Results: We found that 47.95%(187/390) of our patients had a history of allergy. Allergic patients showed elevated incidence of salivary glands, paranasal sinus, and skin affection, while non-allergic patients had more renal, large artery involvement and retroperitoneal fibrosis. Allergic patients also exhibited significantly up-regulated eosinophil, serum IgG4, IgE levels and IgG4/IgG ratio, while non-allergic patients presented with increased ESR, CRP, IgG1 levels, IgG1/IgG ratio, and higher incidence of anemia. No significant differences were found in baseline treatment options and the recurrence rate during follow-up.

Conclusion: Clinical study put forward that allergic reaction did relate to different characteristics in IgG4-RD patients, therefore, basic research is needed to clarify the potentially related mechanism.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Vasculitis Poster II: Behçet's Disease and IgG4-Related Disease

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: In IgG4-related disease (IgG4-RD), spontaneous, or at least temporary, remissions without treatment have been reported, and watchful waiting may be appropriate in certain patients with asymptomatic and inactive disease. However, the outcomes of patients with IgG4-RD who do not undergo treatment are still unclear. This study aimed to clarify the outcomes of untreated patients with IgG4-RD and the factors related to the outcomes.

Methods: We retrospectively evaluated clinical features including laboratory data and involved organs at diagnosis in 107 patients (pts) with IgG4-RD, who were followed up for more than 6 months, at a single center in Japan. Among them, 27 patients were followed up without treatment after the initial diagnosis. We compared the clinical features of these 27 patients with those of the 80 patients who underwent treatment. The outcomes of untreated patients were investigated, and logistic regression analysis was performed to assess factors related to the outcomes. Deterioration of IgG4-RD was defined as symptomatic, radiological, or functional exacerbation of the organ involved or new organ involvement.

Results: The patients comprised 73 men and 34 women (mean age 65.7 years). The mean follow-up periods were 64.1 (range 7–252) months, and the serum IgG4 levels at diagnosis were 706 (range 10.7–3,610) mg/dL. The 27 untreated patients had significantly lower IgG4-RD responder index (10.8 ± 5.1 vs 13.8 ± 6.8 , $P=0.048$), fewer affected organs (1.9 ± 1.2 vs 3.0 ± 1.6 , $P=0.001$), and lower frequency of ophthalmic and renal parenchymal lesions (25.9% vs 53.8%, $P=0.015$, and 3.7% vs 26.3%, $P=0.012$, respectively) than did the 80 patients who underwent treatment. Of these 27 patients, 8 experienced deterioration of IgG4-RD 62.8 (range 3–232) months after the diagnosis. New organ involvement was observed in all 8 patients, 2 of whom concurrently suffered exacerbation of the organs involved. In age- and sex-adjusted logistic regression analysis, serum IgG4 elevation (per 100 mg/dL, odds ratio 1.194, 95% confidence interval 1.017–1.402, $P=0.030$) was the only significant factor related to deterioration of disease in untreated patients with IgG4-RD, whereas serum IgG4 levels did not relate to deterioration in patients who underwent treatment (per 100 mg/dL, odds ratio 0.995, 95% confidence interval 0.921–1.075, $P=0.901$).

Conclusion: The present study suggests that serum IgG4 levels may be a useful predictor of the outcomes of untreated patients with IgG4-RD, who tend to have fewer affected organs and lower IgG4-RD responder index.

Session Date: Monday, October 22, 2018

Session Title: Vasculitis Poster II: Behçet's Disease and IgG4-Related Disease

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic vasculitis is one of the major manifestations of Behçet's disease (BD). Takayasu's arteritis (TA) is a chronic vasculitis that primarily affects the aorta and its branch. While BD and TA differ in their clinical characteristics, it is difficult to differentiate them in particular when BD presented with major arterial involvement. Our study was to compare clinical characteristics and angiographic findings between TA and BD patients with arterial involvement.

Methods: We retrospectively reviewed medical records of 206 TA patients and 50 BD patients between 1995 and 2015. Angiographic lesions were evaluated based on CT, MRI and/or angiography findings. The diagnosis was confirmed according to the American College of Rheumatology 1990 criteria for TA and the International Criteria for BD.

Results: Patients with TA were more likely female than those with BD (83.5% vs 40.0%, $p = 0.000$). In clinical manifestation, fever (9.2% vs 30.0%, $p = 0.000$) and arthralgia (7.3% vs 36.0%, $p = 0.000$) were more frequently seen in patients with BD. Serum levels of C-reactive protein was significantly higher (2.08mg/dL vs 5.84mg/dL, $p=0.000$) in BD than in TA. Stenosis (89.8% vs 60%, $P=0.000$) and occlusion (65.5% vs 32%, $P=0.000$) were more frequently observed in patients with TA than in those with BD. In contrast, BD patients were more likely to have aneurysmal lesions (62% vs 20.9%, $P=0.000$). In terms of the site of vascular lesions, subclavian artery (71.4% vs 16%, $p=0.000$), carotid artery (73.3% vs 30%, $p=0.000$), descending aorta (35% vs 12%, $p=0.002$), brachiocephalic trunk (13.6% vs 2%, $p=0.020$), superior mesenteric artery (18.4% vs 4%, $p=0.012$) and renal artery (23.8% vs 10%, $p=0.032$) were more commonly involved in TA, whereas femoral artery (10% vs 2.4%, $p=0.027$) was more frequently involved in patients with BD.

Conclusion: TA patients differ from BD patients with arterial involvement in terms of clinical features and vascular involvement pattern.

Table 1. Angiographic findings in TA and BD with arterial involvement

	Stenosis		Occlusion		Dilatation		Aneurysm	
	TA (n=206)	BD (n=50)	TA (n=206)	BD (n=50)	TA (n=206)	BD (n=50)	TA (n=206)	BD (n=50)

Is the Number of IgG4+ Plasma Cells Observed By Immunostaining Important Beyond Its Diagnostic Utility in IgG4-Related Disease?

Eduardo Martín Nares¹, Jacobo Guerrero Castillo², Arturo Angeles Angeles² and Gabriela Hernandez-Molina¹,

¹Department of Immunology and Rheumatology, Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico City, Mexico, ²Department of Pathology, Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico City, Mexico

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Vasculitis Poster II: Behçet's Disease and IgG4-Related Disease

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The histopathological findings in IgG4-related disease (IgG4-RD) includes the presence of dense lymphoplasmacytic infiltrate, obliterative phlebitis, storiform fibrosis and the presence of marked IgG4+ plasma cell infiltration observed by immunostaining. The latter has been used in clinical practice only as a diagnostic tool. Whether

the number of IgG4+ plasma cells in tissue is associated with any clinical or serological feature has not been previously evaluated. The purpose of this study was to evaluate if the grade of IgG4+ plasma cell infiltration is associated with any clinical or serological outcome.

Methods: We included patients with biopsy proven IgG4-RD according to the Comprehensive Diagnostic Criteria (definitive and probable IgG4-RD) who regularly attended a tertiary referral center in Mexico City (2000-2017). We collected demographics, clinical (organ involvement, relapses and the disease activity assessed by the IgG4-RD Responder Index [IgG4-RD RI] at baseline) as well as baseline laboratory data (C3, C4, total eosinophil count, IgG4 levels). Patients were divided in three groups according to the number of IgG4+ plasma cells in biopsies as follows: <50 IgG4+ plasma cells/HPF, 50-100 IgG4+ plasma cells/HPF, and >100 IgG4+ plasma cells/HPF.

Results: We included 30 patients, 17 (56.6%) women, mean age 53 ± 13.9 years and median disease duration 13 months. The biopsies were from the following tissues: lacrimal gland (n=6), pancreas (n=5), orbit (n=4), kidney (n=4), lymph node (n=3), mediastinum (n=2), salivary gland (n=2) and other tissues (n=4). Eleven patients (36.6%) had <50 IgG4+ plasma cells/HPF, 9 patients (30%) 50-100 IgG4+ plasma cells/HPF and 10 (33.3%) patients >100 IgG4+ plasma cells/HPF. We did not find any difference regarding age, gender, time of follow up, number of involved organs and relapses. The median baseline IgG4-RD RI was 9, 6 and 15, for the <50 IgG4+ plasma cells/HPF, 50-100 IgG4+ plasma cells/HPF, and >100 IgG4+ plasma cells/HPF groups respectively, however, there was not a statistical difference. The group with >100 IgG4+ plasma cells/HPF had more frequently lymphadenopathy when compared with the other groups (36.4%, 66.7% and 80%, $p=0.02$; respectively) while the proportion of involvement of the remaining anatomic sites were similar. We found a statistical difference in serum C3 levels (99.5 mg/dl, 159 mg/dl, 78.5 mg/dl, $p=0.04$) and a tendency for serum C4 levels (20 mg/dl, 27 mg/dl, and 6 mg/dl, $p=0.08$) among the groups with >100 and ≤ 100 IgG4+ plasma cells/HPF, respectively; whereas the levels of serum IgG4 and the eosinophil count were similar. The C3 and C4 serum levels negatively correlated with the basal IgG4-RD RI ($t=-0.48$, $p=0.005$ and $t=-0.58$, $p=0.001$).

Conclusion: Our results show that the number of IgG4+ plasma cells observed by immunostaining in IgG4-RD may be of value in identifying a subset of patients with hypocomplementemia, lymphadenopathy and higher baseline disease activity. The finding of an association between hypocomplementemia and higher tissue infiltration by IgG4+ plasma cells expands the evidence that complement activation may contribute to the pathogenesis of IgG4-RD.

Shear Wave Elastography in the Evaluation of Submandibular Gland Characteristics in IgG4-Related Disease

Keisuke Nishimura, Keiichiro Kadoba, Hiroki Mukoyama, Rintaro Saito, Daisuke Waki and Toshihiko Yokota, Department of Endocrinology and Rheumatology, Kurashiki Central Hospital, Kurashiki, Japan

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Vasculitis Poster II: Behçet's Disease and IgG4-Related Disease

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: IgG4-related disease (IgG4RD) is a chronic and systemic disease that can involve multiple organs. One of the most commonly involved organs are the salivary glands. Shear wave elastography is an ultrasonography technique that provides an estimate of tissue elasticity. We present the salivary gland sonographic findings in IgG4RD patients.

Methods: We retrospectively investigated the salivary gland sonographic features of IgG4RD patients who fulfilled the diagnostic criteria for IgG4RD. Salivary gland ultrasonography was performed in our hospital from April 2016 to April 2018. We assessed sex, age, symptoms, and ultrasonographic findings. Shear wave elastography was performed in 9 patients with IgG4RD, 33 patients with Sjogren syndrome and 13 healthy controls. Mean shear wave velocity (SWV) in m/s was compared between IgG4RD patients, Sjogren syndrome patients and healthy controls.

Results: The mean age of IgG4RD patients was 69.7 ± 8.58 years old. From 11 IgG4RD patients (7 males and 4 females), 7 patients had multiple hypoechoic lesions in the submandibular glands. Only one IgG4RD patient had multiple hypoechoic lesions in the parotid glands. For the submandibular glands, mean SWV was significantly higher in the active IgG4-related sialadenitis group than in the stable IgG4RD group (2.54 ± 0.92 vs 1.58 ± 0.29 , $p < 0.001$). A significant decrease in both SWV and the volume of the glands was also observed in active IgG4-related sialadenitis patients who achieved remission ($p < 0.01$, $p < 0.05$, respectively). For the submandibular glands, mean SWV values were significantly

Submandibular shear wave velocity in IgG4-related disease patients.

Changes in submandibular shear wave velocity in IgG4-related disease patients.

higher in the active IgG4-related sialadenitis group than in the Sjogren syndrome group (2.54 ± 0.92 vs 1.54 ± 0.24 , $p < 0.001$), and in the active IgG4-related sialadenitis group than in the healthy controls (2.54 ± 0.92 vs 1.66 ± 0.27 , $p < 0.001$), respectively.

Conclusion: Changes in the submandibular glands affected by IgG4-RD could be easily detected using ultrasonography. Shear wave elastography of submandibular gland may contribute to the evaluation of disease activity in IgG4-related sialadenitis.

Retrospective Analysis of IgG4-RD Patient Population at the Cleveland Clinic between 2007-2017

Chan Mi Lee¹, Mohamed Alalwani², Richard Prayson^{1,3} and Carmen E. Gota^{1,4}, ¹Education, Cleveland Clinic Lerner College of Medicine of Case Western Reserve University, Cleveland, OH, ²Hospital Medicine, Cleveland Clinic, Cleveland, OH, ³Anatomic Pathology, Cleveland Clinic, Cleveland, OH, ⁴Orthopedic and Rheumatologic Institute, Cleveland Clinic, Cleveland, OH

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Vasculitis Poster II: Behçet's Disease and IgG4-Related Disease

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: IgG4-related disease (IgG4-RD) is a rare multisystem fibro-inflammatory condition, characterized by organ mass lesions, IgG4+ lymphoplasmacytic infiltrate, and storiform fibrosis. To gain better understanding of its prevalence, clinical presentation, and outcomes of treatment, we conducted a retrospective study of patients with IgG4-RD at Cleveland Clinic.

Methods: The Cleveland Clinic pathology database search for IgG4 staining between 2007-2017 found 1,481 results. Of 119 cases positive for tissue IgG4+plasma cells ≥ 10 and/or IgG4/IgG plasma cells ratio $>40\%$, 57 cases were classified as highly likely (N=28; 49%) if they met at least two of three pathology criteria of lymphoplasmacytic infiltration, fibrosis, and obliterative phlebitis, or probable IgG4-RD (N=29; 51%) if they met only one criteria. Serum IgG4 levels were available in only 15 patients, thus this criterion was not used for classification. Patients' age, gender, type of treatment, and outcome were retrieved from medical records. Patients were designated as being in "remission" if indicated in the chart and/or symptom and objective findings-free for >6 months, "relapsed", if symptoms/findings recurred following remission, "active" if no remission was achieved during follow up, and as "unable to determine" if duration of follow-up was <60 days or lost to follow up.

Results: Of 57 patients, 63% were males, age 57.9 ± 14.8 years, 57.9% were white, 26.3% African-American, 1.8% Asian, 1.8% multi-racial and 12.3% unknown. The average follow-up was 2.7 ± 2.2 years. Organs involved were pancreas (26.4%), salivary glands (8.8%), lacrimal glands (7%), biliary ducts (7%), aorta (7%), thyroid (5.3%), orbit (3.5%), lung (3.5%), lymph nodes (1.8%), and others (24.6%). On histopathologic examination, 94.7% had lymphoplasmacytic infiltration, 68.4% fibrosis, 31.6% obliterative phlebitis, and 14 patients (24.6%) met all three criteria. Eosinophilic infiltration was present in 8 patients (14%). Average IgG4+ plasma cell count was 49.7 ± 36.2 /hpf. Almost half of the patients (45.6%; N=26) were managed surgically, 21.1% (N=12) medically only, and 24.6% (N=14) received both. Medical treatment included prednisone (45.6%), methotrexate (5.3%), azathioprine (7%); 58.3% of patients took more than one medication, and 5 patients received rituximab (8.8%). Remission was achieved by 52.6% of surgical, 21.1% of medical, and 26.3% of recipients of both treatments. Two of five patients treated with Rituximab achieved remission, during the follow up period of 2.39 (0.33-6.46) years.

Conclusion: In this retrospective study, one of the largest to date, we confirm that IgG4-RD is more common in middle age/elderly men. Only about half of the cases who met the IgG4 staining criteria satisfied the IgG4-RD histopathology criteria. Pathology findings were variable, with only half of the patients having at least two of the characteristics of lymphoplasmacytic infiltration, fibrosis and obliterative phlebitis, and a quarter displaying all three. These results underline the difficulty of making a definitive diagnosis of IgG4-RD. In our cohort, surgical treatment compared to medical treatment appeared to be more successful in achieving remission.

Cigarette Smoking Is a Risk Factor for IgG4-Related Disease

Rachel Wallwork¹, Hyon K. Choi², Cory A. Perugino³, Yuqing Zhang⁴, John H. Stone⁵ and Zachary Wallace⁶, Department of Medicine, Massachusetts General Hospital, Boston, MA, ²Division of Rheumatology, Allergy, and Immunology, Massachusetts General Hospital, Boston, MA, ³Ragon Institute of MGH, MIT and Harvard, Cambridge, MA, ⁴Department of Rheumatology, Allergy and Immunology, Massachusetts General Hospital, Boston, MA, ⁵Rheumatology Medicine, Massachusetts General Hospital, Harvard Medical School, Boston, MA, ⁶Division of Rheumatology, Allergy and Immunology, Massachusetts General Hospital, Harvard Medical School, Boston, MA

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Vasculitis Poster II: Behçet's Disease And IgG4-Related Disease

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: IgG4-related disease (IgG4-RD) is a fibroinflammatory condition characterized by tumefactive lesions that can occur at nearly any site, often associated with an elevated serum IgG4 concentration. Despite advances in the recognition and treatment of IgG4-RD, its etiology and pathogenesis remain unknown. Prior studies suggest that cigarette smoking may be a risk factor for IgG4-RD. We performed a case-control study to evaluate the association between cigarette smoking and the risk of IgG4-RD.

Methods: All patients seen in the Center for IgG4-RD at Massachusetts General Hospital who were diagnosed with IgG4-RD between 2010 and 2018 and completed a smoking questionnaire were included in this study. Participants in the Partners HealthCare Biobank who completed a smoking questionnaire (N=30,536) were used as a source of controls. For each case and control, a smoking status (never, former, current) was determined. Each case was matched to up to 5 controls based on age (5-year category) and sex. We used conditional logistic regression to compare the proportion of cases and controls with a history of cigarette smoking using odds ratios (OR) and 95% confidence intervals (CIs).

Results: We identified 194 IgG4-RD cases which were matched to 970 controls (**Table 1**). The mean age for cases and controls was 57 years (± 13) and 57 years (± 13), respectively, and the majority of patients were male (62% and 62% in both groups). There was a greater proportion of current and former smokers among IgG4-RD cases (Current=23 [12%], Former=58 [30%]) compared with controls (Current=72 [7%], Former=211 [22%]). Compared with controls, IgG4-RD cases had nearly a two-fold higher odds of being current smokers (OR 1.85 [95% CI 1.11-3.07]) or former smokers (OR 1.66 [95% CI 1.16-2.39]). The association between cigarette exposure and the risk of IgG4-RD seemed to be driven by a strong association among the subgroup of patients with retroperitoneal fibrosis (RPF, 16% of cases) (OR 4.91 [95% CI 1.81-13.34]).

Conclusion: In this case-control study of patients with IgG4-RD, current and former smoking statuses were strongly associated with the risk of IgG4-RD, especially among IgG4-RD patients with RPF. Biologically, cigarette smoking is known to stimulate fibrogenesis, a key feature of IgG4-RD. While these findings require additional confirmation, cigarette smoking may be the first recognized modifiable risk factor for IgG4-RD. Further research is necessary to understand the mechanism by which smoking increases the risk of IgG4-RD. Patients with IgG4-RD may need to be counseled against smoking.

Table 1. Association Between Cigarette Smoking and Risk of IgG4-RD

	IgG4-RD (N [%])	Controls (N [%])	OR (95% CI)
All			
Current Smoker	23 (12%)	72 (7%)	1.85 (1.11-3.10)

Salivary Gland Disease in IgG4-Related Disease Is Associated with Allergic Histories

Samantha Sanders¹, Emanuel Della Torre², Cory A. Perugino³, Aidan Long⁴, Hyon K. Choi⁴, John H. Stone⁵ and Zachary Wallace⁶, ¹Harvard Medical School, Boston, MA, ²Unit of Medicine and Clinical Immunology, San Raffaele Scientific Institute, Milan, Italy, ³Ragon Institute of MGH, MIT and Harvard, Cambridge, MA, ⁴Division of Rheumatology, Allergy, and Immunology, Massachusetts General Hospital, Boston, MA, ⁵Rheumatology Medicine, Massachusetts General Hospital, Harvard Medical School, Boston, MA, ⁶Division of Rheumatology, Allergy and Immunology, Massachusetts General Hospital, Harvard Medical School, Boston, MA

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Vasculitis Poster II: Behçet's Disease And IGG4-Related Disease

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The etiology of IgG4-related disease (IgG4-RD) remains unknown. The role of T-helper type 2 (Th2) cells in the pathogenesis of IgG4-RD is controversial. Given Th2 cells' involvement in allergic responses and prior IgG4-RD studies suggesting their importance in the pathogenesis, it has been hypothesized that allergic mechanisms contribute to the development of IgG4-RD. We investigated the association between allergies and IgG4-RD.

Methods: The Center for IgG4-RD at Massachusetts General Hospital maintains a database of all IgG4-RD patients, including details of demographics and disease history. Allergy histories were obtained from patients via a 34-question allergist-developed survey administered at their baseline visit. Patients were considered to have a history of allergies if they reported prior symptoms or diagnosis. We included all patients who completed the allergy survey; for certain analyses, some patients were excluded because of missing data. Statistical significance was determined by Fisher's exact test or unpaired t-test, as appropriate. P values < 0.05 were considered significant.

Results: Our study included 185 IgG4-RD patients from a database of 289 patients. Of the 185 patients, 140 (76%) reported any allergic symptom or diagnosis (**Table 1**). There was no significant difference with regard to age (P=0.1) or sex distribution (P=0.7) between patients with and without allergy symptoms. Skin allergies (41%), food allergies (20%), and anaphylaxis (8%) were less common than respiratory allergies (61%) in IgG4-RD. Patients with allergies tended to have any ear, nose, and throat (ENT) manifestations of IgG4-RD more often than those who did not have allergies (55% vs 36%, P=0.058). This trend was largely driven by a significant difference in the proportion of patients with salivary gland IgG4-RD (e.g., sialoadenitis) among those with allergies compared with those without a history of allergies (41% vs 22%, P=0.03). We found a similar difference when comparing salivary gland involvement between those with and without respiratory allergies (72% vs 28%, P=0.039).

Conclusion: In a large IgG4-RD cohort, we found a significant association between IgG4-related salivary gland disease and allergic histories. More generally, we found a trend towards an association between ENT involvement and allergic histories. Of the reported allergies, respiratory allergies were most common. Respiratory allergies appear more prevalent in this cohort than the general US population: 61% of cohort patients reported a history of respiratory allergies, compared to 30% of Americans who completed a similar survey (*Allergy Asthma Proc* 2008; 29:600). While it is possible that shared pathogenesis is responsible for these observations, a shared upper respiratory exposure may also explain our observations given the associations between head and neck disease with allergic histories.

Table 1. Characteristics of IgG4-RD relative to history of allergies

	All	History of any allergies*	No history of allergies	P-value
N	185 (100%)	140 (76%)	45 (24%)	
Age (yrs)				
Age at first visit, mean ± SD	57.2 (±14.7)	56.8 (±15.0)	58.7 (±13.5)	0.096
Age distribution				
<20	5 (3%)	5 (4%)	0 (0%)	
20-29	4 (2%)	3 (2%)	1 (2%)

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Vasculitis Poster II: Behçet's Disease and IgG4-Related Disease

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: IgG4-related disease (IgG4-RD) is a fibroinflammatory condition that may involve essentially any organ. The disease spectrum is also often associated with elevated serum IgG4, and thus serum IgG4 level remains an important biomarker in the diagnosis and monitoring of IgG4-RD. Immunonephelometry is the most common method used internationally to measure IgG4 (and other IgG subclass) levels, with IgG4 test results varying by reagent vendor. Mass spectrometry is a less costly approach pioneered at our institution with fewer errors in the measurement of other subclasses as compared to nephelometry. In this study, we aim to determine the difference in the Binding Site immunonephelometry (BSIN) method and liquid chromatography tandem mass spectrometry (LC-MS/MS), with regard to the respective clinical test characteristics for the diagnosis of IgG4-RD.

Methods: This retrospective chart review study was approved by the Research Ethics Board at the University of British Columbia. IgG subclass data was retrieved from the laboratory for the period from December 2011 to December 2017. BSIN was the method in use between December 2011 and September 2016, and LC-MS/MS was the method in use from September 2016 to December 2017. For both assays, elevated IgG4 levels were defined as any value above the upper limit of the reference range 1.25 g/L, with both methods calibrated to the same standard. Cases of IgG4-RD were defined as those with histopathologic findings meeting consensus guidelines for IgG4-RD and non-biopsy proven, but possible IgG4-RD cases, were excluded. Only the first IgG4 level at baseline and off of treatment were reported for a given patient using each method. Test performance characteristics were compared using the Fisher exact test.

Results: In total there were 908 IgG4 subclasses measured. For BSIN, there were 33 IgG4-RD positive cases and 161 disease negative cases. For LC-MS/MS, there were 27 IgG4-RD positive cases and 105 disease negative cases. The IgG4-RD patients in the BSIN group were a mean age of 62 ± 13 years and for LC-MS/MS it was 64 ± 11 years and the sexes were well-matched (2.3:1 versus 2:1 M:F ratio, respectively). False positive diagnoses were comparable between BSIN and LC-MS/MS IgG4 measurements with hypereosinophilic syndrome (n=4; n=1), hypergammaglobulinemia (n=4; n=3) and connective tissue disease (n=3; n=2) being the most common, respectively. The specificity of both BSIN and LC-MS/MS was 85%. Sensitivity was 81% for BSIN and 70% for LC-MS/MS. Positive and negative predictive values, respectively, were 53% and 96% for BSIN and 54% and 92% for LC-MS/MS. The sensitivity and specificity of BSIN versus LC-MS/MS were equivalent ($p=0.36$, $p=1.0$).

Conclusion: Not surprisingly, since the two methods are calibrated to the same standard for IgG4, they have similar sensitivity and specificity for the diagnosis of IgG4-RD. Given the potential advantages, a lower incidence of measurement errors, and a lower cost, the LC-MS/MS could be considered instead of BSIN where possible.

Results: We analyzed 214 mimickers. IgG4-RD, Erdheim-Chesterdisease (ECD), Rosai-Dorfman disease (RDD) and multicentric Castleman's disease (MCD) were male predominant, whereas SS, vasculitis, lymphoma and sarcoidosis tended to be female predominant (**Table 1**). IgG4-RD, lymphoma and GCA tended to have an older age of onset compared with SS, ANCA-associated vasculitis (AAV) and other mimickers. Organ involvement differed by mimicker, as expected. Submandibular gland involvement was equally common in IgG4-RD and SS, but isolated parotid involvement was more typical of SS and lacrimal gland more characteristic of IgG4-RD. Lymphadenopathy, serum IgG4 elevations,

[illegible]

lymphoplasmacytic infiltrates and significant IgG4+ cell infiltrates were observed in many mimickers. Exclusion criteria were crucial to differentiating mimickers from IgG4-RD despite these similarities. 91.1% of mimickers fulfilled exclusion criteria as compared to only 7.1% of IgG4-RD cases (Table 2). Ro or La excluded 78.7% of SS cases. In AAV, ANCA, fever and necrotizing vasculitis on pathology excluded IgG4-RD in 81.2%, 71.0% and 52.2% of cases, respectively. In lymphoma, rapid radiographic progression, splenomegaly and a malignant infiltrate on pathology excluded IgG4-RD in 45.5%, 27.3% and 100% of cases, respectively. Exclusion by pathology (71.4-100%) was vital in separating ECD, MCD, RDD and sarcoidosis from IgG4-RD.

Conclusion: IgG4-RD and mimickers share many features, including demographics, organ involvement and elevated serum IgG4 levels. Exclusion criteria were critical to the 2018 ACR/EULAR classification criteria development, identifying key features that distinguish IgG4-RD from its mimickers. These clinical, serologic, radiologic and pathology features serve as a useful guide for clinicians considering the IgG4-RD differential.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Vasculitis Poster II: Behçet's Disease and IgG4-Related Disease

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Immunoglobulin G4-related disease (IgG4-RD) is a systemic, immuno-mediated fibro-inflammatory disease that affects various organ systems, with typical pathological findings and increased IgG4 levels. Glucocorticoids are the first-line of treatment however relapse rates are high and our knowledge is limited regarding the effects of immunosuppressives. Case reports on rituximab efficacy in the treatment of IgG4-RD are published in addition to an open-label pilot study. The objective of this study was to evaluate the efficacy and safety of treatment with rituximab in 10 subjects diagnosed with IgG4-RD and followed-up in our clinic.

Methods: This study retrospectively investigated the demographic data, clinical features, laboratory findings, immunosuppressive therapies and the outcomes in 10 subjects who had been followed in our clinic for at least 6 months and met the diagnostic criteria for IgG4-RD by clinical, serological and/or tissue biopsy findings and received at least one course of treatment with rituximab (1000 mg twice two weeks apart). IgG4-RD Response Index (IgG4-RD RI), PET-CT and acute phase reactants were used for disease activity evaluation. 8 subjects receiving rituximab treatment had an exacerbation of the disease under low-dose prednisolone therapy and conventional immunosuppressive treatments. In 2 subjects, rituximab was the first choice of immunosuppressive treatment in addition to prednisolone therapy.

Results: IgG4-RD patients had a mean age of 55 years (43-63; 8 male/2 female) and the mean follow-up period was 47 months. Aortitis-chronic periaortitis was found in 8 subjects followed for IgG4-RD, renal involvement in 4, hepatobiliary-pancreatic involvement in 3, and pericardial and pulmonary involvement in 2. The mean IgG4 level was 519.5 mg/dL (145-1160) and IgG4-RD RI was 10.9 (6-21) at the time of diagnosis. The median follow-up period after the first course of rituximab was 18 months (12-24). Remission was achieved in 9 of 10 patients treated with rituximab and the mean daily prednisolone dosage was reduced to below 5 mg/day. Prednisolone therapy was permanently discontinued in 2 subjects. The unresponsive case had membranous glomerulonephritis. After treatment, the mean IgG4 level was 51.3 mg/dL (6-145) and IgG4-RD RI was 1.2 (0-7). No exacerbation was observed during the follow-up period in 9 subjects in whom remission was achieved, and rituximab was repeated as a maintenance therapy at 6 months of treatment. The subject who had severe nephrotic syndrome during follow-up and was given high-dose prednisolone plus cyclosporine in addition to rituximab treatment died due to pneumonia at 6 months of treatment.

Conclusion: The case series for which the retrospective data are presented, consist mainly of patients managed by rheumatology with predominant involvement being aortitis/periaortitis. Rituximab treatment was found to be effective in

terms of achieving and preserving remission, and reducing glucocorticoid doses although retreatment is often necessary. No safety issues that require discontinuation of treatment were identified in this group of patients except a case of severe infection with nephrotic syndrome

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Vasculitis Poster II: Behçet's Disease and IgG4-Related Disease

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Pathology associated with IgG4-related disease (IgG4-RD) has been described in virtually every tissue and organ of the body. The heterogeneous clinical manifestations of IgG4-RD are a consequence of the variation in clinical presentation for any given IgG4-RD patient. The clinical presentation in early IgG4-RD is rarely definitive especially in the absence of more obvious manifestations such as pancreatitis. For example, more apparent clinical presentations such as swollen salivary glands and lymph nodes, swollen eyelids, and intraocular discomfort may not be readily diagnosed as IgG4-RD. When combined with prevalent tumefactive modules in the lung and/ spleen, all of these clinical manifestations are diagnostic for IgG4-RD. Swelling or nodules of multi-sites combined with histopathological features of tumefactive lesions and laboratory examinations to exclude neoplasm and infection may improve better and more rapid diagnosis of IgG4-RD. Given the propensity of IgG4-RD to progressively affect more tissues and organs, the latter concern is critical.

Methods: We retrospectively examined the clinical and laboratory records for 59 patients with definite IgG4-RD collected from all departments of West China Hospital between January 2012 and December 2017.

Results: A total number of 59 patients were enrolled, including male 41 (70%), female 18 (31%). The maximum and minimum onset age were 85 and 15 respectively. The majority of patients had multiple sites and/or organs involved: 90% of patients were suffering from 3 and more sites or organs affected; 8.5% of patients, 2 sites or organs involved; and only 1.7% with single site or organ involvement. The mostly commonly recorded pathologies involved sites were lung, manifested as small nodules (71%) and lymph nodes (54%). Other involved sites included: salivary glands (42%) which included submandibular (29%), parotid (12%), and labial (1.7%) glands; kidney (36%); pancreas (32%); periorbital tissues (31%) including intraorbital lesions (14%) and swollen eyelids (17%); liver (27%); biliary tree (19%); spleen (15%); nasal sinus (15%); lacrimal glands (15%); and thyroid glands (14%). Other involved tissues included gastrointestinal tract, skin, glottis/pharynx, peritoneum, pericardium, pleura, and large arteries (3.4-8.5%). Rarely involved sites were gingiva, spine, pituitary glands, and mediastinum (1.69%). Elevated serum IgG4 was found in 44 (75%) patients, and antinuclear antibody in 17 (29%) of patients.

Conclusion: Almost any tissue or organ can be affected in IgG4-RD. The most commonly involved organs identified in this retrospective study were lung, lymph node, salivary glands, kidney, and pancreas, respectively. Clinical manifestations may be more obvious with pancreatitis and enlarged lymph nodes; however, small nodules in lung, liver and spleen may be overlooked due to the absence of accompanying symptoms. Our goal is to increase awareness among physicians in general that tumefactive lesions in any site or organ, especially if they occur in multiple tissues or organs, in asymptomatic early stage disease may be indicators for diagnosis of IgG4-RD.

Abstract Number: 1788

Predictive Factors for Work-Day Loss in a Multi-Center Study in Behçet's Disease: Indirect Costs for Healthcare

Haner Direskeneli, Rheumatology, Marmara University, School of Medicine, Istanbul, Turkey

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Vasculitis Poster II: Behçet's Disease and IgG4-Related Disease

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: In chronic diseases, work-day loss due to health problems is associated with indirect costs for healthcare management. The aim of this multi-center study is to assess predictive factors for work-day loss as a productivity measure in Behçet's disease (BD).

Methods: In this cross-sectional, multi-center study, 834 BD patients (F/M: 441/393, mean age: $38,4 \pm 10,9$ years) were included. Data were collected by a questionnaire regarding organ involvement, treatment protocols, disease duration (less than 5 years vs ≥ 5 years), smoking pattern, frequency of medical visits/ during the previous year (>4 visits vs ≤ 4 visits) and self-reported work-day loss during the previous year. Cut-off points of these variables were calculated according to median levels for the binary logistic regression analysis.

Results: Work-day loss was observed in 16,2% of the group ($n=135$). The majority of these patients were males ($n=103$, 76,3%). The mean work-day loss was $30,8 \pm 57,7$ days (1-365 days) and was higher in males ($31,7 \pm 54,2$ vs $27,9 \pm 68,8$ days, $p=0.007$). The mean age and disease duration were lower ($34,3 \pm 8,4$ and $7,04 \pm 6,04$ years, respectively) in patients with work-day loss compared to others during the previous year ($39,2 \pm 11,2$ and $9,4 \pm 7,8$ years, respectively, $p<0.0001$). Increase in the work-day loss was prominent in patients with vascular involvement ($19M/1F$, $56,1 \pm 85,9$ vs $26,4 \pm 50,6$ days) ($p=0.046$), whereas no similar relationship was observed with any other organ involvement. Being a smoker (OR:1,7), disease duration less than 5 years (OR:2,05), male gender (OR:3,9) and more than 4 visits/previous year (OR:2,5) were found to be predictive factors for work-day loss according to binary logistic regression analysis ($p<0.05$).

Conclusion: Work-day loss was associated with vascular involvement in our study. Male gender, increase in the frequency of visits, being a current smoker and early period of the disease were predictive factors for work-day loss in patients with BD.

Abstract Number: 1789

Mucocutaneous Activity Index As a Patient-Reported Outcome Measure in Behçet's Disease: A Multi-Center Study from Turkey

Haner Direskeneli, Rheumatology, Marmara University, School of Medicine, Istanbul, Turkey

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Vasculitis Poster II: Behçet's Disease and IgG4-Related Disease

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Organ-specific patient-reported outcome (PRO) measures may help management decisions of Behçet's disease (BD). The aim of this prospective study was to evaluate the factors associated with the score of mucocutaneous activity index (MI), a validated patient-reported outcome tool, for Behçet's Disease (BD).

Methods: In this study, 834 BD patients (F/M: 441/393, mean age: $38,4 \pm 10,9$ years) followed in twelve tertiary centres from Turkey were included. Validated mucocutaneous activity index (MI) and its subgroup activity indices regarding oral ulcer (OI), genital ulcer (GI) and erythema nodosum (EI) were assessed. Scores of each subgroup were between 0=inactive and 10=very active. Total MI score composed of these subgroups (0-30 points). Transformed Behçet's disease current activity form (BDCAF) was used to evaluate global activity.

Results: Active BD patients (n=567, 67,9%) were mainly in the mild group with mucocutaneous involvement (n=420). Disease duration was lower ($9,7\pm6,9$ vs $11,1\pm8,1$ years, $p=0.001$) and patients were younger ($36,4\pm10,2$ vs $41,9\pm11,2$ years, $p=0.001$) in the active group. The ratio of non-smokers was also higher in active patients (76,1% vs 67,6%, $p=0.011$). A higher MI score was observed in females ($8,2\pm4,6$) compared to males ($7,3\pm3,9$) among active patients ($p=0.023$). It was higher in females ($8,1\pm4,3$) than males ($6,7\pm3,6$) in non-smokers (n=419) ($p=0.002$), whereas a significant relationship was not present in current smokers (n=132, $p=0.85$) with gender. MI score was also higher in patients whose disease durations were less than 5 years ($6,5\pm2,6$) than the others ($4,7\pm4,7$) ($p=0.001$).

Being a non-smoker (OR:1,7), disease duration less than 5 years (OR:2,4) and female sex (OR:1,5) were found as predictive factors for mucocutaneous activity according to binary logistic regression analysis ($p<0.05$). Increases in both MI score and BDCAF score were observed in immunosuppressive (IS) medication group (n=86; $9,6\pm5,3$; $6,6\pm2,9$) compared to non-IS group (n=316; $7,7\pm4,1$; $5,5\pm2,5$) in active patients with mucocutaneous involvement ($p=0.001$ and $p=0.008$).

Conclusion: Female gender, smoking and disease duration were associated with higher MI scores in our study. An organ-specific and reliable PRO measure such as mucocutaneous index might be a candidate scale for future clinical studies and clinical follow-up of mucocutaneous manifestations in BD patients.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Vasculitis Poster II: Behcet's Disease and IgG4-Related Disease

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Efficacy of current management approaches for oral ulcer treatment in routine clinical practice is insufficiently explored in Behcet's disease (BD) patients. The aim of this multi-national study was to assess whether an unmet need for oral ulcer activity is present in patients with Behcet's disease.

Methods: Behcet's disease (n=197) patients from Jordan (n=50), Brazil (n=46), United Kingdom (n=41) and Turkey (60) (F/M: 100/97, mean age: $40,7\pm11,6$ years) were included in this cross-sectional study. Data were collected by a questionnaire regarding oral ulcer activity during the previous month, treatment protocols and smoking patterns. Transformed BDCAF score was used to evaluate the general disease activity during the last month.

Results: In the whole BD group, 41,1% (n=81) of patients were treated with non-immunosuppressive medications (non-IS) and 53,3% (n=105) by ISs, irregular medication use/no medication was observed in 5,6% (n=11). The number and healing time of oral ulcers were $3,3\pm3,2$ and $6,5\pm4,6$ days, respectively in patients with active oral ulcers (n=114, 57,9%). The number of oral ulcers were significantly higher in patients treated with non-IS medications ($4,04\pm3,9$) and non-smoker patients ($3,6\pm3,4$) than those treated with ISs ($2,5\pm2,1$) and current smokers ($2,3\pm2,1$) ($p<0.0001$ and $p=0.021$, respectively). In binary logistic regression, non-IS medication use was found to be a predictive factor for oral ulcer activity (OR:2,3; $p=0.011$). Transformed BDCAF score was also lower in patients treated with ISs ($4,02\pm3,5$) than those using a non-IS treatment protocol ($6,6\pm3,1$) ($p=0.009$).

Conclusion: Since oral ulcer activity and global activity assessed by BDCAF were higher in patients treated with non-IS medications, an 'unmet need' was observed with milder, non-IS-based treatment protocols in a multi-national setting of clinical practice in BD patients.

SESSION INFORMATION

Session Date: Monday, October 22, 2018
Session Title: Vasculitis Poster II: Behçet’s Disease and IgG4-Related Disease
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Behçet’s syndrome is a chronic, multi-systeminflammatory disorder characterized by recurrent oral ulcers (OU) that can bedisabling and negatively affect quality of life. Apremilast (APR), an oralphosphodiesterase 4 inhibitor that modulates inflammatory pathways, has demonstratedefficacy in the treatment of OU of Behçet’s syndrome in a phase III, multicenter,randomized, double-blind, placebo (PBO)-controlled study (RELIEF).

Methods: In this phase III, multicenter study,adult patients with active Behçet’s syndrome (with ≥3 OU at randomizationor ≥2 OU at screening + randomization, without active major organinvolvement) were randomized (1:1) to receive APR 30 mg BID or PBO BID for 12weeks followed by a 52-week active-treatment phase. The primary endpoint was area under the curvefor total number of OU over 12 weeks (OU AUC_{Wk0-12}). AUC reflectsthe change in the number of OU over time, accounting for the clinicalcharacteristic that OU repeatedly remit and recur. In a planned analysis, OUAUC_{Wk0-12} was examined among subgroups of patients defined by BLdemographics and disease characteristics.

Results: A total of 207 patients were randomized and received ≥1 dose of study medication (APR:n=104; PBO: n=103). At BL, mean numbers of OU were 4.2 for APR and 3.9 for PBO. At Week 12, least-squares mean OU AUC_{Wk0-12} (LSmean ±SE) was significantly lower in patients receiving APR vs. PBO (129.5 ± 15.9 vs. 222.1 ±15.9; P<0.0001). A treatment effect in favor of the APR treatment group vs. PBO was observed for AUC_{Wk0-12} for OU counts in each of the

prespecified subgroups examined. A favorable treatment effect was observed for each demographic subgroup, BL disease characteristic (including duration of disease and BL OU count), geographic region, and prior use of colchicine and corticosteroids (Figure). The incidence of adverse events (AEs) was comparable between APR and PBO (78.8% and 71.8%, respectively). The most common AEs were diarrhea, nausea, headache, and upper respiratory tract infection; most AEs were mild or moderate in severity.

Conclusion: Subgroup analyses of the AUC for the number of OU from BL through Week 12 demonstrated the consistent efficacy of apremilast in all of the subgroups analyzed. The safety profile was consistent with the known safety profile of APR.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Vasculitis Poster II: Behçet's Disease And IgG4-related disease

Session Type: ACR Poster session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Behcet's syndrome (BS) is most active during young adulthood and working years, thus affecting productivity. Work disability was previously reported especially among BS patients with eye, vascular and joint involvement.

	Behçet's syndrome (n=125)	Ankylosing spondylitis (n=90)	Healthy controls (n=30)
Male, n (%)	103 (82)	25 (82)	18 (60)
Mean (SD) current age	36.3 ± 7.8	36.7 ± 8.9	37.9 ± 6.3
Mean (SD) disease duration	8.1 ± 5.7	8.1 ± 5.7	N/A
WIS (mean±SD)	12.2 ± 3.8	11.8 ± 5.0	8.1 ± 4.3
WPAI-Absenteeism (mean±SD)	10.0 ± 18.6	7.7 ± 18.1	1.7 ± 7.0
WPAI-Presenteeism (mean±SD)	17.0 ± 13.9	17.3 ± 14.8	9.3 ± 23.0
WPS-Absenteeism (mean±SD)	1.8 ± 4.2	1.3 ± 3.4	0.1 ± 0.3
WPS-Presenteeism (mean±SD)	4.2 ± 7.0	4.1 ± 6.2	1.7 ± 3.3
BDCAF (mean±SD)	4.1 ± 2.7	N/A	N/A
BSAS (mean±SD)	20.5 ± 17.0	N/A	N/A
BDQoL (mean±SD)	19.7 ± 8.2	N/A	N/A
BASDAI (mean±SD)	N/A	3.4 ± 1.7	N/A
BASFI (mean±SD)	N/A	3.0 ± 2.8	N/A

N/A: Not applicable; Behçet Disease Quality of Life: BDQoL; Behçet's Disease Current Activity Index (BDCAI); Behçet's Syndrome Activity Score (BSAS)

In this study, we aimed to evaluate the work productivity and instability of patients with BS compared to ankylosing spondylitis (AS) patients and healthy controls (HC).

Methods: 125 (103 M/22 F) consecutive BS patients who were routinely followed in our dedicated BS center were studied. Patients with AS (30; 25 M/5 F) who were followed in the rheumatology outpatient clinic of our unit and HC (30; 18 M/12 F) were included as controls. Work Productivity and Activity Impairment Questionnaire (WPAI), Work Productivity Survey (WPS), Work Instability Scale (WIS) were used. Quality of life was assessed with the Behcet Disease Quality of Life (BDQoL) scale and disease activity with the Behcet's Disease Current Activity Index.

