followed up between 1994-2018 in our clinic, were collected according to a pre-defined protocol and ACR/EULAR2017 were applied to patients. Muscle biopsy scoring was performed on 70 patients who had biopsy records. Sensitivities and specificity on subset determination of the criteria of were analysed.

Results: The median age of patients was 46±15 and average follow up was 77 months. In 66% of the patients, the diagnosis was dermatomyositis (DM), in 28% polymyositis (PM), in 6% was immune-mediated necrotizing myopathy (IMNM) and inclusion body myositis (ICM). The frequency of arthritis, dysphagia, respiratory muscle involvement, interstitial lung disease and malignancy were detected 25, 35, 12, 29, 24% respectively, and mortality was 19%. ANA positivity was 38% and anti Jo-1 was present in 12% of the patients. Definite or possible IIM according to ACR/EULAR2017 was found in 95% of the patients regardless of muscle biopsy scoring (Possible IIM: 7%; definite IIM: 87%). The classification percentage of DM was 99 (all definite), PM 91 (probable and definite PM: 21 and 70%), IMNM 100 (probable and definite IMNM: 33 and 67), ICM 0 when ACR/EULAR2017 were applied to subsets of IIM without muscle biopsy scoring. On the other hand; in the classification made by including muscle biopsy scoring on the IIM subsets DM

was 100% (probable and definite: 3 and 97%), PM was 93% (probable and definite PM: 30 and 63%), IMNM 83% (all probable), ICM 100% (probable and definite ICM: 50 and 50%).

One of the DM patients and a patient with DM without dermatitis were classified as PM, 4 patients with hypomyopathic DM (HDM) were classified as amyopathic DM (100%) and 6 patients with IMNM was classified as PM (100%).

Conclusion: Without muscle biopsy and EMG, 95% of 123 IIM patients fulfilling Bohan/Peter criteria can be classified with the new ACR/EULAR2017. The sensitivity of the criteria is higher in DM (%99) but lower in PM (91%) and increased when muscle biopsy records are included (98%). On the other hand insufficient biopsy results may cause a slight change from definite to probable PM. ADM patients within the subset of DM were defined 100% correctly. Although ACR/EULAR2017 might have drawbacks in the classification of HDM and IMNM, significant improvement in the classification process with the advantage of weighting towards clinical assessment have been observed.

DM specific skin lesion	8†	6	10	9†	5	2	39
Dysphagia	2	2	2	3	2	1	16

†p<0.05 *p<0.01

Background/Purpose: Since Bohan and Peter first described their diagnostic criteria for idiopathic inflammatory myopathies (IIM) in 1975, new discoveries such as myositis-specific and myositis-associated autoantibodies (Abs) have been made.

To investigate correlations between specific myositis Abs and their frequencies and clinical associations across different IIM groups, collectively demonstrating the utility of the new clinicoserologic classification in Korean adult patients with IIM.

Methods: We conducted a multicenter cohort study including 67 adult patients (age, 18 years) who have been diagnosed as IIM by ENMC criteria. Immunoblot assay with Euroline strip (EUROIMMUN, Germany) was performed using the sera of definite dermatomyositis (DM, n=36), definite polymyositis (PM, n=25), amyopathic DM (n=4), DM sine dermatitis (n=1), and immune mediated necrotizing myopathy (IMNM, n=1). Patients were classified based on three classifications: 1) novel clinicoserologic classification suggested by Troyanov et al. in 2017. 2) 2017 EULAR/ACR classification criteria. 3) 2004 European neuromuscular center (ENMC) criteria. Associations of myositis Abs and clinical subsets of IIM were investigated.

Results: The distribution of the various IIM differed strikingly from those using the 3 classifications (Fig 1). According to the 2004 ENMC classification and 2017 EULAR/ACR classification criteria, DM and PM was the most and the second frequent entities (DM: 55.2%, 56.7 %; PM: 35.8%, 37.3%). But, using the new clinicoserologic classification, overlap myositis (OM) is the major type of IIM and the frequency of PM is significantly decreased. Anti-ARS Abs specificity included anti-Jo-1 (16.4%), -OJ (4.6%), -EJ (6.2%), -PL-7 (3.1%), and -PL-12 (4.6%). Interstitial lung disease was closely associated with anti-MDA5, and anti-ARS Abs, while DM-specific skin lesion was frequently observed in patients with anti-TIF1- γ and anti-ARS Abs. Seven patients with cancer-associated DM were identified. They were positive for anti-TIF1- γ (5/7) and anti-SRP (3/7) (Table 1).

Conclusion: Novel classification based on distinctive features and new myositis Abs reflects the clinical phenotype of IIM better. Establishment of a system routinely available to screen myositis Abs is needed. This will be beneficial to provide more precise diagnosis and proper management for patients with IIM.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Muscle Biology, Myositis and Myopathies Poster III: Treatment and Classification Criteria

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with IIM have been classified mainly according to Bohan and Peter (B&P) criteria, proposed in 1975. In 2017 the new EULAR/ACR criteria were proposed. They are able to classify patients with both adult/juvenile form of IIM and they are applicable also in patients with amyopathic DM (ADM) and in IBM even without the results of muscle biopsy. The objective of this study was to evaluate the performance of the new classification criteria for IIM in a large retrospective cohort of patients.

Methods: Consecutive patients with a clinical diagnosis of IIM, based on physician opinion, referred to a rheumatology unit from 1995 to 2018 were included and assessed according to the B&P and the EULAR/ACR criteria. Data were collected from an existing database and, when missing, additional variables were retrieved from the patient's records when available. Cohen's kappa (K) was used to measure the agreement between physician opinion and the classification criteria; in addition, sensitivity and specificity were calculated.

Results: A total of 424 patients were included in the analysis (M 157, F 269, mean age at the onset 53.5 ± 17.5 years). In 18 patients the onset <18. According to the physician opinion 190 patients had PM, 51 IBM, 146 DM, 11 Juvenile DM (JDM), 4 ADM and 22 incomplete IIM.

Applying the B&P criteria, 406 patients (94.8%) were classifiable as IIM (172 definite, 141 probable, 93 possible): 277 PM (95 def, 106 prob, 76 poss) and 129 DM (77 def, 35 prob, 17 poss). With the EULAR/ACR criteria 351 (82.8%), could be classified as IIM (258 def, 89 prob, 4 poss): 161 PM (83 def, 76 prob, 2 poss), 121 DM (117 def, 4 prob), 44 IBM (41 def, 3 prob, 1 poss), 11 ADM, 13 juvenile IIM (11 DM, 2 PM). The Cohen's K, the sensitivity and the specificity for the criteria are reported in table 1. Eighteen patients were not classifiable according to B&P criteria (11 PM, 1 DM, 1 ADM and 3 incomplete IIM) and 73 according to EULAR/ACR criteria (52 PM, 9 DM, 1 ADM, 1 JDM, 10 incomplete IIM). Missing detailed information on patterns of muscle weakness and muscle biopsy features were explanations for not being able to classify most patients.

Conclusion: The new EULAR/ACR criteria performed well in a retrospective cohort using data from a myositis register and patient records from a myositis clinic, but they depend on muscle strength testing of upper and lower extremities as well as of proximal and distal muscles in the legs.

Criteria	Subtype	Cohen's K	Sensitivity	Specificity
Bohan and Peter	Overall	0.108	0.97	0.16
	PM	0.479	0.97	0.38
	DM	0.705	0.75	0.91
EULAR/ACR	Overall	0.142	0.84	0.45
	PM	0.492	0.72	0.84
	DM	0.755	0.76	0.96
	IBM	0.765	0.93	0.98

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Muscle Biology, Myositis and Myopathies Poster III: Treatment and Classification Criteria

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The new European League Against Rheumatism / American College of Rheumatology (EULAR / ACR) classification criteria for inflammatory myopathies are able to identify patients with dermatomyositis (DM). However, approximately 25% of patients with purely cutaneous DM do not meet 2 out of the 3 hallmark skin signs and fail to meet the criteria for myositis. To allow a more inclusive definition of cutaneous DM, we are developing a skin-focused classification criteria based on the consensus of international experts in the Rheum/Derm field. This project specifically aims to distinguish skin findings in DM from potential mimickers.

Methods: An extensive literature review was done. International experts participated in several nominal group discussions to generate items for the Delphi. Items were grouped into categories of distribution, morphology, symptoms, antibodies, histology, and contextual factors. Using REDCap, participants rated these items in terms of their appropriateness and their ability to distinguish DM from other diagnoses. The relevance score ranged from 1 to 100 and the median of each item determined the rank-ordered list. A pre-specified median score cut-off was decided by the steering committee and the participants. There were 2 rounds in this Delphi criteria project.

Results: There were 50 respondents composed of dermatologists and rheumatologists from North America, South America, Europe and Asia. After subjecting the items to a cut-off score of 70 during the first round, 37 out of the 54 items were retained and carried over to the next round. The cut-off was then raised to 80 for the second round, and a list of 22 items (Table 1) was generated for potential inclusion into a set of items that will be used to validate classification criteria in a prospective case-control study.

Conclusion: This project is a key step in the development of prospectively validated criteria that will create well-defined cohorts for clinical research on novel treatments for DM.

Table 1: Potential Cutaneous DM Classification Criteria*

Distribution(median)	Morphology(median)	Symptomatology (median)	Path / Lab(median)	Contextual Factors(median)
Eyelid (85.5) Shawl (83.5) V of Neck (80) Elbow, Knee (80)	Violaceous erythema (90) MCP IP Joints papules (90) MCP, IP joint macules (86) Nailfold Capillary loops (86.5) Nailfold erythema (80) Cuticular Dystrophy (85) Poikiloderma (80) Fissuring of digits (80) Linear extensor erythema (80) Eyelid edema (80) Palmar macules and papules (81)	Pruritus of scalp (80) Photosensitivity (80)	Interface dermatitis (90) Dermal Mucin (80) Presence of myositis antibodies (88.5)	Interstitial lung disease (80) Muscle weakness (85)

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Osteoporosis and Metabolic Bone Disease – Basic and Clinical Science Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: We previously demonstrated that denosumab increased lumbar spine and total hip bone mineral density (BMD) significantly more than risedronate at 12 and 24 months in glucocorticoid (GC)-treated individuals (Saag *ACR*2016; Saag *ECTS* 2018). Prespecified subgroup analyses of lumbar spine BMD at 12 months indicated that denosumab was superior to risedronate across 7 subgroups of GC-treated individuals (Saag *ASBMR* 2017). This analysis explored the effects of denosumab and risedronate on lumbar spine BMD in the same subgroups of GC-treated individuals at 24 months.

Methods: The phase 3, randomized, double-blind, double-dummy, active-controlled study enrolled women and men age ≥ 18 years receiving ≥ 7.5 mg prednisone or equivalent daily for < 3 months (GC-initiating) or ≥ 3 months (GC-continuing) before screening. All subjects age < 50 years were required to have a history of osteoporotic fracture. GC-continuing subjects age ≥ 50 years were required to have lumbar spine, total hip, or femoral neck BMD T-score ≤ -2.0 ; or ≤ -1.0 with a history of osteoporotic fracture. Subjects were randomized 1:1 to denosumab 60 mg SC every 6 months or risedronate 5 mg PO daily for 24 months. All subjects were to receive daily calcium (≥ 1000 mg) and vitamin D (≥ 800 IU). The treatment difference (denosumab – risedronate) for percentage change from baseline in lumbar spine BMD at 24 months was estimated in the GC-initiating and GC-continuing subpopulations, both overall and in 7 prespecified subgroups where treatment effect might differ (sex, race, age, baseline BMD T-score, geographic region, menopausal status, and baseline GC daily dose).

Results: The study enrolled 795 subjects (290 GC-initiating, 505 GC-continuing). Baseline characteristics were balanced between treatment groups within each subpopulation. Denosumab was superior to risedronate for gains in lumbar spine

Table. Treatment Difference [Denosumab [DMAb] – Risedronate [RIS]] in Lumbar Spine BMD Percentage Change From Baseline at Month 24

	GC-initiating Subpopulation (N = 133 RIS / 128 DMAb)				GC-continuing Subpopulation (N = 230 RIS / 228 DMAb)

CI = confidence interval; N = Number of randomized subjects with a baseline measurement and ≥ 1 postbaseline measurement for the lumbar spine BMD; n=number of subjects with observed value. * $p < 0.001$, denosumab vs risedronate. [†] $p < 0.05$, denosumab vs risedronate. [‡]Qualitative p-values > 0.05 support consistent directionality of treatment effect within the subgroups. [§]In prednisone equivalents.

BMD at 24 months in both the GC-initiating and GC-continuing subpopulations. Within each subgroup (Table), denosumab was consistently associated with a greater increase in lumbar spine BMD at 24 months compared with risedronate. Significant quantitative interactions were observed only in the sex and race subgroups in the GC-initiating subpopulation. However, qualitative tests indicated the direction of the denosumab effect did not differ significantly by sex or race in this subpopulation.

Conclusion: Denosumab consistently increased lumbar spine BMD more than risedronate at 24 months in both GC-initiating and GC-continuing subpopulations, with no evidence of directional heterogeneity in treatment effect across 7 prespecified subgroups of GC-treated individuals. Denosumab may be a useful addition to the osteoporosis armamentarium in the common clinical setting of GC use.

Compliance with Screening and Supplementation Guidelines for Glucocorticoid-Induced Osteoporosis, How Bad Did We Do This Time?

John Zawidniak¹ and John Waterman², ¹Rheumatology, University of Connecticut, Farmington, CT, ²Rheumatology, Connecticut VA Healthcare System, Newington, CT

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Osteoporosis and Metabolic Bone Disease – Basic and Clinical Science Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Glucocorticoid-induced osteoporosis (GIOP) is a well-established and well-studied phenomenon that is a sequela of the treatment of many inflammatory diseases. Many studies over the years have looked at compliance with guidelines for the prevention and treatment of GIOP. Previous studies have shown compliance with recommendations to be quite poor in regards to DXA screening, as well as calcium and vitamin D supplementation. This study aimed to give a current look at this issue, particularly in light of the most recent release of ACR GIOP guidelines in 2017, to see if compliance has improved over the years.

Methods: Patients who had received a prescription of prednisone between July 2016 to July 2017 from the VA Connecticut Health System were identified. The first 300 patient's charts were reviewed. Patients were excluded if they had received one time tapers of prednisone or if they were receiving prednisone for malignancy and were since deceased. Subsequently 266 patients were included for analysis (on prednisone for ≥ 3 months, dose ≥ 2.5 mg daily, and any indication). Data on age, last dosage of prednisone, duration of treatment, diagnosis, DXA status, DXA results, vitamin D levels, and whether patients were on calcium or vitamin D supplementation were collected.

Results: Of 266 patients included for analysis, mean age was 71 (standard deviation 12 years), mean dosage 7.65mg (range 1-50mg). 120 patients had undergone DXA examination (45.1%), 146 had not. The most frequent diagnoses were RA with 49 patients, COPD 40, PMR 37, transplant 23, and myasthenia gravis 13. Prescriber specialty 114 patients rheumatology, 50 primary care physician, 24 pulmonary, 19 nephrology, 15 each hematology-oncology and neurology, 29 other. Rheumatologists had a rate of DXA scans of 53.5%, primary care physicians 38%, pulmonary 29.2%, renal 42.1%, hematology-oncology 33.3%, and neurology 46.67%. Taking into consideration the 2017 guidelines, with patients ≥ 40 years of age, 45.9% of appropriate patients underwent DXA, 54% did not. Per 2017 guidelines 51.7% were appropriately on calcium supplementation and 57.5% appropriately on vitamin D supplementation.

Conclusion: There have been many studies over the years regarding compliance with guidelines for GIOP. In this particular study, as seen previously, we show poor compliance with only 45.1% of patients appropriately undergoing DXA screening. If accounting for the 2017 guidelines in the cohort of patients ≥ 40 years of age this improves to 45.9%. Patients are still largely not undergoing proper screening and even when they do a large proportion, 48.3% for calcium, 42.4% for vitamin D are not receiving the appropriate calcium and vitamin D supplementation. With each new iteration of guidelines for GIOP it becomes imperative to adjust practice habits appropriately. Unfortunately study after study shows this is not

occurring. Given the continued poor compliance on the part of providers it is worth considering a reduction in frequency of revision of guidelines and better provider education to finally lead to improved compliance.

Session Title: Osteoporosis and Metabolic Bone Disease – Basic and Clinical Science Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatologic diseases (RDs) have been associated with an increased risk of osteoporosis (OP) and osteoporotic fractures, however, most patients do not receive diagnosis and adequate treatment. The aim of our study was to study the prevalence of OP and osteoporotic fractures in relation to RDs.

Methods: We used National Inpatient Sample (2000-2014) to identify hospitalizations ≥ 18 years of age with OP and osteoporotic fractures and excluded fractures due to other etiologies. We studied the yearly trends of OP and osteoporotic fractures as well as compared the trends among hospitalizations with or without RDs in terms of Annual Percentage Change (APC).

Results: OP was noted to have an increasing trend from 2000 - 2009 (APC=5.81, $p<0.05$) with a decline thereafter (APC=-3.88, $p<0.05$). In contrast, osteoporotic fracture showed an initial downward trend from 2000-2010 (APC=-7.31, $p<0.05$), followed by a slowly rising trend (APC=2.0, $p=NS$) (**Figure 1**). The trends were similar in groups with or without RDs (**Figure 2**). RDs had higher odds of OP [ORs 2.58 (95 % CI 2.55 – 2.60), $p<0.001$] and osteoporotic fractures [OR 1.28 (95% CI 1.25 -1.31), $p<0.001$] (**Table 1**).

Conclusion: RDs were associated with increased OP and osteoporotic fractures; the pathogenesis includes disease-related (chronic inflammation) and treatment-related (glucocorticoid induced) factors. Decreasing trend was noted along with a halt in a previously declining fracture rates. The noted decrease in OP might represent a true decline due to better

Figure 2: Trends of Osteoporosis and Fragility fractures among hospitalizations with and without Rheumatologic Diseases (RD)

prevention, but may also be due to decreased screening and subsequent detection. Also, if the decreased trend was due to better prevention, one would expect osteoporotic fractures to decrease as well. Potential explanations include inadequate screening per guidelines, suboptimal treatment and decreasing patient compliance, which have also been documented in many prior studies.

In conclusion, primary and secondary prevention measures for OP have been underutilized by both physicians and patients alike, although several possibilities exist. Awareness of this is vital to increase physician prescribing practices and patient compliance.

Session Date: Tuesday, October 23, 2018

Session Title: Osteoporosis and Metabolic Bone Disease – Basic and Clinical Science Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Wrist fractures are the most common fracture of the upper extremity and increase subsequent fracture risk in women with postmenopausal osteoporosis. Most wrist fractures occur at the ultradistal (UD) radius. Abaloparatide (ABL) is a selective activator of the PTH1 receptor signaling pathway that stimulates bone formation. In the ACTIVE phase 3 study, 18 months of ABL significantly increased bone mineral density (BMD) at the UD radius and

maintained BMD at the 1/3 distal radius vs placebo (PBO) and teriparatide (TPTD). BMD effects were associated with a trend for numerically lower wrist fracture incidence for ABL vs TPTD ($P=0.052$). Women receiving ABL or PBO in ACTIVE were offered enrollment in the ACTIVEExtend extension study in which both groups received 24 months of open-label alendronate (ALN) 70 mg/wk for a total of 43 months (18 months ABL or PBO, 1 month for reconsent, 24 months ALN). Our objective was to determine the efficacy of ABL followed by ALN (ABL/ALN) vs PBO/ALN on BMD at the UD radius over 43 months.

Methods: Forearm BMD data (ACTIVE baseline and month 43) were measured for 213 and 233 women in ABL/ALN and PBO/ALN groups, respectively. BMD was centrally analyzed and adjusted for machine differences. DXA scanner and baseline BMD were included as covariates. Wrist fracture event rates were estimated for the ACTIVEExtend ITT population (558 ABL/ALN; 581 PBO/ALN) by KM method.

Results: Over the 18 months of the ACTIVE trial, BMD of the UD radius decreased in the placebo group but increased with ABL; these increases were maintained over the ALN extension (Figure). There were 15 women with wrist fractures in the ABL/ALN group (KM estimate: 2.8%) and 20 in the PBO/ALN group (3.6%). Although the number of wrist fractures was low, these fractures were numerically lower with ABL/ALN vs PBO/ALN (HR=0.77, 95% CI [0.39, 1.50], $P=NS$).

Conclusion: The BMD gains at the UD radius following treatment with ABL were maintained over the subsequent 24 months of treatment with ALN. Wrist fracture risk was numerically lower with ABL/ALN vs PBO/ALN. These results, together with previous ACTIVE analyses, suggest that BMD of the UD radius, which is rich in trabecular bone, may be a better predictor of wrist fracture than the 1/3 distal radius.

Figure. Mean (\pm SE) Percent Change in Ultradistal Radius BMD from Baseline Through Month 43. Missing BMD data imputed using the method of last observation carried forward. ABL, abaloparatide; ALN, alendronate; SE, standard error.

Session Date: Tuesday, October 23, 2018

Session Title: Osteoporosis and Metabolic Bone Disease – Basic and Clinical Science Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Abaloparatide (ABL) is a selective activator of the PTH1 receptor signaling pathway that stimulates bone formation. In the ACTIVE Phase 3 study, ABL significantly increased BMD and reduced the risk vertebral, nonvertebral, clinical, and major osteoporotic fractures in women with postmenopausal osteoporosis compared with placebo (PBO). In ACTIVEExtend, the ABL and PBO arms were switched to receive alendronate (ALN) 70 mg weekly for two years. The objective of these analyses was to evaluate bone mineral density (BMD) response rates with ABL/ALN vs PBO/ALN in ACTIVEExtend.

Methods: BMD was measured at the lumbar spine, total hip, and femoral neck from the beginning of ACTIVE to the end of ACTIVEExtend (18 months of ABL or PBO followed by 1 month for reconsent, followed by 24 months of ALN treatment for a total of 43 months). Measurements were collected from 1,139 women enrolled in ACTIVEExtend, and were centrally analyzed. Patients experiencing BMD gains of >0%, >3%, and >6% at the lumbar spine, total hip, and femoral neck were evaluated. A responder was defined as a patient with BMD increases at all three sites. A Chi-square test was used to determine the difference in number of responders between treatment groups.

Results: From ACTIVE baseline through month 43 of ACTIVEExtend, BMD increases of >3% were observed at the lumbar spine in 93.1% (472/507 evaluable patients) and 79.4% (404/509) patients, at the total hip in 80.1% (406/507) and 52.1% (263/505) patients, and at the femoral neck in 67.5% (342/507) and 34.9% (176/505) patients in ABL/ALN and PBO/ALN groups, respectively. A greater percentage of patients in the ABL/ALN group responded with BMD changes from ACTIVE baseline of >0%, >3%, and >6% at all three sites combined compared with the PBO/ALN group ($P<0.0001$ for each comparison). At month 43, 60.7% (307/506) vs 24.0% (121/505) of patients experienced BMD increases of >3% at all three sites in ABL/ALN vs PBO/ALN groups, respectively ($P<0.0001$). Increases of >6% at all three sites were experienced by 33.2% (168/506) vs 4.0% (20/505) of patients in ABL/ALN vs PBO/ALN groups, respectively ($P<0.0001$).

Conclusion: In conclusion, from ACTIVE baseline through the 43 months of ACTIVEExtend, BMD response increased in both ABL/ALN and PBO/ALN groups, with significantly greater response rates in the ABL/ALN group at the total hip, femoral neck, and lumbar spine. Results are consistent with significant BMD response with ABL vs PBO observed in ACTIVE, and continued fracture risk reduction from ACTIVE through ACTIVEExtend with sequential ABL/ALN compared with PBO/ALN treatment.

Session Date: Tuesday, October 23, 2018

Session Title: Osteoporosis and Metabolic Bone Disease – Basic and Clinical Science Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Changes in bone turnover marker (BTM) are known to offer an information regarding a dynamics of bone remodeling, treatment outcome in primary osteoporosis (OP). However, this has not been robustly investigated in real-world OP patients with rheumatoid arthritis (RA). The aim of this study is to investigate a serial change of BTMs after initiation of antiresorptive therapy in patients with active RA and OP, and compared it with newly diagnosed primary patients.

Methods: By retrospective reviewing of medical records, two groups of study population was designated. Group 1 is patients who newly diagnosed with active RA and OP both, and started antiresorptive therapy (bisphosphonate or selective estrogen receptor modulator) with a concomitant start of disease-modifying immunosuppressive agent and oral

glucocorticoid (above 5mg prednisolone equivalent per day). Group 2 is patients who newly diagnosed with primary OP. Along with demographic parameters, biologic maker of bone formation (osteocalcin) and bone resorption (serum telopeptide of type I collagen (CTX)) was checked on starting and after 3-6 months, 12 months of therapy. BMD by DEXA was checked on starting and after 12 months of treatment. A non-parametric comparison of BTMs, DEXA value between two groups were done. Spearman's correlation and multivariate regression analysis on the effect of followed-up BTM level to good responder after 12 months treatment was investigated.

Results: The mean age of group 1 (34 patients, all female) was 58.5 ± 11.7 years old, which was significantly younger then group 2 (37 patients, all female, 65.8 ± 7.9 years old). The achievement of T-score > -2.5 on lumbar spine or hip (reimbursement guideline of Korean FDA to halt medication for 1 year) was 14 patients (41.2%) in group 1 and 15 patients (40.5%) in group 2. Suppression of BTM after 3-6 months of antiresorptive treatment was sustainable in group 1, 2 and more evident in bisphosphonate group. In group 1, the achievement of T-score > -2.5 was associated with the achievement of low disease activity during treatment of RA and OP. The effect of BTM level at initiation or after 3-6 months antiresorptive treatment on 1 year increment of bone density was not statistically significant in after adjusting demographic parameters and concomitant medication.

Conclusion: BTM suppression and increment of bone density after antiresorptive treatment in RA patients was comparable with response of primary OP. A patient with high RA disease activity during OP medication showed less increment of bone density.

Peripheral Arterial Disease is Associated with an Increased Risk of Subsequent Hip Fracture: A Systematic Review and Meta-Analysis of Cohort Studies

Abstract:

Background/Purpose: Studies have suggested an increased risk of hip fracture among patients with peripheral arterial disease (PAD) although the results were inconsistent. This systematic review and meta-analysis was conducted with the aim to comprehensively investigate the risk of hip fracture among patients with PAD by reviewing all available studies.

Methods: A comprehensive literature review was conducted using MEDLINE and EMBASE databases through April 2018 to identify all cohort studies that compared the risk of subsequent hip fracture among patients with PAD with individuals without PAD. Effect estimates and 95% confidence intervals (CI) of the included studies were extracted and combined together using the random-effect, generic inverse variance method of DerSimonian and Laird. Visualization of funnel plot was used for evaluation of publication bias.

Results: The systematic review process yielded 6 eligible cohort studies that comprised of 15,895 patients with PAD. The risk of subsequent hip fracture among patients with PAD was significantly higher than individuals without PAD with the pooled risk ratio (RR) of 1.64 (95% CI, 1.17-2.29; I^2 80%). Subgroup analysis by study design revealed significant results for both prospective studies (pooled RR 1.60; 95% CI, 1.12 – 2.28; I^2 0%) and retrospective studies (pooled RR 1.72; 95% CI, 1.07 – 2.77; I^2 92%). The forest plot of this meta-analysis is shown as figure 1. The funnel plot (figure 2) was relatively symmetric and, thus, was not suggestive of the presence of publication bias in favor of positive studies although interpretation of the funnel plot was limited by the relatively small number of included studies.

Conclusion: This systematic review and meta-analysis demonstrated a significantly increased risk of subsequent hip fracture among patients with PAD compared with individuals without PAD.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Osteoporosis and Metabolic Bone Disease – Basic and Clinical Science Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Optimal diet is important for bone health. Low protein intake is prevalent among individuals hospitalized for hip fractures. Studies in the aging mouse model have shown that aromatic amino acids (AAA) (tryptophan, tyrosine, phenylalanine) may help promote bone formation, thus implicating a possible role in the prevention and management of osteoporosis and fragility fractures. The objective of this study was to examine the association of dietary intakes of AAA with incident hip fracture, bone mineral density (BMD) and measures of body composition in the Cardiovascular Health Study (CHS)

Methods: The 5,187 CHS participants who completed food frequency questionnaires in 1989-1990, from which mean daily intakes of AAA were estimated, were included in the hip fracture analysis. Subsequent hip fractures were defined by a hospital discharge International Classification of Diseases, Ninth Revision (ICD-9), code 820.xx. 1,591 of these subjects had a DXA scan from 1994-1995 and were included in analyses on BMD and body composition (percent and total fat mass, percent and total lean mass, and total body mass), all modeled as continuous variables. Cox proportional hazard models were used to estimate the hazard ratio (HR) of incident hip fracture associated with each dietary AAA. In the sub cohort with BMD measurements, linear regression analysis was used to estimate the association between dietary AAA and total hip BMD and body composition measures.

Results: During a median follow-up of 13 years, 725 (14%) of 5,187 subjects had an incident hip fracture (1.09 per 100 person-years). The mean intake of tryptophan was 1.1 g/day; phenylalanine, 4.3 mg/day; and tyrosine, 3.5 mg/day. In multivariable models adjusted for demographics, health history (including lifestyle measures), medication use, cystatin C and diet (calcium, vitamin D, protein, and energy), neither tryptophan, tyrosine, nor phenylalanine were significantly associated with incident hip fractures ((HR=0.14; 95%CI 0.01, 1.89), (HR=0.59; 95%CI 0.27, 1.32), and (HR=0.6; 95%CI 0.23, 1.55), respectively), total hip BMD ($p \geq 0.06$) or any measure of body composition ($p \geq 0.10$).

Conclusion: In this cohort of older community dwelling adults, dietary intake of AAA was not significantly associated with incident hip fracture, hip BMD or body composition.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Osteoporosis and Metabolic Bone Disease – Basic and Clinical Science Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid Arthritis (RA) has been considered an independent osteoporotic risk factor. Nowadays, RA patients have a better disease control and corticosteroid use is less intense. Our objective was to compare incidence of osteoporotic fractures in RA patients diagnosed after year 2000 with matched controls from a university hospital-based health management organization (HMO).

Methods: Consecutive RA patients (n=100) diagnosed after year 2000 (all fulfilling criteria ACR/EULAR 2010 of AR), from the HMO, were matched (age and sex) with controls (1:2). The follow-up period began at the index date, defined as the date of RA diagnosis for RA patients and the date of the first medical claim at the HMO for the non-RA patients. Subjects were then followed until they voluntarily left the HMO, a fracture occurred, the end of study (May 1st 2018), or death. Electronic medical records were reviewed and demographic, clinical and treatment data were collected. Incidence rates per 1000 persons-years (PY) of distinct types of fractures after index dates were calculated and compared between groups. A multivariate cox regression analysis was performed to identify factors associated with fractures.

Results: Patients characteristics are shown in table. RA patients were 97.9% (CI 92.0-99.5) seropositive (Rheumatoid Factor and/or ACPA) and were treated with conventional DMARDs in 94% (CI 87.1-97.3) and biologic DMARDs in 20

% (CI 13.2-29.1). 69% (CI 59.2-77.3) of RA patients used corticosteroids, but only 5% (CI 2.1-11.5) have ever used prednisone > 20 mg/d. No difference was found in the overall fracture incidence rate per 1000 PY between RA and controls (19.5, CI 12.7-28.6 vs 12.1, CI 7.7-18.7, p 0.07). In the Cox regression analysis, only age (HR 1.06, 1.02-1.11, p 0.006) and a prior fracture (HR 9.85, 2.97-32.64, p <0.001) were associated with fractures after the index date. Nor RA diagnosis (HR 0.86, CI 0.24-3.07, p 0.81) not a prolonged use (>3 months) of low dose corticosteroids (HR 1.57, CI 0.39-6.23, p 0.52) were associated with increased fracture risk. When analyzing each type of fracture, only vertebral fractures were more common in RA patients compared with controls (12.9 per 1000 PY, CI 8.9-25.8, versus 3.4, CI 1.4-8.1, p 0.01, respectively) but vertebral fractures were not associated to prolonged use of low dose corticosteroids (HR 3.43, CI 0.74-15.82, p 0.11).

Conclusion: in this cohort of RA patients with diagnosis after year 2000, no overall increased risk of fractures was found in comparison with matched controls. This may be due to a better disease control and rational use of corticosteroids.

Abaloparatide for Risk Reduction of Nonvertebral and Vertebral Fractures in Postmenopausal Women with Osteoporosis: A Network Meta-Analysis

Jean Yves Reginster¹, Florence Bianic², Rosanne Campbell², Monique Martin², Setareh A. Williams³ and **Lorraine A Fitzpatrick**³, ¹Université de Liège, Liège, Belgium, ²inVentiv Health, London, United Kingdom, ³Radius Health, Inc., Waltham, MA

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Osteoporosis and Metabolic Bone Disease – Basic and Clinical Science Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: To assess the relative efficacy of abaloparatide compared with other osteoporosis treatment options (alendronate, denosumab, ibandronate, raloxifene, risendronate, romosozumab, strontium ranelate, teriparatide, zoledronic acid).

Methods: PubMed®, Embase® and Cochrane Central Register of Controlled Trials were searched for all randomized controlled trials published prior to December 20, 2017 including postmenopausal osteoporotic women (PMO) with and without prior fractures. Selection of trials for inclusion in the network meta-analysis (NMA) was based on populations (inclusion/exclusion criteria), interventions (dose/frequency), and outcomes (fracture assessment). NMA was conducted by fracture sites with relative risk (RR) of fractures as the main clinical endpoint.

Results: For vertebral fractures (VF) and nonvertebral fractures (NVF), 18 studies informed a network of 11 treatments and 21 studies informed a network of 11 treatments, respectively. For VF, abaloparatide had the greatest effect relative to placebo (RR 0.13; 95% CrI: 0.04-0.34) with estimates ranging from 0.27 for teriparatide to 0.71 for strontium ranelate. For NVF, abaloparatide had a greater risk reduction versus placebo (RR 0.50; 95% CrI: 0.28-0.85) and most effective (with a probability of 0.70) versus teriparatide (RR 0.62; 95% CrI: 0.47-0.82) and romosozumab (RR 0.64; 95% CrI: 0.49-0.81). In a further evaluation of specific fracture sites, 10 studies reporting wrist fractures informed a network of 8 treatments. Abaloparatide was associated with the greatest effect versus placebo (RR 0.39; CrI: 0.15- 0.90) and reduced the risk of fractures versus teriparatide (RR 0.45; CrI: 0.17-1.03) and denosumab (RR 0.47; CrI: 0.18-1.12). The NMA illustrated a good level of agreement with the direct trial evidence and direct pairwise comparisons.

Conclusion: Based on the current NMA, abaloparatide treatment resulted in a greater reduction in RR of both vertebral and nonvertebral fractures in PMO versus placebo in comparison with other treatment options. Generalizability is limited to the trials' population included in the NMA.

Implementation of a Primary Prevention, Population-Based Virtual Osteoporosis Clinic Dramatically Increases the Number of Rural Veterans Receiving Osteoporosis Screening and Treatment

Karla L. Miller¹, Shardool Patel², Grant W. Cannon³ and Zachary L. Anderson², ¹Salt Lake City VA Medical Center and University of Utah, Salt Lake City, UT, ²Salt Lake City VA Medical Center, Salt Lake City, UT, ³Division of Rheumatology, Salt Lake City VA Medical Center and University of Utah, Salt Lake City, UT

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Osteoporosis and Metabolic Bone Disease – Basic and Clinical Science Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The delivery of osteoporosis services is sub-optimal nationally and throughout the Veterans Affairs (VA) healthcare system and particularly poor for rural Veterans. To meet this critical need, we developed a Rural Bone Health Team (BHT), to provide efficient, evidence-based primary prevention osteoporosis services to rural Veterans. We compared the proportion of osteoporosis screening and treatment in Veterans choosing to participate and those who did not participate, both before and after the establishment of the BHT.

Methods: To identify Veterans with osteoporosis risk factors, we operationalized evidence-based screening guidelines into queries to the VHA Corporate Data Warehouse (CDW), a repository of medical and pharmacy records. Captured risk factors included Osteoporosis Self-assessment Tool (OST) score, sex, age, and/or chronic exposure to high risk medications. Veterans at risk were sent enrollment letters, invited to receive care by the BHT, and on acceptance evaluated by clinical nurse educators via standard protocols. As appropriate, enrolled Veterans received DXA scans, education on bone healthy lifestyle, additional fracture risk assessment, and triage for treatment if identified as either osteoporosis or high-risk osteopenia. Advanced practice providers then evaluated Veteran's need for osteoporosis pharmacotherapy, performed laboratory evaluations for secondary causes of bone loss, discussed risks/benefits of pharmacological therapies, and when indicated, therapy initiated and monitored therapy at scheduled intervals. For this study, we included Veterans contacted by the Rural BHT between 12/1/2016 and 02/01/2018. A non-experimental cohort design was utilized to assess pre-specified outcome and process measures, including the number of Veterans contacted, Veterans electing enrollment, DXAs completed, and Veterans receiving pharmacological therapy.

Results: During the first 15 months of implementation, the Rural BHT contacted 3,582 Veterans, with 1,241 (34.6%) Veterans accepting enrollment and 1,132 (91.2%) enrollees completing a DXA scan. Of those participating Veterans, 318 (25.6%) met criteria for and accepted pharmacological therapy. As illustrated in the Table Veterans choosing to participate in the Rural BHT were significantly more likely to complete a DXA scan (91.2% vs. 2.6%, $p < 0.0001$) and to receive pharmacological therapy (25.6% vs. 2.4%, $p < 0.0001$) than those choosing not to participate.

Conclusion: Enrollment in the Rural BHT significantly increases the likelihood that rural Veterans will received appropriate screening and treatment for osteoporosis. This model for the delivery of primary prevention services for

Session Date: Tuesday, October 23, 2018

Session Title: Osteoporosis and Metabolic Bone Disease – Basic and Clinical Science Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Many vertebral fractures occur in individuals classified by dual X-ray absorptiometry (DXA) as low risk for fragility fractures. No studies have performed a concomitant evaluation of moderate/severe vertebral fractures, high-resolution peripheral quantitative computed tomography (HR-pQCT), trabecular bone score (TBS) and areal BMD in general elderly population. Thus, we sought to verify the association between moderate/severe vertebral fractures and bone microarchitecture and strength using HR-pQCT, TBS and DXA in older adults.

Methods: 276 older adults from community (176 women and 100 men) were assessed by questionnaire. Lateral scans of spine obtained from Vertebral Fracture Assessment (VFA) by DXA were done to assess vertebral fractures (semiquantitative method). HR-pQCT was performed at the distal radius and tibia and the following parameters were analyzed: volumetric bone mineral density (vBMD) - total (Tt), trabecular (Tb) and cortical (Ct), structural parameters - trabecular number (Tb.N), trabecular thickness (Tb.Th.), trabecular separation (Tb.Sp), cortical thickness (Ct.Th) and strength variables - Stiffness (S), Estimated ultimate failure load (Fult). TBS was performed using DXA iNsight software. Logistic regression was used to identify independent risk factors for fractures.

Results: At least one vertebral fracture was observed in 42.6% of women and 28% of men. At distal tibia, women with moderate/severe vertebral fractures had lower vBMD (Tt.vBMD, $p=0.001$; Tb.vBMD, $p<0.001$; Ct.vBMD, $p=0.017$), lower Tb.N, $p=0.002$, higher Tb.Sp, $p=0.003$ and lower strength parameters (S, $p<0.001$; Fult, $p<0.001$) and men with moderate/severe vertebral fractures had lower Tb.N, $p=0.028$, higher Tb.Sp, $p=0.026$ and lower strength parameter (Fult, $p=0.046$). At distal radius, women with moderate/severe vertebral fractures had lower vBMD (Tt.vBMD, $p=0.003$; Tb.vBMD, $p=0.031$; Ct.vBMD, $p=0.003$), lower structural parameters (Tb.Th, $p=0.026$; Ct.Th, $p=0.003$) and lower bone strength (S, $p=0.005$; Fult, $p=0.003$) and men with moderate/severe vertebral fractures had lower Tb.vBMD, $p=0.031$ and lower strength parameter (S, $p=0.044$; Fult, $p=0.041$). No differences were observed in TBS in female group ($p=0.584$) and male group ($p=0.667$). After adjusting for potential confounding variables, logistic regression model revealed that Tb.vBMD at distal tibia in women (OR 0.980, 95%CI 0.963–0.997, $p=0.022$) and areal femoral neck BMD in men (OR 0.002, 95%CI 0–0.607, $p=0.033$) were independently associated with moderate/severe vertebral fractures.

Conclusion: HR-pQCT images detected marked differences on bone microstructure between older women with moderate/severe vertebral fractures independent of areal BMD and TBS by DXA and could be useful tool to assess fracture risk. Differently, in men, areal BMD at femoral neck was associated with moderate/severe vertebral fractures and DXA continue an important clinical tool for predicting vertebral fracture in male gender.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Osteoporosis and Metabolic Bone Disease – Basic and Clinical Science Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: This study aimed to investigate whether tumor necrosis factor inhibitors (TNFi) have beneficial effects on bone mineral density (BMD) in rheumatoid arthritis (RA) patients with osteoporosis receiving bisphosphonate (BP).

Methods: A total of 239 RA patients, who were diagnosed with osteoporosis and treated with BP between Jan 2005 and Mar 2017, were reviewed retrospectively. The BMD (g/cm^2) of the lumbar spine, femur neck, trochanter, and total femur was measured by dual-energy X-ray absorptiometry. Changes in the BMD percentage were compared between patients treated with and without TNFi. Multivariate analysis was performed to identify the factors associated with improvement of BMD in RA patients receiving BP.

Results: Among 239 RA patients receiving BP, 35 patients were exposed to TNF inhibitors, and 204 patients were not exposed. The last follow-up BMD was obtained at a median of 2.23 (IQR, 1.13–4.25) years after the initial acquisition of BMD. An improvement in the BMD of the lumbar spine was observed for patients treated with BP; however, there was no significant difference in BMD between patients treated with and without TNFi (4.92% (IQR, 1.6–9.42) vs. 4.99% (IQR, 0.68–10.1), $P = 0.437$). In addition, BMD changes in the femur neck, trochanter, and total hip were not significantly different between the two groups (Table 1). Furthermore, in multivariate analysis, the use of TNFi was not associated with

significant BMD improvement in any sites after adjusting for age, sex, RA duration, cumulative steroid dose, or intake of vitamin D. On the other hand, cumulative steroid dose was significantly associated with a lower improvement in BMD.

Conclusion: In RA patients with osteoporosis receiving BP, TNFi did not provide an additional beneficial effect on BMD improvement.

Table 1 BMD changes in patients treated with and without TNF inhibitors

	With TNFi (n=35)			Without TNFi (n=204)			Intergroup P value
	Baseline	Change, %	P value	Baseline	Change, %	P value	
Lumbar	0.821 (0.11)	4.92	<0.001	0.795 (0.728–0.84)	4.99	<0.001	0.437
Femur neck	0.695 (0.14)	0.26	0.806	0.675 (0.102)	0.89	0.810	0.769
Trochanter	0.549 (0.01)	1.44	0.511	0.546 (0.102)	1.97	0.052	0.725
Femur total	0.765 (0.648–0.798)	0.59	0.512	0.714 (0.106)	0.69	0.549	0.701

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Spontaneous Vertebral Fractures after Denosumab Discontinuation.

H. Florez, J. Ramírez, A. Monegal, N. Guañabens, P. Peris.

Department of Rheumatology. Hospital Clinic, University of Barcelona.

Background/Purpose: Denosumab (Dmab) is an antiresorptive treatment with demonstrated efficacy in osteoporosis. However, discontinuation of Dmab has been associated with rapid bone loss, and recently, the development of vertebral fractures (VF) in some patients. It is essential to identify the risk factors for these adverse events and follow its evolution. The objective of this study is to analyse the clinical characteristics, parameters of bone metabolism and evolution of patients developing VF after Dmab discontinuation.

Methods: Seven women with spontaneous VF after Dmab discontinuation were included (median age 64 years [56-75]). The clinical history, cause of osteoporosis, treatments received, fractures, Dmab treatment duration and discontinuation period were reviewed. Additionally, the clinical and densitometric evolution, and bone mineral parameters were also analysed after Dmab discontinuation.

Results: All the patients had postmenopausal osteoporosis, and two were receiving glucocorticoid treatment; 4/7 patients had previous fractures (2 VF, 1 calcaneus and 1 MTT); 5/7 had previously received antiosteoporotic treatment (hormone replacement therapy, risedronate, alendronate, zoledronate [once or consecutively]) during 6 months - 23 years. All had received Dmab for 24-53 months (median 38). The reasons for treatment discontinuation were: dental indication (2 patients), BMD improvement (T-score -1.2) (1 patient), poor adherence (1), prescription problems and/or delay in administration (3). The median bone mineral density T-scores prior to VF were -2.45 (-1.2/-4) at the lumbar spine and -2.1 (-0.6/-3.1) at the femoral neck. The mean time between the last Dmab dose and VF was 10 months (8-20), with a median of 5 VFs/patient (2-8). No patient showed 25-OH vitamin D <20 ng/ml. After Dmab discontinuation, bone turnover markers increased (median increase +364% in PINP and +287% in NTx); one patient presented hypercalcaemia (calcium 11.3mg/dL); and BMD decreased 1-21% in the lumbar spine and 2-6% in total hip at 8-22 months. After VF, 3 patients restarted Dmab, 1 Dmab+Teriparatide, 1 received zoledronate and 2 alendronate. No new fractures occurred during follow-up.

Conclusion: Discontinuation of Dmab is associated with an increase in bone turnover markers and bone loss which can be associated with the development of spontaneous VF. Previous bisphosphonate therapy does not seem to decrease this risk. Further studies are needed to assess the optimal antiresorptive treatment and its duration after Dmab discontinuation.

Disclosure: H. Florez, None; J. Ramírez, None; A. Monegal, None; N. Guañabens, None; P. Peris, None.

The Efficacy of Denosumab for Prevention of Osteoporotic Fractures in Patients with Connective Tissue Diseases Receiving Very High Doses of Glucocorticoid

Keiichiro Kadoba, Keisuke Nishimura, Hiroki Mukoyama, Rintaro Saito, Daisuke Waki and Toshihiko Yokota, Department of Endocrinology and Rheumatology, Kurashiki Central Hospital, Kurashiki, Japan

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Osteoporosis and Metabolic Bone Disease – Basic and Clinical Science Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Osteoporosis is a common complication of glucocorticoid therapy, contributing to significant morbidity especially in patients receiving very high doses of glucocorticoid (GC). There have been insufficient data supporting the antifracture efficacy of denosumab in glucocorticoid-induced osteoporosis, and its efficacy in patients receiving very high doses of GC has not been demonstrated so far. We aimed to verify the efficacy and safety of denosumab in patients receiving very high doses of GC.

Methods: We retrospectively reviewed the clinical data of patients with connective tissue diseases initiating very high-dose GC treatment (prednisolone ≥ 0.8 mg/kg/day) in our hospital from January 2012 to April 2017. We recruited patients initiating osteoporosis prophylaxis either with denosumab or bisphosphonates within six months after the initiation of GC treatment. We compared the risk of clinical osteoporotic fractures and safety profiles between the denosumab group and the bisphosphonate group.

Results: Among patients initiating very high-dose GC treatment during January 2012 to April 2017, 56 patients (median age: 65 years old) received osteoporosis prophylaxis with bisphosphonates and 16 patients (median age: 69 years old) received osteoporosis prophylaxis with denosumab. The bone mineral density of the femoral neck at baseline was $0.87 \pm 0.23 \text{ g/cm}^2$ in the denosumab group and $0.79 \pm 0.11 \text{ g/cm}^2$ in the bisphosphonate group ($p > 0.05$). No patients suffered clinical osteoporotic fractures in the denosumab group (median observation period: 21.5 months), while seven patients suffered clinical osteoporotic fractures in the bisphosphonate group (median observation period: 30.5 months). The risk of clinical osteoporotic fractures was similar between two groups ($p = 0.21$). Avascular necrosis of the femoral head (AVNFB) occurred in eight patients (14%) in the bisphosphonate group, while no patients suffered AVNFB in the denosumab group. Osteonecrosis of the jaw occurred in one (6%) patient in the denosumab group and one (2%) patient in the bisphosphonate group. Transient hypocalcemia occurred in three (19%) patients in the denosumab group and six (11%) patients in the bisphosphonate group, all of which resolved without any intervention.

Conclusion: Denosumab is a useful option for osteoporosis prophylaxis in patients initiating very high-dose GC treatment, having at least equivalent efficacy and safety with bisphosphonates.

Ratio of BMI to BMD at Different Sites and Association with Fragility Fractures

Marco Massarotti¹ and Marwan Bukhari², ¹Rheumatology, Royal Lancaster Infirmary, University Hospital of Morecambe Bay NHS Foundation Trust, Lancaster, United Kingdom, ²Lancaster Medical School, Lancaster University, Lancaster, United Kingdom

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Osteoporosis and Metabolic Bone Disease – Basic and Clinical Science Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Low body mass index (BMI) is linked to increase risk for osteoporosis, and fragility fractures and is therefore included in most fracture prediction tools. A previous work from our department (Oldroyd et al. Int J Clin Pract. 2014) demonstrated that very high BMI might also be a risk factor for osteoporosis and other authors have recently reported the ratio between lumbar spine BMD and BMI to be strongly correlated with trabecular bone score (TBS) and predictive of fragility fractures in a cohort of obese patients (Watanabe et al. Endocrine Practice. 2018). The aim of our study was to assess the influence of the BMI/BMD ratio on the risk of fractures in an observational cohort of all weight categories.

Methods: All patients referred to our department for having a dual X-ray absorptiometry (DEXA) scan between June 2006 and October 2016 were queried. Results of first scans only were included in our analysis. Risk factors for osteoporosis and fragility fractures were recorded at the time of the scan and included age, gender, comorbidities, medication history, menopause age and fragility fracture history. The ratio of BMI/BMD was obtained and divided into quintiles. Logistic models were fitted unadjusted and adjusted for age and gender comparing those patients who had

presented with a fragility fracture versus those who did not have a fracture. The ratios were calculated for the lumbar spine and both femoral neck and total hip.

Results: 35,759 patients were included in the analysis, 30,095 (84.2%) were female. Mean age was 62.2 years (SD 12.8). 12,186 (34.1%) had sustained a fragility fracture. Mean BMI was 26.8 (SD 5.2). The results of the logistic models are shown in the table below for each site

site	quintile	Unadjusted OR	95%CI	Adjusted OR	95%CI
Lumbar spine N=35,759	1	Ref	Ref	Ref	Ref
	2	1.23	1.15,1.33	1.18	1.09,1.27
	3	1.49	1.38,1.60	1.36	1.26,1.46
	4	1.80	1.67,1.93	1.58	1.47,1.70
	5	2.29	2.14,2.47	1.97	1.83,2.12
Femoral neck N=27,956	1	Ref	Ref	Ref	Ref
	2	1.37	1.27,1.48	1.27	1.17,1.37
	3	1.59	1.47,1.71	1.39	1.29,1.51
	4	1.91	1.77,2.06	1.60	1.49,1.73
	5	2.55	2.37,2.75	2.07	1.87,2.18
Total hip N=27,956	1	Ref	Ref	Ref	Ref
	2	1.51	1.38,1.65	1.39	1.27,1.52
	3	1.97	1.80,2.15	1.73	1.59,1.89
	4	2.31	2.12,2.52	1.94	1.78,2.12
	5	3.33	3.07,3.63	2.61	2.39,2.85

Conclusion: BMI/BMD ratio to BMD appears to be a useful way of predicting fragility fractures in all weight categories in this large observational cohort. Further work looking at site of fracture and the utility of the ratio in a clinical setting will be presented. Particular attention will be given to the role of BMI/BMD ratio at predicting fractures in patient subsets where BMD is known to be less strongly associated with fracture risk (e.g. steroid therapy, diabetes).

Opportunistic Screening for Osteoporosis Using Thoraco-Abdomino-Pelvic Computed Tomography Assessing the Vertebral Density in Rheumatoid Arthritis Patients

Julia Perrier-Cornet¹, Abdou Yacoubou OMOUROU², Marine FAUNY¹, Damien Loeuille³ and Isabelle Chary-Valckenaere⁴, ¹Rheumatology, University Hospital of Nancy, VANDOEUVRE LES NANCY, France, ²Inserm, CIC-1433 Clinical Epidemiology, University Hospital of Nancy, VANDOEUVRE LES NANCY, France, ³Rheumatology, University Hospital of Nancy, NANCY, France, ⁴Rheumatology, CHRU Nancy, Vandoeuvres les Nancy, France

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Osteoporosis and Metabolic Bone Disease – Basic and Clinical Science Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Screening for osteoporosis is crucial in rheumatoid arthritis (RA) patients. The aim of this study was to assess the value of thoraco-abdomino-pelvic CT-derived bone mineral density (BMD) results in L1, compared to dual energy X-ray absorptiometry (DXA) results for osteoporosis screening in rheumatoid arthritis patients.

Methods: Consecutive RA patients who underwent a CT-scan and DXA within a two-year period were retrospectively included. The CT sagittal images were then evaluated for vertebral fractures from T4 to L5 using the Genant classification. The CT attenuation values (in Hounsfield units [HU]) of trabecular bone in L1 were measured on axial images and compared to the DXA results.

Results: This study included 105 patients (mean age 61.1 years (\pm 9.5), 78.1% women). There were 28 patients (26.7%) with DXA-defined osteoporosis and 32 (30%) with osteoporotic fractures (vertebral and/or non-vertebral). The CT assessment indicated that the mean (SD) vertebral L1 attenuation was 142.2 HU (\pm 18.5). The diagnostic performance for the vertebral CT-attenuation measurement was acceptable: the AUC was 0.67 for predicting osteoporotic fractures and of 0.69 for predicting vertebral fractures. Among patients with osteoporotic fractures, there were 23 (74%) patients

categorized as osteoporotic with a L1 CT-attenuation of 135 HU or less, whereas there were only 13 patients (42%) identified by DXA.

Conclusion: CT offers a combined opportunistic screening for osteoporosis by assessing both vertebral fractures and bone density on routine CT-scans. This approach may be particularly interesting for RA patients with a high osteoporosis risk.

Errors and Discrepancies in DXA Scans in Imaging Centers in Ecuador

Genesis Maldonado¹, Maria Jose Intriago¹, Maria Larroude², Gabriel Aguilar³, Mario Moreno⁴, Jose Gonzalez⁵, Sara Vargas⁵, Claudia Vera⁶, Roberto Guerrero¹, Karla Ríos¹ and Carlos Rios¹, ¹Universidad Espiritu Santo, Guayaquil, Ecuador, ²Centro Diagnostico Rossi, CABA, Argentina, ³Centro de Diagnostico Rossi, Buenos Aires, Argentina, ⁴Rheumatology, Hospital Luis Vernaza, Rheumatology Service, Guayaquil, Ecuador, ⁵Ecuadorian Rheumatology Society, Guayaquil, Ecuador, ⁶Universidad Catolica Santiago de Guayaquil, Guayaquil, Ecuador

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Osteoporosis and Metabolic Bone Disease – Basic and Clinical Science Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Dual-energy X-ray absorptiometry (DXA) is recognized as the gold standard for measuring bone mineral density (BMD) with acceptable errors, good precision and reproducibility. However, the training of operators in different centers and countries is not standardized and the lack of knowledge can lead to errors both in the acquisition of information, as well as in its analysis and subsequent interpretation. The purpose is to determine the most common errors in the performance of bone densitometry from different imaging centers in Ecuador.

Methods: Cross-sectional descriptive study. We collected DXA scans from different imaging centers in Ecuador. Demographic information from patients included age, sex, height, weight, body mass index (BMI) and main diagnosis. Data from the DXA scan included city of origin, type of specialist that requested it and densitometry diagnosis. The DXA images provided were analyzed double blind by experts in the field from Argentina, according to patient position, presence of artifacts and region of interest correctly placed we.

Results: From a total of 180 patients with a mean age of 63.5 years, 93.6% were women. 78% of the DXA scans came from private imaging centers and 22% from public centers, 95% of all came from the city of Guayaquil. The machines

Figure 1: Spine Incorrect alignment and prosthetics

used were Hologic 51.2% and Lunar 48.8%. The densitometric diagnosis was 16.3% normal, 46.1% osteoporosis and 37.6% osteopenia. 112 left hip and 49 right hip scans were analyzed from which 31.1% and 22.4% had errors in patient positioning, respectively, mainly internal or external rotation. 140 lumbar scans were analyzed from which 21.4% had patient positioning errors (not centered or not straight). Also in 38.5% the vertebral area did not correspond to L1-L4. 3.5% had artefacts such as a metal bar or implant. The region of interest was misplaced in 24.1% of the lumbar scans and 19.9% of the femur.

Conclusion: Much of the responsibility of a DXA falls on the operator as he has to review the patient's health history, enter demographic data, perform the acquisition of the image with a correct positioning and analyze it. When studies are performed incorrectly, it can lead to important errors in diagnosis and therapy.

Figure 2. Femur Incorrect vs. correct alignment

Figure 3. Spine Incorrect vs. correct alignment.

¹Rheumatology, University Hospital Center of Algarve, Faro, Portugal, Faro, Portugal, ²Servico de Reumatologia, Hospitais Universitários de Coimbra, Coimbra, Portugal, Coimbra, Portugal, ³Centre of Marine Sciences, University of Algarve, Faro, Portugal, Faro, Portugal, ⁴Department of Biomedical Sciences and Medicine, University of Algarve, Faro, Portugal, Faro, Portugal

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Osteoporosis and Metabolic Bone Disease – Basic and Clinical Science Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Paget's disease of bone (PDB) is a metabolic bone disorder whose prevalence increases with age and affects ~3% of Caucasian individuals older than 55 years (1,2). Recent evidence suggests that may be caused by an accumulation of mutations/variants in different genes. In 15 to 30 % of PDB patients, it appears to have an autosomal dominant mode of inheritance but with incomplete penetrance, which makes it often difficult to determine the familiar history due to the high percentage of asymptomatic individuals carrying the mutations. The first gene mutations associated to PDB were identified in the sequestosome 1 (*SQSTM1*) gene at the PDB3 locus (chromosome 5) (3,4). Later, we and others (5,6) have found that PDB6 locus (chromosome 10) was also linked to PDB, including the Optineurin (*OPTN*) gene, which variant rs1561570 was found to be the most significantly associated with PDB. The aim of this study is to characterize clinically and to investigate the presence of those mutations in PDB patients from the south of Portugal (Algarve and Alentejo).

Methods: This study was approved by the Ethics Committee of University Hospital Center of Algarve, where patients were recruited. In a pilot experiment, the clinical history of 12 patients previously diagnosed with PDB (aged 58 to 81 years old) and 16 healthy controls (aged 47 to 84 years old) was collected and they were also analysed. After DNA extraction from freshly collected biological samples (blood or epithelial swabs), the fragments of interest were amplified by PCR using specific primers for the corresponding loci and the amplified fragments sequenced and compared with the wild type genes.

Results: PDB patient's mean age was 70.8±8.2 years. There was a male predominance (10; 83%). There were more patients with the polyostotic form (10; 83%). Three patients (25%) complained about bone pain and that led to the diagnosis of PDB. The others were identified in routine blood tests where alkaline phosphatase (AF) was included. Treatment consisted mainly of zoledronic acid with excellent results in terms of controlling bone pain and AF levels but it wasn't able to avoid some bony deformities, which occurred in three patients (25%).

The P392L causal mutation of *SQSTM1* was detected in one of the patients (8%) without a familial history of PDB and in none of the healthy controls. Our results also showed that the SNP rs1561570 in the *OPTN* gene had a higher prevalence of allele T in the PDB patients (55%) than in healthy controls (44%) while none of the patients presented the C allele in homozygosity. We have previously shown (7,8) that the presence of the rs1561570 may contribute to PDB since its T allele results in the loss of a methylation site in patients' DNA, higher levels of *OPTN* expression in patients' osteoclasts, higher levels of NF-κB translocation into the nucleus and increasing expression of its target genes, thus contributing to the increased activity of osteoclasts observed in PDB.

Conclusion: The clinical results obtained are in agreement with literature and the genetic study confirm the heterogeneity of PDB and despite the small number of patients so far analyzed the results are in agreement with previous data in terms of type and incidence of mutations in the patients' population.

Fracture Liaison Service in an Open Health System: Outcomes and Challenges

Donna Jose¹, Karina Torralba², Christina Downey², Micah Yu¹ and Lorena Salto³, ¹Internal Medicine, Loma Linda University Medical Center, Loma Linda, CA, ²Loma Linda University Medical Center, Loma Linda, CA, ³Loma Linda University, Loma Linda, CA

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Osteoporosis and Metabolic Bone Disease – Basic and Clinical Science Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The “osteoporosis care gap” is noted by findings that 80% of patients do not receive treatment after an initial fracture. An initial fracture portends a 60% risk of re-fracture. A Fracture Liaison Service (FLS) is an effective means of addressing secondary fracture prevention. The type of health system model potentially impacts FLS outcomes. A closed model like Kaiser Permanente’s Healthy Bones Program, led by Orthopedic Surgery, resulted in a 40% reduction in hip fractures. Geisinger Health System’s FLS led by Rheumatology, an open-model, has noted 75% treatment rates versus 13.8% for those seen by primary care doctors alone.

Loma Linda University Medical Center (LLUMC) launched a multidisciplinary FLS in 2017. Pre-LLUMC FLS studies (2015-2016) showed that 85% of patients pre-fracture were never screened nor treated for osteoporosis; post-fracture, only 10% of patients were treated, and only 6% had dual x-ray absorptiometry (DXA). Notably, 30% had a prior fracture. LLUMC is the only tertiary medical center in the Inland Empire of Southern California. It has an open health system, historically known for specialty services. The FLS goal was to achieve a 10% improvement in therapy initiation and DXA completion. This study aims to assess the FLS’s effectiveness during the initial eight-month period.

Methods: Data extraction from our Epic® electronic health record (EHR) through the LLUHS Patient Safety and Reliability Office was done to determine the number of inpatient FLS referrals and total eligible fractures from September 2017-April 2018. Outpatient transition to in-network osteoporosis specialist, pharmacotherapy initiation, DXA ordering and completion, vitamin D measurement, number of deaths, transition to dependent living facilities, availability of a primary care provider (PCP) in- or out-of-network were among the metrics determined.

Results: 70 patients were referred to the FLS. 81% and 14.4% had femoral and vertebral fractures, respectively. All had Vitamin D level determination. DXA was set up for 61.5% upon discharge. 13 (18.6%) transitioned to an outpatient LLUHS specialist, while 57 (81.4%) did not. Patients lost to follow-up were characterized by the following traits: lived >30 miles from LLUMC, had no regular PCP or had no in-network PCP, patient/family belief regarding lack of benefit to treatment or non-association of fractures with osteoporosis. Mortality was noted in 6 (10%) patients due to sepsis/other infection. 991 fracture encounters excluding other non-osteoporosis-related causes were admitted during the same time period.

Conclusion: Low recruitment rates in an open-health system FLS require more outreach and coordination with both in and out-of-network primary care providers (PCP) Also increasing PCP, hospital-based provider and patient education regarding the osteoporosis care gap is essential. Since April 2018, an FLS coordinator (nurse practitioner) was hired and community-based education activities for PCPs practicing within 30-60 miles of LLUMC were done. Outcomes in 12 months are to be determined.

Adherence to Guideline Recommendations for Screening and Treatment of Glucocorticoid Induced Osteoporosis in Patients with Rheumatoid Arthritis on Long Term Glucocorticoid Therapy at a Tertiary Care Center

Patrick Webster¹ and Tarun S. Sharma², ¹Internal Medicine, Allegheny Health Network, Pittsburgh, PA, ²Rheumatology, Lupus Center of Excellence, Allegheny Health Network, Pittsburgh, PA

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Osteoporosis and Metabolic Bone Disease – Basic and Clinical Science Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Glucocorticoid induced osteoporosis (GIOP) is an under-recognized and under-treated condition. Many long-term glucocorticoid (GC) users never receive therapy to prevent bone loss or are only treated after a fracture occurs, despite having known risk factors and available effective therapies to prevent fracture. Our quality improvement study measures 1) osteoporosis (OP) screening rates, and 2) adherence to 2017 ACR guidelines for prevention and treatment of GIOP in the rheumatoid arthritis (RA) patient population at our tertiary care academic rheumatology practice.

Methods: A retrospective review of RA patients (ICD codes M05 and M06) over age of 50 yrs and on long-term GC (≥ 3 months) from 1/1/2015 through 12/31/2017 was performed. The following variables were recorded and validated manually: demographics (age/sex/ethnicity/height/weight), smoking status, GC dose and duration (excluding non-oral formulations and oral tapers), DEXA scans, and left femoral neck T-score (LFNTS). OP screening rates with DEXA scans were measured. A FRAX score was calculated using the online University of Sheffield FRAX calculator. The FRAX score for major osteoporotic fracture risk and hip fracture risk was increased by 15% and 20% respectively for high dose GC use ($>7.5\text{mg/day}$) per ACR guideline recommendations. Patients were risk-stratified as high (LFNTS ≤ -2.5 , or FRAX 10 yr risk of major and hip OP fracture of $\geq 20\%$ and $\geq 3\%$ respectively), moderate (FRAX 10 yr risk of major and hip OP fracture of 10-20% and 1-3% respectively) or low risk (FRAX 10 yr risk of major and hip OP fracture of $<10\%$ and $<1\%$ respectively). We measured the percentage of patients in each category on appropriate OP treatment (defined for high and moderate risk categories as bisphosphonates, and for low risk as calcium/vit D supplementation and/or bisphosphonates).

Results: We identified 1,746 patients with RA over age of 50 yrs during the 3 year study period. Of these, 127 patients were on long term GC (≥ 3 months). Mean age was 65 yrs, 79% were female, 88% were Caucasian, and 54% were current smokers, mean GC dose was 6.5mg/day (prednisone equivalent), and 28% were on high dose GC ($>7.5\text{mg/day}$). Appropriate DEXA screening was performed in 80 (63%) patients. The OP fracture risk stratification of these 80 patients was as follows: 43, 23, and 14 patients were in the high, moderate, and low risk category respectively. The percentage on appropriate treatment in the high, moderate, and low risk categories were 44%, 52%, and 86% (low risk breakdown = 9 calcium/vit D supplementation and 3 bisphosphonates) respectively. Multivariate analysis of predictive risk factors for non-adherence to screening and treatment is ongoing.

Conclusion: In our study on GIOP screening and treatment in RA patients on long term GC therapy, 63% received appropriate OP screening, whereas 44% of the high fracture risk patients and 52% of the moderate risk patients were found to be on appropriate GIOP treatment. A multi-faceted QI initiative to improve GIOP management is underway at our institution- creation of an EHR best practice alert and EHR FRAX calculator along with continued medical education and shared performance metrics. We plan to measure performance closely over time post-intervention.

Abstract Number: 2320

Multimorbidity Is Associated with Hip Fractures in Both Women and Men and across Different Races

Shreyasee Amin¹, Elizabeth J. Atkinson² and Sundeep Khosla², ¹Rheumatology, Mayo Clinic, Rochester, MN, ²Mayo Clinic, Rochester, MN

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Osteoporosis and Metabolic Bone Disease – Basic and Clinical Science Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Multimorbidity, the coexistence of 2 or more chronic conditions, is associated with increased disability and poor functional status, and may serve as an important clinical marker for hip fracture risk. We examined the role of multimorbidity on hip fracture risk and whether this differed between women and men, or by race.

Methods: Using de-identified administrative claims data from a large commercial insurance database, we identified both women and men aged ≥ 50 yrs who had a hip fracture between Jan 1, 2006-Dec 31, 2016, and had at least 1 yr health plan coverage pre-fracture. Subjects without known hip fracture were matched to cases exactly on sex, age, race, year, geographic region, and insurance; they were also required to have at least 1 yr health plan coverage pre-index date.

Diagnostic codes and medications were captured for the year prior to fracture/index date. Using the score from the Elixhauser Comorbidity Index (Elix Index), a set of 31 comorbidities, we categorized subjects into 3 groups (0-1, 2-3, and ≥ 4) and used conditional logistic regression to examine the association with hip fracture. We focused on subjects identified as White, Black or Asian, and examined women and men separately.

Results: We studied 50,136 White/5,770 Black/1,130 Asian women (median age [IQR], yrs: 79[72, 83]/ 78 [71, 83]/ 79 [71, 83], respectively) and 22,329 White/2,419 Black/451 Asian men (median age [IQR], yrs: 77 [66, 82]/ 75 [66, 81]/ 78 [67, 83], respectively) with hip fractures and an equal number of matched controls. Compared to the referent group (Elix Index 0-1), higher Elix Index was associated with increased hip fracture risk with findings similar in women and men and across races studied (Table). In further analyses with a gradient boosting model, a higher Elix Index ranked as the top influence on hip fracture risk over the individual 31 comorbidities (data not shown). In a multivariable penalized logistic regression model, the addition of medication categories to the 31 comorbidities did not contribute additional information on hip fracture risk (data not shown).

Conclusion: Multimorbidity, as assessed using the Elix Index, is associated with an elevated risk for hip fracture, in both women and men, and across races studied. A higher number of co-existing chronic conditions is associated with an even greater risk of hip fracture. Further work is necessary on determining whether specific combinations of comorbidities have a greater impact on risk.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Osteoporosis and Metabolic Bone Disease – Basic and Clinical Science Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Dickkopf-1 (DKK1) is a natural inhibitor of Wnt signaling pathway that could be involved in promoting osteoclastogenesis through suppression of osteoprotegerin (1,2). Systemic sclerosis (SSc) patients present an increased risk of low bone mass and of osteoporosis (OP) as a result of different causes (3,4). The aim of this study is to investigate in different nailfold videocapillaroscopic (NVC) patterns (“Early”, “Active”, and “Late”) in SSc patients and to evaluate possible correlations between DKK-1 levels and Trabecular Bone Score (TBS), finally to compare the results with healthy subjects (CNT).

Methods: 60 SSc patients and 60 CNT were enrolled. Dkk-1 serum levels were measured in all 120 subjects by ELISA methods (Quantikine Human DKK-1 Immunoassay R&D System, Minneapolis, USA). Nailfold videocapillaroscopic (NVC) and TBS analysis and Bone Mineral Density (BMD, g/cm²) were also performed.

Results: DKK-1 levels were statistically significantly higher in SSc patients with “Late” NVC pattern than in those both “Active” and “Early” ($p < 0.0001$) and its levels were correlated with Trabecular Bone Score only in patients with “Late” NVC pattern ($p = 0.001$). Serum DKK-1 levels were significantly higher in patients with SSc than in CNT ($p < 0.007$). A negative correlation between Raynaud’s phenomenon duration (years expressed) and DKK-1 levels ($p < 0.01$) was also observed.

Conclusion: Dickkopf-1 values is increased in SSc patients with “Late” nailfold capillaroscopy pattern than in both “Active” and “Early” pattern and in SSc patients than in CNT, furthermore its level correlates with TBS in “Late” NVC pattern.

Intervals of Bone Mineral Density Measurement during Treatment for Osteoporosis in Patients with Rheumatoid Arthritis

Seung Yun Lee¹, Seong Ryul Kwon¹, Mie Jin Lim², Kyong-Hee Jung³ and Won Park⁴, ¹Division of Rheumatology, Department of Internal Medicine, Inha University Hospital, Incheon, Korea, Republic of South, ²Division of Rheumatology, Departments of Internal Medicine, Inha University Hospital, Incheon, Korea, Republic of South, ³Rheumatology, Inha University Hospital, Incheon, Korea, Republic of South, ⁴Medicine/Rheumatology, Inha University Hospital, Incheon, Korea, Republic of South

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Osteoporosis and Metabolic Bone Disease – Basic and Clinical Science Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: There is controversy about the intervals of retesting bone mineral density (BMD) in patients treated for osteoporosis. The objective of this study is to investigate proper intervals of BMD measurement during treatment of osteoporosis in patients with rheumatoid arthritis (RA).

Methods: We retrospectively studied 297 patients (271 women and 26 men) with RA who were treated for osteoporosis with mean age of 65.7 ± 8.8 years and the mean duration of treatment for osteoporosis of 8.2 ± 3.9 years. BMD had been measured every year for five years. Annual changes of BMD and T-score at lumbar spine (L1-L4), femoral neck and total hip were evaluated. Treatment failure was defined as an occurrence of two or more fractures, or a reduction in BMD more than the least significant change (LSC) despite adequate treatment. The values of the LSC were 5.3% in lumbar spine, 6.9% in femoral neck, and 5.0% in total hip in the 95% confidence interval.

Results: 48 (16.2%) patients stopped treatment for osteoporosis due to improvement of T-score. They had an average treatment duration of 4.3 ± 0.5 years before discontinuation. 227 (76.4%) patients were consistently treated with osteoporosis. 18 (6.1%) patients discontinued treatment due to improvement of T-score and then re-started treatment again with deterioration of T-score on follow-up of BMD test. The number of patients with osteoporotic fracture was 80 (30.3%), and among them 57 (19.2%) patients had sustained fractures before starting treatment and 23 (7.7%) patients had incident fractures during treatment for osteoporosis. Annual changes of BMD were -0.28%, 1.24%, 0.84%, and 2.46% at lumbar spine after the first year to the fourth year of treatment compared to the results of previous year respectively, -1.39%, 1.77%, -0.51%, and 1.78% at femoral neck and -0.56%, -0.49%, 0.97%, and 0.24% at total hip respectively. The changes of BMD from the baseline after one, two, three, and four years of treatment were -0.28%, 1.14%, 1.90%, and 4.31% at lumbar spine, -1.39%, 0.41%, -0.10%, and 2.10% at femoral neck and -0.56%, -0.97%, -0.10%, and 0.28% at total hip respectively (Figure 1). The treatment failure after one year of treatment to the four year compared to the baseline were 11.4%, 7.4%, 5.8% and 3.1% at lumbar spine, 14.7%, 10.1%, 8.4%, and 4.7% at femoral neck and, 13.9%, 12.7%, 9.1%, and 6.3% at total hip respectively.

Figure 1. The changes of BMD from the baseline after one, two, three, and four years of treatment.

Conclusion: Despite treatment for osteoporosis, patients with RA did not show significant improvement of BMD by one year. Considering these results, the reasonable interval of BMD measurement would be at least four years during the anti-osteoporotic treatment because the treatment failure is continuously decreasing. Moreover, many patients with RA need continuous treatment for osteoporosis regardless of BMD due to high incidence of fracture.

Session Date: Tuesday, October 23, 2018

Session Title: Osteoporosis and Metabolic Bone Disease – Basic and Clinical Science Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: In Osteoporosis, hip fractures account for significant disease burden, with increased morbi-mortality and financial load on the patient and healthcare system. This study aimed to assess cumulative survival rate of patients with hip fragility fracture aged ≥ 65 years old, referred to a Rheumatology Department's Fracture Liaison Service (FLS) after admission to the Orthopaedics Inpatient Care Department, and to determine predictors of mortality.

Methods: Longitudinal retrospective study of patients referred to a Rheumatology Department's FLS from March 2015 until March 2017. Demographic and clinical data were collected. Statistical analysis was performed with STATA. Survival cumulative probabilities were calculated through Kaplan-Meier curves and hazard ratios (HR) through cox regression, adjusted to age/degree of care dependency.

Results: 522 patients were referred to the FLS, 79.7% female, with median age of 84 years old (65-103). Table 1 summarizes clinical and demographic characteristics. One hundred and nineteen patients (22.8%) died, 36 still during inpatient care. The cumulative survival probability (image 1) at 1, 3, 6, 12 and 24 months was 94.1% (95%CI 91.7-95.9), 91.1% (95%CI 88.2-93.3), 86.3% (95%CI 82.9-89.0%), 81.7 (95%CI 77.9-84.8) and 73.8% (95%CI 69.2-77.8) respectively. Patients ≥ 80 years old presented lower survival rate (HR 1.64, $p=0.02$), as well as partially dependent and totally dependent patients (HR 1.93, $p=0.047$; HR 5.3, $p=0.000$, respectively). Higher femur BMD (HR 0.01, $p=0.023$) and T-score (HR 0.67, $p=0.038$) were predictors of better survival outcome. Considering laboratory measurements, higher beta-crosslaps serum values predicted worse survival outcome (HR 4.27, $p=0.007$). Gender, fracture classification, type of surgical intervention, presence of vertebral fractures, BMI, serum vitamin D and osteocalcin didn't have impact on survival.

Conclusion: Knowledge of mortality predictors in hip fracture is essential to optimize survival in these patients. In our study, age, autonomy degree, femur BMD/T-score and beta-crosslaps had impact on survival outcome.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Osteoporosis and Metabolic Bone Disease – Basic and Clinical Science Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Hip fractures are associated with substantially elevated morbidity and mortality and thus represent a serious public health problem. The purpose of this study is to assess cumulative refracture free survival probability and possible predictors of refracture in patients older than 65 years admitted by hip fragility fracture.

Methods: Longitudinal retrospective study of patients referred to the Rheumatology department's Fracture Liaison Service (FLS) from march 2015 until march 2017. Demographic and clinical data were collected. Statistical analysis was performed with STATA. Survival cumulative probabilities were calculated with Kaplan-Meier curves. Hazard ratios (HR) were calculated through cox regression, adjusted to age and degree of dependence.

Results: 522 patients were referred to the FLS, with a median age (min-max) of 84 years (65-103); 79,7% (N=416) were female. 47 out of 522 had a subsequent fragility fracture (9%). The cumulative survival probability without refracture at 1, 6, 12 and 24 months was 99,4%, (95%CI [98,2-99,8]), 96% (95%CI [93,8-97,4]), 93%(95%CI [90,2-95,0]) and 89,3% (95% CI [85,8-92,0]), respectively. Neurologic disease and chronic obstructive pulmonary disease (COPD) were both predictors of worst refracture free survival outcome (HR 2,37, 95%CI [1,05-5,37] and HR 3,25, 95%CI [1,09-9,61], respectively). Gender, age, body mass index, degree of dependence, fracture and intervention type, calcium intake, sedative drugs, radiographic vertebral fractures, total femur BMD and T-score, vitamin D, osteocalcin and β crosslaps, discharge to home or institution, supplementation with calcium and vitamin D and anti-osteoporotic treatment didn't have significant impact on survival cumulative probabilities of refracture.

Figure 1: Cumulative refracture free survival probability

Figure 2: Cumulative refracture free survival probability (with neurologic diseases Vs without neurologic diseases)

Figure 3: Cumulative refracture free survival probability (with COPD Vs without COPD)

Conclusion: Knowledge of the predictors of refracture is essential for secondary prevention. Our sample suggests that neurologic disease and COPD may increase the risk of subsequent fracture after prior fragility fracture, but further studies are needed.

Session Title: Osteoporosis and Metabolic Bone Disease – Basic and Clinical Science Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Frailty in the general population is associated with poor outcomes including osteoporosis (OP), fracture and death. Frailty occurs at a higher rate in RA than in the general population. It is not known, however, if frailty is associated with lower bone mineral density (BMD) in RA. We investigated associations between frailty, RA clinical characteristics, medication use, and body composition and BMD in patients with RA.

Methods: We performed a cross-sectional analysis of a longitudinal RA cohort study from years 2007-2009. All patients met ACR classification criteria for RA. Frailty was evaluated using the Fried Index, categorizing each participant as robust, pre-frail or frail. We used linear regression to evaluate the association between predictors and femoral neck BMD. To

Table 1. Multivariable linear regression of the entire cohort on the outcome of femoral neck BMD (g/cm²) (N=135, r²= 0.37).

Variables	β	95% CI	p-value
Age	-0.003	-0.005 to -0.001	0.002

Frail Category*:			
Robust	ref	ref	ref
Prefrail	-0.036	-0.095 to 0.022	0.210
Frail	-0.093	-0.176 to -0.008	0.029

*CCP: cyclic citrullinated peptide antibody; LMI: lean mass index.

*High positive anti-CCP >60 units.

*Frail categories based on Fried Index.

*Note: OP medication use had a negative association with BMD suggesting confounding by indication; therefore it was not included in the multivariable model.

Table 2. Multivariable linear regression on the outcome of femoral neck BMD (g/cm²) stratified by sex, Females (N=81, r²=0.31), Males (N=53, r²=0.47).

Variables	Females (N=81)			Males (N=53)		
	β	95% CI	p-value	β	95% CI	p-value
Age	-0.002	-0.004 to 0.001	0.102	-0.005	-0.008 to -0.002	0.003
CCP Positive	-0.047	-0.101 to 0.008	0.095	-0.058	-0.134 to 0.018	0.130
Disease Duration	-0.001	-0.003 to 0.001	0.339	-0.001	-0.005 to 0.005	0.975
Fat Mass Index	0.005	-0.003 to 0.013	0.212	--	--	--
Arm/leg LMI	0.037	0.001 to 0.073	<0.0001	0.042	0.016 to 0.067	0.002
Prednisone dose	-0.005	-0.011 to 0.002	0.168	--	--	--
Frail Category:						
Robust	ref	ref	ref	ref	ref	ref
Prefrail	-0.027	-0.097 to 0.043	0.440	-0.084	-0.197 to 0.030	0.144
Frail	-0.048	-0.177 to 0.079	0.449	-0.160	-0.277 to -0.042	0.009

*CCP: cyclic citrullinated peptide antibody; LMI: lean mass index.

*High positive anti-CCP >60 units.

*Frail categories based on Fried Index.

*Note: OP medication use had a negative association with BMD suggesting confounding by indication; therefore it was not included in the multivariable model. The model for male sex did not include fat mass index and prednisone dose due to the small number of male subjects.

identify independent predictors of BMD, we performed a multivariable linear regression analysis that included variables significant in the univariable analyses at $p < 0.10$. Because sex differences in frailty were noted, we performed additional sex-stratified multivariable analyses.

Results: There were 138 participants (82 females, 56 males) and the mean age was 58.0 ± 10.8 years. 70% were rheumatoid factor positive, and 55% were high anti-cyclic citrullinated peptide (CCP) positive (>60 units). Mean disease duration was 19 ± 10.9 years. 52% had low BMD based on a T or Z score ≤ -1.0 . 44% of participants reported taking prednisone and 27% reported taking OP medications. Males had higher rates of frailty (11% robust, 63% prefrail, 27% frail) compared to females (22% robust, 72% prefrail and 6% frail). In the entire cohort, age, high positive anti-CCP and frailty had independent negative associations with BMD ($\beta = -0.003$, -0.052 and -0.093 respectively, $p < 0.05$) (Table 1). Appendicular lean mass index (ALMI) had a positive linear association with BMD ($\beta = 0.042$, $p < 0.0001$). In females, only ALMI had a significant independent association with BMD ($\beta = 0.037$, $p < 0.0001$). In males, frailty carried the strongest independent association with BMD ($\beta = -0.160$, $p < 0.01$). Age and ALMI also maintained their independent associations with BMD in males ($\beta = -0.005$ and 0.042 respectively, $p < 0.01$).

Conclusion: Frailty, high positive anti-CCP, ALMI and age were independently associated with BMD in patients with RA. Males had higher rates of frailty than females, and in sex-stratified analysis, frailty was independently associated with BMD in males but not in females. Our findings suggest that frailty is an important factor associated with low BMD and that sex may influence the development of frailty in patients with RA.

Outcomes One Year after Hip Fracture Repair in the Elderly: Does Social Isolation Matter?

Lisa A. Mandl¹, Serena Lian¹, Jackie Szymonifka², Kirsten Grueter³, Aidan Hadad³ and Joseph Lane³, ¹Rheumatology, Hospital for Special Surgery, New York, NY, ²Hospital for Special Surgery, New York, NY, ³Orthopaedic Surgery, Hospital for Special Surgery, New York, NY

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Osteoporosis and Metabolic Bone Disease – Basic and Clinical Science Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Hip fractures are a serious public health issue with a significant population burden, especially among those over age 65. Social isolation—how integrated a patient is in their community—is a novel and potentially modifiable risk factor for poor health outcomes after low energy hip fracture. This study evaluates the association of pre-operative social isolation with death, adverse events, and patient-reported outcomes in elderly patients 1 year after surgical repair of low energy hip fracture.

Methods: The Lubben Social Networks Scale-18 (LSNS-18), a validated instrument specifically designed to measure social isolation in the elderly; PROMIS-29, which measures a variety of important patient-reported domains; and the Lower Extremity Activity Scale (LEAS), which measures physical function, were administered to cognitively intact patients \geq age 65 with no active cancer, 2-4 days after surgical repair of hip fracture. Patients were specifically instructed to answer based on their pre-fracture status. Patients were contacted at 4 weeks, 3 months, and 1 year after surgery. The LSNS-18, PROMIS-29, and LEAS were re-administered at 1 year. Data were analyzed using t-tests, chi-square tests, Wilcoxon rank-sum tests and Spearman correlations.

Results: 203 patients enrolled: 71.9% female, 91.6% white, 78.7% college educated, with a median age of 81.8 [74.1, 87.3] years. 36% were socially isolated. Of the 9 known deaths within 1 year, 6/9 (67%) were socially isolated, a much higher percentage than the overall cohort, though not statistically significant ($p = 0.095$).

73/99 (74%) of subjects who were 1-year post-fracture repair completed 1-year questionnaires (20 withdrew consent/were lost to follow-up, and 6 were mentally/physically unable to participate). There was no statistically significant difference in number of adverse events/severe adverse events between socially isolated and non-socially isolated subjects. There was also no difference in LEAS score or any PROMIS-29 domain between isolated and non-isolated subjects 1 year after surgery. However, socially isolated patients were more likely to improve their LSNS-18 score than those who were not socially isolated prior to fracture repair ($\Delta 6.1 \pm 13.3$ vs. $\Delta -1.2 \pm 13.7$; $p = 0.03$).

Conclusion: There is a trend suggesting social isolation may be associated with 1-year mortality in cognitively intact elderly patients undergoing surgical repair of low energy hip fracture. Although there was no association between pre-fracture social isolation and adverse events or self-reported patient reported outcomes, on average socially isolated patients were less isolated 1 year after fracture repair than pre-fracture. Whether the magnitude of improvement in social isolation is associated with improved health status will be evaluated as this study continues to recruit.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Osteoporosis and Metabolic Bone Disease – Basic and Clinical Science Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: : High doses of glucocorticoids (GC) are often used in the treatment of Systemic Lupus Erythematosus (SLE), however, studies suggest that SLE patients do not receive adequate screening for glucocorticoid induced osteoporosis (GIOP).

The purpose of our study was to evaluate providers' decisions to order DEXA screening in SLE patients who receive high doses of glucocorticoids for 3 months or longer, in a pragmatic clinical setting

Methods: We conducted a retrospective cohort study using a large healthcare system clinical database from the years 2011 to 2016. SLE cases with long-term prednisone use (≥ 3 months) at doses of at least 7.51 mg daily were identified via database search and manually reviewed by two clinicians for accuracy. Osteoporosis risk factors were assessed retrospectively via chart review. Fracture Risk Assessment (FRAX[®]) score was estimated for patients older than 40 years based on chart review. GIOP screening practices were compared with the 2017 American College of Rheumatology Guideline for the Prevention and Treatment of Glucocorticoid-Induced Osteoporosis as the gold standard. A classification tree was used to identify the key patient-related factors that discriminate screening.

Results: 203 SLE patients met inclusion criteria, with 240 total episodes of high dose glucocorticoid usage for ≥ 3 months. 130 patients were 40 years of age or older. Of the patients younger than 40 years, 69 (95%) were female, their median daily dose of prednisone was 15 [10-20.9] mg/day, and the median duration of prednisone usage was 219 [150-409] days. Among those 40 years and older, 105 (81%) were female, their median daily dose of prednisone was 12.5 [10-18.9] mg/day, and the median duration of prednisone usage was 252 [165-518] days. In the younger age group, 27% of patients had DEXA scans ordered vs 8% deemed appropriate per ACR guidelines. Of patients 40 years and older, 63% underwent DEXA scans, versus 100% recommended by ACR guidelines. In a classification tree analysis, DEXA screening was most likely to be ordered for women, those with an estimated FRAX score greater than 9.95, prednisone use duration of 17 months or longer, and a medication count greater than 10.

Conclusion: Among SLE patients on high dose GC therapy, those younger than 40 had more DEXA scans than deemed appropriate per ACR guidelines, while older patients had fewer. Female sex, higher estimated fracture risk, longer prednisone use, and a higher medication count were key patient-related factors associated with providers' decisions to order DEXA.

Session Title: Osteoporosis and Metabolic Bone Disease – Basic and Clinical Science Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: In 2010, the Canadian Osteoporosis guidelines recommended that patients with osteoporosis be supplemented with vitamin D and to achieve serum levels ≥ 75 nmol/L. Past studies, most of which were completed before these guidelines could be implemented, showed that there is a large proportion of patients whose levels are below this target. For this reason, we aimed to assess the current uptake of these guidelines in osteoporosis patients by: 1) Determining the current prevalence of patients who are vitamin D-sufficient (≥ 75 nmol/L); 2) Assessing factors associated with vitamin D insufficiency; and 3) Identifying groups of patients who are not on vitamin D supplementation.

Methods: We retrospectively reviewed charts of patients referred to a single osteoporosis clinic in Hamilton, Canada, seen between April and October 2017. Inclusion criteria were a lumbar spine or femoral neck T-score ≤ -2.5 or a major fragility fracture, and age above 18 years. Data from the initial consultation appointment was extracted. We also collected absolute vitamin D levels and determined vitamin D insufficiency (< 75 nmol/L) as well as its prevalence. Further, we determined the effects of age, sex, vitamin D intake, BMI, eGFR, fracture history, and PPI use on vitamin D sufficiency and supplementation rates and investigated their role on PTH, calcium levels, fracture prevalence, and BMD. Where appropriate, we completed a Pearson's chi-squared analysis or a Pearson correlation analysis.

Results: Charts were reviewed from 180 patients, mean age 65.8 years (SD 11.9) 78.3% (141/180) female, 82.2% (148/180) reported taking vitamin D supplements. The average vitamin D level was 93.7nmol/L (SD 34.1) and 75% (135/180) were vitamin D-sufficient. We found that patients with vitamin D insufficiency were significantly older (69.2 vs 64.6 years, $r=0.169$, $p=0.023$) with no effect on other bone parameters. We also found that vitamin D-insufficient patients had a significantly lower eGFR (69.6 vs 78.3mmol/L, $r=0.210$, $P=0.005$), which was inversely correlated with PTH level ($r=-0.229$, $p=0.002$). Lastly, we found a difference in sex and vitamin D supplementation rates, as males were less likely to be on vitamin D supplementation (57.9% vs. 91.3%, $X^2=24.86$, $p<0.001$). Other bone parameters were not significantly affected.

Conclusion: In our retrospective analysis, we found that currently, there is strong adherence to the Canadian guidelines for vitamin D status in patients with osteoporosis in Hamilton, Ontario. However, we identified that there continues to be a care gap for patients who are older, male, or have a lower eGFR with regards to their vitamin D status, which are factors that we recommend for practitioners to follow more closely.

Session Date: Tuesday, October 23, 2018

Session Title: Osteoporosis and Metabolic Bone Disease – Basic and Clinical Science Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Inflammatory arthritis patients had increased risk of atherosclerosis and osteoporosis. The association between presence of carotid plaque and volumetric BMD (vBMD)/microarchitecture is yet to be explored. The aim of this study was to explore the relationship between volumetric bone mineral density (vBMD)/microstructural features and presence of carotid plaque (CP) in patients with inflammatory arthritis.

Methods: 175 inflammatory arthritis patients (81 [46%] PsA, 94 [54%] RA; 70 [40%] males; age: 53 ± 12 years) were recruited into an ongoing prospective study assessing the relationship between inflammation, osteoporosis and carotid atherosclerosis. Carotid plaque and intima-media thickness (IMT) were measured by carotid ultrasound. Areal BMD (aBMD) was measured by dual energy X-ray absorptiometry (DXA). Microarchitecture features and vBMD of distal radius were measured using high-resolution peripheral quantitative computed tomography (HR-pQCT).

Results: No patients had established cardiovascular disease (CVD). Data from 172 patients at baseline were analyzed for this cross-sectional study. Patients were sub grouped according to the presence or absence of carotid plaque (CP+ group, n=68 [40%]) and CP- group, n=132 [60%]). CP+ group were older (59 ± 10 vs 49 ± 11 , $p < 0.001$), more likely to be male (54% vs 31%, $p = 0.002$), had higher systolic blood pressure (130 ± 19 vs 124 ± 17 mmHg, $p = 0.034$) and CVD risk (15.7 ± 14.2 vs 7.9 ± 8.6 , $p < 0.001$) according to the Framingham Risk Score (FRS) then the CP- group. aBMD, vBMD and microarchitecture were significantly compromised in the CP+ group. Distal radius aBMD, distal radius total vBMD, trabecular (Tb) vBMD, Tb thickness, cortical (Ct.) vBMD, Ct. thickness and bone volume fraction were 5% ($p = 0.004$), 12% ($p < 0.001$), 8% ($p = 0.007$), 8% ($p = 0.004$), 4% ($p = 0.007$), 10% ($p = 0.001$) and 8% ($p = 0.007$) lower in the CP+ group. The differences remained significant after adjustment for gender, disease type and FRS (Table 1).

Conclusion: Inflammatory arthritis patients with carotid plaque had lower aBMD, vBMD and compromised bone microarchitecture in the distal radius even after adjustment for gender, disease type and FRS, suggesting that inflammation may be the common link for both conditions.

Table – Distal radius vBMD/microarchitecture and presence of plaque

	Carotid plaque						p value	Adjusted p value*
	No (n=104)			Yes (n=68)				
Total radius								
aBMD, g/cm ²	.575	±	.087	.547	±	.091	0.095	0.004
Distal radius								
Total vBMD, mmHA/cm ³	353.8	±	77.8	315.3	±	69.7	0.001	<0.001
Trabecular BMD, mmHA/cm ³	141.5	±	46.2	131.4	±	38.8	0.138	0.007
Bone volume fraction	.118	±	.039	.110	±	.032	0.142	0.007
Trabecular thickness, mm	.077	±	.017	.071	±	.013	0.019	0.004
Cortical vBMD, mmHA/cm ³	902.6	±	58.0	870.0	±	63.5	0.001	0.007
Cortical Thickness, mm	.882	±	.177	.792	±	.211	0.009	0.001

Vitamin D and Bisphosphonate Therapy in SLE Patients Who Receive Glucocorticoids: Are We Offering the Best Care?

Smarika Sapkota¹, Sara Baig², Toy Hess³, Ann Marie O'Connell⁴, Jeremiah Menk³, Parastoo Fazeli⁵ and Anna K. Shmagel⁶, ¹Division of General Internal Medicine, University of Minnesota, Minneapolis, MN, ²Department of Internal Medicine, University of Minnesota, Minneapolis, MN, ³University of Minnesota, Minneapolis, MN, ⁴University of Minnesota, Minneapolis, MN, ⁵Rheumatology, University of Minnesota, Minneapolis, MN, ⁶Rheumatic & Autoimmune Diseases, University of Minnesota, Minneapolis, MN

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Osteoporosis and Metabolic Bone Disease – Basic and Clinical Science Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Glucocorticoids(GC) are frequently used for the treatment of systemic lupus erythematosus (SLE), and glucocorticoid induced osteoporosis (GIOP) is a well-known complication of long term glucocorticoid therapy. American College of Rheumatology (ACR) guidelines recommend vitamin D supplementation for all patients on long term GC, and bisphosphonate therapy - for patients with moderate to high risk of osteoporotic fracture. We aimed to evaluate physicians' decisions to prescribe vitamin D and bisphosphonates to SLE patients receiving long-term high dose GC, and compare them with the 2017 ACR GIOP guidelines.

Methods: A retrospective cohort of SLE patients who had received care within a large healthcare system in Minnesota between 2011 to 2016 was identified from electronic medical records. Patients receiving prednisone doses of 7.5 mg or higher for at least 90 days were included in the analysis. Demographic data, duration and dosage of GC use, weight, height, previous history of fracture, family history of osteoporosis, smoking and alcohol use were ascertained from medical records, as well as use of vitamin D supplements and bisphosphonates within 6 months of starting high-dose GC therapy. Contraindications to bisphosphonates were also reviewed. Fracture Risk Assessment (FRAX) score was estimated for patients older than 40 years based on chart review. Two clinicians ascertained indication for bisphosphonate through chart review using the 2017 ACR guidelines as a gold standard. A classification tree was used to identify factors that discriminate prescribing bisphosphonates for those 40 and older.

Results: 203 SLE patients met inclusion criteria. Of those, 130 patients were aged 40 years or older. Vitamin D supplement was prescribed to 83% of patients, however, 8.4% were prescribed less than 800 Units per day. Serum vitamin D levels were checked in 30% of patients during high-dose GC therapy, and on average were vitamin D insufficient (median serum vitamin D level 25 [18.5, 30.0]). Thirty-three patients were prescribed a bisphosphonate within 6 months of starting high-dose GC, 32 of them were older than 40. In the older age group, where recommendations for bisphosphonate therapy are available, 25% were prescribed bisphosphonate therapy, compared with 36% who met indications for bisphosphonates per ACR guidelines. A single node was identified in the classification tree. Patients with FRAX scores (for major osteoporotic fracture) of 23.5 or greater were more likely to be prescribed bisphosphonates.

Conclusion: Both vitamin D supplements and bisphosphonates were under prescribed to SLE patients at risk for osteoporotic fracture. Patients were most likely to receive a bisphosphonate prescription if they had a major osteoporotic fracture risk of over 23.5% in 10 years.

Obesity Might Positively Affect TNF Mediated Bone Metabolism in RA Patients

Mie Jin Lim¹, Won Park², Seong Ryul Kwon³, Kyong-Hee Jung⁴ and Seung Yun Lee³, ¹Division of Rheumatology, Departments of Internal Medicine, Inha University Hospital, Incheon, Korea, Republic of South, ²Medicine/ Rheumatology, Inha University Hospital, Incheon, Korea, Republic of South, ³Division of Rheumatology, Department of Internal Medicine, Inha University Hospital, Incheon, Korea, Republic of South, ⁴Rheumatology, Inha University Hospital, Incheon, Korea, Republic of South

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Osteoporosis and Metabolic Bone Disease – Basic and Clinical Science Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: In this study, we tried to find out the effect of obesity on bone metabolism after one year of anti-TNF agent use.

Methods: Thirty-two seropositive RA patients were enrolled. They had been refractory to antirheumatic drugs and anti TNF therapies including etanercept, adalimumab and infliximab were administrated for one year. Etanercept, adalimumab and infliximab at approved dose were given to 11, 13 and 8 patients, respectively. Body mass index (BMI) was calculated according to patient's weight and height at baseline. BMI 25Kg/m² was considered to be obese. Bone mineral densities (BMD) were measured at baseline and one year after treatment. Blood sampling was done at baseline, 6 months and 1 year after the treatment. Peripheral blood mononuclear cells were cultured and number of osteoclasts was counted. Bone turnover markers including c-terminal telopeptide (CTX), bone specific alkaline phosphatase (BSALP) were measured using enzyme linked immunosorbent assay. In addition, RA disease activity including DAS28 was assessed along with serum level of IL-6.

Results: After 1 year of anti-TNF treatment, bone mineral density (BMD) in non-obese patients worsened although BMD remained still in obese patients (Table 1). Bone resorption pits by cultured osteoclasts from non-obese patients showed marked reduction at 6 months but seemed to increase at 12 months of treatment despite number of the osteoclasts were continuously decreasing. On the contrary, obese patients failed to show significant change in number of osteoclasts after the treatment but resorption pits by the osteoclasts seemed to decrease in trend. DAS28 improved in both non-obese and obese RA patients and significant reduction of serum IL-6 was noted in non-obese patients (Table 2).

Conclusion: One year treatment of anti-TNF agent did not change BMD in obese RA patients although there was a significant reduction in BMD in non-obese patients. Number of osteoclasts from non-obese patients decreased after treatment but the function of osteoclasts reflected as bone resorption pit did not respond to the treatment. Despite no change in number of osteoclasts from obese patients after treatment, function of osteoclasts from obese patients seemed to improve, resulting in no change in BMD. Therefore, we believe obesity might positively affect TNF mediated bone metabolism in RA patients.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Osteoporosis and Metabolic Bone Disease – Basic and Clinical Science Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is a progressive auto-immune disease characterized by chronic inflammation which leads to joint deformity and disability. However, the bone and muscle are also affected. The aim of this study was to evaluate the total bone mineral density (tBMD) and total lean mass in rheumatoid arthritis patients.

Methods: A total of 50 adult's women with RA and a control group (CG, n=34) matched by sex, age and body mass index (BMI) were included. All patients had more than 18 years and were from Rosario city (32°52'18''S), Argentina. Exclusion criteria: pregnancy, intestinal malabsorption, chronic liver or kidney disease, cancer and drug which could affected the bone mass except glucocorticoids. The whole body composition was performed by Dual X-Ray Absorptiometry (DXA) (Hologic discovery Wi). The muscle strength was evaluated by handgrip strength (Baseline Hydraulic Hand Dynamometer, USA) and the physical performance by sit to stand test and timed up and go test. Data are expressed as mean±SD. Differences between groups were analyzed using the Student t test or Mann-Whitney test as appropriate. Correlations were performed with Pearson or Spearman's correlation test. Contingency tables were evaluated with χ^2 test. The difference was considered significant if $p < 0.05$.

Results: No differences in age (CG: 55.1±12.7 y, RA: 53.5±11.7 y), BMI (CG: 26.0±5.1, RA: 27.8±4.6) and percentage of pre and postmenopausal women were included. According to BMI no differences in total mass by DXA were observed (CG: 66.9±13.1 kg, RA: 68.0±13.1 kg). The total bone mineral content (tBMC) and tBMD were found decreased in RA patients (tBMC= CG: 2111±319 g, RA: 1874±343 g, $p=0.0036$; tBMD= CG: 1.072±0.094 g/cm², RA: 1.016±0.109 g/cm², $p=0.0255$). Furthermore, a tendency to low lean mass in RA patients were observed (CG: 57.3±5.2, RA: 55.7±5.3, $p=0.06$). The muscular involvement was confirmed in muscle strength and physical performance tests. The RA group had significantly lower handgrip strength (CG: 21.4±4.9 kg, RA: 12.3±6.7, $p<0.0001$), lower performance in the sit to stand test (CG: 14.7±4.5 s, RA: 17.9±5.7 s, $p=0.0126$) and timed up and go test (CG: 8.8±1.9 s, RA: 11.6±3.7, $p=0.0003$). A significant correlation between tBMD and total lean mass were found ($r: 0.3$, $p=0.0128$). In addition, significant correlation between regional BMD (left arm, right arm, left leg and right leg) and the lean mass of each region were observed. Therefore the loss of lean mass could explain the loss of bone mass. On the other hand, higher percentage of fat was found in RA patients (CG: 39.4±5.7, RA: 41.9±5.7, $p=0.06$).

Conclusion: the disease activity could affect not only the joint and bone mass, but also the muscle which contributes to bone loss and lead to osteopenia and osteoporosis in RA patients.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Osteoporosis and Metabolic Bone Disease – Basic and Clinical Science Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Osteoporosis is one of the most common morbidities in postmenopausal women. Although serum uric acid (SUA) accounts for about 50% of extracellular antioxidant activity, the role of hyperuricemia in osteoporosis, a condition characterized by high oxidative stress level, has not been investigated in a Nation-wide scale. The aim of this study is to evaluate an association between SUA and incidence of osteoporosis in postmenopausal women.

Methods: Data of postmenopausal women from the 2016 Korean National Health and Nutrition Examination Survey were included and retrospectively analyzed. Weighted prevalence and logistic regression analysis were used to determine the incidence of osteoporosis and the effect of SUA on osteoporosis in postmenopausal women.

Results: One-thousand three-hundred eighty-two (weighted $n = 7,064,137$) of postmenopausal women were observed. Of these, 401 (29.0 %, weighted $n = 1,880,586$) women developed osteoporosis. Mean age of participants was 63.2 years and mean of SUA was 4.4 mg/dL. The effect of SUA on osteoporosis in postmenopausal women was not statistically significant according to univariable logistic regression (OR 0.977, 95 % CI 0.855-1.116, $p = 0.729$). However, SUA was negatively associated with incidence of osteoporosis in postmenopausal women with statistical significance after adjusting for age, obesity, amount of drink, smoking, intake of calcium, rheumatoid arthritis, thyroid diseases, and loss of activity (OR 0.867, 95 % CI 0.752-0.999, $p = 0.048$).

Conclusion: Our data demonstrated that high SUA is associated with lower incidence of osteoporosis in postmenopausal women. This result suggests a protective role of SUA in metabolic bone diseases.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Osteoporosis and Metabolic Bone Disease – Basic and Clinical Science Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Hand osteoarthritis (OA) and its more severe subset erosive hand OA are common causes of pain and morbidity. Some metabolic factors were suggested to be implicated in erosive disease. Few studies investigated differences in systemic bone loss between erosive and non-erosive hand OA.

Methods: Consecutive patients with symptomatic HOA fulfilling the American College of Rheumatology (ACR) criteria were included in this study. Erosive hand OA was defined by at least one erosive interphalangeal joint. All patients underwent clinical assessments of joint swelling and radiographs of both hands. DEXA examination of lumbar spine, total femur and femur neck was performed at the baseline and after two years.

Results: Altogether, 144 patients (15 male) with symptomatic nodal HOA were included in this study and followed between April 2012 and January 2018. Out of these patients, 82 had erosive disease after two years. The disease duration ($p < 0.01$) was significantly higher in patients with erosive compared with non-erosive disease at baseline. Osteoporosis (T-score < -2.5 SD) was diagnosed in 12.5% (9/72) of patients with erosive hand OA and in 8.06% (5/57) of patients with non-erosive hand OA. BMD was significantly lowered in patients with erosive compared with non-erosive disease at baseline (lumbar spine: 1.05g/cm² vs. 1.13 g/cm², $p < 0.05$, total femur: 0.90 g/cm² vs. 0.97 g/cm², $p < 0.01$ and femur neck: 0.86 g/cm² vs. 0.91, $p < 0.05$). T-scores of lumbar spine (-0.96 vs. -0.41 SD, $p < 0.05$), total femur (-0.69 vs. -0.33 SD, $p < 0.05$) and femur neck (-1.14 vs. -0.88 SD, $p < 0.05$) were also significantly lowered in patients with erosive compared with non-erosive disease. Furthermore, we found significant decrease in BMD in patients with erosive compared with non-erosive disease over two years (lumbar spine: -3.30% vs. 1.06%, $p < 0.05$, total femur (-1.58% vs. 0.82%, $p < 0.05$) and femur neck (-3.2% vs. 0.02%, $p < 0.05$). The decrease in T-score of lumbar spine (-3.66% vs. 15.52%, $p < 0.01$) and total femur (-4.29% vs. 7.68%, $p < 0.05$) was also significantly higher in erosive compared with non-erosive hand OA.

Conclusion: These results suggest that patients with erosive hand OA are at higher risk for the development of general bone loss.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Osteoporosis and Metabolic Bone Disease – Basic and Clinical Science Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Osteoporosis-related fractures (fractures) are a leading cause of morbidity and disability in the US. Epidemiological data on the occurrence of fractures are limited and required to inform healthcare providers, payers, and policymakers on the scope of this disease. The objective of this analysis was to assess the incidence of fractures in a population of managed care enrollees over the past decade.

Methods: The study included commercial and Medicare Advantage health plan members who had evidence of a qualifying fracture between Jan 2007 and May 2017 (identification period). Fractures were considered qualifying if they were either identified during an inpatient stay or were identified in an outpatient setting based on primary or secondary ICD-9 or ICD-10 accompanied by a repair procedure code. Patients ≥ 50 years of age with evidence of a qualifying fracture were included. The denominator population comprised members who were ≥ 50 years of age during the year of interest. The number of days the member was enrolled in the health plan during the year was calculated and was used to determine the total person-years (py) of enrollment for the denominator. Incidence rate is reported as number of events per 1000 py of enrollment during each year from 2007-May 2017. Rates are presented stratified by age category (50-64 vs ≥ 65) and gender (male vs. female). Patients were categorized by 5-year age increments and gender, and an overall age-gender adjusted rate was calculated.

Results: Of 1,841,263 members with fractures in the identification period, 513,176 met the eligibility criteria. The overall age-gender adjusted rate fell from 14.67/1000 py in 2007 to 11.80/1000 py in 2012, and then did not decrease from 2013-May 2017. Among females ≥ 65 years old the incidence of fractures declined from 27.49/1000 py in 2007 to 22.08/1000 py in 2013, and then did not decrease from 2014-May 2017. Similarly, among males ≥ 65 years old incidence decreased from 12.00/1000 py in 2007 to 10.72/1000 py in 2013 and then did not decrease from 2014-May 2017. For males and females ages 50-64 the rates were consistent across years, approximately 4.2 and 7.2 fractures per 1000 py, respectively.

Figure. Incidence of Osteoporotic Fractures Per 1000 Person Years: 2007-May 2017
Fracture rate per 1000 person years

Conclusion: The current study findings suggest fracture incidence has remained the same and potentially rising since 2014. The current study results may reflect insufficient diagnosis and treatment of osteoporosis and support the call to action to increase diagnosis and treatment of osteoporosis especially in older adults.

Session Date: Tuesday, October 23, 2018

Session Title: Osteoporosis and Metabolic Bone Disease – Basic and Clinical Science Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Identification of osteoporosis as a reason for vertebral fractures in patients with rheumatoid arthritis and non-inflammatory musculoskeletal diseases – A comparison between trabecular bone score (TBS) and bone mineral density (BMD)

Buehring B, Baraliakos X, Thomas J, Braun J.
Rheumazentrum Ruhrgebiet, Herne, Germany.

Background/Purpose: Osteoporosis-related fractures are common in patients with rheumatoid arthritis (RA). Measurement of bone mineral density (BMD) by dual energy X-ray absorptiometry (DXA) alone does not adequately predict fracture risk. Trabecular bone score (TBS) is a surrogate marker for trabecular microarchitecture which independently predicts fracture risk. In this study we assessed the prevalence of low BMD, low TBS and osteoporotic related vertebral fractures in patients with RA in comparison to controls with non-inflammatory musculoskeletal diseases.

Methods: In retrospective study design, we analyzed the data of all patients with available TBS and DXA data presenting to our hospital in the last 5 years. All diagnoses were made by rheumatologists. Comparisons between groups were made by Mann-Whitney-Test and Wilcoxon-Test where appropriate, after adjustment for age, cortisone intake and body mass index.

RA-Patients		TBS	
		low	normal
DXA	low	45 (86,5 %)	2 (3,8 %)
	normal	17 (32,7 %)	2 (3,8 %)

Controls		TBS	
		low	normal
DXA	low	23 (95,8 %)	0 (0,0 %)
	normal	5 (20,8 %)	1 (4,2 %)

Results: There were 143 patients with RA (mean age 72.1 ± 11.1 years, 72% female) and 106 controls (mean age 69.6 ± 12.6 years, 74.5% female). Vertebral fractures were found in 36.4% (n=52) RA patients and in 22.6% (n=24) controls (p=0.02). Overall, there were no differences in the mean DXA BMD (for both, spine and hips) and the mean TBS values in all patients. On the other hand, there were statistically more RA patients with low BMD (n=102; 71.3%) and TBS scores (n=125; 87.4%) than controls (n=61; 57.5% and n=79; 74.5%, respectively, p=0.009). In addition, in patients with a vertebral fracture, a low TBS with a normal DXA was more frequently observed in both groups (numerically higher in RA than in controls), while low BMD with a normal TBS was rare (Table). This was not the case in patients without a vertebral fracture.

Conclusion: Low TBS in the setting of normal BMD was found more frequently in patients with vertebral fractures, especially in patients with RA, whereas the reverse is rare. This suggests TBS might prove to be a useful tool for identification of deteriorated bone microarchitecture and strength in patients with vertebral fracture with normal BMD.

Table: Prevalence of low and normal BMD and TBS results in patients with incident vertebral fractures

Session Title: Osteoporosis and Metabolic Bone Disease – Basic and Clinical Science Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with RA have high rates of osteoporosis and fractures and RA induces articular and extra-articular bone loss. Seropositivity for any CCP antibody is associated with risk of erosions and osteoporosis. In vitro, human antibodies against citrullinated vimentin bind osteoclast cell surfaces, activate their bone resorptive activity and in an animal model, induce bone loss. In humans, it is not known whether these antibodies are a specific risk factor for osteoporosis. The aim of this study was to assess the prevalence of radiographic vertebral compression fractures (VCF), as a marker of skeletal fragility, in an established RA cohort and whether the presence of antibodies to citrullinated vimentin were associated with this.

Methods: Data was obtained from a prospective established RA cohort (ACR/EULAR 2010 or ACR 1987 criteria) undergoing elective arthroplasty. VCF were identified on the lateral pre-operative chest radiograph by two independent readers utilizing the Genant semi-quantitative method. Antibodies to citrullinated vimentin epitopes were measured by mean fluorescence intensity utilizing a custom, bead-based, antigen array comprising CCP and RA-associated citrullinated antigens. To identify risk factors predictive of vertebral compression, univariate logistic regression analysis was performed including known potential risk factors for bone loss in RA.

Table 1: Distribution and grade of vertebral compression fractures as scored by the Genant semi-quantitative method

	No vertebral compression (n=105)	Vertebral compression (n=75)		
		Grade 1 (n=59)	Grade 2 (n=15)	Grade 3 (n=2)
Male	19	13	4	1
Female	86	46	11	1

Table 2: Univariate logistic regression of risk factors for vertebral fracture

Univariate models	Odds ratio (95% CI) for fracture grade 1, 2 or 3	p-value
Age, per 5 years	1.19 (1.04 - 1.38)	0.014
Sex		
Female	0.71 (0.34 - 1.47)	0.389
Male	1.00 (reference)	—
Race		
White	1.32 (0.68 - 2.56)	0.406
Asian	0.92 (0.15 - 5.64)	0.929
Black or African American	0.79 (0.18 - 2.00)	0.396
BMI, per 1 kg/m ²	0.98 (0.93 - 1.03)	0.408
CCP raw value, per 10 units	1.00 (0.99 - 1.01)	0.954
RE raw value, per 10 units	1.00 (0.99 - 1.01)	0.448
DAS28-ESR	0.92 (0.70 - 1.21)	0.566
CDAI	1.01 (0.98 - 1.04)	0.621
Disease duration	0.99 (0.96 - 1.02)	0.419
Symptom duration	0.98 (0.96 - 1.01)	0.243
Current steroid use	0.87 (0.31 - 1.87)	0.808
Prior steroid use	0.80 (0.28 - 1.20)	0.189
Current MTX/DMSARD use	1.15 (0.59 - 2.26)	0.681
Current biologic use	1.25 (0.65 - 2.36)	0.462
Current or former smoker	1.27 (0.66 - 2.44)	0.486
Current alcohol use	1.42 (0.74 - 2.71)	0.289
Prior diagnosis of osteoporosis or current medical therapy for osteoporosis	1.40 (0.17 - 7.12)	0.857
Family history of hip fracture	0.66 (0.26 - 1.77)	0.405
Vimentin 56-77 cit3 cyclic smab-I, IgG	0.82 (0.70 - 1.21)	0.504
Vimentin 56-77 cit3 cyclic smab-I, IgM	0.94 (0.61 - 1.09)	0.417
Vimentin 56-77 cit3 cyclic smab-I, IgE	0.49 (0.22 - 1.08)	0.075

Results: 181 participants had an available chest radiograph. Median age was 65 years [IQR 56, 71] and median disease duration 11 years [IQR 3, 20]. 80% were female, 37% were on current glucocorticoid therapy and 21% had prior exposure. Only 3% self-reported a diagnosis of osteoporosis or use of osteoporosis medications. Despite these numbers, almost half, 76/181 (42%) [58 female] had radiographic VCF (Table 1). Participants with VCF were older [median age 68 years vs. 64 years, $p=0.03$]. In univariate analysis of potential risk factors, only age was associated with VCF (Table 2). No significant differences were seen in antibody levels, including antibody isotypes to citrullinated vimentin.

Conclusion: Vertebral compression fractures were prevalent in patients in this established RA cohort. The strongest risk factor for VCF was age. Antibodies to citrullinated vimentin, implicated in early RA models, were not associated with VCF. Our results highlight the profound detrimental skeletal effects of RA. Further studies are needed to investigate the mechanisms of focal versus generalized bone loss, as well as skeletal changes that occur with RA progression.

Abstract Number: 2338

Pharmacological and Non-Pharmacological Approaches in a Group of Osteoporotic Patients Referring to a Rehabilitation out-Patient Clinic

Pinar Borman¹, Esra Gizem Koyuncu¹, Aysegul Yaman¹ and MERVE PARLAK², ¹University of Hacettepe Faculty of Medicine, Dept of PMR, Ankara, Turkey, ²University of Hacettepe Faculty of Medicine, Dept of Public Health, Ankara, Turkey

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Osteoporosis and Metabolic Bone Disease – Basic and Clinical Science Poster – ARHP

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Non-pharmacologic treatments are generally kept in the background in management of osteoporosis. The aim of this retrospective study was to evaluate characteristics and frequency of pharmacologic and non-pharmacologic treatments for patients with osteoporosis (OP), in a university hospital, outpatient clinic of Physical Medicine and Rehabilitation, during the last 6 months.

Methods: A hundred and fifty-five OP patients, who were not having any malignancy and/or terminal-term chronic disease, were included to this study. Demographic properties (age, gender, disease duration), clinical characteristics (fracture history, comorbidities, drugs) and treatment approaches for OP (pharmacologic and non-pharmacological) were recorded from files. Descriptive statistics were used for clinical variables and frequency of treatment approaches.

Results: 137 female, 18 male OP patients with a mean age of 66.11 ± 11.21 years, were included to the study. Post-menopausal osteoporosis was present in 130 (83.8%) and secondary OP was determined in 25 (16.2%) of the subjects. The mean duration of OP was 6.95 ± 1.11 years. 24.5% of the patients had at least one porotic fracture. The most frequently causes of secondary OP were drugs (mostly steroids) and comorbid diseases (endocrine diseases, asthma, rheumatic conditions). Pharmacological treatments were prevalent and the most commonly prescribed drugs were denosumab (35.7%), alendronate (22.4%) and ibandronate (10.5%) followed by zoledronic acid (7.7%), teriparatide (2.8%) and risedronate (2.7%). Majority of the patients (68.1%) were concurrently on calcium and/or Vit D therapies. Non-pharmacologic treatments were suggested in 60% of the patients, mostly as exercise (50%), diet (37.5%), lifestyle modifications (28.6%); but only 50% of the subjects were performing regular exercises.

Conclusion: Pharmacologic approaches were common and mostly denosumab and bisphosphonates were the first choices for OP treatment in our study group. Although non-pharmacologic approaches are of great value in OP management (1,2), approximately only half of our patients were prescribed these interventions in our study. We believe that there is an unmet need for non-pharmacologic management in OP. We suggest and emphasize the concurrent recommendations of non-pharmacologic interventions in OP patients, especially in rehabilitation clinics.

The Patient's Perspective of Glucocorticoid Use: A Systematic Literature Review of Quantitative and Qualitative Studies

Jonathan Cheah^{1,2}, Joanna Robson^{3,4}, Rachel Black^{5,6}, Susan M. Goodman^{7,8}, Susan Lester^{9,10}, Sarah Mackie¹¹ and Catherine Hill^{6,12}, ¹Medicine, Hospital for Special Surgery, New York, NY, ²Medicine, Weill Cornell Medicine, New York, NY, ³Faculty of Health and Applied Science, University of the West of England, Bristol, United Kingdom, ⁴School of Clinical Sciences, University of Bristol, Bristol, United Kingdom, ⁵Rheumatology, Royal Adelaide Hospital, Adelaide, Australia, ⁶Medicine, The University of Adelaide, Adelaide, Australia, ⁷Rheumatology, Weill Cornell Medicine, New York, NY, ⁸Hospital for Special Surgery, New York, NY, ⁹Rheumatology Unit, The Queen Elizabeth Hospital, Adelaide, Australia, ¹⁰Discipline of Medicine, Faculty of Health and Medical Sciences, The University of Adelaide, Adelaide, Australia, ¹¹NIHR-Leeds Musculoskeletal Biomedical Research Unit, University of Leeds, Leeds, United Kingdom, ¹²The Queen Elizabeth Hospital, Adelaide, Australia

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Patient Outcomes, Preferences, and Attitudes Poster II: Patient Perspectives

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Glucocorticoids (GCs) remain widely used and have well documented adverse effects. However, the impact of these adverse effects from the perspective of the patient, rather than of the clinician, remains relatively unexplored. Additionally, no general patient reported outcome measure has been developed to assess GC adverse effects and impact across rheumatological conditions. The aim of this literature review was to identify the impacts of systemic GC use that are of importance to patients.

Methods: An academic librarian searched OVID EMBASE, OVID MEDLINE, PsycINFO and CINAHL for articles published from inception to October 2017, related to three concepts: GCs, the patient perspective and adverse effects.

Figure: Study selection process

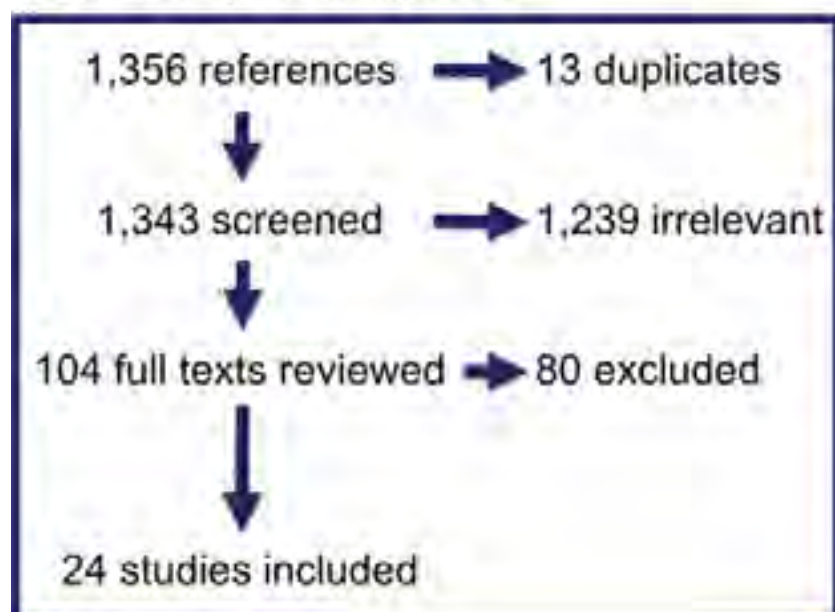

Table: Outcomes with the highest frequency effect size per theme

Theme	Outcome	Frequency effect size (%)
Physical symptoms	Weight gain	74
	Sleep problems	74
	Skin changes	65
	Upper GI problems	65
	Cardiopulmonary	63
Psychological symptoms	Intimacy and mood swings	74
	Depression	43
	Anxiety	35
	Hypersensitivity and asthma	30
	Process of smoking GC use	22
Participation	Impact on sexual relationships	13
	Impact on work	9
	Impact on family	4
Contextual factors	Lack of support of community or media	13
	Self-management and mastery	9
	Lack of support of family and friends	4

Inclusion criteria included systemic GC use for any indication in an adult population and both qualitative and quantitative research methodology. Titles and abstracts were then manually screened by two independent reviewers and subsequent quality assessment and data extraction also completed by two independent reviewers. A meta-synthesis of the qualitative data was performed separately by two independent researchers before qualitative meta-summary was utilized to quantitatively aggregate the findings (combining quantitative and qualitative results), including the derivation of frequency effect sizes to identify those outcomes most prominently featured across all reviewed articles.

Results: The initial search retrieved 1,356 articles, of which 24 (18 quantitative, 6 qualitative) were deemed suitable for quality assessment and data extraction (Figure). Studies included the assessment of GC use across a variety of diseases both rheumatologic (e.g. RA, vasculitis) and non-rheumatologic (including asthma, inflammatory bowel disease and multiple sclerosis). Four major themes emerged amongst the 71 discrete outcomes (Table): physical symptoms (44), psychological symptoms (18), effect on participation (6) and contextual factors (3).

Conclusion: Patients with a broad range of inflammatory diseases and demographic features describe key cross-cutting themes in relation to GCs and their impact on health-related quality of life. This work will inform the development of a core domain set for clinical trials involving GCs and a patient reported outcome to measure the impact of GCs from the patient's perspective.

Disclosure: J. Cheah, None; J. Robson, ChemoCentryx, 5, ABROGATE trial, 6; R. Black, None; S. M. Goodman, Roche, Novartis, 4; S. Lester, None; S. Mackie, PMRGCAuk, 6, PMR and GCA North East, 6, Sanofi, 5, GSK, 5; C. Hill, None.

Table: Description of themes from thematic analysis of interview transcripts

Theme	Key Points with Quotes
Benefits	<p>Pain and swelling</p> <p>'... it does reduce the swelling. And when the swelling is reduced, the joints feel much better.'</p> <p>Return to functional activities</p> <p>'If I can't move my hands, I can't take a shower I can't wash my hair I can't brush my teeth. So how do I get to work? For me that was debilitating... the prednisone allowed me to do that because I would feel the effects within 2-3 days.'</p>
Challenges	<p>Physical (e.g. weight gain and recurrent infections)</p> <p>'I looked like a white whale with a sarpaon in my hip... I looked like Moby Dick.'</p> <p>'I had a respiratory infection a lot I seem subject to those I would get skin infections. I had to be so careful not to break my skin and things.'</p> <p>Emotional (e.g. anger and low mood)</p> <p>'... inside I felt like a terrorist. I really did. I could have killed somebody, I'm not kidding I had a terrible temper.'</p> <p>'My parents... for them to see me unhappy and just not feeling like myself in that way is really hard on them and its hard on me.'</p>
Necessity	<p>Frustration with need</p> <p>'I was angry that I had to take them, I did not want to take them but I had no choice, because they do reduce the inflammation.'</p>
Attribution	<p>Unclear if GCs solely responsible</p> <p>'...when I'm taking all this... it's hard to precisely point to what's working and what's not working what's good what's bad...'</p>

Results: Eleven participants (9 female) were interviewed. All met either the 2010 ACR/EULAR or 1987 ACR classification criteria for RA. Ages ranged from 26-83 years with 8 participants being on GCs at the time of the interview (range 2-20 mg daily of prednisone equivalent). Seven participants had a disease duration >10 years, while 6 had been on chronic GCs for >5 years. The mean RAPID3 score was 9.9 (range 0-19.3). Four themes emerged (Table). Overall, GCs had been beneficial in the control of RA symptoms such as swelling and pain. However, this had 'come at a price', alluding to the unintended impact of GCs, both physical and emotional, such as weight gain and anger. Further important unintended effects included recurrent infections and sweating (Figure). Additionally, there was an acknowledgement of the necessity of GC use in certain contexts due to the need to be able to function for family and work purposes. Finally, there was uncertainty over attribution of potential symptoms solely to GCs or to other DMARDs or to RA itself.

Conclusion: Participants described significant benefits from the use of GCs to control their RA, albeit accompanied by major unintended effects, both physical and emotional, allowing for better understanding of the life impact of chronic GC use in RA. This understanding of the lived experience will be used to design future measurement tools of GC impact in order to better systematically compare GCs to other potential therapeutic options in the research setting.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Patient Outcomes, Preferences, and Attitudes Poster II: Patient Perspectives

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Patient (pt)–rheumatologist (rheum) communication may influence symptom reporting and disease control in psoriatic arthritis (PsA). This online survey evaluated pt–rheum communication and assessed PsA symptoms/life impact and satisfaction in pts who reported good/suboptimal communication.

Methods: The survey was conducted in the USA from Nov 2 to Dec 1 2017 (pts) and Dec 11 2017 to Jan 25 2018 (rheums). Eligible pts (≥ 18 years) self-reported having had PsA for >1 year, had visited a rheum or dermatologist in the past year, and reported using ≥ 1 synthetic(s)/biologic(b) DMARD for PsA. Rheums saw ≥ 10 PsA pts/month with $\geq 50\%$ of pts receiving a s/b DMARD. Differences in pt-reported PsA impacts are evaluated by pt–rheum communication status (Table). Analyses are based on descriptive statistics and two-tailed tests for proportions.

Results: In total, 301 pts with PsA responded, mean (SD) age 45 (14.2) years, 61% female, 89% self-reported moderate/severe PsA. 256 pts (85%) were managed by a rheum and are the focus of this analysis. Most pts (93%) and rheums (88%) were satisfied with their current communication. Over 40% of pts reported aspects of suboptimal pt–rheum communication that may impact satisfaction (Table). Overall, 93% of pts were comfortable raising concerns/fears (acknowledged by 94% of rheums) while pts with suboptimal communication were less comfortable doing so (Table). Rheums generally demonstrated good understanding of PsA-related pt worries, and rheums and pts (50% and 52%, respectively) identified ability to perform activities of daily living and/or live independently as a key concern. The negative impact of PsA on physical activity, emotional/mental well-being, work productivity, and romantic relationships/intimacy was considered major/moderate by most rheums (88%, 79%, 75%, 59%, respectively) in alignment with pt reports (80%, 66%, 61%, 55%, respectively). In suboptimal communication pt groups, the impact of PsA on aspects of HRQoL was greater than in good communication groups (Table; $p < 0.05$). Overall, rheums expressed a desire for greater pt understanding of PsA symptoms (86%) and consequences of untreated PsA (88%) and pts expressed a desire to discuss PsA and treatment goals; however, pts with suboptimal communication were less likely to share PsA symptoms with their rheum (Table).

Conclusion: The majority of pts and rheums were satisfied with communication, and rheums were generally aware of pts' worries and impact of PsA on HRQoL. Over 40% of pts reported communication gaps. Pts who reported suboptimal communication were more reluctant to discuss symptoms, ask questions, or share concerns/fears and experienced a greater impact of PsA on HRQoL. Pts reported that rheums did not devote sufficient time to discuss treatment goals. Communication tools may facilitate shared decision-making.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Patient Outcomes, Preferences, and Attitudes Poster II: Patient Perspectives

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is a chronic autoimmune disease with fluctuating levels of disease activity, which may require frequent encounters with the medical system and complex treatment decisions. Doctor-patient communication is an important indicator of health-care quality, with better communication associated with higher health self-management and improved health outcomes. We describe perceptions of doctor-patient communication in lupus patients and the extent to which sociodemographic, disease related and depressive symptoms influence doctor-patient communication.

Methods: Baseline data from patients in the Canadian Network for Improved Outcomes in SLE (CaNIOS) centers participating in the MyLupusGuide™ randomized clinical trial were analyzed. Consenting participants completed on-line questionnaires. Five subscales (eliciting concerns, general clarity, explaining results, decision-making, and compassionate interpersonal style) from the Interpersonal Processes of Care (IPC) instrument measured doctor-patient communication. Each subscale was dichotomized to reflect optimal or suboptimal communication, defined as a score of <4 (range 0 to 4). Self-reported data on demographic (age, sex, ethnicity), disease characteristics and depression were collected using validated measures. Descriptive statistics were performed and univariate logistic regressions estimated with a generalized linear mixed model examined factors associated with each IPC subscale.

Results: Baseline data were available for 532 of 1916 patients, with a mean (SD) age of 50 (14) years, 91% female and 74% self-identified as white. Optimal doctor-patient communication across the subscales ranged between 22.6-35.5%, with shared decision-making receiving the lowest and general clarity the highest ratings. Age (younger) was associated with suboptimal patient perceptions related to eliciting concerns ($p=0.011$) and explanation of test results during patient-doctor interactions ($p=0.035$). Shorter disease duration was associated with suboptimal ratings of general clarity ($p=0.027$) in doctor communication style. More males reported suboptimal communication related to general clarity (83.8%, $p=0.017$) and shared decision making (91.9%, $p=0.042$) compared to females (63.5%, 76.4%, respectively). A greater proportion of participants with depressive symptoms compared to non-depressed reported suboptimal ratings related to their doctor eliciting and responding to their concerns (78.4% vs. 68.2%, respectively; $p=0.01$), explaining test results (72.4% vs. 63.8%, $p=0.04$) and shared decision making (82.4% vs. 73.8%, $p=0.02$). None of the variables examined were associated with the compassionate interpersonal style subscale.

Conclusion: Many lupus patients report suboptimal communication experiences with their doctor, with certain domains being more impacted for patients who are younger, with shorter disease duration, male and depressed. Further research into the factors associated with perceptions of poor communication in the clinical encounter and strategies to improve more patient-centred communication are needed.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Patient Outcomes, Preferences, and Attitudes Poster II: Patient Perspectives

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Adolescents with juvenile idiopathic arthritis (JIA), one of the most common causes of chronic musculoskeletal pain among youth, face many difficult decisions. However, we know little about their decision making needs. Therefore, we sought to explore decision making needs about pain management among adolescents with JIA and their parents/caregivers.

Methods: We have conducted semi-structured individual interviews with adolescents with JIA (13-18 years of age) and one of their parents/caregivers using a qualitative descriptive study design. Using purposive sampling, we recruited adolescents and their parents/caregivers at the Children's Hospital of Eastern Ontario (CHEO) Rheumatology Clinic, and through the Pediatric Rheumatology Care and Outcomes Improvement Network. Eligible participants took part in either face-to-face or online interviews with a research team member. The interview guide was based on a conceptual model developed by the Outcome Measures in Rheumatology (OMERACT) shared decision making working group. Interviews were audiotaped, transcribed verbatim and analyzed using content analysis with NVivo 11 software. We aim to interview fifteen adolescents and their parents, an estimated sample to reach data saturation.

Results: To date, five female adolescents with JIA and five parents have participated in interviews. Most adolescents and parents reported that the disease was not currently active. The median pain value reported by adolescents and their parents was 30 out of 100 mm (range: 3-50 mm) on a visual analogue scale. Adolescents and parents reported having used both medication and non-pharmacological options (e.g., rest, heat, ice, splints, stretching) to manage pain, with the number of treatments ranging from 2 to 6. The most important consideration when choosing pain management options was the effectiveness of treatments. Most adolescents also wanted to avoid injections and splints, while parents wanted to avoid pills, and the short and long term adverse effects of medication. All participants mentioned that adolescents played an active role in choosing pain management options. They also reported discussing their preferences with their healthcare team, but usually in the context of medication to control disease activity. Adolescents and parents wished to know more about a variety of pain management options, potential risks and estimated effectiveness of treatments. Parents preferred receiving this information from an app or website, while adolescents preferred receiving it from their healthcare providers. Adolescents and parents preferred to be involved in the decision making process.

Conclusion: Results of initial interviews suggest an unmet need to receive more information on pain management options and for tools to clarify families' pain management preferences. Adolescents and parents also expressed differences in how they prefer to receive the information. Additional interviews will help inform the development of decision support

interventions to help families make more informed, value-based decisions about pain management options, while simultaneously helping to foster communication within families and with their healthcare providers.