Results: The mean age of BS patients was 36 ± 7.8 and the mean disease duration was 8.2 ± 5.6 years (Table). 35 of BS patients with only mucocutaneous, 40 with eye, 28 with vascular and 22 with neurologic involvement were included. Among BS patients 42% reported missing work days (mean 1.8 days/mo), and 48% reported that their productivity was reduced at least by half (mean 4.3 days/mo). The mean WIS score was 12.2 (9.8) in BS patients. 59 BS patients had moderate and 18 BS patients had high work instability. Patients with BS had significantly higher absenteeism (10.0% vs. 1.7%), presenteeism (37.0 % vs. 9.3%), and daily activity impairment (26.4% vs. 8.6%) than HCs ($p < 0.001$) assessed by WPAI. Scores were similar between BS and AS patients. WIS and WPS scores were also similar between BS and AS patients and worse than healthy controls. Work impairment was more pronounced in patients with eye involvement compared to mucocutaneous involvement ($p = 0.04$) and there were no differences between other BS groups. The WPAI presenteeism score was moderately correlated with Behcet Disease Quality of Life scale score ($r = -0.57$). Multivariate analysis showed that QoL ($OR = 0.77$, 95% $CI = 0.66-0.88$) and disease activity ($OR = 1.66$, 95% $CI = 1.01-2.50$) were related with WPAI-presenteeism.

Conclusion: Work productivity is impaired in BS patients, especially among those with eye involvement. Work instability is frequent and correlated with disease activity and quality of life.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Vasculitis Poster II: Behçet's Disease and IgG4-Related Disease

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: There is an unmet need for reliable, validated, and widely-accepted outcome measures for clinical trials in Behçet's syndrome (BS). The Outcome Measures in Rheumatology Clinical Trials (OMERACT) Behçet's Syndrome Working Group has worked to advance the creation of a data-driven Core Domain Set for use in all clinical trials.

Methods: The Core Domain Set was developed through a comprehensive, iterative, multi-stage, multi-year project that followed the methodologically rigorous processes and standards set forth by OMERACT: i) a systematic review; ii) a survey among experts in BS; iii) an outcome measures interest group meeting during the International Conference on Behçet's Disease; iv) qualitative patient interviews; v) a three-round modified Delphi exercise involving both patients with BS and a multidisciplinary set of physicians expert in BS, focused on obtaining consensus on the domains of illness necessary in the study of BS; and vi) utilization of the data, insight, and feedback generated by the outlined processes to develop a final Core Domain Set. The final Core Set was presented and put up for a vote of endorsement at the 2018 OMERACT meeting.

Results: All steps in the processes outlined were completed. The systematic review clearly demonstrated the substantial variability in the domains studied in clinical trials of BS and a lack availability of validated outcome measures in BS. The

survey of physicians, the in-person meeting of experts, and the qualitative research with patients all helped generate an extensive list of candidate domains and sub-domains to consider for use in clinical trials. It also became clear that there was a need and strong interest in delineating domains across the several major organ systems involved in this disease and in recognizing that clinical trials in BS often focus on specific manifestations and not the disease in its entirety. The Delphi involved 74 physicians expert in BS from 21 countries and from a wide range of specialties, and 64 patients from 10 countries. The Delphi utilized both ratings and rankings to prioritize the 56 domains and sub-domains originally under consideration.

The final proposed Core Set included 5 sub-domains mandatory for study in all trials in BS, with additional sub-domains mandatory for study of specific organ-systems when that system is the focus of a trial: mucocutaneous (2 additional sub-domains), ocular (4), central nervous system (3), musculoskeletal (2), vascular (4), and gastrointestinal (2). The final Core Set was strongly endorsed at the 2018 OMERACT meeting.

Conclusion: Multiple disease-related domains in BS have been identified by physicians and patients as important to address in clinical trials, leading to the development and endorsement of a final Core Set of Domains for use in clinical trials in BS. The Core Set provides the foundation through which the international research community, including clinical investigators, patients, the biopharmaceutical industry, and government regulatory bodies can harmonize the study of this complex disease, compare findings across studies, and advance development of effective agents.

Venous Vessel Wall Thickness in Lower Extremity Is Increased in Male Behcet's Disease Patients

Fatma Alibaz-Oner¹, Rabia Ergelen², Aydan Mutis³, Zeynep Erturk¹, Ruslan Asadov⁴, Tulin Ergun⁵ and Haner Direskeneli⁶, ¹Rheumatology, Marmara University School of Medicine, Istanbul, Turkey, ²Marmara University School of Medicine, Radiology, ISTANBUL, Turkey, ³Marmara University, School of Medicine, Rheumatology, ISTANBUL, Turkey, ⁴Marmara University School of Medicine, Radiology, Istanbul, Turkey, ⁵Marmara University, School of Medicine, Dermatology, Istanbul, Turkey, ⁶Rheumatology, Marmara University, School of Medicine, Istanbul, Turkey

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Vasculitis Poster II: Behcet's Disease And IGG4-Related Disease

Session Type: ACR poster session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Vascular involvement is seen in up to 40% of the patients with Behcet's Disease (BD), especially in young males and is one of the major causes of mortality and morbidity. Lower extremity vein thrombosis due to vascular inflammation is the most frequent form of vascular involvement in BD. Recently, assessment of vessel wall thickness (VWT) and venous dilatation by US is suggested to be valuable in patients with vascular inflammation. In this study, we investigated whether vessel wall thickness or dilatation is present in young male BD patients prone to venous vascular disease.

Methods: Thirty male patients with BD without major organ involvement and 29 male patients with Vascular BD (VBD) followed in Marmara University Behcet's Clinics, 24 healthy male controls and 27 male patients with ankylosing spondylitis (AS) were included the study. Bilateral lower extremity venous doppler ultrasonography (US) was performed by an experienced radiologist blinded to cases. No patients except VBD were under immunosuppressive treatment. Bilateral common femoral vein (CFV) wall thickness and great/small saphenous vein dilatations were examined. Behcet Syndrome Activity Score (BSAS) was used for the general assessment of disease activity. In 10 patients, CFV wall thickness was measured by 2 different radiologist (RE, RA) in the same day to calculate "inter-observer reliability". Correlation between radiologists was good ($r = 0.765$, $p < 0.001$).

Results: Mean disease duration was 9.1 ± 6 years in patients with BD. BSAS score was 24 ± 17 . All venous measurements were significantly higher in BD compared to AS and healthy controls ($p < 0.001$ for all, Table 1). When we compared mucocutaneous BD (m-BD) vs VBD, all measurements of patients with VBD were higher than m-BD, however only left CFV thickness and width of right great saphenous vein reached statistical significance ($p < 0.001$, and $p = 0.028$, respectively). There were no correlations between BSAS, acute phase reactants and venous wall measurements.

Disclosure: H. Nishikawa, None; Y. Taniguchi, None; S. Inotani, None; M. Kawano, None; Y. Terada, None.

Table 1 Venous wall measurements of lower extremity in study groups.

	Behçet's Disease (n=59)	Ankylosing Spondylitis (n=27)	Healthy Controls (n=28)	P Value
Age, years	32.5 (23-42)	32 (20-37)	31.5 (25-42)	0.23
Body Mass Index (kg/m ²)	25.1 (18-33)	25 (18-32)	23.8 (20-29)	0.213
Right Common femoral VWT (mm)	0.8 (0.04-1.8)	0.3 (0.1-0.6)	0.25 (0.06-0.4)	<0.001
Left Common femoral VWT (mm)	0.8 (0.3-1.6)	0.3 (0.1-0.5)	0.2 (0.04-0.6)	<0.001
Right Great saphenous width (mm)	3.1 (0-6.4)	2.5 (1.1-3.5)	2.1 (1.3-3.5)	<0.001
Left Great saphenous width (mm)	3.1 (0-7.4)	2.6 (0.3-4.8)	2.4 (1.6-3.6)	<0.001
Right Small saphenous width (mm)	2.8 (0-5.3)	1.7 (1-3.1)	1.4 (0.9-3.7)	<0.001
Left Small saphenous width (mm)	2.7 (0-5.2)	1.8 (1.1-3.4)	1.6 (0.8-3.6)	<0.001

VWT: Venous wall thickness

Conclusion: In our study, an increased venous vessel wall thickness in lower extremity was shown in male BD patients with or without vascular involvement. As a similar change was not observed in control groups, increased VWT might be an early sign of venous inflammation in patients with BD rather than a result of non-specific systemic inflammation.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Vasculitis Poster II: Behçet's Disease and IgG4-Related Disease

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Major organ involvement such as vascular or ocular disease, especially in young males, is one of the main causes of mortality and morbidity in Behçet's Disease (BD). However, the prognosis and predictors of major organ involvement is insufficiently studied. We aimed to follow young, male BD patients with only mucocutaneous symptoms which have the highest risk for new major organ involvement prospectively.

Methods: Thirty-six male patients with BD consecutively consulted in the outpatient clinics of Marmara University, Istanbul, 35 males with ankylosing spondylitis and 36 healthy males were included in the study. Bilateral upper and lower extremity venous doppler ultrasonography (US) and brachial and carotid arterial US (for assessing endothelial dysfunction) were performed in baseline visit for all study groups and in the first year follow-up visit for BD patients. Patients with BD were assessed prospectively with 3-6 months intervals and in any urgent visits.

Results: At baseline, the mean disease duration was 3.3 years in patients with BD. The rate of venous insufficiency was higher in male BD patients without vascular events compared to healthy controls (BD vs HC: 30.5% vs 0%) and similar to patients with AS (BD vs AS: 30.5% vs 32%). Markers of endothelial dysfunction (FMD and NID) were similar between BD patients and healthy controls, however CIMT (Carotid intima media thickness) was significantly higher in BD (0.54 mm vs 0.47 mm, p=0.033). The mean follow-up duration was 56.6 months. Major organ involvement developed in 5 (13.8%, 3 vascular and 2 ocular involvement) patients during follow-up. Immunosuppressive (IS) therapy was required in 27% (n=10) of patients, due to major organ involvement in 5 (13.8%), refractory mucocutaneous symptoms in four (11%) and chronic arthritis in one (2.7%) patient. In the first year follow-up visit, endothelial functions and CIMT were observed to be significantly improved compared to baseline (Baseline vs Follow-up: 6.8±4 vs 10.9±4.5, p=0.003 for FMD, 0.55±0.13 vs 0.47±0.1 for CIMT, p=0.004). Patients requiring IS treatment in the follow-up had significantly lower FMD at baseline compared to the rest of the group (4.4 vs 8.5, p=0.005).

Table 1. Clinical characteristics of patients with immunosuppressive need during follow-up

	Reason for IS use	Age at Diagnosis	Disease duration when IS started	IS agent
Patient 1	Pulmonary aneurysm	35	1 year	Azathioprine
Patient 2	Refractory OU	25	5 years	Cyclosporine
Patient 3	Deep venous thrombosis	38	10 years	Azathioprine
Patient 4	Uveitis	20	5 years	Azathioprine
Patient 5	Refractory OU	28	7 years	Azathioprine
Patient 6	Refractory OU	23	6 years	Cyclosporine
Patient 7	Refractory EN	35	1 years	Azathioprine
Patient 8	Deep venous thrombosis	23	1 years	Azathioprine
Patient 9	Atrhritis	28	7 years	Methotrexate
Patient 10	Uveitis	18	4.	Azathioprine

F/U:Follow-up, IS: Immunosuppressive, OU: Oral ulcer, EN: erythema nodosum

Conclusion: Our study demonstrated a lower incidence of major vascular events in male BD patients during prospective follow-up compared to historic controls in the literature. The decreased rate of baseline FMD in patients with later IS requirement suggest that FMD might be a predictor for major organ involvement in BD.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Vasculitis Poster II: Behçet's Disease and IgG4-Related Disease

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: There is some evidence that incident Behcet's syndrome (BS) might be becoming less severe (1, 2). We compared clinical findings at presentation of BS patients registered in a large, long standing dedicated multidisciplinary outpatient clinic at 4 time points during a 40-years period.

Methods: There were 4 groups. Group 1 included patients registered in 1979- 1981, Group 2 those registered in 1990, Group 3 in 2000 and Group 4 in 2010. Only demographic and clinical findings at initial presentation were recorded on prepared forms.

Results: As shown in Table 1, over 4 decades, male/female ratio decreases gradually. While mean age at presentation does not change, the median disease duration got shorter. Almost all clinical manifestations except genital ulcers and neurological involvement tended to decrease in frequency. This was also true when genders were separately analyzed. Importantly the severity of vascular and eye disease decreased (Table 2). The slope of vascular disease was more obvious.

Conclusion: Our observations support the notion that incident BS might be getting milder. There might be a list of explanations for this observation. 1. It might be a true biological phenomenon due to changing environmental causes. In this line the significant decrease in papulopustular lesions could be due to a more sanitary environment while the rather unchanging frequency of neurologic involvement might be its possible independence from the environment. 2. It might be that the awareness of BS is increasing and we are recognizing less severe cases earlier. 3. Another explanation might be the more effective treatment these patients received before they were referred which was not specifically sought in this survey.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Vasculitis Poster II: Behçet's Disease And IGG4-Related Disease

Session Type: ACR Poster Session B

Session Time: 9:00am-11:00am

Background/Purpose: Pulmonary artery involvement (PAI) is the most common form of arterial involvement in Behçet's syndrome (BS). A previous survey (1) by our group had analyzed the clinical characteristics and outcome in 47 pts with PAI registered between 2000-2007 and, as compared to our previous experience showed that: 1.the overwhelming male predominance was decreasing; 2.1/4th of the pts had isolated pulmonary artery thrombosis (IPAT); and 3. the mortality rate was 26% after a mean follow-up of 7 yrs. Recently we had the impression the percentage of female pts was perhaps further increasing; the number of pts with IPAT were increasing and we started to use more biologics. We aim to look at these assumptions formally in a recent group of BS pts with PAI.

Methods: We reviewed the records of 3390 pts with BS in our multidisciplinary clinic between Jan 2008 and Jan 2018. We identified 47 (42M/5F) pts with PAI and recorded all information regarding clinical characteristics, outcome, radiological studies and treatment.

Results: The prevalence of pts with PAI decreased from 1.9% to 1.4% in the recent cohort. The M/F ratio, the mean age at the onset of PAI and the frequencies of other vascular involvement were similar across the 2 cohorts. However, there were more pts with neurological disease in the recent cohort. As usual, PAI were mostly bilateral and involved descending lobar arteries. On the other hand, types of PAI involvement at presentation had changed substantially: those with IPAT

Figure. Kaplan-Meier survival curve comparing two cohorts

reached a share of 45%. Forty-five (96%) pts received cyclophosphamide (Cy) for a mean of 6 ± 4 courses, which was significantly shorter compared to the previous cohort. Twenty-three (49%) pts received anti-TNF because of relapsing course, side effects or unresponsiveness for a mean follow-up of 8 ± 4 mo while only 2pts received anti-TNF's in the older cohort. 4 pts had lung surgery, lobectomies in 3 due to giant rapidly progressing aneurysms and a cavectomy in 1. Bronchial artery embolization was done in 3 pts due to refractory hemoptysis. The outcome of information was available on 45/47 pts: 4 pts (8%) had died, 2 were lost to follow-up after 12 and 16 mo of follow-up and the remaining were alive after a median follow-up of 5 [IQR:3-9] yrs. The causes of deaths were massive hemoptysis in 3, severe pulmonary hypertension in 1. The survival has improved significantly in the recent yrs (figure).

Conclusion: The surveys of 2 cohorts showed the prevalence of PAI perhaps mildly decreased, IPAT type of involvement was with considerably higher frequency and the outcome was getting better. Cy was still the first agent however its duration of use became much shorter and anti-TNF's were used in about half of the cohort. The survival seems to have improved significantly. This could have been due to a decreased severity of the type of PAI, with IPAT becoming the most frequent type and or a better management.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Vasculitis Poster II: Behçet's Disease and IgG4-Related Disease

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Table. Demographic and clinical characteristics of the pts with leg ulcers in 24 pts with BS	
n (Male/ Female)	24 (23/1)
Mean age at disease onset	27.5 ± 7.1
Median time interval between disease onset and ulcer development	4.0 [2.5-11.5]
Median follow-up duration	7.8 [2.9-14.2]
Unemployment due to the leg ulcers (%)	11 (46)
Eye disease, n (%)	7 (29)
Large vessel involvement (%)	9 (38)
Dural sinus thrombosis (%)	3 (12.5)
Vena cava sup./thr (%)	1 (4)
Pulmonary artery inv. (%)	5 (21)
Other arterial inv. (%)	1 (4)
Vena cava inferior-iliac vein thrombosis (%)	8 (33)
Lower extremity vein thrombosis (%)	20 (83)
Bilateral (%)	15 (62.5)
Femoral vein (%)	20 (83)
Popliteal vein (%)	14 (58)
Superficial vein (%)	7 (29)
No venous thrombosis or insufficiency (%)	4 (17)
Pts with a solitary ulcer (%)	12 (50)
Pts with more than 1 ulcer (>1) (%)	12 (50)
Pts with healed ulcers (%)	11 (46)
Pts with active ulcers (%)	13 (54)
Anatomical localization (total n = 14)	
Medial malleolus (%)	15 (44 %)
Anterior surface of the tibia (%)	14 (41 %)
Other (%)	5 (5 %)

Background/Purpose: Formal experience with leg ulcers in Behcet's syndrome (BS) is limited. It is a relatively rare complication that can be seen during the course of mainly post-thrombotic syndrome. They can be difficult to manage and cause disability leading to unemployment and severe impairment in quality of life. In this observational survey, we aimed to describe clinical characteristics of pts with leg ulcers.

Methods: A total of 24 pts (23 M/ 1F) that were seen in our out-patient BS clinic between May 2016 and Jan 2018 were evaluated with the help of a standardized questionnaire. Venous Doppler US and if necessary abdominal CT were used to evaluate localization of venous involvement. Biopsies were done if needed. Medical and other interventional treatments were recorded.

Results: The mean age at disease onset was 27.5 ± 7.1 yrs (Table). The median time interval between the disease onset and ulcer development was 4.0 [2.5-11.5] yrs. The median follow-up was 7.8 [IQR:2.9-14.2] yrs. Eleven (46 %) were unemployed due to leg ulcers. Venous involvement was present in 20 pts (83 %). Lower extremity vein thrombosis was present in all 20. It was mostly bilateral (15/20). The same 9/20 pts had other large vessel involvement. Four pts did not have any venous thrombosis or insufficiency. Histopathologic studies could be done in 3 and showed features of necrotizing vasculitis in 2 and venous stasis in the 3rd. Twelve pts (50 %) had solitary ulcers while the remaining had 2 or more. We observed a total of 34 ulcers in 24 pts. They were mostly found around the medial malleolus (15/34) and the anterior surface of the tibia (14/34). Five pts had leg ulcers at unusual places such as lateral malleolus (n=2), popliteal fossa (n=1) and posterior surface of the tibia (n=2). Immunosuppressives including azathioprine, cyclophosphamide, interferon-alpha, infliximab and corticosteroids were used. Iloprost infusions were given in 13 (54 %) for a median duration of 6 mo. Additionally, larvae of *Lucilia sericata* were tried in 9 pts. Skin graft insertion was used in 2 pts, however, was successful only in 1. 17 ulcers in 11 (46 %) pts healed in a median 24 mo [IQR: 9- 78]. In the remaining 13 (54 %) pts 17 ulcers remained unhealed for a median 7 yrs [IQR: 5- 11], despite all treatment. The mean age at BS onset was significantly younger (24.4 ± 5.4 vs 30.4 ± 7.3 yrs; p< 0.05) and the median time between disease onset and ulcer development was significantly shorter (3 [IQR: 1-4.5] vs 10 [IQR: 4-14 yrs, p< 0.05] in pts with the healed ulcers. There were no apparent associations with the type of management and the severity of venous involvement.

Conclusion: Leg ulcer develops mainly due to venous disease in the lower extremities. Peripheral arterial occlusive disease seems to be rarely associated. Leg ulcers may cause unemployment and be resistant to treatment. Ulcers that appear early during the disease course heal faster and are more responsive to treatment.

Increased Vein Wall Thickness in Behçet's Syndrome

Migena Gjoni¹, Serkan Akbas², Emine Sebnem Durmaz², Atilla Süleyman Dikici², İsmail Mihmanlı², Hasan Yazici³ and Emire Seyahi⁴, ¹Istanbul University, Cerrahpasa Medical Faculty, Department of Internal Medicine, Istanbul, Turkey, ²Radiology, Istanbul University, Cerrahpasa Medical Faculty, Department of Radiology, Istanbul, Turkey, ³Istanbul Academic Hospital, Istanbul, Turkey, ⁴Istanbul University, Cerrahpasa Medical Faculty, Department of Internal Medicine, Division of Rheumatology, Istanbul, Turkey

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Vasculitis Poster II: Behçet's Disease And IGG4-Related Disease

Session Type: ACR Poster Session B

Session Time: 9:00 am-11:00 am

Background/Purpose: Lower extremity vein thrombosis (LEVT) is the key feature of vascular involvement in Behçet's syndrome (BS). Vein wall thickness (VWT) is proposed to be a surrogate marker of venous disease. A pilot MR study done in 7 BS patients and controls, had demonstrated increased VWT and signal enhancement in the lower extremity veins of BS patients without vascular disease. Another study, using USG, found that VWT was increased among BS patients without vascular disease compared to patients with ankylosing spondylitis and healthy controls. We reassessed VWT in proximal lower extremity veins in BS patients with LEVT and suitable controls in a formal, masked protocol.

Methods: We studied 47 (40 M/ 7 F) BS patients with LEVT, 50 (43 M/ 7 F) BS patients without any vascular involvement and 38 (31 M/ 7 F) age and gender matched apparently healthy controls. Two independent radiologists, blinded to the diagnosis of BS, used USG to measure VWT of common femoral vein (CFV), superficial femoral vein (SFV) and vena saphena magna (VSM) in both legs.

Results: As shown in Table 1, mean age at disease onset and the disease duration were similar between BS study groups. The mean age at thrombosis onset of the patients with LEVT was 26.4 ± 5.8 years. There was good concordance between the 2 observers (kappa: 0.9) The mean VWT was significantly increased among both BS patients with LEVT and those without any vascular involvement when compared to the healthy controls while those with LEVT had the thickest veins.

Table 1. Disease duration and VWT

	BS with vascular involvement (n=47; 40 M/ 7 F)	BS without vascular involvement (n=50; 43 M/ 7 F)	Healthy controls (n=38; 31 M/ 7 F)	P value
Age, years	37.06 ± 5.26	36.98 ± 4.47	34.87 ± 7.22	0.296
Disease duration	10.96 ± 6.45	9.68 ± 5.89	-	0.31
Vein wall thickness, mean \pm SD, mm				
Right CFV 1st observer	0.91 ± 0.67	0.69 ± 0.15	0.57 ± 0.11	0.001
Right CFV 2nd observer	0.93 ± 0.76	0.70 ± 0.18	0.58 ± 0.09	<0.001
Left CFV 1st observer	1.04 ± 0.85	0.66 ± 0.11	0.56 ± 0.07	<0.001
Left CFV 2nd observer	1.09 ± 0.83	0.69 ± 0.16	0.57 ± 0.07	<0.001
Right SFV 1st observer	0.79 ± 0.38	0.60 ± 0.11	0.51 ± 0.9	<0.001
Right SFV 2nd observer	0.80 ± 0.42	0.62 ± 0.13	0.52 ± 0.07	<0.001
Left SFV 1st observer	0.88 ± 0.38	0.62 ± 0.12	0.49 ± 0.09	<0.001
Left SFV 2nd observer	0.90 ± 0.40	0.63 ± 0.13	0.51 ± 0.07	<0.001
Right VSM 1st observer	0.60 ± 0.22	0.52 ± 0.11	0.43 ± 0.07	<0.001
Right VSM 2nd observer	0.64 ± 0.25	0.53 ± 0.13	0.46 ± 0.08	<0.001
Left VSM 1st observer	0.67 ± 0.23	0.53 ± 0.11	0.42 ± 0.09	<0.001
Left VSM 2nd observer	0.65 ± 0.27	0.53 ± 0.11	0.43 ± 0.07	<0.001

CFV: common femoral vein, SFV: superficial femoral vein, VSM: vena saphena magna

Conclusion: VWT of proximal deep and superficial lower extremity veins was found to be increased among BS patients without any clinical and radiological vascular involvement.

A Declining Trend in Frequency of Secondary Amyloidosis in Behçet's Syndrome

Guzin Karatemiz¹, Sinem Nihal Esatoglu¹, Yesim Ozguler¹, Sebahattin Yurdakul¹, Vedat Hamuryudan¹, Melike Melikoglu¹, Izzet Fresko¹, Emire Seyahi¹, Serdal Ugurlu¹, Huri Ozdogan¹, Hasan Yazici² and Gulen Hatemi¹, ¹Istanbul University, Cerrahpasa Medical Faculty, Department of Internal Medicine, Division of Rheumatology, Istanbul, Turkey, ²Istanbul Academic Hospital, Istanbul, Turkey

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Vasculitis Poster II: Behçet's Disease and IgG4-Related Disease

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: A decline in the frequency of AA amyloidosis secondary to RA and infectious diseases has been reported. This is probably due to more effective treatment strategies. We had previously reported that although amyloidosis occurs in less than 0.5% of BS pts. It is one of the leading causes of death (1-3). We aimed to determine the change in the frequency of AA amyloidosis over years in BS pts in addition to elaborating on clinical characteristics and outcome.

Methods: We performed a chart review to identify all pts with amyloidosis in our BS center since 1976. We noted demographic characteristics, BS manifestations, age at BS and AA amyloidosis diagnosis, treatment modalities of these pts. Our endpoints were death and end stage renal disease (ESRD) requiring renal replacement therapy. The prevalence of AA amyloidosis was calculated separately for 2 periods (pts registered between 1976-2000 and 2000-2017)

Results: Among our 9410 BS pts, 27 (0.29%) had amyloidosis. We identified 24 pts with amyloidosis among the 3820 pts in the earlier cohort and 3 additional amyloidosis among the 5590 pts in the recent cohort. The frequency of AA amyloidosis had declined from 0.62% to 0.054% in the recent cohort. M/F ratio was 22/5 and mean age at BS diagnosis was 29.5±7.4 yrs. Twenty-two (82%) of the pts with AA amyloidosis had major organ involvement (vascular inv. in 15, eye inv.in 13 and neurologic inv.in 2). AA amyloidosis was diagnosed after a mean duration of 9.8±6.7 yrs and was confirmed with renal biopsy in 14 pts and rectal biopsy in 13. Eight pts had non-nephrotic range proteinuria at amyloidosis diagnosis. After amyloidosis diagnosis, 24 pts continued their previous immunosuppressives and colchicine. Two of these 24 were on anti-TNFs at amyloidosis diagnosis. Biologics were initiated in 3 pts who were most recently diagnosed to have amyloidosis, anti-TNFs in 2 and tocilizumab in 1. Fourteen (52%) pts had died after a median follow-up of 3 (IQR:1-8.75) yrs, 3 were lost to follow-up just after amyloidosis diagnosis and 10 (37%) are still alive after a median follow up of 16 (IQR:10-23) yrs. The reasons for death were infections in 5, related to ESRD in 5, subarachnoid hemorrhage, gastric adenocarcinoma, liver cirrhosis probably associated with amyloidosis and iatrogenic bowel perforation in 1 pts each. 10 (71%) of these 14 pts had developed ESRD before their deaths. Overall, 15/27 pts developed ESRD after a median follow-up of 3.5 (IQR:1.25-6.5) yrs after amyloidosis diagnosis. 5 of them had renal transplantation, all but 1 are still alive after 3, 4, 6, and 12 yrs. The last one died 11 years after transplantation due to subarachnoid hemorrhage as explained above.

Conclusion: AA amyloidosis appears to be a rare, but fatal complication of BS. Around 50% of pts died after a median follow-up of 3 yrs after amyloidosis. This study showed a decreasing trend of amyloidosis due to BS similar to that observed in other inflammatory and infectious causes. The shorter follow-up duration may be contributing for the lower prevalence of amyloidosis in the recent cohort.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Vasculitis Poster II: Behçet's Disease and IgG4-Related Disease

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Uveitis in Behçet's syndrome (BS) follows a recurrent disease course with inflammatory exacerbations causing damage in the uvea, retina and optic nerve even with treatment. Frequent attacks and posterior involvement are considered as predictors of poor visual outcome. The aim of this study is to delineate the predictors of damage in more detail using a standard screening method among a group of BS patients with long-term regular follow-up.

Methods: Patients with uveitis who were registered in our multidisciplinary BS clinic between 1990 and 2008 were screened. Among these, 50 patients who were followed for at least 10 years, who were regularly seen in our clinic at least once in every 4 months, who did not have > Grade 2 damage at baseline, and who represented different levels of damage severity during the last visit (between Grade 0 and 5) were selected. The damage severity was graded according to a validated damage grading instrument (5=worst) specifically developed for BS uveitis (Ozyazgan et al. in preparation). One patient was later excluded because it was realized that he did not fulfill these criteria. A standard form was used for retrieving data on demographics, baseline and final visual acuities, number and localization (anterior/posterior / panuveitis) of attacks during follow-up, presence of retinal infiltration, retinal hemorrhage and hypopyon uveitis. Candidate factors for damage progression were compared between patients who had a progression in damage score and those who did not.

Results: 98 eyes of 49 patients (M:F 35:14, mean age at baseline 27 ± 8 years, mean follow-up duration 20.9 ± 5.5 years, mean number of visits 76.5 ± 35.2) were evaluated. The mean visual acuity was 0.02 ± 0.08 at baseline and 0.47 ± 0.52 at the final visit. The mean number of attacks was 13.2 ± 9.4 . Damage grades at baseline were Grade 0 in 79, Grade 1 in 16 and Grade 2 in 3 eyes. Damage grades at final visit were Grade 0 in 15, Grade 1 in 21, Grade 2 in 32, Grade 3 in 12, Grade 4 in 10 and Grade 5 in 8 eyes. There was damage progression in 81/98 eyes at the final visit. Isolated anterior uveitis attacks were not associated with progression of damage (2.5 ± 2.9 vs 2.8 ± 5.5 , $p=0.7$). Parameters that were significantly more frequent among patients with damage progression were: number of attacks (14.5 ± 10.8 vs 23.3 ± 12.3 ; $p=0.008$), number of posterior attacks (0.4 ± 1.2 vs 6.5 ± 4.9 , $p<0.001$), number of panuveitis attacks (0.8 ± 1.3 vs 6.6 ± 5.0 , $p<0.001$), number of attacks with severe vitreous opacity preventing examination of the retina (0 vs 3.2 ± 3.8 , $p<0.001$), retinal infiltration (0.2 ± 0.4 vs 1.4 ± 1.9 , $p<0.001$) and retinal hemorrhages in the arcuate region (0.1 ± 0.2 vs 0.7 ± 1.4 , $p<0.001$), and the number of hypopyon attacks (0.2 ± 1.0 vs 0.9 ± 1.3 , $p=0.019$).

Conclusion: This study confirmed that the anterior uveitis attacks are not associated with progressive damage in BS, whereas posterior and panuveitis attacks, attacks causing severe vitreous opacity, retinal infiltrates and hemorrhage in the arcuate region and hypopyon attacks are important predictors of damage. Patients showing these features should be treated more aggressively.

Behçet's Disease in the Southwestern United States

Maheswari Muruganandam¹ and Noelle Rolle², ¹Rheumatology, University of New Mexico Health Sciences Center, ALBUQUERQUE, NM; ²Rheumatology, University Of New Mexico Health Sciences Center, ALBUQUERQUE, NM

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Vasculitis Poster II: Behçet's Disease and IgG4-Related Disease

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Behçet's disease (BD) in the US is estimated to have a prevalence of 5.2-6.6 per 100,000 populations which is similar to that of European countries but lower than that reported along the Silk Road and in Turkey (400 per 100,000). We now report the demographic and clinical characteristics of BD in understudied populations in Southwest US.

Methods: Under IRB approval, we identified BD patients actively seen during 2014 to 2017 and determined the demographic and clinical characteristics of BD. BD was defined using the International Behçet's Study Group criteria. Incomplete BD patients were excluded.

Results: 63 patients (82.5% female, 17.5% male, female: male ratio: 4.7:1) were identified who fulfilled definite BD criteria in a service population of 710,000 individuals, resulting in an estimated prevalence of 8.9 per 100,000 which is higher than reported previously in the US. 84.1% (53/63) were incorrectly diagnosed with other primary diagnoses like inflammatory arthritis (15.9%), primary fibromyalgia (7.9%), other forms of vasculitis (7.9%), or systemic lupus erythematosus (7.9%) prior to BD diagnosis. Most common BD manifestations were oral ulcers (100%) (Figure 1), genital ulcers (61.9%) (Figure 2), acneiform lesions (69.8%), papulopustular lesions (52.4%) (Figure 2), pseudofolliculitis (42.9%), inflammatory arthritis (41.3%), anterior uveitis (23.8%), posterior uveitis (15.9%), pathergy (15.9%), deep vein thrombosis (14.3%), non-ocular vasculitis (11.1%), erythema nodosum (7.9%), arterial thrombosis (6.3%), and retinal vasculitis (1.6%). 50.8% of BD had concomitant fibromyalgia. BD was distributed ethnically as follows: 49.2% Spanish-American (SA), 31.7% Non-Spanish European-American (EA), 14.3% Native American (NA), and only 1.7% Silk Road. HLA-B51 was present in 70.5% percent of the total BD population and demographically segregated as to HLA-B51 more commonly in NA (89.0%, $p=0.02$) and SA (74.2%, $p=0.02$) compared to EA (42.1%).

Conclusion: BD is more common in Southwester US than anticipated from prior US-based studies. BD occurs amongst all local ethnic groups including EA, SA, and NA. 84.1% of BD patient have been incorrectly diagnosed with some other disease prior to the BD diagnosis, and 50.8% have concomitant fibromyalgia, complicating the diagnosis. The prevalence of HLA-B51 in BD amongst SA and NA is high (74-89%) and greater than in EA (42%). This is one of the first reports of the characteristics of BD in Southwest US, and specifically in SA and NA populations, and provides the basis for further future study.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Vasculitis Poster II: Behçet's Disease and IgG4-Related Disease

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Vascular involvement is seen in about one third of patients with Behçet Disease (BD). DVT (deep venous thrombosis) is the most common form of vascular Behçet Disease (VBD). Post-thrombotic syndrome (PTS) developing after a thrombotic event in lower extremity is one of the major complications of DVT and affects negatively patients' quality of life. In this study, we aimed to assess the presence, severity and risk factors of PTS and venous disease specific quality of life in VBD.

Methods: This study included 96 patients with BD (Female/Male: 18/78, mean age: 38.8±8.74 years) having history of DVT from 3 tertiary Rheumatology centers in Turkey. Villalta scale was used to assess PTS. According to scale; PTS is present if score >4 and degree of PTS mild, moderate and severe if score 5-9, 10-14, >14 respectively. The Venous Disability Score (VDS) and the Venous Clinical Severity Score (VCSS) were used for the assessment of venous disease. All patients were assessed with color Doppler ultrasonography (US) by experienced radiologists within 1 week following the clinical examination. In each patient, a total of 16 superficial and deep veins in both legs were assessed for the presence or absence of obstruction, recanalization, reflux and collaterals.

Results: When vascular involvement developed, mean age was 32.7±8.65. Venous assessment was done after 6(0-26) years first vascular event. During venous assessment, median disease duration was 9(0-34) years. Eighty (84.2%) patients were under immunosuppressive (IS) treatment and 13 of these patients were under anticoagulation treatment in addition to ISs. Median IS time 37.5 (1-256); anticoagulation time 12 (1-156) months. PTS was present in 57(61.3%) out of 93 patients and severe PTS was present in 19(19.8%) patients. There was no association between presence of PTS and sex, age during DVT, compression stocking treatment usage, presence of relaps, duration of thrombosis. There was no difference between patients with or without anticoagulant usage regarding PTS presence (p=0.817) and also there is no difference at duration of IS and AC treatment between patients with or without PTS. Doppler US examination shows no abnormalities at 10 (10.6%) patients, 5(50%) of these patients had PTS. Bilateral leg vessel involvement was present in 31(31.4%) patients. Forty (47.6%) patients had both upper

and lower leg vessel involvement. But we didn't find any association with PTS presence and doppler US findings such as bilateral involvement, upper and lower leg vessel involvement, reflux or thrombosis at any vessel in the affected leg.

When VBD patients with and without PTS were compared, quality of life (VEINES-QoL/Sym) and VCSS were significantly worse. The Behçet Syndrome Activity Score was also significantly higher in patients with PTS

Conclusion: We found that PTS develops in more than half of the patients with VBD during follow-up. We didn't find any predictor factor for development of PTS. About one third of patient with PTS were severe PTS. Our results confirm that PTS is very frequent clinical problem for physicians treating VBD in daily practice. During management of patients with VBD, PTS should be taken into account as much as preventing vascular relapses.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Vasculitis Poster II: Behçet's Disease and IgG4-Related Disease

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Uveitis is the most common ocular manifestation in Behçet Disease (BD), which can cause irreversible blindness. Once the efficacy, safety and cost-effectiveness of Adalimumab (ADA) have been demonstrated in a

large series of patients with uveitis due to BD (Martín-Varillas *et al. Ophthalmology* 2018), we propose, based on this report, a treatment optimization protocol.

Methods: Multicenter study of 65 ADA-treated patients with BD uveitis refractory to conventional immunosuppressants. Following remission, based on a shared decision between the patient and treating physician, ADA optimization was performed by increasing the ADA dosing interval progressively.

Results: Based on our experience we propose an optimization protocol of ADA treatment as follow: after 12 months of treatment with ADA and once remission was achieved and sustained for at least 3-6 months, we recommend increase very slowly but progressively the dosing interval with regular monitoring of ocular inflammation parameters. Once the dosing interval has been increased up to every 6 weeks and there is no ocular inflammation data, we recommend discontinuing treatment but keeping close monitoring (FIGURE).

If relapse occurs, the patient should be switched to the standard dose of 40 mg/s.c./2 weeks.

Following this protocol, we perform an annual-cost analysis in which we compare the optimized and non-optimized patients, finding a statistically significant (6101.25 euros/patient/year vs.12339.48; $p < 0.01$). In addition, no severe side effects were observed after optimization.

Conclusion: ADA optimization in BD uveitis refractory to conventional therapy is effective, safe and cost-effective.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Vasculitis Poster II: Behçet's Disease and IgG4-Related Disease

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Central nervous system involvement is one of the most serious complications in Behçet's disease (BD). This condition is referred to as neuro-BD (NB) and can be classified into acute type (ANB) and chronic progressive type (CPNB) based upon differences in the clinical course and responses to corticosteroid treatment. It has been well appreciated that Human Leukocyte Antigen (HLA)-B51 is significantly associated with BD. Of note, HLA-B51 has been found in >80% of patients with CPNB. Thus, genetic factors, such as Major Histocompatibility Complex (MHC), have been implicated in the pathogenesis of CPNB. However, there have been no reports on MHC class II antigen in CPNB. The current studies were carried out to examine whether there is any association of MHC class II antigen in CPNB.

Methods: Forty Japanese BD patients meeting the International Criteria for Behçet's Disease (ICBD) were enrolled for analysis, including 11 patients with ANB and 15 patients with CPNB. Since CPNB has high positivity for HLA-B51, 14 patients of HLA-B51-positive non-NB were included as a control group. The diagnosis of ANB and CPNB was performed according to the diagnostic criteria proposed by the Japanese research committee for BD (Mod Rheumatol (2012) 22:405-413). The genotype determination of HLA-DR was performed using peripheral blood by polymerase chain reaction (PCR)-sequence based typing.

Results: The HLA-B51-positive rate was 36.4% in ANB(4/11), 86.7% in CPNB (13/15), and 100% in non-NB (14/14). HLA-DRB1*0901 were found in 9.1%, 66.7%, and 4.3% of ANB, CPNB and non-NB HLA-B51 positive control, respectively. The relative risk and odds ratio of ANB and CPNB due to the presence of HLA-DRB1*0901 was 2.727 (Fisher's exact test: $p=0.0052$) and 20.0 (95% confidence interval (CI): 1.966 to 203.4), respectively. The relative risk and odds ratio of CPNB and HLA-B51-positive non-NB due to the presence of HLA-DRB1*0901 was 2.833 (Fisher's exact test: $p=0.0078$) and 12.0 (95% CI: 1.901 to 75.75), respectively. The results of HLA-DR genotyping are shown in Table.

Table. HLA-DRB1 allele frequencies in Japanese BD patients

ANB (n=11)			CPNB (n=15)			non-NB (n=14)		
Alleles	No.	Freq. (%)	Alleles	No.	Freq. (%)	Alleles	No.	Freq. (%)
HLA-DRB1*01:01	1	10.0	HLA-DRB1*01:01	1	6.7	HLA-DRB1*01:01	1	7.1
HLA-DRB1*04:01	1	10.0	HLA-DRB1*04:01	2	13.3	HLA-DRB1*04:01	1	7.1
HLA-DRB1*04:05:01	1	36.4	HLA-DRB1*04:05:01	1	6.7	HLA-DRB1*04:05:01	4	28.6
HLA-DRB1*04:10:01	1	10.0	HLA-DRB1*04:10:01	4	26.7	HLA-DRB1*04:10:01	1	7.1
HLA-DRB1*08:01:01	4	45.5	HLA-DRB1*08:01:01	1	6.7	HLA-DRB1*08:01:01	5	35.7

HLA-DRB1*08:04:01	1	10.0	HLA-DRB1*08:04:01	1	6.7	HLA-DRB1*08:04:01	3	21.4
HLA-DRB1*08:08:01	1	10.0	HLA-DRB1*08:08:01	2	13.3	HLA-DRB1*08:08:01	1	7.1
HLA-DRB1*12:01:01	1	10.0	HLA-DRB1*12:01:01	1	6.7	HLA-DRB1*12:01:01	2	14.3
HLA-DRB1*12:02:01	1	10.0	HLA-DRB1*12:02:01	1	6.7	HLA-DRB1*12:02:01	1	7.1
HLA-DRB1*13:01:01	1	10.0	HLA-DRB1*13:01:01	2	13.3	HLA-DRB1*13:01:01	4	28.6
HLA-DRB1*13:02:01	1	10.0	HLA-DRB1*13:02:01	1	6.7	HLA-DRB1*13:02:01	1	7.1
HLA-DRB1*14:01:01	1	10.0	HLA-DRB1*14:01:01	1	6.7	HLA-DRB1*14:01:01	1	7.1
HLA-DRB1*14:02:01	1	10.0	HLA-DRB1*14:02:01	1	6.7	HLA-DRB1*14:02:01	1	7.1
HLA-DRB1*15:01:01	1	10.0	HLA-DRB1*15:01:01	1	6.7	HLA-DRB1*15:01:01	1	7.1
HLA-DRB1*15:02:01	1	10.0						

ANB=acute neuro-Behçet's disease; CPNB=chronic progressive neuro-Behçet's disease; Freq.=frequency.
HLA=Human Leukocyte Antigen; BD=Behçet's disease.

Conclusion: These results disclosed that HLA-DRB1*0901 is significantly associated with CPNB. Moreover, the data suggest that HLA-B51 as well as HLA DRB1*0901 might be involved in the pathogenesis of CPNB possibly continuing production of interleukin (IL)-6.

Spinal Cord Involvement in Behçet's Disease- Experience of a Vasculitis Centre at Silk Road

Ertugrul Cagri Bolek, Alper Sari, Levent Kilic, Ali Akdogan, Meryem Asli Tuncer and **Omer Karadag**, Hacettepe University Vasculitis Center (HUVAC), Ankara, Turkey

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Vasculitis Poster II: Behçet's Disease and IgG4-Related Disease

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Spinal cord involvement may occur in the course Behcet's Disease (BD). It may present with distinct manifestations such as sphincter and/or sexual dysfunction. We aimed to investigate the frequency and clinical features of spinal cord involvement of BD in our Hacettepe University Vasculitis Center (HUVAC) cohort.

Methods: Patients enrolled in prospective HUVAC database were searched in terms of spinal cord involvement of BD. Of 1585 patients recorded since October 2014, 419 patients were BD patients (329 complete and 90 incomplete for ISG Criteria), and 77(18.4%) of them had NBD (61 definite, 16 possible) according to International Consensus Recommendations (ICR). Spinal cord involvement was diagnosed with neurological examination and spinal magnetic resonance imaging (MRI). Demographics, clinical features and treatment characteristics of patients were evaluated.

Results: Fifty two (12.4%) patients had parenchymal central nervous system involvement (CNS) whereas 12 (2.8%) had spinal cord involvement. The mean age at diagnosis was not different for spinal with pNBD and spinal without pNBD (24.9 ± 5.4 vs. 29.2 ± 9.24 , $p=0.22$). Median time period between diagnosis of BD and NBD is 5.29 years (IQR=9.95). Detailed clinical features of BD patients with spinal cord involvement were summarized in Table. Three patients had total atrophy of spinal cord. Cervical and/or thoracic segments of spinal cord was predominantly involved. Twenty five percent of spinal with pNBD had only one attack of NBD. Corticosteroids (IV pulse = 37/49, 75.5% and oral maintenance =45/50, 90%), interferon (40/52 79%) and cyclophosphamide (28/49,57.1%) were the most frequently preferred treatment regimens for parenchymal NBD. Over half of them had more than one attack. Almost all had sphincter dysfunction. One third of patients had deceased.

Table. Demographic and clinical features of parenchymal NBD patients with spinal cord involvement

No	Age (years)	Sex	Duration (years)	Oral ulcers	Genital ulcers	Skin lesions	Joint symptoms	Abdominal symptoms	Neurological symptoms	Spinal cord involvement	Spinal cord segment	Treatment	Outcome
1	25, M	-	-	-	-	-	-	-	-	-	-	-	-
2	20, M	-	-	-	-	-	-	-	-	-	-	-	-
3	26, M	-	-	-	-	-	-	-	-	-	-	-	-
4	41, M	-	-	-	-	-	-	-	-	-	-	-	-
5	35, M	-	-	-	-	-	-	-	-	-	-	-	-

7	36, M	-	-	-	-	-	-	-	-	-	-	-	-
8	28, F	-	-	-	-	-	-	-	-	-	-	-	-
9	26, M	-	-	-	-	-	-	-	-	-	-	-	-
10	41, M	-	-	-	-	-	-	-	-	-	-	-	-
11	33, M	-	-	-	-	-	-	-	-	-	-	-	-
12	22, F	-	-	-	-	-	-	-	-	-	-	-	-

Abb: Not Available
*Had both parenchymal and vascular (NBD) involvement

Conclusion: Spinal cord involvement is very rare in BD. However, it has a big impact on morbidity and mortality of BD patients. Awareness, early diagnosis and recent effective biologic agents might decrease this dramatic scenario.

Clinical Features and Disease Course of Neurologic Involvement in Behcet's Disease

Ertugrul Cagri Bolek, Alper Sari, Berkan Armagan, Abdulsamet Erden, Levent Kilic, Umut Kalyoncu, Meryem Asli Tuncer, Sedat Kiraz and **Omer Karadag**, Hacettepe University Vasculitis Center (HUVAC), Ankara, Turkey

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Vasculitis Poster II: Behçet's Disease and IgG4-Related Disease

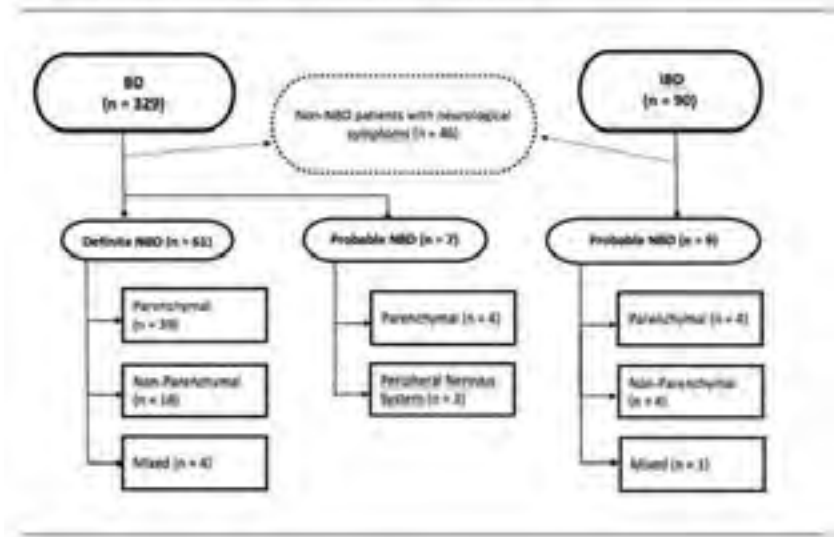

Background/Purpose: Neurological involvement (NBD) is a rare complication of BD. Although NBD is not common in the course of BD, it is related with significant mortality and morbidity. We aimed to evaluate disease course and outcome of NBD patients registered in Hacettepe University Vasculitis Center (HUVAC) prospective data base starting from October 2014.

Methods: Totally, 456 patients were recorded as BD and 329 of them had fulfilled International Study Group (ISG) criteria. Ninety patients who did not meet criteria were considered to have incomplete BD after a review of an experienced rheumatologist. Altogether, 419 patients with complete or incomplete BD were included in this study. One hundred and seventeen patients with neurological complaints/symptoms were retrospectively evaluated. Forty-six patients who did not meet definite or probable NBD ICR criteria were excluded from the study. In final analysis, 77 NBD patients (61 definite, 16 possible) were included.

Table: Clinical features and comparison of all BD and NBD patients

	All (n = 419)	Non-NBD (n = 342)	Paraneuronal NBD (n = 25)	Non-paraneuronal NBD (n = 22)	Mixed NBD (n = 30)	p
Female (%)	52.7%	52.9%	48.0%	45.5%	53.3%	0.38
Age at diagnosis, mean (SD)	47.0 (13.3)	47.3 (13.3)	46.2 (13.3)	47.4 (13.3)	47.3 (13.3)	0.74

Figure: Distribution and number of attacks of NBD patients

Results: Demographic and clinical features of BD patients with and without neurological involvement are summarized in Table. Neurologic involvement of BD is seen more frequently in patients with eye involvement (Table). Distribution of patients having parenchymal, non-parenchymal and mixed NBD are 47 (61%), 22 (28.5%), 5 (6.5%), respectively. Median time period between diagnosis for BD and parenchymal NBD is 5.7 years (IQR=11). Brainstem is the most frequently affected parenchymal area (72.9%), followed by white matter and diencephalon (64.6%, 37.5%). Twelve (25.5%) patients had spinal cord involvement. Fifty-eight percent of patients with acute onset parenchymal disease had only one attack. Corticosteroids (IV pulse: in 75.5% and oral in 90%), cyclophosphamide (57.1%), interferon (79%) and Anti-TNFagents (%23.5) were the most frequently preferred treatment options for parenchymal NBD. Ten, twenty and thirty year survival rates was 97.4%, 89.6% and 89.6% in NBD and 100%, 99.7% and 98.8% in non-NBD group, respectively (log rank $p<0.001$). Nine deaths were observed in all patients with NBD whereas no death was observed in patients with non-parenchymal NBD.

Conclusion: Neurologic involvement was seen median 5 years after BD diagnosis and these patients had more eye involvement compared to non-NBD group. Over half of patients had just one attack and no death was seen in non-parenchymal group. Interferon-alpha and anti-TNF agents were used in majority of patients.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Vasculitis Poster II: Behçet's Disease and IgG4-Related Disease

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Superior vena cava syndrome (SVCS), is a medical emergency and can also be seen in Behçet's syndrome (BS). Contrary to the severe outcome seen in malign conditions, SVCS in BS usually has a benign course, complicated rarely by hemoptysis, pleural effusion and a chylothorax. We had noted that BS patients with SVCS frequently complained of sleep disturbances, snoring and sleep apnea, suggesting an obstructive sleep apnea (OSA) disorder. We formally surveyed the degree of risk for OSA among BS patients with SVCS and suitable controls using the Berlin questionnaire, a screening questionnaire for OSA with a high sensitivity and modest specificity (1).

Methods: Because of the lower frequency of female patients with VCSS (n= 2), only males were included. We studied 28 BS patients with SVCS (Group 1), 80 BS patients with vascular involvement without a SVCS (Group 2), and 59 BS patients with no vascular involvement (Group 3). Also 80 apparently healthy individuals (Group4) of similar age and gender to BS patients were studied. The Berlin questionnaire was used to assess risk of OSA (1). Polysomnography was performed in patients at high risk for OSA according to the Berlin questionnaire.

Results: There were no differences regarding demographic characteristics, disease duration and variables associated with OSA among the groups (Table). The Berlin questionnaire categorized 57.1 % (16/28) of the BS patients with SVCS (Group 1) as having a high risk for OSA and this was significantly higher compared to that found in the control groups. The frequency of those at high risk for OSA was 15 %, 8.5 %, 11.3 % in Group 2, 3 and 4, respectively ($p>0.05$). Until now, polysomnography was performed in 12 subjects (5 patients with SVCS, 1 patient with vascular involvement without a SVCS and 6 healthy controls). OSA was detected in 3/5 patients with SVCS and 1/1 patient with vascular involvement without a SVCS and 4/6 healthy controls.

Conclusion: This study shows that BS patients with a history of VCSS are at high risk of OSA. This is probably due to the external pressure of the significant venous collaterals on the upper airways.

Session Title: Vasculitis Poster II: Behçet's Disease and IgG4-Related Disease

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The usual onset of Behçet syndrome (BS) is in the 3 decade. Older age-onset defined as fulfilling the International Study Group (ISG) criteria after 40 years (yrs) of age is rare and our knowledge about it is limited. One

Table 1. Clinical characteristics of older age-onset and classical-onset BS pts (Males/Females)

	Older onset males (n=70)	Classical onset males (n=163)	P	Older onset females (n=64)	Classical onset females (n=105)
Age at ISG criteria fulfilling, yrs	47.0 \pm 6.0	24.2 \pm 4.3		46.6 \pm 5.7	23.1 \pm 4.4
Oral ulcer, n (%)	69 (99)	163 (100)	-	64 (100)	105 (100)
Genital ulcer, n (%)	60 (86)	137 (84)	0.845	51 (80)	90 (86)
Papulopustular lesions, n (%)	49 (70)	135 (82)	0.050	19 (31)	71 (68)
Nodular lesions, n (%)	15 (21)	76 (47)	0.0001	29 (45)	60 (57)
Arthritis, n (%)	10 (14)	43 (26)	0.028	13 (20)	25 (24)
Eye involvement, n (%)	24 (34)	88 (54)	0.006	26 (41)	41 (39)
Only vitreous cells (+), n (%)*	2 (8)	25 (28)	0.058	7 (27)	14 (34)
VA: \geq 0.1 on either or both eyes*	8 (33)	27 (33)	0.941	4 (15)	9 (23)
Vascular involvement, n (%)	13 (19)	27 (17)	0.710	2	0
Pathergy positivity, n (%)**	19 (56)	94 (58)	0.878	14 (53)	49 (47)
CNS involvement, n (%)	3	3	-	2	2
GIS involvement, n (%)	1	1	-	0	1
Activity score, mean \pm SD	3.60 \pm 3.36	6.38 \pm 3.15	0.020	3.28 \pm 2.21	4.79 \pm 2.19

*): Calculations are made only among those with eye involvement.

**): Pathergy test was made only in 70 older onset and 163 younger onset male pts, 64 older onset and 105 younger onset female pts. VA: visual acuity

early study from our center had reported the severity of eye disease was not different between early onset (≤ 24 yrs) and late onset (≥ 25 yrs) group, while the total clinical activity scores were smaller in the late onset group (1). While there is ambiguity in the definition of older onset, a few case series (2-4) coming mostly from ophthalmology or dermatology settings describe a similar or less severe clinical picture among late onset patients (pts) compared to that seen in early onset. The aim of this retrospective study was to evaluate clinical characteristics of pts with older onset BS pts, to compare them with a group of classic onset BS pts.

Methods: The charts of 3335 BS pts who were registered between Jan 2000 and Dec 2010 were reviewed retrospectively. Pts who fulfilled the ISG criteria for BS after 40 yrs of age (≥ 40) were defined as older onset, while those who fulfilled the criteria before 30 yrs of age as classic onset. For each older onset chart, 2 consecutively registered early onset charts were selected. Only clinical manifestations at initial presentation were recorded. A clinical activity index (1) was modified, calculated for each pt.

Results: There were only 134(70M/64 F) pts with older onset BS, which gave a prevalence of 4% in the whole cohort. Age of onset was 40-44 yrs of age in 54 pts, 45-49 yrs in 47 and 50+ in 32. As controls 268(163 M/105 F) classic onset pts were selected. Demographic/Clinical characteristics among older and classic onset pts are described for males and females separately, in Table. The frequency of skin manifestations, arthritis and eye disease as well as the mean clinical activity scores were significantly higher among male classic onset pts compared to older onset male pts. Interestingly, frequency of those with positive pathergy test, vascular involvement and severe eye involvement did not seem to be different among older onset and classic onset male pts. Clinical characteristics and total activity scores were similar between the older onset and classic onset groups among females (Table). The main limitation is that the information was based solely on patient's charts and outcome information was not available.

Conclusion: Compared to classic onset pts, males tend to be less frequent in the older cohort. At presentation, older onset male pts had significantly less frequent skin, joint, eye disease, and significantly lower total activity scores compared with classic onset pts. There was no difference between the classic and older onset group, among females.

Initial Visit Symptoms in Probable Behçet's Predictive of ISG Criteria Behçet's: Data from New York and Amsterdam Cohorts

Floor Kerstens¹, Christopher J. Swearingen², Franktien Turkstra¹ and Yusuf Yazici³, ¹Amsterdam Rheumatology & Immunology Centre - Reade, Amsterdam, Netherlands, ²Department of Medicine, Division of Rheumatology, New York University School of Medicine, New York, NY, ³Rheumatology, New York University School of Medicine, New York, NY

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Vasculitis Poster II: Behçet's Disease and IgG4-Related Disease

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Behçet's syndrome (BS) is formally diagnosed using the International Study Group (ISG) criteria, where recurrent oral ulceration and any two other symptoms (recurrent genital ulceration, uveitis, skin lesions and pathergy positivity) are required. The allowance of various symptomology in the ISG criteria has led to the reporting of varied manifestations, and differences in clinical presentation can complicate BS diagnosis, especially in areas where the disease prevalence is low. The purpose of this study was to explore clinical BS symptoms present at initial patient visit that are predictive of ISG criteria diagnosis at follow-up.

Methods: Data from consecutive patients monitored in outpatient clinics in New York and Amsterdam were abstracted. Patients were included if diagnosis at initial visit was "suspected" or "probable BS"; patients given a formal diagnosis by ISG criteria at initial visit or a non-BS diagnosis at initial visit were excluded. Demographic data, including ancestry/ethnicity, clinical symptoms, duration of symptoms and RAPID3 were abstracted from initial visit, with follow-up ISG status (defined as meeting criteria ISG+ vs not meeting criteria ISG-) abstracted from last visit. Univariable logistic regression was used to screen initial visit clinical features and symptoms with follow-up ISG status. All variables that passed screening at $P \leq 0.10$ were included in the final multivariable model².

Results: 189 patients were included: 169 from NY and 20 from Amsterdam. 71 (37.6%) patients were classified as ISG+ with an average of 9.4 years (\pm 8.3 years) of symptoms. Age, gender, ethnicity, duration of symptoms at enrollment, duration of follow up as well as RAPID3 and almost all clinical manifestations at baseline were comparable between ISG+ And ISG- patients.

Presence of morning stiffness, family history of BS, genital ulceration, labial ulceration, skin lesions, eye disease and retinitis were each identified in the univariable model as being possibly associated with prevalence of ISG+. The final multivariable model did not include correlated symptoms (i.e. genital and labial ulceration as well as eye disease and retinitis). In the final model, presence of morning stiffness, genital ulcers, skin lesions, and eye disease were associated with increased odds of ISG+, adjusting for age, symptom duration and family history (**Figure**). Area under the curve was 0.718, indicating acceptable predictive capability of the final model.

Conclusion: Based on our data, over a third of patients with suspected or probable Behçet's developed new manifestations over time that led to classification as ISG+ Behçet's. Despite development of these new manifestations, the presence of morning stiffness, genital ulcers, skin lesions, and eye disease at initial visit were independently associated with significantly higher odds in developing ISG+ Behçet's during followup.

Abstract Number: 1811

Efficacy and Safety of Interferon α 2a As an Add-on Treatment for Refractory Behçet's Uveitis

Jing Shi¹, Chan Zhao², Jiaxin Zhou³, JinJing Liu¹, Fei Geo², Xiaofeng Zeng⁴, Meifen Zhang² and **Wenjie Zheng**¹,
¹Rheumatology, Peking Union Medical College Hospital, Beijing, China, ²Department of Ophthalmology, Peking Union Medical College Hospital, Beijing, China, ³Department of Rheumatology, Peking Union Medical College Hospital, Beijing, China, ⁴Rheumatology, Peking Union Medical College and Chinese Academy of Medical Sciences, Peking Union Medical College Hospital, Beijing, China

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Vasculitis Poster II: Behçet's Disease and IgG4-Related Disease

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Uveitis is one of the leading causes of morbidity in Behçet's patients which may result in irreversible vision loss. Evidence is accumulating that interferon (IFN) α 2a might be a promising treatment for Behçet's Uveitis (BU) refractory to conventional immunosuppressive agents. The practical value of these studies, however, is limited by their heterogeneity in terms of ethnic and racial backgrounds of the patients, indication, dosage and duration of IFN treatment. In addition, while IFN was commonly given only with corticosteroids, whether and (if so) how it could be used as a

combinatorial agent to conventional immunosuppressants remains to be further elucidated. In this study, we aimed to investigate the efficacy and safety of IFN α 2a as an add-on treatment for refractory BU.

Methods: Twenty-six refractory BU patients who received IFN α 2a treatment in Peking Union Medical College Hospital between February 2015 and October 2017 were retrospectively reviewed. IFN α 2a was used mainly as an add-on treatment for BU patients who underwent relapse under corticosteroids and conventional immunosuppressive agents. The primary outcomes were treatment success rate and changes in ocular relapse rates before and after initiation of IFN α 2a. Disease activity, corticosteroid- and immunosuppressant-sparing effects, as well as side effects were secondary outcomes.

Results: A total of 26 patients (23 males and 3 females) with a mean age of 30.5 ± 8.6 years were included. Eighteen patients (69.2%) were treated with at least 2 immunosuppressive agents before the initiation of IFN α 2a. Treatment success was achieved in 24 patients (92.3%), and the median uveitis relapse rate decreased from 8 (range 2-12) to 0 (range 0-6) per patient-year ($p=0.000008$) during a mean follow-up of 13.6 ± 6.0 months, corticosteroids were lowered in 20 cases (76.9%) and completely withdrawn in 2 (7.7%). In addition, immunosuppressive agents were reduced in number and dosage in 16 (61.5%) and 23 patients (88.5%), respectively, and were completely withdrawn in 5 cases (19.2%). No severe adverse events were observed and serum autoantibodies remained negative during the treatment of IFN α 2a.

Conclusion: IFN α 2a is effective and relatively safe in refractory BU, with significant steroid- and immunosuppressant-sparing effects.

Characterization and Prevalence of Morbus Behçet in Switzerland

Sabine Adler¹, Rahel Villiger², Lukas Buetikofer³ and Peter M. Villiger⁴, ¹Department of Rheumatology, Immunology and Allergy, Inselspital, University Hospital of Bern, Bern, Switzerland, ²Rheumatology, Immunology and Allergy, University Hospital Bern, Switzerland, Bern, Switzerland, ³Clinical Trials Unit, University of Bern, Bern, Switzerland, ⁴Rheumatology and Clin Immunol, Bern, Switzerland

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Vasculitis Poster II: Behçet's Disease and IgG4-Related Disease

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: To evaluate the clinical presentation of patients with Morbus Behçet (MB) in a cohort from Switzerland and to calculate the prevalence of MB in Switzerland. To identify differences in diagnostic delay and clinical presentation regarding Swiss or non-Swiss ethnic background.

Methods: MB patients fulfilling the revised International Criteria for Behçet's Disease were recorded in a database. Medical history, clinical and laboratory examinations were performed at inclusion and at regular intervals. Disease severity was calculated with respect to major organ affections and their respective intensity. Prevalence was calculated based on geographic distribution of the patients and the respective population density (data of the federal statistical office).

Results: 52 MB patients were recorded with a mean age of 47.8 years (range 34-57) at inclusion into the database. Male to female distribution was almost equal (54% male, 46% female, ns). Ethnic background was Swiss in 61%, and Turkish, South-East European, Italian, Spanish, Portuguese, Indian, and other in the remaining patients. Median time from onset of first symptoms to diagnosis was 8 years in the entire cohort (range 2.8 – 17) with a tendency to delayed diagnosis in Swiss versus non-Swiss background (9 versus 7 years, respectively). Disease severity reached the highest mean values of 5 points (range 4-7) at a mean age of 36.4 years (range 27-44). Women showed a higher severity score than men (6 versus 5 points, $p=0.02$). All patients were diagnosed at the time of maximum disease intensity with 96% of patients receiving medication at time of inclusion into the database. Most frequent medication were systemic and topic glucocorticoids (80 and 60%, respectively), azathioprine (60%), colchicine (52%), non-steroidal anti-inflammatory drugs (50%), methotrexate (40%), infliximab (30%), adalimumab and cyclosporine (24% each). We calculated a prevalence of 5.8 / 100.000 inhabitants in Switzerland.

Conclusion: MB patients in Switzerland are diagnosed with substantial delay in time and at maximum intensity of disease severity regardless of their ethnic background. The higher disease severity in women might reflect a tendency to delayed diagnosis due to a lack of knowledge of MB manifestations in women. The calculated prevalence of 5.8 is within mid-European range of e.g. 4.9 in Germany and 7.1 in France.

Non-Aphthous Beginning As an Independent Risk Factor for the Course of Behçet's Disease

Muhammed Aydin¹, Bahar Artim-Esen¹, Murat Inanc², Lale Ocal¹ and Ahmet Gül¹, ¹Department of Internal Medicine, Division of Rheumatology, Istanbul University, Istanbul Faculty of Medicine, Istanbul, Turkey, ²Department of Internal Medicine, Division of Rheumatology, Istanbul University, Istanbul Faculty of Medicine, Istanbul, Turkey

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Vasculitis Poster II: Behçet's Disease and IgG4-Related Disease

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Behçet disease (BD) is a multisystem inflammatory disorder characterized by recurrent manifestations in mucocutaneous tissues, eyes, joints, blood vessels, intestines and brain. Since there is no pathognomonic clinical and laboratory finding, diagnosis of BD relies on constellation of a group of manifestations. Recurrent oral aphthous ulcers (ROU) are the commonest manifestation, and widely used classification criteria require ROU in all patients. However, some patients may not have ROU at disease onset, which may cause a challenge and delay in the diagnosis of BD. This study aimed to investigate the disease course and appearance of the manifestations in those patients with or without ROU at the disease onset.

Methods: The study group consisted of 570 patients, who fulfilled the International Study Group (ISG) diagnostic criteria and followed between 1976 and 2016. All patients interviewed personally for their disease course and their medical records were investigated retrospectively. Differences in the disease course were analyzed according to the type of manifestations at the disease onset, sequence of appearance of other manifestations, and their smoking status.

Results: Non-aphthous beginning (NAB) at the disease onset was found in 13.6% of patients, and it was more frequent among smokers compared to non-smokers (18.4% vs 6.8% in males, $p=0.019$; 22.9% vs 9.7% in females, $p=0.038$). Frequency of uveitis (54.1% vs 30.2%, $p<0.001$) and cardiovascular involvement (39.3% vs 24.2%, $p=0.019$) was higher in patients with NAB compared to the patients with ROU at onset. Both NAB group and ROU at onset group fulfilled the ISG diagnostic criteria within similar disease duration (median 48 vs 54 months). However, a 3-month delay in diagnosis was noted after the fulfillment of ISG criteria in patients with ROU at onset despite a 5.3-month delay in NAB group ($p=0.003$). Overall, the most frequent manifestations developing at the onset of BD were ROU, genital ulcers, and uveitis; and the latest manifestation during the course was pulmonary parenchymal involvement. Erythema nodosum-like lesions as initial findings were more frequent in females (11.3% vs 5.1%, $p=0.024$), and deep-vein thrombosis (DVT) was more frequent in males (4.6% vs 0.9%, $p=0.04$). NAB was identified as an independent risk factor for the development of uveitis ($OR=2.06$) and DVT ($OR=2.25$) by logistic regression analysis. None of the BD patients had arterial aneurysms or thrombosis, pulmonary parenchymal, gastrointestinal or genitourinary involvement as initial manifestations.

Conclusion: This retrospective study revealed that 13.6% of BD patients may not have ROU at the disease onset, and those patients with NAB may have different features in their disease course with a tendency for higher risk of uveitis and DVT. Smoking may also have a role in the increased frequency of NAB in BD patients.

Interferon-Alpha for the Management of Lower Extremity Deep Vein Thrombosis in Behçet's Syndrome: A Case Series

Yesim Ozguler¹, Gulen Hatemi², Firat Cetinkaya³, Koray Tascilar⁴, Serdal Ugurlu¹, Emire Seyahi¹, Hasan Yazici¹ and Melike Melikoglu¹, ¹Istanbul University, Cerrahpasa Medical Faculty, Department of Internal Medicine, Division of Rheumatology, Istanbul, Turkey, ²Istanbul University Cerrahpasa Medical School, Istanbul, Turkey, ³Istanbul University, Cerrahpasa Medical Faculty, Department of Radiology, Istanbul, Turkey, ⁴Numune Research and Teaching Hospital, Ankara, Turkey

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Vasculitis Poster II: Behçet's Disease and IgG4-Related Disease

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Lower extremity deep vein thrombosis (LEDVT) is a disabling complication of Behçet's syndrome (BS). Relapses are frequent and cause permanent disability due to post-thrombotic syndrome (1). The management of LEDVT in Behçet's syndrome (BS) constitutes mainly of azathioprine (AZA) and corticosteroids (CS) as first-line agents (2). Interferon- α (IFN) has been used with good results in the management of eye involvement of BS. However, data regarding its efficacy for vascular involvement has been scarce (3). We aimed to evaluate the efficacy and safety of IFN for LEDVT in BS.

Methods: All BS pts who had a first episode of acute LEDVT since March 2010 are being prospectively followed with a standard protocol in our dedicated BS center. Acute LEDVT is confirmed by Doppler ultrasonography (DUS) at initial diagnosis and serial DUS assessment is performed and also repeated in case of clinical suspicion of relapse. Our standard treatment strategy consists of AZA and CSs in pts with LEDVT. IFN has been used in pts who were refractory or intolerant to this regimen, or who had co-existing eye involvement. Our endpoints for assessing the efficacy of IFN have been recanalization of the index thrombus and prevention of relapses. Recanalization has been assessed in the transverse plane and defined as the ratio of the vein area at maximum compressibility to the non-compressed vein area. Good recanalization was defined as a ratio of at least 50%. Adverse events during IFN use were recorded.

Results: 33 pts with LEDVT (26 M/7 F) were prospectively followed for a mean of 40.7 ± 13.4 mo. Among these IFN was started in 17/33 for mainly vascular involvement. In 2 pts IFN was started at the first episode of LEDVT due to co-existing uveitis. Seven pts were treated with IFN due to LEDVT relapses under AZA. In the remaining 9 pts, the reasons for switching from AZA to IFN were adverse events with AZA (n=2), relapse of superficial thrombophlebitis (n=4), leg ulcers due to severe post-thrombotic syndrome (n=2) and eye involvement (n=1). Among 17 pts treated with IFN during a mean follow-up of 29 ± 20 mo, 3 pts already had good recanalization when starting IFN. In the remaining 14 pts, 13 (93%) had good recanalization under IFN. Two pts (11%) experienced relapses. One of the 2 pts who had a relapse had had poor recanalization despite IFN. In contrast, among the 29 pts treated with AZA with a mean follow-up of 20.2 ± 15.8 mo, only 13 (45%) had good recanalization. 13 (45%) pts experienced relapses under AZA treatment and 9 (69%) of those pts had poor recanalization. Overall we observed 23 LEDVT relapses in 15 pts. Relapse rates were 29%, 37% and 45% at 6, 12 and 24 mo respectively. The only adverse event with IFN causing drug withdrawal was thyroiditis in 1 patient.

Conclusion: The relapse rate for LEDVT in BS is high despite AZA treatment. IFN seems to be a promising agent for preventing LEDVT relapses and achieving good recanalization, an important predictor of relapse. The small number of pts and the lack of a parallel control group are the limitations of this prospective study.

Aneurysmal Lesions in Behçet's Disease: A Report of 69 Cases from a Single Center

Jiaxin Zhou¹, Jing Shi², Xiuhua Wu², JinJing Liu² and Wenjie Zheng², ¹Department of Rheumatology, Peking Union Medical College Hospital, Beijing, China, ²Rheumatology, Peking Union Medical College Hospital, Beijing, China

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Vasculitis Poster II: Behçet's Disease and IgG4-Related Disease

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: To analyze the clinical features of patients with Behçet's disease (BD) complicated with aneurysmal lesions.

Methods: We retrospectively reviewed the clinical data of patients with BD complicated with aneurysmal lesions in Peking Union Medical College Hospital from 1997 to 2017, the treatment and outcome were also studied.

Results: A total of 69 patients (56 male and 13 female) were included. The average period between BD onset and diagnosis of aneurysmal lesion was 5.4 ± 5.5 years. A total of 120 arterial aneurysmal lesions were found, including 29 aneurysms, 68 pseudo aneurysms, 2 dissecting aneurysms, and 21 with uncertain classification. Thirty-four patients (49.3%) presented with two or more aneurysmal lesions. Abdominal aorta was the most common site of involvement (29/120), followed by pulmonary artery (20/120), femoral artery (15/120), thoracic aorta (11/20), coronary artery (10/120) and iliac artery (9/120). Swelling, pain and palpable masses in the affected artery's area are major symptoms. Patients are more intended to have other types of vascular involvement. 48 (69.6%) patients were treated with large dose of glucocorticosteroids (prednisone at 0.8-1.2 mg/kg per day, or equivalent doses) and 7 (10.1%) patients received methylprednisolone pulse therapy. Cyclophosphamide was the most commonly used immunosuppressant (60/69). Biological agents were administered in 5 refractory cases. 40 patients received surgical therapy or interventional procedures. With a mean follow up of 3.8 ± 3.5 years, 48 patients (69.6%) achieved clinical improvements with no newly-onset arterial lesions occurred, while 3 received a second interventional therapy, 5 died (mortality rate 7.2%).

Conclusion: Aneurysmal lesions are severe and life-threatening complications in BD patients. BD patients diagnosed with aneurysmal lesions should be further evaluated to detect possible associated vascular involvements or aneurysmal lesions at other sites. Achieving BD remission and performing surgical or interventional procedures are both important in the treatment of BD patients with aneurysmal lesions.

Session Title: ACR Abstract: Plenary Session II

Session Type: ACR Plenary Session

Session Time: 11:00AM-12:30PM

Background/Purpose: While recent trials have examined short-term (~ 2 year) outcomes of surgical and nonoperative treatment of meniscal tear in the setting of osteoarthritis there has been little study of longer term outcomes of these treatments.

Fig: KOOS Pain (shaded 95% CI) stratified by treatment in piecewise linear model

Methods: We examined 5-year outcomes of subjects in MeTeOR (Clintrials.govNCT00597012), a multicenter randomized trial of physical therapy (PT) vs. PTplus arthroscopic partial meniscectomy (APM) for subjects with knee pain, meniscal tear and OA changes on xray or MRI. The primary outcome for this analysis was the Knee Osteoarthritis and Injury Outcome Score (KOOS) Pain Scale (0-100, 100 worst). Total knee replacement (TKR) was a secondary outcome. To address changes in KOOS Pain over 5 years, we used a piecewise linear mixed model, stratified by treatment group (randomized to and received APM; randomized to and received PT; randomized to PT but received APM during follow-up). The model censored subjects who had TKR and adjusted for age, sex, BMI, and mental health status. We used a pattern mixture model to assess whether the findings were biased by missing data due to TKR or losses to follow-up. We calculated the frequency of TKR over follow-up and used a Cox proportional hazards model to estimate the risk of TKR for treatment groups and KL grades, adjusting for baseline factors.

Results: The 351 subjects had mean age 58; 57% were female. 164 were randomized to and received APM; 109 were randomized to and received PT; 68 were randomized to PT and crossed over to receive APM. 10 subjects were randomized to but did not receive APM and were not analyzed. 66% of subjects completed ≥ 9 of 12 follow-up questionnaires, with similar completion rates across treatment groups. The piece wise linear model (Figure) showed similar pain improvement in the 3 treatment groups, with baseline KOOS Pain scores of 40-50 improving to 20-25 by 6 months and little change between 6 and 60 months. The pattern mixture models demonstrated similar patterns in pain scores as the main analysis, suggesting TKR and other losses to follow up did not bias these findings. 25 participants (7%) had TKR over follow-up. In the Cox model, the hazard of TKR was higher in those treated surgically (randomized to APM or crossed over) than those randomized to and receiving PT (HR 5.0, 95% CI: 1.2, 21.8), and in those with KL-3 radiographs vs. KL0-2 (HR 2.7, 95% CI 1.2, 6.4).

Conclusion: Pain relief was similar across treatment groups, while the few TKR's were more common in those with KL3 and those receiving APM. These data suggest that persons with degenerative meniscal tear generally experience substantial pain relief over 5 years, irrespective of initial treatment. The greater risk of TKR in those treated with APM could reflect selection effects and/or faster progression of OA following surgery than following PT, and merits further study.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: ACR Abstract: Plenary Session II

Session Type: ACR Plenary Session

Session Time: 11:00AM-12:30PM

Background/Purpose: Autophagy gets rids of unwanted proteins or organelle keeping cells to stay functional upon encountering adverse stresses. While non-coding microRNAs interfere with mRNA targets engaging in tissue metabolism, their actions to chondrocyte autophagy during osteoarthritis (OA) pathogenesis remain elusive. This study is aimed to utilize human knee OA specimens, and chondrocyte-specific microRNA-128 (miR-128) knockout mice to verify the role of miR-128a signaling in chondrocyte autophagy and OA.

Methods: OA articular were harvested from 28 patients with end-stage knee OA who required total knee arthroplasty, non-OA cartilage tissues were collected from 17 participants with a femoral neck fracture. Articular integrity in chondrocyte-specific miR-128 knockout mice (Col2 α 1-cre miR-128(f/f)) and wild-type mice upon destabilized medial meniscus (DMM) surgery or intra-articular injection of collagenase were characterized using equilibrium partitioning ionic contrast- μ CT imaging, histomorphometry, and immunostaining. Autophagosome, autophagic marker expression, and apoptosis of chondrocytes were quantified using RT-PCR, immunofluorescence, and annexin V-probed flow cytometry.

Results: Human OA cartilage showed 60-72% decreases in autophagic markers Atg4, Atg12, p62, and Beclin expression, and weak autophagosome component LC3 immunostaining along with 2.3-fold increases in miR-128 expression. In vitro, forced miR-128 expression significantly inhibited autophagic program, like LC3-II conversion, Atg12 expression, and fluorescent autophagic puncta formation, speeding up apoptosis and cartilage matrix underproduction of chondrocytes. Silencing miR-128 shielded them off the IL-1 β -induced inhibition of survival, autophagy, and chondrogenesis. Of interest, chondrocyte-specific miR-128 knockout mice showed abundant cartilage development within joints, like spacious cartilage morphology, dense matrix synthesis, and intensive chondrocyte proliferation along with strong autophagic reactions. More strikingly, these effects significantly compromised the severity of DMM- or collagenase-mediated cartilage breakdown, synovitis, and osteophyte deposition in affected joints improving walking patterns, body axis, and mobility. Mechanistically, miR-128 hindered chondrocyte autophagy through targeting 3'-untranslated region of Atg12 impeding its mRNA expression as evident from luciferase reporter assays. Epigenetic pathway histone methyltransferase EZH2-mediated trimethyl lysine 27 of histone 3 signaling reciprocally controlled miR-128 transcription in inflamed chondrocytes.

Conclusion: Increased miR-128 signaling correlates with aberrant chondrocyte autophagy in human knee OA. miR-128 is detrimental to autophagy causing apoptosis and matrix loss in chondrocytes. miR-128 deletion promotes cartilage development and wards off excessive articular damage slowing down OA progression. Robust analyses shed light on the inhibitory actions of miR-128 to chondrocyte function and convey a perspective of miR-128 signaling blockade strategy beneficial for cartilage anabolism.

Session Date: Monday, October 22, 2018

Session Title: ACR Abstract: Plenary Session II

Session Type: ACR Plenary Session

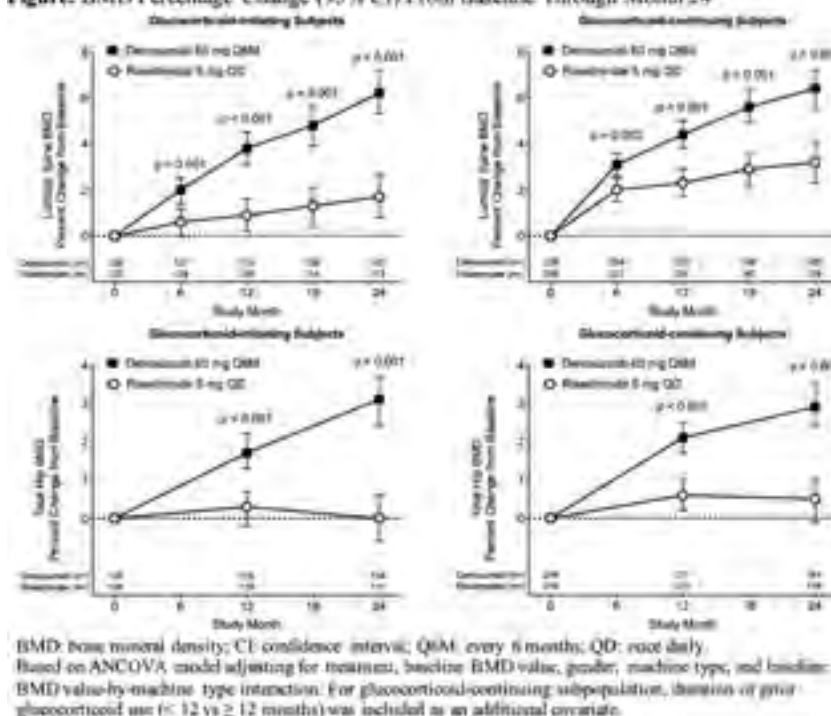

Session Time: 11:00AM-12:30PM

Background/Purpose: Denosumab 60mg subcutaneously every 6 months (Q6M) increased spine and hip BMD significantly more than risedronate 5 mg orally once daily (QD) at 12 months in glucocorticoid-treated subjects (as previously reported¹). This analysis compared the BMD effects of denosumab vs risedronate and further characterized denosumab safety in this population at 24 months.

Methods: This phase 3, randomized, double-blind, double-dummy study enrolled adults ≥ 18 years receiving ≥ 7.5 mg daily prednisone (or equivalent) for < 3 months (glucocorticoid-initiating subpopulation) or ≥ 3 months (glucocorticoid-continuing subpopulation). All subjects < 50 years had to have a history of osteoporotic fracture. Glucocorticoid-continuing subjects ≥ 50 years had to have a lumbar spine, total hip, or femoral neck BMD T-score ≤ -2.0 , or ≤ -1.0 and a history of fracture. Subjects were randomized 1:1 to denosumab 60 mg subcutaneously Q6M or risedronate 5 mg orally QD for 24 months. This analysis assessed denosumab superiority over risedronate for percentage change from baseline in lumbar spine and total hip BMD at 24 months.

Results: Of 795 randomized subjects, 590 (74.2%) completed the 24-month study (glucocorticoid-initiating: 109/145 denosumab, 117/145 risedronate; glucocorticoid-continuing: 186/253 denosumab, 178/252 risedronate). Denosumab was superior to risedronate for increases from baseline in lumbar spine and total hip BMD at all time points assessed through 24 months in each subpopulation (Figure). Adverse events, serious adverse events (including infection), and fractures were similar between groups.

Figure. BMD Percentage Change (95% CI) From Baseline Through Month 24

Conclusion: Denosumab was superior to risedronate for increases in spine and hip BMD through 24 months. The overall safety profile was similar between groups. Denosumab may offer a valuable osteoporosis treatment option for patients receiving glucocorticoids.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: ACR Abstract: Plenary Session II

Session Type: ACR Plenary Session

Session Time: 11:00AM-12:30PM

Background/Purpose: Given phenotypic similarities between rheumatoid arthritis-associated interstitial lung disease (RA-ILD) and idiopathic pulmonary fibrosis (IPF), we hypothesized that the strongest risk factor for the development of IPF, the gain-of-function *MUC5B* promoter variant rs35705950, would also contribute to the risk of ILD in patients with RA.

Methods: Using a discovery population and multi-ethnic validation case series, we tested the association of the *MUC5B* promoter variant in RA-ILD (N=620), RA without ILD (N=614), and unaffected controls (N=5448).

Results: The discovery population revealed an association of the *MUC5B* promoter variant minor allele with RA-ILD when compared to unaffected controls ($OR_{adj}=3.8$ 95%CI [2.8-5.2]; $P=9.7 \times 10^{-17}$). Similar to the discovery population, the *MUC5B* promoter variant was significantly over-represented among the RA-ILD cases in the multi-ethnic study case series when compared to unaffected controls ($OR_{adj}=5.595$ 95%CI [4.2-7.2]; $P=4.7 \times 10^{-35}$), and when the discovery population and the multi-ethnic case series were combined ($OR_{combined}=4.795$ 95%CI [3.9-5.8]; $P=1.3 \times 10^{-49}$). Additionally, the *MUC5B* promoter variant was found to increase the risk of ILD among patients with RA ($OR_{combined}=3.195$ 95%CI [1.8-5.4]; $P=7.4 \times 10^{-5}$), however, no statistical association with the *MUC5B* promoter variant was observed for RA alone. The association of the *MUC5B* promoter variant with RA-ILD increased significantly when restricted to usual interstitial pneumonia (UIP) pattern by high-resolution computed tomography ($OR_{combined}=6.1$ 95%CI [2.9-13.1]; $P=2.5 \times 10^{-6}$). Given our results, we decided to explore 12 other common variants previously reported to be associated with IPF (*LLRC34* rs6793295, *FAM13A* rs2609255,

TERT rs2736100, *EHMT2* rs7887, *DSP* rs2076295, rs4727443, *OBFC1* rs11191865, *TOLLIP* rs5743890 and rs111521887, *ATP11A* rs1278769, *IVDr*s2034650 and *DPP9* rs12610495). In this exploratory analyze, we found that 2 other IPF risk variants, *TOLLIP*rs5743890 and *IVD* rs2034650, were also preliminarily associated with RA-ILD (OR_{combined}=2.1 95%CI [1.1-4.1]; P=0.02 and OR_{combined}=0.5995%CI[0.4-0.9]; P=0.01, respectively). These findings should be replicated to further conclude to their role in the RA-ILD genetic background.

Conclusion: Our findings demonstrate that the *MUC5B* promoter variant rs35705950 is a risk factor for RA-ILD specifically associated with radiologic evidence of the UIP pattern. Furthermore, other IPF related common variants may also participate in RA-ILD genetic susceptibility

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: ACR Abstract: Plenary Session II

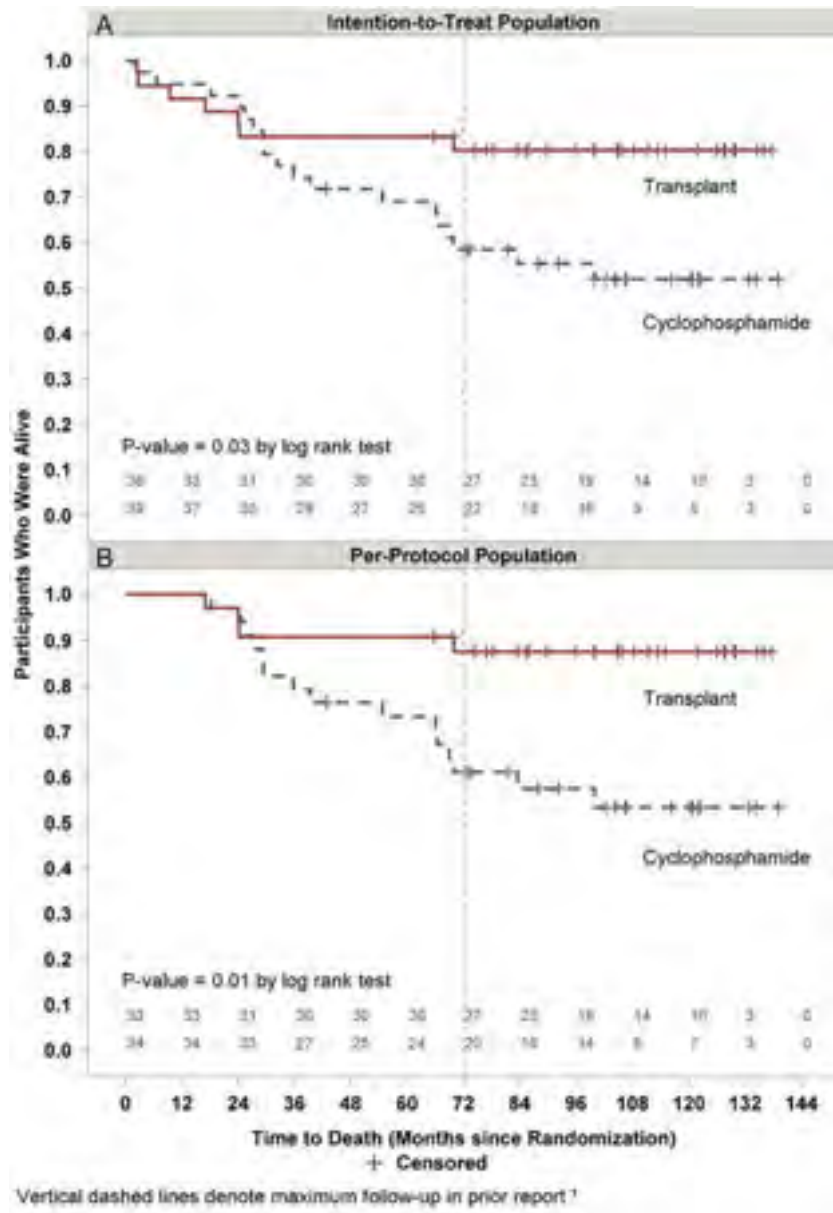

Session Type: ACR Plenary Session

Session Time: 11:00AM-12:30PM

Background/Purpose: The Scleroderma:Cyclophosphamide or Transplantation (SCOT) trial demonstrated that for adults with severe scleroderma (ACR 1995 criteria) and internal organ involvement, myeloablative CD34+ selected autologous hematopoietic stem cell transplantation(HSCT) led to significantly improved clinical outcomes compared to 12 monthly infusions of cyclophosphamide (CYC)¹. Participants were randomized between 2006 and 2011 and followed to 72 months. We report here survivor status, late effects and outcomes 6-11 years after randomization on the SCOT trial.