Session Type: ACR Poster Session C

Table. Most frequent^a reasons for choosing or not choosing each treatment mode as 1st choice

Reasons for choosing OR, n (%) (N=57)		Reasons for not choosing OR, n (%) (N=43)	
Speed of administration	30 (52.6)	Don't want to take another pill	16 (37.2)
Ease of administration	30 (52.6)	Difficulty remembering	15 (34.9)
Portability	23 (40.4)	Possible drug-drug interactions	11 (25.6)
Reasons for choosing SI, n (%) (N=29)		Reasons for not choosing SI, n (%) (N=71)	
Speed/ease of administration	16 (55.2)	Avoidance of pain due to needles	33 (46.5)
Frequency of dosing	12 (41.4)	Avoidance of needles	30 (42.3)
Having a feeling of control	11 (37.9)	Difficulties when traveling	19 (26.8)
		Need to refrigerate	18 (25.4)
Reasons for choosing CI, n (%) (N=2)		Reasons for not choosing CI, n (%) (N=98)	
Wanting someone else to do it	1 (50.0)	Requiring too much time to go to/wait at the clinic/office/hospital; inconvenience	69 (70.4)
Feeling comfortable with experts doing it	1 (50.0)		
Works better	1 (50.0)		
Works faster	1 (50.0)		
Makes me feel safe	1 (50.0)		
Fast to administer	1 (50.0)		
Reasons for choosing INF, n (%) (N=16)		Reasons for not choosing INF, n (%) (N=84)	
Frequency of dosing	13 (81.3)	Requiring too much time to go to/wait at the clinic/office/hospital; inconvenience	56 (66.7)
Feelings of safety and care	5 (31.3)	Long infusion time	23 (27.4)

^aReported by ≥25% of patients

CI, clinic-injection; INF, infusion; OR, oral; SI, self-injection

Session Time: 9:00AM-11:00AM

Background/Purpose: Treatment recommendations in RA emphasize shared decision-making,¹ but little is known about patient(pt) perspectives. Through qualitative research, we aim to understand pt preferences for RA treatment modes of administration and reasons for these preferences, to help guide pt-physician shared decision-making.

Methods: Pt-reported demographic and disease activity information was obtained at screening alongside qualitative interviews conducted using a semi-structured interview guide among adult pts with RA in Brazil, France, Germany, Italy, Spain, Switzerland, UK, and US who were currently taking a DMARD(biologic or non-biologic, including a JAK inhibitor). A 100-point allocation task was used to evaluate the strength of preference (0–100; 100 = strongest) across 4 treatment modes: oral (OR; once daily), self-injection (SI; weekly), clinic-injection (CI; weekly), and infusion (INF; monthly). Transcripts were developed in English; ATLAS.ti software (v7.5) was used for qualitative coding and analysis.

Results: 100 interviews were conducted (female: 75.0%; mean age: 53.9 yrs; mean time since diagnosis: 11.6 yrs). Of the 98 pts who described the severity of their RA, most (70.4%) experienced moderate/severe RA. The most commonly reported symptoms were pain/ache (90.0%), swelling/inflammation (58.0%), and fatigue (54.0%). Current RA medication modes included OR (60.0%), injection (57.0%), and INF (14.0%); 79.0% and 37.0% of pts had experience with injection and INF medications, respectively.

Among the 4 treatment modes, OR was allocated the highest mean (standard deviation) preference points (47.3 [33.1]) and was ranked as 1st choice by the greatest percentage of pts (57.0%), followed by SI (29.7 [27.7]; 29.0%), INF (15.4 [24.6]; 16.0%), and CI (7.5 [14.1]; 2.0%). Notably, the percentage of pts with a 1st choice rank for OR was greater in the US vs Europe (73.3% vs 50.0%; $p < 0.05$). Overall, 56.0% of pts had a 'strong' 1st choice preference (ie, point allocation ≥ 70); the majority of these pts chose OR (62.5%) vs SI (23.2%), INF (10.7%), or CI (3.6%). Speed/ease of administration was the most common reason for pts choosing OR or SI (Table; 52.6%, 55.2%). The most common reason for pts not choosing OR was not wanting to take another pill (37.2%), and for not choosing SI it was to avoid pain due to needles (46.5%).

Conclusion: These data show the most important issues to pts regarding mode of administration of RA medication. Most pts preferred OR as an RA treatment mode, followed by SI. Rationales for preference included ease of use, safety concerns, dosing frequency, feelings of control, and avoidance of pain and needles. While 56.0% of pts had a strong preference for their 1st choice, nearly half did not and may be receptive to, and benefit from, discussions with their healthcare professional and/or pt support groups about RA treatment mode options to guide shared decision-making.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Patient Outcomes, Preferences, and Attitudes Poster II: Patient Perspectives

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Chronic musculoskeletal (MSK) pain is common and disabling; it is among the top reasons for doctor's visits in the US. Most treatment decisions for chronic MSK pain are preference-sensitive, meaning that there is more than one reasonable treatment option. Patient decision aids (PDAs) are tools to help patients participate in their healthcare decisions. We performed a systematic review of PDAs for adults deciding about treatment for chronic MSK pain.

Table 1: Characteristics of Included Studies and Selected Outcomes

Reference	Participants	Decision and Condition	Decision Aid and Combination	Selected Outcomes
Allen 2016	N = 159 Mean age: 61.4 years	Joint replacement vs medical management for hip or knee OA	Video and booklet decision aid vs internet based decision aid	Both groups had an increase in knowledge and decrease in decisional conflict but there was no statistically significant difference between groups.
Bock 2011	N = 121 Mean age 63 years	Joint replacement vs medical management for hip or knee OA	Video and booklet decision aid with pre-visit phone call to construct a question list vs educational booklet and appointment reminder phone call	Lower proportion of patients undecided in the intervention group. No statistically significant difference in surgery rates between groups.
de Achaval 2012	N = 208 Mean age 63 years	Joint replacement vs medical management for knee OA	Video and booklet decision aid alone or with computer-based adaptive conjoint analysis tool vs educational booklet	Greater reduction in decisional conflict in the intervention groups. The greatest reduction was in the decision aid alone group.
Graham 2011	N = 658 Mean age 63 years	Joint replacement vs medical management for knee OA	Video decision aid alone or motivational interviewing alone or combined video decision aid and motivational interviewing vs educational booklet	Increase in knowledge with both the decision aid alone and in combination with motivational interviewing. Increased patient-practitioner communication in all intervention groups. No statistically significant difference in number of referrals to orthopedics.
Ibrahim 2017	N = 304 Mean age 59 years	Joint replacement vs medical management for knee OA	Video decision aid vs educational booklet	Higher rate of total knee replacement at 12 months in the intervention group.
Patel 2014	N = 148 Mean age 48 years	Choice among physiotherapy treatments for low back pain	Booklet decision aid with shared decision-making training for physiotherapists vs usual care	No difference in patient satisfaction. Less improvement in the Roland Morris Disability Questionnaire in the intervention group but otherwise no difference in pain, disability, anxiety, depression, pain self-efficacy, or fear avoidance beliefs between the groups.
Rhodes 2001	N = 100 Mean age 50 years	Surgical vs medical management for low back pain	Video and booklet decision aid vs booklet decision aid alone	Greater increase in knowledge score in the combined video and booklet decision aid group. No difference in preference for surgery.
Shen 2011	N = 182 Mean age 63 years	Joint replacement vs medical management for hip or knee OA	Video and booklet decision aid vs booklet decision aid alone	No statistically significant increase in knowledge score in either group. No difference in willingness to participate in the decision process, stage of decision making, or satisfaction between the groups.
Stachy 2014	N = 157 Mean age 67 years	Joint replacement vs medical management for knee OA	Video and booklet decision aid with a patient preference report for the surgeon vs educational booklet and a clinical assessment report for the surgeon	Higher knowledge scores and decision quality in the intervention group. No difference in decisional conflict between the groups. Higher proportion of patients undecided in the intervention group. No statistically significant difference in the percentage of patients choosing surgery or the wait times for surgery between the groups.
Stachy 2016	N = 154 Mean age 66 years	Joint replacement vs medical management for hip or knee OA	Video and booklet decision aid with a patient preference report for the surgeon vs educational booklet and a clinical assessment report for the surgeon	Higher knowledge scores, decision quality, and accuracy of risk perception in the intervention group. No difference in decisional conflict between the groups. No statistically significant difference in the percentage of patients choosing surgery.
Veroff 2011	N = 9925 Mean age 55 years	Surgical vs medical management for knee or hip OA, lower back, or back pain	Video and booklet decision aid alone or in combination with telephone health coaching vs usual care	Higher knowledge scores in both the decision aid alone and decision aid with health coaching groups. No statistically significant difference in decisional conflict between the groups. No statistically significant difference in rates of surgery between the groups.
Vine 2016	N = 490 Mean age 62 years	Joint replacement vs medical management for knee OA	Video decision aid and motivational interviewing vs educational booklet	No statistically significant difference in percentage of patients referred to orthopedic surgery between the groups.

Methods: We searched Ovid MEDLINE, Ovid MEDLINE In-Process and EPubA head of Print, Ovid Embase, Ovid PsycINFO, EBSCO CINAHL, Cochrane CENTRAL, clinicaltrials.gov, and the International Clinical Trials Registry Platform from inception until March 2017. We included randomized controlled trials of adults using PDAs to make treatment decisions for chronic MSK pain in the outpatient setting. We evaluated outcomes related to decision making (knowledge, accurate risk perception, choice congruence with values, decisional conflict, patient-practitioner communication, satisfaction), pain, functional status, and surgery utilization.

Results: We reviewed a total of 342 abstracts, and 12 met our inclusion criteria. Five studies evaluated patients with knee osteoarthritis (OA) alone. Four studies evaluated patients with either hip or knee OA. Two studies evaluated patients with lower back pain. One study evaluated patients with knee pain, back pain, knee or hip OA.

In one study, patients used the PDA to decide between conservative management options for chronic lower back pain. This was the only study that evaluated pain and function outcomes. There was less improvement in one disability score but otherwise no difference with the PDA compared to control.

In the other 11 studies, patients were deciding between surgical and medical management using a video PDA. Seven of eight studies found no difference in the proportion of patients choosing surgery. The effects of the PDAs on decision-related outcomes were mixed. Six of seven studies found improved knowledge scores with use of a PDA. Two of five studies found an improvement in decisional conflict with use of a PDA. The addition of motivational interviewing, an adaptive conjoint analysis tool, or telephone-based health coaching to a PDA did not improve any of the outcomes compared to the use of the PDA alone. Characteristics of included studies and selected outcomes are reported in the table.

Conclusion: PDAs may improve the decision-making process and decision quality for patients deciding between operative and medical management of hip/knee OA and chronic back pain. Additional research is needed to evaluate the effect of PDAs on pain and function. Especially for older adults with multi-morbidity and polypharmacy, who are often not surgical candidates, further research should develop PDAs for non-surgical treatment of chronic MSK pain.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Patient Outcomes, Preferences, and Attitudes Poster II: Patient Perspectives

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Although physical activity is a key component of optimal arthritis self-management, levels of physical activity typically fall below expert recommendations among persons with arthritis.[1] Wearable technologies could support persons with arthritis to be physically active; however, questions remain about potential burden that persons with arthritis may experience in the context of their daily lives if wearables are to be integrated into self-management.[2] We aim to broaden understanding of ethical issues in using wearables to support physical activity from the perspectives of persons living with arthritis.

Methods: An exhaustive search of 5 electronic databases (including Medline, CINAHL and Embase) from inception to Jan 2018 was carried out using the SPIDER (Sample, Phenomenon of interest, Design, Evaluation, Research type). We also performed hand-searching of reference lists of included studies. Title/abstract and full-text screening were conducted independently by 4 reviewers. Qualitative studies were eligible if they examined the use of physical activity wearables from the perspectives of persons with arthritis. Eligible articles were appraised using the McMaster Critical Review Form. All relevant data were extracted from eligible articles and coded inductively with thematic analysis.

Results: From a search yield of 4750 records, 63 were read in full and 5 papers from 4 studies met inclusion criteria. Studies were conducted in Canada, Australia, UK and Ireland. Sample included 74 persons with arthritis (62 women, 12 men, aged 43-85). 57 live with osteoarthritis and 17 live with inflammatory arthritis. At least 53 participants have some experience of using a wearable. Across the 4 studies, preliminary themes are: 1) *Becoming more aware*: Participants identified that use of a wearable had made them more aware of their inactivity. While some participants felt motivated to be more active, others highlighted greater awareness alone would not guarantee increased activity; 2) *Seeking appropriate supports*: Participants described seeking appropriate supports (e.g., written instructions) that could guide their early use of wearables, but commonly felt "limited" when these supports were not readily available; 3) *Improving patient-doctor*

communication?: Many participants anticipated that their wearable data would better equip them to improve communication (e.g., by supporting mutual understanding during assessments) with their health professionals.

Conclusion: Themes speak to relational ethics as they direct attention to situations within which autonomy is exercised in daily life.[3] For example, greater awareness of inactivity may empower some persons with arthritis to be more active, and some persons with arthritis may feel a sense of underachievement if their use of wearables is unaccompanied by appropriate supports. Findings also pose questions about how wearables may impact ways of respecting another's autonomy in patient-doctor interactions.

Effectiveness of Shared Decision Making in Systemic Lupus Erythematosus Patients at OSU

Juliette Yedimenko¹, Paige Hackenberger², Emily Sullivan³, Kelly Morris⁴ and Alexa Meara⁵, ¹The Ohio State University Wexner Medical Center, Columbus, OH, ²The Ohio State University School of Medicine, Columbus, OH, ³The Ohio State University Wexner Medical Center, Columbus, OH, ⁴Rheumatology and Immunology, The Ohio State University, Columbus, OH, ⁵Internal Medicine/Rheumatology, The Ohio State University Wexner Medical Center, Columbus, OH

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Patient Outcomes, Preferences, and Attitudes Poster II: Patient Perspectives

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Patient autonomy is an integral part of the treatment process. For effective shared decision making (SDM) patients must fully understand their disease process, prognosis and treatment. Systemic lupus erythematosus (SLE) patients have significant challenges due to the complex pathophysiology of the disease, multiple treatment regimens, and heterogeneous manifestations including neurocognitive effects. Our prior study demonstrated that one third of the SLE patients did not recognize comorbidities of SLE and medication side effects. The aim of our current study is to use CollaboRATE, a validated SDM tool, to investigate the effectiveness of the SDM process in a subset of SLE patients at OSU.

Methods: Patients >18 years were recruited from The Ohio State University Lupus and Vasculitis Glomerulonephritis Clinic. Patient demographics are described in Table 1. After IRB approval, patients were contacted by phone and administered a 3 item multiple-choice validated CollaboRATE questionnaire that was graded on a 5 point Likert scale (0-4) (Table 1). Data was analyzed as an average score per question and a total sum (max 12 points). A top score was obtained by giving 1 point to individuals who gave the maximum possible response to all 3 questions, and 0 points to everything else.

Results: A total of 52 patients completed the questionnaire. The average score for question 1 was 3.1(+/-1), question 2 was 3.3 (+/- 0.9), and question 3 was 3.1 (+/-1) (Table 2). Sixteen out of 52 patients received a max score of 12, and 30/52 patients scored at least a 10/12 (83%)

Conclusion : The CollaboRATE questionnaire targets the areas of SDM including explanation of the health issues, determination of preferences, and healthcare usage. On average, our SLE cohort feel significant effort is made to help them understand their disease and include their values. Despite this, only about 57% of patients reported a high score (meaning high SDM effectiveness). Based on these results and the prior study by Meara et al, there remains an apparent gap regarding patient knowledge of SLE diagnosis and treatment, putting them at a disadvantage in SDM. This discrepancy may be due to multiple factors. Further studies are needed to investigate the best information delivery methods to improve knowledge in an effort to empower them in the SDM process.

Table 1: Demographic Information

Average age	46.9 +/- 13.5 years			
Ethnicity	48% African American 44% Caucasian 2% Asian 2% Latino/Hispanic 2% Other 2% Refused to answer			
Average duration of disease	12.9 +/- 8.9 years			
Average SLICC	2.7 +/- 1.6			
Average SLEDAI	2.6 +/- 3.4			
CollaboRATE Questions	Scores +/- Standard Deviation (N=52)			
How much effort was made to help you understand your health issues?	3.1 (+/-1)			
0	1	2	3	4
No effort was made	A little effort was made	Some effort was made	A lot of effort was made	Every effort was made
How much effort was made to listen to the things that matter most to you about your health issues?	3.3 (+/- 0.9)			
0	1	2	3	4
No effort was made	A little effort was made	Some effort was made	A lot of effort was made	Every effort was made
How much effort was made to include what matters most to you in choosing what to do next?	3.1 (+/-1)			
0	1	2	3	4
No effort was made	A little effort was made	Some effort was made	A lot of effort was made	Every effort was made

Prescriber Attitudes and Beliefs about Triple Therapy for Patients with Rheumatoid Arthritis: Knowledge Exchange in Internet Forums and Social Media

Maria A. Lopez-Olivo¹, Jude K. A. des Bordes¹, Gregory Pratt² and Maria Suarez-Almazor¹, ¹Section of Rheumatology and Clinical Immunology, Department of General Internal Medicine, The University of Texas MD Anderson Cancer Center, Houston, TX, ²Research Medical Library, The University of Texas MD Anderson Cancer Center, Houston, TX, USA, Houston, TX

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Patient Outcomes, Preferences, and Attitudes Poster II: Patient Perspectives

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Several forums on the internet serve as repositories of personal experiences and exchange of health information. Online discussions among healthcare providers about management of patients with rheumatoid arthritis occur on a regular basis. Therefore, we explored and characterized the discussions about the use of triple therapy (methotrexate, sulfasalazine, hydroxychloroquine) on Internet forums, as differences in utilization among countries have been reported.

Methods: Online discussions were collected from three "leading edge" forums (ResearchGate, Medscape, and Twitter). Threads of discussion were systematically examined and interpreted to reveal recurring topics and patterns. Each post was coded and arranged into broader categories, which were combined into overarching themes.

Results: Twelve threads with 96 posts were identified. Seventy-nine of the posts were categorized. Seventeen were discarded because they were questions or comments unrelated to the topic discussed in the original thread. Four themes emerged during the analysis: (i) effectiveness (i.e., results from TEAR, Swefot and RACAT trials), (ii) costs, (iii) safety, and (iv) adherence. The first theme dealt primarily with the effectiveness of triple therapy compared with tumor necrosis factor inhibitors [discussion were around being as effective, but not in the first 12 weeks of treatment, or no improvement in radiographic progression]. The second theme focused on the costs. Although the majority agreed that it is a cost-saving

alternative, especially in developing countries, some believed that biosimilars will be as cost-saving and more effective. Some were of the opinion that in the United States patients would have to pay 3 copays for the triple therapy regimen as opposed to 2 with a biologic option. The third theme involved a multitude of safety concerns, such as retinopathy, Stevens-Johnson syndrome, high liver enzymes or low blood cells, or the need for special monitoring in individuals with hepatitis C infection or nonalcoholic steatohepatitis. Tolerance was also a concern when sulphasalazine was not enteric-coated. Some suggested using other combinations such as adding fish oil or replacing sulphasalazine with leflunomide. The last theme covered the use of multiple drugs, which minimizes adherence.

Conclusion: The discussions in online forums showed extensive and cumulative discussions on attitudes and beliefs exchanged about triple therapy. Main concerns included radiographic progression, safety, and adherence which could partially explain low utilization of triple therapy in some countries.

“I Was Prepared for the Other Side Effects; I Wasn’t Prepared for This One.”: A Qualitative Study of the Patients’ Experience of Inflammatory Arthritis Due to Immune Checkpoint Inhibitor Therapy for Cancer

Laura C. Cappelli¹, Suzanne Grieb², Ana-Maria Orbai³, Ami A. Shah¹ and Clifton O. Bingham III⁴, ¹Division of Rheumatology, Johns Hopkins University School of Medicine, Baltimore, MD, ²Johns Hopkins Bayview Medical Center, Center for Child and Community Health Research, Baltimore, MD, ³Johns Hopkins University School of Medicine, Baltimore, MD, ⁴Rheumatology, Johns Hopkins University School of Medicine, Baltimore, MD

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Patient Outcomes, Preferences, and Attitudes Poster II: Patient Perspectives

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Patients treated for cancer with immune checkpoint inhibitors (ICI) can develop a variety of adverse events. Inflammatory arthritis (IA) is an increasingly recognized event that can persist after cessation of ICI therapy. Patients face a unique clinical experience of having not one, but two functionally consequential illnesses, advanced cancer and IA. We aimed to evaluate the patient experience of ICI-induced IA.

Methods: Participants were identified from a longitudinal cohort of patients with rheumatologist diagnosed ICI-induced IA. We aimed to explore the processes of diagnosis and treatment, symptoms and impacts of ICI-induced IA, coping mechanisms, and the treatment decision-making process through semi-structured one-on-one interviews. Two researchers

performed inductive thematic analysis independently on a subset of transcripts, identified and reconciled codes which were then applied to all subsequent transcripts. The final hierarchical coding structure was developed through data review and discussion among three researchers.

Results: Ten patients with ICI-induced IA participated in one-on-one interviews. The mean (SD) age of participants was 54 (12.1) years, and five were women (50%). Melanoma was the most common underlying cancer (N=5), with hematologic malignancies and other solid tumors also represented. Eight patients (80%) had additional adverse events from ICIs, including colitis, pneumonitis, thyroiditis and hypophysitis. Five main themes were identified: the complex and often delayed process for diagnosis, the significance of IA compared to other side effects, the physical and emotional impacts of IA, complex decision-making processes for treatment and continuing ICI therapy, and differing perceptions of social support for IA versus cancer. From these themes, we propose a conceptual framework for patient experiences with ICI-induced IA that highlights the awareness gap of ICI-induced IA as a potential side effect, the support gap from peers, and the complex decision making for patients (Figure 1).

Conclusion: In this novel qualitative study of cancer immunotherapy patients, ICI-induced IA has a significant impact physically and emotionally, even as compared to other side effects of ICIs. Patients experienced delay in diagnosis that they attributed to lack of awareness of this condition. Fear of their cancer returning influenced the treatment decision-making process.

Examining Ethnic Differences in Osteoarthritis (OA) Patients' Knowledge and Attitudes Regarding Prescription Nonsteroidal Anti-Inflammatory Drugs (NSAIDs)

Hana Masood¹, Michael J. Hannon², C. Kent Kwok¹, Jazmin Dagnino³ and Ernest Vina⁴, ¹Medicine, Division of Rheumatology, University of Arizona School of Medicine, University of Arizona Arthritis Center, Tucson, AZ, ²Medicine, University of Pittsburgh School of Medicine, Pittsburgh, PA, ³University of Arizona Arthritis Center, Tucson, AZ, ⁴University of Arizona School of Medicine, University of Arizona Arthritis Center, Tucson, AZ

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Patient Outcomes, Preferences, and Attitudes Poster II: Patient Perspectives

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: NSAIDs are commonly prescribed for the treatment of OA. While there are documented differences between Hispanics and non-Hispanic whites (NHWs) in their treatment preferences for arthroplasty, little is known about ethnic differences in treatment preferences for NSAIDs. The extent to which minority patients convey reluctance to accept proven treatments can contribute to disparities in the utilization of these treatments and in clinical outcomes. The purpose of this study was to determine if there are ethnic differences in OA patients' treatment preferences for, familiarity with, and perceptions of efficacy and risk of prescription NSAIDs.

Methods: Participants with chronic, frequent pain due to knee or hip OA were recruited from a university medical center. Those with cognitive dysfunction, hip/knee arthroplasty, and inflammatory arthritis were excluded. Participants were given a questionnaire to assess their knowledge and attitudes towards OA treatments, including questions regarding their willingness to receive (2 items), familiarity with (3 items, yes/no), and perceptions of benefits (4 items) and risks (3 items) of both prescription oral and topical NSAIDs. Responses to all (except familiarity) question items were based on a five-category ordinal response scale. Fisher's exact or Wilcoxon-Mann-Whitney tests were conducted to determine if individual items of knowledge and perceptions about prescription NSAIDs differed by ethnicity.

Results: In our cohort of patients with knee or hip OA, Hispanics (n=119), in comparison to NHWs (n=186), were younger (mean age 61.5 vs. 65.6) and less likely to have an annual income of \geq \$40,000 (21.6% vs. 55.8%). No differences were found between Hispanics and NHWs in willingness to try prescription oral or topical NSAIDs. Hispanics were less likely to have heard about prescription oral NSAIDs as treatment for OA compared to NHWs (75.22% vs. 85.95%, $p=0.0293$). Hispanics were less likely to believe oral NSAIDs are helpful in OA patients ($p=0.0104$) or for themselves ($p=0.0223$), but they were also less likely to believe oral NSAIDs are risky or dangerous in OA patients ($p=0.0009$) or have concerns about complications from the medication ($p=0.0402$) compared to NHWs (Table 1). Additionally, Hispanics were

Table 1. Perception of Benefits and Risks of Prescription Oral NSAIDs in Hispanic and Non-Hispanic White Osteoarthritis Patients

Perception of Benefits/Risk	Hispanic (n = 119)					Non-Hispanic White (n = 188)					p-value*
	Not at all		Moderate			Not at all		Moderate

	1	2	3	4	5	1	2	3	4	5	
Risky/Dangerous	18 (16.22)	34 (30.63)	38 (34.23)	16 (14.41)	5 (4.50)	7 (3.87)	54 (29.89)	57 (31.48)	53 (29.28)	10 (5.53)	0.0009
Seriousness of Complications	36 (31.86)	29 (25.84)	27 (23.88)	18 (16.15)	5 (4.42)	17 (9.33)	57 (31.32)	38 (20.68)	42 (21.99)	10 (5.49)	0.0594
Concern about Complications	33 (28.32)	40 (35.40)	12 (10.62)	17 (15.04)	12 (10.62)	18 (10.77)	50 (30.08)	26 (14.21)	40 (21.86)	24 (13.11)	0.0492

less likely to believe topical NSAIDs are harmful compared to NHWs ($p=0.0040$). Items pertaining to familiarity with and perceptions of benefits of topical NSAIDs did not significantly differ by ethnicity.

Conclusion: Among patients with knee or hip OA, Hispanics were less familiar with oral NSAIDs, less likely to believe in their efficacy, and less likely to believe that they are harmful, compared to NHWs. Treatment preferences for prescription NSAIDs however did not vary by ethnicity. Improving patient knowledge and attitudes about prescription NSAIDs may reduce ethnic differences in the utilization of this OA treatment.

Three Devices	47 (39%)	13 (12%)	
Perceived Added Convenience of VTC	121 (95%)	61 (50%)	$p < 0.001$

IQR = Interquartile Range

Background/Purpose: Video Teleconferencing (VTC) telehealth is a synchronous medium in which patients may interact with physicians using their own personal electronic device or at a designated remote clinic site. We evaluated the attitudes and interest toward VTC telehealth at two Veteran Affairs (VA) rheumatology clinics.

Methods: Adult rheumatology patients were approached during return clinic visits at the VA Greater Los Angeles Healthcare System to participate in a descriptive survey. The paper survey assessed electronic health literacy, previous VTC and other telehealth use, current barriers to accessing in-person rheumatology care, concerns about VTC telehealth, and perceptions of telehealth. These were rated on a 5-point Likert scale. The validated EuroQOL-5D-3L evaluation was included to assess self-rated quality of life. Patients rated their interest in VTC telehealth as a substitute for some in-person rheumatology clinic follow-up visits on a 7-point Likert scale. Fisher's exact test and Kruskal-Wallis testing was used for univariate analysis for categorical and continuous variables, respectively. Ordered logistic regression was used to analyze variables associated with interest in VTC telehealth.

Results: 337 patients were approached to take the survey and 267 (79%) patients agreed to take it. 130 (49%) respondents expressed interest in VTC (defined as 5+ on a 7-point Likert scale). We found interest in VTC telehealth to be associated with the number of electronic devices owned (OR: 1.38, 95% CI [1.05, 1.81], $p=0.022$), comfort using video chat technology such as Skype or Face time (OR: 5.06, 95% CI [2.84, 9.00], $p<0.001$), and perceived added convenience with adoption of VTC telehealth (OR: 9.70, 95% CI [5.25, 17.95], $p<0.001$). Patients with concerns about privacy were less likely to be interested in VTC telehealth (OR: 0.38, 95% CI [0.22, 0.65], $p<0.001$). We found interest in VTC telehealth not to be associated with age, self-rated quality of life, education, or time/distance traveled to clinic.

Conclusion: VA patient interest in utilizing VTC telehealth as a substitute for some follow-up rheumatology appointments was found to be correlated with the number of electronic devices owned, comfort using video chat, and perceived added convenience. This interest is inversely associated with concerns about potential privacy issues. Interest in VTC telehealth is not associated with distance/time required to travel to clinic nor perceived inconvenience of travelling to clinic, though the study may not be powered to evaluate this.

Predictors of Patient and Physician Perceptions of Gout Disease Activity

Nicola Dalbeth¹, Christopher Frampton², Scott Baumgartner³, Maple Fung³ and Hyon K. Choi⁴, ¹University of Auckland, Auckland, New Zealand, ²University of Otago, Christchurch, New Zealand, ³Formerly Ardea Biosciences, San Diego, CA, ⁴Division of Rheumatology, Allergy, and Immunology, Massachusetts General Hospital, Boston, MA

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Patient Outcomes, Preferences, and Attitudes Poster II: Patient Perspectives

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: It is unknown what factors contribute to patient and physician perceptions of gout disease activity, and how these perceptions align. The aim of this study was to understand the clinical variables that contribute to the patient and physician perceptions of gout disease activity, and to understand reasons for discordant assessments of gout disease activity.

Methods: Patients (n=223) with gout according to the 1977 ARA gout classification criteria and on allopurinol ≥ 300 mg daily attended a standardized gout assessment visit which recorded gout flare in the preceding 3 and 12 months, physical examination for tophus, laboratory tests and patient questionnaires. Study participants and physicians completed questionnaires rating their global assessment of gout disease activity, (numerical rating scale (NRS); 0=no activity, 10=extremely active). Discordance in the global assessment of gout disease activity was defined as an absolute difference of >2 units between the patient and physician assessments (Desthieux et al, Arthritis Care Res 2016). Data were analysed using linear and logistic regression models.

Results: The mean (SD) patient global assessment of gout disease activity was 2.08 (2.35), and physician global assessment of disease activity was 2.52 (2.58), $P=0.01$. Gout flare in the last 12 months, presence of tophus, gout flare in the last 3 months and serum urate <0.36 mmol/L were independent predictors of patient and physician assessments (Table). Male sex also predicted physician global assessment of gout disease activity, but not patient assessment. Discordant patient and physician scores for gout disease activity were present in 63 (28.3%) participants. In logistic regression models, gout flare in the last 3 months predicted discordant gout disease activity scores >2 (patient assessed gout disease activity as more

severe, n=23); odds ratio 2.8, P=0.021, whereas gout flare in the last 12 months predicted discordant gout disease activity scores <-2 (physician assessed gout disease activity as more severe, n=40); odds ratio 10.4, P<0.001.

Conclusion: For both patients and physicians, gout flares, tophus and serum urate control contribute to assessments of gout disease activity. However, discordance between patients and physicians in their assessment of gout disease activity is not uncommon, with recent gout flares contributing to higher patient global assessments of disease activity, and distant flares contributing to higher physician global assessments of disease activity.

Table. Linear regression models showing predictors of patient and physician global assessments of gout disease activity, ordered by the standardized coefficient, n=223.

Dependent variable	Predictors	B	SE	Standardized coefficient	Sig	Model statistics
Patient global assessment of gout disease activity	Gout flare in the last 12 months	34.69	9.50	0.28	<0.001	Adjusted R ² =0.26, F=16.3, P<0.001
	Gout flare in the last 3 months	26.28	10.11	0.20	0.010	
	Presence of tophus	21.81	8.26	0.15	0.009	
	C-reactive protein	0.82	0.39	0.13	0.035	
	Serum urate <0.36mmol/L	-15.81	7.86	-0.12	0.046	
Physician global assessment of gout disease activity Beliefs about Medicine Questionnaire	Gout flare in the last 12 months	50.53	8.40	0.40	<0.001	Adjusted R ² =0.44, F=30.2, P<0.001

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Patient Outcomes, Preferences, and Attitudes Poster II: Patient Perspectives

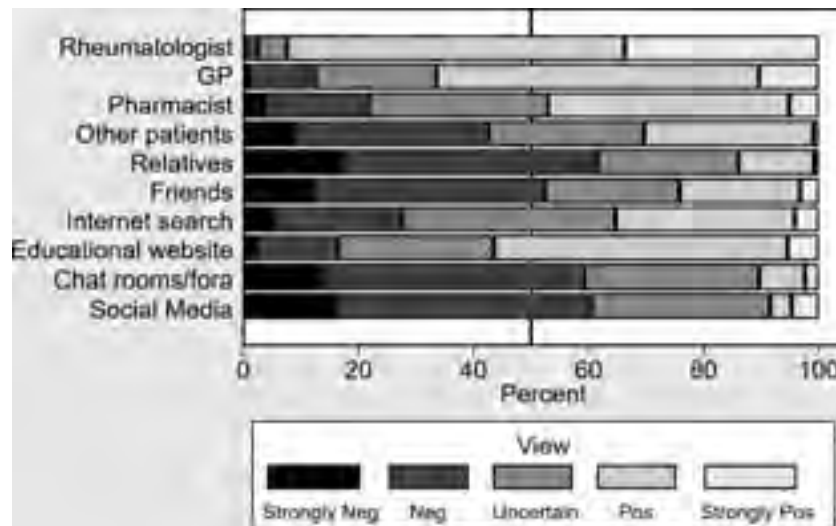

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: To determine beliefs about methotrexate (MTX) in patients with Rheumatoid Arthritis (RA) in relation to views obtained from a range of information sources.

Methods: RA patients, who had completed an online questionnaire on a national RA database within the previous 12 months, n=1010, were invited to participate in an additional online questionnaire (Survey Monkey) regarding their use and views of MTX. Participants who had ever-used MTX were asked about sources consulted for MTX information, and whether positive or negative views were obtained. The Beliefs about Medicine Questionnaire (BMQ), consisting of general medication (overuse and harm) and MTX specific (necessity and concerns) was used to measure patient specific beliefs about MTX. Demographic and clinical information of the survey respondents was obtained by linkage to the national database.

BMQ Scale	MTX Current Use (n = 494)	MTX Previous Use (n = 248)	Difference	p-Val
MTX-Specific-Necessity	1.54 (1.47, 1.60)	1.50 (1.42, 1.59)	2.03 (1.92, 2.14)	< 0.001
MTX-Specific-Concerns	2.49 (2.42, 2.56)	2.63 (2.52, 2.74)	-0.14 (-0.23, -0.02)	0.027
General-Overuse	2.62 (2.55, 2.70)	2.71 (2.60, 2.82)	-0.09 (-0.12, 0.04)	0.18
General-Harm	2.18 (2.08, 2.19)	2.16 (2.08, 2.24)	-0.02 (-0.12, 0.07)	0.64

Results: The survey response rate was 804/1010 (80%). MTX survey data was analysed for 742 RA participants (age 59 years, 76% female, disease duration 19 years, 75% rheumatoid factor positive) who had ever-used MTX, with 494/742 (67%) reporting current use.

Current MTX users scored substantially higher on the BMQ MTX specific Necessity scale, and slightly lower on the MTX-specific Concerns scale (Table 1). Table 1. Beliefs about Medicine Questionnaire results by MTX use. Participants consulted multiple information sources (median 3, IQR 1-5), which was associated with younger age, higher education levels, higher MTX-specific concerns and general medication BMQ scores ($p < 0.05$, multiple Poisson regression). Rheumatologists (98%), GPs (55%), internet search engines (39%), educational websites (38%), and Pharmacist (37%) were the most common information sources. When consulted, positive MTX information was most often obtained from rheumatologists (93%), GPs (67%), and educational websites (56%) (Figure 1). Figure 1. Reported MTX Views by Source

Negative MTX information was most often obtained from relatives, social media, internet chat rooms, and friends. Positive information from Rheumatologists ($p < 0.001$) and Educational websites ($p = 0.021$) was influential on favourable MTX-specific necessity and concerns BMQ scores (MANOVA analysis).

Conclusion: RA patients have significant concerns regarding MTX and consult a variety of sources for MTX information. However, the patient perception of this information varies widely. Rheumatologists and educational websites are the most important information sources in terms of utilisation, positive information, and influence on the patient's perception of MTX.

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Patient Outcomes, Preferences, and Attitudes Poster II: Patient Perspectives

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Cardiovascular disease (CVD) is the most common cause of death among patients with inflammatory arthritis (IA) such as rheumatoid arthritis (RA), psoriatic arthritis (PsA) or ankylosing spondylitis (AS). Our

purpose was to elicit perspectives of patients with IA to inform the design of a patient-centered intervention for a CVD risk reduction intervention.

Methods: This was a qualitative study guided by Bandura’s Social Cognitive Theory, placing special emphasis on knowledge about the relationship between arthritis and CVD as well as barriers and facilitators to receiving healthcare related to CVD risk such as screening and management for hyperlipidemia. We recruited patients from a single academic center with either RA, PsA, or AS to participate in focus groups. Data were analyzed thematically.

Results: We conducted three focus groups with a total of 17 participants (5 participants in two and 7 participants in one of the focus groups) of mean age 56 (SD±7.7) years; 15 were women; 3 were on a statin; and 1 previously had a stroke. Five themes emerged (Table):1) Need for more information about IA and its medications; 2) Lack of understanding regarding the association between CVD risk and IA; 3) Holistic approach to CVD risk reduction including lifestyle changes; 4) Possible uses for peer coaches around relevant CVD risk factor mitigation approaches; and 5) Improving doctor-patient communication about IA. In summary, these themes showed that many participants were not aware of the relationship between CVD and IA. They demonstrated interest in learning about IA, IA medication side effects, and prognosis of IA. Participants prioritized learning about IA, its prognosis, and treatment followed by learning about preventive measures for CVD risk within the context of their IA rather than CVD as a separate condition.

Conclusion: Providing a clear understanding about the systemic effects and treatments for IA should be integrated into a CVD risk reduction intervention targeted at patients with IA.

Table Themes and Key Points That Emerged From Focus Groups of Patients with Inflammatory Arthritis

Theme	Quotes from patients
Need for information about IA and medications	<i>“When I was first diagnosed, as far as the medications and the side effects and what I could expect. Like I said, everything I read was bad, and it didn’t—I’m probably going to take it the rest of my life, and you have to get your blood tested every three months to make sure everything’s looking good.”</i>
Lack of understanding regarding the association between CVD risk and IA	<i>“I never even thought about it. Had no idea that it would even affect my heart like that. I’m still in shock [laughter] that that has to do with the arthritis.”</i>
CVD risk reduction as an integrated lifestyle modification	<i>“They (doctors) know about the medicines and everything, so I’ll ask them, ‘Is there something’ I could do or take that would help it?’ We’ve got to do our part, too. We’ve got to exercise. We got to watch what we eat. Stress. I know stress will cause a lot of stuff to come on.”</i>
Possible uses for peer coaches around relevant CVD risk factor mitigation approaches	<i>“It would’ve been helpful if I would talk to somebody who, maybe, was on the medication and could tell me, ‘Well, I haven’t had any problems with it,’ or, ‘Yeah, it does this.’ I’m sure it affects different people differently.”</i> <i>“I guess if it would involve exercising takin’ a walk, it’d be nice to do it with somebody if they’ve got the same (arthritis)—and do it together, that would be motivating.”</i>
Improving doctor-patient communication about IA	<i>“It’s like, first of all, I don’t care for him (doctor). [Laughter] He’s an older doctor and he’s like, ‘I’m only going to see you for one thing.’ I’m like, ‘No, if I have four things wrong with me, you need to see me for four things.’”</i> <i>“The peer coach could go with you to your appointments and to help you to understand. I’ve thought about that, to completely understand and to help communicate.”</i> <i>“If I’m at home, and all of a sudden, I’m like, ‘Why didn’t I ask her that? Let’s write it down. Then when I go to my peer coach, maybe, with those questions, they can also help me to understand that.’”</i>

Assessment of Barriers to Exercise Participation in Patients with RA

Kathryn Gibson^{1,2,3}, Geraldine Hassett¹ and Joseph Descallar⁴, ¹Rheumatology, Liverpool Hospital, Sydney, Australia, ²Ingham Research Institute, Liverpool, Australia, ³University of New South Wales, Sydney, Australia, ⁴Ingham Research Institute, Sydney, Australia

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018
Session Title: Patient Outcomes, Preferences, and Attitudes Poster II: Patient Perspectives
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: The benefits of exercise for patients with rheumatoid arthritis are widely reported and include sustained improvements in pain, fatigue and self-efficacy.¹ Despite this, the rates of physical activity in patients with arthritis are often lower than is recommended.^{2,3} Assessment of self-reported exercise frequency and of barriers to

participation in exercise can be facilitated by use of the Multidimensional Health Assessment Questionnaire (MDHAQ) and may assist in encouraging appropriate exercise participation in these patients.

Methods: All patients with RA seen at one academic rheumatology centre complete an MDHAQ at all visits. The MDHAQ queries the frequency of physical exercise (>30 minutes with at least some shortness of breath, sweating) with 5 response options: >3 times weekly, 1–2 times weekly, 1–2 times monthly, no exercise and cannot exercise due to disability or handicap. For analysis, the first two categories were grouped into “regular exercise” and the last three into “no regular exercise”. Scores for a range of variables including physical function, pain, patient global estimate (PATGL), fatigue, BMI and dealing with feelings of depression or anxiety were also recorded. Multilevel models were used to analyse the frequency of physical exercise, adjusting for these variables and time.

Results: 194 patients with RA and a total of 1593 clinic visits were included in the analysis (mean 8.2 visits per patient). The mean age (\pm SD) was 56 ± 14.5 years at the first visit. 79.9% were female. Patient reported ethnicity was 52% White, 19% Asian and 29% Other. The average BMI was 28.2 ± 6 kg/m². Only 33.2% reported regular exercise participation. In multivariable modelling, corrected for age, sex, time from first visit and ethnicity, patients whose average physical function score was higher (indicating worse function) demonstrated a significantly increased odds of non-participation in regular exercise (OR 1.43; $p < 0.0002$). In contrast, improved function was associated with exercise participation of at least once per week compared with no regular exercise.

Conclusion: Despite the known safety and benefits of exercise in people with RA, self-reported exercise participation remains low. Poorer physical function reduces the odds of regular exercise participation. Routine assessment of physical function and exercise participation may assist clinicians to address the importance of exercise as part of usual clinical care in patients with RA.

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Patient Outcomes, Preferences, and Attitudes Poster II: Patient Perspectives

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Although SLE disproportionately affects minority racial groups, they are significantly under-represented in clinical trials. This may lead to false, underpowered conclusions in race-based sub-group analyses. We conducted focus groups to evaluate perceptions of clinical trial participation by diverse lupus patients. The analysis was guided by the Theory of Planned Behavior, a construct that behavior is determined by attitudes (*behavioral beliefs*), the opinions of others (*normative beliefs*), and perceptions about the level of control (*control beliefs*).

Methods: A qualitative research design was employed, using three 90-minute focus groups with 23 patients aged 21-72 years, enriched for minority participants (15/23; 65%). A trained moderator asked open-ended questions about clinical trial participation including: advantages and disadvantages (*behavioral beliefs*), person(s) who would approve or disapprove (*normative beliefs*), and enhancers and barriers (*control beliefs*). Discussions were recorded, transcribed, and analyzed to identify emerging themes.

Characteristics of Focus Group Participants (n=23)	
Female (n, %)	20 (87.0)
Race/Ethnicity (n, %)	
Black/African American	7 (30.4)
Hispanic/Latino	5 (21.7)
White/Caucasian	8 (34.8)
Native American	3 (13.0)
Age (median, IQR)	48.1 [41.5, 57.5]
Duration of SLE in Years (median, IQR)	11.1 [8.0, 16.8]
Healthcare Payor	
Private Insurance	10 (43.5)
Government (e.g. Medicare)	11 (47.8)
Self Pay	2 (8.7)
Employment Status	
Full Time	8 (34.8)
Retired	3 (13.0)
Disabled	6 (26.1)
Unemployed	6 (26.1)
Marital Status (n, %)	
Married	10 (43.5)
Widowed	1 (4.3)
Divorced	2 (8.7)
Separated	3 (13.0)
Single	7 (30.4)
Distance from Clinic in Miles (median, IQR)	10.7 [7.0, 17.6]
Geographic Residence (n, %)	
Urban	11 (47.8)
Suburban	8 (34.8)
Rural	4 (17.4)

Table 1. Patient Characteristics Demographic and socioeconomic information for all SLE focus group participants. Duration of SLE diagnosis ranged from 2 to 26 years and the distance traveled to the clinic ranged from 1 to 88 miles. All participants met the 1997 revised ACR classification criteria for SLE.

Results: Patient characteristics are summarized in Table 1. Initial interrater reliability was high (93%), and the discrepancies were resolved through discussion. Perceived advantages to trial participation included a better understanding of SLE, benefit for current and future patients, and access to otherwise costly or unavailable care and medication. Disadvantages included concerns about unknown aspects (placebo receipt and side effects), information burden (jargon, lengthy and redundant forms that are difficult to process), letdown (exclusion from trials, lack of efficacy, withdrawal of effective therapy), issues with life and health balance (time away and travel), inadequate feedback, and additional procedures in trials. Although some patients engaged in discussions about research participation with approving or disapproving family, friends, or co-workers, self-approval superseded external approval. Comorbidities and costs were identified as barriers. Factors identified that would ease participation in atrial included flexibility in time and scheduling, advanced notice of studies for contemplation and arrangements (childcare, work), streamlined forms with the option of electronic technology, post-study feedback, and the hope of SLE improvement (personal, drug discovery, cure).

Conclusion: Knowledge about potential benefits of trial participation was high, and minority patients appeared to be equally confident as others in making their own informed decisions. Disadvantages and barriers to clinical trial

participation identified by an SLE population enriched for minority patients include the burden of forms, and difficulties with travel, childcare, and work. These suggest a major impact from *behavioral* and *control beliefs* which will need to be considered during trial design and implementation.

Reactions to Online Testimonials: A Cluster Analysis of Risk Perception and Decision Making

Changchuan Jiang¹ and Liana Fraenkel², ¹Department of Medicine, Mount Sinai St Luke's and Mount Sinai West Hospitals, Icahn School of Medicine at Mount Sinai, New York, NY, ²Yale University School of Medicine, New Haven, CT

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Patient Outcomes, Preferences, and Attitudes Poster II: Patient Perspectives

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Testimonials have been shown to have a strong influence on patients' decision-making. Patients are increasingly accessing the Internet as a source of medical information. In this study, we sought to examine whether people differ in the way they react to online treatment testimonials.

Methods: We administered a survey to Mechanical Turk workers (\bar{x} 50 years old). Participants received information describing outcomes for an osteoporosis medication. Participants' likelihood to take medication, subjective knowledge, perceived benefit, riskiness, and worry related to the medication and perceived severity of osteoporosis were measured on 11-point numeric rating scales before and after reading the description of the medication. We classified participants who accessed at least one online testimonial into different groups using cluster analysis based on the changes in the six listed outcomes. We used ANOVA and Chi-square tests to compare demographic characteristics across the clusters.

Results: 322 participants read one or more online testimonials. The mean (SD) age was 59 (7), and the majority were female (61%), white (73%) and college graduates (67%). Six clusters were identified based on the changes in six outcomes. 64 participants (Cluster A) reacted positively to the testimonials (i.e., more likely to take medication, improved subjective knowledge, the greater perceived benefit of medication, and less perceived riskiness and worry about the medication). Nineteen participants (Cluster E) surprisingly had more misunderstanding of disease then made suboptimal decisions after the intervention. Meanwhile, the intervention changed participants risk perception (Clusters B, D, F) differently, but had a very limited influence on their likelihood to take medication.

We found a statistical difference in ethnicity ($p < 0.01$) and numerical level ($p = 0.02$) across six clusters. Higher numeracy level is positively associated with the better perception of disease and treatment.

Conclusion: Participants reacted drastically different to online testimonials. Only a small proportion of participants benefits significantly from online testimonials, which tend to be high numerates. Table 1. Description of the sample according to the clusters of participants

Figure 1. Changes in each outcome across six clusters

Cluster	A	B	C	D	E	F	p-Value

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Patient Outcomes, Preferences, and Attitudes Poster II: Patient Perspectives

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Discordance between patient global assessment (PGA) and physician global assessment (PhGA) of RA disease activity may be problematic in clinical practice. Previous studies, including ours (Tago, Int JRheum Dis, 2018), have shown that PGA-PhGA discordance is most strongly associated with pain, followed by functional impairment. The aim of the present study was to investigate the factors responsible for 5-year persistence of PGA-PhGA discordance using a nationwide RA database in Japan (*NinJa*).

Methods: Positive discordance and concordance were defined as PGA minus PhGA (PGA-PhGA) ≥ 3 cm and between -3 cm and 3 cm, respectively. RA patients whose 10-cm visual analog scale (VAS) data were available and who were registered in both *NinJa* 2011 and *NinJa* 2016 (n=4484) were investigated for the association of positive PGA-PhGA discordance in 2016 with clinical manifestations observed in 2011, including age, sex, age at RA onset, disease duration, pain VAS, tender joint counts (TJC), swollen joint counts (SJC), modified Health Assessment Questionnaire (mHAQ), stage, class, disease activity score in 28 joints-C-reactive protein level (DAS28-CRP), and PGA-PhGA discordance status.

Results: The mean PGA-PhGA was significantly higher in 2016 (1.14 ± 1.96) than in 2011 (1.03 ± 1.80) ($p < 0.01$). On reviewing the discordance status in 2011, we found that the mean PGA-PhGA of RA patients who had been classified as showing positive discordance was 2.13 ± 2.13 in 2016, which was significantly higher than those classified as concordance in 2011 (1.12 ± 1.74) ($p < 0.01$). Categorical variable-based analysis also demonstrated that 41.2% of RA patients in the positive discordance group in 2011 remained in the same group in 2016, while only 13.1% in the concordance group shifted to the positive discordance group in 2016; this difference was significant ($p < 0.01$). Stepwise multivariate logistic regression analysis identified high mHAQ values, pain VAS, age, and positive discordance status as significant risk factors for the shift into positive discordance 5 years later (Table 1).

Conclusion: We have demonstrated that PGA-PhGA discordance expanded significantly over the 5-year period, and that this positive discordance can be persistent. Functional impairment, pain, existing discordance, and age are risk factors for persistent discordance. Therefore, RA care providers should focus on ameliorating functional impairment and alleviating pain to circumvent the development of PGA-PhGA discordance.

Table 1 Univariate (unadjusted) and stepwise multivariate (adjusted) logistic regression analysis of predictors of discordance 5 years later regarding PGA-PhGA discordance.

Systemic Lupus Erythematosus Outcome Concerns: Identifying Pain As the Major Discrepancy between Rheumatologists and Patients

Isabela Bertoglio¹, GlauCIA Abrahão¹, Eloisa Bonfa² and Michelle Lopes³, ¹Rheumatology, Hospital das Clínicas da Faculdade de Medicina da USP, São Paulo, Brazil, ²Rheumatology Division, Hospital das Clínicas, Faculdade de Medicina, Universidade de São Paulo, São Paulo, Brazil, ³Rheumatology Division, Hospital das Clínicas da Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Patient Outcomes, Preferences, and Attitudes Poster II: Patient Perspectives

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Now-a-days there is a growing trend of switching to a more patient-centered healthcare system, with a widespread use of patient-reported outcomes (PROs). However, most of PROs questionnaires are designed by physicians/specialists and patients are underrepresented in this development. This research's purpose was to identify and compare major outcomes that matter for patients and rheumatologist aiming to better address patient's needs.

Methods: 75 consecutive SLE patients (SLICC criteria, 2012) and 53 Rheumatologists from a tertiary center were invited to answer an open questionnaire inquiring their 5 major concerns regarding lupus outcomes. Among the 53 Rheumatologists there were 5 SLE specialists and 20 rheumatology fellows. The top 5 concerns of each group were assessed and frequencies were compared with appropriate tests. The agreement rate was calculated considering the sum of lowest frequency of each concern that appeared in all the analyzed groups.

Results: The top 5 concerns raised by patients were: pain (47%), renal function (18%), skin lesions (16%), thrombosis (10%) and fatigue (10%). The top 5 concerns among rheumatologists were: SLEDAI (40%), SLICC-Damage Index (SDI) (22%), prednisone dose (16%), quality of life (12%) and renal function (11%). The agreement rate between all rheumatologists was 63% (all agreed that SLEDAI, SDI and prednisone dose were major concerns). Fellows pointed laboratory tests (such as anti-DNA and Complement levels) as a major concern not reported by the other rheumatologists ($p=0.002$). SLE specialists pointed comorbidities (such as hypertension and obesity) as main concerns not reported by the other rheumatologists ($p=0.032$). The agreement rate between patients and rheumatologists was 45% (renal function, skin lesions and thrombosis). The main difference between patients and rheumatologists were the pain ($p=0.0001$) and fatigue ($p=0.023$). Fatigue was reported as an outcome concern by 10% of the patients but less than 2% of rheumatologists, however quality of life pointed by rheumatologists may address partially the fatigue concept. Regarding pain, half was related to generalized pain and the other half related solely to arthralgia and therefore the majority would not be scored by SLEDAI (that consider only arthritis as a domains).

Conclusion: We identified that there are different outcome concerns between patients and rheumatologists for lupus treatment. Pain was the most important discrepancy since it is not adequately addressed by the routine SLE indexes reported as the top 5 Rheumatologists outcome concerns. Improving physician's awareness of patient's outcome concerns and of comorbidities, as pointed out by the specialist, may provide a better assistance and ensure treatment adherence in this disease.

Figure 1. Top 5 major outcome concerns among SLE patients and Rheumatologists

Session Date: Tuesday, October 23, 2018

Session Title: Patient Outcomes, Preferences, and Attitudes Poster II: Patient Perspectives

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Empowering RA patients through education is linked to improved adherence, treatment decisions and speeding up the assessment process during consultation. The purpose of the study is to evaluate perceptions of patients with RA about self-assessment of their disease activity after watching an educational video about self-assessment using Disease Activity Score 28 (DAS28).

Methods: An educational video was developed to instruct patients with RA on how to assess their disease activity using DAS28 (autoDAS). Consecutive RA patients attending rheumatology clinics during their routine visits (Bahrain, Egypt, Jordan, Lebanon, KSA, UAE) were invited to participate in a structured interview with the study coordinator after the doctor's visit. A purposely-designed video was displayed first, followed by the interview that consisted of a combination of closed and qualitative open-end questions.

Results: 62 patients participated in the study (Fig 1). 95% stated that performing their own assessment was feasible or partially feasible, and 97% said that they felt totally or partially capable of doing it. 59% answered that they felt confident

Question	Answer, n (%)		
	Yes	Partially	No
How feasible it is for you to do your own assessment of your disease activity using auto-DAS?	78	22	2
Do you feel capable in doing your own assessment using auto-DAS?	56	29	3
Do you feel confident in doing your own assessment using auto-DAS?	55	33	9
Do you think that your own evaluation of your disease using auto-DAS can replace the doctor's visit?	1	18	76
Will you continue to do your own self-assessment using auto-DAS on the long term and after the completion of the study?	44	30	8
Do you think that the video was helpful in facilitating your self-assessment using auto-DAS?	91	5	6

in performing auto-DAS all the times. Nevertheless, 76% stated that it will not replace the doctor's visit. The majority (96%) felt that the video was easy and helpful in facilitating their self-assessment (Fig 2).

Open-end questions identified the main advantages: Better understanding of the disease ("makes me aware when disease is active, provides good education about disease, will help me cope better"), Easier communication with physician ("will inform me about the joint I need to tell my doctor about"), Time management ("Less time with physician, less visits meaning less cost"). They also identified some challenges: Calculation was cumbersome (with the calculator being easier than a website), Auto-assessment needs practice.

Conclusion: The majority of patients felt that the video was helpful in many aspects of disease assessment, and felt capable of performing auto-evaluation, with DAS calculation being the hardest part. Most stated that it will not replace the doctor's visit but will help better understanding of the disease and coping, thus better informing the doctor and reducing visit time. Figure 1. Patients Characteristics

Patients, N	62
Age, mean	51.2 yo (SD 13.4)
Female	86%
University education	40%
RA duration, mean	9.3 years (SD 6.6)
Time to diagnosis, mean	1.9 years (SD 6.4)
Rheumatoid Factor +	67%
ACPA +	46%
Bone erosions	48%
Biologic treatment	32%
Targeted Synthetic DMARD	11%
Corticosteroids	24%
Common Comorbidities	Smoking 19%, Hypertension 13%, Osteoporosis 13%, Dyslipidemia 11%, Diabetes 11%, Fibromyalgia 6%

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Patient Outcomes, Preferences, and Attitudes Poster II: Patient Perspectives

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Figure 1. Top 10 aspects to be addressed by the ideal self-management app.

Background/Purpose: While the increasing availability of apps may enable people with rheumatic and musculoskeletal diseases (RMDs) to better self-manage their health, evidence on the development and evaluation of apps for patients that fulfill quality requirements for their implementation as part of routine care is lacking. This work aims to explore the needs, experiences and views of people with RMDs about mHealth apps, seeking to obtain direct patient feedback on preferences for components, content and structure of mHealth apps for self-management of their conditions.

Methods: This was a mixed methods study starting with an initial qualitative phase involving a patient focus group (UK). The latter was followed by a survey based on the key themes emerging from this focus group. The survey validation involved a pre-survey test round based on 5 patients (UK, Slovakia, Germany, The Netherlands, Cyprus). Feedback was collected during the test phase and used to improve the survey. Survey was disseminated through patient associations across EU, USA, Canada and Australia.

Results: The focus group included 6 rheumatoid arthritis (RA) patients. Half of them had used a self-management app at least once. The use of existing apps was reported as time consuming and not always useful due to lack of functionality, with the need for more tailored apps expressed by all patients. Survey participants: 304 patients across European countries, USA, Canada and Australia. Main age category was 45-54 years (25.7%), 78% were women. Patients were diagnosed mostly with RA (n=115, 37.8%), psoriatic arthritis (n=53, 17.4%), ankylosing spondylitis (n=47, 15.5%), fibromyalgia (n=43, 14.1%), osteoarthritis (n=41, 13.5%). Most patients (n=141, 46.7%) had been diagnosed for over 10 years. Most were using a smartphone (n=261, 85.9%); 20.7% (n=63) were using a mHealth Apps. 71% (n=218) agreed that such Apps could make clinic visits more efficient. Patients were mostly interested in an app enabling self-monitoring of health parameters (58.6%), disease activity (51.3%), lifestyle (40.7%); communication with their health care providers (43.4%) and dealing with medication side effects (40.1%). The top ten aspects to be addressed by an ideal App are detailed in Figure 1. Collection of anonymized health data for research purposes is mostly accepted by the patients (57.9%, n=176).

Conclusion: Patients considered that the use of an App tailored for disease self-management and developed in close collaboration with them could benefit their health. The development of such Apps will require standardization and quality check processes. This work will be used as a background for developing future EULAR points to consider for the development, evaluation and implementation of mobile health applications for self-management in patients with rheumatic diseases.

Understanding Patients' Perceptions of Gout

Kelly Gavigan¹, Kayla Jordan², Alexa Meara³ and W. Benjamin Nowell¹, ¹Global Healthy Living Foundation, Upper Nyack, NY, ²University of Texas at Austin, Austin, TX, ³Internal Medicine/Rheumatology, The Ohio State University Wexner Medical Center, Columbus, OH

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Patient Outcomes, Preferences, and Attitudes Poster II: Patient Perspectives

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Past research has shown that patients' (pts') knowledge of their disease influences health-related behavior. The objective of this study is to explore gout pts' knowledge of the disease, treatment options and chronic management, as well as identify their sources of health information. With only half of gout pts adherent to gout medications, our goal is to guide the development of gout support tools by identifying gaps in pt knowledge.

Methods: We developed an online survey to gather information about pts' knowledge, beliefs and perceptions of gout. Pt members of the Arthritis Power registry or Creaky Joints community were asked to participate if they had a self-reported diagnosis of gout. Pts completed six (Pain Interference, Fatigue, Sleep Disturbance, Physical Function, RAPID3, Gout Flare) pt-reported outcome measures. Pearson's Chi-squared test was used to assess significance. Open-ended questions were analyzed with LIWC 2015, an automated text analysis program.

Results: To date, 103 participants completed the survey; 55% were female, 53% had an annual income \geq \$50,000, 84% white and average age of 56 years (range 32 – 80). 85% believe uric acid causes gout, however, only 50% believe uric acid-controlling medication is the best way to manage the disease. Additionally, 81% believe gout is best managed by diet change. Pts currently experiencing a gout flare were more likely to believe gout is best managed with NSAIDs than those not experiencing a flare (37% vs 16%; $p=0.02$) (Table). The qualitative results showed that non-flaring pts tended to use risk-oriented language while flaring pts used reward-oriented language (Figure). Pts receive information about gout from online health education sites and their PCP at similar rates (60% and 53%, respectively). Non-flaring pts preferred to get information online more than flaring pts (63% vs. 44%; $p=0.06$). Men were more likely to seek information from their rheumatologist than women (28% vs 13%; $p=0.05$).

Table: Patients' Perceptions of Causes of Gout

	N (N=103)	Flare (n=41)	No Flare (n=62)	p-value
What do you believe is the main cause of gout?	n (%)	n (%)	n (%)	
Diet	80 (77.7)	25 (61.0)	55 (88.7)	<0.01*
Alcohol consumption	35 (34.0)	10 (24.4)	25 (40.3)	0.09
Obesity	45 (43.7)	17 (41.5)	28 (45.2)	0.71
Medical conditions	47 (45.6)	26 (63.4)	21 (33.9)	<0.01*
Certain medications	22 (21.4)	12 (29.3)	10 (16.1)	0.11
Family history of gout	51 (49.5)	23 (56.1)	28 (45.2)	0.28
Age and sex	23 (22.3)	8 (19.5)	15 (24.2)	0.58
Recent surgery or trauma	6 (5.8)	2 (4.9)	4 (6.5)	0.74
What do you believe causes gout attacks?	n (%)	n (%)	n (%)	
Diet	59 (57.3)	16 (39.0)	43 (69.4)	<0.01*
Alcohol consumption	14 (13.6)	4 (9.8)	10 (16.1)	0.36
Certain medications	11 (10.7)	8 (19.5)	3 (4.8)	0.02*
Uric acid level	87 (84.5)	37 (90.2)	50 (80.7)	0.19
Stress	25 (24.3)	10 (24.4)	15 (24.2)	0.98
How do you believe gout is best managed?	n (%)	n (%)	n (%)	
Diet change	83 (80.6)	29 (70.7)	54 (87.1)	0.04*
Limiting alcoholic beverage intake	34 (33.0)	8 (19.5)	26 (41.9)	0.02*
Exercising regularly and losing weight	50 (48.5)	19 (46.3)	31 (50.0)	0.72
Alternative remedies	27 (26.2)	10 (24.4)	17 (27.4)	0.73
NSAIDs	25 (24.3)	15 (36.6)	10 (16.1)	0.02*
Colchicine	28 (27.2)	14 (34.2)	14 (22.6)	0.20
Corticosteroids	12 (11.7)	9 (22.0)	3 (4.8)	0.01*
Medications that block uric acid production or improve uric acid removal	50 (48.5)	19 (46.3)	31 (50.0)	0.72

*statistically significant at $\alpha=0.05$

Flare status as determined by gout flare assessment (Gaffo et al., 2012)

Figure: Risk-Oriented Language vs. Reward-Oriented Language

Conclusion: The survey shows variation in beliefs about gout and in words used to describe gout by gender, age and gout flare status. Food and lifestyle misconceptions remain a large component of pts' conversations surrounding gout. The majority of pts currently believe gout can be managed through diet rather than prescribed medications, suggesting insufficient pt knowledge about gout. While many pts prefer to access information online, there is still an underutilization of rheumatologists. Developing decisional support tools available at health care offices may help increase knowledge about gout and improve gout health care outcomes.

Examining Workplace Supports in the Context of RA Disease Activity

W. Benjamin Nowell¹, Kelly Gavigan¹, Guillermo Ernest Gonzales², Shilpa Venkatachalam¹, Jeffrey R. Curtis³, Sheiva Ghazanfari⁴, Danielle Cavazzini⁴ and Leticia Ferri⁴, ¹Global Healthy Living Foundation, Upper Nyack, NY, ²Silver School of Social Work, New York University, New York, NY, ³University of Alabama at Birmingham, Birmingham, AL, ⁴Bristol-Myers Squibb, Princeton, NJ

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Patient Outcomes, Preferences, and Attitudes Poster II: Patient Perspectives

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: RA can diminish patients' (pts) work productivity and increase the risk of long-term disability, economic insecurity and worsening health, but limited research informs these issues. The objective was to identify associations between RA and treatment status on pts' productivity and workplace support, using real-world data from the Arthritis Power registry.

Methods: US-resident adult pts with physician-diagnosed RA and a history of or current DMARD use were surveyed from the Arthritis Power registry via smartphone or web app. Pt-reported outcomes included Patient-Reported Outcomes Measurement Information System (PROMIS) pain interference, fatigue, sleep disturbance, physical function, social participation and Routine Assessment of Pt Index Data 3 (RAPID3) score. The Work Productivity and Activity Impairment (WPAI) questionnaire was used to rate how RA affected pt work productivity for past 3 months (scale: 0 [no effect] to 10 [completely prevented from working]).

Results: Of 296 pts, 88% were currently treated with DMARDs (non-biologic and biologic) and 74% had high disease activity (HDA) assessed by RAPID3 (>12). HDA was associated with lower education, lower employment and lower full-time employment, with a higher proportion of pts with HDA reporting being disabled ($p<0.05$ for each). Average self-reported days missed from work due to problems associated with RA in the past 3 months differed between pts with and without HDA (6.1 vs 3.8 days, respectively; $p<0.05$). Pts without HDA missed more work days for medical appointments than pts with HDA (2.6 vs 1.2 days, respectively). Pts with HDA missed more days due to side effects from RA treatment than pts without HDA (mean: 0.5 vs 0.1 days, respectively). RA affected work productivity to a greater extent in pts with HDA than without (WPAI scores 5.3 and 3.3, respectively; $p<0.05$). Unemployed pts had more physically demanding tasks

(e.g. heavy load lifting) in their most recent paid position than currently employed pts (Table 1). Pts who were employed had access to greater workplace flexibility (e.g. changes in start and finish times, working from home) than unemployed pts.

Conclusion: Despite treatment with DMARDs, the majority of HDA pts with RA were more likely to be unemployed or disabled. Physically demanding tasks and less flexible work arrangements were associated with a higher unemployment rate. Attaining lower disease activity and facilitating workplace flexibility (i.e. assign fewer physical tasks, permit flexible hours) may help pts with RA remain employed. Work flexibility policies have been proposed or passed federally in 33 states, yet there is a need for greater visibility, compliance and accessibility to these options for pts with RA. Indirect costs of RA in the workplace should be considered when determining the total cost of RA care.

Medical writing assistance: Carol Keys, PhD (Caudex); funding: Bristol-Myers Squibb.

Table 1 Workplace environment and flexibility by employment status (N=296)

Employment characteristics, n (%)	Currently employed (n=170)	No longer employed (n=126)

Vasculitis Patient Journey: A Scoping Review of Patient Experiences with Vasculitis

Navjeet Gill and Elaine Yacyshyn, Medicine, University of Alberta, Edmonton, AB, Canada

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Patient Outcomes, Preferences, and Attitudes Poster II: Patient Perspectives

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Optimal management of vasculitis needs to address disease aspects of significance to patients. Understanding the patients' journey with vasculitis allows clinicians to identify patient goals for treatment. We aimed to review the existing literature regarding patient perceptions of vasculitis' effect on four main domains of health: physical, psychological, social, and financial.

Background/Purpose: Patients' illness perceptions (IP) influence self-management, adherence, and outcomes. Little is known about how cultural background and the lived experiences influence IP among rheumatoid arthritis (RA) patients. We compared IP in people with inflammatory arthritis in men and women, by age of onset (juvenile idiopathic arthritis - JIA vs. RA), and by language/culture (English vs. French Canadian).

Methods: RA patients receiving care at an academic RA Clinic in Montreal, Canada completed the illness perception questionnaire –revised form (IPQ-R) between 2013 and 2015 during a clinic visit. Sociodemographic and RA clinical characteristics were also collected. T-tests and chi-square were used to compare characteristics and mean IPQ-R domain scores between groups by sex, diagnosis and language.

Results: Patients were mostly female, well-educated, spoke English, and had established RA. Over half (56%) were in remission or low disease activity. Mean HAQ ($p<.01$) and pain ($p<.01$) were significantly higher among women. Age, % speaking English, and education were significantly higher, and disease duration and CRP were lower in RA vs. JIA ($p's<.05$). Sociodemographic and RA characteristics were similar by language. Personal and treatment control, timeline-acute/chronic, and disease consequences were similar among groups. As compared to those with RA, JIA patients had significantly higher mean Illness Coherence and Identity scores, and lower emotional representations Table 1. English speaking patients had significantly higher mean Timeline-cyclical scores; a similar trend was seen for women vs. men.

Conclusion: Illness perceptions related to the chronicity of their disease, and confidence that treatment and lifestyle choices could help control their disease were similarly high among all subgroups. As compared to people with RA, those with JIA reported a better understanding of disease-related symptoms, were more likely to identify having JIA as part of who they are, and reported less emotional distress in relation to their disease. English speaking patients and women reported less confidence in their ability to predict their symptoms and disease course. Understanding how patients view themselves, their inflammatory arthritis, and perceptions of timelines and controllability may offer new insight into ways to positively influence treatment expectations, adherence, and self- management.

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Shared decision making is key to optimizing management of patients (pts) with psoriatic arthritis (PsA).¹ Few studies have evaluated pt preferences for treatment administration across different countries. Qualitative research allows understanding of pt perspectives to help guide this process. This study aimed to understand PsA pt preferences, with pt justification, for treatment administration modes.

Methods: Pt-reported demographic and disease information was obtained at screening with qualitative interviews conducted using a semi-structured interview guide in adult PsA pts with current DMARD (biologic/non-biologic) experience in the US, UK, France, Germany, Italy, Spain, and Brazil. Choice ranking and 100-point allocation tasks were used to evaluate order and strength of preference (0 to 100 [low to high]) across 4 treatment modes: oral (once daily), self-injection (SI; weekly), clinic injection (CI; weekly), and infusion (monthly). Transcripts were in English. Analyses were descriptive (ATLAS.ti v7.5).

Results: 85 interviews (25 US; 10 in each other country) were conducted (60% female; mean age, 49.6 years; mean age at PsA diagnosis, 39.7 years). Most pts (70.6%) reported moderate/severe PsA with mean joint pain (4.7), fatigue (5.2), and joint/skin severity (5.9) on a 0 to 10 (low to high) numeric rating scale. Most commonly reported symptoms were pain (87.1%), skin plaques (69.4%), stiffness (52.9%), and joint swelling (48.2%). Current PsA treatment mode was oral (62.3%), injection (63.5%), and infusion (5.9%); 80.0% and 29.4% of pts had experience with injections and infusions, respectively. Oral was allocated the highest mean (standard deviation) preference points (43.9[31.9]) and was more frequently ranked 1st choice (49.4%) vs SI (32.4 [24.8];34.1%), infusion (14.5 [20.0]; 15.3%), and CI (9.2 [10.0]; 1.2%). More US than European pts (88.0% vs 38.0%; p<0.001) ranked oral as 1st choice. Overall, 48 (56.5%) pts had a 'strong' 1st choice preference (point allocation ≥60); most chose oral (66.7%) vs SI (27.1%), infusion (6.3%), and CI (0.0%). Speed of administration was the most common reason for choosing oral (76.2%; Table) and for SI was home administration (75.9%). The most common reason for not choosing oral was possible interaction with other pills (51.2%) and for SI was to avoid needle pain (55.4%).

Conclusion: More pts preferred oral as a PsA treatment mode followed by SI, and preference for oral was greater in the US than Europe. Reasons for pt preferences included speed/ease of use, safety concerns, feeling of control, and to avoid pain/needles; 56.5% of pts felt strongly about their 1st choice preference. Discussions with health care professionals and/or pt support groups about PsA treatment mode options may help the shared decision-making process for choosing appropriate treatment. 1. Acceptance Rate and Sociological Factors Involved in the Switch from Originator to Biosimilar Etanercept (SB4)

Marc Scherlinger^{1,2,3}, Vincent Germain¹, Emmanuel Langlois⁴ and Thierry Schaeffer⁵, ¹Department of Rheumatology, Bordeaux University Hospital, Bordeaux, France, ²FHU ACRONIM, Bordeaux, France, ³Rheumatology, UMR CNRS 5164 - Immunoconcept, France, Bordeaux, France, ⁴CNRS-UMR 5116 Centre Emile Durkheim, Bordeaux, France, ⁵Department of Rheumatology, Bordeaux University Hospital, BORDEAUX, France

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Patient Outcomes, Preferences, and Attitudes Poster II: Patient Perspectives

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Biosimilars represent major potential savings while preserving treatment quality. However, few data are known on how to address the switch from originator to biosimilar in outpatient settings. Our aim was to study acceptance rate and factors influencing acceptance of the switch from originator etanercept (Enbrel®) to biosimilar etanercept (SB4, Bénépali®) in patients with rheumatic disease.

Methods: Patients with a well-controlled rheumatic disease consulting in our rheumatology department were offered the switch for SB4. After oral and written information concerning biosimilar, free choice to accept the switch was left to the patients. The main outcome was primary switch acceptance rate defined by switch acceptance during the initial consult. Real switch adherence, socio-cultural factors and beliefs influencing switch acceptance rate were retrieved during a telephonic interview at distance from the consultation.

Results: Fifty-two patients were eligible for the switch: 32 (62%) with spondyloarthritis and 20 (38%) with rheumatoid arthritis. At the time of the consult, the primary acceptance rate was 92% (48/52). Patients refusing the switch were more likely to report a bad opinion on generic drugs (100% vs 11%, $p < 0.001$). Other patient characteristics were roughly identical except for a statistical trend in the refusal group toward older age (61.4 vs 50.7 years, $p = 0.08$) and longer disease duration (26 vs 12.1 years, $p = 0.05$). Despite initial acceptance, two patients did not begin SB4 after receiving negative information by their regular pharmacist. Real SB4 switch rate (defined as biosimilar use) was 85% (44/52) and 86% (38/44) of patients reported a good experience of the switch.

Conclusion: When presented with positive and reassuring information, most patients agree to the switch from originator to biosimilar etanercept. Patient information, physician and pharmacist knowledge on biosimilars should be addressed in order to improve their diffusion.

Patient Preferences for Disease Modifying Anti-Rheumatic Drug Treatment in Rheumatoid Arthritis: A Systematic Review

Caylib Durand¹, Maysoon Eldoma¹, Deborah A. Marshall² and Glen Hazlewood^{1,3}, ¹Department of Medicine, Cumming School of Medicine, University of Calgary, Calgary, AB, Canada, ²Community Health Sciences, University of Calgary, Calgary, AB, Canada, ³Departments of Medicine and Community Health Sciences, University of Calgary, Calgary, AB, Canada

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Patient Outcomes, Preferences, and Attitudes Poster II: Patient Perspectives

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Treatment choices in rheumatoid arthritis (RA) involve trade-offs in risks, benefits and other considerations such as dosing. Understanding patient preferences for these trade-offs is critical for making patient-centred treatment recommendations. The objective of this study was to summarize patients' preferences for disease modifying anti-rheumatic drug (DMARD) therapy in RA.

Methods: A systematic review was conducted to identify English-language studies in adult RA patients that measured patients' preferences for DMARDs or health states and treatment outcomes relevant to DMARD decisions. We included any study that provided a quantitative assessment of patient preferences, which was defined according to the MeSH definition in the National Library of Medicine as an "individual's expression of desirability or value of one course of action, outcome, or selection in contrast to others". Study quality was assessed using a published quality assessment tool. Data on the importance of treatment attributes and associations with patient characteristics was summarized across studies.

Results: From 7951 abstracts, we included 36 studies, from a variety of countries. Most studies were in patients with established RA and were rated as medium (n=19) or high quality (n=12). The methods to elicit preferences varied, with the most common being discrete choice experiment (DCE) (n=13). Twenty two were focused on decision-making between advanced therapeutics. Despite heterogeneity of attributes in DCE studies, collectively, treatment benefits were usually more important than both serious and non-serious adverse events. Dosing and administration attributes were typically less important than benefits while route and frequency were more important than adverse events. Risk tolerance varied considerably and 3 out of 5 studies showed patients preferred subcutaneous over intravenous therapy. Patient preferences were more commonly associated with sociodemographic variables rather than RA disease characteristics.

Conclusion: Overall, the results support current RA intensive 'treat-to-target' treatment paradigms, but the variability in preferences highlights the need to individualize treatment choices in a shared decision-making context.

Patients Preference Goes to MTX Autoinjectors over Prefilled Syringes: Results from a Phase III Trial

Alain Saraux¹, Christophe Hudry², Elena Zinovieva³, Agnès Courbeyrette⁴ and Hélène Herman-Demars³, ¹Rheumatology, CHU Brest, Brest, France, ²AP-HP Hôpital Cochin, Paris, France, ³Medical Department Nordic Pharma, Paris, France, ⁴Medical Department, Nordic Pharma, Paris, France

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Patient Outcomes, Preferences, and Attitudes Poster II: Patient Perspectives

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The offer of injectable MTX worldwide expanded during past few years with different types of enhanced devices such as prefilled syringes and autoinjector pens. SELF_i trial intended to compare historical MTX prefilled syringes vs a new MTX autoinjector in terms of treatment adherence, functional capacity, and patients' preference at 6 months in RA patients.

Methods: SELF_i was a phase III, randomized open-label trial, conducted in France between Sept. 2015 and March 2017. It included RA patients, treated by oral or injectable MTX for ≥3 months in monotherapy or in association. Patients were randomized in two arms: MTX in prefilled syringes (PS) or MTX in autoinjectors (AI) at the dosage decided by the investigator. Primary co-criteria of the study were non-inferiority of AI vs PS in terms of patients' compliance (measured by the investigator at each visit) and functional capacity (HAQ-DI) at 6 months. Secondary criteria included patients' satisfaction and preference.

Results: Between Sept. 2015 and Sept. 2016, 50 rheumatologists, mostly with private practice, included 271 patients, 197 of which composed the *per protocol* population. Patients baseline characteristics were [mean (\pm SD)]: age: 59.2 (\pm 12.3) yrs; BMI: 26.0 (\pm 4.9) kg/m²; RA duration: 5.35 (\pm 6.70) yrs; DAS28: 3.1 (\pm 1.2); HAQ-DI: 0.6 (\pm 0.6). All patients were treated by MTX (1/3 oral; 2/3 parenteral) at a mean dose of 15.4 (\pm 4.1). There were no significant differences at baseline between PS and AI arms. Proportion of good compliers ($>80\%$) was 89.9% vs 94.9% (AI vs PS): -5% [CI 95% -18.9%; 8.9%]. HAQ decreased by a mean of 0.06 in both groups. Percentage of change was 21.3% vs 22.4% (AI vs PS): -1.1% [-35.0%; 32.7%]. Due to the high data variability, the non-inferiority could not be proved in strict sense, but differences did not appear as relevant.

Patients' reported satisfaction (Likert Scale) secondary criteria	Easy to use AI/PS	Pleasant AI/PS	Satisfying AI/PS	Motivating for further utilization AI/PS	Reassuring AI/PS	Not constraining AI/PS	Not stressful AI/PS	Not painful AI/PS
Strongly agree	60%/21%	7%/0%	63%/21%	61%/35%	30%/14%	51%/36%	55%/41%	51%/38%
Agree	32%/42%	20%/11%	31%/50%	23%/34%	52%/60%	18%/17%	23%/26%	21%/31%
Neither agree nor disagree	4%/23%	32%/26%	2%/19%	9%/17%	9%/15%	19%/24%	14%/17%	25%/24%
Disagree	1%/6%	26%/30%	2%/6%	6%/10%	4%/5%	10%/15%	4%/8%	1%/6%
Strongly disagree	4%/8%	14%/33%	1%/4%	1%/4%	5%/6%	2%/8%	8%/9%	1%/1%
Significance level	p < 0.001	p < 0.001	p < 0.001	p = 0.001	p = 0.02	p = 0.02	p = 0.05	p = 0.15

Patients' reported satisfaction was very significantly higher ($p \leq 0.001$) in AI arm vs PS for the following criteria: easy to use, pleasant, satisfying, willingness for further utilization and significantly higher ($p < 0.05$) for reassuring and not constraining. Of the 132 patients who could try the both devices (during the study or in previous experiences), 127 (96%; $p < 0.001$) preferred the autoinjector over the historical prefilled syringe. No unexpected safety issues were observed during this trial and injection point safety tolerance satisfaction was higher for AI vs PS.

Conclusion: SELFi trial showed that although the non-inferiority of the new MTX autoinjector vs the historical prefilled-syringe was not proved in strict statistical sense, they seem comparable in terms of treatment compliance and functional capacity improvement. Besides the pen is significantly superior in terms of patients' satisfaction and more than 95% of patients who have tried both devices declare preferring it over the syringe.

Physician and Patient Preferences for Treating SLE: Insights into the Choice of Intravenous Infusion and Subcutaneous Injection

Matthew Lau¹, Christopher F Bell¹, Christine Poulos² and Ameya Benegal³, ¹GlaxoSmithKline, Research Triangle Park, NC, ²RTI Health Solutions, Research Triangle Park, NC, ³RTI Health Solutions, RTP, NC

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Patient Outcomes, Preferences, and Attitudes Poster II: Patient Perspectives

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is a chronic, multisystem autoimmune disease characterized by diverse clinical manifestations, chronic inflammation, and significant morbidity that can be fatal¹. Treatment strategies for SLE focus on managing symptoms, reducing flares, preventing organ damage, and improving health-related quality of life^{2,3}. Specific treatment goals should reflect shared decision making between the physician and patient. Currently, patients and physicians have a choice regarding mode of administration for SLE treatments, which range from oral medications, intravenous infusions (IV) and subcutaneous injections (SC). Given these choices, it is important to understand patient and physician characteristics that may drive the choice of selecting a mode of administration. The primary objective of the study was to examine patient and physician characteristics that are associated with the choice of IV or SC for an unspecified SLE treatment.

Methods: An online exploratory stated preference study was conducted with patients and physicians recruited from a web panel in the U.S. among 200 SLE patients and 200 rheumatologists who treat SLE. The survey development was informed by the results of qualitative interviews with physicians who treat SLE and the final surveys were pretested with SLE patients and physicians who treat SLE. The direct elicitation questions described hypothetical SLE treatments with different modes of administration. Pairwise and multivariate analyses were used to estimate the odds ratio (OR) for the likelihood of choosing SC over IV for a variety of respondent characteristics.

Results: Among the respondents, the mean (SD) age was 50.4 (14.0) in patients with SLE (86% female) and 51.4 (10.9) in rheumatologists who treat SLE (>50% in practice for >10 years). Analyses from the patient survey indicated that older respondents were more likely to select SC (OR=4.2); respondents with a fear of needles or self-injection (OR=0.1) and those who never need assistance with household activities (an indicator of higher quality of life) were less likely to choose SC (OR=0.1). Analyses from the physician survey suggested that 15 years or fewer years of training (OR=1.4) and a general preference for SC or IV (OR=2.1) are associated with physician's choice of SC over IV. Treating 21-40 SLE patients each week rather than more (OR=0.6), having two-thirds of treated SLE patients with mild disease rather than more (OR=0.6), having more than 8 infusion chairs in clinic (OR=0.6), and spending more than 80% of the time (OR=0.7) in direct patient care are associated with physician's choice of IV over SC.

Conclusion: This exploratory study is among the first preference studies conducted with SLE patients and physicians who treat SLE. Patient's age, severity of the disease, as well as a range of physician characteristics may play a role in choosing one route of administration over another. These insights may inform shared decision making, which may lead to better alignment between treatment choice and patient preferences, treatment satisfaction, adherence, and improved patient outcomes. The results of this study may inform the development of hypotheses for future studies. (Study funded by GSK HO-16-16706)

Abstract Number: 2371

Use of Social Media Among Patients with Rheumatic Diseases

Mustafa Erdogan¹, Okan Aydin² and Emire Seyahi¹, ¹Istanbul University, Cerrahpasa Medical Faculty, Department of Internal Medicine, Division of Rheumatology, Istanbul, Turkey, ²Internal Medicine, Division of Rheumatology, Istanbul University, Cerrahpasa Medical Faculty, Istanbul, Turkey

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Patient Outcomes, Preferences, and Attitudes Poster II: Patient Perspectives

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The impact of social media on individual or institutional communication and knowledge acquisition is non-negligible. Whether patients (pts) with rheumatic diseases share information about their health on social media is unknown. We aimed to investigate how often and to what extent pts with a rheumatic condition use social media. We also wanted to know whether they communicate with their doctors through social media and what are their expectations.

Figure. Social Media Use Frequency Among Patients with Internet Connectable Device (n=202).

Methods: Consecutive pts with diverse diagnoses attending a rheumatology outpatient clinic were studied. Pts completed a self-administered questionnaire (1) which was modified. Information on demographic features, educational status and diagnosis was also recorded.

Results: We studied 244 (154 F/ 90 M) pts with a median age of 46 years [IQR: 35-55]. Pts were diagnosed as RA (30%), SpA (29%), connective tissue disease (14%), Behcet's syndrome (12%), familial Mediterranean fever (11%) and other diseases (4%). 44% were only elementary school educated. 17% (n=42) did not have any of the communication devices, hence presumed to be social media non-users. Among the remaining 202 pts with devices, 12 (6%) additional pts were defined again as non-users, thus social media users reached 77% (190/244) in total. Smart phone users were in the majority (74%). Facebook was the most preferred social media website (79%), followed by Instagram (70%), Twitter (50%) and Pinterest (13%). While, Facebook users and non-users were similar according to age, gender or educational status, Twitter users were more likely to be male and more educated (Figure). The majority of the pts (78%) thought that social media was a useful information source about health. A total of 77% had no communication connection with their rheumatologist. While 96% were willing to communicate with their doctors through one of the social media source, 75% desired to be friends with their rheumatologist on the Facebook. When we asked "why would you like to communicate with your rheumatologist?"; the majority (39%) responded that it would be easier to understand each other; % 32 thought that they would feel more connected, % 27 thought that their rheumatologist would be more responsible, and 21% thought that their disease will get better.

Conclusion: This survey showed that younger and more educated pts had significantly more communication devices. Facebook was the most preferred social media website. More educated pts prefer using Twitter, Instagram and Pinterest and younger pts Instagram and Pinterest. The majority thought that social media was a useful information source about health. While only 23% had an actual connection with their rheumatologist through social media, 75% desired to be friends with their rheumatologist on the Facebook.

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Patient Outcomes, Preferences, and Attitudes Poster II: Patient Perspectives

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Smartphone applications and social media (SM) are increasingly used, transforming the way in which people communicate. Peer interaction, remote information access and community building are just some of the uses of SM, presenting novel opportunities and challenges, especially for people with chronic conditions such as rheumatic and musculoskeletal diseases (RMDs). This study aimed to explore the perspectives of people with RMDs on using social media for health-related purposes.

Methods: A questionnaire-based survey, co-designed in English by rheumatologists and patient research partners and translated into German, Italian, Spanish, Russian and French, was launched at the beginning of May 2018, distributed via patient organizations and SM platforms. We report on interim data analyses after 4 weeks of data collection.

Results: A total of 417 complete responses were received across 44 countries (50% of the UK, Russia, Spain and Italy). 13% of respondents were from non-European countries, with USA and New Zealand being the largest contributors. More than half of respondents were between 35 and 54 years, 87% were female, two thirds had >1 RMD, with inflammatory arthritis and connective tissue diseases being most prevalent. Sixty percent of participants had multimorbidity, with gastrointestinal, thyroid disease and hypertension leading. 38% were involved in patient organizations or as research

A Why did you start using social media for health-related reasons?

B In your opinion, what are the advantages of using social media for health-related reasons?

C In your opinion, what are the disadvantages or barriers of using social media for health-related reasons?

partners and 65% had a higher education diploma. Practically all (96%) were using SM, half of them more than 6 hours per week. Three quarters reported using SM for health-related purposes, in particular to connect with other people living with the same condition (63%), with Facebook, YouTube and Twitter being the top 3 commonly used platforms (Figure 1A). There was an overall positive perspective for SM, as an easy means to acquire different experiences and exchange knowledge with peers. However, more than half voiced concerns regarding confidentiality (Figure 1B + C). Only 6% had experiences with virtual medical appointments, in most cases for follow-up, with 28% indicating to have more than one RMD. SM use was comparable between groups with different levels of multimorbidity, although general health rating

was poorer than those with ≤ 1 comorbidity ($p=0.002$), they were older and more frequently considered that information provided by primary care physicians was inadequate ($p=0.005$).

Figure:

Conclusion: This study demonstrates that use of SM for health-related purposes is widespread among people with RMDs and is mainly used as a means to connect with peers and exchange knowledge and experience, supporting empowering patients in managing their disease. Despite concerns about confidentiality and the sharing of sensitive data, the considerable use of SM by patients with RMDs is impressive and represents new avenues to explore in health care.

How Do Patients Describe Their “New Normal” in Systemic Lupus Erythematosus? Use of Probabilistic Topic Modelling to Characterize Patients’ Experiences Recorded in an Online Health Community

Stephanie Eaneff¹, Timothy Vaughan¹, **Volkan Barut**², Jesper Havsol³, Brad Nohe⁴ and Cathy Emmas⁵, ¹PatientsLikeMe, Boston, MA, ²Global Medical Affairs, AstraZeneca, Cambridge, United Kingdom, ³Advanced Analytics Centre, AstraZeneca, Gothenburg, Sweden, ⁴AstraZeneca, Gaithersburg, MD, ⁵Patient Centricity, AstraZeneca, Cambridge, United Kingdom

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Patient Outcomes, Preferences, and Attitudes Poster II: Patient Perspectives

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Patients living with systemic lupus erythematosus (SLE) must typically adapt to altered quality of life and tailor coping mechanisms (e.g. non-pharmacological interventions) to address their personal “new normal”. Patient interactions in online communities provide an opportunity to understand their new way of living with SLE, outside of a clinical setting.

Methods: Topics related to the new normal in SLE were studied by analyzing free text data from patients self-reporting a diagnosis of SLE on PatientsLikeMe, an online community and health network. These data included patients’ brief autobiographies, forum posts and replies, and annotation of their health data. Latent Dirichlet allocation (LDA), a form of probabilistic topic modeling, was used to identify topics from within this corpus. Further analysis of relevant topics, identified by manual review, focused on the language used by patients, effect on their lives and the steps taken to mitigate impact.

Results: 138,409 free-text SLE-related posts from 15,060 users on PatientsLikeMe were analyzed using LDA. 150 unique topics – clusters of related words – were identified, including 12 topics identified as relevant patients’ “new normal” in living with SLE. These 12 topics were then named to reflect their component words and grouped into 3 domains; Emotions (Uncertainty, Isolation, Guilt), Symptoms (Fatigue, Pain, Hair Loss) and Daily Challenges (Inability to work, limited time outdoors, daily variability, managing drugs, hiding symptoms/illness and proving symptoms/illness). Patients reported feeling overwhelmed by pain and fatigue. Patients describe a constant struggle to overcome isolation and communicate their feelings to their family, friends, health care providers (HCPs) and employers. This leads to hiding symptoms, withdrawal and feelings of guilt. In addition, pain management strategies from physicians feel largely ineffective, as do many drug treatments. Patients struggled with the unpredictability of these symptoms and conveyed a sense of resignation and acceptance to this new normal. They accepted that many daily activities (e.g. taking a shower or housework) would never be easy again and adapted their lives accordingly. Patients discussed how they were forced to restrict their social lives and seek support from others for family responsibilities such as childcare. Many patients reduced, changed or stopped employment, negatively impacting finances and self-esteem. However, patients also use the online community to help support each other in their shared experiences with SLE, sharing creative lifestyle modifications, such as using cell phone alarms for limiting sun exposure.

Conclusion: Computational approaches that summarize large volumes of patient-generated free text data in online communities provide direct insight into the ways in which SLE patients live with their condition and how they manage the “new normal” in their lives with its changed lifestyle and expectations. These findings can be used to highlight unmet medical needs from the patient perspective, and help patients and their HCPs create a more complete approach to SLE management.

Flare Warnings: People with Rheumatoid Arthritis' Perceptions of Their Flares

Nancy A. Baker¹, Laurel Person Mecca² and Sara R. Piva³, ¹Department of Occupational Therapy, Tufts University, Medford, MA, ²University of Pittsburgh, Pittsburgh, PA, ³Physical Therapy, University of Pittsburgh, Pittsburgh, PA

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Patient Outcomes, Preferences, and Attitudes Poster II – ARHP

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Flares are exacerbations of rheumatoid arthritis (RA) symptoms of sufficient intensity to require some change in treatment. Even when well-managed, more than half of people with RA experience flares within six months.¹ Despite their common and debilitating nature, there are few studies that examine flare-management. Many people with RA may not know the best methods to control their own flare activity.

We held two 90-minute focus groups with RA patients to discuss their experiences with flares and to identify flare warnings, triggers, and flare-management strategies, both preventative and treatment.

Methods: We recruited 11 people with doctor-diagnosed RA, 9 females and 2 males, 10 white and 1 African American, aged 40 to 78. Their disease duration ranged from 1 to 44 years. Seven reported flare activity within the previous 3 months. We analyzed group transcripts for participant responses and identified common themes about flares.

Results: We found that experiences varied widely, but there were two important commonalities. Flare activity diminished participants' ability to take part in important activities, such as work, family gatherings, playing with grandchildren, and socializing. Flare activity affected simple tasks typically taken for granted. One participant commented, "It's so ridiculous that my feet hurt so bad that I didn't want to go to the bathroom." Group members agreed that coping with RA was challenging without flares, and that the uncertainty of flares made the disorder that much more difficult to manage. As one participant said, "You never know what it's going to be, but it's always something."

Participants reported few concrete signs of imminent flare (Table). They identified multiple flare triggers, many of which related to changes in their lives, such as stressful events, the weather, or overdoing activities. Flare prevention strategies tended to be healthful habits, such as taking prescribed medications, diet, exercise, and sticking to routines. Flare management focused on short-term pain relief, such as increased medication or modalities, and methods to distract and rest the system.

Conclusion: Despite advances in medications for RA, flares are common and triggered by multiple common activities and events. Patients with RA currently have few opportunities to predict flare activity, and are dependent upon their flare management strategies to cope when flares occur. We need more focused research on how to prevent flares, and barring prevention, the most effective methods to manage flares when they occur. ¹Bykerk et al. *J Rheumatol.* 2014;41(2):227-234.

Table: Participant reported flare signs, triggers, prevention and management

Flare Signs	No warning; worsening symptoms; changes in mood
Flare Triggers	Stopping medication; stressful events; changes in barometric pressure (weather, flying); humidity; overdoing it (too much physical activity); fatigue; diet (eating allergens)
Flare Prevention	Appropriate medications; exercise; diet; reduce activity; stick to routines
Flare Management	Additional/increased medications; modalities (heat, cold); distraction (reading, watching tv, playing games); rest; socialize

When Are People Receptive to Self Management Education Information, and What Information Appeals to Them? : An Analysis of Digital Data

Teresa Brady¹, Meghan Lewis² and Carla Cartwright², ¹Clarity Consulting and Communications, Atlanta, GA, ²Porter Novelli, Atlanta, GA

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Patient Outcomes, Preferences, and Attitudes Poster II – ARHP

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: CDC pilot-tested a marketing campaign to promote self-management education (SME) as a chronic disease management strategy. The campaign targets adults ages 45-75 with any chronic condition, including arthritis. The campaign includes a variety of paid ads (digital, print, radio, billboard, physician office) along with earned media and partner activities. The campaign call to action is to visit www.cdc.gov/LearnMoreFeelBetter to learn more about SME. Digital ads are easily tracked (e.g., Did the receiver click on the ad presented?), which allows us to assess variations in campaign tactics. Web analytics also can track how many visits each page of a website receives. The purpose of this analysis is to compare the productivity of digital SME ads depending on what terms the person was searching when they received the ad, and to explore what web pages attract the most interest on the SME website.

Methods: As part of the pilot-test, campaign ads were presented to people who conducted Google searches for information about a variety of chronic diseases including arthritis, and one of 4 different clusters of search terms (e.g., Arthritis +Signs/Symptoms/Diagnosis, +General information, +Care/Treatment, +Management). The Google ad vendor reported how many times each cluster of search terms was searched so the ad could be presented (i.e., Impressions). Site Catalyst, a web analytics software program, tracked productivity defined in 3 ways: number of times people receiving the ad clicked on it (Clicks), percentage of people who clicked on ad out of all exposed to the ad (Click thru Rate [CTR]), total cost to run ad divided by number of clicks (Cost per Click [CPC]), and average number of minutes spent on the website by those who clicked through the ad to the site (Minutes on Site [MOS]). The campaign website homepage linked to 4 subpages: Site Catalyst was used to track how often these pages were visited from the homepage.

Results: During the campaign pilot-test, Google ad words produced 115,925 Impressions and 5,737 Clicks. The following table reports Impressions and productivity of digital ads by CTR, CPC, and MOS depending on search term used.

Google Ads Runs Time: January 23 – July 23, 2017					
Search Terms	Impressions	Clicks	Avg. CTR	Avg. CPC	Avg. MOS
Signs/Symptoms/ Diagnosis	33,964	3,316	9.76%	\$1.70	1.52
General	60,696	1,878	3.09%	\$2.36	1.94
Care/Treatment	19,903	485	2.44%	\$2.89	3.64
Management	1,362	58	4.26%	\$2.63	0.48
Totals or Averages	115,925	5,737	Avg. 4.9%	Avg. \$1.85	Avg. 1.83

17% of the 26,851 visits to the homepage (from all sources) resulted in visits to at least 1 subpage. SME programs subpage received the most views (1501), followed by What is SME, About the Campaign, and What Others are Saying/Testimonials (811, 330, 293 views respectively).

Conclusion: Although searches for disease General Information many more opportunities to present the SME ads, people searching for Signs/Symptoms/Diagnosis were 3 times as likely to click on the SME ad. Those who received the SME ad while searching Care/Treatment spent the most time on the SME site. People who reached the SME site were most interested in SME Programs, and least interested in Testimonials. This information can help shape SME marketing.

Abstract Number: 2376

Something for Us: Client Perspectives on Lupus Self-Management Programming Using the 5-a Behavior Change Model

Brenda L Frie, Occupational Therapy Dept., St. Catherine University, St. Paul, MN

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Patient Outcomes, Preferences, and Attitudes Poster II – ARHP

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic lupus erythematosus is the most common and most severe form of lupus involving multiple body systems including the blood, muscles, joints, organs and the nervous system. The Lupus Foundation of America (2012) estimates around 5 million people worldwide have a form of lupus. There is no cure for lupus, so treatment consists of minimizing and managing symptoms. The 5-A model has been shown to be an effective model to facilitate behavior change in those living with chronic disease (Caroll et al., 2012, Glasgow, Emont, Miller, 2006). The purpose of the study was to capture participants voice regarding the value of community based self-management programming based on the 5-A model.

Methods: This retrospective qualitative study was designed to analyze the statements of 48 participants in self-management programming designed based on the 5-A Behavior Change Model. Thirty-eight masters of occupational therapy students (2011-2015) used the 5-A model to design and implement six-week self-management programs as part of their master's project coursework. The students reviewed the literature, designed, and implemented five programs covering the topics of fatigue management, physical activity, stress and pain management. The programs were designed in collaboration with the Lupus Foundation of Minnesota. They were offered free of charge in face to face and online formats. Participants response was assessed through post program assessment of objectives and thematic analysis of participants statements during and following the program.

Results: Forty eight members of the Lupus Foundation of Minnesota participated in the study and were included in the analysis. The majority of participants had SLE (n=42), were female (n=43) and white (n=38). All participants used a four-point scale to indicate if unit objectives were met (1=strongly disagree, 2=disagree, 3=agree and 4=strongly Agree). The average scores per unit ranged from an average of 3.4 to 4 indicating the objectives were met for all programs. Qualitative thematic analysis (Braun & Clark, 2006) of recorded participant statements showed the participants valued the programming and felt it was effective. Thematic analysis uncovered four themes: Learning through understanding, changing routines, adapting life, and gratitude and appreciation.

Conclusion: Qualitative evidence supports use of the 5-A Behavior Change Model as an effective model for self-management education in online and face to face format for those with lupus. Post-program quantitative measures showed those who participated the programming felt the objectives were met. Qualitative analysis revealed evidence-based education increased patients understanding of the rationale for recommendations and promoted behavior c in routines and adaptations that improved quality of life. Those that participated in the program were grateful and appreciative of programming designed specifically for them stating "finally something for us."

Body Image in Rheumatic Diseases: A Systematic Review

Shadi Gholizadeh¹, Annie Meier², Sarah D. Mills³ and Vanessa L. Malcarne⁴, ¹Clinical Psychology, SDSU/UC San Diego Joint Doctoral Program in Clinical Psychology, San Diego, CA, ²Psychology, San Diego State University, San Diego, CA, ³Medicine, Lineberger Comprehensive Cancer Center University of North Carolina, Durham, NC, ⁴SDSU/UC San Diego Joint Doctoral Program in Clinical Psychology, San Diego, CA

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Patient Outcomes, Preferences, and Attitudes Poster II – ARHP

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: In health conditions that cause changes in appearance, especially in areas of the body that are highly visible and socially salient (e.g., face and hands), there can be alterations in body image, self-esteem, and role-evaluation. Given their chronic and progressive nature and disproportionate impact on women, the rheumatic diseases are an important area for the study of body image in chronic illness. Body image has been explored in various rheumatic conditions, such as systemic sclerosis, rheumatoid arthritis, and systemic lupus erythematosus. To date, no systematic review has summarized the literature on body image in multiple rheumatic diseases.

Methods: PubMed/Medline, PsycINFO, and CINAHL databases were searched on May 13, 2016 and updated on December 19, 2017. Results were limited to English-language studies. Additionally, a manual search was undertaken wherein reference lists of selected articles were screened for inclusion. Grey literature (i.e., conference abstracts and dissertations) was excluded. Studies were screened and evaluated for inclusion by two investigators. Full articles were reviewed to determine eligibility based on the following inclusion criteria: 1) study participants comprised of adult patients with rheumatic diseases that can cause visible differences, and 2) at least one validated measure of body image was used. Studies that focused on surgical outcomes were excluded.

Results: Forty-eight articles were eligible for inclusion in the present review. The majority of studies used disease-specific measures of body image. Eligible studies were identified for lupus, rheumatoid arthritis, scleroderma, and ankylosing spondylitis. No single correlate was found to consistently associate with body image. However, younger age, greater depressive symptomatology, presence of active disease flares, and greater functional deficits were most commonly associated with poorer body image scores.

Conclusion: Rheumatic diseases that cause changes in appearance can have significant impacts on body image. The multidimensional nature of the construct of body image and the use of disease-specific measures complicated the synthesis of the findings across groups or comparisons with non-rheumatic disease samples. However, some disease correlates appeared most commonly associated with poorer body image across disease groups and can be useful in guiding intervention efforts.

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Pediatric Rheumatology – Clinical Poster III: Juvenile Idiopathic Arthritis and Uveitis

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The effect of biologic DMARDs on different juvenile idiopathic arthritis (JIA) categories is poorly understood. In patients (pts) with JIA aged 2–17 years (y), SC abatacept (ABA) was effective and well tolerated.¹ Here, effectiveness and HRQoL of SC ABA in pts aged 2–17y by JIA categories over 24 months (M) are presented.

Methods: The design of this single-arm, two-cohort, open-label Phase III study (ClinicalTrials.gov, NCT01844518) has been described.¹ Eligible pts with JIA received SC ABA (50, 87.5 or 125 mg by body-weight tier) weekly for 4M; JIA-ACR criteria 30% improvement (JIA-ACR30) responders at 4M could receive ABA for another 20M. Pre-specified analyses included JIA-ACR30, 50, 70, 90 and 100 responses and inactive disease (modified criteria)² status. *Post hoc* analyses included Juvenile Arthritis Disease Activity Score on 27 joints (JADAS27-CRP) and proportion of pts with minimal clinically important difference (MCID) in Childhood HAQ-DI (CHAQ-DI; MCID –0.188)³ by JIA category (polyarticular [PA] RF positive (+), PA RF negative (–), extended oligoarthritis [EOA], systemic [SA], psoriatic [PsA], enthesitis-related [ERA], persistent oligoarthritis [POA] and undifferentiated[UA] JIA) and overall safety. Due to low pt numbers, separate data for SA, PsA, ERA, POA and UA were not interpreted; data were pooled for JADAS27-CRP.

Results: In 219 treated pts, median (min, max) age was 11.0 (2.0, 17.0) y and disease duration was 1.0 (0.0, 15.0) y. Overall, 19.6% of pts discontinued over 24M with 10.0% discontinuing due to lack of efficacy. Data for SA, PsA, ERA, POA and UA are provided for completeness (Figs 1, 2). In PA RF+, PA RF– and EOA, pts responded early to SC ABA and showed robust JIA-ACR30 responses over time (4M: 80.5–96.6%). More stringent JIA-ACR50 (Fig 1), 70, 90 and 100 responses, inactive disease status and JADAS27-CRP (Fig 2) improved across these categories up to M4 and were sustained to M24; similar results were observed in a JADAS27-CRP pooled analysis of other categories. A trend for

Figure 1. JIA-ACR50 Response Rates Over Time for all Treated pts by JIA Category to M24*

improvement in CHAQ-DI MCID was evident across categories (24M: 50.0–61.2%). None w/unexpected AEs were observed; a safety summary per age cohort over 24M was reported previously.¹

Conclusion: In this analysis of pts aged 2–17 yrs with JIA, SC abatacept was effective and well tolerated and improved HRQoL across JIA categories over 24M.

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Pediatric Rheumatology – Clinical Poster III: Juvenile Idiopathic Arthritis and Uveitis

Background/Purpose: Tocilizumab (TCZ) administered intravenously (IV) was shown to improve the signs and symptoms of polyarticular(p) JIA and systemic (s) JIA.^{1,2} An ongoing 3-year, long-term extension (LTE) of two 52-week, open-label studies in patients (pts) with pJIA/sJIA will evaluate long-term safety and efficacy of subcutaneous (SC) TCZ; 90-day safety results to the clinical cutoffs December 1, 2017 (pJIA) and February 28, 2018 (sJIA) are reported.

Methods: Pts aged 1-17 years received body weight (BW)-based TCZ SC dosing regimens: pJIA pts received TCZ 162 mg every 3 weeks (Q3W) for BW <30 kg or every 2 weeks (Q2W) for BW ≥30 kg; sJIA pts received TCZ 162 mg Q2W for BW <30 kg (every 10 days until week 14) or weekly (QW) for BW ≥30 kg. pJIA pts had failed MTX treatment or could not tolerate MTX and sJIA pts had inadequate response to NSAIDs and glucocorticoids. All pts had to discontinue biologic DMARDs (except TCZ IV, which was switched to SC). After 52 weeks, eligible pts continued TCZ treatment according to BW in the LTE; we report 90-day safety data for pJIA and sJIA as adverse events (AEs), serious AEs (SAEs), and AEs of special interest (AESIs). The safety populations included all pts who received ≥1 dose of TCZ SC and had ≥1 postdose safety assessment.

Results: Of pJIA pts (n = 44), 72.7% were female and 88.6% white. Of sJIA pts (n = 38), 55.3% were female and 84.2% white. Median (range) age in both groups was 9.0 (2-18) years. AE rates (Table [image]) were similar regardless of BW. Most AEs were grade 1 or 2; grade ≥3 AEs were reported by 10/44 (20.8%) pJIA pts and 4/38 (10.5%) sJIA pts. The most common AE was nasopharyngitis in both pJIA (17/44 [38.6%]) and sJIA (11/38 [28.9%]). Other AEs reported in ≥15% of pts were arthralgia, gastroenteritis, cough, vomiting, diarrhea, pyrexia, headache, and oropharyngeal pain in pJIA, and upper respiratory tract infection, cough, pyrexia, arthralgia, and rash in sJIA. AESIs were consistent with the 52-week data, and no opportunistic infections developed. Neutropenia AEs were reported by 6 pJIA pts (13.6%) and 7 sJIA pts (18.4%). Of pJIA pts, 5/44 (11.4%) experienced SAEs (furuncle, appendicitis, pneumonia, eye pain/headache, infectious mononucleosis); only pneumonia was considered treatment related. Of sJIA pts, 2/38 (5.3%) experienced SAEs (pneumonia, craniocerebral injury from a fall); neither was considered treatment related. Neutralizing anti-TCZ antibodies developed in 2 pJIA pts (4.7%) and 0 sJIA pts. No deaths were reported in the LTE to the data cutoff.

Session Title: Pediatric Rheumatology – Clinical Poster III: Juvenile Idiopathic Arthritis and Uveitis

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Adalimumab (ADA) has been approved for the treatment of polyarticular juvenile idiopathic arthritis (pJIA) with long-term use often required to maintain disease control. The purpose of this analysis was to describe the safety of ADA among children with pJIA treated in current clinical practice with fixed-dosing (F-D, by weight category, in the United States [US] and Australia) or body surface area-dosing (BSA-D, in European countries).

Methods: This is a year (yr) 8 interim analysis of an ongoing, multicenter, observational registry of patients (pts) with pJIA with up to 10 yr safety follow-up. Pts included in the registry were treated with ADA, alone or in combination with methotrexate (ADA±MTX), or MTX alone as a comparison arm, according to routine clinical care in PRINTO/PRCSG centres in the US, Australia, and Europe. This analysis included only ADA±MTX-treated pts who were sub-grouped according to enrolling site into two groups: F-D (10 - <15 kg, 10 mg every other week [eow]; 15 - <30 kg, 20 mg eow; ≥30 kg, 40 mg eow) or BSA-D (24 mg/m² [maximum of 40 mg] eow). MedDRA observational adverse events (AEs) were recorded from registry entry through last contact, irrespective of duration of registry treatment with ADA±MTX.

Results: Of the 537 pts enrolled in the ADA±MTX arm, 272 and 263 received F-D and BSA-D, respectively. At registry entry, F-D and BSA-D groups were similar for mean JIA duration (3.5 yrs vs. 3.9 yrs), JADAS27 (CRP) (10.8 vs. 12.2), and CHAQ-DI (0.6 for both). Registry follow-up in the F-D and BSA-D groups were comparable [mean (range) in yrs: 3.96 (0.00–8.92) vs. 3.58 (0.00–7.01)]. Overall, 166 pts (61%) in the F-D and 128 (49%) in the BSA-D group discontinued registry drug. Frequencies and rates of observational AEs per 100 pt years of observation time (from registry entry up to last contact, irrespective of drug treatment duration) were comparable between groups (Table), including rates of serious infection. Two pts from the BSA-D group reported latent TB, although there were no cases of active TB across enrolling sites. One pt (0.2%) from the BSA-D group reported an event of opportunistic infection (fungal oesophagitis). There were no reports of death, malignancy, oral candidiasis, demyelination, or congestive heart failure.

Conclusion: Overall, ADA±MTX was well-tolerated in pts with pJIA where administration has been with a fixed dose, per weight category, or based on BSA, respectively. Table. Overview of the observational adverse events per 100 PYs

	Fixed-dosing ADA±MTX (N=272) PYs=1076 E (E/100 PYs)	BSA-dosing ADA±MTX (N=263) PYs=940.8 E (E/100 PYs)
Any AE	453 (42.1)	358 (38.1)
AE at least “possibly drug related” per the investigator	155 (14.4)	101 (10.7)
Severe AE	47 (4.4)	26 (2.8)

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Pediatric Rheumatology – Clinical Poster III: Juvenile Idiopathic Arthritis and Uveitis

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Figure. A.) Proportions of patients achieving sustained (≥ 6 continuous months) JADAS27 inactive disease over time; B.) Regression tree analysis selecting JIA ACR90 response at week 12 as significant factor associated with sustained JADAS27 inactive disease.

Background/Purpose: Juvenile idiopathic arthritis (JIA) is a broad term that describes a clinically heterogeneous group of arthritides of unknown cause, which begin before 16 years (yrs) of age and continues into adulthood.¹ The purpose of this analysis was to evaluate the long-term safety and effectiveness, including predictors of sustained disease control, of adalimumab (ADA) among patients (pts) with JIA through 6 yrs of treatment.

Methods: Children aged 4 - 17 yrs with polyarticular JIA were enrolled in a 32-week (wk), phase 3, randomized-withdrawal, double-blind, placebo (PBO)-controlled trial following a 16-wk open-label (OL) lead-in period. Following completion of the double-blind (DB) period, pts were eligible to enter into a long-term extension (LTE) through 360 wks and receive OL ADA based on body surface area (BSA, 24 mg/m², maximum of 40 mg eow) for ≥44 wks and fixed dosing (FD, <30 kg: 20 mg eow; ≥30 kg: 40 mg eow) thereafter. Pts were stratified by baseline (BL) MTX use. Adverse events (AEs) were monitored throughout study duration and 70 days beyond last dose. Effectiveness assessments by visit included JIA ACR30/70/90 responses, and the proportions of pts achieving JADAS27 low disease activity (LDA, 1.1 – 3.8) and inactive disease (ID, ≤1). Pts achieving sustained LDA and ID for ≥6 continuous months were evaluated. Regression tree analysis was used to identify BL and post-BL factors associated with sustained ID. Data were as observed without imputation.

Results: A total of 171 pts were enrolled, and 133 were randomized to PBO or ADA. Of these pts, 128 completed the DB period and entered the LTE. Sixty-two pts completed the LTE (primary reasons for study discontinuation: lost to follow-up [n=14], withdrawal of consent [n=20], other [n=22]). Pts on average were 11 yrs of age, and three-fourths were female with nearly 4yrs of active disease (mean JADAS27, 22.5). Twelve serious infections in 11 pts were reported through >500 pt-yrs of ADA exposure. There were no cases of congestive heart failure-related AEs, demyelinating disease, lupus-like syndrome, malignancies, TB, or deaths reported during any period of the study. At wk 312, 19/28 (68%) and 17/30 (57%) of pts achieved JIA ACR90 and JADAS27 ID, respectively; mean JADAS27 was reduced to 2.5. A total of 63 pts (37%) achieved sustained ID, with a median time of 216 wks to reach sustained ID (Figure). BL factors did not consistently predict sustained ID; however, early JIA ACR responses were associated, with ~75% of pts who achieved JIA ACR90 by wk 12 attaining sustained ID.

Conclusion: ADA appeared well-tolerated among children aged 4-17 with polyarticular JIA through up to nearly 7 yrs of exposure. Significant clinical responses, such as JIA ACR90 and JADAS27 ID, were readily achieved among pts who continued in the study. Early clinical response appeared to predict sustained ID.

*No cases of other ADRs of interest (malignancy, autoimmune diseases, pancytopenia, demyelinating diseases, congestive heart failure, and intestinal perforation) were reported during the study.
ADR, adverse drug reaction

Background/Purpose: The safety and efficacy of adalimumab (an anti-TNF- α antibody) treatment in patients with JIA have been demonstrated in clinical trials. This study was conducted to investigate the safety and effectiveness of adalimumab in patients with JIA in real-world settings in Japan.

Methods: This all-case post-marketing surveillance (NCT01412021) was conducted at 108 centers in Japan. All patients receiving adalimumab treatment for JIA affecting multiple joints were enrolled between July 1, 2011 and February 26, 2016 and observed for 24 weeks and 1-/2-year follow-ups. The primary endpoint was incidence of adverse drug reactions (ADRs) and secondary endpoint was DAS28-4/ESR remission (<2.6) rate at each study time point.

Results: Of 375 patients enrolled, 356 were included in the safety cohort (Table 1). Adalimumab was administered at a dose of 20 mg every 2 weeks in 65 of 72 patients weighing 15 kg–<30 kg and at a dose of 40 mg in 236 of 240 patients weighing ≥ 30 kg. Mean (standard deviation) treatment duration was 159.0 (31.2) days and number of administration was 11.3 (3.8) times. Treatment was discontinued in 44 (12.4%) patients with the most common reason being ineffectiveness in 28 (7.9%), and the second reason as adverse event in 9 (2.5%) patients. Overall, 174 ADRs were reported in 106 (29.8%) patients (Table 2). No cases of malignancy were reported during the study and at the 1- and 2-year follow-ups. Incidence of ADRs gradually decreased from treatment initiation over time (duration [weeks], %: 0–4, 12.6%; 5–8, 7.1%; 9–12, 4.3%; 13–16, 2.4%; 17–20, 1.9%). Incidence of ADRs was numerically higher in children aged < 15 years (34.6% [79/228]) than in patients aged ≥ 15 years (21.1% [27/128]) and in those weighing 15–<30 kg (47.2% [34/72]) than in those <15 kg (12.5% [1/8]) and ≥ 30 kg (27.5% [66/240]). Self-administration errors were reported in 2 (0.8%) patients. In the effectiveness population (n=205), the DAS28-4/ESR remission rate increased from 22.4% (38/170 patients) at baseline to 75.0% (114/152 patients) at 24 weeks (Figure 1).

Conclusion: In patients with JIA, adalimumab treatment was well tolerated with acceptable safety and effectiveness in real-world settings.

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Pediatric Rheumatology – Clinical Poster III: Juvenile Idiopathic Arthritis and Uveitis

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Long-term surveillance of biologics is particularly important in pediatric patients (pts) who may require prolonged treatment. Since 2001, the German Biologics JIA Registry (BIKER) allows follow up of an unlimited number of pts in routine clinical care. Long term safety with regard to adverse events of special interest was assessed.

Methods: BIKER was used to identify non-systemic JIA pts on biologics. Safety assessments based on adverse events (AE) reports for 25 predefined AEs of special interest (AESI) including serious and medically important infection, uveitis, chronic inflammatory bowel disease, cytopenia, hepatic event, anaphylaxis, depression, pregnancy, malignancy, and death. Events per 100 patient-years (PY) were calculated using AEs reported after first dose through 70 days after last dose. Rates were compared by Wald test.

Results: 3591 courses of biologics with a total exposure time of 6837 PY were identified with Etanercept (ETA, 5015 PY) as most frequently used followed by Adalimumab (ADA, 1298 PY), Tocilizumab (TOC, 251 PY), Abatacept (ABA, 106 PY), Infliximab (INF, 99 PY), and Golimumab (GOL, 72 PY). Differences in JIA category distribution and concomitant treatment between these cohorts were noted. A total of 5155 AE (rate 75.4/100 years), 461 SAE (5.4) and 611 AESI (8.9) were reported. The most common AESI were uveitis (227) followed by medically important infections (146), cytopenias (44), hepatic events (37), other autoimmuneopathies (27), chronic inflammatory bowel disease (22), depression (22), anaphylaxis (18), pregnancies (10) evolving hypertension (9) and malignancies (7). There were marked differences in the rate of AESI between the biologic-cohorts. Risk Ratios for serious infections were higher with ADA&GOL and lower with ETA. One case of latent tuberculosis infection but no further opportunistic infections were reported. RR for uveitis reports were significantly higher in all TNF-antibody cohorts and lower with ETA or TOC which presumably is biased by indication. RR for hepatic events were significantly higher in the TOC cohort and lower with ETA. RR for cytopenias was significantly higher with TOC. RR for anaphylaxis were significantly higher in the ABA, TOC and INF cohorts probably due to the intravenous route of application. RR for inflammatory bowel disease was higher upon Infliximab which presumably is biased by indication. There was no death in this cohort.

Hypertension		4/0.3 5.4 [1.4-20] p=0.012	5/0.1 0.5 [0.1-1.7] P=0.24		1/1.1 12 [1.4-98] P=0.022	
Malignancy			6/0.1 2.2 [0.3-18] P=0.47			

*Data outlined as n (rate/100 years), RR=Risk ratio[95% CI], p-value.

Conclusion: These data provide support for the long-term and comparative safety of biologics in JIA pts. Overall, tolerance is acceptable. Surveillance of pharmacotherapy as provided by BIKER is an import approach especially in the case of long-term treatment of children. Differences between several biologics were noted and should be considered in daily patient care.

BiKeR is sponsored by unrestricted grants from Abbvie, Chugai, MSD, Novartis, Pfizer, Roche

Biosimilar Use in Young Adults with Juvenile Idiopathic Arthritis in Germany

Jens Klotsche¹, Martina Niewerth¹, Gerd Horneff² and Kirsten Minden^{3,4}, ¹Program Area Epidemiology, German Rheumatism Research Center, Berlin, Germany, ²Department of Pediatrics, Asklepios Clinics St. Augustin, Sankt Augustin, Germany, ³Charité–Universitätsmedizin Berlin, Berlin, Germany, ⁴German Rheumatism Research Center, Berlin, Germany

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Pediatric Rheumatology – Clinical Poster III: Juvenile Idiopathic Arthritis and Uveitis

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The first biosimilars have been approved for the treatment of juvenile idiopathic arthritis (JIA) in the last two years. To date, only a few reports exist about the experience with biosimilars in the treatment of JIA. The objectives of our study was to describe disease characteristics of young adults with JIA at biosimilar treatment start and the onset of adverse events during Treatment.

Methods: We used data collected until May 2018 from the prospective, longitudinal JuMBO (Juvenile arthritis Methotrexate/Biologics long-term Observation) cohort. JIA patients who were originally included in the pediatric register BiKeR (biologics in paediatric rheumatology) with start of a bDMARD or csDMARD will continue to be monitored in the follow-up register JuMBO into adulthood. Details on disease activity, treatment and the onset of adverse events under treatment were half-yearly reported by the treating physician.

Results: Overall, 22 JIA patients started treatment with a biosimilar (SB4: n=20, GP2015: n=1, CT-P13: n=1) in JuMBO until May 2018. The mean age and disease duration at treatment initiation was 23 years (SD=5.2) and 14.9 years (SD=7.4). Three quarters of patients had polyarticular JIA and were female. Etanercept (n=12, 55%) and MTX monotherapy (n=5, 23%) were the most recently used DMARDs before treatment start with the biosimilar. The original DMARD was discontinued due to ineffectiveness (n=7, 32%), economic reasons (n=10, 46%), an adverse event (n=1, 4%) and other reasons (n=4, 18%). The mean cJADAS10 at treatment start was 8.2 (SD=4.5) and the mean physician's global assessment of disease activity on a numerical rating scale was 3.4 (SD=2.2). Patients were treated with the biosimilar in mean for 6 months (SD=6, median=0.5, 13 exposure year). Five patients discontinued SB4 in mean after 4 months (SD=4, median=3) due to ineffectiveness (n=2, 40%), adverse events (n=2, 40%) and after attaining an inactive disease (n=1, 20%). These patients switched to etanercept (n=3, 75%) and golimumab (n=1, 25%) after biosimilar discontinuation. Seven adverse events (rate of 53.8 events per 100 exposure years) at all and 3 serious adverse events (23.1 events per 100 exposure years, hospitalization and two medical procedures) were reported during the observation period.

Conclusion: This study gives a first overview about the use of biosimilars in young adults with JIA in Germany. Economic reasons were the primary reason for switching from the original bDMARD to the biosimilar in Germany. More patients and a longer follow-up are necessary to compare the effectiveness and safety of a biosimilar with its originator in patients with JIA.

Session Title: Pediatric Rheumatology – Clinical Poster III: Juvenile Idiopathic Arthritis and Uveitis

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: There is significant variation in the timing of when biologic medications are started during initial treatment for polyarticular juvenile idiopathic arthritis (P-JIA) in clinical practice. The Childhood Arthritis and Rheumatology Research Alliance (CARRA) developed three consensus treatment plans (CTPs) that reflect the most commonly-used strategies for when to start biologic treatment. The CARRA Start Time Optimization of Biologic Therapy in Polyarticular JIA (STOP-JIA) study is comparing the effectiveness of the three CARRA-P-JIA CTPs using a prospective, observational study design and aims to enroll 400 children. It is expected that enrollment will be completed in July 2018. This abstract describes interim baseline characteristics and CTP choices for the patients enrolled.

Methods: Untreated P-JIA patients with 5 active joints were enrolled into the CARRA Registry at the time of treatment initiation. Providers and patients together chose one of the CTPs to follow: 1) Step-Up treatment (initial therapy with DMARD and biologic added after 3 months, if needed); 2) Early Combination (initial therapy with both DMARD and biologic); and 3) Biologic First (initial treatment with biologic monotherapy). Providers had the option of prescribing glucocorticoids at baseline per their usual practice. Glucocorticoid tapering suggestions were provided.

Table 1. Baseline Patient Characteristics

	Total Cohort (n= 335)	Step up (n= 218)	Early Combination (n=84)	Biologic First (n=33)
Female N (%)	246 (73)	163 (75)	61 (73)	22 (67)
White N (%)	228 (68)	156 (72)	53 (63)	19 (58)
Age in yrs - mean (range)	10 (1-18)	10 (1-18)	11 (1-17)	11 (1-18)
JIA Category N (%)				
Extended Oligoarticular	9 (3)	9 (4)	--	--
Polyarticular (RF-)	211 (63)	149 (68)	48 (57)	14 (42)
Polyarticular (RF+)	58 (17)	32 (15)	20 (24)	6 (18)
Psoriatic	22 (7)	12 (6)	5 (6)	5 (15)
Enthesitis-related	26 (8)	12 (6)	8 (10)	6 (18)
Undifferentiated	8 (2)	3 (1)	3 (4)	2 (6)
Number of Active joints - mean (range)	13 (5-50)	12 (5-49)	16 (5-50)	11 (5-41)
Physician Global Assessment of Disease Activity - mean (range)	5 (0-10)	5 (0-10)	6 (1-10)	6 (1-10)
Juvenile Arthritis Disease Activity Score - mean (range)	18 (5-29)	17 (5-29)	20 (6-29)	20 (14-28)
CHAQ Score - mean (range)	1 (0-3)	1 (0-3)	1 (0-3)	1 (0-3)
Oral steroids prescribed at baseline - N (%)	85 (25)	57 (26)	23 (27)	5 (15)

Results: Three hundred and fifty-two patients were enrolled at 43 sites in the US and Canada between 1 Nov 15 and 22 May 18. Data for the 335 patients with baseline data available are summarized in Table 1. The most commonly chosen CTP was Step-Up (n=218; 65%). Early Combination CTP was the next most common choice (n=84; 25%). To date, 823 follow up visits have been entered and 152 patients have completed their 12-month endpoint visit. Of the patients with follow-up data available, 31 patients were reported to have changed CTP at least once during STOP-JIA participation. There were 26 Serious Adverse Events (SAE) or non-serious Events of Special Interest (ESI) including 7 cases of new onset uveitis, 8 infections, and 3 episodes of hepatitis.

Conclusion: With > 85% of patients enrolled to date, patients have been enrolled into all 3 CTP choices, with the Step-Up CTP being the most common. Ongoing, prospective data collection from these patients will allow for a comparison of the effectiveness of the strategies.

Abstract Number: 2386

Secukinumab Is a Promising Treatment for Patients with Juvenile Enthesitis Related Arthritis Nonresponsive to Anti-TNF Treatment

Ivan Foeldvari and Jean Baer, Hamburg Center for Pediatric and Adolescent Rheumatology, Hamburg, Germany

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Pediatric Rheumatology – Clinical Poster III: Juvenile Idiopathic Arthritis and Uveitis

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Secukinumab (SEC) is licensed to treat adults with spondyloarthritis. It is not licensed for pediatric patients with Juvenile Idiopathic Enthesitis related Arthritis (enthJIA) yet. Only anti-TNF is licensed as biologic treatment for enthJIA. Not all patients get into remission with an anti-TNF therapy. We review our first patients, who did not reach remission under anti-TNF and were switched to SEC.

Methods: We conducted a retrospective chart review in our unit of patients with enthJIA, who were treated with SEC.

Results: 14 patients were treated with SEC. 85% of them were female. All patients were diagnosed with enthJIA. The mean age of the patients at the start of the treatment was 18.7 years and the mean weight 61.6 kilograms. The patients received before SEC in average 1.93 different anti-TNF's, where they reached no remission, the JADAS-10 was 8.07 at the time initiation of SEC. SEC was applied according the adult dosing schedule. The mean dose at week 0 was 192 mg/dose and at 12 months 262 mg/dose. At month three already 3 of 14 patients, at month six 6 of 10 patients and at months twelve 6 of 8 patients received 300 mg per application. Mean follow up of the patients under SEC was 6 months. JADAS 10 decreased from 8.07 at timepoint 0 to 6.35 at months 3 (n=14 patients); 5.2 at months 6 (n=10 patients) and 6.00 at months 12 (n=8 patients). The mean number of active enthesitis points decreased from 0.86 at timepoint 0 to 0.25 at months 3, 0.3 at months 6 and 0.25 at months 12. The CHAQ/HAQ score stayed stable around 0.4 during the whole observation period. No patient discontinued the treatment because of AE or SAE.

Conclusion: In this small sample of anti-TNF nonresponder patients SEC showed quite good effectiveness regarding the improvement in JADAS 10 score, at 6 months the JADAS score reached acceptable disease activity (<5.4) and the number of active enthesitis sites decreased. The 150 mg dose seemed to be not sufficient, in over half of the patients the dose had to be increased to 300 mg /dose per application.

Resurrecting Triamcinolone Hexacetonide (the Steroid Formerly Known as Aristospan®): Efficacy and Safety of a Compounded Preparation of Triamcinolone Hexacetonide for Intra-Articular Injection in Children with Arthritis

C. April Bingham¹, Lisabeth Scalzi¹, Diane Boomsma², Brandt Groh¹, Natalya Gaffney¹, Sarah Sertial¹, Timothy Hahn¹, Vincent Lacroce³ and Barbara Ostrov¹, ¹Pediatrics, Penn State Children's Hospital, Hershey, PA, ²Pharmacy, Custom Prescriptions of Lancaster, Lancaster, PA, ³Pharmacy, Penn State Milton S. Hershey Medical Center, Hershey, PA

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Pediatric Rheumatology – Clinical Poster III: Juvenile Idiopathic Arthritis and Uveitis

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Intra-articular triamcinolone hexacetonide (TH) historically provided longer-lasting control of chronic arthritis in children than comparator intra-articular glucocorticoid preparations such as triamcinolone acetonide (TA) (J Rheumatol. 2012; 39:374). Prior to 2015, pediatric rheumatologists in the U.S. commonly injected joints with TH to control oligoarticular disease or to provide adjunctive therapy to systemic treatment with methotrexate and/or biologics for polyarticular disease. Since 2015, however, TH is no longer produced or marketed in the U.S. The lack of availability of TH in the past 3 years has required use of the less-effective TA or escalation of systemic therapy. In May 2017, we were able to identify a compounding pharmacist (DB) who could produce compounded TH (cTH). We sought to determine if there was a difference in time to recurrence of swelling in joints injected with cTH versus TA.

Methods: cTH 20mg/ml is prepared with TH, USP powder, sorbitol solution 70% USP, polysorbate 80 NF, benzyl alcohol NF and sterile water for injection, USP. Testing is done as per USP 797 guidelines for sterility, potency and fungal testing. Stability testing done by Compounder's International Analytical Laboratory, and a 90 day beyond use date is established. cTH is ordered as a patient specific prescription and requires lead time for preparation and quality testing. Use of cTH caused some unique barriers. Our Pharmacy had to vet the compounding pharmacy to assure it met FDA rules and USP 797 standards for compounding sterile products. Insurance reimbursement is not consistently approved for compounded products, and reimbursement strategies had to be established. Our pharmacy created a memo to ensure injections of cTH could be performed throughout our organization. We report results of one year of using cTH in children. Demographic information, diagnoses, and prior injection data are summarized. Side effects, including steroid atrophy, are reported.

Results: 82 joints with chronic arthritis were injected with cTH from 5/2017 to 5/2018. 39 joints were injected with TA from 2/2016 to 5/2018. Flares occurred in 16 of 82 cTH joints (20%) versus 28 of 39 TA joints (72%) (p<0.001). There was no difference in time to flare from injection date with either cTH or TA for those individuals who had recurrence of joint swelling. There were no injection site reactions, bleeding, or infections with either cTH or TA. Atrophy was rare in each group.

	# Individuals	# Joints injected	# Knees injected	Recurrence	p-value	Time to flare (months) (#)	p- value
cTH	41	82	67% (55/82)	20% (16/82)	<0.001	4.7 ± 2.8 (16/82)	0.54
TA	18	39	59% (23/39)	72% (28/39)		4.3 ± 2.0 (28/39)	

Conclusion: cTH was effective in managing arthritis in children. Results were similar to that reported in the literature with fewer flares using cTH. We conclude that use of cTH is a viable approach to counter the lack of commercially available TH intra-articular glucocorticoid in the USA for pediatric arthritis patients.

Assessment of Treatment Responses, with Special Reference to Remission Using Juvenile Arthritis Disease Activity Score (JADAS), in the Different Categories of Juvenile Idiopathic Arthritis

Debanjali Sinha¹, Sumantro Mondal¹ and Alakendu Ghosh², ¹Rheumatology, Senior Resident (Academic), Kolkata, India, ²Rheumatology, Professor and Head of Department, Kolkata, India

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Pediatric Rheumatology – Clinical Poster III: Juvenile Idiopathic Arthritis and Uveitis

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Juvenile Idiopathic Arthritis (JIA) is the most common chronic rheumatologic disease in children, which can significantly compromise quality of life. The objective of the study was to assess treatment responses and remission in the different categories of JIA.

Methods: Children with JIA were treated from their first presentation in a tertiary centre according to ACR recommendations for JIA, for a duration of 18 months. Responses to treatment at the end of 18 months were monitored by change in Juvenile Arthritis Disease Activity Score (JADAS) 27 and PedACR30, 70 and 90. Remission was assessed by JADAS27, JADAS10 and cJADAS10 inactive disease state and Wallace remission criteria. Disability was quantified by CHAQ-Disability index at end of follow-up.

Results: Two hundred and twenty children with JIA were included in the study: 80 (36.3%) had Polyarticular JIA, 71 (32.2%) Enthesitis-related, 34 (15.4%) each had Systemic and Oligoarticular and 1 (0.5%) Psoriatic JIA. After 18 months, there was significant drop in mean JADAS27 (from 26.8 to 10). Inactive disease state according to JADAS27 was achieved in 13.9% children overall (13.75% Polyarticular, 15.49% Enthesitis-related, 8.82% Systemic and 17.65% of Oligoarticular JIA; no statistically significant difference between any group). JADAS27 low disease activity was achieved in 29.5% children. JADAS10 and cJADAS10 inactive disease state were achieved by 14.6% and 15.4% children respectively (Table 1). There was strong correlation between JADAS10 and cJADAS10 (Spearman's correlation coefficient at baseline and 18 months, 9.5 and 9.76, respectively). Wallace remission criteria was satisfied by 23.9% children. PedACR 30, 70 and 90 responses were achieved in 81.8%, 50.7% and 26.7% respectively. Mean CHAQ-DI at 18 months was 0.5 (0.31 Polyarticular, 0.23 Enthesitis-related, 1.37 Systemic and 0.08 in Oligoarticular JIA; significantly more in Systemic and Polyarticular JIA versus Oligoarticular). Eighteen percent children required no DMARDs (only NSAIDs and intra-articular corticosteroids), 73% one DMARD and 9% two DMARDs. Systemic steroids was required in 32.4% children overall, being significantly more in Systemic JIA (88.2%). Biologic therapy was given to 28/220 (12.7%) children, being significantly more in Systemic JIA, 15/34 (44.1%) in comparison to 7/71 (9.8%) of Enthesitis related JIA, 5/80 (6.2%) of RF +ve Polyarticular JIA and 1/34 (3%) of Oligoarticular JIA. Tocilizumab was used in Systemic JIA, Rituximab in Polyarticular JIA and anti-TNF in Oligoarticular and Enthesitis-related arthritis. At 6 months after biologics, 19/28 (67.9%) of the children achieved JADAS27 inactive state and 3/28 (10.7%) achieved JADAS27 low disease activity.

Conclusion: Remission according to JADAS27 occurred in only a minority of children with JIA, despite optimum treatment. cJADAS10 may be an effective substitute to JADAS10.