Methods: We conducted scripted telephone interviews with survivors and searched public death records in mid-2017. Endpoints included time to death or organ failure (see table). Current health status, physical functioning, toxicities, DMARD use and quality of life measures were solicited, and the current HAQ disability index and SF-36 health surveys compared to last assessments. Events are listed as occurring before or after prior reporting¹.

Results: Of 75 randomized SCOT participants, 7HSCT and 18 CYC recipients have died. For HSCT, no new deaths were identified in the follow-up study compared to 4 new deaths for CYC (table A). Overall survival is depicted in the intention-to-treat (figure A) and per-protocol (received HSCT or >= 9 doses CYC) (figure B) populations. At 11 years

after randomization, Kaplan Meier estimates of overall survival were 80% vs 52% and 88% vs 53% (HSCT vs CYC; Figure A and B, $p=0.03$ and 0.01 , respectively).

Among the 25 HSCT and 18 CYC follow-up participants, physical functioning and weight gain were improved following HSCT (table B). Organ failure developed in 2 HSCT (cardiac ablation and pacer) and 6 CYC recipients (3 heart failure, 2 oxygen use and lung transplant). No subsequent malignant or myelodysplastic events were observed. Performance status was significantly better after HSCT while employment rates and measures of physical and social functioning trended higher but were not statistically different. DMARDS were being taken by 2 HSCT and 7 CYC recipients, with 92% and 61% of the two respective treatment groups remaining DMARDS-free ($p=0.01$).

Conclusion: This follow-up analysis demonstrates that the clinical benefits of HSCT previously reported¹ are durable 6-11 years after randomization. Survival and functional status were significantly better with HSCT, and continuing control of scleroderma was demonstrated by 92% of transplant survivors remaining free of DMARDS and disease.

Filgotinib, an Oral, Selective Janus Kinase 1 Inhibitor, Is Effective in Psoriatic Arthritis Patients with an Inadequate Response to Conventional Disease-Modifying Anti-Rheumatic Drugs: Results from a Randomized, Placebo-Controlled, Phase 2 Study

Methods: This was a 16-week, randomized, placebo (PBO)-controlled, double-blind, multicenter, Phase 2 study. Eligible pts had PsA (meeting CASPAR criteria) for ≥ 12 weeks, active arthritis (≥ 5 tender and ≥ 5 swollen joints), prior/current plaque psoriasis, IR to ≥ 1 cDMARD and prior exposure to ≤ 1 TNF-inhibitor. Pts were allowed to continue cDMARDs during the trial.

Pts were randomized 1:1 to FIL 200 mg once daily (qd) or PBO. Disease activity was assessed at screening, baseline and weeks 1, 2, 4, 8, 12 and 16. The primary endpoint was the percentage of pts achieving a 20% American College of Rheumatology (ACR20) response at week 16. Secondary endpoints included the proportion of pts achieving ACR50/70, improvement from baseline in HAQ-DI, Minimal Disease Activity (MDA), 75% reduction in the Psoriasis Area and Severity Index (PASI75), Leeds Enthesitis Index (LEI) and Leeds Dactylitis Index (LDI).

Results: Of 131 pts randomized, 124 pts (94.7%) completed the study. Demographics and baseline disease characteristics were similar between the 2 groups: mean age 50 years, 50.4% female, mean duration of PsA 7 years, mean HAQ-DI 1.40, mean PASI 11.3 (in pts with $\geq 3\%$ body surface area (BSA)).

For FIL and PBO pts respectively, ACR20 response at week 16 was achieved by 80.0% and 33.3% ($p < 0.0001$), MDA was achieved by 23.1% and 9.1% ($p = 0.0212$), HAQ-DI change from baseline was -0.57 and -0.28 ($p = 0.0009$) and PASI75 was achieved by 45.2% and 15.0% ($p = 0.0034$).

Week 16, %, NRI	Filgotinib 200mg qd	Placebo	p-value
All randomized and exposed pts	N=65	N=66	
ACR20	80.0	33.3	<0.0001
ACR50	47.7	15.2	<0.0001
ACR70	23.1	6.1	0.0037
HAQ-DI improvement from baseline ≥ 0.35	65.1	41.9	0.0085
MDA	23.1	9.1	0.0212
Pts with baseline BSA $\geq 3\%$	N=42	N=40	
PASI75	45.2	15.0	0.0034
Pts with baseline LEI > 0	N=33	N=43	
LEI resolution (LEI = 0)	51.5	25.6	0.0089
Pts with baseline LDI > 0	N=19	N=27	
LDI resolution (LDI = 0)	73.7	65.5	0.6310

NRI: non-responder imputation

Adverse event (AE) rates (FIL: 56.9%; PBO: 59.1%), infection rates (FIL: 21.5%; PBO: 21.2%) and discontinuation rates (FIL: 7.7%; PBO: 3%) were similar between the groups. There were 2 serious AEs; 1 hip fracture (PBO) and 1 pneumonia (FIL), which was the only serious infection and the only fatal outcome in the study. There were no malignancies/lymphomas, venous thromboembolic events or opportunistic infections (including tuberculosis). There was 1 case of Herpes zoster, confined to a single dermatome (FIL). One patient permanently discontinued the FIL treatment for safety reason (endometrial hypertrophy). Safety laboratory results over 16 weeks in the FIL group included increased hemoglobin (+6 g/L), decreased platelets (-16 GI/L), stable NK cell counts, and increased total cholesterol (+0.45 mmol/L), mainly driven by increased HDL (+0.37 mmol/L) with a 15% decrease in LDL/HDL ratio vs. baseline.

Conclusion: FIL showed superior efficacy versus PBO in pts with PsA, by ACR20 response and by secondary outcomes. No new safety signals were identified.

Session Title: Rheumatoid Arthritis – Animal Models

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: In rheumatoid arthritis (RA), synovial fibroblasts secrete inflammatory cytokines, degrade cartilage and mediate bone destruction. We have previously identified three synovial fibroblast subsets with distinct transcriptomic profiles. However, whether synovial fibroblast subsets exhibit differential effector functions during inflammatory arthritis remains unclear. Here, we sought to determine if fibroblast subsets display unique or shared effector functions using a K/BxN serum transfer arthritis model in mice.

Methods: Synovial tissue was isolated from bilateral knees of normal, non-arthritic mice (n = 25) or mice after K/BxN serum transfer (n = 35). Following enzymatic digestion, synovial fibroblasts were divided into three fibroblast subsets: CD90+, CD90-CAD11+, and CD90-CAD11-. In parallel, we isolated human synovial fibroblast subsets (CD90+C34+, CD90+CD34-, and CD90-) from RA and OA (n=10) synovial tissue. Transcriptomic profiles were generated using 1000 cells from each fibroblast subset by Smart-Seq2. Synovial leukocyte (CD45+) infiltration for each tissue sample was determined by flow cytometry to identify inflamed samples (>45% leukocytes).

Results:

1. **CD90+ fibroblast subset corresponds to sublining fibroblasts in mice.** Principal component analysis using the top 3000 most variable genes identified distinct transcriptomic profiles among mouse fibroblast subsets sorted based on expression of CD90 and CAD11. Consistent with synovial lining fibroblasts, lining markers *PRG4* and *FN1* were significantly upregulated in CD90- fibroblasts ($p < 9.1 \times 10^{-5}$ and $p < 3.84 \times 10^{-6}$, respectively). In contrast, sublining markers *CD34* and *MEAP5* were highly expressed by CD90+ fibroblasts. PCA of human synovial fibroblast subsets separates lining from sublining fibroblast subsets, suggesting conserved subsets between human and mouse.
2. **Lining and sublining fibroblasts exhibit markedly distinct responses in the setting of serum transfer arthritis.** We identified 999, 537, and 122 significantly upregulated genes ($P < 0.0088$) in CD90-CAD11+ lining fibroblasts, CD90-CAD11- lining fibroblasts, and sublining fibroblasts, respectively. While there were many genes that were significantly up-regulated by both CD90-CAD11+ and CD90-CAD11- subsets (61), there were only a few that were up-regulated by both CD90+ and CD90-CAD11+ (9) as well as CD90+ and CD90-CAD11- (2). Remarkably, no genes were significantly up-regulated by all three fibroblast subsets, suggesting lining and sublining fibroblasts exhibit unique responses to serum transfer induced arthritis.

Conclusion: Transcriptomic profiling of mouse and human synovial fibroblasts reveals distinct lining and sublining fibroblast subsets. During inflammatory arthritis, synovial fibroblasts exhibit distinct subset-specific responses to inflammation, suggesting they play different pathologic roles in arthritis.

Session Title: Rheumatoid Arthritis – Animal Models

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: We established a mouse model (HUPO) by deletion of Flip in CD11c+ cells that spontaneously develops erosive inflammatory arthritis resembling rheumatoid arthritis (RA). Since CD11c is expressed in F4/80(hi) macrophages (MΦs) and since MΦs and MΦ-derived cytokines are important in RA and are increased in the joints of HUPO mice, we examined the phenotype and function of MΦs in the joints of HUPO mice.

Methods: HUPO arthritis was evaluated by clinical score. Five subsets of synovial tissue MΦs were defined by flow cytometry: three F4/80(int) (FI) subsets included Ly6C+MHCII- (FI1), Ly6C+MHCII+ (FI2) and Ly6C-MHCII+ (FI3);

and 2 F4/80^{hi} (FH) subsets were further defined as MHCII⁻ (FH1) and MHCII⁺ (FH2). These synovial MΦ populations, as well as classical (CM) and non-classical (NCM) monocytes from HUPO mice with arthritis and littermates controls, were sorted by flow cytometry and processed for RNAseq. The gene expression profiles and pathways were analyzed by Genee software and GOrilla database. The origin of monocytes and macrophages from monocyte bone marrow progenitors was performed by BrdU labeling, bone marrow chimeras and treatment with clodronate liposomes (CL).

Results: The total number of synovial MΦs was increased in HUPO mice, especially the FI2, FI3 and FH2 subsets, while there was a significant reduction of FH1 MΦs. Further, the % of FH1 MΦs, which are the tissue resident MΦs (TRM) of the synovial tissue in control mice, but not other MΦ subsets, inversely correlated with clinical arthritis and granulocyte accumulation. Bone marrow chimera experiments confirmed that arthritis developed after the FH1 population decreased. Fifty-60% of CMs and FI1 and FI2 MΦs were BrdU⁺ within 24 hours, similar to the controls. In HUPO mice FI3, FH1 and FH2 MΦs became BrdU⁺ on days 3 and 5, consistent with their origin from monocytes. Examination of cells 30 minutes after BrdU injection and following treatment with CL, suggested that at least a portion of the FI1 population derived directly from the bone marrow monocytes in HUPO mice, rather than the circulation. Further, the reduction of the FI2 and FI3 populations following CL is consistent with their origin from circulating monocytes. HUPO FI3 MΦs demonstrated the most distinct gene expression pattern from controls, suggested that FI3 subset may represent a turning point in synovial MΦ homeostasis. Comparing FH subsets between HUPO and control mice, the differentially expressed genes (DEGs) down regulated were those regulating intracellular signaling, wound healing and lipid homeostasis. In contrast, the DEGs up regulated related to pro-inflammatory signaling, endogenous TLR ligands, angiogenesis and joint destruction in HUPO mice.

Conclusion: HUPO arthritis develops following the reduction of FH1 TRMs, which inversely correlate with inflammation. In HUPO mice with arthritis, in contrast to controls, bone marrow monocytes, at least in part, have direct access to the joint. These observations suggest a potential new paradigm in which a reduction of TRM may contribute to the pathogenesis of RA.

Session Title: Rheumatoid Arthritis – Animal Models

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Rheumatoid arthritis (RA) patients in sustained clinical remission or low disease activity may continue to accrue periarticular bone erosions despite control of inflammation. Osteoclasts are responsible for bone erosions and systemic bone loss in RA. However current anti-resorptive drugs are suboptimal in RA because they could lead to issues by shutting down physiologic remodeling in long term treatment supporting the need for alternative therapies. Autotaxin (ATX) is a secreted lysophospholipase D converting lysophosphatidylcholine into lysophosphatidic acid. ATX is upregulated in the synovial liquid of patients with RA and contributes to synovial inflammation. However, ATX role in bone resorption is totally unknown.

Methods: ATX was targeted by conditional genetic ablation in osteoclasts (Δ ATX^{Ctsk} mice) and by treatment with anti-ATX drug (BMP22). Arthritic and erosive diseases were studied in arthritis models using human tumor necrosis factor transgenic (*hTNF*^{+/+}) mice and K/BxN serum-treated mice. Systemic bone loss was in addition analysed after ovariectomy (OVX) and in the Lipopolysaccharide (LPS)-induced inflammation model. Joint inflammation and osteoclasts were assessed by histology and bone mass and bone erosion by microcomputed tomography (micro-CT). ATX expression was assessed using RT-qPCR and Western blot. The role of ATX on osteoclastogenesis and osteoclast activity were analysed by murine and human assays.

Results: Here, we found that ATX was up regulated during the course of osteoclastogenesis and LPS or TNF applied to mature osteoclasts further enhanced ATX expression. *In vitro* osteoclast-derived ATX was necessary for bone resorption activity that was blocked by pharmacological ATX inhibitors (PF-8380, BMP22). LPS injections induced a 43 % decrease

of the trabecular BV/TV in control mice but had no impact on bone in $\Delta\text{ATX}^{\text{Ctsk}}$ mice. The challenge with K/BxN serum transfer which induces severe arthritis revealed that $\Delta\text{ATX}^{\text{Ctsk}}$ mice were protected from systemic bone loss, and displayed almost no bone erosion. Intriguingly, in a non-inflammatory bone loss condition as observed in mice after OVX, $\Delta\text{ATX}^{\text{Ctsk}}$ and control mice revealed similar impact on bone 4 weeks post-OVX with a 30% decrease in BV/TV. As supported by an absence of bone phenotype at steady state on $\Delta\text{ATX}^{\text{Ctsk}}$ mice, these results indicate that osteoclast-derived ATX might be dispensable for osteoclast function under non-inflammatory conditions. By using a pharmacological approach on a second inflammatory mouse model exploiting hTNF mice, we found that albeit inefficient on synovitis, BMP22 induced a 28% increase in BV/TV and a 50% decrease in the extent of bone erosion (BS/BV).

Conclusion: These results establish that ATX is a new factor produced by osteoclasts that controls inflammation-induced bone loss without interfering with osteoclast function in non-inflammatory conditions. ATX might be a promising therapeutic target for the prevention of bone erosion occurrence in RA.

Session Title: Rheumatoid Arthritis – Animal Models

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Genetic polymorphisms at the *PTPN2* locus, which encodes the tyrosine phosphatase TC-PTP, cause reduced gene expression and are linked to rheumatoid arthritis (RA). *PTPN2* is an important regulator of cytokine signaling, however it remains unknown by which mechanism polymorphisms in *PTPN2* promotes RA. We model the effect of *PTPN2* haplo insufficiency in the SKG mouse, a spontaneous CD4⁺ T-cell-driven model of autoimmune arthritis.

Methods: Development of spontaneous and/or mannan-induced arthritis was evaluated in SKG mice. CD4⁺ SKG T-cells were transferred to RAG2^{-/-} mice. Clinical scoring of arthritis was followed by histological assessment. Flow cytometry was used to assess T-cell populations. Mann-Whitney or un-paired T tests were used for statistical differences.

Results: In SKG mice, haplo insufficiency of *PTPN2* caused increased severity of both spontaneous ($P=0.003$) and mannan-induced ($P=0.003$) arthritis. Furthermore, increased susceptibility to arthritis could be transferred to RAG2^{-/-} mice by *PTPN2*^{+/-} CD4⁺ T-cells ($P=0.011$ vs *PTPN2*^{+/+} CD4⁺ T-cells). Next we generated a novel C57BL/6 mouse carrying the SKG mutation and the H2^d haplotype (B6.H2^d.SKG), which showed similar arthritis development as BALB/c SKG mice. B6.H2^d.SKG carrying T-cell specific haplo insufficiency of *PTPN2* (Lck-Cre⁺.*PTPN2* floxed/wild type) developed increased severity of arthritis ($P=0.002$) when compared to WT mice. Further investigation revealed an increased accumulation of Th17 cells in arthritic ankles ($P=0.007$) of *PTPN2*^{+/-} mice. Importantly, neutralization of IL-6 and IL-17 equalized development of arthritis between *PTPN2*^{+/-} and *PTPN2*^{+/+} SKG mice, indicating that enhanced arthritis in *PTPN2* haplo insufficient mice were mediated through the IL-6/IL-17 pathway. Mechanistically this was supported by an increased sensitivity to IL-6 induced activation of STAT3 in *PTPN2*^{+/-} CD4 T-cells.

Conclusion: Haplo insufficiency of human RA-associated *PTPN2* mediates autoimmune arthritis in mice by promoting expansion of pathogenic Th17 cells. We also validate our newly generated B6.H2^d. SKG model as a novel powerful tool for mechanistic studies of RA pathogenesis.

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Animal Models

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: High-speed technologies for genome sequencing have completely changed the study of disease genetics, but with limited knowledge of the functional value of most genetic changes. Using an innovative individual approach by studying tissue samples from a young woman with an unusual association of breast cancer, polycythemia vera and rheumatoid arthritis (RA), we identified hypothetic mutations involved in her cancer and autoimmune diseases then used a mice model to validate the implication of these mutations both in cancer and autoimmune diseases. We here present a new model of autoimmune disruption displaying RA features for studying pathophysiological pathways of articular dysimmunity.

Methods: Using whole genome analyses, we identified one cMET point mutation common to the breast cancer cells and to the CD34+ bone-marrow progenitors of the patient. We established a Knock-in transgenic mice using CRISPR-Cas9 technology and obtained *MET*-mutated transgenic mice.

Results: *MET*-mutated transgenic mice show a cancer skin disease and myeloproliferative disorders. Moreover they develop a 90% of penetrance arthritis, with autoantibodies (both ACPA, and auto-SSA and anti-SSB) and histological signs of Sjögren disease. Using ELISA, serum levels of anti-SSA and anti-SSB murine antibodies are significantly higher in the mutated mouse than in the wild-type mouse. Histological signs of synovial hyperplasia of a distal joint are observed in the mutated mouse concomitantly with high serum levels of ACPA. Transgenic mice also display signs of thyroiditis with lymphocyte infiltrate between abnormal thyroid follicles. Using an anti-MET drug, we were able to modulate the biological signs of auto-immunity and myeloproliferation, and the occurrence of skin cancers. We finally demonstrated for the first time a genetic link between myeloproliferative disorders, rheumatoid arthritis, and cancers.

Conclusion: Our study opens a large field of application in the domain of constitutional genetics but above all describes a new model for studying autoimmunity in mice through a non destructive RA model with ACPA. This non-destructive RA model is of major interest to decipher pathways that could lead from articular autoreactivity to autoimmunity. Furthermore, anti-immune-regulatory checkpoint molecules are now currently used in metastatic cancers and enlighten the close relation between cancers and autoimmune diseases because new autoimmune disorders can rise out in anti-PD1 treated cancer patients. This new arthritis model observed because of a cancer gene mutation could be an original approach to explore the autoimmune disruption in the context of cancer disease.

Session Title: Rheumatoid Arthritis – Animal Models

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Understanding the genetic and epigenetic background of rheumatoid arthritis (RA) is complex since multiple genes and environmental factors are involved. By conducting congenic mapping in mice and genome-wide association studies (GWAS) in humans a number of arthritis risk loci were explored. One of the arthritis loci was identified on human chromosome 9 that is syntenic with mouse chromosome 2. Transcriptome analyses identified the PHD finger protein 19 (*PHF19*) gene in this chromosomal region that showed differential expression in arthritic samples. PHF19 is a component of a multiprotein complex, which is responsible of heritable silencing of genes. To understand the molecular function of *PHF19* in autoimmune arthritis, Phf19^{-/-} KO animals were generated and investigated in a murine model of RA.

Methods: Phf19 gene was ablated from the mouse genome by conventional KO methodology. Human proteoglycan (PG)-induced arthritis (PGIA) model was used to investigate Phf19 function in arthritis. Since PGIA is MHC-controlled autoimmune disease, speed congenic approach was employed to put the ablated Phf19 region into full BALB/c genetic background. PGIA susceptibility was tested in Phf19^{-/-} KO and wild type BALB/c mice. Flow cytometry was used to identify the affected cell types in bone marrow and secondary lymphoid organs. Phf19 ablation provoked gene expression profile change was explored using gene expression microarray platforms. Quantitative reverse transcription PCR was employed to verify microarray data.

Results: Phf19-ablated adult mice had normal body weight, and no visible skeletal malformation was observed. Genetic deletion of *Phf19* did not affect fertility and embryogenesis and normal pups of normal litter size was born from Phf19^{-/-} KO animals. However, Phf19^{-/-} KO female mice were more susceptible for PGIA. We detected altered B cell development in bone marrow and secondary lymphoid organs. The genetic ablation triggered gene expression profile changes are under investigation.

Conclusion: Our studies provide the first experimental evidence that Phf19, an epigenetic factor, is directly involved in arthritis pathogenesis and can be considered as a risk factor in autoimmune arthritis. The exact role of Phf19 in arthritis must be explored by investigating the associated gene regulatory network, which might reveal some additional druggable genes.

Gut-Joint T Cell Trafficking in a Model of Bacteria-Driven Murine IBD-Spa

Eric Norman¹, Adam Lefferts¹ and Kristine A Kuhn^{1,2}, ¹Rheumatology, University of Colorado Denver, Aurora, CO, ²Mucosal Inflammation Program, University of Colorado Denver, Aurora, CO

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Basic Science

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Significant bacterial dysbiosis occurs in individuals with IBD and SpA, and individuals with SpA have evidence of circulating intestinal-derived cells, lending credence to the gut-joint hypothesis. In order to understand the mechanistic linkage between microbiota, mucosal immune development, and subsequent pathogenic targeting of joints in SpA, we utilized the TNF^{ΔARE/+} murine model of ileitis and arthritis, which spontaneously develop around 6 weeks of age due to increased TNF-α mRNA stability. We hypothesized that bacteria are required to generate disease, and that gut-joint trafficking could be observed in this model.

Methods: The microbiome was evaluated in 4-8 week old mice by sequencing the V3V4 region of bacterial 16S rRNA in fecal samples from TNF^{ΔARE/+} mice and littermate controls. Then microbiota were depleted by administration of broad-spectrum antibiotics (ampicillin, neomycin, metronidazole, and vancomycin) in the drinking water from 4-8 weeks of age. Assessment of ileitis and arthritis was done by histology. Cells from intestinal tissue and Achilles' entheses were evaluated by flow cytometry. To demonstrate trafficking of cells from the intestine to the joints, we utilized transgenic KikGR mice, which contain a transgene for a photoconvertible green-to-red fluorescent protein, that were crossed with the TNF^{ΔARE/+} line. Endoscopy-guided violet light allowed photoconversion of the distal colon in vivo. Trafficking of photoconverted lymphocytes was determined by flow cytometry.

Results: TNF^{ΔARE/+} mice become increasingly dysbiotic as disease develops between 4 and 8 weeks of age. Ileitis and arthritis were dependent upon an intact microbiota as mice treated with antibiotics had significantly decreased histologic damage. At 4 weeks of age, TNF^{ΔARE/+} mice had significantly expanded colon TCRβ+ and TCRγδ+ intraepithelial lymphocytes (IELs, T cells residing in the epithelium) compared to littermate controls, that decreased to control numbers by 8 weeks of age. These IELs produced significant TNF-α as compared to littermate controls. At 8 weeks of age, both TCRβ+ and TCRγδ+ T cells were significantly expanded in the Achilles entheses of TNF^{ΔARE/+} mice compared to littermate controls. Finally, we observed trafficking of TCRγδ+ IELs from the colon to the joint in both TNF^{ΔARE/+} mice and littermate controls within 72 hours and sustained up to 1 week after photoconversion.

Conclusion: These data demonstrate a key role of bacterial dysbiosis in the development of both ileitis and arthritis as mice depleted of bacteria through the administration of antibiotics had significantly reduced tissue damage. Furthermore, we observe an expansion of colon IELs prior to disease onset that return to control numbers at the time when T cells are expanding in the inflamed joints. TCRγδ+ IELs specifically were identified to traffic from the colon to the joint. These data suggest a working hypothesis that bacteria educate T cells in the gut that traffic to the joint where they may initiate inflammation. Studies are now directed at understanding the specific mechanisms underlying this hypothesis.

Session Date: Monday, October 22, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Basic Science

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: The microbiome serves a number of important functions, including modulation of the immune system and protection from pathogenic microorganisms¹. Many autoimmune diseases have been associated with intestinal microbial dysbiosis¹. Recent studies have also demonstrated that microbiota can affect the lifetime, bioavailability and efficacy of drugs². Conversely, even drugs designed to specifically target human cells have been associated with changes in microbial composition³. To date, most research has focused on bacterial microorganisms and little is known about the role that fungal microorganisms (the mycobiome) play, including their interactions with bacteria. In this study, we characterized the ecological effects of biologic therapies on the intestinal mycobiome.

Methods: Fecal samples were collected from SpA patients pre- and post-treatment with either tumor necrosis factor inhibitors (TNFi; n=15) or secukinumab (n=14), an anti-IL-17A monoclonal antibody (IL-17i). Subjects treated with TNFi were naïve to biologic therapy, whereas those treated with secukinumab previously failed or had incomplete response to TNFi. Samples underwent DNA extraction, amplification, and gene sequencing of the ITS1 region conserved in fungi. In parallel, gene sequencing of the 16S rRNA gene region conserved in bacteria was also performed. Sequences were analyzed with R and Quantitative Insights into Microbial Ecology (QIIME).

Results: ITS fungal data revealed that, on average, subjects treated with TNFi and IL-17i did not have major differences in overall microbial alpha or beta diversity pre- and post-treatment. However, there were dramatic shifts in the relative abundance of specific taxa, such as *Candida albicans*, which were more prominent in the IL-17i cohort compared to the TNFi cohort (p=0.04). The IL-17i cohort also demonstrated similar changes in certain 16S bacterial taxa, including Clostridia (p=0.02) and Clostridiales (p=0.02).

Conclusion: We characterized, for the first time, the effects of two biologic therapies on human intestinal fungal and bacterial microbiota composition. Treatment with biologics, particularly IL-17i, leads to a gut microbial dysbiosis characterized by significant changes in abundance of *C. albicans* and Clostridia in a subgroup of SpA patients. This is in line with the known increased risk of candidiasis seen with IL-17i, and may at least partially explain the potential link between IL-17 blockade, intestinal dysbiosis, and the subclinical and clinical gut inflammation observed in some patients treated with these molecules. Further studies to understand the downstream effects of these perturbations may allow for the development of precision medicine approaches in PsA and SpA.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Basic Science

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Spondyloarthritis (SpA) is common, with a prevalence of ~1% in the United States. Patients with SpA suffer from pain and disability due to inflammation and ossification at enthesial sites, the mechanism of which remains unclear. BMP2 has been reported to be upregulated in mesenchymal stem cells derived from AS patients and has been implicated as an essential factor in bone formation and fracture repair in other settings, but the specific role of BMP2 in enthesal bone formation in SpA is not known.

Methods: Bone forms at enthesial sites in SpA through the process of endochondral bone formation, in which cartilage is laid down and subsequently remodeled into bone. We used a murine model of inflammatory arthritis, the antigen-induced arthritis (AIA) model, in which enthesial bone formation occurs at predictable sites around the knee, to determine the essential role of BMP2 in enthesal bone formation. By crossing the BMP2^{fl/fl} mouse with limb mesenchymal cell-specific (Prx1) Cre transgenic mice, we generated conditional knockout mice (KO) in which BMP2 expression is deleted in limbs, and littermate control mice (WT). We induced AIA in knee joints at 8 and 14 weeks of age.

Results: At 8 and 14 weeks, both KO and WT mice showed similar degrees of inflammation in arthritic knees. Histologic analysis of 8 week-old WT mice revealed endochondral bone formation with cartilage development by day 9, angiogenesis (CD-31 expressing cells), TRAP-positive osteoclasts and bone at entheses by day 15. In contrast, KO mice developed only

cartilage, but not bone, at entheses. Furthermore, angiogenesis and osteoclasts were absent at entheses in KO mice. To determine whether enthesal bone formation was simply delayed in KO mice, we prolonged AIA until day 36. Bone formation, angiogenesis and osteoclasts were still not observed at entheses of KO mice. AIA induced in 14 week-old WT mice showed enthesal bone formation by day 15. In contrast, KO mice did not develop cartilage or bone at the enthesis. Enthesal cells and bone marrow stromal cells (BMSCs) were then harvested from 14 week-old WT and KO mice. After 3 weeks in osteoblast differentiation media, enthesal cells and BMSCs from WT mice differentiated and mineralized, but cells from KO mice did not. To determine the molecular mechanism, we dissected entheses from 14 week-old WT and KO mice with AIA (day 9) using laser capture microscopy. Gene expression was analyzed using Affymetrix whole transcriptome arrays. The Wnt antagonist, Sfrp4 (known to inhibit Wnt signaling and osteoblast proliferation), was upregulated but chondroadherin (known to mediate chondrocyte adhesion) and Cxcl5 (known to promote bone metastasis) were downregulated in KO entheses. qPCR analysis revealed that Sfrp4 mRNA was also upregulated in BMSCs from KO mice.

Conclusion: These results demonstrate that in this model, mesenchymal cell-derived BMP2 is essential for enthesal bone formation in the setting of inflammation. A role for Wnt signaling is likely in this process. These results have implications for the inhibition of enthesal bone formation in SpA.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Basic Science

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Loss of function *RUNX3* variants are associated with ankylosing spondylitis (AS) risk but the mechanism is unknown. Disturbances in immune regulation, intestinal microbial dysbiosis and subclinical intestinal inflammation characterize AS, and flares in intestinal inflammation are associated with arthritis severity. Intestinal regulatory T cells (Foxp3⁺ Treg) limit inflammation, and TCRαβ+CD4+CD8⁺ cytotoxic T cells (CD4CTL) control intracellular bacteria at epithelial interfaces. CD4CTL develop in response to antigen presented by retinoic acid (RA)-producing dendritic cells. TGF-β and RA enhance CD4⁺ T cell Runx3 and suppress ThPOK for CD4CTL trans-differentiation. ZAP70^{W163C} mutant (SKG) mice have reduced ZAP70 signaling, spondyloarthritis and ileitis. We investigated ZAP70 in Runx3 signaling and CD4CTL development.

Methods: We isolated ileal intraepithelial and lamina propria lymphocytes and analysed Treg and CD4CTL. CD4CTL were generated in vitro by culture of OVA-specific DO11.10 and SKG.DO11.10 T cells with OVA peptide, TGF-β and RA, and in vivo by transfer of OVA-specific T cells to immune-deficient mice fed OVA. Differentially-expressed genes from terminal ileum of 8 naïve SKG and 3 BALB/c mice were assessed by RNA microarray (Illumina). We compared enrichment of Runx3-regulated genes uncovered by ChIP-seq and transcriptome analysis in SKG and BALB/c mice. T cells isolated from human colon, ileum and blood of 5 AS patients and 5 healthy controls (HC) were analyzed.

Results: CD4CTL and Runx3 expression were reduced, while Foxp3⁺ pTreg were increased SKG relative to BALB/c ileum. Tissue resident memory T cell-associated genes e.g. *Cd3e*, *Ilgae*, *Ccl5*, and *Ilgb7*, and antigen processing and presentation genes e.g. *H2-ab1*, *H2-Dma*, *H2-ea*, *Tap1*, and *H2-q8*, were downregulated in SKG relative to BALB/c ileum. 36% of differentially-expressed genes are Runx3-regulated genes, previously identified by ChIP-Seq. The SKG ZAP70-mediated TCR loss of function prevented effective intestinal CD4CTL but not pTreg differentiation in context of TGF-β

and RA in vitro and in vivo, resulting in Runx3 and ThPOK dysregulation. CD4CTL and their expression of perforin, IFN- γ , NFAT and Runx3 were decreased in intestine and blood of AS patients compared with HC.

Conclusion: High-affinity TCR-ZAP70 signaling is required for RUNX3-mediated intestinal CD4CTL differentiation and the balance with Foxp3⁺ Treg. Runx3 deficiency links intestinal pathology in mice and humans through CD4CTL. Since deficiency of CD4CTL cells with cytotoxic function should limit host control of intracellular pathobiont species, reduced TCR-ZAP70-RUNX3 is a key pathogenetic pathway in spondylo arthropathy.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Basic Science

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Current data suggests that immune events in the gut may impact on joint inflammation in ankylosing spondylitis (AS) but what directs cells in the gut-joint axis is undefined. For this reason, we examined the expression of trafficking molecules on immune cells using Cytometry by Time-of-flight (CyTOF), and the expression of differentially regulated genes using bulk RNA-sequencing (RNA-seq). Our objectives are to utilize proteomic and transcriptomic analysis to 1) assess differential expression patterns of trafficking molecules between patients and controls, 2) generate joint-specific cellular signatures, and 3) obtain genetic profiles of noteworthy cell subpopulations.

Methods: Male subjects under 40 years of age fulfilling the mNY criteria were recruited. The following cells were surface stained using a 36-marker antibody panel: (i) Peripheral blood mononuclear cells (PBMC) from AS patients, and healthy controls; (ii) Synovial fluid mononuclear cells (SFMC) from AS and rheumatoid arthritis (RA) patients. After acquiring on CyTOF2, data were analysed using SPADE, viSNE and FlowJo programs for data visualization and statistical analysis. Additionally, bulk RNA-seq was performed on CD8⁺ T cell subpopulations from the synovial fluid. Pathway analysis of differentially expressed genes was conducted using the ClueGo application from the Cytoscape program.

Results: Mature CD8⁺ T cells were increased in frequency in AS SFMC, with significant changes in their phenotype: β 7⁺, CD103⁺, CD29⁺ and CD49a⁺ integrin expression was increased in CD8⁺CD45RO⁺ cells in AS SFMC vs paired AS PBMC (mean 7.51% vs 0.87%, $p=0.0035$). A similar comparison in RA SFMC vs paired RA PBMC revealed less dramatic changes (mean 3.11% vs 0.33%, $p=0.0056$). RNA-seq data analysis of CD103⁺CD49a⁺ cells in AS SFMC revealed elevated GZMA, GZMB, PRF1 and IL-10 cytokines, in addition to a cytotoxicity regulation profile. Signaling molecules, such as TNFAIP3 and TIAF1, and transcription factors, such as RUNX1 and IRF4, were elevated as well.

Conclusion: We identified a novel integrin-expressing mature CD8⁺ T cell subset (CD49a⁺CD103⁺ β 7⁺CD29⁺) that appears to be more prevalent in AS SF than RA SF. These cells possess a dual proinflammatory and regulatory profile, suggesting these roles may be microenvironment-dependent. Further experiments are ongoing to provide evidence of gut-joint trafficking capabilities using murine models. Examinations of patient gut and synovial tissue biopsies, as well as murine gut and joint tissue are essential to determine the arthritogenic potential of these cells. A global analysis encompassing transcriptional and proteomic changes is mandated to provide crucial insights into the inflammatory relationship between the gut and joint, which in turn would be important to design innovative immunotherapy for AS.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Basic Science

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Recent mouse studies of SpA pathogenesis have suggested that $\gamma\delta$ T-cells accumulate at enthesal regions in an IL-23 overexpression model and that these cells are responsible for the majority of local IL-17A production. Moreover a specific subset of $\gamma\delta$ T-cells (V δ 6) has been implicated in murine enthesitis and bone regeneration. This study aimed to examine the local distribution of $\gamma\delta$ T-cell subsets in normal human entheses and identify which are most likely to participate in IL-23/17 axis driven inflammation.

Methods: Human enthesal soft tissue (EST) and peri-enthesal bone (PEB) was harvested from normal spinous process in patients undergoing elective spinal orthopaedic procedures. Interspinous EST was dissected from PEB and enzymatically digested. Cell sorting was used to isolate $\gamma\delta$ T-cells expressing the V δ 1 or V δ 2 isoforms of the TCR receptor $\gamma\delta$ T-cells expressing other V δ isoforms were also collected. Following isolation RNA was purified and analysed by TaqMan array. Healthy enthesal tissue and peripheral blood collected from patients with either PsA or AS was stimulated with phorbol 12-myristate 13-acetate (PMA)/ionomycin and intracellular IL-17A production was measured in T-cell subsets.

Results: Healthy EST contained a similar proportion of $\gamma\delta$ subsets, (37%V δ 1 and 57%V δ 2) as was observed in peripheral blood (28%V δ 1 and 63%V δ 2), PEB contained a higher proportion of the V δ 1 subset and a lower proportion of the V δ 2 subset (50% and 39% respectively). The V δ 2 subset expressed a high relative abundance of IL-23/17 pathway associated transcripts including IL-23R, RORC and CCR6 they also expressed high relative abundance of TGF β 1 transcript, a cytokine associated with immunomodulation and tissue residency. Following PMA stimulation IL-17A was robustly detected in CD4⁺ T-cells and in $\gamma\delta$ T-cells was detected predominantly in the V δ 2 subset although some signal was also observed in V δ 1 cells.

Conclusion: The V δ 2 subset of $\gamma\delta$ T-cells are present in enthesal tissues, their transcriptional profile and functional characteristics are consistent with IL-23 responsive IL-17 producing cells and closely resemble enthesitis associated murine V δ 6 $\gamma\delta$ T-cells. This data suggests that in humans the V δ 2 subset of $\gamma\delta$ T-cells are most likely to participate in SpA pathogenesis.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Fibromyalgia and Other Clinical Pain Syndromes

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Up to 50% of sleep apnea (SA) patients have fibromyalgia (FM). Little is known about the prevalence and associations of SA and FM, and the impact of continuous positive airway pressure (CPAP) use in patients with FM.

Methods: Consecutive patients diagnosed with FM by clinical and/or ACR 2010 criteria, were enrolled and classified according to reported history of SA and CPAP use. Sleep characteristics and FM measures of severity, depression and function were compared between groups.

Results: Characteristics of 667 FM patients were: age 45.9 ± 37.6 , 89.5% female, 79.9% white, BMI 30 ± 8.7 , Fibromyalgia impact questionnaire score 63.5 ± 20.1 , Epworth Sleepiness Scale 9.5 ± 5.9 , hours of sleep 6.1 ± 2.0 , 85.9% reported unrefreshing sleep, 65% trouble falling asleep, 73.7% trouble staying asleep. Prior diagnosis of SA was reported by 154 (21%) FM patients, of which 50 patients (32.4%) used CPAP, for 6.4 ± 1.4 days/week. Comparisons between FM with SA and without, and between CPAP users and non users are presented in Table 1 and Table 2.

Table 1 Comparison between FM patients with and without a prior history of sleep apnea.

	No prior diagnosis of sleep apnea N 513	Prior diagnosis of sleep apnea N 154	p
Age	45.4 ± 11.1	48.12 ± 11.8	0.746
BMI	29 ± 7.7	33.6 ± 10.5	0.000
Hours of sleep/night	6.0 ± 1.9	6.3 ± 2.2	0.559
ESS	9.1 ± 5.9	10.5 ± 5.7	0.014
Patient health questionnaire -9 (PHQ-9)	12.2 ± 6.1	11 ± 6.94	0.006
Fibromyalgia impact questionnaire (FIQ)	63.6 ± 18.5	64.3 ± 23.7	0.587
Health assessment questionnaire -disability index (HAQ-DI)	1.0 ± 1.46	1.2 ± 1.1	0.411
Widespread pain index (WPI)	12.1 ± 9.0	12.4 ± 4.4	0.905
Symptom severity scale (SS)	8.8 ± 2.3	9.3 ± 2.4	0.021
Fibromyalgianess scale (PSD)	21.1 ± 10.0	22.1 ± 5.4	0.559
Unrefreshing sleep	89.5% N 459	86.4% N 133	0.000
Trouble falling asleep	67.6% N 347	65.6% N 101	0.000
Trouble staying asleep	78% N 400	75.3% N 116	0.000

Table 2 Comparison between FM patient with sleep apnea who used CPAP regularly with those who did not use CPAP

	Not using CPAP N 104	Using CPAP N 50	p
Age	47.6 ± 13.0	49.5 ± 9.4	0.7
BMI	32.0 ± 10.2	36.3 ± 11.0	0.000
Hours of sleep/night	6.2 ± 2.4	6.4 ± 2.0	0.491
ESS	9.6 ± 7.0	12.0 ± 5.9	0.006
PHQ9	14.4 ± 7.0	13.1 ± 6.8	0.013
FIQ	63.5 ± 23.9	65.9 ± 24.0	0.405
HAQDI	1.2 ± 1.3	1.2 ± 1.1	0.487
WPI	12.0 ± 4.5	12.8 ± 4.3	0.812
SS	9.1 ± 2.5	9.4 ± 2.0	0.408
PSD	21.5 ± 5.5	22.5 ± 5.3	0.684
Unrefreshing sleep	88.7% N 86	84.7% N 42	0.259
Trouble falling asleep	71.5% N 69	56% N 29	0.215
Trouble staying asleep	82.5% N 80	60% N 30	0.033

Conclusion: Quality of sleep was poor in FM; SA was reported by 1/5 FM patients, who had higher BMI, SS, and were more depressed; 1/3rd of FM SA patients used CPAP; compared to those who did not, CPAP users were more obese, had higher daytime sleepiness, were less depressed and had less trouble staying asleep. Longitudinal studies are needed to determine the true prevalence of sleep apnea in FM, confirm and understand the directionality of these observations.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Fibromyalgia and Other Clinical Pain Syndromes

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Recent studies have suggested that fibromyalgia is inaccurately diagnosed in the community, and that approximately 75% of persons reporting a physician diagnosis of fibromyalgia would not satisfy published criteria. To investigate possible misclassification, we studied fibromyalgia diagnosis by comparing expert physician diagnosis with published criteria.

Methods: In a university rheumatology clinic, 497 consecutive unselected patients completed the Multi-dimensional Health Assessment Questionnaire (MDHAQ) as well as the 2010 American College of Rheumatology (ACR) preliminary diagnostic criteria for fibromyalgia questionnaire (FCQ) modified for self-administration during their ordinary medical visit. Patients were evaluated and diagnosed by university rheumatology staff who did not review the FCQ.

Results: Of the 497 patients, 121 (24.3%) satisfied fibromyalgia criteria while 104 (20.9%) received a clinician ICD diagnosis of fibromyalgia. The overall agreement between clinicians and criteria was 79.2%. However, agreement beyond chance was only fair: kappa 0.41 [probabilistic category 0.20 -0.40]. Physicians failed to identify 60 (49.6%) of criteria positive patients and incorrectly identified 43 (11.4%) of criteria negative patients as shown in Figure 1.

As shown in Figure 2, clinician diagnosed case varied widely in PSD scores, while criteria positive cases and criteria and clinician negative cases had appropriate PSD scores.

Because there were approximately 4 times as many clinical fibromyalgia negative patients, the total counts of positive and negative misclassifications (60 vs. 43) were closer than the percentages suggested. In a subset of 88 patients with rheumatoid arthritis, the kappa statistic was 0.32, indicating slight to fair agreement [0.00-0.20]. Universally, higher PSD scores and criteria based diagnosis were associated with more abnormal MDHAQ clinical scores. Women, patients with

more symptoms but fewer pain areas, and those with lower polysymptomatic distress (PSD) scores were more likely to receive a clinician's diagnosis than to satisfy fibromyalgia criteria.

Conclusion: There is considerable disagreement between clinical diagnosis as recorded in ICD codes and criteria determined diagnosis of fibromyalgia, confirming diagnostic problems found in the community and calling into question ICD based fibromyalgia studies. Fibromyalgia criteria were easy to use, but problems regarding clinician bias, meaning of a fibromyalgia diagnosis, and the validity of physician diagnosis were substantial.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Fibromyalgia and Other Clinical Pain Syndromes

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Multiple clinical and epidemiological studies have provided estimates of fibromyalgia prevalence and sex ratio, but different criteria sets and methodology, as well as bias, have led to widely varying (0.4%->11%) estimates of prevalence and female predominance (>90% to <61%). In general, studies have failed to distinguish Criteria based fibromyalgia (CritFM) from Clinical fibromyalgia (ClinFM) or fibromyalgia diagnosed by clinicians. In the current study we compare CritFM with ClinFM to investigate gender and other biases in the diagnosis of fibromyalgia.

Methods: We used a rheumatic disease databank and 2016 fibromyalgia criteria to study prevalence and sex ratios in a selection biased sample of 1761 referred and diagnosed fibromyalgia patients and in an unbiased sample of 4342 patients with no diagnosis with respect to fibromyalgia. We compared diagnostic and clinical variables according to gender, and were analyzed a German population study (GPS) (n=2435) using revised 2016 criteria for fibromyalgia.

Results: In the selection-biased sample of referred patients with fibromyalgia, more than 90% were women. However, when an unselected sample of rheumatoid arthritis (RA) patients was studied for the presence of fibromyalgia, women represented 58.7% of fibromyalgia cases. Women had slightly more symptoms than men, including generalized pain (36.8% vs. 32.4%), count of 37 symptoms (4.7 vs. 3.7) and mean polysymptomatic distress score (10.2 vs. 8.2), and we found a linear relation between the probability of being females and fibromyalgia and fibromyalgia severity – as shown in the figure below. Women in the GPS represented 59.2% of cases.

Conclusion: The perception of fibromyalgia as almost exclusively (90% or greater) a disorder of women is not supported by data in unbiased studies. Using validated self-report criteria and unbiased selection, the female proportion of fibromyalgia cases was less than or equal to 60% in the unbiased studies, and the observed CritFM prevalence of fibromyalgia in the GPS was approximately 2%. ClinFM is the public face of fibromyalgia, but is severely affected by selection and confirmation bias in the clinic and publications, underestimating men with fibromyalgia and overestimating women. We recommend the use of 2016 fibromyalgia criteria for clinical diagnosis and epidemiology because of its updated scoring and generalized pain requirement. Fibromyalgia and generalized pain positivity, widespread pain (WPI), symptom severity scale (SSS) and polysymptomatic distress (PSD) scale should always be reported in order to adequately characterize subjects in fibromyalgia studies.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Fibromyalgia and Other Clinical Pain Syndromes

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Fibromyalgia Syndrome (FMS) is a multi-symptom disorder, characterized by somatic and cognitive manifestations, such as impaired working memory, executive function and attention (1,2).

The updated criteria for diagnosis of FMS (2016) recognize cognitive symptoms as a valid feature of the disease (3). These criteria use the Widespread Pain Index (WPI), a patient – reported tool reflecting the degree of pain dispersion, as well as

the Symptom Severity Scale (SSS), reflecting a sum of accompanying symptoms. The SSS itself includes a cognitive index score (SSS-Cog), focused on cognitive manifestations experienced by FMS patients (4,5,6).

Previous studies have shown inconsistency in correlating subjective and objective cognitive impairment in FMS patients (7,8). This study aims to check the validity of the SSS-Cog, by evaluating the correlation between patient-reported cognitive symptoms of FMS and a battery of computerized normalized cognitive tests.

Methods: FMS patients were recruited at a specialized FMS clinic. Participants were over 18 and diagnosed with FMS according to the 2010/2011 ACR diagnostic criteria (n=50, 86% women, 7% men). Secondary FMS patients were excluded. NeuroTrax™ computerized cognitive assessment battery was used for evaluation of cognitive function, in addition to filling up the Fibromyalgia impact questionnaire (FIQ), WPI and SSS.

Depressive symptoms, which may alter cognition, were assessed by the Beck Depression Inventory (BDI)-II. Level of effort during cognitive testing was evaluated with the Test of Memory Malingering (TOMM).

A Spearman correlation coefficient was used to assess whether the SSS-Cog index correlated with performance on the computerized cognition tests. Further correlations were performed between the SSS-Cog and other questionnaires used in the study (WPI, FIQ, BDI-II).

Results: The SSS-Cog results did not correlate with scores of the NeuroTrax™ cognitive assessment battery (rs= -.132, p= .361). Positive correlations were found between the SSS-Cog and the FIQ (rs= .438, p= .001), especially the pain measures utilized in it (VAS-pain, rs= .304, p= .032), as well as with the WPI (rs= .333, p= .018). The lack of correlation between the SSS-Cog and objective cognitive performance persisted when excluding a subgroup of 8 low-effort participants with a TOMM score ≤45. Age and BDI-II (depression) scores were also shown not to be confounding factors.

Conclusion: There is a strong correlation between FMS patients' subjective evaluations of cognitive impairment and self-measures of daily functioning, symptom intensity and experienced pain. However, a notable lack of correlation was found between patients' self-reported cognitive impairment and objective cognitive scores, indicating that the SSS-cog does not reflect its self-proclaimed purpose – assessing cognitive impairment. These findings highlight the need for development of alternative tools in assessing cognitive impairment in FMS patients.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Fibromyalgia and Other Clinical Pain Syndromes

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Clinicians must commonly differentiate fibromyalgia (FM) from other chronic pain diagnoses. Numerous symptoms, including those from the 2016 criteria, have been proposed to accomplish this differentiation -- but little is known about their relative importance. Moreover, other potential symptom candidates have been neglected. Herein we rank 26 symptoms according to how well (or not) they differentiate FM patients from other chronic pain patients. We highlight symptoms that are most important and identify others that have received little or no attention.

Methods: The data for this study was taken from a previously published paper (2018, J of Evaluation in Clinical Practice, 24(1): 173-179). A total of 352 patients (mean age 50 ± 16.3 years, 70% female) were studied. They comprised of 52 patients (14.8%) who carried a chart diagnosis of FM, 108 (30.7%) with chronic pain but not FM, and 192 who had neither pain nor FM. All patients completed a questionnaire that documented pain at 28 locations, the Revised Symptom Impact Questionnaire (SIQR) which included 10 symptoms and 16 additional novel questions related to other common symptoms often co-occur with FM. The 26 symptoms were ranked in their capacity to predict FM vs. chronic pain no FM using the Somers' D statistic.

Results: These data suggests that VAS pain itself is not a useful symptom in diagnosing FM in a population of patients with chronic pain (lowest rank). The most useful clusters for differentiating FM patients from chronic pain patients without FM were: “*I have a persistent deep ache over most of my body*” combined with 4 other symptoms (*poor balance, sensitivity to noise, environmental sensitivity and pain after exercise*; *Odds ratio =9.30*), or the deep ache question in association with *poor balance, environmental sensitivity, pain after exercise and tenderness to touch*; *Odds ratio =9.27*). Symptoms used in the Symptom Severity Scale (SSS) of the 2016 Revised Fibromyalgia Criteria, (unrefreshing sleep, dyscognition, fatigue , IBS symptoms, depression and headache) have relatively low discriminatory value (*Odds ratio = 2.96*).

Conclusion: These data attest to the potential usefulness of a cluster of symptoms that are not commonly used in current diagnostic guidelines for FM. Furthermore, they are notably different from symptoms advocated in the established 2016 revised guidelines.

Somers'D (rank)	Symptom VAS (range 0-10)	FM Mean n=50 (rank)	Pain No FM Mean n=108 (rank)	Mean difference

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Fibromyalgia and Other Clinical Pain Syndromes

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Lifestyle modifications, including of diet and exercise, have been widely disseminated for the prevention and treatment of chronic pain. However, the relationships between dietary habits and fibromyalgia (FM) impact, and psychosocial or quality of life (QoL) outcomes have not been well studied.

Table 1. Associations of diet quality (HEI-2010 scores) with pre-intervention fibromyalgia impact scores, various psychosocial and quality of life measures, self-efficacy, and sleep quality in 26 women with fibromyalgia

Pre-intervention measure (maximum score range)	Healthy Eating Index 2010 (HEI-2010) (0-100 points)
Physical health Quality of Life (SF-36 PCS) [0-100 points]	$r = 0.32$ ($p < .12$)
Mental health Quality of Life (SF-36 MCS) [0-100 points]	$r = 0.20$ ($p < .30$)
Chronic Pain Self-Efficacy Scale [0-10 points]	$r = 0.07$ ($p = .91$)
Revised Fibromyalgia Impact Questionnaire (FIQR) [0-10 points]	$r = 0.27$ ($p = .10$)
Beck II Depression Inventory (BDI) [0-63 points]	$r = -0.17$ ($p = .40$)
Pittsburgh Sleep Quality Index (PSQI) [0-21 points]	$r = -0.10$ ($p = .48$)
Hospital Anxiety Score (HADS) [0-21 points]	$r = -0.24$ ($p = .08$)
Hospital Depression Score (HADS) [0-21 points]	$r = -0.47$ ($p < .02$)

r : > 0.30 , 0.15 , and 0.7 indicates weak, moderate, and strong association, respectively.

^aHigher score is better.

^bHigher score is worse.

Table 2. Healthy Eating Index 2010 (HEI-2010) Total and Component Scores in the Study Participants (n=26), and in the U.S. Adults and Older Adults

HEI-2010 Dietary Component (maximum score)	Study Participants 24-75 years (n=26)	U.S. Adults 18-64 years (n=4,044) ^a	U.S. Older Adults ≥ 65 years (n=1,032) ^a
Adequacy (higher score indicates higher consumption)	Mean Score (standard error)		
Total Fruit ^b (5)	4.20 (0.25)	2.61 (0.11)	3.84 (0.22)
Whole Fruit ^b (5)	4.38 (0.23)	3.52 (0.15)	4.99 (0.08)
Total Vegetables ^b (5)	4.24 (0.22)	3.54 (0.09)	4.16 (0.19)
Greens and Beans ^b (5)	4.09 (0.31)	3.03 (0.16)	3.58 (0.47)
Whole Grains (10)	2.48 (0.31)	2.75 (0.18)	4.23 (0.34)
Dairy ^b (10)	4.99 (0.57)	6.78 (0.13)	8.99 (0.18)
Total Protein Foods ^b (5)	4.46 (0.18)	6.00 (0.00)	6.00 (0.00)
Seeds and Plant Protein ^{b,c} (3)	4.52 (0.19)	3.98 (0.22)	4.93 (0.18)
Fatty Acids (10)	7.13 (0.46)	4.02 (0.19)	6.60 (0.36)
Moderation (higher score indicates lower consumption)			
Refined Grains (10)	6.04 (0.30)	6.36 (0.17)	7.34 (0.31)
Sodium (10)	6.62 (0.51)	4.04 (0.08)	3.66 (0.26)
Empty Calories (20)	18.89 (0.84)	12.53 (0.38)	14.90 (0.44)
Total HEI-2010 score (100)	71.42 (1.63)	58.27 (0.98)	68.29 (1.76)

^a Calculated using the population ratio method. Data source: National Health and Nutrition Examination Survey, 2011-2012 (available from <https://www.cdc.gov/nchs/data/healthyeatingindex/>)

^b Includes 100% fruit juice.

^c Includes all forms except juice.

^d Includes any beans and peas not counted as Total Protein Foods.

^e Includes all milk products, such as fluid milk, yogurt, and cheese, and fortified soy beverages.

^f Beans and peas are included here (and not with vegetables) when the Total Protein Foods standard is otherwise not met.

^g Includes seafood, nuts, seeds, soy products (other than soybeans), as well as beans and peas counted as Total Protein Foods.

^h Ratio of poly- and monounsaturated fatty acids (PUFAs and MUFA) to saturated fatty acids (SFA).

ⁱ Calories from solid fats, alcohol, and added sugars, threshold for counting alcohol is > 13 grams/1,603 kcal.

Methods: Participants in a large comparative effectiveness randomized trial of Tai Chi versus aerobic exercise for FM were recruited. Participants were excluded from this study if they had participated in any dietary intervention since the end of the original trial. The National Cancer Institute Diet History Questionnaire (DHQ-II past year recall without portion sizes) was used to assess diet quality, using the Healthy Eating Index 2010 that assesses compliance with the 2010 U.S. Dietary Guidelines for Americans (DGA). Associations of diet quality with the pre-intervention FM impact scores, various psychosocial and QoL measures, self-efficacy, and sleep quality (Table 1) were examined using Pearson's correlation coefficient (r)

Results: A total of 26 female participants (mean age = 56 y; mean pre-intervention BMI =29.6) were included in the analyses. Of which, six (3 in each intervention arm) participants reported that their diet has changed since the end of the original trial. Diet quality of these participants was better than general U.S. adult population (Table 2). Higher pre-intervention self-efficacy and physical health QoL were associated with higher diet quality ($r = 0.62$ and 0.32 , respectively). Higher pre-intervention levels of anxiety and depression were associated with lower diet quality ($r = -0.43$ and -0.47 , respectively). There were no significant associations between diet quality and pre-intervention severity of depressive symptoms, mental health QoL, sleep quality, or FM impact scores (Table 1).

Conclusion: Better diet quality as recommended by the 2010 DGA may be associated with more favorable psychosocial and physical health QoL outcomes in women with FM. Our results are consistent with a large cross-sectional study in women with FM from Spain (J Acad Nutr Diet. 2017 Mar; 117(3):422-432). Future studies evaluating the effects of healthy dietary patterns on psychosocial and physical outcomes in individuals with FM are warranted.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Healthcare Disparities in Rheumatology

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: The treatment and prognosis of rheumatoid arthritis (RA) patients have improved tremendously, but patients across the world may not benefit similarly. One of the potentially critical factors may be poorer access to expensive biologic (b) DMARDs. We aimed to investigate daily practice data regarding bDMARD use in different countries worldwide and assess if a lower country's socioeconomic status (SES) is associated with worse clinical outcomes and lower usage of bDMARDs.

Methods: Data on disease activity and drug use from countries that contributed ≥ 100 RA patients after 1-1-2000 were extracted from the daily practice, observational METEOR database. Missing data were imputed using multivariate normal imputation (30 cycles). Gross domestic product (GDP) per capita in international dollar (Intl\$) was used as indicator of SES. Per country average DAS28 and the proportion of patients in DAS28-remission ($\text{DAS28} < 2.6$) were calculated by taking the average of all patients at the last available visit. Univariable logistic regression analyses were performed to assess associations between GDP, bDMARD-use and disease outcomes at a country level.

Results: In total, 20,379 patients were included from 12 countries: United States, Mexico, South-Africa, Japan, Brazil, United Kingdom, Spain, Ireland, Portugal, France, India and the Netherlands. The number of patients ever using a bDMARD varied between 0.9% (South-Africa) and 75% (Ireland). The proportion of patients in remission at the final visit varied between 2% (India) and 39% (Netherlands).

Figure 1. Associations between 'GDP per capita (Intl\$)', '% bDMARD use' and 'disease activity', IN=India, SA=South-Africa, BR=Brazil, MX=Mexico, PT=Portugal, ES=Spain, JP=Japan, UK=United Kingdom, FI=France, NL=Netherlands, US=United States, IE=Ireland

Patients in countries with a higher GDP per capita had a lower average DAS28 and consequently, a higher proportion of them were in DAS28-remission: -0.32 (95%CI -0.41; -0.021) lower DAS28 and an additional 4.2% (0.14; 8.26) of patients in DAS28-remission for every 10,000 Intl\$ additional GDP.

To underscore the assumption that the association between SES and DAS28 is mediated by bDMARD use, we assessed whether SES was associated with bDMARD use per country. Indeed, a higher GDP per capita was associated with a higher proportion of patients using a bDMARD: 11.2% (95% CI 4.82; 17.5) more patients using a bDMARD per 10,000 Intl\$ additional GDP. Furthermore, DAS28 was -0.14 (-0.28; -0.0054) lower and 2.8% (-0.13; 5.8) more patients achieved DAS28-remission per 10% increase in proportion of patients using a bDMARD, figure 1.

Conclusion: RA patients in countries with a lower SES had worse disease activity. Although patients in countries with a lower SES less often used bDMARDs, the effect of bDMARD use on disease activity was smaller than expected, indicating that other factors than access to bDMARDs may contribute to the effectiveness of RA-treatment.

Current Rheumatology Fellows Experiences with Health Disparities and Disparity Education: A Qualitative Study

Irene Blanco¹ and Cristina Gonzalez², ¹Rheumatology, Albert Einstein College of Medicine, Bronx, NY, ²Medicine, Albert Einstein College of Medicine, Bronx, NY

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Healthcare Disparities in Rheumatology

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Health disparities (HD) are pervasive across all specialties including rheumatology; such that the ACGME has mandated that all programs teach house officers about HD. To inform future curriculum development, we conducted a qualitative study to explore rheumatology fellows perceptions of and experiences with HD instruction.

Methods: We conducted 5 focus groups (FG) in New York and Pennsylvania using a semi-structured interview guide. Questions focused on fellows' experiences with HD in their practices and if/how they have been taught to address these issues. FG audio recordings were transcribed by a third party contractor, de-identified and systematically analyzed using grounded theory by 2 reviewers. FG were conducted until there was a saturation of themes. This project was approved by the Einstein IRB and fellowship names/locations are not reported to protect the fellows' anonymity.

Results: 25 fellows participated in our FG --most saw what they considered to be urban/suburban populations; 1 program treated rural patients. 3 major themes emerged from our data: **1. HD Create a Sense of Being Overwhelmed 2. Scarcity of Role-Modeling 3. Learning is Haphazard.**

1. BEING OVERWHELMED

All fellows felt that they were seeing evidence of disparate care among their patients and were at a loss on how to address these issues: *"you can't do things for the patients, and I think over time it gets really burdensome and frustrating."* *"I think these are the things we bang our heads against the wall on".*

2. ROLE-MODELS

Fellows were not observing their faculty regularly address these issues and potentially encounters can be problematic. *"...there are a few faculty members who I think understand certain barriers and certain patients as opposed to others who can't."* *"I know I have seen their implicit bias play out. ... I've had patients who may get frustrated if they find out who the precepting attending is for them. Like oh, I got to see this one - -. It exists. Then the fellow role actually becomes sometimes protecting the patient a little bit. Which is awkward."*

3. HAPHAZARD LEARNING

In addition to this lack of informal instruction and occasional negative role modeling, there is a lack of formal instruction. *"I can't remember it being done. I don't know, but maybe I'm blanking but I don't remember having anything formal."* Fellows are left to discuss issues with each other: *"I was going to say talk about it amongst each other case by case, but not as a group, not as a division officially. Just a lot of complaining in the fellow's office".* This is reinforced by the programs *"A lot of social aspects of medicine we put on the back burner because I don't know, in two years of fellowship I still feel like there's so much other stuff that I also need to know."* *"It's just the culture but it has what's expected and what's expected is you pick a topic that is rheumatology ... like a good randomized controlled trial study and then you talk about that..."*

Conclusion: Currently fellows are not learning about HD in a formal way or how to address HD in their patients, despite the fact that this is mandated by the ACGME, . The development of GME specialty-specific curricula will be key if we are to train providers that will advocate for our most marginalized populations and contribute to health equity.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Healthcare Disparities in Rheumatology

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Lupus is a chronic, auto immune disease that disproportionately affects African American individuals. Community-based educational interventions that capitalize on rich social networks can be used to promote positive health-seeking norms and behaviors. Our academic-community partnership adapted the CDC's Popular Opinion Leader (POL) evidence-based practice to develop and implement an African American POL program that leverages community leaders' social networks to disseminate culturally appropriate lupus education and promote care-seeking norms. The first phase of implementation was in greater Boston neighborhoods with a higher demographic representation of African Americans.

Methods: Academic lupus clinicians and disparities researchers partnered with two local lupus support groups comprised primarily of women of African descent, and a local community-based health education, research and service organization, to recruit POLs. Recruitment targeted community and neighborhood organizations, churches and support groups in medically underserved, predominantly African American neighborhoods. Participants attended four, 2-3 hour POL training sessions at an urban community center. An interactive, live-streaming webinar option was also available. The training included lupus and disparities education, application of the POL model, and strategies to disseminate lupus education, change norms, and document impact. Detailed observational and qualitative data were collected at the trainings and analyzed the matically. POLs disseminated information formally and informally through their social networks and communities and documented conversations, venues and number of people reached.

Results: We trained 18 Boston area POLs, 11 with lupus, 7 without (3/7 with relatives with lupus). Seventeen were female, 3 were ≤45 years, 11 were 45-65 years, 4 were >65 years. 16 were African American, 1 African American/Native American, and 1 Caucasian. Nine held graduate degrees, 6 associates/bachelors', and 3 high school. Key themes raised by POLs at the trainings included challenges with patient-MD communication, stigma/misconceptions surrounding lupus as a disfiguring or contagious disease, racial and gender discrimination in healthcare, challenges engaging family members, and the importance of support networks for lupus patients. Within 2 months of the training, POLs engaged 269 individuals in 14 neighborhoods in conversations about lupus and the importance of early and sustained care (**Table**).

Conclusion: We implemented a community-based African American POL model in the greater Boston area which resulted in the ongoing dissemination of lupus-related information through diverse social networks. A parallel implementation initiative is underway in Chicago, as well as quantitative data analysis at both sites, to prepare to scale the intervention nationally.

Table. Community dissemination data collected by trained lupus Popular Opinion Leaders (POL) in the two months following POL training

	# of POLs	# of People Reached	POL Reported Community-based Venues
Urban Boston Neighborhoods			
Dorchester	6	87	Lupus Support Group, Elementary School, Neighborhood Development Coalition, Community Health Center, Hair Salon, Market, Convenience Store, Library, Gym, Grocery Store, Community Resource Fair, Square Park Meeting, Community Event, Golf Course, Fraternity/ Masonic Lodge, Parking Lot, National Alliance on Mental Illness

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Healthcare Disparities in Rheumatology

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: We previously demonstrated that a small group of high risk, high cost patients (HRHC) account for majority of the hospitalizations, length of stay (LOS) and overall cost among all lupus patients admitted to an academic medical center. Herein, we assessed the impact of an intervention to improve access to rheumatology care for HRHC lupus patients by comparing the number of hospital admissions and LOS in the HRHC cohort compared to hospitalized lupus patients not meeting HRHC criteria.

Methods: Lupus patients who required 3 or more admissions over a 3-year period between 2013 and 2016 were categorized as HRHC patients. Most of these patients were from the poor, urban communities and were mostly African American. A project to improve quality for low-income, underprivileged, poor, underage, SLE (IQ-LUPUS) patients was started in July 2018. One of the goals of the IQ-LUPUS project is to enhance access for the HRHC patients to rheumatology care by offering direct access to a nurse care coordinator and a social worker who provide medical advice, remind and facilitate outpatient visits, enable educational activities and organize home visits. Additionally, we opened a clinic in the urban community. We compared the no show rates for the HRHC patients with all lupus patients and all rheumatology patients seen in the outpatient clinics at URM for the fiscal year (FY) 2017 (prior to project) with FY 2018 (since starting project). We also determined the hospitalization rates and LOS for all admissions among the HRHC patients enrolled in the project, for first 10 months of FY 2017 with the first 10 months of FY 18. The gender, age and the diagnoses on admission were all documented.

Results: A total of 54 HRHC patients are enrolled in the IQ-LUPUS project to date. No show rates for these HRHC patients was 12.1% for FY 2017, 5.8% for all lupus patients and 4.3% for all patients seen at the Rheumatology clinic. The no show rates for the HRHC patients decreased 1.3% for FY 2018 (p=0.62) but increased in all lupus patients (0.8%) and all rheumatology patients (0.7%). In 2017, 16 of the HRHC patients had 52 admissions in 2017 for a total LOS of 231 days. All patients were female with a mean age of 32.9 years. In 2018, the number of admissions decreased to 36 (p=0.3). These admissions included 17 patients and a total LOS of 159 days (p=0.5)). All patients were female with a mean age of 32.5 years. The number of 30-day readmissions also decreased from 21 in 2017 to 14 in 2018. Although no statistical significance was noted early results of the IQ-LUPUS project suggests that improving access can decrease hospitalizations.

Conclusion:: Methods aimed at improving access to rheumatology care through care coordination and special clinics can decrease the number of hospitalizations and LOS among high risk SLE patients. Further studies are needed to further define and implement targeted interventions that decrease hospital admissions and improve quality of care for this vulnerable population.

	High-Risk, High-Cost Lupus patients		All lupus patients	
	2017	2018	2017	218
No show rates	54 (12.1%)	43 (10.8%)	178 (5.8%)	147 (6.6%)
Admissions	52 (36.6%)	36 (21.3%)	142	169
Length of stay	231 (21.8%)	159 (12.9%)	1060	1225

Racial Disparities and Accelerated SLE Mortality from a Population-Based Registry: The Georgia Lupus Registry

S. Sam Lim¹, Charles G. Helmick², Gaobin Bao³, Caroline Gordon⁴, Jennifer M. Hootman² and Cristina Drenkard⁵,
¹Emory University School of Medicine, Atlanta, GA, ²Arthritis Program, Centers for Disease Control and Prevention, Atlanta, GA, ³Department of Medicine, Division of Rheumatology, Emory University School of Medicine, Atlanta, GA,

Session Date: Monday, October 22, 2018

Session Title: Healthcare Disparities in Rheumatology

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Population-based SLE mortality studies have depended on administrative data from vital statistics records to identify cases. However, a high proportion of SLE deaths have no SLE code. We studied mortality trends from a population-based registry that overcame many of these limitations.

Methods: The Georgia Lupus Registry is a CDC funded population-based registry of validated SLE patients in Atlanta, Georgia from 2002-04. The state privacy exemption for surveillance allowed health care providers and facilities to provide access to protected health information without written patient consent, allowing for validation of diagnoses on a population level using ≥ 4 ACR criteria or 3 ACR criteria with a final diagnosis of SLE by a board-certified rheumatologist. All incident and prevalent SLE cases were matched to the National Death Index, which contains information for all deaths

Table 1. Standardized Mortality Ratios of Prevalent SLE Patients, adjusted by age, gender, and race

Sub-Group	Total Cases	Mortality		Standardized Mortality Ratio (95% CI)
		Observed	Expected	
Overall	1335	29	8	3.63 (2.52-5.22)
Male	135	4	1	4.00 (1.50-10.7)
Female	1200	25	7	3.57 (2.41-5.29)
Black	1024	24	6	4.00 (2.68-5.97)
White	311	5	2	2.50 (1.04-6.01)
Black Female	924	21	5	4.20 (2.74-6.44)
White Female	276	4	2	2.00 (0.75-5.33)

*Adjusted for age, gender, and race

*Sample sizes too small for non-black or non-whites

*Age at 7/1/2002 was used for adjustment

in the U.S. as derived from information on death certificates and provided by local vital records offices, through 2016. Cumulative mortality survival analysis and standardized mortality rates (SMR) were analyzed.

Results: Of 336 incident SLE patients in 2002-04, 86.9% were female, 73.8% black and 22.9% white, and mean age of 40.6 years at SLE diagnosis. Of 1353 prevalent SLE patients in 2002, 89.9% were female, 75.7% black and 23% white, and mean age of 34.6 years at SLE diagnosis. There were 97 deaths through 2016. Blacks had significantly greater cumulative mortality than whites (Figs. 1 and 2) and were younger at death for both incident (51.8 ± 17.5 vs. 64.4 ± 18.9 , $P=0.013$) and prevalent (52.3 ± 15.9 vs. 65.0 ± 16.3 , $P<0.0001$) cases. Whites had a marked lower mortality after diagnosis compared with blacks; For incident cases, whites did not die until 5 years after SLE diagnosis, whereas blacks had significant and persistent higher mortality from the start. There were no significant differences by gender. SMR's were calculated for prevalent patients (Table 1).

Conclusion: Despite increasing awareness and advancements in treatment, mortality in SLE continue to remain high and disparate across combined gender and race groups with the highest standardized mortality ratio in black females. Defining and addressing reversible mortality factors must be high priorities in mitigating racial disparities and improving overall outcomes in SLE.

Defining and Examining Retention in Care in an Urban Lupus Cohort

Umber Ahmad¹, Ian Chang², Marit Johnson³, Ann Rosenthal³, Amanda Perez⁴ and Christie M. Bartels⁴, ¹Consultant Care (CC111W) - Rheumatology/Medicine, Milwaukee VA Medical Center, Milwaukee, WI, ²Medicine/Rheumatology, Medical College of Wisconsin, Milwaukee, WI, ³Division of Rheumatology, Medical College of Wisconsin, Milwaukee, WI, ⁴Rheumatology/Medicine, University of Wisconsin - Madison, Madison, WI

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Healthcare Disparities in Rheumatology

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Systemic Lupus Erythematosus (SLE) disproportionately impacts black patients and those of low socioeconomic status who experience higher rates of kidney disease and premature mortality. Similar disparities are being addressed in HIV care by defining a care continuum starting with "retention in care." Studies show that retention in care, defined as one visit or viral load every 6 months by CDC and WHO, correlate with viral suppression, an apt comparison for SLE care. Current SLE research is limited regarding factors that impact retention in care across diverse populations. The objectives of this study were to validate a cohort of patients with confirmed SLE to define retention in lupus care and examine its predictors.

Methods: Potential cases were identified from an academic urban medical center, with at least one ambulatory rheumatology encounter and an ICD code for SLE between 1/1/2013 and 6/30/2014. Inclusion required age > 17 years old, SLE diagnosis, and living through 2015. Manual record abstraction entered in Redcap system confirmed SLE diagnosis by the 1987 ACR or 2012 SLICC classification criteria. Abstraction included sociodemographics, tobacco use, first SLE diagnosis date, and 30 items examining ACR and SLICC criteria. Predictors examined included sociodemographic factors (age, sex, race, ethnicity), socioeconomic status (neighborhood poverty using a zip code area deprivation index [ADI]), number of SLE criteria, and health behavior data (tobacco use).

Retention in SLE care outcomes were defined using a variation of the WHO/CDC definitions in HIV requiring one ambulatory visit and one lab test (complement level) every 6 months. Multivariable logistic regression was used to model predictors using STATA v.15.0.

Results: A total of 397 individuals met ACR or SLICC classification criteria for SLE. Most were female (91%) and race varied (60% white, 40% black, 5% Hispanic). Overall, 60% met visit retention definitions, and 39% met complement lab testing definitions. There was no statistical difference seen with retention in care based on age, gender or race in either model. However, individuals residing in the most disadvantaged neighborhood are as (ADI quartile 4) were 60% less likely to have at least two clinic visits annually (Table 1). Data also showed 50% of black patients living in ADI quartile 4. Smoking history was also a negative predictor for visit retention.

Conclusion: Defining retention in lupus care is a critical step to meet the unmet need to identify and assist SLE patients at risk for gaps in care and outcome disparities. Race did not seem to predict retention; however, the most disadvantaged neighborhoods (ADIquartile 4) were a strong predictor of poor retention in care. Future interventions could prospectively identify such at-risk populations and explore approaches such as multi-disciplinary care models to reduce care disparities.

Menarchal Status at Diagnosis and Final Height in Females with Childhood-Onset Systemic Lupus Erythematosus

Watchareewan Sontichai¹, Daniela Dominguez¹, Lawrence Ng¹, Deborah M. Levy¹, Jonathan Wasserman², Earl Silverman¹ and Linda Hiraki¹, ¹Division of Rheumatology, The Hospital for Sick Children, Toronto, ON, Canada, ²Division of Endocrinology, The Hospital for Sick Children, Toronto, ON, Canada

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Pediatric Rheumatology – Clinical I: Outcomes and Comorbidities

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: The diagnosis of systemic lupus erythematosus (SLE) in childhood affects growth due to disease and therapy. To date, there are few studies of final adult height achieved in children diagnosed with SLE and no study examining the relationship of pubertal status at diagnosis and final height. Our aim was to examine the relationship between age at menarche and final adult height, accounting for ethnicity.

Methods: We completed a retrospective cohort study, reviewing 564 female patients < 18 years of age at diagnosis, and followed at a tertiary care, pediatric center from July 1982 to March 2016. All patients met American College of Rheumatology and/or Systemic Lupus International Collaborating Clinics classification criteria for SLE. Patients with documented vertebral collapse (15 patients) or growth hormone therapy (4 patients) were excluded. We reviewed prospectively collected demographic and clinical data including self-reported ethnicity, height, age at menarche, age at diagnosis, disease activity, disease damage and medication use. Final height was the height achieved after <1 cm growth per year for 2 years following menarche or height at 18 years of age. We compared age at diagnosis and menarche as well as final height between patients diagnosed with SLE pre- and post-menarche using a t-test. We divided patients diagnosed post-menarche into females who grew >1 cm post-menarche and females who had achieved final height at diagnosis (no growth). We examined SLE diagnosis post-menarche, compared with pre-menarche in association with final height, adjusting for ethnicity, in linear regression models.

Results: Our cohort included 401 female SLE patients with final height and menarche data. Of those, 115 patients (29%) were diagnosed pre-menarche (mean age of diagnosis 10.7 years [SD 2.2 years]) and 286 patients (71%) were diagnosed post-menarche (mean age of diagnosis 15.1 years [SD 1.6 years]). Age of menarche was 13.5 years (SD 1.4 years) in the

pre-menarche group, compared to 12.5 years (SD 1.4 years) in the post-menarche group ($P < 0.001$). The mean final height for females diagnosed post-menarche was greater than those diagnosed pre-menarche (Table 1). In subgroup analysis of the post-menarche group, the mean final height of girls with no growth (161.9 cm [SD 6.8 cm]) was greater than girls diagnosed pre-menarche ($p=0.001$). In regression analysis, those diagnosed post-menarche were significantly taller than those diagnosed pre-menarche, adjusted for ethnicity (Beta = 2.6cm, SD 0.7cm, $P < 0.001$).

Conclusion: In this large cohort study of females with childhood-onset SLE, patients diagnosed post-menarche achieved a taller final height than those diagnosed pre-menarche even after accounting for ethnicity. Future analyses will explore the relationship of disease activity, damage and medication use with growth velocity and final adult height.

Table 1 Comparison of final height between females diagnosed with SLE pre-menarche and post-menarche

	Number (%)	Final height (cm), mean \pm SD		P value
		SLE diagnosis pre-menarche	SLE diagnosis post-menarche	
Total cohort*	401	158.8 \pm 7.3	161.4 \pm 6.9	0.001

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Pediatric Rheumatology – Clinical I: Outcomes and Comorbidities

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Despite high rates of depression and anxiety in pediatric lupus, standardized mental health screening is not routinely practiced by pediatric rheumatologists. Our objectives were to screen youth with lupus for depression and anxiety in pediatric rheumatology clinics and assess patient and parent acceptability of screening in this clinical setting.

Methods: In a multi-center study of 6 collaborating clinics from the Childhood Arthritis and Rheumatology Research Alliance, patients with lupus ages 12-21 years were consecutively screened with the Patient Health Questionnaire-9 (PHQ9) for depression and the Generalized Anxiety Disorder 7-item scale (GAD7) for anxiety. Screens were administered by tablets prior to and reviewed during clinical visits. Patient reported outcomes (PROs) for depression, anxiety, fatigue, pain, and physical and social functioning were collected using the Patient Reported Outcomes Measurement Information System. Correlation analyses examined the relationship between these PROs, the PHQ-9 and GAD-7 scores. Follow up surveys emailed to patients and/or parents assessed acceptability of screening. All patients had to meet either the ACRSLE Classification Criteria or the SLICC Classification Criteria.

Figure 1. Beliefs and preferences of youth with lupus and their parents: survey responses after mental health screenings in the pediatric rheumatology clinic

Results: Fifty-three patients were screened and follow up surveys completed for 74%. The median age was 16.2 years, 87% were female, and 75% were of minority race/ethnicity. Of those screened, 26% screened positive for depression, 19% for anxiety, and 15% had suicidal ideation. Only 17% of patients reported previously screenings by their general pediatricians; 15% were newly identified as having symptoms of depression or anxiety. PHQ9 and GAD7 scores were highly correlated to PROs of fatigue ($r=0.7$, $p<0.0001$; $r=0.6$, $p<0.0001$) and pain interference (both $r=0.5$, $p<0.0001$) as well as depression ($r=0.7$, $p<0.0001$; $r=0.7$, $p<0.0001$) and anxiety ($r=0.6$, $p<0.0001$; $r=0.7$, $p<0.0001$) (Table 1). In follow up surveys, 91% felt comfortable being screened by their rheumatologist, and 74% felt they should continue to be routinely screened by their rheumatologist (Figure 1).

Conclusion: Mental health screening in pediatric rheumatology clinics may improve symptom detection for depression, anxiety and suicidal thoughts in young patients with lupus. Screening in this setting was important and acceptable practice to patients and parents across diverse demographics. Using patient-reported outcome measures alongside validated mental health screening tools may enhance our understanding of mental health in these patients.

Table 1 Correlations between depression (PHQ9) score, anxiety (GAD7) score, and patient reported outcomes in youth with lupus

	PHQ9 score	GAD7 score
GAD7 score	0.8, $p<0.0001$	1.00
PROMIS measures:		
Worse depression	0.7, $p<0.0001$	0.7, $p<0.0001$
Worse anxiety	0.6, $p<0.0001$	0.7, $p<0.0001$
Worse fatigue	0.7, $p<0.0001$	0.6, $p<0.0001$
Stronger peer relationships	0.2, $p=0.6$	0.1, $p=0.6$
Lower physical functioning	0.4, $p=0.003$	0.3, $p=0.02$
Higher pain interference	0.5, $p=0.0004$	0.5, $p=0.0002$
Higher pain severity	0.4, $p=0.003$	0.4, $p=0.002$

PHQ9 (Patient Health Questionnaire-9) scores ranged from 0-27; GAD7 (Generalized Anxiety 7-item scale) scores ranged from 0-21. PROMIS (Patient Reported Outcome Measurement Information System) scores were measured as T-scores, except for pain severity measured on a scale of 1-10. Spearman rho correlation coefficients shown.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Pediatric Rheumatology – Clinical I: Outcomes and Comorbidities

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Juvenile Idiopathic Arthritis (JIA) is one of the more common chronic diseases of childhood that often persists into adulthood and can result in significant long-term morbidity. Cardiovascular disease (CVD) is an important cause of mortality and morbidity in patients with rheumatoid arthritis and possibly other forms of adult inflammatory arthritis. However, the long-term risk of CVD for individuals with JIA remains uncertain

Objective: To determine whether adults with JIA in remission and medium-long duration of the disease have an increased risk of CVD.

Methods: This is a cross-sectional study including 27 patients diagnosed with JIA according to the International League of Associations for Rheumatology criteria (ILAR 2001) were compared to 27 age- and sex-matched controls. Remission was determined by JADAS27<1 and according to Wallace criteria. An extensive clinical analysis including body index mass, lipid profile, HOMA-IR and intra-arterial blood pressure was performed. Intima media thickness of the common carotid artery (CIMT) was measured as a marker of subclinical atherosclerosis. Proinflammatory cytokines (TNF α , IL1b and IL6), molecules involved in endothelial dysfunction (VEGF, ICAM-1 and E-Selectin) and adipokines (leptin, adiponectin, resistin and visfatin) were analyzed on serum by ELISA

Results: Mean duration of the disease was 14.51 ± 2.20 years. Mean age was 29.31 ± 0.78 . Time in remission was 4.22 ± 0.64 years. Metabolic comorbidities such as obesity and metabolic syndrome were more prevalent in our cohort of JIA patients compared to controls. Levels of cholesterol were significantly elevated in patients. CIMT was higher in JIA patients compared to controls, although it did not reach the statistical significance. Serum levels of cytokines (TNF α , IL6 and IL1b) and endothelial activation markers (VEGF and ICAM-1) were elevated in JIA adult patients. Serum levels of adiponectin were significantly decreased. In contrast, levels of resistin and visfatin were higher in JIA patients. Disease duration significantly correlated with CIMT values, cholesterol and TNF α levels. In addition, there was an association among levels of lipids, adipokines and inflammatory mediators.

Conclusion: In adult JIA patients with clinical remission, CIMT and levels of inflammatory cytokines, adipokines and endothelial activation markers were elevated, molecules with a relevant role in the onset and progression of endothelial dysfunction and atherosclerosis. These results might suggest that long-term JIA patients could have higher cardiovascular risk, although they are in sustained remission. Thus, cardiovascular risk assessment should be considered as part of routine clinical care in those patients.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Pediatric Rheumatology – Clinical I: Outcomes and Comorbidities

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Innovative changes towards targeted treatment have improved the outcome dramatically for juvenile idiopathic arthritis (JIA) but the question remains how well these patients perform during long-term follow-up. The aim of the study was to assess the disease activity, remission rate and damage 18 years after JIA onset in a population-based setting.

Methods: 510 consecutive cases of JIA with disease onset between 1997 and 2000 from Denmark, Norway, Sweden and Finland were prospectively included in a close to population-based 18-year (mean 17.5 years; range 14.2-20.2) follow-up study. The follow-up visit included an update on the demographic and clinical data such as a joint examination and remission status (preliminary Wallace criteria).

Results: In total 434/510 (85%) eligible JIA participants with a mean age (\pm SD) of 24.0 (\pm 4.4) years were included. Of those, 76 participants (15%) were lost to follow-up. Out of the included participants 329 (76%) attended a follow-up visit, and 105 participants (24%) were evaluated by a telephone interview.

The distribution of the JIA categories was as follows: 3% systemic, 27% persistent oligoarticular, 20% extended oligoarticular, 16% polyarticular RF negative, 1% polyarticular RF positive, 7% psoriatic, 10% enthesitis-related arthritis (ERA) and 15% undifferentiated JIA.

Treatment with synthetic disease-modifying anti-rheumatic drugs were given to 66 participants (15 %) and biologics to 84 patients (19%) at the follow-up.

For the 329 participants the median active joint count was 0 (range 0-15), however during the 18 years of disease course the median cumulative joint count was 8 (range 1-59). The median composite juvenile arthritis disease activity score JADAS71 was median 1.5 (range 0-31.6) with the ERA category having the highest median score of 4.5 (range 0-16.5) ($p=0.003$). In the cohort 48% had a JADAS71 score <1 indicating inactive disease.

Articular damage (JADI-A) was found in 20% of the participants who had a follow-up visit and 12.5% had developed extra-articular damage (JADI-E), most commonly as ocular damage, found in 26/41 (63%). The highest JADI-A and JADI-E scores were found in the polyarticular RF negative and psoriatic categories.

Remission off medication (CR) was documented in 44%, but still 39.8% had active disease (Fig. 1). Extensive variability was found among the categories. Achievement of CR was most often seen in persistent oligoarticular and systemic arthritis in contrast to the lowest rate observed in ERA (*: $p<0.001$, fig 1).

Conclusion: A significant proportion of the JIA cohort does not reach remission despite new treatment options. Notably more than one third receive systemic treatment even 18 years after disease onset. The worst outcome was evident in the ERA category and in general the JIA disease burden in adulthood remains extensive.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Pediatric Rheumatology – Clinical I: Outcomes and Comorbidities

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Childhood-onset chronic rheumatic diseases (ChildCRD) are rheumatic diseases with onset <18 years old, including juvenile arthritis (JA) and systemic autoimmune rheumatic diseases (SARD). ChildCRD patients experience poor health during their school years, which could impact educational performance and future employment. Previous studies have not demonstrated poorer educational outcomes in ChildCRD, but were limited to clinic populations and therefore may not produce generalizable results. We have used a population-based approach to compare the grade 12 academic performance of ChildCRD individuals to that of matched controls without ChildCRD.

Methods: *Population* All ChildCRD patients for the province of Manitoba, Canada: JA and SARDs (systemic lupus erythematosus, Sjogren's syndrome, inflammatory myositis and systemic sclerosis), were ascertained from a clinic registry (1984-2014) maintained by a single pediatric rheumatologist. Registry data were anonymously linked to the administrative health, education and social data housed at the Manitoba Centre for Health Policy (MCHP), including: health insurance registry (to ascertain healthcare coverage and demographics), hospital records, physician billing claims, education, social services and employment records. The ChildCRD cohort included individuals from the 1979- 1998 birth cohorts (i.e., completed grade 12 in 1996- 2015). The control population was derived by matching 5:1, by age, sex and residential postal codes. **Outcomes:** MCHP has developed a language arts achievement index (LAI) and maths achievement index (MAI), using scores from the grade 12 standards tests and enrollment information. **Prognostic factors:** Socioeconomic status was defined from an area-based socioeconomic factor index 2 (SEFI2) based on census data. Psychiatric comorbidity was defined using validated diagnostic algorithms. Social factors included maternal age at first childbirth, family ever on income assistance, family ever involved with child welfare services.