Table 1: Proportions of children inactive or low disease activity according to JADAS and Wallace remission criteria

	Polyarticular JIA	Enthesitis related JIA	Systemic JIA	Oligoarticular JIA	Overall
JADAS27 inactive disease state	13.75% (n=11)	15.49% (n=11)	8.82% (n=3)	17.65% (n=6)	13.9%
JADAS27 low disease activity state	23.8% (n=19)	26.8% (n=19)	23.5% (n=8)	44.1% (n=15)	29.5%
JADAS 10 inactive state	13.75% (n=11)	15.49% (n=11)	11.76% (n=4)	17.64% (n=6)	14.6%
JADAS 10 low disease state	23.75% (n=19)	25.35% (n=18)	20.58% (n=7)	26.47% (n=9)	24%
cJADAS 10 inactive state	13.75% (n=11)	18.31% (n=13)	11.76% (n=4)	17.64% (n=6)	15.4%
cJADAS 10 low disease state	22.5% (n=18)	21.12% (n=15)	23.53% (n=8)	17.65% (n=6)	21.4%
Wallace Remission	15% (n=12)	39.43% (n=28)	14.7% (n=5)	26.47% (n=9)	23.9%

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Pediatric Rheumatology – Clinical Poster III: Juvenile Idiopathic Arthritis and Uveitis

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: It is widely accepted that the treatment goal for juvenile idiopathic arthritis (JIA) is remission. PR-COIN, a quality improvement collaborative comprised of pediatric rheumatology centers, measures JIA disease activity in patients using the ACR provisional criteria for Clinical Inactive Disease (CID). Significant center-level differences in the percentage of patients in CID have been observed across the network. The objective of the current study was to identify differences between patient-level variables in centers with higher vs lower percentage of patients in CID, although we hypothesize that these differences are primarily driven by center-level factors rather than patient case-mix.

Methods: This study used cross-sectional data provided by PR-COIN that was collected by PR-COIN centers in the ACR Rheumatology Clinical Registry between March 2015 and May 2016. For each patient, variables from the most recent visit were recorded and included age, gender, race, insurance status, duration of diagnosis, ILAR subtype, ANA status, patient global assessment, pain score, Childhood Health Assessment Questionnaire (CHAQ) score, and current medication use. Patients were grouped into two categories based on the percentage of patients in CID at their center (above or below the network average). Statistical analyses were performed using R software, including descriptive analyses and two-group comparisons with chi-square for categorical variables and independent t-tests for continuous variables. Missing data were excluded with each analysis.

Results: There were 3806 patients eligible for analysis from 15 centers. The median center-level rate of CID was estimated at 45.6% with a range from 26.1% to 57.9%. The 7 centers categorized as “higher performing” contained 2136 patients and the 8 centers categorized as “lower performing” contained 1670 patients. Comparing patients from the “higher” vs. patients from the “lower” centers, key significant differences included race, insurance status, disease duration, patient global assessment, pain score, and current use of non-biologic DMARDs, biologic DMARDs, TNF inhibitors, NSAIDs, and glucocorticoids (see Table 1).

Conclusion: By leveraging the framework of a quality improvement learning network such as PR-COIN, we are able to determine predictors of disease activity outcomes using data from clinical practice. This analysis demonstrates preliminary differences in patient characteristics between patients at centers with higher vs lower rates of CID; more advanced modeling is needed to further evaluate these findings. Future directions include development and implementation of interventions to address identified predictors, which can then be tested and spread through the multi-center infrastructure of PR-COIN. This work has the potential to directly impact care delivery and improve outcomes for JIA.

Incidence of and Risk Factors for Adrenal Suppression Following Ultrasound-Guided Intra-Articular Corticosteroid Injection with Triamcinolone Acetonide in Juvenile Idiopathic Arthritis

Katherine K Ngo¹, Angelina Bernier¹, Melissa E Elder², Renee F Modica² and Akaluck Thatayatikom¹, ¹Pediatrics, University of Florida, Gainesville, FL, ²Department of Pediatrics, University of Florida, Gainesville, FL

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Pediatric Rheumatology – Clinical Poster III: Juvenile Idiopathic Arthritis and Uveitis

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Intra-articular corticosteroid injection (IACI) is routinely used in juvenile idiopathic arthritis (JIA) with oligoarticular disease and as adjunct therapy for other types of JIA. Adrenal gland suppression following IACI with Triamcinolone Acetonide (TA) has been scantily reported, but its incidence and risk factors are unknown. We studied 23 JIA patients following ultrasound guided IACI with TA to determine the incidence of adrenal gland suppression and risk factors for its development.

Methods: This was a case-control study of patients who satisfied ILAR classification criteria for JIA, received ultrasound-guided IACI with TA between 01/2017-04/2018, had 8AM serum cortisol levels measured 2 weeks after joint injection and had not received systemic steroid therapy for over 3 months. Case subjects were those who developed adrenal gland suppression as defined by 8AM serum cortisol level of <7 micrograms/dL. Control subjects were those who received IACI but did not develop adrenal suppression. Repeat 8AM serum cortisol levels were measured 6 weeks post-IACI in case subjects who had documented adrenal suppression initially. Incidence and risk factors including total dose of TA per body weight, age, number of injected joints and types of JIA were analyzed.

Results: Twenty-three patients, ages 2 to 21 years (mean 11.3 ± 1.09 years), with diagnoses of oligoarticular (9), polyarticular (8), psoriatic (4), and enthesitis-related JIA (2) receiving 0.43-6.8 mg/kg TA were studied. Incidence of adrenal suppression after receiving IACI was 43.5% (10/23); 5 with polyarticular JIA, 4 with oligoarticular JIA, and 1 with enthesitis-related arthritis. Total numbers of injected joints with adrenal suppression were 5 in 3 patients, 4 in 1 patients, 2 in 4 patients and 1 in 2 patients. The means of TA dose and age of patients with and without adrenal suppression were 2.986 mg/kg, 95% CI (2.116, 3.856), 8.9 years, 95% CI (5.1, 12.8) and 2.045 mg/kg, 95% CI (1.119, 2.972), 13.2 years, 95% CI (10.8, 15.7) respectively. Only significant risk factor for adrenal suppression was age ≤ 8 years (odd ratio 8.2, $p = 0.03$), but not TA dose, number of injected joints or types of JIA. Of the 10 patients who developed adrenal gland suppression, only one experienced symptomatic adrenal suppression. All patients with adrenal gland suppression at 2 weeks post-injection had normal 8AM serum cortisol levels by 6 weeks post-injection.

Conclusion: Adrenal gland suppression may be seen in JIA patients 2 weeks post IACI. Children ≤ 8 years are at most risk. The suppression is transient and spontaneously recovers by 6 weeks post-IACI. Unexplained symptoms after IACI may be a manifestation of adrenal insufficiency. Further study of risk factors for adrenal gland suppression following IACI in JIA is warranted.

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Pediatric Rheumatology – Clinical Poster III: Juvenile Idiopathic Arthritis and Uveitis

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Since MTX metabolism varies depending on age and dosage, we need to know optimal MTX administration method in children. We performed multi-center prospective study to examine the relationship between MTX dosage and safety using the concentration of MTX polyglutamates in red blood cells (MTX-PG).

Methods: This study is a part of research projects for intractable diseases supported by Health and Welfare Research Expenditure in Japan. Seven hospitals participated and received approval from each ethical review board. Forty-nine JIA patients who had been undergoing the same MTX dosage for 3 months and whose consent had been obtained were included. The total and each fragment of MTX-PG were measured by previously reported methods and calculated as concentration per administration dose per weight. The factors that may influence to MTX-PG were evaluated, such as age, dose per body (mg/m²), dose regimen (split or single), timing of the meal and combination of folic acid. In addition, we examined the presence of gastrointestinal adverse effect, and the above factors were compared in groups with and without that. The values in each group are expressed in median and 25-75% quartile. Fisher's bilateral test and Wilcoxon rank sum test were used for statistical analysis.

Results: The mean age was 10 (6-14) years old and the mean MTX dose was 7.24mg/ m²/W (5.48-8.62). The mean MTX-PG_{total} increased linearly until MTX dose reached to 10mg/ m²/W, and became a plateau. MTX administration

Table. Comparison between group with and without nausea mean (25-75% quartile)			
	With nausea (n=14, 28.6%)	Without nausea (n=35, 71.4%)	P
mean age (year)	11.5 (10-15)	9 (5-14)	0.0597
mean body mass surface (m ²)	1.28 (1.11-1.44)	1.01 (0.76-1.37)	0.0336
Male (%)	5 (35.7%)	12 (34.3%)	1.000
mean MTX (dose) (mg/W/m ²)	7.12 (5.23-8.06)	7.70 (5.48-9.45)	0.45
Single dose regimen (%)	10 (71.4%) *	30 (85.7%)	0.25
post meal regimen (%)	10 (71.4%) **	10 (28.6%)	0.0078
mean MTX-PG _{total} (nmol/L/mg/kg)	358.9 (248.4-444.3)	250.1 (202.1-410.2)	0.1993
mean MTX-PG ₁ (nmol/L/mg/kg)	150.7 (116.3-217.7)	104.3 (64.3-208.8)	0.2851
mean MTX-PG ₂ (nmol/L/mg/kg)	99.1 (80.0-125.0)	69.6 (42.2-108.3)	0.1381
Combination of folic acid (%)	7 (50%)	14 (40%)	0.54
Combination of bDMARD	10 (71.4%)	24 (68.6%)	1.000
mean JADAS 27	3.65 (0-8.3)	0 (0-0)	0.0065
mean ALT (U/L)	15.5 (12-21.5)	15 (11-21)	0.8156
mean MCV (fL)	85.3 (82.2-87.1)	86.7 (83.6-87.2)	0.2032

* Two cases were switched to split dose regimen because of nausea.

** Nine cases were switched to post meal regimen because of nausea.

Fisher's bilateral test

Wilcoxon rank-sum test

of 5 to 10 mg/ m²/W was required for effective and safe range (60 to 100 nmol/L) of MTX- PG_{total} ($y = -1.5446X^2 + 30.989X - 58.527$). The mean MTX- PG_{total} per administration dose per weight gradually increased as age rose, from 224.7 nmol/L/mg/kg in infants to 462.1 nmol/L/mg/kg in adolescents, and that was higher in split regimen group than in single regimen group (344.6 vs. 252.7, $p = 0.0216$) and higher in post meal regimen group than in pre meal regimen group (384.2 vs. 230.6, $p = 0.0043$). As for each fragment, only MTX-PG₁ and MTX-PG₂ were higher in split regimen group ($p = 0.0102$, 0.0332) and post meal regimen group ($p = 0.0072$, 0.0092). The complaint of nausea was seen more in post meal regimen group than in pre meal regimen group (52.6% vs. 13.3%, $p = 0.0078$). The combination of folic acid did not affect MTX- PG_{total}. Compared with the group without nausea, the concentration of MTX- PG_{total} and MTX-PG₁₋₂ tended to be higher in group with nausea (there was no significant difference. see Table). The group with nausea showed significant correlation with higher body surface area, post meal regimen and higher JADAS27.

Conclusion: We recommend that children be administered 5 to 10 mg / m²/W of MTX and take it singly before meal, although it is necessary to consider reduction during puberty when the MTX-PG is prone to increase and nausea is likely to occur. The MTX-PG₁₋₂ increases by post meal administration and may cause nausea.

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Pediatric Rheumatology – Clinical Poster III: Juvenile Idiopathic Arthritis and Uveitis

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Methotrexate (MTX) intolerance is common in juvenile idiopathic arthritis (JIA) and poses the risk of premature termination of an effective treatment. MTX intolerance is a compound concept of stomachache, nausea, vomiting and behavioral symptoms associated with low-dose MTX and covers anticipatory and associative symptoms. Large

inter-individual variation in the level of MTX intolerance exists and genetic factors may play a role. The objective is to investigate if MTX intolerance is associated with selected single nucleotide polymorphisms (SNPs) in MTX transporter proteins in children with JIA treated with low-dose MTX.

Methods: The local research ethics committee approved this observational study. Eligible children were diagnosed with JIA (ILAR criteria), aged ≥ 9 years and treated with low-dose MTX. The enrolment period was December 2013–July 2016. MTX intolerance was assessed by the parents' completion of the MTX intolerance severity score (MISS) (1). A child was categorized MTX intolerant if the MISS score ≥ 6 and min. 1 point in an anticipatory, associative or behavioral symptom. At enrolment a blood sample was drawn for the SNP analysis. DNA was extracted from EDTA blood using salt precipitation. The SNP analysis was performed by PCR amplifying an amplicon containing the selected SNP and then Sanger Sequencing (Eurofins Genomics). Statistic analyses for the SNPs were performed using PLINK 1.9, logistic regression of additive effect of alleles, filtering for Hardy-Weinberg equilibrium and accounting for more than two possible alleles present in the study population for one SNP.

Results: The selected SNPs within genes encoding the MTX transporter proteins were: SLCO1B1 (rs4149056; rs4149081), SLCO1B3 (rs2117032), SLC19A1 (rs1051266), ABCC2 (rs2273697; rs3740066; rs717620), ABCB1 (rs2032582; rs1045642). The study population consisted of 121 JIA patients, 82 girls and 39 boys, with a median age of 13.3 years (IQR: 11.3–15.1). The median MTX dose was 9.7 mg/m²/week (IQR: 9.0–10.9) and the median MTX treatment duration was 340 days (IQR: 142–766). A completed MISS and SNP analysis was available for 118 patients (the MISS: 1 missing; the SNP analysis: 2 missing) and 72 children were categorized as MTX intolerant.

Table 1

	SNP	Alleles Major > minor	MTX _{intolerant} Allel count	MTX _{tolerant} Allel count	OR (95% CI)	p	Gene	Chr.	BP	Consequence
Efflux	Rs2273697	G>A	36	22	1.05 (0.61–1.80)	0.87	ABCC2	10	99804058	Missense

Influx	Rs4149056	T>C	25	13	1.28 (0.62–2.66)	0.51	SLCO1B1	12	21178615	Missense
	Rs4149081	G>A	27	15	1.19 (0.59–2.43)	0.62	SLCO1B1	12	21225087	Intron variant
	Rs2117032	C>T	52	34	0.97 (0.57–1.64)	0.90	SLCO1B3	12	20921188	Downstream 3'UTR
	Rs1051266*	G>A	64	38	1.20 (0.67–2.13)	0.54	SLC19A1	21	45537880	Missense

OR; Odds Ratio. Chr; Chromosome. BP; Base Position.

*SNP variant not available for 1 child

Conclusion: MTX intolerance was not significantly associated with any of the selected SNPs in the MTX transporter proteins. This could indicate that focus in future should be directed at other genetic targets, possibly SNPs in genes encoding other MTX relevant factors.

Is Methotrexate-Induced Nausea in Juvenile Idiopathic Arthritis Influenced By Anxiety or Coping Strategies?

Nini Kyvsgaard¹, Mikael Thastum², Torben Mikkelsen¹, Anne Estmann³ and Troels Herlin¹, ¹Pediatric and Adolescent Medicine, Aarhus University Hospital, Aarhus N, Denmark, ²Department of Psychology and Behavioural Sciences, Aarhus

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Pediatric Rheumatology – Clinical Poster III: Juvenile Idiopathic Arthritis and Uveitis

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Nausea to low-dose methotrexate (MTX) is a significant clinical challenge in the treatment of juvenile idiopathic arthritis (JIA). There exists a large inter-individual variation in the level of MTX-induced nausea. Anxiety and coping strategies have been associated to nausea and vomiting induced by high-dose chemotherapy, but has not been investigated in low-dose MTX treatment of JIA. The objective is to investigate if MTX-induced nausea is associated with anxiety or coping strategies in children with JIA treated with low-dose MTX.

Methods: Children were eligible if diagnosed with JIA (ILAR criteria), aged ³9 years, and treated with low-dose MTX. If children were cognitively impaired or not fluent in Danish they were excluded. Enrolment was from December 2013 - July 2016. The anxiety level was determined using Beck's Youth Inventory – Anxiety (BYI-A) (1). Coping strategies were evaluated by a nausea coping questionnaire (NCQ)[1]. MTX-induced nausea was registered by the children's completion of a nausea diary. The local research ethics committee approved this observational study.

Results: Enrolled were 121 children with JIA (82 girls: 39 boys), the median age (IQR) was 13.3 (11.3-15.1) years. The nausea diary was completed for 1 day by 100 children and for min. 7 days by 77 children. The BYI-A and the NCQ were completed by 119 children. MTX was given orally to 45 patients (MTX_O) and subcutaneously to 76 patients (MTX_{SC}). Fifty-six children had MTX-induced nausea deduced from the diaries (MTX_O:16/27; MTX_{SC}: 40/50; p=0.051). The BYI-A raw score was higher for children with self-reported MTX-induced nausea compared to all others (Table 1). The coping strategy internalizing was used more often by children with MTX-induced nausea compared to all others. No significant associations were found for the remaining coping strategies.

Table 1

	JIA	p
MTX _O : MTX _{SC} , n	45: 76	
MTX dose, median (IQR) mg/m ² /week	9.7 (9.0 – 10.9)	-
MTX _O : MTX _{SC}	9.6 (9.0-10.7) : 9.8 (8.8-11.1)	0.86
MTX treatment duration, median (IQR) days	340 (142-766)	-
MTX _O : MTX _{SC}	261 (143-543) : 417 (134-853)	0.39
BYI-A raw score (total 0 – 60), median (IQR)	26 (22-30)	-
MTX-induced nausea: All others (Diary)	27 (23-32) : 24 (22-27)	0.0164
Coping Strategies, median (IQR)	9 (7-12)	-
Internalizing (range 5-25)	10 (8-13) : 7 (5-8)	<0.0001
MTX-induced nausea: All others (Diary)	5 (5-7)	-
Externalizing (range 5-25)	5 (5-7) : 5 (5-6)	0.29
MTX-induced nausea: All others (Diary)	15 (11-19)	-
Positive Self Statements (range 5-25)	15 (11-18) : 13 (10-19)	0.79
MTX-induced nausea: All others (Diary)	17 (13-21)	-
Information seeking (range 8-40)	17 (14-22) : 16 (14-19)	0.32
MTX-induced nausea: All others (Diary)	13 (10-16)	-
Behavioral Distraction (range 4-20)	13 (10-16) : 12 (10-18)	0.70
MTX-induced nausea: All others (Diary)	21 (18-24)	-
Cognitive Distraction (range 6-30)	21 (18-25) : 22 (20-23)	0.51
MTX-induced nausea: All others (Diary)	15 (12-20)	-
Seeking Social Support (range 6-30)	16 (13-20) : 16 (12-22)	0.50
MTX-induced nausea: All others (Diary)		

Conclusion: MTX-induced nausea was significantly associated with the coping strategy internalizing and anxiety in children with JIA. These psychological factors need attention when children with JIA commence low-dose MTX treatment, in order to intervene when appropriate.

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Pediatric Rheumatology – Clinical Poster III: Juvenile Idiopathic Arthritis and Uveitis

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Anti-adalimumab antibody (AAA) production may lead to reduced adalimumab (ADA) serum levels and therapy failure. There are, however, scarce and conflicting data regarding ADA immunogenicity in juvenile idiopathic arthritis (JIA) patients. Importantly, none of these three studies performed AAA production kinetics nor they have evaluated predictors of therapy response. Thereby, our objectives were to assess the longitudinal production of AAA and baseline risk factors for this antibody development in JIA patients initiating ADA.

Methods: From June 2010 to October 2016, 30 consecutive JIA patients under ADA therapy were prospectively followed in the biologic therapy center of Rheumatology Division of a tertiary university hospital. JIA clinical/laboratorial/treatment data and sera for ADA and AAA assays (ELISA and bridging ELISA) were obtained at baseline (BL), 2 months (2M), 3 months (3M), 6 months (6M) and 12 months (12M). Patients with therapy failure requiring ADA withdrawn had their sera evaluated at their last medical visit prior to biologic switch (blinded to ADA and AAA levels).

Results: The mean age at ADA start was 14.5 ± 5.4 years, 67% were females and the mean disease duration until biologic therapy initiation was 8.4 ± 5.8 years. Subtype distribution was 43% polyarticular subtype, 27% systemic, 20% oligoarticular, 7% enthesitis related arthritis and 3% psoriatic arthritis. In 20% patients, active uveitis was the indication for ADA. AAA was absent at BL, first detected at 2M after ADA initiation in 2/30 (7%) patients with a significant increase at 3M [10/29 (34%), $p=0.013$] and no major change in 6M [11/30 (37%)] and 12M [9/26 (35%)]. Of note, at 3M AAA levels correlated negatively with ADA levels ($r=-0.781$, $p=0.0001$). Analysis of BL predictors revealed a significantly higher risk of developing AAA in patients with female gender (odds ratio [OR] 21; 95% confidence interval [CI], 1.08-406.57, $p=0.044$), ESR >30 mm/1st hour (OR 5.44; 95% CI, 1.04-28.53, $p=0.045$) and leflunomide use (OR 9.33; 95% CI, 1.51-57.66, $p=0.016$). In contrast, concomitant use of methotrexate was protective for AAA appearance (OR 0.08; 95% CI, 0.01-0.53, $p=0.009$). At 3M evaluation, AAA positive patients showed higher disease activity parameters: patient VAS [4.5 (0-7) vs. 1 (0-5), $p=0.043$], physician VAS [3 (0-6) vs. 0 (0-5), $p=0.035$] and JADAS-71 [9.8 (0-31.8) vs. 2.7 (0-14.9), $p=0.005$]. After 12M of ADA, 60% of AAA-positive patients required drug switch for drug failure compared to 15% in AAA-negative group ($p=0.03$).

Conclusion: This study provides novel evidence of AAA production kinetics demonstrating a timely significant increase starting at 3M and stable throughout 12M. We also identified female gender, increased ESR and leflunomide use as relevant risk factors for AAA production at BL, whereas methotrexate was protective. Early systematic monitoring of AAA from 3M to 6M may therefore, guide drug switching in these patients.

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Pediatric Rheumatology – Clinical Poster III: Juvenile Idiopathic Arthritis and Uveitis

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The development of psoriasis while on TNFi is a paradoxical effect of agents that treat psoriasis and is described in larger cohorts inflammatory bowel disease (IBD) and rheumatoid arthritis. However, there is a paucity of data available on this entity in JIA. The objectives of this study were to determine the prevalence of TNFi-induced psoriasis in patients with JIA at two pediatric centers, and psoriasis response to therapy modifications.

Methods: A retrospective chart review at two pediatric institutions was performed on patients with JIA treated with TNFi (adalimumab, etanercept, infliximab) who developed psoriasis. TNFi-induced psoriasis was defined as any incident diagnosis of psoriasis after starting a TNFi. Patients with a personal history of psoriasis prior to TNFi therapy were excluded. Following diagnosis, improvement or worsening of psoriasis with medication changes were defined based on physician assessments.

Results: Twelve of 169 (7.1%) patients on TNFi for JIA were diagnosed with TNFi-induced psoriasis, including 7.9% and 6.4% at Children's Hospital of Philadelphia and Goryeb Children's Hospital respectively. All 12 cases were female, taken from a mostly female cohort (64%). The median age was 12 (range 2-18) yrs. One patient had a family history of psoriasis. Time from initiation of TNFi agents to onset of psoriasis was a median of 19 (range 7 to 40) mos. All affected patients experienced plaque psoriasis including seven (58%) with moderate to severe scalp involvement. Three (25%) patients achieved significant improvement or complete resolution of rash after switching to a different class of biologic agents while 3 (25%) patients had significant improvement or complete resolution following discontinuation of biologic therapy (and no concomitant changes to other systemic therapy). One of 5 patients who switched to a different TNFi had significant improvement, while 4 had worsening symptoms or partial improvement.

Conclusion: Our findings demonstrate the prevalence of TNFi-induced psoriasis in JIA at two centers. Based on these findings, additional larger cohort studies that adjust for confounding by indication are needed to assess psoriasis response to different treatments.

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Pediatric Rheumatology – Clinical Poster III: Juvenile Idiopathic Arthritis and Uveitis

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Average dose of methotrexate or prednisone pre- and post-initiation of etanercept in pediatric patients with continuing co-treatment

Background/Purpose: In Canada, the pediatric indications of etanercept (ETN) are active ankylosing spondylitis (AS), plaque psoriasis (PsO) and moderate to severely active juvenile idiopathic arthritis (JIA; in those who have had an inadequate response to ≥ 1 DMARDs and are ≥ 4 years of age). A previous analysis of Canadian pediatric claims data showed a 78% yearly retention rate over Year 1 for ETN, which remained high over Years 2-6 (80-90% per year). However, changes in co-medication during ETN treatment in pediatric patients have rarely been evaluated in the real-world setting.

Objective: To evaluate co-treatment utilization and ETN costs in Canadian pediatric patients initiating ETN therapy.

Methods: A retrospective study was conducted using longitudinal prescription drug claims data from the IQVIA Private Drug Plan, Ontario Public Drug Plan, and Quebec Public Drug Plan databases. Biologic-naïve pediatric patients (<18 years, with no biologic treatment in the preceding 12 months) were included if they initiated ETN during the selection period (Jan 2008-Jan 2016). Disease indications were inferred through patient drug history. Analyses of ETN doses and co-treatments were conducted in patients <17 years at index and with no missing data or drug histories indicative of conditions other than JIA, AS, or psoriatic arthritis. Weekly ETN dose was estimated for those who completed 12-month continuous ETN therapy ($7 \times [\text{mg dispensed}/\text{days between claims}]$). Co-treatments were captured for the 6 months preceding and 12 months following index. Drug costs of ETN were estimated for those <18 years who initiated ETN therapy. Editorial support was provided by Jon Edwards, PhD, of Engage Scientific Solutions and was funded by Pfizer.

Results: The study identified 391 patients <18 years old who initiated ETN and had not received a biologic in the preceding 12 months. Of these, 330 provided data for the evaluation of ETN doses, co-treatments, and cost (67% female, 39% aged 10-14 years). Among the 316 patients who completed 12 months of continuous ETN therapy, the average weekly ETN dose was 31 mg (range 14-41 mg), but varied with age. Overall, 31% (n=103) used methotrexate (MTX) before initiating ETN, with 83% (n=85) continuing MTX through the first 12 months of ETN treatment; 28% (n=92) used prednisone (PRD) before initiating ETN, with 50% (n=46) continuing PRD during the first 12 months of ETN treatment. In patients continuing co-treatment, weekly dosages were significantly reduced (Figure). The average yearly cost of ETN was \$13,671 (Canadian \$ per year).

Conclusion: This evaluation of Canadian claims data demonstrated that nearly a third of pediatric patients initiating ETN were co-treated with MTX or PRD. Many patients discontinued their co-therapies, and weekly dosages of MTX or PRD were significantly lower within the first year of initiating ETN treatment for those who continued therapy with these agents. SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Pediatric Rheumatology – Clinical Poster III: Juvenile Idiopathic Arthritis and Uveitis

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Children with one or more subtypes of juvenile idiopathic arthritis, such as enthesitis-related arthritis (ERA), often exhibit growth impairments. The purpose of the analysis was to explore the impact of adalimumab (ADA) on growth in pediatric patients (pts) with ERA.

Methods: Pts aged 6-<18 with ERA were enrolled in a phase 3, multicenter, randomized, double-blind, study. Following 12 weeks of treatment with ADA (24 mg/m² BSA up to 40 mg every other week [eow]) or placebo, pts were eligible to enroll in an open-label extension and receive ADA eow for up to an additional 192 weeks. For this analysis, all pts who received ≥1 dose of ADA were included, and pts were grouped by baseline height percentiles into 2 categories: ≤25th and >25th percentiles based on the World Health Organization (WHO) growth charts. Mean WHO percentile changes in height, weight, and body mass index (BMI) percentiles were calculated through 204 weeks. Per protocol, bone age and familial height were not collected. Growth and efficacy data were analyzed as observed.

Results: Among the 46 pts who received ≥1 dose of ADA in this study, 67% were male with a mean age of 12.9 years; no pts had associated IBD. Eleven pts (24%) were in the ≤25th height percentile, and these pts had a numerically lower baseline height (147.7 cm) and weight (42.5 kg) compared with those pts who were in the >25th height percentile (156.0 cm and 51.5 kg, respectively). Additionally, numerically higher proportions of pts in the ≤25th percentile received concomitant corticosteroids than did the >25th percentile group (54.5% vs 28.6%). Pts in the ≤25th percentile group experienced a larger change in mean height percentile through 204 weeks of ADA treatment (70.3 vs 20.5 for the >25th percentile), a finding that was evident within the first 6 months of treatment. Juvenile males in the ≤25th baseline height percentile demonstrated the numerically highest rates of growth, although similar levels of growth improvement were observed for the lowest quartile of females as well. None of the 11 pts in the ≤25th baseline height percentile remained in this category at their final study visit (Table). Similar percentile increases were observed for BMI percentiles between groups. ACR Pedi90 response rates improved over time in both ≤25th and >25th percentile groups, reaching approximately 80% at the end of 3 years treatment with ADA.

Conclusion: Long-term ADA treatment was associated with growth improvement and maintenance in children with ERA. These improvements among children in the lowest WHO quartiles at baseline may improve their quality of life and psychosocial environment. ADA treatment improved ERA signs and symptoms, regardless of baseline growth status.

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Pediatric Rheumatology – Clinical Poster III: Juvenile Idiopathic Arthritis and Uveitis

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: To estimate the impact of enthesitis on patient reported outcomes (PROs) in children with juvenile idiopathic arthritis (JIA), irrespective of their JIA category.

Methods: Children with JIA in the Research in Arthritis in Canadian Children emphasizing Outcomes (ReACCh-Out) cohort were studied. Enthesal tenderness by physician examination in 33 defined locations, Juvenile Arthritis Quality of life Questionnaire (JAQQ), Quality of My Life questionnaire (QoML), Childhood Health Assessment Questionnaire (CHAQ), and a pain severity visual analogue scale (VAS) were completed at enrolment, every six months for 2 years, and then yearly for up to 5 years. Analyses consisted of descriptive statistics, multivariate linear mixed models for longitudinal data, and ANCOVA.

Results: Among 1371 patients followed for a median of 35.3 months (IQR 21.1, 49.1), 214 (16%) had enthesitis, of whom 137 (64%) were classified as having enthesitis-related arthritis (ERA). After adjusting for patient characteristics and JIA category, children with enthesitis reported higher JAQQ (0.41 points; 95% CI 0.22, 0.59; 1=no difficulties, 7=difficulties all the time), higher CHAQ (0.14 points; 95% CI 0.07, 0.22; 0 = without any difficulty, 3 = unable to do task), higher pain (0.94 points; 95% CI 0.64, 1.25; 0 = no pain, 10 = maximum pain) and lower QoML (-0.80 points; 95% CI -1.09, -0.51; 0=the worst, 10=the best) scores than children without enthesitis, and these differences persisted during the five years after diagnosis.

Conclusion: Children with enthesitis, regardless of JIA category, report worse PROs than those without enthesitis. Physicians should assess for the presence of enthesitis in all children with JIA. Enthesitis should be considered as a criterion for classification and included in the assessment of treatment response in JIA.

Session Date: Tuesday, October 23, 2018

Session Title: Pediatric Rheumatology – Clinical Poster III: Juvenile Idiopathic Arthritis and Uveitis

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM Bone Density, Structure and Strength in Canadian Children and Youth with Juvenile Idiopathic Arthritis: The LEAP Study (Linking Exercise, Activity, and Pathophysiology in Canadian Children with Arthritis)

Authors: CM Duffy, ABaxter-Jones, L Ward, H Macdonald, H McKay, M Erlandson, AM Huber, S Benseler, M Gibbon, J Guzman, LB Tucker and the LEAP Study Investigators.

Background/Purpose: Children and youth with JIA have lower levels of physical activity (PA) than healthy children; lower levels of PA lead to bone mass deficits. The LEAP study is a prospective study, conducted at 12 centres in Canada, of children and youth with JIA, aimed at describing the trajectory of bone development and its relationship to disease factors and physical activity. Here, we compare bone density, structure and strength parameters of children and youth with JIA at study enrollment to reference standards and identify differences between newly and previously diagnosed subjects.

Methods: Inclusion criteria were confirmed diagnosis of JIA, age 10-17 years, and informed consent. Patients had either newly diagnosed JIA (< 6 months since diagnosis) or previously diagnosed JIA (> 6 months after diagnosis). Using a peripheral quantitative computed tomography (pQCT) scanner, a 2.3 mm slice was obtained at the mid-shaft of the tibia (50% site; proximal to the distal tibial end plate). Total bone area (Tt. Ar, mm²), cortical density (Ct.BMD, mg/cm³) and polar strength-strain index (SSI_p, mm³) were calculated. Appropriate reference standards were used to calculate z-scores (ZTt.AR, ZCt.BMD and ZSSI_p) and described as mean z score ± SD.

Results: Data was available on 124 subjects (66.1% female; mean age 13.3 ± 2.2 yrs); 48 newly diagnosed, 76 previously diagnosed. JIA patients, overall, had significantly lower bone area and strain index - ZTt.AR -0.67 ± 0.09, ZSSI_p -0.64 ± 0.09 but significantly greater Ct.BMD; ZCt.BMD 0.30 ± 0.10, than reference children. Bone parameters for the different JIA groups are shown (Table). There were no significant differences in bone area or strain index between the groups; however, the newly diagnosed JIA group had significantly higher cortical density. Numbers are the mean and standard deviation for age, sex and ethnicity adjusted Z-scores.

pQ CT measure (mid-tibia)	All JIA (n=124)	Newly diagnosed JIA (n=48)	Previously diagnosed JIA (n=76)	p-value (new versus previous)
Total bone area	-0.67 ± 0.09	-0.61 ± 1.14	-0.71 ± 1.05	>0.05
Cortical density	0.30 ± 0.10	0.65 ± 1.11	0.08 ± 1.10	<0.05
Strain index	-0.64 ± 0.09	-0.55 ± 1.14	-0.70 ± 1.06	>0.05

Conclusion: Children with JIA had lower tibial bone area and polar strength-strain index than appropriately matched peers but had higher cortical density. While no differences in total area or strain index were found between JIA groups, the newly diagnosed group had greater cortical density. This higher cortical density may reflect lower bone turnover, as this has been observed in other inflammatory diseases of childhood. However, it is also possible that these initial cross-sectional results suggest that cortical density may be compromised by disease over time. Longitudinal analysis of this cohort will provide a better understanding of cortical density and other included measures over time.

Validating and Developing a Selected Questionnaire to Predict Early Diagnosis of Juvenile Idiopathic Arthritis in German Population

Tristan Scheer¹, Jens Klotsche², Claudio A. Len³ and Ivan Foeldvari⁴, ¹Asklepios Campus Hamburg, Semmelweis University Budapest, Hamburg, Germany, ²Program Area Epidemiology, German Rheumatism Research Center, Berlin, Germany, ³Pediatric Rheumatology Unit, Federal University of São Paulo (UNIFESP - Universidade Federal de São Paulo), São Paulo,, Brazil, ⁴Hamburg Center for Pediatric and Adolescent Rheumatology, Hamburg, Germany

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Pediatric Rheumatology – Clinical Poster III: Juvenile Idiopathic Arthritis and Uveitis

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Juvenile idiopathic arthritis (JIA) is the most common chronic inflammatory rheumatologic disease in children and adolescents with a prevalence of 1:1000 children in Germany. An early referral of children suspected to have JIA to a pediatric rheumatologist is essential for an early diagnosis and starting treatment to reach a better outcome. An easy-to-use and time efficient questionnaire originally developed by a group led by *Claudio Len* may detect children and adolescent under risk for JIA.

Methods: The questionnaire was translated into German by *I. Foeldvari* and were distributed among patients at the first clinical visit. It includes 12 disease-orientated questions with three possible responses, either: “Yes”, “No” or “I don’t know”. A retrospective evaluation of patients diagnosed with JIA or with a non-inflammatory joint pain (NJP) was performed later on. The sample consisted of patients seen between August 2015 and July 2017. All patients were at least older than 2 years and younger than 17 years at the time of evaluation. Only fully answered questionnaires were evaluated. Subsequently, a weighting scheme of individual questions was applied in order to increase the sensitivity of the tool. Standard statistical techniques were used to find associations between the sum scores and clinical characteristics and to compare the weighted and non-weighted sum scores.

Results: In total 165 of 800 questionnaires could be evaluated for the study. 133 (81%) were diagnosed with JIA and 32 (19%) with NJP. The group of JIA patients consisted of 79 (59%) girls, whereas the control group consisted of 21 (66%) girls. The analysis of the individual questions was performed by comparing the rate of a positive response to the questions (“Yes”) between the two groups. Four questions showed a highly significant difference by comparing answers of the control group with a subgroup of JIA patients having at least one active inflammatory joint. In particular, questions regarding physical constraints ($p=0.020$; AUC= 0.62), joint pain ($p=0.040$; AUC = 0.61), swelling in the joints ($p=0.040$; AUC =0.60) and stamina ($p=0.047$; AUC = 0.60) seem to be relevant in the diagnostic approach. A weight of 3 was assigned to the first and seventh, 2.5 to the fourth and sixth, and 1.5 to the third and fifth item. The diagnostic accuracy of the respective weighted sum score increased from 64% to 68% to discriminate between patients with JIA with at least one active joint and the control group in comparison to the ordinary sum score. An optimal cutoff of 6.0 for referral to a pediatric specialist was calculated. Table 1: ROC-Analysis of the questionnaire in different groups

	Sum Score		Weighted Sum Score	
	AUC	95% CI	AUC	95% CI
JIA vs. musculoskeletal pain	0.59	0.49; 0.70	0.63	0.53; 0.74
JIA with at least one active joint vs. musculoskeletal pain	0.64	0.53; 0.75	0.68	0.57; 0.79

Conclusion: The validation of the questionnaire showed a discriminative difference in patients with clinical diagnosed JIA and a control group diagnosed with NJP. Furthermore, the weighted sum score performed better to differentiate between JIA and NJP patients. The modified questionnaire can be useful to screen for JIA and speed up the referral to a pediatric rheumatologist.

The Effects of a Gluten-Free Diet in Juvenile Idiopathic Arthritis – a Pilot Study

Anjali Sura¹, **Stacey Fogarty-Brown**² and **Meredith Riebschleger**³, ¹Pediatric Rheumatology, University of Michigan, Ann Arbor, MI, ²Pediatrics, University of Michigan, Ann Arbor, MI, ³Pediatric Rheumatology & Health Services Research, University of Michigan, Ann Arbor, MI

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Pediatric Rheumatology – Clinical Poster III: Juvenile Idiopathic Arthritis and Uveitis

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The caregivers of children with juvenile idiopathic arthritis (JIA) frequently ask about the utility of dietary restrictions. Some patients and physicians report a good response to gluten-free diets anecdotally, but the evidence to support a gluten-free diet among children with JIA is limited to 2 small case series, with a total of 8 patients.

Methods: This is a single center pilot study of a gluten-free diet in patients with JIA. Exclusion criteria were diagnoses of systemic JIA, inflammatory bowel disease, or celiac disease. All patients were screened for occult celiac disease and excluded if positive. Outcome measures include disease activity (via JADAS-27), medication changes (escalation or weaning), growth parameter changes (percentile for height, weight, and BMI), and pain. Data collection points are at enrollment, 3 months, and 6 months of the gluten-free diet. Adherence and barriers to adherence were assessed at both follow-up visits. Outcomes were compared using paired t-tests.

Results: 27 patients were enrolled in the trial. 2/27 (7%) screened positive for celiac disease (via tissue transglutaminase IgA) and were excluded from the study. The remainder of the abstract will focus on the remaining 25 patients. 80% are female. Mean age at enrollment is 13.8 years (SD 4.4 years). At baseline, 13 patients (52%) were taking NSAIDs, 11 (44%) were on DMARD therapy, and 8 (32%) were on biologic medications. To date, 12/25 patients have had their 3-month follow-up visit. Five patients (42%) have voluntarily dis-enrolled due to difficulty with the gluten-free diet. At 3 months, adherence to the diet on a 5-point Likert scale (1 = poor, 5 = perfect) was 3.8 (mean) \pm 0.27 (SEM). The majority (83%) cited social situations (such as meals at a restaurant or friend's home) as the main barrier to adherence. The next most common barrier was cost (17%). No patients chose taste or health effects of the gluten-free diet as barriers. There have been no significant differences in the patient global assessment score (GAS), physician GAS, and active joint count from the JADAS-27. There has also been no significant difference in patient pain score. Initiation of a gluten-free diet is associated with significantly lower weight and BMI.

Table 1 Characteristics of patients who have completed 3-month follow-up (n=7).

	At enrollment (mean \pm SEM)	At 3 months (mean \pm SEM)	P-value
Physician GAS	1.86 \pm 0.73	1.64 \pm 0.73	0.65
Active joint count	1.00 \pm 0.38	1.27 \pm 0.90	0.69
Patient GAS	1.79 \pm 0.42	1.50 \pm 0.58	0.73
Pain score	2.96 \pm 0.69	2.29 \pm 0.74	0.23
Height (percentile)	56.40 \pm 6.44	56.00 \pm 6.80	0.82
Weight (percentile)	65.90 \pm 7.08	61.70 \pm 7.93	0.03
BMI (percentile)	65.50 \pm 7.34	59.80 \pm 8.48	0.04

Conclusion: There is no significant difference in disease activity or pain in patients with JIA who trial a gluten-free diet at this interim point. Gluten-free diet might be useful for weight loss; however, pure gluten-free diet is difficult to maintain, as evidenced by our high disenrollment rate. Furthermore, given that 7% of patients screened positive for celiac disease in the absence of any symptoms, there may be utility in screening for celiac disease in patients with newly diagnosed JIA.

Acoustic Emissions Generated By the Temporomandibular Joint of Patients with Juvenile Idiopathic Arthritis and Their Implication on Patient Assessment and Screening: A Pilot Study

Daniel Whittingslow^{1,2}, Hyeon Ki Jeong³, Talia Gergely⁴, Lori Ponder⁴, Sampath Prahalad⁵, Omer Inan³ and Shelly Abramowicz⁶, ¹Department of Biomedical Engineering, Georgia Institute of Technology, Atlanta, GA, ²Emory University School of Medicine, Atlanta, GA, ³Electrical and Computer Engineering, Georgia Institute of Technology, Atlanta, GA, ⁴Emory University, Atlanta, GA, ⁵Pediatrics, Emory University, Atlanta, GA, ⁶Surgery, Emory University/Children's Healthcare of Atlanta, Atlanta, GA

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Pediatric Rheumatology – Clinical Poster III: Juvenile Idiopathic Arthritis and Uveitis

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The temporomandibular joint (TMJ) is one of the most commonly affected joints in juvenile idiopathic arthritis (JIA) (up to 45% of cases). There is a discrepancy between clinical signs and presence of arthritis of the TMJ, which makes recognizing TMJ involvement and effective intervention difficult. Currently, combined radiographic and magnetic resonance (MR) imaging studies of the TMJ are necessary for a formal diagnosis. These approaches are time consuming, expensive, restricted to a clinical setting, and may not show involvement until the disease has sufficiently progressed. Thus, the high prevalence and difficulty in identifying the condition justifies the development of a novel

approach for quantitatively and objectively diagnosing and monitoring diseases of the TMJ. The common finding of crepitus in an involved TMJ in patients with JIA inspired the current study. This common, but not well understood sign, led to our development of a novel, inexpensive wearable system for rapid measurement of the acoustic emissions produced during jaw movement. Here, we investigate the use of these sounds as a non-invasively measurable physiological biomarker of TMJ involvement in JIA.

Methods: We built a custom system using contact microphones inside a headset to unobtrusively capture the acoustic emissions generated by the articulation of the TMJ (Fig. 1 A, microphone circled in red). Internal friction between articulating structures of the TMJ during movement produce various frequencies of vibrations that can be detected on the surface of the skin above the joint. To determine the possibility of using these vibrations to classify and diagnose TMJ involvement 6 patients have so far been recruited. 2 of the patients have clinically-diagnosed JIA with TMJ involvement, and 4 served as healthy controls. We recorded the unique audio profile produced by each patient opening and closing their jaw at a rate of 1 cycle / 4 seconds. Several features of the joint sounds were then calculated and compared to determine if they could be used to potentially classify and diagnose the condition.

Results: The time-domain analysis of the signal shows large peaks and a chaotic signal from affected jaws, whereas the healthy jaw produces virtually no sounds with a flat signal (Fig. 1 B). Two of the signal features showing a large difference between the groups are presented (Fig. 1 C).

Conclusion: The signals recorded with our portable TMJ acoustic emission headset may serve as a novel and convenient way to differentiate between patients with affected and unaffected jaws. In this small sample, two signal features were different between patients with affected TMJs and those without. This promising preliminary finding warrants further study, recruitment, and development to determine if this measurement modality can one day serve as a means of screening patients for jaw conditions.

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Pediatric Rheumatology – Clinical Poster III: Juvenile Idiopathic Arthritis and Uveitis

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The therapeutic compliance (TC) is a major issue for the management of Juvenile Idiopathic Arthritis (JIA). The chronic nature of this inflammatory rheumatism requires a strong ability of the child to follow his treatments, where the parental involvement and the link built with the caregiver are essential. The Therapeutic Alliance (TA) measures the multifaceted caregiver-clinician relationship. We hypothesized, that in JIA, TA, that describes the relationship between the child and his (her) therapist, should be a key factor of TC. The aim of this study was to evaluate the link between TA and TC in a large JIA cohort.

Methods: Observational, cross-sectional, multicenter study, in 13 reference centers in France. During a routine consultation, the physicians, rheumatologists or pediatricians, distributed questionnaires to both the children and their parents. Each child, his (her) parents and the physician completed the HAQ-CP TA questionnaire, assessing TA. TC was measured through the Child Adherence Report Questionnaire (CARQ), the Parent Adherence Report Questionnaire (PARQ) and the Morisky questionnaire. Children aged 6 to 18 were included. The treatments, their tolerance, the disease activity and the socio-professional environment of the parents were collected. The univariate relationship between TA and TC, were studied by Pearson correlation coefficient. The multivariate analysis used a multiple linear regression model. 105 patients had to be included to highlight a relationship with a power of 90% at risk alpha 5%.

Results: 119 children (70% girls), age (SD) 12.4 (2.9) were included. The JIAs were oligoarticular (28.6%) or polyarticular (type). The mean disease duration was 73.1 (48.2) months. TA scores were high for parent (86/100), child (84/100) and therapist (80/100). There was a significant correlation between the child's TA and TC ($r=0.31$; $p=0.0009$) and between that of the parent and the child's compliance ($r=0.37$; $p<0.0001$). About factors influencing TC, lifestyle in rural areas was statistically associated to a better adherence ($p=0.0229$) whereas female sex was a factor of poor compliance ($p=0.04$). A poorer child's TA was found when the disease was active ($p=0.048$), when the parents were divorced ($p=0.01$) and in case of sub-urban than in case of rural residence ($p=0.004$). For the parent, TA varied according to the JIA sub-group ($p=0.003$), with lower TA in polyarticular JIA ($p=0.005$). For the therapist, TA varied according to the JIA sub-group with poorer TA in extended polyarticular JIA ($p=0.0326$). A poorer TA was observed when the disease had been evolving for a long time ($p=0.0008$) and the follow-up was long ($p=0.004$).

Conclusion: In JIA, the treatment compliance is highly related to the therapeutic alliance between the child and his (her) therapist. However TA varied widely according to the disease specificities and the child's lifestyle. This must be known by rheumatologists and pediatricians, to improve the adherence to treatment.

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Pediatric Rheumatology – Clinical Poster III: Juvenile Idiopathic Arthritis and Uveitis

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with Juvenile Idiopathic Arthritis (JIA) face physical, social, and emotional issues that affect their quality of life. Health-related quality of life (HRQoL) is a multidimensional construct including those issues and other influences of illness on well-being. Previous validation studies found that JIA patients have lower HRQoL compared to healthy peers. We investigated perceptions of HRQoL based on assessments completed by children and their caregivers at a large referral center. We obtained HRQoL data as an initial phase of a larger project striving to educate school nurses and staff at a large urban school district.

Methods: We assessed HRQoL with the PedsQL 4.0 Generic Core Scale (assesses physical activity, emotional, social, and school functioning) and the PedsQL 3.0 Arthritis Module (measures pediatric rheumatology-specific HRQoL: pain and hurt, daily activities, treatment, worry, and communication). Both surveys have age-specific, validated forms (Ages 5-7, 8-12, and 13-18). After IRB approval, we enrolled a 3-month convenience sample of English speaking JIA patients ages 5 to 18, and caregivers who presented to an outpatient clinic. For each survey we calculated subscale and total score means. Higher scores indicated a better HRQoL. We used descriptive and inferential statistics (Pearson correlation, one-way ANOVA and one sample t-tests) to explore HRQoL data in JIA patients. Results were compared to validated healthy control normative values.

Results: Seventy-nine JIA patients and caregivers completed the surveys. Demographic data included patient age (mean 12.05 ± 3.73), gender (female 68%), ethnicity (49% White or Non-Hispanic, 25% Hispanic). Patient JIA classification included: Polyarticular 46.8%, Oligoarticular 30.4%, Psoriatic 8.9%, Systemic 7.6%, and Entesitis-related 6.3%. The cohort mean total score (72.27) was significantly lower than the previously validated total score for of 83.9 for healthy children (95% CI -15.6 to -7.6; $p < .001$). There were modest, mostly negative and at times significant correlations between age and HRQoL domain scores (Table 1). Statistically significant differences in Physical health, Total score (PedsQL 4.0), Daily Activities and Worry (PedsQL 3.0) were driven by lower scores of children with Polyarticular JIA. These differences appeared independent of age and gender.

Table 1: Child PedsQL 4.0 Generic and PedsQL 3.0 Arthritis Module Domain Scores

		Mean (SD)	Correlation with Age	Significance (2-tailed)
Peds QL 4.0-Generic	Physical	72.60 (20.19)	-.386**	<.01
	Emotional	73.45 (22.45)	-.209	NS
	Social	77.41 (22.50)	-.043	NS
	School	64.99 (23.43)	-.221	.05
	Psychosocial	71.95 (19.87)	-.182	NS
	Total	72.27 (17.90)	-.318**	<.01
Peds QL 3.0-Arthritis	Pain and Hurt	64.82 (27.13)	-.234*	.04
	Daily Activities	90.40 (14.98)	-.111	NS
	Treatment	70.19 (20.55)	.246*	.03
	Worry	67.30 (29.50)	.268*	.02
	Communication	68.67 (24.83)	-.137	NS

Bolded values are below total mean score

* Correlation is significant at the 0.05 level (2-tailed).

** Correlation is significant at the 0.01 level (2-tailed).

NS: Not significant

Conclusion: As per previous studies, PedsQL scores in JIA patients were significantly lower than healthy norms. These differences may be accentuated in older children and polyarticular subtypes. Disease activity factors will be assessed at the completion of cohort data collection. We will use PedsQL data to train public school nurses about the impact of JIA on HRQoL. QoL interventions may depend on age groups, and may constitute an additional parameter in the management of children with rheumatic diseases.

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Pediatric Rheumatology – Clinical Poster III: Juvenile Idiopathic Arthritis and Uveitis

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Pediatric chronic non-infectious uveitis can lead to ocular complications and vision loss. The ophthalmic clinical exam is primarily used to assess uveitis outcomes but may be imprecise since it may not reflect changes in quality of vision and effects of vision impairment. Our goal is to provide a comprehensive assessment of the impact of uveitis on health-related quality of life (HRQOL), mental health, visual function, and vision-related QOL in children with JIA-associated uveitis (JIA-U).

Methods: We reviewed records of 79 children (26 JIA alone, 29 JIA-U, 24 other uveitis types). Parents and patients completed questionnaires on general QOL (Pediatric Quality of Life Inventory- PedsQL), depression and anxiety (Revised Children Anxiety and Depression Scale-RCADs), and visual function and vision-related QOL (Effect of Youngsters Eyesight on QOL-EYE-Q). The EYE-Q has items assessing both visual function (i.e. near, far, color, and night vision) and vision-related QOL (i.e. medication use, school absences, and lab draws). We used Wilcoxon Rank-Sum tests to compare disease groups: 1) children with JIA vs. JIA-U, and 2) children with JIA vs. uveitis of all types.

Results: Of 79 children, most were non-Hispanic (88%), Caucasian (66%), females (70%) (Table 1). Among uveitis patients, most had bilateral (70%), anterior (83%) disease with complications (70%). Children with JIA-U had worse EYE-Q total scores compared to those with JIA alone for Parent reports (median 1.25 vs. 1.15, $p=0.007$). (Table 2) However, there were no differences in the scores of the EYE-Q by child report, RCADS, or PedsQL.

Children with all forms of uveitis (JIA-U and other uveitis types) had worse EYE-Q total scores compared to those with JIA alone by Parent (median 1.25 vs. 1.15, $p=0.001$) and Child reports (1.29 vs. 1.17, $p=0.009$). (Table 2) Results were similar when comparing visual function and vision-related QOL sub scores from the EYE-Q. Child reported PedsQL scores in patients with JIA alone were worse than those with uveitis (80.4 vs. 87, $p=0.023$).

Conclusion: This is one of the first assessments of children with JIA-U to incorporate HRQOL, mental health, visual function, and vision-related QOL. We demonstrate the impact of eye disease as children with uveitis had worse vision-related function and QOL compared to children with JIA, but similar general HRQOL and mental health. Uveitis-specific measures like the EYE-Q may reveal disease-related impairments that affect QOL and are not quantified using general measures. An approach that integrates all aspects of disability should be considered.

Clinical Presentation, Management and Long Term Outcome of Pars Planitis (PP), Panuveitis (PU) and Vogt–Koyanagi–Harada Disease (VKH) in Children and Adolescents

Andreas Reiff, Children's Hospital of Los Angeles, Los Angeles, CA

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Pediatric Rheumatology – Clinical Poster III: Juvenile Idiopathic Arthritis and Uveitis

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Chronic uveitis is a common manifestation of pediatric rheumatologic conditions and may result in irreversible blindness and long term disability. While chronic anterior uveitis is the most commonly encountered ocular manifestation of rheumatic disease, little is known about the clinical presentation, management and long term outcome of more complex eye conditions such as pars planitis (PP), panuveitis (PU) and Vogt–Koyanagi–Harada disease (VKH).

Methods: We retrospectively reviewed a cohort of 75 children and adolescents with idiopathic PP (50), PU (12) and VKH (14) followed by the Pediatric Rheumatology Core at Children’s Hospital Los Angeles and evaluated referral patterns, clinical presentation, treatment response and long term clinical outcome.

Results: The mean age at disease onset was 10 years and patients were followed for an average of 52 months. The average referral time to a pediatric rheumatologist was 13 months (range 1-96 months). Bilateral eye involvement was seen in 87% of the patients, glaucoma was present in 21% and vision loss (<20/40) was present in 87% of the patients at first presentation. Legal blindness (<20/200 or less in the better-seeing eye) was diagnosed in 18% of the PP, 36% of the PU and 21.5% of the VKH patients at first presentation. Topical steroids were used in all patients, but 98% of the patients required additional DMARDs and 73% required therapy with biologics. After a mean of 52 months, 35% of patients across all disease groups had significant vision loss or were blind, while only 28% were in clinical remission off drug. The worst outcome was observed in children with panuveitis. Earlier referral to a pediatric rheumatologist and earlier initiation of DMARD/biologic therapy clearly correlated with better outcome.

Conclusion: PP, PU and VKH have a high risk of permanent vision loss and should be managed as early and as aggressive as possible by a skilled rheumatologist.

Session Title: Pediatric Rheumatology – Clinical Poster III: Juvenile Idiopathic Arthritis and Uveitis

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Uveitis is the most common extra-articular manifestation of juvenile idiopathic arthritis (JIA), often entirely asymptomatic but could be sight-threatening. The most often prescribed biologics in JIA patients without eye involvement is etanercept, which has not effective the uveitis control. Due to known information about new onset of uveitis during etanercept treatment the question about the role of etanercept in new onset of uveitis is still open. The aim of our study was to evaluate the risk of new onset of uveitis in JIA during different types of treatment.

Methods: The clinical charts of all consecutive patients (n=413) who had received a stable management for at least 2 years with or without MTX or etanercept were reviewed. Patients who were given systemic corticosteroids were excluded. Patients with systemic arthritis, rheumatoid factor-positive arthritis, or enthesitis-related arthritis were also excluded. In each patient, the at least 2-year follow-up period after first visit was examined to establish whether uveitis had occurred. All patients according the treatment were divided in 3 groups: i) patients, who received only NSAID and/or intraarticular corticosteroids (IAC) – “no MTX” group; ii) patients who treated with MTX (NSAID and IAC were allowed) – “MTX” group; iii) patients, who treated with etanercept (with or without MTX) – “etanercept” group. For statistical analysis we utilized Cox’s regression models, Log-Rank test, x2 test and Mann-Whitney test. Data are presented by median and interquartile range.

Results: Data of comparison three lines of treatment are presented in the table. In the comparison of treatment curves there was a differences in probability of new onset of uveitis ($p=0.00001$). There were no differences in the time before uveitis in three groups ($p=0.45$). After paired comparison of the treatment arms, there were no difference between “MTX” and “Etanercept” groups $RR=1.47$ (0.54-4.0), $p=0.46$ and were differences between “No MTX” vs “MTX” $RR=4.0$ (2.4;6.7), $p=0.00001$ and “No MTX” vs “Eta” $RR=2.0$ (1.2;3.3), $p=0.002$. After adjustment on ANA status, oligoarticular disease course and JIA onset age <5 years we found out differences. For ANA positive patients $RR=3.2$ (2.0; 5.3), $p=0.000001$, LogRank test $p=0.048$ compare to ANA-negative persons. In the regression models “No MTX” vs “MTX” $RR=3.8$ (2.1; 6.7), $p=0.000006$, “No MTX” vs “Eta” $RR=2.3$ (1.2;4.2), $p=0.01$; “MTX” vs “Eta” $RR=2.2$ (0.6;7.8), $p=0.206$. For patients with oligoarticular disease course $RR=2.9$ (1.9;4.6), $p=0.000002$, LogRank test $p=0.005$. In the regression models “No MTX” vs “MTX” $RR=3.7$ (2.2;6.4), $p=0.000001$, “No MTX” vs “Eta” $RR=1.9$ (1.1;3.2), $p=0.02$; “MTX” vs “Eta” $RR=1.3$ (0.46;3.5), $p=0.65$. For JIA patients less than 5 years $RR = 2.8$ (1.9;4.4); $p=0.000002$, LogRank test, $p=0.18$. In the regression models “No MTX” vs “MTX” $RR=3.6$ (2.1;6.0), $p=0.000002$, “No MTX” vs “Eta” $RR=2.0$ (1.2;3.3), $p=0.006$; “MTX” vs “Eta” $RR=1.4$ (0.5;3.9), $p=0.5$.

Conclusion: The incidence of new onset of uveitis in the etanercept group is the lowest and compare to JIA patients treated with MTX. More likely new onset of uveitis is related to JIA pathogenesis rather etanercept treatment. Further investigation and randomized controlled trials required.

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Pediatric Rheumatology – Clinical Poster III: Juvenile Idiopathic Arthritis and Uveitis

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Children with JIA are at increased risk for uveitis. Known risk factors do not accurately stratify risk. Biomarkers are needed to predict uveitis development in JIA. Aqueous humor (AqH) has been studied, but the clinical application is limited by the invasive nature of collection. Analysis of tears is a non-invasive approach to better identify children with JIA who are most susceptible to uveitis. Our objective is to compare the tear profiles of children with JIA-associated uveitis (JIA-U) to JIA without uveitis (JIA) for the presence of cytokines and chemokines reported in the AqH of adults and children with uveitis.

Methods: Tears were collected from 16 children with JIA-U and 16 with JIA who were ≥ 5 years old using Schirmer strips. Cytokine and chemokines reported in the AqH of children with uveitis (IL-18, IL-8/CXCL8, IP-10/CXCL10, MCP-1, RANTES/CCL5, and sICAM-1) were determined using Milliplex™ Multiplex kits (MilliporeSigma, Darmstadt, Germany). A mixed model approach was used where each cytokine outcome is modeled as a function of diagnosis to compare the tear profile of children with JIA to JIA-U.

Results: There were 29 samples from 16 children with JIA-U, and 32 samples from 16 children with JIA. We did not include the unaffected eye of children with JIA-U in the analysis. Children were primarily Non-Hispanic (93%), White (91%), females (78%) with oligoarticular (72%) or polyarticular rheumatoid factor (RF) negative (28%) JIA. JIA was diagnosed in children with JIA alone at a mean age of 6.7 years (SD 4.2), and in children JIA-U at a mean age of 5.1 years (SD 3.8) (Table 1). Uveitis was diagnosed at a mean age of 6.3 years (SD 4.2). Levels of IL-8, IP-10, and RANTES were significantly increased in JIA compared to JIA-U ($p<0.05$) (Table 2). MCP-1 was significantly increased in JIA-U compared to JIA ($p<0.05$).

Conclusion: In this pilot study, we detected cytokines and chemokines in the tears of children with JIA and JIA-U that were previously identified in AqH. We provide evidence of differences in the tear profile of children with JIA-U and JIA that may differentiate those who develop uveitis. If tears can reflect uveitis activity, similar to AqH, it may be a promising biospecimen for uveitis studies. Use of tears could lead to the discovery of biomarkers for the early detection of uveitis and better prediction models for uveitis onset. Studies in larger cohorts are needed.

Table 1 Characteristics of children with JIA alone and JIA-associated uveitis, N (%) unless indicated

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Pediatric Rheumatology – Clinical Poster II – ARHP

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Adherence to DMARDs such as methotrexate and biologics is critical for patients with Juvenile Idiopathic Arthritis (JIA). Notwithstanding, few studies exist on that topic and we lack information to understand the grounds for adherence.

The RUMAJI study aims, among others, to understand and decipher the parents and children adherence mechanisms and practices.

Methods: Qualitative methods were chosen in order to investigate parents' and children's everyday life with JIA and its treatment. An ethnographic study was designed by a multidisciplinary team including rheumatologists, pediatricians, patient associations members and anthropologists. Parents, children and doctors were interviewed. The study involved 6 doctors (3 paediatricians and 3 rheumatologists) and 15 families (enough to reach saturation), recruited from 5 centers, by diversity of clinical and sociological profiles. The panel included 17 children with JIA, 11 girls and 6 boys, median age 10 [3; 17], median disease duration 2.5 [1; 15]. 4 children were treated with conventional DMARDs in monotherapy, 4 with biologic DMARDs in monotherapy, 5 with cDMARDbDMARD association and 4 with NSAIDs only.

Doctors interviews were conducted first. Parents and children interviews were conducted by anthropologists at family's home using in depth semi directive and biographic methods. 3 fields were explored: organization of everyday life with JIA, treatment practices, impact on school and social activities. Interviews were recorded and transcribed for analysis.

Results: Adherence results from an appropriation process of the JIA and treatment that require both an active role from parents and children, even before the transition. The setting of a partnership-based doctor-children-and-parents relationship has also a positive effect in the family active role. The active role played by children could be either stimulated or inhibited at home according to the family's structure, social background, parents' attitudes toward their child (participation to the decision, explanation of the disease). Children's active role includes in particular: 1) negotiations with parents and physicians, 2) experiments with the treatment (forgetting or involuntary switch from the parents, changing the dosage on their own initiative) and 3) participation to the treatment administration and ritualization.

The manner children consider and manage their DMARDs is the result of an arbitration depending on the positive (a) and side effects (b) they felt in their body and the effects noted by the doctors (c) during the examinations and test results. Dealing with these 3 dimensions requires to link together both a theoretical and practical knowledge of JIA. Thus, children build their own and singular knowledge of their disease and treatment, which is a source of control of their body and their life.

Conclusion: Qualitative methods, through an ethnographic study starting from children, parents and doctors point of view, underline the active role they played by children in their care. Adherence to DMARDs could be improved by supporting children's implication as soon as the beginning of JIA.

Abstract Number: 2410

Determining the Need for Fatigue Management Resources for Young Adults with Rheumatic Disease

Kristine Carandang¹ and Janet L. Poole², ¹Chan Division of Occupational Science & Occupational Therapy, University of Southern California, Los Angeles, CA, ²Health Sciences Ctr OT Program, University of New Mexico, Albuquerque, NM

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Pediatric Rheumatology – Clinical Poster II – ARHP

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Fatigue is a multi-faceted symptom of rheumatic disease that has high priority among patients due to its far-reaching effects on roles and relationships. There is a paucity of resources around the impact of fatigue as experienced by young adults, who are often making decisions around career and family that lay the foundation for their

adult lives. Therefore, the purpose of this study was to determine fatigue impact, gaps in young adult patients' knowledge on fatigue, and preferences for format and content of future fatigue resources.

Methods: Questionnaires and semi-structured interviews were conducted with young adults (18-30 years old) recruited via social media, who self-reported rheumatic diagnoses and had combined fatigue scores of 12+ on the first 3 questions of the Multidimensional Assessment of Fatigue (MAF) Scale. Pregnant women were excluded. The full MAF, PedsQL Multidimensional Fatigue Scale, and Functional Assessment of Chronic Illness Therapy-Fatigue (FACIT-F) assessed fatigue impact and experiential components of physical, emotional, and cognitive fatigue. Interviews focused on perceptions of fatigue, strategies to manage fatigue, and preferences for educational resources. Quantitative data were analyzed descriptively; qualitative data were analyzed using constant comparative analysis.

Results: Participants were 10 women (27.0 ± 2.8 years old), had varying diagnoses (e.g. JIA, MCTD, SLE, PsA, Scleroderma), were a majority white (70%), and all employed (100%) with some part-time school enrollment (40%). Participants were significantly impacted by their fatigue, scoring one standard deviation from established patient norms on all surveys (MAF= 38.1 ± 7.0 ; PedsQL= 40.1 ± 13.8 ; FACIT-F Emotional Well-Being= 14.4 ± 4.5). All participants reported the need for additional information about fatigue at diagnosis; participants were not prepared for the chronicity of fatigue and its effects on daily life. Current fatigue management strategies were developed through trial-and-error with limited support from healthcare teams. Participants felt professional recommendations were often non-specific to fatigue, too basic (e.g. take naps), or were un-relatable to their financial situations and high stress environments (e.g. school, work, motherhood). Participants desired more information about the epidemiology and physiology of fatigue and strategies specific to activities of young adults (e.g. having energy to socialize after work). While most participants agreed that information was more helpful from fellow patients rather than providers, there was discussion about how to combine both sets of expertise using innovative online tools.

Conclusion: Young adults reported that fatigue significantly impacted their participation in desired activities. As such, resources should be tailored to developmental concerns especially within contexts of early careers and family life. While non-pharmacological interventions are shown to be efficacious in reducing fatigue for persons with rheumatic disease, future research should assess the relevance of these interventions in addressing specific needs of the young adult population.

The Ovarian Reserve Measuring the Anti-Müllerian Hormone Is Not Diminished in Patients with Rheumatoid Arthritis Compared to the Healthy Population

Mireia López-Corbeto¹, Sara Marsal¹, Andrea Pluma², Sergio Martinez², Maria Lopez-Lasanta², Agusti Sellas-Fernandez², Juan José de Agustín² and Mireia Barcelo², ¹Rheumatology Research Group, Vall d'Hebron Hospital Research Institute, Barcelona, Spain, ²Vall d'Hebron Hospital Research Institute, Barcelona, Spain

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Reproductive Issues in Rheumatic Disorders Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid Arthritis (RA) is the most prevalent chronic inflammatory arthritis, affecting 0.5-1% worldwide population and predominates in females. Altered fertility has been reported due to a decrease in ovarian reserve secondary to sustained inflammation. The anti-Müllerian Hormone (AMH) is currently the most reliable biomarker of ovarian reserve. However, few and contradictory studies have been reported to analyze the relationship between fertility in RA women patients and AMH. The aim of present study is to determine the AMH serum concentrations in a long-standing RA patients and control group. We also sought to determine the correlation between AMH serum levels and disease activity measured by different parameters and the effect of biological DMARDs.

Methods: Serum AMH levels were measured in 60 women with long-standing RA aged 20-50 y.o. and compared to 59 healthy women. AMH was assessed by ELISA (*Gen II Beckman Coulter Inc.*) and a large data set of clinical and molecular data was annotated. Demographic parameters, RA disease activity measured by DAS28 score and inflammatory biomarkers such as ESR, CRP, lymphocyte CD4+, CD8+, NK cells, IL-10 and IL-6 were determined. A comprehensive gynecological self-administered questionnaire was given. Serum AMH levels were age-correlated. Differences between groups were calculated using Student's t-test or Mann-Whitney U test for continuous variables and Fisher's exact test for categorical

variables. Multivariate analysis was conducted by the partial correlation coefficient. Linear regression analysis was performed to study the effect of different variables on proportional AMH change. *P* value <0.005 were considered significant.

Results: The median age was similar in AR and control groups (37.4 ± 6.23 vs 37.3 ± 6.27 $P=0.937$). Mean disease duration was 8.37 ± 5.36 years. The number of previous treatments was <3 in 71.7% of patients and ≥ 3 in 28.3%. Disease activity measured by DAS28 was 2.89 ± 1.54 . The age-adjusted mean serum concentration of HAM was 1.27 ng/ml [IQR 0.42; 2.24] in RA patients and 1.31 ng/ml [IQR 0.46; 3.09] in controls ($P=0.608$). Neither disease activity ($P=0.862$), nor current or previous bDMARDs treatments ($P=0.871$) were associated with HAM levels. However, a negative linear correlation was observed between HAM and IL-10 levels ($P=0.033$).

Conclusion: Our study shows that ovarian reserve determined by HAM serum levels is not reduced in rheumatoid arthritis patients compared with healthy controls. In our series, HAM levels were not affected by disease activity however a significant correlation was observed between HAM and IL-10 levels. These results support the role of cytokines profile in the female reproductive system and will focus further investigations in this critical area, mainly once biological DMARDs have been recommended in RA pregnant patients.

Evaluating Gaps in Reproductive Health Knowledge Among Women with Rheumatic Diseases

Mehret Birru Talabi¹, Megan E. B. Clowse², Susan J. Blalock³, Lan Yu⁴, Alaina Chodoff⁵ and Sonya Borrero⁴,
¹Rheumatology and Clinical Immunology, University of Pittsburgh School of Medicine, Pittsburgh, PA, ²Department of Medicine, Division of Rheumatology and Immunology, Duke University, Durham, NC, ³Eshelman School of Pharmacy, University of North Carolina at Chapel Hill, Chapel Hill, NC, ⁴Medicine, University of Pittsburgh, Pittsburgh, PA, ⁵General Internal Medicine, UPMC, Pittsburgh, PA

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Reproductive Issues in Rheumatic Disorders Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: While women with rheumatic diseases may face considerable reproductive health challenges, few studies have objectively assessed what these women know about their reproductive risks. This study evaluates patients' knowledge across a range of topical domains, including heritability, preconception health, contraception, fertility, pregnancy management, medication risk, and lactation.

Methods: With input from rheumatologists, women's health experts, a pharmacist, and survey methodologist, we created a 10-item test to evaluate patients' knowledge (ReproKnow). Women aged 18-50 years old were recruited to take ReproKnow and a demographic survey immediately after their physician visit at a participating rheumatology clinic. Descriptive statistics were used to summarize sample characteristics. Each question was scored as correct (1) or incorrect (0). Independent sample t-tests were used to evaluate the associations between total knowledge score and age, race, education, family characteristics, and clinical factors. Questions were grouped into domains based on their conceptual relationships, and mean percentages of correct answers were calculated within these domains.

Results: Our sample included 153 women who were 38.3 years old on average (S.D. 8.2) and predominately white (77%). Half (50%) had attained at least a secondary level of education. Patients' mean total knowledge scores were 5.0 (SD 2.2), with a median of 5.0 (range 0-10). Women who were younger, white, had higher education levels, or had experienced pregnancies after rheumatic disease diagnosis, had higher total knowledge scores ($p<0.05$).

When assessed by reproductive health topics, women were least likely to correctly answer questions about the safety of breastfeeding (28.8% correct) or the frequency of birth defects among children born to mothers with rheumatic diseases (30.8% correct). Approximately 50% of women correctly answered questions about fertility, contraception safety and efficacy, preconception planning, and medication risk.

Conclusion: Our study suggests that some women with rheumatic diseases have significant knowledge gaps about aspects of their reproductive health. Future work is needed to assess how knowledge may influence informed reproductive decision-making, behaviors, and outcomes in this high-risk group of women.

	% Correct	% Correct (Down)
Heritability		
1. Moms with autoimmune diseases pass their diseases on to their children (A: Sometimes)	75.8	75.8
Birth Outcomes		
1. If I have an autoimmune disease, my baby's chances of being born with a birth defect are (A: Low)	32.7	38.8
2. If I am pregnant and have a disease flare, my baby may be (A: Born too early)	28.8	
Fertility		
1. Most women with autoimmune diseases can get pregnant as easily as other women (A: Yes)	51.6	51.6
Contraception		
1. Can most women with autoimmune diseases use birth control safely? (A: Yes)	54.7	55.0
2. Which type of birth control is the best at preventing pregnancy? (A: Intrauterine device (IUD))	41.2

Session Title: Reproductive Issues in Rheumatic Disorders Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Mixed connective tissue disease (MCTD) is characterized by signs and symptoms of a combination of disorders, primarily systemic lupus erythematosus (SLE), scleroderma and polymyositis and is characterized by the presence of high titre antibodies to U1-ribonucleoprotein (RNP).

When planning a pregnancy in patients with connective tissue diseases, ENA profiling is suggested but generally refers to testing for maternal antibodies specifically to components of the SSA/Ro-SSB/La ribonucleoprotein complex since these have been associated with foetal cardiac conduction abnormalities and neonatal skin rashes. Nevertheless, little is known about the maternal and foetal pregnancy outcomes in women with the presence of anti-U1RNP antibodies absent reactivity to SSA/Ro-SSB/La.

Methods: Data was retrospectively collected from S. Giovanni Bosco Hospital and Sant' Anna University Hospital, Turin, Italy, the Lupus Unit, Department of Rheumatology at St Thomas' Hospital, London, UK, Hospital das Clínicas da Faculdade de Medicina da Universidade de Sao Paulo, Sao Paulo, Brazil, Hospital Reina Sofia de Córdoba, Spain, ASST Spedali Civili di Brescia, Brescia, Italy.

Patients Characteristics		All (94)	%
Age at data collection, mean (S.D.), years		45,1 (±10,9)	
Ethnicity			
	Caucasian, n	64	68,1
	Black, n	9	9,6
	Asian, n	4	4,3
	Other, n	17	18,1
Diagnosis			
	MCTD	94	100
Disease duration at data collection, mean (S.D.), years		12,3 (±8,5)	
	MCTD and APS	13	13,8
	MCTD and APS	6	6,4
Clinical manifestations			
	Hematological, n	36	38,3
	Skin, n	57	60,6
	Joints, n	65	69,1
	Cardiac, n	10	10,6
	Bone, n	9	9,6
	Muscular, n	31	33
	Raynaud, n	56	59,6
	Pulmonary, n	27	28,7
	Neurological, n	6	6,4
Cardiovascular risk factors			
	History of smoking, n	10	10,6
	Arterial hypertension, n	13	13,8
	Hypolipidemia, n	11	11,7
	Diabetes, n	2	2,1
Laboratory testing			
	Hypocomplementemia (C3), n	28	29,8
	Hypocomplementemia (C4), n	25	26,6
	anti-dsDNA positive, n	12	12,8
	Hypergammaglobulinemia, n	47	50

Inclusion criteria included: Women ever pregnant who fulfilled the established criteria of MCTD with confirmed anti-U1RNP positivity.

Results: This multicentre retrospective cohort study describes the foetal and maternal outcomes of 203 pregnancies in 94 consecutive women ever pregnant (mean age at data collection 45.1 years old, S.D. 10.9; mean disease duration at data collection 12.9 years, S.D. 8.5). Demographic, clinical and laboratory characteristics are summarized in Figure 1. Of the 203 pregnancies analysed the foetal outcomes were as follows: 146 (71.9%) resulted in live births, 38 (18.7%) in miscarriages, 18 (8.9%) in stillbirths (after 20 weeks gestation) and eleven (5.4%) cases showed intrauterine growth restriction (IUGR). Maternal pregnancy outcomes were as follows: eight (3.9%) cases developed pre-eclampsia, two (0.9%) cases developed eclampsia, 31 (15.3%) women developed gestational hypertension and three (1.5%) cases were diagnosed with gestational diabetes. Moreover, we report a case of complete congenital heart block (0.45%) and a case of skin rash in consecutive offspring born to a mother with anti U1RNP antibodies in the absence of anti-Ro/SSA-SSB/La antibodies.

Conclusion: The observed live-birth-rate was as high as 72%, with poorer foetal outcomes observed in MCTD women with anti phospholipid antibodies and pulmonary or muscular involvement. While the true frequency of heart block associated with anti-U1RNP remains to be determined, this study raises the consideration of echocardiographic surveillance in this setting. Women with MCTD should receive a specific counselling when planning a pregnancy, as it is currently done in women with SLE.

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Reproductive Issues in Rheumatic Disorders Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) and antiphospholipid antibodies (aPL) are associated with pregnancy complications.

Methods: 143 women ever pregnant with SLE who presented in our outpatient clinic were included. The individual GAPSS was calculated for each patient by calculating the sum of each risk factor score, as follows: three for hyperlipidaemia, one for arterial hypertension, five for aCL IgG/IgM, four for anti-b2 glycoprotein I IgG/IgM, 3 for anti-phosphatidylserine/prothrombin antibodies (aPS/PT) IgG/M and four for lupus anticoagulant (LA).

Results: Significantly higher GAPSS values were seen in patients with the following pregnancy history when compared to those without a history of pregnancy complications: any pregnancy complication (mean GAPSS 8.4, S.D. 4.5) vs. no pregnancy complication (mean GAPSS 3.1, S.D. 2.6, mean difference 5.2, t-test: $p=0.000$, 95% CI 4.0-6.4); three or more consecutive miscarriages of < 10 weeks gestation (mean GAPSS 9.4, S.D. 4.5) vs. no miscarriages <10 weeks gestation (mean GAPSS 4.8, S.D. 4.1, mean difference 4.6; t-test: $p=0.002$, 95% CI 1.7-7.4); any miscarriages (mean GAPSS 6.3, S.D. 4.3) vs. no miscarriages (mean GAPSS 4.7, S.D. 4.3, mean difference 1.6, t-test: $p=0.045$, 95% CI 0.03-3.1); fetal death (mean GAPSS 9.0, S.D. 3.8) vs. no fetal death (mean GAPSS 3.8, S.D. 3.4, mean difference 5.3, t-test: $p=0.000$, 95% CI 3.7-6.8); miscarriage <10 weeks gestation (mean GAPSS 9.1, S.D. 4.2) vs. no miscarriage < 10 weeks (mean GAPSS 3.8, S.D. 3.4, mean difference 5.3, t-test: $p=0.000$, 95% CI 3.9-6.7); premature birth (< 34 weeks) (mean GAPSS 7.8, S.D. 4.7) vs. no premature birth (mean GAPSS 4.8, S.D. 4.1, mean difference 2.9, t-test: $p=0.01$, 95% CI 0.7-5.2); pre-eclampsia (PET) (< 34 weeks) (mean GAPSS 7.8, S.D. 5.1) vs. no PET (mean GAPSS 4.7, S.D. 4.0, mean difference 3.1, t-test: $p=0.002$, 95% CI 1.1-5.2); stillbirth (mean GAPSS 9.1, S.D. 5.1) vs. no stillbirth (mean GAPSS 4.8, S.D. 4.1, mean difference 4.3, t-test: $p=0.002$, 95% CI 1.6-6.9); placental infarction (mean GAPSS 10.6, S.D. 4.2) vs. no placental infarction (mean GAPSS 4.9, S.D. 4.1, mean difference 5.6, t-test: $p=0.004$, 95% CI 1.8-9.4).

Conclusion: Higher GAPSS values are found in women with SLE and aPL with previous pregnancy complications compared to those without pregnancy complications. The clinical utility of the GAPSS score in pregnancy seems promising and should be validated in a prospective cohort.

Increased Sperm DNA Fragmentation in Male Systemic LUPUS Erythematosus Patients

Bruno C Tiseo¹, Clovis A Silva², Eduardo Ferreira Borba³, Gabriela A Munhoz³, Miguel Srougi¹, Eloisa Bonfa⁴ and Marcello Cocuzza¹, Discipline of Urology, Hospital das Clinicas HCFMUSP, Faculdade de Medicina, Universidade de Sao Paulo, Sao Paulo, Brazil, ²Pediatric Rheumatology, Hospital das Clinicas HCFMUSP, Faculdade de Medicina, Universidade de Sao Paulo, São Paulo, Brazil, ³Rheumatology, Hospital das Clinicas HCFMUSP, Faculdade de Medicina, Universidade de Sao Paulo, São Paulo, Brazil, ⁴Rheumatology Division, Hospital das Clinicas, Faculdade de Medicina, Universidade de São Paulo, São Paulo, Brazil

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Reproductive Issues in Rheumatic Disorders Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Gonadal dysfunction may affect male systemic lupus erythematosus (SLE) patients. Recently, sperm DNA integrity analysis has shown better diagnostic and prognostic performance for predicting male reproductive potential. In fact, conventional semen analysis, which focus on sperm concentration, motility and morphology, has been demonstrated to be a poor indicator of fertility and pregnancy outcome. There are, however, no studies assessing sperm DNA fragmentation and in male non-azoospermic SLE patients. Therefore the objective of the present study was to

evaluate sperm DNA fragmentation analysis concomitantly with a global gonadal assessment in non-azoospermic male SLE patients.

Methods: Twenty-eight consecutive male SLE patients (ACR criteria) and 34 healthy controls were evaluated for demographic and exposures data, urologic evaluation and hormone. Semen analysis was performed according to the World Health Organization guidelines and sperm DNA fragmentation by alkaline comet assay in both groups. Clinical features, disease activity/damage scores and treatment were also evaluated in SLE patients.

Results: The median age [33 (20-52) vs. 36.5 (25-54) years, $p=0.329$] and frequency of varicocele (25% vs. 32%, $p=0.183$) were similar in SLE patients and healthy controls. Sperm DNA fragmentation showed significantly higher levels of cells class III [44 (9-88) vs. 16.5 (0-80)%, $p=0.001$] and cell class IV [10.5 (3-86) vs. 7 (0-36)%, $p=0.039$] in SLE patients compared to healthy controls. Sperm DNA fragmentation index was also significantly higher in SLE patients [62 (31-97) vs. 25.5 (0-100)%, $p<0.001$]. Conventional sperm parameters (including sperm count, motility and morphology) were similar in both groups ($p>0.05$). In SLE patients no correlations were observed between sperm DNA fragmentation index and age, disease duration, body mass index, SLEDAI-2K and SLICC/ACR-DI scores, and cumulative dose of prednisone, hydroxychloroquine, methotrexate, azathioprine, mycophenolate mofetil and intravenous cyclophosphamide (IVCYC) ($p>0.05$). Further analysis of SLE patients treated with and without IVCYC showed that total sperm motility was significantly lower in the former group [64 (15-83) vs. 72 (57-86)%, $p=0.024$]. Sperm DNA fragmentation index was alike in both groups [52.5 (31-95) vs. 67.5 (34-97)%, $p=0.185$].

Conclusion: To our knowledge, this was the first report that male non-azoospermic SLE patients have increased sperm DNA fragmentation without evident gonadal dysfunction. IVCYC does not seem to be a major determinant for this abnormality. Future prospective study is necessary to determine the impact of this alteration in these patients' fertility.

Abstract Number: 2416

Good Pregnancy and Neonatal Outcomes in Lupus Nephritis Patients with Complete Remission

Weixin Hu, Kang Li, Yinghua Chen, Zhenzhao Liu, Liu Yang, Duqun Chen and Haitao Zhang, National Clinical Research Center of Kidney Diseases, Jinling Hospital, Nanjing University School of Medicine, Nanjing, China

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Reproductive Issues in Rheumatic Disorders Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: To investigate the outcomes of pregnancy and neonatal and the risk factors of lupus flares and pregnancy complications in Chinese patients with lupus nephritis (LN).

Methods: One hundred female patients with LN after complete remission prior to the conception (remission group) were prospectively followed from Jan 2010 to Dec 2016. Twenty-seven LN patients without complete remission prior to conception and unplanned pregnancies were collected concurrently as the control group. Glucocorticoids (GS) or GS plus other applicable immunosuppressant were given during the pregnancy. The rate and risk factors of LN relapse, maternal and neonatal complications, including preeclampsia, abortion, fetal death, intrauterine growth restriction (IUGR) and preterm delivery were analyzed.

Results: In the remission group, 100 LN patients had 104 times of pregnancies and delivered 96 healthy children. During pregnancy, immunosuppressive regimens were GS alone in 74 pregnancies, GS plus other immunosuppressant in 23 pregnancies, no drug in 7 pregnancies. LN relapse developed in 15 (14.42%) pregnancies, logistic regression analysis showed that the duration of complete remission less than 12 months (OR: 200.324 (95% CI 197.967-202.681), $P=0.025$) and positive anti-C1q antibody (OR: 58.159 (95% CI 56.229-60.089), $P=0.035$) before pregnancy were the two independent risk factors for the relapse. Thirty-seven pregnancies (35.85%) developed pregnancy and neonatal complications, including 19 preterm delivery, 5 preeclampsia, 5 IUGR and 8 fetal loss (7 spontaneous abortion, 1 elective abortion due to preeclampsia). Complete remission time less than 6 months before pregnancy (OR: 19.481 (95% CI 18.003-20.959), $P=0.045$) was associated with preterm delivery, while hypocomplementemia (OR: 11.287 (95% CI 10.06-12.514), $P=0.048$) and positive anti phospholipid antibody (OR: 7.118 (95% CI 6.193-8.043), $P=0.034$) before pregnancy were associated with

the fetal loss. In the control group, the rate of lupus relapse (21/27, 77.78%) and pregnancy and neonatal complications (23/27, 85.19%) were significantly higher than that in the remission group ($p < 0.01$).

Conclusion: Complete remission prior to pregnancy and maintaining immunosuppressive treatment during pregnancy showed good pregnancy and neonatal outcomes in patients with lupus nephritis. The duration of complete remission, serum levels of anti-C1q antibody and complement and anti phospholipid antibody were associated with the relapse and pregnant associated complications.

Antonio Avina-Zubieta⁴, ¹Faculty of Medicine, University of British Columbia, Vancouver, BC, Canada, ²Pharmaceutical Sciences, University of British Columbia, Vancouver, BC, Canada, ³Arthritis Research Canada, Richmond, BC, Canada, ⁴Division of Rheumatology, Department of Medicine, University of British Columbia, Vancouver, BC, Canada

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Reproductive Issues in Rheumatic Disorders Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The adverse effects of systemic lupus erythematosus (SLE) on maternal and fetal outcomes in pregnancy have been explored mainly in clinic-based cohorts. However, data comparing maternal and fetal outcomes before and after diagnosis of SLE at the population-based level are scarce. The purpose of our study was to assess fetal and maternal outcomes before and after SLE diagnosis.

Methods: We conducted a population-based, retrospective cohort study from a perinatal registry that included all pregnancies in the province between the 1st of January 2002 and 31st of December 2012. SLE was defined as greater than or equal to 2 ICD-9/ICD-10 codes at least 2 months apart and within a 2-year window. SLE exposure was based on diagnosis before or after date of conception. The groups were defined as post-SLE (pregnancy following SLE diagnosis) or pre-SLE (pregnancy preceding SLE diagnosis). We used logistic, Cox and Poisson regression models to evaluate the effects of SLE on perinatal outcomes (small for gestational age [SGA], congenital anomalies (CA), preterm delivery, major infection in baby) and maternal outcomes (major infections). Infant infections were defined as occurring in the first year of life, while maternal infections were only in the first six weeks following delivery. All models were adjusted for maternal prescription medications, comorbidities, prior pregnancy outcomes, and body mass index.

Results: 405,538 total pregnancies were evaluated, with 608 occurring in SLE patients. Among these, 376 pregnancies were post-SLE, and 232 were pre-SLE. In adjusted analyses, the odds ratios (OR) for the association of SLE with having infants born SGA were 1.91 (95% CI 1.48, 2.46) for post-SLE and 2.28 (95% CI 1.68, 3.09) for pre-SLE when compared to non-SLE pregnancies (See Table 1). The adjusted ORs for CA were also increased in both periods (see Table 1). Furthermore,

Table 1: Association of Systemic Lupus Erythematosus diagnosis before/after conception and risk of fetal and maternal complications

Outcomes	Post-SLE		Pre-SLE	
	OR	(95% CI)	OR	(95% CI)
Small for Gestational Age	1.91	(1.48, 2.46)	2.28	(1.68, 3.09)
Congenital Anomalies	1.59	(1.21, 2.10)	1.45	(1.01, 2.06)
	HR	(95% CI)	HR	(95% CI)
Preterm delivery	1.57	(1.24, 1.98)	1.13	(1.01, 2.62)
	CR	(95% CI)	CR	(95% CI)
Baby infection	0.99	(0.66, 1.49)	1.80	(1.22, 2.67)
Mother infection	1.18	(0.66, 2.03)	0.91	(0.47, 1.80)

the hazard ratios (HR) for the effect of post- and pre-SLE on preterm delivery were also increased. In adjusted analyses, the count ratios (CR) for the association of SLE with a serious newborn infection were increased only in the pre-SLE group, CR = 1.80 (95% CI 1.22, 2.67), when compared to non-SLE pregnancies. No increased risk for serious maternal infection was seen (see Table 1).

Conclusion: We found an increased risk of SGA, CA, preterm delivery, and serious newborn infection in pregnancies of patients with SLE. The risk was increased even in pregnancies before SLE diagnosis. There was no association between SLE and risk of serious maternal infection.

Awareness of Fertility and Contraception Issues Among Women with Rheumatologic Diseases

Christina Payne¹, Meagan Clark², Sneha Patel³, Tanya Allawh³, Mei-An Ty-Arias², Ashley Davis² and Arundathi Jayatilleke⁴, ¹Rheumatology, Drexel University COM/ HUH, Philadelphia, PA, ²Drexel University COM, Philadelphia, PA, ³Internal Medicine, Drexel University COM, Philadelphia, PA, ⁴Rheumatology, Drexel University COM, Philadelphia, PA

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Reproductive Issues in Rheumatic Disorders Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Because many autoimmune conditions preferentially affect women of childbearing age and both disease and treatment can negatively affect pregnancy outcomes, healthcare providers to women with rheumatologic diseases must be aware of and counsel patients regarding reproductive health issues.

Prior studies have shown that women with lupus of childbearing age are at high risk of unintended pregnancy and pregnancy exposure to teratogenic medication (1, 2). Our academic medical center provides care to a diverse urban population. We designed this study:

1. To assess baseline awareness of reproductive health issues in our patient population.
2. To evaluate the efficacy of an educational intervention, in addition to routine counselling, in improving patients' reproductive health knowledge.

Methods: This descriptive study was performed using a survey instrument. Premenopausal females, between the age of 18 to 45 who were seen at Drexel University College of Medicine Rheumatology clinics, with an underlying diagnosis of rheumatoid arthritis, systemic lupus erythematosus, sero-negative spondyloarthropathy, mixed connective tissue disease, scleroderma, and vasculitis were recruited. Participants were asked to complete a baseline survey and were later randomized 1:1 to receive either pamphlet or audiovisual intervention, followed by a post-intervention survey at routine followup visit.

Results: 74 participants enrolled in the study thus far. All completed the baseline survey. The majority were age 25-30 (34%), African American (44.6%) and at least partially-college educated (74%). 41% were unemployed. 49 participants were randomized to and completed the intervention; 22 respondents completed the post-intervention survey. Pre-intervention, 39% of respondents reported consistent contraceptive use; 47% of women who were sexually active with men reported contraceptive use. Of the 53% of sexually active women not using birth control (at risk of becoming pregnant), 59% were also using teratogenic medications.

Post- intervention, 20% more women felt knowledgeable about medication effects on fertility, 21% more about effects on pregnancy and 14% more about effects on breastfeeding compared to pre-intervention.

Conclusion: Survey respondents report poor baseline knowledge of the impact their diseases and treatments on reproductive health. Preliminary post-intervention data show an increase in knowledge regarding medication effects on reproductive health [in both groups]. With these data, we hope to raise awareness of reproductive health issues and improve counseling of women with autoimmune diseases using the educational interventions to maximize quality of care.

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Reproductive Issues in Rheumatic Disorders Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Among women with systemic rheumatic diseases (SRD), poor maternal and fetal outcomes may occur if disease activity and medication use are not optimized preconception. We conducted a needs assessment of rheumatologists' potentially modifiable practices around fertility intention screening and contraceptive prescribing. We then implemented an intervention to ameliorate noted gaps in care.

Methods: Using the electronic medical record (EMR) at a large academic medical center, we identified women 18-50 years with SRD and assessed teratogenic medication use, contraceptive use, and obstetrics and gynecology (OB/GYN) care during the year prior to our intervention. We administered a 13-item survey to the rheumatologists to assess fertility intention screening and contraceptive prescribing. We then introduced our intervention, the validated One Key Question[®] (OKQ), "Would you like to become pregnant in the next year?" to rheumatologists during a rheumatology-OB/GYN Grand Rounds lecture, created an EMR template for OKQ documentation, flagged potentially eligible SRD patients each week in the EMR, and introduced a streamlined referral system to facilitate access to OB/GYN care.

Results: We identified 625 women 18-50 with SRD seen by a rheumatologist ≤ 1 year prior to OKQ implementation. Of these, 66% received ≥ 1 medication with known teratogenic risk. Thirty-three percent of these women had any documented

Figure. Rheumatologist-reported frequency of reproductive health care for women of reproductive age receiving a teratogenic medication (N=32)

contraception and 5% had been referred to OB/GYN in the previous year. We received survey responses from 74%(32/43) of the practicing rheumatologists. While many providers frequently discuss contraception when prescribing a teratogen, few utilize educational materials and almost none provide contraception (Figure). When asked about comfort assessing patients' reproductive goals, 31% felt very comfortable, 50% somewhat comfortable, and 19% not very comfortable or unsure (Table). Providers cited multiple potentially modifiable barriers to screening, most notably lack of time (63%), lack of knowledge (31%) or not knowing where to refer patients (41%). Within 2 months of implementation, the OKQ has been documented in 58 charts by 11 providers, and 11 patients (19%) were referred to OB/GYN.

Conclusion: In this large, academic rheumatology practice, physician comfort with reproductive health was highly variable and referrals for OB/GYN care infrequent. Implementation of a single question fertility intention screen (OKQ) may help ensure that an assessment of patients' family planning needs and appropriate follow-up are incorporated into their rheumatologic care.

Table. Reproductive Health in Rheumatology Practice Selected Survey Results (N=32)

	Response - N (%)
Rheumatologists were asked to rate the following:	
Frequency of contraception discussions	
Very often	14 (44)
Somewhat often	7 (22)
Occasionally/ Not very often/Never	11 (34)
Frequency of pregnancy planning discussions	
Very often	13 (41)
Somewhat often	10 (31)
Occasionally/Not very often/Never	9 (28)
Comfort assessing patients' reproductive goals	
Very comfortable	10 (31)
Somewhat comfortable	16 (50)
Not very comfortable/Not comfortable at all/Not sure	6 (19)
Comfort counseling patients about contraceptive options	
Very comfortable	5 (16)
Somewhat comfortable	15 (47)
Not very comfortable/Not comfortable at all/Not sure	12 (38)
Barriers to counseling about reproductive goals and/or contraception*	
Not enough time	20 (63)
Sensitivity of the issue	7 (22)
Topic is out of practice scope	15 (47)
Limited knowledge about contraceptive options	10 (31)
Moral or religious objections	0 (0.0)
Limited knowledge about medication effects in pregnancy	4 (13)
Limited knowledge about disease activity in pregnancy	2 (6)
Inadequate guidelines	6 (19)
Challenges referring patients	13 (41)
Patients' limited knowledge about risks	8 (25)
Patients' limited knowledge/beliefs/myths about contraceptives	10 (31)
Cultural barriers/communication issues with patients	9 (28)
Rheumatologists were asked to rate how influential the following factors are in their decision whether to prescribe methotrexate to a 25 y/o F who declines non-barrier contraceptives	
Patient autonomy	
Not influential at all/slightly influential/somewhat influential	6 (19)

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Reproductive Issues in Rheumatic Disorders Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Juvenile idiopathic arthritis (JIA) is the leading pediatric rheumatic disease affecting 30 out of a million women. Although spontaneous remission may occur in most patients, physical defects and the associated psychological conditions may impact patients' all aspects of life, including pregnancy. To date, very few studies looked into the maternal and neonatal outcomes among women with JIA, and most of them are focused on the Caucasian population. The aim of this research is to provide proper health counsel for women with Asian descent suffering JIA about the possible complications during pregnancy.

Methods: Using the National Health Insurance database and National Birth Registry, we identified a cohort of all live-births in Taiwan between 2004 and 2014. First child born to mothers with JIA were identified and matched with up to 5 controls by maternal age and birth year. Raw odds ratio (OR) with 95% confidence intervals (CI) and OR with age, infant sex, Charlson comorbidity index, urbanization, income, occupation, birth year, maternal nationality adjustment were used to analyze fetal/neonatal outcomes and maternal outcomes during pregnancies.

Results: Of the 2,100,143 newborn, 0.037% (n=778) were born to JIA mothers. The result for neonatal outcomes suggested that babies born to mothers with JIA were more likely to have low birth body weight, with an adjusted OR of 1.35 (95% CI: 1.02 to 1.79) when compared to babies born to mothers without. No significant differences were found in prematurity, small for gestational age as well as Apgar score <7 at 1 and 5 minutes even after adjustment. In addition, no differences were observed in maternal outcomes between women with and without JIA.

Conclusion: Infants of mother with JIA and women with JIA themselves did not have an increased risk for pregnancy related adverse events. Intensive obstetric and neonatal care may not be necessary for pregnant women with JIA and their infants.

Pregnancy Outcomes in Women with Rheumatic Diseases and Thrombophilia Treated in a Multidisciplinary Unit

Isabel Añón Oñate¹, Irene Notario¹, Miguel Ángel Ferrer¹, Lorena Pérez¹, María Ramírez¹ and Rafael Cáliz², ¹Rheumatology, Hospital Universitario Virgen de las Nieves, Granada, Spain, ²Hospital Universitario Virgen de las Nieves, Granada, Spain

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Reproductive Issues in Rheumatic Disorders Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: To evaluate the efficacy of the treatment on the pregnancy outcomes of women with Rheumatic Diseases and Thrombophilia from a Spanish cohort. Their pregnancies should be considered high obstetric risk and they need close monitoring in a multidisciplinary unit.

Methods: Descriptive, retrospective and open study of 143 patients diagnosed with rheumatic diseases and thrombophilia assisted in a specialized multidisciplinary unit of Rheumatic Diseases and pregnancy (integrated by Gynecologists, Hematologists and Rheumatologists). The following variables were collected: age, maternal pathology, presence of antiphospholipid antibodies (aPL), anti-Ro/La, prior abortions, fetal echocardiograms, treatment during pregnancy, obstetric outcomes births/abortion, pregnancy length and maternal/fetal complications. The statistical analysis was done using the McNemar Test.

Results: 143 pregnant women were included. The baseline characteristics are specified in table 1. Our patients were an average of 33.6 ± 5.44 years old and the 44% were elder than 35 years. 198 pregnancies were developed during the monitoring. Abortions registered are specified in table 2. Before the inclusion in our unit there were 231 abortions with an average of 1.6 ± 1.84 abortions per patient. Only 7 abortions occurred for the patients monitored in our unit. The reduction in the number of abortions was statistically significant ($p < 0.001$). The treatment received is shown in the table 3. 44% pregnant women have higher obstetric risk with an average of 2.48 ± 1.99 abortions per patients. They received treatment with LMWH in combination with ASA and 16 pregnant received also IVIG. The mean gestational age was 38 weeks with an average birth weight of 3058.5 ± 595.6 grams. Only 11% babies were preterm and 34% births were cesarean. 88.4% of our patients did not have complications in the puerperium. All pregnant patients with positive Anti-Ro/La autoantibodies were monitored with periodic fetal echocardiograms from the 16th week of gestation. No Congenital Heart Block or neonatal lupus were registered (100% of newborn were healthy).

Conclusion: The treatment is effective in the decrease in the number of abortions and in a reduction of maternal and fetal morbidity and mortality. The multidisciplinary evaluation is essential in women diagnosed with Rheumatic Diseases and Thrombophilia.

Pregnancy Outcomes in Patients with Interstitial Lung Disease Related to Autoimmune Disease and Sarcoidosis

Stephanie L. Giattino, Amanda M. Eudy and Megan E. B. Clowse, Department of Medicine, Division of Rheumatology and Immunology, Duke University, Durham, NC

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Reproductive Issues in Rheumatic Disorders Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Currently published data regarding pregnancy outcomes in patients with interstitial lung disease (ILD) related to autoimmune disease and sarcoidosis is limited, with widely variant outcomes reported. Some guidelines even suggest that these patients must avoid or terminate pregnancy. This study aimed to retrospectively analyze the pregnancy outcomes in a cohort of patients with ILD to help inform our ability to counsel patients on decision-making surrounding pregnancy and to help guide our management throughout pregnancy.

Methods: Medical records from 1/1/1996-9/27/2017 were retrospectively searched for encounters at our center for ICD-9/10 codes associated with pregnancy and ILD, including sarcoidosis. Each chart was reviewed to corroborate the diagnosis of lung disease, confirm that it temporally preceded the pregnancy, and ensure availability of delivery outcomes. Patients were categorized into two groups: sarcoidosis and autoimmune-related ILD (AI-ILD). Differences in categorical variables were analyzed using Fisher's Exact Test, and continuous variables were analyzed using ANOVA or Wilcoxon rank-sum test.

Results: Of 631 patient charts reviewed, 62 unique patients with 89 pregnancies (5 twins) met inclusion criteria; 63 pregnancies with sarcoidosis (62% biopsy-proven) and 26 with AI-ILD (11 SLE, 1 RA, 3 SSc, 3 PM, 2 SS, 2 EGPA, 2 UCTD, 2 CTD-ILD). The cohort was predominantly black (84.3%), with mean maternal age of 32 years. In total, there were 62 live births (Table 1), of which 11 were preterm (17.7%). Women in 8 pregnancies (12.9%) required oxygen at the time of delivery; however, only 1 (1.6%) required labor induction for maternal lung disease, and no patients required intubation. Two required ICU stays and no women died. Women with AI-ILD had more preeclampsia, but otherwise had similar pregnancy outcomes to those with sarcoidosis. Minimal differences in pregnancy outcomes and maternal morbidity were found when women with severe lung disease by imaging and/or pulmonary function tests were compared to those mild disease. Women with total lung capacity (TLC) <65% predicted more often required oxygen at delivery and had more C-sections, while women with diffusion capacity (DLCO) <60% predicted had no pregnancy outcome differences compared to women with better levels. The rate of pregnancy termination was similar for women with severe lung disease compared to overall (9.6% and 11.2%, respectively). While black women comprised >90% of the severe subgroups, pregnancy outcomes were similar when compared to non-black women with similar severity.

Conclusion: Pregnancies in women with AI-ILD and especially with sarcoidosis appear to be well tolerated from a pulmonary perspective, even in those with more severe disease by imaging and pulmonary function tests. Our data suggest it is not necessary for these women to avoid or terminate desired pregnancies due to lung disease alone.

Births to Women with Systemic Lupus Erythematosus Can be Identified Accurately in the Electronic Health Record

Ashley Blaske¹, Amanda M. Eudy², Jim C. Oates³, Megan E. B. Clowse² and April Barnado⁴, ¹Medicine and Pediatrics, Vanderbilt University Medical Center, Nashville, TN, ²Division of Rheumatology, Department of Medicine, Duke University Medical Center, Durham, NC, ³Division of Rheumatology & Immunology, Department of Medicine, Medical University of South Carolina, Charleston, SC, ⁴Division of Rheumatology and Immunology, Vanderbilt University Medical Center, Nashville, TN

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Reproductive Issues in Rheumatic Disorders Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Studying births in women with systemic lupus erythematosus (SLE) is difficult given its rarity and the challenges of randomized trials. While the electronic health record (EHR) serves as a powerful tool that is efficient and cost effective, accurately identifying SLE births is challenging. Our objective was to develop and then externally validate algorithms that use SLE and pregnancy-related ICD-9 and ICD-10 codes, labs, and medications to identify births to SLE patients.

Methods: We used Vanderbilt's Synthetic Derivative, a de-identified EHR with 2.8 million subjects. We selected individuals with at least 1 count of the SLE ICD-9 code (710.0) or ICD-10 codes (M32.1*, M32.8, M32.9) and at least 1 ICD-9 or ICD-10 code for pregnancy-related diagnoses yielding 433 subjects. For a training set, we randomly selected 100 subjects for chart review. A subject was defined as a case if diagnosed with SLE by a rheumatologist, nephrologist, or dermatologist (specialist) and had a birth documented. Positive predictive values (PPVs) and sensitivity were calculated for combinations of counts of the SLE ICD-9 or ICD-10 codes, ever use of antimalarials, a positive antinuclear antibody (ANA) \geq 1:160, and ever checked dsDNA or complements (C3 or C4). We performed external validation of ICD-9 algorithms in Duke's EHR using a set of 100 subjects randomly selected from the Duke Autoimmunity in Pregnancy Registry. ICD-10 algorithms could not be externally validated due to low sample size. Subjects who had an uncertain diagnosis by a specialist (n = 13, Vanderbilt and n = 6, Duke) and subjects with missing notes (n = 5, Vanderbilt and n = 0, Duke) were excluded from the analysis.

Results: PPVs and sensitivities are shown for the algorithms for training and validation sets in Table 1. In the training set, algorithms with ICD-10 codes alone with PPVs from 95 to 100% performed better than algorithms with ICD-9 codes alone with PPVs from 71 to 90%. Adding clinical data improved the PPVs of the algorithms that only used counts of the ICD-9 code.

Clinical data only minimally improved the PPVs of algorithms using ICD-10 codes alone. The algorithm with the highest combined PPV of 100% and sensitivity of 95% was ≥ 1 count of the ICD-10 codes and ever dsDNA, C3, or C4 checked. Algorithms using the ICD-9 code and clinical data in the training set replicated well in the external validation set (Table 1).

Conclusion: We have developed and validated algorithms to detect SLE patients with births in the EHR. Algorithms using ICD-9 codes may require additional clinical data while ICD-10 codes alone can identify SLE patients accurately. Future work is needed to handle subjects with uncertain diagnoses of SLE. Assembling SLE births within the EHR will enable more powerful studies to inform strategies that reduce adverse outcomes.

Table 1.

Algorithm	Positive Predictive Value Training set ^a	Positive Predictive Value Validation set ^b	Sensitivity Training set	Sensitivity Validation set

Session Title: Reproductive Issues in Rheumatic Disorders Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Recent ACR guidelines on prevention and treatment of CS-induced osteoporosis state that women of childbearing potential who are at moderate-to-high risk of fracture should be given bisphosphonates. However, safety concerns regarding adverse outcomes restrict the prescription of the drugs in women of childbearing potential. Given that relevant human *in vivo* data are limited, we conducted asystematic review of available evidence to assess whether bisphosphonate use in pregnancy and preconception phase (<1 year before pregnancy) increases risk of adverse neonatal and pregnancy outcomes.

Methods:

Results: 24 papers were included in the final analysis, including 15 case reports, 4 case series, 4 cohort studies and covering the impact of 120 preconception or pregnancy exposures to bisphosphonates on pregnancy or neonatal outcome. The majority of exposures were single-dose. Only 4 studies had a comparator group. Indications for bisphosphonate use were malignancy, CS-induced osteoporosis and bone-related disorders like Gaucher.

The quality of evidence in all studies (using the GRADE approach) was “low” or “very low”. Congenital malformations were reported in 7/120 pregnancies including 2 cardiac valvular defects (VSD and PDA), 1 kidney malformation and 3 bony malformative disorders (see Table 1). Rates of congenital malformation and abortion were comparable in bisphosphonate-exposed and controls in studies with a comparator group. Mean birth weight and gestational age were slightly lower than in the general population. Limiting factors include small sample size with varying bisphosphonate formulations and inclusion of case reports and case series. Few studies had a comparator group. Confounding factors include maternal underlying medical condition, concomitant use of corticosteroid, and other immunosuppression.

Conclusion: Our findings suggest that pre-conception and pregnancy exposure to bisphosphonates does not pose major teratogenic risks. These results will be useful when counselling women about risks related to pregnancy and accidental conception. However, further controlled studies are needed to fully establish safety of bisphosphonate use prior to or during pregnancy.

Drug	Duration of exposure/Comments	Pregnancy Outcomes of Interest
Alendronate	56 exposures 1 entire pregnancy 16 first trimester 11 preconception 1 0-5 month of pregnancy	Low birth weight (2900 vs. 3290 gm) Craniotabes Transient hypophosphatemia 6 spontaneous abortions 1 premature birth 1 kidney and cardiac malformation
Diphosphonate	2 exposures in the third trimester	Transient hypocalcemia, Increased uptake on fetal bone scan
Etidronate	8 exposures 2 preconception 1 first trimester	Apert syndrome (before conception to first trimester) patient and baby had FGF gene mutation
Ibandronate	1 exposure in third trimester	No malformation
Pamidronate	20 exposures 6 preconception 2 third trimester 2 lactation	1 Talipes equinovarus 1 Transient hypocalcemia 1 Transient hypocalcemia 1 Low birth weight
Risedronate	18 exposures (exact time of administration not known)	1 prospective study: rate of malformations comparable to general population
Zoledronic acid	exposure through 28 weeks of pregnancy	1 case report: no malformations

The Impact of Biologic Treatment for Rheumatoid Arthritis Patients Who Hope to Conceive

Hiroshi Shimada, Taichi Miyagi, Mikiya Kato, Risa Wakiya, Shusaku Nakashima, Tomohiro Kameda and Hiroaki Dobashi, Internal Medicine Division of Hematology, Rheumatology, and Respiratory Medicine, Kagawa University, Kagawa, Japan

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Reproductive Issues in Rheumatic Disorders Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Previous reports revealed that it was difficult for rheumatoid arthritis (RA) patients to conceive¹⁾. Age, nulliparity, disease activity, NSAIDs, corticosteroid was known as the risk factors of subfertilities²⁾. On the other hand, anti-TNF inhibitor (adalimumab) combined with or without immunoglobulin was reported to improve the outcome of infertility treatment³⁾. We examine the impact of biologic (bDMARDs) treatment on conception and delivery complicated with rheumatoid arthritis.

Methods: We investigated 25 cases (15 cases which had continued bDMARDs until conceiving; group A, 10 cases which discontinued both bDMARDs and conventional synthetic DMARDs at the time of hope to conceive; group B) retrospectively on the period of conception, the disease activity of RA and perinatal outcomes.

Results: Between two groups, disease activities at the time of planning for pregnancy and conceiving were no significant difference. The average period of conception was 6.14±3.80 months in group A, which was shorter than 11.89±6.21 months in group B ($P=0.024$, figure 1). The average birth weight of the babies in group B was 2446.57±375.73, significantly smaller than 2956.60±506.86 in group A ($P=0.039$, figure 2). However, the average gestational week was 38.58±1.16 in group A, which was not different from 38.00±1.41 in group B. There was no significant difference on the rate of abortion, preterm birth, LFD (light for date), premature rupture of membrane between two groups. In the cases of preterm birth and LFD

Figure1. Period from planning to getting pregnancy

Figure2. birth weight

babies, the average dose of corticosteroid during pregnancy was significantly higher than those of full-term birth and no LFD babies ($P=0.028$, 0.013 respectively).

Conclusion: In RA patients who hope pregnancy, continuing bDMARDs at the time of pregnancy had the advantage in conceiving earlier. Using bDMARDs before pregnancy has an influence on perinatal complications and development of their babies.

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Reproductive Issues in Rheumatic Disorders Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Robust data on the outcomes of pregnancy and influence of drug exposure in various inflammatory rheumatic diseases (IRD) are needed. Joint analyses of data from different databases could overcome the issue of small study sizes in single databases. A prerequisite for collaborative analyses would be a common core data set, collected by every collaborator. The objective was to develop a core data set for observational research to measure pregnancy course and outcomes of women with IRD.

Methods: The European Network of Pregnancy registers in rheumatology (EuNeP) consists of scientists who run pregnancy registers, namely EGR2 (France), RePreg (Switzerland), REVNATUS (Norway) and Rhekiss (Germany). During a face-to-face meeting involving all principal investigators of the 4 registers, the scope and core areas of the core data set have been developed according to COS-STAD recommendations¹ by consensus. Furthermore, the steps for developing a core data set, the consensus process and cut offs, as well as participants to be invited have been determined.

Results: The scope was defined as follows: 'To develop a standardized core data set for data collection in prospective observational research and clinical care of pregnant women with IRD. All interventions the women receive will be covered. Patients should be enrolled at the earliest possible moment during pregnancy, and data should ideally be collected once every trimester'. Three core areas were described: 'Maternal information' (including demographics, comorbidities and IRD disease characteristics), 'Treatment' (including medications of IRD and other health conditions) and 'Pregnancy' (including prior and actual pregnancy(ies), delivery and infant outcomes).

An initial list of data items possibly relevant for pregnancy registers will be generated based on (I) data items already collected by registers participating in EuNeP, (II) a systematic literature search and (III) results of a survey among patient representatives regarding their needs during pregnancy. Consensus about the importance of each data item to be included in a final core data set will be reached by applying a 2-step Delphi survey. For each item, the importance must be rated on a numeric scale from 1 to 9 (1-3 = low importance, 4-6 = important but not critical, 7-9 = critical importance). Any data item achieving at least 70% of responses as critical will be included in the core data set. Participants involved in the Delphi survey will be (a) the steering committee of EuNeP, (b) a working group of at least 30 experts in the areas of rheumatology, internal medicine, epidemiology and other health professions, and (c) patient representatives.

So far, the protocol has been set up and finalized, the literature search is currently performed. The first step of the Delphi survey will be presumably undertaken in mid-2018, preliminary results are expected to be available at time of the ACR congress.

Conclusion: A core data set which standardizes the data collection of pregnancy registers in rheumatology will facilitate collaborative analyses of different data sources.

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Reproductive Issues in Rheumatic Disorders Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Certolizumab pegol (CTZ) is a TNF α inhibitor indicated for the treatment of women affected by rheumatoid arthritis (RA) throughout the whole pregnancy. Some concern, regarding a possible immunosuppression of the newborns, still exists. We aimed to assess the immune response and the presence of infective adverse events among the long-term followed-up offspring of RA mothers, treated by CTZ during pregnancy.

Methods: In a 4-years observational gap, we prospectively enrolled 12 newborns born to RA women that signed an informed consent about children recruitment. The outcomes were a 24-months follow-up of the offspring health status, including infections, and, in case of routine/emergency lab test, assessment of the vaccine response according to the administered ones: equivalent diphtheria, tetanus, acellular pertussis, inactivated poliovirus, Haemophilus influenza type b and Hepatitis B virus combined vaccine (DTaP-IPV/Hib/HBV). Immune response was assessed by the following: anti-PRP antibodies (Abs) to Hib, diphtheria antitoxin and polio virus Abs, by neutralisation assays. Tetanus, pertussis and Anti-HBs Abs by ELISA (Thermo Fisher Scientific, Cleveland, OH, USA). The serology response was compared to the general population by Kruskal-Wallis and reverse regression curves statistical analyses (SAS V.6.12, Chiltern International Limited, Berkshire, UK). The immunogenicity cutoffs were set according to literature references.

Results: Among the 12 children constituting the study population, 2 had to be investigated for suspected infections and one for an episode of foreign body ingestion. According to the protocol, a blood sample taken from the planned lab tests, was sent for the assessment. Hib: the proportion of observed infants with an anti-PRP level >0.15 mg/ml was 93.2% (95% CI 86.6 to 96.7) compared with 100% (95% CI 96.4 to 100) to the reference population. The difference was 6.8% (90% CI 2.8 to 12.1). Regarding diphtheria-tetanus, pertussis, polio and HBV, the protective responses (respectively: >0.01 IU/ml, >0.01 IU/ml, >1:8 and ≥ 10 mIU/mL) were 99% in the study population. As the upper bound of the 90% CI was >10%, this difference confirms the non-inferiority of immune response for these children.

Conclusion: Our data are limited, since an ethical issue rises from proposing a series of blood draws to pediatric population. Regarding the reasons of consultations, to notice that none of them suffered from serious infections requiring hospitalization or parenteral antibiotic administration. The vaccine schedule was reported as well tolerated. Their immune response, finally, was shown to be adequate and superposable to the healthy population, including the administration of an alive vaccine (polio). These results further confirm the long-term overall safety of CTZ administration during pregnancy of RA patients, regarding both the mothers and their offspring.

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Reproductive Issues in Rheumatic Disorders Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: aPS/PT is considered to be a risk factor for vascular thrombosis (VT) and/or pregnancy morbidity (PM). Anti- β 2GP1-D1 is potentially superior to anti- β 2GP1 in predicting VT/PM. We examined the correlation between aPS/PT and anti- β 2GP1-D1 and the laboratory criteria for antiphospholipid antibody syndrome (APS): lupus anticoagulant (LAC), anticardiolipin (aCL), and anti- β 2GP1 and their association with VT/PM.

Methods: Multiple serum samples from patients fulfilling the ACR or Systemic Lupus International Collaborating Clinics (SLICC) Criteria for SLE were analyzed for aPS/PT (IgG/IgM) by ELISA (QUANTA Lite, Inova Diagnostics), anti- β 2GP1-D1 by chemiluminescence immunoassay (QUANTA Flash, Inova), LAC using tissue thromboplastin inhibition test and dRVVT, and aCL (IgG) and anti- β 2GP1 (IgG) by ELISA. VT/PM was based on patient self-report and confirmed by chart review. VT included arterial, venous, or small vessel thrombosis; PM included \geq one fetal death >10 weeks, \geq one premature birth <34 weeks or >3 spontaneous abortions <10 weeks.

The Spearman correlation between aPS/PT and anti- β 2GP1-D1 and the conventional AP autoantibodies and between each autoantibody and VT/PM was calculated. The association between number of autoantibodies and VT/PM was assessed using univariate logistic regression.

Results: 199 patients were included, of which 64 had had VT/PM (Table 1). The percentage of patients ever positive for aPS/PT, anti- β 2GP1-D1, LAC, aCL, and anti- β 2GP1 was significantly higher among those with VT/PM (Table 1). The correlation (95% CI) between IgG aPS/PT and LAC, aCL, anti- β 2GP1, and anti- β 2GP1-D1 was 0.54 (0.43, 0.64), 0.40 (0.27, 0.51), 0.43 (0.30, 0.54) and 0.28 (0.14, 0.42), respectively (Table 2). The correlation between IgM aPS/PT and LAC, aCL, anti- β 2GP1 and anti- β 2GP1-D1 was 0.43 (0.31, 0.54), 0.16 (0.02, 0.30), 0.25 (0.11, 0.38) and 0.24 (0.09, 0.38). The correlation between anti- β 2GP1-D1 and LAC, aCL and anti- β 2GP1 was 0.28 (0.13, 0.42), 0.55 (0.43, 0.64) and 0.61 (0.50, 0.69). The correlation between IgG aPS/PT, IgM aPS/PT, anti- β 2GP1-D1, LAC, aCL, and anti- β 2GP1 and VT/PM was 0.17 (0.03, 0.30), 0.05 (-0.09, 0.19), 0.21 (0.06, 0.35), 0.22 (0.08, 0.35), 0.22 (0.08, 0.35) and 0.24 (0.10, 0.37), respectively. The odds (95% CI) of VT/PM increased incrementally by 46% for each additional autoantibody (1.15, 1.86).

Table 1: Demographics and Clinical Characteristics of Cohort at last Follow-up (n = 199)

	VT/PM +ve (n=64)	VT/PM -ve (n=135)

	VT/PM +ve (n=64)	VT/PM -ve (n=135)
LAC	24.6*	8.3*
aCL	21.9*	6.8*
anti-β2GP1	23.4*	6.9*
aPS/PT (IgG)	26.7*	13.0*
aPS/PT (IgM)	33.3	28.2
anti-D1-β2GP1	13.2*	2.6*
≥ 1 Vascular thrombosis, %	90.6	-
≥ 1 Pregnancy morbidity, %	12.5	-

*Significant differences at 95% CI. Table 2: Correlation between aPS/PT and anti-D1- β2GP1 and antiphospholipid antibodies (95% CI)

	aPS/PT (IgG) +ve	aPS/PT (IgM) +ve	anti-D1-β2GP1 +ve
LAC	0.54 (0.43, 0.64)	0.43 (0.31, 0.54)	0.28 (0.13, 0.42)
aCL	0.40 (0.27, 0.51)	0.16 (0.02, 0.30)	0.55 (0.43, 0.64)
anti-β2GP1	0.43 (0.30, 0.54)	0.25 (0.11, 0.38)	0.61 (0.50, 0.69)
anti-D1-β2GP1	0.28 (0.14, 0.42)	0.24 (0.09, 0.38)	-

Conclusion: IgG aPS/PT and anti-β2GP1-D1 are highly correlated with other AP antibodies, which along with the accepted criteria of APS, are all similarly correlated with VT/PM. IgG aPS/PT and anti-β2GP1-D1 should be considered as criteria for APS.

Session Title: Reproductive Issues in Rheumatic Disorders Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Treatment with tumor necrosis factors inhibitors (TNFi) during pregnancy may be required to control maternal disease which can be a threat for maternal-fetal well-being. Information about the follow-up of *in utero* exposed offspring is limited. Aim of this study was to compare health and developmental conditions of children born to mothers with chronic arthritis exposed *in utero* to TNFi with those of unexposed children born to patients with same age and disease.

Methods: Clinical characteristics, pregnancy outcomes were analyzed. An *ad-hoc created* questionnaire was used to collect data on birth and growth parameters, breastfeeding, weaning, developmental milestones, vaccinations and illnesses.

Results: 122 live births in 98 women with chronic arthritis (64 RA, 34 SpA) were observed: 59 pregnancies exposed to TNFi (group A) at conception and 63 pregnancies TNFi-naïve (group B). In 57/59 (group A) pregnancies, TNFi was discontinued at positive pregnancy index as a *general measure* in our Pregnancy Clinic for patients in remission or stable low disease activity. In 2/59 pregnancies TNFi was maintained throughout pregnancy due to active disease at conception.

TNFi was restarted in 16/57 pregnancies (12 etanercept-ETA, 3 certolizumab-CTZ, 1 adalimumab) during the 2nd-3rd trimester due to moderate-severe flare (median exposure 84 days; discontinuation of TNFi between 32-37 gestational weeks). In group B, TNFi (1 ETA, 1CTZ) was introduced in 2/63 pregnancies during the 2nd trimester due to a severe flare. Three flares in 3/63 pregnancies were managed with an increase of prednisone dosage (max 10mg/day). 7 children, exposed to TNFi during 2nd-3rd trimester, were exposed to TNFi (3 CTZ, 3 ETA, 1 golimumab) also during breastfeeding. To investigate the long-term follow-up of children exposed in utero to TNFi, 20 children exposed during 2nd-3rd trimester (median age 29 months) and 20 unexposed children (median age 43 months) were compared (Table 1). No significant differences in growth parameters and developmental milestones were observed. No excess nor particular pattern of congenital defects/malformations were observed. In both groups, vaccinations were performed according to the national schedule (no live vaccines in the first year of life) without relevant complications.

Table 1. Maternal disease characteristics, neonatal outcomes and long-term follow up of children born to patients with chronic arthritis according to the in utero exposure to TNFi.

Pathological conditions after the first year of life	1 autism spectrum disorder	1 speech delay	

ACPA, anti-citrullinated protein antibodies; ADA, adalimumab; aPL, anti-phospholipid antibodies; BMI, body mass index; CRP, C-reactive protein; CTZ, certolizumab; CyA, Cyclosporine A; DAS28, Disease Activity Score in 28 joints; ETA, etanercept; GOL, golimumab; HCQ, hydroxychloroquine; IQR, interquartile range; LDA, low-dose aspirin.

Conclusion: One third of women with chronic arthritis who discontinued TNFi at positive pregnancy test experienced a moderate-severe flare during pregnancy and resumed TNFi. Thanks to the control of maternal disease, pregnancy outcomes were comparable to those of TNFi-naïve pregnancies in which the frequency of flares was low. Children exposed to TNFi had normal growth parameters and did not have severe infections during the first year. These data suggest that TNFi during pregnancy is effective in controlling maternal disease and ensures a good pregnancy outcome without complications to offsprings.

Pregnancy in Women with Ankylosing Spondylitis Is Not Associated with Poor Obstetric Outcomes: Analysis of Nationwide Inpatient Sample Database 2003-2011

Vikas Majithia and Shweta Kishore, Division of Rheumatology, University of Mississippi Medical Center, Jackson, MS

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Reproductive Issues in Rheumatic Disorders Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Outcomes of pregnancy are well studied in a number of rheumatic diseases such as Rheumatoid Arthritis (RA) and systemic lupus erythematosus. When compared, there is very limited data in pregnancy outcomes in patients with spondyloarthritis and in particular ankylosing spondylitis (AS). This study was undertaken to determine the frequency of complications occurring during pregnancy for women with AS and to compare these outcomes with the general obstetric population by using the largest inpatient care database.

Methods: By using the 2003-2011 Nationwide Inpatient Sample of Healthcare Cost and Utilization Project, we estimated the number of obstetric hospitalization, deliveries and caesarean deliveries in women between the age group 18-50 years.

Table 1. Obstetric Outcomes for Pregnancy Related Hospitalizations in Ankylosing Spondylitis					
	Total	AS	Controls	OR	p-value
Number of Pregnancies	42317648	2538	41315110	N/A	N/A
Mean Age		29.96	27.32		<0.001
Fetal Death	259227	14(0.6%)	259213(0.6%)	1.126	0.873
Inpatient Mortality	9628	0	9628 (0%)	N/A	0.986
IUGR	774439	54(2.1%)	774385(1.8%)	0.951	0.769
Pre-term delivery	2798720	159(6.3%)	2798561(6.6%)	0.996	0.961
Cesarean-delivery	11857999	696 (27.4%)	11857303(28%)	0.873	0.008
PROM	1456335	93(3.7%)	1456242(3.4%)	0.759	0.047
Hypertensive Diseases	3757992	250(9.9%)	3757742(8.9%)	0.818	0.029
PPH	1106419	34(1.3%)	1106385(2.6%)	0.390	0.000
APH	863232	55(2.2%)	863177 (2%)	1.292	0.061
Abbreviations: AS: Ankylosing Spondylitis, OR: Odds Ratio, IUGR: Intra-uterine Growth Retardation, PROM: Premature Rupture of Membranes, APH: Ante-partum Hemorrhage, PPH: Post-partum Hemorrhage					

Patients hospitalized with AS were identified. Demographic characteristics and in-hospital outcomes were recorded for both AS and control group. Maternal and pregnancy complications for all pregnancy-related admissions for women with and without AS were compared. Multivariate logistic regression analysis was used to obtain adjusted odds ratio (OR).

Results: The total number of obstetric hospitalization was 42.32 million, of which 2538 were women with diagnosis of AS. Mean maternal age of AS population was higher (29.96 years) than the control group (27.32years). After adjusting for potential confounders, the results in this analysis show that maternal AS population had no significant increase of inpatient mortality or fetal death. Prevalence of preterm delivery and intrauterine growth retardation was also similar among the two groups. Interestingly, the odds of hypertensive diseases and premature rupture of membranes, postpartum hemorrhage and cesarean delivery in AS patients were significantly lower. The results do suggest that AS patients may have a higher risk of antepartum hemorrhage, but the results failed to achieve statistical significance. The frequencies of the above outcomes along with Odds Ratio are provided in Table 1.

Conclusion: Based on our study of national cohort, we conclude that pregnancies in women with AS are relatively safe without any increase in maternal or fetal mortality despite having a higher maternal age. These data are further reassuring that AS patients also do not have higher risk of adverse outcomes of pregnancy than women without AS. This is significantly in contrast to the worse outcomes observed in RA patients in the same analysis and available literature. We suggest that in women with AS, close antenatal and post-delivery monitoring pregnancy be performed but these patients are likely to do well. Further studies are needed to examine these findings in a prospective manner.

Session Title: Reproductive Issues in Rheumatic Disorders Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The goal of this prospective cohort study is to add to the limited data on birth outcomes in psoriatic arthritis (PsA) and ankylosing spondylitis (AS) and to describe patterns of disease activity during pregnancy in these diseases.

Methods: Women enrolled as part of the Organization of Teratology Information Specialists (OTIS) Autoimmune Disease in Pregnancy Project before 20 weeks gestation from 2004-2018. Delivery of at least one live-born infant was eligibility criteria for analysis. Data on pregnancy events, medications, disease activity, and outcomes were obtained by maternal report and validated by medical records. Disease activity was calculated by the Health Assessment Questionnaire (HAQ) or Routine Assessment of Patient Index Data 3 (RAPID3). Poisson regression with robust standard errors was used to estimate risk ratios (RR), multivariable adjusted risk ratios (aRR) and their 95% Confidence Intervals (CI).

Results: In this large prospective cohort analysis, PsA was associated with an increased risk for moderate preterm delivery (aRR 1.81, 95% CI 1.01-3.26), preterm labor (aRR 2.05, 95% CI 1.21-3.48), oligohydramnios (aRR 3.79, 95% CI 1.34-10.74), and caesarian section (aRR 1.63, 95% CI 1.26-2.12), versus healthier comparison women. The AS group had an increased risk for very preterm delivery (aRR 10.19, 95% CI 2.09-49.78), very low birth weight (aRR 11.02, 95% CI 2.24-54.12), and infant hospitalization in NICU (aRR 1.67, 95% CI 1.05-2.67). Disease activity over the course of pregnancy was either stable (by HAQ) or improved (by RAPID3) in PsA, whereas in AS it slightly worsened with both measures, although changes were small in both disease groups (see Figure 1).

Conclusion: Pregnant women with PsA and AS are at increased risk for some adverse pregnancy outcomes. Disease activity is relatively stable over pregnancy, with slight improvement in PsA and slight worsening in AS, although varying by measure of disease activity used. Further analyses would be useful to tease out the role of disease activity and medications on these outcomes.

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Reproductive Issues in Rheumatic Disorders Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Multiple issues surround the peripartum period for IA patients including medication use, risk of disease flare and potential impact on neonatal outcomes. We aimed to better understand these issues by surveying childbearing women with rheumatoid arthritis (RA) and psoriatic arthritis (PsA) in a biologic registry.

Methods: A retrospective survey of 440 peripartum females of less than 50 years of age with RA or PsA in the RAPPORT registry was performed using an anonymous electronic-based RedCap survey. Descriptive statistics and Fisher's exact test were used to analyze the results.

Results: 162 patients (133 RA/29 PsA) completed the survey (103 women having 234 pregnancies), 164 pregnancies occurring before and 70 pregnancies occurring after IA diagnosis. Pregnancy outcomes from 103 patients included: 96% live births, 1.9% stillbirths, 23% miscarriages, and 15% therapeutic abortions. A third of patients had fewer children than desired due to IA disease activity, medications and other reasons. For 63 pregnancies after IA diagnosis: (1) 49% of pregnancies received pre-conception counseling; (2) most described good IA disease control during pregnancy but flared in the first 3 months postpartum; (3) 79% of pregnancies discontinued IA medications; (4) 35% of pregnancies occurred on

biologic therapy at or prior to conception. Gestational age at time of delivery was 37-40 weeks in 58% (33/57) post-IA vs 66% (83/126) pre-IA diagnosis pregnancies. No statistically significant differences occurred between pregnancies before or after IA diagnosis for: pregnancy planning, fertility treatment, pregnancy and labour/delivery complications, birth defect frequency or neonatal complications. Neonatal ICU admissions were significantly lower in pre-IA diagnosis pregnancies compared to post-IA diagnosis pregnancies. No pregnancy complications were noted in 24/54 pregnancies on medications compared to 6/9 pregnancies not on medications.

Conclusion: Women with RA and PsA are faced with multiple peripartum issues emphasizing the importance of informed decision-making before, during and after pregnancy. Table 1. Characteristics of RAPPORT Survey Patients

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Reproductive Issues in Rheumatic Disorders Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: SLE patients have poorer pregnancy outcomes than healthy patients, including a lower rate of live birth and higher rates of small for gestational age (SGA) infants, preeclampsia, hypertension, Cesarean delivery (C-section), neonatal intensive care unit (NICU) admissions, and prematurity. In contrast, there are limited data regarding pregnancy outcomes for women with undifferentiated connective tissue disease (UCTD). Most prior studies include pregnant women identified through a screening questionnaire from among healthy women, making these populations different from women with known UCTD who are followed by a rheumatologist.

Methods: Between 2008 and 2017, patients with UCTD and SLE at an academic medical center were recruited to a prospective pregnancy registry. UCTD was defined a positive autoantibody plus symptoms consistent with a connective tissue disease but not meeting criteria for another rheumatic diagnosis. SLE was defined by ACR or SLICC classification criteria. Data were collected prospectively at baseline, during pregnancy, and post-partum. Disease activity was determined by physician global assessment (PGA) score and classified as low, medium, or high. Differences in proportions were estimated by Fisher's exact test. Differences in continuous variables were estimated by t-test or Wilcoxon rank-sum test, depending on the distribution of the data. Data were analyzed using SAS 9.4 (Cary, NC).

Results: We analyzed 51 UCTD pregnancies and 142 SLE pregnancies (Table 1). There were significantly more Caucasian patients with UCTD and significantly more black patients with SLE. Anti-Ro antibodies were the most common autoantibodies in both groups, and anti-RNP antibodies were second most common in the SLE group. Antiphospholipid syndrome was uncommon in both groups. Hydroxychloroquine was prescribed to most patients. A minority of UCTD patients and slightly less than 50% of SLE patients took steroids in any form. Disease activity was low in most patients, but the disease activity of SLE patients was higher. There was no significant difference in the rate of prematurity. More SLE patients had preeclampsia and SGA infants. Nearly 30% of infants born to SLE patients were admitted to the NICU. In models adjusted for race, having SLE was associated with an increased risk of preeclampsia, SGA, and preterm birth. One infant with complete heart block was born to a woman with SLE. Treatment with dexamethasone reversed early stage heart block in 5 cases.

Conclusion: Compared to women with SLE, women with UCTD have a lower rate of preterm delivery and preeclampsia, and their offspring are less frequently small for gestational age or admitted to the NICU. This data suggests that with appropriate screening, treatment, and monitoring, women with UCTD can have pregnancy outcomes comparable to those of healthy women. Table 1. SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Reproductive Issues in Rheumatic Disorders Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Few case reports and series suggest adverse pregnancy outcomes in patients with Takayasu Arteritis (TA). This study was undertaken to determine the frequency of complications occurring during pregnancy for women with TA and to compare these outcomes with the general obstetric population by using the largest inpatient care database.

Methods: By using the 2003-2011 Nationwide Inpatient Sample of Healthcare Cost and Utilization Project, we estimated the number of obstetric hospitalization, deliveries and caesarean deliveries in women between the age group 18-50 years. Patients hospitalized with TA as one of the diagnoses were identified. Demographic characteristics and in-hospital outcomes were recorded for both TA and control group. Then we compared maternal and pregnancy complications for all pregnancy-related admissions for women with and without TA. Multivariate logistic regression analysis was used to obtain adjusted odds ratio (OR).

Results: The total number of obstetric hospitalization was 42.32million of which 348 were women with diagnosis of TA. The maternal age of TA population was higher (28.1 years) than that in the control group (27 years) ($p < 0.001$). After adjusting for potential confounders, maternal TA population had a significantly higher prevalence of hypertensive diseases. The prevalence of intrauterine growth retardation, preterm delivery and antepartum hemorrhage was higher in TA population but did not reach a statistical significance. However, the odds of cesarean delivery, premature rupture of membranes and postpartum hemorrhage was lower in TA population. The frequencies of the above outcomes along with Odds Ratio are provided in Table 1.