Results: A total of 541 Manitoban ChildCRD patients (497 JA, 44 SARD), 70 % females, mean age at diagnosis 9.33 (\pm 4.91) years, were linked to the administrative data. A total of 2713 matches without ChildCRD (controls) were selected. ChildCRD patients have lower score categories (worse performance) than controls (LAI: -0.220, 95% CI -0.314 – -0.125, $p < 0.0001$; MAI: -0.214, 95% CI -0.310 – -0.119, $p < 0.0001$). In multivariable linear regression models adjusted for birth cohort, SEFI2, maternal age at first childbirth, family on income assistance, child in care and disease course psychiatric comorbidity, ChildCRD patients still had lower LAI and MAI test score categories (LAI: -0.232, 95% CI -0.315 – -0.149; MAI: -0.228, 95% CI -0.313 – -0.142) than controls.

Conclusion: This population-based study of patients with ChildCRD shows that ChildCRD has a detrimental effect on educational results, compared to matched, disease-free individuals. ChildCRD exerts an independent effect on standardized education outcomes independent of socioeconomic, demographic and psychiatric comorbidities.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Pediatric Rheumatology – Clinical I: Outcomes and Comorbidities

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Juvenile myositis (JM) is an inflammatory disease that causes muscle weakness, skin rashes, and significant deconditioning. Little is known about long-term resolution of physical disability. We examined trajectories of physical function in JM.

Methods: JM registry data were collected at routine visits (January 2000 to June 2014) to Ann & Robert H. Lurie Children's Hospital of Chicago and analyzed in this study. Only patients whose baseline visit was < 3 months after initiation of treatment were included. The following variables were extracted: parent-proxy reported Childhood Health Assessment Questionnaire (CHAQ), gender, race, duration of untreated disease, Disease Activity Score (DAS) - muscle/skin domains, Childhood Myositis Assessment Scale (CMAS), muscle enzymes, nail fold capillary end row loops (NFC-ERL), von Willebrand factor antigen (vWFAg), calcinosis (ever experienced), lipodystrophy (ever experienced), TNFalpha-308A allele, and treatments. Descriptive statistics were calculated. Latent trajectory analysis was performed assessing probability of CHAQ > 0 (binary outcome 0 vs > 0). Baseline values for demographic/clinical variables above were compared across identified trajectories (Fisher's exact; Kruskal-Wallis).

Results: Baseline descriptive statistics for n = 104 included patients with median 13.5 study visits and median follow-up 54 months are shown in Table 1. Three trajectories corresponding to mild (n = 46 [44%]), moderate (n = 32 [31%]), and severe disability (n = 26 [25%]) were identified (Figure 1). Statistically significant differences in baseline variables for mild vs moderate vs severe groups were noted for: CHAQ (0.13 vs 0.88 vs 1.35, p < 0.001), DAS-Muscle (4 vs 6 vs 6, p = 0.001), and CMAS (40 vs 31 vs 34, p = 0.01). Median baseline NFC-ERL differed, with higher counts in the mild group (= 5) vs moderate and severe groups (= 3.83 and 4.14), p = 0.047. Race trended toward significance (p = 0.08), with fewer white patients in the severe group (n = 13 white patients vs n = 26 total patients in severe group).

Conclusion: To our knowledge, this is the first study describing longitudinal trajectories of physical function (distinct from disease activity) in JM. Baseline physical function (i.e. CHAQ) and muscle weakness (i.e. DAS-Muscle, CMAS) predict long-term physical function trajectory. Baseline vasculopathy (i.e. NFC-ERL) may be less prominent in JM patients following the mild physical function trajectory. There may also be racial disparities in physical function trajectories among youth with JM, though this requires further study.

Table 1 Baseline Demographic and Clinical Descriptives (n = 104 patients)

	n = # with baseline data	n (%) / median (IQR)

Session Date: Monday, October 22, 2018

Session Title: Reproductive Issues in Rheumatic Disorders

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Pregnancies in systemic lupus erythematosus (SLE) are considered high risk and associated with medical and obstetric complications [1]. Our objective was to study the national trends of obstetric and medical complications in pregnant SLE patients over the past 2 decades.

Methods: Our study analyzed yearly retrospective trends of cross-sectional data using National Inpatient Sample (NIS) database from 1998 to 2014. Diagnoses and procedures were identified using ICD-9 codes. We included pregnancy-related admissions (diagnosis codes 632-649, 650-669, 670-679, V27, procedure code 72-75) with and without SLE (ICD 9 code 710.0). We studied multiple medical and obstetric complications including maternal mortality, cesarean section, intrauterine fetal death, preeclampsia/eclampsia, length of stay and inflation adjusted hospital charges. Univariable logistic regression was performed to assess temporal trend in SLE and non-SLE pregnancies. Logistic regression with interaction term between SLE and year was performed to detect whether SLE was an effect modifier for our outcomes. Weights were applied to represent the nationwide estimates.

	SLE pregnancies n = 87,065	Non SLE pregnancy n = 73,860,579
Number of Deliveries	70,134	68,461,097

Total Hospital Charges (USD)†	22,654	22,654	22,654	22,654	p < 0.001

†Inflation Adjusted by Yearly Personal Health Care Price Indices - Hospital Care

Results: 87,065 pregnant women with SLE and 70,162,163 without SLE had hospitalizations in US from 1998 to 2014. Pregnant SLE patients were older (29.2 \pm 5.8 vs 27.5 \pm 6.2), had a higher proportion of African Americans (21% vs 12%) and had a higher maternal mortality, and intrauterine fetal death, compared to those without SLE. (Table 1) Increased obstetric as well as maternal complications and comorbidities are observed in SLE patients compared to non-SLE patients. There was a decline in maternal mortality and intrauterine fetal death overtime and this decline was greater in SLE patients compared to those without SLE ($p = 0.002$ and 0.034 , respectively).(Figure 1) There was an increase in cesarean section in both SLE and non-SLE pregnancies and the increase in SLE pregnancies was less than non-SLE pregnancies ($p < 0.001$). Length of stay decreased in SLE pregnancies however increased in non-SLE pregnancies ($p < 0.001$). (Table 2)

Conclusion: Maternal and fetal mortality and important clinical outcomes in SLE pregnancies have improved over the past two decades. This is the largest study of SLE pregnancies in the U.S..

Paternal Use of Methotrexate (MTX) and Congenital Malformations – a Systematic Review and Meta-Analysis

Thomas Bo Jensen¹, Mikkel Bring Christensen^{1,2} and Jon Trærup Andersen^{1,2}, ¹Department of Clinical Pharmacology, Copenhagen University Hospital Bispebjerg, Copenhagen, Denmark, ²Faculty of Health and Medical Sciences, University of Copenhagen, Copenhagen, Denmark

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Reproductive Issues in Rheumatic Disorders

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: In rheumatology, fertile men and women are commonly treated with methotrexate (MTX). Maternal preconceptional MTX exposure is teratogenic, but less is known about paternal MTX exposure. Due to possible teratogenic risk, current treatment recommendations advocate that men should discontinue MTX three months before conception. This may lead to impaired adherence to treatment, fear among the future parents and even unnecessary induced abortions.

Here we systematically review and meta-analyse the collective data on paternal MTX exposure and the risk of congenital malformations.

Methods: Systematic searches in the databases PubMed, Embase, Cochrane central, and cinahl were performed 1st March 2018. We included studies with an English abstract that assessed pregnancy outcome following paternal exposure to MTX. No time restriction was applied. Review Manager Version 5.3 was used for the meta-analysis.

Results: We identified twelve studies assessing congenital malformations following paternal exposure to MTX of which 3 were case reports. Three studies were included in the meta-analysis including in total 265 fathers exposed to MTX and 1,004,834 controls. Among the MTX-exposed 13 had malformations of which 7 was major, and among the non-exposed 50,576 had malformations, of which 33,816 was major. Odds ratio for major malformations was 1.02 (95% confidence interval [CI] 0.48-2.20). Odds ratio for all malformations was 0.86 (CI 0.48-1.54). Thus no association was found.

Conclusion: In a systematic review and meta-analysis we found no association between preconceptional paternal MTX use and major or all congenital malformations. Thus, there is no evidence supporting the current recommendations to avoid paternal MTX use before conception.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Reproductive Issues in Rheumatic Disorders

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Systemic lupus erythematosus (SLE) disproportionately affects women of childbearing age. Low disease activity for 6 months prior to conception leads to the best outcomes; however, there is little prospective data describing the relative frequency and predictors of flares during and after pregnancy under such conditions.

Methods: Analyses used data from the PROMISSE study, a multicenter, prospective observational study (2003-2014) of 384 pregnant women meeting ≥ 4 ACR SLE criteria. Subjects were enrolled <12 wks gestation and samples collected

A. Association Between Baseline Characteristics and Occurrence of Mild/Moderate or Severe Flare During Pregnancy				
Characteristic	Total (n = 384)	No Flares (n = 284)	Flares (n = 100)	P Value
Ethnicity/Race				0.019
Non-Hispanic White	188 (49)	149 (52.5)	39 (39)

B. Occurrence of Mild/Moderate or Severe Flare During Pregnancy from Logistic Regression Models				
Baseline Predictor Variables	OR (95% CI)		P Value	
Age at Screening (per increase of 10 years)	9.3 (8.9 – 9.8)		0.0096	
Non-Hispanic white (yes vs no)	0.65 (0.40 – 1.08)		0.096	
Screening SLEPDAI Low Complement (yes vs no)	1.55 (0.93 – 2.55)		0.087	
Screening SLEPDAI PGA Score (per increase of 1)	2.11 (1.38 – 3.24)		0.0006	

throughout pregnancy and post-partum. Exclusion criteria were multi-fetal pregnancy, active disease (prednisone >20 mg/d), or renal disease (proteinuria >1 gm/24h, and creatinine > 1.2 mg/dL). Mild/moderate and severe flares were defined using the SELANA-SLEDAI Flare Index. Flares during pregnancy were assessed in all 384 patients, and post-partum flares in those with study visits 2-6 months post-partum. Logistic regression models were fit to the data to identify independent predictors of experiencing any type of flare during pregnancy and post-partum.

Results: Rates of Flare: 105 flares were recorded during pregnancy (3.8% 1st Trimester, 53.3% 2nd, 42.9% 3rd). Counting one flare per person, 100 of 384 patients (26%) flared at any point during pregnancy; 20.8% of patients had mild/moderate flares and 6.25% had severe. 57 of 234 patients (24.4%) with a study visit 2-6 months post-partum flared; 22.7% had mild/moderate flares and 1.7% severe. Post-partum flares were mild, and 19 of 57 (33.3%) were treated; 13 with an increase in prednisone, 6 with NSAID or hydroxychloroquine, and 1 with mycophenolate mofetil. The rate of any type of flare was 0.39/person-year at any point during pregnancy and 0.84/person-year post-partum. The proportion of subjects who had any flares during and after pregnancy was similar, but the post-partum flares occurred over a shorter duration of follow-up.

Correlates of Flare: Among baseline variables considered (Table) only age, ethnicity/race, low complement, and PGA were independently predictive of having any flare during pregnancy. Clinical features associated with adverse pregnancy outcome (platelet count, antihypertensive use, and LAC) were not predictive of flare. The mean time from the last visit during pregnancy to the post-partum visit was 20 weeks and ranged from 9 to 34 weeks. Neither baseline clinical variables nor clinical variables of the last visit during pregnancy were associated with occurrence of any post-partum flare.

Conclusion: Flares during pregnancy are correlated with clinical and serological activity during the first trimester. Flares during and after pregnancy are typically mild, infrequently require treatment, and occur at similar rates.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Reproductive Issues in Rheumatic Disorders

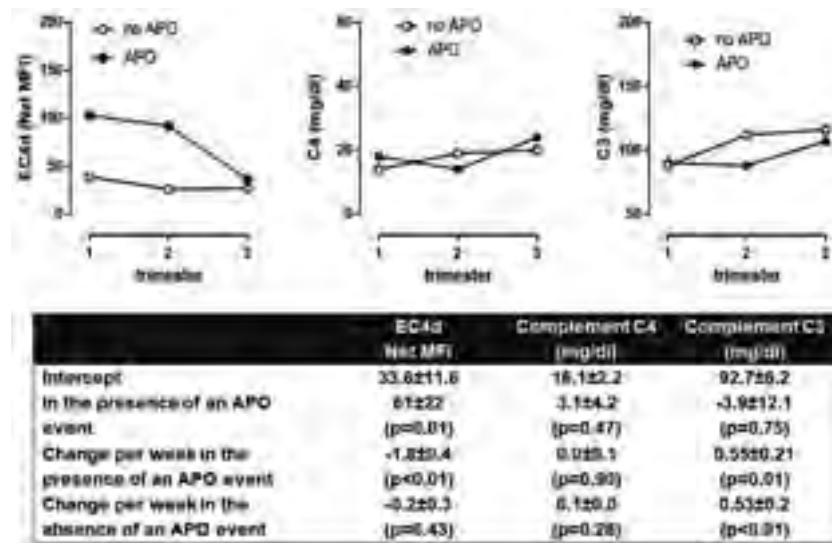

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Activation of the alternative and terminal attack complex of the complement system has been associated with adverse pregnancy outcomes (APOs) in stable/quiescent systemic lupus erythematosus (SLE). This prospective study examined erythrocyte bound C4d (EC4d), a marker demonstrating classical pathway activation, and complement C3/C4 levels in relationship to APO in pregnant SLE patients regardless of disease activity at entry.

Methods: Consecutive pregnant women (fulfilling ACR or SLICC criteria) were enrolled with no restrictions on disease activity or prednisone dosage. Serum C3 and C4 levels were measured using immunoturbidimetry and EC4d was measured from EDTA blood using flow cytometry and expressed as net mean fluorescence intensity (MFI). Whole blood Hydroxychloroquine (HCQ) levels were measured using liquid chromatography. Measures of disease activity consisted of Physician Global Assessment (PGA) visual analogue scale (0-3 cm) and clinical SLE Pregnancy Disease Activity Index (SLEPDAI) without immunology components. Estimates relating EC4d, complement C3 and C4 levels during gestation in the presence or the absence of APO events were analyzed using t-test and linear mixed effect models.

Results: A total of 29 consecutive women (mean age 32±1 years [SEM], 58% Caucasians and 21% African Americans) were enrolled and followed for an average of 3.1±0.2 visits during gestation. At baseline, mean PGA was 0.4±0.1 points and mean clinical SLEPDAI was 1.7±0.6 points, with 92% subjects ANA positive [titers≥1:80]. Six pregnancies (21%) resulted in APO events (two fetal deaths [at 27 and 28 weeks], three pre-term deliveries [range 27-35 weeks] and one

delivery with small gestational age). The Figure highlights the change in EC4d, complement C4 and C3 levels in the patients with or without an APO. As presented in the Table and Figure, EC4d levels were higher during the first trimester in patients who went on to have APOs than in patients without APO (102 ± 34 and 36 ± 11 net MFI; $p < 0.05$). In contrast, C3 and C4 levels were similar irrespective of APO status ($p > 0.47$). During gestation, EC4d levels decreased by 1.8 units per week in those with APOs ($p < 0.01$) but did not vary in those without APOs (estimate = -0.2; $p = 0.43$). C3 increased during pregnancy irrespective of APOs (0.5 mg/dl per week). PGA and clinical SLEPDAI were not associated with APO ($p > 0.08$). 25 patients were prescribed HCQ and there were no differences in the levels between the APO and non-APO groups (mean 1253 ± 253 vs 850 ± 196 ng/ml; $p = 0.28$). In fact, all subjects with APO received HCQ and levels were > 500 ng/ml (range 571-2139 ng/ml).

Conclusion: This prospective study suggests that EC4d is elevated early pregnancy in those destined for APOs, despite compliant HCQ levels in women with SLE. Classical pathway activation as measured by cell based complement products may be an important early biomarker and reveal pathogenesis of APO in SLE.

Abstract Number: 1856

Low Aspirin Use and High Prevalence of Preeclampsia Risk Factors Among Pregnant Women in a Multi-National SLE Inception Cohort

Arielle Mendel, Sasha Bernatsky, Evelyne Vinet, Divisions of Rheumatology and Clinical Epidemiology, McGill University Health Centre, Montreal, QC, Canada

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Reproductive Issues in Rheumatic Disorders

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Because aspirin reduces the risk of preeclampsia in high-risk pregnancies by more than half, best practice guidelines recommend that aspirin be initiated in pregnant women with ≥ 1 high-risk factors for preeclampsia, including SLE. Our objective was to assess the prevalence of aspirin use in SLE pregnancies within a multi-national inception cohort, and compare aspirin use among those with and without additional preeclampsia risk factors.

Methods: Premenopausal women aged 18-45 were enrolled in the Systemic Lupus International Collaborating Clinics (SLICC) Registry (2000-2017) within 15 months of SLE diagnosis. Study visits with a current pregnancy were assessed for aspirin use and preeclampsia risk factors (hypertension, renal disease, diabetes, nulliparity, BMI ≥ 35 , age > 40). Aspirin use was compared among those with and without such risk factors, as well as disease-specific risk factors (e.g. antiphospholipid antibodies [+aPL]), and over time.

Results: We identified 300 women with 475 pregnancies. Half (51%) had ≥ 1 traditional preeclampsia risk factors (in addition to SLE), and a third (33%) had +aPL. We observed aspirin use in 25% of pregnancies (95%CI 22,29), which did not differ among pregnancies with and without ≥ 1 traditional risk factor [25% (95%CI 20,31) versus 26% (95%CI 21,32)]. Aspirin use was higher among those with +aPL [38% (95%CI 24,55)] versus those without [23% (95%CI 15,34)], and was higher in whites [32% (95%CI 26,39)] compared with black women [10% (95%CI 5,18)]. Regional variability was observed in aspirin use (12-37%). We could not establish a trend of increasing aspirin use over time.

Conclusion: In this multi-centre analysis of SLE pregnancies, we observed that most women were not on aspirin and that half had additional preeclampsia risk factors. It is possible that aspirin was introduced at/or following the study visit when the pregnancy was documented, highlighting the importance of the rheumatologist in reviewing aspirin use and initiating it, if not already done, in pregnant SLE women. Our findings suggest black SLE women as a potentially vulnerable group during pregnancy, having the lowest prevalence of aspirin use.

Table 1 Demographic and disease characteristics according to aspirin use

Characteristic	All pregnant visits (n=475)	Pregnant visits with aspirin (n=121)	Pregnant visits without aspirin (n=354)
Patient characteristic

Low Molecular Weight Heparin and Aspirin Combination Therapy Modulates Th1/Th2 Cell Imbalance in Pregnant Patients with antiphospholipid Antibody-Associated Recurrent Pregnancy Loss

Meiying Wang^{1,2}, Peng Zhang³, gengmin zhou¹, jiyang lv¹, chengshan guo⁴ and Qingwen Wang¹, ¹Rheumatology and Immunology, Peking University Shenzhen Hospital, shenzhen, China, ²Rheumatology, David Geffen school of Medicine at UCLA, Los Angeles, CA, ³SHENZHEN INSTITUTES OF ADVANCED TECHNOLOGY CHINESE ACADEMY OF SCIENCES, shenzhen, China, ⁴Rheumatology and Immunology, The people's Hospital of Bao'an District Shenzhen City., shenzhen, China

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Reproductive Issues in Rheumatic Disorders

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Type 1/type 2 T helper (Th1/Th2) cells and their cytokines are implicated in the pathogenesis of autoimmune diseases^[1]; however, their roles in antiphospholipid antibody-associated recurrent pregnancy loss (APA-RPL) remain unclear^[2,3]. Low molecular weight heparin (LMWH) and aspirin combination therapy is a first-line treatment for APA-RPL, but its mechanism remains unclear^[4]. This study aimed to investigate the effect of combination therapy with LMWH and aspirin on Th1/Th2 cells and their cytokines in pregnant patients with APA-RPL.

Methods: Pregnant patients with a history of APA-RPL (n=89) were enrolled in this study. After confirming a positive pregnancy test result, the patients were treated with LMWH and aspirin combination until 35–37 weeks of pregnancy or up to the time of miscarriage. Blood was drawn before starting and after stopping treatment. The therapeutic outcome was evaluated by using live-birth as an efficacy measurement. 31 age matched healthy pregnant women who delivered in our hospital were used as a control group. ELISA was conducted to detect serum levels of the Th1 cytokines interleukin (IL)-2 and tumor necrosis factor alpha (TNF-α) and the Th2 cytokines IL-4 and IL-10. The percentages of CD4⁺-interferon gamma (INF-γ)+ and CD4⁺-IL-4+ cells among the CD4⁺ T cells in peripheral blood were assessed by flow cytometry, and the expression of *T-bet* and *GATA 3* was determined by quantitative real-time PCR.

Results: Of the 89 patients receiving LMWH-aspirin combination therapy, 72(80.9%) had a live birth and the remaining 17 had miscarriages. At 5-7 weeks of gestation in patients with APA-RPL, serum IL-2 ($P=0.006$) and TNF-α ($P<0.001$) levels were significantly higher, while serum IL-4 ($P=0.037$) and IL-10 ($P<0.001$) levels were significantly lower compared to healthy pregnant control women (Figure 1). Similarly, the CD4⁺-INF-γ+-labeled Th1 cell subset was also significantly increased ($P<0.001$), while the CD4⁺-IL-4+-labeled Th2 cell subset was significantly reduced ($P<0.001$) in patients with APA-RPL (Figure 2). Furthermore, gene expression of *T-bet* was significantly elevated ($P=0.003$), while *GATA3* mRNA expression was significantly reduced in patients with APA-RPL ($P=0.002$) (Figure 3). This Th1-biased pattern was reversed in patients who had live birth while receiving the combination therapy. Patients with miscarriages continued to exhibit Th1-bias.

Conclusion: Th1/Th2 cell frequencies and the protein and gene expression levels of their cytokines are perturbed in patients with APA-RPL, suggesting a possible role of Th1/Th2 imbalance in the pathogenesis of APA-RPL. Importantly, LMWH and aspirin combination therapy effectively reverse Th1 cell polarization for APA-RPL patients attaining live births, providing a new understanding of potential immunomodulatory mechanism of LMWH and aspirin combination therapy on APA-RPL.

An Assay Panel Combining Anti-Protein Arginine Deiminase 4 with Rheumatoid Factor Isotypes Distinguishes Anti-Citrullinated Peptide Antibody Negative Rheumatoid Arthritis

Thierry Dervieux¹, Laura Martinez Prat², John Conklin¹, Claudia Ibarra¹, Michael Mahler², Michael E Weinblatt³ and Joel Kremer⁴, ¹Exagen Diagnostics, Inc., Vista, CA, ²Research and Development, Inova Diagnostics, San Diego, CA, ³Brigham and Women's Hospital, Boston, MA, ⁴Albany Medical College and The Center for Rheumatology, Albany, NY

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes II: Diagnosis and Prognosis I

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Anti-citrullinated peptide antibodies (ACPAs) are highly specific for rheumatoid arthritis (RA) but lack sensitivity. We evaluated autoantibodies to protein-arginine deiminase 4 (anti-PAD4) in distinguishing ACPA negative RA from other ACPA negative rheumatic diseases, either alone or in combination with rheumatoid factor (RF) isotypes.

Methods: ACPA negative subjects (n = 1011, 205 RA and 806 non-RA [193 normal healthy individuals, NHV]) were selected from a cohort of 622 RA (34% ACPA negative, all fulfilling the 1987 or 2010 ACR criteria), and 830 non-RA (97% ACPA negative) consented subjects. ACPA status and IgM/IgA RF titers were measured using fluoroenzyme immunoassays (ThermoFisher, Upsala Sweden). Anti-PAD4 titers were measured using a novel particle-based multi-analyte technology (research use only, Inova Diagnostics, San Diego, CA). ACPA negative subjects were grouped into a training set of 554 subjects (157 RA, and 397 non-RA [172 NHV]), and a subsequent independent validation set of 457 consecutive subjects (48 RA and 409 non-RA [21 NHV]). From the training set, a weighted scoring system cumulating log normalized anti-PAD4/RF isotypes titer estimates from multivariate logistic regression was calculated to distinguish ACPA negative RA from ACPA negative non-RA, and was applied to subsequent validation set. Diagnostic performances were estimated using area under the receiver operating curve (AUC), sensitivity, and specificity.

Results: Overall, anti-PAD4 (>1000 Units) was 19% sensitive and 95% specific in distinguishing ACPA negative RA from ACPA negative non-RA subjects (AUC = 0.65±0.02). AUCs for IgM and IgA RF isotypes were 0.67±0.02 and 0.51±0.02, respectively. From training set, multivariate logistic regression estimates for anti-PAD4 (0.36±0.11), and IgM/IgA RF isotypes

(0.66 ± 0.11 and -0.65 ± 0.14 , respectively) antibody systems were significantly and independently associated with RA ($p < 0.001$; intercept = -2.59 ± 0.66), and weighted cumulative score was 37% sensitive and 90% specific (cutoff > -0.4) (AUC = 0.72 ± 0.02 , Figure). In subsequent validation set, the training set based weighted cumulative score distinguished ACPA negative RA and ACPA negative non-RA groups with 35% sensitivity and 95% specificity (AUC = 0.68 ± 0.02). Specificities in distinguishing ACPA negative RA from other ACPA negative rheumatic diseases was 92% for systemic lupus erythematosus (327/354), 97% for Sjogren's syndrome (59/61), 95% for fibromyalgia (80/84), and 91% for NHV. Positivity rate of the weighted cumulative score was 30% among RA diagnosed for less than 2 years and rose to 50% among RA diagnosed for more than 10 years.

Conclusion: These preliminary data establish the feasibility of combining anti-PAD4 with RF isotypes to distinguish ACPA negative RA from other ACPA negative rheumatic diseases.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes II: Diagnosis and Prognosis I

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Rheumatoid factor (RF) and anti-citrullinated protein antibodies (ACPA) are the most specific diagnostic markers of rheumatoid arthritis (RA). Lately we showed that the determination of multiple isotypes of RF and ACPA as well as RA33 antibodies may provide an added diagnostic value since the presence of multiple reactivities in sera of RA patients as compared to disease controls was found to be highly specific for RA¹. Moreover, determination of autoantibody isotypes might even provide a predictive value regarding the response to therapy. It was the aim of this study to investigate the potential predictive value of IgA, IgG and IgM isotypes of RF, ACPA and RA33 antibodies regarding therapeutic response to methotrexate (MTX) in patients with RA.

Methods: An inception cohort of 165 patients starting MTX therapy was analysed for the presence of IgA, IgG and IgM isotypes of RF and ACPA using EliATM assays (Phadia AB, Sweden). RA33 antibody isotypes were detected by newly developed prototype assays using the EliATM platform (Phadia AB, Sweden)¹. Therapeutic responses were analysed after 3-6 months using the American College of Rheumatology (ACR)20 and simplified disease activity index (SDAI)50 response criteria. For generating classification models the machine learning tool Weka was employed.

Results: Patients testing positive for four or more antibodies were found having an increased likelihood to reach an ACR20 response (41%) compared to seronegative patients (24%, $p=0.0038$) or patients with 1 to 3 antibody reactivities (26%, $p=0.0152$). Interestingly, further analyses revealed high levels of IgM-RF (>133 IU/ml) to be associated with the therapeutic response to MTX as 71% of the patients (i.e. 15 of 21) achieved an ACR20 response compared to 28% of patients with IgM-RF <133 IU/ml ($p<0.0001$) and 27% of RF-negative patients ($p<0.0001$). Moreover, also the presence of RA33 antibodies was associated with a favorable MTX response since 47% of patients positive for IgG, IgA or IgM RA33 antibodies achieved an ACR20 response compared to 28% in the RA33 negative population ($p=0.0005$). Remarkably, by combining the RF and RA33 data a population of MTX non-responders could be characterized showing IgM-RF <133 IU/ml and IgG-RA33 <3.2 μ g/l since 91% of these patients ($n=47$) did not reach an ACR20 response compared to 58% non-responders in the total cohort ($p<0.0001$). Virtually identical results were obtained when SDAI50 was used as outcome measure. Interestingly, ACPA isotypes did not appear to be associated with the therapeutic response to MTX.

Conclusion: The detection of antibody isotypes especially IgM-RF and IgG-RA33 may provide valuable additional information regarding the prediction of response to MTX.

Development and Validation of a Microrna Panel to Differentiate between Patients with Rheumatoid Arthritis, Systemic Lupus Erythematosus, and Control Subjects

Michelle J. Ormseth, Joseph F. Solus, Quanhu Sheng, Fei Ye, Qiong Wu, Yan Guo, Annette M. Oeser, Ryan Allen, Kasey Vickers and C Michael Stein, Vanderbilt University Medical Center, Nashville, TN

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes II: Diagnosis and Prognosis I

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: MicroRNAs (miRNAs) are short non-coding RNAs that regulate genes and have utility as disease biomarkers. Use of small RNA (sRNA) sequencing along with unbiased bioinformatics methods has the capacity to reveal new miRNA markers of disease. The objective of this study was to use sRNA sequencing and machine learning methodology to determine a miRNA signature panel capable of reliably differentiating patients with rheumatoid arthritis (RA) from control subjects, and from patients with another autoimmune disease.

Methods: Plasma samples from 167 patients with RA and 91 control subjects frequency-matched for age, race and sex were used for RNA extraction and sequencing library preparation. Sequencing was performed using Illumina NextSeq500. Our in-house pipeline, TIGER, was used to quantify miRNAs. DESeq2 and random forest analyses were used to develop a prioritized list of differentially expressed miRNAs in RA compared to control subjects. Each of the miRNAs was validated by PCR in the same plasma samples. Using the PCR-based plasma concentrations of the miRNAs, we used lasso regression to select a final miRNA panel to distinguish between RA and control subjects. This panel was validated in a separate cohort of 32 patients with RA and 32 control subjects and in 12 patients with SLE. Panel efficacy was assessed by area under the receiver operative characteristic curve (AUC) analyses.

Results: Among the top 15 miRNAs selected separately by DESeq2 and random forest analyses, 12 miRNAs overlapped using both methodologies, thus a total of 18 miRNAs were selected for PCR validation. Using the PCR-based concentrations of the 18 miRNAs, a final panel that included miR-22-3p, miR-24-3p, miR-96-5p, miR-134-5p, miR-140-3p, and miR-627-5p was selected. The panel had an AUC=0.81 for differentiating RA and control subjects, and it was robust among those with seronegative RA (AUC=0.84), among patients whose RA was in remission (AUC=0.85), in a separate RA validation cohort (AUC=0.76), and among patients with SLE compared to control subjects (AUC=0.97). Three of the miRNAs had weak association with disease activity in RA by DAS28 score (miR-24-3p: $\rho = -0.16$, $P = 0.04$; miR-96-5p: $\rho = 0.16$, $P = 0.04$; miR-140-3p: $\rho = -0.16$, $P = 0.05$), and none were associated with disease activity in SLE (SLEDAI).

Conclusion: A miRNA panel identified by unbiased bioinformatics approaches was able to differentiate between patients with RA, SLE and control subjects. The panel may represent an autoimmunity signature which is common to both RA and SLE patients and which is not dependent on active disease or seropositivity. Further studies will be necessary to confirm these findings.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes II: Diagnosis and Prognosis I

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Patients with RA have an increased risk of cardiovascular disease (CVD) accounting for over 50% of premature deaths in the RA population. EULAR recommends repeat assessment of CVD risk every 5 years or when major changes in DMARD therapies are instituted. Lipid screening should be performed to evaluate and mitigate CVD risk. Our objective was to estimate the 5-year lipid screening rate among Medicare beneficiaries with RA based on the specialties of their treating providers, including rheumatology, primary care providers (PCP) and cardiology.

Methods: We conducted a retrospective cohort study using 2011-2015 Medicare claims data (5% representative sample) that included fee-for-service beneficiaries with RA who were continuously enrolled in Parts A and B for 5 years and had at least 1 outpatient visit during continuous enrollment. Lipid screening including non-fasting total cholesterol and high-density lipoprotein (HDL) was ascertained using CPT codes. We estimated the proportion of beneficiaries receiving at least one lipid screening during the 5 years, using logistic regression, based on the specialties of their treating providers. We stratified the analysis by those with and without preexisting CVD or CVD-risk conditions (e.g., hyperlipidemia, hypertension, and diabetes mellitus).

Results: Among 40,120 beneficiaries with RA, 35,330 (88%) had preexisting CVD or CVD-risk conditions. RA patients without preexisting conditions had a 5-year lipid screening rate of 52.8% (95% CI: 51.4, 54.2), while those with preexisting conditions had a screening rate of 71.2% (95% CI: 70.8, 71.7). RA patients without preexisting conditions who only saw a rheumatologist had a lower 5-year lipid screening rate (21.6%, 95% CI: 14.6, 30.9), compared to patients who saw a PCP only (54.4%, 95% CI: 50.5, 58.3) or a cardiologist only (40.0%, 95% CI: 15.8, 70.3). RA patients with preexisting conditions who only saw a rheumatologist had a screening rate of 35.2% (95% CI: 26.7, 44.8), whereas patients who only saw a PCP or cardiologist had screening rates of 71.3% (95% CI: 69.7, 72.8) and 77.3% (95% CI: 65.7, 85.8), respectively. Screening rate estimates for combinations of physician specialties suggest that beneficiaries seen by a PCP and/or a cardiologist have higher rates of lipid screening, with little influence from rheumatology care (Table 1).

Conclusion: Five-year lipid screening rates among Medicare beneficiaries with RA did not meet EULAR recommendations, particularly among those without preexisting CVD or CVD-risk conditions. Patients that were seen by only a rheumatologist had the lowest rate of screening, when compared to patients seen by a PCP or a cardiologist. Rheumatologists need to devise screening implementation strategies to improve comprehensive coordinated CVD preventative care.

Table 1. Five-year lipid screening rate, by specialties of treatment providers

Beneficiary class	Beneficiaries with preexisting conditions	Lipid screening %	(95%CI)	Beneficiaries without preexisting conditions	Lipid screening %	(95%CI)
PCP only	3,320	71.3	(69.7, 72.8)	410	54.4	(50.5, 58.3)
Rheumatologist only	140	35.2	(26.7, 44.8)	97	21.6	(14.6, 30.9)
Cardiologist only	88	77.3	(65.7, 85.8)	10	40.0	(15.8, 70.3)
PCP + Rheumatologist	4,958	65.2	(63.8, 66.5)	1,521	47.5	(45.8, 50.0)
PCP + Cardiologist	3,804	74.5	(73.7, 75.4)	470	60.7	(57.8, 64.4)
Rheumatologist + Cardiologist	115	67.8	(58.8, 75.7)	34	45.9	(27.5, 65.4)
PCP + Cardiologist + Rheumatologist	16,601	71.7	(71.0, 72.4)	1,807	56.6	(54.3, 58.9)
Without PCP, cardiologist or Rheumatologist	156	21.1	(15.5, 26.8)	51	33.7	(18.8, 48.4)

Pre-existing conditions: Hyperlipidemia, Hypertension, Diabetes, and cardiovascular disease.

PCP: Primary Care Providers, including family practice, internal medicine, general practice, nurse practitioner, and physician assistant.

Exploring the Lipid Paradox Theory in Rheumatoid Arthritis: Very Low Circulating Low-Density Lipoprotein Concentration Levels Are Associated with Pro-Atherogenic Biomarkers

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes II: Diagnosis and Prognosis I

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Rheumatoid arthritis (RA) patients with very low levels of circulating low density lipoprotein cholesterol (LDL-C) have been reported to be at particularly high risk for cardiovascular disease (CVD) events. Previously, we reported that this subgroup also had markedly elevated coronary calcium scores, a surrogate for atherosclerosis; however, the mechanisms underlying these seemingly paradoxical findings has not been explored.

Methods: RA patients from 3 cardiovascular cohort studies underwent measurement of fasting serum lipids and a panel of 32 cytokines, chemokines, metalloproteinases, and other immune mediators associated with CVD was measured from serum using various optimized methods (ELISA, Luminex, liquid chromatography/tandem mass spectrometry). Levels of each panel biomarker were compared according to LDL strata, with the lowest stratum (LDL-C<75 mg/dL) being the stratum of interest, using multivariable robust regression to adjust for pertinent confounders.

Results: A total of 454 RA patients [mean age=57 years; 74% female; median RA duration=10 years] were studied. LDL-C<75 mg/dL was observed in 10%, and 32% had an LDL-C>130 mg/dL. Excluding statin users (n=64), those in the lowest LDL-C stratum did not differ from those in higher strata on demographics, CVD risk factors, or RA disease and treatment characteristics with the exception of BMI and waist circumference, which were lower in the lowest LDL-C stratum compared with the highest, and ever and current smoking, which were more prevalent in the lowest LDL-C stratum. After adjustment, mean levels of pro-atherogenic E-selectin, vascular cell adhesion molecule-1 (VCAM-1), and matrix metalloproteinase-9(MMP-9) were higher among those in the lowest LDL-C stratum compared with those with higher LDL-C levels (Fig A-C). In contrast, levels of anti-atherogenic paraoxonase-1 (PON-1) were lowest among those in the lowest LDL-C stratum (Fig D). Seropositivity for rheumatoid factor (RF) was more strongly associated with higher E-selectin, MMP-9, and VCAM-1 levels among those in the lowest LDL-C stratum compared with those with higher LDL-C. Likewise, RF was more strongly associated with lower PON-1 levels among those in the lowest LDL-C stratum.

Conclusion: Higher levels of vascular adhesion molecules and metalloproteinases and lower levels of PON-1 suggest a pro-atherogenic state that would typically not be observed among those with low LDL-C, a group generally at low risk for CVD. Such pro-atherogenic state may account for higher CVD events and atherosclerosis among RA patients with low LDL-C levels and identify a subgroup that may benefit from heightened CVD screening and prevention.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes II: Diagnosis and Prognosis I

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Serum elevations of antibodies to citrullinated protein antigens (ACPA) and rheumatoid factor (RF) can identify individuals at risk for developing rheumatoid arthritis (RA). Prior studies have identified serum calprotectin (seCal) as a promising biomarker for active inflammation among RA patients (Hurnakova 2018). Importantly, identifying biomarkers to accurately predict RA onset within a defined time frame may be especially useful to help design clinical trials for prevention of RA. The goal of this project was to evaluate the role of ACPA, RF and the novel marker seCal in improving the prediction of onset and timing of RA.

Methods: From the Department of Defense Serum Repository we studied pre-RA diagnosis samples from 214 RA Cases (212 meeting 1987 Criteria, and 2 diagnosed with RA by a board-certified rheumatologist), and 1,287 Controls matched to Cases on age, gender, race and duration of sample storage. All Case samples were tested for anti-cyclic citrullinated peptide-3(CCP3, Inova), RFIgM (Inova) and serum calprotectin (seCal, Inova, research only). All Controls were tested

for CCP3, and a subset were tested for RFIgM and seCal to set cutoff levels and evaluate diagnostic accuracy. CCP3 positivity was based on the established range (≥ 20 Units), and 2x and 3x the standard cutoff; RFIgM positivity was based on a level present in $< 5\%$ of a subset of Controls; seCal positivity was based on a level greater than the mean+2 standard deviations (SD) from a set of Controls. The diagnostic accuracy of CCP3 for Cases was compared to Controls. In Cases, the diagnostic accuracy for a sample being within ≤ 3 years before diagnosis was evaluated using positivity of CCP3, RFIgM and seCal in 2x2 table analyses. Across models the positive predictive values (PPV) were compared with chi-squared testing.

Results: CCP3 positivity was 98.5%, 99.2% and 99.8% specific for the Cases versus Controls at standard, 2x, and 3x cutoff values, respectively. Within Cases, CCP3 positivity in a sample was strongly associated with developing RA in ≤ 3 years at all cutoff values although the differences in PPVs across cutoffs were not significant ($p=0.43$) (Table). The addition of RFIgM to CCP3 significantly improved the PPV of an RA diagnosis in ≤ 3 years from 78.9% to 88.0% ($p=0.01$). The addition of seCal to RFIgM and CCP3 (standard cutoff) improved the PPV to 100% although this was not significant ($p=0.37$). In Cases, the mean seCal was 8.6 ng/mL (SD 7.5) and 13.3 ng/mL (SD 19.0) for > 3 and ≤ 3 years to diagnosis, respectively ($p<0.01$).

Conclusion: These findings demonstrate that CCP3 at multiple cutoffs is highly predictive of a diagnosis of RA in ≤ 3 years, with improved prediction if RFIgM positivity is included. These results can be used in the development of clinical prevention trials for RA. SeCal also shows promise in improving prediction of RA although further evaluation is needed, including comparison to other measures of inflammation (e.g. C-reactive protein). Diagnostic accuracy of CCP3 at multiple cutoff values and in combination with RFIgM or RFIgM and calprotectin for a diagnosis of RA in ≤ 3 years within preclinical RA samples from 214 individuals who developed RA identified through the Department of Defense Serum Repository

Biomarkers ¹	Sensitivity ²	Specificity	PPV	NPV	OR (95% CI, p-value) ⁵

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical III: Treatment of Axial SpA

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: COAST-V (NCT02696785) is the first phase 3 study of ixekizumab (IXE), a high-affinity anti-IL-17A monoclonal antibody, inpatients (pts) with active radiographic axial SpA (r-axSpA) who are biologic DMARD(bDMARD) naïve. We report the Week (Wk) 16 primary outcome and key efficacy and safety data from this ongoing 52-wk study.

Methods: Adults with active r-axSpA per Assessment of SpA international Society (ASAS) criteria(sacroiliitis centrally defined by modified New York Criteria and ≥ 1 SpA feature), BASDAI ≥ 4 , back pain ≥ 4 , and inadequate response or intolerance to NSAID therapy, were randomized 1:1:1:1 to subcutaneous placebo(PBO), 80 mg IXE every 4 (Q4W) or 2 wks (Q2W), or 40 mg Q2W adalimumab (ADA; active reference arm) up to Wk 16. The primary endpoint was ASAS40 response at Wk 16. Major secondary endpoints included ASAS20, BASDAI50, AS Disease Activity Score (ASDAS) Inactive Disease, and change from baseline (CFB) in ASDAS, BASFI, MRI spine SpA Research Consortium of Canada (SPARCC) score, Short Form 36-item Physical Component Summary (SF-36 PCS) and ASAS-Health Index (HI). All images were centrally read.

Results: Of 341 subjects randomized, 97% completed Wk 16. Baseline demographics and disease characteristics were comparable among study arms: mean age was 41.7 years; meantime since r-axSpA symptoms onset was 16.0 years, and mean BASDAI was 6.7. Significantly more patients achieved ASAS40 at Wk 16 (primary endpoint) with IXE Q2W (52%) and IXE Q4W (48%) than with PBO (18%, $p < .001$). Compared to PBO, both IXE regimens had significantly higher improvements at Wk 16 for disease activity, functional disability, and spinal and SIJ inflammation. Significant improvements were first observed at Wk 1 for ASAS20, BASFI CFB, and ASDAS CFB, at Wk 2 for ASAS40, and at Wk 4 (first time of assessment) for SF36-PCS CFB and ASAS-HI CFB. At Wk 16, ADA (active reference arm) showed significant improvements versus PBO (ASAS40 effect size vs. PBO 17.2% [95% CI 4.4, 30.0]). The frequency of treatment-emergent adverse events and serious adverse events are provided in the table below. No opportunistic infections were reported in any arm; one *Candida* infection was reported in the ADA active reference arm. One case of inflammatory bowel disease was reported in the IXE Q2W study arm. No malignancies or deaths occurred in any study arm.

Conclusion: The primary and all major secondary endpoints for IXE were met at Wk 16 with no unexpected safety findings. IXE was superior to PBO for improving r-axSpA signs and symptoms, health-related quality of life, and inflammation on MRI in pts with r-axSpA naïve to bDMARDS.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical III: Treatment of Axial SpA

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: The Assessment of SpA international Society Health Index (ASAS HI) is a relatively new measure to assess function, disability, and health in patients with SpA. These are the first data of the ASAS HI in a Phase 3 study testing sensitivity to change and discrimination between active treatment and placebo (PBO).