Conclusion: Based on our study of national cohort, we conclude that women with TA have a higher risk of adverse outcomes of pregnancy than do pregnant women without TA, especially the hypertensive complications. Thus close antenatal and post-delivery monitoring need to be performed in order to reduce complications. The other outcomes did not reach a statistical significance likely due to small number of TA patients. Further studies with larger number of patients are needed to examine these findings.

Pregnancy Outcomes Among Women with Rare Autoimmune Diseases

Jon Golenbiewski, Amanda M. Eudy and Megan E. B. Clowse, Department of Medicine, Division of Rheumatology and Immunology, Duke University, Durham, NC

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Reproductive Issues in Rheumatic Disorders Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Autoimmune disease in pregnancy creates the potential for increased complications and poor pregnancy outcomes. There is a paucity of outcomes data in less-common autoimmune diseases. We present the rare rheumatologic pregnancies managed over a decade from a university rheumatology pregnancy clinic.

Methods: Data were prospectively collected over a 10-year period in a pregnancy registry for women with autoimmune disease at an academic medical center. Disease activity during pregnancy was measured by physician global assessment (PGA) score and classified as low, medium, or high. Pregnancy outcomes in each group were analyzed with simple statistics.

Results: Data on 37 pregnancies in 28 patients with rare autoimmune diseases were analyzed, with an overall mean age of 30.2 years. Patient diagnoses included myositis (n=11), morphea (n=4), scleroderma (n=7) vasculitis (n=6), and sarcoidosis (n=2). There were 7 patients designated as “other autoimmune disease,” consisting of autoimmune hepatitis (n=2 in the same patient), gout, celiac disease, idiopathic optic neuritis (n=2) and orbital pseudotumor. The myositis group included 9 patients with dermatomyositis and 2 patients with polymyositis. The vasculitis group consisted of Bechet’s (n=1), Buerger’s disease (n=1), eGPA (n=1), cutaneous PAN (2), and thrombotic vasculopathy (n=1).

Disease activity during pregnancy overall was low, with only 1 patient with dermatomyositis and 3 patients in the other autoimmune disease category (n=2 autoimmune hepatitis and n=1 Celiac) having high disease activity. The mean gestational age across all groups was 37.4 weeks, ranging from 26 to 40 weeks, with only 6 total preterm births. There were 3 miscarriages (myositis, scleroderma, autoimmune hepatitis), 1 stillbirth (myositis) and 1 medically-indicated termination (myositis with severe lung disease).

Among the 11 myositis pregnancies, 3 resulted in pregnancy losses (miscarriage, stillbirth, the above termination). The one patient with active disease resulted in a live, term birth. Eight patients (72.7%) in the myositis group took prednisone, and 5 (45.5%) azathioprine.

Among the 6 vasculitis pregnancies, 4/6 (66.7%) patients took corticosteroids during pregnancy. Despite 2 patients having moderate disease activity, there was a 100% live birth rate and only 1 preterm delivery.

Conclusion: Despite having autoimmune diseases with a number of potential complications, patients overall had low disease activity and good pregnancy outcomes. This data suggests that patients with rare autoimmune diseases who are carefully managed by a rheumatologist during pregnancy can have a successful pregnancy.

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Reproductive Issues in Rheumatic Disorders Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: During pregnancy, history of lupus nephritis (LN) has been independently associated with increased risk of adverse maternal and fetal outcomes, which are even more frequent when LN is active at conception. The objective of this study was to analyze the impact of different classes of lupus nephritis (LN) as risk variables for maternal and fetal adverse outcomes in a cohort of pregnant lupus patients.

Methods: 146 pregnancies of 136 SLE patients (ACR criteria) were included. Maternal adverse outcomes observed for each nephritis class among LN patients were compared with those without nephritis. Demographic and clinical features of SLE were recorded, including maternal age at delivery, parity and ethnicity, years since the diagnosis of SLE, activity at conception, association with antiphospholipid syndrome, systemic arterial hypertension and permanent damage defined by SLICC/ACR damage index (SDI). Fischer exact test was used for categorized variables and Student's t test was used for the continuous variables.

Results: 54 patients had proliferative LN (classes III and IV), 12 had mesangial or membranous LN (classes II and V) and 80 did not have LN. SLE patients with proliferative LN but not those with classes II and V had more frequently SLE activity at conception ($p=0.02$), flares ($p=0.04$) or continuous active disease during pregnancy and puerperium ($p=0.006$), hospitalization for any cause ($p=0.003$) and due to SLE ($p=0.02$) and preeclampsia ($p=0.05$) than patients without nephritis. When classes II and V LN were compared to patients without LN, there were no statistically significant

SLE=systemic lupus erythematosus, LN=lupus nephritis, SD= Standard deviation, SLICC/ACR-DI= Systemic Lupus International Collaborating Clinics/American College of Rheumatology Damage Index. *Class II- mesangial, **Class III- focal proliferative, ***Class IV-diffuse proliferative ****Class V-membranous.

differences in the main outcomes measured. SDI ≥ 1 was more frequent in classes III and IV than among the other patients, even when renal scores were not included. Adverse fetal outcomes such as prematurity, small for gestational age newborns, admission to NICU and perinatal death were more frequent in patients with proliferative LN (61% vs 42.5%; $p=0.01$), but not with mesangial and membranous LN (41.6% vs 42.5%; $p=0.60$) when compared to lupus patients without LN.

Conclusion: SLE patients with proliferative nephritis (classes III and IV), but not with classes II or V, have a higher frequency of adverse maternal and fetal outcomes. This is probably due to the major impact of proliferative forms of nephritis on women global health, which is corroborated by the higher SDI found. These findings suggest that further LN classification beyond the common term nephritis in the context of lupus pregnancy as the impact on maternal and fetal outcomes varies according to histological classes.

Table 2. Comparison of adverse outcomes between SLE patients with nephritis Classes III and IV and without nephritis

Variable	Classes III and IV n=54		Without Nephritis n=80		p value
Active SLE at conception	22	(40.7%)	20	(25%)	0.02
Maintenance of active SLE in pregnancy / puerperium	18	(33.3%)	12	(15%)	0.006
SLE reactivation in pregnancy / puerperium (inactive at conception)	10	(18.5%)	7	(8.7%)	0.04
Hospitalization related to SLE during pregnancy	13	(35.1%)	12	(15%)	0.003
Hospitalization not related to SLE	10	(33.3%)	15	(18.7%)	0.02
Infection	18	(33.3%)	23	(28.7%)	0.28
Preeclampsia	15	(27.7%)	13	(16.2%)	0.05
Cesarean delivery for maternal or fetal compromise	7	(12.9%)	12	(15%)	0.37
Puerperium Hemorrhage	11	(20.3%)	9	(11.2%)	0.07
Adverse fetal outcome	33	(61.1%)	34	(42.5%)	0.01

Categorical data were expressed by frequency (n) and percentage (%) and compared by the χ^2 test. Adverse fetal outcome includes prematurity, small for gestational age newborn, admission to neonatal intensive care unit and perinatal death (fetal or neonatal).

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Reproductive Issues in Rheumatic Disorders Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is associated with a higher risk of fetal growth restriction and birth of small for gestational age (SGA) concepts. Fetuses with growth restriction have 10-fold higher neonatal mortality, higher risk of hypoxia, meconium aspiration, hypoglycemia, delay in neurodevelopment and cerebral palsy. In adulthood, there is a greater risk of hypertension, type 2 diabetes, hypercholesterolemia and cardiovascular disease. The present study aims to analyze the occurrence of SGA (birth weight below 10th percentile) newborns (NB) in pregnant women with SLE accompanied at a tertiary unit. We studied the association of birth of SGA infants with clinical and laboratory characteristics of maternal SLE prior to conception, during gestation and with maternal comorbidities.

Methods: This is a cohort study with retrospective and prospective data collection, with inclusion of patients with ≥ 4 SLE classification criteria (ACR), single pregnancies and deliveries after 22 weeks. Patients with fetuses with congenital malformations or aneuploidy were excluded. Data were obtained by script-oriented chart review. The comparison between groups was done using Student's t-test or Mann-Whitney test for numerical data and chi-square test (χ^2) or Fisher's exact test for categorical data, with significance of 5%.

Results: 151 patients were included, and 28 had SGA NB (18.5%). Of the variables prior to conception, previous history of nephritis (RR = 3.01, 1.28-7.08, $p=0.01$) and presence of anti-RNP antibody (RR = 2.67, 1.11-6.43, $p=0.02$) were more frequent in patients with SGA NB. Among variables that occurred during gestation, active nephritis (RR = 4.11, 1.68-10, $p=0.002$), pulse therapy with methylprednisolone (RR = 20.3, 2.18-190, $p=0.008$) and consumption of C3 complement (RR = 2.70, 1.09-6.67, $p=0.03$) were associated with SGA group. When considering the SGA NB with altered fetal Doppler subgroup, the associated additional variables were the presence of permanent damage by SDI ≥ 1 (RR = 7.43, 1.50-36.7, $p=0.01$), previous history of neurolupus (RR = 5.16, 1.21-21.8, $p=0.03$), presence of lupus anticoagulant (RR = 4.58, 1.07-19.5, $p=0.04$), antiphospholipid syndrome (RR = 5.21, 1.26-21.5, $p=0.04$), activity at conception (RR = 6.27, 1.26-31.1, $p=0.02$) and during gestation (RR = 6.08, 1.22-30.1, $p=0.02$ per clinical judgment and RR = 9.67, 1.97-47.5, $p=0.004$ per SLEPDAI score ≥ 6), extra-renal activity (RR = 6.08, 1.22-30.1, $p=0.02$), presence of anti-DNA (RR = 4.58, 1.07-19.5, $p=0.04$) and SLE-related hospitalization during pregnancy (RR = 8.6, 1.74-42.3, $p=0.006$). Birth weight and gestational age at delivery were lower in the SGA group (1831g \pm 687g vs 2794g \pm 741g, $p<0.0001$; 36.5 vs 38 weeks, $p=0.05$). Fetal death and admission to neonatal ICU were 4.3 ($p=0.03$) and 3.2 ($p<0.0001$) times more frequent among the SGA NB, as were activity in the puerperium (3.9 times, $p=0.02$) and peripartum hemorrhage (2.3 times, $p=0.04$) among women with SGA NB.

Conclusion: These findings reinforce the importance of SLE remission prior to conception, since prior maternal morbidity combined with the presence of disease activity during pregnancy and treatment with high doses of steroids increase the risk of SGA birth.

Session Date: Tuesday, October 23, 2018

Session Title: Reproductive Issues in Rheumatic Disorders Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with different autoimmune rheumatic diseases are subject to different pregnancy outcomes because of deviant immunity. Systemic sclerosis is known to be associated with higher risk of poor maternal and fetal-neonatal outcomes, such as scleroderma renal crisis and cardiopulmonary complications. The number of pregnancies in patients with systemic sclerosis are relatively lower than other autoimmune diseases such as systemic lupus erythematosus,

ankylosing spondylitis or rheumatoid arthritis in Taiwan. The risks and severity of adverse maternal and neonatal outcomes in systemic sclerosis patients are yet to be documented. This study was designed to analyze the risk of adverse fetal-neonatal and maternal in pregnancies in women with systemic sclerosis in Taiwan.

Methods: We identified 2338180 singleton pregnancies using the birth registry and National Health Insurance Research Database (NHIRD) of Taiwan from 2001 through 2012. 12159 pregnant women suffered from autoimmune rheumatic diseases and 60 were systemic sclerosis. We verified adverse maternal outcomes as death, acute myocardial infarction, acute renal injury, acute respiratory distress syndrome, eclampsia, pulmonary hypertension, sepsis, shock, thrombotic embolism and cerebrovascular disorders. Fetal-neonatal adverse outcomes are verified as stillbirth, low birth weight, low 1 and 5 min APGAR score and fetal distress.

To estimate odds ratios (ORs) and 95% confidence intervals (CIs) for pregnancy outcomes we used an adjusted generalized estimating equation model.

Results: Pregnancy in 60 women with systemic sclerosis were associated with operation on heart and pericardium (OR 24.78 (6.19-99.2)), puerperal cerebrovascular diseases (OR 12.3 (1.73-87.40)), preterm labor (OR 2.43 (1.27-4.68)) and preeclampsia (OR 1.94 (0.62-6.01)). Offspring of women with systemic sclerosis were associated with low birthweight (OR of 2.46 (1.40-4.32)), fetal distress (OR 2.49 (1.25-4.95)), low 1-minute Apgar scores (OR 1.93 (0.62-5.97)) and 5-minute Apgar scores (OR 5.68 (1.45-22.3)). Risks for pregnancy related hypertension (OR 3.06), antepartum hemorrhage (OR 1.52), severe postpartum hemorrhage, and severe postpartum hemorrhage (OR 1.53) were higher in pregnant women with systemic sclerosis. Both maternal and fetal-neonatal outcomes were poor in systemic sclerosis women.

Conclusion: Women with systemic sclerosis were prone to have a higher risk for adverse maternal and neonatal outcomes especially cerebrovascular events and lower APGAR score. Planned pregnancy and rigorous monitoring of renal function, blood pressure and signs and symptoms of cerebrovascular diseases are recommended in women with systemic sclerosis.

Session Title: Reproductive Issues in Rheumatic Disorders Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is a chronic inflammatory autoimmune disease, which predominantly affects women and reaches peak incidence during reproductive years. Periods of high disease activity are associated with maternal and fetal morbidity and mortality. Many medications, disease modifying anti-rheumatic drugs (DMARDs), used to treat SLE also have deleterious pregnancy effects. The literature provides clear guidelines for the best approaches to these practices for women with SLE; however, little is known about current practices. Our aim was to determine contraception practices within The Ohio State University (OSU) Lupus/Vasculitis/Glomerulonephritis (LVG) Registry.

Methods: The OSU LVG Registry prospectively collects clinical data of patient reported surveys including information on reproductive health. Per the Registry and chart review, patient reported sexual activity was assessed. An IRB approved retrospective chart review was conducted on female participants within the LVG cohort who received care for SLE between 2013 and 2018. Data collected included: patient demographics, sexual activity, contraceptive method (oral, surgical, devices, condom, or abstinence), and DMARD use.

Results: Within the registry, we had 259 female patients with SLE. Approximately half of the SLE cohort was on medications considered to be potentially teratogenic or non-compatible with pregnancy. Table 1 shows our SLE cohort demographics. 94% of the cohort self-reported as sexually active, with only about 25% reporting the use of prescription

contraceptives (excluding post-menopausal women). An estimated 14% of sexually active patients reported using only condoms or abstinence while almost 27% use no method of contraception.

Conclusion: Within the LVG Cohort, SLE patients are on high risk medications with the potential for high risk pregnancy complications. This further demonstrates the need for assessing pregnancy intention, providing family planning counseling, and birth control methods in rheumatology practice. Further research is need

Table 1: SLE Cohort Demographics per Intake LVG Registry Questionnaire

Characteristics	(%)
Age (years)

Outcomes of Pregnancy Complicated By ANCA-Associated Vasculitis: A Retrospective Review

Jennifer Strouse¹, Melissa Swee², Manish Suneja¹ and Bharat Kumar³, ¹Internal Medicine, University of Iowa, Iowa City, IA, ²Transplant Nephrology, University of Iowa, Iowa City, IA, ³Internal Medicine-Division of Immunology, University of Iowa, Iowa City, IA

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Reproductive Issues in Rheumatic Disorders Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: ANCA-Associated Vasculitis (AAV) is a small-vessel vasculitis that predominantly affects the kidneys, lungs, and sinuses, among other organs. It has been traditionally associated with older populations, but its occurrence in younger, potentially childbearing, females is increasingly being recognized. In this study, we characterize the outcomes of pregnancy in ANCA-associated vasculitis at a large tertiary care and referral center.

Methods: We performed a retrospective chart review of all patients at the University of Iowa Hospitals and Clinics with a positive PR3 or MPO and a documented diagnosis of vasculitis between 2000 and 2017. Inclusion criteria included female sex and age younger than 45. Charts were reviewed to identify disease activity, clinical manifestations, medication regimens, and pregnancy outcomes.

Results: 24 patients met the inclusion criteria, of which 11 were pregnant at some point, accounting for 29 total pregnancies. Among these, 8 had at least one pregnancy after the diagnosis of AAV and 5 before the diagnosis. Of those who were pregnant after the diagnosis of AAV, all had single pregnancies. They accounted for 16 pregnancies, of which 7 were viable, 2 are currently gravid, and 7 resulted in spontaneous abortions. Among the 8 with a preexisting diagnosis of AAV, the mean age was 29 (age range: 22-34 years). Six patients (75%) were MPO positive while 2 (25%) were PR3 positive. All were in remission at conception. Two patients were on moderate doses of prednisone (15mg – 20mg daily) throughout pregnancy; maintenance immunosuppressive therapy was held for the others. For induction therapy, 5 had cyclophosphamide, 1 had rituximab, and 2 had limited disease not requiring induction therapy. In vitro fertilization was documented in only 1 patient. Four were delivered by Caesarean section. All 7 who have completed pregnancy experienced complications, including premature birth (4), preeclampsia (2), preterm premature rupture of membranes (1), and cholestasis of pregnancy (1). None experienced a relapse in disease activity during pregnancy, although one patient required tracheostomy for preexisting subglottic stenosis at 11 weeks.

Conclusion: Women with AAV should be considered at high risk for pregnancy complications due to the underlying disease and chronic immunosuppressive treatment regimens. With counseling and very close clinical monitoring, women with AAV may be able to conceive and give birth.

Needs and Barriers to Pregnancy Counselling in Women with SLE

Autumn Neville¹, Natalie Dayan¹, Cheryl Barnabe², Susan Elliott³, Laurie Proulx⁴, Deborah Da Costa⁵, Sasha Bernatsky⁶ and Evelyne Vinet⁷, ¹McGill University Health Centre, Montreal, QC, Canada, ²Medicine, University of Calgary, Calgary, AB, Canada, ³GEOGRAPHY AND ENVIRONMENTAL MANAGEMENT, University of Waterloo, Waterloo, ON, Canada, ⁴Canadian Arthritis Patient Alliance, Ottawa, ON, Canada, ⁵Medicine, McGill University, Montreal, QC, Canada, ⁶Divisions of Rheumatology and Clinical Epidemiology, The Research Institute of the McGill University Health Centre, Montreal, QC, Canada, ⁷Divisions of Rheumatology and Clinical Epidemiology, McGill University Health Centre, Montreal, QC, Canada

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Reproductive Issues in Rheumatic Disorders Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Existing data suggest that barriers to pregnancy counselling exist and might represent an area of need in order to optimize outcomes for SLE pregnancies. Yet, this issue has not been comprehensively explored, representing an important knowledge gap. Our objectives were to assess pregnancy counselling needs in women with SLE and to identify potential clinical and psychosocial barriers and facilitators to meet their counselling needs.

Methods: Focus groups were conducted with SLE females contemplating pregnancy or trying to conceive, women with SLE who were pregnant or had recently been pregnant (≤ 2 years), and healthcare professionals (e.g. rheumatologists, maternal-fetal medicine specialists, obstetrician-gynecologists, nurses) until thematic saturation was achieved. Participants were recruited through purposive sampling from community-based practices, as well as peripheral and tertiary care centers from the McGill University's health network. Only women meeting ≥ 4 ACR classification criteria for SLE were included. Transcripts were reviewed by 2 independent investigators using the constant comparative method to identify emerging themes and data were analyzed thematically using grounded theory.

Results: Twenty-four SLE patients and 10 healthcare professionals participated in 10 unique focus groups that lasted 60 minutes each. The following themes emerged: 1) Anxiety - Patients feared their disease would affect the health of their offspring, prevent them from breastfeeding and/or care for a newborn. They also worried over the anticipated extra stress and fatigue associated with pregnancy, and expressed concerns that the stress could cause a lupus flare. The systematic categorization of their pregnancy as “high risk” was verbalized as a source of anxiety. Information on the internet was also perceived as “extremely scary”. 2) Confusion - The consensus was that information available on SLE pregnancy was limited and not always clear, particularly on the internet where forums were seen as unreliable. Although patients saw their rheumatologist as the primary source for information, they felt that the information on pregnancy was vague until the moment they voiced that they wanted to conceive. 3) Frustration - Patients were frustrated that their concerns and anxiety were not taken seriously by members of their support system as few of them know what SLE is and what it entails during pregnancy. Having to plan a pregnancy at a time of disease quiescence was also frustrating. This can fall outside of their personal narrative or outside their cultural value system. Not remembering some of their questions or not having time to ask them all during medical encounters was a common source of frustration among patients.

Conclusion: Our qualitative study provides important insight into the needs and barriers to pregnancy counselling in SLE women. Potential strategies to address these might include facilitating access to psychosocial support (e.g. psychologist, social worker) during pregnancy, developing an educational tool, providing a checklist of questions for medical encounters, and designing prenatal classes dedicated to SLE patients and their partners.

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Reproductive Issues in Rheumatic Disorders Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Familial Mediterranean Fever (FMF) is the most frequent auto-inflammatory disease caused by MEFV gene mutations. Although disease is characterized by intermittent febrile inflammatory attacks of serositis and arthritis some patients may experience complications of disease. Infertility/subfertility is a complication of auto-inflammatory diseases and data is still unclear about FMF associated infertility. The aim of study is to investigate the frequency and possible underlying factors of FMF associated infertility/subfertility.

Methods: All patients recruited from FMF in Central Anatolia (FiCA) cohort. All patients fulfilled Tel Hashomer criteria and all were using colchicine for at least 1 year. Demographic data, FMF attacks and mutation (if available) characteristics, amyloidosis and treatment features were recorded. For this study data on 403 eligible patients (mean age 41.4±10.7, 68.7% female) who had been willing to have children were used.

Results: Proportions of FMF manifestations were fever 83.1%, peritonitis 89.6%, pleuritis 51.4%, arthritis 43.4% and skin rash 28%. MEFV mutations were available for 317 subjects and 77.9% of subjects harboring M694V mutation (27.4% homozygous for M694V). Among all 42 (10.4%) patients were colchicine non-responders. Infertility was present in 45 (11.2%) of patients. Of these 38 (13.7% of females) were female, 7 (5.6% of males) were male. Female sex (odds ratio, 2.9; 95% confidence interval, 1.07–7.98) and colchicine nonresponse (odds ratio, 4.14; 95% confidence interval, 1.75–9.78) were found to be the independent predictors of infertility.

Conclusion: Colchicine nonresponse and female sex were found to be the independent predictors of infertility and effective therapeutic interventions may help to increase fertility in these patients.

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster III: Complications of Therapy, Outcomes, and Measures

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Oncohematological diseases have an increased incidence in Rheumatoid Arthritis (RA) patients. In the last years numerous studies have appeared exploring the relationship between these diseases, RA and its treatments. The introduction of biological therapies and new therapeutic strategies have emerged in the last decades implying an important change in the management and evolution of RA. However, the trend of oncohematological diseases in RA in Spain is unknown. Our objective was to analyze the incidence and trend of hospital admissions for lymphomas and leukemias in patients with RA in Spain during the period between 1999 and 2015.

Methods: We performed an observational retrospective population study analyzing the spanish national administrative database that includes a Minimum Basic Data Set (MBDS) of hospital admissions of patients with RA during the period 1999 to 2015. We selected the MBDSs for lymphomas and leukemias. Cases were identified by the presence in primary and secondary diagnosis of ICD 9 codes. The population at risk was estimated through the population census of the National Institute of Statistics, with an estimated prevalence of RA of 0.5% (0.8% in women and 0.2% in men). Crude and adjusted rates of the selected CVDs were calculated, and the trend was analyzed using the Generalized Linear Model (GLM) with the year as the analysis variable. Statistical analysis was made using SPSS statistical package version 20 (SPSS Inc, Chicago, IL).

Results: 338.343 RA hospital admissions were detected in the period, being 3561 (1.1%) due to lymphomas (2190 women and 1371 men, corresponding respectively to 61.5% and 38.5%) and 1664 (0.5%) leukemias (871 women and 793 men, corresponding respectively to 52.3% and 47.7%). Mean age was 68.94 (SD 11.38) in lymphomas and 71.46 (SD 11.24) in leukemias. There were 372 (10.4%) deaths during admission in lymphomas and 257 (15.4%) in leukemias. Age-adjusted rate during the period for lymphoma was 152.19/10⁵ inhabitants per year (92.05 in women and 240.14 in men). Lymphoma age-adjusted rate increased from 52.46/10⁵ inhabitants per year in 1999 to 187.57 in 2015, both women (from 42.74 in 1999 to 142.95 in 2015) and men (from 280.77 in 1999 to 326.63 in 2015). An annual increase in the lymphoma rate of 6.9% is estimated (RRI 1.069; CI 95% 1.054-1.085). Age-adjusted rate during the period for leukemia was 90.87/10⁵ inhabitants per year (37.09 in women and 144.65 in men). Leukemia age-adjusted rate increased from 18.86/10⁵ inhabitants per year in 1999 to 94.05 in 2015, both women (from 13.80 in 1999 to 65.93 in 2015) and men (from 38.70 in 1999 to 204.84 in 2015). An annual increase in the leukemia rate of 8.2% is estimated (RRI 1.083; CI 95% 1.069-1.097).

Conclusion: In Spain, in the period between 1999 to 2015, lymphoma and leukemia hospital admissions in patients with RA increased, with an estimation of 6.9% and 8.2% annual increase respectively.

Abstract Number: 2444

The Risk of Solid Cancers in Patients with Rheumatoid Arthritis Exposed to Biologic Dmards with/without Prior Cancers

Masaomi Yamasaki, Rheumatology, Shin-Yokohama Arthritis and Rheumatology Clinic, Yokohama, Japan

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster III: Complications of Therapy, Outcomes, and Measures

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: To compare the risk of solid cancer in patient with rheumatoid arthritis treated with biologic disease modifying antirheumatic drugs (b-DMARDs) to that in patients treated with non-biologic (synthetic) DMARDs (sDMARDs) with/without prior cancers.

Methods: 2190 RA patients were enrolled in our rheumatology clinic. Patients were diagnosed according to ACR/EULAR 2010 classification criteria, and treated with DMARDs. Rate of solid cancers were retrospectively examined.

Results: 2175 RA patients without prior cancers were enrolled to this study. Rates of solid cancers in 1897 patients without prior cancers who received sDMARDs (M/F=1671/226, age=60.5+/-14.2) were compared to those in 278 patients without prior cancers who received bDMARDs (M/F=252/26, age=58.7+/-12.5). 50 patients developed a new solid cancer which include 6 gastric cancers, 6 colon cancers, 3 lung cancers, 14 breast cancers and 21 other cancers. The rates of incident solid cancer were 2.33 events/1000 person-years in sDMARDs cohort, 1.59 events/1000 person-years in bDMARDs cohort and 2.08 events/1000 person-years in TNFi cohort. There was no difference in risk of solid cancer for bDMARDs and TNFi compared to sDMARDs treated patients. There was no difference in the relative risk of cancer for any of the individual TNFi therapy.

Secondary we investigate the recurrence of the solid cancers in 15 patients with RA and a history of solid cancer before start of DMARDs. The 0.7% of patients in the sDMARDs cohort had a recurrence of the same cancer in comparison with the 0.4% and the 0.9% in the bDMARDs and TNFi cohorts, respectively.

Conclusion: The addition of bDMARDs to sDMARDs does not alter the risk of solid cancer in RA patients without prior cancers in this study. Although patient numbers are still low, it seems that RA patients with prior cancer received bDMARDs do not have an increased risk of recurrence of same solid cancers.

The Effect of Biologic Agents on Hemoglobin Levels of Patients with Rheumatoid Arthritis

Hwajeong Lee¹, Jung-Yoon Choe², Seong-Kyu Kim³ and Seonghoon Park⁴, ¹Division of Rheumatology, Department of Internal Medicine, Daegu Catholic University School of Medicine, Daegu, Korea, Republic of (South), ²Daegu Catholic University School of Medicine, Daegu, Korea, Republic of (South), ³Rheumatology, Daegu Catholic University School of Medicine, Daegu, Korea, Republic of (South), ⁴Medicine, Daegu Catholic University School of Medicine, Daegu, Korea, Republic of (South)

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster III: Complications of Therapy, Outcomes, and Measures

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Anemia is not considered a major problem in rheumatoid arthritis. But prevalence data suggest that 30-70% of rheumatoid arthritis (RA) patients have anemia. Inflammatory cytokines such as IL-6 and tumor necrosis factor- α are critically involved in its process. We compare the change of hemoglobin, CRP levels and disease activity index in RA patients who were treated with biological disease-modifying anti-rheumatic drugs (bDMARDs) for 12 months.

Methods: The study population was a prospective, observational, multicenter cohort of Korean patients with RA, who were registered to the Korean College of Rheumatology Biologics (KOBIO) registry and followed up for one year after initiating the biologic agent.

Among the patients using bDMARDs, 692 patients had anemia. Among them, a total of 285 patients who received the same bDMARDs for 1 year were analyzed.

We divided the patients into four groups according to the mechanism of bDMARDs.

Results: The number of each group, group 1 (TNFi users), group 2 (rituximab), group 3 (abatacept), group 4 (tocilizumab) was 162, 8, 37 and 78 respectively. The clinical characteristics of the four groups are summarized in Table 1. There were no significant differences between the four groups for the variables. bDMARDs therapy continually improved the anemic status in four groups. Mean haemoglobin values had increased from 11.0 to 11.9 g/dl in TNFi group, from 11.1 to 12.25 g/dl in rituximab group, from 10.9 to 11.8 in abatacept group, from 10.8 to 12.2 g/dl in tocilizumab group. The mean Hb increase was 1.4 g/dl in the tocilizumab group which was the largest between four groups. bDMARDs therapy resulted in significant reduction in DAS28-CRP and serum CRP levels. Tocilizumab was most effective for reducing DAS28-CRP and serum CRP levels.

Conclusion: The change of hemoglobin level was differed according to bDMARDs. Tocilizumab therapy was the most effective for improving anemia and reduced in DAS28-CRP and serum CRP levels. Table 1. Baseline clinical characteristics of patients.

The Combined Use of Folic Acid Influenced the Time until the Development of Lymphoproliferative Disorders in Patients with Rheumatoid Arthritis during Treatment with Methotrexate

Sho Sasaki¹, Yasushi Kondo², Yasuo Suzuki³, Takayoshi Kurabayashi¹, Yasushi Koyama¹, Yuto Izumi¹, Yoko Nakagome¹, Kazuki Hirano¹, Chiho Yamada¹ and Shinji Sato¹, ¹Division of Rheumatology, Department of Internal Medicine, Tokai University School of Medicine, Isehara, Japan, ²Division of Rheumatology, Department of Internal Medicine, Tokai University School of Medicine, Tokyo, Japan, ³Division of Rheumatology, Department of Internal Medicine, Tokai University Hachioji Hospital, Hachioji, Japan, Isehara, Japan

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster III: Complications of Therapy, Outcomes, and Measures

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Lymphoproliferative disorders (LPDs) are a serious complication in patients with rheumatoid arthritis (RA). Methotrexate (MTX) is known to be able to cause a development of LPDs and previous reports have

shown that the cumulative dose of MTX and combination therapy with immunosuppressive agents influence the risk of developing LPDs. However, few reports have focused on the duration from the initiation of MTX to the onset of LPDs. Therefore, the aim of this study is to clarify the factors that influencing the time until the development of LPDs in patients with RA being treated with MTX.

Methods: RA patients who developed LPDs during MTX therapy at Tokai University Hospital between 2001 and 2017 were retrospectively examined. We collected demographic and clinical characteristics and pathological findings from the medical records. The duration from the initiation of MTX to the development of LPDs was calculated. The association between the duration from the initiation of MTX until the development of LPDs and various parameters were analyzed by univariate and multivariate analyses.

Results: A total of 45 patients with RA who developed LPD during MTX therapy were found. Eight patients were excluded from the analysis because of incomplete data and 37 patients (mean 66 years of age) were enrolled. Folic acid (FA), biological disease-modifying anti-rheumatic diseases (bDMARDs), conventional synthetic DMARDs (csDMARDs) and corticosteroid were used in 14, 8 and 16 patients, respectively. The mean duration to the development of LPDs from the first administration of MTX was 6.8 years. In the univariate analysis, the combined use of FA with MTX significantly prolonged the period between the time of MTX initiation and the development of LPDs compared to MTX monotherapy (3.6 years vs. 9.0 years, $p < 0.001$). In addition, we found that the time until the development of LPDs was prolonged in a dose-dependent manner (3.0 years at 0mg; 6.2years at 3mg; 8.7 years at 5mg). In contrast, combination therapy with csDMARDs significantly shortened the time until the development of LPDs compared to without csDMARDs combination therapy (5.1 years vs. 7.9 years, $p = 0.04$). However, no significant association was noted between the time until the development of LPDs and the combined use of bDMARDs or corticosteroids. Complication with Sjögren's syndrome did not influence the time until the development of LPDs. A multiple regression analysis revealed that the combined use of FA was an independent factor that prolonged the time until the development of LPDs ($p < 0.01$).

Conclusion: These results indicated that the combined use of FA with MTX might prolong the time until the development of LPDs during MTX treatment in RA patients.

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster III: Complications of Therapy, Outcomes, and Measures

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Non-alcoholic fatty liver disease, characterized by hepatic steatosis (HS), is a very common form of chronic liver disease in many countries. Limited data are available on liver enzyme elevation in patients (pts) with HS who are receiving medications for inflammatory conditions, such as rheumatoid arthritis (RA), psoriatic arthritis (PsA), and psoriasis (PsO). Tofacitinib is an oral Janus kinase inhibitor for the treatment of RA and PsA, and has also been studied in PsO. The objective of this study was to describe baseline characteristics and liver enzyme abnormalities in pts from the tofacitinib RA, PsA, and PsO clinical programs with/without HS at baseline.

Methods: Pts randomized to the tofacitinib (5 or 10 mg twice daily; doses pooled) and placebo arms of 25 studies in the RA, PsA, and PsO programs were included in this pooled post hoc analysis. Most studies allowed or mandated concomitant treatment with disease-modifying antirheumatic drugs. HS was determined by the investigator and captured per the Medical Dictionary for Regulatory Activities term at baseline. Baseline characteristics, incidence of elevated total bilirubin, aspartate aminotransferase (AST) and alanine aminotransferase (ALT) >1x and >3x the upper limit of normal

Table. Baseline characteristics and liver function up to Month 3, by HS at baseline

^aIncludes patients initially randomized to tofacitinib or placebo; ^bPatients with both baseline and Month 3 CRP

A, change from baseline; ALT, alanine aminotransferase; AST, aspartate aminotransferase; BMI, body mass index; CRP, C-reactive protein; GT, glutamyl transferase; HDL, high-density lipoprotein; HS, hepatic steatosis; LDL, low-density lipoprotein; MTX, methotrexate; N, number of patients analyzed; n, number of patients meeting criteria; NSAID, non-steroidal anti-inflammatory drug; PsA, psoriatic arthritis; PsO, psoriasis; RA, rheumatoid arthritis; SD, standard deviation; ULN, upper limit of normal

(ULN) up to Month (M) 3, and change from baseline in C-reactive protein (CRP) at M3 – all by HS at baseline – are reported.

Results: A total of 10,212 pts were included in the analysis. The prevalence of HS was 1.6% across indications (RA: 87/6,729 [1.3%]; PsA: 27/710 [3.8%]; PsO: 45/2,773 [1.6%]). Baseline characteristics were generally similar in pts with or without HS (Table). However, baseline obesity, diabetes, triglycerides, and liver enzymes were numerically higher, and CRP was numerically lower, in pts with HS than in those without HS (Table). In both tofacitinib- and placebo-treated pts, incidence of elevated total bilirubin, AST and ALT >1x ULN up to M3 was higher in pts with HS than in those without HS, across indications (Table). Incidence of elevated total bilirubin, AST and ALT >3x ULN up to M3 was low across indications, irrespective of HS (Table). Among tofacitinib-treated pts, CRP was reduced at M3 in pts with or without HS, but to a lesser extent in those with HS, across indications. Among placebo-treated pts, changes in CRP were small, irrespective of HS (Table).

Conclusion: In this exploratory analysis, prevalence of HS at baseline was 1.6% across the tofacitinib RA, PsA, and PsO programs. After up to 3 months of tofacitinib treatment, incidence of mildly elevated liver enzymes was higher in pts with HS than in those without HS. Incidence of severely elevated liver enzymes was low overall, and similar inputs with or without HS. Further studies are needed to evaluate the effects of tofacitinib on CRP and liver enzymes, and the potential impact on clinical response, in pts with RA, PsA, or PsO who have comorbid HS.

Correlation between Long-Term Low-Dose Steroid Administration and Reactivation of Hepatitis B Virus in Patients with Rheumatoid Arthritis

WooSeong Jeong¹, Jinseok Kim², Byeongzu Ghang¹ and Byung Cheol Song³, ¹Division of Rheumatology, Department of Internal Medicine, Jeju National University Hospital, University of Jeju School of Medicine, Jeju, Korea, Republic of (South), ²Department of Medicine, Jeju National University Hospital, University of Jeju School of Medicine, Jeju, Korea, Republic of (South), ³Department of gastroenterology, Departments of Internal Medicine, Jeju National University Hospital, University of Jeju School of Medicine, Jeju, Korea, Republic of (South)

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster III: Complications of Therapy, Outcomes, and Measures

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: It is well known that the use of corticosteroids results in increased viral replication and elevated ALT in patients with hepatitis B virus. The use of high dose corticosteroids for more than 4 weeks usually results in hepatitis worsening after cessation of steroids. However, few studies have investigated the effect of low dose corticosteroids on hepatitis B virus (HBV) reactivation. The aim of this study is to investigate the reactivity of HBV in rheumatoid arthritis patients treated with long-term low dose corticosteroids.

Methods: Patients with HBsAg positive who were diagnosed with rheumatoid arthritis and who received prednisolone of less than 10 mg/day over four weeks were selected at four university hospitals. Medical records and laboratory data were retrospectively analyzed and multivariate analysis was performed.

Results: One hundred forty five patients were included in the study and 26 (17.9%) patients were reactivated with HBV. Mean age was 50.7 years and 104 (71.7%) patients were female. Baseline characteristics including sex, age, past medical history and laboratory findings were not significantly different except the level of aspartate aminotransferase (21 vs. 83 IU/L, p <0.001) and alanine aminotransferase (23 vs. 104 IU/L, p <0.001) in patients with HBV reactivation compared to those without HBV reactivation. The administration of low-dose prednisolone did not affect HBV reactivation, and the duration of prednisolone administration, average daily prednisolone dose, and cumulative prednisolone dose did not affect the reactivation of HBV. However, the administration of leflunomide showed a significant difference in the reactivation of

HBV (adjusted odds ratio 3.81; $p=0.034$), and the administration of hydroxychloroquine tended to cause reactivation of HBV (adjusted odds ratio 3.43; $p=0.06$).

Conclusion: The hepatitis B virus can be exacerbated by spontaneous viral reactivation, so it is difficult to conclude that hepatitis is caused by the administration of steroids. In this study, the administration of low-dose steroids did not affect the reactivation of HBV, suggesting that it could be used safely. Further, prospective studies on the effect of conventional disease-modifying antirheumatic drugs such as leflunomide and hydroxychloroquine on the reactivation are needed.

Prevalence and Risk Factors of Serious Infections in Rheumatoid Arthritis Patients Receiving the Biologic/Targeted Synthetic Dmards: A Propensity Score Analysis from the Hong Kong Biologics Registry

Chi Chiu Mok, Ting Hung Wan and Lai Shan Fong, Medicine, Tuen Mun Hospital, Hong Kong, Hong Kong

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster III: Complications of Therapy, Outcomes, and Measures

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: To study the prevalence and risk factors for serious infections (SIs) in rheumatoid arthritis (RA) patients receiving the biologic / target synthetic (b/ts) DMARDs.

Methods: Patients with RA included in the Hong Kong Biologics Registry since 2007 ever treated with b/tsDMARDs were studied. Data on withdrawal of b/tsDMARDs due to serious adverse events (SAEs) and SIs was analyzed. Demographic data, medical comorbidities (eg. diabetes mellitus, chronic lung, kidney and liver diseases) and concomitant use of glucocorticoids (GCs) and csDMARDs were retrieved and their contribution to SIs was evaluated by separate logistic regression. The propensity score for SIs was computed and patients were stratified into 5 quintiles according to the risk. The hazard ratios (HRs) of SIs with respect to individual b/tsDMARDs in each quintile were studied by Cox regression.

Results: 2355 courses of b/tsDMARDs were used in 1355 Chinese patients with RA (83% women; mean age 54.0 ± 12.7 years). The usage of various b/tsDMARDs was: adalimumab (12%), etanercept (24%), infliximab (17%), golimumab (9.4%), certolizumab (0.9%), tocilizumab (19%), rituximab (6.6%), abatacept (7.7%) and tofacitinib (2.7%). After a follow-up of 5056 patient-years, 1433 courses of b/tsDMARDs were discontinued, with major reasons being inefficacy (50%), SAEs (22.4%) and cost (8.4%). Among those b/tsDMARD courses terminated for SAEs, 32% were due to SIs (103 episodes). The rate of SIs was 1.17/100 patient-years. The commonest causes of SIs were pulmonary tuberculosis (TB) (41%), severe pneumonia (33%), soft tissue infection (6.8%), atypical TB (2.9%), urogenital sepsis (2.9%), septic arthritis (2.9%), hepatobiliary / gastrointestinal sepsis (2.9%), central nervous infection (1%), severe viral infections including herpes zoster (5.8%), and opportunistic infections (2.9%). Logistic regression showed that age (OR 1.02[1.001-1.04 per year]), male sex (OR 1.88[1.08-3.26]) and concomitant chronic obstructive pulmonary disease / asthma (OR 2.55[1.05-6.23]) were independent risk factors for SIs. TB infection was most frequent in users of infliximab (2.32/100 patient-years), followed by tofacitinib (1.47), adalimumab (1.27), etanercept (0.62) and tocilizumab (0.36). Non-TB serious infections occurred most frequently with infliximab (2.32/100 patient-years), tofacitinib (1.47) and abatacept (1.15). In the quintile of patients with the highest propensity score for SIs, infliximab had the highest withdrawal rate due to SIs (18%). Cox regression revealed a highest HR for SIs in infliximab users with reference to adalimumab (2.81[0.80-9.88]), followed by tofacitinib (HR 2.12[0.19-23.4]). Concomitant GC was associated with an insignificantly increased risk of SIs.

Conclusion: SIs causing withdrawal of b/tsDMARDs in patients with RA account for one-third of all SAEs. Increasing age, male sex and concomitant chronic chest conditions were independent risk factors for SIs. Infliximab was associated with the highest rates of serious TB and non-TB infection, and this observation was consistent in all quintiles of patients with different propensity to SIs.

Prosthetic Joint Infection in Patients with Rheumatoid Arthritis

John Fredy Jaramillo Gallego¹, Aurelia Luissi¹, Marina Scolnik², Javier Rosa¹ and Enrique R Soriano², ¹Rheumatology Unit, Internal Medicine Service, Hospital Italiano de Buenos Aires, Capital Federal, Argentina, ²Rheumatology Unit, Internal Medicine Service, Hospital Italiano Buenos Aires, Argentina, Buenos Aires, Argentina

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster III: Complications of Therapy, Outcomes, and Measures

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with rheumatoid arthritis (RA) have been shown to have an increased susceptibility to the development of prosthetic joint infection (PJI) after Total Hip or Knee Arthroplasty (THA/TKA). Our aim was to compare the risk of PJI after THA or TKA in patients with RA versus controls.

Methods: All patients with RA (ACR 1987/ACR 2010 criteria) who had undergone joint replacement of the hip or knee in our hospital between 01/01/2008 and 12/31/2016 were included; and compared with patients matched by age and sex (2 to 1), without diagnosis of RA, also subjected to hip or knee joint replacement in the same period. Clinical records were reviewed, collecting demographic data, RA characteristics, treatments and comorbidities. Patients with PJI were identified in cases and controls. Descriptive statistics were performed and risk factors associated with infection were analyzed by logistic regression.

Results: We identified 50 patients with RA who underwent joint replacement surgery in that period, 92% women, mean age at diagnosis of 48.9 years (SD 17.2) and mean age at the time of joint surgery of 60.3 years (DS 15.7) (see table). The cause of joint replacement in control patients was osteoarthritis in 79% of cases. The type of joint surgery in patients with RA was TKA in 27 patients, THA in 20 patients and total hip and knee arthroplasty in 3 patients. At the time of surgery, RA patients were in treatment with: corticosteroids 56%, conventional DMARDs 72% and biologics 34%. DMARD or biological treatment was suspended because of the surgery in 34% of patients. 3 patients with RA (6%, 95% CI: 1.9-17.3) and 2 control patients (2%, 95% CI: 0.5-7.8) had prosthetic infection ($p = 0.2$). All prosthetic infections in patients with RA resolved with prolonged antibiotic treatment, while 1 of the 2 control patients required prosthetic replacement ($p = 0.17$). There was no association between having a PJI with previous comorbidities or with any of the RA treatments.

Conclusion: 6% of the patients with RA undergoing THA/TKA had a prosthetic infection, without difference with the control group.

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster III: Complications of Therapy, Outcomes, and Measures

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Immunosuppressed patients such as Rheumatoid Arthritis (RA) patients have a greater risk (1.5-2 times) of presenting herpes zoster (HZ). Both, the disease itself and the use of immunosuppressive drugs, are involved in this increased risk. Furthermore, in these patients is more frequent disseminated presentation of zoster involving several dermatomes.

In a series of RA patients our aim was analyzed HZ infections and to assess **a)** HZ prevalence and **b)** HZ general features.

Methods: Prospective Single center study of 390 RA patients included in the vaccination program of the Preventive and Rheumatology department of our hospital between October 2011 and October 2016. The follow-up was made until December 2017. HZ vaccination is not included in our program.

RA was diagnosed according to the ACR/EULAR 2010 proposed criteria (Arthritis Rheum 2010; 62: 2569–2581)

The diagnosis of HZ was made according to the clinical manifestations and was confirmed by a dermatologist. These manifestations were characteristic skin rash and blisters, paresthesia and local pain, in one (localized) or more dermatomes (generalized)

Results: We studied 390 patients (307♀/83 ♂), average age 61.28±12.9 years that were included in the vaccination program and followed up.

HZ infection was observed in 12 of 390 (3.07%) in the follow-up (TABLE).

The 12 RA patients (11 women/1 man) with a mean±SD age of 67.5±11.67. More than half of patients, 7 (58.33%) were taking corticosteroids. 8 patients (66.66%) were receiving conventional disease modifying drugs (DMARDs) methotrexate (33.33%), leflunomide (16.66%) and hydroxychloroquine (16.66%). Besides corticosteroids and conventional DMARDs, 7 patients (58.33%) were in treatment with biologic drugs, tocilizumab (n=2), etanercept (n=2), adalimumab (n=2), and rituximab (n=1).

Conclusion: Herpes zoster is a relative frequent viral infection in RA patients non-vaccine for HZ. The female sex, older age, more aggressive RA and treatment with corticosteroids were more frequent. Probably in this group of patients HZ vaccination may be useful. Table General features of 12 RA patients at HZ infection

Case	Sex	Age (years)	Duration of RA (months)	RF+/-	APCA+/-	Erosive RA	HZ Localization	Previous Herpes Viral serology	HZ Treatment	Concomitant treatment for RA

Incidence Rate and Clinical Characteristics of Herpes Zoster Infection in Korean Patients with Rheumatoid Arthritis Patients

Su-Jin Moon¹, Min Jung Kim², Sun Kyung Lee², So Hee Oh², Hyoun-Ah Kim³ and Kichul Shin⁴, ¹Bucheon St. Mary's Hospital, Division of rheumatology, Department of Internal Medicine, College of Medicine, The Catholic University of Korea, Bucheon, Korea, Republic of (South), ²Division of Rheumatology, Department of Internal Medicine, SMG-SNU Boramae Medical Center, Seoul, Korea, Republic of (South), ³Department of Rheumatology, Ajou University School of Medicine, Suwon, Korea, Republic of (South), ⁴Kyungnam villa #102, Division of Rheumatology, Department of Internal Medicine, SMG-SNU Boramae Medical Center, Seoul, Korea, Republic of (South)

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster III: Complications of Therapy, Outcomes, and Measures

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Herpes zoster (HZ) infection is not uncommon in rheumatoid arthritis (RA) patients, especially in those treated with biologic or targeted synthetic (bts) disease-modifying antirheumatic drugs (DMARDs). Detailed analyses of HZ infection in Korean RA patients are limited, i.e. the relative risk of HZ infection compared with conventional (c) DMARD-treated patients.

Methods: By utilizing the data of the Korean college of Rheumatology Biologics Registry, or KOBIO, we investigated the incidence rate of HZ infection in the registered RA patients. We analyzed 1375 btsDMARD users (group 1), and 617 cDMARD-only users (group 2) registered from 2013 to 2017. The hazard ratio (HR) of HZ infection was adjusted for age, baseline corticosteroid usage, eGFR, and DAS28 (model 1), or age, gender, disease duration, baseline corticosteroid usage, comorbidity, smoking, eGFR, and DAS28 (model 2).

Results: Baseline characteristics of in both populations differed (group 1 vs. group 2) in disease activity (mean DAS28 5.67 vs. 3.33), disease duration (mean 7.7 vs. 6.4 years), dose of corticosteroids, and estimated GFR (eGFR). The overall incidence rate (per 100 patient × years) was 1.49 (95% CI 0.96 - 2.00) in group 1, and 0.90 (95% CI 0.53 - 1.46) in group 2; higher in RA patients treated with btsDMARDs. The unadjusted HR of HZ infection in group 1 in reference to group 2 was 1.562 (95% CI 0.874 - 2.791), and the adjusted HR by model 1 was 1.677 (95% CI 0.698 - 4.027), 1.695 (95% CI 0.707 - 4.063) by model 2.

Conclusion: These results indicate that the incidence rate of HZ infection in btsDMARD users may largely be driven by the baseline characteristics which these RA patients reserve, not only by the augmented immunosuppression they receive.

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster III: Complications of Therapy, Outcomes, and Measures

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with rheumatoid arthritis (RA) have a higher risk of surgical site infection than patients with osteoarthritis (OA). Disease modifying therapy is widely used by RA patients, and biologic medications may increase *Staphylococcus aureus* colonization rates. Because *S. aureus* colonization likely increases risk of surgical infection, perioperative assessments and therapies to decrease risk of invasive *S. aureus* infections may be warranted. The objective of this study was to determine if there was a difference in *S. aureus* carriage among patients with RA, OA, and RA on biologics (RA+B).

Methods: An *a priori* power analysis determined 123 participants per group were needed to detect a relative difference of 20% with 80% power. After IRB approval, patients were screened; included patients met ACR classification criteria. Patients were approached between April 2017 and May 2018 and performed a nasal swab using the Center for Disease Control's swabbing protocol; questionnaires pertaining to health status were collected. Swabs were inoculated onto ChromAgar/ChromID MRSA plates for detection of *S. aureus*. Mann-Whitney U and Chi-square tests were used to evaluate baseline differences between groups. Logistic regression evaluated the associations between groups and *S. aureus* carriage. All statistical analyses were performed using SAS Software version 9.3 (SAS Institute, Cary, NC); statistical significance was defined as $p < 0.05$.

Table 1: Patient Characteristics

Variable	All Patients N=369	RA + Biologic N=123	RA N=123	OA N=123	p-value
Age	65.63 ± 13.77	59.15 ± 14.4	65.82 ± 13.85	71.91 ± 9.51	<0.0001

Male	80 (21.68)	15 (12.2)	17 (13.82)	48 (39.02)	
Race					0.002
Asian	17 (4.61)	9 (7.32)	7 (5.65)	1 (0.81)	
White	284 (78.62)	87 (70.73)	87 (70.86)	110 (89.88)	
Black or African American	34 (9.21)	19 (15.45)	7 (5.69)	8 (6.5)	
Other	24 (6.5)	8 (6.5)	12 (9.78)	4 (3.25)	
Smoker (ever)	148 (40.11)	43 (34.96)	42 (34.15)	63 (51.22)	0.009
Smoker (current)	19 (5.15)	10 (8.13)	5 (4.06)	3 (2.44)	0.018
Diabetes	37 (10.03)	6 (4.88)	5 (4.06)	15 (12.2)	0.04
Glucocorticoids	67 (18.16)	32 (26.02)	18 (14.63)	17 (13.82)	0.0211
Antibiotics in past 3 months	164 (44.45)	29 (23.58)	21 (17.07)	54 (43.9)	<0.0001
Hospitalization in past year	89 (24.12)	22 (17.89)	14 (11.38)	53 (43.09)	<0.0001
Years since initial diagnosis	10.72 ± 10.38	13.55 ± 11.00	9.55 ± 10.02	9.04 ± 9.45	
<i>S. aureus</i> growth	59 (16.01)	45 (36.59)	29 (23.58)	25 (20.33)	

*Continuous variables are presented as means & standard deviations.

**Categorical variables are presented as frequency & percent.

Table 2 – Multivariate Analysis of the Relationship between Diagnosis and *S. Aureus* Growth

Risk Factor	OR (95% CI)	p-value
OA vs. RA	0.99 (0.50-2.00)	0.978
RA +biologics vs. RA	1.80 (1.01-3.22)	0.047
Age	0.99 (0.97-1.01)	0.209
BMI	1.01 (0.97-1.04)	0.664
Sex (Male vs. female)	0.80 (0.43-1.50)	0.491
Diabetes (Yes vs. No)	1.29 (0.52-3.19)	0.587
Steroid use (Yes vs. No)	0.79 (0.42-1.48)	0.460
Antibiotics use-last 3 months (Yes vs. No)	0.88 (0.50-1.56)	0.662
Hospitalization in past year (Yes vs. No)	0.82 (0.44-1.53)	0.523

Results: Overall the cohort evaluated had a mean age of 66 (+/-13.7), BMI of 28 (+/-7.0), and were predominantly female (78%) (Table 1). 28% were on antibiotics within three months prior to the swab, 18% were currently on steroids, and 24% had been hospitalized within the last year. We found differences in age ($p<0.001$), BMI ($p<0.001$), sex ($p<0.001$), diabetes ($p=0.04$), steroid use ($p=0.02$), antibiotic use ($p<0.001$), and hospitalizations within the last year ($p<0.001$). *S. aureus* carriage was most prevalent in RA+B (37%), followed by RA (24%), and OA (20%). After multivariate adjustment, RA+B was found to have increased odds of *S. aureus* (OR=1.80, 95% CI 1.00-3.22); $p=0.047$) compared to RA. Use of glucocorticoids, hospitalization, or diabetes did not increase odds of *S. aureus* carriage. The OA group had decreased odds of *S. aureus* compared to the RA group; however this was not statistically significant ($p=0.987$).

Conclusion: RA patients treated with biologics have an increased prevalence of *S. aureus* colonization. Since nasal *S. aureus* carriage may play a role in the pathogenesis of surgical infections, *S. aureus* decolonization should be considered in RA patients on biologics prior to elective surgery.

Abstract Number: 2454

Virus Reactivation Rate in Rheumatoid Arthritis Using Tofacitinib

Yukitomo Urata, Rheumatology, Tsugaru General Hospital, United Municipalities of Tsugaru, Gosityogawara, Japan

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster III: Complications of Therapy, Outcomes, and Measures

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Although the increase in the incidence of Herpes Zoster by tofacitinib (TOF) in rheumatoid arthritis (RA) is well known, the reactivation rate of other viruses is unknown. We clarify the reactivation rate of varicella virus (VZV), hepatitis B virus (HBV), EB virus and cytomegalovirus (CMV) when using TOF for RA patients.

Methods: We measured VZVIgG, VZVIgM, high sensitivity HBs antigen, HBV-DNA, CMVIgG (EIA), CMVIgM (EIA), CMV antigenemer, EBV VCA IgG (EIA, FA) and EBV VCA IgM (EIA, FA) once every 3months. Antigenemia positive, high sensitivity HBs antigen positive, IgG antibody raised by 4 times or more was defined as virus reactivation.

Results: 35 RA patients, 77% of women, 65 years of age, 10 years of disease duration, 74% positive for CCP antibody, SDAI 9.5, corticosteroid (PSL) use rate 14%, mean PSL 2.2 mg / day, MTX usage 23%, mean MTX dose 7.5 mg / week, TOF (average 8 mg / day) was administered on average for 12 months. Each virus reactivation rate was 2.9, 8.6, 25.5 and 0% for CMV, HBV, VZV and EBV, respectively. There were no cases where more than two types of virus reactivation came. As clinical symptoms CMV had fever, VZV showed all cases, eruption. No liver dysfunction was observed in HBV reactivation case. A significant difference (68.8 vs 29.7 $p<0.05$) was observed in the CMV IgG value between the cases of HBV reactivation and no other virus reactivation cases.

Conclusion: Viral reactivation by TOF administration in RA is diverse and its rate is high (37.1%) by highly sensitive virus examination and elaborate observation of body findings, However, it is possible to prevent the seriousness of virus reactivation by TOF by detailed examination and appropriate blood collection, early treatment.

Table 1 Comparison of patient characteristics with or without varicella zoster virus reactivation

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster III: Complications of Therapy, Outcomes, and Measures

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Individuals with rheumatoid arthritis (RA) have an increased risk of venous thromboembolism (VTE), including pulmonary embolism (PE) and deep vein thrombosis (DVT), compared with non-RA populations based on several recent studies^{1,2}. However, information is sparse on the risk of VTE among patients receiving treatment with specific disease-modifying antirheumatic drugs (DMARDs) or categories of therapies. The objective was to estimate the incidence of VTE among patients receiving routine clinical care for RA, specifically during treatment with conventional (c) and biologic (b) DMARDs.

Methods: Incidence rates were estimated in a retrospective cohort study of patients with RA (defined as at least 2 International Classification of Disease, Ninth Revision, Clinical Modification [ICD-9-CM] Diagnostic codes) enrolled in US health insurance plans between October 1, 2010 to September 30, 2015 and participating in the Innovation in Medical Evidence Development and Surveillance (IMEDS) program. These data are formatted into the U.S. Food and Drug Administration's Sentinel Common Data Model and Sentinel's publicly available standardized analysis tools were used to estimate the incidence rates of VTE following initiation of cDMARDs or bDMARDs. Patients were required to be new users of the study drug class, with no evidence of use in the 365 days preceding initiation and were not allowed to re-enter the cohort. Patients were required to demonstrate continuous use of the study drug class to be considered at risk for VTE. VTE was defined based on ICD-9-CM codes, but patients diagnosed in outpatient settings were also required to have evidence of oral anticoagulant dispensing within 31 days of the event. PE and DVT ICD-9-CM codes were also disaggregated to produce separate incidence rates.

Results: During treatment with any cDMARDs (methotrexate or leflunomide) or bDMARDs (abatacept, adalimumab, certolizumab pegol, etanercept, golimumab, infliximab, rituximab, and tocilizumab), patients experienced VTE at a crude incidence rate of 1.49 (95% CI 1.30, 1.71) per 100 person-years (PY) and 0.98 (95% CI 0.83, 1.14) per 100 PY, respectively. For each study drug class, age was an important risk factor for VTE, with increasing age associated with higher rates of VTE; for example, during treatment with bDMARDs incidence rate (IR)_{18-49 years}=0.69, IR_{50-59 years}=0.65, IR_{60-64 years}=0.94, and IR_{65+ years}=2.11 per 100 PY (Figure 1). Men also had higher incidence rates of VTE than women.

In the analyses of PE and DVT, DVT incidence rates were higher than PE incidence rates, and similar incidence rate trends overall and across age strata for cDMARD and bDMARD cohorts were noted.

Conclusion: Venous thromboembolism is an important clinical concern among patients with RA and incidence rates vary by age and sex during routine clinical treatment with DMARDs.

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster III: Complications of Therapy, Outcomes, and Measures

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with RA have an increased risk of venous thromboembolism (VTE), including pulmonary embolism (PE) and deep vein thrombosis (DVT) compared to non-RA populations¹. However, there is limited information available on the risk of VTE among patients receiving treatment with specific DMARDs or categories of therapies. This retrospective cohort study aimed to estimate the incidence of VTE among patients receiving routine clinical care for RA, specifically during treatment with conventional (c) and biologic (b) DMARDs.

Methods: Administrative claims data from TruvenMarketScan, with information on patients enrolled in US commercial or Medicare health plans between January 2010 to September 2015, were used to identify patients diagnosed with RA who had a VTE, PE or DVT during an incident treatment episode. Patients were required to maintain enrollment in the health plan and have drug coverage, with a gap of no more than 45 days, and have at least 2 RA diagnosis codes (International Classification of Diseases, 9th Revision, Clinical Modification [ICD 9-CM]) at least 7 days apart, but within a 365-day period. Medication exposures were based on generic medication names and National Drug Codes and included only incident exposures for the specified medications or medication categories. Incident VTE, PE, and DVT were defined using ICD-9-CM codes and, for events diagnosed in outpatient settings, evidence of dispensing of an anticoagulant within 31 days of the event. All analyses were conducted using SAS v.9.4.

Results: Among 205,785 patients diagnosed with and treated for RA, the crude incidence rate of VTE was 1.05 (95% CI 1.01, 1.09) per 100 person-years (PY). Patients receiving treatment with cDMARDs appeared to have increased risk of

Treatment	Patients (n)	VTE			PE			DVT		
		Events (n)	PY	IR per 100 PY	Events (n)	PY	IR per 100 PY	Events (n)	PY	IR per 100 PY
RA medications, any	205,785	2576	244,940.4	1.05 (1.01, 1.09)	1135	246,199.9	0.46 (0.43, 0.49)	3311	243,903.0	1.36 (1.31, 1.40)
cDMARDs	71,552	719	58,451.5	1.23 (1.14, 1.32)	309	58,710.6	0.53 (0.47, 0.58)	911	58,244.4	1.56 (1.46, 1.67)
bDMARDs	77,086	826	86,827.5	0.95 (0.89, 1.02)	397	86,948.1	0.46 (0.41, 0.50)	1091	86,304.1	1.26 (1.19, 1.34)

bDMARDs=biologic disease-modifying antirheumatic drugs, cDMARD=conventional DMARDs, DVT= deep vein thrombosis, IR=incidence rate, PE= pulmonary embolism, PY=person-years, RA=rheumatoid arthritis, VTE= venous thromboembolism

VTE compared to those treated with bDMARDs (see table), but this difference disappeared when age-stratified incidence rates were examined. For PE and DVT, defined based on diagnostic codes only, the crude incidence rates for patients treated with any DMARD were 0.46 (95% CI 0.43, 0.49) and 1.36 (95% CI 1.31, 1.40) per 100 PY, respectively. Incidence rates of VTE were elevated among those with increased age and rates of DVT were consistently higher than rates of PE.

Conclusion: Patients with RA treated with DMARDs were at risk of VTE. Differences in incidence rates of VTE between patients treated with cDMARDs or bDMARDs were likely due to differences in age distributions between groups, with those in the cDMARD cohort tending to be older than those in the bDMARD cohort.

Association between Biologic Dmards and Weight Change in Patients with Inflammatory Arthritis

Britney Jones¹, Imran Hassan², Walter P. Maksymowych³ and Elaine Yacyshyn⁴, ¹University of Alberta, Edmonton, AB, Canada, ²EPICORE Centre, University of Alberta, Edmonton, AB, Canada, ³CaRE Arthritis, Edmonton, AB, Canada, ⁴Medicine, University of Alberta, Edmonton, AB, Canada

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster III: Complications of Therapy, Outcomes, and Measures

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Inflammatory arthritis (IA) is a chronic disorder that encompasses rheumatoid and psoriatic arthritis. Rheumatoid cachexia is defined as elevated HDL, increased adiposity, and loss of lean muscle mass and affects up to two thirds of patients with IA. This can result in extremes of weight and is associated with higher disease activity, elevated rate of cardiovascular disease, and increased sedentary behavior.

Conflicting evidence exists around weight change associated with biologic Disease Modifying Antirheumatic Drugs (boDMARDs). This study sought to examine if weight or body mass index is correlated with treatment with a boDMARD in patients with inflammatory arthritis. Secondary objectives examined disease activity as a function of weight change.

Methods: This study was a retrospective analysis of 2228 patients with IA enrolled in the Rheumatoid Arthritis Pharmacovigilance Program and Outcomes Research in Therapeutics (RAPPORT) Database. This database is a cohort of patients with Inflammatory Arthritis in Northern Alberta that captures demographic information including weight at baseline, 1 month, 3 months, 6 months, and subsequently yearly. Weight in pounds, body mass index (BMI), and DAS 28 were tracked over time in months using a mixed effect model with subject specific random effects.

Results: There was a small but statistically significant increase in weight (0.02 lbs, 95% CI 0.018-0.03 p<0.001) and BMI (0.006lbs, p<0.001) over time in months. There was also a negative association between DAS 28 and increased weight (-0.56, p<0.001) as well as BMI (-0.08, p<0.001) suggesting an increase in weight was associated with lower disease activity.

Conclusion: Extremes of weight and BMI have previously been shown to be a risk factor for poor long-term outcomes in patients with IA. This study suggests that patients with inflammatory arthritis on boDMARDs tend to gain weight over time, in keeping with previous studies examining the effects of TNFi on weight. This may be reflective of improved disease control given the negative association between increased weight/BMI and decreased DAS 28. Alternately, it may suggest weight stabilization as by comparison, the average Canadian gains approximately 0.25-0.5lbs/year.

Figures:: Figure 1: Weight(lbs) trend over time after initiation of biologics. Number of patients: 2298. Total visits: 16642.

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster III: Complications of Therapy, Outcomes, and Measures

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Rituximab (RTX) is an anti-CD20 monoclonal antibody that selectively depletes B-cell population. Thus, it presents a potential risk for the development of hypogammaglobulinemia and related infectious events. Our aim was to identify predictors of hypogammaglobulinemia in RA patients long-term treated with RTX.

Methods: Multicenter longitudinal observational usual care study including RA patients according to ACR 1987 and/or ACR/EULAR 2010 classification criteria followed and treated with RTX. A previous study assessing the safety profile of RTX in patients with RA reported a median follow-up of 30 months (1). Therefore, we decided to include RA patients on RTX maintenance therapy, after a minimal exposition of 30 months. Serum protein electrophoresis was performed one to three days before each RTX infusion. Hypogammaglobulinemia and severe hypogammaglobulinemia were defined as total gammaglobulin <6g/L and <4g/L, respectively. Safety monitoring included the collection of all adverse events (AE) in particular severe infections.

Results: 134 patients met inclusion criteria: 113 female subjects (84.3%); mean age 52.1 ± 11.4 years. Mean follow-up was 79.5 ± 24.6 months and analysis was based on 854.9 patient-years (pt-yrs) of observation. Mean RTX cumulative dose was 12.0 ± 4.9 g. Baseline gammaglobulin levels were significantly lower in subjects aged >65 years as compared to subjects aged <65 years: 10.42 ± 3.05 g/L vs 12.85 ± 3.89 g/L respectively ($p=0.0002$). Hypogammaglobulinemia (<6g/L) occurred during the follow-up period in 23 patients (2.7 events per 100 pt-yrs), leading to an incidence of 17.1%. The mean time to development of hypogammaglobulinemia was 64 ± 23 months. A total of 9.7% of patients had severe infections (1.5 events per 100 pt-yrs). Patients who developed hypogammaglobulinemia were more likely to experience severe infections (26.1% vs. 6.3%, $P=0.033$). Univariate Cox analysis identified age over 65 years (HR 4.28 [95% CI 0.92-19.97], $P<0.001$), low gammaglobulin levels prior the first RTX infusion (<8g/L) (HR 7.35 [95% CI 1.82-29.68], $P<0.001$) as predictors of protective factor (HR 0.26 [95% CI 0.08-0.87], $P=0.03$).

Conclusion: Our results show that gammaglobulin levels of less than 8g/L at baseline is a strong independent risk factor for developing subsequent hypogammaglobulinemia, whereas concomitant MTX therapy seems to be a protective factor in RA patients treated long-term with RTX. Identifying such predictors will raise clinicians' awareness and allow more tailored monitoring of RA patients long-term treated with RTX.

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster III: Complications of Therapy, Outcomes, and Measures

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Checkpoint inhibitors (CI) for cancer therapy are associated with inflammation that can recapitulate features of autoimmunity, including synovitis resembling rheumatoid arthritis (RA). No reports have investigated cellular infiltrates in the synovial tissue (ST) of these patients and no guidelines exist to manage them. Thus, we provide the first report on ST cellular infiltration in PD1 inhibitor-induced rheumatic immune-related adverse-events (irAE).

Methods: ST biopsies, synovial fluid (SF) and PBMCs from a nivolumab-treated small cell lung cancer (SCLC) patient with severe peripheral inflammatory polyarthritis and inadequate response to DMARDs (negative RF and ACPA); 3 DMARD-naïve patients with seropositive early RA were used as comparators.

Serial sections from fresh-frozen ST blocks were stained with H&E, CD3, CD45RO, CD55 and CD68 and semi-quantitatively scored. ST, SF and PBMC single cell suspensions were stained with Zombie UV[®], CD45RO, PD1, CD3, ICOS, CD8, CD4 CD20 prior to flow cytometric acquisition.

Results: CD68+ macrophage, CD20+ B cell and CD3+ T cell and CD45RO+ memory T cell infiltration in irAE was comparable to RA ST on semi-quantitative scoring, while TNF α staining was markedly elevated in irAE compared to RA (irAE-TNF α ; 4, RA-TNF α ; 2) (Figure 1). Flow cytometric analysis identified persistent CD45RO⁺ memory T cell infiltration in the ST and SF compartments (irAE: ST; 27.7, SF; 24.9) compared to RA (RA: ST mean and SEM; 27.5 \pm 3.63; SF; 35.9 \pm 4.85; n=3 for each), driven by continued occupancy of PD1 by nivolumab even 200-days after cessation of treatment (Figure 2). Finally, treatment with infliximab resulted in partial remission of symptoms and reduced synovitis

Figure 1. A, RA ST sections (images representative of all 3 RA). B, ICI-irAE SCLC ST sections. Images were captured at x10 magnification.

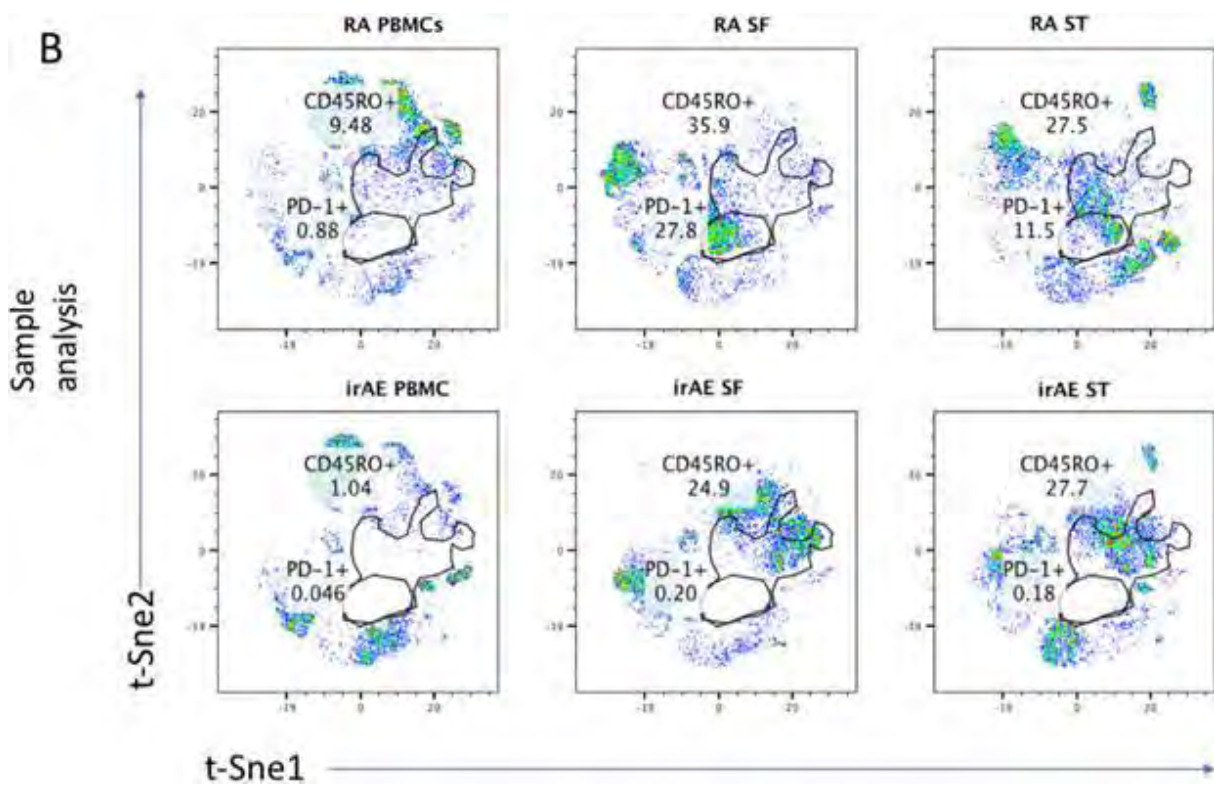

Figure 2. T-Sne global analysis performed on all samples concatenated in a common dimensionally reduced space. Comparable CD45RO+ T cell frequency in ST (irAE; 27.7, RA mean and SEM; 26.5±2.3, n=3) and SF (irAE; 24.9, RA; 36.6±1.79, n=3), flow cytometry revealed a distinct absence of PD1 staining in irAE (ST: irAE: 0.18, SF: 0.20, PBMCs; 0.46) compared to RA (RA: ST; 12.13±1.63; SF; 25.95±2.85; PBMCs; 0.11±0.13, n=3). RA plots representative of all samples.

Conclusion: ST infiltration in irAE SCLC recapitulates many features of RA histopathology. The continued persistence of nivolumab occupancy in rheumatic-irAEs provides a mechanism for exacerbated inflammation. Infliximab treatment was shown to lead to remission in irAE demonstrating high levels of ST TNF α .

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster III: Complications of Therapy, Outcomes, and Measures

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Methotrexate-associated lymphoproliferative disorders (MTX-LPDs) was first reported in 1991. The symptom is known to spontaneously regress after suspending the use of MTX, suggesting its association with LPDs. In recent years, there have been also reports of the disorder's association with biological drugs and immunosuppressive drugs, which are classified as a kind of other iatrogenic immunodeficiency-associated lymphoproliferative disorders (OIIA-LPDs). Regional differences in terms of their frequency, their risk factors, and many other aspects of the disorders still remain unknown.

Methods: The study assessed 16 patients who experienced the onset of OIIA-LPDs during the use of MTX, immunosuppressive drugs, or biological drugs between April 2011 and April 2018. The patients were assessed for their ages, pathological types, MTX dosages, LDH, CRP, lymphocyte counts, sIL-2R, MMP-3, EBER-ISH, EBV-DNA, and DAS28CRP. Also, the study used parameters to analyze the group of patients whose symptoms spontaneously regressed and the other group treated with chemotherapy.

Results: Among the 16 cases, six cases went through spontaneous regression, while two cases terminated in death. Among pathological types, DLBCL accounted for nine cases, followed by four cases with Hodgkin lymphoma. Among the three cases tested with EBER-ISH, two cases were found positive, while one out of four cases tested with EBV-DNA was identified positive. The DAS28CRP level at the onset of LPD was 1.80±0.3 in the spontaneous regression group and 3.8±1.1 in the chemotherapy group, demonstrating a significant decrease ($p=0.01182$) in the spontaneous regression group.

Conclusion: Among the patients with OIIA-LPDs originating in rheumatoid arthritis, the number of EBER-ISH-positive cases was significantly high. Furthermore, the possible association of the active status of rheumatoid arthritis at the onset of LPDs with the necessity of chemotherapy was suggested.

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster III: Complications of Therapy, Outcomes, and Measures

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: There is a well-known risk of developing adverse drug reactions (ADR) in rheumatic patients due, mainly, to the Disease Modifying Drugs (DMARD) widely used. It is mandatory to increase our knowledge of ADR outside of clinical trials; especially those that put the patient live at risk. The purpose of our study was to describe the incidence and characteristics of severe ADR (SADR) to DMARD in patients with incident RA as well as the factors associated to their development.

Methods: We conducted an observational longitudinal study. Patients: all recent onset RA diagnosed between April 15th 2007 and December 31st 2014 followed in outpatient clinic at Hospital Clinico San Carlos until December 31st 2016, which used any DMARD treatment (synthetic and biologic). Primary outcome: development of a SADR (discontinuation and hospitalization or death due to the ADR). Incidence rates of discontinuation (IR) per 100 patient-years were estimated using survival techniques with their respective 95% confidence interval [CI]. Comparisons between associated factors were run by Cox bivariate and multivariate regression models. Results were expressed by hazard ratio (HR) and [CI].

Results: We included 2388 courses of DMARD treatment in 814 patients (3706.14 patient-years). Of these, 77.52% were women with a mean age at diagnosis of 57.53 ± 15.50 years. 72.85% of patients were diagnosed at first visit and the median value of ESR at diagnose was 35.6 ± 26.9 mm/h. From the courses of DMARD, 13.74% were biologicals (72.04% anti-TNF) and 60% were used in monotherapy. There were 56 SADR in 47 patients (IR: 1.51[1.16-1.96]). Infection was the most frequent cause of SADR (n=31, 55.36%), followed by cancer (n=8, 8.93%); 12 patients died due to an ADR (IR: 0.32 [0.18-0.57]), mostly because of sepsis. IR are shown in table 1. We performed a multivariate analysis (table 2). We repeated the model changing the reference category of DMARD and found a higher risk to develop SADR also for Abatacept (HR: 15.38 [1.93-122.75]) and Gold (HR: 2.31 [1.06-5.03]) compared to the other drugs; the rest of DMARD did not achieve statistical significance in the models performed.

Conclusion: The IR of SADR in our cohort was 1.51% patient-years, being infection the main cause. We found differences in discontinuation rates among DMARD due to SADR, with Abatacept, Tocilizumab and Gold being the drugs with the highest risk. Caution should be taken regarding severe ADR in older patients, male sex, patients living alone or institutionalized, with higher values of ESR at the beginning of DMARD and those using combined therapy or with concomitant corticoids.

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster III: Complications of Therapy, Outcomes, and Measures

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: To evaluate the efficacy and safety of rituximab (RTX) in the medium- to long-term for the management of progressive rheumatoid arthritis-related interstitial lung disease (RA-ILD).

Methods: We undertook an open observational study in patients with active symptomatic RA-ILD despite treatment with glucocorticoids and disease-modifying antirheumatic drugs or immunosuppressants. The main efficacy variables evaluated at the end of the follow-up period were the evolution of the respiratory functional tests, distance traveled during the 6-minute walk test (6MWT), and changes in high-resolution chest computed tomography scan (HRCT).

Results: Twenty-three patients were included. The median durations of RA and ILD were 48 months (range, 1-273 months) and 21 months (range, 1-144 months), respectively. Twenty-six percent of the cases corresponded to interstitial usual pneumonia. RA was seropositive in 91% of patients. The number of RTX cycles administered (mean \pm SD) was 4 ± 1.9 (range, 2-10), and the median time of follow-up after RTX treatment was 29 months (range, 12-71 months). At the end of follow-up, the mean DAS28-ESR score decreased to 2.6 ± 0.7 ($P = 0.0001$), and there were improvements in mean FVC values (Delta $+0.86$; $P = 0.711$), DLCO values (Delta $+7.93$; $P = 0.007$), and distance covered in the 6MWT (Delta $+21.63$ m; $P = 0.376$).

Considering the total sample, an improvement or stabilization of the FVC values was achieved in 87% of the cases (improvement: 17% of the cases), in 91% of the cases in the DLCO values (improvement: 56% of cases), and in 83% of cases in the ILD radiologic features (improvement: 13% of cases). The median time between the first and the last HRCT was 26 months (range, 12-65 months).

In addition, at the end of the follow-up period, the average dose of prednisone was reduced to 4.5 mg/d, and it could be suspended in 5 patients.

A significant inverse correlation between the ACPA level and baseline DLCO was found in the entire cohort ($r = -0.45$, $P = 0.04$). This correlation was present even after adjusting for tobacco exposure ($P = 0.01$). In some of the patients, a decrease in the ACPA titer was documented with biologic treatment (median Delta [IQR 25th-75th]: $-159 [-875, -83]$), becoming negative in 4 cases, although there was no significant correlation between the decrease in the ACPA titers (Delta ACPA) and the degree of improvement of the parameters in the PFR at the end of the follow-up (FVC: $r = -0.15$, $P = 0.949$; DLCO: $r = -0.20$, $P = 0.385$).

Globally, patients with UIP had globally worse baseline values in PFTs and 6MWT. In addition, the responses obtained with RTX in this group were numerically lower than those in the group with non-UIP patterns, but the differences were only statistically significant in the case of FVC.

The frequencies of adverse effects (mainly respiratory or urinary infections and transient neutropenia) was high, occurring in 43.5% of patients, but they were severe in only 13%, causing withdrawal of treatment. Two (9%) patients died due to progression of ILD, and 2 (9%) ended up requiring a lung transplant. At the end of the follow-up period, 16 of the 23 patients (69%) were still in treatment

Conclusion: According to this preliminary experience, RTX appears to be effective in the treatment of RA-ILD.

Abstract Number: 2463

Reducing Time to Treatment in Patients with Early and Uncontrolled RA: Implementation of a Collaborative and Systems-Based Approach to Improve Access to Care

Isabelle Amigues, Department of Medicine, Division of Rheumatology, National Jewish Health, Denver, CO

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster III: Complications of Therapy, Outcomes, and Measures

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The first three months following the onset of the first symptoms of rheumatoid arthritis (RA) represent a therapeutic window during which disease-modifying anti-rheumatic drug (DMARD) treatments have been shown to provide disease remission and limit subsequent joint damage. In established RA, the goal of treatment is to achieve minimal disease activity (MDA) as it is associated with less articular and non-articular complications from RA. Delays between symptom onset and the initiation of therapy persist due to multifactorial issues: patient delays in seeking medical advice, primary care physician's (PCP) delays in recognizing symptoms and referring the patient to a rheumatologist, and delays in accessing rheumatology care. While some PCPs are able to recognize early RA (ERA) and start a DMARD, MDA may not be achieved. These factors also delay evaluation by a rheumatologist and potentially cause further damage.

The aim of this study was to decrease the time from first onset of RA symptoms of to rheumatology evaluation and DMARD treatment. If the patient had been prescribed a DMARD by the PCP, the goal was to decrease the time to step-up therapy in those RA patients who were not in the MDA state.

Methods: This 24-month outcomes study using descriptive analysis, focused on improving patient outcomes through enhanced community partnerships, systems-based change and education. Key components of the project's success were the incorporation of a dedicated nurse practitioner, acting as the division's patient case manager, and a medical assistant (MA) who served as a patient navigator to coordinate care. These patients were then prioritized by need and seen by a provider or rheumatology nurse practitioner (NP) who is specifically trained in evaluating and treating patients with RA. Four primary care clinics serving diverse patient populations were selected as partners for this study. A needs assessment was performed in the partner clinics to assess baseline knowledge related to the diagnosis and treatment of RA. Subsequently, targeted education related to ERA treatment and the importance of achieving MDA was created and offered to the partner clinics throughout the duration of the study.

Results: From January, 2017 to May, 2018, 1794 unique patients were referred to our Rheumatology clinic. Of these, 106 were diagnosed with RA while 83 were defined as ERA. Of these RA patients, there were 65 (61%) that were not being treated with DMARD therapy prior to evaluation. The time from referral to evaluation by rheumatology declined significantly from an average of 103 days at baseline to 27 days in the final phase of the study (graph 1). Accordingly, the time between referral to the initiation of DMARD therapy decreased significantly.

Conclusion: This study suggests that the creation of a specific workflow to assess patients with ERA or uncontrolled RA significantly combined with targeted education improved the wait time to a rheumatology evaluation and time to treatment. Our findings are limited by our hospital's status as a tertiary medical center.

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster III: Complications of Therapy, Outcomes, and Measures

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Current guidelines for RA treatment are focused on the importance of defining the duration of symptoms before diagnosis to achieve better outcomes. This concept allows the definition of Early (ERA) and established

Figure 1: Mean Disease Activity measured by DAS-28, during 0, 3, 12, 24, 36 months of follow-up, for patient with Early and Established Rheumatoid Arthritis.

Table 1: Overall mean DMARD dose (MTX, SSZ, LEF), DMARD and biologic use, for patient with Early and Established Rheumatoid Arthritis.

RA classification	Mean DMARD dose														
	INITIAL			3 MONTHS			12 MONTHS			24 MONTHS			36 MONTHS		
	MTX	SSZ	LEF	MTX	SSZ	LEF	MTX	SSZ	LEF	MTX	SSZ	LEF	MTX	SSZ	LEF
Early	16.1	1142.9	120	18.07	1157.9	113.8	18.42	1250	120	21.058	1500	113.8	22.72	1000	112
Established	16.83	1098.4	123.9	18.75	1149.1	120.9	20.49	1151.6	118.6	20.71	1164.4	112.7	20.87	1009.6	112.9

MTX: Methotrexate (mg/week), SSZ: Sulfasalazine (mg/day), LEF: Leflunomide (mg/week).

RA (RA). Evidence suggest that ERA patients achieve better outcomes in terms of disease activity, bone erosions and survival. This study shows the clinimetric and treatment differences between patients with ERA and RA in an excellence clinical care center in Colombia.

Methods: The study used a cohort of Colombian patients with RA (Satisfying ACR/EULAR classification criteria). Data collected from clinical records were: RA classification, disease activity using DAS-28 ESR (DAS-28), number of synthetic and biological DMARDs used, and their respective dose. Data was obtained for 0, 3, 12, 24, and 36 months of follow-up. Patients were classified as ERA or RA. Mean DAS-28, synthetic DMARDs dose, number of synthetic and biologic DMARDs used from each period of time were calculated.

Results: An overall of 805 patients were included; 147 patients with ERA and 658 patients with RA. 82% of patients are seropositive. Both group of patients began with mean DAS-28 corresponding to moderate activity (ERA: 3.67; RA: 3.87). Mean DAS-28 achieve remission since 3 months of follow-up for ERA group. Mean DAS-28 for RA did not achieve remission, but low activity was achieved since 3 months. Mean synthetic and biologic DMARDs use was constantly increasing in both groups, but the number was always greater in RA. About mean DMARD dose for specific drugs, weekly MTX dose stands as it was initially greater in RA, but it achieves an upper limit since 12 months of follow-up. ERA Mean weekly MTX dose constantly increase until 36 months, even surpassing RA mean dose.

Conclusion: Results are consistent with existent evidence of disease behavior in other populations, by showing that Colombian patients with ERA achieve lower disease activity and even remission, and use less medication in comparison to RA patients. DMARD doses were greater in RA group, except for MTX.

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster III: Complications of Therapy, Outcomes, and Measures

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Palindromic rheumatism (PR) (transient acute attacks of articular and/or periarticular inflammation) may progress to rheumatoid arthritis (RA). How often early RA (ERA) patients report joint symptoms that come and go prior to diagnosis and how RA presentation may differ in this patient subset is uncharacterized. This study compared ERA patients who did versus did not report a history of transient episodes of joint inflammation preceding RA diagnosis.

Methods: Data were from patients with early classifiable or suspected RA according to their rheumatologist (symptoms <1 year; 83% met 2010 ACR/EULAR criteria) enrolled in the Canadian Early Arthritis Cohort (CATCH) in 2017 to 2018 who completed a new baseline questionnaire on prior inflammatory joint symptoms that “come and go”. Chi-square and t-tests were used to compare baseline sociodemographic and RA characteristics in ERA patients with versus without a reported history of prior palindromic symptoms. Simple, and multivariable logistic regression with backward selection ($p < 0.1$) were used to identify age and sex-adjusted predictors of palindromic symptoms among baseline ERA characteristics.

Table 1: Logistic Regression Examining Associations between RA Baseline Characteristics and History of Transient Joint Episodes Prior to RA diagnosis

Variable	Unadjusted Model		Adjusted Multivariable Model	
	Odds Ratio (OR)	95% Confidence Interval (CI)	OR	95% CI
Age	1.0	1.0, 1.0	1.0	1.0, 1.1
Female sex	2.5	1.2, 5.1	3.3	1.1, 9.5
Income (>\$50,000)	2.0	0.9, 4.2	3.2	1.2, 9.1
Current smoker	2.1	0.9, 4.7	3.2	0.8, 13.7
Depression	3.4	1.2, 9.6	4.3	1.2, 15.8
RF positive	2.5	1.2, 5.0	3.7	1.3, 10.2

Results: 154 ERA patients were included; 66% were female and mean (sd) age was 54 (15) years. 83 (54%) patients reported having any previous joint pain and swelling prior to current episode; 65 (42%) endorsed prior episodic joint pain and swelling, of whom 31 (48%) reported transient joint symptoms for over six months. Patients reporting previous palindromic symptoms were more often female, RF positive, ACPA positive, had more comorbidities, and lower CRP, swollen joints, and baseline DAS28 ($p<0.05$). Univariate predictors of palindromic symptoms included female sex, RF positivity, higher income, comorbid OA, back/spine problems, and depression, higher rheumatic disease comorbidity index, and lower swollen joint count, CRP, DAS28, and physician global assessment of disease activity ($p<0.1$). In multivariable regression, RF positivity, depression, and higher income remained significant predictors of prior palindromic symptoms ($p<0.05$). Smoking was potentially associated with an average 3-fold increase in prior palindromic symptoms, though the relationship was not statistically significant in adjusted models (Table 1).

Conclusion: ERA patients commonly self-reported experiencing transient episodes of inflammatory arthritis prior to being diagnosed with RA; however, whether these symptoms were actual PR cannot be confirmed. ERA patients who endorsed having joint symptoms that come and go prior to RA diagnosis were more likely RF positive with higher income and more comorbidities at ERA cohort entry, but median time to RA onset was not different.

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster III: Complications of Therapy, Outcomes, and Measures

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Disparities in the initiation of disease modifying anti-rheumatic drugs (DMARDs) in ethnic minorities have been described in rheumatoid arthritis (RA) patients in the US (J Rheumatol 2007;34:2400-7). These disparities are of increased concern, as the early initiation of intensive treatment has become a cornerstone in RA management. Recognizing referral patterns and patient baseline characteristics may help to identify sources of delay. We aimed to evaluate disparities in referral and treatment initiation in RA patients at an academic rheumatology site.

Methods: We conducted a retrospective study of all RA patients (by ICD codes) seen at our rheumatology outpatient clinic between 2011/16. Among 542 RA patients, 152 (28%) received their initial evaluation by a Rheumatologist during this period, and were naive to any DMARD. We determined the duration between initial symptoms and first Rheumatology visit in months. Data extraction included referral source, demographics, and laboratory tests between others. A Multidimensional-Health Assessment Questionnaire, collected routinely in this setting, allowed us to calculate a RAPID3 score for disease activity assessment at baseline. Treatment information also was collected including time to initiate DMARD and prednisone use. Comparison between ethnic groups was performed using ANOVA or Kruskal-Wallis for differences between means or medians and Chi² for proportions.

Results: A total of 152 DMARD naive RA patients were seen; 35% were White, 37% Black, 20% Hispanic, and 8% were others. The median delay to first rheumatology visit ranged from 6 to 8 months for all patients groups, other than Hispanics, for whom delay was 22.7 months (p=0.01) (Table). In the Hispanic group, there was no difference in time to visit between those who selected Spanish as their preferred language and those who selected English. A higher percentage of White and Black patients were referred by PCPs relative to Hispanic patients, who mainly self-referred (p=0.01). Methotrexate was the most prescribed DMARD. No significant differences were seen in time to treatment initiation according to ethnicity. Disease activity by RAPID3 scores (p=0.04) and ESR (p=0.01) was significantly higher in Black and Hispanic groups, but other laboratory tests did not differ between groups.

	ALL N=152	Ethnicity groups			
		White N=53 (35%)	Black N=57 (37%)	Hispanic N=30 (20%)	Other N=12 (8%)
Age, yrs mean (SD)	54.2 (15.5)	57.5 (15.2)	57.2 (15.5)	45.5 (12.6)*	46.8 (14.1)
Female %	81%	74%	86%	83%	83%
Median disease duration, months (IQR)	6.9 (3.0, 24.0)	6.7 (3.5, 23.9)	6.0 (2.1, 22.9)	22.7 (3.0, 47.9)*	8.0 (4.0, 35.9)
Patients treated as early RA (<6m), %	46%	45%	53%	34%	40%
Referral of patients (%):	47%	40%	67%	33%	25%
PCPs	26%	34%	16%	27%	33%
Other physicians self-referral	27%	26%	18%	40%*	42%*
Median time in months to initiate DMARDs (IQR)	0.7 (0.2, 1.4)	0.7 (0.4, 2.0)	0.7 (0.1, 2)	0.7 (0.4, 1.4)	0.5 (0.4, 0.9)
Methotrexate, %	60%	57%	62%	63%	50%
Prednisone dose, %	71%	66%	72%	80%	67%
Mean dose (SD), mg	10.3 (5.0)	10.7 (5.6)	10.7 (5.4)	9.3 (3.4)	9.4 (3.2)
Rheumatoid Factor+, %	60%	46%	66%	72%	56%

Abnormal ESR, % (>27mm/h for women and >17mm/h for men)	50%	36%	62%*	59%	33%
Abnormal CRP, % (>8mg/L)	46%	39%	55%	45%	37%
RAPID3, median (IQR)	14.0 (8.3, 19.0)	13.1 (7.4, 16.9)	16.3* (11.2, 19.0)	15.3 (10.0, 21.5)	8.0 (5.4, 13.2)

Statistical significance in bold *p<0.05. ANOVA or Kruskal-Wallis (continuous variables) or Chi² (discrete values)

Conclusion: RA patients are at risk of poorer outcomes as a consequence of delayed presentation to a rheumatologist leading to delay in treatment initiation. This study demonstrates a considerable delay in initial referral to a Rheumatologist, more pronounced among Hispanic patients, although they appear to have higher disease activity at presentation. Once seen in the clinic, initiation of DMARDs occurred within 1-month, regardless of ethnicity. More knowledge concerning delay in referral may help to develop better strategies for equitable access to effective therapies for all RA patients, regardless of ethnicity.

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster III: Complications of Therapy, Outcomes, and Measures

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Quantitative measures to assess and monitor patients with rheumatoid arthritis (RA) traditionally have been laboratory tests, such as erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP). However, ESR and CRP values have been found to be normal in about 40% of RA patients^{1, 2}. By contrast, RAPID3 (routine assessment of patient index data) self-report scores are reported elevated in more than 75% of RA patients, and generally are more effective than laboratory tests to distinguish active from control treatment in clinical trials³. Normal initial measures can document worsening of clinical status, but not improvement, at future visits. We analyzed the proportion of treatment-naïve RA patients at an initial visit to an academic rheumatology setting for elevated or normal values for RAPID3, ESR and CRP.

Methods: All patients at one academic setting complete a multi-dimensional health assessment questionnaire (MDHAQ), which includes RAPID3 and other scales, at each visit. RAPID3 is an index of the 3 self-report 0-10 measures, physical function, pain, and patient global assessment, compiled into a 0-30 score. A retrospective analysis of RAPID3, ESR, and CRP data at initial visits of RA patients was conducted. RAPID3 scores were classified as remission (≤ 3), low (3.1-6), moderate (6.1-12), and high (≥ 12) severity⁴. ESR and CRP were classified according to normal values at the study site laboratory as ESR $<$ or >17 mm/hr in men, $<$ or >27 mm/hr in women, and CRP $<$ or >8 mg/dl. ESR data for men and women were merged. Cross-tabulations were performed to compare patients in 4 RAPID3 categories, according to whether ESR or CRP or both ESR and CRP were normal or abnormal; chi-square tests were used to analyze statistical significance.

Results: Overall, 105 patients were studied; 78% female, mean (SD) age 54.2 (15), RAPID3 13.9 (7.2), ESR 33.7 (29.9) and CRP 22.1 (47.9). Among all 105 patients, elevated ESR was seen in 49%, elevated CRP in 44%, both elevated CRP and ESR in 32%, and elevated RAPID3 in 93%, including 82% with moderate, and 65% high severity (Table). Among 86 patients whose RAPID3 indicated moderate or high disease severity, elevated ESR was seen in 38 (44%), elevated CRP in 41 (48%), and both elevated ESR and CRP in 29 (34%). By contrast, 5 of 7 patients with RAPID3 <3 had elevated ESR, and 1 elevated CRP as well as ESR (Table). One limitation of is that comorbidities, which can lead to elevated rapid RAPID3 scores, were not collected systematically.

Table. Number of patients who had elevated ESR or CRP or both ESR and CRP according to 4 RAPID3 categories of remission, low, moderate, and high severity among 105 RA patients on initial visit to an academic rheumatology setting

	RAPID3 Categories					P
	Remission (≤ 3)	Low (3.1-6)	Moderate (6.1-12)	High (≥ 12)		
High ESR M>17 mm/hr. F>27 mm/hr.	51 (49%)	5 (5%)	8 (8%)	6 (6%)	32 (30%)	0.189
High CRP >8 mg/dl.	46 (44%)	1 (1%)	4 (4%)	6 (6%)	35 (33%)	0.142
High CRP+ESR	34 (32%)	1 (1%)	4 (4%)	4 (4%)	25 (24%)	0.476
Total No. of patients	105	7 (7%)	12 (11%)	18 (17%)	68 (65%)	

Conclusion: At the initial visit of treatment naïve RA patients, RAPID3 was substantially more likely to be elevated than ESR or CRP to monitor disease status and document improvement.

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster III: Complications of Therapy, Outcomes, and Measures

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Previous reports on a window of opportunity (WOO) in rheumatoid arthritis (RA) may be related to the use of slow acting csDMARDs. We investigated whether onset of action of therapy might influence whether there is a WOO or whether ‘earlier is better’. Therefore we aimed to investigate the association between symptom duration at treatment onset and the achievement of sustained drug free remission (sDFR) in early RA patients initiating therapy including fast acting prednisone or infliximab, compared to patients initiating csDMARD monotherapy.

Methods: We analysed the shape (non-linear or linear) of the association between symptom duration and achievement of sDFR (DAS<1.6 and no DMARDs for ≥1 year) in 3 cohorts: BeSt, IMPROVED and METEOR. Patients had arthritis symptoms <2 years. In BeSt, RA-patients (1987 criteria) were randomised to 4 targeted treatment strategies aimed at DAS≤2.4: arm 1 and 2 initiated csDMARD monotherapy, arm 3 csDMARDs and tapered high dose prednisone and arm 4 csDMARD and infliximab. In IMPROVED RA patients (2010 criteria) were treated with csDMARD and tapered high dose prednisone. Subsequent treatment adjustments aimed at DFR. METEOR is an international observational cohort including daily practice data from RA patients with a diagnosis and treatment according to the rheumatologist. We selected patients who initiated csDMARD monotherapy or a combination of csDMARD with prednisone or anti-TNF and at least 1.5 year follow-up.

Figure 1. Best fit models to depict the relationship between symptom duration and sDFR in the BeSt (a) and IMPROVED (b) trial and in the METEOR registry (c). Applying natural cubic spline functions (allowing a curved relationship) did not result in a superior fit compared to a linear model.

Table 1. P-values of the likelihood ratio tests to compare the fit of a linear and a non-linear Cox regression model

	BeSt	IMPROVED ^a	METEOR
csDMARD monotherapy	0.609	--	0.678
Fast acting combination therapy ^b	0.743	0.337	0.457

^aNo monotherapy in IMPROVED. ^bIncluding prednisone or infliximab.

We performed Cox regression with as outcome sDFR and as predictor symptom duration and used likelihood ratio tests to compare the fit of a linear model and a model with inclusion of natural cubic spline functions (resulting in a hyperbola).

Results: In BeSt (n=469), IMPROVED (n=421) and METEOR (n=1268) 54, 110 and 10 patients who initiated fast acting combination therapy, and 53 in BeSt and 15 in METEOR who initiated csDMARD monotherapy achieved sDFR. A non-linear model did not show a better fit for the data than a linear model (table 1). Thus, we did not find a curved relationship between time of treatment initiation and achieving sDFR. The best fit models indicate that the earlier treatment is started, the higher the likelihood of achieving sDFR (figure 1).

Conclusion: Our data suggest that there is no evidence for a WOO in early RA in 3 cohorts. This was not related to use of fast acting combination therapy instead of slow acting monotherapy nor was it dependent on strict treat-to-target in clinical trials. Instead, our data reaffirm that earlier is better when treating RA.

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster III: Complications of Therapy, Outcomes, and Measures

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) patients from Latin-America present distinctive characteristics when compared to Caucasians, that are known to impact patient's outcomes. Despite early and more aggressive treatment guidelines recently adopted, some patients require reconstructive joint surgery, considered an indicator of poor prognosis. The objectives of the study were to describe incidence rate of orthopedic and hand surgery indication (OHSI) in a cohort of Mexican Mestizo early RA patients treated with conventional DMARDs according to a T2T strategy and to investigate OHSI predictors.

Methods: Patients enrolled in the cohort had a disease duration of <1 year and complete rheumatic assessments at fixed intervals. Up to February 2018, the cohort comprised 185 RA patients recruited from 2004 onwards, with at least fourteen

months of follow-up; 2.7% were dead, 23.3% lost to follow-up and 74% had active follow-up. Charts were reviewed and incidence rate of OHSI was calculated. A nested within a cohort case-control study was designed to investigate predictors; cases (patients with OHSI) were paired to controls (1:4) according to age (± 5 years), sex, baseline RF and ACCP; cumulative disease activity (summarized as DAS28, first sustained remission [SR], time in SR, number of flares and % of follow-up in remission status), cumulative treatment (N° DMARD/patient, patients with corticosteroids and % of time with corticosteroids), and cumulative persistence (N° of patients persistent and % of follow-up patients were persistent) were compared between cases and controls. Logistic regression's models included baseline and cumulative (up to OHSI or equivalent) variables. Local IRB approved the study.

Results: Patients entering the cohort were predominantly middle-aged (mean \pm SD age of 38.5 \pm 12.9 years) female (87.6%), with (mean \pm SD) 5.4 \pm 2.6 months of disease duration. Up to cut-off, the cohort contributed to 1538 patient-years of follow-up. There were 12 patients with incidental OHSI, at a (mean \pm SD) follow-up of 85 \pm 44.5 months; 9 (75%) received orthopedic surgery indication meanwhile 3 (25%) received hand surgery indication; incident global rate was of 0.8/100 patient-years. Regression models included baseline variables (months of symptom's disease duration) and cumulative variables (N° of flares/patient, % of follow-up in remission status, N° of patients persistent and % of follow-up patients were persistent with therapy). Longer symptom's duration at referral to the cohort (OR: 1.313, 95% CI: 1.02-1.68, $p=0.032$) and higher number of flares (OR: 1.608, 95% CI: 1.05-1.61, $p=0.015$) were predictors of OHSI. ROC showed that the best cut-off for symptom's duration and cumulative number of flares to predict OHSI were 6 months (Sensitivity: 0.833; Specificity: 0.665; AUC: 0.746, 95% CI: 0.593-0.899) and 5 flares/patient (Sensitivity: 0.750; Specificity: 0.625; AUC: 0.702, 95% CI: 0.522-0.882), respectively.

Conclusion: Early referral for appropriated management according to a T2T strategy and flares controls may prevent OHSI in Hispanic early RA patients.

The Impact of Frailty on Changes in Physical Function Among Adults with Rheumatoid Arthritis

James Andrews¹, Laura Trupin², Catherine Hough¹, Edward H. Yelin³ and Patricia Katz², ¹Medicine, University of Washington, Seattle, WA, ²University of California San Francisco, San Francisco, CA, ³Medicine/Rheumatology, University of California San Francisco, San Francisco, CA

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster III: Complications of Therapy, Outcomes, and Measures

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Frailty is a state of excess vulnerability to stressors and is associated with increased risk of poor health outcomes including physical disability. Frailty and reduced physical function are common in rheumatoid arthritis (RA). However, the relationship between frailty and change in physical function over time in RA is unknown. We tested the hypothesis that frailty is a risk factor for worsening patient-reported physical function over time in RA.

Methods: Adults from a longitudinal RA cohort (n=124) participated. Using an established definition of frailty¹, individuals with 3 or more of the following physical deficits were classified as frail: 1) body mass index ≤ 18.5 , 2) low grip strength (adjusted for sex and BMI, measured by handheld dynamometer), 3) severe fatigue (measured by the Fatigue Severity Inventory), 4) slow 4-meter walking speed (adjusted for sex and height), 5) low physical activity (measured by the International Physical Activity Questionnaire). Individuals with 1 or 2 deficits were classified as “pre-frail”, and those with no deficits as “robust¹.” In addition, a frailty score (0-5) was calculated based on an individual's number of deficits. Self-reported physical function was assessed by the Health Assessment Questionnaire (HAQ) at baseline and at follow-up approximately 2 years later. Regression analyses modeled associations of baseline frailty category and frailty score with HAQ score at follow-up with and without controlling for age, sex, disease duration, C-reactive protein, use of oral steroids, and pain. In addition, regression analyses modeled the association of baseline frailty category and frailty score with development of a clinically-meaningful worsening (≥ 0.22) in HAQ score at follow-up with and without controlling for covariates.

Results: Among adults with RA, being frail compared to being robust was associated with a 0.42-point (CI:0.13, 0.71) worse HAQ score at follow-up (Table 1) and 11 times (CI:1.58, 76.60) the odds of developing a meaningfully worse HAQ score at follow-up (Table 2) even when adjusting for covariates. In addition, a 1-point increase in baseline frailty score was associated with a 0.12-point (CI:0.05, 0.21) worse HAQ score at follow-up (Table 1) and nearly twice (CI:1.18, 3.30) the odds of developing a meaningfully-worse HAQ score at follow-up (Table 2).

Conclusion: Frailty may be an important, identifiable, and unique risk factor for the development of physical disability in RA. Future studies should address whether modifying frailty improves physical function in RA.

Table 1: Linear Regression Coefficients (95% CIs) for the Effect of Baseline Frailty Category or Frailty Score on HAQ Scores at Follow-up among Individuals with Rheumatoid Arthritis (n=124)

	Model 1	Model 2	Model 3
Frail	0.87*** (0.45, 1.29)	0.41** (0.13, 0.69)	0.42** (0.13, 0.71)
Pre-frail	0.55*** (0.25, 0.85)	0.22* (0.03, 0.41)	0.20* (0.008, 0.39)
Robust	Reference	Reference	Reference
Frailty Score (per 1 point)	0.29*** (0.18, 0.41)	0.15*** (0.07, 0.23)	0.12** (0.05, 0.21)

Model 1: unadjusted

Model 2: adjusted for baseline HAQ score

Model 3: adjusted for baseline HAQ score, sex, age, baseline disease duration, hsCRP, use of oral steroids, and pain.

Frail= ³ physical deficits, Pre-frail= 1-2 physical deficits, Robust= 0 physical deficits (¹Fried LP et al., J Gerontol A Biol Sci Med Sci, 2001; 56: M146)

HAQ scores are 0-3 with higher scores representing worse physical function.

* $p < 0.05$, ** $p < 0.01$, *** $p < 0.001$

Table 2: Odds Ratios (95% CIs) for the Effect of Baseline Frailty Category or Frailty Score on Worsening HAQ Scores at Follow-up among Individuals with Rheumatoid Arthritis (n=124)

	Model 1	Model 2	Model 3
Frail	6.22* (1.20, 32.21)	7.95* (1.40, 45.04)	11.00* (1.58, 76.60)
Pre-frail	2.99 (0.81, 11.04)	3.55 (0.91, 13.77)	3.84 (0.89, 16.50)
Robust	Reference	Reference	Reference
Frailty Score(per 1 point)	1.73* (1.13, 2.66)	1.88** (1.19, 2.96)	1.98** (1.18, 3.30)

Model 1: unadjusted

Model 2: adjusted for baseline HAQ score

Model 3: adjusted for baseline HAQ score, sex, age, baseline disease duration, hsCRP, use of oral steroids, and pain.

Frail= ³ physical deficits, Pre-frail= 1-2 physical deficits, Robust= 0 physical deficits (¹Fried LP et al., J Gerontol A Biol Sci Med Sci, 2001; 56: M146)

HAQ scores are 0-3 with higher scores representing worse physical function. Worsening HAQ score is defined as an increase of at least 0.22, because the minimum clinically significant difference for the HAQ is 0.22.

* $p < 0.05$, ** $p < 0.01$, *** $p < 0.001$

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster III: Complications of Therapy, Outcomes, and Measures

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: There is a high prevalence of upper limbs involvement in Rheumatoid Arthritis (RA), with a lack of useful tools in daily practice assessing the functional capacity of this particular anatomical region. Dreiser et al. developed the Functional Index for Osteoarthritis of hands (FIHOA), aimed to evaluate the functional capacity of patients with hand osteoarthritis (HOA), whose Argentinian version was validated 2016. However, this instrument has not been validated yet in patients with RA. The aim of this study was to validate FIHOA in RA patients.

Methods: Analytical, observational, prospective cross-sectional study including consecutive patients with diagnosis of RA (ACR/EULAR 2010). Demographic and RA characteristics, disease activity measures and treatment were recorded. Patients completed the following self-administered questionnaires: HAQ-A (Health Assessment Questionnaire Argentine Version), HAQUP (Health Assessment Questionnaire-Upper extremity), FIHOA and Quick DASH (Quick Disabilities of the Arm, Shoulder and Hand). For a patient subgroup, an occupational therapist performed an objective evaluation of the functional capacity of the upper limbs using the Sequential Occupational Dexterity Assessment (SODA). To assess reproducibility, 30 patients with similar clinical and therapeutic conditions to their first evaluation completed the questionnaire again 10 to 15 days later. *Statistical analysis:* Patient and disease characteristics were described with means, medians, absolute numbers, proportions, standard deviation (SD) and interquartile ranges (IQR). Reliability was assessed using the Cronbach test. Construct validity was analyzed through the correlation with other functional capacity questionnaires and disease activity parameters using the Spearman coefficient. Reproducibility was estimated using test-retest reliability. A linear regression model was constructed with FIHOA as the outcome variable and those variables that proved significant on bivariate analysis.

Results: We included 100 patients, 83% women, mean age 57.9 years (SD 11.6). Cronbach's alpha test was 0.94. There were no redundant questions by inter-item correlation. FIHOA showed an excellent correlation with HAQ-A ($r = 0.89$); HAQUP ($r = 0.89$); Quick DASH ($r = 0.90$) and SODA ($r = -0.80$). It also showed good correlation with DAS28 ($r = 0.65$) and other composite disease activity measures as well as with other disease parameters [visual analog scale (VAS) for pain, patient and physician global assessment of the disease, tender and swollen joint count]. There was no correlation between FIHOA and age or disease duration. Questionnaire reproducibility was 0.73. A multiple linear regression adjusted for age and sex showed morning stiffness as the main determinant of FIHOA, followed by patient global assessment VAS and glucocorticoid use.

Conclusion: FIHOA was found to be reliable, valid and reproducible in patients with RA, providing a valuable tool for the evaluation of functional capacity of the upper limbs in these patients.

The Impact of Disease Activity and Patient Reported Outcomes on Grip Force over Time in Early Rheumatoid Arthritis

Maria Rydholm^{1,2}, Ingegerd Wikström^{1,2}, Sofia Hagel³, Lennart Jacobsson⁴ and Carl Turesson^{1,2}, ¹Department of Rheumatology, Skane University Hospital, Malmö, Sweden, ²Rheumatology, Department of Clinical Sciences, Malmö, Lund University, Malmö, Sweden, ³Rheumatology, Department of Clinical Sciences, Lund, Lund University, Lund, Sweden, ⁴Department of Rheumatology and Inflammation Research, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster III: Complications of Therapy, Outcomes, and Measures

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Although patients with early rheumatoid arthritis (RA) have substantially reduced grip strength compared to the general population, some improvement over time has been demonstrated in many patients. The objective of this study was to identify early predictors of future grip strength in patients with RA.

Methods: An inception cohort of patients with early RA (symptom duration ≤ 12 months), recruited in 1995-2005, was investigated and followed in a structured program (4 examinations over 5 years), including clinical evaluation and grip force measurement. Grip force was measured using the electronic instrument Grip pit (AB Detektor, Gothenburg,

Impact of baseline patient reported outcomes and disease activity on grip force (% of expected value) over time; by quartile

		Intercept (95% CI)	Estimated mean difference (95% CI)	Change/year (95% CI)	Difference in change/year (95% CI)
DAS28	Quartile I (0-3.6)	61.4% (53.4% to 69.4%)	Reference	1.3% (0.02% to 2.6%)	Reference
	Quartile II (3.7-4.7)	48.2% (41.8% to 54.5%)	10.7% (2.0% to 19.4%)	2.6% (1.4% to 3.9%)	1.3% (-0.4% to 3.1%)
	Quartile III (4.8-5.7)	41.3% (34.6% to 47.9%)	16.7% (7.9% to 25.5%)	3.1% (1.9% to 4.4%)	1.8% (0% to 3.6%)

	Quartile IV (1.30-3.0)	28.8% (22.8% to 34.8%)	30.6% (22.0% to 39.2%)	3.5% (2.0% to 5.0%)	1.5% (-0.3% to 3.4%)

Sweden). Average grip force values of the dominant hand were evaluated at each visit, and compared to the expected, based on age- and sex-specific reference values from the literature. Patients in each of the three higher quartiles of baseline disease activity (DAS28), disability (HAQ), pain (visual analogue scale, VAS) and patient global assessment (VAS global) were compared to the lowest quartile. Differences in percentage of expected grip force values over the study period, and differences in change over time, were estimated using mixed linear effect models.

Results: A total of 233 patients with early RA (70% women, mean age 60.5 years, median symptom duration 7 months) were investigated. The mean value for the average grip force of the dominant hand increased from 40% of expected at baseline to 57% at the 5-year follow-up. Patients with baseline parameters in the three higher quartiles had significantly lower mean grip force values over time, compared to the lowest quartiles (Table). Patients in the highest quartile of DAS28 had significantly greater improvement compared to the lowest quartile (estimated difference in change per year 3.1% of expected; 95% CI 1.4 to 4.9). By contrast, there was no difference in improvement for those in the highest quartiles of VAS pain (estimated difference in change per year 0.5% of expected; 95% CI -1.3 to 2.3) or VAS global (Table), compared to those in the lowest quartiles.

Conclusion: Patients with a severe disease phenotype at baseline had particularly impaired grip force over the first 5 years after RA diagnosis. However, those with high initial disease activity experienced greater improvement in grip force, likely due to successful treatment. By contrast, poor patient reported outcomes at baseline were associated with persistent impairment of grip strength.

The Relation between Inflammatory Joint Activity and Disability Related to the Lower Extremities in Early Rheumatoid Arthritis

Maria Mellblom Bengtsson^{1,2}, Sofia Hagel³, Lennart Jacobsson⁴ and **Carl Turesson**^{1,2}, ¹Department of Rheumatology, Skane University Hospital, Malmö, Sweden, ²Rheumatology, Department of Clinical Sciences, Malmö, Lund University, Malmö, Sweden, ³Rheumatology, Department of Clinical Sciences, Lund, Lund University, Lund, Sweden, ⁴Department of Rheumatology and Inflammation Research, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster III: Complications of Therapy, Outcomes, and Measures

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Arthritis in the lower extremities has a major impact in many patients in rheumatoid arthritis (RA), but has not been extensively studied. The objective of this study was to investigate the relation between inflammatory joint involvement and disability related to the lower extremities in early RA.

Methods: An inception cohort of patients with early RA (symptom duration ≤ 12 months), recruited in 1995-2005, was investigated and followed in a structured program. All patients were examined by the same rheumatologist. To estimate disability based on self-reported activity limitations, we used the Health Assessment Questionnaire Disability Index (HAQ-DI). In order to more specifically address disability of the lower extremities, we calculated a sub score, HAQ-DI lower extremities (HAQ-DI-LE), based on the 10 questions that cover activities that are mainly dependent on function of the lower extremities (Ekdahl et al. J Clin Epidemiol 1989;42: 947-54). HAQ-DI LE scores in those with vs without current synovitis of individual joints were compared using the Mann Whitney test.

Results: A total of 233 patients with early RA (70% women, mean age 60.5 years, median symptom duration 7 months) were investigated. The median HAQ-DI LE at inclusion was 0.6 (interquartile range 0.2-1.2). Knee synovitis, ankle synovitis and MTP joint synovitis was present at inclusion in 18%, 26% and 39%, respectively. Proportions with synovitis in the lower extremities declined over time (Table). Knee synovitis was associated with significantly higher HAQ-DI-LE scores at inclusion ($p < 0.001$) and after 6 months ($p = 0.01$), but not at later follow-up visits (Table). Patients with ankle synovitis had higher HAQ-DI-LE at 6 months ($p = 0.02$), 1 year ($p = 0.006$) and 2 years ($p < 0.001$). MTP joint synovitis was also associated higher HAQ-DI-LE, in particular at baseline ($p = 0.045$). However, differences in HAQ-DI-LE for those with vs without synovitis were numerically smaller at 1 year and at 2 years for MTP joint synovitis compared to ankle synovitis (Table).

Conclusion: Knee synovitis was associated with disability related to the lower extremities, in particular in very early RA, whereas ankle synovitis had a greater impact after 1-2 years than at diagnosis. Large joint synovitis maybe more important for lower extremity function compared to synovitis of the MTP joints. These findings underline the importance of assessment of the joints of the lower extremities in patients with RA.

HAQ-DI for the lower extremities at different time points in early RA, by presence of synovitis

	Synovitis status	Inclusion	6 months	1 year	2 years	5 years
Knees	Present	1.2 (0.75-1.6) (n=42) $p < 0.001$	0.7 (0.4-1.2) (n=28) $p = 0.01$	0.8 (0.2-1.2) (n=12) $p = 0.15$	0.7 (0.35-1.6) (n=14) $p = 0.12$	1.0 (0.2-1.4) (n=13) $p = 0.08$

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster III: Complications of Therapy, Outcomes, and Measures

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Fatigue in patients with rheumatoid arthritis (RA) maybe measured with the 13-item Functional Assessment of Chronic Illness Therapy-Fatigue instrument (FACIT-F). The Patient-Reported Outcomes Measurement Information System (PROMIS) was developed using a population-calibrated T-score metric (mean 50, SD 10). PROMIS Fatigue includes the FACIT-F items, making their scores interchangeable. Crosswalk tables and a pattern scoring system have been developed to link legacy to PROMIS instruments, including fatigue.¹ A subset of 10 FACIT-F items has also been identified as relevant to patients with RA. We assessed treatment response in two phase 3 baricitinib RA trials based on linked FACIT and PROMIS Fatigue scores using both crosswalk tables and the scoring algorithm.

Methods: In RA-BEAM, patients with inadequate response to MTX were randomized 3:3:2 to placebo (PBO) once daily (QD), baricitinib (bari) 4 mg QD, or adalimumab (ADA) 40 mg biweekly.² In RA-BEACON, patients with inadequate response to biological DMARDs were randomized 1:1:1 to receive PBO or bari 2 mg or 4 mg QD.³ Patient-level FACIT-F scores were linked to PROMIS Fatigue scores using validated crosswalk tables¹ (<http://www.prosetastone.org/>) and the scoring algorithm at <http://www.healthmeasures.net/explore-measurement-systems/promis>. Analysis of covariance was conducted on PROMIS score conversions to compare bari to all treatment arms.

Results: At baseline, average PROMIS Fatigue scores across treatment groups and scoring methods ranged from 56.8 to 59.7 in RA-BEAM (FACIT-F range 27.6 to 28.6) and 60.1 to 63.7 in RA-BEACON (FACIT-F range 22.2 to 23.4); they thus reflected severe fatigue compared with the population means (e.g., approaching or exceeding 1 SD above). PROMIS Fatigue scores in RA-BEAM reached normal levels (mean <55) by week 4 for bari and ADA (data not shown). For both studies, at 24 weeks, bari was associated with clinically meaningful improvements from baseline (exceeding 0.5 SD/5 points on the T-score metric) for PROMIS Fatigue scores, and with significant improvements in PROMIS Fatigue for bari 4-mg versus placebo (Table).

Conclusion: These results support the FACIT-F to PROMIS Fatigue crosswalk and scoring algorithm approaches, with similar results shown for the subset of 10 FACIT-F items deemed most relevant to RA. This approach enables comparisons across studies using FACIT-F or PROMIS Fatigue item subsets, and their interpretation relative to US general population norms.

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster III: Complications of Therapy, Outcomes, and Measures

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: PROMIS (Patient Reported Outcomes Measurement Information System) has been used in rheumatoid arthritis (RA) patients (Pts) to assess disease activity across multiple domains (i.e. physical function, fatigue, pain interference). AWARE (Comparative and Pragmatic Study of Golimumab IV Versus Infliximab in Rheumatoid Arthritis) is an ongoing Phase 4 study designed to provide a real-world assessment of intravenous Tumor Necrosis Factor inhibitor (TNFi) medications in RA pts. The study utilizes PROMIS and Clinical Disease Activity Index (CADE) to assess effectiveness. This analysis examined select PROMIS measures to assess (1) relationship between baseline (BL) CADE and PROMIS-scores, (2) responsiveness of PROMIS after initiation of TNFi and (3) relationship between PROMIS T-scores of the 4 item Profile 29v2 Fatigue and Pain Interference domains and respective PROMIS Short Forms (SF).

Methods: AWARE is a prospective, noninterventional, 3-year study at 100 US sites. RA pts were enrolled when initiating TNFi treatment. Treatment decisions are at the discretion of the treating rheumatologist. We report on data from Pts' BL PROMIS Pain Interference 6b (PI), Fatigue 7a (F), Profile 29v2 and CDAAI. PROMIS T-scores were compared across CDAAI disease category (high, moderate etc) using ANOVA. We dichotomized pts based on whether their BL T-score was within 0.5 SD of the population mean (i.e. 'normal') or not to evaluate for effect modification in the subsequent change in PROMIS T-scores. Data shown are mean \pm std dev.

Results: Pts (N=1220) were 59.5 ± 13.2 yrs, disease duration 8.2 ± 9.9 yrs, 83.4% female, body weight 85.1 ± 24.2 kg, BMI 31.4 ± 8.51 , BL CDAAI 32.4 ± 15.6 . A significant relationship between PROMIS T-scores (PI, F) and BL CDAAI disease activity category was confirmed. There was minimal change in T-score of pts with BL PI and F T-scores ≤ 45 and ≥ 45 over 5 infusions (approx. 5-7 months). Depending on domain, 14.7-27.3% of pts had initial PROMIS T-scores within 0.5SD of normal. There was a significant ($p < 0.0001$) relationship between PI and F T-scores and the respective 4 questions on the P29v2.

**PROMIS Physical Function T-Score Change:
Effect of Baseline Assessment**

**PROMIS Pain Interference SF6b T-Score Change:
Effect of Baseline Assessment**

**PROMIS Fatigue SF7a T-Score Change:
Effect of Baseline Assessment**

Conclusion: Avoiding floor effects in pts who initiated TNFi therapy with near-normal PROMIS scores, PROMIS instruments demonstrated a robust T-score change in response to initiation of TNFi therapy.

Analysis of the Disease Activity and Functional Measures of Young Patients with Rheumatoid Arthritis Undergoing Total Joint Arthroplasty By Using the Database of Nation-Wide Observational Cohort

Kimio Masuda¹, Tatsuou Ikenaka¹, Toshihiro Matsui² and Shigeto Tohma³, ¹Department of Rehabilitation Medicine, National Hospital Organization Sagamihara Hospital, Sagamihara, Japan, ²Department of Rheumatology, National Hospital Organization Sagamihara Hospital, Sagamihara, Japan, ³National Hospital Organization Tokyo National Hospital, Kiyose, Japan

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster III: Complications of Therapy, Outcomes, and Measures

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The aim of this study was to investigate the impact of total joint arthroplasty (TJA) on the disease activity and functional measures of young patients with rheumatoid arthritis (RA).

Methods: Totally 15341 RA patients were registered with NinJa (National Database of Rheumatic Diseases by iR-net in Japan), which is one of the biggest database of nation-wide observational cohort in JAPAN. The data including HAQ-DI (Health Assessment Questionnaire Disability Index), EQ-5D (EuroQol 5 Dimension) as well as SDAI (Simplified disease activity index), CDAI (Clinical Disease Activity Index) and DAS28 (Disease Activity Score 28) was analyzed.

Results: Among them, 1960 patients were under 50 years old, 85 with TJA (group T) and 1875 without TJA (group C). The age at onset of RA was 25.1 years old in group T and 33.5 years old in group C. Methotrexate was used in 54 patients (63.5%) in group T and in 1333 patients (71.5%) in group C, and biologics was used in 49 patients (57.6%) in group T and in 639 patients (34.1%) in group C. In group T, HAQ-DI was 0.97, EQ-5D was 0.68, DAS28 was 2.98, SDAI was 9.06, and CDAI was 8.59. Each score was inferior to that in group C (0.27,0.81,2.51,6.17,5.78, respectively). Moreover, in comparison with 11126 patients over 50 years old without TJA (group O), each score in group T was also inferior to that of group O (0.55,0.77,2.90,6.82,6.28, respectively).

Conclusion: The data demonstrated that patients of group T showed higher disease activity and lower functional ability as well as lower QOL status despite functional reconstruction with TJA, suggesting that the more aggressive therapeutic strategy should be needed for better functional outcome in young patients undergoing TJA.

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster III: Complications of Therapy, Outcomes, and Measures

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Treat-to-target is the recommended strategy for the appropriate management of Rheumatoid arthritis (RA) which involves regular assessment and monitoring of disease activity using a validated measure. Currently 6 measures are recommended by the American College of Rheumatology (ACR) for use in clinical practice.

1. Clinical Disease Activity Index (CDAI)
2. Disease activity Score with 28 Joint Counts (DAS 28)
3. Patient Activity scale (PAS)
4. Patient Activity Scale II (PASII)
5. Routine Assessment of Patient Index Data-3 measures (RAPID-3)
6. Simplified Disease Activity Index (SDAI).

The table lists the key features of each:

Methods: 50 patients diagnosed with RA based on ACR/EULAR 2010 criteria were consented and asked to fill a questionnaire during that visit and follow up visits making a total of 100 encounters. The questionnaire included questions

	CDAI	DAS-28 CRP	PAS	PAS II	RAPID3	SDAI
Methodology:						
Patient health assessment and function questionnaire	No	No	Yes	Yes	Yes	No
Patient Global assessment of disease activity (scale)	Yes	Yes	Yes	Yes	Yes	Yes

for the Health Assessment Questionnaire (HAQ), HAQ II and the Multidimensional Health Assessment Questionnaire (MDHAQ) along with the patient global Assessment. The treating physician filled out the Provider Global Assessment (0 – 10), 28 joint count for swollen and tender joints and documented their clinical impression (1- stable, 2- mild flare, 3- moderate flare or 4- severe flare). The Disease activity measures were calculated using the ACR calculator and recorded (1-remission, 2- Low disease activity, 3- Moderate disease activity and 4- high disease activity). The Pearson correlation coefficient was calculated for each of the six markers compared to the physician's clinical impression.

Results: Patient characteristics

The best correlation was found to be with CDAI (0.84), followed by DAS 28 CRP and SDAI (0.79), then PAS (0.53), PAS II (0.47) and finally RAPID-3 (0.39).

Conclusion: The PAS, PAS II and RAPID-3 which are patient reported are not very well correlated possibly due to over-estimation of symptoms by patients for various reasons. The dependence of SDAI and DAS-28 on CRP value makes them slightly less favorable in practice since the lab value may be reported after the patient encounter has been completed, thus making it less efficient to calculate, document and utilize. CDAI is the best correlated and due to the fact that it does not require any lab evaluation, it is evidently the best measure to adopt.

Do Age and Education Influence the Disease Activity Score? an Explorative Analysis in the Norwegian Register of Dmards

Marloes van Onna¹, Polina Putrik¹, Elisabeth Lie², Tore Kvien³, Annelies Boonen¹ and Till Uhlig², ¹Rheumatology, Maastricht University Medical Center, Maastricht, Netherlands, ²Rheumatology, Diakonhjemmet Hospital, Oslo, Norway, ³Dept. of Rheumatology, Diakonhjemmet Hospital, Oslo, Norway

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster III: Complications of Therapy, Outcomes, and Measures

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: While ageing influences auto-immune inflammation and the structure of the joints, knowledge about its influence on appraisal of disease outcomes is more limited.

The purpose of this study was to examine the effect of age and education on the components of the 28-joint Disease Activity Score (DAS28-ESR) in patients with rheumatoid arthritis (RA).

Methods: Baseline data of Disease Modifying Anti-Rheumatic Drug (DMARD)-naive patients with RA from the Norwegian Register of DMARDs (NOR-DMARD) were used. Linear regression models, adjusted for gender and education (low, intermediate and high level), were used to investigate the strength of the association between age (<45, 45-65 and >65 years) and each DAS28-component (Erythrocyte Sedimentation Rate (ESR), 28-tender joint count (28-TJC), 28-swollen joint count (28-SJC), and patient global assessment of disease activity (PGA)). Adjusted scores for components of DAS28 and total DAS28-ESR were computed and relative change across age categories was explored. Interactions between age and gender and age and education were also tested.

Results: Baseline data from 2037 patients (mean (SD) age 55.2 (14.0) years, 68% female) were available. Regression models were stratified for gender (p –interaction <0.05); education was a significant covariate in all regression analyses. Older males (>65 years) with an intermediate level of education would have a 21% higher ESR and 14% higher 28-SJC, as compared to their younger counterparts (<45 years). For females in the intermediate education category, the corresponding differences were 16% and 15%, respectively. Conversely, differences in 28-TJC and the PGA between the highest and lowest age group were negligible in both males and females (Table 1). In absolute effects on DAS28, this means that in male patients the adjusted DAS28 for those >65 years was 4.8 compared to 4.3 in patients <45 years (females 5.0 compared to 4.6). For low and high levels of education, the results were comparable in terms of relative contribution to each DAS28-component.

Conclusion: As expected, DAS28 increases with age. However, the components of DAS28 increase at different rates. The age-related increase in ESR and 28-SJC without a simultaneous increase in 28-TJC and PGA might imply that age-related processes (e.g. osteoarthritis and physiological increase in ESR) drive the DAS28 in older patients. The observed patterns were largely comparable between males and females. The age effect on DAS28 is relevant in a treat-to-target strategy and may be considered when identifying a defined target in individual patients.

Table 1 Effect of age on DAS28 (ESR) for patients with an intermediate educational level.

Component Predicted values	< 45 years (reference) n = 181 (25%)	45 – 65 years n = 419 (58%)	> 65 years n = 123 (17%)	Difference between highest and lowest age group (%)
Males				
28-TJC	1.32	1.33	1.34	2%

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster III: Complications of Therapy, Outcomes, and Measures

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) related morning stiffness is a cause of early retirement and disability. We hypothesized that circadian variation in hormones or immune cells may contribute to this problem. We compared signs and symptoms of stiffness and disease activity, labs, and hand ultrasounds of RA patients with and without morning stiffness.

Methods: We conducted a prospective feasibility observational study of patients who met ACR2010/EULAR classification criteria for RA and reported stiffness lasting more than one hour or less than 30 minutes. Ten patients were admitted for three days to Rockefeller University hospital. Patients continued standard of care treatment and were matched for steroid use (\pm 2.5 mg prednisone equivalent). The RADAI-5 questionnaire was used to assess symptoms every four hours while awake. CBC, ESR, CRP, and serum cortisol were measured every four hours. Disease activity scores, CDAI and DAS28CRP, and ultrasounds were performed at 8AM and 4PM each day. Ultrasound images of wrists and MCPs 2-5 bilaterally (10 joints) were obtained using a Vevo MD standard 10-22MHz linear probe. A musculoskeletal radiologist used the OMERACT semiquantitative scoring (0-3) system to assess both tendons and synovium and these scores were summed.

Results: The study participants were all seropositive females, with a mean of 57 years of age (Table). Stiffness severity was significantly increased in the morning compared to all other time points in the stiff group ($p < 0.02$). Patients who were stiff had significantly increased tender joint counts, swollen joint counts, patient global assessments of disease activity, CDAI,

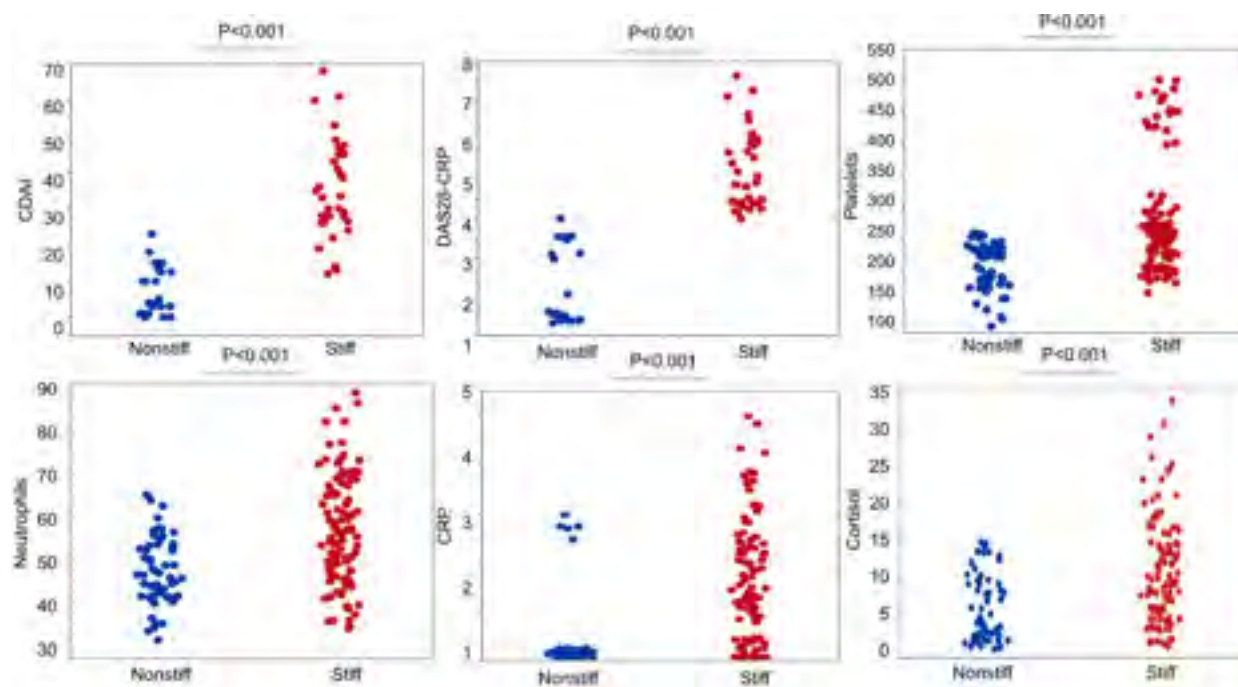

Figure. Comparison of CDAI, DAS28-CRP, platelet count, neutrophils, CRP and Cortisol level between stiff and nonstiff groups. P value: <0.001 is significant in all stiff patients.

Table. Patient Baseline Characteristics			
Variable	Stiff n= 6	Nonstiff n=4	Total n=10
Age (mean)	55.5	60.5	57.5
Female	6 (100)	4 (100)	10 (100)
% Hispanic	0 (0)	1 (25)	1 (10)
Race			
African American	0 (0)	1 (25)	1 (10)
White	6 (100)	3 (75)	9 (90)
BMI (mean)	28.7	27.1	28.1
Current cigarette smoker	2 (34)	0 (0)	2 (20)
years of Symptom duration (mean)	17.8	15.3	16.8
years of Diagnosis duration (mean)	14.2	12.3	13.4
Swollen Joint Count (mean)	11.3	3	8.0
Tender Joint Count (mean)	15.7	0.8	9.7
Seropositive (ACPA or RF)	6 (100)	4 (100)	100 (100)
Erythrocyte sedimentation rate (ESR)	34.8	42	37.7
C-reactive protein (CRP)	0.9	1.0	1.0
Current Medications			
NSAIDs	5 (83)	3 (75)	8 (80)
Glucocorticoids	1 (17)	1 (25)	2 (20)
DMARDs	5 (83)	4 (100)	9 (90)
Biologics	3 (50)	2 (50)	5 (50)

and DAS28-CRP (all $p < 0.001$) compared to nonstiff patients. Platelets, neutrophils, CRP and serum cortisol were all significantly higher in stiff compared to nonstiff patients (all $p < 0.001$) (Figure). Eosinophils demonstrated significant circadian variation in the stiff group ($p < 0.02$). There was significantly increased synovial greyscale scores between stiff and non-stiff patients ($p = 0.03$), and a nonsignificant trend of increased synovial greyscale summary scores between morning and evening time points.

Conclusion: We conclude that stiff patients have increased disease activity, blood levels of platelets, neutrophils, CRP, and cortisol, as well as increased morning eosinophils. This work lays groundwork for follow up studies and suggests that morning stiffness may be reflected in increased synovial gray scale.

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster III: Complications of Therapy, Outcomes, and Measures

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: International registries and cohorts could potentially provide long-term data on patient-centered outcomes. In recent years there has been a concerted effort to define a core set of outcome measures in rheumatoid arthritis (RA) patient registries to reduce the heterogeneity and enhance analysis of data. We conducted an environmental scan in 2016 to identify registries and cohorts (Google, PubMed, patientregistry.ahrq.gov, and clinicaltrials.gov) collecting data on patients with RA. We updated this previous study focusing on patient-reported outcome measures (PROMs). This study will aid in determining the degree of heterogeneity of PROMs worldwide to aid in a systematic effort to define a core set of outcome measures that are truly critical to patients and would probably not be collected in a randomized trial.

Methods: An expert librarian searched Medline and Embase using registries from our previous environmental scan. The name/acronym of each registry or cohort was cross referenced with terms or acronyms to select for RA. We included active registries or cohorts with articles published in the last five years. Two independent reviewers collected data and discrepancies were resolved by consensus or adjudication. Data was summarized using descriptive statistics.

Results: We included 131 registries and cohorts. Registries/cohorts were identified in 46 countries. The majority of these were from Europe (76 [58%]) and the rest from North America (24 [18%]), South America (9 [7%]), and Asia/Oceania (22 [17%]). PROMs measuring a functional impairment domain was frequently measured by the health assessment questionnaire, (HAQ)-HAQ-DI (77 [59%]), MDHAQ (13 [10%]), HAQ-II (5 [4%]), and visual analogue scale function (12 [10%]). Individual PRO domains included pain (44 [34%]), fatigue (16 [12%]), sleep (6 [5%]), quality of life, work productivity and patient-reported disease activity. Quality of life was measured with the medical outcomes Study Short Form with 6 items (2 [2%]), Rheumatoid Arthritis QoL (2 [2%]), Short Form-36 (23 [18%]), and different versions of EuroQoL (EQ) such as EQ-VAS (4 [3%]) and EQ-5D (20 [15%]). Working capacity was measured by the Work Productivity and Activity Impairment Questionnaire in 4 (3%) of the registries and cohorts. Patient-reported disease activity measures included the patient global assessment (49 [37%]), Rheumatoid Arthritis Disease Activity Index (9 [7%]), Rheumatoid Arthritis Impact of Disease (4 [3%]), and the Routine Assessment of Patient Index Data (6 [4%]).

Conclusion: Functional impairment was the most frequently recorded patient-reported outcome. As expected this study reveals a significant heterogeneity and infrequent use of the same PROMs. These data suggests far more effort must be made to include and define a core set of critical outcomes in longitudinal observational studies – outcomes that are critical to patients, and would not be feasible in a randomized trial.

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster III: Complications of Therapy, Outcomes, and Measures

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: There are multiple instruments to measure rheumatoid arthritis disease activity using various patient, lab or physician parameters. Since the RAPID3 has been published, there have been a few studies re-evaluating the target scores based on clinical experience. We re-evaluated the RAPID3 value for low disease activity and comparing it to two well established instruments approved by ACR, namely CDAI and SDAI.

Methods: A retrospective observational study was done from a single practice database in a community-based rheumatology clinic. Random visits from 345 patients with a diagnosis of rheumatoid arthritis who had documented RAPID3, CDAI and SDAI were studied. Baseline patient demographics, RAPID3, CDAI, SDAI, tender count, swollen count, physician global, pain scale, patient global function was collected. Receiver operator curves (ROC) were created using either low CDAI (CDAI ≤10.0) or low SDAI (SDAI ≤11.0) and a complete sensitivity/specificity report was analyzed using random patient visits.

Results: Study population consisted of 345 patients with documented RAPID3 scores with a mean of 10.19 (0-30) and SD 6.89. The comparison of RAPID 3 with low CDAI, it yielded an area under the curve of 0.84 on the ROC (95% CI 0.80-0.88) (Figure 1) with a sensitivity of 74.21% and specificity of 83.87% for a RAPID3 score of 8.0 (0-30). Similarly, in comparison with low SDAI, it yielded an area under curve of 0.84 on the ROC (95% CI 0.79 – 0.87) with a sensitivity of 74.69% and specificity of 83.06% for a RAPID3 score of 8.2 (0-30). If we reconsider a low disease activity score of 8.0 on the RAPID3, approximately 10% of this patient population were misclassified.

Figure 1. Receiver Operator Curve RAPID3 vs low CDAI

Conclusion: In this cohort, low CDAI and SDAI disease activity were found to be correlated to a higher RAPID3 score cut off. Currently, CDAI low disease activity is defined as >2.8-10, SDAI low disease activity as 3.3-<11 and RAPID3 low disease activity as >3.0-6.0. Using the current low disease activity cut off, our treat to target goal may be misclassifying these patients from low to moderate disease activity thereby overtreating them. We propose that the definition of low disease activity for the RAPID 3 to be <8.0 on a 0-30 scale. Further studies comparing these findings as well as other cut off ranges using larger number of patients are required to substantiate this study.

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster III: Complications of Therapy, Outcomes, and Measures

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with rheumatoid arthritis (RA) report a reduction in quality of life (QoL) in several aspects when compared to the healthy population. QoL can be evaluated by the 12-Item Short-Form Health Survey (SF-12), a questionnaire that considers the individual's perception of their health in the last 4 weeks and, through a specific algorithm, measures two scores: Physical Component Summary (PCS) and Mental Component Summary (MCS). The score of both ranges from 0 to 100, and higher scores are associated with better QoL indexes. In the present study, we related clinical, laboratory and therapeutic aspects of a large RA cohort with the PCS indexes of SF-12.

Methods: A prospective multicenter cohort study involving 13 centers specialized in the care of patients with RA. All patients underwent at least 3 clinical evaluations over a 12-month period. Only patients older than 18 years and classified as having RA according to the criteria of 1987 (ACR) or 2010 (ACR/EULAR) were evaluated. SF-12 was used to assess QoL, and only the components relevant to the PCS were considered. The comparison between groups was performed using the Mann-Whitney and Kruskal-Wallis tests.

Results: A total of 1,116 patients (89.43% females, mean age 58 ± 11 years) participated in the study. Patients with erosive disease presented lower PCS score ($p = 0.0004$) than those without this characteristic. Regarding medications, the use of at least one conventional synthetic DMARD is associated with a higher score ($p = 0.0004$); the use of at least one biologic or targeted-synthetic DMARD is associated with a lower score ($p = 0.0142$); and the use of abatacept and tocilizumab is associated with a lower score ($p = 0.0276$ and $p = 0.0116$, respectively). In a linear regression model ($p < 0.0001$), it was found that the patient with the highest score of SF-12 physical component is the one using a synthetic DMARD ($p = 0.0016$) and not using tocilizumab ($p = 0.0374$) and abatacept ($p = 0.0151$). The results are summarized in Table 1.

Conclusion: The best QoL indexes observed in patients using any conventional synthetic DMARD reinforce the importance of this class of medications in the treatment of RA. The results obtained with non-anti-TNF biologic DMARDs may reflect the usual choice of these drugs as third-line therapy.

Major Secular Trends of Patient Characteristics and Inclusion Criteria in RA Clinical Trials

Andreas Kerschbaumer¹, Bruno Bierbaumer², Josef S. Smolen³ and Daniel Aletaha⁴, ¹Department of Internal Medicine III, Division of Rheumatology, Medical University of Vienna, Vienna, Austria, ²Independent, Munich, Germany, ³Division of Rheumatology, Department of Medicine 3, Medical University of Vienna, Vienna, Austria, ⁴Department of Medicine III, Division of Rheumatology, Medical University of Vienna, Vienna, Austria

SESSION INFORMATION

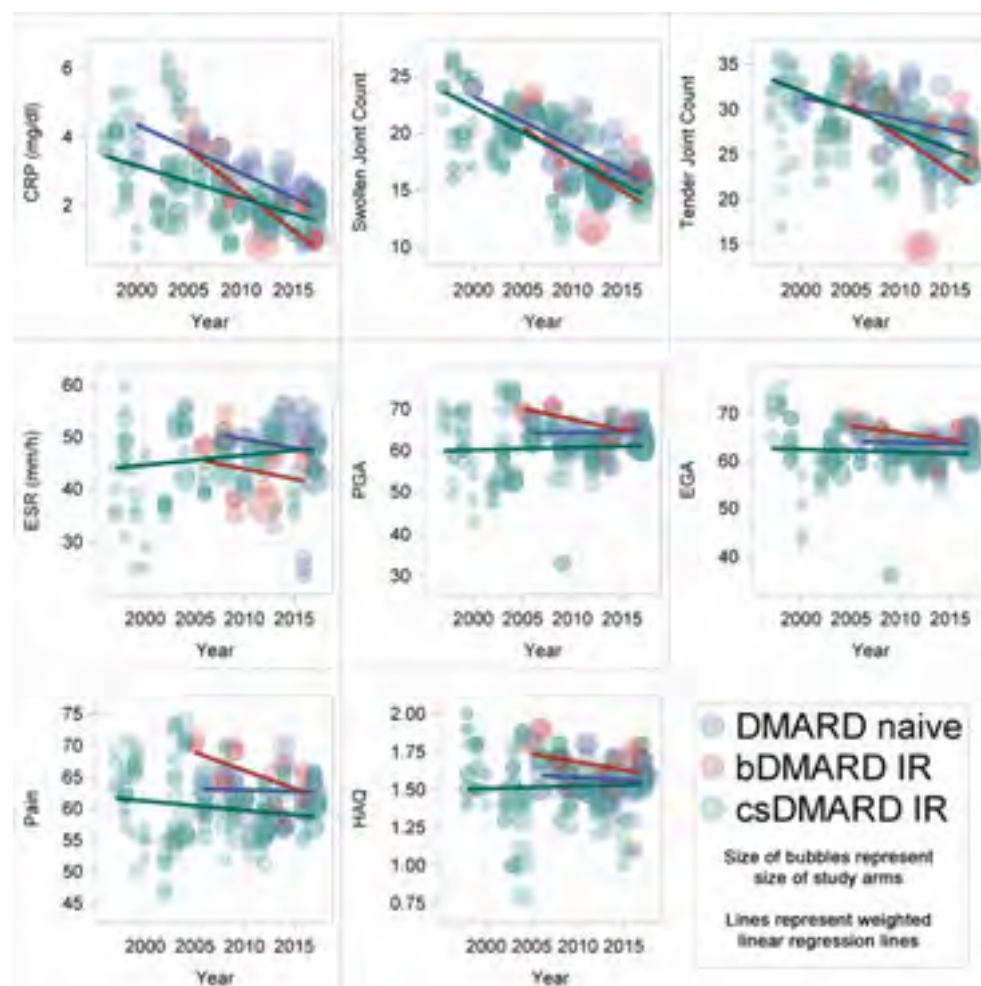

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster III: Complications of Therapy, Outcomes, and Measures

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is among the most intensively studied chronic inflammatory musculoskeletal diseases. Over the past two decades numerous new compounds have been tested in RA. Although the results from any new clinical trial in RA is usually interpreted in the context of existing data from previous trials, it is not clear whether trial populations are necessarily historically comparable. We investigated secular trends in characteristics of patient populations enrolled in RA clinical trials and inclusion criteria as possible influencing factors.

Methods: We performed a systematic literature review of randomized, controlled, double-blind trials, investigating biological therapies in RA. Reports were identified using PUBMED, EMBASE and the Cochrane Library. Populations were stratified into conventional disease modifying anti-rheumatic drug (DMARD) naïve, DMARD inadequate responders (IR), and biological DMARD IR. The following variables at baseline were extracted from reports: swollen and tender joint counts (SJC, TJC), pain, patient and evaluator global (PGA, EGA), acute phase measures (erythrocyte sedimentation rate, ESR and C-reactive protein, CRP), as well as the Health Assessment Questionnaire Disability Index (HAQ). In addition, we obtained the year of publication and the inclusion criteria (IC) of each trial. We then performed a mixed model meta-regression of year of publication on each of the mentioned variables and IC.

Results: Out of 697 abstracts selected for screening, 73 studies were chosen as relevant; 3 studies with mixed populations were excluded, resulting in 70 studies included for analysis. Table 1 shows the medians and quartiles for the baseline characteristics. Meta-regression showed a significant decrease of SJC ($\beta=-0.415$; $p<.001$), TJC ($\beta=-0.378$; $p<.001$), and CRP ($\beta=-0.123$; $p<.001$) over the years (figure 1); for all other core set measures, there was no trend or significance. IC showed similar trends over time for SJC ($\beta=-0.154$; $p<.001$), TJC ($\beta=-0.243$; $p<.001$), and CRP ($\beta=-0.065$; $p<.001$). Furthermore, there were significant linear associations of IC with SJC ($\beta=1.33$; $p<.001$), TJC ($\beta=1.14$; $p<.001$) and CRP ($\beta=1.16$; $p<.001$) at baseline.

Conclusion: There is a progressive drift towards lower number of swollen and tender joints and lower CRP-levels at trial entry of time, which is at least partly related to a similar trend in inclusion criteria for RA. The constancy of patient-reported outcomes suggests that the baseline activity is still perceived as similarly high. Differences in overall baseline inflammatory activity may pose a challenge for comparing newer with older trial results.

Effect of Biologic Agents on Synovial Tissues from Patients with Rheumatoid Arthritis

Ayako Kubota¹, Toru Suguro¹, Arata Nakajima², Masato Sonobe³ and Kazuaki Tsuchiya¹, ¹Toho University Omori Medical Center, Tokyo, Japan, ²Orthopaedics, Toho University Sakura Medical Center, Sakura-city, Chiba, Japan, ³Toho University Sakura Medical Center, Chiba, Japan

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster III: Complications of Therapy, Outcomes, and Measures

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Multiple studies addressing the effects of biologics on the synovial tissue in rheumatoid arthritis (RA) patients have been reported. There are, however, few studies comparing histopathological changes in the synovial tissue in the same RA patients between before and after biologics treatment. We examined the inflammation of synovium before and after biologic agents in the patients with rheumatoid arthritis (RA) and to investigate the association between synovial histopathology and disease activity.

Methods: Synovial tissues were collected from 34 RA joints before and after biologics. The average age and disease duration of the study subjects were 64.0 and 22.5 respectively. Histopathological changes in the synovial tissues were compared based on Rooney's score, and presence or absence of fibrinoid degeneration, proliferation of villi and plasma cell infiltration in the subsynovial tissue. We examined correlation between pathological findings in RA synovium and disease activity under biologics. Disease activity was assessed by CDAI. Etanercept, Infliximab, Tocilizumab, Adalimumab and Abatacept was used as biological drug for 18, 6, 5, 3 and 2 joints respectively.

Results: Rooney score between before and after biological drug usage improved from 28.4 to 12.0 showing significant difference. Significant improvement in Rooney score was observed in all items. Fibrinoid degeneration was observed in 29 cases (85.3%) and 6 cases (17.6%) before and after biologics treatment, respectively, demonstrating a significant reduction with biologics treatment. Proliferation of villi was observed in 32 cases (94.1%) and 11 (32.4%) before and after biologics treatment, respectively, demonstrating a significant reduction with biologics treatment. After the use of biologic agents, Moderate disease activity group had significantly higher in scores of focal aggregates of lymphocytes ($P=0.02$), diffuse infiltrates of lymphocytes ($P=0.019$), and Rooney total scores ($P=0.002$) than Remission and Low disease activity groups.

Conclusion: The study results demonstrated that biologics treatment significantly decreased inflammatory changes in the synovial lining layers and sublining layers. In addition, the results suggested that histopathological findings in the subsynovial tissue reflected disease activity.

Comparison of Risk for Infection-Related Hospitalization and Associated Costs of Biologic Experienced Rheumatoid Arthritis Patients Treated with Abatacept Versus Other Targeted Disease Modifying Antirheumatic Drugs

Damemarie Paul¹, Laura McDonald¹, Alexander Marshall², Tammy Curtice³, Melissa Lingohr-Smith⁴, Brandy Menges⁴ and Jay Lin⁴, ¹Bristol-Myers Squibb, Lawrenceville, NJ, ²HEOR, Bristol-Myers Squibb, Lawrenceville, NJ, ³Bristol-Myers Squibb, Princeton, NJ, ⁴Novosys Health, Green Brook, NJ

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster III: Complications of Therapy, Outcomes, and Measures

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Abatacept is a targeted disease-modifying antirheumatic drug (tDMARD) that has demonstrated a lower risk for infection in comparison with other tDMARDs among rheumatoid arthritis (RA) patients. The potential cost differences associated with the reduced risk of infection among RA patients treated with abatacept vs. other tDMARDs is not well understood. We therefore compared infection-related hospitalization risk and associated costs of RA patients experienced with a tumor necrosis factor- α inhibitor (TNFi) who subsequently received abatacept vs. other tDMARDs, including another TNFi or other non-TNF- α inhibitor (non-TNFi).

Methods: Patients initiating a tDMARD (index drug/date) who had ≥ 1 inpatient diagnosis or ≥ 2 outpatient diagnoses of RA in the 12 months prior to the index date were identified in MarketScan data (1/1/2010-3/31/2016). Patients were required to have been previously treated with a TNFi and have 12 months of insurance coverage prior to the index date (baseline period) and throughout the follow-up period (≥ 12 months; up to 36). Unadjusted and multivariable adjusted regression were used to evaluate the impact of the index drug on infection-related hospitalizations and the per-patient per-month (PPPM) associated costs. Log transformation and gamma distribution were used in the regression analysis of cost data where cost values plus \$1 were used so that after the log transformation the original cost data of \$0 will have the value of $\log(1)=0$.

Results: Of the study population, 308 patients (mean age: 55 years; 86% female) were treated with abatacept, 1,032 with a TNFi (mean age: 52 years; 82% female), and 321 with another non-TNFi (mean age: 55 years; 76% female). Compared to the baseline period, the proportion of patients with infection-related hospitalizations declined in the follow-up period, as did infection-related hospitalization cost among patients treated with abatacept, while increasing in the follow-up period for both the TNFi and non-TNFi cohorts (Table). After adjusting for differences in patient characteristics, Cox regression analysis showed that the risk for an infection-related hospitalization was significantly greater for RA patients treated with a TNFi vs. abatacept (HR: 2.6; 95% CI: 1.2-5.8, $P=0.02$) and numerically higher for those treated with another non-TNFi vs. abatacept (HR: 1.9; CI: 0.7-4.7, $P=0.19$). The change in infection-related hospitalization cost PPPM was significantly higher

Table. Unadjusted Comparison of Infection-related Hospitalizations and Associated Costs PPPM in the Baseline and Follow-up Periods

	Abatacept n=308	TNFi n=1,032	Non-TNFi n=321
Baseline infection-related hospitalization, n (%)	14 (4.6)	21 (2.0)	8 (2.5)
Follow-up infection-related hospitalization, n (%)	7 (2.3)	52 (5.0)	14 (4.4)
Mean baseline infection-related hospitalization cost PPPM	\$120	\$35	\$68
Mean follow-up infection-related hospitalization cost PPPM	\$22	\$68	\$75
Cost change (follow-up — baseline)	-\$98	\$32	\$7

for RA patients treated with a TNFi vs. patients treated with abatacept (\$73; 95% CI: \$16-\$201, $P=0.006$); and was numerically higher but not statistically significant for patients treated with another non-TNFi (\$66; 95% CI: -\$8-\$211, $P=0.08$).

Conclusion: In the real-world setting in the US, patients treated with abatacept vs. a TNFi had a lower risk for infection-related hospitalization and lower associated hospitalization cost.

Real-World Outcomes Associated with Triple Therapy Vs. TNFi Combo Therapy: Results from the Corrona Registry

Jeffrey R. Curtis¹, J. Lynn Palmer², George W. Reed³, Jeffrey Greenberg⁴, Dimitrios A. Pappas⁵, Leslie R Harrold⁶ and Joel Kremer⁴, ¹University of Alabama at Birmingham, Birmingham, AL, ²Corrona Research Foundation, Albany, NY, ³UMass Medical School, Worcester, MA, ⁴Corrona LLC, Waltham, MA, ⁵Columbia University, New York, NY, ⁶University of Massachusetts Medical School, Worcester, MA

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster III: Complications of Therapy, Outcomes, and Measures

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Despite several randomized controlled trials showing comparable clinical outcomes with triple therapy (Triple; MTX, SSZ, HCQ) versus combination therapy with MTX+TNFi (TNFi Combo), the real-world experience comparing these two strategies may differ.

Methods: We identified new users of Triple vs. TNFiCombo amongst RA patients in the Corrona registry. Initiation of these therapies could have been simultaneous or sequential, but patients had to receive all therapies simultaneously and could not have ever received Triple or TNFi Combo treatment previously. Patients must have had moderate/high disease activity (CDAI >10) at baseline and have ≥1 follow-up visit.

Treatment failure was defined as starting/adding a new biologic/JAKi, csDMARD, or discontinuation of any of the medications in Triple or TNFi Combo exposures. Patients were censored if they attained low disease activity (CDAI < 10). Propensity score (PS) matching (1:3, and 1:1 as part of a sensitivity analysis) was used to balance exposure groups (8-1 digit Greedy Match), with caliper widening if required for higher order matches. Treatment failure was evaluated using KM curves. Cox models were used to control for residual imbalance in baseline factors and account for clustering of the

matched PS pairs. An additional sensitivity analysis evaluated adjusted treatment failure in the entire unmatched sample, controlling for baseline factors and excluding patients in the non-overlapping tails of the PS.

Results: A total of 2156 TNFi Combo and 105 Triple patients were eligible for analysis. Before PS matching, numerous factors were imbalanced between the two groups, with Triple patients being older (mean age: 62 vs. 56 yrs), having longer RA disease duration (9 vs. 6 yrs), and a higher proportion with history of malignancy, diabetes, and serious infections. They also had lower baseline disease activity (mean Triple: 21.2 vs. TNFi Combo: 26.6).

After 1:3 PS matching (n=103 in Triple, n=309 in TNFi Combo in each group), balance was improved but some residual differences remained. Treatment failure was more likely in the Triple group (Figure). After multivariable adjustment, treatment failure was more likely in the Triple group compared to the TNFi combo group (adjusted hazard ratio [aHR] = 1.38, 95% CI 1.02-1.88). Results from both sensitivity analyses (n=2240 patients in entire sample, n=204 in matched sample) were similar (HR=1.45, 95% CI 1.10 to 1.92; aHR=1.64, 95% CI=1.12-2.38 matched, respectively).

Conclusion: Based on real world evidence from a large U.S. RA registry, use of Triple is uncommon, and outcomes associated with Triple are less favorable compared to combination therapy with TNFi+MTX.

Figure: Treatment Failure associated with Triple Therapy (n=103) versus Combination TNFi+MTX (n=309)

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster III: Complications of Therapy, Outcomes, and Measures

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: EQ-5D-3L is frequently used for evaluation of quality of life (QOL). However, there are several problems when using EQ-5L-3L. Evaluation using EQ-5L-3L might not properly reflect the health status of patients since patients can choose from only three levels (no problems, some problems, extreme problems). Another limitation is the ceiling effect, whereby a value of 1 for QOL means “complete health”. Recently, EQ-5D-5L was developed to resolve these problems. Few reports are available which assess both methods for evaluation of QOL in the context of rheumatoid arthritis (RA). This was a comparative study of EQ-5D-3L and EQ-5D-5L in patients with RA conducted using the IORRA cohort to examine the usefulness of the EQ-5D-5L.

Methods: The subjects were Japanese RA patients who participated in the IORRA survey in October 2016. QOL evaluation using EQ-5D-3L and EQ-5D-5L were conducted at the same time, and the following analyses were cross-sectionally examined. The difference in QOL value distribution between EQ-5D-3L and EQ-5D-5L was investigated. The QOL values of EQ-5D-3L and EQ-5D-5L were compared stratified by sex, age, RA disease duration, RA disease activity, dysfunction level, and medications (steroid use, methotrexate [MTX] use and biological DMARD [bsDMARD] use). Among RA patients who evaluated themselves as “complete health” using EQ-5D-3L, the percentage of the patients which did not satisfy “complete health” was investigated.

Results: A total of 5,023 RA patients were included in this study. Baseline clinical features in this cohort were as follows: 94% women; average age of 61 years old; mean RA disease duration: 15.7 years; average DAS28: 2.6; proportions of steroid, MTX and bsDMARD use: 27.2%, 77.0%, and 23.7%, respectively. The average (SD) values of QOL using EQ-5D-3L and EQ-5D-5L were 0.83 (0.18) and 0.85 (0.16), respectively. Although among RA patients who evaluated themselves as “1”, which means “no problems” using EQ-5D-3L in the 4 dimensions (mobility, self-care, usual activities, and anxiety/depression), most of the patients also evaluated themselves as “1” using EQ-5D-5L, while among RA patients who evaluated themselves as “1” using EQ-5D-3L for “pain/discomfort”, most of the patients evaluated themselves as “2” which means “some problems” using EQ-5D-5L. The average QOL value using EQ-5D-3L stratified by each clinical feature was lower than that using EQ-5D-5L regardless of patients’ backgrounds and medications. The percentage of RA patients who evaluated themselves as “complete health” which was scored as “1” in all 5 dimensions using EQ-5D-3L and EQ-5D-5L, were 45.0% and 32.3%, respectively. Among RA patients who evaluated themselves as “complete health” using EQ-5D-3L, 28.2% were omitted from “complete health” using EQ-5D-5L. The dimension of “pain/discomfort” had the most influence on omission from “complete health”.

Conclusion: The problem of ceiling effect was improved by using EQ-5D-5L in RA patients, and was especially influenced by the dimension of “pain/discomfort”, suggesting that the EQ-5D-5L questionnaire might properly reflect the health status of RA patients.

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster III: Complications of Therapy, Outcomes, and Measures

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: EULAR and ACR recommendations on the management of rheumatoid arthritis (RA) mainly focus on early RA and medication.^{1,2} Following these recommendations, several patients nevertheless remain symptomatic, which makes them difficult-to-treat.³ The estimated prevalence of difficult-to-treat RA ranges from 5 to 20%.⁴ A difficult-to-treat RA classification would enable making recommendations on its comprehensive management. We aimed to identify

Figure 2. Additional characteristics of difficult-to-treat RA and clinical issues to be covered in management recommendations

a. Additional characteristics and suggested criteria for difficult-to-treat RA

b. Additional clinical issues or comorbidities to be addressed in the workup and management of these patients

c. Clinically relevant situations which are not covered by the current RA recommendations

RA: rheumatoid arthritis; US: ultrasonography

* e.g. tapering strategies, adverse events, polypharmacy

characteristics of difficult-to-treat RA and issues to be addressed in its comprehensive workup and management that are not covered by the current RA management recommendations.

Methods: Among rheumatologists, an international survey was conducted. It included multiple-choice questions on disease characteristics of difficult-to-treat RA and open questions on additional items to be addressed and items missing in current management recommendations.

Results: 410 rheumatologists (a few of them in training) from 33 countries, mostly in Europe, completed the survey between July 2017 and March 2018 (Figure 1a). For disease characteristics of difficult-to-treat RA, 50% of respondents selected disease activity score assessing 28 joints (DAS28) >3.2 OR signs suggestive of active disease; 42% selected fatigue; 48% selected failure to ³2 conventional synthetic disease-modifying anti-rheumatic drugs (DMARDs) AND ³2 biological/targeted synthetic DMARDs; 89% selected inability to taper glucocorticoids below 5 or 10 mg prednisone equivalent daily (Figure 1b). Over 400 responses to the open questions were received (Figure 2). Comorbidities, extra-articular manifestations and polypharmacy were identified as important issues missing in current management recommendations.

Conclusion: Concepts of difficult-to-treat RA vary considerably. Important issues regarding patients with difficult-to-treat RA, such as comorbidities, extra-articular manifestations and polypharmacy, are not addressed by current RA management recommendations.

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster III: Complications of Therapy, Outcomes, and Measures

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Registry data have shown that treatment with bDMARDs induces remission or LDA (RLDA) in up to 50% of RA patients. Approximately 30-50% of patients have moderate disease activity (MDA) after treatment with bDMARDs, nevertheless data for this group are limited. We sought to assess long term outcome and characterize RA patients with persistent MDA (pMDA) on bDMARDs in clinical practice.

Methods: We analyzed data from the University of Crete Rheumatology Clinic. Disease activity, function, treatments of all patients starting a bDMARD are recorded prospectively every 3-6 months. Herein, we included patients with at least 3

years of follow-up, irrespective of switches. If DAS28-ESR was at the same disease activity range for at least 50% of the follow-up time, patients were assigned to one of 3 groups: persistent RLDA (pRLDA), pMDA and persistent high disease activity (pHDA). HAQ at 3 years was the primary outcome, while baseline characteristics and predictors of pMDA were assessed.

Results: Out of 479 patients with complete data, 357 could be assigned to one of the aforementioned groups; 33,164 and 160 patients in pRLDA, pMDA and pHDA respectively. At baseline, pMDA patients were older, more often women, have received more csDMARDs and had higher DAS28, HAQ and EuroQol status compared to pRLDA group (Table 1).

Table 2. Baseline determinants of achieving persistent moderate disease activity		
Baseline characteristics	Univariable	Multivariable
Gender (female vs. male)	2.04 (1.38-4.2), p=0.002	4.6 (1.93-11.02), p=0.001
Seropositive (yes vs. no)	0.76 (0.51-1.13), p=0.175	
Age	1.00 (0.99-1.02), p=0.735	
Disease duration	0.99 (0.97-1.02), p=0.566	
Nr of previous csDMARDs	1.04 (0.88-1.24), p=0.652	
Monotherapy (yes vs. no)	1.69 (0.86-3.33), p=0.126	
Concomitant MTX (yes vs. no)	0.84 (0.56-1.28), p=0.419	
1 st bDMARD is TNFi (yes vs. no)	0.77 (0.48-1.23), p=0.272	
HAQ	0.82 (0.55-1.21), p=0.316	
CRP	1.02 (0.92-1.15), p=0.684	
Tender joint count (per 1 joint)	0.96 (0.93-0.98), p=0.001	
Swollen joint count (per 1 joint)	0.96 (0.93-0.99), p=0.004	
VAS global	1.01 (1.00-1.01), p=0.189	
VAS pain (per 10 mm)	1.00 (0.99-1.02), p=0.396	
VAS physician (per 10 mm)	1.00 (0.99-1.02), p=0.448	1.02 (1.00-1.04), p=0.028
ESR (per unit increase)	1.00 (0.99-1.00), p=0.321	
DAS28-ESR	0.78 (0.65-0.93), p=0.006	0.62 (0.48-0.80), p<0.001

During follow-up, pMDA had more bDMARDs switches as compared to pRLDA [median (IQR) 1 (2) vs 0 (1), p=0.01]. Notably, although patients in pMDA had significant improvement in HAQ [baseline vs 36 months, median (IQR) HAQ: 1 (0.9) and 0.5 (0.8) respectively, p<0.001], HAQ at 3 years was significantly higher for pMDA compared to pRLDA group [0 (0.25) vs 0.50 (0.83), p<0.001] (Figure 1A). Of note, HAQ trajectories according to DAS28 grouping were clearly defined early at treatment course (6 months) and did not intersect throughout follow-up (Figure 1B). Multivariate analysis indicated that female sex, physician's evaluation and DAS28 were independent predictors for clustering patients in the pMDA group (Table2).

Conclusion: In clinical practice 34% and 33% of RA patients on bDMARDs have persistent MDA or HDA in spite of bDMARDs switches. Although patients on pMDA present early significant improvement in HAQ, they still have worse functional status, compared to patients in pRLDA, after 3 years of follow up.

Abstract Number: 2490

Real World Evidence Describing Infliximab Utilization Patterns in Rheumatoid Arthritis Patients in Community Rheumatology Practices in the United States: Implications for Cost Efficiencies?

Sergio Schwartzman¹, Dennis Parenti², Shawn Black², Stephen Xu³, Wayne Langholff³ and Shelly Kafka², ¹Weill Cornell Medical College, New York, NY, ²Janssen Scientific Affairs, LLC, Horsham, PA, ³Janssen Research & Development, LLC, Spring House, PA

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster III: Complications of Therapy, Outcomes, and Measures

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: AWARE (Comparative and Pragmatic Study of Golimumab IV Versus Infliximab in Rheumatoid Arthritis) is an ongoing prospective Phase 4 comparator study designed to provide a real-world assessment of intravenous golimumab (GLM) and infliximab (IFX) in patients (pts) with rheumatoid arthritis (RA). The primary endpoint compares the proportion of GLM and IFX pts with an infusion reaction (52wks). Here we report on IFX dose escalation (DE,

Fig A: Percent of Patients With Dose Escalation Above Starting Dose of ≥ 5 mg/kg

defined as at least 1 increase in prescribed dose above baseline) patterns from an interim analysis (IA) of the ongoing AWARE study. The baseline dose was chosen to judiciously evaluate DE by not focusing on pts at 3mg/kg that may be “routinely” moved to 5 mg/kg, but rather to report on the DE pattern of what may be considered more significant IFX DEs.

Methods: AWARE is a noninterventional 3-year study at 100 US sites. All treatment decisions including prescribed dose are made at the discretion of the treating rheumatologist. We report on DE patterns of IFX pts with a starting dose (infusion 1) of ≥ 5 mg/kg. Data shown are mean \pm standard deviation.

Results: Here we report on IFX pts, who’s first prescribed dose was ≥ 5 mg/kg, age = 53.7 ± 13.46 yrs, body weight = 85.1 ± 24.38 kg, BMI = 31.6 ± 10.8 kg/m² and 75.4% were female. Baseline CDAI of DE pts = 32.0 ± 16.17 . Among pts with initial prescribed dose ≥ 5 mg/kg, 26.4% were DE after the first infusion, and 38.2% of pts had two or more consecutive infusion intervals < 7 weeks duration (37.7% had both a DE and contraction of dosing interval). Among this cohort of pts who had ≥ 3 infusions, 16.7% had at least one dose ≥ 8 mg/kg. The pattern of DE is shown in the figure below, and in the table the % of pts prescribed ≥ 8 mg/kg at each infusion visit is shown.

Infusion #	# Pts Treated	# of Pts with Prescribed Initial Dose ≥ 8 mg/kg IFX	% of Pts with Prescribed Initial Dose of ≥ 8 mg/kg IFX
1	61	9	14.80
2	53	7	13.20
3	48	5	10.40
4	43	6	14.00
5	34	5	14.70
6	26	3	11.50
7	23	2	8.70
8	17	2	11.80
9	14	1	7.10
10	10	2	20.00

Conclusion: Of this subset of IFX pts, close to 20% were DE by infusion 4, with 10-14% dosed ≥ 8 mg/kg. Dose interval shortening could further affect the impact of DE. The AWARE study will utilize these data to assess the impact on IFX utilization in a real-world rheumatology practice setting.

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster III: Complications of Therapy, Outcomes, and Measures

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: T2T, achieving a DAS28 score lower than 3.2 is the main management strategy recommended by ACR and EULAR. HAQ is the most widely used in evaluation of physical function in RA. However, T2T may not always associate with good HAQ. Our purpose is to quantify phenomenon of mismatch between T2T and HAQ in RA patients, identify influential factors from real world data mining in smart system of disease management (SSDM).

Table 1. The mean scores for each functioning category in HAQ and the top 3 target joints.

	Mean score	The top 3 target joints
1 Dress yourself including shoelaces and buttons	0.43	Wrist, shoulder, middle finger
2 Get in and out of bed	0.3	Knee, wrist, shoulder
3 Lift a full glass to your mouth	0.32	Wrist, shoulder, middle finger
4 Walk outdoors on flat ground	0.38	Knee, wrist, shoulder
5 Wash and dry your body	0.48	Wrist, shoulder, elbow
6 Bend down to pick up clothing from the floor *	0.81*	Knee, wrist, shoulder
7 Turn faucets (or corks) on and off	0.47	Wrist, middle finger, index finger
8 Get in and out of a car	0.48	Knee, wrist, shoulder

* P < 0.001.

Methods: SSDM is a novel mobile tool of disease management. The patients were trained to master SSDM by health professionals and conducted DAS28 and HAQ self-evaluations once a month. The data were synchronized with their physicians and uploaded onto cloud for analysis.

Results: From June 2014 to June 2018, 31,230 RA patients from 587 hospitals in China used SSDM, of which 22,862 patients made 42,498 DAS28 and HAQ self-evaluations. The T2T rates were 29% at baseline (n=22,862) and 58% after 6 months (n=4,783).

Inpatients who achieved T2T, 76% had normal physical function (HAQ = 0), but 24% were with HAQ score higher than 0 with mean score 0.46, indicating physical dysfunction. The “Bend down to pick up clothing from the floor” was the move being affected most, with a mean score of 0.81, significantly higher than other dysfunctions, $P < 0.001$. The mean numbers of tender and swollen joints among T2T patients were 1.53 and 1.32 respectively. The analysis of correlation between physical dysfunction and the affected joints showed the knees were the top targets. Table 1 showed the mean scores for each functioning category in HAQ and the top 3 target joints.

Inpatients who did not achieve T2T, 32% had HAQ scores of 0, showing that these patients had normal physical function despite failure in achieving T2T. The mean number of tender and swollen joints in these patients was 4.31 and 2.85, respectively. The affected joints were mainly hand joints.

According to the cluster weights for the impact of impact joints on physical function, the weighted coefficient of affected joints impacting on physical function was obtained. The highest score was for knee (0.46), followed by wrist (0.35), middle finger (0.19), index finger (0.18), shoulder (0.15), ring finger (0.13), elbow (0.09) and little finger (0.07).

Conclusion: 1/4 RA patients suffer physical dysfunctions even though T2T are achieved. Diseased knees, wrists and middle fingers are the top 3 joints critically impacting on corresponding physical dysfunctions and contribute to a mismatch between T2T and HAQ. Conversely, diseased shoulder, elbow and other small hand joints are less likely resulting in physical dysfunction. Therefore, not all joints are equal, and joints of knees, wrists and middle fingers deserve higher weighing coefficient in evaluation of disease activity. T2T guided by DAS28 is not good enough and may misleading. A modified DAS28 should be considered for overcome the mismatch with HAQ and a special attention should be paid on these top three joints for rehabilitations.

Conclusion: After proactive disease management via SSDM for more than 6 months, the rate of T2T in RA patients increased significantly. The patients who bear better HAQ scores and perform more self-evaluations through SSDM had lower probability of relapse and higher T2T maintaining and achievement. SSDM is a valuable tool for long term RA

	Baseline Total (2,666)	Achiever of T2T (1,638, 39%)		Failure of T2T (1,028, 61%)

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster III: Complications of Therapy, Outcomes, and Measures

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Patients satisfaction with their treatment is important for adherence to medications, particularly for chronic conditions such as rheumatoid arthritis (RA). The aim of this analysis was to explore the relationship between patient satisfaction with treatment and features of disease activity as well as to identify thresholds of disease severity optimally associated with satisfaction of RA patients treated in routine clinical care.

Methods: Abatacept Best Care (ABC) is a prospective, multicenter, observational study of patients with RA starting subcutaneous abatacept. Patient expectations in regard to RA activity, pain, function, and fatigue were assessed at baseline using a VAS mm scale (0=no expectation, 100=highest expectation), and patient satisfaction with treatment for each aspect during treatment was assessed in a similar fashion. The correlation of patient satisfaction at 6 and 12 months and TJC28, SJC28, physician global (MDGA), patient global (PtGA), DAS28, CDAI, RAPID3, HAQ, pain, and fatigue (and changes from baseline in these variables) was assessed with the Pearson's correlation coefficient (r). ROC analysis was used to identify thresholds of CDAI, pain, HAQ, and fatigue optimally associated with patient satisfaction (>50mm).

Results: 275 patients (74.8% females) were included with a mean (SD) age of 59.7 (11.7) years and disease duration of 7.4 (8.7) years. At baseline, mean (SD) parameters were: CDAI (30.0 [10.7]), pain (64.6 [23.4]), HAQ (1.5 [0.6]), and fatigue (63.3 [23.4]); patient expectations were: RA activity (70.3% [23.9]), pain (72.1% [24.4]), function (71.1% [23.8]), and fatigue (69.1% [25.7]).

At 6 months, weak-to-moderate negative correlations ($0.2 < r < 0.6$) were observed between patient satisfaction with treatment and all parameters studied, the strongest being with MDGA, DAS28, CDAI, PtGA, and pain. Similar results were observed at 12 months, however patient satisfaction with treatment in terms of function was only correlated (moderately) with DAS28. Regarding the correlation of patient satisfaction with changes from baseline in disease parameters, again, weak-to-moderate negative correlations were observed which were lower at 12 months compared to 6 months. No correlation between patients with high expectations of treatment outcome and satisfaction was observed at any time.

In ROC analysis, optimal thresholds of disease severity were identified for all aspects of patient satisfaction which showed statistically significant ($p < 0.001$) fair precision ($\text{ROC} \approx 0.7$; Table 1).

Conclusion: Weak-to-moderate correlation was observed between patient satisfaction with treatment and various outcomes. Specific thresholds corresponding to moderate disease activity, moderate and mild pain at 6 and 12 months, respectively, and mild functional disability and fatigue were identified which could be targeted in routine clinical care.

Table 1 ROC Analysis for Detection of Optimal Thresholds Associated with Patient Satisfaction with Treatment

	Patient Satisfaction with Treatment in Terms of:							
	RA Activity		Pain		Functional		Fatigue	
	6m	12m	6m	12m	6m	12m	6m	12m
CDAI*	13.5 / 0.76	11.8 / 0.73						
Pain (VAS)*			54.0 / 0.75	32.0 / 0.69				
HAQ*					0.88 / 0.70	1.00 / 0.67		
Fatigue (VAS)*							42.9 / 0.68	40.0 / 0.67

*Optimal threshold/AUC

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster III: Complications of Therapy, Outcomes, and Measures

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Swelling or tenderness of specific joints may differentially impact the ability of rheumatoid arthritis (RA) patients to perform daily activities and work. The aim of this analysis was to explore the relationship between specific joint involvement and work or activity impairment due to RA.

Methods: The Abatacept Best Care Study (ABC) is a prospective, multicenter, observational study evaluating the usefulness and adherence to a T2T approach vs. standard of care in real-life management of patients with active RA starting subcutaneous (SC) abatacept 125 mg once weekly. Interim data were used. Based on joint involvement evaluated with the 28-joint count, five groups were created: shoulder(s), elbow(s), wrist(s), hand(s), and knee(s). The impact of specific joints on % activity impairment (AI) and overall work impairment (WI) due to health at baseline as well as their change from baseline to 12 months, as measured with the Work Productivity and Activity Impairment (WPAI) questionnaire were assessed with general linear regression adjusting for age, gender, and total swollen and tender joint counts.

Results: 255 patients (74.8% females) were included with a mean (SD) age of 59.5 (11.6) years, 7.9 (4.7) swollen joints, and 9.7 (6.2) tender joints at baseline. Of these, 86 (33.7%) had information on WI at BL. At 12 months, 182 (71.4) and 58 (22.7%) had information on AI and WI, respectively. At baseline, increased number of tender, but not swollen, joints was associated with significantly increased AI (increase by 1.3 percentile units for each additional tender joint, $p<0.001$) and WI (increase by 1.9 percentile units for each additional tender joint, $p=0.002$). For specific joints, swollen shoulder(s) and knee(s), and tender shoulder(s) and elbow(s) were associated with increased, but not statistically significant, AI. Swollen shoulder(s) and elbow(s), and tender shoulder(s) and elbow(s), were associated with numerically, but not statistically, higher WI. For hand(s), nearly all patients had swollen and tender MCPs and/or PIPs so a baseline association was not performed.

At 12 months, swollen/tender wrist(s) ($p=0.015/p=0.003$) and hands ($p<0.001/p<0.001$) were associated with significantly lower improvement from baseline in AI (Table 1). Similarly, swollen/tender wrist(s) ($p=0.002/p<0.001$) and hands ($p<0.001/p<0.001$), as well as tender elbows ($p=0.032$) were associated with significantly lower improvement in WI.

Conclusion: Swelling and tenderness at specific joints has differential impact on the ability to work and perform daily activities. Residual involvement of upper limb joints after 12 months of treatment was associated with persistent activity and work impairment.

Table 1 Relationship Between Specific Joint Involvement at 12 Months and Improvement in AI/WI from Baseline

Swelling in:	Difference in Δ AI*	Difference in Δ WI*	Tenderness in:	Difference in Δ AI*	Difference in Δ WI*
Shoulder(s)	13.2 / $p=0.14$	-12.3 / $p=0.57$	Shoulder(s)	11.4 / $p=0.06$	4.6 / $p=0.80$
Elbow(s)	10.3 / $p=0.36$	36.0 / $p=0.09$	Elbow(s)	13.8 / $p=0.08$	36.8 / $p=0.032$
Wrist(s)	11.9 / $p=0.015$	28.1 / $p=0.002$	Wrist(s)	14.3 / $p=0.003$	30.9 / $p<0.001$
Hand(s)	17.7 / $p<0.001$	26.1 / $p<0.001$	Hand(s)	18.9 / $p<0.001$	28.5 / $p<0.001$
Knee(s)	11.0 / $p=0.16$	36.0 / $p=0.09$	Knee(s)	10.1 / $p=0.08$	19.2 / $p=0.08$

*Adjusted difference in improvement (from baseline to 12 months) in % impairment when joint is affected vs. not affected at 12 months. More positive values indicate lower improvement over time.

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster III: Complications of Therapy, Outcomes, and Measures

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: In rheumatoid arthritis (RA), women may be less likely to achieve clinical remission. These sex differences remain incompletely understood and might relate to differences in performance of disease activity measures, rather than biological sex differences. We evaluated sex differences in remission and low disease activity in patients with RA, comparing composite disease activity measures and definitions.

Methods: This longitudinal cohort study utilized data from the Veterans Affairs Rheumatoid Arthritis registry. Participants fulfilled ACR criteria for RA. Remission and low disease activity were defined based on composite scores (DAS 28 joints with ESR [DAS28-ESR], DAS 28 joints with CRP [DAS28-CRP], clinical disease activity index [CDAI], routine assessment of patient index data 3 [RAPID3]). We also studied achievement of low disease activity based on individual measures applying Boolean and other published criteria (tender joint count 28 joints [TJC28], swollen joint count 28 joints [SJC28], ESR, CRP, physician global assessment [PhGA], patient global assessment [PtGA]). We assessed 1) the likelihood of point remission at any time and 2) the time to sustained remission (2 consecutive visits) among those not in remission at enrollment. Logistic regression models incorporated generalized estimating equations to account for repeated disease

activity measures and adjusted for age, race, smoking, and disease duration. Multivariable Cox proportional hazard models assessed differences in the time to sustained remission.

Results: At enrollment, women (n=252, 10.2%) were younger, less likely to be smokers, used less prednisone, and had fewer comorbidities. Considering all points in time, the odds of remission for women were lower only for DAS28-ESR [OR 0.71, (95% CI 0.55, 0.91), p<0.01] (Table 1). In contrast, women were more likely to attain CDAI low disease activity [OR 1.36, (95% CI 1.08, 1.73), p=0.01]. Women were more likely to achieve favorable individual measures- low SJC 28, CRP, and PhGA, except for having an ESR <30 mm/hour [OR 0.72, (95% CI 0.57, 0.90), p<0.01]. Using an age-, sex-specific definition, women were more likely to achieve a low ESR [OR 1.32, (95% CI 1.05, 1.64), p=0.02]. In Cox models, women were less likely to reach sustained remission only by DAS28-ESR [HR 0.53, (95% CI 0.35 - 0.80), p<0.01]. There were no significant differences in sustained remission rates using DAS28-CRP, CDAI, or RAPID3.

Conclusion: The comparison of remission rates between men and women varied greatly based on the composite disease activity measure selected. Sex- specific differences in the ESR bias towards lower rates of remission among women using DAS28-ESR. This study suggests selection of disease activity measure may have influenced prior research suggesting low remission rates in women and illustrates the need for sex-specific treatment targets for the DAS28-ESR.

Table 1 Odds Ratio of being in remission or low activity for women versus men at any observation adjusted for age, race, smoking, and disease duration.

	Observations	Total n (women)	OR (95% CI)	p-value
Remission				
DAS28-ESR (<2.6)	26148	2398 (238)	0.71 (0.55 – 0.91)	<0.01
DAS28-CRP (<2.6)	24875	2330 (233)	1.14 (0.91 – 1.42)	0.25
CDAI (≤2.8)	20261	2227 (221)	1.28 (0.96 – 1.71)	0.09
RAPID3 (≤3)	26261	2348 (231)	0.97 (0.67 – 1.39)	0.85
Low Disease Activity				
DAS28-ESR (≤3.2)	26148	2398 (238)	0.87 (0.71 – 1.08)	0.21
DAS28-CRP (≤3.2)	24875	2330 (233)	1.19 (0.96 – 1.48)	0.12
CDAI (≤10)	20261	2227 (221)	1.36 (1.08 – 1.73)	0.01
RAPID3 (≤6)	26261	2348 (231)	1.04 (0.80 – 1.35)	0.76
Component Measures				
TJC28 (≤1)	28991	2475 (249)	1.07 (0.88 – 1.31)	0.48
SJC28 (≤1)	28999	2476 (249)	1.51 (1.22 – 1.88)	<0.001
ESR (<30 mm/hour)	26714	2442 (249)	0.72 (0.57 – 0.90)	<0.01
ESR (age-, sex- specific)	26714	2442 (249)	1.32 (1.05 – 1.64)	0.02
CRP (≤1.0 mg/dL)	25196	2366 (243)	1.26 (1.01 – 1.59)	0.04
PhGA (≤1, 0 to 10 scale)	20363	2238 (222)	1.54 (1.23 – 1.93)	<0.001
PtGA (≤1, 0 to 10 scale)	28705	2457 (245)	1.22 (0.95 – 1.56)	0.11

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster III: Complications of Therapy, Outcomes, and Measures

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Previous studies have demonstrated the efficacy of a treat-to-target approach to optimize therapeutic outcomes for patients with RA using measures of clinical disease activity to monitor patient response. The Multi-Biomarker Disease Activity (MBDA) test is an objective molecular measure of 12 serum biomarkers that has been validated as a measure of disease activity and predictor of radiographic progression. A recent study has also demonstrated that adjusting the MBDA score for age, sex and adiposity improves its ability to predict radiographic progression relative to the unadjusted MBDA score and clinical measures of disease activity (i.e. DAS28). Short-term variation in test biomarkers can be observed as day-to-day (daily) or within-day (diurnal) fluctuations. Establishing a minimally important difference (MID) in the MBDA score – the smallest score change that exceeds inherent variability – accounts for such fluctuations and provides a reference point for interpreting MBDA score changes over time. This study evaluated daily and diurnal variation in MBDA scores adjusted for age, sex and adiposity. The data were used to determine the MID and establish a cut point for meaningful change in the MBDA score.

Methods: 28 adult, seropositive RA patients with clinically stable disease were enrolled from a single US rheumatology research center. MBDA testing was performed for each patient on 9 non-fasting serum samples obtained over 4 consecutive days: 6 samples during the first 24 hours (8 AM, 12 PM, 4 PM, 8 PM, 12 AM, and 8 AM), 1 sample at 12 PM in the next 24-hour period, 1 sample at 8 AM on each of the two following days. Patients were stratified by MBDA disease activity category (high, >44; moderate, 30-44; low, <30). MBDA scores were also adjusted for age, sex and adiposity, using serum leptin as a proxy for adiposity. MBDA score variation was assessed for daily and diurnal timeframes. The standard deviation (SD) of MBDA scores was calculated using a linear mixed model that included random effects for patient, day, and time of day. The MID was calculated as $z_{0.95} \sqrt{2 \times \text{total variance of MBDA scores}}$, where $z_{0.95}$ is the standard normal deviate corresponding to the 95th percentile. The MID was assessed for the unadjusted and adjusted MBDA scores for all patients as well as for those with clinically active disease (moderate/high).

Results: In a combined daily-diurnal variation analysis including all patients, the SD of MBDA score change was 4.7, and the MID was 11. In a subset analysis of moderate/high disease activity categories (n=22), the total SD of MBDA scores was 3.6, and the MID was 8 MBDA units. When the MBDA was adjusted for age, sex and adiposity, the MID for patients with moderate/high disease activity was unchanged at 8 units.

Conclusion: For individuals with moderate or high disease activity based on the adjusted or unadjusted MBDA score, the MID was determined to be 8 MBDA score units. A change in MBDA score greater than or equal to the MID represents a change in RA disease activity that clinicians can use as a benchmark for therapeutic drug efficacy and can be incorporated in a treat-to-target strategy that combines both clinical and molecular metrics.

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster III: Complications of Therapy, Outcomes, and Measures

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: We examined the relationship between the difficulty rheumatoid arthritis (RA) patients have being able to afford their arthritis medications and illness intrusiveness. Illness intrusiveness reflects the extent to which an illness interferes with daily activities, including both instrumental activities and interpersonal relationships.

Methods: Participants (n=300) with physician-diagnosed RA and moderate/severe disease activity were recruited to participate in a longitudinal study. Data were collected via online questionnaires. At baseline, participants were asked if they had difficulty affording their RA medications (no trouble, a little trouble, a lot of trouble) and illness intrusiveness and self-efficacy were assessed using standardized questionnaires. The illness intrusiveness and self-efficacy measures were re-administered at a 6-month follow-up. We used a 13-item illness intrusiveness scale; participants were asked how their illness and/or its treatment interfere with different aspects of their lives ranging from 0 (not very much) to 100 (very much). To measure self-efficacy participants were asked how certain they were that they can manage their disease independently. Responses are scored from 0 (very uncertain) to 100 (very certain). Data were analyzed using linear regression.

Results: At baseline, controlling for education, race, and gender, participants who reported no trouble being able to afford the medications they need to control their RA, reported less illness intrusion than participants who reported having either a little or a lot of trouble (adjusted means=44.1, 51.8, and 57.7, $p < 0.0001$). At the 6-month follow-up, controlling for illness intrusion at baseline, education, race and gender, participants who had reported no trouble being able to afford their RA medications at baseline, reported less illness intrusion than participants who had reported having a lot of trouble (adjusted means=46.8 and 55.9, respectively, $p=0.02$). Participants who had reported having a little trouble fell between the other two groups (adjusted mean=48.5) and differed only from those who had reported having a lot of trouble ($p=0.06$). In exploratory analyses, we found that the relationship between trouble affording one's medications and illness intrusiveness appears to be mediated by self-efficacy. At the 6-month follow-up, controlling for self-efficacy at baseline, education, race, and gender, participants who reported no trouble being able to afford their RA medications had greater self-efficacy than participants who had reported having either a little or a lot of trouble (adjusted means=53.7, 43.7, 35.1, $p < 0.0001$). After controlling for self-efficacy at the 6-month follow-up, the relationship between trouble affording ones medications and illness intrusiveness was no longer statistically significant ($p=0.36$).

Conclusion: Financial barriers that limit access to the medications needed to control one's disease may have a deleterious effect on patient self-efficacy and contribute to lifestyle disruptions experienced by people with RA.

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster III: Complications of Therapy, Outcomes, and Measures

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Vitamin D deficiency is a common hallmark of rheumatic diseases, and some controversy exists about its effect on rheumatoid arthritis (RA), in particular about the association between vitamin D levels and lipid profiles. Several factors influence this cross-talk, including polymorphisms in vitamin D bioactivating enzymes (CYP27A1 and CYP2R1) and signaling (vitamin D receptor), and 7-dehydrocholesterol reductase (7DHCR7), an enzyme using a common metabolite to vitamin D and cholesterol syntheses. The contribution of these factors to the association between vitamin D and lipid profiles in RA is unknown. The main aim of this study was to evaluate the impact of vitamin D-related polymorphisms and DHCR7 serum levels on the association between vitamin D and lipid profile in RA.

Methods: Serum 25 (OH)-vitamin D and DHCR7 levels were measured in a cross-sectional group of 211 RA patients (EULAR/ACR 2010 criteria) and 94 healthy controls (HC). An additional group of 13 RA patients undergoing anti-TNF α treatment was prospectively followed for 3 months and samples were taken before and after TNF α -blockade. VDR-

rs2228570, CYP27A1-rs933994, CYP2R1-rs10741657 and DHCR7-rs12785878 polymorphisms were genotyped with TaqMan Assays.

Results: RA patients exhibited decreased vitamin D levels ($p<0.001$), but no associations with disease activity, duration, HAQ or treatments were found. Vitamin D levels were correlated with HDL-cholesterol ($r=0.217$, $p<0.001$) and total-/HDL-cholesterol ratio ($r=-0.227$, $p=0.004$). This correlation was restricted to patients harboring the VDR-rs2228570 AG/AA genotype, and vitamin D levels remained the only predictor of HDL-cholesterol in these patients in a multivariate regression analysis adjusted for age, gender, seasonality, disease activity and treatments (B[95% CI], p : 0.246 [0.036, 0.455], $p=0.022$). Vitamin D deficiency (<20 ng/ml) was associated with lower HDL-cholesterol ($p=0.028$), higher tender ($p=0.005$) and swollen ($p=0.002$) joint counts, higher DAS28 ($p=0.018$) and HAQ ($p=0.024$) in AG/AA-patients but not in their GG-counterparts (all $p>0.050$). No differences in the distribution of any of the polymorphisms was found between patients and controls none of them showed any effect on HDL-cholesterol. On the other hand, decreased DHCR7 serum levels were observed in RA compared to HC in individuals sampled in winter/spring ($p=0.012$) but not in summer/autumn ($p=0.354$). RA patients with a previous history of CV disease exhibited decreased DHCR7 levels than their CV-free counterparts ($p=0.024$). The associations among DHCR7, vitamin D and lipid profile followed a seasonal pattern, decreased DHCR7 ($p=0.008$) and vitamin D ($p<0.001$) together with increased total-cholesterol ($p=0.025$) being found in winter/spring. Finally, increasing vitamin D upon TNF α -blockade was positively correlated to the change in DHCR7 levels ($r=0.766$, $p=0.002$).

Conclusion: The adverse impact of vitamin D deficiency on the lipid profile and clinical features in RA is influenced by the VDR-rs2228570 polymorphism and DHCR7 levels. DHCR7 may be a missing link to better understand the connections between vitamin D, lipid profiles and seasonality in RA.

Predictors of Rheumatoid Arthritis Development in Patients with Early Undifferentiated Arthritis: A 2-Years Follow-up Study

Juan Molina¹, Maria Gabriela Gonzalez Álvarez², Victoria Navarro-Compán², Laura Nuño³, Alejandro Villalba², Diana Peiteado², Patricia Bogas² and Alejandro Balsa², ¹Rheumatology, Rheumatology, La Paz University Hospital, Madrid, Spain, ²Hospital Universitario La Paz, Madrid, Spain, ³Rheumatology, La Paz University Hospital, Madrid, Spain

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster III: Complications of Therapy, Outcomes, and Measures

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Early treatment of RA improves longterm outcomes. However, at the beginning of the disease, some patients with RA fall within undifferentiated arthritis (UA) patients. Almost half of patients with UA may experience spontaneous remission. So, in order to prevent overtreatment and poor outcomes, the identification of predictors of RA development is desirable. The objective of this research is to determine the frequency of patients with UA evolving into RA after 2 years of follow-up and the factors contributing to predict this outcome.

Methods: A prospective analysis of an early arthritis cohort of 1377 patients from 1993 to 2017 was undertaken. For this study, 2-years follow-up data of patients who presented with UA were analyzed. A detailed baseline assessment was completed including clinical features, physical examination and laboratory tests. Patients were stratified in two groups based on progression to RA (according to physician's diagnosis) or to another disease (non-RA). First, differences between groups were tested using chi-squared and Student-t tests in the univariate analysis. Second, multivariate logistic regression models were employed to investigate the association between possible predictive factors and RA development.

Results: A total of 471 UA patients were included for analysis. Mean age was 48.7 ± 17.5 years, 352 (74.9%) were females, and mean symptoms duration was 13.9 ± 13.9 weeks. After 2 years of follow-up, 93 (19.7%) of UA patients evolved into RA. Meanwhile, 175 (37.2%) remained undifferentiated and 203 (43.1%) developed into other musculoskeletal diseases. Baseline characteristics between both groups are compared in Table 1. In the univariate analysis, the presence of rheumatoid factor (RF) and anti-citrullinated peptides antibodies (ACPA), tender and swollen joint count, duration of morning stiffness, smoking, symmetry and ESR values were significantly associated with RA development. In the

multivariate analysis, RF (OR= 5,899; 95% CI 1,795-19,382), ACPA (OR= 123,238; 95% CI 29,353-517,410) and swollen joint count (OR=1,233; 95% CI 1,048-1,450), remained significantly associated with RA development (Table 2).

Conclusion: Approximately, 1 out of 5 patients with UA evolves into RA after 2-years of follow-up. Swollen joint count, and the presence of rheumatoid factor (RF) and anti-citrullinated peptides antibodies (ACPA) are independent predictors for the development of RA, supporting the early DMARDs initiation in such patients.

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster III: Complications of Therapy, Outcomes, and Measures

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Anti-citrullinated protein antibody (ACPA) is a highly specific biomarker for RA¹ and ACPA-seropositive patients have a tendency toward severe erosive disease and more rapid disease progression.²⁻⁴ Little is known regarding the impact of poor prognostic factors, such as ACPA and erosive disease, on healthcare resource utilization (HCRU). The purpose of this analysis was to characterize the rate of HCRU between anti-cyclic citrullinated peptide (anti-CCP; a surrogate of ACPA) positive (+) patients with or without erosions who initiated biologic (b) DMARD treatment.

Methods: This analysis included patients aged ≥ 18 years who were enrolled in a large sequential RA registry (October 2001–August 2017) and who had known erosions, as measured by radiography, and anti-CCP+ status at or prior to bDMARD initiation visit and a 12-month (± 3 months) follow-up visit. Anti-CCP+ was defined as ≥ 20 U/mL. Rates of HCRU, including all-cause hospitalizations, all joint surgeries (total and partial; all sites), radiographic procedures and use of assistive devices, were estimated over 12 months of follow-up from the bDMARD initiation visit in anti-CCP+ patients with or without erosions. Rates of HCRU per 100 patient-years and risk ratios, adjusted by baseline age, were estimated with 95% CI using a Poisson regression model.

Results: A total of 2047 anti-CCP+ patients were included in this analysis, 868 with and 1179 without erosions. At biologic initiation visit, mean (SD) age was 58.9 (12.5) and 55.9 (12.5) years and disease duration was 11.7 (10.1) and 6.4 (7.5) years, respectively, in anti-CCP+ patients with and without erosions. Over 12 months of follow-up, the rates of HCRU were higher among anti-CCP+ patients with versus without erosions at baseline bDMARD initiation visit (Table).

Conclusion: ACPA seropositivity with erosive disease predicts high utilization of healthcare resources, suggesting that early therapeutic intervention may be warranted in anti-CCP+ patients to achieve better disease control and reduce complications from RA.

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM **Disease Activity is the Major Discriminator When Defining Refractory Rheumatoid Arthritis**

M Bécède, JS Smolen, D Aletaha.

Medical University of Vienna, Vienna, Austria

Background/Purpose: Rheumatoid arthritis (RA) is characterised by the presence of a progressively destructive joint inflammation. Even in times of modern therapeutics, a subgroup of patients continues to be refractory to numerous consecutive therapeutic interventions with regards to control of inflammation, joint damage. To date, there exists no definition for refractory RA.

Methods: To explore different modifications of a definition for refractory RA, we defined the base case of refractory RA as patients who had experienced ≥ 3 treatment courses (with at least one biological failure) over a minimum of 18 months since first treatment initiation (to avoid counting treatment courses that were given for a too short period), and the lack of reaching the treatment goal of low disease activity or remission (defined by a Clinical Disease Activity Index, CDAI, >10). We then modified our working definition based on these four variables (disease duration: 12/18/24 months; disease activity: moderate/high; number of treatment courses: $\geq 3/\geq 4$; different biologic agents: $\geq 1/\geq 2$).

Results: From our clinic's ongoing longitudinal data set we identified 68 refractory patients out of 688 RA outpatients. There was virtually no difference based on modifying disease duration, so we kept our working definition of a minimum disease duration of at least 18 months (n=464; 12 months: n=466; 24 months: n=453). Changing the disease activity component of the definition had a great impact on the identified refractory RA population, by requiring high instead of moderate disease activity (MDA: CDAI >10 , n=129 vs. HDA: CDAI >22 , n=31). In both, the MDA and the HDA group of patients, we could observe $\geq 60\%$ of patients, who already experienced at least three treatment courses (MDA, n=82/129; HDA, n=21/31). Above a half in each group qualified as refractory also with the criterion of an addition fourth failed treatment course (MDA, n=64/129; HDA, n=15/31). When further stratifying patients based on the number of failed different biologic DMARDs, we could observe that regardless of the level of disease activity and number of failed treatment courses, most patients experienced at least one or even a second biologic agent (table).

Conclusion: The level of disease activity is the major discriminator when defining a population of refractory RA. The duration of treatment does not significantly impact the identification of refractory RA. The number of failed treatment courses and insufficient responses to biologic DMARDs further helps characterizing patients with refractory RA. Considerations of the impact of these different characteristics of refractory disease may well inform future criteria for refractory RA.

Last clinical visit ≤ 6 months ago + Disease duration ≥ 18 months n=464	Moderate disease activity (CDAI >10) n=129	≥ 3 failed treatment courses n=82	≥ 1 failed bDMARD n=68 ≥ 2 failed bDMARDs n=49
		≥ 4 failed treatment courses n=64	≥ 1 failed bDMARD n=58 ≥ 2 failed bDMARDs n=46
	High disease activity (CDAI >22) n=31	≥ 3 failed treatment courses n=21	≥ 1 failed bDMARD n=17 ≥ 2 failed bDMARDs n=11
		≥ 4 failed treatment courses n=15	≥ 1 failed bDMARD n=13 ≥ 2 failed bDMARDs n=10

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster III: Complications of Therapy, Outcomes, and Measures

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Torque teno virus (TTV) is an endogenous anellovirus that is highly prevalent in adult healthy subjects (up to 90%) without known pathogenicity. Increased replication has been associated to immunosuppression, leading to higher viral loads in patients with HIV infection or in transplanted patients on immunosuppression. Therefore, it has been proposed as an indirect marker of immunosuppression with potential predictive value of infectious complications.

The aim of our study was to analyze whether the biologic agents used in the treatment of chronic arthritis induce an increase in TTV viremia, compared to healthy controls and to patients with arthritis on conventional DMARD.

Methods: A cross-sectional study was performed in 79 patients with chronic arthritis on biologic therapy (58 rheumatoid arthritis and 21 spondyloarthritis). In a single visit, clinical and analytical data were collected, and a plasma sample was obtained for the analysis of viremia (TTV DNA load assessed by quantitative PCR). A group of 54 healthy individuals sex and age matched, and a group of 23 patients with chronic arthritis treated with conventional DMARDs (leflunomide and/or methotrexate) were used as control groups. In another group of 29 patients with chronic arthritis starting biologic therapy, a longitudinal study was performed, comparing baseline and follow-up (after 4 months on biologic) samples. Mean TTV viremia in the different groups was compared using ANOVA with Dunnett's multiple comparison test. Correlation between different quantitative variables and viremia was analyzed by the Spearman or Pearson test where appropriate. Mean viremia in groups stratified by different qualitative variables was compared using the Student's t-test, defining $p < 0.05$ as statistically significant.

Results: In the cross-sectional sample of 79 patients, TTV load was significantly higher in abatacept, infliximab and tocilizumab groups compared to healthy and to arthritic DMARD groups (ANOVA $p < 0.0001$). Healthy and arthritic patients treated with DMARD showed similar TTV loads. Patients on rituximab did not show an increased TTV load compared to the control groups. In the group of patients longitudinally analyzed, there was a significant increase in the TTV load after 4 months of biologic compared to the baseline (pre-biologic) sample ($p = 0.042$). Significant correlations between the TTV load and the clinical or analytical variables analyzed (age, disease duration, concomitant glucocorticoid or DMARD therapy, diabetes, CRP, ESR, lymphocytes, disease activity) were not found. Patients with previous history of severe infection did not have higher levels of TTV viremia.

Conclusion: Patients with chronic arthritis on therapy with abatacept, tocilizumab or anti-TNF have an increased TTV viremia compared to arthritic on conventional DMARD or to healthy control groups, while it was similar in patients treated with rituximab. TTV viremia was similar in patients with arthritis on DMARD compared to healthy controls. In this population, no correlation between TTV viremia and other clinical or analytical factors was found.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster III: Complications of Therapy, Outcomes, and Measures

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Tobacco smoking and rheumatoid arthritis (RA) are independent risk factors for short-term complications following total hip and total knee arthroplasty (THA/TKA). We aimed to investigate the impact of smoking on 1-year post-operative mortality in RA patients undergoing THA/TKA.

Methods: Nationwide register-based cohort study from Denmark from 2000-14. The study population was RA patients (diagnosed according to either ACR 1987 or ACR/EULAR 2010 criteria) registered in the Danish rheumatology register (DANBIO) and in the linked Danish Hip or Knee Arthroplasty Registers with a first elective THA/TKA surgery. Information on smoking status (exposure), DAS28, HAQ-DI, biological and conventional synthetic DMARD (bDMARD and csDMARD) and glucocorticoid treatment within 90 days preceding surgery (confounders) was gathered from DANBIO. Information on pre-existing comorbidities and mortality data (outcome) was obtained by linkage to the Danish National Patient Register and the Civil Registration System. Using multivariable Cox proportional hazards models, we calculated hazard ratios (HR) for death during the first year following surgery among patients who at the time of surgery were active and previous smokers, respectively, compared with never-smokers. We used multiple imputation for missing information on smoking, DAS28 and HAQ-DI.

Results: We identified 1,946 RA patients undergoing an elective THA/TKA with available smoking status for 1,092 patients: 255 (24 %) current, 417 (39 %) ex- and 420 (37 %) never smokers (Table). Compared with never smokers, current smokers were more likely to be males, treated with glucocorticoids, have COPD and ischemic heart disease. During the first year post-operatively, 24 patients died. Current smokers had increased HRs for death in uni- and multivariable analyses: adjusted HR 3.33 (95% CI 0.84-13.20) compared with never smokers. Similar results were observed in complete case and imputed analyses.

Conclusion: We found a 3-fold borderline significant increased 1-year mortality risk among RA patients who were active tobacco smokers at the time of elective THA/TKA surgery. Considering the increased risk of death associated with RA by itself, these results emphasize the importance of smoking abstinence/ cessation prior to major surgery in this vulnerable group of patients.

Table. Number of patients, demographics, pre-surgical characteristics and results of regression analyses on 1-year mortality risk in current, previous and never smoking rheumatoid arthritis (RA) patients with elective total hip or total knee arthroplasty.

	Current smoker	Previous smoker	Never smoker	p-value*

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster III: Complications of Therapy, Outcomes, and Measures

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: In Rheumatoid Arthritis (RA), sustained remission is associated with less disability ^(1,2), and this outcome should be the goal in the RA treatment; however, there are scarce of data about the impact of prolonged remission in health-related quality of life (HRQoL) in RA patients in our region. The aim of this study is to determine the impact of time under remission in to achieve a better HRQoL status in RA

Methods: Prospective study in a RA cohort from a single center. Subjects with at least two visits performed, were included. Visits were performed every six months; socio-demographic, clinical data (including disease activity status) and HRQoL measured by the *36-Item Short Form Health Survey questionnaire* (SF36), were recorded in each visit. Remission and low disease activity (LDA) statuses were defined as *Clinical Disease Activity Index* (CDAI) definition (<2.8 and 2.9-10, respectively) and time in remission was categorized in percentiles of time (>50, >25% and ≤50%, and ≤25%) in remission. The outcome was the value of each SF36 component and domain at the final visit. Univariable and multivariable lineal regression models, adjusted by age at diagnosis, disease duration, treatment [use of corticosteroid, synthetic(s) and biologic (b) Disease Modifying Rheumatic Drugs (DMARDs)], time of follow up and each baseline SF36 component or domain were performed in order to determine the associations.

Results: Four hundred nine patients were included; 369 (90.2%) were female, age at diagnosis was 44.49 (13.84) years and disease duration at baseline was 16.57 (11.50) years. sDMARDs and bDMARDs were used at baseline by 58.7% and 9.5% respectively. The mean follow-up was 1.39 (0.49) years. Percentage of time under remission and LDA status during the follow up were 13.33(26.39) and 49.61(39.16) respectively. In the multivariable analyses the better percentile under remission (>50%) predicted a better HRQoL performance in the Physical Component Summary(PCS): $B=0.170(0.705-1.635)$; $P<0.001$, and in the following components: physical functioning [$B=0.078$; (0.033; 0.122); $p<0.001$], role physical [$B=0.215$ (0.163-0.267); $p<0.001$], body image [$B=0.293$; (0.251-0.335); $p<0.001$], global health [$B=0.127$ (0.083-0.171); $p=0.001$], role emotional [$B=0.184$ (0.126-0.242); $p<0.001$]; mental health [$B=0.051$; (0.011-0.091); $p=0.012$]. There were not statistically significant associations with the other component and domains.

Conclusion: A more prolonged time under remission predicted a better HRQoL status in our RA patients. Prolonged remission in addition with sustained remission could be a treatment goal to avoid disability.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster III: Complications of Therapy, Outcomes, and Measures

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Variable outcomes in early rheumatoid arthritis (ERA) may be explained by heterogeneous latent disease activity trajectories, the predictors of which are not well defined. Hence, the study aims to characterise distinct disease activity trajectories and describe the relationship between disease, disability and health-related quality of life (HRQoL) trajectories.

Methods: Data were collected prospectively from patients in the Singapore Early Arthritis Cohort over 3 years. Disease activity, disability and HRQoL were assessed using the Disease Activity Score in 28 Joints with ESR (DAS28ESR), modified Health Assessment Questionnaire (mHAQ) and EuroQol-5D Index (EQ5D Index) respectively. Group-based trajectory modelling (GBTM) was used to identify latent disease activity trajectories. Multi-trajectory modelling was used to describe the relationship between disease, disability and HRQoL trajectories. Multinomial logistic regression was used to identify predictors of trajectory membership.

Results: 213 ERA patients (73.2% female, 58.2% Chinese, age 51.3 ± 12.6 years, symptom duration 21.8 ± 15.3 weeks) were included. Three disease activity trajectories were identified [T1: moderate disease activity to remission (57.8%); T2: high to low disease activity/remission (30.1%); T3: high to moderate/low disease activity (12.1%)]. Non-Chinese patients were more likely to belong to T2 and T3 as compared to T1 [RRR (95% CI) 2.29 (1.09, 4.84) and 2.03 (1.07, 5.84) respectively]. Patients with higher body mass index (BMI) were more likely while patients with tertiary education were less likely to belong to T3 compared to T1 [RRR (95% CI) 1.13(1.02, 1.28) and 0.13 (0.02, 0.75) respectively]. Seropositivity and radiographic erosions were not significant predictors of trajectory membership. A higher proportion of patients in T3 were treated with combination disease modifying anti-rheumatic drugs (DMARDs). Trajectories of disability and HRQoL were closely associated with disease activity trajectories.

Conclusion: In this Asian cohort of ERA patients, sociodemographic factors, rather than seropositivity and radiographic erosions, predicted poorer outcomes (trajectory 3) in spite of more aggressive treatment. Efforts to improve health-literacy may be the key to improving outcomes in these patients.

Figure 1 Disease activity trajectories based on DAS28ESR score. Dotted lines represent the 95% confidence intervals. Estimated probabilities of each trajectory are labelled in the legend. The estimated probabilities may differ from the number of patients assigned to each group based on the maximum probability assignment rule. Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster III: Complications of Therapy, Outcomes, and Measures

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Secondary Sjögren's syndrome (sSS) is considered a poor prognostic factor in RA and is a common extra-articular manifestation of RA. We estimated prevalence of sSS and joint disease burden in patients (pts) with RA with sSS based on physician diagnosis or Ro-antibody positive (SSa), plus presence of dry eyes or dry mouth.

Methods: Data from adult pts with RA enrolled in a longitudinal RA registry were analyzed. Pts in the registry were evaluated by a rheumatologist annually for disease activity and treatments and semi-annually for multiple clinical pt-reported outcomes (PROs) and resource utilization parameters. For this analysis, pts with RA were categorized into two cohorts: pts with sSS and pts with RA only. Prevalence estimates of pts with sSS were based on clinician diagnosis or meeting ACR/EULAR 2016 classification of primary Sjögren's syndrome. Baseline characteristics between the two cohorts were compared using the Kruskal-Wallis test for continuous variables and chi-square test for categorical variables, with a significance level of 0.05. Mean change from baseline to 12 months in disease activity measures and PROs of fatigue were assessed for pts with data available at baseline and follow-up.

Results: A total of 1471 pts with RA were included in the analysis. The prevalence of sSS was 28.2% (n=415); the remaining 71.8% (n=1056) were included in the RA only cohort. Physician diagnosis comprised ~10% of pts with sSS; the remainder was based on SSa positivity and symptoms of dry eyes or dry mouth. Compared with the RA only cohort, pts with RA with sSS were more likely to be female, have early onset of RA, longer RA disease duration, greater seropositivity, higher antibody titers, higher disease activity levels (Rheumatoid Arthritis Disease Activity Index, CDAI and DAS28 [CRP]), higher fatigue and more likely to have comorbidities of vasculitis, neuropathy and pulmonary nodules (Table 1). In addition, a greater proportion of pts with RA with sSS had prior biologic (b)DMARD exposure (n [%] 248 [59.8] vs 463 [43.8]; p<0.0001), with a higher proportion currently taking bDMARDs (195 [47] vs 382 [36.2]; p=0.0001). Pts with RA with sSS continued to experience higher disease activity and fatigue at 12 months, with a significantly lower reduction in disease activity versus pts in the RA only cohort (Table 2).

Conclusion: The prevalence of sSS was 28% in pts with RA. Although the majority of pts with RA with sSS compared with pts with RA without sSS had exposure to bDMARDs, they continued to experience higher autoantibody burden (RF and ACPA), joint disease activity and fatigue.

Table 1. Baseline Characteristics in Patients With sSS Compared With Patients With RA Only

	Pts with sSS		Pts with RA only		p value*

Healthcare Resource Utilization in Patients with Secondary Sjögren's Syndrome Associated with RA Compared with Patients with RA in an Insured Population

Evo Alemao¹, Aarti Rao², Chidananda Samal² and Robert Wong¹, ¹Bristol-Myers Squibb, Princeton, NJ, ²Mu Sigma, Bangalore, India

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster III: Complications of Therapy, Outcomes, and Measures

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Secondary Sjögren's syndrome (sSS) is a rheumatic disease that may coexist with RA. Joint disease is more severe in patients (pts) with RA with versus without sSS.¹ There are limited data on healthcare resource use (HCRU) of pts with RA with sSS.

Methods: Pts (≥ 18 years) from the Optum™ Clinformatics™ Data Mart administrative claims database with incident RA (≥ 2 claims for RA with International Classification of Diseases [ICD]-9 [714.0] or ICD-10 [M05.xxx/M06.0xx/M06.8xx/M06.9] and ≥ 1 claim for a conventional DMARD) from Jan 2010 to Jun 2016 were included. Two mutually exclusive RA cohorts were created: one with incident sSS (≥ 2 claims for SS with ICD-9 [710.2] or ICD-10 [M35.0x]) and one without sSS. The index date was the first diagnosis date of sSS (RA with sSS) or RA (RA without sSS). All-cause HCRU was captured during a 12-month period from (and including) the index date (post-index period). Statistical differences in HCRU between cohorts were assessed using chi-square and Kruskal-Wallis tests. For RA with sSS, HCRU during the 12 months pre- and post-index period was compared using McNemar and Wilcoxon sign rank tests.

Results: Overall, 1858 pts with RA with sSS and 21,264 with RA without sSS met inclusion criteria and were analyzed. Of pts with RA with sSS, first sSS diagnosis occurred before RA in 630 (33.9%), after RA in 978 (52.6%) and on the same date in 250 (13.5%). Pts with RA with (vs without) sSS were younger, more likely to be female and had higher incidences (standardized difference $>10\%$) of fibromyalgia, gastrointestinal reflux, hypothyroidism, osteoporosis, systemic sclerosis/scleroderma and systemic lupus erythematosus (Table 1). After sSS diagnosis, proportionally more pts with RA with sSS had inpatient admissions (vs the pre-index period, Table 2). Mean length of stay and number of inpatient visits, outpatient visits and prescriptions were higher in the post-index period (Table 2). Pts with RA with sSS had more outpatient visits and prescriptions than pts with RA without sSS (Table 3).

Conclusion: Pts with RA with sSS (vs pts with RA without sSS) had more comorbidities at baseline. Also, pts with RA with sSS had an increased HCRU post-sSS diagnosis. Further research is needed to understand if HCRU use is associated with clinical manifestation of sSS.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster III: Complications of Therapy, Outcomes, and Measures

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is a debilitating chronic disease with an unmet need for additional therapeutic approaches. Bioelectronic therapy (BET), such as electrical neurostimulation of the vagus nerve to activate innate protective neuro-immune reflexes, represents a novel means of treating diseases characterized by systemic inflammation. We performed a proof-of-concept study in RA patients using a marketed vagus nerve stimulation device at very low duty cycles (1-4 min/day), showing reduction of clinical disease activity, concomitant with reductions in TNF- α and IL-6 (PNAS 2016;113:8284). We have developed a novel advanced generation neurostimulation device, the MicroRegulator System, which is being evaluated in a first-in-man clinical study.

Methods: The MicroRegulator System is unique in that it is implanted directly on the vagus nerve as a single unit that contains an application specific integrated circuit (ASIC), pulse generator with a wireless rechargeable battery, as well as a self-contained nerve-encapsulating cuff and electrodes that function without vagus nerve lead wires (Figure 1). Low power requirements allow for miniaturization of the device (< 2 cc). External components include an intermittently worn flexible collar that generates a radio frequency field for recharging and telemetry, as well as an iPad-based control device programming application.

Results: The first-in-man study is a USA-based multi-centered double-blind trial, designed to look at safety and efficacy of the implanted MR system in refractory RA patients that have insufficient response to ≥ 2 biologic or targeted synthetic DMARDs of ≥ 2 modes of action. This study is unique in its use of a neurosurgical sub-investigator paired with the rheumatologist to manage the first weeks of the study period. Implanted subjects, washed off biologics and on stable background of methotrexate, are randomized to 1 min of sham, QD, or QID stimulations for 12 weeks. Efficacy outcomes include standard RA clinical disease measures as well as quantitative MRI joint scoring, validated RA-specific biomarker panels, autonomic balance measurements and immune cell bioassays.

Conclusion: A novel neurostimulation device has been developed and deployed in a first-in-man clinical study. BET, a non-pharmacological intervention, will potentially give rheumatologists a novel alternative means to treat RA, including those patients who have failed conventional treatments.

Session Title: Rheumatoid Arthritis – Treatments Poster III: Biosimilars and New Compounds

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: EXTEND (NCT01146652) is an ongoing open-label extension study enrolling patients completing five sarilumab originator studies (MOBILITY [NCT01061736]; TARGET [NCT01709578]; ASCERTAIN [NCT01768572]; ACT11575 [NCT01217814]; ONE [NCT02121210]) in adults with rheumatoid arthritis (RA). This analysis assessed safety and efficacy of sarilumab+csDMARDs after 4 years' treatment.

Methods: Patients received open-label sarilumab 200 mg q2w SC (reduced to 150 mg q2w if indicated). Primary outcome was treatment-emergent (TE) adverse events (AEs), and secondary outcomes comprised efficacy endpoints. This analysis included only patients receiving sarilumab+csDMARDs enrolling into EXTEND. Data are presented as observed.

Results: Patients (mean age 52 years; 81% female) originally enrolled in MOBILITY (n=1283), TARGET (n=454), ASCERTAIN (n=168) and ACT11575 (n=7) were included. Median drug survival time was 312 weeks. At baseline, mean (range) duration of RA was 9.74 (0.3-54) years and 47.9% of patients had received prior bDMARDs. After 6007.1 patient-years' follow-up, overall incidences of TEAEs, serious AEs and TEAEs leading to discontinuations were 186.0, 13.3, and 7.3 /100 patient-years, respectively. Infections were the most common AE of special interest (AESI; Table); incidences of serious infections and opportunistic infections were 3.7 and 0.9/100 patient-years, respectively. There were 24 deaths over the study period (11 due to infection). Incidences of AST/ALT>3x the upper limit of normal and Grade 3/4 neutropenia were 3.5%/8.6% and 10.4%/1.1%, respectively. Neutropenia was not associated with increased risk of infection. Confirmed GI perforations (0.1/100 patient-years) and thrombotic events were rare. Efficacy (DAS28-CRP, CDAI, SDAI and HAQ-DI) was sustained over the study period (Figure). By Week 216, over 60% of continuing patients had achieved DAS28-CRP <2.6. In patients switched to sarilumab 200 mg q2w from placebo or lower doses, efficacy quickly (over the first 12–24 weeks) reached that of sarilumab 200 mg q2w and was sustained.

Conclusion: Through 4 years' follow-up, the safety profile of sarilumab 200 mg q2w was consistent with anticipated class effects and no new safety signals were identified. The rate of serious infection remained consistent over the treatment period. Efficacy was sustained over time.

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster III: Biosimilars and New Compounds

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: GSK3196165 is a high-affinity anti-GM-CSF cytokine IgG mAb currently in development for RA, with reported efficacy using IV dosing. This study evaluated the effects of GSK3196165 in RA.

Methods: 39 adult subjects with RA per ACR 2010 criteria, ≥ 4 each of swollen and tender joints, DAS28(CRP) ≥ 3.2 , CRP ≥ 3.0 mg/L, were randomized (1:3) to placebo or GSK3196165 180 mg SC weekly for 5 injections, then every other week for 3 further injections. Primary outcome was change from baseline (CFB) in exploratory serum biomarkers, effects on circulating cells, assessment of inflammatory joint damage in the hand/wrist using DCE-MRI, and clinical outcomes.

Results: A total of 7/11 (64%) subjects in the placebo group and 23/28 (82%) in the GSK3196165 group completed the study. Patients characteristics were well balanced. Observed PK exposures were lower than anticipated from previous studies. During the 5 weekly doses, maximum pre-dose concentrations were observed at Week 4 with geometric mean of 2,790 ng/mL (CV_b 65.3%), however concentrations dropped unexpectedly after reducing dosing frequency. At Week 12, pre-dose geometric mean concentration was 991 ng/mL (CV_b 86.5%). GM-CSF-mAb Complex (target engagement) in the GSK3196165 group increased during weekly dosing, to peak at 138 ng/L (CV_b 151%) at Week 4. Consistent with the PK profile, the Complex declined from Week 6 to Week 12 and was undetectable after cessation of treatment.

CCL17 declined in only the GSK3196165 group, with a 35% CFB at Week 2. Consistent with the PK profile, after Week 8 CCL17 then increased back towards baseline. Week 12 results are in the Table below. No observable differences between placebo and GSK3196165 groups were noted for most biomarkers.

All imaging measures of synovial inflammation showed a reduction at Week 12 (see Table). No structural changes were observed.

The onset of clinical effect across most endpoints was seen at Week 1, but appeared to plateau from Week 6 onwards. The difference of active over placebo at Week 12 was reflected in other clinical endpoints with or without acute-phase reactants (see Table).

GSK3196165 was well-tolerated, AEs were similar across both arms. No SAEs, significant infections and/or pulmonary events were observed.

Conclusion: Clinical efficacy with consistent improvement in MRI synovitis score was observed in this study. Lower than predicted exposure following dosing every two weeks was reflected in lower concentration of GM-CSF-mAb complex and less suppression of CCL17. Further studies are required to confirm the additional clinical benefit expected with increased exposure from weekly dosing of GSK3196165 in patients with RA.

Study NCT02799472 was funded by GSK.

Endpoint at Week 12	Placebo (N=11)	180mg (N=28)

Benepali Switches in Clinical Practice – a Positive Single Centre Experience

Hoda Alkoky, Angela Pakozdi and **Hasan Tahir**, Rheumatology, Barts Health NHS Trust, London, United Kingdom

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster III: Biosimilars and New Compounds

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Benepali (SB4), an etanercept (ETN) biosimilar, has demonstrated comparable efficacy in randomised controlled trials. Switching patients to biosimilars has cost benefits to the national health systems (NHS). However, there is reluctance to switch patients, due to lack of real world data about its efficacy and safety. The impetus for this study was to determine the real data trends of efficacy and safety in SB4 switching during treatment of patients with inflammatory arthritis.

Methods: Inflammatory arthritis patients, (rheumatoid arthritis (RA), psoriatic arthritis (PsA) and axial spondyloarthritis (AS)) switching from ETN to SB4, between Mar/17 and Oct/17, were included in this prospective observational single centre study. Disease activity scores and CRP before, and 3-6 months after switch, were calculated. Factors associated with SB4 withdrawal were recorded. DAS28, spinal VAS, BASDAI, and 66/68 swollen joint (SJ) and tender joint (TJ) counts were captured to measure efficacy. Flares were defined as a change of 1.2 points in DAS28, whilst a change of 22.55% in BASDAI was considered clinically significant.

Results: A total of 158 inflammatory arthritis SB4 switch patients were identified (87 RA, 30 PsA and 41 AS). Patients switched from ETN after a median time of 67 (RA), 110 (PsA) and 51 (AS) months. Demographics are shown in Table 1. Disease activity measurements before, and 3-6 months after switch, are shown in Table 2. In RA, no statistical difference was found in mean DAS28 scores ($p=0.344$). In PsA, no significant difference was found in 68 TJ counts ($p=0.565$) and 66 SJ counts ($p=0.475$). In AS, there was no difference in mean BASDAI ($p=0.893$) or VAS scores ($p=0.108$). Median CRP level was comparable in the three groups ($p=0.363$). 144 (91.14%) patients continued to receive SB4 at six months. In total, 14 patients (8.9%) switched back to ETN from SB4: 4 AS (2.5%) patients had disease flare. 7 patients (4.4%) had mild adverse reaction (pruritus (2), rash (1), dizziness (1), bruising (2) and blurred vision (1)), and 3 RA patients (1.9%) had a subjective deterioration with unchanged DAS 28. All 14 patients achieved improvement after switching back to ETN.

Table 1. Baseline demographics of Barts patient cohort

	RA (n=87)	PsA (n=30)	AS (n=41)
Age (mean \pm SD)	61.68 \pm 13.61	54.77 \pm 13.54	41.90 \pm 9.80
Female gender, n (%)	70 (80.5%)	12 (29.3%)	7 (23.3%)
Duration of ETN (months), median [IQR]	67 [38.75-115]	110 [85-115]	51 [20.5-86.0]
Other biologic drug prior to ETN, n (%)	6 (6.9%)	1 (2.4%)	3 (10%)

ETN indicates etanercept; RA, rheumatoid arthritis; PsA, psoriatic arthritis; AS, axial spondyloarthritis

Table 2. Disease activity scores before and 3-6 months after switch

	ETN (mean \pm SD)	SB4 (mean \pm SD)	p-value
DAS28	2.82 \pm 1.49	3.03 \pm 1.47	0.344
BASDAI	3.27 \pm 2.59	3.32 \pm 2.24	0.893
Spinal VAS	3.22 \pm 2.95	4.12 \pm 2.99	0.108
68 TJC	4.26 \pm 10.55	3.81 \pm 9.76	0.565
66 SJC	0.78 \pm 1.97	0.93 \pm 1.64	0.475

ETN indicates etanercept; SB4, benepali

Conclusion: In this real-life observational study, biosimilar switch of SB4 was successful in over 90% of cases. The efficacy of SB4 seemed comparable to ETN and was well tolerated. In this cohort, the switch to SB4 resulted in an approximate cost saving of £370,000/yr to the NHS. It is hoped these results will encourage other centers to switch their patients from originator ETN to biosimilar SB4.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster III: Biosimilars and New Compounds

Figure. Treatment continuation in bionaive patients enrolled with a start of treatment with either SB4 or oETN .

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The number of biosimilars approved for the treatment of rheumatoid arthritis (RA) is constantly increasing. Until now, there are just a few analyses investigating retention rates of biosimilars and the respective originators. We compared treatment survival on SB4 to the originator etanercept (oETN) using real-world data.

Methods: We used data gathered until April 2018 from the prospective, longitudinal RABBIT (*R*heumatoid *A*rrthritis: *O*bservation of *b*iologic *t*herapy) cohort. RA patients are enrolled in RABBIT when they start a biologic, biosimilar or new csDMARD treatment. Bionaive patients enrolled since 2015 starting a treatment with either SB4 or oETN who had at least one follow-up visit were compared. The drug survival rates during the first six months were analyzed using Kaplan-Meier curves.

Results: Overall, 266 patients treated with SB4 and 313 with oETN fulfilled the inclusion criteria. Compared to oETN patients, those enrolled with SB4 had lower disease duration (7.5 vs. 8.7 years), were younger (58 vs. 59 years) and significantly fewer patients had three or more comorbidities (39% vs. 47%). Kaplan-Meier curves show higher retention rates over 6 months for SB4 than oETN (figure). Patients switching from oETN to SB4 or vice versa were censored and not counted as discontinuations (oETN to SB4: n=7, SB4 to oETN: n=1). Adjusting for disease duration and comorbidities had no significant influence on the results. 9% (n=25) of SB4 patients and 18% (n=55) of oETN patients stopped treatment during the first 90 days. Additional 8% (n=21, SB4) / 12% (n=37, oETN) stopped the treatment within 180 days after enrolment. The most frequent reasons for discontinuation of both treatments were adverse events (AE) in 48% (21 of 44, SB4) / 54% (49 of 91, oETN) and ineffectiveness in 36% (16 of 44, SB4) / 36% (33 of 91, oETN) of patients. The most frequent AE leading to discontinuation was 'flare' in SB4 patients (12%, 4 of 33 AEs), and 'skin reactions at the injection site' in oETN patients (26%, 18 of 68 AEs). Overall, injection site reactions occurred in 7% (n=23) of oETN patients and 3% (n=7) of SB4 patients (leading to discontinuation in only one patient).

Conclusion: We found higher retention rates for bionaive patients starting the biosimilar SB4 compared to those starting the originator oETN. Whereas both treatments were equally effective, patients treated with oETN had more injection site reactions. We cannot rule out selection bias since there is practice variation in the usage of biosimilars in Germany (regional quota systems). In addition, patients receiving either oETN or SB4 were not entirely comparable (e.g. more comorbidities on oETN).

Change in Disease Activity after Switching Etanercept (originator) to Biosimilar (Benepali) Is Associated with Active Disease at Baseline

Kaushik Rajamani¹ and Ernest Choy^{2,3,4,5,6,7}, ¹Adult Rheumatology, University Hospital of Wales, Cardiff, United Kingdom, ²Section of Rheumatology, Cardiff University, Cardiff, Great Britain, ³Section of Rheumatology, Cardiff University School of Medicine, Cardiff, United Kingdom, ⁴CREATE Center, Division of Infection and Immunity, Cardiff University, Cardiff, United Kingdom, ⁵CREATE Center, Cardiff University School of Medicine, Cardiff, Great Britain, ⁶Cardiff University, Institute of Infection and Immunity, Tenovus Building, University Hospital of Wales, Cardiff, United Kingdom, ⁷CREATE Center, Division of Infection and Immunity, Cardiff University School of Medicine, Cardiff, United Kingdom

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster III: Biosimilars and New Compounds

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Biosimilar contains a version of active substance similar of an already approved biological agent in terms of quality, characteristic, biological activity, safety and efficacy. The price of biosimilars is often less than their original biologic agents. Many healthcare providers have the option of switching patients from original biologic agents to biosimilars to reduce cost. The Purpose of this study was to compare the effectiveness and safety of the Etanercept Biosimilar (Benepali) with Originator (Enbrel) after switching in patients with rheumatoid arthritis (RA) in Wales, United Kingdom

Methods: A retrospective study was conducted across all hospitals within Wales in the United Kingdom as a national audit. Patients switched from Enbrel to Benepali were identified. Efficacy was assessed by change in DAS28CRP disease activity status before and after switching. We included both biologic naïve and experienced patients.

Results: ± 9.2 yrs. Enbrel was used as first line biologic treatment in 105 patients, second line in 14 and third line in 1 patient. Rheumatoid Factor and ACPA were positive in 72% and 63% of patients respectively. Most patients were taking concomitant DMARDs (96/120). Only 24 patients were not taking any conventional DMARDs, however, 8 patients were treated with prednisolone. Methotrexate was the most commonly used DMARD. After switching to biosimilar, 47 (39.1%) patients out of 120 patients had increase in their DAS28CRP score of which 27 patients (22.5%) moved from a lower disease state to a higher disease state (Table). Out of 102 patients who were in remission at the time of switching, 17 (17%) patients developed low, moderate or high diseases activity. At baseline, 18 patients were in low or moderate disease activity, 10 (56%) moved to moderate or high disease activity. Amongst 47 patients who had increase in DAS28CRP, 18 reported disease flares. Most flares occurred within the first 4 months of switching (16 out of 18 flares). Half of these patients (9 out of 18) were switched back to Enbrel. 13 adverse reactions were noted after switching to on Benepali, which included 5 infections (chest and urinary), 4 others (shortness of breath, oral ulcerations, eczema, neutropenia 1 patient each) and 4 unspecified.

Table

Baseline N=120	After Switching			
	Remission	LDA	MDA	HAD
Remission (n=102)	85	8	8	1
LDA (n=7)	0	0	6	1
MDA (n=11)	0	0	8	3
HAD (n=0)	0	0	0	0

LDA –low diseases activity MDA-Moderate diseases activity HDA-High diseases activity

Conclusion: After switching from Enbrel to biosimilar Benepali, many patients experience increase in disease activity, this is more likely if patients are not in disease remission at the time of switching suggesting that these may be due to natural fluctuation or spontaneous disease flares in patients with unstable disease. Only 18 (15%) patients reported disease flare and 9 (8%) patients had to switch back to Enbrel.

Session Title: Rheumatoid Arthritis – Treatments Poster III: Biosimilars and New Compounds

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Intravenous (IV) use of CT-P13, an infliximab (INX) biosimilar, has resulted in comparable efficacy, safety and immunogenicity as innovator INX in various indications including rheumatoid arthritis (RA)¹ and Crohn's disease (CD)². A subcutaneous (SC) formulation of CT-P13 is developed to provide patients with opportunities for self-injection, thereby enhancing convenience and flexibility in treatment. This work aimed to investigate immunogenicity by post-hoc analysis of two randomized controlled trials comparing pharmacokinetics of CT-P13 IV and CT-P13 SC.

Methods: Patients with RA (6 or more swollen and tender joints and serum C-reactive protein [CRP] concentration >0.6 mg/dL) and active CD (Crohn's Disease Activity Index [CDAI] score of 220 – 450) were treated with CT-P13 IV at Weeks 0 and 2. At Week 6, patients were randomized for continuation with IV or SC administration. The IV cohorts received CT-P13 IV (3 mg/kg for RA and 5 mg/kg for CD) every 8 weeks and the SC cohorts were treated with CT-P13 SC (90, 120, 180 mg for RA and 120, 180 and 240 mg for CD) every 2 weeks up to Week 30. Trough serum concentrations (C_{trough}) were assessed at Weeks 6, 14 and 22 for IV and Weeks 6, 8, 10, 14, 22, 24, 26 and 28 for SC. Target exposure level was considered as 1 µg/mL for RA^{3, 4} and 5 µg/mL for CD^{5, 6}. Anti-drug antibody (ADA) was assessed before study drug administration at Weeks 0, 6, 14, 22 and 30 by a drug-sensitive, enzyme-linked immunosorbent assay.

Results: In total, 92 patients were randomized at Week 6 to IV (RA: n=13, CD: n=13) or SC (RA: n=35, CD: n=31). All RA patients used methotrexate as concomitant medication throughout the study. Among CD patients, immunomodulators were used at Week 6 by 9 (69.2%) and 15 (48.4%) patients in IV and SC cohorts, respectively. Efficacy results (EULAR [CRP] responder rate for RA and CDAI-70 responder rate for CD) were comparable between the IV and SC. Systemic safety profiles observed from CT-P13 SC after randomization were also comparable to those of IV. A sub-therapeutic C_{trough} level below target exposure was detected at least once in 23 (92.0%) and 9 (14.1%) patients in IV and SC cohorts, respectively. ADA were detected at least once in 16 (64.0%) versus 11 (18.1%) of patients in the IV and SC cohorts ($p<0.0001$), respectively.

Table. Efficacy, C_{trough} and immunogenicity among RA and CD patients

Efficacy	IV cohort	SC cohort	p value a
EULAR (CRP) responder rate at Week 30 in RA patients	12/13 (92.3%)	32/32 (100%)	0.2889
CDAI-70 responder rate at Week 30 in CD patients	8/10 (80.0%)	24/26 (92.3%)	0.3048
C_{trough}	IV cohort (N=25)	SC cohort (N=64)	p value a
$C_{trough}<$ target exposure at least once	23 (92.0%)	9 (14.1%)	<0.0001
$C_{trough}\geq$ target exposure throughout the study	2 (8.0%)	55 (85.9%)	
Immunogenicity	IV cohort	SC cohort	p value a
Anti-drug antibody positive at least once	16/25 b (64.0%)	11/61 b (18.1%)	<0.0001
RA patients	9/13 (69.2%)	8/33 b (24.2%)	0.0071
CD patients	7/12 b (58.3%)	3/28 b (10.7%)	0.0033

Note: ^a p value was derived from Fisher's exact test.

^b Patients who reported ADA positive at Week 0 or 6 (before randomization) were excluded.

Conclusion: After initial loading two doses of CT-P13 IV, patients subsequently receiving biweekly maintenance treatment with CT-P13 SC achieve more stable steady state therapeutic blood levels of INX and have lower rate of ADA compared

with patients receiving continued IV treatment. Further work to corroborate these findings is ongoing through a confirmatory efficacy trial.

Session Title: Rheumatoid Arthritis – Treatments Poster III: Biosimilars and New Compounds

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: CT-P10 is a biosimilar of the reference rituximab (RTX) and has been approved by several regulatory agencies including EMA. Pharmacokinetic and therapeutic equivalence from phase III study (NCT02149121) in rheumatoid arthritis has been reported previously^{1,2}. The objective of this report is to evaluate radiographic joint damage progression and its association with disease activity states in terms of disease activity score by 28 joint counts (DAS28)

Table 1 Comparison of Disease Activity States between CT-P10 and RTX

Week	Disease activity state	DAS28-CRP		DAS28-ESR		CDAI		SDAI	
		CT-P10	RTX	CT-P10	RTX	CT-P10	RTX	CT-P10	RTX
24	Remission	35 (25.2%)	50 (25.9%)	16 (11.5%)	27 (14.0%)	20 (14.4%)	33 (17.1%)	18 (12.9%)	31 (16.1%)
	LDA	27 (19.4%)	35 (18.1%)	19 (13.7%)	22 (11.4%)	43 (30.9%)	54 (28.0%)	45 (32.4%)	56 (29.0%)
	Remission/LDA	62 (44.6%)	85 (44.0%)	35 (25.2%)	49 (25.4%)	63 (45.3%)	87 (45.1%)	63 (45.3%)	87 (45.1%)

	MDA/HDA	73 (52.5%)	108 (55.8%)	101 (72.7%)	144 (74.6%)	73 (52.5%)	106 (54.9%)	72 (51.8%)	106 (54.9%)
48	Remission	45 (32.4%)	65 (33.7%)	24 (17.3%)	44 (22.8%)	28 (18.0%)	43 (22.3%)	26 (18.7%)	41 (21.2%)
	LDA	24 (17.3%)	29 (15.0%)	24 (17.3%)	22 (11.4%)	49 (35.4%)	55 (28.5%)	47 (33.2%)	56 (29.0%)
	Remission/LDA	69 (49.6%)	94 (48.7%)	48 (34.5%)	66 (34.2%)	74 (53.2%)	98 (50.8%)	73 (51.8%)	97 (50.3%)
	MDA	56 (40.3%)	73 (37.8%)	63 (45.3%)	81 (42.0%)	38 (27.3%)	60 (31.1%)	45 (32.4%)	64 (33.2%)
	HDA	6 (4.2%)	15 (7.8%)	21 (15.1%)	36 (18.7%)	20 (14.4%)	25 (13.0%)	13 (9.4%)	21 (10.9%)
	MDA/HDA	62 (44.6%)	88 (45.6%)	84 (60.4%)	117 (60.6%)	58 (41.7%)	85 (44.0%)	58 (41.7%)	85 (44.0%)

Note: Data was shown in the number (%) of patients with each disease activity state. Percentages were calculated using the number of subjects who received two treatment courses as denominator.

Table 2 The Proportion of Radiographic Non-Progressor between CT-P10 and RTX depending on Disease Activity States

Activity States		Radiographic non-progressor (n/N)	
Week	Disease activity state	SvdH ≤ 2.76 (SDD)	
DAS28-CRP		CT-P10	RTX
24	Remission/LDA	48/50 (96.0%)	60/66 (90.9%)
	MDA/HDA	55/59 (93.2%)	76/86 (88.4%)
48	Remission/LDA	64/65 (98.5%)	71/77 (92.2%)
	MDA/HDA	39/44 (88.6%)	64/74 (86.5%)
DAS28-ESR		CT-P10	RTX
24	Remission/LDA	29/30 (96.7%)	37/39 (94.9%)
	MDA/HDA	75/80 (93.8%)	99/113 (87.6%)
48	Remission/LDA	45/46 (97.8%)	51/54 (94.4%)
	MDA/HDA	59/64 (92.2%)	85/98 (86.7%)
CDAI		CT-P10	RTX
24	Remission/LDA	48/50 (96.0%)	60/66 (90.9%)
	MDA/HDA	56/60 (93.3%)	76/86 (88.4%)
48	Remission/LDA	66/67 (98.5%)	71/80 (88.8%)
	MDA/HDA	38/43 (88.4%)	65/72 (90.3%)
SDAI		CT-P10	RTX
24	Remission/LDA	48/50 (96.0%)	60/66 (90.9%)
	MDA/HDA	55/59 (93.2%)	76/86 (88.4%)
48	Remission/LDA	65/66 (98.5%)	72/80 (90.0%)
	MDA/HDA	36/43 (83.7%)	63/71 (88.7%)

Note: n = Patients with changes from baseline of SvdH \leq 2.76 (SDD) at week 48 by each disease activity state. N = Patients who received two treatment courses and had SvdH score at both baseline and week 48 by each disease activity state.

based on C-reactive protein (CRP) and erythrocyte sedimentation rate (ESR), clinical disease activity index (CDAI) and simplified disease activity index (SDAI) for 48 weeks.

Methods: Patients with RA were randomized to CT-P10 or RTX (US or EU sourced rituximab) groups and received 2 courses of either CT-P10 or RTX at weeks 0 and 24. Radiographic progression was evaluated using the van der Heijde modified Sharp Scoring system (SvdH). The smallest detectable difference (SDD) was calculated to define radiographic non-progressor (defined as change in SvdH lesser than or equal to SDD at Week 48)³. The proportions of patients achieving remission or low disease activity (LDA) and, moderate disease activity (MDA) or high disease activity (HDA) in terms of DAS28, CDAI, and SDAI were compared at weeks 24 and 48.

Results: The mean (standard deviation) increase from baseline in SvdH score was similar between CT-P10 and RTX (1.85 [9.03] vs 1.24 [2.98]) at Week 48. Comparable proportion of radiographic non-progression was observed between CT-P10 and RTX; 94.5% vs. 89.5% based on calculated SDD (SvdH equal to 2.76). The proportion of patients with remission or LDA and, MDA or HDA was generally comparable between CT-P10 and RTX at weeks 24 and 48 for various disease activity indices (DAS28-CRP, DAS28-ESR, CDAI, SDAI) (Table 1). The proportion of radiographic non-progressors was comparable between two groups within each disease activity state with an increasing trend as disease activity improved (Table 2).

Conclusion: Comparable disease activity and effect of inhibition for joint damage progression were shown between CT-P10 and RTX groups. The evaluation of radiographic progression with disease activity states by DAS28, CDAI and SDAI showed a trend of higher proportion of radiographic non-progressors in Remission or LDA than that of MDA or HDA.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster III: Biosimilars and New Compounds

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The safety and efficacy of certolizumab pegol (CZP) for treating patients (pts) with rheumatoid arthritis (RA) are well-established in a clinical trial setting.^{1,2} However, data describing these outcomes in routine clinical practice are needed.

Methods: This was a prospective, observational, multicenter study conducted in France. Data are reported from 2014–2017. Eligible pts were adults with moderate-to-severe, active RA starting treatment with CZP following inadequate response to DMARDs (incl. MTX). Safety outcomes were measured in the safety set (SS; all pts who received ≥ 1 dose CZP); efficacy in the full analysis set (FAS; SS pts with no protocol deviations).

The primary endpoint was EULAR response at the 12-month(mo) visit, and has been reported previously.³ Other measures included clinical disease activity index (CDAI), fatigue assessment scale, health assessment questionnaire-disability index (HAQ-DI), patient's assessment of arthritis pain (PtAAP), and patient/physician global assessment of disease activity (Pt/PhGADA). Adverse drug reactions (ADRs) and serious ADRs (SADRs) included events with known relationship to CZP, or for which causality was not determined. Data were collected at baseline and routine clinical visits at ~3, 6, 12, 18, 24 and 36mo. Here we report final observed data from 36mo follow-up.

Results: 792 pts were included: 776 (98.0%) in the SS, 733 (92.6%) in the FAS. In the FAS, most pts were female (78.0%), and the mean age at baseline was 55.1 years. Most pts had moderate (n=320, 49.5%) or high (n=265, 41.0%) baseline disease activity based on DAS28(ESR).

The proportion of pts with a EULAR response increased up to the 12mo visit and was sustained to 36mo (**Figure**); the proportion of non-responders also remained stable from 12mo. These improvements were reflected in other measures of clinical effectiveness (**Table A**). Overall, 776 ADRs were reported in 350 (45.1%) pts, including 242 SADRs in 151 (19.5%) pts (**Table B**). The most frequent ADRs by System Order Class were infections and infestations (268 events in 179 [23.1%] pts). ADRs were consistent with the known safety profile for CZP, with no new safety signals identified.

Conclusion: RA pts treated with CZP in French clinical practice experienced improvements in disease outcomes after 12mo that were sustained up to 36mo in pts still receiving CZP, with a safety profile that reflects trial data.

Figure: EULAR response over 36 months of follow-up (FAS)

Observed data from patients who completed CZP treatment at each timepoint. EULAR, European League Against Rheumatism; FAS, Full Analysis Set; MC, month completers.

Table A: Clinical effectiveness of CZP over 36 months of follow-up (FAS)

Mean (SD) [n]	Baseline	12-month completers	36-month completers
CDAI	25.74 (12.34) [n=700]	8.22 (7.93) [n=357]	5.87 (7.51) [n=214]
Fatigue [a]	6.13 (2.22) [n=707]	4.38 (2.47) [n=344]	4.13 (2.60) [n=196]
HAQ-DI	1.28 (0.69) [n=707]	0.71 (0.65) [n=345]	0.63 (0.66) [n=199]
PtAAP [b]	52.92 (23.63) [n=706]	25.41 (23.14) [n=361]	20.01 (21.21) [n=223]
PhGADA [c]	56.02 (18.73) [n=727]	20.64 (19.24) [n=372]	13.83 (15.84) [n=228]
PtGADA [c]	56.06 (22.25) [n=715]	27.07 (22.76) [n=362]	20.73 (20.49) [n=224]

Observed data from patients who completed CZP treatment at each timepoint. [a] Measured using the fatigue assessment scale, which ranges from 0 (no fatigue) to 10 (worst fatigue); [b] Measured using a 100 mm visual analog scale, where 0=no pain and 100=severe pain; [c] Measured using a 100 mm visual analog scale, where 0=very good, asymptomatic and no limitation of normal activities and 100=very poor, very severe symptoms, which are intolerable, and inability to carry out all normal activities. CDAI: Clinical Disease Activity Index; CZP: certolizumab pegol; FAS: Full Analysis Set; HAQ-DI: Health Assessment Questionnaire-Disability Index; PtAAP: Patient's Assessment of Arthritis Pain; PhGADA: Physician's Global Assessment of Disease Activity; PtGADA: Patient's Global Assessment of Disease Activity.

Taylor¹, Bryan Downie², Luting Zhuo², Yevgeniy Gindin², Jacqueline Tarrant³, Jinfeng Liu², René Galien⁴ and Amer M Mirza⁵, ¹University of Oxford Botnar Research Centre, Kennedy Institute of Rheumatology, Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, Oxford, United Kingdom, ²Bioinformatics, Gilead Sciences Inc., Foster City, CA, ³Gilead Sciences Inc., Foster City, CA, ⁴Galapagos SASU, Romainville, France, ⁵Biomarker Sciences, Gilead Sciences Inc., Foster City, CA

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster III: Biosimilars and New Compounds

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Filgotinib (FIL), an oral JAK1- selective inhibitor, has shown good safety and efficacy in active rheumatoid arthritis (RA) patients with inadequate response to MTX in two phase 2b studies: with methotrexate (DARWIN 1) and as monotherapy (DARWIN 2). To better understand and define the differences in molecular pathways in these RA patients, their correlation to disease severity, and the impact of FIL on these pathways, a large-scale RNA sequencing study was conducted.

Methods: PAX gene blood samples from 150 RA patients in DARWIN 1 (D1) on either a stable dose of MTX and placebo (PBO) or FIL 200mg once daily (QD); and 92 RA patients in DARWIN 2 (D2) on either PBO or FIL monotherapy 100mg or 200mg QD, were collected and analyzed at baseline, week 1 and/or week 12. RNA in whole blood was sequenced (Illumina HiSeq 2500) after globin depletion. Differential gene expression analysis was performed on all time-paired subject data after subtracting gene expression changes in the PBO group. Pathway analysis was performed using GSEA and GO enrichment. Spearman's rank correlation of gene expression to disease activity score (DAS28-CRP or VectraDA) was calculated on samples without missing values to define disease-associated molecular pathways. A false-discovery rate (FDR) of 10% was applied for all analyses.

Results: Of the 14,984 genes evaluated, 6,413 genes correlated with DAS28-CRP or VectraDA baseline disease activity and defined a Transcriptional Disease Profile (TDP). FIL treatment reversed the expression of 70% of the TDP genes in D1 and 74% in D2, with 3,801 (59%) reversed in both D1 and D2. Of the 607 genes differentially expressed in D1 or 2, FIL significantly reversed 337 genes in the TDP, suggesting an impact on disease biology with or without MTX. DAS28-CRP or VectraDA-associated genes reversed by FIL were enriched in processes for neutrophil and granulocyte activation, blood coagulation and inflammatory responses. Genes associated with innate immune responses and c-Jun N-terminal kinase signaling correlated with the TDP but were not significantly impacted by FIL. Following FIL treatment, disease-correlated gene set enrichment scores were also significantly reversed for PD1 signaling, JAK/STAT signaling via IL-6, epithelial-mesenchymal transition, and extracellular matrix regulation. Patients with increased expression of a RA-associated interferon gene set showed a reduced clinical response (median ACR-N) at 12 weeks with PBO (D1 p=0.15, D2 p=0.35) but trended toward an increased clinical response with FIL (D1 p=0.049, D2 p=0.33). Patients receiving FIL showed a reduced interferon profile at 12 weeks (D1 p =0.032, D2 p < 0.001), while no significant change was observed for patients on PBO.

Conclusion: Disease-associated molecular pathways relevant to DAS28-CRP and VectraDA were shown to be significantly improved at 12 weeks after FIL therapy. This work helps elucidate the molecular correlates of RA disease activity as well as the selective impact of FIL on key relevant pathways. Consistent with previous data, a blood based RA interferon signatures was prognostic for reduced clinical response with PBO and here predicted and showed an improved response with FIL.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster III: Biosimilars and New Compounds

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Spleen tyrosine kinase (SYK) mediates immunoreceptor signaling and is essential in activation of cells including B lymphocytes, monocytes, macrophages, dendritic cells, and osteoclasts. SYK may play an important role in the initiation and progression of autoimmune diseases, including rheumatoid arthritis (RA) and lupus. GS-9876 is a novel, potent, highly selective, oral inhibitor of SYK in phase 2 trials for autoimmune diseases.

Methods: Patients with active RA with prior inadequate response to methotrexate (MTX) or a biologic anti-rheumatic drug were randomized 1:1:1:1 to receive GS-9876 30 mg, GS-9876 10 mg, selective JAK inhibitor filgotinib (FIL) 200 mg or matching placebo once daily for 12 weeks on a stable background of oral MTX. The primary endpoint for GS-9876 was the change in DAS28(CRP) at week 12. Pharmacokinetics (PK) and various biomarkers were evaluated at several time points, including VectraDA and stimulation of whole blood in TruCulture (Myriad RBM) tubes.

Results: A total of 83 patients received study drug and 79 completed the study. Fourteen patients (16.9%) were male and 69 (83.1%) were female. The majority were white (77 patients, 92.8%). The mean (SD) age at baseline was 55 (11.5) years (range 18 to 73). The primary and secondary endpoints are reported in Table 1. For DAS28(CRP), the mean (SD) at baseline was 5.75 (0.961) with a median of 5.69; a statistically significant reduction at week 12 was observed only in patients receiving FIL as compared to placebo (Table 1). Adverse events (AE) were reported across all groups (37.5% in the combined GS-9876 arms, 38.1% in FIL, 40.9% in placebo). No deaths or serious AE were reported. Plasma exposures of all study drugs were comparable to those observed in healthy subjects and historical data. *Ex vivo* stimulated whole blood identified differential responses between GS-9876 and placebo.

Conclusion: Clinical efficacy of GS-9876 in RA was not observed, but GS-9876 was safe and well-tolerated over a 12 week period in patients with active RA on MTX. FIL showed favorable safety and clinical efficacy consistent with prior data, validating the study concept and design. Additionally, biomarker changes with GS-9876 support the continuation of studies in lupus-related diseases.

Table 1. Key endpoints at week 12; *p (compared to placebo)

	DAS28(CRP) Primary endpoint (mean change from baseline to week 12)	ACR20/50/70 Secondary endpoints (% achieving at week 12)	HAQ-DI Secondary endpoint (mean change from baseline to week 12)

Exposure-Efficacy Analysis in DMARD Inadequate Response Rheumatoid Arthritis Patients Treated with GSK3196165 Along with Methotrexate

Anubha Gupta¹, Chiara Zecchin¹, Elena Fischeleva^{1,2}, Mark Layton³ and Stefano Zamuner⁴, ¹GlaxoSmithKline, Stevenage, United Kingdom, ²Currently at Biomed UK Ltd, London, United Kingdom, ³ImmunoInflammation, GlaxoSmithKline, Stevenage, UK, Stevenage, United Kingdom, ⁴Clinical Pharmacology, GlaxoSmithKline, Stevenage, United Kingdom

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster III: Biosimilars and New Compounds

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: GSK3196165 is an anti-GM-CSF mAb being developed for RA. In a phase IIb dose-finding study (NCT02504671), RA patients with inadequate response to methotrexate were administered placebo or GSK3196165 (22.5, 45, 90, 135 and 180 mg SC 5 weekly doses followed by administration every other week for 50 weeks) with background methotrexate therapy. The study results are reported in a separate abstract. This analysis aimed to characterize exposure-efficacy relationship for DAS28(CRP), ACR20 and ACR50, and describe the time course of change in DAS28(CRP).

Methods: All available PK data from 222 randomized patients and PK data from previous studies were used to develop a population PK model. ACR data at Week 12 and time-course DAS28(CRP) were used for exposure-response analyses and analysed using both graphically and model-based approaches.

Change from baseline in DAS28(CRP) and proportion of ACR20/50 responders were plotted for placebo group and quartiles of GSK3196165 steady-state trough concentrations. Longitudinal data for DAS28(CRP) was modelled using an indirect response model to describe the treatment effect, placebo effect was described by an exponential decline. Exposure-efficacy relationship for ACR20 and ACR50 at Week 12 was analysed using logistic regression analysis. PK/PD models for DAS28(CRP) and ACR20/50 were utilized to inform optimal dose and regimen for subsequent clinical trials.

Results: GSK3196165 exhibited linear PK over the tested dose range with a mean systemic clearance (CL) of 0.93 L/day and bioavailability (F) of 0.35 in healthy volunteers which is significantly higher CL and lower F than a typical monoclonal antibody. The apparent clearance in RA patients (CL/F) was 2.5 times faster than predicted, resulting in significantly lower trough levels at steady-state. The elimination half-life in RA population was estimated to be 10 days.

At Week 12, higher response for both DAS28(CRP) and ACR20/50 was associated with higher exposures of GSK3196165. The highest quartile showed a median change from baseline of 1.63 points over placebo for DAS28(CRP), while ACR20 and ACR50 showed 59% and 34% response, respectively (12% and 9% in the placebo group). Using population PK and PK/PD models, a dose of 150 mg weekly is predicted to achieve a steady state trough concentration of 2,500 ng/mL, DAS28(CRP) change from baseline of 1.67 over placebo, and ACR50 response rate of 44%.

Conclusion: GSK3196165 has high CL/F compared to typical monoclonal antibody against soluble cytokines. A clear exposure-response relationship was observed with a greater efficacy achieved at higher trough concentration. The predictions suggest that weekly SC administration of 150 mg GSK3196165 can be associated with the clinically-meaningfully higher response rate in both DAS28(CRP) and ACR50 compared with the observed data in study NCT02504671. Further studies are now required to confirm the expected clinical benefit of increased exposure with weekly dosing of GSK3196165 in patients with RA.

Efficacy of the Reference Biologic Agents in Two Different Types of Randomized Clinical Trials: 1/ the Ones Comparing Their Efficacy Vs. Placebo and 2/ the Ones Comparing Their Efficacy Vs. Biosimilar in Rheumatoid Arthritis: A Systematic Review of Literature and Meta-Analysis

Lea Lopez¹, Christophe Richez², Marie-Elise Truchetet², Bernard Bannwarth³, Thomas Barnetche⁴ and Thierry Schaevebeke⁵, ¹Aquitaine, Bordeaux, Bordeaux, France, ²Department of Rheumatology, Bordeaux University Hospital, Bordeaux, France, ³Rheumatology, CHU de Bordeaux, Bordeaux, France, ⁴Rheumatology, Centre hospitalier universitaire de Bordeaux - Service de Rhumatologie, Bordeaux, France, ⁵Department of Rheumatology, Bordeaux University Hospital, BORDEAUX, France

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster III: Biosimilars and New Compounds

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Recent randomized clinical trials (RCTs) have shown similar efficacy of biosimilar agents compared to reference agents. Is the efficacy of reference biologic agents different in pivotal RCTs and in recent RCTs comparing these agents vs biosimilar?

To compare the reference agent efficacy (infliximab, etanercept, adalimumab, rituximab) in pivotal RCTs (reference agent vs. placebo), with their efficacy in non-inferiority RCTs (reference agent vs. biosimilar), in rheumatoid arthritis (RA).

Methods: We searched in MEDLINE and EMBASE (until March 2018) for randomized, double-blind, placebo-controlled (Reference-pbo group) or biosimilar controlled trials (Reference-bs group) in rheumatoid arthritis. We included the RCTs in methotrexate/disease-modifying anti-rheumatic drug incomplete or inadequate responders (MTX/DMARD-IR). RCTs in monotherapy, in MTX-naïve patients, and biologics incomplete or inadequate responders (bDMARD-IR) were excluded. The primary endpoint was the American College of rheumatology 20% response criteria (ACR 20) of reference agents. We calculated the global rate of ACR 20 responders in Reference-pbo group and in Reference-bs group by performing a

meta-analysis using the inverse variance approach with fixed or random effect model according to heterogeneity estimation.

Results: We included 22 articles within the 783 found: 12 in Reference-pbo group, 10 in Reference-bs group. We excluded Rituximab because Rituximab-bs trials (3) were only in bDMARD-IR patients. Global rate of ACR 20 response of the reference biologic agents is 58% (54%-62%) in Reference-pbo group and 70% (64%-76%) in Reference-bs group. Global rate of ACR 50 response of the reference biologic agents is 34% (30%-39%) and 44% (37%-51%) in Reference-pbo and Reference-bs groups, respectively. The time frame was comparable in the two groups: mostly 24 weeks. The inclusion criteria in both groups were similar. The characteristics of the population (disease duration, disease activity, seropositivity % and MTX dose) in both groups were similar.

Conclusion: The efficacy of reference agents is better in recent non-inferiority RCTs where all patients were treated with the reference agents or its biosimilar, than in pivotal RCTs where the patients could potentially be treated with the biologic agents or a placebo. Inclusion criteria or characteristics of the population in these different trials seem comparable. We believe that a nocebo effect could explain this difference.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster III: Biosimilars and New Compounds

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: PF-06438179/GP1111 (IFX-PF) is an infliximab (IFX) biosimilar for the treatment of immune-mediated inflammatory diseases, including RA. This randomized, double-blind, comparative clinical study evaluated the efficacy, safety and immunogenicity of IFX-PF and IFX reference product sourced from the European Union (IFX-EU) in patients (pts) with moderate to severe active RA with inadequate response to MTX and ≤ 2 doses of 1 non-depleting, non-IFX biologic (NCT02222493). We report results from Week (Wk) 54 to Wk 78.

Methods: Pts (N=650), stratified by geographic region, were initially randomized (1:1) in treatment period 1 (TP1) to IFX-PF or IFX-EU (3 mg/kg IV at Wks 0, 2, 6, and then every 8 wks), both given with MTX (10–25 mg/wk). The primary endpoint was ACR20 at Wk 14. Secondary efficacy endpoints included ACR20 (other than at Wk 14), DAS28-CRP and other measures of clinical response or remission. At Wk 30 (beginning of TP2), patients receiving IFX-EU were blindly re-randomized (1:1) to remain on IFX-EU or transition to IFX-PF for 24 wks. During TP3 (beginning at Wk 54), all pts received open-label treatment with IFX-PF; 3 groups were evaluated in TP3 corresponding to the treatment sequence (TP1/TP2/TP3) during the study: IFX-PF/IFX-PF/IFX-PF; IFX-EU/IFX-EU/IFX-PF; IFX-EU/IFX-PF/IFX-PF.

Results: Of the pts initially randomized (TP1) (IFX-PF, n=324; IFX-EU, n=326), 566 pts entered TP2 at Wk 30. At Wk 54, all pts remaining on IFX-EU were switched to IFX-PF; 505 pts continued to participate in TP3. The majority of TP3 pts were female (79.2%) and White (78.6%). ACR20 response rates and DAS28-CRP scores were sustained and comparable across the 3 groups during TP3 (Table). IFX-PF was well tolerated during TP3; the safety profile was comparable across all 3 groups. Incidence of treatment-emergent adverse events during TP3 was 29.3% overall and 28.9% (IFX-PF/IFX-PF/IFX-PF), 30.2% (IFX-EU/IFX-EU/IFX-PF), and 29.4% (IFX-EU/IFX-PF/IFX-PF); the incidence of infusion-related reactions was 2.0% overall and 1.2%, 3.2% and 2.4% in the 3 groups, respectively. Pre-dose (TP3) anti-drug antibody (ADA) rates at Wk 54 were 44.3%, 47.6% and 53.2% for the IFX-PF/IFX-PF/IFX-PF, IFX-EU/IFX-EU/IFX-PF and IFX-EU/IFX-PF/IFX-PF groups, respectively. The incidences of pts with a first positive ADA result occurring during TP3 (6.0%, 8.0% and 6.4% for the IFX-PF/IFX-PF/IFX-PF, IFX-EU/IFX-EU/IFX-PF and IFX-EU/IFX-PF/IFX-PF groups, respectively) and overall, post-dose ADA rates in TP3 (56.9%, 63.5%, and 65.1%, respectively) were comparable among groups.

Conclusion: In line with earlier findings from this study, results from TP3 (Wks 54–78) show the absence of clinically meaningful differences in efficacy, safety and immunogenicity between treatment groups, independent of a single treatment transition from IFX-EU to IFX-PF at Wk 30 or Wk 54.

Table

Klimiuk⁴, Nuala Peter⁵ and Girish Jayadeva², ¹Metroplex Clinical Research Center, Dallas, TX, ²Boehringer Ingelheim, Ingelheim a.R., Germany, Ingelheim, Germany, ³Inland Rheumatology, Upland, CA, ⁴Medical University of Bialystok and Gabinet Internistyczno-Reumatologiczny, Bialystok, Poland, ⁵Boehringer Ingelheim, Biberach a.d.R., Germany, Ingelheim a.R., Germany

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster III: Biosimilars and New Compounds

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Clinical equivalence of BI 695501 to the adalimumab RP has been shown in pts with moderately-to-severely active RA in the Phase III VOLTAIRE®-RA study (NCT02137226), through similar American College of Rheumatology 20% (ACR20) responses at Weeks (wks) 12, 24 and 48 (Cohen et al 2018. ARD <https://doi.org/10.1136/annrheumdis-2017-212245>). Here we present long-term safety, efficacy and immunogenicity data.

Methods: This 48-wk, open-label, multicenter, Phase IIIb extension study (VOLTAIRE®-RAext, NCT02640612) included 430 adults with moderately-to-severely active RA who wished to continue, and could benefit from continuing (per investigator's assessment), treatment with BI 695501 following participation in the VOLTAIRE®-RA study. All pts received 40 mg BI 695501 self-administered via pre-filled syringe every 2 wks. The primary endpoint was proportion of pts with drug-related adverse events (AEs) from the start of VOLTAIRE®-RAext to end of 10 wks' follow-up. Secondary efficacy endpoints included change from baseline in Disease Activity Score 28 (DAS28)-erythrocyte sedimentation rate (ESR), and proportion of pts achieving EULAR response, ACR/EULAR remission and ACR20 response at Wk 48 (using VOLTAIRE®-RA baseline as reference). Further endpoints included ACR50/70.

Results: All 430 pts in this study received BI 695501; 225 from the BI 695501 continuous (BI 695501-CONT), 102 from the adalimumab RP to BI 695501 switch at 24 wks (SWITCH), and 103 from the adalimumab RP continuous (RP-CONT) arms of VOLTAIRE®-RA. Baseline demographics were balanced across treatments arms in the parent study. A total of 87 (20.2%) pts experienced ≥1 drug-related AE, with a slightly lower proportion in the SWITCH arm (n=18; 17.6%) compared with BI 695501-CONT (n=48; 21.3%) and RP-CONT (n=21; 20.4%) arms (Table 1). 26 (6.0%) pts experienced ≥1 serious AE and 1 pt (BI 695501-CONT arm) experienced AEs leading to death (investigator assessed as not drug-related). Anti-drug antibody (ADA) and neutralizing antibody (nAb) data were similar between treatment arms. At Wk 48, clinical efficacy was similar irrespective of treatment arm in the parent study (Table 2). 42 (9.8%) and 36 (8.4%) pts prematurely discontinued the trial and treatment, respectively.

Conclusion: No new safety or immunogenicity findings were identified in this extension study. The clinical efficacy observed at wk 48 in VOLTAIRE®-RA (Cohen et al 2018. ARD <https://doi.org/10.1136/annrheumdis-2017-212245>) was sustained for up to 2 years in pts in the BI 695501-CONT arm, 72 wks in pts in the SWITCH arm, and 1 year in pts who switched to BI 695501 when entering VOLTAIRE®-RAext.

Table 1. Overview of treatment-emergent AEs* during VOLTAIRE®-RAext (SAF)

Pts, n (%)	BI 695501-CONT (n = 225)	SWITCH (n = 102)	RP-CONT (n = 103)	Total (n=430)
≥1 AE	116 (51.6)	34 (33.3)	43 (41.7)	193 (44.9)
≥1 drug-related AE	48 (21.3)	18 (17.6)	21 (20.4)	87 (20.2)
≥1 serious AE	14 (6.2)	4 (3.9)	8 (7.8)	26 (6.0)
AE leading to study drug discontinuation	7 (3.1)	2 (2.0)	7 (6.8)	16 (3.7)

AE = treatment-emergent adverse event.

SAF = safety analysis set.

* All AEs occurring between the start of treatment (VOLTAIRE®-RAext baseline) and 10 wks after the last dose of trial drug.

Table 2. Clinical efficacy at Wk 48 (FAS)

	BI 695501-CONT (n = 225)	SWITCH (n = 101†)	RP-CONT (n = 103)	Total (n=429)

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster III: Biosimilars and New Compounds

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Upadacitinib (UPA), an oral JAK inhibitor selective for JAK1, demonstrated efficacy in patients (pts) with moderate to severe rheumatoid arthritis (RA) with an inadequate response (IR) to csDMARDs or bDMARDs in the SELECT-NEXT¹ and SELECT-BEYOND² trials, respectively. The purpose of the analysis was to investigate the speed of response to UPA across disease measures in csDMARD- and bDMARD-IR pts.

Methods: 661 pts in NEXT and 498 in BEYOND received UPA 15mg or UPA 30mg once daily (QD) or placebo (PBO) for 12 weeks (wks)^{1,2}. Time to first achievement of clinically meaningful outcomes, including ACR20/50, DAS28-CRP ≤ 3.2 and Low Disease Activity (LDA) measures of CDAI (≤ 10) and SDAI (≤ 11) was evaluated. The cumulative incidences of ACR20/50, DAS28-CRP ≤ 3.2 and LDA by CDAI and SDAI over 12 wks were estimated. Hazard ratios between UPA and PBO were obtained using Cox proportional hazards model with treatment group, corresponding baseline values and main stratification factors, without control for multiple comparisons. All analyses were based on observed data without imputation.