Methods: The ASAS HI was assessed in biologic DMARD(bDMARD)-naive patients with active radiographic axial SpA (r-axSpA) in a Phase3 study of ixekizumab (IXE), an IL-17A monoclonal antibody (COAST-V [NCT02696785]). The ASAS HI consists of 17 dichotomous items, total score ranging from 0 (good health) to 17 (poor health). Scores ≤5 are considered “Good health state,” while the smallest detectable change (SDC) is 3. In COAST-V, the scale was administered at screening, baseline, and Weeks 4, 8, and 16 to adults with active r-axSpA per ASAS criteria (sacroiliitis defined centrally by modified New York Criteria and ≥1 SpA feature), BASDAI ≥4, back pain ≥4, and inadequate response or intolerance to NSAID therapy. Patients were randomized 1:1:1:1 to PBO, adalimumab (ADA) 40 mg every 2 weeks (Q2W), or IXE80 mg every 4 weeks (Q4W) or Q2W up to Week 16. Change from baseline in ASAS HI was analyzed using a mixed-effects

Figure. ASAS HI outcomes over time.

model of repeated measures (MMRM). Categorical analyses were performed using a logistic regression model. Association between ASAS HI changes with clinical response was assessed using ANCOVA.

Results: Changes from baseline in ASAS HI total score at Weeks 4, 8, and 16 are presented in Figure. The ASAS HI separated between PBO and all active treatment groups at all time points. At Week 16, ASAS HI scores in the IXE Q4W, IXE Q2W, and ADA groups had improved by ≥ 3 (SDC) in 41.8%, 50.6%, and 42.7%, respectively, versus 34.5% in the PBO group. At Week 16, the percentage of patients in ASAS HI Good health state in the IXEQ4W, IXE Q2W, and ADA groups were 46.3%, 45.6%, and 40.3%, respectively, versus 25.0% in the PBO group. In patients treated with IXE, better ASAS20/ASAS40 responses were associated with greater improvements in ASAS HI scores at Week16 (Table).

Conclusion: The ASAS HI separated at all time points between actively-treated and PBO-treated patients. This proves good discrimination of this new outcome measure. In a Phase 3 study of bDMARD-naïve patients with r-axSpA, those treated with ixekizumab experienced significantly better ASAS HI outcomes than PBO, with the best outcomes occurring in ASAS40 responders.

Study Sponsor Statement: This study was supported by Eli Lilly and Company. Lilly participated in the study design, data collection, and the analysis and reporting of study results.

SESSION INFORMATION

Session Date: Monday, October 22, 2018
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical III: Treatment of Axial SpA
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: Increased incidence of IBD, such as Crohn's disease (CD) and ulcerative colitis (UC), has been observed in patients (pts) with PsA or plaque psoriasis (PsO) compared to those without. A greater incidence of IBD has been reported in pts with coexistent PsA and PsO.¹ Animal and human studies suggest a role for IL-17 in PsA, PsO, and IBD.² We report the incidence of IBD in pts treated with ixekizumab (IXE), a high-affinity mAb selectively targeting IL-17A,³ in pts with PsA, PsO, or comorbid PsA and PsO.

Methods: Adverse events of suspected IBD were collected for IXE-treated pts in an integrated database of 3(2 randomized, controlled) PsA phase 3 studies (SPIRIT-P1, -P2, -P3) and 12 studies in moderate-to-severe plaque PsO (1-phase 1, 1-phase 2, and 10-phase 3 [includes UNCOVER-1, -2, -3, -A, and -J]). Suspected IBD cases were adjudicated by internationally recognized classification criteria (EPIMAD). Adjudication data were summarized by indication. Percentage and exposure-adjusted incidence rates (IR) per 1000 patient year (PY) were calculated.

Results: During the double-blind (DB) placebo controlled period of PsO studies (Weeks 0-12), 3 (0.1%; IR=5.6/1000PY) IXE-treated pts had IBD events compared to none in placebo or etanercept arms; none were detected in any arm of the PsA DB study periods (Weeks 0-24). Of 1118 pts in PsA trials (1822 PY) who received at least one dose of IXE, 2 pts (IR=1.1/1000PY; 1 CD, 1 UC) had adjudicated IBD; both events occurred at 6 months to 1 year of treatment with IXE 80 mg every 2 weeks. Of 5898 pts in PsO trials (16313 PY) who received at least one dose of IXE, 26 pts (IR=1.6/1000PY; 7 CD, 19 UC) had adjudicated IBD. In 19 of 26 pts, events occurred within 1 year of IXE exposure (9 at <6 months; 10 at 6 months to 1 year). Among 28 adjudicated pts, 19 (PsO) were previously adjudicated;⁴ and 9 (7 PsO; 2 PsA) were newly adjudicated for IBD.

Conclusion: Events of CD and UC occurred infrequently among IXE-treated pts from 3 PsA trials and 12 PsO trials. Additional analysis and adjudication of longer-term data is currently ongoing and are required to further understand the relationship between IBD and IXE treatment.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical III: Treatment of Axial SpA

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Figure. Twenty-four month drug retention rates for the 1st, 2nd and 3rd TNFi in patients with axSpA in the EuroSpA collaboration

Drug retention and response rates of TNFi treatment in 21,470 patients with axial spondyloarthritis treated in clinical practice– pooled data from the EuroSpA Research Network Collaboration

Background/Purpose: A research network collaboration of 15 European registries sharing data on patients with spondyloarthritis (SpA), “EuroSpA”, has recently been created to strengthen research capabilities in the real world setting¹. We aimed to investigate Tumour Necrosis Factor inhibitor (TNFi) retention and response rates at 6, 12 and 24 months in patients with axial SpA (axSpA) treated with their 1st, 2nd or 3rd TNFi in clinical practice across Europe.

Methods: A common data model was agreed upon by the EuroSpA Scientific Committee. Registry data managers clarified data availability and uploaded anonymized data through the secure Virtual Private Network pipelines to the EuroSpA server. Baseline characteristics, drug retention and response rates after 6, 12 and 24 months were investigated with non-parametric descriptive statistics. Kaplan-Meier estimation was used to investigate TNFi retention rates. Both crude and Lundex adjusted² response rates were calculated for BASDAI remission (BASDAI<4) and ASDAS inactive disease (ASDAS<1.3 unit).

Results: In May 2018, 10 of the 15 registries participating in EuroSpA had completed data upload to the EuroSpA server, including 21,470 patients with axSpA. Baseline characteristics of the pooled population are shown in Table. For the 1st TNFi, 6 and 24 months’ retention rates were 87% and 71%, respectively. Corresponding retention rates for the 2nd TNFi were 80% and 63%, and for the 3rd TNFi 81% and 62%, respectively (Table and Figure). For the 1st TNFi, 6 and 24 months Lundex adjusted BASDAI remission rates were 57% and 36%. Corresponding remission rates for the 2nd TNFi were 42% and 25%, and for the 3rd TNFi, 36% and 20%. For the 1st TNFi, 6 and 24 months Lundex adjusted ASDAS inactive disease rates were 26% and 17%, respectively. Corresponding ASDAS inactive disease rates for the 2nd TNFi were 16% and 11%, and for 3rd TNFi, 12% and 6%.

Conclusion: These initial analyses demonstrate that the creation of a large European database of axSpA patients treated in routine care based on a common data model is feasible, offering important opportunities for future research. In this pooled dataset from 10 European registries, we found decreasing retention rates for the 2nd and 3rd TNFi compared to the 1st TNFi, and lower response rates with increasing number of previous TNFi.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical III: Treatment of Axial SpA

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: In the USA, certolizumab pegol (CZP) is approved for treatment of adults with active ankylosing spondylitis (AS) and not for non-radiographic axial spondyloarthritis (nr-axSpA). The Food and Drug Administration (FDA) expressed concerns that the natural history of nr-axSpA is poorly understood, with potential for spontaneous remission. C-axSpA was initiated, following FDA recommendations, to assess CZP efficacy vs conventional standard of care treatment in patients (pts) with active nr-axSpA and objective signs of inflammation (OSI) during a 52-week (wk) placebo (PBO)-controlled study.

Methods: C-axSpA (NCT02552212) was a 52-wk, phase 3, multicenter, double-blind, PBO-controlled study. Pts were randomized 1:1 to PBO or CZP (400 mg at Weeks 0, 2, and 4, then 200 mg every 2wks) and stratified by sacroiliitis on MRI and C-reactive protein (CRP) at baseline (BL) and region. Pts were ≥18 years with OSI (elevated CRP and/or

positive MRI of the sacroiliac [SI] joint), symptom duration ≥ 12 months, documented diagnosis of axSpA and met ASAS (but not modified New York) classification criteria. Randomized pts could switch to open-label (OL) CZP treatment or alternative OL treatment at any time, and concomitant medication could be adjusted at any point during the trial. The primary efficacy variable was Ankylosing Spondylitis Disease Activity Score Major Improvement (ASDAS-MI; defined as ASDAS decrease from BL ≥ 2.0 points or reaching lowest possible value) at Wk52. ASAS40 Wk12 response was assessed as the first secondary variable.

Results: 317 pts were randomized (PBO: 158, CZP: 159; Table). At Wk52, ASDAS-MI response was shown in 47.2% CZP vs 7.0% PBO pts (p-value: <0.001 ; Figure). All sensitivity analyses supported the primary outcome. Rapid improvement (ASDAS-MI Wk2 response) was observed in 20.8% CZP vs 1.3% PBO pts. ASAS40 response was reached in 47.8% CZP vs 11.4% PBO pts at Wk12. 60.8% PBO pts escaped to OL CZP vs 12.6% CZP pts by Wk52. No new safety signal was identified.

Conclusion: C-axSpAnd is the first study to assess efficacy of an anti-TNF in nr-axSpA using a 52-wk, PBO-controlled period. Clinically relevant and statistically significant improvements were seen in CZP vs PBO pts. This study shows clear evidence for the limitations of current standard of care to provide adequate disease control in nr-axSpA pts.

This study was funded by UCB Pharma, medical writing by Eleanor Thurtle, Costello Medical, UK.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical III: Treatment of Axial SpA

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Secukinumab provided significant and sustained improvement in the signs and symptoms of ankylosing spondylitis (AS) over 2 years in the MEASURE 3 study, which evaluated the highest dose of secukinumab tested to date in spondyloarthritis (NCT02008916).^{1,2} Here we report longer term final efficacy and safety results for secukinumab from this 3-year study.

Methods: 226 patients (pts) were randomized to intravenous (IV) secukinumab 10mg/kg (baseline, Weeks (Wks) 2 and 4) followed by subcutaneous (SC) secukinumab300 or 150 mg every 4 wks (IV→300/150 mg), or matched placebo (PBO). At Wk 16,PBO pts were re-randomized to SC secukinumab 300 or 150 mg. Analysis at Wk 156 included pts initially randomized to secukinumab and those who switched from PBO to secukinumab at Wk 16 (Any secukinumab 300 mg, N = 113 and Any secukinumab 150mg, N = 110). Outcome measures at Wk 156 included ASAS20 and 40, hsCRP, ASAS5/6, BASDAI, ASAS partial remission (PR) and ASDAS-CRP inactive disease. Analyses stratified by anti-TNF α status (anti-TNF α -naïve and anti-TNF α inadequate response [IR]) were pre-specified. Data are reported as observed. Safety analyses included all pts who received ≥ 1 dose of secukinumab.

Results: 80.5% (91/113; Any secukinumab 300 mg) and 80.9% (89/110; Any secukinumab 150 mg) pts completed 156 wks of treatment. Clinical responses with secukinumab were sustained through Wk 156 (Table). At Week 156, response rates on more stringent clinical endpoints (e.g. ASAS40, ASAS PR) were higher with the 300 mg dose, particularly in anti-TNF-IR pts. The safety profile of both secukinumab doses was similar through Wk 156 (mean exposure: 980.3 days [300 mg] and 990.8 days [150 mg]). Exposure-adjusted incidence rates for *Candida* infections and serious infections/infestations were 0.7 and 0.7 per 100 patient-years, respectively, in the combined group of secukinumab doses over the entire treatment

Table: Summary of Efficacy Results at Weeks 156

Overall population				
Variable, % responders (n/N) unless otherwise specified	Any Secukinumab 300 mg	Any Secukinumab 150 mg		
ASAS20	75.0 (89/92)	68.2 (60/88)		
ASAS40	36.5 (52/92)	47.7 (42/88)		
hsCRP, mean change from baseline \pm SD (N)	-5.0 \pm 12.8 (93)	-8.6 \pm 18.3 (89)		
ASAS5/6	60.0 (40/92)	47.7 (42/88)		
BASDAI, mean change from baseline \pm SD (N)	-3.6 \pm 2.0 (92)	-2.8 \pm 2.0 (88)		
ASAS-PR	28.3 (26/92)	15.9 (14/88)		
ASDAS-CRP inactive disease	25.0 (23/92)	18.4 (16/87)		
By anti-TNF α status				
Variable, % responders (n/N)	Anti-TNF α -naïve		Anti-TNF α -IR	
	Any Secukinumab 300 mg	Any Secukinumab 150 mg	Any Secukinumab 300 mg	Any Secukinumab 150 mg
ASAS20	74.7 (56/75)	68.0 (19/28)	65.5 (12/18)	54.7 (11/20)
ASAS40	60.0 (45/75)	62.9 (17/27)	45.2 (7/15)	29.4 (5/17)
ASAS-PR	28.0 (21/75)	19.7 (14/71)	29.8 (5/17)	0 (0/17)

ASAS, Assessment of Spondyloarthritis International Society; ASDAS, Ankylosing Spondylitis Disease Activity Score; BASDAI, Bath Ankylosing Spondylitis Disease Activity Index; hsCRP, high sensitivity C-reactive protein; IR, incidence of (or off of) the (naïve) group with (inadequate) PR; partial remission; SD, standard deviation

period. No cases of inflammatory bowel disease, including Crohn's disease or ulcerative colitis, were reported, and no deaths occurred in the study.

Conclusion: Secukinumab (300 and 150 mg) provided sustained improvements through 3 years in the signs and symptoms of active AS. Secukinumab was well-tolerated with a safety profile consistent with previous reports.^{1,2}

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Edmond L. Dubois, MD Memorial Lecture: Systemic Lupus Erythematosus – Clinical

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Two randomized, controlled trials of rituximab in patients with lupus and lupus nephritis (LN) did not meet their primary endpoints. A potential explanation is the observation that after treatment with rituximab, serum BAFF levels are elevated and may lead to disease flare by facilitating expansion of and re-population with autoreactive B cells. The CALIBRATE study (NCT 02260934) was designed to test this hypothesis, to determine whether addition of anti-BAFF (belimumab) could enhance the clinical effects of anti-CD20 (rituximab), and assess safety of the combination.

Methods: 43 subjects with active, proliferative LN despite conventional therapy were enrolled in a prospective, randomized, open-label trial that compared two therapeutic regimens. All subjects received iv rituximab (1000 mg), cyclophosphamide (750 mg), and methylprednisolone (100 mg) at wks 0 and 2, and an initial prednisone dose of 40 mg/d with taper to 10 mg/d by wk 12. At wk 4, subjects were randomized to belimumab (10 mg/kg iv at wks 4, 6, 8, and every 4 wks) plus prednisone (RCB group, n=21) versus prednisone alone (RC group, n=22). Complete response (CR) was defined as: (i) urine protein:creatinine ratio (UPCR) <0.5; (ii) eGFR ≥120 or, if <120, eGFR >80% of screening; and (iii) prednisone dose of 10 mg/d. Partial response (PR) differed only in the UPCR criterion (>50% reduction).

Results: The rate of renal response at wk 48 was similar between the two groups (Table I). CR rate was 32% in the RC group and 38% in the RCB group. B cell depletion occurred in both groups by wk 12, but repopulation occurred at different rates (Table II). Median IgG levels remained well within the normal range in both groups (Table II). 5 subjects in the RC group and 2 in the RCB group experienced grade 3 or higher infectious adverse events, and all resolved.

Conclusion: There was no difference in the rate of renal response at wk 48 in subjects who received anti-CD20 therapy followed by anti-BAFF therapy compared with anti-CD20 therapy alone. Anti-BAFF resulted in delayed peripheral B cell repopulation, but was not associated with hypogammaglobulinemia or an increase in serious infectious adverse events. Further analyses at wk 96 will provide information on the effects of anti-BAFF on B cell repertoire and longer term clinical outcomes.

Table I

	CR	PR	Failed *	Withdrawn**
RC Group (n=22)	7 (32%)	2 (9%)	12 (55%)	1 (5%)
RCB Group (n=21)	8 (38%)	3 (14%)	8 (38%)	2 (10%)

* Includes subjects who failed at any point due to lack of renal response, inability to taper steroids, renal flare, or non-renal flare.

** Includes subjects withdrawn for reasons unrelated to lupus. Table II

	Median B Cell Count (cells/uL)				Median IgG Level (mg/dl)		
	Wk 0	Wk12	Wk 24	Wk 48	Wk 0	Wk 24	Wk 48
RC Group	105	1	21	31	1050	1110	1410

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Edmond L. Dubois, MD Memorial Lecture: Systemic Lupus Erythematosus – Clinical

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: There is a well-documented increase in atherosclerosis (ATH) in SLE that is not fully explained by traditional risk factors. Several non-Framingham biomarkers, including pro-inflammatory HDL (piHDL), leptin, plasma soluble TNF-like weak inducer of apoptosis (sTWEAK), and homocysteine are individually associated with subclinical ATH in SLE. We previously demonstrated that these biomarkers, combined with clinical variables such as age and diabetes, create a risk profile we have called *PREDICTS*. The *PREDICTS* profile more accurately identified SLE patients at risk for future subclinical ATH progression than any one variable alone. We set out to determine whether a high-risk *PREDICTS* score could also identify patients at risk for future cardiovascular events.

Methods: 392 SLE patients participated in this longitudinal prospective cohort study. 205 patients were included in this analysis, based on availability of 10-year cardiac event and/or mortality data. piHDL was measured using a published cell-free assay. Leptin and sTWEAK were determined at baseline using ELISA (R&D Biosystems). Homocysteine was determined by radioimmunoassay in the clinical laboratory of an academic medical center. Cardiac events were defined as myocardial infarction, a positive stress test, angioplasty, or percutaneous coronary intervention. Cerebrovascular events were defined as stroke or documented TIA. We defined high-risk *PREDICTS* as ≥ 3 of identified predictors or diabetes + ≥ 1 predictor.

Results: 16.1% (33) of SLE patients experienced a cerebrovascular accident during the 10-year follow-up period. 8.3% (17) of subjects had a cardiac event. 8.3% (17) of subjects died. Patients with a high-risk *PREDICTS* score at cohort entry were significantly more likely to have a cerebrovascular event (19.1% vs. 7.0%, $p=0.04$), or a cardiac event (10.9% vs. 0%, $p=0.012$). In addition, a high-risk baseline *PREDICTS* score also was also more likely to be found in patients that suffered any cardiovascular event or death (34.4% vs. 7%, $p<0.0001$). In multivariate analysis, baseline high-risk *PREDICTS* associated with a 3.7-fold increased odds for death or cardiovascular event over 10 years ($p=0.004$). Hypertension at baseline also was associated with increased odds for death or cardiovascular event (OR=4.9, $p=0.001$). No association with death or cardiovascular events were observed with hyperlipidemia, baseline carotid plaque, gender, or tobacco use.

Conclusion: A high-risk *PREDICTS* score and a history of hypertension at cohort entry confer significantly increased odds for a cardiovascular event or death in SLE patients over a 10-year follow-up. Further studies are necessary to identify proactive treatment strategies to prevent cardiovascular morbidity and mortality in SLE.

Safety and Efficacy of Allogeneic Umbilical Cord-Derived Mesenchymal Stem Cells in Patients with Systemic Lupus Erythematosus: Results of an Open-Label Phase I Study

Diane L. Kamen¹, Paul J. Nietert², Hongjun Wang³, Tara Duke³, Colleen Cloud³, Angela Robinson³ and Gary S. Gilkeson⁴, ¹Medicine/Rheumatology & Immunology, Medical University of South Carolina, Charleston, SC, ²Public Health Sciences, Medical University of South Carolina, Charleston, SC, ³Medical University of South Carolina, Charleston, SC, ⁴Department of Medicine, Medical University of South Carolina, Charleston, SC

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Edmond I. Dubois, MD Memorial Lecture: Systemic Lupus Erythematosus – Clinical Session type: ACR concurrent Abstract Session

Session Time: 2:30pm-4:00pm

Background/Purpose: Mesenchymal stem cells (MSCs) are known to possess significant immunosuppressive and tissue protective properties, and their use in refractory systemic lupus erythematosus (SLE) is supported by promising safety and efficacy in autoimmune animal models and human trials. We conducted this phase I open-label study to test the hypothesis that a single infusion of human allogeneic umbilical cord-derived MSCs (IND 16377) is safe when added to standard-of-care therapy for active SLE.

Methods: Patients (N=6) with active SLE (SLEDAI ≥ 6) who signed informed consent and met all inclusion and exclusion criteria sequentially received 1×10^6 cells/kg umbilical cord-derived MSCs given as an IV infusion in Plasma-Lyte A solution. Post-infusion, Week 1 and 2 safety data from each participant was reviewed by the Data Safety Monitoring Board prior to enrolling the next patient. The primary safety outcome is frequency of Grade 3 or higher adverse events (AEs) by Week 24. The primary efficacy outcome is change in SLE disease activity between Baseline and Week 24 measured by SLEDAI score and prednisone dose. Each patient is followed for a total of 52 weeks.

Results: Table 1 summarizes the demographics, visit SLEDAI scores, number of AEs and serious adverse events (SAEs). The 6th participant completed her Week 24 visit on April 11, 2018. To date, there has been one SAE and no AEs higher than Grade 2 by NCI-CTCAE scoring. The SAE was prolonged hospitalization following a partial dose infusion of rituximab IV leading to anaphylaxis. Rituximab was started for persistent SLE disease activity (patient dropped out of the study after Week 8) and was given in the hospital ICU setting due to her prior history of anaphylaxis to Tween (polyethoxylated surfactant found in IV and SQ medications). Anaphylaxis resulted in a prolonged hospital stay of 2 days, resolving with treatment without sequelae. The SAE was attributed to her known allergy to ingredients in the rituximab infusion and deemed unrelated to the MSCs that she received several months earlier. The AEs “possibly” attributable to the investigational product were Grade 2 nausea, Grade 2 tachycardia, and Grade 1 flushing with Grade 1 toe paresthesias – all of which resolved without sequelae.

Among the 5 patients who completed their Week 24 evaluations, all showed improved SLE activity (mean SLEDAI score 8.6 ± 1.9 at Baseline improved to 2.6 ± 2.8 at Week 24) with stable or lower doses of prednisone and stable background immunosuppressants. Mean physician global assessment (PGA) scores also improved from 1.71 ± 0.48 at Baseline to 0.32 ± 0.17 at Week 24.

Conclusion: A single-dose of umbilical cord-derived MSCs was safe and well-tolerated in this open-label phase I trial for six patients with active SLE. Initial efficacy data for MSCs in SLE appears promising and will be further tested in a larger controlled trial.

Table 1

Subject	Baseline Age, Race/Ethnicity, Sex	SLEDAI Score					Non-Serious AEs (#)	SAE (#)
		Baseline	Week 4	Week 8	Week 12	Week 24		
1	32 yo Black Female	6	4	2	0	0	3 Grade 1 5 Grade 2 0 Grade ≥ 3	0
2	38 yo Caucasian Female	8	8	8	2	2	0 Grade 1 2 Grade 2 0 Grade ≥ 3	0

Abstract Number: 1873

Age- and Cause-Specific Standardized Mortality Ratio of Systemic Lupus Erythematosus Patients in Ontario, Canada over 43 Years (1971-2013)

Konstantinos Tselios, Dafna D Gladman, Barry Sheane, Jiandong Su and Murray Urowitz, University of Toronto, Toronto Western Hospital, Toronto, ON, Canada

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Edmond L. Dubois, MD Memorial Lecture: Systemic Lupus Erythematosus – Clinical

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: The major causes of early death in systemic lupus erythematosus (SLE) include active disease and infections, while cardiovascular complications and malignancies dominate the late stages. In recent years, there has been a significant decrease in all-cause mortality. The aim of the present study was to assess the all cause, age and cause-specific standardized mortality ratios (SMR) of lupus patients from 1971 to 2013.

Methods: Our long-term longitudinal cohort followed 1732 patients between 1971-2013. Causes of death were retrieved from death certificates, autopsy reports, hospital records or the records of the family physicians for each patient. They

were categorized as atherosclerotic (acute coronary syndrome, ischemic cardiomyopathy, cerebrovascular accident), infection (sepsis), malignancy, active lupus and others. Patients were also categorized according to the age at death in 10-year intervals (15-24, 25-34 etc.). For the calculation of the SMR, data from the general population of Ontario, Canada were used (retrieved from Statistics Canada for the same time period). Statistical analysis was performed with SAS 9.4.

Results: Two hundred and forty-nine patients (205 females) died (infections 24.5%, atherosclerosis 15.7%, active lupus 13.3%, malignancy 9.6%); mean age was 53.2±16.6 years and mean disease duration 15.2±11.7 years. The mean age at death and SMRs for all-cause and cause-specific mortality over the decades are shown in Table 1.

Table 1 Mean age at death and Standardized Mortality Ratio* (all-cause and cause-specific) for SLE from 1971 to 2013

	1971-79	1980-89	1990-99	2000-09	2010-2013
Mean age (y±SD)	42.2±12.9	50.4±16.8	57.2±16.9	54.1±15.9	58.8±14.6
All-cause	13.5 (8.6-18.5)	6.5 (4.9-8.2)	4.7 (3.6-5.8)	3.2 (2.4-4)	2.2 (1.4-3.1)
Atherosclerosis		8.3 (3.8-12.8)	6.7 (3.8-9.5)	2.3 (0.8-3.8)	3.2 (0.1-6.3)
Infection		14.2 (8-20.4)	6.5 (3.8-9.1)	2.5 (1.2-3.9)	0.9 (0-1.9)
Malignancy		14.1 (4.3-23.9)	3 (1.1-4.8)	4.4 (1.5-7.3)	1.4 (0.2-2.7)

* As compared to the general population of Ontario, Canada (1971-2013). Values are given as SMR (95% Confidence Interval)

The age-specific SMR was particularly high in younger (15-44 years old) patients [SMR=12.4, 95% CI=9.7-15.1] as compared to the patients who were older than 45 years [SMR=3.1, 95% CI=2.6-3.6]. Details are given in Figure 1.

An analysis of the cause-specific SMR in the age groups 20-39 and ≥40 showed that younger patients had a higher SMR for all these causes, details in Table 2.

Table 2 Cause-specific Standardized Mortality Ratio for patients 20-39 years old and ≥40 years (1978-2013)

Causes of death	Deaths (20-39 years), n	SMR (20-39 years)	Deaths (≥ 40 years), n	SMR (≥ 40 years)
All cause	58	12.4 (95% CI=9.7-15.1)	191	3.1 (95% CI=2.6-3.6)
Atherosclerosis	3	14.6 (95% CI=0-43.3)	36	4.7 (95% CI=3.3-6)
Infection	30	30.2 (95% CI=14.4-46)	31	3.5 (95% CI=2.5-4.5)
Malignancy	4	31.9 (95% CI 0.6-63.1)	20	3 (95% CI=1.9-4.1)

Conclusion: The SMR for all-cause and cause-specific mortality has significantly decreased over time, likely reflecting the advances in the management of SLE and atherosclerosis, infections and malignancies. The SMR is particularly high for younger patients (<40 years old) and it remains higher than that of the general population even for the older patients.

Session Title: Edmond L. Dubois, MD Memorial Lecture: Systemic Lupus Erythematosus – Clinical

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Over the last few years the importance of treating patients with SLE towards achieving either Remission or LDAS (Treat-to-Target approach) has become evident. We have now aimed at determining the beneficial effects of achieving these states in lupus patients from a multi-ethnic, multicenter lupus cohort (LUMINA for Lupus in Minorities: Nature vs. Nurture).

Methods: The LUMINA cohort was started in 1993 and up to 2009 recruited nearly 600 patients of either Caucasian (28%), African (37%) or Hispanic (35%) ancestry, at three institutions: Alabama, Texas and Puerto Rico. Visits were performed every 6 months for the first year and yearly thereafter. Socioeconomic, demographic and clinical data were obtained at all visits. Disease activity was ascertained with the Systemic Lupus Activity Measure (SLAM) and disease damage with the SLICC Damage Index (SDI). We have now examined all patients' visits and classified them as corresponding to Remission (SLAM score=0 and Prednisone \leq 5 mg/day and no immunosuppressants), LDAS [(not in Remission), SLAM score \leq 3, prednisone $<$ 7.5 mg/day, no immunosuppressants) or neither: active. Because of the relatively small number of visits corresponding to Remission, Remission and LDAS visits were examined as a single variable. The association between the last SDI and the percent of time on Remission/LDAS was modeled using Poisson regression with adjustment for variables known to affect this outcome (age, gender, ethnic/racial group, baseline disease activity and disease damage). In a separate multivariable regression model, mortality, adjusting for variables known to affect this outcome, was the end-point.

Results: Visits for 558 patients (total number of visits: 3979; median number of visits per patient: 6.8, interquartile range 4-6) were examined. The longer patients were on Remission/LDAS, the less likely they were to accrue damage [Estimate 0.3503, 95% CI 0.2497 to 0.4905 ($p < 0.001$)]. In terms of mortality the direction of the association was as expected (protective) but statistical significance was not reached [Parameter estimate OR 0.303 (Wald 95% CI 0.063 to 1.456 ($p = 0.1360$))].

Conclusion: The longer lupus patients are in remission/LDAS, the less likely they are to accrue damage. Other significant variables in this analysis, were, as expected, associated with damage (older age, male gender, not being from Puerto Rico, higher disease activity at baseline and higher damage at the baseline visit). Although the direction of the association in terms of mortality was as expected, statistical significance was not reached. These data have implications for the management of patients with lupus regardless of their ethnic/racial background.

Table 1 Poisson Multivariable Regression Model of Damage in LUMINA patients

Variable	Estimate	Wald 95% CI	p value
Age	0.0120	1.0070-1.0170	<0.0001
Gender (male)	1.1177	0.9216-1.3557	0.2581
Race/ethnic group			
Hispanic (Puerto Rico)	Ref.		
Caucasian	2.6104	2.0069-3.3950	<0.0001
African American	2.1843	1.7064-2.7960	<0.0001
Hispanic (Texas)	1.7690	1.3638-2.2945	<0.0001
SDI (baseline)	1.3214	1.2693-1.3758	<0.0001
SLAM score (baseline)	1.0258	1.0057-1.0373	<0.0001
Remission/LDAS	0.3503	0.2497-0.4945	<0.0001

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Sclerosis and Related Disorders– Clinical II: Clinical Trial Results, Predictors, Design

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Recent studies on large cohorts of patients with systemic sclerosis (SSc) have shown that lowering the upper threshold of the modified Rodnanskin score (mRSS) as a study inclusion criterion leads to cohort enrichment with patients with progressive skin disease. Limitations of these studies were lack of racial diversity and low proportion of patients with anti-RNA-Polymerase III (Pol3) antibodies. As the Texas-based GENISOS cohort is an ethnically diverse cohort, including a large proportion of Pol3-positive patients, this study aimed to assess the effect of different mRSS cut-off values at baseline on progression of skin fibrosis after one year of follow-up.

Methods: We extracted data from GENISOS for patients fulfilling the 1980 ACR criteria for SSc and the Le Roy criteria for diffuse cutaneous SSc, who had a minimum mRSS of 7 at inclusion and a follow-up visit with documented mRSS at 12±2 months. Progressors were defined as having an increase in mRSS >5 points and ≥25% from the baseline to 2nd visit, while regressors were defined as having a decrease in mRSS of >5 points and ≥25%. To identify the optimal cut-off of baseline mRSS that yields the highest sensitivity for progressive skin fibrosis, we developed ROC curves and logistic regression models with “progression” as outcome variable and a binary variable of baseline mRSS cut-off point as predictor.

Results: 152 patients (age and disease duration [median, Q1-Q3, years] 49.5, 40.2-57.3 and 2.2, 1.1-3.3 respectively, 22.4% males) matched the inclusion criteria. The proportion of patients of African American ethnicity was 32/152 and 50/152 patients were Pol3-positive.

After one year of follow-up, 17 patients (11.2%) classified as progressors and 51 (33.6%) as regressors. Progressors were more frequently positive for anti-topoisomerase antibodies (37.5% vs. 15.3%, $p=0.028$), negative for anti-Pol3 antibodies (93.8% vs. 62.3 %, $p=0.012$), had a shorter disease duration (median, Q1-Q3: 1.3, 0.5-2.2 vs. 2.4, 1.1-3.5 years, $p=0.005$) and lower mRSS (median, Q1-Q3: 21, 11-25 vs. 24, 16-31, $p=0.012$) than the remainder of the patients.

Sixteen of 17 progressors, but only 33 of 51 regressors had a baseline mRSS ≤27. The mRSS cut-off of ≤27 had the highest probability of progression (odds ratio 9.1, 95% confidence interval 1.2-70.9, $p=0.035$, area under the curve 0.652). Using this cut-off as an inclusion criterion in a clinical trial (vs. no cut-off) would have included 94% of all progressors, but only 65% of all regressors and 67% of all patients. The figure displays absolute numbers of progressors and regressors at 1 year for each mRSS cut-off.

Conclusion: This analysis reconfirmed, in a population rich in patients of African American origin and with high prevalence of Pol3 antibodies, that setting a lower upper threshold of mRSS at study inclusion increases the proportion of progressors and reduces the absolute number of regressors.

Session Title: Systemic Sclerosis and Related Disorders– Clinical II: Clinical Trial Results, Predictors, Design

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: The SCOT (Scleroderma:Cyclophosphamide or Transplantation) trial (Sullivan K. *et al*, 2018) demonstrated the clinical benefit of hematopoietic stem cell transplant (HSCT) compared to cyclophosphamide(CYC) in dcSSc. We analyzed gene expression data from peripheral blood mononuclear cells (PBMCs) of SCOT participants to identify molecular changes and intrinsic gene expression subsets associated with treatment response.

Methods: PBMC gene expression data were generated from 67 SCOT participants at baseline (36 CYC, 31 HSCT) and at 48/54 months (12CYC, 14 HSCT). Significant differentially expressed genes (DEGs; False Discovery Rate <5%) were identified between baseline and 48/54 month samples using Significance Analysis of Microarrays and were annotated with

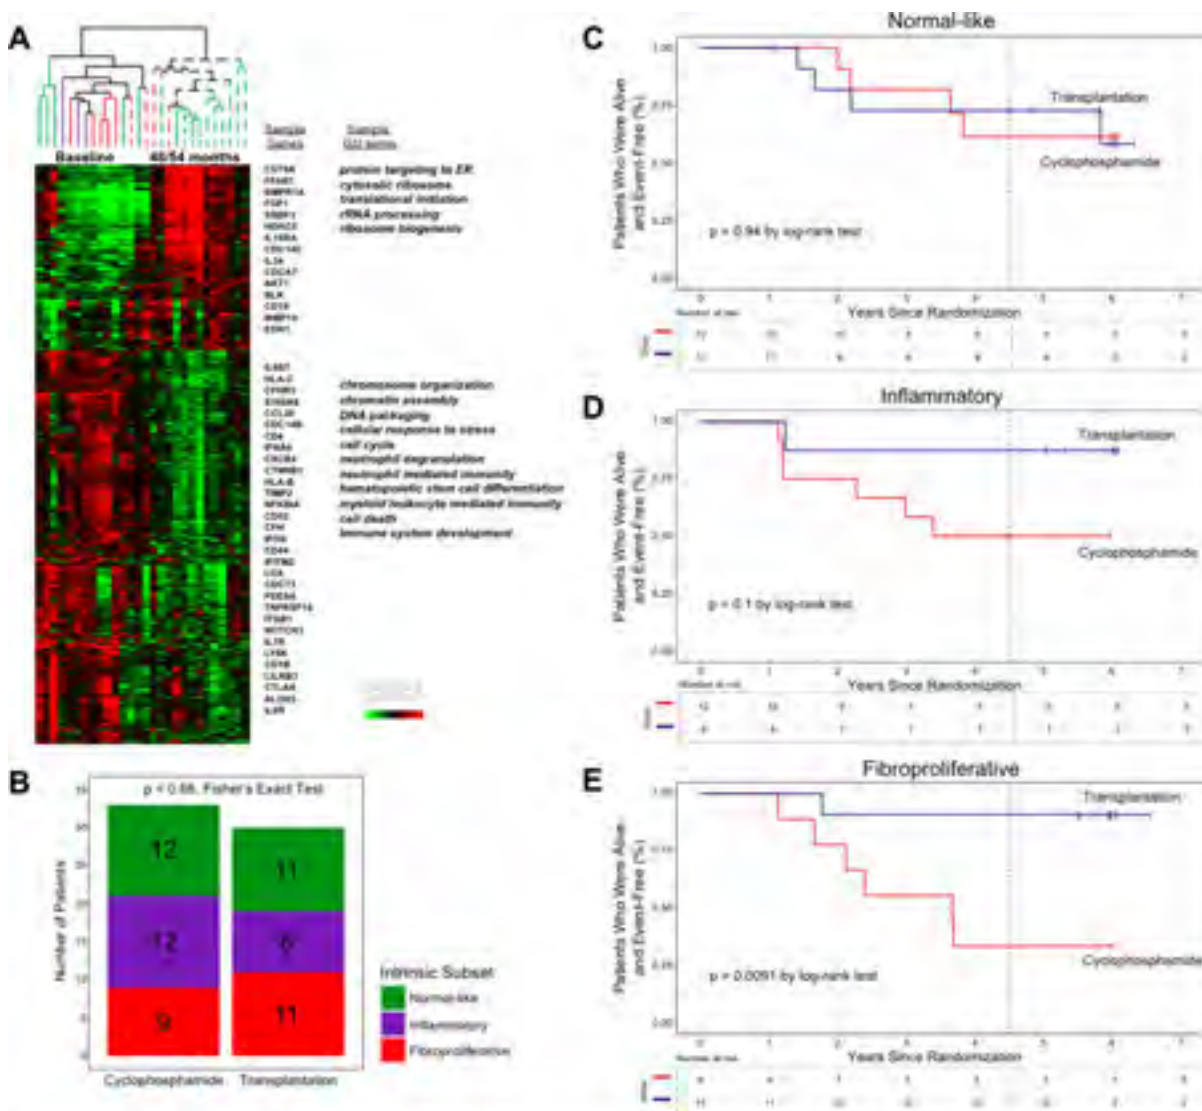

Figure 1: (A) Sample DEGs (and associated GO terms) modulated between baseline and 48/54 months of treatment for patients randomized to the HSCT arm. **(B)** Comparison between treatment arms in terms of the number of patients assigned to each intrinsic subset at baseline. **(C-E)** EFS analysis by treatment arm (HSCT in blue, CYC in red) for patients assigned to the normal-like (C), inflammatory (D), and fibroproliferative (E) intrinsic subsets.

Gene Ontology functional terms via g:Profiler. Participants who completed treatment protocol (Per-Protocol Population) were assigned to intrinsic gene expression subsets at baseline using a machine learning classifier based on elastic net multinomial regression previously trained and tested on five independent SSc cohorts. The relationship between intrinsic subsets and event-free survival (EFS) was analyzed at 54 months.

Results: The participants included in the gene expression analyses were representative of the full cohort in the SCOT trial; there were no significant differences in sex, age, race, or baseline phenotypic measures. In the subset of participants with 48/54 month samples, we observed considerably more DEGs in HSCT arm (4788 genes) than in CYC arm (21 genes). Participants in HSCT showed a decrease in the expression of genes associated with cell proliferation and immune response and an increase in expression of genes associated with translation compared to baseline (Fig. 1A). Participants were assigned to intrinsic gene expression subsets at baseline (Fig. 1B) in both treatment arms. EFS did not differ between treatment arms for the participants assigned to the normal-like subset ($p=0.94$, Fig. 1C), consistent with the lack of active immune response in these participants. Participants assigned to the inflammatory subset trended towards improved chance of EFS in HSCT arm ($p=0.1$, Fig. 2D). Participants assigned to the fibroproliferative subset who received HSCT experienced significant improvement in EFS compared to fibroproliferative participants who received CYC ($p=0.0091$, Fig. 1E).

Conclusion: The HSCT arm of the SCOT trial showed substantially larger changes in gene expression compared to CYC arm. Participants assigned to the normal-like subset did not show benefit from HSCT treatment over CYC. Importantly, participants assigned to the fibroproliferative subset, who tend not to improve on immunosuppressive therapy (e.g. MMF or abatacept), were the most likely to benefit from HSCT.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Sclerosis and Related Disorders– Clinical II: Clinical Trial Results, Predictors, Design

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Interstitial lung disease (ILD) is the leading cause of death in systemic sclerosis (SSc). While some SSc-ILD patients are stable or improve with immunosuppressive therapy, others have progressive decline and currently available clinical parameters do not reliably predict outcomes. We investigated whether two specific pneumoproteins, Krebs von den Lungen-6 [KL-6] and CC chemokine ligand 2 [CCL18] predict response to immunosuppression with cyclophosphamide (CYC) and mycophenolate (MMF) in SSc-ILD.

Methods: 142 patients in Scleroderma Lung Study (SLS) II were randomized to receive either mycophenolate (MMF) for 2 years or oral CYC for 1 year followed by 1 year of placebo. All available serum baseline and 12-month samples were investigated. CCL18 was assayed by commercially available ELISA while KL-6 was measured using antibody coated latex microbeads and an automated analyzer. The forced vital capacity (FVC) and the diffusing capacity for carbon monoxide (DLCO) were measured every 3 months. Quantitative Lung fibrosis (QLF) and Quantitative ILD (QILD) scores for whole lung (WL) and zone of maximum involvement (ZM) were measured at baseline. To investigate the relationship between baseline CCL18 and KL-6 and progression of ILD, joint models were created with the outcomes of the course of the FVC and DLCO over 1 year.

Results: Baseline serum KL-6 and CCL18 correlated with extent of ILD. KL-6 levels correlated with (r, *P*-value): DLCO (-0.3; 0.0002) QLF-WL (0.5; <0.0001) QLF-ZM (0.4; <0.0001), and QILD-WL (0.5; <0.0001), QILD-ZM (0.5; <0.0001); Baseline CCL18 levels were correlated with QILD-WL (*r*=0.2; *p*=0.04) and QILD-ZM (*r*=0.3; *p*=0.009), but not with the FVC or DLCO. CCL18 and KL6 levels declined significantly in the first year in both arms (Figure 1). After adjusting for baseline disease severity, higher baseline KL6 levels predicted progression of ILD as measured by the course of the FVC (CYC/MMF: Estimate -0.31/-0.74; *P*=0.024/<0.001) and DLCO (CYC/MMF: Estimate -1.30/-1.29; *P*<0.001/<0.001) over 1 year for both treatment arms. Similarly, higher baseline CCL18 levels predicted progression of ILD as measured by the course of the FVC (CYC/MMF: Estimate -1.24/-0.35; *P*<0.001; 0.007) and DLCO (CYC/MMF: Estimate -1.87/-1.24; *P*=0.001/0.002) over 1 year for both treatment arms.

Conclusion: In the context of a rigorously conducted clinical trial for SSc-ILD, baseline KL-6 and CCL18 levels correlated with several surrogate measures of ILD severity. Patients with higher baseline KL-6 and CCL18 levels were more likely to experience disease progression despite treatment with CYC and MMF. KL-6 and CCL18 could be used to identify patients with progressive ILD that require closer monitoring in clinical practice. KL-6 and CCL18 may also be used to enrich SSc-ILD clinical trials with those at risk of accelerated ILD progression with conventional immunosuppressive therapy.

Immunosuppression in Diffuse Systemic Sclerosis Improves Outcomes Using a Novel Composite Response Index

Boyang Zheng¹, Mianbo Wang² and Murray Baron³, ¹Rheumatology, McGill University Health Center (MUHC), Montreal, QC, Canada, ²Lady Davis Institute for Medical Research, Montreal, QC, Canada, ³Rheumatology, McGill University, Jewish General Hospital, Montreal, QC, Canada

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Sclerosis and Related Disorders– Clinical II: Clinical Trial Results, Predictors, Design

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Diffuse systemic sclerosis (dcSSc) is a devastating multi-organ disease where the mainstay of treatment is immunosuppression. Data on these therapies are mostly based on skin or organ specific outcomes such as lung involvement. However, a new composite response index in dcSSc (CRISS) was proposed to improve assessment of treatment interventions¹. Our aim is to examine the effect of current immunosuppressive therapy on the CRISS in an observational dcSSc cohort.

Methods: Adult dcSSc patients without prior immunosuppression followed in the Canadian Scleroderma Research Group (CSRG) registry between 2005 and 2017 were included. Patients newly treated with methotrexate, azathioprine, mycophenolate and/or cyclophosphamide for ≥ 2 years were the exposed group and untreated patients with at least the same follow up duration were controls. To account for disparity between treated and untreated patients, inverse probability of treatment weighting (IPTW) was performed to balance potential confounders: age, sex, disease duration and CRISS variables (modified Rodnan skin score, forced vital capacity, patient and physician global assessments, and HAQ-DI). Overall disease evolution after 1 year was qualified using CRISS which defines improvement as a score ≥ 0.6 . Missing data were multiply imputed and logistic regression was used to obtain pooled odds ratios and confidence intervals.