Results: Pts had a disease duration of 7 and 13 years in NEXT and BEYOND respectively.^{1,2} In BEYOND, pts were treatment-refractory as evidenced by 53% having received ≥ 2 prior bDMARDs². Median times to achieve ACR20 were similar, irrespective of pt population, being 4 wks for UPA 15mg QD and 2-3 wks for UPA 30mg QD vs 12 wks on PBO ($p < .001$). In general, the median times to achieve ACR50 and DAS28-CRP ≤ 3.2 for UPA 15mg and 30mg QD were -12 wks and -8 wks for both csDMARD-IR and bDMARD-IR pts, whereas the median was not reached for pts on PBO during the first 12 wks ($p < 0.001$, Table 1). The median time to LDA by CDAI and SDAI was -12 wks across UPA doses and populations, but was not reached for pts receiving PBO within that time. Pts receiving UPA were 2-4 times more likely to achieve clinical responses vs pts receiving PBO. In general, both UPA doses performed similarly across pt populations, with numerically quicker responses observed in pts receiving UPA 30mg vs UPA 15mg QD. Median times to achieve 20% and 50% improvements in tender and swollen joint counts were 1-2 wks and 2-4 wks respectively, for both UPA doses, irrespective of pt population. Median times to achieve 20% improvements in morning stiffness duration and severity were approximately 2 wks in each of the UPA arms vs 4 wks on PBO ($p < 0.001$).

Conclusion: Pts receiving UPA at either 15mg or 30mg QD were more likely to achieve clinical responses at significantly earlier time points when compared with pts receiving PBO. Irrespective of being csDMARD-IR or bDMARD-IR, times to achieve various clinical responses were consistent between pt populations.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster III: Biosimilars and New Compounds

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Although treatment with csDMARDs and bDMARDs can lead to remission in patients with RA, many patients still experience pain and morning (AM) stiffness, which have a meaningful negative impact on quality of life. We assessed the effect of upadacitinib (UPA), a selective JAK-1 inhibitor, alone or in combination with csDMARDs vs background therapy on pain and AM stiffness in patients with active RA who had an inadequate response (IR) to csDMARDs or bDMARDs.

Methods: Data from the SELECT-NEXT (NCT02675426), SELECT-BEYOND (NCT02706847), and SELECT-MONO (NCT02706951) randomized controlled trials were analyzed. Patients in NEXT (csDMARD-IR) and BEYOND (bDMARD-IR) received UPA (15 mg or 30 mg daily) or PBO with csDMARDs for 12 weeks (wks), and those in the MONO trial (csDMARD-IR) received UPA monotherapy (15 mg or 30 mg daily) or MTX (mean dose: 17 mg/wk) for 14 wks. Pain and duration of AM stiffness were assessed through 12/14 wks. Least squares mean (LSM) percent changes from baseline (BL) to wk 12/14 were based on mixed effect repeated measures models. Percentages of patients reporting $\geq 50\%$ improvement in pain, those reporting no pain or mild pain (absolute pain score < 20), and those reporting AM stiffness < 15 minutes were determined at each time point for UPA (both doses), PBO, or MTX; comparisons between groups used Cochran-Mantel-Haenszel tests with prior bDMARDs use as stratification factor.

Results: Across all 3 trials, statistically significant LSM percent changes from BL to wks 12/14 in pain and duration of AM stiffness were reported in both UPA dose groups (except AM stiffness duration in BEYOND) compared with PBO or MTX groups (**Figures 1 and 2**). Across trials, significantly ($p < 0.05$) more UPA-treated patients (15 mg: 41–51%, 30 mg: 42–56%) reported $\geq 50\%$ improvement in pain at wks 12/14 compared with PBO or MTX (19–25%). Significantly ($p < 0.05$) more UPA-treated patients (15 mg: 30–36%, 30 mg: 36–44%) reported no pain or mild pain at wks 12/14 compared with PBO or MTX (14–15%). The percentage of UPA-treated patients (15 mg: 26–42%, 30 mg: 29–43%) reporting AM

stiffness duration <15 minutes at wks 12/14 was approximately twice that in PBO or MTX (15–23%) groups. Across all measures, improvements in UPA-treated patients were evident as early as wk 2.

Conclusion: Treatment with UPA in combination with csDMARDs vs PBO resulted in significant and rapid improvements in pain and AM stiffness across different RA patient populations including csDMARD-IR and bDMARD-IR. Similar improvements vs MTX were reported when UPA was administered as monotherapy.

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster III: Biosimilars and New Compounds

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: To characterize the exposure-response (ER) relationship between systemic exposure to sirukumab (an anti-interleukin-6 [IL-6] human monoclonal antibody) and the occurrence of selected safety events in patients with active rheumatoid arthritis (RA). The safety events of interests include serious infection, clinical laboratory abnormalities (neutropenia, thrombocytopenia, elevations of alanine aminotransferase [ALT], triglyceride, total cholesterol, low-density lipoprotein (LDL) or bilirubin, and abnormal high-density lipoprotein [HDL]), major adverse cardiovascular events (MACE), malignancy, and death.

Methods: Serious infection and laboratory abnormalities were assessed based on pooled data from 4 phase 3 trials of sirukumab (ie, data through Week 52 from SIRROUND-D and -M, and data through Week 24 from SIRROUND-T and -H). MACE, malignancy, and death were assessed through the BLA safety data cut (September 2016) to leverage as much

data available as possible due to lower incidence of events. Established population PK model of sirukumab was used to generate empirical Bayesian estimates of exposure metrics for individual patients using actual dosing records, including cumulative area under the curve (AUC), maximum (C_{max}), minimum (C_{min}) and average (C_{ave}) concentrations at steady-state. For serious infection and laboratory abnormalities, two analyses were performed, quartile analysis where the proportion of patients with events were assessed by 4 PK quartile subgroups and the distribution of PK exposure versus the occurrence of events or laboratory abnormality toxicity grade reached (worst grade experienced over the assessment period). For MACE, malignancy and death, distribution plots of PK exposure versus events were generated.

Results: Based on the distribution plots and/or the quantile analysis of pooled data, there was no trend of increasing occurrence of events with higher sirukumab exposures for MACE, malignancy, death, serious infection, triglyceride elevation or thrombocytopenia. Weak correlations were observed between sirukumab exposure and neutropenia, ALT elevation, LDL elevation, total cholesterol elevation, abnormal HDL or bilirubin elevation, where patients who had higher exposure to sirukumab tended to have more abnormal laboratory measures.

Conclusion: No apparent correlation was identified between sirukumab exposure and MACE, malignancy, and death in RA patients receiving up to 5 years of SC sirukumab treatment. Small ER trends were observed for neutropenia, ALT elevation and abnormal lipid parameters, which were consistent with the known modulation effects of anti-IL6 agents as reported for other anti-IL-6 biologics in patients with RA.

Abstract Number: 2526

Revealing and Addressing Knowledge Gaps Regarding Biosimilars in Rheumatology Practice with Targeted Continuing Education and Patient Surveys

Katie Robinson and Robert Esgro, Vindico Medical Education, Thorofare, NJ

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster III: Biosimilars and New Compounds

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: With the recent introduction of biosimilars in the US market, providers lack knowledge of how these agents compare to reference biologics and the implications for clinical practice. Targeted continuing education (CE) is a suitable platform to assess knowledge of and attitudes towards biosimilars among providers of patients with rheumatic disease as well as to address persisting gaps towards enhanced patient care.

Methods: Vindico Medical Education partnered with Kynectiv, Inc. to provide an interactive CE activity targeted to rheumatologists, internists, and pharmacists who care for patients with rheumatoid arthritis (RA). A survey of 17 patient influencers representative of over 650,000 patients with RA was also sent to gauge alignment of patient/provider views of biosimilars. Data was collected from October 2016 through October 2017.

Results: Overall, 49% of providers (n=598) indicated that their knowledge regarding the differences between biosimilars and reference biologics was fair or poor; the gap was more striking among pharmacists (n=186) versus rheumatologists (n=161). Similarly, 66% lacked knowledge of the regulatory pathway for biosimilars, though there was minimal difference across disciplines. Despite these knowledge gaps, nearly 78% of rheumatologists report willingness to prescribe biosimilars. Regarding pharmacy-level substitution of biosimilars, 57% of pharmacists agree that it should be allowed without restriction if deemed interchangeable by the FDA, though only 16% of rheumatologists agreed. Instead, most rheumatologists felt that a biosimilar should be substituted only if the prescriber was informed. Regarding patient concerns about biosimilars, physicians and pharmacists over-estimated concerns regarding decreased efficacy and under-estimated concerns regarding side effects. The greatest concern among patients was being forced to switch from a reference biologic to a biosimilar due to payor restrictions. Importantly, following completion of the activity, there was an 84% relative increase in knowledge regarding biosimilars, and 87% had begun talking to patients about biosimilars.

Conclusion: Physicians and pharmacists lack knowledge regarding the approval and regulation of biosimilars as well as how these agents differ from reference biologics. In addition, they do not recognize patient concerns regarding biosimilars.

These knowledge and practice gaps were closed via participation in this targeted CE activity, demonstrating the continued need for CE to activate learning and ensure the proper use of biosimilars.

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster III: Biosimilars and New Compounds

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Sarilumab has shown efficacy in RA both as monotherapy and in combination with csDMARDs in Phase 3 trials. We assessed long-term safety from the sarilumab clinical development program in adult pts with RA who received sarilumab+csDMARD or sarilumab monotherapy from: MOBILITY (NCT01061736); TARGET (NCT01709578); ASCERTAIN (NCT01768572); MONARCH (NCT02332590); ACT11575 (NCT01217814); ONE (NCT02121210); COMPARE (NCT01764997); EASY (NCT02057250); and an ongoing open-label extension EXTEND (NCT01146652), which enrolled pts completing originator studies.

Methods: Data (cut-off Jan 30, 2018) were pooled from pts on sarilumab+csDMARD (N=2887) or sarilumab monotherapy (N=471). Pts had received sarilumab 200 mg or 150 mg q2w SC, except 151 pts from MOBILITY Part A who received 100 mg qw, 150 mg qw, or 100 mg q2w. Treatment-emergent (TE) adverse events (AEs), AEs of special interest (AESI), and discontinuations were assessed.

Results: Baseline characteristics were similar between sarilumab+csDMARD and monotherapy pools (mean age 52 yrs; 81–83% female). At baseline, mean RA duration was 9.4 vs 8.3 yrs in combination and monotherapy pools, respectively, with 38.7% vs 8.5% of pts having received prior bDMARDs. Cumulative drug exposure was 7,985.5 vs 798.7 pt-yrs, with maximum duration 7.3 vs 3.5 yrs for sarilumab+csDMARD vs monotherapy, respectively. Exposure-adjusted rates of TEAEs, serious AEs, and TEAEs leading to discontinuations were similar between pools (Table). Infections were the most common AESI. Serious infection event rates were 3.7 vs 1.0/100 pt-yrs for combination vs monotherapy, respectively, and not associated with decreased absolute neutrophil counts (ANC). Incidences of ALT >3x upper limit of normal were 10.3% and 5.5% for sarilumab+csDMARD and monotherapy, and ANC <1.0 Giga/L were 12.7% and 14.9%, respectively. Rates of confirmed GI perforation for combination vs monotherapy were 0.1 vs 0/100 pt-yrs. Analyzing data by 6-month intervals showed no increase in rate over time for serious infections, malignancy, major adverse cardiac events, or ANC <1.0 Giga/L (Figure).

Conclusion: The long-term safety profile of sarilumab (a human IL-6R blocker recently approved for the treatment of RA), either as monotherapy (observed for >3.5 yrs) or with csDMARD, (observed for >7 yrs) remains stable and consistent with the anticipated profile of an IL-6R α blocker.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster III: Biosimilars and New Compounds

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is an autoimmune disorder associated with chronic inflammation and commonly treated with disease-modifying anti-rheumatic drugs (DMARDs) and corticosteroids. Repository corticotropin injection (RCI) is approved in the United States as adjunctive therapy for short-term administration (during an acute episode or exacerbation) in RA (selected cases may require low-dose maintenance therapy). Here, we present interim data from the initial 12-week open-label phase of an ongoing phase 4, multicenter, 2-part study evaluating the efficacy, safety, and appropriate duration of RCI therapy in patients with persistently active RA despite receiving 1 or 2 conventional synthetic or biologic DMARDs (cs/bDMARDs) and corticosteroids.

Methods: In the open-label period (Part 1, Weeks 0–12), all enrolled patients received RCI 1 mL (80 U) subcutaneously (SC) twice per week for 12 weeks. After the initial 12 weeks, patients who achieved low disease activity (LDA; DAS28-ESR score <3.2) at Week 12 continued in the double-blind maintenance phase of the trial (Part 2), during which they were randomized 1:1 to receive either RCI 1 mL (80 U) SC or matching placebo 1 mL SC twice per week for an additional 12 weeks. The primary endpoint was the proportion of patients who achieved LDA at Week 12. Secondary endpoints included assessment of the safety and tolerability of RCI. Disease activity was also assessed by the proportion of patients who achieved 20%, 50%, and 70% improvement in American College of Rheumatology (ACR) response criteria (ACR20, ACR50, and ACR70, respectively) at Week 12.

Results: As of 10 May, 2018, 116 patients had enrolled, 100 had completed, 2 were ongoing, and 14 had discontinued the 12-week open-label period of the study. Among patients who completed the open-label period, 84% were female, and the mean age of patients was 54 years. Twelve weeks of RCI treatment resulted in >60% of patients achieving LDA; patient baseline characteristics and the results of the primary and select secondary endpoints for this interim analysis are presented in Table 1. Forty six adverse events (AEs) were reported among the 116 patients enrolled in the study, and 2 patients reported serious AEs (chest pain and pneumonia). The most common AEs were headache (n=10), urinary tract infection (n=4), hyperglycemia (n=3), and pharyngitis (n=3).

Table 1. Interim Results at Baseline and at Week 12 for Patients Who Completed the Open-label Period (N=100)

Endpoints	Baseline	Week 12
LDA (DAS28-ESR <3.2)	1%	61%
DAS28-ESR score, mean	6.3	3.5
Tender joint count,* mean	14.8	3.5
Swollen joint count,* mean	11.1	2.6
ACR20		85%
ACR50		66%
ACR70		34%

* Sub-components of the 28-joint count, a measure used to determine the DAS28-ESR score and ACR criteria scale.

Conclusion: In this ongoing study, RCI was a potentially safe and effective treatment option in patients with persistently active RA who were nonresponsive to corticosteroids and cs/bDMARD treatment, as demonstrated by improvement in multiple measures of disease activity during a 12-week open-label period.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster III: Biosimilars and New Compounds

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Sarilumab showed efficacy in RA and superiority to placebo and adalimumab in Phase 3 trials. This post hoc analysis investigated LFT levels in three sarilumab Phase 3 trials.

Methods: The adalimumab-controlled MONARCH (NCT02332590) and placebo-controlled TARGET (NCT01709578) and MOBILITY (NCT01061736) studies allowed alanine- (ALT) or aspartate aminotransferase (AST) levels $\leq 1.5\times$ upper limit of normal (ULN) at entry. Patients who received ≥ 1 dose of sarilumab and had ≥ 1 post-baseline measurement of ALT or AST were categorized by baseline and maximum on-study ALT, AST, total bilirubin, and alkaline phosphatase (AP).

Results: In MOBILITY (MTX-IR), among patients with normal ALT at baseline (n=1085), maximum on-study ALT $>3\times$ ULN was seen in 8.0% (n=29) and 7.8% (n=28) of patients in sarilumab 150 and 200 mg + MTX groups, respectively, versus 2.2% (n=8) with placebo + MTX (Table 1). Among patients with ALT $>ULN$ at baseline (n=106), maximum on-study ALT $>3\times$ ULN was seen in 23% (n=9) and 16% (n=6) in sarilumab 150 and 200 mg + MTX groups, respectively, versus 3.6% (n=1) with placebo + MTX. In the monotherapy MONARCH study, the proportion of patients with maximum on-study ALT $>3\times$ ULN was 2.4% (n=4) in patients with normal baseline ALT and 15% (n=2) in patients with baseline ALT $>ULN$ in the sarilumab group, and 1.7% (n=3) and 20% (n=2), respectively, in the adalimumab group (Table 2). ALT elevations in TARGET (TNF-IR; Table 3) were less frequent compared with MOBILITY. There were no cases of Hy's Law attributable to sarilumab treatment. Laboratory investigations (including LFT elevations) led to treatment discontinuation in 0.2–0.6% of placebo- and 0.5–2.8% of sarilumab-treated patients.

Conclusion: LFT elevations with sarilumab, an IL-6R blocker recently approved for the treatment of RA, were more likely in combination with csDMARDs than with monotherapy, and more likely in patients with baseline elevations. Incidence of ALT $>3\times$ ULN was similar between monotherapy sarilumab and adalimumab. Importantly, LFT elevations rarely necessitated treatment discontinuation

Uncovering Clinicians' Gaps and Attitudes Toward Biosimilars: Impact of a 2-Phase Educational Program

Zachary Schwartz¹, Jenny Schulz¹, Angelique Vinther¹, Alyce Kuklinski¹ and Kenneth Saag², ¹Clinical Care Options, Reston, VA, ²University of Alabama at Birmingham, Birmingham, AL

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster III: Biosimilars and New Compounds

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Biosimilar agents have changed the clinical landscape in rheumatology, gastroenterology, and dermatology. We sought to measure clinicians' competence and knowledge of biosimilars and to address identified educational gaps related to their clinical application.

Session Time: 9:00AM-11:00AM

Background/Purpose: Baricitinib (BARI) 2 mg and 4 mg once daily demonstrated significant clinical improvements compared to placebo in the phase 3 study of RA patients on 1 or 2 csDMARDs with an inadequate response or intolerance to ≥1 tumor necrosis factor (TNF) inhibitors (bDMARD-IR)(RA-BEACON).¹ In this RA population, patients often experience pain, a key factor influencing quality of life. The objective of this *post hoc* analysis was to characterize the effects of BARI on pain relief by baseline pain and RA treatment history.

Methods: 527 patients were randomized to placebo (n=176), BARI 2 mg (n=174), or 4 mg (n=177) once daily for 24 weeks. The time of the primary endpoint was Week 12. Pain was assessed using a visual analog scale (VAS, 0-100 mm) at each study visit. The proportion of patients achieving ≥30%, ≥50%, and ≥70% pain relief at Week 12 was compared between BARI 2 mg or 4 mg vs placebo using logistic models. The treatment comparisons within each subgroup category (pain < median [68] vs ≥median, number of prior TNF inhibitors [1 vs >1] and prior bDMARDs [<3 vs ≥3]) on pain relief were performed. Missing pain values were imputed using modified last observation-carried-forward (mLOCF).

Results: Mean baseline pain scores were 65, 62, and 66 mm for placebo, BARI 2 mg, and BARI 4 mg, respectively. Approximately 40% of patients had received >1 TNF inhibitor and a quarter of patients had received ≥3 bDMARDs, representing patients with highly refractory disease. At Week 12, significantly more patients achieved ≥30%, ≥50%, and ≥70% pain relief with BARI 2 mg or 4 mg vs placebo (P<0.05, for all comparisons).² Consistent results were observed regardless of baseline pain (Table). Prior TNF inhibitor history appeared to influence the achievement of ≥70% pain relief, but had limited effect on the ≥30% and ≥50% pain thresholds. Variability in response for the 3 treatment groups was observed at the different pain relief thresholds for patients with <3 vs ≥3 bDMARDs. Regardless of treatment history, patients receiving BARI 2 mg or 4 mg were more likely to reach all pain relief thresholds than placebo.

Conclusion: BARI 2 mg or 4 mg provided greater pain relief in bDMARD-IR patients with RA compared with placebo in all patients and inpatients with different baseline pain severity and prior treatment history.

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster III: Biosimilars and New Compounds

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Biosimilar infliximab (CT-P13) has been used to treat patients with rheumatoid arthritis (RA), ankylosing spondylitis (AS) and psoriatic arthritis (PsA) in Turkey since 2013. The aim of this study was to examine its efficacy and drug survival and compare it to the original reference infliximab (inf) in patients with inflammatory rheumatic diseases based on the database from the Turkish TURKBIO registry.

Methods: All patients with RA, SpA, PsA, and other diseases receiving CT-P13 and original infliximab registered in the TURKBIO database between the dates of June 2013 and January 2017 were included in the study. Demographic information, laboratory parameters and disease indices were collected (at baseline, and months 6 and 12). We used Kaplan Meier survival curves to examine drug survival patterns.

Results: Data collected from a total number of 614 patients were analyzed (Table 1). The analysis of each treatment group was made according to gender, age, and diagnosis. In both groups most of the patients were diagnosed as having axial SpA, followed by RA, PsA and other diseases. CT-P13 group had female predominance. In patients with RA and PsA, baseline DAS28 scores were found to be higher in CT-P13 group. Baseline values of ASDAS-CRP in SpA patients and CRP in all patients were similar for both groups (Table 2). Mean CRP levels at month 6 and ASDAS scores at month 12 were found to be higher in inf group. The ratio of males was higher in axial SpA patients receiving inf, but did not statistically affect the 12th month ASDAS results. The results of the database analysis showed that the drug survival rate of CT P13 (78,4%) is higher than inf (63,6%) at year 4 (Figure 1). At 4-year follow-up, drug withdrawal was observed in both groups due to ineffectiveness (CT-P13; n=13 54,16%, inf; n=89 41,58%) and side effects (CT-P13; n=8 33,33%, inf; n=43 20,09%). In CT-P13 group, six patients had switched from inf to biosimilar and other 20 had used ≥ 1 previous biologicals. Of the 503 patients who used inf, 164 had used ≥ 1 biologicals previously.

Conclusion: The results of this study demonstrated long term higher drug survival rate of biosimilar CT-P13. The study also suggested that efficacy of CT-P13 on disease activity was similar to original infliximab in patients with inflammatory rheumatic diseases.

Switching Patients with Arthritis from Etanercept (Enbrel) to the Biosimilar Drug, Benepali: A Single- Center Retrospective Observational Study

Anastasia- Vasiliki Madenidou¹, Andrew Jeffries², Sneha Varughese², Stephen Jones², Helen Veevers², Hanadi Sari-Kouzel² and Chandini Rao², ¹Rheumatology, Blackpool Teaching Hospitals NHS Foundation Trust, Blackpool, United Kingdom, ²Blackpool Teaching Hospitals NHS Foundation Trust, Blackpool, United Kingdom

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster III: Biosimilars and New Compounds

Background/Purpose: Benepali, the etanercept biosimilar, is licenced in the UK for the same indications as the reference product, Enbrel.

In 2016, the Rheumatology Department at Blackpool Teaching Hospitals, after informing all the patients on Enbrel about Benepali, switched the patients that gave consent.

A proportion of these patients requested a switch back to Enbrel and therefore we aimed to investigate the reasons for Benepali withdrawal and if the loss of effect (LOE) is reflected in change of disease activity measures.

Figure 1: Kaplan-Meier survival curve of biosimilar infliximab and original reference infliximab ($p < 0.05$)

Table 2. Disease activity at baseline and months 6 and 12

	CT-P13	Infliximab	P value
DAS28, mean			
Baseline	3.95	3.47	0.007
Month 6	2.54	2.27	0.385
Month 12	2.18	2.17	0.959
CRP, (mg/L)			
Baseline	21.00	21.82	0.818
Month 6	4.06	13.09	<0.001
Month 12	10.52	9.97	0.889
ASDAS, mean			
Baseline	3.47	3.31	0.280
Month 6	1.57	1.90	0.093
Month 12	1.23	1.87	0.008

Methods: We included all the patients switched to Benepali from July 2016 to April 2018, identified from the departmental biologics database. Data were collected from patients' records.

Baseline characteristics associated with Benepali withdrawal were explored by multivariate logistic regression analysis stratified by diagnosis (RA, SpA, PsA) and included age, gender, duration of disease, co-treatment with DMARDs, concomitant Methotrexate, number of biological DMARDs (bDMARDs) before Enbrel, duration on Enbrel, number of swollen and tender joints, baseline ESR and CRP; only for RA: seropositivity for RF and/or ACPA, DAS-28 before any bDMARD, baseline DAS-28 and Patient Global Score (PGS); only for SpA: HLA-B27 status, BASDI before any bDMARD, baseline BASDI and pain Visual Analogue Score (VAS) and only for PsA: Baseline Patient (PtGA) and Physician Global Assessment (PGA).

Wilcoxon signed-rank test was performed to compare the various expressions of disease activity (DAS-28 and PGS for RA, BASDI and pain VAS for SpA, PtGA and PGA for PsA, ESR, CRP) before switching to Benepali and before Benepali withdrawal in patients with LOE.

Results: A total of 72 patients on Enbrel were switched to Benepali, of which 19 (26,4%) switched back to Enbrel after 6 months [interquartile range (IQR) 3.5- 10] on the biosimilar product (Table). All the 19 patients had remained on Enbrel until the time of data analysis [follow-up period: 12 months (IQR 7.5- 15.5)].

The reasons of withdrawal were LOE (58%), adverse events (32%), infection (5%) and difficulty using the pen device (5%). In RA, the duration on Enbrel was associated with Benepali withdrawal [OR 1.43 (95% CI 1.02, 2.00)] and no statistically significant factors were found in SpA and PsA.

For RA, LOE is reflected in the DAS-28 increase (2.99), PGS increase (40 mm), increase in tender joints (3.5) and CRP increase (2 mg/dl) (all $p < 0.05$), whereas for SpA and PsA there was no statistically significant change in disease activity measures.

Conclusion: The majority (73,6%) had a good response to Benepali, which is in keeping with the current evidence. In RA, LOE is reflected only in the subjective measures, except for CRP. Interestingly, all the patients switching back to Enbrel, stayed on this treatment, which may indicate other contributing factors in withdrawal not identified by this study, due to the limitation of the small sample size.

Table: Baseline characteristics of patients switched to Benepali

	Rheumatoid arthritis	Axial Spondyloarthritis	Psoriatic arthritis
Number, n	36	23	13
Female, n (%)	27 (75%)	7 (30%)	6 (46%)
Age, years	62 (56- 77)	56 (46- 66)	54 (51.5- 67.5)
Duration on Etanercept (Enbrel) before switching to Benepali, years	3.8 (2.3- 7.5)	5.2 (3.1- 7.5)	2.8 (2.3- 6.6)
Duration of disease before switching to Benepali, years	15 (8.2- 21)	29 (17.3- 38)	17 (12.5- 26.5)
Co-treatment with DMARDs, n (%)	32 (89%)	2 (8,7%)	9 (69,2%)
Concomitant Methotrexate, n (%)	26 (72%)	1 (4,3%)	6 (46,2%)
On other bDMARDs before Enbrel, n (%)	8 (22,2%)	4 (17,4%)	2 (15,4%)
DAS- 28 before any bDMARD	6.18 (5.72- 6.71)	NA	NA
DAS- 28 before switching to Benepali	2.87 (1.89- 3.73)	NA	NA
BASDI before any bDMARD	NA	7.01 (6.25- 8.68)	NA
BASDI before switching to Benepali	NA	2.95 (1.94- 4.85)	NA
ESR before switching to Benepali, mm/hr	12.50 (6.00- 19.75)	6.00 (2.00- 9.00)	7.00 (5.00- 26.50)
CRP before switching to Benepali, mg/dl	2.00 (1.00- 5.00)	4.00 (1.00- 7.90)	2.00 (1.00- 9.50)

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster III: Biosimilars and New Compounds

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Biosimilars of biotechnological agents represent an important opportunity to increase accessibility to these medications. Clinicians still maintain reservations regarding the similarity of their efficacy and safety in practice. Our purpose was to evaluate the clinical consequences of a block switch of etanercept (ETN) original to biosimilar in a clinical practice setting.

Methods: The study included all patients aged 18+ treated in a Tertiary Rheumatology Department with original ETN who were switched to his biosimilar following a decision by the hospital administration, accepted by rheumatologists. Disease activity and adverse events were evaluated at baseline (time of switch) and 3 months after and were compared using Paired samples T-test and Wilcoxon test, as appropriate. A $p < 0.05$ was considered statistically significant. Adaptation to the drug delivery instrument was also evaluated. Continuous variables are presented as means and categorical variables as proportions.

Results: From 98 patients treated with original ETN in our department, 89 were switched to his biosimilar. The remaining ones maintained the treatment with the reference biological product for several reasons. Twelve patients were excluded from this analysis: poor adherence to treatment ($n=3$), early interruption of treatment [$n=3$, due to surgery ($n=1$), respiratory infection ($n=1$) and suspected allergic reaction to biosimilar ($n=1$)] and 3 months observations still to be performed ($n=6$). Of the remaining 77 patients (58.4% female, mean age 55.3 ± 11.7 years), 39% had RA, 37.7% SpA, 20.8% PsA and 2.6% JIA. Disease activity was stable over the followup in patients with RA, PsA and SpA, as no statistically significant differences were observed in acute phase reactants, patient or physician global assessment between the two time points. Minor adverse events were reported by 2 patients (pain and local cutaneous reaction) and another 2 report impression of disease exacerbation that was not confirmed by clinical and analytical evaluation. Two patients reported minor infections. Good adaptation to the drug delivery instrument was reported by 93% of patients.

Table 1. Acute phase reactants, disease activity, joint count and patient and physician global assessment through follow-up

	Baseline	3 Months after switch
ESR (mm/h)f	8.50(9.80)	8.00(11.00)
CRP (mg/dL) f	0.21(0.56)	0.31(0.59)
DAS-28-ESR §*	2.08(0.97)	2.23(1.01)
Tender joint-28§	0.24(0.09)	0.45(0.10)
Swollen joint-28§	0.49 (0.12)	0.54(0.12)
PtGA (0-100)f	40.00(40.00)	40.00(33.00)
PhGA (0-100)f	7.50(11.00)	5.00(20.00)

IQR – Interquartile range; PhGA physician global assessment; PtGA- patient global assessment; SD - standard deviation; f median(IQR); § mean (SD). *Only for RA and PsA patients ($n=46$). None of the differences was statistically significant by paired tests.

Conclusion: The non-medical switch from ETN to his biosimilar in this group of patients followed in routine care did not affect the overall efficacy and safety of treatment. However, these observations only cover 3 months of follow up. A longer observational period is necessary to assess the long-term response.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster III: Biosimilars and New Compounds

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: HDAC6 is a pleiotropic enzyme which removes of acetyl groups from non-histone proteins. HDAC6 inhibition represses inflammatory responses such as cytokines, chemokines and cell adhesion molecules by repressing NADPH Oxidase activity in macrophage as well as enhance Treg function by enhancing transcriptional activity of FOXP3 which induces several immunomodulatory proteins such as CTLA4. Thus, HDAC6 was proposed as a therapeutic target to provide significant therapeutic benefit to patients with severe immune disorders. CKD-506 is an oral hydroxamate HDAC6 selective inhibitor without genotoxicity. CKD-506 has shown strong therapeutic efficacy in adjuvant-induced arthritis (AIA) rheumatoid arthritis model. Furthermore, CKD-506 showed strong synergistic therapeutic efficacy in combination with methotrexate (MTX). In RA patients' PBMC and fibroblast like synoviocytes (FLS), CKD-506 suppressed inflammatory cytokines such as TNF α , CXCL10 and CCL2 and induced the anti-inflammatory cytokines such as IL-10, strongly implying that CKD-506 may be efficacious in RA patients.

Objective: To evaluate the safety, tolerability, pharmacokinetics (PK), and pharmacodynamics (PD) of CKD-506 in single ascending dose (SAD) and multiple ascending dose (MAD) in healthy volunteers.

Methods: This first-in-human study consisted of two randomized, double-blind, placebo-controlled parts: Part A, 7 SAD cohorts (50 – 1000 mg) and in Part B, 5 MAD cohorts with 14 days treatment (200, 400, 600 mg and 800 mg QD and 400 mg BID). Adverse events (AEs), clinical labs, vital signs and electrocardiogram (ECGs) were evaluated. Plasma PK concentration were assessed by LC-MS/MS. PD was assessed by measuring the acetylated α -tubulin and histone H3 using flow cytometry.

Results: CKD-506 was safe and well-tolerated following single and multiple doses for 14 days without significant changes in vital sign, ECG and laboratory measurements. All treatment-emergent adverse events (TEAEs) were mild in severity and the most common AEs were headache, hot flush, rash, pruritus and abdominal discomfort. Following single doses of CKD-506, CKD-506 was rapidly absorbed with median time to maximum observed concentration (t_{max}) between 0.5-1 hour. Following multiple doses of CKD-506, exposure reached steady state on day 6 for all QD dosing and day 12 for the 400 mg BID dosing. A minimal accumulation was observed with mean accumulation ratio (R_{ac}) ranged from 1.05 to 1.30. The mean changes-from-baseline for acetylated α -tubulin and histone H3 generally displayed a dose-dependent increase in CD3⁺ T cells and monocytes on day 1 and day 14. The maximum levels of acetylated α -tubulin was observed between 1-4 hours post-dose on day 1 and 14 with returned to near basal levels by 24 hours.

Conclusion: CKD-506 was generally safe and well-tolerated following single and multiple doses in healthy volunteers. Plasma exposure was relatively dose proportional. The levels of acetylated α -tubulin increased dose dependently. These results support further clinical development of CKD-506 with once daily dosing regimen for the treatment of RA and other inflammatory and autoimmune diseases.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster III: Biosimilars and New Compounds

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: RA is a debilitating chronic disease with an unmet need for additional therapeutic approaches. Modulating innate neuro-immune reflex pathways by stimulation of the vagus nerve (VNS) could represent a novel means of treating RA (van Maanen MA et al. NatRev Rheumatol. 2009; 5:229-32). We recently reported a 12-week proof of concept study using a VNS device, approved for drug-resistant epilepsy, showing reductions in the DAS28-CRP and in TNF- α and IL-6 levels (Koopman FA et al. PNAS 2016;113:8284). To understand the long term safety and efficacy of this

novel treatment approach, we followed the patients in a 24 months long-term extension study and report on the safety and clinical efficacy data.

Methods: In the primary study, VNS devices were implanted into 17 RA patients, mostly with insufficient response to multiple conventional and biologic DMARDs, on stable background of methotrexate (≤ 25 mg weekly) therapy. The devices electrically stimulated the vagus nerve, 1-4 min/day, over a 12 week open label period. On completion, subjects were offered to enroll into a follow-up study, where the study physicians were given flexibility to alter VNS dosing parameters and/or to add a biologic DMARD to the treatment regimen. DAS28-CRP and Health Assessment Questionnaire-Disability Index (HAQ-DI) were collected over 2 years.

Results: All subjects electively continued on VNS treatment through 24 months of the long term follow-up study. Biologic DMARDs were started in 1 and restarted in 8 of 17 subjects; of these, 4 were non-responders to VNS in the primary study, and 5 had stable improvement but had not yet achieved disease remission on VNS alone (Table 1). At the start of the follow-up study, the mean DAS28-28 and HAQ-DI were significantly reduced compared to the pre-implant baseline (mean difference \pm SE in DAS28-CRP = -1.60 ± 0.37 , $p < 0.0001$; mean difference \pm SE in HAQ-DI = -0.44 ± 0.21 , $p < 0.037$), and the depth of effect was retained through 24 months. No association between DAS28-CRP and stimulation frequency (Range = 1X-8X/day) was observed. At 24 months, both the subjects using VNS monotherapy and those using a combination of VNS and biologic DMARDs exhibited stable improvements in DAS28-CRP and HAQ-DI. No difference in the adverse events profile between the two groups was observed.

Conclusion: The data presented here demonstrate that VNS in subjects with RA is associated with a substantial reduction in disease activity that is sustained for 24 months without untoward safety signals. Further, the data suggest that biological DMARDs may be initiated safely in combination with VNS treatment, though this requires validation in larger cohorts. These results support additional development of VNS devices as an alternative therapeutic approach for RA treatment, which potentially can safely be combined with biologic DMARDs.

Table 1. Two Year Efficacy of VNS Treatment. Mean DAS28-CRP at primary study baseline (month -3.5) and at visits over 2 years of long term follow up (months 0-24).

Study Month	All subjects (n=17)			VNS as Monotherapy (n=8)			VNS + Re-initiated Biologic (n=9)			VNS Monotherapy Survival

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster III: Biosimilars and New Compounds

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: SB4, a biosimilar to the reference ETN, received EU marketing authorisation in January 2016, based on the totality of evidence from pre-clinical and clinical Phase I and III studies that demonstrated similar efficacy, bioequivalence, and comparable safety and immunogenicity to ETN. There are few published data on outcomes of transition from originator to biosimilar outside the controlled setting of randomised clinical trials.

Objectives: Provide real world evidence on the outcomes of transition from ETN to SB4 in routine clinical practice.

Methods: This ongoing observational study is designed to enrol 600 subjects with RA or axSpA, who initiated SB4 as part of routine clinical practice following a minimum of 6 months treatment with a stable dose of originator ETN, at clinics in France, Germany, Italy and Spain. Data are captured from clinic records, retrospectively for 6 months prior to switch and prospectively and/or retrospectively for 6 months following switch. Outcome measures include disease score (DAS-28 for RA, BASDAI for axSpA) over time, clinical characteristics and management, and adverse events. This interim analysis (IA) describes baseline characteristics and clinical outcome 3 months post-initiation of SB4.

Results: In this interim analysis, 255 subjects have been included: 163 with RA and 92 with axSpA, both groups possibly representing longer-standing established disease; neither group experienced a clinically significant difference in disease score from baseline to 3 months post-transition, with mean individual change of 0.0 (95% CI -0.1, 0.2) and 0.4 (95% CI 0.0, 0.9) in RA and axSpA subjects respectively.

Table 1: Baseline characteristics of subjects at transition, and 3-month disease score outcomes

	RA (N=163)		AxSpA (N=92)	
	Mean (SD)	Q1, Q3	Mean (SD)	Q1, Q3

DAS-28, Disease Activity Score 28; BASDAI, Bath Ankylosing Spondylitis Disease Activity Index; BMI, body mass index; SD, standard deviation.

*Data available for 157 and 86 subjects respectively. **Conventional synthetic disease-modifying antirheumatic drug. ***Data available for 109 and 42 subjects respectively.

Conclusion: This IA provides a first insight into clinical outcomes in a contemporary cohort of EU patients with established RA and axSpA, transitioned from originator to biosimilar ETN in a study of clinical practice: data do not indicate loss of treatment effectiveness in the 3 months following transition. Subsequent to these preliminary data, the study will provide ongoing, pertinent information about 3- and 6-month outcomes in these populations, helping to inform evidence-based treatment decisions.

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster III: Biosimilars and New Compounds

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is an autoimmune disease characterized by chronic inflammation of the joints. We found that there was an imbalance between Th17 and Treg cells in the patients with active refractory RA, reduced absolute number of Treg cells was found in these patients. To observe the medium-term curative effect of rapamycin in the treatment of 25 cases newly diagnosed rheumatoid arthritis.

Methods: Collecting 25 patients of newly diagnosed rheumatoid arthritis, which accorded with RA diagnosis standard of ACR in 1987. The patients were treated with rapamycin at a dose of 0.5 mg every 2 days for 24 weeks, then we observed the change of clinical improvement and immunological assessments after 24 weeks.

Results: There was 25 patients were enrolled. After rapamycin treatment for 24 weeks, the mean DAS28 of them was decreased from 5.36[1.42] to 3.45[1.29] (P=0.001). The absolute number of Treg^{CD4+CD25+Foxp3+} cells significantly higher than baseline (30.24 [14.44], 46.64 [27.54], P=0.025). The absolute number of Th17 cells was not significantly different (6.40 [4.46], 7.03 [5.60], P>0.05), and the same as the ratio of Th17/Treg cells (0.25 [0.18], 0.19 [0.16]), P>0.05). Meanwhile, the mean dose of prednisone was decreased from 11.25 mg/d to 9.6 mg/d.

Conclusion: Rapamycin could induce the balance of Th17 cells and Treg cells, especially up-regulate the absolute number of Treg cells, thus induce remission in patients with newly diagnosed RA.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster III: Biosimilars and New Compounds

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: In the United Kingdom (UK) since 2016, etanercept biosimilars (SB4) are since 2016 a first-line treatment option for the management of severe rheumatoid arthritis (RA) defined as non-response to ≥ 2 csDMARDs. However, real world data, including how it compares with the etanercept originator (ETN) are lacking. This study aims to compare the short-term effectiveness of etanercept originator with its biosimilar in patients with RA when used as a first biologic following csDMARDs.

Methods: This study included patients with RA registered with the British Society for Rheumatology Biologics Registers for RA (BSRBR-RA) at the point of starting either ETN or an SB4 since 2016 as their first biologic. Baseline information is collected at drug start and includes demographic and clinical data. Follow-up (FU) data are captured every 6 months and include details on therapy changes, current disease activity, and development of any adverse events. The primary outcome of this study is effectiveness as calculated by change in the 28 joint count disease activity score (DAS28). Only patients with a complete DAS28 at baseline and their first FU were included in the final analysis of this study. Hazard ratios (HR) comparing drug survival and risk of first serious adverse event (SAE) between ETN and SB4 patients were calculated using adjusted Cox regression.

Results: Between January 2016 and 27 March 2018, 322 and 855 patients starting ETN or SB4 respectively as first biologic were recruited to the BSRBR-RA. Complete DAS28 data at baseline and first FU were available for 192 ETN patients and 301 SB4 patients. Patient characteristics were similar between the 2 cohorts (Table). Only the baseline DAS28 was slightly higher in the ETN patients compared with the SB4 patients ($p=0.02$). After adjusting for baseline patient and clinical characteristics, no difference between groups was observed in DAS28 ($p=0.1$) or remission status ($p=0.5$) at first FU.

Thirteen (7%) and 11 (3%) ETN and SB4 patients stopped their respective treatments by the first FU. The adjusted hazard ratio for stopping ETN versus SB4 over this time period was similar (HR=1.0 (95% CI 0.4-2.5); $p=0.9$). Risk of SAEs over the first 6 months was also similar between groups (HR (SB4 versus ETN) =0.5 (95% CI 0.3-1.1); $p=0.1$), with 13 (14%) and 19 (6%) SAEs reported in ETN and SB4 patients respectively until first FU.

Conclusion: In the UK, etanercept biosimilars are now frequently used as first-line biologics in RA patients. These short-term follow-up data demonstrate in routine clinical care that SB4 appears to have comparable short-term effectiveness to ETN in terms of drug response, drug survival and safety profile.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster III: Biosimilars and New Compounds

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Good evidence suggests a relationship between rheumatoid arthritis (RA) and periodontitis. We aimed to investigate if a good oral hygiene could improve activity of RA.

Methods: BHYRRA (Buccal HYgiene and Reduction of activity of RA) is a randomized trial nested in the French early arthritis ESPOIR cohort. The patients with RA according to ACR/EULAR 2010 criteria and included in the ESPOIR cohort were randomized into 2 groups:

- Group A: treated according to a periodontal care program of good oral hygiene proposed to the general population, which included: (1) tooth brushing twice a day with a Triclosan polymer dentifrice (Colgate Total®); (2) mouth rinse once a day with an antiseptic mouthwash including essential oils (Listerine®); (3) scaling by a periodontist twice a year.
- Group B: no specific intervention and no specific information was given to the patients.

In both groups the treatment of RA was conducted according to the decision of the physician.

The primary endpoint was the delta between M12 and M0 DAS28-VS in both groups. The ability of the intervention to decrease the gingiva bacterial load was also analyzed.

Given the fact that it was expected that numbers of patients in whom the intervention will be proposed will not accept it, the primary analysis was a complier average causal effect (CACE) analysis, restricted to patients having their first visit to the dentist planned in group A. Two approaches were used for CACE analyses; 1) weighting and 2) instrumental variable (IV).

PCR analysis of nine periodontal pathogens was performed at M0 and M12.

Results: 472 patients from the ESPOIR cohort were randomized, 238 in the intervention group (A) and 234 in the control group (B). 92/238 from group A accepted the procedure but only 81/92 had a first visit to the dentist. Duration of RA was 9.7 +/- 1.1 years. Baseline DAS28-VS was 2.65 +/- 1.31 and 2.72 +/- 1.26 in group A and B, respectively. Delta DAS was -0.19 +/- 1.37 and -0.02 +/- 1.18 in group A and B respectively (weighted difference: -0.02 (95 %CI -0.38; 0.33), p =0.90; IV: -0.37 (CI 95% -1.12; 0.37) p = 0.33). In anti-CCP positive patients, the delta DAS28-VS was -0.20 +/- 1.51 and 0.03 +/- 1.26 in group A and B respectively (weighted difference: -0.03 (95% CI -0.55; 0.49), p =0.92; IV: -0.43 (CI 95% -1.37; 0.51), p = 0.37). For the patients becoming negative to the red complex, there was a decrease of DAS albeit not significant (-0.30 (95% CI -1.12; 0.51), p=0.47)

Microbiological analysis of the periodontal bacteria indicated a significant decrease in the red complex involved in the pathogenesis of periodontitis; i.e. *Porphyromonas gingivalis* (p = 0.002), *Tannerella forsythia* (p = 0.002) and *Treponema denticola* (p = 0.019).

Conclusion: Following in RA patients the recommendations to the general population for a good oral hygiene decreased the bacterial load of bacteria involved in periodontal disease but did not improve RA activity. In the present study, the lack of clinical effect on RA may be due (1) to the relatively long duration of the disease in the patients enrolled (10 years), and (2) to the very good control of the disease at baseline (DAS28-VS around 2.7). The efficacy of oral prevention, through the above simple approach should be tested in patients with earlier RA and more active disease.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster III: Biosimilars and New Compounds

Background/Purpose: Upadacitinib (UPA), an oral, JAK1-selective inhibitor, demonstrated efficacy through 12 and 24 weeks (wks) in phase 3 trials of patients (pts) with active rheumatoid arthritis (RA) and inadequate response (IR) to csDMARDs and bDMARDs, respectively.^{1,2} Efficacy evaluations at Wk 12 are an important assessment point according to T2T recommendations.³ The purpose of this analysis was to assess the impact of UPA at 12 wks on individual and composite measures of RA disease activity.

Methods: Pts received UPA 15mg or 30mg once daily (QD) or PBO for 12 wks in two phase 3 trials. SELECT NEXT¹ and SELECT BEYOND² enrolled csDMARD- and bDMARD-IR pts, respectively. For this investigation, responses at Wk 12, were defined as $\geq 50\%$ improvement in ACR components. Among ACR50 responders, the proportions of pts achieving $\geq 50\%$ improvement in all 7 components of the ACR response criteria [Tender Joint Count (TJC68), Swollen Joint Count (SJC66), Pt Global Assessment (PtGA), Physician Global Assessment (PhGA), Pt Pain, Health Assessment Questionnaire-Disability Index (HAQ-DI), and high sensitive C-reactive protein (hsCRP)] were assessed. Differences in the cumulative distributions of CDAI, DAS28-CRP, and SDAI between baseline (BL) and Wk 12 were assessed. All analyses were based on observed data without imputation.

Results: Pts in both studies, on average, had established, moderate to severe RA at BL, with (mean) disease durations of 7.3 and 13.2 years, CDAI of 38.2 and 40.9, in csDMARD-IR and bDMARD-IR, respectively; 53% of bDMARD-IR pts had exposure to ≥ 2 bDMARDs.^{1,2} In both populations, significantly more pts on UPA vs PBO achieved $\geq 50\%$ improvements in each ACR component at Wk 12 (Table). Among pts who achieved ACR50 at Wk 12, approximately one-half of the csDMARD-IR and one-third of the bDMARD-IR pts achieved $\geq 50\%$ improvement in all 7 ACR components. While there were no differences at BL, cumulative distributions of CDAI, DAS28-CRP, and SDAI separated by treatment at Wk 12 ($p < 0.001$); for the lowest quartiles for UPA 15mg and 30mg vs PBO, CDAI levels dropped to 6.2 and 5.1 vs 12.5 in csDMARD-IR; and 7.2 and 8.2 vs 13.1 in bDMARD-IR.

Conclusion: In pts with an insufficient response to either csDMARDs or bDMARDs, treatment responses at 12 wks were observed in significantly higher proportions with UPA vs PBO. Favorable effects with UPA were seen in the composite scores and the individual parameters, including PROs and acute-phase reactants.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster III: Biosimilars and New Compounds

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Upadacitinib is an oral, selective inhibitor of Janus kinase 1 (JAK1) which is currently being evaluated for the treatment of several autoimmune disorders, including rheumatoid arthritis (RA). Upadacitinib demonstrated favorable efficacy and acceptable safety in two Phase 2b studies in subjects with moderate to severely active RA who had inadequate response to anti-TNF therapies (BALANCE I) or to methotrexate (BALANCE II). The presented analyses were conducted to characterize the relationships between upadacitinib plasma exposures and various efficacy endpoints, as well as effects on select laboratory parameters of interest to support the selection of doses to evaluate in Phase 3.

Methods: The analyses included data from 574 patients who had completed BALANCE I and II studies. Logistic regression analyses were conducted for the relationship between upadacitinib average plasma concentration during a dosing interval (C_{ave}) and the probability of achieving various efficacy endpoints (ACR50, ACR70, low disease activity and clinical remission based on DAS28CRP) or experiencing a certain degree of change in select laboratory parameters (hemoglobin, NK cells, LDL-C, HDL-C, neutrophils). Data from BALANCE I and II were analyzed separately for efficacy, and data from both studies were pooled for the laboratory parameters analyses.

Figure 1. Model-Predicted Percentage of Subjects with RA who Achieve the Different Efficacy Endpoints or Experience Specific Changes in Laboratory Parameters Based on Exposure-Response Analyses of Phase 2b Studies

Colored lines represent the median predicted percentage of subjects meeting the different efficacy endpoints or changes in laboratory parameters.

Vertical gray lines represent the median C_{ave} for different BID immediate-release doses evaluated in BALANCE I and BALANCE II studies.

Results: The percentage of subjects achieving ACR50, ACR70, low disease activity, and clinical remission increased with increasing upadacitinib plasma exposures. With increasing upadacitinib plasma exposures, there was also an increase in the percentage of subjects experiencing decreases in hemoglobin and NK cells and increases in HDL-C and LDL-C from baseline to Week 12. There was no relationship between upadacitinib plasma exposures and neutropenia (< 1000 cells/L). The model-predicted percentage of subjects who achieve various efficacy endpoints or experience specific changes in laboratory parameters is shown in Figure 1.

Conclusion: Upadacitinib plasma exposures associated with 6 mg BID to 12 mg BID using the immediate-release formulation (equivalent to 15 mg QD to 30 mg QD using the extended-release formulation, respectively) are predicted to achieve near maximum efficacy in RA patients while having limited effects on NK cells, hemoglobin, LDL-C, and HDL-C. Exposures higher than 12 mg BID are not predicted to result in additional efficacy benefits in subjects with RA, but they have the potential for greater effects on laboratory parameters. Results from these analyses supported the evaluation of extended-release formulation 15 mg and 30mg QD in Phase 3 trials in RA.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster III: Biosimilars and New Compounds

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: CT-P13 is a biosimilar prescribed in a number of countries for indications approved for the reference infliximab (RINF) including rheumatoid arthritis (RA), ankylosing spondylitis (AS), and inflammatory bowel diseases. Clinical data of CT-P13 have been analyzed in previous clinical trials, demonstrating non-inferiority of efficacy and equivalence pharmacokinetic profile to RINF. However, there are few studies showing long-term data of its drug survival or safety. This study is to investigate the drug retention rate and safety data of biosimilar CT-P13 in Korean RA patients.

Methods: Subjects were RA patients enrolled in the Korean College of Rheumatology biologics registry (KOBIO). Data from patients who received RINF and CT-P13 were included in the analysis (Dec 2012 ~ Dec 2017). Discontinuation was defined as switching or stopping the biologic agent. Kaplan-Meier curve were used for further analysis. Reason for RINF or CT-P13 discontinuation was also assessed.

Results: Data from 199 RA patients (CT-P13; 147, RINF; 52) were analyzed. The mean age of patients was 51.3 years in the CT-P13 group, and 12% were males. The mean disease duration was 7.7 years. Eighty four percent of CT-P13 treated patients were first-time biologic users. The overall drug retention rate of CT-P13 versus RINF was comparable ($p = 0.8382$), as well as the retention rates of first-line ($p = 0.6609$) and second or more (≥ 2)-line users ($p = 0.9552$) of agents. The reasons for discontinuing were inefficacy (31.8% in CT-P13, 34.8% in RINF), adverse events (20.0% in CT-P13, 23.9% in RINF), clinical improvement (3.0% in CT-P13, 4.3% in RINF), and others (10.4% in CT-P13, 4.3% in RINF). The incidence of adverse events in CT-P13 treated patients leading to discontinuation was comparable to that of RINF; infusion reaction (10.2%), skin eruption (2.0%), and herpes zoster (0.68%).

Conclusion: Our study demonstrates that the drug retention rate of CT-P13 was similar to RINF, and CT-P13 showed a reasonable long-term safety profile comparable to RINF in Korean RA patients.

Changes of CD4-(CD8+) Regulatory T Cells in Rheumatoid Arthritis Patients and during Interleukin-2 Therapy

Xiaoxia Jia¹, Fang Li², Jing Luo³, Chong Gao⁴ and Xiao-Feng Li¹, ¹Rheumatology, the Second Hospital of Shanxi Medical University, Taiyuan, China, ²Department of Rheumatology, the Second Hospital of Shanxi Medical University, Taiyuan, China, ³the Second Hospital of Shanxi Medical University, Taiyuan, China, ⁴Department of Pathology, Brigham and Women's Hospital, Harvard Medical School, Boston, MA, Cambridge, MA

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster III: Biosimilars and New Compounds

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Recent studies have showed that quantitative and/or functional abnormalities of the regulatory T cells (Tregs) may play a vital role in the development of rheumatoid arthritis (RA). It is reported that CD25⁺FOXP3⁺ T cells include CD4⁺CD25⁺FOXP3⁺ T (CD4⁺Tregs) and CD8⁺CD25⁺FOXP3⁺ T cells (CD8⁺ Tregs). CD8⁺ Tregs also have been showed even stronger immunosuppressive function and more sensitive to IL-2 than CD4⁺Tregs in vivo. Our study was designed to clarify the level of peripheral CD8⁺ T cell subsets in RA patients, especially CD4⁺(CD8⁺) CD25⁺FOXP3⁺ T cells, and to investigate the role of recombinant human interleukin-2 (IL-2) in the regulation of CD4⁺(CD8⁺)CD25⁺FOXP3⁺ T cells in RA patients to provide a basis to IL-2 therapy.

Methods: Total 231 Patients with RA were enrolled, including 75 new-onset RA and 156 treated with low dose IL-2 (50 WIU/day for 5 days, subcutaneous injection), and 90 healthy adults were included as controls. The clinical data of RA patients were collected, including gender, age, joint swelling, tenderness and so on. And laboratory parameters were erythrocyte sedimentation rate (ESR), C reactive protein (CRP), rheumatoid factor (RF) and anti-cyclic citrullinated peptide antibody (Anti-CCP). At the same time, the DAS28 score of RA group was calculated. The absolute number of CD4⁺CD25⁺FOXP3⁺ T cells in peripheral blood were detected by flow cytometry. We assume that CD4⁺ T cells with CD25⁺ and FOXP3⁺ were mostly CD8⁺CD25⁺FOXP3⁺ T cells, i.e. 8⁺ Tregs.

Results: As compared with the healthy controls, the absolute number of CD8⁺ Treg cells decreased significantly in the new-onset RA patients [0.92(0.42,1.39) vs 1.31(0.72,2.52), $P < 0.001$]. The absolute number of CD8⁺ Treg cells was significantly negative correlated with tenderness joints, DAS28 score and RF, ($r = -0.249$, $P = 0.032$; $r = -0.294$, $P = 0.010$; $r = -0.365$, $P = 0.001$); The absolute number of CD8⁺ Treg cells was no significantly correlated the swelling of the joints, ESR, CRP, Anti-CCP antibody ($r = -0.199$, $P = 0.087$; $r = -0.202$, $P = 0.082$; $r = 0.008$, $P = 0.947$; $r = -0.083$, $P = 0.480$). After treatment with IL-2, the absolute number of CD8⁺ Treg cells increased significantly as compared with that before treatment [0.88 (0.42,1.51) vs 1.98(0.91,3.37), $P < 0.001$].

Conclusion: The absolute number of CD8⁺ Treg cells in initial diagnosed patients was lower than that of healthy controls, implying that the immunosuppressive function was attenuated by disease itself, rather than immunosuppression therapy, which may be an important factor in the pathogenesis of RA. Low dose IL-2 can expand CD8⁺ Treg cells in peripheral blood, and thereby improve the immune function, so that RA patients were relieved. We are about to detect CD8⁺ Treg cells using more accurate technique to verify this theory.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster III: Biosimilars and New Compounds

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: To describe the use of oral complementary medicine (CM) in people with inflammatory arthritis.

Methods: The Australian Rheumatology Association Database (ARAD), an observational database, collects outcome data from people with rheumatoid arthritis (RA), ankylosing spondylitis (AS), psoriatic arthritis (PsA) and juvenile idiopathic arthritis (JIA). Participants complete semi-annual then annual questionnaires. CM use from baseline questionnaire for participants recruited between 2006 and 2016 was categorised into fatty acids (eg. fish oil, evening primrose oil), herbs (eg. ginger, turmeric) or supplements (eg. glucosamine, vitamins). Changes in CM use over time were also determined.

Results: Of 4,425 ARAD participants 43.4% were taking CM at enrolment (RA: 1,324 (45.7%), AS: 261 (40.7%), PsA 307 (43.2%), JIA: 31 (17.7%)). Use was more prevalent in women (OR 1.37; 95% CI 1.25-1.59), those with tertiary education (OR 1.26; 95% CI 1.10-1.44), private health insurance (OR 1.30; 95% CI 1.01-1.52), drinking alcohol sometimes compared to never (OR 1.24; 95% CI 1.06-1.44), and less prevalent in current smokers (OR 0.75; 95% CI 0.62-0.91). Levels of pain in the last week were not different between CM users and non-users (OR 1.00; 95% CI 1.00-1.00). Overall, 35% were taking fatty acids, 7% herbs and 19% supplements. The most common CMs were fish oils (1,489 (34%)) followed by glucosamine (605 (14%)), although both have declined in use over the last decade (fish oil 2006-2016: 31%-28%, $p=0.85$; glucosamine 20%-9%, $p<0.001$). Over time, there has been increased use of supplements, particularly vitamin D (2006-2016: 1.6%-3.3%, $p<0.001$) and magnesium (2006-2016: 0.4%-2.7%, $p=0.02$), turmeric has also increased (2006-2016: 0%-1.2%, $p<0.001$), while the use of krill oil has declined (2012-2016: 3.9%-0.3%, $p<0.001$) and calcium has remained level (2006-2016: 3.0%-2.4%, $p=0.71$).

Conclusion: Just under half of ARAD participants were taking CM at ARAD entry. Types of CM used by people with inflammatory arthritis appear to change over time but appear to have no influence on levels of pain. Further research could investigate what prompts use of these products.

The Association between Patient Reported Outcomes and Clinical Measures Among Rheumatoid Arthritis Patients: Analyses Using Phase 3 Clinical Trials of Upadacitinib

Vibeke Strand¹, Nemanja Damjanov², Craig Scoville³, Namita Tundia⁴, Heidi S. Camp⁴, Kun Chen⁴, Jessica Suboticki⁴ and Ronald van Vollenhoven⁵, ¹Division of Immunology/Rheumatology, Stanford University, Palo Alto, CA, ²Institute of Rheumatology, Belgrade University School of Medicine, Belgrade, Serbia, ³Idaho Falls Arthritis Clinic, Idaho Falls, ID, ⁴AbbVie Inc., North Chicago, IL, ⁵Amsterdam Rheumatology and Immunology Center ARC, Amsterdam, Netherlands

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster III: Biosimilars and New Compounds

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Patient-reported outcomes (PROs) in RA are important to evaluate total disease impact, although treatment decisions may often be guided by traditional physician-derived measures of disease activity. The purpose of this analysis was to determine the association between PROs and composite outcomes in RA patients receiving the JAK1-selective inhibitor, upadacitinib (UPA), with prior inadequate responses (IR) to conventional synthetic (cs) or biologic (b) DMARD(s).

Methods: Data were analyzed from two 12-week (wk), phase 3, RCTs in csDMARD-IR (SELECT-NEXT) and bDMARD-IR (SELECT-BEYOND) patients receiving UPA 15 or 30 mg daily (QD) or placebo and background csDMARD therapy; as well as from a third trial (SELECT-MONOTHERAPY), in which MTX-IR patients received UPA monotherapy or MTX (blinded) for 14 wks. Moderate and substantial improvements in pain ($\geq 30\%$ and $\geq 50\%$ improvement from baseline [Δ BL], respectively), and normative values in HAQ-DI (≤ 0.25) and functional assessment of chronic illness therapy-fatigue (FACIT-F: ≥ 43.6 , SELECT-NEXT only) were evaluated. Associations between clinical outcomes (total and swollen joint counts [TJC, SJC], physician global assessment [MDGA], CRP and composite measures [ACR, DAS28-CRP, CDAI]), and PROs (pain [VAS], HAQ-DI, patient global assessment [PtGA], morning stiffness, FACIT-F) were evaluated through Pearson correlations and a univariate logistic model, controlling for treatment group and BL value.

Results: Patients enrolled in the SELECT-NEXT and SELECT-BEYOND trials had moderate to severely active RA (mean DAS28-CRP: 5.6 and 5.8, respectively), with disease durations of 7 and 12 years, respectively. In general, Δ BL in pain and HAQ-DI scores were marginally correlated with individual physician-derived measures (SELECT-NEXT: pain, 0.161-0.537, HAQ-DI, 0.081-0.425; SELECT-BEYOND: pain, 0.131-0.511, HAQ-DI, 0.052-0.409); moreover, moderate to high correlations were observed between pain, HAQ-DI and PtGA in both RCTs (SELECT-NEXT: pain, 0.835-0.851, HAQ-DI, 0.418-0.518; SELECT-BEYOND: pain, 0.828-0.871, HAQ-DI, 0.479-0.520). In regression analyses, improvements in individual disease assessments were associated with significant improvements in pain at Wk12 across RCTs (**Table**). In addition, patients with improvement in composite measures were more likely to report substantial improvements in pain. Similar associations were evident for HAQ-DI scores at Wk12 across RCTs (including SELECT-MONOTHERAPY), as well as for FACIT-F in SELECT-NEXT.

Conclusion: Achieving substantial improvements in pain, physical function, and fatigue was associated both with individual physician-derived measures and with composite disease outcomes. These data support the use of PROs in RCTs and also imply that, although PROs may be included in composite endpoints, they are distinct parameters that provide additional insights into the true impact of RA.

Upadacitinib Monotherapy Improves Patient-Reported Outcomes in Patients with Rheumatoid Arthritis and Inadequate Response to Methotrexate

Vibeke Strand¹, Maya Buch², Namita Tundia³, Heidi S. Camp³, Jessica Suboticki³, Debbie Goldschmidt⁴ and Alvin F. Wells⁵, ¹Stanford University, Palo Alto, CA, ²NIHR Leeds Musculoskeletal Biomedical Research Centre, Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom, ³AbbVie Inc., North Chicago, IL, ⁴Analysis Group Inc., New York, NY, ⁵Rheumatology and Immunotherapy Center, Franklin, WI

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster III: Biosimilars and New Compounds

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Upadacitinib (UPA) is a selective JAK-1 inhibitor with demonstrated patient-reported benefits in the treatment of active rheumatoid arthritis (RA).^{1,2} The objective of this analysis was to evaluate the effect of UPA compared to MTX on PROs in the SELECT-MONOTHERAPY randomized controlled trial (RCT).

Methods: SELECT-MONOTHERAPY (NCT02706951) is a Phase 3 RCT conducted in patients with active RA with inadequate responses to MTX (MTX-IR) that were switched to UPA monotherapy (15mg or 30 mg once daily) or continued on MTX. The following PROs were included: Patient Global Assessment of Disease Activity (PtGA) by visual analog scale (VAS), pain by VAS, Health Assessment Questionnaire Disability Index (HAQ-DI), and health-related quality of life (HRQOL) by 36-Item Short Form Health Survey (SF-36). Least squares mean (LSM) changes from baseline to Week 14 were based on mixed effect repeated measures models. The percentage of patients reporting improvements \geq minimum clinically important differences (MCID) in PROs from baseline to Week 14 and scores \geq normative values were determined; comparisons between groups used chi-square tests, statistical significance at the 5% level.

Results: Data from 648 patients (215, 217, and 216 in the UPA 30 mg, UPA 15mg, and MTX group [mean dose: 17 mg/week], respectively) were analyzed. Mean age was 54.3 years, 80.7% were female, and 42.3% had RA for ≥ 5 years. At Week 14, both UPA doses resulted in statistically significant LSM changes from baseline vs MTX in PtGA, pain, HAQ-DI, SF-36 Physical (PCS) and Mental Component Summary (MCS), and all SF-36 domain scores (Table). Compared with MTX, statistically more patients reported improvements \geq MCID across all PROs in UPA 30 mg and all but SF-36 MCS and SF domain scores in UPA 15 mg (Table). Scores \geq normative values were reported across all PROs in UPA 30mg and all but SF-36 MCS and RP, GH, RE, and MH SF-36 domains in UPA 15 mg.

Conclusion: Treatment with UPA 15 mg or 30 mg as monotherapy for 14 weeks resulted in statistically significant and clinically meaningful improvements in PROs compared with MTX, including disease activity, pain, physical function, and HRQOL among MTX-IR patients.

The Impact of Rheumatoid Arthritis on Patient-Reported Outcomes: Comparison between Sarilumab Clinical Trials and Real-World Patient Data

Vibeke Strand¹, Colleen M. Carpinella², Lulu K. Lee², Susan Boklage³ and Matthew Reaney⁴, ¹Stanford University School of Medicine, Palo Alto, CA, ²Kantar Health, San Mateo, CA, ³Regeneron Pharmaceuticals, Inc., Tarrytown, NY, ⁴Sanofi, Guildford, United Kingdom

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster III: Biosimilars and New Compounds

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) and its treatment have significant impacts on health-related quality of life (HRQoL), work productivity (WP) and activity participation. Data are limited comparing the magnitude of impacts observed in routine clinical practice and randomized controlled trials (RCTs). This study evaluated the impact of RA on HRQoL, WP and activity participation among adult RA patients in the US general population compared with patients from two sarilumab pivotal phase 3 RCTs. Sarilumab is a human anti-IL-6R α monoclonal antibody for treatment of moderate-to-severely active RA.

Methods: “Real world” data were from adult participants of the cross-sectional 2015 US National Health and Wellness Survey (NHWS) with a patient-reported diagnosis of RA, moderate/severe disease activity and administered disease-modifying anti-rheumatic drugs (DMARDs) at the point of survey. RCT data were from MOBILITY – Part B and TARGET trials comparing the efficacy and safety of sarilumab subcutaneous (SC) 150 mg and 200 mg every 2 weeks

Figure. SF-36 individual domain scores for NHWS versus MOBILITY and TARGET, respectively

NHWS vs MOBILITY

NHWS vs TARGET

(q2w)plus methotrexate in MOBILITY or conventional DMARDs in TARGET versus placebo in patients with moderate-to-severely active RA and inadequate responses to methotrexate (MTX-IR, MOBILITY) or tumor necrosis factors inhibitors (TNF-IR, TARGET). HRQoL was measured using the Short Form-36v2 (SF-36v2) in the NHWS, and both RCTs at baseline and Week 24; WP impairment (WPI) and activity impairment (AI) were measured via the WPAI scale in the NHWS and MOBILITY. Bivariate analyses evaluated between-group differences in SF-36v2 physical (PCS) and mental (MCS) component summary and domain scores and WPAI absenteeism, presenteeism (%work time missed), overall WPI and AI.

Results: Mean ages of the analyzed cohorts were 54, 51 and 53 years; 61%, 82%, and 80% were female, respectively in NHWS (n=2016), MOBILITY (n=799) and TARGET (n=365). At baseline, versus NHWS patients, those enrolled in MOBILITY reported greater presenteeism (47.25 vs 37.50; $P < 0.001$), overall WPI (51.29 vs 43.11; $P = 0.001$) and AI (62.42 vs 50.96; $P < 0.001$). Patients in MOBILITY and TARGET reported significantly lower baseline scores versus NHWS in SF-36v2 PCS (31.27, 29.42 vs 38.54) MCS (38.86, 38.73 vs 43.97), and all domain scores ($P < 0.001$; Figure) indicating greater HRQoL impairment. At Week 24 both trial cohorts reported improved HRQoL (Figure) and AI in MOBILITY (34.08 vs 39.76, respectively; $P < 0.05$) following treatment with sarilumab than the NHWS cohort scores.

Conclusion: Patients in both sarilumab RCTs reported worse baseline HRQoL, and in MOBILITY greater WPI and AI than NHWS RA patients. After 24 weeks treatment with sarilumab, both RCT cohorts reported improvements exceeding NHWS scores, with few exceptions. These data offer perspective on the benefits of sarilumab treatment on HRQOL, **WP** and **AI**.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster III: Biosimilars and New Compounds

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Sarilumab is a human monoclonal antibody that binds to membrane and soluble IL-6R, which is approved for the treatment of moderate to severe rheumatoid arthritis (RA) in adult patients. In MONARCH (NCT02332590), sarilumab 200 mg monotherapy administered every 2 weeks (q2w) was superior to adalimumab monotherapy 40 mg q2w, among patients with RA intolerant of, inappropriate candidates for, or inadequate responders to methotrexate (MTX-IR).¹ Safety profiles of both therapies were consistent with previously reported data with this class.¹ Patients completing MONARCH could enter the open-label extension (OLE [maximum duration 276 weeks]), where all patients received sarilumab 200mg q2w. The objective of the study was to compare patient-reported outcomes (PROs) among patients remaining on sarilumab (continuation group) vs patients switching from adalimumab to sarilumab (switch group) in the OLE.

Methods: PROs assessed at entry into the OLE and at week 24 of the OLE are shown in the Table. Patient global assessment of disease activity (PtGA) by visual analog scale (VAS), pain VAS and Health Assessment Questionnaire Disability Index (HAQ-DI) were also assessed at week 48 of the OLE. *P*-values for all PROs in the OLE were considered nominal. Available safety data were reported for all patients who reached week 52 of the OLE as of March 2017.

Table. Mean scores for PROs at week 24 of the double-blind MONARCH study (week 0 of OLE, week 0E) and at week 24 of the OLE (week 24E) of MONARCH

Results: Of 321 patients who completed MONARCH, 320 entered the OLE; 155 in the switch and 165 in the continuation groups. From entry to the OLE through week 24 of the OLE, when all patients received sarilumab, the switch and continuation groups reported further improvements in PROs, including FACIT-F and RAID. Patients in the continuation group reported better SF-36 physical component summary (PCS), physical and social functioning domain scores, and less work days missed due to RA ($P \leq 0.05$) (Table). PtGA VAS, pain VAS, and HAQ-DI were stable in both groups from week 24 of the OLE through week 48 of the OLE (data not shown). Available safety data showed 76.1% vs 70.9% treatment-emergent adverse events (TEAEs), 11.0% vs 3.6% serious adverse events, and 6.5% vs 7.3% TEAEs leading to treatment discontinuation in the switch and continuation groups, respectively. Two deaths occurred in the switch and one in the continuation groups.

Conclusion: Sarilumab was superior to adalimumab in many PROs at the end of MONARCH. In the OLE, where all patients received sarilumab, patients in the switch group reported similar improvements in PROs as the continuation group, with the two groups reporting similar outcomes by weeks 24 and 48 of the OLE, except in SF-36 PCS, physical function and social function domains, and work days missed due to RA, where patients in the switch group reported better scores.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster III: Biosimilars and New Compounds

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Compared to ETN, GP2015 has equivalent efficacy, and comparable safety and immunogenicity in patients with chronic plaque-type psoriasis.¹ The purpose of this study is to compare the efficacy and safety of GP2015 and ETN and evaluate the effects of switching from ETN to GP2015 in patients with moderate-to-severe rheumatoid arthritis (RA).

Methods: EQUIRA was a 48-week, randomized, double-blind, Phase 3, two treatment period confirmatory study. The primary endpoint was equivalent change from baseline (BL) in DAS28-CRP at week 24. Patients ≥ 18 years with active RA (ACR 1987 or ACR/EULAR 2010 criteria for ≥ 6 months before BL and active disease defined as DAS28-CRP ≥ 3.2 and CRP > 5 mg/L or ESR ≥ 28 mm/h) and inadequate response to methotrexate (MTX) were randomized 1:1 to 50 mg GP2015 or ETN subcutaneously once weekly for 24 weeks (Treatment period 1 [TP1]). Patients with at least moderate EULAR response at Week 24 either continued GP2015 treatment or, in the ETN group, were switched to receive 50 mg GP2015 up to 48 weeks (Treatment period 2 [TP2]). All patients continued to receive concomitant MTX (10–25 mg/week) at a stable dose and folic acid. Efficacy outcome measures included change in DAS28-CRP, EULAR and ACR20/50/70 responses.

Results: Baseline characteristics were comparable between the GP2015 (n=186) and ETN (n=190) groups. The primary endpoint for equivalence during TP1 was met and previously presented.² At Week 48, the ACR 20 response rates were

comparable between patients who continued on or switched to GP2015 (Figure 1). In TP2, treatment-emergent adverse events (AEs) (Figure 2) occurred in 42.9% vs 38.0% patients with only 13.1% vs. 11.4% considered drug related in the continued GP2015 (n=175) vs the switched (n=166) groups; serious AEs occurred in 2.3% vs 2.4% patients (TP2 safety set). Injection site reactions occurred in 6 (3.6%) patients in the switched group but none in the continued GP2015 group. In TP2, four (2.4%) patients in the continued GP2015 group had single-event, very low titer, non-neutralizing antidrug antibodies detected.

Conclusion: The efficacy of GP2015 over 48 weeks was comparable to that of ETN. In addition, the switch from ETN to GP2015 did not impact efficacy and safety of etanercept in patients with moderate-to-severe RA.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Treatments Poster III: Biosimilars and New Compounds

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The orally administered, selective inhibitor of Janus Kinase 1 (JAK1), filgotinib (FIL), is currently being investigated for the treatment of rheumatoid arthritis (RA) in Phase 3 studies and in other inflammatory diseases. The long-term safety and efficacy of FIL in patients (pts) with RA is being evaluated in the DARWIN 3 (Phase 2b) open-label extension (OLE).

Methods: Two 24-week Phase 2b studies, DARWIN 1 and 2 (Ref 1, 2) evaluated the safety and efficacy of FIL in pts with moderately to severely active RA. Eligible pts from these studies could enroll in DARWIN 3. In this OLE study, pts received FIL 200 mg QD or 100 mg BID or 100 mg QD (US males only). Here we present cumulative safety data (from the first dose of FIL in the DARWIN program through 20 Feb 2018) and efficacy data (from DARWIN 3 Day 1 to Week 132).

Results: Of 877 pts from DARWIN 1 and 2, 790 (90%) completed the study, and 739 (84%) enrolled in DARWIN 3; 603 (82%) were female, mean age was 53 years. At analysis, 469/739 (64%) remained in the OLE. Cumulative patient years of exposure (PYE) was 2081, median time on study drug was 1197 days. Key safety data are summarized in Table 1; laboratory abnormalities are shown in Table 2. No new trends or safety signals were identified. Efficacy data revealed that 89%, 70%, and 49% of pts had ACR20/50/70 responses, respectively, and 69% achieved DAS28-CRP ≤ 3.2 (observed case analysis).

Conclusion: Filgotinib continues to demonstrate a favorable safety and tolerability profile in pts with RA over a 2.5-year period, with maintenance of therapeutic response in the long-term.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: To investigate improvement in fatigue in adult patients with active psoriatic arthritis (PsA) treated with intravenously administered (IV) golimumab, an anti-TNF α monoclonal antibody, and to evaluate improvement in fatigue at Week 8 in predicting ACR 20, 50, minimal disease activity (MDA), and health-related quality of life (HRQoL) outcomes at Week 24.

Methods: GO-VIBRANT is a Phase 3, multicenter, randomized, double-blinded, placebo-controlled trial. Adults with active PsA who were biologic-naïve (n=480; aged ≥ 18 years) were randomized to IV golimumab 2 mg/kg at Weeks 0 and 4 and every 8 weeks thereafter (n=241), or placebo at Weeks 0, 4, 12, and 20 with crossover to IV golimumab at Week 24 (n=239). Fatigue was measured using the Functional Assessment of Chronic Illness Therapy-Fatigue (FACIT-F), and HRQoL and physical function were measured by the Short-Form 36 (SF-36) and Health Assessment Questionnaire Disability Index (HAQ-DI). ANCOVA, T-test, CMH test, and Chi-square test were used for various analyses.

Results: There was greater mean improvement in the FACIT-F score from baseline with IV golimumab than placebo at Weeks 8, 14, and 24 (7.9 vs 2.0; 8.4 vs 2.2; 9.2 vs 2.3, respectively, all $p < 0.0001$) (Table 1a). A larger proportion of golimumab-treated patients achieved a ≥ 4 -point improvement in FACIT-F as early as Week 8 vs placebo ($p < 0.0001$) (Table 1b). Similar results were found after adjusting for ACR 20 and 50 response. General linear models suggested patients with clinically meaningful improvement in fatigue (≥ 4 points) at Week 8 (on average) achieved improvements in HAQ-DI and (SF-36) Mental Component Summary (MCS) and Physical Component Summary (PCS) at Week 24 (Table 2b). Logistic regressions suggested that clinically meaningful improvement in fatigue at Week 8 was associated with ACR 20 and ACR 50 responses, as well as clinically meaningful improvements in SF-36 MCS, PCS (≥ 5 points), and HAQ-DI (≥ 30) at Week 24, but not MDA responses (OR 1.54 [95% CI 0.89-2.67, p -value 0.1184) (Table 2a). Fatigue improvements at Week 8 did not predict normal SF-36 MCS and PCS scores (≥ 50) at Week 24.

Conclusion: Adult patients with active PsA treated with IV golimumab showed larger mean improvement in fatigue vs placebo. Early improvement in fatigue is associated with 24-week outcomes in ACR 20, 50, and HRQoL.

Table 1a. Summary of Change from Baseline in FACIT-Fatigue Through Week 24 Without ACR 20 and 50 adjustments

Mean \pm SD change from baseline in FACIT-F score	Time point	Golimumab (N is between 231 - 233)	Placebo (N=between 221-225)	P-value*
	Week 8	7.9 \pm 9.53 (n=232)	2.0 \pm 7.89 (n=225)	<0.0001
	Week 14	8.4 \pm 9.86 (n=233)	2.2 \pm 7.60 (n=222)	<0.0001
	Week 24	9.2 \pm 9.77 (n=231)	2.3 \pm 7.80 (n=221)	<0.0001
*p-value is based on ANCOVA controlling for baseline MTX usage (Yes, No) and baseline FACIT-fatigue score.				
1b. Number of Subjects Who Achieved at Least a 4-Unit Improvement from Baseline in FACIT-Fatigue Through Week 24				
Number (%) of patients who achieved ≥ 4 -unit improvement from baseline in FACIT-F score	Week 8	161 (69.4) (n=232)	91 (40.4) (n=225)	<0.0001**
	Week 14	159 (68.2) (n=233)	92 (41.4) (n=222)	<0.0001**
	Week 24	162 (70.1) (n=231)	95 (43.0) (n=221)	<0.0001**
**p-value is based on CMH test controlling for baseline MTX usage (Yes, No)				

Table 2a. Logistic regression of ACR 20, 50, Minimal Disease Activity, and HRQoL at Week 24 (dependent variable) on FACIT-fatigue improvement of ≥ 4 at Week 8 (independent variable)

	Odds ratio	95% CI	P-value*
Week 24			
ACR 20 (N=457)	1.98	1.28-3.07	0.0022
ACR 50 (N=457)	2.19	1.33-3.60	0.0020
HAQ-DI (≥ 30) (N=449)	2.31	1.53-3.51	<.0001
Minimal Disease Activity (N=449)	1.54	0.89-2.67	0.1184
SF-36 MCS (≥ 50) (N=457)	0.94	0.63-1.41	0.7615
SF-36 PCS (≥ 50) (N=457)	1.14	0.63-2.07	0.6634
SF-36 MCS improvement (≥ 5 points) (N=457)	2.22	1.48-3.34	0.0001
SF-36 PCS improvement (≥ 5 points) (N=457)	2.20	1.45-3.33	0.0002

*p-value is based on Chi-Square test controlling for treatment

2b. General linear model of quality of life parameters at Week 24 (dependent variable) on FACIT-fatigue improvement of ≥ 4 at Week 8 (independent variable)

	Estimate**	P-value*
Week 24		
HAQ-DI (N=449)	0.229	<.0001
SF-36 MCS (N=457)	-2.842	0.0003
SF-36 PCS (N=457)	-3.340	<.0001

*p-value is based on t-test controlling for baseline value of quality of life parameters.

All variables are based on observed score, **estimate represents the average impact of having a 4-point FACIT-F improvement (compared to not having a 4-point FACIT-F improvement) on the quality of life parameters

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Improving health-related quality of life (HRQoL) is a key goal of psoriatic arthritis (PsA) therapy. Secukinumab, a fully-human IL-17A inhibitor, has been shown to rapidly and sustainably improve multiple clinical domains of PsA. This comprehensive pooled analysis assessed the impact of secukinumab on HRQoL, assessed by the Short Form-36 Health Survey (SF-36), in TNF inhibitor (TNF)-naïve and TNF inhibitor inadequate responder/intolerant (TNF-IR) patients (pts) with PsA in FUTURE 2, 3, 4 and 5 (NCT01752634; NCT01989468; NCT02294227; NCT02404350).

Methods: Pts with active PsA, stratified by TNF status, were randomized to subcutaneous placebo (PBO) or secukinumab 75 mg (FUTURE 2), 150 mg (FUTURE 2, 3, 4, 5), 150 mg no load (FUTURE 4, 5) or 300 mg (FUTURE 2, 3, 5) administered at baseline (BL) and Wks 1, 2, 3 and 4, followed by every 4 wks (or every 4 wks from BL in no load arms). At Wk 16 or 24, pts on PBO were re-randomized to secukinumab. Mixed-model for repeated measures was used to assess change in SF-36 from BL to Wk 16; observed data are presented at Wk 52. The proportion of pts reporting improvements meeting or exceeding the minimal clinically important differences for SF-36 physical (PCS responders), mental component

summary (MCS responders) and individual SF-36 domains was assessed. Non-responder imputation was used, and the proportion of SF-36 responders was compared using Fisher's exact test. Pooled data for pts receiving licensed doses of secukinumab (300 or 150 mg) or PBO are shown.

Results: Of 2049 pts overall, 461, 572, 335 and 681 were in the secukinumab 300 mg, 150 mg, 150 mg (no load) and PBO groups, respectively, of whom approx. 30% were TNF-IR. Least squares mean changes from BL in PCS and MCS at Wk 16 were significantly improved vs PBO for all secukinumab doses, overall and in both TNF-naïve and TNF-IR pts (Table 1). All individual domain scores were also significantly improved with secukinumab vs PBO, except role-emotional in TNF-IR pts with secukinumab 150 mg. There was a significantly higher proportion of SF-36 responders (PCS, MCS and individual domains) in the secukinumab groups at Wk 16 vs PBO in the overall sample (Table 2), except for role-emotional with secukinumab 150 mg. There were consistent trends for higher SF-36 response rates with secukinumab vs PBO regardless of TNF status, with higher SF-36 response rates in TNF-naïve pts. Improvements in PCS, MCS, individual domain scores and response rates were sustained to Wk 52.

Conclusion: Secukinumab 300 mg and 150 mg offered significant and sustained improvements in HRQoL (SF-36) up to 52 wks in pts with PsA, regardless of TNF status.

Table 1. Least squares mean changes from baseline to Week 16 in SF-36 scores in TNF-naïve and TNF-IR patients in a pooled analysis of FUTURE 2, FUTURE 3, FUTURE 4, and FUTURE 5 RCTs.

LS mean change from baseline	Secukinumab 300 mg			Secukinumab 150 mg			Secukinumab 150 mg (no load)			Placebo

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: In the randomized, placebo (pbo)-controlled Phase III ASTRAEA study (ClinicalTrials.gov, NCT01860976) patients (pts) with active psoriatic arthritis (PsA) were randomized to abatacept (ABA) or pbo; ABA significantly improved ACR20 responses at 24 weeks (wks).¹ MTX was permitted but not required; randomization was by concurrent MTX resulting in a subgroup of pts receiving ABA or pbo without MTX. This *post hoc* analysis evaluates the efficacy of ABA in pts not receiving MTX.

Methods: Pts with PsA and inadequate response/intolerance to conventional synthetic (cs)DMARDs were randomized (1:1) to SC ABA 125 mg or pbo weekly for 24 wks. At Wk 16, pts without $\geq 20\%$ improvement in joint counts escaped to open-label ABA.¹ MTX, other csDMARDs and corticosteroids (≤ 10 mg prednisone equivalent) at enrollment could be continued at a stable dose. Baseline pt characteristics were analyzed descriptively by concomitant MTX use. Outcomes including ACR20 responses (95% CI) and adjusted mean changes in DAS28 (CRP) from baseline were evaluated in pts not receiving MTX.

Results: Of 424 randomized pts, 168 were not receiving concomitant MTX (ABA [n=84], pbo [n=84]). Pts not receiving MTX vs pts receiving MTX were more likely to be from N America, less likely to be from S America, had longer disease duration, and higher rates of TNF inhibitor or experience with ≥ 2 prior csDMARDs (Table 1). In pts not receiving MTX, the percentage of female pts and baseline structural damage were greater in the ABA vs pbo group. At Wk 24, ABA without MTX significantly increased ACR20 responses (95% CI) vs pbo (32.1% [22.2,42.1] vs 11.9% [5.0, 18.8]; Figure 1) and improved adjusted mean changes in DAS28 (CRP) from baseline to Wk 24 (95% CI) vs pbo (−1.49 [−1.87, −1.12] vs −0.68 [−1.11, −0.26]; adjusted difference −0.81 [−1.34, −0.28]; Figure 2).

Conclusion: In this *post hoc* analysis of ASTRAEA, abatacept without MTX significantly improved ACR20 responses and DAS28 (CRP) in pts with PsA. Improvements in outcomes in the pbo group help characterize the true pbo response and the variable nature of PsA symptoms. These data suggest that abatacept without MTX may be successfully used in pts with PsA and inadequate response/intolerance to MTX.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Treatment

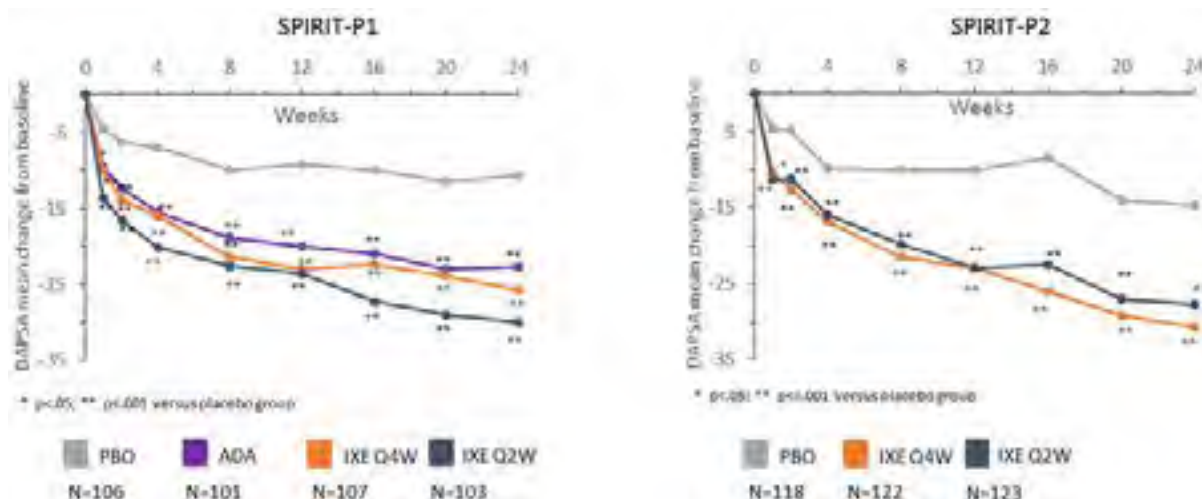

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The DAPSA is a composite tool that assesses several domains of psoriatic arthritis (PsA) manifestations and was developed as a disease activity measure for clinical trials and clinical practice. Ixekizumab is a high affinity mAb against IL-17A recently approved for the treatment of PsA, and in this analysis, we evaluated the impact of ixekizumab treatment on disease activity assessed with the DAPSA through 52 weeks in patients who are biologic DMARD (bDMARD)-naïve or TNF- inadequate responders (TNF-IR).

Methods: Data from the 24-week, randomized, double-blind, placebo-controlled periods from 2 Phase 3 clinical trials (SPIRIT-P1, NCT01695239; SPIRIT-P2, NCT02349295) and their extension periods were analyzed. Patients from SPIRIT-P1 were bDMARD-naïve (N=417) and patients from SPIRIT-P2 had inadequate response or intolerance to TNF inhibitors (N=363). Patients were randomized to receive subcutaneous placebo (PBO), adalimumab (ADA, SPIRIT P1 only) or 80 mg ixekizumab every 2 (IXE Q2W) or 4 wks (IXE Q4W), after a 160 mg starting dose. The components of the DAPSA (68 tender joint counts, 66 swollen joint counts, patient assessment of pain, patient global assessment and CRP) were assessed at each visit. Comparisons versus placebo were made on changes in each component of DAPSA and the composite DAPSA score through week 24 using mixed effects model for repeated measures. Mean change values were reported through week 52 for patients initially randomized to ixekizumab treatment arms for the intent-to-treat population using last observation carried forward for imputing the missing values.

Results: Baseline DAPSA was 44.7 for bDMARD- naïve and 50.4 for TNF-IR patients. After 24 weeks of treatment in bDMARD-naïve patients, the mean change from baseline in DAPSA was -25.7 (IXE Q4W), -30.0 (IXE Q2W), -22.6

(ADA) versus -10.7 (PBO; $p<0.001$ vs PBO for all comparisons; FIGURE). Similarly, in TNF-IR patients, mean change from baseline in DAPSA was -30.6 (IXE Q4W), -27.7 (IXE Q2W) vs -14.7 (PBO; $p<0.001$ vs PBO for all comparisons; FIGURE). In both populations, significant differences versus PBO were observed as early as Week 1. Furthermore, improvements persisted through 52 weeks with changes of -31.0 (IXE Q4W) and -33.8 (IXE Q2W) in the bDMARD-naïve population and -31.7 (IXE Q4W) and -32.1 (IXE Q2W) in the TNF-IR population from baseline to week 52. Consistent, rapid and sustained improvements were observed with each component of the DAPSA.

Conclusion: Ixekizumab treatment resulted in significant and rapid improvements in DAPSA and its components from week 1 to week 24 which persisted through 52 weeks in 2 independent trials, SPIRIT-P1 (bDMARD-naïve patients) and SPIRIT-P2 (TNF-IR patients).

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Secukinumab, a fully human monoclonal IgG1 antibody that neutralizes IL-17A, has shown significant and sustained improvement in the signs and symptoms of active ankylosing spondylitis (AS) through 3 years in the MEASURE 2 study (NCT01649375).¹ Here, we report the longer-term (4-year) efficacy and safety of subcutaneous (s.c.) secukinumab 150 mg in the MEASURE 2 study.

Methods: AS patients (pts; N = 219) were randomized to receive s.c. secukinumab 150 mg, 75 mg or placebo at baseline, Weeks (Wks) 1, 2 and 3 and every 4 wks from Wk 4. At Wk 16, placebo-treated pts were re-randomized to receive secukinumab 150/75 mg. Efficacy results are reported for pts initially randomized to secukinumab 150 mg and those who switched from placebo to secukinumab 150 mg at Wk 16 (N = 106). Outcome measures at Wk 208 included ASAS20 and 40, BASDAI, SF-36 PCS, and ASAS partial remission. Analyses stratified by anti-TNF status (anti-TNF-naïve and anti-

TNF inadequate response [IR]) were pre-specified. Safety analysis included all pts who received ≥ 1 dose of secukinumab. Results are reported as observed.

Results: The retention rate from Wk 16 to 208 was 85% (85/100) for secukinumab 150 mg. Sustained improvements were observed with secukinumab 150 mg across all endpoints through 4 years (Table). These improvements were maintained regardless of prior exposure to anti-TNF therapy; greater responses were demonstrated in anti-TNF-naïve pts. Over the entire study period, the mean exposure (\pm SD) to secukinumab was 1189.3 ± 452.9 days. Exposure-adjusted incidence rates (per 100 pt-years) with any secukinumab dose for selected adverse events were: serious infections/infestations (1.5), *Candida* infections (1.2), Crohn's disease (0.6), major adverse cardiovascular events (0.6), uveitis (0.6), and malignant/unspecified tumours (0.4).

Conclusion: Secukinumab 150 mg provided sustained improvement in the signs, symptoms, and physical function in pts with AS through 4 years of treatment with 85% retention rate. The safety profile of secukinumab remained favorable and was consistent with previous reports.¹⁻³ References: 1. Marzo-Ortega, et al. RMD Open. 2017;3:e000592; 2. Marzo-Ortega et al. Ann Rheum Dis. 2016;75:812-3; 3. Baraliakos X, et al. Clin Exp Rheumatol 2017.

Table. Clinical improvements with secukinumab 150 mg at Weeks 52 and 208

Variable	Week	Secukinumab 150 mga		
		Total	Anti-TNF-naïve	Anti-TNF-IR
ASAS20, % responders (n)	52	74.2 (93)	80.0 (60)	63.6 (33)
	208	73.3 (86)	74.6 (59)	70.4 (27)
ASAS40, % responders (n)	52	57.0 (93)	63.3 (60)	45.5 (33)
	208	60.5 (86)	62.7 (59)	55.6 (27)
BASDAI, mean change \pm SD (n)	52	-3.2 \pm 2.3 (93)	-3.3 \pm 2.3 (60)	-3.0 \pm 2.1 (33)
	208	-3.2 \pm 2.3 (86)	-3.5 \pm 2.4 (59)	-2.7 \pm 2.0 (27)

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: In PSUMMIT 1&2, Phase 3 trials of ustekinumab (UST) in adults w/ active psoriatic arthritis (PsA), 30.1% & 22.4% of patients (pts) had peripheral arthritis w/ physician-reported spondylitis (PA-PRS), respectively. To evaluate the proportion of anti-tumor necrosis factor (TNF)-naïve pts w/ PA-PRS from pooled data in PSUMMIT 1&2

treated w/UST achieving Ankylosing Spondylitis Disease Activity Score (ASDAS) responses and other axial disease response measures.

Methods: Pts had active PsA (≥ 5 swollen & tender joints, CRP ≥ 3.0 mg/L) for ≥ 6 mo despite treatment w/ csDMARDs &/or NSAIDs (PSUMMIT 1&2) &/or anti-TNF agents (PSUMMIT 2). In both studies, pts were randomized to SC injections of placebo (PBO) or UST 45mg or 90mg at wks 0, 4 & every 12 wks. PBO pts crossed over to UST 45mg at wk 24. At wk 16, early escape (PBO, UST 45mg; UST 45mg, UST 90mg; UST 90mg, UST 90mg) was possible. The proportion of pts achieving ASDAS responses of inactive disease (<1.3), major improvement (decrease ≥ 2.0), & clinically important improvement (decrease ≥ 1.1) at wks 12 & 24 were calculated. Modified Bath Ankylosing Spondylitis Disease Activity Index (mBASDAI) scores were calculated at wks 12 & 24 (based upon BASDAI w/o Q#3).

Results: Of 747 TNF-naïve pooled pts, 223 had PsAw/ PA-PRS. For the PA-PRS subset, baseline mean scores included BASDAI 6.57 (UST 45mg), 6.60 (UST 90mg), and 6.37 (PBO); ASDAS 3.86 (UST 45mg), 3.90 (UST 90mg), 3.68 (PBO); BASDAI Q#2 6.62 (UST 45mg), 6.84 (UST 90mg), 6.14 (PBO); and mBASDAI 6.52 (UST 45mg), 6.56 (UST 90mg), 6.27 (PBO). A numerically greater change from baseline in mBASDAI was achieved in both UST 45mg & 90mg groups vs PBO at both wks 12 and 24 (Table 1). Additionally, significantly greater proportions of pts in both UST 45mg & 90mg groups vs PBO achieved ASDAS inactive disease by wk 24 (Table 2). Similarly, by wk 24, significantly greater proportions of pts in both 45mg & 90mg UST groups vs PBO achieved ASDAS major improvement and clinically important improvement.

Conclusion: Approximately half of UST-treated PA-PRS pts attained meaningful improvements in ASDAS by wk 24, and similar numerically greater changes from baseline were observed in mBASDAI. These results are limited and should be interpreted with caution as this was a heterogenous patient group in the absence of definitive imaging, and improvements in extra-axial domains, such as peripheral arthritis and enthesitis, may have contributed to the changes in ASDAS and mBASDAI scores. Further research is needed to examine the efficacy of UST in treatment of spondylitis in PsA patients.

Table 1. Mean change from baseline in mBASDAIa in PA-PRS subset at wk 12 & 24 in PSUMMIT 1&2

	PBO	UST 45mg	UST 90mg	UST Combined
PA-PRS Subset, n	84	66	73	139
Wk 12, n	77	61	70	131
Mean change (SD)	-0.52 (1.47)	-1.81 (1.84)	-1.78 (2.11)	-1.79 (1.98)
Wk 24, n	71	63	69	132
Mean change (SD)	-0.59 (1.58)	-1.73 (2.13)	-2.41 (2.20)	-2.09 (2.18)

BASDAI=Bath Ankylosing Spondylitis Disease Activity Index; mBASDAI=modified BASDAI; PA-PRS=peripheral arthritis with physician-reported spondylitis; PBO=placebo; SD=standard deviation; UST=ustekinumab

a mBASDAI scores were calculated based on the BASDAI with question #3 removed ($0.25[F+S+E+0.5 \times \text{DURATION}]$).

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: C-OPTIMISE is the first trial to evaluate whether certolizumab pegol (CZP) can be reduced/discontinued in patients with radiographic (r)-axSpA/ankylosing spondylitis (AS) and non-radiographic (nr)-axSpA achieving sustained remission after 48 weeks' (wks') treatment. Here, we report interim efficacy and safety data for both subpopulations from the ongoing trial.

Methods: Up to wk 48, C-OPTIMISE (NCT02505542) was open-label (Part A), followed by 48-wk parallel-group, double-blind, placebo-controlled treatment (full dose and half dose) to wk 96 (Part B). Patients with adult-onset axSpA of <5 years' duration, fulfilling ASAS classification criteria, were recruited. Part A: patients received CZP (400mg at wks 0/2/4, then 200mg Q2W); patients achieving sustained remission (ASDAS<1.3 at wk 32 and <2.1 at wk 36 [or vice versa], and <1.3 at wk48) were eligible for Part B (secondary outcome). Primary outcome (not reported): percentage of patients in Part B not experiencing a flare. Missing values were imputed using non-responder imputation (NRI) and last observation carried forward (LOCF).

Results: Part A: Of 736 patients (**Table 1**), 43.9% achieved sustained remission (r-axSpA/AS: 42.8%; nr-axSpA: 45.3%; NRI). At baseline, 98.5% patients had high/very high disease activity (ASDAS≥2.1); at Wk48, 52.7% (r-axSpA/AS: 52.6%; nr-axSpA: 52.9%) had inactive disease (ASDAS<1.3; LOCF; **Table 2**). The treatment-emergent adverse event (TEAE) rate/100 patient-years' exposure was 224.2; 3.9% patients discontinued CZP due to TEAEs. No new safety signal was identified.

Conclusion: The run-in phase of C-OPTIMISE shows that similar and substantial proportions of patients with r-axSpA/AS and nr-axSpA achieved sustained remission during 48 wks' CZP treatment. No new safety signal was identified. The study was funded by UCB Pharma, medical writing by Hinal Tanna, Costello Medical, UK. We thank the patients who contributed.

Efficacy and Safety of Ixekizumab in Patients with Active Psoriatic Arthritis and Previous Inadequate Response to TNF Inhibitors: Two-Year Follow-up from a Phase 3 Study

Ana-Maria Orbai¹, Amanda M. Gellett², Lisa Kerr² and Arnaud Constantin³, ¹Johns Hopkins University School of Medicine, Baltimore, MD, ²Eli Lilly and Company, Indianapolis, IN, ³Hopital Pierre-Paul Riquet, Toulouse, France

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Ixekizumab (IXE), a high-affinity monoclonal antibody that selectively targets IL-17A, was superior to placebo(PBO) at Week (Wk) 24 for treating PsA signs and symptoms in patients (pts) with active PsA and prior inadequate response or intolerance to TNF inhibitors (TNFi)(Nash et al. Lancet, 2017). We report efficacy and safety results of IXE following 2 years of treatment in SPIRIT-P2.

Methods: Adult subjects (N=363) who met Classification for PsA (CASPAR) criteria with active PsA and inadequate response or intolerance to TNFi were randomized 1:1:1 to 80 mg IXE every 4 wks (Q4W, N=122) or 2 wks (Q2W, N=123) following a 160-mg starting dose of IXE at Wk 0 or PBO (N=118). Pts randomized to PBO were re-randomized 1:1 to IXE Q2W or Q4W at either Wk 16 if inadequate responders (<20% improvement in both tender joint count [TJC] and swollen joint count [SJC]) or Wk 24. From Wk 32, pts were discontinued from the study if they had <20% improvement in both TJC and SJC. Efficacy outcomes were ACR20/50/70 response, Psoriasis Area and Severity Index (PASI) 75/90/100 response, Leeds Enthesitis Index (LEI), Leeds Dactylitis Index-Basic (LDI-B), Minimal Disease Activity (MDA), and HAQ-Disability Index (DI). Ad-hoc efficacy analysis for the combined treatment periods from Wk 0-108 included pts initially randomized to IXE. Missing values were imputed by modified nonresponder imputation (mNRI) for categorical data or modified baseline observation carried forward (mBOCF) for continuous data. Safety analyses included all available safety data at the time of Wk 108 database lock for pts receiving ≥ 1 dose of IXE and was summarized as incidence rates (IR) per 100 pt-years.

Results: Overall, 54.2% of randomized pts completed 108 wks of treatment. Wk 108 responses (mNRI) for pts initially randomized to IXE Q4W or IXE Q2W, respectively, were 59.6% and 47.9% for ACR20, 33.2% and 27.8% for MDA, 65.1% and 48.3% for PASI 75, 45.5% and 37.5% for LEI=0, and 63.0% and 60.0% for LDI-B=0; mean (SD) change from baseline (mBOCF) in HAQ-DI was -0.4 (0.5) for IXE Q4W and -0.4 (0.6) for IXE Q2W. IRs of treatment-emergent adverse event (AE) are provided in the table below; most were mild or moderate in severity. Serious AE IRs were 5.8 (IXE Q4W) and 7.7 (IXE Q2W). Three deaths occurred; causes of death were myocardial infarction (IXE Q2W/IXE Q2W), metastatic renal cell carcinoma (IXE Q4W/IXE Q4W), and cardiopulmonary arrest (PBO/IXE Q2W).

Conclusion: IXE provided clinically meaningful and sustained improvement in PsA signs and symptoms for up to 2 years of treatment among pts with prior inadequate response or intolerance to TNFi, consistent with responses during earlier treatment periods of SPIRIT-P2. No unexpected safety outcomes were reported and the safety profile was consistent with the IXE Phase 3 program in pts with active PsA and with moderate-to-severe plaque psoriasis.

Table. Efficacy and Safety Outcomes at Week 108 of SPIRIT-P2

Efficacy (Intent-to-Treat—Patients Randomized to IXE at Week 0)	IXE Q4W N=122	IXE Q2W N=123
<i>Response rate (mNRI), n/Nx (%)</i>		
ACR20	73/122 (59.6)	59/123 (47.9)
ACR50	56/121 (46.2)	40/123 (32.5)
ACR70	28/122 (23.2)	27/121 (22.6)
MDAa	41/122 (33.2)	34/123 (27.8)

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: VOYAGE1 & 2 were the pivotal Ph3 GUS trials for plaque PsO.^{1,2} Here we compare efficacy of GUS vs PBO & adalimumab (ADA) on PsO involving scalp, nail & palmoplantar (palmoplantar pustular PsO excluded per protocol) PsO in subgroup of pts w/ self-reported PsA, given the association between these distinct PsO phenotypes & PsA.

Methods: VOYAGE 1(n=837) & VOYAGE 2(n=992) enrolled adult pts who had plaque PsO for ≥6 months, an Investigator Global Assessment (IGA) score ≥3, PASI score ≥12, ≥10% BSA involvement at baseline (BL), & were candidates for phototherapy or systemic treatment for PsO. Pts were randomized to GUS, PBO or ADA at BL, w/ PBO crossover to GUS at wk16. This post-hoc analysis used observed pooled efficacy data for scalp-specific (ss-IGA), Physician's Global Assessment (PGA) of Hands &/or Feet (hf-PGA), fingernail PGA (f-PGA), & Nail Psoriasis Area & Severity Index (NAPSI) in subset of pts self-reporting PsA.

Results: In VOYAGE 1 & 2 combined, 335 (18.3%) PsO pts self-reported PsA (PBO 76, GUS 153, ADA 106). Baseline demographics were generally comparable across all 3 treatment groups, w/ history of methotrexate use: PBO 64.5%, GUS 70.6%, ADA 61.3%. A significantly greater proportion of GUS-treated pts achieved a ss-IGA score of 0/1 (absent/very mild) at wk16 vs PBO, & at wk24 vs ADA (Figure A). Significantly higher proportions of GUS-treated pts achieved a hf-PGA score of 0/1 (clear/almost clear) vs PBO at wk16 w/ numerically greater differences at wk24 vs ADA (Figure B). At wk16, proportions of pts achieving a f-PGA score of 0/1 (clear/minimal) were 47.6% for GUS vs 17.0% for PBO (p<0.001). The proportions of pts achieving a f-PGA score of 0/1 for GUS vs ADA were comparable at wk16 (47.6% vs 46.4%) & wk24 (67.0% vs 60.9%), but were higher for GUS by wk48 (82.5% vs 57.5%, Table). Mean (SD) % improvement from BL in NAPSI score was significantly higher for GUS vs PBO [39.5 (48.9) vs 6.5(47.5), p<0.001] at wk16 & was comparable for GUS vs ADA at wk24 [58.0 (51.3) vs 59.9(40.4)]. By wk48, mean % improvement from BL in NAPSI score was higher for GUS vs ADA (70.8% vs 61.3%, Table).

Conclusion: GUS-treated PsO pts w/self-reported PsA showed clinically meaningful improvements vs ADA in ss-IGA & hf-PGA scores at wks 16 & 24. Although improvements in f-PGA & NAPSI were similar in pts treated w/ GUS vs. ADA at earlier time points, numerically greater differences were observed w/ GUS by wk48, likely requiring the additional duration to discriminate between treatments in this slow-growing cutaneous appendage.

Rapid and Sustained Improvements in Patient-Reported Signs and Symptoms with Ixekizumab in Biologic-Naive and TNF-Inadequate Responder Patients with Psoriatic Arthritis

Ana-Maria Orbai¹, Dafna D Gladman², Julie Birt³, Amanda M. Gellett³, Chen-Yen Lin³ and Tore Kvien⁴, ¹Johns Hopkins University School of Medicine, Baltimore, MD, ²University of Toronto, Toronto, ON, Canada, ³Eli Lilly and Company, Indianapolis, IN, ⁴Diakonhjemmet Hospital, Oslo, Norway

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Ixekizumab (IXE), a high-affinity mAb that selectively targets IL-17A, has shown improvements up to Week (Wk) 24 across several domains of PsA (including ACR20) compared to placebo in 2 Phase 3 trials in PsA patients (SPIRIT-P1 and SPIRIT-P2).^{1,2} We analyzed the onset and duration of patient-reported improvements in symptoms of PsA, including patient-reported pain and fatigue, following treatment with IXE up to Wk 52.

Methods: The SPIRIT-P1 and -P2 study designs have been reported previously.^{1,2} Patients with active PsA either naive to biologic DMARDs (bDMARD-naive; SPIRIT-P1) or with inadequate response to or intolerance to prior TNF-inhibitors (TNFi-IR; SPIRIT-P2) were randomized to placebo (PBO; Wk 0-24 only) or 80 mg IXE every 4 (IXE Q4W) or 2 wks (IXE Q2W) after a 160-mg starting dose. We analyzed change from baseline for the joint pain visual analog scale (VAS; 0-100 scale), patient global assessment (PatGA VAS; 0-100 scale), fatigue Numerical Rating Scale (NRS; 0 [no fatigue] to 10 [worst imaginable]), and Health Assessment Questionnaire-Disability Index (HAQ-DI) up to Wk 52 (double-blind treatment period, Wk 0-24; and extension period, Wk 24-52). Continuous data were analyzed using a mixed-effects model for repeated measures (MMRM) from baseline to Wk 24. From Wk24 onward, all missing data were imputed using the multiple imputation (MI) method.

Results: Patients treated with both IXE doses reported rapid and statistically significant reductions compared to PBO in pain VAS, PatGA, and HAQ-DI scores as early as Wk 1, which persisted or improved through Wk 52. Improvements were consistent in bDMARD-naive (SPIRIT-P1) and TNFi-IR (SPIRIT-P2) patients (Table). Fatigue scores improved in the IXE dose groups compared to PBO in both the studies at the earliest time point measured (Wk 4 in SPIRIT-P1; Wk 2 in SPIRIT-P2); results were statistically significant at Wk 24 in SPIRIT-P2, but not SPIRIT-P1 (Table).

Conclusion: Patients treated with IXE achieved significantly greater improvements compared to PBO as early as Wk1 in joint pain, HAQ-DI, and PatGA. Fatigue also improved significantly, at the earliest time point measured (Wk 4). Improvements for pain, PatGA, and physical function persisted up to Wk 52, and were generally consistent in the bDMARD-naive (SPIRIT-P1) and TNFi-IR (SPIRIT-P2) populations.

Table: Summary of Change from Baseline in Individual Clinical Responses over Time up to Week 52

Outcomes	Visits	SPIRIT-P1			SPIRIT-P2

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Secukinumab, a fully human monoclonal antibody that selectively neutralizes IL-17A, has demonstrated efficacy for patients with psoriatic arthritis (PsA) in multiple phase 3 clinical trials.¹⁻⁴ To improve and standardize the assessment of PsA outcomes, the PsA core domain set, initially implemented in 2006,⁵ has been updated by the Group for Research and Assessment of Psoriasis and Psoriatic Arthritis (GRAPPA) and endorsed by Outcome Measures in Rheumatology (OMERACT)⁶ in 2016. The updated PsA core domains are: musculoskeletal disease activity (arthritis, enthesitis, dactylitis, and spine symptoms), skin disease activity (psoriasis and nail psoriasis), pain, patient global assessment, physical function, fatigue, health-related quality of life, and systemic inflammation; structural damage assessment is recommended at least once in the development program of PsA medications. Here we report the efficacy of secukinumab vs placebo across individual PsA core domains, using pooled data from 4 phase 3 FUTURE studies.

Methods: Patients with active PsA participated in the phase 3 clinical trials FUTURE 2, 3, 4, and 5 (397, 414, 341, and 996 patients, respectively).¹⁻⁴ Data were pooled from the studies using secukinumab dosed at 150 mg (load vs no load), 300 mg, or placebo at the end of the 16-week double-blind period, and efficacy evaluated according to the updated GRAPPA-OMERACT PsA core domains. Core domains were assessed using multiple instruments (Table 1) with improvement defined as percentage of patients achieving $\geq 50\%$ improvement (joints), complete resolution (arthritis, enthesitis, dactylitis), or minimal clinically important difference in PsA where known and/or least squares mean change from baseline (patient-reported outcomes). Axial data are from MEASURE 2 (not assessed in FUTURE studies).

Results: 2049 patients were included, of whom 461 received secukinumab 300mg, 572 received secukinumab 150 mg, 335 received secukinumab 150 mg no load, and 681 received placebo. Baseline demographics and disease characteristics were broadly similar in all treatment groups. Efficacy results for each core domain are provided in Table 1.

Conclusion: Secukinumab demonstrated efficacy across GRAPPA-OMERACT PsA core domains in the phase 3 clinical trials program using multiple instruments and thresholds to measure improvement. Secukinumab 300 mg had the greatest efficacy across domains vs placebo. Our results indicate that secukinumab improves both the disease manifestations and life impact of PsA as demonstrated using the PsA core domain set.

Session Date: Tuesday, October 23, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: BMS-986165, a potent and highly selective oral tyrosine kinase 2 inhibitor, inhibits signal transducer and activator of transcription (STAT)-dependent signalling pathways of interleukin-23 and type I interferons involved in the pathology of immune-mediated diseases. A 12-week (wk), placebo (pbo)-controlled, Phase II, dose-ranging study

(ClinicalTrials.gov, NCT02931838) investigated the efficacy and safety of BMS-986165 in patients (pts) with moderate-to-severe plaque psoriasis (PsO).

Methods: Adults with PsO for ≥ 6 months and moderate-to-severe disease (body surface area [BSA] $\geq 10\%$, Psoriasis Area and Severity Index [PASI] ≥ 12 , static Physician Global Assessment [sPGA] ≥ 3) were randomized to pbo or BMS-986165 (3 mg every other day [QOD], 3mg every day [QD], 3 mg twice daily [BID], 6 mg BID, 12 mg QD). Primary endpoint was PASI 75 at Wk 12. Pain was assessed by ACR pain visual analog scale (VAS).

Results: For the 267 pts randomized and treated, baseline characteristics (mean age 45 years, male 73%, median disease duration 15 years, prior biologic experience 43%, mean BSA 23%, mean PASI score 18.0) were generally balanced among treatment arms. At Wk 12, a significantly greater proportion of pts achieved PASI 75, PASI 90 and sPGA 0/1 at doses ≥ 3 mg QD vs pbo ($p < 0.05$), with dose response observed across all efficacy measures (Table 1). Efficacy was observed in both biologic-naïve and biologic-experienced pts, with rapid onset of response by Day 15. Pain VAS score showed a dose-dependent decrease, with the three top dose groups reaching $\sim 70\%$ decrease at Wk 12 (Figure). None of the five serious AEs were considered drug-related: two events in one pbo pt (hemorrhagic anemia, hemorrhoidal hemorrhage) and three events with BMS-986165 (3 mg QOD: gastroenteritis rotavirus; 3 mg QD: eye injury; 3 mg BID: dizziness). AEs were reported in 51% (pbo), 59% (3 mg QOD), 55% (3 mg QD), 64% (3 mg BID), 80% (6 mg BID) and 77% (12 mg QD) of pts. The most common AEs reported by pts across treatment arms (ranges) included nasopharyngitis (2–16%), headache (4–9%), and diarrhea (2–9%). AEs were generally mild to moderate and resulted in drug discontinuation in 4% of pbo pts and 2–7% of pts across the active doses. There were no significant changes in liver enzymes, blood counts or lipid levels.

Conclusion: In pts with moderate-to-severe PsO, BMS-986165 demonstrated statistically greater efficacy on skin measures vs pbo at doses ≥ 3 mg QD and a dose-dependent decrease in pain. BMS-986165 was generally well tolerated. Further evaluation in PsO and psoriatic arthritis is warranted. Medical writing assistance provided by Bu Reinen, PhD (Caudex), funded by Bristol-Myers Squibb.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Secukinumab provided rapid, significant and sustained improvement in the signs and symptoms of psoriatic arthritis (PsA) in multiple Phase 3 studies.¹⁻⁴ Herein, we report individual patient meta-analysis data for secukinumab on achievement of high hurdle efficacy endpoints versus placebo (PBO) at Week (Wk) 16 in patients (pts) with PsA from four Phase 3 studies: FUTURE 2, 3, 4 and 5. Analyses in subgroups by baseline (BL) disease activity, BL psoriasis, prior Anti-TNF and concomitant Methotrexate (MTX) use were also evaluated.

Methods: Overall, 397, 414, 341, and 996 pts with active PsA were randomized in FUTURE 2, 3, 4, and 5 studies, respectively. Secukinumab doses included subcutaneous 300 mg and 150 mg administered at BL with loading doses (LD) at Wks 1, 2, and 3, followed by maintenance dose every 4 wks (q4w) starting at Wk 4. Data collected up to Wk 16 were pooled. Assessments included: ACR 50/70/PASI90 responses, PASDAS-Low Disease Activity (PASDAS-LDA), and Minimal Disease Activity (MDA) in overall population. ACR 50/70 and PASI 90 responses by BL Disease Activity Score (DAS) 28- C-Reactive Protein (CRP) (≤ 5.1 and > 5.1), BL CRP (≤ 10 mg/L and > 10 mg/L), BL Body Surface Area (BSA) ($\geq 3\%$ - $<10\%$, and $\geq 10\%$) with psoriasis and prior Anti-TNF and concomitant MTX use were also assessed. Results are reported after application of non-responder imputation.

Results: A total of 2049 pts were included in the meta-analysis, of which 461, 572, 335, and 681 pts received secukinumab 300mg, 150mg, 150mg without LD and PBO, respectively. Improvements were observed with secukinumab (300 mg, 150 mg, and 150mg without LD) vs PBO for all endpoints at Wk 16 in the overall population (Figure 1) and in all subgroups (data not shown). Secukinumab 300 mg was associated with greater improvements compared to the 150 mg dose for all endpoints in overall population and in subgroups.

Conclusion: Secukinumab provided improvements in high hurdle efficacy endpoints in patients with active PsA in the overall population and in subgroups with various levels of baseline disease activity and psoriasis. Secukinumab 300 mg was associated with higher responses compared to secukinumab 150 mg across all endpoints and in all groups.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Tofacitinib is an oral Janus kinase inhibitor for the treatment of psoriatic arthritis (PsA). We report the safety, tolerability, and efficacy of tofacitinib in patients (pts) with active PsA from an ongoing, open-label, long-term extension (LTE) study (OPAL Balance, NCT01976364; August 31, 2017 data-cut; study ongoing, database not locked; some values may change in final, locked database).

Methods: Eligible pts from 2 Phase (P) 3 tofacitinib PsA studies (OPAL Broaden, NCT01877668; OPAL Beyond, NCT01882439) entered a 3-year LTE \leq 3 months after completing the P3 study or discontinuing for reasons other than treatment-related adverse events (AEs). Pts received tofacitinib 5 mg twice daily (BID) to Month (M) 1, after which dose adjustments between 5 and 10 mg BID were permitted to improve efficacy, or for safety reasons. Pts receiving a conventional synthetic disease-modifying antirheumatic drug (csDMARD) at P3 study entry continued the same

csDMARD in the LTE. Primary endpoints were incidence and severity of AEs, incidence of clinical abnormalities, and changes from baseline (Δ) in laboratory values. Safety data are reported up to M36. Efficacy was evaluated up to M30 (when N>60) as a secondary endpoint.

Results: 686 pts were treated in OPAL Balance; 468 (68.2%) remained in the study at data cut-off. Mean (range) LTE tofacitinib treatment duration was 614 (1–1,032) days. On Day 1, 675 pts (98.4%) received a csDMARD, which was discontinued in 86 pts (12.7%). To M36, 2,189 AEs were reported in 546 pts (79.6%), 95 pts (13.8%) had serious AEs, and 59 pts (8.6%) discontinued due to AEs. Serious infections occurred in 12 pts (1.7%), herpes zoster in 20 pts (2.9%; 1 serious event), major adverse cardiovascular events in 5 pts (0.7%), malignancies in 24 pts (3.5%; including 12 pts with non-melanoma skin cancer), and uveitis in 2 pts (0.3%). No AEs of gastrointestinal perforation or inflammatory bowel disease were reported. There were 5 deaths (not attributed to treatment, as assessed by the investigator) due to metastatic pancreatic carcinoma, acute cardiac failure/hypertensive heart disease, chronic obstructive pulmonary disease, pulmonary embolism, and cardiovascular insufficiency. Four AEs of latent tuberculosis were reported in pts whose previously negative QuantiFERON response became positive. Alanineaminotransferase was elevated $\geq 3\times$ the upper limit of normal (ULN) in 27 pts (4.0%), and aspartate aminotransferase $\geq 3\times$ ULN in 15 pts (2.2%). Changes in laboratory values observed in P3 studies were generally stable in the LTE, except for a modest decrease in absolute lymphocyte count over time. Eight pts (1.2%) discontinued (protocol-mandated) due to laboratory value changes. ACR responses, Δ Health Assessment Questionnaire-Disability Index, Psoriasis Area and Severity Index $\geq 75\%$ improvement response, Δ Leeds Enthesitis Index, Δ Dactylitis Severity Score, and Δ Pain were maintained up to M30.

Conclusion: Over 36 months in the LTE, the safety profile of tofacitinib in active PsA pts was generally similar to that of the P3 studies. No new safety risks were identified. Efficacy across various PsA disease domains was maintained over time.

Impact of Guselkumab Versus Placebo and Adalimumab on Patient Reported Outcomes in Patients with and without Psoriatic Arthritis in a Phase 3 Pivotal Psoriasis Study

Luis Puig¹, Chenglong Han², Ronald Vender³, Michael Song², Yin You², Yaung-Kaung Shen² and Peter Foley⁴, ¹Hospital de la Santa Creu i Sant Pau and Universitat Autònoma de Barcelona Medical School, Barcelona, Spain, ²Janssen Research & Development, LLC, Spring House, PA, ³McMaster University, Hamilton, ON, Canada, ⁴University of Melbourne, St. Vincent's Hospital, Melbourne and Skin & Cancer Foundation Inc., Carlton, Australia

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: VOYAGE 2 is a phase 3 double-blind, placebo/active comparator-controlled trial comparing guselkumab (GUS) with placebo (PBO) and adalimumab (ADA) in patients (pts) with moderate-to-severe PsO. The impact of treatment on patient-reported outcomes (PROs) was evaluated.

Methods: Pts were randomized to GUS 100mg (wks 0 & 4, then q8 wks), ADA (80 mg wk 0, 40 mg wk 1, then 40 mg q2 wks), or PBO (wks 0, 4, & 12, then GUS 100mg wks 16 & 20). We evaluated PROs using the Work Limitations Questionnaire [WLQ; work productivity], the Hospital Anxiety & Depression Scale [HADS], and the Medical Outcomes

Study 36-Item Short Form (SF-36; health related quality of life) at wk16 (GUS vs PBO) and wk24 (GUS vs ADA) in pts with and without PsA.

Results: In all, 18% of pts reported a history of PsA. At wk16, GUS pts had numerically greater improvements vs PBO in work productivity, anxiety and depression, and SF-36 PCS & MCS scores regardless of PsA status. The least square (LS) mean differences (95% CI; adjusted for baseline value) for GUS vs PBO for all PROs were generally similar between pts with and without PsA. At wk24, GUS pts had numerically greater improvements vs ADA in all PROs regardless of PsA status. The LS mean differences for GUS vs ADA were generally greater for pts with PsA vs pts without PsA (Table).

Conclusion: GUS showed better improvements in all PROs vs PBO at wk16 and vs ADA at wk24. Improvements vs PBO were similar regardless of PsA status, while improvements vs ADA were greater for pts with PsA.

Table: Summary of Change from Baseline in WLQ, HADS and SF-36 Scores from VOYAGE 2

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: GO-VIBRANT was a Phase 3 trial of intravenous (IV) golumumab (GLM) in adult patients (pts) w/ active psoriatic arthritis (PsA). To evaluate improvement in skin, nail psoriasis & Dermatology Life Quality Index (DLQI) w/ IV GLM.

Methods: Adult bio-naïve PsA pts w/ active disease (≥5 swollen & tender joints, CRP ≥0.6mg/dl, active plaque psoriasis or documented history, & despite treatment w/csDMARDs&/or NSAIDs) were randomized to IV GLM 2mg/kg at wks 0, 4, & every 8 wks thereafter or PBO at wks 0, 4, 12, & 20 w/ crossover to GLM at wk24. Pts w/≥3% body surface area (BSA)

psoriasis at baseline (BL) were assessed using Psoriasis Area and Severity Index (PASI, 0-72) 75/90/100% & modified Nail Psoriasis Severity Index (mNAPSI, 0-130) at BL, wks 14 & 24 (in pts w/mNAPSI >0 at BL). DLQI was assessed at BL, wks 8, 14 & 24.

Results: 394 pts (PBO: n=198; GLM: n=196) had $\geq 3\%$ BSA psoriasis at BL; 76.5% had mNAPSI>0 at BL (mean 18.6). Pts on GLM achieved a greater PASI 75 response vs PBO (59.2% vs 13.6%, $p<0.001$) at wk14 & at wk24 (64.8% vs 13.1%, $p<0.001$). At wk14, pts on GLM achieved greater PASI 90/100 responses vs PBO (39.3/16.8% vs 6.6/4.5%; $p<0.001$ for all) & at wk24 (42.9/25.5% vs 7.6/5.6%; $p<0.001$ for all) (Table 1). At wk14, similar proportions of pts in the GLM groups, regardless of BL MTX use, achieved PASI 90/100 responses. At wk24, greater proportions of pts on GLM +MTX & GLM only achieved PASI 100 vs PBO (+MTX: 30.5% vs 7%, $p<0.001$; -MTX: 15.4% vs 1.8%, $p<0.010$) (Table 1). The mean decrease (improvement) from BL in the mNAPSI score was greater in GLM vs PBO (-9.6 vs -1.9, $p<0.001$) at wk14 & at wk24 (-11.4 vs -3.7, $p<0.001$). At wk8, the mean decrease (improvement) from BL in DLQI was greater in GLM vs PBO (-7.2 vs -1.7, $p<0.001$), at wk14 (-7.7 vs -1.8, $p<0.001$) & wk24 (-8.1 vs -1.9, $p<0.001$). At wk14, 55.1% of pts treated w/ GLM achieved a PASI 50 response & improvement in DLQI ≥ 5 vs 7.1% treated w/ PBO ($p<0.001$) & at wk24, 59.2% vs 8.1% ($p<0.001$).

Conclusion: As early as wk14, IV GLM demonstrated clinically meaningful improvements in skin psoriasis irrespective of MTX use & nail psoriasis. Improvement in DLQI was seen as early as wk8, w/ continued improvement at wks 14 & 24.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Summary of Efficacy Results at Week 260			
Efficacy endpoints (n/M unless otherwise stated)		Secukinumab IV→150 mg Group (N = 161)*	Secukinumab IV→75 mg Group (N = 147)*
ACR20		89/131 (67.9)	98/127 (77.2)
ACR50		69/131 (52.7)	65/127 (51.2)
ACR70		49/131 (37.4)	43/127 (33.9)
^a PASI 90		48/72 (66.7)	47/71 (66.2)
HAQ-DI, mean change from baseline (SD)		n = 131, -0.4 (0.58)	n = 126, -0.5 (0.61)
SF-36 PCS, mean change from baseline (SD)		n = 131, 6.6 (8.33)	n = 123, 5.9 (9.36)
^b Resolution of enthesitis		67/81 (82.7)	60/77 (77.9)
^c Resolution of dactylitis		63/67 (94.0)	63/70 (90.0)
ACR Response before and after dose escalation (based on patients with complete data up to 56 weeks after the escalation)			
		Responses post-escalation (150 mg to 300 mg) M = 126	
Variables	Pre-escalation (150 mg), %	12 to 32 weeks	36 to 56 weeks
ACR < 20 (non-responder)	42.9	31.7	27.8
20 ≤ ACR < 50	25.4	24.6	21.4
50 ≤ ACR < 70	16.7	18.3	24.6
ACR ≥ 70	15.1	25.4	26.2
N total number of randomized patients; M is number of evaluable patients; n, number of responders ^a Secukinumab 150 and 75mg arms include 60 and 121 patients, respectively, who were dose escalated at Wk 156 or later; ^b Patients with psoriasis affecting ≥3% body surface area at baseline (150 mg: N = 89; 75 mg: N = 82) ^c Patients (N = 99 [150 mg], and 91 [75 mg]) with enthesitis at baseline ^d Patients (N = 83 [150 mg], and 77 [75 mg]) with dactylitis at baseline			
Pre-escalation is defined as the last assessment done on or before the patient administered the escalated dose; 126 patients (including placebo switchers) with both pre and all post-dose escalation assessments data available are included in the analysis			

Background/Purpose: Secukinumab (SEC), a fully human monoclonal IgG1 antibody, provided rapid and significant improvements in all key clinical domains of psoriatic arthritis (PsA) in the FUTURE 1 study (NCT01392326) with improvements sustained through 3 years.¹ Here, we present the final 5 year efficacy and safety results of the study, including efficacy results in patients who had a dose escalation during the study.

Methods: Overall, 606 adults with active PsA were originally randomized to receive SEC IV→150 mg, IV→75 mg, or placebo) and then re-randomized to SEC 150 mg or 75 mg. The study design has been previously described.¹ At Wk 104, 460 patients entered the 3-year extension study. As per the protocol amendment, patients could have SEC dose escalated from 150 to 300mg and from 75 mg to 150/300mg from Wk 156, based on physician's judgement. Assessments at Wk 260 included ACR20/50/70, PASI 90, HAQ-DI, SF-36 PCS, and resolution of dactylitis and enthesitis and are reported for patients originally randomized to the SEC 150 mg and 75 mg groups (observed data). Dose escalation results are reported for all patients who entered the extension study (i.e. including placebo-switchers). Safety is reported as exposure adjusted incidence rate/100 patient-years (EAIR) for all patients (n =587) who received ≥1 dose of study treatment.

Results: Overall, 132/161 (82%) and 124/147 (84.4%) patients entered the extension study who were originally randomized to SEC 150mg/75 mg, respectively, completed 260 Wks of treatment. Clinical responses were sustained or further improved through 5 years treatment (Table 1). A total of 86/236 (36.4%) patients on SEC 150 mg dose in extension were escalated to 300mg, while 180/221 (81.4%) patients on SEC 75mg dose were escalated to 150/300mg. Post-escalation, the proportion of patients with non/low level ACR responses improved with corresponding increases in the proportion of patients achieving moderate/high ACR responses (Table 1). Over the entire study period (SEC mean exposure of 2320 patient-years), the safety profile of SEC was consistent with previous reports.¹ EAIR of selected adverse events for SEC were serious infections (1.8), ulcerative colitis (0.04), Crohn's disease (0.1), and MACE (0.5). Six deaths (3 in each dose group) were reported in any SEC group through 5 years.

Conclusion: Over 80% of patients who entered the extension study completed 5 years of treatment. Secukinumab provided sustained improvements in the signs and symptoms in the major clinical domains of PsA through 5 years. Efficacy improved with dose escalation to secukinumab 150 mg or 300 mg during the study. Secukinumab was well tolerated with no new safety signals identified and safety profile was consistent with that previously reported.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Enthesitis, a key pathology in non-radiographic axial spondyloarthritis (nr-axSpA), has been difficult to treat with conventional therapies and may take longer to resolve than other disease manifestations. It is unknown if failure to attain resolution of enthesitis affects achievement of normal quality of life (QoL) and clinical response. This analysis aimed to assess if enthesitis at baseline (BL) and after 12 wks of adalimumab (ADA) treatment in the ABILITY-3 study associates with achieving normal QoL and clinical response in patients (pts) with nr-axSpA.

Methods: ABILITY-3 enrolled adult pts with nr-axSpA with objective evidence of inflammation (MRI positive or elevated hsCRP), active disease at BL (ASDAS ≥ 2.1 , BASDAI ≥ 4 , and Patient's Assessment of Total Back Pain score ≥ 4), and an inadequate response to ≥ 2 NSAIDs. Pts received ADA 40 mg every other wk during a 28-wk open-label lead-in. Pearson's correlation coefficients were used to assess the relationship between total enthesitis count (sum of Maastricht Ankylosing Spondylitis Enthesitis Score [MASES] and plantar fascia enthesitis score) and QoL and disease activity at BL. Multivariable stepwise logistic regression was used to evaluate the relationship between total enthesitis count/location and normal QoL (EQ-5D ≥ 0.898 or SF36 MCS/PCS ≥ 50) and clinical response (ASDAS-ID [ASDAS < 1.3], ASAS40, or BASDAI50) at wk 12.

Results: At BL, 74% (501/673) of pts had enthesitis, and mean (95% CI) total enthesitis count was 3.7 (3.42, 3.98). Enthesitis resolved in 39% (196/501) of pts, and total enthesitis count was 1.9 (1.68, 2.12) at wk 12 of ADA treatment. At BL, total enthesitis count significantly correlated with all QoL and disease activity measures (**Table**). Each 1-unit increase in BL total enthesitis count was associated with 7% lower odds of ASDAS-ID (OR [95% CI]: 0.93 [0.88, 0.99], $P=0.018$) and 6% lower odds of BASDAI50 (0.94 [0.89, 0.99], $P=0.024$) at wk 12 and was not associated with normal QoL or ASAS40 at wk 12. Total enthesitis count at wk 12 was associated with lower odds of normal QoL and clinical response at wk 12 (**Table**). Achievement of normal QoL at wk 12 was less likely if pts had BL enthesitis at the posterior (EQ-5D ≥ 0.898) or anterior superior iliac spine (SF36 PCS ≥ 50), and pts with BL enthesitis at the 7th costochondral joint were less likely to achieve clinical response at wk 12 (**Table**).

Conclusion: 39% of pts achieved complete resolution of enthesitis after 12 wks of ADA treatment. Total enthesitis count at BL was not associated with normal QoL and inversely associated with clinical response at wk 12. Total enthesitis count at wk 12 was negatively associated with normal QoL and clinical response. Our exploratory analysis suggested possible inverse associations of specific BL enthesitis sites with achievement of normal QoL and clinical response; additional research is needed to further define these relationships.

Table. Association of Total Enthesitis Count With QoL and Diseases Activity at BL and Clinical Response at Wk 12

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The ability to predict responses to apremilast (APR) could impact treatment decisions. This post-hoc analysis was conducted to (1) assess the predictive values of baseline (BL) clinical disease status on achieving long-term Clinical Disease Activity for Psoriatic Arthritis (cDAPSA) targets at Week 52 and (2) examine the association between early response to APR at Week 16 and the achievement of cDAPSA targets at Week 52.

Methods: Pooled analyses of 3 phase III trials (PALACE 1-3) were performed among subjects assigned to receive APR 30 mg BID at BL. Data were analyzed using multiple imputation to account for subjects who discontinued or had missing values, using all available cDAPSA scores. Probability of shifting across different cDAPSA categories from BL to Week 52 was calculated within these subjects. Binary logistic regression was also performed to confirm the results. To determine the extent of changes (from BL to Week 16) associated with achieving treatment targets at Week 52, we analyzed mean cDAPSA over time (from BL to Week 52) by cDAPSA category at Week 52.

Results: A total of 496 subjects who received APR were included in the analyses. The estimated probabilities of achieving either cDAPSA low disease activity (LDA) or remission (REM) at Week 52 were 47.6% in subjects with BL moderate disease activity (cDAPSA >13 to ≤27) and 72.1% in subjects with BL LDA (cDAPSA >4 to ≤13) (Table). In subjects with BL high disease activity (cDAPSA >27), the probability of achieving LDA or REM by Week 52 was 25.1%. Binary logistic regression provided similar results. In subjects with moderate or low disease activity at BL, mean cDAPSA scores ranged from 21.0 to 22.4. Among these subjects, those who further achieved Week 52 LDA and REM had a mean cDAPSA at Week 16 of 14.9 and 8.2, respectively, suggesting that a reduction of ≥30% in cDAPSA by Week 16 predicts achievement of LDA or REM at Week 52.

Conclusion: Subjects with low or moderate disease activity at BL exhibited the highest likelihood of achieving and maintaining an improvement in LDA or REM with continued APR treatment to Week 52. Early response, based on changes in mean cDAPSA level from BL to Week 16, was associated with the achievement or maintenance of cDAPSA LDA or REM by Week 52.

**Probability of Achieving cDAPSA Disease Status at Week 52
(APR 30 mg BID From BL)**

Baseline cDAPSA	Chance of Achieving Target Scores at Week 52				
	High	Moderate	Low	REM	Low/REM
Low	2.7%	25.1%	54.1%	18.0%	72.1%
Moderate	12.6%	39.8%	36.6%	10.8%	47.6%
High	36.3%	38.6%	20.9%	4.2%	25.1%

Multiple imputation.
cDAPSA=Clinical Disease Activity for Psoriatic Arthritis; REM=remission (cDAPSA ≤4); Low=low disease activity (cDAPSA >4 to ≤13); Moderate=moderate disease activity (cDAPSA >13 to ≤27); High=high disease activity (cDAPSA >27).

 Subjects with ≥1 disease activity category improvement
 Subjects with ≥1 disease activity category decline
 Subjects with no change in disease activity target score

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: In patients (pts) with active non-radiographic axial spondyloarthritis (nr-axSpA) in the ABILITY-3 study who achieved sustained remission with adalimumab (ADA), continued ADA therapy was associated with significantly fewer pts flaring than treatment withdrawal. Sustained remission is an important treatment goal in pts with nr-axSpA, but factors predicting sustained remission and absence of flare are unknown. The purpose of this analysis was to determine whether an ADA concentration threshold is predictive of achievement of sustained remission and absence of flare in pts with nr-axSpA.

Methods: ABILITY-3 included a 28-wk open-label (OL) ADA (40 mg every other wk) lead-in in which pts who achieved sustained remission (ASDAS <1.3 at wks 16, 20, 24, and 28) were randomized to double-blind (DB) placebo (PBO) or continued ADA for 40 wks (68 wks total). Pts not achieving remission were discontinued at wks 20, 24, or 28. The primary efficacy variable was the proportion of pts who did not experience a flare (ASDAS ≥2.1 at 2 consecutive visits) by wk 68. Pts who flared received OL ADA rescue. ADA trough concentrations at wks 12 or 28 were used to predict achieving sustained remission by wk 28 (all OL patients, N=673) and absence of flare at wk 68 (patients randomized to DB ADA, n=152). Threshold analysis was conducted by constructing receiver operating characteristic (ROC) curves (R Ver 3.3.3) to assess predictive ADA trough concentration thresholds based on specificity and sensitivity values.

Results: Of 673 pts enrolled in the OL phase, 305 met criteria for remission at wk 28 and were randomized to DB treatment. Mean ± SD ADA trough concentrations were 6.68±5.23 µg/mL at wk 12 and 8.36±5.27 µg/mL at wk 28. During the DB phase, 81 and 45 pts flared and 68 and 36 pts received ≥12 wks of OL ADA rescue in PBO (n=153) and ADA (n=152) arms, respectively. ADA mean ± SD trough concentration at wk 68 for pts randomized to DB ADA with flare (7.64±5.22 µg/mL) was slightly lower than for DB ADA pts without flare (8.12±4.35 µg/mL). ROC curves showed AUC values ≤0.6 for achieving sustained remission by wk 28 and absence of flare at wk 68, with no concentration threshold meeting sensitivity and specificity criteria for reliable prediction of such endpoints (**Figure**).

Conclusion: ROC analyses did not identify an ADA trough concentration threshold that reliably predicted whether a pt with nr-axSpA would achieve sustained remission (by wk 28) or absence of flare (at wk 68).

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

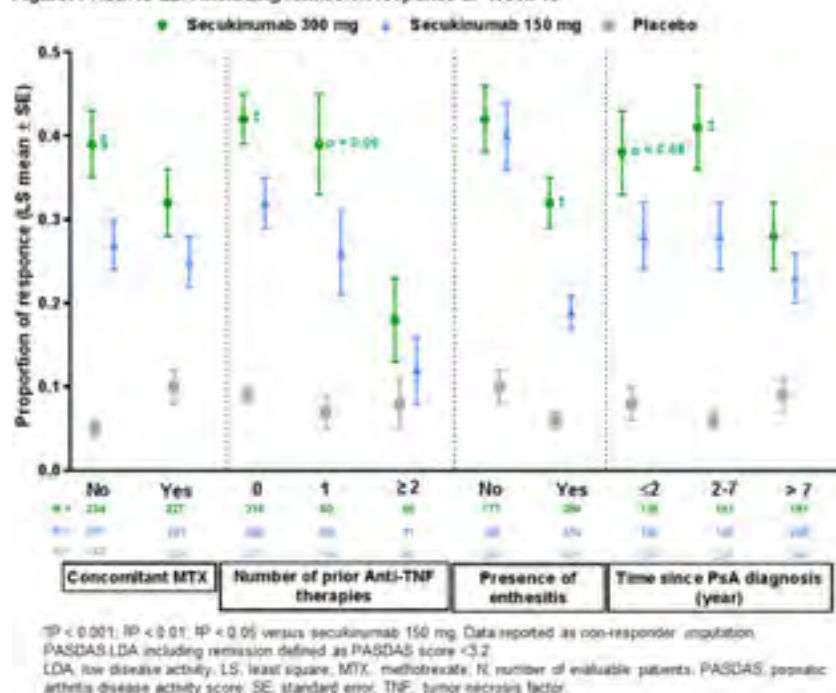

Session Time: 9:00AM-11:00AM

Background/Purpose: Subcutaneous secukinumab 150mg and 300mg are approved doses for the treatment of psoriatic arthritis (PsA) with the higher dose recommended for patients with anti-TNF inadequate response or moderate-to-severe psoriasis. Although multivariate logistic regression analysis can predict if a specific group of patients can benefit from the higher dose, machine learning surpasses these traditional estimation-focused analyses with a higher area under the Receiver Operating Characteristic curve. The objective is to investigate if specific baseline clinical characteristics can be used to predict which patients gain additional benefit from the 300mg dose using pooled data from the secukinumab phase 3 studies.

Methods: Bayesian Elastic net was used to analyze 4 studies (FUTURE 2-5) with 2148 patients investigating a total of 275 predictors (baseline demographic, disease characteristics in both main effects and interaction effects). Eleven endpoints were analyzed at Week 16 including ACR50, PASI90, and psoriatic arthritis disease activity score (PASDAS). Heatmaps were used to identify common predictors across endpoints at Week 16. PASDAS low disease activity (LDA), including remission (REM) (PASDAS LDA+REM; PASDAS score < 3.2)¹, is reported as a recommended disease activity target using meta-analytic techniques. Missing responses are imputed as non-responders.

Results: There was no single predictor which alone could adequately predict which patients would achieve PASDAS LDA+REM with 300mg compared to 150mg. However, several predictors jointly produced adequate predictions: no prior use of biologic, 1 previous anti-TNF therapy, no use of concomitant methotrexate (MTX), presence of enthesitis at baseline and earlier time since PsA diagnosis (**Figure**).

Figure: PASDAS LDA including remission response at Week 16

Conclusion: Machine learning on this pooled dataset confirmed previous clinical findings for the additional benefit of secukinumab 300mg over 150mg in patients with moderate to severe psoriasis in PsA², and in PsA patients with previous exposure to anti-TNF and in patients without concomitant MTX³. In addition, early PsA, and presence of enthesitis were identified as predictors of PASDAS LDA+REM that warrant further investigation.

Sieper, 2014	r-axSpA	12 weeks	Sarilumab (5 dose regimens) vs PBO (301)	Secondary	ASAS-PR between 1.9%-8.2% Sarilumab vs 2% PBO ($p>0.05$ for all dose regimens) at w.12

Legend: ADA: adalimumab; ASAS-PR: ASAS- Partial Remission; ASDAS-ID: ASDAS Inactive Disease; CZP: certolizumab pegol; ETN: etanercept; GOL: golimumab; IFX: infliximab; NPX: naproxen; nr-axSpA: non-radiographic axial spondyloarthritis; PBO: placebo; Q2W: every 2 weeks; Q4W: every 4 weeks; r-axSpA: radiographic spondyloarthritis; SEC: secukinumab; SSZ: sulfasalazine; TNFi: tumor necrosis factor inhibitor; TNFi- IR: inadequate response/intolerance to one TNFi; vs - versus

Background/Purpose: The treat-to-target concept is currently recommended in Axial Spondyloarthritis (axSpA) and remission is the main objective of treatment. Although consensual definitions of remission are lacking, ASAS-Partial Remission (ASAS-PR) and ASDAS-Inactive Disease (ASDAS-ID) have gained wide acceptance as clinical remission-like definitions in current practice.

Methods: In this review we assessed the efficacy of different biologic disease-modifying anti-rheumatic drugs (bDMARD) in achieving ASAS-PR or/and ASDAS-ID, as remission-like outcomes. Data from placebo-controlled phases of randomised controlled trials (RCTs) were included. A systematic literature review was performed using the MEDLINE database (May 1 2018) with the filters “published since the year 2000” and “humans”. The PICO (P, population; I, intervention; C, comparison; O, outcome) concept was used to perform the analysis according to: Patients- adults (>18 years old) with radiographic axSpA (r-axSpA) or non-radiographic axSpA (nr-axSpA); Intervention - any bDMARD regardless of formulation or duration; Comparison - placebo and/or any different drug; Outcomes: ASAS-PR and ASDAS-ID. For each outcome, we assessed whether the treatment group was superior, equal or inferior to the comparator group regarding the achievement of the ASAS-PR or ASDAS-ID, as primary outcomes.

Results: After screening 152 references, 19 RCTs fulfilled the inclusion criteria – 15 concerning tumor necrosis factor inhibitors (TNFi), 3 secukinumab (anti-IL17A) and 1 sarilumab (anti-IL6R). Eleven studies were conducted in r-axSpA, four in nr-axSpA and four in both populations. ASAS-PR was the dominant remission-like definition, used in 18 of the trials. Only 1 RCT used these remission-like endpoints as primary outcomes, in the remaining 18 trials, ASAS-PR or ASDAS-ID were just focused as secondary measures (Table 1). Concerning TNFi bDMARDs, 14 of the 15 trials provide evidence of efficacy in achieving remission, with the proportion of patients achieving ASAS-PR and ASDAS-ID varying between 16-61.9% and 24-40.2% respectively with a minimum and maximum of placebo-controlled phase duration of 12 to 48 weeks. Secukinumab was effective in achieving ASAS-PR when an initial intravenous loading dose was applied (MEASURE 1), while sarilumab was not able to induce remission in axSpA.

Conclusion: Clinical trials addressing remission-like concepts as outcomes are limited. Most studies were conducted in r-axSpA and ASAS-PR score was the preferred remission outcome. Considering nowadays-aimed treatment targets, these data raise the unmet need for improved treatment options favoring optimized remissions rates in axSpA patients.

Session Date: Tuesday, October 23, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Tumor necrosis factor inhibitors (TNFi) are effective in treating patients with axial spondyloarthritis (axSpA), but they are associated with adverse effects and high costs. According to the ASAS-EULAR recommendations, if patients are in sustained remission or low disease activity, tapering of TNFi can be considered. We aimed to assess the risk of relapse after TNFi tapering strategies compared to standard dose continuation in patients with axSpA.

Methods: We conducted a systematic search of the literature using Medline, Embase and Cochrane databases up to 27 February 2018. All randomized controlled trials (RCTs) and controlled cohort studies (CCTs) comparing the rate of relapse in patients with tapering dose versus standard dose of TNFi after achieving remission or low disease activity were selected. For the meta-analysis, the estimated event was the number of patients who had relapsed or not maintained remission or low disease activity in each treatment group (tapering versus standard dose). Data were extracted independently by two investigators. A global risk ratio (RR) was estimated using an inverse variance approach with fixed or random effect model, according to the level of heterogeneity (I², Cochran's Q-test). All these computations were performed using RevMan 5.3 software with a p-value threshold of 0.05.

Results: Among the 544 publications screened, 5 studies (3 RCTs including one available only as abstract and 2 CCTs) were included, involving 230 patients who tapered TNFi dose and 226 treated with standard dose. Clinical heterogeneity between the trials was low: mean age between 46.0 and 46.7 years, male: 72.6% - 87.2%, ankylosing spondylitis according to modified New York criteria: 74% - 100%, HLA-B27 positive: 91.0% - 93.0%. Methodological heterogeneity between the trials was high: all tapering modalities, relapse definitions, duration of the follow-up and evaluation times were different. None of tapering strategies were disease activity guided.

Tapering TNFi dose was not associated with a statistically significant increase of relapse (RR [95% CI] = 1.51 [0.99 to 2.31], $p = 0.05$ in comparison with standard dose continuation [Figure]. A relapse was observed in 22.2% of patients who tapered TNFi versus 13.3% in patients with standard doses.

Conclusion: Tapering doses of TNFi does not seem to increase the risk of relapse compared to TNFi standard dose continuation. However, data are scarce and heterogeneous, a need exists for additional, well designed, randomized controlled trials on this topic.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Ankylosing Spondylitis (AS) is not only characterized by pathological bone formation leading to ankylosis, but also by bone loss which may lead to vertebral fractures (VFX). TNF-alpha inhibitors (TNFi) have proven to be effective in blocking the inflammation process. A few studies also showed an increase of Bone Mineral Density (BMD) in AS patients treated with TNFi¹⁻³ but the incidence of VFX after two years of treatment was increased.³⁻⁴ To evaluate the long-term effect of TNFi on BMD and the incidence of VFX in patients with AS.

Methods: Consecutive TNFi naive patients diagnosed with AS according to the Modified New York criteria were included. Patients were recruited from the VUmc and the Amsterdam Outpatient clinic Reade and were treated with TNFi for 4 years. BMD at hip and lumbar spine (LS) were measured at baseline and after 4 years. T-scores were categorized as 'normal BMD', 'osteopenia' and 'osteoporosis', based on the WHO osteoporosis criteria.⁵ The incidence of VFX was determined by two observers using the Genant method.⁶

Results: In total, 107 AS patients with complete datasets (68.2% male) were included. The mean age was 42.6 years and the disease duration (time since diagnosis) was 11.0 years. At baseline 40.1% of the patients had a decreased BMD of the hip and 40.2% of the spine, of whom 27 patients (26%) had both a decreased hip BMD as well as a decreased lumbar

BMD. The BMD of spine and hip improved after 4 years of TNFi treatment (Table 1). In 13 patients (12.1%), 14 VFx were observed both at baseline. After 4 years of TNFi-treatment 26 VFx were observed in 21 patients. After 4 years, 4 out of 21 patients with ≥ 1 VFx had a decreased BMD at hip and lumbar spine whereas the other 17 patients had a normal BMD. The majority of VFx was localized in the mid or lower thoracic spine.

Table 1: BMD measurement in spine and hip of 107 AS patients treated with TNFi.

	Baseline*	After 4 years of TNFi**	p-value
Osteopenia LS	34 (31.8)	25 (23.4)	<0.001
Osteoporosis LS	9 (8.4)	2 (1.9)	
Abnormal BMD LS	43 (40.2)	27 (25.3)	
Osteopenia total hip	39 (36.4)	31 (29.0)	
Osteoporosis total hip	4 (3.7)	3 (2.8)	
Abnormal BMD total hip	43 (40.1)	34 (31.8)	0.03
Patients with VFx	13 (12.1)	21 (19.6)	0.004
Total number of VFx	14	26	

*1 patient with spondylodesis; 4 patients with a total hip replacement

** 2 patients with spondylodesis; 5 patients with a total hip replacement

LS: lumbar spine, Abnormal BMD = osteopenia and/or osteoporosis according to WHO guideline⁶

Vertebral fractures (VFx) are presented in number of patients with a VFx and the actual prevalence of VFx. Outcomes are presented in n (%)

Conclusion: The percentage of relatively young AS patients with a decreased BMD at baseline of the hip and lumbar spine was high (40%). After 4 years of TNFi-treatment the BMD of the lumbar spine improved in 14.9% of the patients and of the hip in 8.3% of the patients. At baseline, several vertebral fractures were found and a few additional vertebral fractures were observed after 4 years of treatment.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Anti-drug antibody (ADA) development can potentially affect the efficacy of biologics; concomitant MTX decreases the development of ADA for some biologics.¹ Ixekizumab (IXE), a mAb that selectively targets IL-17A, may be used with or without MTX. In IXE-treated patients (pts) with active PsA, we evaluated whether ADA development was affected by concomitant MTX or had an effect on long-term efficacy.

Methods: Two Phase 3 randomized, double-blind, placebo-controlled clinical trials evaluated IXE treatment in adult pts with PsA who were biologic-naïve (SPIRIT-P1; NCT01695239) or inadequate responders/intolerant to TNF inhibitors (SPIRIT-P2; NCT02349295). Study details were published^{2,3}; all pts met the Classification Criteria for PsA. Pts received placebo or 80 mg IXE every 2 weeks (Wks; Q2W) or 4 Wks (Q4W) after a 160- mg loading dose. Pts continued stable concomitant conventional DMARDs through Wk 24 (except inadequate responders at Wk 16 who received rescue therapy). Analyses included ADA evaluable pts initially randomized to IXE. ADA, titer, and neutralizing antibody (NAb)

status were stratified by MTX use (Integrated data). ACR20 responses stratified by ADA and NAb status were analyzed for SPIRIT-P1 and -P2, separately. Missing values were imputed by non-responder imputation for ACR20 and last observation carried forward for ADA titer.

Results: Of 223 pts treated with concomitant MTX, 96 (89.7%) of IXE Q4W and 110 (94.8%) of IXE Q2W were ADA negative (-); 11 (10.3%) of IXE Q4W and 6 (5.2%) of IXE Q2W were ADA positive (+). Similarly, of 222 pts without concomitant MTX, 103 (88%) of IXE Q4W and 96 (91.4%) of IXE Q2W were ADA-; 14 (12.0%) of IXE Q4W and 9 (8.6%) of IXE Q2W were ADA+. The majority of ADA+ pts had low titer ADA. The table shows ADA, titer, and NAb status stratified by MTX use. The proportion of SPIRIT-P1 pts achieving ACR20 at Wk 52 when ADA- was 63.8% (n=60) of IXE Q4W and 66.7% (n=60) of IXE Q2W, and when ADA+ was 50.0% (n=6) of IXE Q4W and 54.5% (n=6) of IXE Q2W. The proportion of SPIRIT-P2 pts achieving ACR20 response at Wk 52 when ADA- was 57.1% (n=60) of IXE Q4W and 50.9% (n=59) of IXE Q2W, and when ADA+ was 92.3% (n=12) of IXE Q4W and 50.0% (n=2) of IXE Q2W (Figure).

Conclusion: The absolute number of ADA+ pts with IXE was relatively small and the majority were low titer. The presence of ADA did not affect the long-term efficacy of IXE in PsA pts. Concomitant MTX did not appear to have a meaningful effect on ADA development.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: PsA is a chronic and complex inflammatory disease with both articular and extra-articular symptoms, including joint pain, enthesitis, dactylitis, fatigue, and skin and nail manifestations. Improvements in signs and symptoms of PsA have been demonstrated with ixekizumab treatment in patients experienced with biological DMARDs. Here we provide patient-reported outcomes through 2 years of ixekizumab treatment in patients with an inadequate response or intolerance to TNF inhibitors (TNFi).

Methods: In a Phase 3 study, patients who met CASPAR Classification Criteria for PsA and had an inadequate response or intolerance to 1 or 2 TNFi received subcutaneous ixekizumab 80 mg every 2 weeks (IXEQ2W) or every 4 weeks (IXEQ4W), after a 160 mg starting dose, or placebo (PBO) for up to 24 weeks. At Week 16, patients not meeting predefined criteria received rescue therapy. At Week 24, PBO patients were rerandomized to IXEQ2W or IXEQ4W. The ensuing ad hoc analyses are derived from patients in the intent-to-treat population initially randomized to ixekizumab. Patients self-rated multiple areas of health and quality of life on various scales, including the Fatigue Severity Numeric Rating Scale (Fatigue NRS[not yet validated]; 0 [none] to 10 [worst imaginable]), the Medical Outcomes Study 36-Item Short Form Health Survey (SF-36; 0 [no improvement] to 100 [better function or health]), the European Quality of Life-5 Dimension visual analog scale (EQ-5D VAS; 0 [worst imaginable] to 100 [best imaginable]), and the Work Productivity and Activity Impairment-Specific Health Problem (WPAI-SHP). Missing values were imputed by a modified baseline observation carried forward approach.

Results: At 108 weeks of treatment, patients receiving either dose of ixekizumab showed sustained improvements in their level of fatigue, mental and physical component scores on the SF-36, quality of life on the EQ-5D, percentage of presenteeism, overall work impairment, and percentage of activities outside of work. Patients receiving IXEQ4W also showed sustained improvement in percentage of absenteeism, whereas those receiving IXEQ2W did not.

	Baseline		Change from Baseline at Week 108	
	IXEQ4W N=122 n=120	IXEQ2W N=123 n=119	IXEQ4W N=122 n=109	IXEQ2W N=123 n=105
Fatigue NRS	5.9±2.5	6.0±2.5	-1.8±2.8	-2.3±2.9
SF-36, mental component score	48.5±12.1	47.9±12.3	3.7±11.6	3.0±9.9
SF-36, physical component score	32.7±9.2	32.2±9.5	6.8±10.2	6.9±10.5
EQ-5D VAS	53.9±22.4	53.9±19.7	12.2±22.5	10.7±22.5
WPAI-SHP, percentage of absenteeism	11.6±26.6	8.8±23.2	-0.13±19.8	4.2±31.1

Table . (Cont'd)

	Baseline		Change from Baseline at Week 108	
WPAI-SHP, percentage of presenteeism	n=60 45.0±25.7	n=59 37.0±25.0	n=56 -21.1±28.1	n=53 -20.0±26.8
WPAI-SHP, overall work impairment score	n=60 46.9±26.7	n=59 38.8±26.6	n=56 -20.5±29.8	n=53 -18.5±28.6
WPAI-SHP, percentage of impaired activities outside of work	n=118 53.9±24.9	n=119 49.3±26.5	n=107 -23.6±28.8	n=105 -19.6±28.6

Data are mean±standard deviation.

Modified baseline observation carried forward method was used to impute missing data.

EQ-5DVAS=European Quality of Life-5 Dimension visual analog scale; IXEQ2W=ixekizumab 80 mg every 2 weeks; IXEQ4W=ixekizumab 80 mg every 4 weeks; N=number of patients in the analysis population; n=number of patients with non-missing data; NRS=Numeric Rating Scale; SF-36=Medical Outcomes Study 36-Item Short Form Health Survey; WPAI-SHP=Work Productivity and Activity Impairment-Specific Health Problem.

Conclusion: In patients with PsA and inadequate response or intolerance to TNFi, improvements in patient-reported outcomes were sustained through 2 years of ixekizumab treatment.

Abstract Number: 2578

Exposure Response Analyses to Describe the Relationship between Ixekizumab Concentrations and ACR Responses in Psoriatic Arthritis Patients

C. Steven Ernest II, Nieves Velez de Mendizabal and **Leijun Hu**, Eli Lilly and Company, Indianapolis, IN

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Ixekizumab is a high-affinity monoclonal antibody that selectively targets interleukin (IL)-17A. It has been approved to treat adult patients with moderate-to-severe plaque psoriasis and adult patients with active psoriatic arthritis (PsA). Exposure-response relationships nowadays provide important information to help determine the optimal dose/regimens.¹ The analyses described herein characterized the exposure-efficacy relationships for 20, 50, and 70% improvement in the American College of Rheumatology criteria (ACR 20, 50, and 70, respectively) at Week 24, using data from 2 Ph3 PsA studies.

Methods: In both Ph3 studies, Ixekizumab was administered subcutaneously as a 160mg starting dose followed by repeated 80mg doses given every 2 weeks (Q2W) or every 4 weeks (Q4W). An ordered categorical model was used to describe the relationship between observed ixekizumab serum concentrations and the likelihood of ACR response at Week 24. Data from placebo patients were also included in the model fitting to allow estimation of the placebo effect. Using this model, ACR20/50/70 responses were fit simultaneously, and patient specific factors affecting the ACR response rates were explored.

Results: The models adequately characterized the ACR20/50/70 responses at Week 24. The ACR model results suggested similar efficacy between the 80mg Q2W and Q4W dosing regimens, consistent with the trial observations, and a relatively flat exposure - ACR response relationship in the ixekizumab serum concentration range observed in the trials. Age and sex were found to be significant covariates for the drug effect on ACR responses, which however do not affect the selection of optimal regimen for PsA treatment.

Conclusion: In patients with active PsA, the exposure response analyses suggest that increasing the dosing frequency from Q4W to Q2W would not offer additional clinically important ACR improvement. The analyses support the approved ixekizumab regimen for PsA patients, i.e., 160mg at week 0, followed by 80mg given Q4W as the recommended dose.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Ixekizumab (IXE), an IL-17A antagonist, is approved in the USA for the treatment of PsA including patients (pts) with pre-existing enthesitis or dactylitis. Previous results have shown significantly higher resolution of enthesitis (SPIRIT-P1) and dactylitis (SPIRIT-P1 and -P2) after 24 wks.^{1,2} The purpose of the study was to investigate the impact of IXE treatment on the resolution of enthesitis or dactylitis and whether such improvements were associated with improved function and health-related quality of life (HRQoL).

Methods: Pts with active PsA who were biologic-naïve (SPIRIT-P1)¹ or with prior inadequate response to tumor necrosis factor inhibitor(s) (SPIRIT-P2)² were randomized to placebo (PBO) or 80-mg IXE every 4 (IXEQ4W) or 2 weeks (wks; IXEQ2W), after a 160-mg starting dose. At Wk 16, all inadequate responders received rescue therapy (changes in background therapy). Leeds Enthesitis Index (LEI), Leeds Dactylitis Index-Basic (LDI-B), HAQ Disability Index (HAQ-DI), and EuroQoL-5D Visual Analog Scale (EQ-5D VAS) were measured at Wk 24. Missing data or data from inadequate responders were considered non-response or imputed with last observation carried forward for categorical and continuous measures, respectively. Statistical comparisons between PBO and IXE treatment groups were performed with a logistic regression model using Wald's test with treatment and study as factors. In post hoc-analyses, associations between enthesitis and dactylitis with HAQ-DI and EQ-5D VAS are based on an ANCOVA model adjusting for study and Disease Activity of PsA (DAPSA).

Results: In the integrated SPIRIT-P1 and -P2 dataset (N=679), 403 pts (59% of total) had baseline enthesitis (LEI>0) with a mean 2.9 LEI score, and 155 pts (23% of total) had baseline dactylitis (LDI-B>0) with a mean 56.4 LDI-B score. Both IXEQ4W and IXEQ2W had significantly higher enthesitis and dactylitis resolution than PBO at Wk 24 (Table). In ad-hoc analysis, IXE treatment had significantly higher resolution of enthesitis compared to PBO at the enthesal points comprising the LEI score (Table). For all PBO- and IXE-treated pts at Wk 24, least squares mean (SE) HAQ-DI

Table: Enthesitis and Dactylitis Resolution from the Integrated SPIRIT-P1 and SPIRIT-P2 Dataset (Wk 24)

	PBO	IXEQ4W	IXEQ2W
LEI=0	26/126 (21%)	53/136 (39%)*	49/141 (35%)*
Lateral epicondyle=0	24/79 (30%)	39/85 (46%)*	39/86 (45%)
Medial femoral condyle=0	23/79 (29%)	41/92 (45%)*	45/100 (45%)*
Achilles tendon insertion=0	19/64 (30%)	37/75 (49%)*	38/74 (51%)*
LDI-B=0	10/42 (24%)	52/67 (78%)**	30/46 (65%)**

Data presented as n/N (%). IXEQ4W/IXEQ2W=80-mg ixekizumab every 4 or 2 weeks; LDI-B=Leeds Dactylitis Index-Basic; LEI=Leeds Enthesitis Index. N=patients with baseline enthesitis (LEI>0), depicted enthesal points, or dactylitis (LDI-B>0); n=responding patients; PBO=placebo.

*p<0.05; **p<0.01

improvement from baseline were -0.44 (0.05) and -0.25 (0.03; $p<0.01$) for pts who did and did not resolve enthesitis, and -0.41 (0.06) and -0.31 (0.07; $p=0.34$) for pts who did and did not resolve dactylitis. Corresponding EQ-5D VAS improvements were 12.3 (2.2) and 5.8 (1.5; $p=0.02$) for pts who did and did not resolve enthesitis, and 10.8 (2.8) and 9.8 (3.5; $p=0.83$) for pts who did and did not resolve dactylitis.

Conclusion: Treatment with IXE resulted in significant improvement in enthesitis and dactylitis in pts with pre-existing enthesitis or dactylitis. Resolution of enthesitis symptoms was associated with improvements in pts' function and HRQoL.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The purpose of this study was to compare treatment patterns in the 2 years following the initiation of TNF inhibitor (TNFi) in AS patients.

Methods: Adult patients with ≥ 2 AS diagnostic codes (ICD-9: 720.0 and ICD-10:M45.x) were included in this retrospective analysis of data from the Truven MarketScan Commercial Claims database. Patients who newly initiated a TNFi from 01/01/2009-12/31/2013 were indexed on their first TNFi. Patients were required to have a 1-year pre-index clean period of TNFi and continuous enrollment 1-year pre-index and 2-years post-index. Patients were excluded if they had ≥ 2 diagnostic codes for the following conditions: RA, juvenile idiopathic arthritis, PsA, Crohn's disease, ulcerative colitis, plaque psoriasis, hidradenitis suppurativa, or uveitis. Demographic, clinical, and treatment patterns were analyzed. Treatment patterns included switching to a new TNFi, discontinuation (≥ 90 -day gap in therapy), or persistence (no gaps in therapy ≥ 90 -days) during the 2-year follow-up period. Logistic regression analyses predicting persistent vs. non-persistent and switching vs. discontinuation were conducted.

Results: 1,372 AS patients (846 M/ 526 F) met the inclusion criteria for this study. Males (M) had a mean age of 44.29 years, while females (F) had a mean age of 42.31 years. Adalimumab was the first biologic for the majority of patients (44.6% M/ 43.3% F), followed by etanercept (40.4% M/ 41.6% F), infliximab (10.4% M/ 10.8% F), golimumab (4.6% M/ 3.8% F), and certolizumab pegol (0.0% M/ 0.4% F). During the follow-up period, 32.6% of males were persistent on their first TNFi, while only 22.8% of females were persistent. The majority of male (67.4%) and female patients (77.2%) discontinued their first TNFi during the 2-year follow-up period. Patients prescribed cDMARDs were more likely to be persistent, while females and opioid users were less likely to be persistent on their first TNFi (Table 1). Among those that discontinued their first TNFi, 32.8% ($n=187$) of males and 43.6% ($n=177$) of females switched to a 2nd TNFi. Females, cDMARD users, and non-opioid analgesic users were more likely to switch to a 2nd TNFi (Table 2).

Conclusion: This study suggests that approximately 67% of male AS patients and 77% of female AS patients newly initiating a TNFi do not remain on the index therapy 2 years post initiation. In this AS population, the proportion of female patients switching to a second TNFi is higher than the proportion of male patients.

Table 1. Logistic regression analyses predicting persistent vs. non-persistent to first TNFi

	Regression Coefficient	Standard Error	Chi-Square	Odd Ratio (95% CI)	P-value
Intercept	-0.9700	0.2470	15.4200		<0.0001

Comparing Treatment Patterns of Non-Radiographic Axial Spondyloarthritis Patients in the United States and Europe

Theresa Hunter¹, David Sandoval Calderon¹, Steve Lobosco², Rachel Moon², Gary Milligan³ and Rebecca Bolce¹, ¹Eli Lilly and Company, Indianapolis, IN, ²Adelphi Real World, Macclesfield, United Kingdom, ³Adelphi Real World, Macclesfield,, United Kingdom

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: To compare TNF inhibitor (TNFi) use and switching patterns among patients with nr-axSpA in the United States (US) and Europe (EU).

Methods: Data from a cross-sectional, multi-national survey of rheumatologists and their consulting axSpA patients conducted in France, Germany, Italy, Spain, United Kingdom, and the US were analyzed. Rheumatologists and patients completed forms containing information on current treatment and reasons for switching therapies.

Results: Data from 391 rheumatologists (299 EU/92 US) and 1,995 patients with nr-axSpA (1513 EU/482 US) were included in this analysis. In the US, 43.8% of patients were female, with a mean age of 42.6 years, while in the EU, 46.6% of patients were female, with a mean age of 41.0 years. In the US, 30.9% were in remission (as reported by their rheumatologist) compared to 41.3% patients in the EU. In the US sample, 57.7% of patients were receiving a TNFi, 35.1% were receiving a cDMARD and 46.3% were receiving a NSAID. In the EU sample, 54.1% were receiving a TNFi, 30.4% were receiving a cDMARD, and 48.3% were receiving a NSAID (Table 1).

US and EU patients that received TNFi (n=1079) had significantly higher physician-reported severity (p<0.0001) and higher levels of pain (p<0.0001) immediately prior to initiation of the current treatment regimen than those patients not receiving biologic therapy (n=916). Of the US patients prescribed a TNFi, 83.6% were receiving their first, 12.2% their second and 4.2% their third or more. Of the EU patients that were prescribed a TNFi, 91.1% were receiving their first, 6.9% their second, and 2.0% their third or more. Lack of remission, poor pain control, and worsening of condition were the main reasons that US patients switched to their current TNFi. Loss of response over time, worsening of condition, and lack of remission were the main reasons that EU patients switched to their current TNFi (Figure 1).

Conclusion: Even though over half of the patients in this survey were prescribed either a TNFi, cDMARDs, and/or NSAIDs, less than one-third of US patients and less than half of EU patients were in remission. While there was minimal

switching of TNFi, when it was done, it was usually due to lack of efficacy, lack of pain relief, and inability to induce or maintain remission. New therapies such as IL-17 inhibitors were not included in this analysis. Additional research needs to be conducted to better understand how IL-17s can be utilized to help nr-axSpA patients achieve better outcomes.

Table 1. Medication use of nr-axSpA patients in the US and EU

	EU (n=1,513)	US (n=482)
TNF inhibitors	818 (54.1%)	277 (57.4%)
Adalimumab	321 (21.2%)	116 (24.1%)
Etanercept	208 (13.7%)	90 (18.7%)
Infliximab	107 (7.1%)	48 (10.0%)
Certolizumab Pegol	60 (4.0%)	17 (3.5%)
Golimumab	122 (8.1%)	8 (1.7%)
cDMARDs	460 (30.4%)	169 (35.1%)
Methotrexate	284 (18.7%)	90 (18.7%)
Sulfasalazine	145 (9.6%)	61 (12.7%)
Leflunomide	16 (1.1%)	6 (1.3%)
Hydroxychloroquine	4 (0.3%)	7 (1.5%)
Azathioprine	11 (0.7%)	5 (1.0%)
NSAIDs	731 (48.3%)	223 (46.3%)
Cox inhibitors	167 (11.0%)	21 (4.4%)
Non-opioid analgesics	150 (9.9%)	12 (2.5%)
Opioids	50 (3.3%)	23 (4.8%)
Oral Steroids	104 (6.9%)	23 (4.8%)
Injection Steroids	17 (1.1%)	12 (2.5%)

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Secukinumab, a fully human monoclonal IgG1 antibody that selectively neutralizes IL-17A, is currently approved in >75 countries for use in psoriasis /psoriatic arthritis and ankylosing spondylitis with over 150,000 patients treated. Pooled safety data for secukinumab from clinical trials in >7350 patients representing >16,000 patient-treatment years (PY) exposure demonstrated a consistent safety profile.^{1,2} Post-marketing data is considered complementary to data from randomized clinical trials (RCTs); here we report cumulative post-authorization safety data for secukinumab from ongoing periodic safety update reports (PSUR).

Methods: We report the cumulative number of cases along with patient-treatment exposure and exposure-adjusted reporting rates (EARR) across 5 successive PSUR periods covering Dec 26, 2014 to June 25, 2017 for the following adverse events: infections, neutropenia, hypersensitivity, malignant and unspecified tumors, major adverse cardiac events (MACE), inflammatory bowel disease (IBD), immunogenicity, hepatitis B reactivation and interactions with live vaccines.

Results: The cumulative post-marketing exposure to secukinumab was estimated to be ~96,054 PY across the approved indications. Overall EARRs are summarized in the Table. EARR for infections and serious infections were 4.7 and 1.8 per 100 PY, respectively. Neutropenia was reported at the rate of 0.07 per 100 PY. Hypersensitivity reporting rate was 2.4 per 100 PY. EARR for malignancies and MACE were both 0.2 per 100 PY with most assessable cases having multiple confounders, risk factors, or alternative explanations for the events. Total IBD was reported at the rate of 0.2 per 100 PY. There was one case of immunogenicity, and no cases of either hepatitis B reactivation or interactions with live vaccines reported. The safety profile from the PSUR was consistent to that reported in RCTs with secukinumab.^{1,2}

Conclusion: Secukinumab was associated with a consistent safety profile in the post-marketing setting across the approved psoriasis, psoriatic arthritis and ankylosing spondylitis indications. There were no new or changing safety signals reported in successive PSUR periods.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Secukinumab has demonstrated rapid and sustained improvements in the signs and symptoms of ankylosing spondylitis (AS) across multiple randomized controlled trials. Using pooled data from MEASURE 1,2 and 4 (NCT01358175; NCT01649375; NCT02159053), this comprehensive analysis investigated the effect of secukinumab on health-related quality of life (HRQoL), assessed by the Short Form-36 Health Survey (SF-36), in TNF inhibitor (TNF)-naïve and TNF inhibitor-inadequate responder/intolerant(TNF-IR) patients (pts) with AS.

Methods: Pts with active AS were randomized to secukinumab (10 mg/kg intravenously followed by 150 or 75 mg subcutaneously [SC] in MEASURE 1; 150 or 75 mg SC in MEASURE 2; and 150 mg SC with/without loading in MEASURE 4) or placebo (PBO) for 16 wks, stratified by prior TNF inhibitor therapy. At Wk 16 (or Wk 24 in MEASURE 1 depending on ASAS20 response), pts on PBO were switched to secukinumab. Mixed-model for repeated measures was used to assess change in SF-36 from baseline (BL) up to Wk 16; observed data are presented at Wk 52. The proportion of pts reporting improvements meeting or exceeding the minimal clinically important differences (MCID) for SF-36 physical (PCS responders), mental component summary (MCS responders) and individual SF-36 domains was assessed. Missing data were imputed as non-response, and the proportion of responders at Wk16 were compared between treatment groups using Fisher's exact test. Pooled data for pts receiving the licensed dose of secukinumab (150 mg) or PBO are shown.

Results: A total of 743 pts were included: 430 and 313 in the secukinumab 150 mg and PBO groups, respectively, of whom approximately 30% were TNF-IR. The least squares mean changes from BL to Wk 16 in SF-36 were significantly greater

with secukinumab 150 mg vs PBO for PCS (6.09 vs 2.75; $p < 0.0001$), MCS (4.40 vs 2.45; $p < 0.01$), and all individual domain scores. Similar improvements were reported with secukinumab 150 mg vs PBO in TNF-naïve pts at Wk 16 (PCS: 7.23 vs 3.40, $p < 0.0001$; MCS: 5.22 vs 2.92, $p < 0.01$). In TNF-IR pts, PCS score was significantly improved with secukinumab 150 mg vs PBO at Wk16 (4.79 vs 2.44; $p < 0.05$). There was a significantly higher proportion of PCS responders in the secukinumab 150 mg group at Wk 16 vs PBO, regardless of TNF status (Table). Similar results were reported for all individual domains in the overall population. Consistent trends for higher response rates in favour of secukinumab 150 mg were observed in both TNF subgroups, with the TNF-naïve subgroup reaching statistical significance across all individual domains except mental health. Improved PCS, MCS, individual domain scores and responder rates were sustained to Wk 52 with secukinumab 150 mg.

Conclusion: Secukinumab 150 mg resulted in significant, clinically meaningful, and sustained improvements in HRQoL (SF-36) up to Wk 52 in both TNF-naïve and TNF-IR pts with AS.

Table. Proportion of SF-36 responders (≥ 2.5 point improvements in PCS and MCS; ≥ 5 points for individual domains) at Wks 16 and 52 in the overall, TNF-naïve, and TNF-IR groups in a pooled analysis from MEASURE 1, MEASURE 2, and MEASURE 4 RCTs.

Responder rates (%)	Secukinumab 150 mg						Placebo		
	Week 16			Week 52			Week 16

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Uveitis, a common extra-articular manifestation of spondyloarthritis (SpA), has an estimated prevalence of 33.2% in patients with ankylosing spondylitis (AS), which increases with duration of disease and positive HLA-B27 status.¹ The exposure-adjusted incidence rates (EAIR) of uveitis (combined new-onset and flares) reported in AS patients treated with TNF inhibitors is 2.6–3.5 per 100 patient-years.^{2–5} Here we report the incidence of uveitis in secukinumab-treated AS patients in long-term pooled clinical data from three Phase 3 trials (MEASURE 1–3 [NCT01358175, NCT01649375, NCT02008916]) and from post-marketing analyses.

Methods: Analysis included pooled patient-level data from all patients (N=794) who received any dose (≥ 1) of secukinumab up to the last patient attending Week 156 study visit in MEASURE 1, and up to visit Week 156 in MEASURE 2 and visit Week 104 in MEASURE 3 for each patient, respectively. Post-marketing data were from the most recent periodic safety surveillance report. Incidence of uveitis is reported as EAIR per 100 patient-years of secukinumab exposure.

Results: In the three Phase 3 clinical trials of AS patients, 135 (17%) reported pre-existing (but not active or ongoing) uveitis at baseline and 589 (74.2%) were HLA-B27 positive. The EAIR for uveitis was 1.4 per 100 patient-years over the entire treatment period (N=794; **Table**). Among all cases of uveitis (n=26), 14 (54%) were flares in patients with a history of uveitis at baseline. The EAIR of uveitis in the post-marketing data (based on cumulative secukinumab exposure of 96,054 patient-years) was 0.03 per 100 patient-years.

Conclusion: In secukinumab-treated patients with active AS, a low incidence of uveitis was observed, including new-onset cases and flares, in both clinical trials and post-marketing analyses.

Session Date: Tuesday, October 23, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Secukinumab, a fully human monoclonal IgG1 antibody (mAb) that selectively targets IL-17A, is efficacious for the treatment of psoriasis, psoriatic arthritis (PsA) and ankylosing spondylitis (AS). mAb therapies may be associated with immunogenicity and the production of anti-drug antibodies (ADAb) that may cause adverse events (AEs) and/or affect drug pharmacokinetics and clinical response. Secukinumab immunogenicity occurred in 0.4% of patients with plaque psoriasis and not associated with loss of efficacy or issues of clinical concern.¹ Here we report the immunogenicity of secukinumab in PsA and AS patients treated with secukinumab for up to 52 weeks (Wks).

Methods: Immunogenicity in patients with PsA (FUTURE 1–3 studies) and AS (MEASURE 1–4 studies) exposed to secukinumab was evaluated at baseline (BL) and Wks 16 (AS only), 24, and 52. ADAb were defined as a positive ADAb (ADAb⁺) signal in ≥1 post-secukinumab treatment sample in patients negative at BL. ADAb positive samples were analyzed for drug-neutralizing potential, immunogenicity-related AEs and ADAb impact on secukinumab pharmacokinetics and efficacy through Wk 52.

Results: Of 1414 treated PsA and 1163 treated AS patients with samples for immunogenicity evaluation, 5 (0.35%) and 8 (0.68%) developed ADAb, respectively, over 52-wks (Table). All but 1 ADAb⁺ PsA patients were biologic-naïve; 2/5 PsA and 1/8 AS ADAb⁺ patients received concomitant methotrexate, and 2/8 AS ADAb⁺ patients received concomitant sulfasalazine. Associations between ADAb and secukinumab dose, frequency or mode of administration were not observed. ADAb were neutralizing in only 1 patient (with PsA), and none were associated with any immunogenicity-related AE. All ADAb were associated with normal secukinumab pharmacokinetics and none were associated with loss of secukinumab efficacy over 52 wks (Table). In the pharmacokinetics samples from patients with PsA or AS at the time points that immunogenicity was measured, 96% had secukinumab serum concentration below the drug tolerance level of 53.8 µg/ml, confirming sufficient immunogenicity sensitivity during treatment with secukinumab.

Conclusion: Secukinumab treatment was associated with a low incidence of immunogenicity in PsA and AS patients, as shown by ADAb detection in only 0.35% PsA patients and 0.68% AS patients over 52 wks in a database of >2500 patients, which is consistent with the low incidence of immunogenicity (0.4%) seen with secukinumab in patients with plaque psoriasis.¹

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Tofacitinib is an oral Janus kinase (JAK) inhibitor for the treatment of psoriatic arthritis (PsA). Cytokines involved in lymphocyte development, function, and homeostasis signal through JAKs, and reductions in mean lymphocyte count overtime have been reported in tofacitinib-treated patients (pts) with rheumatoid arthritis.¹

Methods: Data were pooled from 2 placebo (PBO)-controlled, double-blind, Phase (P) 3 studies (OPAL Broaden [12 months; NCT01877668]; OPAL Beyond [6 months; NCT01882439]). Pts had active PsA and inadequate response to ≥ 1 conventional synthetic DMARD (OPAL Broaden) or to ≥ 1 tumor necrosis factor inhibitor (OPAL Beyond). Pts were randomized to tofacitinib 5mg twice daily (BID), tofacitinib 10 mg BID, adalimumab 40 mg subcutaneous injection once every 2 weeks (active control; OPAL Broaden only), or PBO. PBO pts advanced in a blinded manner to tofacitinib 5 or 10 mg BID at Month (M) 3. Absolute lymphocyte counts (ALCs) and lymphocyte subset counts (LSCs) were assessed every 3 months as part of safety monitoring procedures in the P3 studies (any abnormalities were confirmed by retesting). Median ALCs and LSCs are reported up to M6. Incidence rates (pts with event/100 pt-years) for serious infections (SIs) were assessed by confirmed (2 sequential measurements) ALC categories (≥ 2.0 , <2.0 – 1.5 , <1.5 – 1.0 , and <1.0 – $0.5 \times 10^3/\text{mm}^3$) up to M12.

Results: The analysis included 816 pts: tofacitinib 5 mg BID, n=238; tofacitinib 10 mg BID, n=236; adalimumab, n=106; PBO, n=236. Up to M6, minimal decreases in median ALC were observed in pts who received tofacitinib 5 mg BID, tofacitinib 10 mg BID, and no change observed in PBO (up to M3 only) (Table). LSCs, including total T cells (CD3+), cytotoxic T cells (CD8+), and NK cells (CD16+56+), showed a similar trend to ALC for both tofacitinib doses (Table), with minimal decreases observed over 6 months. B cells (CD19+) showed numerical increases across treatments. Percentage

changes from baseline in LSCs at M6 showed a generally similar pattern to absolute values. In adalimumab-treated pts, ALCs and all LSCs increased over 6 months. Up to M6, no pts receiving tofacitinib or adalimumab had confirmed ALC $<0.5 \times 10^3/\text{mm}^3$; 1 pt receiving PBO had a confirmed ALC $<0.5 \times 10^3/\text{mm}^3$ over 3 months, resulting in discontinuation from

Table. Median (range) absolute lymphocyte counts and lymphocyte subset counts up to Month 6, pooled across OPAL Broaden and OPAL Beyond

^aOPAL Broaden only; ^bPlacebo-controlled period was 3 months

ALC, absolute lymphocyte count; BID, twice daily; N, number of patients with observations at baseline; NK, natural killer; Q2W, once every 2 weeks; SC, subcutaneous

the study before advancing to active treatment. Up to M12, SIs were reported in 7 tofacitinib- (including 2 pts who advanced from PBO) and 1 adalimumab-treated pt; only 1 SI (PBO advanced to tofacitinib) occurred >6 months after treatment initiation. There was no trend that suggested an increased risk of SIs in any ALC category (data not shown).

Conclusion: Minimal changes in ALCs and LSCs were observed up to M6 in tofacitinib-treated pts with active PsA. Incidence of SIs did not appear to be related to ALC in this clinical trial setting.

The Impact of Tumor Necrosis Factor Inhibitors on Diabetes Mellitus Among Patients with Inflammatory Arthritis

Santhi Mantravadi¹, Michael D. George² and Alexis Ogdie³, ¹Department of Clinical Pharmacology, Division of Rheumatology, Jefferson University School of Medicine, University of Pennsylvania, Philadelphia, PA, ²Division of Rheumatology, University of Pennsylvania, Philadelphia, PA, ³Medicine/Rheumatology and Epidemiology, University of Pennsylvania, Philadelphia, PA

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Tumor necrosis factor (TNF) is a key inflammatory cytokine in the pathogenesis of psoriatic arthritis (PsA), RA, ankylosing spondylitis (AS), and diabetes mellitus (DM). TNF inhibitors (TNFi) have been shown to be associated with a decreased incidence of DM, but it is unknown whether treatment of PsA, RA, or AS with TNFi has off-target therapy benefits for patients with DM. The objective of this study is to determine whether initiation of a TNFi, compared to initiation of MTX or metformin, results in a decrease in Hemoglobin A1c (HbA1c) in patients PsA, RA, or AS with DM and elevated HbA1c.

Methods: A retrospective cohort study was conducted in OptumInsight from 2000-2014, a de-identified administrative claims database that includes laboratory values for approximately 10% of patients. We identified patients with PsA, RA, or AS, and DM (defined by ICD-9-CM codes), with an HbA1c ≥ 7 and examined change in HbA1c among new initiators of a TNFi (etanercept, adalimumab, certolizumab, golimumab, or infliximab), MTX, or metformin (positive control). A baseline period of 12 months prior to the index date was required to capture potential confounders. All patients were required to have one HbA1c in the six months prior to and one HbA1c in the 6 months after drug initiation. We compared median HbA1c change in each treatment group using Wilcoxon Rank Sum (unadjusted). Linear regression models were used to compare change in HbA1c between treatment using MTX as the reference with adjustment for age, sex, baseline A1c, DM medications, and comorbidities in the baseline period, with clustering to account for multiple new drug initiations per patient.

Results: Among 13,135 drug initiations in 12,689 patients with PsA, RA, or AS, diabetes and available HbA1c values, HbA1c was ≥ 7 before 255 (35%) of TNFi initiations, 411 (37%) of MTX initiations, and 5894 (52%) of metformin initiations. The average time between baseline and follow-up HbA1c values was 227 days. Median HbA1c change was -0.30 (IQR -1.10, 0.30) after TNFi initiation, -0.40 (IQR -1.20, 0.30) after MTX initiation, and -0.80 (IQR -1.70, -0.10) after metformin initiation. In adjusted analyses, TNFi initiators had a significantly smaller decrease in HbA1c compared to MTX initiators, β 0.25 (95% CI: 0.04, 0.47), while Metformin initiators had a significantly greater change in HbA1c than MTX patients, β -0.33 (95% CI: -0.47, -0.18).

Conclusion: TNFi and MTX initiation lead to a decline in HbA1c by approximately half as much as metformin.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Pain is a core domain of psoriatic arthritis (PsA), and it is recommended that all randomized controlled trials (RCTs) in patients (pts) with PsA include an assessment of pain.¹ Tofacitinib is an oral Janus kinase inhibitor for the treatment of PsA. The objective of this post hoc analysis was to determine the impact of pain severity at baseline as a predictor of time to pain improvement in pts with active PsA following treatment with tofacitinib for up to 12 months.

Methods: Data from pts randomized to tofacitinib 5 mg twice daily (BID) in 2 Phase 3 RCTs were included in this analysis. Pts had active PsA and an inadequate response to ≥ 1 conventional synthetic DMARD (csDMARD) (OPAL Broaden; NCT01877668), or to ≥ 1 tumor necrosis factor inhibitor (OPAL Beyond; NCT01882439). All pts continued on a stable dose of a single csDMARD. Current arthritis pain severity was reported by pts using a 100 mm visual analog scale, where higher scores indicated greater severity of pain. Pain improvement was defined as the first post-baseline pain improvement of $\geq 30\%$ (meaningful change), $\geq 50\%$ (substantial change), and $\geq 70\%$ relative to baseline.² Median time to pain improvement was assessed using a parametric model. The model was fitted to examine the relationship between baseline pain severity and time to pain improvement.

Results: Overall, 236 pts who received tofacitinib 5 mg BID were included in this analysis. The Table and Figure present an estimated relationship between baseline pain score and the median time to response. It was shown that, for pts with a baseline pain level of 90 mm, the predicted median time to achieve $\geq 30\%$ pain improvement was 39.3 days, meaning that 50% of pts with baseline pain of 90 mm were estimated to achieve $\geq 30\%$ pain improvement during the first 39.3 days. For a baseline pain level of 50 mm, the predicted median time to achieve $\geq 30\%$ pain improvement was 56.7 days (Table; Figure).

Figure. Predicted median time (days) to pain improvement ($\geq 30\%$, $\geq 50\%$, and $\geq 70\%$ improvement) as a function of baseline pain severity in pts with PsA receiving tofacitinib 5 mg BID

Table. Predicted median time (days) to pain improvement ($\geq 30\%$, $\geq 50\%$, and $\geq 70\%$ improvement) as a function of baseline pain severity in pts with PsA receiving tofacitinib 5 mg BID

Baseline pain, mm (VAS)	Predicted median time to improvement, days (95% CI)		
	$\geq 30\%$ improvement	$\geq 50\%$ improvement	$\geq 70\%$ improvement

80	43.0 (34.3, 54.3)	81.1 (62.7, 104.9)	186.5 (134.7, 258.1)
90	39.3 (29.6, 52.0)	77.5 (56.5, 106.4)	182.4 (123.0, 270.5)
100	35.8 (25.5, 50.3)	74.2 (50.6, 108.7)	178.4 (114.3, 280.0)

BID, twice daily; CI, confidence interval; PsA, psoriatic arthritis; pts, patients; VAS, visual analog scale.

Conclusion: In pts with active PsA treated with tofacitinib 5 mg BID, the time to pain improvement was dependent upon baseline pain severity, with lower pain scores at baseline associated with longer time to improvement than higher pain scores. Pts with higher pain severity at baseline achieved clinically meaningful pain improvements faster than pts with lower severity of pain. It is important to consider the non-linearity of change in pain, and the decreased ability to assess change in pain among pts with lower pain scores at baseline, when interpreting these findings.

Fibromyalgia	5 (7.8)	8 (6.1)
History of prior biologic use, n (%) [‡]	60 (93.8)	61 (46.2)
No. of prior biologics, n (%) [‡]		
0	4 (6.3)	71 (53.8)
1	22 (34.4)	39 (29.5)
≥ 2	38 (59.4)	22 (16.7)
History of prior csDMARD use, n (%) [‡]	40 (62.5)	39 (29.5)
History of prior prednisone use, n (%)	14 (21.9)	39 (29.5)

BMI, body mass index; csDMARD, conventional synthetic disease-modifying antirheumatic drug; PsA, psoriatic arthritis.

* Other biologics included abatacept, adalimumab, etanercept, certolizumab, infliximab, golimumab, and ustekinumab.

[†] All values are presented as mean (SD) unless otherwise stated.

[‡] P < 0.05 for comparisons between secukinumab and other biologic initiators.

Background/Purpose: Few real-world studies have characterized patients with psoriatic arthritis (PsA) who initiate secukinumab. This study described characteristics of patients who initiated secukinumab and other biologics for the treatment of PsA in the US Corrona PsA/SpA Registry.

Methods: This study included adult patients with PsA enrolled in the Corrona PsA/SpA Registry who initiated secukinumab or other biologics (abatacept, adalimumab, etanercept, certolizumab, infliximab, golimumab, and ustekinumab) at a Corrona visit between April 2017 and March 2018. Patient demographics, clinical characteristics, treatment profile, disease activity, quality of life, and work productivity were assessed at the time of biologic initiation (baseline) and compared between patients who initiated secukinumab and other biologics using *t* tests or χ^2 tests.

Results: Of the 196 patients with PsA who initiated a biologic, 64 (32.7%) initiated secukinumab and 132 (67.3%) initiated other biologics. Secukinumab initiators were less likely to work full time (45.3% vs 62.6%) and more likely to be disabled from working (17.2% vs 4.6%), had longer mean symptom (12.3 vs 7.9 years) and disease duration (8.4 vs 5.2 years), and were more likely to have depression (23.4% vs 12.1%) vs those who initiated other biologics (**Table 1**; all *P* < 0.05); secukinumab initiators were also twice as likely to have prior biologic (93.8% vs 46.2%) and csDMARD use (62.5% vs 29.5%) (**Table 1**; both *P* < 0.05). Secukinumab initiators had significantly higher mean SPARCC Enthesitis Index scores (4.0 vs 2.4), were less likely to have dactylitis (14.1% vs 26.5%), and had a worse health state (mean EQ VAS, 59.4 vs 66.3) compared with other biologic initiators (**Table 2**; all *P* < 0.05). Although no significant differences were noted for other measures of disease activity, quality of life, and work productivity, secukinumab initiators on average had higher tender joint counts (8.3 vs 6.6) and worse pain (54.5 vs 49.4), fatigue (51.2 vs 48.1), and patient global skin assessment scores (48.0 vs 41.3) compared with other biologic initiators.

Conclusion: In this real-world study of US patients with PsA, secukinumab initiators had more established disease, were less likely to be working full-time, and had increased prior biologic use compared with other biologic initiators. Although there were few significant differences across several disease activity, quality of life, and work productivity measures (eg,

Table 2. Disease Activity, Quality of Life, and Work Productivity Among Patients With PsA Who Initiated Secukinumab or Other Biologics*

*Assessed among patients with swollen joint count > 1 at initiation.

§Assessed in patients who did not meet criteria for either cDAPSA remission or low disease activity at the time of treatment initiation. Change at 6 months was calculated as the 6-month visit value minus the baseline value.

MCID=minimal clinically important difference.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The effectiveness of therapies has rarely been studied in the subpopulation of patients with oligoarticular psoriatic arthritis (PsA). The objective of this study was to examine the baseline characteristics and 6-month clinical assessments of patients with PsA who had oligoarthritis (≤ 4 swollen joints) and initiated treatment with apremilast (APR) or methotrexate (MTX) monotherapy in the Corrona Psoriatic Arthritis/Spondyloarthritis (PsA/SpA) Registry, a prospective, US-based observational cohort study. Patients initiating biologic disease-modifying anti-rheumatic drug (bDMARD) monotherapy were also examined as a point of reference.

Methods: Patients ≥ 18 years of age with PsA and oligoarthritis in the registry who initiated monotherapy with APR, MTX, or a bDMARD and had a 6-month follow-up visit between June 2014 and March 2018 were included in the analysis. Descriptive statistics were calculated for patients' clinical characteristics and disease assessments at treatment initiation and at the 6-month follow-up visit.

Results: The analysis included 150 patients initiating therapy (APR: n=34; MTX: n=15; bDMARD: n=101). Among APR and MTX initiators, 80% and 20% received at least 1 prior bDMARD, respectively (Table 1). APR was associated with higher levels of disease activity at baseline, including higher swollen joint count, Clinical Disease Activity for Psoriatic Arthritis (cDAPSA) (moderate and high: 50% [APR] vs. 27% [MTX]) and disease impairments represented by numerically higher scores of patient-reported outcome (PRO) measures, including the HAQ. Taken together, results suggest that APR initiators had more refractory oligoarthritis compared with MTX initiators. Clinical assessments at the 6-month follow-up indicate that patients who initiated APR experienced numerically higher improvements in disease activity and various PRO measures compared with MTX, as well as achievement of ≤ 1 swollen joint, HAQ minimal clinically important difference, and cDAPSA remission or low disease activity (Table 2). Of note, results associated with bDMARDs were more comparable to that of APR.

Conclusion: In this analysis of the Corrona PsA/SpA Registry, APR monotherapy was more often used in patients with refractory oligoarthritis compared with MTX monotherapy. Despite this, the APR group experienced numerically greater improvements in disease activity measures. Improvements observed with APR in patients with long-standing disease and refractory oligoarthritis were modest and comparable to that of bDMARDs.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Until recently, inhibitors of TNF (TNFi) had been the only bDMARD treatment option for patients with axial spondyloarthritis (AxSpA). This situation changed when anti-interleukin-17A monoclonal antibody secukinumab (SEC) became available in March 2017. We aimed to characterize and compare patient populations starting treatment with SEC versus TNFi during the first year of SEC availability in Czech Republic.

Methods: All adult patients with AxSpA who either started biological therapy or switched to a new drug during the period of March 1st 2017 and March 1st 2018 were considered. Baseline characteristics of patients were described and compared between the two treatments. Mean \pm SD and absolute/relative frequencies were used to describe continuous and categorical variables, respectively. P-value of Fisher's exact test and Mann-Whitney test is given when assessing difference between groups in categorical and continuous variables. Odds for the prescription of SEC versus TNFi were assessed using logistic regression. ATTRA is a computerized registry of patients receiving bDMARD therapy in the Czech Republic. Both TNFi and SEC is indicated for patients with AxSpA who have failed treatment with NSAIDs, have CRP \geq 1 mg/dl and BASDAI score \geq 4. The choice of drug is left to the discretion of treating rheumatologist.

Results: A total of 500 bDMARD treatments were initiated or changed during the study period, 460 were included in the analysis (77 SEC, 383 TNFi). SEC was initiated as first line therapy in 48.1%, TNFi in 49.9% (P=0.804). Significant differences between SEC and TNFi were observed for some baseline patient characteristics (Table 1). Overall, patients starting SEC tended to have higher disease activity and worse measures of physical functioning. Patients after failure of \geq 3 bDMARDs are 4.2 times more likely to receive SEC compared to patients starting their first line bDMARD (P <0.001). Odds of receiving SEC increase with increasing values of CRP (P = 0.027), BASDAI (P = 0.004), ASDAS (P = 0.024), BASFI (P = 0.004) and decrease with higher scores of SF36 physical role functioning (P = 0.008), physical functioning (P = 0.004) and bodily pain (P = 0.005) domains. Baseline disease activity and physical functioning measures were not significantly different between SEC and TNFi among a subgroup of 228 patients (37 SEC, 191 TNFi) receiving first line bDMARD.

Conclusion: Our data suggest that in real-life SEC is used as a first line bDMARD just as often as TNFi, however after failure of at least three bDMARDs patients are more likely to receive SEC. Overall patients starting SEC tend to have higher disease activity compared to patients starting TNFi.

Table 1: Selected baseline characteristics of patients starting SEC or TNFi treatment for AxSpA

Parameter	SEC	TNFi	P-value
Female gender, N (%)	23 (29.9%)	125 (32.6%)	0.690

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Until recently, inhibitors of TNF (TNFi) had been the only bDMARD treatment option for patients with psoriatic arthritis (PsA). This situation changed when anti-interleukin-17A monoclonal antibody secukinumab (SEC) became available in March 2017. We aimed to characterize and compare patient populations starting treatment with SEC versus TNFi during the first year of SEC availability in Czech Republic.

Methods: All adult patients with PsA who either started biological therapy or switched to a new drug during the period of March 1st 2017 and March 1st 2018 were considered. Baseline characteristics of patients were described and compared between the two treatments. Mean \pm SD and absolute/relative frequencies were used to describe continuous and categorical variables, respectively. P-value of Fisher's exact test and Mann-Whitney test is given when assessing difference between groups in categorical and continuous variables. Odds for the prescription of SEC versus TNFi were assessed using logistic regression. ATTRA is a computerized registry of patients receiving bDMARD therapy in the Czech Republic. Both TNFi and SEC is indicated for patients with PsA who have previously failed treatment with csDMARD. The choice of drug is left to the discretion of treating rheumatologist.

Results: A total of 243 bDMARD treatments were initiated or changed during the study period, 222 were included in the analysis (59 SEC, 163 TNFi). SEC was initiated as first line therapy in 47.5%, TNFi in 55.2% (P=0.361). Significant differences between SEC and TNFi were observed for some baseline patient characteristics (Table 1). Overall, patients starting SEC tended to have higher disease activity and worse measures of physical functioning. Patients after failure of 2 bDMARDs are 2.5 times more likely and after failure of ≥ 3 bDMARDs are 6.5 times more likely to receive SEC compared to patients starting their first line bDMARD (P<0.05). Odds of receiving SEC increase with increasing values of DAS28 (P = 0.003), SDAI (P = 0.014), and HAQ (P = 0.003) and decrease with higher scores of EUROQOL (p=0.002) and SF36 physical role functioning (P = 0.046), bodily pain (P = 0.004) and social role functioning (P = 0.040) domains. Baseline disease activity and physical functioning measures were not significantly different between SEC and TNFi among a subgroup of 118 patients (28 SEC, 90 TNFi,) receiving first line bDMARD.

Conclusion: Our data suggest that in real-life SEC is used as a first line bDMARD just as often as TNFi, however after failure of two or more bDMARDs patients are more likely to receive SEC. Overall patients starting SEC tend to have higher disease activity compared to patients starting TNFi.

Table 1: Selected baseline characteristics of patients starting SEC or TNFi treatment for PsA

Parameter	SEC	TNFi	P-value
Female gender, N (%)	31 (52.5%)	86 (52.8%)	1.000
Age in years, mean (±SD)	48.8 (9.0)	51.6 (11.6)	0.081
Disease duration in years, mean (±SD)	12.6 (9.0)	11.2 (7.9)	0.464
BMI, mean (±SD)	30.1 (6.5)	28.8 (5.2)	0.248
CRP in mg/dL, mean (±SD)	2.18 (2.38)	1.80 (2.55)	0.187
Presence of psoriasis, N (%)	36 (92.3%)	133 (91.1)	1.000
DAS28, mean (±SD)	5.0 (1.2)	4.2 (1.6)	0.004
SDAI, mean (±SD)	29.2 (13.3)	23.3 (15.1)	0.015
HAQ, mean (±SD)	1.4 (0.6)	1.1 (0.7)	0.005
EUROQOL, mean (±SD)	0.2 (0.3)	0.4 (0.4)	0.004
SF-36 social role functioning, mean (±SD)	43.4 (22.5)	50.9 (23.3)	0.039
SF-36 bodily pain, mean (±SD)	29.9 (15.4)	40.8 (24.9)	0.020
1st line bDMARD, N (%)	28 (47.5%)	90 (55.2%)	0.361

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: IBI303, an injection of recombinant human anti-tumor necrosis factor- α monoclonal antibody, is adalimumab biosimilar candidate. Physicochemical properties assessment and non-clinical studies showed the structure, pharmacodynamics and pharmacokinetics of IBI303 were similar to adalimumab. This study compared the efficacy and safety of IBI303 with adalimumab in patients with ankylosing spondylitis (AS).

Methods: This was a randomized, double-blind, and adalimumab-controlled phase III clinical study. Patients met the classification criteria of the 1984 modified New York criteria for AS and in active disease were enrolled, and assigned to IBI303 or adalimumab groups in 1:1 ratio. The primary endpoint was the percentage of patients achieving the Assessment of SpondyloArthritis International Society (ASAS) 20 response criteria at week 24. Patients without data at week 24 were treated as non-responders. The safety and immunogenicity of the two groups were also compared.

Results: A total of 438 patients were randomized (IBI303, n=220; adalimumab, n=218). Baseline demographics were generally similar between the two groups. At week 24, there were 75.0%(165/220) and 72.5%(158/218) patients achieved ASAS20 response in IBI303 and adalimumab group, respectively, and 95% confidence interval (CI) of differences between the two groups was -5.7% to 10.8%, indicating the IBI303 was equivalence to that of adalimumab in efficacy. Results of other efficacy endpoints were comparable between the two groups (Table 1). The overall incidence of adverse events (AEs) was 79.1% for IBI303 group and 81.7% for adalimumab group, respectively (Table 2). The most common AEs in IBI303 group were upper respiratory tract infection (24.5%), alanine aminotransferase increased (12.7%) and hyperuricaemia (10.5%), while in adalimumab group were upper respiratory tract infection (20.6%), alanine aminotransferase increased (19.3%) and Aspartate aminotransferase increased (10.6%). The positive rate of antidrug antibodies was 58.6% and 61.9%, and the positive rate of neutralizing antibodies was 46.5% and 51.1% in IBI303 and adalimumab group, but had no observable impact on ASAS20 response.

Conclusion: This study demonstrated IBI303 is similar to adalimumab in clinical efficacy, safety and immunogenicity in patients with moderate to severe AS.

Table 1. ASAS response rates at week 24 (Full analysis set)

	IBI303 N=220 n (%)	Adalimumab N=218 n (%)	difference (95% CI)	P value
ASAS20	165(75.0)	158(72.5)	2.5% (-5.7%, 10.8%)	0.5732
ASAS40	137(62.3)	134(61.5)	0.8% (-8.3%, 9.9%)	0.8636
ASAS partial remission	65(29.5)	74(33.9)	-4.4% (-13.1%, 4.3%)	0.3724

Table 2. Summary of AEs

	IBI303 N=220 n (%)	Adalimumab N=218 n (%)
Treatment-emergent adverse events	174 (79.1)	178 (81.7)
Significant AEs	119 (54.1)	113 (51.8)
Serious adverse events	7 (3.2)	8 (3.7)
AEs leading to study discontinuation	6 (2.7)	5 (2.3)

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Pain is a core domain of psoriatic arthritis (PsA).¹ Rapid, sustained pain reduction is a priority for patients (pts) and physicians when choosing treatment. Tofacitinib is an oral Janus kinase inhibitor for the treatment of PsA. This post hoc analysis aimed to estimate time to clinically meaningful pain improvement with tofacitinib.

Methods: Data were analyzed from 2 Phase 3 studies of tofacitinib in pts with active PsA and an inadequate response to ≥1 conventional synthetic DMARD (OPAL Broaden; NCT01877668; 12-month study) or to ≥1 tumor necrosis factor inhibitor (OPAL Beyond; NCT01882439; 6-month study). Pts treated with tofacitinib 5 mg twice daily (BID) and placebo (PBO) advanced to tofacitinib 5 mg BID at Month 3 (PBO-tofacitinib), in combination with csDMARDs, were included in

this analysis. Current arthritis pain severity was reported by pts using a 100 mm visual analog scale, where higher scores indicated greater severity of pain. Pain improvement was defined as the first post-baseline improvement of $\geq 30\%$ (meaningful change), $\geq 50\%$ (substantial change), or $\geq 70\%$ relative to baseline.² Time-to-event analyses were performed using a Kaplan-Meier (KM) method on pooled data. Descriptive analyses of the rate of improvements by study were performed.

Results: Overall, 354 pts were available for analysis. Rates of pain improvement overtime with tofacitinib 5 mg BID were approximately the same in both studies (Figure). By Month 1, $\geq 40\%$ of pts experienced $\geq 30\%$ pain improvement, and by Month 2, approximately 55% of pts experienced $\geq 30\%$ pain improvement (Figure). KM analyses showed that pts receiving tofacitinib 5 mg BID achieved improvements in pain severity of 30–70% significantly faster compared with pts in the PBO-tofacitinib group (Table). The median time to $\geq 30\%$ pain improvement was 55 days in the tofacitinib 5 mg BID group and

Figure. Proportion of pts receiving tofacitinib 5 mg BID with $\geq 30\%$ improvement in pain, by study

Table. Median time (days) to clinically meaningful pain improvement by improvement threshold in pts with PsA

VAS pain improvement threshold	Median time (days) to pain improvement		Test of equality between groups Log-rank test, p value
	Tofacitinib 5 mg BID	PBO switching to tofacitinib 5 mg BID at Month 3	
$\geq 30\%$	55	106	0.0132
$\geq 50\%$	85	169	0.0068
$\geq 70\%$	184	337	0.0033

Derived using non-parametric KM models for time to event

BID, twice daily; KM, Kaplan-Meier; pts, patients; PBO, placebo; PsA, psoriatic arthritis; VAS, visual analog scale

106 days in the PBO-tofacitinib group (pts switched to tofacitinib 5 mg BID at Month 3; $p=0.0132$). Similar trends between treatment groups were observed across other pain improvement thresholds.

Conclusion: In pts with active PsA, faster, clinically meaningful pain improvements were reported in pts receiving tofacitinib 5 mg BID vs pts receiving PBO who switched to tofacitinib 5 mg BID at Month 3. After switch from PBO to active treatment, pain improvement was observed in line with pts receiving active treatment from Day 0. To achieve pain improvement at greater thresholds, longer duration of active treatment was required.

Thomas⁵, ¹Medical Centre of Rheumatology, Munich, Germany, ²Rheumatology and Clinical Immunology, Charité-University Medicine Berlin, Berlin, Germany, ³Rheumazentrum Ratingen, Ratingen, Germany, ⁴Lehrstuhl für Gesundheitsmanagement, Universität Erlangen-Nürnberg, Nürnberg, Germany, ⁵Medical Affairs, MSD Sharp & Dohme GmbH, Haar, Germany

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Golimumab (GLM) has shown its efficacy and safety in various clinical trials. Data from socio- and health economic parameters and costs in daily clinical practice in Germany are rare.

Methods: Descriptive post-hoc analysis of socio- and health-economic parameters of the non-interventional, multicenter, prospective GO-NICE study ($n=1,458$), compared baseline (BL) to the situation at 24 months (M24) ($n=664$, 45.5%). To explore the impact of GLM days of sick leave / absenteeism, days of impaired capability / presenteeism, as well as the work productivity, quality of work and normal course of life (in the past 30 days and 6 months) were analyzed. Further, the number of consultations, ambulatory treatments, days of hospitalizations and rehabilitation measures in the previous 6 months. Socioeconomic costs were calculated based on administrative charges and rates or on official statistics.

Results: The mean number of sick leave days in the previous 30 days decreased from baseline (BL) 4.0 to 0.9, and in the past 6 months from BL 13.7 to 3.3 at M24. The improvement was greatest in patients (pts.) with RA. The mean number of days with impaired capability in the previous 30 days decreased from BL 14.9 to 4.5, in the previous 6 months from BL 65.8 to 19.8 at M24. The improvement was greatest in pts. with AS. On a numeric rating scale (range: 0=no limitation to 10=very strong limitation), the pts' mean ratings on the impact of disease during the previous 6 months on work productivity decreased from BL 5.5 to 2.5 points, on quality of work from 4.8 to 2.2 points, and on the normal course of life from 5.3 to 2.4 points at M24, respectively. The decrease in the mean scores BL to M24 was comparable in pts. with RA, PsA and AS. Intersubject variability was high. On retrospective evaluation for the past 6 months, the percentage of pts. with physician consultations declined from BL to M24: with general practitioners in pts. with PsA -19.7%, AS -17.8%, RA -6.8%. A marked decline was also observed in the percentage of pts. with PsA having dermatologist consultations (-15.0%). The percentage of patients receiving physiotherapy, massages, occupational therapy and packs declined from BL to M24, primarily the application of physiotherapy (-16.9%, -10.9% and -9.1%) in pts. with AS, PsA and RA. The

frequency of hospitalizations decreased from 10.4 / 7.6 / 14.0% at BL to 1.7 / 2.2 / 0.8%, and the frequency of rehabilitation decreased from 3.3 / 3.7 / 7.5% at BL to 0.6 / 1.8 / 2.1% at M24 in pts. with RA, PsA, and AS. Applying a standard cost model, treatment with GLM may generate savings of 2,400 from a public perspective (including costs for absenteeism) and 1,350 from the German health insurance perspective per patient and year.

Conclusion: This evaluation showed remarkable improvements in socio- and health-economic parameters. On GLM treatment, there was a reduction in the days of absenteeism from work, impaired capability / presentism and the days with limited productivity, while the quality of work increased, in a very similar manner across the three indications. The proportion of pts. requiring physician consultations, days of hospitalization and furthermore the need for rehabilitation measures decreased on GLM 50mg treatment, and savings can be generated.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

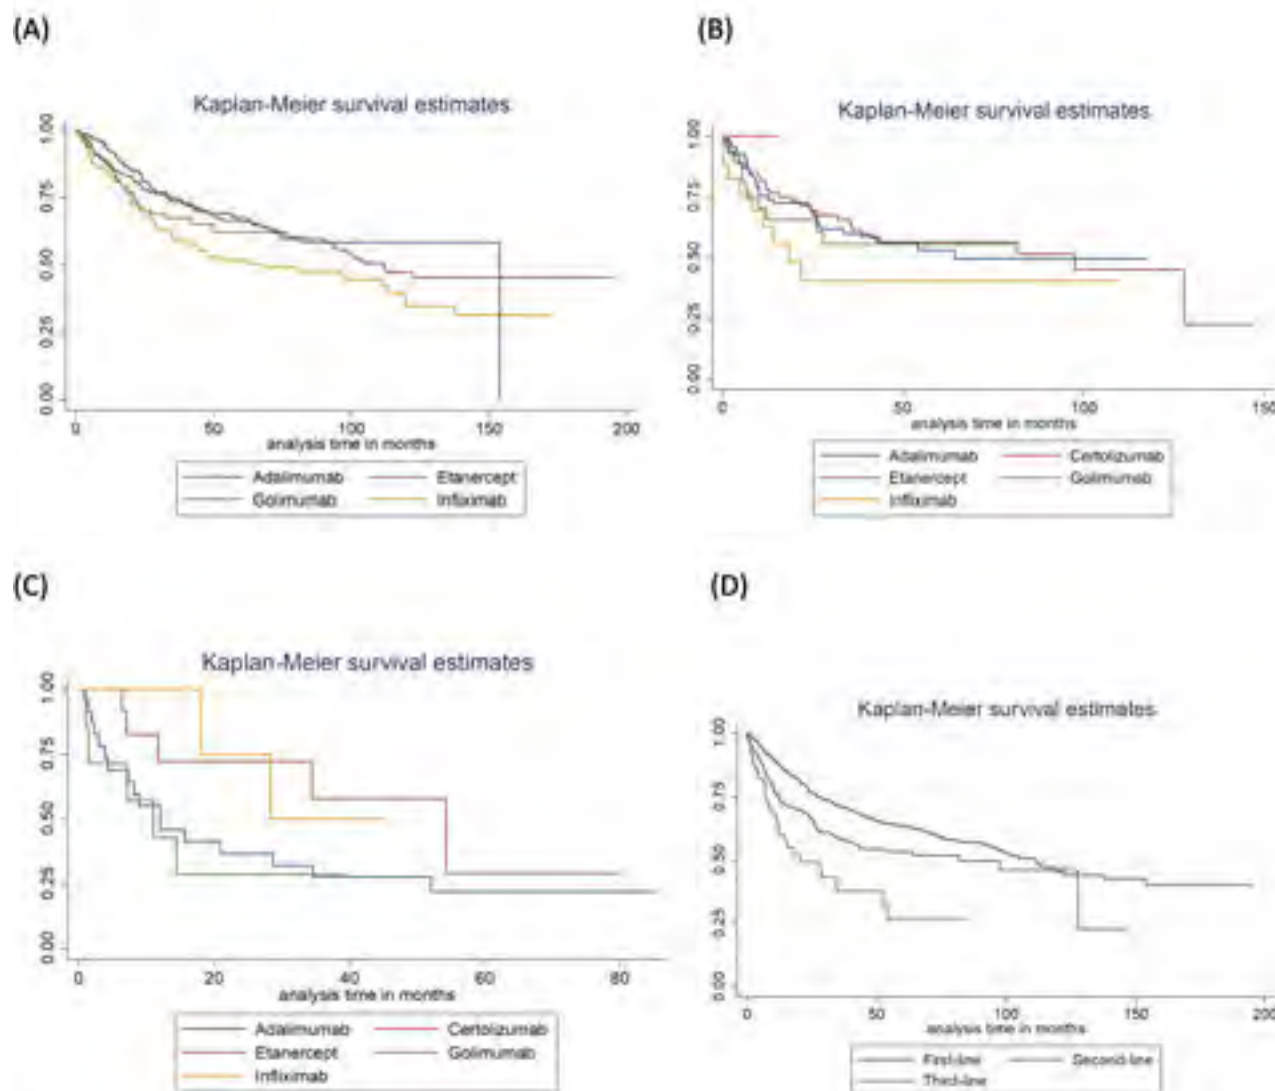

Session Time: 9:00AM-11:00AM

Background/Purpose: Tumor necrosis factor inhibitors (TNFi) lead to a dramatic improvement in the management of psoriatic arthritis (PsA). Nevertheless, a significant proportion of patients do not respond or are intolerant to TNFis, requiring treatment switch for an adequate control of disease activity. The aim of this study is to assess long-term TNFis drug retention and predictors for TNFi discontinuation in PsA patients registered at Rheumatic Diseases Portuguese Registry (Reuma.pt).

Methods: All PsA patients registered at Reuma.pt, with at least one TNFi prescription were included. Drug retention for a 1st, 2nd and 3rd-line TNFi was assessed by Kaplan-Meier survival analysis. Comparative analysis of survival curves was performed using the Wilcoxon (Breslow) for the equality of survival functions. The reasons for TNFis discontinuation were described as frequencies. Predictors of discontinuation, were studied using a Cox model considering discontinuation of the first TNFi, independently of the indication.

Results: 750 PsA patients were identified, with a mean age of 47.6 years; 50.3% female. 185 patients (26.2%) were treated with adalimumab, 322 (45.7%) etanercept, 100 (14.2%) golimumab and 98 (13.9%) with infliximab as first TNFi. The overall retention of TNFi was 49±40 months when treated with a 1st TNFi, decreasing to 36±33 months for the 2nd TNFi, and 23±23 months for the 3rd TNFi. After being treated with a 1st TNFi, 35.8% discontinued therapy, 53.5% due to lack or loss of effectiveness and 24.4% due to adverse events. The rates of discontinuation for the 2nd and 3rd TNFi were of

Figure 1. Drug retention in psoriatic arthritis patients treated with a first (A), second (B) and third-line (C) tumor necrosis factor inhibitor (TNFi) and overall TNFi survival (D).

39% and 54%, respectively, with similar proportions for lack/loss of effectiveness and adverse events for the 2nd (62.3%; 21.6%) and 3rd TNFi (63.0%; 22.2%). When considering predictors of discontinuation for the first TNFi, independently of the indication, being female increased by 2.1 times the risk of discontinuation (HR=2.1, p-value=0.003). In addition, each increase of one unit in DA28 at baseline, increased the risk of discontinuation by 18% (HR=1.18, p-value=0.039). Finally, being treated with infliximab in comparison with etanercept, increased by 2.0 times the risk of discontinuation, assuming the other variables as constant (HR=2.0, p-value=0.007, global p-value=0.012).

Conclusion: The overall persistence of a 1st TNFi was high in PsA patients registered at Reuma.pt, decreasing on average 13 months, in those who switched to a 2nd TNFi or a 3rd TNFi. Lack or loss of response were the main reasons for TNFi discontinuation, independently of TNFi position. Female gender and higher peripheral disease activity (DAS28) at baseline, were associated with an increased risk of discontinuation of TNFis. Likewise, Infliximab doubled the risk of discontinuation when compared with etanercept.

Financial support for statistics and report writing was provided by Novartis, S.A.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Patient reported outcomes (PROs) have gained relevance in the evaluation of axial SpA (axSpA), as they convey a more objective patient perspective. The concept of minimally clinical important difference (MCID) informs if a numerical difference on a given outcome measure (*ie*, PRO) over time is related to a relevant clinical effect (1). This review assessed the efficacy of different biologic DMARDs (bDMARDs) on several PROs in randomised controlled trials (RCT) in axSpA.

Methods: A systematic literature review (SLR) was performed using the MEDLINE (May 1st, 2018) with the filters “published in the last 10 years” and “humans”. The PICO(P, population; I, intervention; C, comparison; O, outcome) concept was used according to: P: adults (>18 years old) with radiographic axSpA (r-axSpA) or non-radiographic axSpA (nr-axSpA); I: any bDMARD regardless of formulation or duration; C: placebo (PBO) and/or any different drug; O: BASDAI, BASFI, the Ankylosing Spondylitis Quality of Life (ASQoL), the EuroQol-5D (EQ-5D), the Short Form 36 Health Survey physical component summary (SF36-PCS), the Short Form 36 Health Survey mental component summary (SF36-MCS), and the Functional Assessment of Chronic Illness Therapy – Fatigue (FACIT-F). The efficacy of bDMARDs on PROs was evaluated through MCID concept or differences between baseline and a later time point.

Results: After screening 84 initial references and manually adding other 9, 17 RCTs fulfilled the inclusion criteria (11r-axSpA, 4 nr-SpA and 2 with both phenotypes), corresponding to 27 publications (table 1). All of them assessed TNF inhibitors (TNFi) or IL17 inhibitors (IL17i).

Only 6 RCTs reported quantitative differences in MCID achievement between treatment arms (table 2). Most of the RCTs reported the mean difference of a given PRO between baseline and a later time point (as absolute values or percentage of variation), providing a statistical test (confidence interval and/or p-value) to express the magnitude of the difference between the treatment and PBO arm. A significant high proportion of MCID achievement is recorded using bDMARDs (table 2).

Conclusion: PROs are reported in an unstandardized way, and there is scarce information regarding clinical implications of the differences achieved (*ie* MCID). Our results launch a call for reporting PROs in a clinically relevant and standardized way and to define cut-offs that may reflect remission. However, bDMARDs seems to contribute to MCID achievement in a high proportion of patients.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Treatments and diagnosis of SpA is a public health problem. The efficacy of anti-TNF alpha treatment is different from one patient to another. In 2013, the ASAS society modified the Berlin algorithm, allowing us to define different subgroups of patients. The aim of the study was to compare the anti-TNF alpha response in the eight phenotypes of patients defined by the ASAS modified Berlin algorithm.

Methods: This French retrospective study was performed using the active file of patients suffering of SpA, in the University Hospital of Rouen, since 2005 from 2015, and using an anti-TNF alpha treatment. Patients diagnosed as having SpA by the rheumatologists of the hospital were included. The ASDAS-CRP and BASDAI score were calculated for all the patients at the initiation of the treatment (M0) and one year later (M12). The primary endpoint was the improvement of the ASDAS-CRP score after one year of treatment.

Results: 331 patients were included and distributed according to the modified algorithm (figure 1). 69(%) had radiographic sacroiliitis, 117 (35%) had positive MRI, and 149(45%) had positive HLA-B27. All the groups were similar for their average age at the start of the treatment. The duration of the disease was lower in the group 7 (7.2 ± 3 years), higher in group 1 (14.7 ± 11.3 years). The male and female distribution was similar only in the first three groups, the proportion of female were higher in groups 4 to 8 (Table 1). The ASDAS-CRP and BASDAI scores were significantly improved in all groups except in the group 6. Nevertheless, the magnitude of this improvement is greater in the groups 1, 2 and 3. In group 1: ASDAS-CRP at M0 was 3.41 and 2.04 at M12 ($p < 0.0001$). In group 2 ASDAS-CRP M0 was 3.12 and 2.15 at M12 ($p < 0.0001$). In group 3 ASDAS-CRP M0 was 3.1 and 1.9 at M12 ($p < 0.0001$) (figure 2).

Conclusion: This study demonstrates the heterogeneous response in patients with SpA, distributed according to the modified algorithm of Berlin, after one year of treatment with anti-TNF alpha. This algorithm which is basically a diagnostic tool, can help us to define the populations of patients for which anti TNF alpha treatment would be more relevant.

The Agreement between TNFi Treatment Responses and Fatigue Responses Is Weak to Moderate Suggesting Heterogeneity between Experienced Fatigue and Joint Inflammation: A Danish Population-Based Cohort Study

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Despite better control of inflammation, e.g. with biological treatments, some patients with psoriatic arthritis (PsA) continue to cite fatigue as one of the most challenging aspects of their disease as it decreases their health-related quality of life. The aim of this study was to investigate the associations between fatigue and disease activity. A second aim was to explore the agreement between VAS fatigue responses and ACR treatment responses in Danish patients with PsA.

Methods: All PsA patients registered in DANBIO during the period from 2000 to 2015 and in treatment with their first TNFi were identified and considered eligible for participation in the study. For the assessment of associations between fatigue and disease activity patients were stratified based on number of swollen joint / tender joint ratio (STR) either being <0.5 or ≥ 0.5 . Kappa statistics were used to assess agreement between fatigue and ACR20/ACR50/ACR70 responses, respectively at 6-month follow-up.

Results: From 2000 to 2015, 880 patients were identified eligible for analyses. 14.22% of patients in the upper median fatigue group with $STR \geq 0.5$ showed 70% improvement in fatigue when treated with TNFi, compared to the $STR < 0.5$ group where only 7.67% showed 70% fatigue improvement. The same applied for patients in the lower median fatigue group where 22.47% of patients with $STR \geq 0.5$ showed 70% improvement in VAS fatigue, compared to 12.56% for $STR < 0.5$ (Figure). The kappa values between ACR20, 50, 70 and VAS fatigue responses in the upper median fatigue group with $STR \geq 0.5$ were 0.49, 0.45 and 0.47 ($p < 0.005$), respectively (Figure). Whereas the kappa value in the lower median fatigue group with $STR < 0.5$ were 0.29, 0.40 and 0.24 ($p < 0.05$), respectively (Figure).

Conclusion: Fatigue remains a dominating symptom after TNFi treatment. More patients with relatively more swollen joints ($STR \geq 0.5$) reached improvement in both VAS fatigue and ACR responses compared to patients with relatively more tender joints ($STR < 0.5$) showing less effect of TNFi treatment on fatigue. The agreement between ACR treatment responses and VAS fatigue responses was weak to moderate suggesting heterogeneity between experienced fatigue and joint inflammation. Our results suggest that fatigue is a clinical domain with some independence from pure disease activity, using ACR response as a surrogate for disease activity response to treatment. This observation contributes to our understanding of why it is important to have fatigue as a separate item in the PsA Core Domain set (OMERACT) and why a measure of fatigue should ultimately be in the PsA Core Measurement set.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: To evaluate the effect of guselkumab (GUS) on Health-Related Quality of Life (HRQOL) and correlate changes of HRQOL and disease activity in patients with psoriatic arthritis (PsA).

Methods: Patients from the Phase 2a, multicenter, randomized, double-blind, placebo-controlled study evaluating the efficacy and safety of guselkumab in the treatment of patients with active PsA were analyzed. Patients with active PsA and $\geq 3\%$ body surface area (BSA) of plaque psoriasis despite current or previous treatment with standard-of-care therapies, including those previously exposed to anti-TNF α agents, were randomized 2:1 to receive GUS 100mg subcutaneously or placebo (PBO) at wks 0, 4, and every 8 wks (q8w) thereafter through wk44. At wk16, pts from either group with $< 5\%$ improvement from baseline in both swollen and tender joint counts were eligible for early escape to open-label ustekinumab. At wk24, all remaining PBO pts crossed-over to receive GUS 100 mg, and then received GUS at wk28, and q8w thereafter through wk44. HRQOL was assessed using 36-Item Short Form Health Survey (SF-36) which assesses general health from 8 functional areas. A physical and mental component summary scores (PCS and MCS) were derived from 8 scale scores. A change of ≥ 5 points from the baseline in PCS or MCS was defined as clinically meaningful. Correlations of changes in SF-36 PCS and MCS with changes in Disease Activity in Psoriatic Arthritis (DAPSA) were evaluated using Spearman correlation at Week 24.

Results: The mean (SD) of SF-36 PCS and MCS at the baseline was 33.8 (7.4), 44.2 (11.9), respectively, which were significant below the US population norm (50 +/-10). At wk24, patients in the GUS group achieved statistically greater mean improvement in SF-36 PCS (6.6) and MCS (4.7) than PBO group (0.5 in PCS, -0.1 in MCS) (all $p < 0.01$); and greater proportions of patients in GUS group achieved a clinically meaningful improvement in PCS (55%) and MCS (47%) than patients in PBO group (22.5% in PCS, $p < 0.001$; 26.5% in MCS, $p = 0.017$). Additionally, greater mean improvements in all SF-36 scales score in GUS group than PBO group were observed. At wk44, patients randomized to PBO at the baseline and crossed over to GUS at wk24 achieved improvements in SF-36 PCS (8.0) or MCS (5.5). The magnitude of these changes was similar to patients randomized to GUS at baseline (8.3 in PCS, 5.6 in MCS). Change in DAPSA score at wk24 was significantly correlated with change in PCS ($r = -0.57$, $p < 0.001$) and MCS ($r = -0.45$, $p < 0.001$).

Conclusion: GUS-treated PsA patients demonstrated significant improvement in HRQOL and in all subscales of SF-36, indicating patient-perceived improvements in health status. Improvement in SF-36 was highly correlated with reduction in PsA disease activity.

Nonsteroidal Anti-Inflammatory Drugs Attenuate Active Inflammatory Sacroiliac Joint Lesions in Patients with Early Axial Spondyloarthritis

Hong-Ki Min¹, Hyonjoung Cho² and Sung-Hwan Park³, ¹Division of Rheumatology, Department of Internal Medicine, College of Medicine, The Catholic University of Korea, Seoul, Korea, Republic of (South), ²Division of Rheumatology, Department of Internal Medicine, Armed Forces Capital hospital, Armed Forces Medical Command, Seongnam, Korea, Republic of (South), ³Division of Rheumatology, Department of Internal Medicine, Seoul St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Seoul, Korea, Republic of (South)

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The purpose of the present study was to examine the therapeutic effect of NSAIDs on active inflammatory lesions (bone marrow oedema [BMO]) in the sacroiliac (SI) joint in early axial spondyloarthritis (SpA). The aim was to propose optimal duration of treatment in initially diagnosed axial SpA patients with a good response to NSAIDs.

Methods: We enrolled 19 patients with axial SpA who were initially diagnosed in our hospital, and prescribed full-dose NSAIDs for 12 weeks. Twelve patients completed the 12-week protocol. We collected demographic, clinical, laboratory, and radiologic data at the time of enrolment and after 6 and 12 weeks of NSAID treatment. Baseline, 6-week, and 12-week data were compared using the Friedman test.

Results: The total SPondyloArthritis Research Consortium of Canada (SPARCC) score decreased significantly at 6 and 12 weeks (*P* value for 6 weeks and 12 weeks, 0.001, 0.025, respectively). The SPARCC score was significantly correlated with the ESR and CRP (*P* value for ESR and CRP, 0.041, 0.001, respectively). Univariate and multivariate regression analyses showed that the body mass index was significantly associated with changes in the SPARCC score.

Conclusion: Active inflammation in the SIJ was significantly attenuated by 6 weeks of full-dose NSAIDs. The SPARCC score was well-correlated with CRP and ESR. Therefore, at least 6 weeks of full-dose NSAIDs can decrease active SIJ lesions, and initial full-dose NSAIDs may prevent further structural damage as shown by reverting early radiologic change (BMO).

Session Date: Tuesday, October 23, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Biologicals revolutionized the management of PsA. Since the introduction of the first TNF inhibitor (TNFi) in the early 2000s, therapeutic options for PsA are increasing steadily and a new generation of biologicals allows distinct targeted approaches.

Purpose: To investigate whether PsA patient population (demographic and clinical characteristics), selected for biological treatment in daily practice, changed over time.

Methods: PsA patients (CASPAR criteria) were included in the KU Leuven BioSPAR register, a prospective cohort treated with biologicals and apremilast. Demographics, prior drug use, disease characteristics and activity parameters were recorded at the initiation of biological treatment.

Tree treatment periods were defined: First period: from the date the 1st patient started TNFi therapy (infliximab, etanercept or adalimumab) until the “second generation” of anti-TNF (golimumab and certolizumab) were available: 09/15/2000-06/03/2006. Second period: end of period 1 until the “third generation” of biologicals (ustekinumab, secukinumab) or apremilast were available: 06/04/2006- 03/22/2016. Third period: after period 2: 03/23/2016-02/28/2018. Statistical analysis was performed using SPSS statistical software, version 24.0 with descriptive statistics, one-way ANOVA, Kruskal-Wallis or Chi-square tests as appropriate.

Results: The PsA cohort includes 185 Caucasian patients. We found no difference in the age of patients, mean weight or BMI at the time of biological initiation in 3 time groups. Proportion of male/female patients was also similar. Disease duration was significantly longer in the 1st, compared to the 2nd (*p*=0.006) and 3rd (*p*=0.017) time periods. However, there was no difference in disease duration between period 2 and 3 (*p*=0.19). Further, patients in period 1 had more tender joints than patients in period 3 (*p*=0.012). But the difference in TJC68 was not significant between period 1 and 3 or period 2 and 3. Number of swollen joints in the period 1 was significantly higher than in patients in the second and third time periods (*p*=0.0001). Skin and nail psoriasis were more frequent in earlier compared to the later treatment periods (*p*<0.0001 for both). In our study population, the proportion of patients with dactylitis or enthesitis was similar in tree time periods.

CRP levels, but not ESR, significantly differed between the groups, being higher in period 1 compared 2 (*p*=0.006) and 3 (*p*= 0.023). Clinical scores for psoriasis, enthesitis and disease activity did not reach statistical difference between the three time periods.

Conclusion: The population of patients, selected for treatment escalation, changed significantly over time since the introduction of biologicals. Although patient characteristics were similar in all time periods, disease duration and objective disease activity characteristics (swollen and tender joints, psoriatic nail and skin involvement, CRP) were lower in the later

time periods. Our results suggest that with years of experience, PsA patients might be considered earlier and with less active disease for therapy intensification, to obtain a tight disease control and to prevent long term damage.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Etanercept (ETN), an anti-TNF medication, was among the first biologics approved for psoriasis. Additional psoriasis medications that have been developed, or are in development, may benefit patients (pts) who do not adequately respond to ETN. The efficacy of tildrakizumab (TIL), a high-affinity, humanized, anti-interleukin-23p19 monoclonal antibody, was evaluated in pts with moderate to severe chronic plaque psoriasis who were partial responders (Psoriasis Area and Severity Index [PASI] ≥ 50 – <75) or nonresponders (PASI <50) to ETN and were subsequently rerandomized to TIL in a phase 3 trial.

Methods: Pts with psoriasis ($\geq 10\%$ body surface area, Physician's Global Assessment [PGA] ≥ 3 , and PASI ≥ 12) participated in a 3-part, 52-week, randomized controlled trial (reSURFACE 2; NCT01729754). In Part 1 (Week [W]0–W12), pts were randomized to subcutaneous placebo (PBO), TIL 100 mg, or TIL 200 mg administered at W0 and W4, or ETN 50 mg administered 2x/wk. In Part 2 (W12–W28), TIL and ETN pts remained on the same treatment (TIL administered at W16; ETN 1x/wk), whereas PBO pts were rerandomized to TIL 100 or 200 mg. In Part 3 (W28–W52), ETN responders (PASI ≥ 75) were discontinued; partial and nonresponders were switched to TIL 200 mg (administered at W32, W36, W48). For this post hoc analysis, the proportions of pts (\pm SD) with PASI responses and PGA response (score of 0 [“clear”] or 1 [“minimal”] with at least a 2-grade score reduction from baseline) were determined at W52.

Results: In all, 1090 pts were randomized. Of the 313 pts randomized to ETN, by W28 there were 83 partial responders and 39 nonresponders. At W52 (after 20 weeks of TIL treatment) for ETN partial responders, $75\% \pm 5\%$, $34\% \pm 5\%$, $15\% \pm 4\%$, and $58\% \pm 5\%$ had achieved PASI 75, 90, 100, and PGA responses, respectively, with TIL 200-mg treatment. At W52 for ETN nonresponders, $54\% \pm 6\%$, $31\% \pm 5\%$, $10\% \pm 3\%$, and $56\% \pm 5\%$ had achieved PASI 75, 90, 100, and PGA responses, respectively, with TIL 200-mg treatment. Adverse events were similar in pts switched from ETN to TIL at W28 compared with the pts who were maintained on TIL through W52.

Conclusion: A substantial portion of patients with moderate to severe chronic plaque psoriasis who are partial responders or nonresponders to ETN may respond after switching to treatment with TIL 200 mg. TIL may be a reasonable option for those with inadequate response to ETN.

Analyses presented at the American Academy of Dermatology Annual Meeting, February 16–20, 2018, San Diego, CA, USA.

Session Date: Tuesday, October 23, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Tildrakizumab (TIL), a high-affinity, humanized, immunoglobulin G1κ, anti-interleukin-23p19 monoclonal antibody, has demonstrated efficacy in the treatment of chronic plaque psoriasis.^{1,2} Here, we evaluate the incidence of gastrointestinal (GI) adverse events (AE), specifically cases of inflammatory bowel disease (IBD), reported during the TIL clinical development program.

Methods: Patients with moderate to severe plaque psoriasis were randomized in 3 large clinical trials: P05495 (phase 2; NCT01225731),¹ reSURFACE 1 (phase 3; NCT01722331),² and reSURFACE 2 (phase 3; NCT01729754).² In this post hoc analysis, we identified serious GI AEs and new onset or exacerbation of preexisting IBD from a pooled dataset of patients receiving TIL in these 3 studies, which followed patients up to 52 (P05495 and reSURFACE 2) or 64 (reSURFACE 1) weeks. TIL doses were 5 mg, 25 mg, 100 mg, and 200 mg in P05495, and 100 mg and 200 mg in the reSURFACE studies.

Results: In this analysis, we pooled 1911 patients from the 3 trials who received either TIL 100 mg or 200 mg. There were no new cases of IBD reported; among 6 patients with a history of IBD randomized to TIL, none experienced an exacerbation. The number (rate per 100 patient-years) of patients in the pooled dataset who experienced serious GI AEs was 8 (0.80) for TIL 100 mg and 4 (0.43) for TIL 200 mg. These serious GI AEs included abdominal pain, constipation, diverticulum, dyspepsia, gastritis, thrombosed hemorrhoids, esophageal polyp, and pancreatitis (1 patient each) among patients receiving TIL 100 mg and abdominal hernia, upper abdominal pain, acute pancreatitis, and salivary gland enlargement (1 patient each) among patients receiving TIL 200 mg.

Conclusion: Serious GI AEs were found to be infrequent in this post hoc analysis of patients with chronic plaque psoriasis receiving TIL in 3 large randomized clinical trials. No new cases of IBD or exacerbations of preexisting IBD were observed during treatment with TIL.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Drug retention and response rates of TNFi treatment in 13,170 patients with psoriatic arthritis treated in routine care – pooled data from the EuroSpA Research Network Collaboration

Background/Purpose: A research network collaboration of 15 European registries sharing data on patients with spondyloarthritis (SpA), “EuroSpA”, has recently been created to strengthen research capabilities in the real world setting¹. We aimed to investigate Tumour Necrosis Factor inhibitor (TNFi) retention and response rates at 6, 12 and 24 months in patients with psoriatic arthritis (PsA) treated with their 1st, 2nd or 3rd TNFi in clinical practice across Europe.

Methods: A common data model was agreed upon by the EuroSpA Scientific Committee. Registry data managers clarified data availability and uploaded anonymized data through the secure Virtual Private Network pipelines to the EuroSpA server. Baseline characteristics, drug retention and response rates were investigated with non-parametric descriptive statistics. Kaplan-Meier estimation was used to investigate TNFi retention rates. Both crude and Lundex adjusted² response rates were calculated for DAS28 remission (DAS28≤2.6) after 6,12 and 24 months and ACR20/50/70 after 6 months.

Results: In May 2018, 10 of the 15 registries participating in EuroSpA had completed data upload to the EuroSpA server, including 13,170 patients with PsA. Baseline characteristics of the pooled population are shown in Table.

For the 1st TNFi, 6 and 24 months’ retention rates were 86% and 67%, respectively. Corresponding retention rates for the 2nd TNFi were 79% and 59%, and for the 3rd TNFi 77% and 55%, respectively (Table and Figure). For the 1st TNFi, 6 and 24 months Lundex adjusted DAS28 remission rates were 44% and 30%. Corresponding remission rates for the 2nd TNFi were 34% and 22%, and for the 3rd TNFi, 26% and 16%. For the 1st TNFi, 6 months Lundex adjusted ACR 20/50/70 response rates were 40%, 27% and 15%, respectively. Corresponding ACR 20/50/70 response rates for the 2nd TNFi were 21%, 13% and 6% and for the 3rd TNFi, 20%, 10% and 5%, respectively.

Conclusion: These initial analyses demonstrate that the creation of a large European database of PsA patients treated in routine care based on a common data model is feasible, offering important opportunities for future research. In this

pooled dataset from 10 European registries, we found decreasing retention rates and response rates with increasing number of previous TNFi.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Adalimumab (ADA) inhibited radiographic progression in patients (pts) with moderate to severe PsA in the ADEPT study and its open label extension (OLE). These post-hoc analyses evaluated long-term inhibition of radiographic progression and impact on quality of life (QoL) in ADA treated pts with respect to the presence or absence of baseline (BL) radiographic damage.

Methods: Pts who completed the ADEPT study (phase 3, double-blind, placebo [PBO]-controlled, 24-week [wk] study in TNF inhibitor naive PsA pts) were eligible to enroll in the 120-wk OLE with ADA 40 mg every other wk (eow). Only pts who continued into the OLE were included in these analyses of observed data. Radiographic damage at BL (BLrd) was defined as a modified Total Sharp Score (mTSS) >0.5; radiographic progression was defined as a change (Δ) from BL in mTSS by >0.5. Radiographic progression and changes in general health (SF-36), fatigue (FACIT-F) and physical function (HAQ-DI) were evaluated until Wk 144 in pts grouped by presence or absence of BLrd and treatment (PBO/ADA or ADA/ADA in the ADEPT/OLE studies, respectively).

Results: BLrd was observed in 81% (n=231/285) of the enrolled pts. At Wk 144, 49.8% (n=115/231) of those with BLrd and 51.9% (28/54) of those without BLrd, did not progress radiographically. Radiographic progression by Wk144 was significantly smaller in pts without than with BLrd (mean Δ mTSS from BL: 0.85 vs. 2.91, $p<0.01$). Further, in pts without BLrd who initially received ADA, fewer progressed (Wk 144: 12% vs. 24%), with significantly less mean radiographic progression up to Wk 144 (mean Δ mTSS from BL: 0.49 vs. 1.12, $p<0.05$). Mean radiographic progression through Wk 144 did not significantly differ between pts initially receiving ADA or PBO who had BLrd (mean Δ mTSS from BL: 3.41 vs. 2.43, NS). At Wk 144, there were no statistically significant differences in the mean changes from BL in HAQ-DI, FACIT-F, and SF-36 (PCS and MCS) in pts with or without BLrd (-0.40 vs. -0.33, 6.11 vs. 6.45, 7.50 vs. 7.98, and 2.88 vs. 3.44, NS). However, pts who received ADA compared with PBO exhibited significantly greater improvement in physical function (both SF-36 PCS and HAQ-DI, $p<0.01$) by wk 24 regardless of BLrd (**Table**).

Conclusion: Moderate to severe PsA pts with BLrd experienced more long-term radiographic progression than those without. Interestingly, among pts without BLrd, initial treatment with ADA compared with PBO resulted in 50% fewer pts with radiographic progression and significantly lower mean radiographic progression through 144 weeks, whereas no long-term difference has been observed for physical function and QoL parameters.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Limited spinal mobility is a cardinal sign of ankylosing spondylitis (AS) and shows a close relationship with functional disability which leads to high individual socioeconomic consequences and lifetime costs. To measure the metrologic outcomes which may be critical in daily clinical practice, BASMI is used in conjunction with chest expansion which is for more accurate assessment of thoracic spinal mobility. ASDAS, a composite index score, was developed for assessment of disease activity and efficacy of treatment. Recently, ASDAS is known to be related with spinal mobility and radiographic spinal progression. In this study, we investigated whether early ASDAS changes is related with the longitudinal improvements of spinal mobility in patients treated with TNF- α blockers.

Methods: This was an observational study in 126 adult AS patients who were treated with TNF- α blockers up to 33 months. All outcome measures, including disease activity and metrologic outcomes, were performed at baseline and month 3, and then every six month up to month 33. Clinical efficacy was presented by ASAS and ASDAS response criteria, such as ASDAS major improvement (ASDAS-MI). Cumulative probability plots were used for association between ASDAS changes and metrologic improvements. Differences in BASMI₁₀ and chest expansion at any time point between responder and non-responder groups were examined with a mixed linear model.

Results: The BASMI₁₀ showed a rapid and significant improvement to month 3 ($p<0.001$), a further response to month 9 ($p=0.003$), and then maintained to month 33. The chest expansion considerably increased to month 3 ($p=0.011$) and then slowly improved up to month 33. ASDAS-CRP improved prominently at month 3 ($p<0.001$), a further significantly at months 9 ($p<0.001$) and mildly up to month 33. The cumulative probability plots, in which scatter plots of the individual 3-month ASDAS-CRP changes in cumulative order versus the 33-month BASMI₁₀ and chest expansion changes, demonstrated a significant tendency toward 33-month BASMI₁₀ improvements with 3-month ASDAS-CRP changes ($r=0.383$, $p<0.001$). The 33-month chest expansion changes showed a weak, but significant, tendency to increase with respect to 3-month ASDAS-CRP changes ($r=-0.245$, $p=0.031$). ASDAS-MI responders at month 3 had a significant improvement in 33-month BASMI₁₀ ($p=0.011$) and chest expansion changes ($p=0.015$), compared to non-responders, while baseline BASMI₁₀ and chest expansion were not significantly different. The mixed linear model revealed that a significant difference between two groups were detected in both BASMI₁₀ ($p=0.0099$) and chest expansion ($p=0.0189$). On the contrary, ASAS20 responders at month 3 did not show a significant difference in 33-month BASMI₁₀ and chest expansion

improvements. On the analysis using a mixed linear model, BASMI₁₀ showed a significant difference between two groups ($p=0.00375$), while chest expansion scores were not different.

Conclusion: These results suggested that ASDAS-MI responsiveness at month 3, not ASAS20 responsiveness at month 3, may be related with an outstanding improvement in metrologic outcomes of long-term TNF- α blocker treatment in AS.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Secukinumab (SEC), a fully human monoclonal IgG1 antibody that selectively neutralizes IL-17A, provided sustained improvement in the signs and symptoms of active psoriatic arthritis (PsA) over 2 years (yrs) in the FUTURE 2 study.¹ Herein, long-term (4-yr) efficacy and safety results in patients (pts) from FUTURE 2 study, including results of dose-escalation, are reported.

Methods: Overall, 397 pts with active PsA were randomized to either SEC (300, 150, or 75mg) or placebo weekly followed by every 4 weeks (wks) starting at Wk 8.¹ Of the overall randomized pts, approximately 1/3 had inadequate response [IR] to prior anti-TNF use. Pts were escalated from 150 to 300mg and from 75 to 150/300mg starting at Wk 128, if active signs of disease were observed based on physician's judgement; the escalated dose was maintained thereafter. Assessments at Wk 208 included ACR20/50/70, PASI 75/90, HAQ-DI, SF-36 PCS, and resolution of dactylitis and enthesitis. Analyses by prior anti-TNF use (naïve/IR) and with/without concomitant methotrexate (MTX) were also assessed. ACR responses for dose-escalated pts included placebo-switchers. Data are reported as observed. Safety analysis included all pts who received ≥ 1 dose of SEC.

Results: Overall, 69/100 (69%), 70/100 (70%), and 62/99 (63%) pts originally randomized to SEC 300, 150, and 75mg, respectively, completed 208 wks of treatment. A total of 46/100 (46%) pts in the 150mg group were escalated to 300mg and 56/99 (57%) pts in the 75mg group escalated to 150/300mg. Clinical responses were sustained through Wk 208 with 300mg and sustained/further improved following dose-escalation to 300/150mg in the 150 and 75mg groups (Table). ACR20 response rates at Wk 208 in anti-TNF-naïve pts were 75.5%, 76.5%, and 71% in the 300, 150, and 75mg groups, respectively; corresponding rates in anti-TNF-IR pts were 60%, 71%, and 64%. ACR20 response rates in pts with concomitant MTX were 67.6%, 77.1%, and 78.8% in the 300, 150, and 75mg groups, respectively; corresponding rates in pts without concomitant MTX were 74.4%, 73%, and 58.6%. After dose-escalation, the proportion of pts with non/low level ACR responses improved, with corresponding increases in the proportion of pts achieving moderate/high ACR responses (Table). Over the study (SEC exposure of 238.6 pt-yrs), the type, incidence, and severity of adverse events were consistent with previous report.¹ Treatment-emergent anti-drug antibody was reported in 3 pts, with no neutralizing antibody or loss of efficacy. In the entire study, one death (due to sepsis) was reported in the 150mg group over 4 yrs.

Conclusion: SEC 300 and 150mg provided sustained improvement in the signs and symptoms of PsA over 4 yrs. Efficacy was sustained/further improved following dose-escalation. SEC was well tolerated, with no new/unexpected safety signals. Reference: 1. McInnes IB, et al. *Rheumatology* (Oxford) 2017;56:1993–2003.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Psoriatic arthritis (PsA) is a chronic inflammatory disease that benefits from DMARDs, in this regard knowing more about these therapies is a great step forward in the management of these patients in daily clinical practice. Objectives: To evaluate the survival of DMARDs used in recent diagnose PsA patients as well as the causes of discontinuation and to analyze the possible associated factors

Methods: Retrospective longitudinal observational study. **Subjects:** Inception cohort of patients from January 2010 to December 2014, and followed up to December 2016, diagnosed with PsA according to ICD-10 code. **Main outcome:** discontinuation of conventional DMARDs (cDMARDs) and biological DMARDs (bDMARDs) due to: Adverse drug reactions (ADRs); Improvement or remission; Inefficacy; Patient's decision and Physician's decision. **Covariables:** sociodemographic and clinical. **Statistical analysis:** To estimate DMARDs discontinuation rates, survival techniques were used, expressing the incidence rate (IR) per 100 patients*year with their respective CI at 95%. Multivariate Cox regression models were performed to analyze the factors associated with DMARDs discontinuation and the results were expressed in Hazard ratio(HR) and 95% CI.

Results: 191 patients with recent diagnosis of PsA were included, with a 379.7 Patients*year follow-up. 50.3% were male, the mean age at diagnosis was 50±14.6 years old. 46.6% of the patients had a history of cutaneous psoriasis. HLA-B27 was positive in 20% of patients. 50% of the patients started a DMARD at the first visit. Throughout the follow-up, all patients received cDMARDs and 23 used bDMARDs. The median DMARD per patient was 2[1-3]. Methotrexate (MTX) was the most used drug 69.7%. According to the treatment regimen, 30% were on combination therapy, the most frequent was antiTNF+MTX (33%). 103 discontinuations were recorded with a IR 27.1[22.3-32.9] within these, 44 were related with ADRs (IR 11.5[8.6-15.5]), 24 (IR 6.3[3.5-11.1]) were due to inefficiency, 9 (IR 2.3[1.2-4.5]) were registered after remission, 12 (IR 3.1[1.7-5.5]) by decision of the patient and 12 (IR 3.1[1.7-5.5]) by doctor's decision. The DMARDs median survival was 1.8 years [1.4-2.7]. Table 1 shows the discontinuation rates for each type of DMARDs and the multivariate analysis for the factors associated with DMARDs discontinuation is in Table 2.

Conclusion: In our study, the DMARD discontinuation rate was 27.1, mainly related with ADRs. We have also found some clinical and therapy regimen factors that can modify the DMARDs survival on PsA. We observed that MTX, presented the longest survival independent of the rest of the factors.

Table 1.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Measurement of serum drug levels can help clinicians tailor treatment with TNF-inhibitors.

An association between certolizumab pegol (CP) serum levels and response has previously been found in patients (pts) with rheumatoid arthritis (1). Data for pts with axial spondyloarthritis (axSpA) are lacking. Here, we examine the association between serum CP levels and treatment response in pts with axSpA and tentatively identify a therapeutic target level.

Methods: Patients with a clinical diagnosis of axSpA starting standard treatment with CP included in the NOR-DMARD study with biobank sample at 3 months follow-up, were included in the present analyses. Serum drug levels (non-trough) were analysed with an in-house immunofluorometric assay automated on the AutoDELFIA immunoassay platform.

Associations between CP level and improvement in ASDAS-CRP and response (defined as ASDAS clinically important improvement (CII)) were assessed by multivariable linear and logistic regression (adjusting for age, sex and prior bDMARD (Y/N)), respectively.

Results: Median serum drug level at 3 month follow up was 35.0 mg/L (IQR 21.3-45.3) in 116 pts. Response data were available in 110/116 patients.

Serum CP level ≥ 20 mg/L was associated with improvement in ASDAS at 3 months ($\beta=0.55$, (95% CI 0.12-1.98), $P=0.01$).

Serum CP level ≥ 20 mg/L was associated with ASDAS CII at 3 months (OR 3.4 (95% CI 1.0-11.1, $P=0.045$)).

Only 18.2 % of pts with CP level <20 mg/L achieved ASDAS CII at 3 months, while 53.2% of pts with CP level 20-40 mg/L and 36.6 % with ≥ 40 mg/L were responders.

Conclusion: Serum CP level was associated with clinical response after 3 months of treatment in pts with axSpA. We suggest 20 mg/L as a lower target level for non-trough samples. No additional benefit of having a certolizumab level over 40 mg/L was observed. These results suggest that a therapeutic level of 20-40 mg/L can be implemented in clinical practice for non-trough serum samples in pts with axSpA.

Multidrug Resistant AxSpA: No Advantage of Switching Class in Patients with Inadequate Response to Two Prior TNFi Agents

Sevket Ercan Tunc¹, Ismail Sari¹, Robert D Inman² and Nigil Haroon², ¹Rheumatology, Toronto Western Hospital, University of Toronto, Spondylitis Clinic, Toronto, ON, Canada, ²Rheumatology, Toronto Western Hospital, Toronto, ON, Canada, Toronto, ON, Canada

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Lack of efficacy (LOE) to TNF inhibitor (TNFi) treatments is an important issue and can be seen in up to 40% of the patients with axial Spondyloarthritis (axSpA). In patients with LOE, further treatment responses have been reported to be lower: 6 month BASDAI 50% response rates of 37% for a 2nd TNFi and 30% for a 3rd TNFi.

Secukinumab, an IL-17 inhibitor (IL-17i) is a relatively new treatment option for patients with active axSpA. However, there are currently limited data regarding the treatment responses in inadequate responders to ≥ 2 prior TNFi agents.

We aimed to compare the treatment outcomes of patients switching to TNFi or IL-17i following LOE to ≥ 2 TNFi.

Methods: Patients who fulfilled ASAS classification criteria for axSpA and who were on the 3rd or 4th biologic because of LOE to prior biologic treatments were identified. Patients who discontinued prior biologics because of intolerance or financial reasons were excluded. Patients were stratified into two groups based on the class of most recent biologic: TNFi or IL-17i. Demographic and clinical data including disease activity scores were collected from the database. Treatment responses at 6 months were compared between the groups. Good response was defined as ≥ 2 unit or $\geq 50\%$ decrease in BASDAI. Other outcome measures assessed include clinically important improvement (CII; $\Delta \geq 1.1$) and major improvement (ASDAS-MI; $\Delta \geq 2.0$) in ASDAS-CRP.

Results: There were 106 patients (89 AS, 17 nr-axSpA) on a 3rd or 4th course of biologic medication following LOE to former biologic agents. Overall, 34 patients were on IL-17i and 72 on TNFi. Baseline demographics and clinical parameters are presented in **Table 1**. In the IL-17i group there were more patients with psoriasis and only one with IBD. There was no significant difference in other parameters between groups. The response rates were similar in IL-17i and TNFi treated patients (**Table 2**). BASDAI ≥ 2 response rates were 15.2% for IL-17i and 14.8% for TNFi. ASDAS-CII was seen in 3.0% for IL-17i and 11.7% for TNFi. No patients achieved ASDAS-MI and there was no significant difference between sexes in the analysis.

Table 1: Baseline demographics and clinical parameters of 3rd and 4th biologic users

	TNFi group (n: 72)	IL-17i group (n: 34)	p value
Sex, male, n (%)	48 (66.7%)	21 (61.8%)	0.67
Age (mean \pm SD)	39.2 \pm 13.6	40.0 \pm 11.3	0.79
Dis. Duration (mean \pm SD)	16.2 \pm 11.6	19.3 \pm 10.3	0.21
Baseline ESR (mean \pm SD)	13.2 \pm 18.2	17.1 \pm 16.3	0.32
AS, n (%)	60 (83.3)	29 (85.3)	0.52
Nr-axSpA, n (%)	12 (16.7)	5 (14.7)	0.52
HLA B27 +, n (%)	50 (69.4)	25 (73.5)	0.43
Baseline CRP (mean \pm SD)	10.3 \pm 18.9	10.65 \pm 21.7	0.93
Baseline BASDAI (mean \pm SD)	6.04 \pm 1.7	6.3 \pm 1.5	0.47
Baseline TBP (mean \pm SD)	6.3 \pm 2.1	6.9 \pm 1.8	0.12
Baseline PGA (mean \pm SD)	6.3 \pm 2.2	6.7 \pm 1.8	0.37
Baseline BASDAI	6.0 \pm 1.7	6.3 \pm 1.5	0.47
Baseline ASDAS ESR	3.0 \pm 0.9	3.3 \pm 0.8	0.07
Baseline ASDAS CRP	3.3 \pm 0.9	3.5 \pm 0.8	0.30
Arthritis, n (%)	63 (87.5)	32 (94.1)	0.24
IBD, n (%)	14 (19.4)	1 (2.9)	0.017
Psoriasis, n (%)	11 (15.3)	11 (32.4)	0.04
Enthesitis n (%)	35 (48.6)	20 (58.8)	0.40
Uveitis, n (%)	27 (37.5)	13 (38.2)	0.56
F. History of SpA, n (%)	17 (23.6)	6 (17.6)	0.34
Smoking History, n (%)	32 (44.4)	13 (38.2)	0.35

Table 2: Clinical response rates of 3rd and 4th biologic users

	TNFi group (n: 60)	IL-17i group (n: 33)	p value
BASDAI ≥ 2 unit, n (%)	9 (14.8)	5 (15.2)	0.59
BASDAI 50 n (%)	3 (4.9)	2 (6.1)	0.58
CII ASDAS CRP, n (%)	7 (11.7)	1 (3.0)	0.25

CII: Clinically Important Improvement; $\Delta \geq 1.1$ in ASDAS CRP.
There were no patients with major improvement.

Conclusion: Clinical response rates to a 3rd or 4th biologic, regardless of class, were low in AxSpA patients.

Abstract Number: 2612

Utility of Infiltration with Steroids in Dactylitis. Is the Infiltration Guided By Ecography Better THAN Conventional?

Rosalía Martínez Pérez¹, Alberto Ruiz Roman², Esteban Rubio-Romero³, Clara Aguilera Cros¹, Elena Alonso¹ and Juan Povedano⁴, ¹Rheumatology, University Hospital Virgen del Rocío, Seville, Spain, ²Department of Rheumatology, Hospital Virgen del Rocío, Seville, Spain, ³Hospital Universitario Virgen del Rocío. Sevilla. Spain, Sevilla, Spain, ⁴Rheumatology, University Hospital Virgen del Rocío, Sevilla, Spain

Session Information**Session Date:** Tuesday, October 23, 2018**Session Title:** Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Treatment**Session Type:** ACR Poster Session C**Session Time:** 9:00AM-11:00AM

Background/Purpose: Dactylitis, also called “sausage fingers”, is considered one of the differential signs characteristic of Spondyloarthritis (SpA). The absence of knowledge of its pathophysiology make it a clear manifestation of a difficult clinical treatment. The use of imaging techniques, such as resonance or ultrasound, have demonstrated that there is more inflammation at the level of the tendons than synovitis, with soft edema parts, and that the target organ in these cases is the enthesis. The standardized treatment is the use of NSAIDs, steroids and local infiltration. Different biological treatments have shown good results (secukinumab, antiTNFs). Our objective is to evaluate how local infiltration with steroids modifies both expression clinical, and echographic changes typical of dactylitis. As well as evaluate if there is a difference between the guided ultrasound Vs infiltration.

Methods: Clinical trial, randomized, with blind and unicentric radiological evaluation. They were included patients with clinical dactylitis who presented echographic signs that confirmed the diagnosis. All of them tributaries of local infiltration with steroids. Simple patients’ randomization was done, according to the order of assignment in the study. Paired patients with conventional infiltration and odd patients with guided ultrasound infiltration. The response to the treatment using ultrasound (tenosynovitis, synovitis and Doppler) and clinical criteria were evaluated at 2 and 6 months of infiltration. The assessment of the clinical remission of dactylitis was made under the yes or no dichotomous variable. The assessment of clinical remission of dactylitis was assessed when the Flexor tenosynovitis and Doppler scored 0.

Results: A total of 28 patients were collected, with a total of 50 fingers, the average age was 47.57 ± 10.99 , with an average of fingers per patient of 1.78 ± 0.56 . 42.9% were diagnosed of psoriatic arthritis, the rest still to be affiliated. All the patients presented clinical and ultrasonographic dactylitis, 100% ecográfica tenosynovitis with positive PWD signal, 54% (27) grade 1 and 46% (23) grade 2. Of the 28 patients, 16 had MCF arthritis and 12 of them MCF and IFP. They underwent conventional infiltration to 28 Vs 22 patients who were echoguided. Two months after the infiltration, clinical and sonographic remission was achieved in 68% (34) maintained after 6 months of follow-up. From the 34 fingers that achieved remission, 21 performed ultrasound-guided infiltration and 13 conventional (p 0.002). Only arthritis was resolved associated in 2 of the patients.

Conclusion: We can conclude that steroid infiltration guided by ultrasound is a good option treatment in patients with dactylitis. Conventional infiltration should not be done given the low efficiency.

Abstract Number: 2613

Patterns of Medication Use in a Validated Cohort of Psoriatic Arthritis (PsA) Patients

Madeline J. Epstein¹, Lisa A. Mandl¹, Jackie Szymonifka² and Sergio Schwartzman¹, ¹Rheumatology, Hospital for Special Surgery, New York, NY, ²Hospital for Special Surgery, New York, NY

Session Information**Session Date:** Tuesday, October 23, 2018**Session Title:** Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Treatment**Session Type:** ACR Poster Session C**Session Time:** 9:00AM-11:00AM

Background/Purpose: There is currently a lack of consensus among experts on the optimal therapeutic management of psoriatic arthritis (PsA). EULAR and GRAPPA recommendations support initial treatment with classic synthetic (cs) DMARDs. Recently the American College of Rheumatology /National Psoriasis foundation have presented draft recommendations suggesting that treatment naïve patients with active PsA be treated with anti-TNF agents first. In clinical practice it is assumed that treatment with a csDMARD, usually methotrexate (MTX), precedes therapy with biologic agents. In this analysis we evaluated whether the current pattern of PsA treatment in a validated academic cohort of PsA patients begins with MTX.

Methods: All patients with ICD-9 or -10 codes for PsA seen at a single academic center between January 1, 2013 and December 31, 2016 were identified. Patients who met CASPAR classification criteria and consented were enrolled. Patients were sent a survey eliciting date of PsA diagnosis, medication use, efficacy of therapy and reason for stopping medications.

Results: 161/336 (47.9%) of patients completed the survey: mean age 58.3 years (range 22-100), 50.3% female, 88.2% white, 3.4% Hispanic. 64.6% had been on MTX at some point in time and of these, 32.4% were currently using MTX. 35.4% had never been on MTX. 88.2% of patients who took MTX received it without ever being prescribed a biologic or prior to starting a biologic; of these 36.6% were never prescribed a biologic. Of the patients still on MTX, 84.4% took MTX orally and 15.6% via injection, with a mean oral MTX dose of 15.3mg weekly (range 2.5-25). 83.9% of patients who were currently taking MTX believed it helped their PsA, and 43.1% of patients who stopped MTX believed it had helped their PsA. Overall 77.6% of patients who were once on MTX discontinued; 46.4% because MTX was ineffective and 40.6% because of side effects, fatigue being the most frequent (See Table 2). 26.1% of patients had at some point been on a non-MTX csDMARD. 65.2% of patients had been on a biologic agent at some point in time, and of these 56.2% have taken ≥ 2 biologic agents. 48.4% of patients were currently taking a biologic agent.

Table 1. Penetrance of drugs in CASPAR criteria validated cohort of PsA patients (N=161).

Drug	n (%)
Biologics	105 (65.2%)
adalimumab	81 (50.3%)
etanercept	63 (39.1%)
secukinumab	20 (12.4%)
infliximab	18 (11.2%)
ustekinumab	16 (9.9%)
certolizumab	12 (7.5%)
golimumab	9 (5.6%)
abatacept	6 (3.7%)
ixekizumab	4 (2.5%)
rituximab	3 (1.9%)
Targeted synthetic	
apremilast	26 (16.1%)
tofacitinib	4 (2.5%)
Synthetic DMARDS	117 (72.7%)
methotrexate	104 (64.6%)
leflunomide	12 (7.5%)
hydroxychloroquine	10 (6.2%)
azithioprine	3 (1.9%)
Other drugs	115 (71.4%)
NSAIDs	91 (56.5%)
prednisone	51 (31.7%)
methylprednisolone	18 (11.2%)
minocycline	1 (0.6%)

Table 2. Self-reported reasons PsA patients stopped methotrexate (MTX).

Reason for stopping MTX	n (%) (n=69 stopped)
Ineffective	32 (46.4%)
Side effects	28 (40.6%)
Fatigue	14 (20.3%)
GI problems	12 (17.4%)
Abnormal liver tests	11 (15.9%)
Hair loss	8 (11.6%)
Ulcers in mouth	5 (7.2%)
Infections	4 (5.8%)
Rash	3 (4.3%)
Abnormal blood counts	1 (1.4%)
Other side effects	7 (10.1%)
Patient Preference	9 (13.0%)
Symptoms improved	5 (7.2%)
Other reason	11 (15.9%)

Conclusion: Nearly 9 out of 10 patients in an academic PsA Registry received MTX prior to a biologic, and 32.4% of MTX users remained on it. Interestingly, among those who discontinued, 43.1% believed it helped their PsA. These patterns suggest a benefit from MTX, and that even in a center where patients and physicians have access to biologics, MTX remains standard of care as initial therapy. Given the lower cost and patient self-report of benefit, in selected patients MTX should remain a first-line treatment.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The humoral response to vaccination may be affected by the use of immunosuppressive drugs. The effect of secukinumab on the humoral response of vaccines is unknown. We aimed to assess the immunogenicity and safety of vaccination against seasonal influenza in psoriatic arthritis (PsA) patients treated with secukinumab in comparison with healthy controls

Methods: Patients with PsA fulfilling the CASPAR criteria treated with secukinumab for at least 3 months and healthy controls were vaccinated with the Sanofi Pasteur vaccine recommended by the WHO in 2017 composed of 3 antigens (H3N3, H1N1 and B/Victoria). Clinical and laboratory assessments were performed on the day of the vaccination and 4-6 weeks later. The immunogenicity of the vaccine was evaluated by haemagglutination inhibition assay against the 3 antigens included in the vaccine. Responders to each antigen were defined as patients who had a 4- fold increase in the titer of the antigen or if they seroconverted in cases where the baseline level was below 1/40.

Results: The study included 32 consecutive PsA patients treated with secukinumab for more than 3 months with a median age of 52 years, 18(56%) females, 10 (31%) treated with concomitant conventional synthetic DMARDs, mostly methotrexate and 17 age/gender matched healthy controls (median age=48.5, females=6 (35%), males=11 (65%)). A significant increase in the geometric mean titers of each antigen was observed in both groups. The number of responders in each group was similar for H3N2, H1N1 and significantly higher in the PsA group for B /Victoria. The proportion of patients with a seroprotective level defined as a titer above 1/40 was high and similar in both groups. No correlation was found between the rate of response and factors such as age, gender and parameters of disease activity. No increase was found in the different parameters of disease activity which included tender and swollen joint counts, Leeds enthesitis index, physician and patient global assessment, PASI and CRP.

Conclusion: Treatment with secukinumab does not affect the humoral response to influenza vaccine in patients with PsA.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The aim of the study was to investigate the impact of smoking on disease activity, treatment adherence and treatment response in psoriatic arthritis (PsA) patients on tumour necrosis factor-alpha inhibitor (TNFi) therapy in a real-life cohort.

Methods: PsA patients treated with their first TNFi therapy (including adalimumab, certolizumab, etanercept, golimumab and infliximab) in TURKBIO registry were included in the study. Demographic and clinical features of current smokers were compared with never smokers and previous smokers.

Treatment response was evaluated as achievement of EULAR-good-response (yes/no) at the 3-months' and 6-months' visits. We classified patients as 'responders' if they achieved clinical response at the both 3-months' and 6 months' visits.

DAS28-CRP, CDAI and HAQ measurements and also ESH and serum CRP levels were compared between the study groups at baseline. After 3 months and 6 months, changes in these parameters were measured again and recompared between the groups.

Results: Among 102 PsA patients analysed (62 % women; mean age: 41.5) in the study, 97 (95%) had known smoking status. The median follow-up time was 1.3 years (IQR: 0.2-2.3) and disease duration was 3 years (0.6-7.7). No significant difference was found in these parameters between current, never and previous smokers.

At baseline, current smokers were younger and had higher methotrexate use rate ($p=0.009$) compared with previous smokers. Never smokers had female predominance and higher erythrocyte sedimentation rate (ESR) compared with current smokers. Disease duration, body mass index, CRP and baseline disease indexes (DAS28CRP, CDAI, HAQ) were not found to be different between current and never smokers and also previous smokers. Treatment adherence for TNFi showed no difference between the groups (Table 1). The use of concomitant DMARDs was also similar.

Treatment response (EULAR good response) was found to be similar between current, never and previous smokers. The changes in the measurements of DAS28-CRP, CDAI and HAQ at the month 3 and 6 revealed also no difference.

In multivariate analysis, patients with high CRP (OR: 2.8; 95% CI (0.91-8.55), $p=0.07$) and longer biologic follow up time (>1 year) (OR: 15.47; 95% CI (5.52-43.35), $p<0.01$) were found to be associated with EULAR-good responses.

The treatment adherence was better in patients having high ESR (HR: 1.87; 95% CI (1.08-3.25), $p=0.03$) and high clinical disease activity (CDAI >22) (HR: 2.5; 95% CI (1.27-5.10), $p=0.009$). However, smoking status was neither associated with treatment response (EULAR-good response) nor treatment adherence in the patients.

Conclusion: This study suggested that smoking might not be associated with disease activity, treatment adherence and treatment response in PsA patients treated with TNFi in clinical practice.

Table 1. Baseline demographic and clinical features; and treatment adherence and responses in study groups

	Smoking status			P*	P**

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Although there is good evidence that smoking has a dose-dependent impact on structural damage progression in ankylosing spondylitis (AS) the evidence is poor for its impact on disease activity, physical mobility, life quality and treatment response.

Therefore we aimed to investigate the impact of smoking on disease activity, treatment adherence and treatment response in Turkish patients with AS treated with their first tumour necrosis factor-alpha inhibitor (TNFi) therapy in a real-life cohort.

Methods: 561 patients fulfilling the modified New York criteria for AS and treated with their first TNFi therapy (including adalimumab, certolizumab, etanercept, golimumab and infliximab) since 2009 from 9 centers in Turkey were included in the analysis.

Treatment response was evaluated as achievement of 'BASDAI50' or 'ASDAS Clinically important improvement (CII)' at the 3-months' and 6 months' visits. We classified patients as 'responders' if they achieved clinical response at the both 3-months' and 6 months' visits.

Clinical and demographic parameters were compared between current/never and current/previous smoker groups.

Demographic and descriptive data are presented by medians/interquartile ranges (IQRs). Groups were compared by non-parametric tests (χ^2 , Kruskal Wallis and Mann Whitney tests).

Results: Among 561 AS patients analysed (40 % women, mean age: 37.9 ± 11), 506 (90 %) had known smoking status. The median follow-up time was 1.9 years (IQR 0.85-3.5) and disease duration was 3.1 years(0,6-7,7).

At baseline, current smokers were younger compared with never and previous smokers. Current smokers had male predominance; lower erythrocyte sedimentation rate and higher change in BASMI at 3 months compared with never smokers. HLA status, body mass index, CRP, baseline disease indexes (BASDAI, BASFI, BASMI, ASDAS) and treatment response was not found to be different between current and never smoker patients in our population. (Table 1).

Treatment adherence was better in previous smokers compared with current smokers but no difference was found between current and never smoker patients(Table 1).

In multivariate analysis, male (OR: 1,98; 95% CI (1,39-2,82), $p < 0,01$), HLA positive (OR: 1,54; 95% CI (1,08-2,18), $p = 0,016$) and active DMARD user (OR: 1,84; (95% CI 1,12-3,01) $p = 0,015$) patients had better treatment response and treatment adherence ((HR: 1,93; 95% CI (1,36- 2,73); HR: 1,60; 95% CI (1,13-2,27); HR: 1,80; 95% CI (1,10-2,95) all $p < 0,005$) but smoking status were not significant ($p > 0,05$).

Conclusion: This study suggested that smoking might not be associated with disease activity, treatment adherence and treatment response in AS patients treated with TNFi in clinical practice.

Table 1. Baseline demographic and clinical features; and treatment adherence and responses in study groups

Session Date: Tuesday, October 23, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: On regulatory approval in India, challenging socioeconomics and infection prone scenario compelled us to seek prolonged effectiveness of short term anti-TNF therapeutic regimen (Chopra et al. APLAR Congress 2005). However, there was very little professional and industrial support to research this approach. With the advent of 'Biosimilars', we decided to evaluate the effectiveness of a shorter therapeutic regimen of a Biosimilar Adalimumab in AS

Methods: 62 consenting severely symptomatic patients (86% B27+) with failed NSAID response were screened; 12 were suspected latent TB and offered INH prophylaxis. 50 patients (42 males, mean age 31.2 years, mean duration 98.8 months) were enrolled into an observational design study in a community practice setting; mean of AS-DAS 4.6, ESR 88mm, CRP 64 mg/dl (nephelometry, cut off 5 mg/dl). 40 mg Biosimilar Adalimumab (Bsmr-ADL) (Exemptia™) was administered subcutaneous every fortnight for 12 weeks as per protocol and standard (ACR) clinical and laboratory monitoring performed. Cytokines assay Standard intention-treat analysis was performed (Student T and matched sign rank); significant p <0.05.

Results: Improvement was rapid (week 4- mean ESR 29.1 mm), significant and sustained (Figure). The Tables shows the proportion of patients showing index improvement and ASDAS change. 10 patients failed ASAS 20 at week 12 and despite additional Bsmr-ADL (2 injections, 2 week apart) did not show ASAS based improvement at later time points (data not shown). 12 patients withdrew (1 drug fear, 4 logistics, 5 poor response, 2 unknown). None had active TB/severe AE. Cytokine assay (IL-6, TNF α and IL-17) at baseline and a-priori endpoints will be presented. We continue to monitor patients and have completed 18 months post ADA. We lacked active control and did not study structure modification.

Conclusion: This investigator initiated study demonstrated prolonged benefit of a 12 week regimen with Biosimilar ADA in several patients of severe AS. This is a promising way forward in our setting. But validation studies are required..

Acknowledgment: Zydus Cadila India provided a generous research grant and substantial free of cost Biosimilar ADL injections.

Table shows the proportion of patients with severe AS showing response at study end points

Index	12-14 weeks	22-26 weeks	46-52 weeks
ASAS 20 (%)	80	72	52
ASAS 40(%)	68	60	38
ASDAS (mean)	2.4	2.9	3.5
ASAS partial remission (%)	34	22	12

Figure shows the mean Efficacy Measures in severe AS treated with Biosimilar Adalimumab

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Ustekinumab and secukinumab are two new Biologic Disease-modifying Antirheumatic Drugs (bDMARDs) in severe psoriatic arthritis (PsA), targeting respectively IL12-23 and IL 17. Data in real-world are missing for these treatments. For ustekinumab, there is only one study with a large number of patients (160). For secukinumab, there are only the data from clinical trials. The objective was to assess drug survival, efficacy and remission of ustekinumab (UST) and secukinumab (SEK) in a retrospective multicentric cohort of 161 PsA.

Methods: This is a multicentric retrospective study of patients suffering from PsA (CASPAR criteria) from July 2011 to April 2018. Drug survival is defined as the time from initiation to discontinuation (stop/switch) of biologic therapy on the registry. Using Kaplan-Meier survival curves and Cox-regression analyses [hazard ratios (HR) and 95% confidence intervals (CIs)], time to discontinuation was compared across the cohort. For peripheral forms, treatment was considered to be effective for patients with a favourable expert opinion or > 30% clinical improvement of swollen and tender joint counts (SJC and TJC). For axial forms, efficacy criteria were: improvement of BASDAI by at least 2 points on a scale from 0 to 10 or 50% improvement (BASDAI 50) or expert opinion. Remission was considered if TJC ≤ 1, SJC ≤ 1, PASI ≤ 1, patient Visual Analogue Scale (VAS) ≤ 15, Patient global activity VAS ≤ 20 and Tender enthesal points ≤ 1 (Very Low Disease Activity (VLDA) criteria except HAQ).

Results: 161 were included with a mean follow up greater than or equal to 6 months. The sex ratio was balanced with 54.7% of women. The mean age was 50.2 years old and the body mass index(BMI) was 27.6 kg/m². The disease duration was 9.6 years. 47.7% of patients did not smoke. The patients presented axial PsA in 59.0%, peripheral PsA in 94.9% and

Fig. 1 Drug survival of secukinumab and ustekinumab in ustekinumab and secukinumab-naïve patients

enthesitis in 31.4%. Patients were bDMARD-naïve in 13.0%. The median drug survivals for UST AND SEK were respectively 11 and 12 months. There was no impact of the age, the sex, the disease duration, smoking status or the BMI on the drug survival. The drug survival was similar in UST and SEK-naïve patients (HR, 1.07 (0.67 to 1.70), $p=0.77$) (Fig 1) as efficacy for both treatments ($p=0.15$) whereas remission was higher in SEK group (36.2% vs 18.2%, $p=0.012$).

Conclusion: This is the first real-world study which compares these two new treatments in psoriatic arthritis. Ustekinumab and secukinumab in psoriatic arthritis have similar drug survival and efficacy in our study. However, remission based on VLDA criteria was achieved more often with secukinumab.

Effect of Statins on CRP Elevation in Patients with Psoriatic Arthritis

Lesley Jackson¹, Jeffry Bieber^{1,2} and R. Eric Heidel³, ¹Graduate School of Medicine, Department of Internal Medicine, University of Tennessee Medical Center Knoxville, Knoxville, TN, ²UT Rheumatology, Knoxville, TN, ³Graduate School of Medicine, Division of Biostatistics, and Department of Surgery, University of Tennessee Medical Center Knoxville, Knoxville, TN

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: It is well established that psoriatic arthritis is associated with increased cardiovascular disease risk. The use of statins may impart anti-inflammatory effects, possibly through blocking mevalonate production, thereby preventing induction of trained immunity. Mevalonate activates mammalian target of rapamycin (mTOR) and other mediators, subsequently modifying inflammatory pathways. Several studies confirm beneficial effects of statins on C-reactive protein (CRP) in patients with rheumatoid arthritis and lupus. CRP enhances mTOR signaling. Therefore, we aimed to evaluate whether statin therapy affects psoriatic arthritis disease activity by evaluating the degree of systemic inflammation, using CRP elevation as a marker, in an outpatient population at a hospital based clinic.

Methods: A retrospective analysis was performed on the University of Tennessee Knoxville Patient Database for all patients with an ICD-10 code corresponding to psoriatic arthritis that had a CRP checked in the last 10 years. From the selected patients, we divided them into two separate groups: the first group of 54 patients were on statin therapy, and the second group of 152 were not on a statin. We also recorded the most recent CRP concentration, as well as other

parameters including ESR, BMI, and specific treatments for psoriatic arthritis including any DMARD, biologic, or steroid use in each of these patients. Non-parametric Mann-Whitney *U* tests were used for between-subject comparisons using CRP concentration and other parameters with either the presence or absence of statin therapy. The association between CRP level and patient's BMI was tested using Spearman's rho correlation.

Results: Out of a total of 220 patients with an ICD-10 code corresponding to psoriatic arthritis in our system over the last 10 years, 206 had CRP levels on record. In this group of 206, significant beneficial role of statin medication on CRP level was found when prescribed with or without conventional DMARDs or biologic agents. CRP level was found to be significantly lower in the patients on adjunct statin medication compared to the non-statin group ($p = 0.003$), with the statin group of 54 patients demonstrating lower median CRP level of 0.2 (IQR = 0.4) compared to non-statin group of 152 patients with median CRP of 0.4 (IQR = 0.6). ESR elevation was not significantly different between the groups though there was a trend, with lower levels seen in the statin group compared to the non-statin group ($p = 0.07$). The statin group demonstrated lower median ESR level of 5 (IQR = 8.0) compared to the non-statin group median ESR of 7 (IQR = 13.0). There was a statistically significant positive correlation between CRP and BMI with $r_s = 0.35$, $p < 0.001$.

Conclusion: These results suggest a potentially beneficial role of statin therapy in patients with psoriatic arthritis. Statins produced significant biochemical improvement based on CRP level. More studies are needed to further characterize the effect of statins on clinical outcomes. These results also suggest that the pathogenesis of psoriatic arthritis may involve alterations in trained immunity.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: There had been a lot of new therapeutic agents for the treatment of Psoriatic Arthritis (PsA) in the last decade. In this study we aimed to assess the treatment choices of rheumatologists in real life in the era of new options, focusing on new diagnosis of PsA.

Methods: The Psoriatic Arthritis Registry of Turkey (PsART) is a multicenter web-based PsA registry (1). At the time of the analysis, 283 out of 1353 patients for the registry had new diagnosis and were given treatment for PsA for the 1st time. Within these 283 patients, 174 also had at least one follow up visit where the changes in the medications and response rates were documented. Fourteen of 174 patients who had used synthetic DMARDs because of psoriasis, were not assessed for treatment strategies. Psoriatic arthritis minimal disease activity (MDA) parameters were collected at baseline and during follow-up period.

Results: Overall, 160 patients (56.9% female), with a mean (SD) age of 44.9±12.6 were assessed. Polyarticular, mono-oligoarticular, and axial disease were 27.6%, 48.2%, and 34.5%, respectively. Baseline minimal disease activity parameters were followed; tender and swollen joint counts 4.8 (4.7) and 2.3 (3.5), body surface area 13.0 (16.6), Leeds enthesitis index 0.08 (0.36), patients global assessment of disease activity-VAS 60 (21), pain-VAS 58 (25) and HAQ-DI 0.89 (0.60). Baseline and last control visit treatments were given at table 1. Mean (SD) and median (range) follow-up duration was 16 (13) months and 14 (min-max 3-43) months. The retention rates of methotrexate, sulphasalazine, leflunomide were 90.3%, 91.5%, and 100%, respectively. Twenty-one (13.1%) patients were switched synthetic DMARDs to anti-TNF treatments during follow up period. The baseline characteristics of patients who remained on synthetic DMARDs versus who were switched to biologics did not differ. Only 40% of patients achieved to minimal disease activity in the last visit.

Table 1. Baseline and follow-up treatment choices in psoriatic arthritis

	Baseline n=160	Last control visit N=160
Only NSAID drugs, n (%)	20 (12.5)	0 (0)
Methotrexate, n (%)	120 (75.0)	124 (77.5)
Sulphasalazine, n (%)	42 (26.3)	47 (29.4)
Leflunomide, n (%)	3 (1.9)	19 (11.9)
Glucocorticoids, n (%)	62 (38.7)	37 (23.1)
Anti-TNF, n (%)	0 (0)	21 (13.1)
Combination synthetic DMARDs treatment, n (%)	32 (20.0)	55 (34.4)

Conclusion: Methotrexate is the most commonly used drug for newly diagnosed PsA patients in real life. Sulphasalazine was chosen either in combination or as monotherapy for a subgroup of patients although not being a part of the EULAR or GRAPPA recommendations. Leflunomide seems to be a second line treatment option. The cross-sectional assessment of PsART cohort, almost 31% of patients used biological DMARDs (1). Moreover within 16 months, 13% of new diagnosed PsA patients were switched from synthetic DMARDs to anti-TNF treatments. Glucocorticoid usage decreased during follow-up period.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Biologics therapy survival is often used as a proxy for treatment effectiveness and safety. However, it may be influenced by patient characteristics, utilization patterns, and available treatment alternatives, which tend to change over time. The objective of this analysis was to assess in Canadian routine clinical practice the survival of treatment with adalimumab (ADA) in AS and PsA, and the determinants of ADA survival.

Methods: COMPLETE-AS is an ongoing Canadian observational study of anti-TNF α naïve adults with active AS or PsA who require, per the judgment of the treating physician, change in current treatment. Patients are followed for up to 2 years. In the current analysis, patients initiating ADA were included. Kaplan Meier (KM) estimates and Cox proportional models were used in the analysis. Potential predictors evaluated were age, gender, enrollment period, combination treatment with non-biologic DMARD(s) (nbDMARDs) vs. monotherapy, baseline disease activity (AS: BASDAI; PsA: DAS28), and baseline functional activity (AS: BASFI; PsA: HAQ). In a secondary analysis, the achievement of BASDAI 50 (AS) and Δ DAS28 ≥ 1.2 (PsA) at 3 months were also considered.

Results: A total of 459 AS and 278 PsA patients were included in the analysis. Mean age of the AS and PsA patient cohorts was 43.9 and 52.0 years, respectively. Mean BASDAI and DAS28 scores in AS and PsA patients were 6.4 and 4.8,

Figure 1. Adjusted Survival Curve for Time to ADA Discontinuation by Achievement of BASDAI 50 at 3 Months

respectively. KM-based mean (95% CI) time to ADA discontinuation was 1.77 (1.72-1.82) years and 1.83 (1.77-1.88) years for AS and PsA patients, respectively.

Among AS patients, BASFI score at baseline was identified as the only significant predictor of ADA survival, (HR [95% CI]: 1.17 [1.08-1.28]). In the secondary analysis considering response to treatment at 3 months, achievement of BASDAI 50 was associated with significantly lower hazard for discontinuation (0.36[0.20-0.65]; Figure 1); in this analysis, age (0.98 [0.97-1.00]) and baseline BASFI score (1.24 [1.11-1.39]) were also significant predictors of ADA retention.

Among PsA patients, male gender was identified as the only significant (positive) predictor of ADA survival, both in the primary (0.50 [0.29-0.85]) and secondary (0.39 [0.18-0.85]) analysis.

Conclusion: The results of this analysis have shown that early achievement of BASDAI 50 is associated with improved long-term retention of ADA treatment among AS patients. Furthermore, gender differences may exist in the real-world survival of ADA treatment in PsA.

Session Date: Tuesday, October 23, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Treatment selection in Canadian routine clinical care is based on the judgment of the treating physician but is also affected by treatment guidelines and regional reimbursement which may vary over time. The objective of this analysis was to describe the regional and temporal variability of the profile of anti-TNF naïve patients with ankylosing spondylitis (AS) at initiation of adalimumab (ADA) following failure of initial non-biologic treatment.

Methods: COMPLETE-AS is an ongoing Canadian observational study of anti-TNF α naïve adults with active AS who require, per the judgment of the treating physician, change in current treatment. Patients are followed for up to 2 years. Regional variation between the following regions was assessed: Alberta/British Columbia/Manitoba (AB/BC/MB) vs. New Brunswick/Newfoundland/Nova Scotia (NB/NL/NS) vs. Ontario (ON) vs. Quebec (QC). In a sensitivity analysis, patients from AB and MB were excluded due to low numbers. Temporal variation over the following periods was assessed: 2011-2012 vs. 2013-2014 vs. 2015-2017. To evaluate the independent impact of region and time period on disease activity (BASDAI) and function (BASFI) multivariate linear regression was used.

Results: A total of 459 patients were included of whom 95 (20.7%) were from AB/BC/MB, 39 (8.5%) from NB/NL/NS, 202 (44%) from ON and 123 (26.8%) from QC. By period, 133 (29%) were enrolled in 2011-2012, 133 (29%) in 2013-2014, and 193 (42%) in 2015-2017.

In univariate analysis, significant regional variation was observed in mean age (range from 41.1 to 48.4; $p=0.013$), gender (males from 46.3% to 64.2%; $p=0.036$), tobacco use (current smoking: 15.4% to 30.7%; $p=0.003$), alcohol use (non-drinker 17.9% to 52.6%; $p=0.007$), disease duration (4.2 to 9.7 years; $p<0.001$), and use of ADA monotherapy (71.6% to 87.2%; $p=0.033$). No differences in BASDAI and BASFI were observed. Similar results were observed in the sensitivity analysis. In terms of temporal variation, more recent years (2015-2017) were associated with lower BASDAI (6.4 vs. 6.7 vs. 6.2; $p=0.040$) and BASFI (5.6 vs. 5.9 vs. 5.1; $p=0.013$) scores without any other differences. In multivariate analysis adjusting for age and gender, enrollment period but not region was associated with BASDAI ($p=0.034$) and BASFI ($p=0.006$) levels, with patients in more recent years having less severe disease when initiating ADA.

Conclusion: The results of this analysis have shown that significant regional and temporal variation exists in the profile patients selected for ADA treatment in Canadian routine care. Furthermore, a significant independent association was identified between more recent years and lower BASDAI and BASFI scores at ADA initiation.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Psoriatic arthritis (PsA) is a heterogeneous disease. Patients with PsA may have predominant axial (axPsA) or peripheral (pPsA) manifestations but the factors influencing on this are unknown. Recently, the recommended disease activity indexes have been updated, being these ASDAS for axial manifestations and DAPSA for peripheral manifestations. However, the impact of these changes in the outcomes of patients treated with biological therapies is unclear. Our objective is to analyse the efficacy of treatment in patients with axPsA and pPsA starting TNFi and the predictive factors of clinical presentation in clinical practice.

Methods: An observational study analysing data from a prospective cohort including 93 patients (pts) with axPsA or pPsA treated with TNFi from 2002-2018 was conducted. Demographic information, disease activity indexes (ASDAS for axPsA and DAPSA for pPsA) and laboratory tests were collected before starting TNFi (baseline visit) and 6 months later (6 m visit). At 6 m, the percentage of pts achieving inactive disease (ASDAS <1.3) and low disease activity (LDA)

	Total n=93		p-value
	axPsA n=45	pPsA n=48	
Male, n (%)	28 (62%)	20 (42%)	0.04
BMI, Mean (SD)	27.4 (5.5)	26.4 (5.5)	0.01
Age at diagnosis (years), mean (SD)	37 (15.3)	42 (12.7)	0.02
Age at start biologic (years), mean (SD)	43 (14.1)	51 (13.1)	0.03
Smokers, n (%)	25 (55%)	8 (17%)	0.2
Disease duration (years), mean (SD)	19 (10.8)	18 (8.4)	0.8
Biologic use time (years), mean (SD)	5.8 (8.1)	6.8 (5.3)	0.3
HLA B27, n/N (%)	8/22 (36%)	—	
RF, n/N (%)	—	3/44 (6.8%)	
ACPA, n/N (%)	—	0/45	
αDMArDA, n (%)	28 (69.7%)	35 (74.5%)	0.5
ASDAS, mean (SD)	5.1 (1.2)	—	
hASAS, mean (SD)	—	4.7 (1.3)	
CRP mg/L, mean (SD)	12.9 (14.8)	10.1 (14.7)	0.3
ESR, mean (SD)	29.4 (28.4)	28.8 (20.1)	0.3

(ASDAS 1.3-2.1) for axPsA, or remission (DAPSA < 4) and LDA (DAPSA 4.1-15) for pPsA as well as the percentage of pts achieving clinical improvement (defined as ASDAS-clinically important improvement = delta-ASDAS > 1.1- or delta-DAPSA50) was determined. Baseline predictor factors for developing axial or peripheral manifestations were identified using a univariable and multivariable binary regression models adjusted for confounder factors.

Results: Out of 93 included pts, 45 pts had predominant axPsA and 48 pPsA. Administered TNFi were etanercept for most pts (42%), infliximab in 29%, adalimumab in 22% and golimumab in 7%. Baseline characteristics are shown in Table 1. In axPsA, 49% clinically improved, 56 % pts reached LDA and 35% reached inactive disease. In pPsA, 56% pts clinically improved, 67% pts reached LDA and 25% pts were on remission at 6 m. The univariate analysis demonstrated in our cohort of patients with PsA that patients with younger age at diagnosis (OR, p=3.5; p=0.03), younger age at starting the biologic (OR, p=4.9; p=0.03), obesity (OR, p=6.4; p=0.03), and male gender (OR, p=3.0; p=0.03) had more risk to present axPsA. After multivariable analysis, only the obesity reached significance (p=0.01) for risk of presenting axPsA.

Conclusion: According to newly recommended disease activity indexes (ASDAS and DAPSA) 1 out of 3 pts with axPsA and 1 out of 4 in pPsA is on remission 6 m later after initiating a TNFi in clinical practice. Additionally, around 1 out of 2 clinically improve in both groups. The presence of obesity, male gender and younger age at diagnosis or when initiating TNFi are associated with developing axial predominant manifestations in PsA.

Cost-Effectiveness of Swapping Strategy for Established Psoriatic Arthritis and Immediate Versus Standard Swapping Strategy for Early Psoriatic Arthritis

Dongze Wu¹, Tingting Xu², Isaac T. Cheng¹, Steven H.M. Lam¹, Jiang Yue¹, Priscilla Wong¹, Edmund Li¹, Tena K. Li¹ and Lai-Shan Tam³, ¹Department of Medicine & Therapeutics, The Prince of Wales Hospital, The Chinese University of Hong Kong, Hong Kong, China, Hong Kong, China, ²China Center for Health Development Studies, Peking University, Beijing, China; Department of Health Policy and Administration, Peking University School of Public Health, Beijing, China, Beijing, China, ³Department of Medicine & Therapeutics, The Prince of Wales Hospital, The Chinese University of Hong Kong, Hong Kong, China, Hong Kong, Hong Kong

Session Information

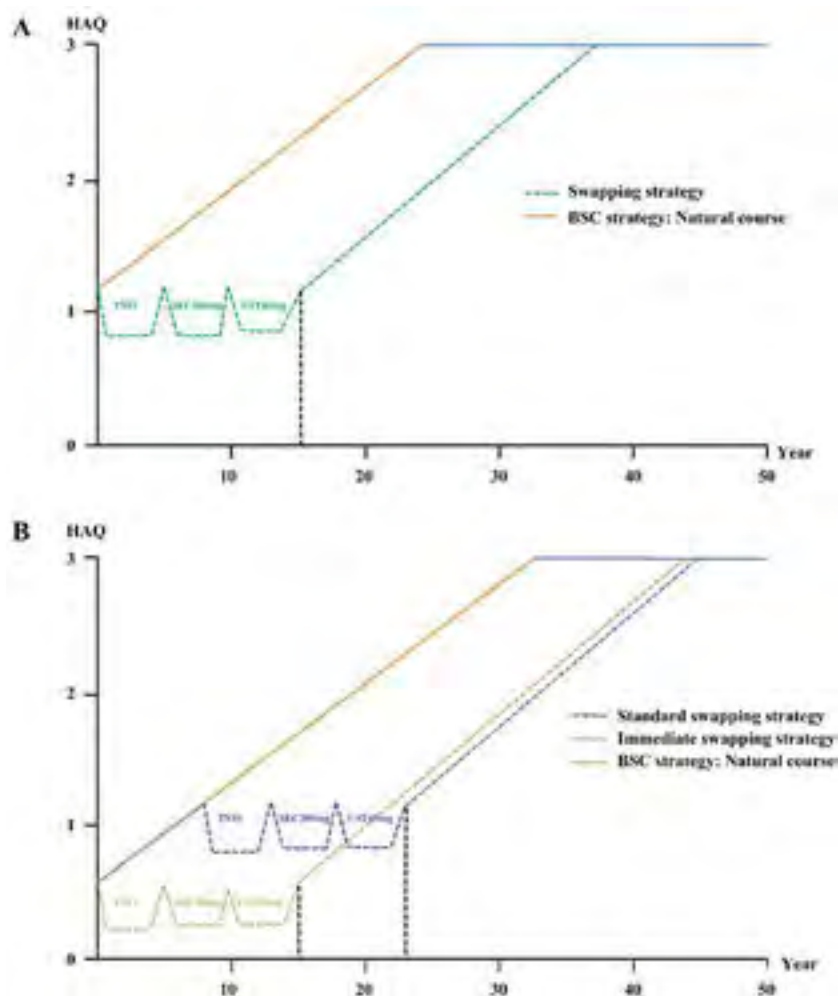

Session Date: Tuesday, October 23, 2018

Background/Purpose: For patients with psoriatic arthritis (PsA) failing the first TNF-inhibitor, switching to biologic DMARDs [bDMARDs] with different mechanism of actions (swapping strategy) may be superior than switching to another anti-TNF (cycling strategy) ^[1,2].

The aims of the study were to evaluate the cost-effectiveness of 1) swapping strategy for established PsA and 2) immediate versus standard swapping strategy for early PsA from the Hong Kong (HK) societal perspective

Methods: A swapping York model with life time horizon was developed for two hypothetical subpopulations: 1) established PsA (age=47, HAQ=1.22, Figure A) received five swapping strategies and 2) early PsA (age=40, HAQ=0.71, Figure B) received immediate (start bDMARDs after diagnosis) or standard (initially given BSC and then start bDMARDs when HAQ increase to 1.22) use of the most cost-effective swapping strategy. Both subpopulations were further classified into mild to moderate psoriasis (MMP, PASI=0.73) and moderate to severe psoriasis (MSP, PASI=12.5). All five swapping strategies started with an anti-TNF, followed by secukinumab 300mg and then ustekinumab 45mg. The cost-effectiveness of each strategy was determined using a willingness-to-pay (WTP) threshold of £32,356/quality-adjusted life-year (QALY) (HK Gross Domestic Product per capita).

Results: For the base-case scenario, all five swapping strategies are cost-effective versus BSC strategy for established PsA, which are associated with greater QALY gain and lower treatment related direct costs, psoriasis cost and productivity loss. In established PsA with MMP and MSP, etanercept swapping strategy is likely to be the most cost-effective strategy with an incremental cost £9,518.93 and £9,084.58 per QALY gained over BSC strategy respectively. For early PsA with MMP and MSP, the base-case results indicated that standard etanercept swapping strategy was cost-saving (£-50,635.74 and £-67,843.32) and more effective (1.20 and 1.32 QALYs); while immediate etanercept swapping strategy was costlier (£13294.95 and £8986.16), more effective (3.82 and 3.27 QALY), and had relative low ICER (£3482.36 and £2745.35 per QALY gained) relative to BSC strategy.

Conclusion: Swapping strategy showed favorable cost-effectiveness for established PsA as well as early PsA. The increased costs of biologic agents are offset by the gain in benefits from long-term HAQ reduction.

TNF Inhibitor Reduces ASDAS Faster and More Stable in Ankylosing Spondylitis Patients: Results from a Real World Prospective Cohort Managed By Smart Phone System

Xiaojian Ji, Jian Zhu, Jianglin Zhang and **Feng Huang**, Rheumatology, Chinese PLA General Hospital, Beijing, China

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The Smart-phone Spondyloarthritis Management System (SpAMS) is a mobile health tool, specifically designed to conduct prospective clinical studies on SpA/AS in China, using real-world clinical workflows. The aim of this study was to explore the effectiveness of tumor necrosis factor inhibitors (TNFi) in controlling disease activity in a real-world setting.

Methods: The Chinese Ankylosing Spondylitis Prospective Imaging Cohort (CASPIC) is a nation-wide, ongoing, prospective, and state-funded cohort study, launched in conjunction with SpAMS. All patients fulfilled the 1984 modified NY criteria. Patients on medication and with full medication records were enrolled in this study. Generalized additive mixed models were used to study the relationship between TNF inhibitor(TNFi) treatment (users or non-users) and AS Disease Activity Score (ASDAS)during the follow-up period. The model adjusted for gender, symptom duration, HLA-B27, BMI, smoking status, peripheral arthritis, and treatment with NSAIDs and DMARDs.

Results: A total of 1201 AS patients were recruited in CASPIC from April 2016 to April 2018. Sixty-eight patients (5.7%) with no medication records or withdrawals were removed (Figure 1).The characteristics of 332 TNFi user and 801 nonuser were summarized in Table 1. Mean (SD) followed-up duration were 12.3 (5.9) months. Mean (SD) duration of TNFi use were 9.3 (5.9) months. TNFi user were slightly younger, more likely to present with peripheral arthritis, had higher baseline disease activity scores, higher baseline inflammation marker levels, and were less likely to be prescribed NSAIDs and DMARDs. TNFi user had a higher ASDAS at baseline which subsequently declined rapidly, and then remained at a

Figure 1. Flow chart of the participants enrolled in this study

Figure 2. Smoothing analysis curves pertaining to ASDAS and follow-up duration stratified by TNFi treatment status

consistently lower level throughout the first 12 months than did nonuser (Figure 2). ASDAS decline were significantly more in TNFi user than they were in those of nonuser in the first 3 months (0.62 units, 95% CI 0.13 to 1.10, P=0.017).

Conclusion: The use of TNFi in AS patients may reduce disease activity in a faster and more stable fashion.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: It is important to understand the association between early changes in inflammatory biomarkers and treatment response at later times after initiation of a biologic DMARD. In the SPIRIT-P1 (NCT01695239) and SPIRIT-P2 (NCT02349295) phase 3, multicenter, double-blind studies of patients with active PsA, high-sensitivity CRP (hs-CRP) levels declined rapidly during the first 4 weeks (wks) of treatment with ixekizumab (IXE), a high affinity monoclonal antibody against IL-17A. This post-hoc analysis used data from the 2 studies to describe and compare efficacy outcomes at wk 24 according to change in hs-CRP levels from baseline (wk 0) to wk 4.

Methods: In SPIRIT-P1, biologic naïve patients received subcutaneous IXE 80 mg every 4 (Q4W; N=107) or 2 wks (Q2W; N=103) after a starting dose of 160 mg at wk 0, or adalimumab 40 mg every 2 wks (N=101), or placebo (PBO; N=106).¹ In SPIRIT-P2, patients with an inadequate response/intolerance to TNF inhibitors received IXE Q4W (N=122) or Q2W (N=123), or PBO (N=118).² For this analysis, the 2 IXE dose groups were combined and 3 patient hs-CRP subgroups were defined: normal (<6.0 mg/L) hs-CRP levels at wks 0 and 4; hs-CRP levels that normalized during treatment (elevated ≥6.0 mg/L at wk 0, normal at wk 4); and elevated hs-CRP levels (normal/elevated at wk 0, elevated at wk 4). Between-treatment differences (combined IXE vs. PBO) across hs-CRP subgroups in efficacy outcomes were evaluated using the Cochran-Mantel-Haenszel general association test.

Results: Baseline patient characteristics, including BMI, was generally similar between the 3 hs-CRP subgroups, but with a numerically higher disease activity in those with elevated hs-CRP. Across the 3 subgroups, responses to active treatment were rapid and sustained at wk 24. In both studies, differences between IXE and PBO for clinical outcomes (ACR20/50/70, minimal disease activity, DAPSA low disease activity/remission) differed statistically significantly across hs-CRP subgroups as early as wk 4 or 8 (Tables 1 and 2). Numerically greater differences in the normalized hs-CRP subgroup was

observed. Although performed on a smaller sample size, efficacy results across the 3 subgroups were generally consistent with those previously reported at wk 24 for the overall population in both studies.

Conclusion: In PsA, a response can be achieved after 24 wks of treatment with IXE regardless of prior biologic use, even when hs-CRP is still elevated at wk 4.

Not All Clinical Responders in SLE Are Equal: Comparison of Subcutaneous Belimumab + Standard of Care Responders to Placebo + Standard of Care Responders

William Stohl¹, Milena Kurtinecz², Joe Eastman³, Vanessa Castellano⁴, Chrysa Mahoney⁴, Tania Gonzalez-Rivera² and Bonnie Pobiner⁴, ¹Division of Rheumatology, University of Southern California Keck School of Medicine, Los Angeles, CA, ²GlaxoSmithKline, Philadelphia, PA, ³GlaxoSmithKline (at the time of the study), Research Triangle Park, NC, ⁴GlaxoSmithKline, Research Triangle Park, NC

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: To determine whether degree of response among responders to subcutaneous (SC) belimumab (BEL) + standard of care (SoC) is greater than that for responders to placebo (PBO) + SoC.

Methods: Patients with SELENA-SLEDAI (SS) ≥8 on stable SoC ≥30 days were randomized (2:1) to weekly SC BEL 200 mg + SoC or PBO + SoC in BLISS-SC (NCT01484496). Primary endpoint was SLE Responder Index 4 (SRI4) at week (Wk) 52 (≥4-point SS reduction, <0.3 increase in Physician's Global Assessment [PGA], and 0 new BILAG A or ≤1 new BILAG B organ domain scores, all vs baseline [BL]). SRI4 responders were compared based on treatment (BEL vs PBO) for changes in clinical and laboratory parameters. SRI4 non-responders were also evaluated.

Results: 61.4% of BEL + SoC and 48.4% of PBO + SoC were SRI4 responders¹. BEL + SoC responders had better outcomes than PBO + SoC responders at Wk 52 (Table 1) and during the trial: greater % reductions in SS (Wk 20-52, $p \leq 0.0199$) and PGA scores (Wk 20-52, $p \leq 0.0304$); organ system improvement (SS Wk 52 immunologic [$p = 0.0064$] and vascular [$p = 0.0199$] and BILAG vasculitis [Wk 16-52, $p \leq 0.0301$]); 65% reduced risk of severe flare (HR=0.35 [95% CI: 0.13, 0.94], $p = 0.0367$); normalized complement levels (Wk 16-20,28-36, 44, 52: C3 $p \leq 0.0232$ and Wk 16-24, 36-52: C4 $p \leq 0.0303$). Percent of patients with ≥ 5 , 6, 7, or 8 point reductions in SS excluding serology (anti-dsDNA, complement) were numerically greater for BEL + SoC responders from Wk 8-52, with significant differences at earlier time points (Table 2). Among patients receiving BL prednisone >7.5 mg/day, more BEL + SoC responders reduced their CS dose $\geq 25\%$ to ≤ 7.5 mg/day during Wks 40-52 vs PBO + SoC responders but did not reach statistical significance (23.8% vs 14.6%, OR 1.79 [95% CI: 0.89, 3.59], $p = 0.1008$). Anti-dsDNA shifts and FACIT-fatigue score improvements were similar between groups. Non-responders had no significant differences, irrespective of treatment, in changes in SS (\pm serology) or PGA, organ system involvement, flares, steroid use, complement, anti-dsDNA, or FACIT-fatigue scores. BL BAFF levels (range 1.574-1.769 ng/mL) and SoC medications were similar across treatment groups regardless of SRI4 response. No gender differences were noted.

Conclusion: SRI4 responders with BEL + SoC had greater degree of response compared to PBO + SoC based on clinical and serological measures. Earlier SS reductions (\pm serology) for BEL + SoC responders points to more rapid clinical improvement. These observations add robustness to existing knowledge that treatment with BEL could add therapeutic benefit to SoC alone.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Antiphospholipid antibodies in SLE may be changed by treatment, but past studies have been conflicting. We examined the impact of starting or stopping two treatments (hydroxychloroquine and prednisone) on levels of antiphospholipid antibodies.

Methods: 943 SLE patients, who had at least 10 quarterly visits for testing for each anticardiolipin isotype (IgG, IgM and IgA) and dRVVT (lupus anticoagulant; LA), were included in the study. Treatment was recorded at every visit. Visits during which a patient was treated were compared to visits when the same patient was not treated with respect to levels of each antibody using conditional logistic regression.

Results: Hydroxychloroquine treatment reduced the levels of all antibodies, except for IgA aCL (Table 1).

Table 1 – Hydroxychloroquine Reduces All Antiphospholipid Antibodies EXCEPT for aCL IgA.

Definition of aPL	Number of patients informative for the analysis ¹	Odds ratio of having the antiphospholipid antibody on visits with HCQ compared to visits without HCQ	P-value
aCL IgG>20	149	0.56 (0.43, 0.72)	<0.0001
aCL IgG> 40	56	0.35 (0.22, 0.55)	<0.0001
aCL IgM>20	169	0.51 (0.39, 0.67)	0.0002
aCL IgM> 40	80	0.56 (0.36, 0.87)	0.010
aCL IgA>20	56	1.08 (0.62, 1.87)	0.80
aCL IgA> 40	25	2.28 (0.99, 5.26)	0.053
dRVVT>45	268	0.65 (0.53, 0.80)	<0.0001
Any of the above	377	0.64 (0.55, 0.75)	<0.0001

¹ In each cell, individuals are informative if they have at least one visit with antiphospholipid positivity, at least one visit without antiphospholipid antibody, at least one visit with when treated with HCQ, and at least one visit when not treated with HCQ. Prednisone reduced aCL IgG and aCL IgA, but not aCL IgM or dRVVT (seconds prolongation) (Table 2).

Table 2 – Prednisone Reduces aCL IgG and IgA but not lupus anticoagulant (by dRVVT).

Definition of Antiphospholipid	Number of informative strata	Current Prednisone Dose	Odds ratio of having aPL at visits by Prednisone exposure	P-value
aCL IgG>20	2207	No Prednisone	1.0 (Ref)	<0.0001
		Some but less than 10mg/d	0.54 (0.40, 0.72)	
		10+mg/day	0.35 (0.25, 0.49)	
aCL IgG>40	83	No Prednisone	1.0 (Ref)	0.16
		Some but less than 10mg/d	0.68 (0.40, 1.16)	
		10+mg/day	0.57 (0.32, 1.03)	
aCL IgM>20	231	No Prednisone	1.0 (Ref)	0.19
		Some but less than 10mg/d	1.23 (0.90, 1.67)	
		10+mg/day	0.88 (0.62, 1.23)	
aCL IgM>40	110	No Prednisone	1.0 (Ref)	0.059
		Some but less than 10mg/d	1.65 (0.98, 2.78)	
		10+mg/day	1.03 (0.59, 1.80)	
aCL IgA>20	80	No Prednisone	1.0 (Ref)	0.058
		Some but less than 10mg/d	0.57 (0.32, 1.02)	
		10+mg/day	0.49 (0.24, 0.97)	
aCL IgA>40	32	No Prednisone	1.0 (Ref)	0.57
		Some but less than 10mg/d	1.38 (0.46, 4.10)	
		10+mg/day	2.69 (0.78, 9.34)	
dRVVT <45	338	No Prednisone	1.0 (Ref)	0.64
		Some but less than 10mg/d	1.07 (0.82, 1.39)	
		10+mg/day	1.17 (0.88, 1.56)	
Any of the above	511	No Prednisone	1.0 (Ref)	0.90
		Some but less than 10mg/d	0.99 (0.81, 1.20)	
		10+mg/day	0.86 (0.69, 1.07)	

Conclusion: Hydroxychloroquine use was associated with reduced lupus anticoagulant (by seconds of prolongation) and reduced titers for most of the isotypes of anticardiolipin, except for IgA. Prednisone did not reduce the seconds of dRVVT prolongation. Anticardiolipin IgA seemed the most resistant to therapy. These data will help clinicians pick prophylactic therapy, which needs to be based on the antiphospholipid subtype.

Longitudinal Analysis of Persistent Positivity of Antiphospholipid Antibodies in Systemic Lupus Erythematosus

Michelle Petri¹, Mertcan Avci² and Laurence S Magder³, ¹Medicine (Rheumatology), Johns Hopkins University School of Medicine, Baltimore, MD, ²Medicine, Istanbul Faculty of Medicine, Istanbul, Turkey, ³Epidemiology and Preventive Medicine, University of MD, Baltimore, MD

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: ‘Persistent positivity’ has been a part of laboratory criteria for antiphospholipid syndrome classification criteria and requires two positive tests. We investigated the clinical utility of multiple measures of lupus anticoagulant and anticardiolipin antibodies in SLE patients over the course of clinical care.

Methods: We studied 943 SLE patients in a large single-center cohort who were assessed for lupus anticoagulant (by dRVVT) and anticardiolipin (aCL) IgG, IgM and IgA at at least 10 clinic visits. For each patient, we determined the percent of follow-up time positive for antiphospholipid antibodies and assessed the relationship between this percent and lifetime history of thrombosis.

Results: Among those ever positive for antiphospholipid antibodies, the large majority of SLE patients were positive less than 25% of time followed (Table 1).

Table 1. Most SLE Patients are Positive for aCL or dRVVT Less Than 25% of time followed

aPL definition	Proportion of time during follow-up in which aPL were positive				
	0	>0-0.25	>0.25-0.5	>0.5-0.75	>0.75
aCL IgG \geq 20	728 (77%)	149 (16%)	33 (4%)	15 (2%)	18 (2%)
aCL IgG \geq 40	856 (91%)	66 (7%)	11 (1%)	5 (1%)	5 (1%)
aCL IgM \geq 20	693 (73%)	185 (20%)	26 (3%)	14 (1%)	25 (3%)
aCL IgM \geq 40	829 (88%)	85 (9%)	14 (1%)	7 (1%)	8 (1%)
aCL IgA \geq 20	861 (91%)	69 (7%)	9 (1%)	0 (0%)	4 (<1%)
aCL IgA \geq 40	909 (96%)	29 (3%)	2 (<1%)	1 (<1%)	2 (<1%)
dRVVT>45	564 (60%)	273 (29%)	49 (5%)	22 (2%)	35 (4%)
Any of above	378 (40%)	369 (39%)	90 (10%)	35 (4%)	71 (8%)

For the lupus anticoagulant, there was a progressively increasing association of history of thrombosis with greater proportion of time positive (Table 2). For anticardiolipin antibodies or lupus anticoagulant, even those with relatively infrequent positive measures had a greater likelihood of a history of thrombosis than those who were never positive.

Table 2: Associations of aCL and dRVVT with Thrombosis.

aPL Definition	Proportion of time with aPL	Any Thrombosis

	>0.25-0.5	2	1 (50%)	1.7 (0.4, 6.8) ²	0.46
	>0.5-.75	1	0 (0%)		
	>0.75	2	1 (50%)		
dRVVT>45	0	564	91 (16%)	1.0 (Ref)	
	>0-0.25	273	68 (25%)	1.5 (1.1, 2.0)	0.018
	>0.25-0.5	49	19 (39%)	2.7 (1.6, 4.43)	0.0001
	>0.5-.75	22	8 (36%)	2.2 (1.1, 4.5)	0.033
	>0.75	35	15 (43%)	3.4 (2.0, 5.9)	<0.0001
Any of the above	0	378	60 (16%)	1.0 (Ref)	
	>0-0.25	369	81 (22%)	1.3 (1.0, 1.9)	0.095
	>0.25-0.5	90	25 (28%)	1.8 (1.1, 2.8)	0.016
	>0.5-.75	35	8 (23%)	1.5 (0.7, 3.1)	0.31
	>0.75	71	27 (38%)	2.6 (1.6, 4.1)	<0.0001

¹ Based on a Cox Model. ² RR and p-value are for >0.25-0.5, >0.5-0.75, and >0.75 groups combined compared to Reference.

Conclusion: In SLE, antiphospholipid antibody positivity tends to be at a minority of visits. Yet, even those with sporadic positive findings are at increased risk of thrombosis. This contrasts with the natural history of primary antiphospholipid antibodies/syndrome. These data strongly support prophylactic therapy in those who are sporadically positive.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Lupus anticoagulant (LAC) is an established risk factor for thrombosis in systemic Lupus erythematosus (SLE). Emerging data suggest that activation of the complement system is also involved in the pathogenesis of thrombosis. Our objective was to evaluate the relationships between complement C4d split products deposited on erythrocytes (EC4d), Platelets (PC4d) and thrombosis in SLE.

Methods: This was a cross sectional analysis of 148 consented SLE patients (by ACR or SLICC criteria; 82% ANA positive [$>1:80$] by indirect immunofluorescence; mean age: 47 ± 1 years, 32% taking prednisone; mean SELENA-SLEDAI: 2.5 ± 0.2 points). SLE were classified with ($n=16$, 11%) or without ($n=132$, 89%) a history of thrombotic events (venous or arterial) in the past 5 years. EC4d and PC4d levels were measured using quantitative flow cytometry, and expressed as mean fluorescence intensity (MFI) (abnormal EC4d >14 net MFI, PC4d >20 net MFI, each corresponding to the 99th percentile of normal healthy group). Complement C3, C4 and LAC were measured using immunochemistry (low C3 <81 mg/dl, low C4 <12.9 mg/dl) and Dilute Russell Viper Venom Time (positive DRVVT >37 seconds), respectively. Statistical analysis consisted of Mann Whitney test and logistic regression.

Results: SLE with a history of thrombosis in the past 5 years presented with 5.5 and 2.2-fold higher median PC4d (27 [IQR: 8-79 net MFI] vs 5 [IQR: 2-14 net MFI] net MFI) and EC4d (19 [IQR: 9-59 net MFI] vs 9 [IQR: 6-19] net MFI) levels, respectively, than SLE without thrombotic events ($p<0.001$; $n=148$). Low C3 (OR=10.5 [CI 95%: 2.6-42.0]), low C4 (OR=3.5 [CI 95%: 1.1-11.1]), abnormal PC4d (OR=19.0 [CI 95%: 3.7-96.4; $n=148$]), EC4d (OR=4.0 [CI 95%: 1.3-11.8]), and LAC (OR=5.3 [CI 95%: 1.1-24.5; $n=144$]) were all significantly associated with thrombosis ($p<0.035$). Prednisone was also associated with thrombosis (OR=3.2 [CI 95%: 1.1-8.9]) ($p=0.037$). Multivariate analysis revealed that low C3, abnormal PC4d and LAC were all independently and significantly associated with thrombosis ($p<0.027$) and the cumulative presence of these abnormalities resulted in higher likelihood of thrombosis (OR range: 81.9 CI 95%: 9.7-688.5; $n=144$) ($p<0.001$) (Figure). These results remained significant after adjusting for prednisone.

Conclusion: Complement C4d split products associate with thrombotic events in SLE, independent of other risk factors. A composite score of risk factors performed better than single risk factors alone, and should be studied prospectively.

Hydroxychloroquine Blood Levels Are Significantly Associated with Cardiovascular Risk Factors

Michelle Petri¹, Daniel Goldman¹ and Laurence S Magder², ¹Medicine (Rheumatology), Johns Hopkins University School of Medicine, Baltimore, MD, ²Epidemiology and Public health, University of Maryland School of Medicine, Baltimore, MD

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: In studies of SLE patients, the benefits of hydroxychloroquine (HCQ) extend beyond control of disease activity. In particular, HCQ use has decreased multiple cardiovascular risk factors (cholesterol and risk of diabetes) and reduced thrombosis in those with antiphospholipid antibodies. However, the amount of HCQ needed to obtain these benefits has not been ascertained. We asked whether blood HCQ levels were associated with cardiovascular risk benefit.

Methods: HCQ blood levels were measured by liquid chromatography-tandem mass spectrometry as described by Füzéry, et al (Clin Chim Acta 2013;421:79-84). We looked at the within-person relationship between HCQ blood concentration and three cardiovascular risk factors (systolic or diastolic blood pressure, cholesterol and glucose). To perform this analysis we calculated the mean HCQ blood level across each person. For each visit, we calculated the difference between the HCQ blood level at that particular visit and the patient's mean. We then assessed whether there was a relationship between these differences and the patient's cardiovascular risk factor level at a particular visit. The results indicate whether changes in HCQ blood concentration correspond to changes in cardiovascular risk factors.

Results: The association between changes in HCQ blood concentration and changes in cardiovascular risk factors is shown in Table 1.

Table 1. Association between changes in HCQ blood concentration and changes in cardiovascular risk factors.

Cardiovascular Risk Factor	Expected change in cardiovascular risk factor per 500 ng/ml increase in HCQ blood concentration (95% CI)	P-value
Systolic Blood Pressure (mmHg)	-0.9 (-1.2, -0.6)	<0.0001
Diastolic Blood Pressure (mmHg)	-0.4 (-0.6, -0.2)	0.0005
Cholesterol mg/dl	-1.0 (-1.6, -0.3)	0.0039
Glucose	-0.75 (-1.16, -0.34)	0.0003

We next looked to see whether increases in HCQ blood concentration among those with low levels (<500 ng/ml) had more of an effect than changes in the therapeutic range (500-1999 ng/ml). We also looked at changes in the super-therapeutic range (>2000 ng/ml). The results are in Table 2 below.

Table 2. Association between changes in HCQ concentration by ranges and changes in cardiovascular risk factors.

Cardiovascular Risk Factor	Expected change in cardiovascular risk factor per 500 ng/ml increase in HCQ concentration (95% CI)		
	Changes < 500 ng/ml	Changes between 500 and 1999 ng/ml	Changes over 2000 ng/ml
Systolic Blood Pressure (mmHg)	-1.2 (-2.6, 0.2) p=0.087	-0.7 (-1.2, -0.3) p=0.003	-1.1 (-1.9, -0.2) p=0.012
Diastolic Blood Pressure (mmHg)	-0.6 (-1.5, 0.4) p=NS	-0.4 (-0.7, -0.1) p=0.023	-0.2 (-0.8, 0.3) p=NS
Cholesterol mg/dl	-5.2 (-8.2, -2.2) p=0.0006	-0.3 (-1.4, 0.7) p=NS	-0.3 (-2.1, 1.4) p=NS
Glucose	-2.4 (-4.3, -0.6) p=0.0097	-0.36 (-0.99, 0.3) p=NS	-0.95 (-2.1, 0.2) p=0.098

For cholesterol, a change of HCQ of 500 ng/ml in the sub-therapeutic range (i.e. an increase from 0 to 500 ng/ml) was associated with a relatively larger improvement in cholesterol (decline of 5.2 mg/dl). However changes in cholesterol in the HCQ therapeutic or super-therapeutic range were not associated with a decrease in cholesterol.

Conclusion: HCQ blood levels are statistically associated with blood pressure, cholesterol and glucose (proven for the first time). For cholesterol, the association is also meaningful clinically. The benefit is achieved when the HCQ blood level moves from 0 to 500 (low end of therapeutic range).

Rates and Predictors of Thirty-Day Readmission Among Patients Hospitalized for Systemic Lupus Erythematosus at a Single Tertiary Care Center

Stephen Mullis¹ and Dennis Ang², ¹Department of Internal Medicine, Section on Rheumatology and Immunology, Wake Forest School of Medicine, Winston Salem, NC, ²Wake Forest University School of Medicine, Winston-Salem, NC

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) has a 27.2% all-cause 30 day readmission rate, the 6th highest principle diagnosis among all medical conditions. The primary objective of the current study was to determine the 30-day all-cause readmission rate for adults with SLE at Wake Forest Baptist Medical Center (WFBMC). The secondary objective was to determine risk factors associated with 30-day readmission.

Methods: Using the electronic medical record, we conducted a retrospective chart review of patients who met the following criteria: ICD 9 code for SLE, age >18, and had at least one hospital admission within a 2-year study period (8/1/2012-7/31/2014). Individual charts were manually reviewed to validate the diagnosis of SLE. Planned hospitalizations were excluded. The primary outcome was all cause-readmission within 30 days of initial hospital discharge. We recorded demographics, health care system-related variables and clinical data including comorbidity illness burden using the Charlson Comorbidity Index (CCI).

Results: Over a 24 month period there were a total of 74 unique patients with SLE who had a total of 233 admissions. Of these 233 admissions, 82 (35.2%) were 30-day readmissions. The mean age of the cohort was 43.8 (SD 14.22), 85.1% female, 67.6% African Americans and 23.0 % on Medicaid/self-pay. Of these 74 patients, 27 (36.5%) had at least one 30-day readmission and contributed to 70% of total admissions. On bivariate analysis, serositis, higher CCI, estimated GFR <60, greater number of ER visits and less frequent rheumatology clinic visits were significant predictors of 30-day readmission. On multivariate analyses, significant predictors of 30-day readmission included estimated GFR < 60 (OR 3.34; p=.0224), presence of serositis as a prior criterion for lupus diagnosis (OR 11.87; p=.0071), and more frequent ER visits (OR 1.04; p=0.0010). More frequent rheumatology clinic visits (OR 0.74; p=<.0001) was associated with less readmission during the 2-year study period.

Conclusion: We found a 35.2% 30-day readmission rate that was substantially higher than the previously cited 27.2% readmission rate. Serositis (as a criterion in SLE diagnosis), EGFR < 60, and more frequent ED visits were associated with increased rate of 30-day readmissions. On the other hand, higher number of completed rheumatology visits was associated

Table 1: Odds of 30-day readmission among adults with SLE

	OR (95% CI)	P for 95% CI
Demographic and Socioeconomic Characteristics		
Age	1.01 (0.98, 1.04)	.4954

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Patient (pt)-reported outcome measures (PROMs) are important to inform shared decision-making between pts with SLE and physicians.¹ Established measures of disease activity and organ damage are predictors of disease progression, prognosis and survival.^{2,3} However, there is no established correlation with PROMs. We used registry data from well-characterized Swedish pts with recent-onset SLE to identify potential correlations of disease activity and organ damage with PROMs.

Methods: Consecutive and newly diagnosed pts of the Clinical Lupus Register in Northeast Gothenburg who met the 1982 ACR⁴ and/or the 2012 Systemic Lupus International Collaborating Clinics (SLICC)⁵ SLE classification criteria with no prior organ damage were followed prospectively after diagnosis. Pts were seen by a rheumatologist at Months 0 (inclusion), 6, 12, 24, 36, 48 and 60, with collection of SLE Disease Activity Index-2000 (SLEDAI), SLICC/ACR organ damage index score and PROMs (quality of life [QoL]: EuroQoL-5 Dimensions [EQ-5D]; pain and fatigue: visual analog scale [VAS] 0–100 mm) at each visit. The incidence rate (IR) of organ damage and Pearson correlations of SLEDAI and organ damage with PROMs were calculated.

Results: Of the 41 pts in the study at baseline: median age 39 years, 80% female, 85% white, 88% met ACR-82 criteria and 37% had lupus nephritis. Organ damage occurred at an overall IR of 13.6 per 100 pt-years (Figure 1), with neuropsychiatric, ocular and cardiovascular damage as most common (Figure 2). SLEDAI significantly correlated with pain at Months 6, 36 and 48 ($p<0.03$; Figure 3). SLICC/ACR damage index score significantly correlated with EQ-5D ($p=0.003$) and fatigue ($p=0.009$) at Month 24.

Conclusion: Our findings illustrate the importance of the interplay between the physician's and pts' perception of SLE, which may affect compliance and adherence to therapy, and play a role in achieving successful outcomes in SLE management.

Figure 1: Incidence Rate of Organ Damage* by Year and Overall

*Incidence rates were calculated as the number of incident cases of organ damage in the study period over the person-time at risk. Person-time at risk was calculated as the time a patient remained in the database without organ damage.

Figure 2. Incidence Rate of Organ Damage* by Organ System and Overall

*Incidence rates were calculated as the number of incident cases of organ damage in the study period over the person-time at risk. Person-time at risk was calculated as the time a patient remained in the database without organ damage

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Hydroxychloroquine (HCQ) is a commonly used medication for SLE because of its highly favorable risk-benefit ratio. Drug-induced retinopathy is one of very few serious toxicities associated with long-term use. Studies have reported varied prevalence of HCQ retinopathy ranging from 0.5% to 7.5%. In 2016, the American Academy of Ophthalmology published revised guidelines for drug-induced retinopathy prevention. Despite the guidelines, there is some degree of expected variability in clinical practice. We reviewed a large, diverse cohort of SLE patients at an academic center in order to characterize physician practices and patient behaviors with regard to HCQ retinopathy screening and prevention.

Methods: A retrospective chart review was conducted of patients in our SLE cohort. There were 301 SLE patients reviewed, all of whom were seen at academic rheumatology practices between 2004 and 2018. Patients were categorized according to HCQ use at the time of most recent clinic visit. For patients who had been on HCQ, we determined timing of last retinopathy screening exam. We reviewed patients with documented eye-related concerns to determine specific findings and next steps taken.

Results: Of the 301 patients reviewed, 65% were taking HCQ as of the most recent visit and 91% had been on HCQ at some time. There were 205 patients with available rheumatology records for whom HCQ retinopathy screening was indicated. Based on the documentation, 46.8% were up to date on retinopathy screening, 10.2% were overdue, 7.8% had discussed screening with a rheumatologist but follow-up was unclear, and 35.1% had unknown screening status. Among 274 active or former HCQ users, 11.7% had eye-related concerns while on HCQ. These included 1.8% with true drug-induced retinopathy, 5.1% with nonspecific retinal findings leading to HCQ discontinuation, and 4.7% with retinal pathology not attributed to HCQ who continued the drug. Six patients with eye-related concerns had been tested for antiretinal antibodies and 100% were positive. HCQ was discontinued in four of these cases: one had confirmed drug-induced retinopathy and three had nonspecific retinal abnormalities. In the remaining two cases, HCQ was continued with close monitoring.

Conclusion: Our data suggest that there may be inconsistent compliance with ophthalmology guidelines for HCQ retinopathy screening. In addition, only a small subset of patients in our cohort with retinal abnormalities detected by screening was found to have confirmed HCQ retinopathy. Lastly, a select group of patients on HCQ with nonspecific

retinal pathology had positive antiretinal antibodies. Further research is needed to determine the incidence of antiretinal antibodies in HCQ users without retinal pathology in order to understand the implications of this finding.

Combined Panel of Nine Tests Has the Greatest Sensitivity but the Lowest Specificity to Detect Antiphospholipid Antibody Syndrome in Patients with Systemic Lupus Erythematosus

Saika Sharmeen¹, Katalin Banki² and Andras Perl³, ¹Medicine, State University of New York Upstate Medical University, Syracuse, NY, ²Clinical Pathology, SUNY Upstate Medical University, Syracuse, NY, ³Medicine, SUNY Upstate Medical University, Syracuse, NY

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Antiphospholipid antibody syndrome (APS) is an autoimmune hypercoagulable state caused by antiphospholipid antibodies (aPL) which represent a diagnostic criterion and underlie significant comorbidities in patients with and without systemic lupus erythematosus (SLE). Although several tests exist for APS diagnosis, their utilization has been highly variable among laboratories and physicians. Therefore, we have evaluated a panel of nine tests and conducted a retrospective study to determine their sensitivity and specificity for supporting the diagnosis of APS in SLE at our Institution between 2010 and 2018.

Methods: 1633 SLE patients, who satisfied the ACR criteria for a definitive diagnosis (*Arthritis Rheum.* **25**,1271, 1982; *Arthritis Rheum.* **40**, 1725, 1997), were evaluated for the presence of APS as earlier described (*J. Thromb. Haemost.* **4**, 295 (2006). Lupus anticoagulants were assessed by Sta clot LA hexagonal phase phospholipid neutralization assay (HPPNA; delta <8 seconds), Sta clot diluted Russell viper venom test (dRVVT; <1.2 normalized ratio) obtained from Stago (Parsippany, NJ, USA). Platelet neutralization procedure (PNP; delta < 1 second) has been performed using a STA-R Evolution instrument by Stago, as earlier described (*Am. J. Clin. Pathol.* **79**, 678, 1983; *Am. J. Clin. Pathol.* **124**, 586, 2005). IgG and IgM antibodies against β 2-glycoprotein 1 (a β 2-IgG, a β 2-IgM) and cardiolipin (aCL-IgG, aCL-IgM) were measured in house while IgA isotypes (a β 2-IgA, aCL-IgA) were tested by LabCorp Diagnostics (Burlington, NC).

Table 1. Sensitivity and Specificity of Nine Tests for Detection of APS in SLE Patients										
TEST	HPPNA	PNP	dRVVT	a β 2-IgG	a β 2-IgM	a β 2-IgA	aCL-IgG	aCL-IgM	aCL-IgA	All 9 tests
APS+ TEST+	102	35	36	15	14	13	21	28	8	73
APS+ TEST-	96	77	155	191	192	173	195	185	181	26

p value	<0.0001	<0.0001	<0.0001	0.0046	NS	NS	0.0316	NS	NS	<0.0001
Sensitivity (%)	52	31	19	7	7	7	10	13	4	74
p value vs HPPNA		0.0006	<0.0001	<0.0001	<0.0001	<0.0001	<0.0001	<0.0001	<0.0001	0.0003
PPV (%)	21	31	27	26	20	22	21	19	16	25
Specificity (%)	66	87	92	97	96	96	94	91	96	52
p value vs HPPNA		<0.0001	<0.0001	<0.0001	<0.0001	<0.0001	<0.0001	<0.0001	<0.0001	<0.0001
NPV (%)	89	87	88	87	87	86	87	87	86	90
Number of Patients Tested	1370	726	1466	1534	1534	1345	1595	1581	1119	550

Sensitivities, specificities, and positive (PPV) and negative predictive values (NPV) for detection of APS were calculated and compared by 2-tailed chi-square tests using GraphPad software.

Results: 222/1633 SLE patients had APS when using a combination of nine tests. Table 1 shows the frequency of positive and negative test results and p value for each assay. The greatest sensitivity was seen when all nine tests were performed together for detecting APS in SLE patients (74%; χ^2 p=0.0003). In contrast, combining all tests had the lowest specificity (52%; p<0.0001). Importantly, the 2nd most sensitive test for detection of APS was the HPPNA at 52%, this test also had the second lowest specificity (66%). Similar trends were seen when individual APS comorbidities, such as deep venous thrombosis (DVT), pulmonary embolism (PE), and stroke, were separately analyzed. Among the charts reviewed, the complete 9-test panel was only performed in 550 of 1633 patients (Table 1).

Conclusion: This study demonstrates that utilizing a combined 9-test panel has the greatest sensitivity but lowest specificity for detecting APS in SLE subjects. Thus, a failure to employ the complete panel may lead to exclusion of patients who may meet criteria for identifying patients with APS who need long-term anticoagulation for preventing life-threatening thrombotic events.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Twenty to sixty percent of patients with systemic lupus erythematosus (SLE) can progress to lupus nephritis (LN) and those that do can develop end stage renal disease 15% of the time. Belatacept is a new immunosuppressive agent with 7 year post transplant outcomes showing patient/graft survival and mean estimated

glomerular filtration rate (eGFR) to be significantly higher than cyclosporine [1]. These effects have not been confirmed in LN patients who can benefit from improving strategies.

Methods: LN patients who underwent renal transplants were identified within the United Network for Organ Sharing (UNOS) database from 2008 to 2014 and a cohort was established based on the use of tacrolimus or cyclosporin, mycophenolate mofetil (MMF) and steroid maintenance medications. This cohort was stratified by use of Belatacept and propensity score matching was used to match non-Belatacept patients to 39 Belatacept patients based on age, gender, race, history of diabetes, status of a living donor, and year of transplant. Pre- and post-match Belatacept use was cross classified by each categorical variable and was examined with the chi-square test; the Mann-Whitney test was used to compare continuous variables. The Kaplan-Meier method was used to examine unadjusted graft failure and survival. A linear mixed model with a heterogeneous autoregressive covariance structure was used to examine follow up creatinine and eGFR values over time of the matched patients.

Results: There were no graft failures or deaths within the Belatacept group and a single patient who experienced graft failure and death within the matched non-Belatacept group. Results of the linear mixed models for creatinine and GFR provided evidence of no difference between groups. For every year there was a significant increase in creatinine (0.22 mg/dL; $p = 0.009$) and decrease in GFR ($-7.20\text{mL/min/1.73 m}^2$; $p < 0.001$).

Conclusion: Belatacept has been used in a limited number of patients requiring renal transplants with LN since 2008. In our study, no significant difference in graft survival, death or renal function in cohorts using standard therapy versus Belatacept was noted. No improvement in mean eGFR was seen in the Belatacept group as seen in prior work [1]. Future studies are needed to evaluate the impact of Belatacept based regimens in LN patients post-transplant.

Hydroxychloroquine Improves Disease Activity and Allows Reduction of Corticosteroid Dose Regardless of Background Treatment in Japanese Patients with Systemic Lupus Erythematosus

Hironari Hanaoka, Harunobu Iida, Tomofumi Kiyokawa, Yukiko Takakuwa and Kimito Kawahata, Division of Rheumatology and Allergology, Department of Internal Medicine, St. Marianna University School of Medicine, Kawasaki, Japan

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Hydroxychloroquine (HCQ) was not approved in Japan until 2015 and its therapeutic potential remains poorly understood in the population. In this study, we evaluated the additional therapeutic effect of HCQ in Japanese patients with systemic lupus erythematosus (SLE) on maintenance therapy.

Methods: Patients with SLE who visited our hospital from 2015 to 2016 and were taking prednisolone (PSL) at < 20 mg/day were retrospectively evaluated. All patients were divided into 3 groups according to their maintenance treatment regimen: PSL plus immunosuppressant (IS), PSL alone, and no treatment. We compared changes in the SLE disease activity index (SLEDAI), PSL dose, and cumulative flare rate between patients who were and were not treated with HCQ.

Results: Among the 165 patients evaluated, 35 (21.2%) were treated with HCQ. The mean period of observation did not differ between patients who did and did not receive HCQ ($p = 0.3$). The SLEDAI (Figure 1A) and PSL dose (Figure 1B) were significantly reduced in patients who received HCQ regardless of their background treatment regimen. We next

Figure 2

(A)

(B)

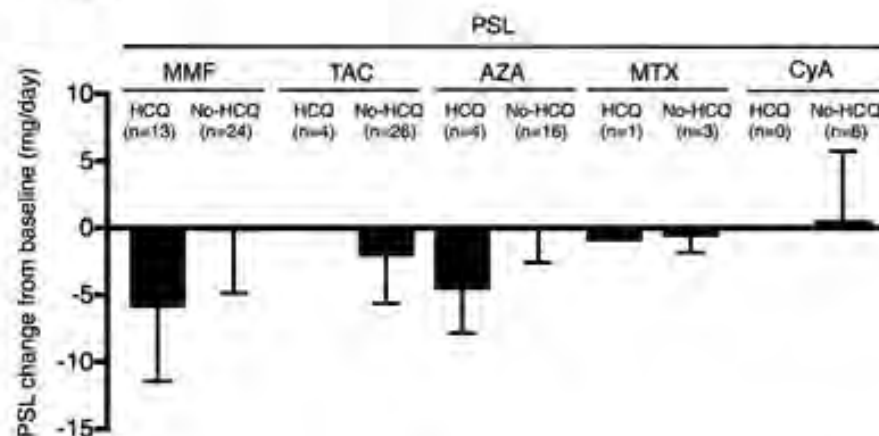

Figure 3

focused on the change in SLEDAI and PSL dose depending IS use (Figure 2). Addition of HCQ on mycophenolate mofetil and azathioprine might have superior efficacy to other combinations and we found less additional therapeutic effect on tacrolimus (TAC) users. The cumulative flare rate was lower in patients who received HCQ compared to those who did not in the PSL plus immunosuppressant and no maintenance treatment groups ($p = 0.03$ and $p = 0.05$, respectively) (Figure 3).

Conclusion: The addition of HCQ reduced disease activity and permitted PSL dose reduction regardless of background treatment in Japanese patients with SLE. In the view of combination with IS, however, our results suggested addition of HCQ on TAC might have less additional clinical efficacy than other IS combination.

Tacrolimus Use in Hispanic Patients with Refractory Lupus Nephritis

Phillip Aleksiejuk¹ and Elizabeth Ortiz², ¹Rheumatology, University of Southern California, Los Angeles, CA,

²Department of Rheumatology, University of Southern California, Los Angeles, CA

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Lupus nephritis is one of the most common and severe manifestations of patients with SLE. Studies assessing the use of Tacrolimus (TAC) in lupus nephritis are promising, however results are primarily based on patients of Asian ethnicity and limited by significant heterogeneity. The Los Angeles County + University of Southern California Medical Center (LAC+USC) serves a largely Hispanic, underinsured, indigent population. The purpose of this study is to evaluate the use and effectiveness of TAC in LAC+USC Rheumatology clinic.

Methods: This is a retrospective analysis of adult patients with SLE, satisfying the 1997 ACR criteria, from LAC+USC medical center seen from January 2010 to January 2018. Patients with biopsy proven lupus GN were identified and screened for previous or current use of TAC. Patient demographics, 2003 International Society of Nephrology (ISN)/Renal Pathology Society (RPS) Classification of lupus nephritis, treatment history, laboratory features, and SLEDAI were noted. Renal response as defined by the 2006 ACR response criteria for proliferative and membranous renal disease was calculated for each patient.

Results: Ten patients were included (100% female, mean age 32.3 ± 8.8 years, mean disease duration 8.2 ± 5.2 years). Ninety percent were Hispanic and 10% were African American. Hypertension was present in 70% of patients and diabetes mellitus in 10%. Eighty percent of patients were on an angiotensin converting enzyme inhibitor/angiotensin II receptor blocker. According to ISN/RPS class, patients were Class V (50%), III/V (40%), IV/V (10%). The most common indication of TAC was refractory or resistant lupus nephritis therapy as determined by physician judgment, persistent proteinuria, persistent active sediment, hypocomplementemia or elevated dsDNA. Median daily dose of TAC was 4mg. Mean duration of therapy 1.2 ± 0.8 years. Previous medications included GC (70%; mean daily dose 7.5mg), CYC (70%), MMF (100%), AZA (60%), RTX (80%), CSA (10%), Belimumab (30%), HCQ (70%). According to ACR response criteria, 60% of patients had no change, 10% worsened, 10% had partial response, 20% achieved complete response, 0% improved. Median urine protein creatinine ratio increased from 2.0 at baseline to 2.3 ($p=0.99$). Median SLEDAI decreased from 16.5 at baseline to 16.0 ($p=0.97$). Median creatinine did not change from baseline 0.7mg/dL ($p=0.16$). TAC was discontinued in 8 patients due to inefficacy.

Conclusion: The study demonstrates the use of TAC in a primarily Hispanic population with refractory lupus nephritis. Although small and uncontrolled, the data proposes that TAC may not be as effective in Hispanics with refractory lupus nephritis in achieving a partial or complete response. This is in contrast to results from previous studies performed in Asian patients. Larger prospective studies are needed to better understand the potential role of TAC in the treatment of lupus nephritis.

Bone Mineral Density Is Not Associated with Osteoporotic Fractures in Premenopausal Women and Men < 50 Years Old with Systemic Lupus Erythematosus

Tracy Driver¹, Maureen A. McMahon², Betty Tsao³ and Jennifer M. Grossman⁴, ¹Medicine, Rheumatology, UCLA David Geffen School of Medicine, Los Angeles, CA, ²UCLA David Geffen School of Medicine, Los Angeles, CA, ³Medical University of South Carolina, Charleston, SC, ⁴Division of Rheumatology, UCLA David Geffen School of Medicine, Los Angeles, CA

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Osteoporosis is common in patients with systemic lupus erythematosus (SLE). Guidelines for the treatment and prevention of glucocorticoid induced osteoporosis (GIOP) are detailed for postmenopausal women and older men. However, there are less data on risk factors for osteoporotic fracture in premenopausal women and men <50 years old with SLE resulting in conditional recommendations in the 2017 American College of Rheumatology GIOP guidelines. The goal of this project is to identify risk factors for osteoporotic fracture in premenopausal women and men < 50 with SLE.

Methods: In this retrospective chart review of SLE patients at an academic medical center, 218 premenopausal women (defined as age < 45 or age at menopause) and men (age <50) with bone mineral density (BMD) results were identified. All patients fulfilled the 1997 ACR criteria for the classification of SLE. Variables collected included BMD, osteoporotic fracture (rib, sacrum, hip, spine, wrist, forearm, humerus, ankle, tibia/fibula fractures¹), smoking, BMI, gender, SLE disease duration, bisphosphonate and oral contraceptive (OCPs) use, ethnicity, age, vitamin D, and lifetime cumulative prednisone dose categorized as <10, 10-20, and >20 grams. Variables were collected at the time of BMD or fracture. The fracture and non-fracture groups were compared using Student's *t*-test for continuous variables and chi-squared test for categorical variables. Multivariate analysis was used to examine potential variables associated with fracture.

Results: This study included 202 women and 16 men who had a mean age of 34.5 years. Out of the 218 subjects, 15 (2 men, 13 women) had an osteoporotic fracture. One subject had 2 fractures. Fractures included 2 tibia, 2 forearm, 1 ankle, 2 rib, 1 hip, and 8 vertebral. No difference was found in BMD of the lumbar spine, hip, or femoral neck between those with fracture vs no fracture. Lifetime cumulative prednisone dose, BMI, smoking, vitamin D level, use of bisphosphonates or OCPs, gender, ethnicity, and SLE disease duration were not associated with increased risk of fracture. In those with fracture, 9 had used >20g of cumulative lifetime prednisone use, 3 had used 10-20g, and 3 <10g; however, these findings did not reach statistical significance. There were no associations between fracture and age, lumbar BMD, cumulative prednisone dose, ethnicity, or BMI on multivariate analysis.

Conclusion: Osteoporotic fractures were infrequent (6.9%) in premenopausal women and men < 50 with SLE, but higher than would be expected in a healthy population. There was no significant association between fracture risk and BMD nor cumulative prednisone dose highlighting a need for further studies to determine risk factors to identify patients most likely to benefit from preventive osteoporotic medications.

Hematologic Activity in Systemic Lupus Erythematosus: Is Splenectomy Our Best Choice?

María Fernanda Zavala-Miranda¹, Samuel Govea-Peláez², Ricardo Vázquez-Rodríguez², Roberto Reyna², Sandra Morales², Diana Gómez-Martín³, Jorge Alcocer-Varela³, Javier Merayo-Chalico² and Ana Barrera-Vargas², ¹Internal Medicine, Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico City, Mexico, ²Immunology and Rheumatology, Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico City, Mexico, ³Department of Immunology and Rheumatology, Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico City, Mexico

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Hematologic manifestations are found in up to 30% of SLE patients. Although splenectomy is considered an acceptable therapeutic option for both refractory thrombocytopenia and autoimmune hemolytic anemia in different primary hematologic disorders, its role in SLE has been controversial, mainly because of its potential surgical complications and possible association with SLE flares. The aim of this study was to determine safety and efficacy of splenectomy in a cohort of SLE patients when compared to patients with hematologic activity who only received medical treatment.

Methods: We included all patients with SLE who fulfilled ≥ 4 ACR criteria and underwent splenectomy because of refractory hematologic activity between 2000 and 2016 in a tertiary care center in Mexico City. We also included SLE patients who were hospitalized during that same period because of hematologic activity, but who did not undergo surgical treatment. Patients with other rheumatic diseases (except for APS) were excluded. We recorded demographic, clinical and serologic characteristics at baseline and during follow-up.

Results: We included 30 patients in whom splenectomy was performed and 32 patients with hematological activity without splenectomy. Most patients were female (87%) and mean age was 31 years. Patients who underwent surgery had lower platelet levels at baseline (23,500 vs 73,000/ μ l, $p < 0.01$) and had a higher cumulative prednisone dose in the previous year (8.77 ± 5.93 vs 2.25 ± 1.08 grams, $p < 0.001$). Regarding splenectomy, 83% were laparoscopic and there were surgical complications in 4 patients (13%), all of which resolved.

Mean follow-up time was 63 months in patients with splenectomy and 66 months in those without it. Patients who underwent surgery achieved remission in a shorter time (2.4 ± 1.2 vs 4.8 ± 3.8 months, $p < 0.01$). However, after 12 months, there was no difference in the remission rates between both groups (78 vs 86%, $p = 0.44$). Although the cumulative prednisone dose after one year of surgery/hospitalization was similar between groups (5.41 ± 3.54 vs 5.24 ± 3.71 gr, $p = 0.86$), the prednisone dose in patients with splenectomy was lower than the previous year (5.41 ± 3.54 vs 8.77 ± 5.93 gr, $p = 0.02$) whereas in patients without surgery it was higher (5.24 ± 3.71 vs 2.25 ± 1.08 gr, $p < 0.01$). There were no differences in SLEDAI or SLICC damage index scores at one year or at the end of follow-up.

Major infections were more frequent in patients who underwent splenectomy (43 vs 9%, $p < 0.01$). Among patients with infectious complications, 69% had a complete immunization schedule. After multivariate analysis, considering factors such as vaccination, splenectomy remained as an independent risk factor for infection during follow-up (RR 5.15, 95% CI 1.05-25.11, $p = 0.043$).

Conclusion: Splenectomy may seem like an attractive alternative for SLE patients with refractory hematologic activity, since it is associated with shorter time to remission and the possibility of lowering glucocorticoid doses. However, it represents a significant risk factor for major infections, regardless of the patients' immunosuppressive treatment and vaccination status.

Hydroxychloroquine Could Modulate S100 Proteins Expression, Which Reflect the Activity of Lupus Nephritis or Skin Lesion, in Systemic Lupus Erythematosus Patients with Low Disease Activity

Risa Wakiya, Tomohiro Kameda, Shusaku Nakashima, Hiromi Shimada, Mikiya Kato, Taichi Miyagi, Kiyo Ueda and Hiroaki Dobashi, Internal Medicine Division of Hematology, Rheumatology, and Respiratory Medicine, Kagawa University, Kagawa, Japan

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: To find the effect of HCQ treatment on expression of S100 proteins which were reported to reflect the activity of SLE including lupus nephritis or skin lesion.

Methods: We enrolled 51 SLE patients treated without additional immunosuppressive therapy more than 3 months before HCQ treatment in our institute from Jan 2016 to Dec 2017. Serum levels of S100A8 and S100A9 proteins were measured by ELISA (CircuLex ELISA Kit, MBL) at the screening, 3 months and 6 months after HCQ administration. Disease activity of SLE was measured using the SLENA-SLEDAI 2011. Cutaneous disease activity was evaluated by Cutaneous Lupus Erythematosus Disease Area and Severity Index (CLASI). Immunological activity of SLE was also evaluated by the measurement of serum complement level(C3, C4, CH50), anti-dsDNA anti-body titer and blood cell count.

Figure.1 The change of serum level S100 proteins by HCQ treatment

Serum S100A8 and S100A9 levels at baseline were compared to the level after 3 and 6 months of HCQ treatment. Serum S100A8 and S100A9 levels significantly decreased by HCQ treatment in SLE patients. For statistical analyses: *** $p < 0.0001$

Figure.2 The changes amount of serum S100 proteins expression compared with presence($n=5$) or absence($n=35$) of lupus anticoagulant(LAC).
The changes amount of serum S100A9 levels in LAC-positive SLE patients are significantly lower than in LAC-negative SLE patients.
For statistical analyses: * $p<0.05$, p value: t test
lupus anticoagulant: LAC.

Results: 43 patients were enrolled in this study (M:F; 3:40, average age; 38.5±11.5) (Table 1).

At the screening before HCQ administration, serum levels of S100A8 and S100A9 proteins were significantly elevated in SLE patients with the history of renal involvement. These S100 proteins expression were decreased significantly after 3 and 6 months of HCQ treatment (Figure 1).

Additionally, this effect of HCQ treatment on serum S100A8 and S100A9 expression was observed in SLE patients with or without the history of renal involvement. As for the correlation with skin involvement, serum S100A8 and S100A9 expressions decreased by HCQ treatment in only SLE patients with improvement of CLASI activity score significantly. The changes of serum S100A9 levels in SLE patients with lupus anti-coagulant (LAC) are lower compared than those without LAC significantly (Figure 2).

We considered these effects on S100 proteins expression were induced by HCQ treatment mainly.

Conclusion: S100 proteins were reported to correlate with the pathogenesis of organ involvements in SLE patients. Our findings could suggest that HCQ affect the improvement of organ improvements in SLE through the modulation of S100 proteins expression especially in renal or skin involvement. Further investigation is needed to clarify the mechanism of these modulations by HCQ use.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Atacept targets the B-cell-stimulators BLyS and APRIL, and is in development for the treatment of patients (pts) with SLE. Here, we integrated non-clinical and clinical data to determine an appropriate atacept dose for a Phase 3 (P3) study in auto-antibody positive SLE pts with high disease activity (HDA).

Methods: Non-clinical data for atacept were obtained from two murine models: a spontaneous SLE model (given control or mouse TACI-Fc 5 mg/kg intraperitoneally [IP] 3 times per week [wk]) and a 4-hydroxy-3-nitrophenylacetyl-Keyhole Limpet Haemocyanin (NP-KLH) vaccinated model to assess immunomodulation (given control or atacept 1, 3 or 10 mg/kg IP every third day). Clinical data were obtained from a P1 pharmacokinetic (PK) study in healthy participants (Study 022; single-dose atacept 25, 75 or 150 mg) and two P2 studies in pts with autoantibody-positive SLE (APRIL-SLE [NCT00624338]; ADDRESS II [NCT01972568]). In both P2 studies, pts were randomized (1:1:1) to once-wkly (QW; initial 4 wks of twice-weekly dosing in APRIL-SLE) subcutaneous atacept (75 or 150 mg) or placebo (PBO). Primary endpoints: APRIL-SLE, proportion of pts with BILAG A/B flare over 52 wks; ADDRESS II, SRI-4 response at Wk 24. An analysis of SRI-6 response at Wk 24 was performed in ADDRESS II pts with Screening HDA (SLEDAI-2K \geq 10). A population PK model was developed and population PK model-derived exposure vs probability of clinical response (BILAG A/B flare, SRI-4, SRI-6) evaluated. An exploratory analysis of the impact of atacept exposure on safety was also performed.

Results: In the spontaneous SLE model, TACI-Fc 5 mg/kg prevented proteinuria development and glomerular damage. In atacept-treated NP-KLH vaccinated mice, anti-KLH IgG decreased markedly (>50% reduction vs control at all doses), with mean atacept serum trough concentrations (C_{min}) of ~2.3 μ g/mL (1 mg/kg), ~5 μ g/mL (3 mg/kg) and ~8.5 μ g/mL (10 mg/kg). Atacept 150 mg QW resulted in greater clinical responses than PBO (APRIL-SLE: BILAG A/B flare, time to flare; ADDRESS II: SRI-4 [modified intention-to-treat] and SRI-6 response [HDA]). In both studies, atacept exposure-response (E-R) relationships were identified. For maximal flare reduction, atacept AUC τ (area under the concentration curve over one dosing interval, i.e. 1 wk) \geq 1 mg \cdot hr/mL was identified and was more achievable with 150 than 75 mg (60% vs 15% probability); AUC τ was the exposure metric that contributed to the P3 dose selection. Atacept exposure for maximal flare reduction corresponded to a C_{min} of 5 μ g/mL which was similar to that observed in the murine models. SRI-4 and SRI-6 (HDA) response rates increased with increasing atacept AUC within the exposure range observed in ADDRESS II. Atacept 150 and 75 mg had acceptable safety profiles in SLE pts; there was no apparent E-R relationship for serious infections.

Conclusion: Integrated non-clinical, clinical and E-R data demonstrate an acceptable benefit-risk profile for atacept in SLE pts with HDA and support the selection of 150 mg QW for P3 studies.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Ustekinumab(UST), a monoclonal antibody that targets the shared p40 subunit of the cytokines IL-12 & IL-23, is being investigated in patients (pts) w/ active systemic lupus erythematosus (SLE). While traditional SLE Disease Activity Index 2000 (SLEDAI-2K) scoring assesses complete SLE response for individual disease manifestations, the SLEDAI-2K Responder Index-50 (S2K RI-50) can be used to evaluate SLE responses using partial improvement ($\geq 50\%$) in each domain. To evaluate SLEDAI-2K vs S2K RI-50 response in a randomized, placebo (PBO) controlled trial of UST in pts w/ active SLE.

Methods: We conducted a phase 2, PBO-controlled study in adults w/ active disease (SLEDAI score ≥ 6 with ≥ 1 BILAG A &/or ≥ 2 BILAG B scores) despite standard-of-care therapy. Pts (n=102) were randomized (3:2) to receive UST IV ~6 mg/kg or PBO at week (wk) 0, followed by SC injections of UST 90mg q8w or PBO beginning at wk8, both added to standard of care. We calculated S2K RI-50 response at wk24 using various thresholds to define response including a decrease of at least 1, 2, 3, 4, 5, or 6 points from baseline in the S2K RI-50 score. We also compared the proportion of patients w/ SLEDAI-2K response vs S2K RI-50 response in pts receiving UST (n=62) vs PBO (n=40) at wk24.

Results: Change from baseline SLEDAI-2K & S2K RI-50 scores were strongly correlated ($R=0.92$, $p<0.0001$) at wk24. A greater proportion of UST vs PBO pts achieved S2K RI-50 response at wk24, regardless of threshold used to define response (Table). The greatest differences in S2K RI-50 response rates between UST vs PBO were observed for a 4-point decrease (23.3%, $p=0.010$), a 5-point decrease (22.8%, $p=0.023$), & a 6-point decrease (26.5%, $p=0.014$) from baseline. S2K RI-50 captured more responders than SLEDAI-2K at wk24, however, the difference in SLEDAI-2K 4-point response in UST vs PBO was $\square 27\%$ ($p=0.005$) while S2K RI-50 was $\square 23\%$ ($p=0.010$).

Conclusion: S2K RI-50 is an instrument that can capture partial clinically important improvement of $\geq 50\%$ in SLE disease manifestations. The data suggests cut points for defining S2K RI-50 response in clinical trials of patients with moderate-to-severe SLE disease activity.

Table 1. S2K RI-50 response rates at Wk24 for various thresholds to define response

Decrease from Baseline	UST (%) ^{a,b}	PBO (%) ^{a,b}	Difference between UST & PBO	p-value ^c
1 Point Decrease	95.3	88.6	6.7	0.1334
2 Point Decrease	93.5	79.3	14.2	0.0337
3 Point Decrease	84.1	70.9	13.2	0.0820
4 Point Decrease	84.0	60.7	23.3	0.0104
5 Point Decrease	73.5	50.7	22.8	0.0234
6 Point Decrease	70.5	44.0	26.5	0.0138

Note: S2K RI-50 response is defined differently in each row using different cutoffs.

S2K RI-50 uses partial response definition of $\geq 50\%$ improvement for each individual SLEDAI-2K descriptor.

^a Values for subjects meeting treatment failure criteria are set to missing from point of treatment failure forward.

^b Response based upon multiple imputations for missing data from Wk16 to Wk24, where Markov chain Monte Carlo method is used to make missing pattern monotone & serial logistic regression is used to impute monotone missing. The imputation model includes treatment group & baseline SLEDAI-2K covariate.

^c Test for greater treatment effect in UST over PBO (alternative hypothesis) is based upon logistic regression w/ treatment group, baseline SLEDAI-2K, baseline medication use for SLE & race as covariates.

Identifying Response for the Systemic Lupus Erythematosus Disease Activity Glucocorticoid Index (SLEDAI-2KG)

Zahi Touma¹, Dafna D Gladman², Jiandong Su¹, Nicole Anderson³ and Murray Urowitz², ¹University of Toronto, Toronto Western Hospital, Toronto, ON, Canada, ²Rheumatology, University of Toronto, Toronto Western Hospital, Toronto, ON, Canada, ³Division of Rheumatology, University of Toronto, Toronto Western Hospital, Toronto, ON, Canada

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic Lupus Erythematosus Disease Activity Index-2000 (SLEDAI-2K) Glucocorticoid Index (SLEDAI-2KG) is a valid index able to measure disease activity while accounting for glucocorticoid (GC)dose SLEDAI-2KG has the same descriptors as SLEDAI-2K in addition to a new descriptor “GCs” with different weight scores based on the dose of GCs. We aimed to: 1) determine the best cut-off for SLEDAI-2KG in identifying responders, 2) compare the performance of SLEDAI-2K and SLEDAI-2KG in identifying responders.

Methods: Patients seen between January 1995 – April 2018, at a single lupus centre, with SLEDAI-2K ≥ 6 and on GC ≥ 5 mg/day at baseline, and follow-up visits at 3, 6 and 9 months were studied.

Response to SoC therapy, at follow up visits were assessed by SLEDAI-2K and SLEDAI-2KG. The weighted GC score is as follows: <5 mg/day = 0; 5 mg/day = 1; 7.5 mg/day = 2; 10-12.5 mg/day = 3; 15-17.5 mg/day = 4; 20-22.5mg/day = 5; 25-30 mg/day = 6; 32.5-42.5 mg/day =7; ≥ 45 mg/day=8. The performances of SLEDAI-2K and SLEDAI-2KG were compared using different cut-off points; 4, 5 and 6. Descriptive statistics and McNemar’s tests for paired responses at the same time point and level were performed in the analysis. A sensitivity analysis was conducted for patients on GC ≥ 10 mg/day. To gain insight on the decrease of SLEDAI-2KG scores, we evaluated SLEDAI-2K scores and GCs weighted scores change on follow up visits.

Results: Of the 247 patients, 86.2% female, 47.9% Caucasian, 19.7% Black, 15.4% Asian, 17.0% other. The mean age at SLE diagnosis was 31.0 ± 13.0 and mean age at baseline was 35.7 ± 13.4 years. SLE duration was 9.02 ± 7.74 years. Mean SLEDAI-2K and SLEDAI-2KG at baseline was 13.8 ± 6.9 and 19.3 ± 7.8 respectively. The mean GC dose at baseline was 28.6 ± 19.7 mg/day.

The results confirmed that a **cut-off of 5** is the best for SLEDAI-2KG in identifying responders and SLEDAI-2KG identified more responders at 3, 6 and 9 months in patients taking ≥ 5 mg and ≥ 10 mg/day of GCs (table 1).

The decrease in SLEDAI-2KG scores on follow-up is the result of decrease in the scores of its components SLEDAI-2K and GCs weighted scores. Figure 1 illustrates the mean SLEDAI-2KG scores and its component scores including both the SLEDAI-2K component and the weighted GC dose at baseline, 3, 6 and 9 months follow-up.

Figure 1. Mean SLEDAI-2KG and components scores: SLEDAI-2K and weighted GC score at 3, 6 and 9 months and

Conclusion: The cut-off 5 is the most appropriate to identify responders by SLEDAI-2KG. Also, SLEDAI-2KG, is superior to SLEDAI-2K in identifying responders at 3, 6 and 9 months in patients taking ≥ 5 and ≥ 10 mg/day of GCs. The decrease of SLEDAI-2KG scores resulted from the decrease of its components-SLEDAI-2K scores and the weighted scores of GC.

Table 1. Responders by SLEDAI-2K and SLEDAI-2KG at 3, 6 and 9 months after baseline using different cut-offs

The Impact of Metformin on Disease Activity in Systemic Lupus Erythematosus

Cara McLeod¹, Gbemisola Olayemi¹, Nitasha Bhatia², Frank Migliore³ and Robert Quinet¹, ¹Rheumatology, Ochsner Medical Center, New Orleans, LA, ²Ochsner Medical Center, New Orleans, LA, ³Rheumatology, Allegheny Health Network, Pittsburgh, PA

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Metformin is a mainstay of therapy for type 2 diabetes mellitus. Newer evidence suggests that metformin may reduce lupus flares. An entity called neutrophil extracellular traps (NETs) has been found to be important in the pathogenesis of lupus, as they promote plasmacytoid dendritic cells (PDCs) to differentiate and activate. These PDCs, when activated, release interferon α (IFN α), which plays a pivotal role in the pathogenesis of lupus. The formation of NETs is reactive oxygen species (ROS) dependent. Metformin can selectively inhibit mitochondrial respiratory chain complex I and decrease NADPH oxidase activity leading to a reduction in ROS production. A November 2015 article by Wang H, et al in Arthritis and Rheumatology designed a randomized, proof-of-concept trial to evaluate the efficacy and safety of metformin on a background of corticosteroids and conventional immunosuppressive agents in patients with mild or moderate lupus. That study demonstrated that add-on metformin reduced the risk of disease flares by 51% compared with conventional treatment only. Prednisone exposure was also lower in the metformin add-on group than in the conventional treatment group. The objective of our study is to compare the disease activity of lupus patients on metformin versus those not on metformin.

Methods: We conducted a retrospective review of lupus patients followed in our Rheumatology clinic over one year. The primary outcome was to determine if lupus patients on metformin had lower disease activity compared to those not taking metformin. The population for review included those from the Lupus Initiative. We compared the mean Systemic Lupus Erythematosus Activity Index (SLEDAI) scores which measures disease activity between the two groups.

Results: In total, 15 patients out of 1446 patients with lupus were taking metformin. Using a Wilcoxon rank sum test, there was a statistically significant difference in patients SLEDAI scores between the lupus patients taking metformin versus the lupus patients not taking metformin (SLEDAI $z=-2.7$, $p=0.0061$). We found that the average SLEDAI score in those patients taking metformin was lower compared to those who were not on metformin. This is likely due to the mechanism of metformin which selectively inhibits mitochondrial respiratory chain complex I and decreases NADPH oxidase activity leading to decreased production of ROS. Reduced ROS production thus leads to fewer NETs forming, thus fewer PDCs differentiate and there is reduced release of IFN α which is a pivotal player in the pathogenesis of lupus. Further study comparing the mean prednisone dose between the two groups is currently underway.

Conclusion: We identified that lupus patients taking metformin had a lower median SLEDAI score compared to the patients not taking metformin. Metformin may play an important role in decreasing lupus flares by targeting NET activity and further research into this association should be done, as this may be one of the new approaches to treating lupus.

Disparities in Antimalarial Prescribing for Systemic Lupus Erythematosus Nephritis Using a Real-World, Electronic Health Record

Wenlu Xiong¹, J.B. Boone¹, Cecilia P. Chung¹, Leslie Crofford² and April Barnado², ¹Medicine, Vanderbilt University Medical Center, Nashville, TN, ²Division of Rheumatology and Immunology, Vanderbilt University Medical Center, Nashville, TN

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Antimalarials (AMs) improve survival in patients with systemic lupus erythematosus (SLE). Current guidelines suggest AMs for all SLE nephritis patients. Studies using patient-reported data showed AMs are not universally prescribed. Using a real-world electronic health record (EHR) cohort, SLE nephritis vs. non-nephritis patients were less likely to be prescribed AMs. We examined if patient or prescriber characteristics impact AM prescribing patterns.

Methods: Potential SLE cases were from a de-identified EHR with 2.8 million subjects using a previously validated algorithm of 4 or more counts of the SLE ICD-9 code(710.0) and antinuclear antibody (ANA) positive (titer $\geq 1:160$) while excluding dermatomyositis and systemic sclerosis ICD-9 codes. A subject was a case if diagnosed with SLE by a specialist (rheumatologist or nephrologist). SLE nephritis was defined as positive renal biopsy or clinical diagnosis by a specialist. We assessed for current use of AMs as documented by a specialist's note closest to October 1, 2015 (end of ICD-9 coding). We collected age at time of analysis, sex, race/ethnicity, specialist prescribing AM, and whether patients underwent dialysis or kidney transplant. The kidney function and blood counts closest to the specialist's note date were recorded. We evaluated for differences in SLE cases currently prescribed AMs vs. those not using the Mann-Whitney U test for continuous variables and chi-square or Fisher's exact test for categorical variables.

Results: Our validated algorithm identified 1147 potential SLE subjects with 977 chart-confirmed SLE cases and 244 SLE nephritis cases. Of the SLE nephritis cases, mean age was 43 ± 16 years with 89% female, 47% Caucasian, 44% African American, 6% Asian, and 3% Hispanic. Among cases, 81% were followed by a rheumatologist with 38% ever on dialysis and 21% receiving kidney transplant. Only 63% ($n = 153$) of SLE nephritis cases were current AM users. No retinopathy was noted in cases not prescribed AMs. There were no differences in sex or race between current vs. non-current users (Table 1). Current users were significantly younger than non-current users ($p < 0.001$). Patients were more likely to be prescribed AMs when followed by a rheumatologist vs. a nephrologist (76% vs. 37%, $p < 0.001$). Current vs. non-current users were less likely to be on dialysis ($p < 0.001$) and less likely to have had a kidney transplant ($p < 0.001$). Current vs. non-current users had significantly lower creatinine ($p < 0.001$), lower urine protein/creatinine ratio ($p = 0.04$), and higher hemoglobin ($p < 0.01$).

Conclusion: Using a large EHR cohort, only 63% of SLE nephritis cases are currently prescribed AMs. As AMs reduce renal damage in SLE nephritis, our results demonstrate an opportunity to target future efforts to improving adherence to guidelines for AM prescribing.

Table 1.

SLE nephritis cases (n = 244)	Currently Prescribed Antimalarials (n = 153)	Not Currently Prescribed Antimalarials (n = 88)	p value ^a

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: We present the long-term follow-up of patients with lupus nephritis who completed the randomized controlled trial on comparison of low-dose intravenous cyclophosphamide (IV CYC) with oral mycophenolate mofetil (MMF) as the induction therapy.

Methods: Prospective data on kidney function and survival in 83 out of 100 patients, who completed the initial trial, were collected over at least 36 months. Response, number of relapses, and time to first relapse were compared between the low dose IV CYC and oral MMF group on follow-up. Response, complete remission (CR) and partial remission (PR) and relapse (mild, moderate and severe) were defined according to Kidney Disease Initiative Global Outcomes (KDIGO) criteria.

Results: Of the initial 100 patients randomized to two groups, 83 patients (42 in IV CYC arm and 41 in oral MMF arm) completed 24 weeks study period. Of these, 67 patients had achieved treatment response, while 16 patients did not achieve response. All the 67 responders were started on azathioprine as the maintenance agent. On follow-up, 15 relapses occurred in the MMF group (13 patients had 1 relapse each and 2 had more than 1 relapse) and 12 relapses were seen in the IV CYC group (12 patients had 1 relapse each) on a follow-up of 36 months ($p > 0.05$). Of the 15 relapses in the MMF group, 9 were mild, 5 were moderate and 1 was severe relapse, respectively. The patient with severe relapse died due to disease activity at 36th month of follow-up. Of the 12 relapses in the IV CYC group, 8 were mild and 4 were moderate relapses, respectively.

Of the 16 non-responders, 11 were started on azathioprine, 4 were started on alternate induction agent and one patient was continued on the same induction agent. Of the 11 patients on azathioprine, the mean time to achieve response was 9.38 months in all, except in 3 lost to follow-up and 3 had mild relapse on follow-up. Of the 4 patients on alternate induction therapy, 2 required further change in therapy, 1 responded at 18 months and 1 died at 12 months due to disease activity. The patient on the same induction agent achieved response at 30 months. Overall, the mean time to first relapse was 23.95 months in the IV CYC group and 23.22 months in the oral MMF group ($p=0.807$).

Conclusion: Long term follow-up data shows that both low dose IV CYC and oral MMF induction therapy followed by azathioprine maintenance are equally effective in maintaining response in patients with lupus nephritis.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: To identify patterns (clusters) of damage manifestation within a large cohort of juvenile SLE (jSLE) patients and evaluate their possible association with mortality.

Methods: This is a multicentre, descriptive, cross-sectional study of a cohort of 345 jSLE patients from the Spanish Society of Rheumatology Lupus Registry (RELESSER). Organ damage was ascertained using the Systemic Lupus International Collaborating Clinics Damage Index. Using cluster analysis, groups of patients with similar patterns of damage manifestation were identified and compared.

Results: Mean age (years) \pm S.D. at diagnosis was 14.2 ± 2.89 ; 88.7% were female and 93.4% were Caucasian. Mean SLICC/ACR DI \pm S.D. was 1.27 ± 1.63 . A total of 12 (3.5%) patients died. Three damage clusters were identified: Cluster 1 (72.7% of patients) presented a lower number of individuals with damage (22.3% vs. 100% in Clusters 2 and 3, $P<0.001$); Cluster 2 (14.5% of patients) was characterized by renal damage in 60% of patients, significantly more than Clusters 1 and 3 ($P<0.001$), in addition to increased more ocular, cardiovascular and gonadal damage; Cluster 3 (12.7%)

was practically the only group with musculoskeletal damage (100%), significantly higher than in Clusters 1 and 2 ($P<0.001$). The overall mortality rate in Cluster 2 was 2.2 times higher than that in Cluster 3 and 5 times higher than that in Cluster 1 ($p<0.017$ for both comparisons).

Conclusion: In a large cohort of jSLE patients, renal and musculoskeletal damage manifestations were the two dominant forms of damage by which patients were sorted into clinically meaningful clusters. We found two clusters of jSLE with important clinical damage that were associated with higher rates of mortality, especially for the cluster of patients with predominant renal damage. Physicians should be particularly vigilant to the early prevention of damage in this subset of jSLE patients with kidney involvement.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Cancer is one of the main causes of morbidity and mortality worldwide. The overall risk of cancer in SLE is higher than in the general population (SIR 1.14). Objectives: To determine the incidence and prevalence of cancer in patients with SLE. To identify prevalent types of cancer and associated risk factors. To estimate mortality of patients with SLE due to neoplastic etiology.

Methods: A cohort study was conducted, all medical charts of patients diagnosed with SLE (ACR 1982/97 classification criteria) by different Rheumatology Services from January 2000 to June 2016 were reviewed. We studied sociodemographic variables and those related to SLE and to cancer. Statistical analysis: Descriptive, Prevalence, Incidence, Chi²-exact test, T Test and Mann Whitney, ANOVA, Multiple Linear Regression, Kaplan-Meier curves.

Results: We included 303 SLE patients, 88.4% women. Twenty-two cancers were diagnosed in 18 patients, determining a prevalence of 5.9% [IC 95% 3.3-8.6] and an annual incidence rate of 5.2 / 1000 inhabitants, both rates being higher compared to the general population ($p=0.0001$, $p=0.02$ respectively), and a risk of cancer of 2.4. The mean age at diagnosis of cancer was 46 ± 12.9 years, 94.4% were women and 16.6% (3/18) had a family history of cancer. Five types of cancers were observed: 8 cervical, 3 breast, 3 ovarian, 3 thyroid, 1 non-Hodgkin's lymphoma. All patients received treatment (14 surgeries, 1 chemotherapy and 3 combined), 15 remitted and 2 developed metastases. Three patients had 2 cancers and 1 patient had 3. There was no association between the presence of cancer and smoking, alcoholism, obesity or immunosuppressive treatment. Patients with cancer had more comorbidities such as arterial hypertension (55.5% vs 44.5%, $p=0.031$) and diabetes (22.2% vs 3.9%, $p=0.009$) compared with those who did not have cancer. In the regression analysis, greater cumulative damage, older age at diagnosis of SLE, longer disease duration and HPV infection were significantly associated with cancer. The mean survival time in patients with SLE who had cancer was 10.8 years. Thirty six patients died, 33 due to other causes and 3 due to cancer. The cancer mortality rate per year was 3.9%.

Conclusion: The prevalence of cancer in patients with SLE was 5.9%, with an annual incidence of 5.2 / 1000 inhabitants. The most frequent types of cancer were: cervix, breast, ovarian, thyroid and lymphoma. The risk factors that were associated with cancer were HPV infection, higher SLICC/SDI, older age at diagnosis of SLE and longer time of evolution of SLE. The death rate due to cancer was 3.9%.

Session Title: Systemic Lupus Erythematosus – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: To investigate effectiveness, safety, and predictors of response to belimumab in patients with active SLE in clinical practice setting.

Methods: Four hundred and one active SLE patients (ACR criteria) with positive anti-dsDNA antibody and low C3 and/or C4, from 22 Italian Centers, were treated with belimumab (10 mg/kg day 0, 14, 28 and then every 28 days), as add-on therapy. They were 366 (91.27%) females, mean age 43.51±11.20 years; mean disease duration 12.79±8.74 years. SLEDAI-2K, anti-dsDNA, C3, C4, prednisone daily dose, DAS-28, 24-hours proteinuria, CLASIa (Cutaneous LE Disease Area and Severity Index Activity), PGA, Fatigue (VAS 0-10) were recorded at baseline and every 6 months. SLICC-DI was evaluated 5-years before belimumab initiation, at baseline and every year after belimumab initiation. Response was evaluated according to SLE Responder Index-4 (SRI-4) at 12, 24, 36 and 48 months. Adverse events (AEs) were subdivided in noninfectious or infectious AE, and infusion reactions. AE was defined as severe (SAE) when hospitalization was required and/or death and/or life-threatening manifestations occurred. Statistics were performed by pairs T-test, chi-square test and multiple logistic regression analysis using SPSS package (version 22.0).

Table. Variation of clinical and serologic disease activity variables in patients with active lupus treated with belimumab

	N° pts*	Baseline	6 months	12 months	18 months	24 months	36 months	48 months	60 months	p
SLEDAI-2K	401	8.03±3.36	4.96±3.23	3.81±2.70	3.81±3.15	3.52±2.77	2.64±2.31	2.82±2.42	2.67±2.03	<0.0001
Prednisone daily dose (mg/day)	401	10.44±8.05	6.65±4.58	3.32±4.71	4.31±4.03	3.76±3.66	3.46±2.88	3.39±4.30	3.44±4.48	<0.0001
DAS-28	389	3.35±1.69	2.48±1.54	2.18±1.55	1.94±1.35	1.70±1.25	1.61±1.46	1.44±1.39	1.43±1.41	<0.0001
CLASI-a	234	3.29±4.66	1.88±3.30	1.00±2.18	0.35±2.12	0.60±1.78	0.38±1.39	0.56±1.39	0.22±0.73	<0.0001

*Number of patients at baseline.

p calculated using univariate analysis

SLEDAI-2K: Systemic Lupus Erythematosus Disease Activity Index-2000; CLASI-a: Calcutta Lupus erythematosus Activity and Severity Index-

activity; DAS-28: disease activity score-28 joints; anti-dsDNA: anti-double stranded DNA ELISA; Enzyme-Linked Immunosorbent Assay; pts:

patients; CLIA: chemiluminescent immunoassay

Results: Mean follow-up was 21.07±15.34 months (range 3-60). Active manifestations requiring the use of belimumab were articular in 40.82%, mucocutaneous in 21.84%, renal in 14.56%, hematologic in 16.32% and serositis in 6.24% of cases. SRI-4 was achieved by 68.2%, 73.3%, 74.7% and 68.3% of patients at 12, 24, 36 and 48 months, respectively. The improvement in clinical and serological variables during the follow-up are reported in the Table.

We observed a decrease in the mean number of flare during belimumab treatment compared with the corresponding period before belimumab initiation (p<0.0001).

SLEDAI-2K ≥10 resulted as an independent predictor of response by logistic regression at month 12 and 24 (p=0.003 and p=0.025).

Mean SLICC-DI was 0.71±1.07 five years before belimumab initiation, 0.96±1.31 at baseline and 1.00±1.52, 1.09±1.70, 1.27±1.91 at 24, 36 and 48 months of follow-up, respectively. We observed a significant increase in mean SLICC-DI between 5 years before belimumab initiation and baseline (p<0.01), but not between baseline and 2-year follow-up.

A total of 8,831 infusions were analyzed. A total of 681 AEs were observed in 298 patients, SAEs were 32 in 29 patients. No severe infusion reactions were observed; 15 patients had infective SAEs, and 18 non infective SAEs.

Conclusion: Belimumab reduces global and organ specific disease activity, frequency of flares and prednisone daily dosage. SLEDAI-2K ≥10 at baseline was the best predictor of response in our cohort of patients with active SLE. Belimumab was well tolerated.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Over the last few years, the importance of treating patients with systemic lupus erythematosus (SLE) towards achieving Remission or Low Disease Activity State has become the goal. Nevertheless, some patients remain with active disease despite full immunosuppressive drugs, and are usually called active refractory lupus. The present study was conducted to describe the clinical characteristics and treatment patterns for refractory lupus patients from a multi-ethnic, multicenter lupus cohort (GLADEL for Latin American Group for the Study of Lupus).

Methods: Between 1997 and 2005, GLADEL established an observational inception cohort constituted by more than 1400 SLE patients. This cohort comprises 34 centers with experience in SLE (tertiary referral centers with a lupus clinic, an academic profile and a rheumatology training program). Sociodemographic, clinical, immunological, treatment characteristics, disease activity and damage data were obtained at all visits. For the purpose of this study, refractory SLE was defined as patients with SLE Disease Activity Index (SLEDAI)–2K ≥ 6 points and a stable treatment regimen with fixed doses of prednisone ≥ 7.5 mg/day, or immunosuppressive drugs for at least 30 days at any point during follow up. The renal and CNS items of the SLEDAI–2K were not considered for scoring the SLEDAI-2K. Sociodemographic, clinical, immunological, treatment characteristics and disease activity are described as median (interquartile range, IR) and number (percentages); All analyses were performed using the SAS software, version 9.4 (SAS Institute, Cary, NC, USA).

Results: The cohort consisted of 1432 patients; 262 (18.3%) of them had refractory SLE. Of them, 229 (87.4%) were women and their median ages (diagnosis, refractory) were 27.0 and 28.8 years; 137 (52.3%) patients were Mestizos, 87 (33.2%) Caucasians and 29 (11.1%) were African-Latin Americans. Table 1 depicts these patients' sociodemographic and SLEDAI–2K clinical and immunological characteristics, while Table 2 shows their patterns of treatment at time of being refractory.

Conclusion: In this pre-biologic period, refractory Latin American lupus patients presented most frequently with arthritis and new rash while they were treated with glucocorticoids, azathioprine and cyclophosphamide.

Table 1. Sociodemographic and SLEDAI clinical and immunological characteristics of GLADEL patients with refractory disease.

Variable, (n, %)	Refractory lupus (n=262)
Age at diagnosis, years, median	27.0 (20.0-36.0)
Age at refractory, years, median	28.8 (21.5-36.6)

Tracey⁴ and Betty Diamond¹, ¹The Feinstein Institute for Medical Research, Manhasset, NY, ²Feinstein Institute for Medical Research, Manhasset, NY, ³Autoimmune and Musculoskeletal Disease, The Feinstein Institute for Medical Research, Manhasset, NY, ⁴Laboratory of Biomedical Science, Feinstein Institute for Medical Research, Manhasset, NY

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Musculoskeletal (MS) pain is a common symptom of patients with Systemic Lupus Erythematosus (SLE) affecting up to 95% of patients and contributing to a reduced quality of life. Safe and efficacious treatment remains an unmet need for this disease feature. The cholinergic anti-inflammatory pathway is a physiologic mechanism diminishing inflammation. Stimulation of the vagus nerve results in reduction of inflammatory mediators with beneficial effects in both human inflammation and animal models of disease. We proposed to evaluate transcutaneous, noninvasive stimulation of the vagus nerve through its auricular branch in SLE patients with MS pain.

Methods: 18 SLE patients with MS pain ≥ 4 on an anchored 10cm Visual Analog Scale for pain and MS activity defined by SLEDAI-2K arthritis or a BILAG MS score $\geq C$, were randomized (2:1) in this double-blind study to receive 5 minutes of transcutaneous auricular vagus nerve or sham stimulation (taVNS or SS) for 4 consecutive days. Patients with a diagnosis of fibromyalgia were excluded. For sham stimulation, electrodes were placed on the earlobe and no current was delivered. Evaluations at baseline, day 5 and day 12 included patient assessments of pain, disease activity (PtGA) and fatigue. Tender and swollen joints, SLEDAI-2K and the Physician Global Assessment (PGA) were completed by a blinded

¹ Mann-Whitney Exact test

² Higher FACIT-F scores correspond to lower fatigue

³ Data shown for 7 taVNS and 5 SS subjects with swollen joints at baseline

physician. Potential biomarkers were also determined at these times and included serum levels of acute phase reactants, inflammatory cytokines as well as cytokine levels following whole blood stimulation (WBS) with TLR 4, 7 or 9 agonists.

Results: taVNS and SS were well tolerated with no significant adverse events in 19 enrolled subjects. Per protocol, 1 subject who withdrew after day 3 with a flu-like winter illness was replaced. Baseline characteristics of subjects receiving VNS or SS were similar. Following 4 consecutive days of stimulation, at day 5, subjects receiving VNS had a significant decrease in pain and fatigue compared to SS (Table 1), were more likely (OR =25 p=.02) to experience a minimal clinical significant reduction (1.58) in pain and were more likely to report improvement on a Likert scale. PtGA, joint counts and PGA were improved at day 5 in taVNS compared to SS subjects.. Pain reduction and improvement of fatigue correlated (R=0.49 p=.04, R=.83 p=.003 respectfully) with the average stimulation level. In general, response was maintained through day 12. Examination of serum and WBS biomarkers showed no significant differences at days 5 or 12 compared to baseline.

Conclusion: In a pilot study, VNS resulted in a significant reduction of pain, fatigue and joint scores in SLE patients with MS pain. Additional studies evaluating this promising intervention and its potential mechanisms are warranted.

Contraceptive Documentation in Systemic Lupus Erythematosus Patients at a Safety Net Hospital

Ola Azzouqah¹ and Bonnie L. Bermas², ¹Department of Rheumatic diseases, UT Southwestern Medical Center and Parkland Hospital, Dallas, TX, ²Division of Rheumatic Diseases, UT Southwestern Medical Center, Dallas, TX

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic Lupus Erythematosus (SLE) predominately affects reproductive aged women. Contraceptive counseling is an important quality indicator in SLE patient care. Here we evaluate current practice in the documentation of contraceptive use amongst reproductive aged women with SLE cared for at a large safety net hospital.

Methods: Using ICD10 codes for SLE (M32, M320, M321, M328, M329), we identified reproductive aged (ages 16-50) female SLE patients, who presented to the outpatient rheumatology clinic at Parkland Hospital between 07/01/17 and 11/

30/17. We performed a retrospective chart review for contraceptive use documentation. Medication use including potential teratogenic medications was also assessed.

Results: Among 131 clinic encounters, contraceptive use was documented in 61% of encounters. Amongst those women prescribed a potentially teratogenic medication, mycophenolate mofetil was the most common followed by methotrexate. Amongst those on teratogenic medication, documentation of contraception was present in 67% of clinic notes. The average age of women who were on potentially teratogenic medicine and had documented contraception was younger (mean 30, SD 7) than those in whom contraception was not documented (mean 37, SD 10). Greater than 50 % of those patients on potentially teratogenic medicine used less reliable contraceptive methods: abstinence or condoms. Providers rarely documented other information in regard to reproductive health such as pregnancy planning and the desire to have children.

Fig 1. Contraceptive methods used among SLE patients who are on potentially teratogenic medications.

Conclusion: Contraceptive use documentation amongst reproductive aged women with SLE in a safety net hospital is often lacking even amongst those on potentially teratogenic medication. Documentation of contraception is more common in younger women. Identifying barriers to contraceptive use documentation and implementing interventions to facilitate documentation is a future goal.

Exposure to Air Pollution and the Onset and Progression of Systemic Lupus Erythematosus

Gaurav Gulati¹, Cole Brokamp², Patrick Ryan² and Hermine I. Brunner³, ¹Division of Immunology, Allergy and Rheumatology, University of Cincinnati College of Medicine, Cincinnati, OH, ²Department of Biostatistics and Epidemiology, Cincinnati Children's Hospital and Medical Center, Cincinnati, OH, ³Pediatric Rheumatology Collaborative Study Group (PRCSG), Cincinnati Children's Hospital Medical Center, Cincinnati, OH

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Air pollution may contribute to many autoimmune diseases including systemic lupus erythematosus (SLE), but limited information is available on its role in the onset and progression of SLE. The objective of the current study was to determine the relationship between air pollution exposure and characteristics associated with expression and severity of SLE.

Methods: In this retrospective cohort study, we identified patients with childhood onset SLE (cSLE) residing in the greater Cincinnati, OH region at the time of their SLE diagnosis and being followed for their care at Cincinnati Children's Hospital Medical Center (CCHMC). Demographic and clinical information at the time of diagnosis were extracted from our cSLE cohort, and included phenotypic information on SLE (1997 American College of Rheumatology classification criteria) and SLE disease activity index (SLEDAI). Patients' home address at the time of diagnosis was geocoded. Exposure to traffic-related pollutants was estimated for each participant by calculating the distance to the nearest major road. In addition, a previously developed and validated land-use regression model for the study region was applied to estimate the concentrations of elemental carbon attributable to traffic (ECAT), a surrogate marker for traffic related air pollution and specifically attributable to diesel exhaust. SLEDAI scores were categorized as high (> 8) or low to moderate activity (≤8). ECAT concentrations were log transformed and logistic regression was used to estimate the association between air pollution exposures and SLEDAI (high/low) and ACR classification criteria for phenotypic expression of disease.

Results: The cSLE patients' (n = 158) mean age at diagnosis was 16.9 (SD 4.2) years. The majority (76.7%) were female with nearly equal representation of Caucasians and African Americans (42.1% and 41.5%, respectively). ECAT exposures were not associated with overall disease activity (SLEDAI) (Odds Ratio (OR) 1.4 (95% CI 0.3 – 7.1). However, as shown in Table 1 with higher ECAT exposures there was a significantly increased risk for renal involvement (OR = 3 (95% CI 1.0-8.7)) also a trend towards experience more commonly serositis (OR = 3.8 (95% CI 0.8 – 18.2)).

Conclusion: Our preliminary study suggests that environmental exposure to air pollution is associated with increased risk for certain manifestations of cSLE. Further work is needed to establish longitudinal effect of air pollution on the disease activity and cumulative damage and cSLE phenotypes over time.

TABLE 1: Logistic Regression Analysis of log (ECAT) values versus presence of phenotypic features of cSLE at disease onset

Dependent Variable (ACR classification Criteria)	log (ECAT)		P value
	OR	95% CI

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: SLE diagnosis and classification can be challenging. The low incidence of SLE limits primary care physician experience with the disease, but the impact of early diagnosis & treatment on long term outcome makes a compelling case for early referral for rheumatology consultation upon suspicion of SLE. ANA testing, currently used for screening of suspected SLE patients, is characterized by high false positive rates increasing the likelihood of misplaced suspicion of SLE. The diagnostic workup for referred patients is long, costly and often inconclusive, with a high rate of misdiagnosis. Misdiagnosis can lead to use of medications with potential side effects and even irreversible damage as well as significant psychological distress, anxiety and/or depression for the patient as well as family members. Access to a simple serological test to rule out a diagnosis of SLE would contribute to all the stakeholders involved in lupus diagnosis; patients, physicians and payers. The SLE-key® test may represent such a test. The SLE-key® Rule Out test was developed and validated to rule out a diagnosis of SLE with 94% sensitivity and 75% specificity (Putterman C, J Imm Meth 2016). The goal of the current study was to monitor the clinical and financial impact of the test in clinical practice.

Methods: 245 patients were referred from five busy, geographically independent rheumatology clinics. Serum samples and clinical information were collected from both patient and physician with informed consent in a HIPAA compliant manner. Sera along with clinical data were sent to ImmunArray's CLIA-certified laboratory, Veracis (Richmond, VA) for SLE-key® RuleOut testing and evaluation using ImmunArray's iCHIP® platform.

Results: The SLE-key® test effectively ruled out a diagnosis of SLE in >54% of patients referred, including patients with personal or family history of autoimmune disease. Over 300 ANA tests were recorded for this cohort and almost 90% of the patients had at least one positive ANA test result sometime during their clinical evaluation. 55% of these were Ruled Out using the SLE-key test. These included patients referred with multiple symptoms including joint pain, mouth sores and rashes in addition to their ANA positive test. Clinical data from at least one visit post SLE-key® testing was available for

98/134 patients where SLE was ruled out. Clinical diagnosis in 5 (5%) of these cases was SLE. For an additional 8 (8%) cases, SLE remained under consideration as part of the differential diagnosis.

Conclusion: The SLE-key® test can be used to enhance the efficiency of triage of patients referred into the rheumatology practice. More than half of patients referred with symptoms leading to a suspicion of systemic autoimmune rheumatic disease (SARD) may have a diagnosis of SLE quickly eliminated from the diagnostic algorithm. Thus, the SLE-key Rule Out test, can significantly reduce unnecessary costs and diagnostic time and increase the efficiency of healthcare delivery.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Skin lesions of lupus may be refractory to standard therapy. Apremilast is an orally small molecule which inhibits phosphodiesterase-4 (PDE-4) that modulates some inflammatory pathways. Our aim was to assess the efficacy of apremilast in lupus rashes refractory to conventional treatment.

Methods: We set up a retrospective study on 6 lupus patients treated with apremilast at standard dose of 30 mg twice daily, with the initial 5-day titration schedule. The outcome was improvement of lupus rashes.

Results: We studied 6 patients (5 women/1 male); mean age, 40.6±11.5 years with extensive skin lesions due to lupus. Three patients had a discoid lupus and other three patients had systemic lupus erythematosus (SLE) (one with panniculitis, one with polycyclic ring lupus and the other one with psoriasiform lupus). The cutaneous lupus was confirmed in all patients by skin biopsy.

Prior to apremilast all patients had received conventional treatment: topical corticosteroids (n=6), antimalarials (n=6), topical tacrolimus (n=3), oral corticosteroids (n=3), thalidomide (n=1), belimumab (n=2) and rituximab (n=2).

The duration of the cutaneous lesions until Apremilast onset was 148±90.6 months. After a mean follow-up of 6.2±2.9 months, all the patients experienced improvement of the skin lesions (in two patients was complete). In one patient it was necessary to reduce the dose of apremilast to 30 mg/day because of digestive symptoms (diarrhoea and vomiting) (TABLE).

Conclusion: Apremilast can be useful in the treatment of refractory skin lesions of lupus.

TABLE

Patient	Age/Sex	Skin lesions	Previous treatments	Months from diagnosis to Apremilast onset	Apremilast onset		Apremilast follow-up			
					Antinuclear Antibody (ANA)	Simultaneous treatment	Months from Apremilast onset	Adverse effects	Discontinued	Response
1	46 / Female	Polycyclic ring lupus	Prednisone Hydroxychloroquine Thalidomide Belimumab, RTX	300	ANA 1/1280	Prednisone	2	diarrhoea	No	Partial
2	45 / Female	Lupus panniculitis	Prednisone Hydroxychloroquine	156	ANA 1/1280	Prednisone Hydroxychloroquine	7	No	No	Complete
3	36 / Male	Discoid lupus	Prednisone Hydroxychloroquine	ND	ANA (-)	Prednisone Hydroxychloroquine	6	Diarrhoea vomiting	No. 30 mg/24 h	Complete

Assessment of Habitual Physical Activity and Performance during Maximal Exercise Test in Systemic Lupus Erythematosus Patients

Rosane Machado¹, Nilzio A. da Silva^{1,2}, **Vitalina Barbosa¹**, Jozelia Rêgo¹, Heloísa Machado¹, Cláudio Lira¹ and Ricardo Viana¹, ¹Universidade Federal de Goiás, Goiânia, Brazil, ²GLADEL, Goiás, Brazil

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with systemic lupus erythematosus (SLE) present low physical capacity when compared to healthy controls. In addition to chronotropic incompetence during exercise, slow recovery of post-exertion heart rate and lower values of maximal strength and muscle function are found in SLE when compared with healthy controls. The aim of this study was to evaluate the habitual physical activity measured by the Baecke questionnaire and evaluate performance during maximal exercise in SLE patients and healthy controls.

Methods: Thirty one women with SLE, who met the ACR criteria of 1997 and the Systemic Lupus International Collaborating Clinics criteria of 2012, and 24 healthy women, who were matched by sex, age and body mass index, participated in this study. All participants answered the Habitual Physical Activity Questionnaire (Baecke). This questionnaire is a reminder instrument of the last 12 months, comprising 16 questions and addressing magnitudes such as occupational physical activity (8 questions), physical exercise in leisure (4 questions) and physical leisure and locomotor physical activity (4 questions). The participants were submitted to a maximal exercise test on a motorized treadmill, with increases in velocity every minute until exhaustion in order to assess velocity (km/h), heart rate, Borg scale (6-20) and the reason to interrupting the test (fatigue and/or dyspnea). The test was considered maximal if it reached at least 90% of the maximum heart rate (by the formula 220-age) or reached values of 19 to 20 in the Borg scale.

Results: The evaluation of the habitual physical activity by Baecke questionnaire revealed no significant differences between groups regarding to occupational (p=0.506), sports activity (p=0.945) and physical leisure domains (p=0.904). Half of the controls walked 16 to 30 min/day, while only 22.6% of SLE patients walked the same time. In the maximal exercise test, the control group presented a higher mean maximum heart rate (p=0.001) and maximum velocity (p=0.002). The main reason for discontinuing the test was the occurrence of dyspnea in both, controls and SLE patients (66.67% vs 46.43%).

Conclusion: During the exercise test, the maximum heart rate and maximum velocity reached during the test was lower in SLE patients than the controls. These results suggest cardiorespiratory capacity impairment and low tolerance to physical effort in SLE patients.

Real World Medication Use in Incident Systemic Lupus Erythematosus and Lupus Nephritis Patients

Lin Xie¹, Furaha Kariburyo¹, Janvi Sah¹, Jennifer Lofland² and Nan Li³, ¹STATinMED Research Inc., Ann Arbor, MI, ²Janssen Scientific Affairs, LLC, Horsham, PA, ³Janssen Research & Development, LLC, Spring House, PA

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Systemic Lupus Erythematosus – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is an autoimmune disease that causes inflammation in connective tissues and can involve multiple organs systems. Lupus nephritis (LN) is an inflammatory kidney disease caused by SLE. There is a gap in the literature regarding the standard of care in SLE and LN patients. This study generated real world medication use among SLE and LN patients.

Methods: This retrospective study used data from two large administrative databases in the US: Truven Health MarketScan[®] and Optum[®] databases to identify adult patients (≥18 years of age) with ≥2 medical claims on different dates for SLE or LN diagnoses from 01 JAN 2013-31 DEC 2015. SLE was identified using the International Classification of Diseases, 9th and 10th Revision, Clinical Modification [ICD-9-CM] codes (710.0) OR ICD-10-CM (M32.10-M32.19, 32.8, 32.9). LN was captured as a subset of SLE using [ICD-9-CM: 710.0 AND (581.81 or 582.81 or 583.81); OR (ICD-10-CM: M32.14)]. The first SLE or LN diagnosis was designated as the index date. Patients were required to have continuous health plan enrollment for 1 year pre-index date (baseline period) and 1 year post-index date (follow-up period) and no prior SLE/LN diagnosis claims or belimumab medical/prescription claim during the baseline period to ensure incident patients were captured. The Truven Health MarketScan[®] and Optum[®] databases were pooled together and duplicates were identified and retained in MarketScan[®] only. Patient demographics and clinical characteristics during the baseline period were assessed. SLE treatment used during the follow-up period was evaluated and the proportion of patients that used SLE medications and average number of medical/prescription claims (#Rx)for each medication were provided.

Results: A total of 31,345 patients were identified including 30,086 SLE and 1,259 LN patients. Key results are shown in Table 1. The mean age was 52.7 years for SLE and 48.3 years for LN patients. Over 80% of the patients were female, with a mean Charlson Comorbidity Index (CCI) score of 1.1 and 1.8 for SLE and LN patients respectively. The most common comorbidities at baseline were hypertension and infections. Corticosteroids (SLE= 58.3%, #Rx=4.5; LN=66.2%, #Rx=6.5) and hydroxychloroquine (SLE=43.4%, #Rx=5.8; LN=40.7% #Rx=6.2) were most commonly used SLE medications during 1-year follow up period. Approximately 2% of patients used biologics including belimumab (SLE=1.1%, #Rx=8.8; LN=1.4%, #Rx=8.3)and rituximab (SLE=0.9%, #Rx=4.2; LN=2.1%, #Rx=4.0).

Conclusion: Our findings indicate a nominal use of biologics (~2%) among SLE and LN patients. Corticosteroids and hydroxychloroquine were most commonly used SLE treatment. These data reveal an unmet need for availability of advanced therapy to treat SLE and LN. Future studies are warranted to understand the underlying causes.

Session Title: Systemic Lupus Erythematosus – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: GLADEL (Grupo Latino Americano De Estudio de Lupus) has previously shown that a 14.1% of its patients have relatives with an autoimmune disease (1). The present study was conducted to contrast the clinical features, damage accrual and survival of GLADEL patients with familial and sporadic SLE.

Methods: Familial SLE was defined as patients with a first degree relative with SLE (parents, siblings and offspring); these relatives were interviewed in person or by telephone and examined, if warranted. Patients with second and third degrees relatives with SLE were excluded from these analyses. All other patients were considered as having sporadic lupus. The sociodemographic, clinical, immunological, treatment characteristics plus disease activity, damage and mortality, were compared between the two patient groups using Wilcoxon test and Chi-square tests for continuous and categorical variables, respectively. Odds ratios (OR) and 95% confidence intervals (CI) were estimated. Time-to-damage and mortality were examined with Cox multivariable regressions [Hazard ratios (HR) and 95% CI] in which variables previously found to be associated were also included. Statistical significance was set at $p \leq 0.05$; All analyses were performed using the SAS software, version 9.4 (SAS Institute, Cary, NC, USA).

Results: The cohort consisted of 1176 patients; 66 (5.6%) of them had familial and 1110, sporadic lupus. The majority of patients in both groups were women, of comparable age and all ethnic groups were represented. None of the sociodemographic variables examined were significantly associated with familial SLE. As shown in Table 1, there were some differences in terms of the clinical variables with discoid lupus [22.7% versus 12.9%; $p = 0.024$; OR 1.97 (1.08- 3.60)] and neurologic disorder [(45.4% versus 33.5%; $p = 0.047$; OR 1.65 (1.00- 2.73)] being significantly associated with familial SLE. In contrast, pericarditis was negatively associated with familial SLE [7.6% versus 19.1%; $p = 0.01$; OR 0.35 (0.14- 0.87)]. The SLEDAI and SDI were similar in both groups; in the Cox analyses, familial lupus was not significantly associated with damage accrual (HR=1.00; 0.53– 1.89; $p = 0.99$) or higher mortality (HR 1.01; 0.24– 4.31; $p = 0.99$).

Conclusion: Familial SLE was associated with the presence of neurologic manifestations and of discoid lupus and with the absence of pericarditis, which has not been previously reported; however, no differences in hard endpoints such as disease activity, damage accrual and/or mortality were observed when compared with sporadic SLE.

Table 1. Characteristics of GLADEL patients associated with familial lupus versus all other GLADEL patients

Variable, (n, %)	Familial lupus (n=66)	Sporadic lupus (n=1110)	p-value	OR (CI _{95%})
Malar rash	44 (66.6%)	714 (64.3%)	0.699	
Discoid lupus	15 (22.7%)	144 (12.9%)	0.024	1.97 (1.08- 3.60)
Photosensitivity	38 (57.6%)	666 (60.0%)	0.696	
Oral ulcers	30 (45.4%)	494 (44.5%)	0.880	
Arthritis	53 (80.3%)	920 (82.9%)	0.590	
Pleuritis	16 (24.2%)	288 (25.9%)	0.759	
Pericarditis	5 (7.6%)	212 (19.1%)	0.019	0.35 (0.14- 0.87)
Neurological disorder	30 (45.4%)	372 (33.5%)	0.047	1.65 (1.00- 2.73)
Renal disorder	40 (60.6%)	641 (57.7%)	0.648	
Haematological disorder	52 (78.8%)	873 (78.6%)	0.979	
Immunological disorder (*135)	50 (83.3%)	795 (81.0%)	0.659	
ANA	62 (93.9%)	1061 (95.7%)	0.531	
Raynaud's phenomenon	21 (31.8%)	347 (31.3%)	0.924	
Anti-dsDNA antibodies (*7)	44 (66.7%)	650 (58.5%)	0.193	
Anti-SSA/Ro (*110)	15 (22.7%)	274 (24.7%)	0.719	
Anti-SSB/La (*117)	11 (16.7%)	155 (13.9%)	0.5401	
Antiphospholipid antibodies (*74)	26 (39.4%)	383 (34.5%)	0.4178	
Hypocomplementemia (*30)	39 (59.1%)	642 (57.84%)	0.8412	
Mortality in the follow-up (n, %)	4 (6.0%)	73 (6.58%)	0.8692	
SLEDAI at cohort entry (*147) (median, IQR)	9 (13.0)	8 (11.0)	0.692	
SDI accrual (median, IQR)	1.0 (2.0)	1.0 (2.0)	0.859	

* Missing data; OR (odd ratio); IQR (Interquartile range); ANA (Anti-nuclear antibodies); SLEDAI (Systemic Lupus Erythematosus Disease Activity Index); SDI (SLICC/ACR Damage Index)

Session Title: Systemic Lupus Erythematosus – Clinical Poster III: Treatment

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Lupus nephritis (LN) is a common and serious organ manifestation of SLE and is associated with substantial patient morbidity and mortality. The production of interleukin-2 (IL-2), a key cytokine that regulates the differentiation and activation of CD4⁺ T cell subsets, is impaired in LN patients. Previous studies have shown IL-2 can expand Treg cell numbers and reduce Tfh and Th17 effector CD4⁺ T cell subsets in SLE. However, the efficacy of low-dose IL-2 to refractory LN is still unclear.

Methods: We conducted a prospective, open-label study to evaluate the effects of low-dose rhIL-2 (recombinant human IL-2^{Ser125}, Beijing SL Pharma) in patients with refractory LN. Three cycles of rhIL-2 were administered subcutaneously at a dose of 1 million IU every other day for 2 weeks (a total of 7 doses), followed by a 2-week break. After the initiation of IL-2, no increase in any other treatments for SLE was permitted. Clinical and laboratory data were measured at baseline and every 4 weeks thereafter until week 12. Refractory disease was defined as no or incomplete response to conventional 2-drug immunosuppressive therapy. Ten patients with refractory LN were eligible in IL-2 group and 10 in Placebo Group.

Results: Significant reductions of 24 h proteinuria and urine erythrocyte ($p < 0.05$) in IL-2 group compared with placebo group. Serum albumin also demonstrated improvement. Both C3 and C4 increased significantly at week 12 ($P < 0.01$). In addition, anti-dsDNA and Anti-Nuclear Ab titer decreased significantly ($P < 0.01$). Immunological analysis revealed that low-dose rhIL-2 administration was associated with selective expansion of Treg cells and conversely with reductions of Tfh and Th17 cells.

Conclusion: Low-dose IL-2 therapy was effective in refractory LN.

Session Time: 9:00AM-11:00AM

Table 1 changes of Th17/Treg cell expression after metformin treatment

组别	Th17 细胞 (个/ml)	Treg 细胞 (个/ml)	Th17/Treg
MET 治疗 0 周	5.96 (7.52)	25.41 (19.13)	0.25 (0.31)
MET 治疗 6 周	5.60 (5.87)	25.78 (25.89) *	0.24 (0.24)
MET 治疗 12 周	4.56 (5.38)	21.09 (13.25)	0.22 (0.23)

Note that: * means $p < 0.05$.

Table 2 changes of ESR(mm/h), SLEDAI Score after metformin treatment

组别	ESR (mm/h)	SLEDAI 评分
MET 治疗 0 周	7 (20.25)	2 (1)
MET 治疗 6 周	6 (9.75)	1 (0)
MET 治疗 12 周	9 (12.5) *	0 (0.25)

Note that: * means $p < 0.05$.

Table 3 Changes of drugs after metformin treatment

组别	Pre(mg/d)	HCQ(g/d)
MET 治疗 0 周	16(28.0)	0.4(0.15)
MET 治疗 6 周	11.15(28.10)*	0.4(0.05)
MET 治疗 12 周	6.5(19.5)**	0.4(0.10)

Note that: * means $p < 0.05$, ** means $p < 0.001$.

Background/Purpose: To observe the clinical efficacy of metformin in the treatment of SLE and regulation of CD4⁺ Treg and Th17 cells.

Methods: Thirty-one patients with SLE, fulfilled the ACR 1997 standard, were enrolled in this study. Their average age was 37.21 ± 15.65 years, and disease duration was 58.33 ± 56.48 months. They were administered with metformin (MET) 250mg Bid combined with conventional therapy for 12 weeks. At week 0, week 6 and week 12, the absolute numbers of Th17 and Treg cells were assayed by flow cytometry and SLEDAI score and drug doses were collected.

Results: At week 0, 6 or 12 after metformin treatment combined with conventional therapy, the absolute number of Treg cells in 31 patients was 25.41 ± 7.52 , 25.78 ± 25.89 ($P=0.054$), or 21.09, while that of Th17 cells was 5.96 ± 7.52 , 5.60 ± 5.87 , or 4.56 ± 5.38 . The dosage of prednisone in SLE patients was decreased from 16(28.0) mg/d to 11.15(28.10) mg/d ($P=0.019$) or 6.5 (19.5) mg/d ($P=0.003$).