Results: 301 dcSSc patients were analyzed. Of these, 47 (15.7%) were treated and 254 (84.4%) were untreated. At baseline, treated compared to untreated patients were younger (50.1 ± 10.4 vs. 55.1 ± 12.3 years respectively, $p=0.008$), had significantly shorter disease duration (5.5 ± 7.4 vs. 11.7 ± 9.3 years respectively, $p<0.001$) and higher mean physician global assessment scores (4.2 ± 2.3 vs. 2.5 ± 1.9 points respectively, $p<0.001$). IPTW used to correct for the different treatment probabilities and confounders showed excellent balance between the two groups. Prior to IPTW, treated patients trended towards more improvement after 1 year. However, after IPTW correction, treated patients were significantly more likely than untreated patients to have improved disease, regardless of age, sex, or disease duration (Table 1).

Conclusion: Assessing the effects of treatment in an observational cohort is intrinsically biased as treated patients will likely have more severe disease. After balancing using IPTW to reduce these confounders, we demonstrated that patients on immunosuppression are more likely to experience substantial improvement than untreated patients after 1 year using the CRISS score, a newly proposed global measure of disease severity.

Session Date: Monday, October 22, 2018

Session Title: Systemic Sclerosis and Related Disorders– Clinical II: Clinical Trial Results, Predictors, Design

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: The soluble guanylate cyclase stimulator riociguat is approved for the treatment of pulmonary arterial hypertension associated with connective tissue disease. It was anticipated that riociguat might, through its vasodilatory and anti-remodeling properties, decrease the number and severity of Raynaud's attacks and reduce net digital ulcer burden in patients with diffuse cutaneous systemic sclerosis (dcSSc). We present exploratory endpoints from the RISE-SSc study (NCT02283762) on the effect of riociguat in early dcSSc patients with Raynaud's phenomenon and digital ulcers.

Methods: RISE-SSc was a Phase IIb, multicenter, randomized, double-blind, placebo-controlled study. Inclusion criteria were: diagnosis of SSc fulfilling ACR/EULAR criteria, diffuse cutaneous involvement, disease duration ≤ 18 months, and modified Rodnan skin score ≥ 10 and ≤ 22 units. Patients were assigned to placebo or riociguat individually adjusted from 0.5 mg up to 2.5 mg 3 times daily. Exploratory efficacy endpoints included 1) change in Raynaud's attacks from baseline to Week 14, assessed by the following individual outcome measures: Raynaud's condition score (analyzed using ANOVA), patient/physician assessment of Raynaud's phenomenon (analyzed using ANOVA), attack symptoms, attack duration, and average No. of attacks per day; and 2) change in net digital ulcer burden from baseline to Week 52, assessed by ulcer count, ulcer burden, and visual analog score (as part of the Scleroderma Health Assessment Questionnaire) for patient-reported severity. Endpoints were analyzed using mixed-model repeated measures from baseline up to Week 52, unless otherwise stated.

Results: In total, 121 patients were enrolled. At Week 14, a numerically greater relative reduction in attack duration and attack frequency was observed from baseline in the riociguat group vs placebo (Table). Improvements in Raynaud's attack symptoms and disability measured by pain, numbness, tingling, and patient/physician global assessment were also observed with riociguat vs placebo (Table). At Week 52, reductions in net digital ulcer burden were -0.09 ± 0.50 for riociguat and -0.08 ± 1.47 for placebo (estimated treatment difference: -0.11 [95% CI: $-0.38, 0.17$; $p=0.44$]). At baseline, 9 patients (15.0%) had digital ulcers in the riociguat arm vs 6 patients (9.8%) in the placebo arm. At Week 52, 1 patient (2.1%) had digital ulcers in the riociguat arm vs 4 patients (8.2%) in the placebo arm.

Conclusion: There was a numerical tendency toward a reduction of Raynaud's phenomenon symptoms with riociguat treatment compared with placebo. While there was no significant difference in reduction of net digital ulcer burden between riociguat and placebo, data suggest that riociguat may prevent digital ulcer recurrence in patients with early dcSSc.

Adelphi Communications Ltd, Bollington, UK provided medical writing support. Table. Change in Raynaud's attacks from baseline to Week 14 (full analysis set)

Endpoint	Riociguat			Placebo		
	Baseline, mean \pm SD (range)	Absolute change	Relative change (%) ^a	Baseline, mean \pm SD (range)	Absolute change	Relative change (%) ^a

Session Date: Monday, October 22, 2018

Session Title: Systemic Sclerosis and Related Disorders– Clinical II: Clinical Trial Results, Predictors, Design

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Cardiac involvement, due to impairment of coronary microcirculation and myocardial fibrosis, affects prognosis in individuals with SSc, and represents one of the leading causes of death in this population. There is limited data on the risk of atherosclerotic cardiovascular disease (CVD) in SSc. We aimed to compare the prevalence of traditional CVD risk factors and incidence of atherosclerotic CVD events among incident cases of SSc vs age- and sex-matched comparators.

Methods: Medical records of patients with a diagnosis or suspicion of SSc in a geographically well-defined area from Jan 1, 1980 to Dec 31, 2016 were reviewed to identify incident cases of physician diagnosed SSc. Fulfillment of the 1980 and 2013 SSc classification criteria was ascertained. A 2:1 cohort of age- and sex-matched non-SSc subjects from the same population base was randomly selected for comparison. Data on SSc characteristics, traditional CVD risk factors (i.e., smoking status, obesity, hypertension, dyslipidemia, diabetes mellitus [DM]), and CVD events (i.e., coronary artery disease [CAD], peripheral artery disease [PAD], abdominal aortic aneurysm [AAA], cerebrovascular disease [stroke/TIA], and heart failure) were collected. Cumulative incidence was adjusted for the competing risk of death.

Results: The cohort included 79 incident SSc cases and 158 non-SSc comparators (mean age of 56 ± 16 years at diagnosis/index, 90% female for both cohorts; 87% [SSc] and 93% [non-SSc] Caucasian). Mean body mass index was significantly lower in SSc (26.5 ± 5.9 kg/m²) than non-SSc (29.3 ± 8.1 kg/m²; $p=0.01$). Diabetes mellitus was also less common in SSc than non-SSc at diagnosis/index (3% vs 9%, $p=0.05$). There were no differences in smoking, hypertension or hyperlipidemia. Prior to SSc diagnosis/index, there was no difference in the prevalence of any CVD events (15 SSc vs 19 non-SSc; $p=0.17$). During the median follow up of 9.8 y (SSc) and 8.9 y (non-SSc), 19 SSc and 15 non-SSc patients developed CVD events, for a 10-year cumulative incidence of 22.4% among SSc and 10.6% among non-SSc. This corresponded to a 3 fold increased risk (hazard ratio [HR]: 3.25; 95% confidence interval [CI]: 1.64-6.46, $p=0.001$) in SSc patients vs. comparators. This increased risk was predominately due to CAD (HR: 3.20; 95% CI: 1.56-6.72, $p=0.002$), but PAD/AAA risk also approached significance (HR: 4.20; 95% CI: 0.99-17.91, $P=0.052$). There was no evidence of increased risk of cerebrovascular events (HR: 1.06; 95% CI: 0.23-4.94, $p=0.94$).

Conclusion: Patients with incident SSc have a lower BMI and prevalence of DM than non-SSc comparators. Despite having no significant difference in the prevalence of traditional CVD risk factors and CVD events at baseline, patients with SSc have a >3 fold increase of CVD events after SSc diagnosis when compared to non-SSc comparators, predominately due to CAD. This increased rate warrants a high vigilance for CAD in patients with SSc. It may potentially be related to the increased risk of endothelial dysfunction, microvascular injury and chronic inflammation characteristic of the disease, but warrants further detailed study.

Session Title: Vasculitis I: Population-Based Studies

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Takayasu's arteritis (TAK) is characterized by variable patterns of damage throughout the large arteries. This study aimed to develop and validate a novel disease classification system in TAK based on distribution of arterial lesions using data-driven methods.

Methods: Data was used from patients with TAK from four independent cohorts: one in India and three in North America (NA). All patients underwent whole-body angiography of the aorta and branch vessels, with categorization of involvement (stenosis, occlusion, or aneurysm) in 13 arterial territories. K-means cluster analysis was performed to identify subgroups of patients based on pattern of angiographic involvement. Cluster groups were identified in the Indian cohort and independently validated in the NA cohorts. Recursive partitioning was used to develop a decision tree to predict cluster assignment.

Results: 581 and 225 patients with TAK were included from the Indian and NA cohorts, respectively. Three distinct clusters were identified in the Indian cohort and validated in the NA cohorts. Patients in Cluster 1 had significantly more disease in the abdominal aorta, renal, and mesenteric arteries ($p < 0.01$). Patients in Cluster 2 had significantly more bilateral disease in the carotid and subclavian arteries ($p < 0.01$). Compared to Clusters 1 and 2, patients in Cluster 3 had asymmetric disease with fewer involved territories ($p < 0.01$). When serial angiography was available for review, only 1 of 109 patients changed cluster assignment over time. There were more patients from India in Cluster 1 (41% vs 24%; $p < 0.01$) and more patients from NA in Cluster 3 (41% vs 32%; $p = 0.03$). Recursive partitioning predicted cluster assignment in the Indian cohort with 92% accuracy and cross-predicted cluster assignment of the NA cohorts with 87% accuracy based on involvement of the abdominal aorta, carotid, subclavian, mesenteric, and renal arteries. In the Indian and the NA cohorts, patients in Clusters 1 and 2 compared to Cluster 3 were more likely to have arterial occlusions (58% vs 82% vs 37%; $p < 0.01$) and a history of tuberculosis (8% vs 10% vs 3%; $p = 0.03$). Disease onset in childhood (28% vs 16% vs 19%; $p < 0.01$) and hypertension (71% vs 42% vs 39%; $p < 0.01$) were more common in Cluster 1. Stroke (0% vs 22% vs 5%; $p = 0.03$), vision loss (0% vs 33% vs 6%; $p = 0.01$), carotidynia (3% vs 26% vs 9%; $p = 0.01$) and persistent disease activity (46% vs 59% vs 44%; $p = 0.02$) were significantly more prevalent in Cluster 2.

Conclusion: This large study in TAK identified and validated three novel subsets of patients based on patterns of arterial disease. The same subsets were seen in patients from India and NA; however, prevalence of patients within each subset differed by country. Angiographic-based disease classification may help identify causal disease factors and enable stratified clinical decision making in this complex, clinically heterogeneous disease.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Vasculitis I: Population-Based Studies

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Takayasu arteritis (TAK) typically affects young women under 40 years old, whereas patients with onset age over 40 years are occasionally observed. It still remains unclear whether the treatment outcomes in patients with elderly onset TAK are different from those in patients with young onset TAK. The aim of this study is to compare clinical features of TAK in patients under 40 years old (yoTAK) with those over 40 years old (eoTAK).

Methods: From a retrospective, multi-center, nationwide registry of TAK and giant cell arteritis (GCA), we enrolled 130 newly diagnosed TAK patients who were treated with glucocorticoids (GCs) between 2007 and 2014. Diagnosis of TAK was made according to the criteria for TAK established by the Ministry of Health, Labour and Welfare for intractable disease in Japan. Overall, 75 of the 130 patients (58%) satisfied the ACR classification criteria for TAK; 54 of 83 (65%) patients with yoTAK (26±7 y.o.) and 21 of 47 (45%) patients with eoTAK (59±12 y.o.). None except one patient in eoTAK met the ACR classification criteria for GCA. The primary outcomes were achievement of remission (disappearance of clinical symptoms with normal C-reactive protein) and relapse-free survival rate.

Results: Among the complication of TAK, hypertension, diabetes mellitus and dyslipidemia were more frequent in eoTAK than yoTAK. No significant differences were observed in chief clinical symptoms (high fever, systemic symptoms, large-vessel lesion, cranial lesion, musculoskeletal disorders, ulcerative colitis) at onset. One-fourth of yoTAK complicated aortic regurgitation, compared with 44% in eoTAK ($p=0.0543$). Regarding laboratory data, no significant differences were observed between yoTAK and eoTAK except anemia. Serum C-reactive protein concentration in eoTAK tended to be higher than that in yoTAK (yoTAK; 5.1 ± 4.6 mg/dL eoTAK; 7.0 ± 6.7 mg/dL, $p=0.0674$) but was not statistically significant. HLA-B*52 did not differ between yoTAK (66%) and eoTAK (65%). Remission was achieved 95.2% in yoTAK and 89.4% in eoTAK throughout observational period of two years. The cumulative rate of remission of the yoTAK was significantly higher than that of eoTAK (log-rank test, $p=0.0444$). The relapse-free survival rate was 50.0% in yoTAK and 41.0% in eoTAK ($P=0.4657$). The cumulative rate of relapse was not significantly different between yoTAK and eoTAK (log-rank test, $p=0.2351$). One patient with yoTAK and two patients with eoTAK deceased; no significant difference were found in the cumulative rate of survival between yoTAK and eoTAK.

Conclusion: Clinical features such as symptoms, complications and HLA-B*52 positivity were similar between yoTAK and eoTAK, in Japan. Although both yoTAK and eoTAK achieved remission within 2 years without any significant differences, cumulative rate of remission was poorer in eoTAK.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Vasculitis I: Population-Based Studies

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Previous studies have implicated infections as a risk factor for giant cell arteritis (GCA). The purpose of this study was to investigate the association between occurrence of infections and the development of GCA.

Methods: Patients diagnosed with biopsy-proven giant GCA between 2000 and 2016 were identified through the database of the Department of Pathology in Skane, the southernmost region in Sweden. For each GCA case, 10 controls were randomly selected from the background population matched for age, sex, and area of residence. The index date for the controls was the same as the diagnosis date of their respective cases. We identified all infection events diagnosed before the date of GCA diagnosis (and before index date for controls) between 1998 and 2016, using the Skane Healthcare Register based on International Classification of Diseases -10th version (ICD-10) codes. First, we calculated the odds ratio (OR) of being exposed to an infection in GCA cases vs controls. Second, we evaluated the type of infection closest to the biopsy-proven GCA diagnosis (or index date). Conditional logistic regression models were used to calculate OR and 95% confidence intervals (CI).

Results: 1005 patients with biopsy-proven GCA (714 women, 71%) and 10 050 controls were included in this study. In total, 476 unique infection diagnoses were assigned for GCA cases prior to the biopsy-proven diagnosis as compared to 3722 unique infections for controls. Infections were more common among patients going to develop GCA vs. controls (47% vs. 37%) yielding the OR of 1.76 (95% CI 1.51–2.05). The median time from the latest diagnosed infection to GCA diagnosis was 0.9 years (interquartile range (IQR) 0.1 - 3.5), whereas the corresponding median time for the controls was 2.2 years (IQR 0.8-4.7). Acute upper respiratory tract infections, pneumonia, influenza and non-specific bacterial infections, but not skin or gastrointestinal infections, were associated with increased probability for later biopsy-proven GCA (Figure 1).

Conclusion: Infections, especially upper respiratory tracts infections, pneumonias and influenza were associated with later development of biopsy-proven GCA. Our findings corroborate previous reports of an association between GCA and infectious pathogens of the respiratory tract. The observed associations with unspecified infections may partly reflect diagnostic uncertainty in the early phase of GCA.

Figure 1. Odds ratios for developing GCA associated with prior exposure to infection

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Vasculitis I: Population-Based Studies

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Polyarteritis nodosa (PAN) is a rare subgroup of the primary systemic vasculitides. Furthermore, various subgroups of PAN have been described, such as hepatitis B virus (HBV)-related, cutaneous PAN and monogenic forms. There is a paucity of information on the current phenotypes, ethnic and geographic differences of PAN. This worldwide global study group collated the demographic, clinical features and outcomes of PAN cohorts from the United Kingdom (UK), Slovenia, Japan and Turkey (TR).

Methods: A retrospective survey of databases from five vasculitis centres between 1990-2016 for PAN patients fulfilling the EMEA Vasculitis Classification algorithm. Patients with typical angiographic and/or histopathologic findings consistent with PAN were included. We evaluated baseline characteristics, including demographics, organ involvement, treatment, activity and damage indices [BVAS, Five Factor Score (FFS), Disease Extent Index (DEI), Vasculitis Damage Index (VDI)] patient survival and time to relapse.

Table) Comparison of clinical characteristics and outcomes of patients with only-cutaneous and systemic PAN

	Total (n=150)	Only-cutaneous PAN (n:36)	Systemic PAN (n:114)	p
Age at onset, years	37 (23-57)	21 (24-55)	36 (25-50)	0.723
Paediatric onset, %	23.4	19.4	13.7	0.603
Any monogenic relationship, %	12.8	2.9	15.7	0.043
Sex, male, %	39.3	41.6	39.1	0.613
Time to diagnosis, months	33 (9-251)	6 (1.3-112)	34 (7-51)	0.049
Any constitutional symptoms, %	76.8	58	85.3	<0.001
• Fever	• 57.1	• 36.3	• 64.0	0.003
• Fatigue	• 60.1	• 36.3	• 77.6	<0.001
• Weight loss	• 46.7	• 21.2	• 54.9	0.002
Any cutaneous manifestations, %	76.3	100	67.2	<0.001
Follow-up, months	60 (20-109)	60 (23-100)	58 (19-131)	0.511
Response to treatment, %				0.231
• Complete	67.5	68.7	61.7	
• Partial	30.1	14.3	29.8	
• No response	6.3	0	8.5	
Any relapse, %	44.3	58.0	42.6	0.48
Time to relapse, months	12 (10-19.25)	16.5 (10.8-30.9)	12 (8.5-18)	0.119
Death, %	14.8	0	16.8	0.886

Results: 150 (M/F: 89/61) patients (UK: 47, TR: 67, Slovenia:14, Japan: 22) were included in the study. Median age at disease onset was 37.0 (IQR 25.0-57.0) years. Four were HBV-related, 23.4% had paediatric onset. Sixteen of TR patients had a monogenic form of disease (FMF association in nine, deficiency of adenosine deaminase 2, DADA2, in seven). Female predominance was found in cutaneous PAN (Table, p=0.013). No difference was found in the phenotype between paediatric and adult onset patients except for frequency of cutaneous lesions (100% vs. 63.8%, p=0.001, respectively). Neurologic, renal and abdominal involvements were seen 42%, 49.3%, and 41.4% of patients, respectively. 55% of patients had radiologic, 70.3% had biopsy-proven PAN. Distribution of patients according to FFS score 0, 1 and 2 was; 52.4%, 31.3% and 16.3%, respectively. Mean BVAS score was 13.9 (8.2), VDI 1.1 (1.4) and DEI was 5.26 (2.8). Biologic agents have been used in 32 (21.3%) of them. During median 60 (20-109) months follow-up, nearly half of the patients relapsed around a year. Twenty-one patients died (nine of them during 5-year follow-up, six deaths were related to PAN). BVAS score was significantly higher in deceased group (24.5 (7.7) vs. 11.9 (7.9), p=0.003). FFS was significantly related to mortality (Figure, p<0.001).

Conclusion: This global study showed an extremely rare presentation of HBV-related PAN and a female predominance in cutaneous PAN in contrast to systemic PAN. FFS and BVAS scores are useful indices for morbidity and mortality in PAN. Biologic agents were required in 20% of patients.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Vasculitis I: Population-Based Studies

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Data regarding long term outcome of patients with thromboangiitis obliterans (TAO) are lacking and most series come from India and Japan. We assess long-term outcome and prognostic factors in a large cohort of TAO.

Methods: Retrospective multicenter study of characteristics and outcomes of 224 TAO patients fulfilling Papa's and/or 5 Shinoya's criteria were analyzed. Factors associated with vascular events and amputations were identified.

Results: The median age at diagnosis was 38.5 [32-46] years, 51 (23.8 %) patients were female and 81.7% were Caucasians. After a mean follow up of 5.7 years, vascular events were observed in 58.9%, amputations in 21.4% and death in 1.4%. The 5-, 10- and 15-year vascular event free survival and amputation free survival were 41% and 85%, 23% and 74% and 19% and 66%, respectively. Ethnic group (non-Caucasian) (HR 2.35 [1.30-4.27] p=0.005) and limb infection at diagnosis (3.29 [1.02-10.6] p=0.045) were independent factors of vascular events. Factor associated with amputation was limb infection (HR=12.1[3.5-42.1], p<0.001). Patient who stopped their tobacco consumption had lower risk of amputation (p=0.001) than those who continued.

Conclusion: This nationwide study shows that 34% of TAO patients will experience an amputation within 15 years from diagnosis. We identified specific characteristics that identified those at highest risk for subsequent vascular complications and amputations.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Vasculitis I: Population-Based Studies

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: IgG4-related disease (IgG4-RD) is a multi-organ condition of uncertain etiology characterized by substantial morbidity if not diagnosed and treated promptly. Identifying IgG4-RD subgroups based on the distribution of organ involvement may facilitate diagnosis, illuminate our understanding of the pathogenesis, and guide management. We sought to identify phenotypic clusters of IgG4-RD using an unbiased method.

Methods: Our study patients consisted of 493 IgG4-RD cases diagnosed by 76 IgG4-RD specialists from North America, South America, Europe, and Asia. For each case, investigators reported age at disease onset and diagnosis, race/ethnicity, organ involvement, and lab results. We performed latent class analysis to identify subgroups with distinct patterns of organ involvement. Cases were assigned to the cluster in which they had the highest probability of membership. We used logistic regression adjusted for baseline covariates and probability of an individual's cluster membership to estimate the odds ratio (95% CI) comparing the distribution of covariates between clusters, using one cluster as the reference group. To validate our results, we repeated the analysis in a separate cohort.

Results: Of the 493 IgG4-RD cases, the mean age was 59.5 (\pm 14.0) years and 65% were male. Of the cases, 40% were Caucasian, 45% were Asian, and 12% were Hispanic. We identified four clusters (Table 1). Cluster 1 ("Pancreato-Hepatobiliary") included 31% of patients. Cluster 2 ("Retroperitoneum/Aorta") included 24% of patients. Cluster 3 ("Head/Neck") included 24% of patients. Cluster 4 ("Mikulicz/Systemic") included 22% of patients. Compared to the "Head/Neck" cluster (Table 2), individuals in other clusters were significantly more likely to be older (OR Range 1.17-1.28) and male (OR Range 9.21-11.93). Individuals in other clusters were significantly much less likely to be Asian (OR Range 0.14-0.16) compared to the "Head/Neck" cluster. The "Mikulicz/Systemic" cluster included patients who tended to have quite elevated serum IgG4 levels compared to the "Head/Neck Cluster" [OR 1.12 (1.02-1.22)]. We replicated our results in the second cohort.

Conclusion: Using an unbiased method, we identified four phenotypic clusters of IgG4-RD patients. Besides differences in organ involvement, clusters were distinguished by age at diagnosis as well as race/ethnicity, gender distribution, and serum IgG4 concentrations. These clusters may identify patients with IgG4-RD resulting from different risk factors or exposures and those likely to respond differently to treatment.

Table 1. Clusters of IgG4-RD Using the 2018 Classification Criteria Validation Cohort (N=478)

*	Pancreato-Hepato-Biliary	Retroperitoneum and Aorta	Head and Neck	Mikulicz with Systemic Disease
Proportion of Cohort (%)	30.8%	23.7 %	23.9%	21.6%
Average Probability of Cluster Membership (Mean \pm SD)**	92.9% (\pm 11.5%)	91.6% (\pm 13.6%)	89.8% (\pm 14.1%)	90.2% (\pm 15.0%)
Input Variables / Proportion of Organ Involvement in Each Cluster†				
Pancreas	87.0%	12.3%	14.5%	46.2%
Liver	12.9%	0.9%	1.6%	5.0%
Biliary	54.5%	0.1%	0.1%	26.9%
Orbital	0.01%	3.3%	22.1%	0.02%
Extra-Ocular Muscle	0.01%	1.0%	13.1%	3.8%
Sinusitis	2.5%	0.2%	16.9%	16.3%
Parotid	1.9%	0.9%	21.6%	48.9%
Submandibular	15.3%	5.2%	50.4%	77.3%

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Health Services Research – ACR/ARHP I: Focus on Big Data

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Biologic DMARDs and tofacitinib account for a large proportion of drug spending in the U.S. Although TNFi drugs have dominated sales, use of other novel agents in RA is increasing. Given the lack of comparative effectiveness studies, understanding patterns around the prescription of second-line drugs is warranted. We used data from the RISE registry to perform cross-sectional analysis of prevalent prescriptions for biologics and tofacitinib among U.S. rheumatologists.

Methods: RISE is a national, EHR-enabled registry that passively collects data on all patients seen by participating practices, thus reducing the selection bias present in single-insurer claims databases. As of June 2017, RISE held validated data from 663 providers in 110 practices, representing an estimated 19% of the U.S. clinical rheumatology workforce. We identified patients with ≥ 2 codes for RA ≥ 30 days apart between July 2016 and June 2017. We tallied the proportion of patients prescribed a TNFi, abatacept, rituximab, tocilizumab, or tofacitinib at least once during this period, overall, by region, and by practice. In this cross-sectional analysis of prevalent prescriptions, each patient was included only once; i.e., patients with >1 of these drugs were assigned to the first drug prescribed during the study period. To reduce variability in practice-level estimates, practices with < 30 RA patients (23 of the 110 practices) were excluded.

Figure. Proportion of RA patients prescribed biologics or tofacitinib, aggregated by practice, for practices with at least 30 patients with RA, between July 2016 and June 2017.

Table. Proportion of RA patients in the RISE registry who were prescribed biologics or tofacitinib, by geographic region, between July 2016 and June 2017.

	Total patients with RA (N)	TNFi (%)	Abatacept (%)	Rituximab (%)	Tocilizumab (%)	Tofacitinib (%)
Geographic Region						
New England (CT, ME, MA, NH, RI, VT)	1,170	28%	5%	3%	1%	3%
Mid Atlantic (DE, NJ, NY, PA)	6,675	19%	3%	1%	3%	4%
East North Central (IL, IN, MI, OH, WI)	11,945	27%	4%	1%	2%	3%
West North Central (IA, KS, MN, MO, NE, ND, SD)	10,656	25%	4%	1%	2%	3%
South Atlantic (FL, GA, MD, NC, SC, VA, DC, WV)	27,061	27%	5%	2%	3%	4%
East South Central (AL, KY, MS, TN)	9,637	27%	4%	2%	2%	6%
West South Central (AR, LA, OK, TX)	8,696	34%	6%	3%	3%	6%
Mountain (AZ, CO, ID, MT, NV, NM, UT, WY)	638	33%	3%	3%	4%	5%
Pacific (AK, CA, HI, OR, WA)	2,540	27%	5%	2%	4%	4%
Total	79,027	27%	5%	2%	3%	4%

Results: We included 79,027 patients from 87 practices. Overall, 40% of patients were prescribed any biologic or tofacitinib during the study period. Besides TNFi, abatacept was most commonly prescribed (4.7% of patients), followed by tofacitinib (4.2%), tocilizumab (2.7%), and rituximab (1.9%). Patterns were similar across regions (Table), but there was wide practice-level variation (Figure): For example, among practices that prescribed any abatacept (N=85), abatacept represented 2-36% of all biologics prescribed for RA within that practice. Similar patterns were seen for tocilizumab (N=83, range 1-38%), and tofacitinib (N=82, range 2-35%).

Conclusion: We found significant practice-level variation in prescriptions for newer DMARDs for RA, especially for non-TNFi biologics and tofacitinib. Future studies should assess differences in outcomes and the role of payers among populations receiving different treatments.

Abstract Number: 1888

SLE Among the Leading Causes of Years of Potential Life Lost in Young Women: Population-Based Study, 2000-2015

Eric Yen and **Ram R. Singh**, UCLA, Los Angeles, CA

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Health Services Research – ACR/ARHP I: Focus on Big Data

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Ten-year survival of SLE has improved from <50% in the 1950s to ~95% in the 2000s. However, the relative and true disease burden for SLE is not understood. Disease burden can be measured using a variety of indicators such as mortality, morbidity or financial cost. A recent analysis of 62,843 SLE deaths from the Centers for Disease Control (CDC)'s mortality database showed that the age-standardized mortality rate for SLE remains high relative to general population mortality rate. However, mortality rates may not adequately measure SLE burden, because among those who died, a fifth of SLE patients died before reaching 40 years of age. Premature mortality is an important way to quantify disease burden. In constructing a measure of premature death, an arbitrary limit to life is chosen, and the calculation of the difference between an age at death and this arbitrary limit is defined as the life lost as a result of that death. Here, we measured the years of potential life lost (YPLL) for SLE relative to CDC's top 15 leading causes of death and to 12 other autoimmune diseases.

Methods: This is a population-based study. Death counts were obtained from the CDC-WONDER database. Number of deaths between January 1, 2000 and December 31, 2015 were tabulated for 28 diseases, including SLE, top 15 CDC's leading causes-of-death, and 12 other autoimmune diseases. To calculate YPLL, each decedent's age at death from a specific disease was subtracted from a predetermined age of 75 years. The years of potential life lost were then added together to yield the total YPLL.

Results: SLE was recorded as the underlying or a contributing cause of death in 28,411 women from 2000 to 2015. The ranking of SLE deaths relative to the CDC's official leading-causes-of-death list in females showed that SLE is within the top 15 leading causes-of-death in reproductive age women (15-44 years) and tenth among women ages 15-24 years. Hence, we calculated YPLL for SLE relative to the top 15 leading causes-of-death in women ages 15-44 and 15-24 years. YPLL for SLE was 304.2 thousand years in women ages 15-44 and 66.2 thousand years in women ages 15-24. SLE-YPLL ranked 14th in women ages 15-44 and 8th in women ages 15-24 above diabetes mellitus, HIV disease, septicemia, chronic lower respiratory disease, anemias, nephritis, and cerebrovascular disease. Among autoimmune diseases, SLE ranked #2 above insulin-dependent diabetes mellitus, myocarditis, multiple sclerosis, systemic sclerosis, rheumatoid arthritis, Addison's disease, dermatomyositis, chronic active hepatitis, myasthenia gravis, primary biliary cirrhosis, and autoimmune hemolytic anemia in women ages 15-44 years. SLE ranked #1 autoimmune disease cause of YPLL in women ages 15-24 years.

Conclusion: SLE is among the leading causes of YPLL in young women, underscoring SLE as an important public health issue. SLE ranked #1 leading autoimmune disease cause of YPLL in women ages 15-24. These data warrant further studies on SLE disease burden, which can be used to develop and prioritize public health programs, assess performance of changes in SLE management, identify high-risk populations, and set research priorities and funding, which may eventually reduce SLE burden.

Abstract Number: 1889

Patterns of Glucocorticoid Use and Provider-Level Variation in a Commercially Insured Incident Rheumatoid Arthritis Population

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Health Services Research – ACR/ARHP I: Focus on Big Data

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Glucocorticoids (GC) reduce RA-related disability and joint damage; RA guidelines endorse short term use during DMARD initiation and flares. Long-term high-dose GC exposure (>3months, ≥ 10 mg/day prednisone equivalent) can be toxic, but risk/benefit balance varies across patients. GC exposure patterns and user characteristics have not been described in a national commercially insured cohort. Provider-level factors may affect patterns of GC use in RA, and may interact with patient factors to alter risk/benefit balance. We hypothesize that GC are commonly used for incident RA and are continued inappropriately once DMARD treatment is established, and that wide provider-level variation in GC use exists.

Methods: Using OptumInsightTM commercial claims data, we identified 9,221 adults with incident RA diagnosed 2010-2014 and ≥ 12 months of preceding medical and pharmacy benefits. We assessed GC exposure for 3 months before and 12 months following diagnosis (“study period”), cumulatively and stratified by 3 month quarter and GC prescriber specialty (rheumatologist, primary care provider, other). We examined variation among 117 rheumatologists by dividing per-patient distribution of GC dose and duration for each quarter into quartiles.

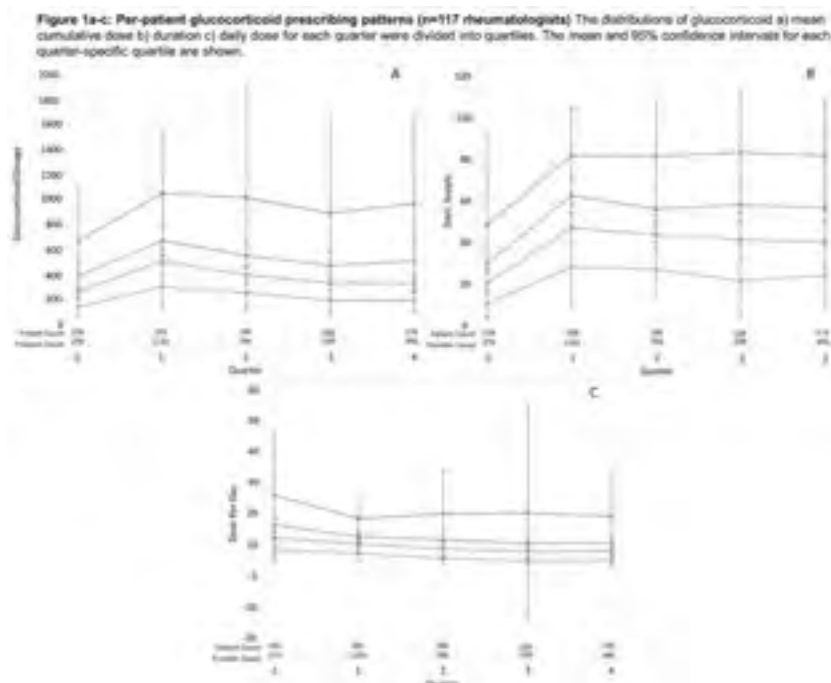

Table 1: Per-patient glucocorticoid prescribing patterns over the study period, stratified by quarter and prescriber specialty

	Quarter -1 (Days -91 to -1)	Quarter 1 (Days 0-81)	Quarter 2 (Days 92-182)	Quarter 3 (Days 183-273)	Quarter 4 (Days 274-365)
Number Enrolled	9221	9221	9108	8666	8191
Number Using GC	2866	4869	3253	2692	2394

PCP	24.3 (15.4) ^{***}	21.5 (17.2)	21.6 (26.5)	19.1 (13.7)	20.4 (14.8)
Other	24.7 (16.6) ^{***}	16.2 (15.1)	17.9 (16.3)	16.5 (19.5)	17.8 (16.2)

GC = glucocorticoid; PCP = primary care provider

¹Dose in prednisone equivalents²Duration in days, with maximum 90 days per quarter

*** p < 0.001, using quarter 1 value as reference

** p < 0.01, using quarter 1 value as reference

* p < 0.05, using quarter 1 value as reference

Results: 6,717 RA patients (73%) received GC during the study period. There were no clinically important differences in demographics or baseline health status between GC users and non-users, or by cumulative GC exposure level. GC use rose with frequency of rheumatologist visits and number of DMARD prescriptions. 76% of patients filled a DMARD prescription in quarter 1, and 17% received a biologic DMARD by quarter 4 (Table 1).

During quarter 1, 53% of patients received GC with per-patient mean daily dose 15mg prednisone equivalent/day and duration 57 days. During quarter 4, 29% of patients received GC with per-patient mean daily dose 14mg/day and duration 48 days. Rheumatologists prescribed >60% of all dispensed GC, with mean daily dose 11-18mg and duration 30-60 days per quarter (Table 1). Per-patient dose and duration of GC prescribed vary widely at the provider level over the study period (Fig. 1).

Conclusion: In this commercially insured incident RA cohort, rheumatologists commonly prescribe long term high dose GC up to 1 year after RA diagnosis, despite appropriate DMARD and biologic use. Rheumatologist practices regarding GC use for RA vary widely. Further work is needed to evaluate the relationship between 1) specific patient and provider-level factors and GC exposure, and 2) GC exposure and DMARD initiation and persistence in this population.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Health Services Research – ACR/ARHP I: Focus on Big Data

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Rheumatoid Arthritis (RA) is a complex systemic inflammatory disease with variable course that is difficult to precisely predict. Deep Learning (DL), a branch of artificial intelligence, has become state of the art in longitudinal predictions. It is unknown whether DL can be used to prognosticate RA outcomes. We aimed to use structured data from electronic health records (EHR) to build a deep learning model that would predict future RA disease activity.

Methods: Data were derived from rheumatology clinics at two distinct health systems (an university health center and public safety net hospital) with different EHR platforms. We extracted structured data including demographics, diagnoses, medications, and prior disease activity measured by the Clinical Disease Activity Index (CDAI). We developed a multivariate longitudinal DL method to predict disease activity, grouped as controlled disease activity (low or remission) vs. uncontrolled (moderate or high), for RA patients at their next rheumatology clinic visit. We compared the predicted disease activity from our model to actual CDAI scores and calculated Area Under the Receiver Operating Characteristic curve (AUROC). Performance was compared to predictions based on the population-level likelihood of each outcome

Figure 1 : Performance of Deep Learning Models in Predicting Rheumatoid Arthritis Disease Activity at the Next Visit

Table: Characteristics of Individuals with Rheumatoid Arthritis in the Two Health Systems Studied

	University Clinic N = 578	Safety Net Clinic N = 242
Age in years, Mean \pm SD	57 (15)	60 (15)
Female, n (%)	477 (83)	195 (81)
Race/Ethnicity, n (%)		
White	296 (51)	30 (12)
African American	33 (6)	19 (8)
Hispanic	97 (17)	89 (37)
Asian	101 (17)	70 (30)
Other	51 (9)	34 (13)
EHR System	Epic	eClinicalWorks
Average Number CDAI/person	6.9	4.3
Median Time Between CDAI	100 days	180 days
Medication, n (%)		
Conventional Synthetic	534 (94)	191 (79)
Biologic	364 (63)	70 (29)
JAK Inhibitor	29 (5)	0 (0)

N: Number; SD: Standard deviation; EHR: Electronic Health Record; DMARD: disease modifying antirheumatic drug; CDAI: clinical disease activity index

category (Baseline 1) as well as the probability of switching outcome from the prior visit (Baseline2). We evaluated whether the model developed in one health system was generalizable to a second and assessed model interoperability strategies.

Results: The university and safety net clinics were substantially different (Table). At the university hospital, the model was trained on a subset of patients (U1, n=462) and then tested on a separate group (U2, n=116) and reached an AUC of 0.91 (Figure). When trained on all patients at the university, the model generalized well (AUC 0.74) to a cohort of patients from the safety net hospital (SN2, n=117) and outperformed a model trained on a separate cohort of patients (SN1, n=125) from the safety net (AUC=0.63). In both settings the deep learning models outperformed baselines.

Conclusion: We built accurate, generalizable longitudinal DL models to forecast patient outcomes on populations that only number in the hundreds. Our findings suggest that the RA model can be shared across hospitals with different EHR systems and diverse patient populations. Testing of artificial intelligence models in clinical practice is warranted to evaluate their usefulness in helping clinicians and patients prognosticate RA outcomes or simulate outcome trajectories under different treatment scenarios.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

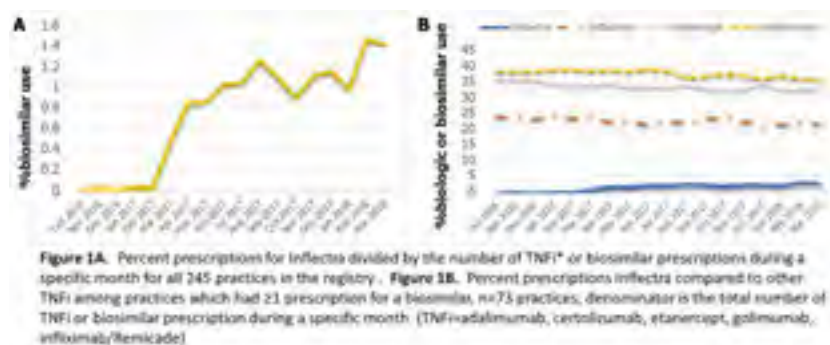

Session Title: Health Services Research – ACR/ARHP I: Focus On Big Data

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: In the U.S., the first biosimilar tumor necrosis inhibitor (TNFi) was approved in 2016. To date, only biosimilars for infliximab are available in the U.S., with limited data on biosimilar utilization. The objective of this study was to examine the early experience in prescribing patterns of biosimilar use in a U.S. based rheumatology registry.

Methods: This study was performed using the ACR's RISE Registry consisting of electronic medical record (EMR) data from 245 rheumatologist practices across the U.S. We studied data from September 9/1/2016, one month prior to the first biosimilar prescription through 3/31/18. In this time period, we studied all subjects with at least one encounter ≥ 6 months to the first biosimilar or TNFi prescription. Biosimilar data were identified through a combination of billing for procedures ('J codes') and text string searches for the two available biosimilars: infliximab-dyyb (Inflectra), infliximab-abda (Renflexis). For clarity, we refer to the trade names. Data were extracted on demographics, diagnosis codes, location of practice, and insurance. We used descriptive statistics to compare characteristics of patients who were ever treated with a biosimilar compared to Remicade.

Results: At baseline, 857 patients received a biosimilar at 73 rheumatology practices (30% of all practices in RISE), all for Inflectra. Mean age of patients receiving Inflectra was 57.5 years, 70% female; characteristics were similar to those receiving Remicade (Table). A higher %of patients prescribed Inflectra had a diagnosis code for RA compared to Remicade. In absolute numbers, the highest numbers of prescriptions for Inflectra were from California (n=137), West Virginia (n=101), and Texas (n=96). Among patients who received Inflectra, 63.4% were previously on Remicade and the rest were naïve to Remicade. Over 15 months of follow-up, there were no significant differences in the types of biologics prescribed after Inflectra vs Remicade. Inflectra use increased modestly (Figure 1A), without significant change in overall TNFi usage for patients at practices who treated ≥ 1 patient with biosimilar-infliximab(Figure 1B).

Conclusion: This preliminary study examining the first 1.5 years after biosimilar approval in the U.S., observed a modest uptake in biosimilar usage, all for Inflectra. Nationwide rheumatology registries can provide important aggregate data on early biosimilar utilization using realworld data.

Disclaimer: This data was supported by the ACR's RISERegistry, however the views expressed represent those of the authors, not necessarily those of the ACR.

Table 1 Comparison of subjects initiating biosimilar-infliximab compared to infliximab October 2016 to March 2018.

	Inflectra	Remicade
Clinical characteristics	n=857	n=4863
Age, mean years	57.5	57.5
Female (%)	70.3	72.7
Race (%)*	N=781	N=3635
White (w)	86.3	75.1
Black (b)	4.0	8.8
Other (o)	9.7	16.1
Diagnoses codes (%)		
RA	68.5	48.1

Session Date: Monday, October 22, 2018

Session Title: Health Services Research – ACR/ARHP I: Focus on Big Data

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: The Department of Veterans Affairs (VA) operates the largest integrated health care system in the U.S. The proportion of Veterans with RA who receive high quality care within VA is unknown. Our objective was to quantify the proportions of Veterans with RA nation wide who were prescribed a DMARD in 2016, and identify Veteran- and system-level correlates of DMARD receipt.

Methods: Cross-sectional study of national VA data examining DMARD receipt in 2016 among Veterans with RA who received care within VA. RA and DMARD use were identified using HEDIS technical specifications (including ICD-9 and ICD-10 diagnosis codes) for 2016. Veteran-level (age, gender, race, poverty level, comorbidity score, substance use disorder, post-traumatic stress disorder (PTSD)) and system-level (healthcare region, facility complexity, rheumatologist shortage area) correlates were examined using bivariate and multivariate logistic regression.

	Adjusted* Proportions for DMARD Receipt	Difference, Percentage Points (95% CI)	
Overall DMARD Use	80.5		
Gender			
Female	82.1	1.6	(1.5, 2.0)

Receive Care within a Rheumatology Shortage Area[§]			
Yes	72.0	-9.9	(-10.2, -9.7)
No	81.9	reference	

*Adjusted for all variables listed in table

^aPTSD = Post traumatic stress disorder - Has been associated with increased risk of RA and poorer outcomes

[‡]Facility complexity model classifies VA facilities at levels 1a, 1b, 1c, 2, or 3 with level 1a being most complex (high volume, high risk patients; large research and teaching programs) and level 3 least complex (low volume, low risk patients; small or no research and teaching programs)

[§]Rheumatology Shortage Area defined as >2,000 patients per rheumatologist

Results: 28,443 unique Veterans with RA were identified in the VA health care system: 13% were female, 77% white, and 55% age 65-80. Nearly half had a Charlson comorbidity ≥ 3 , 12% had PTSD and 6% substance use disorder. Overall, 80.5% received a DMARD in 2016. DMARD receipt was similar by race and sex, but we found significant variation based on older age, presence of substance use disorder, and higher Charlson comorbidity score (see Table). We also found significant geographic and system-level effects, including lower DMARD use in less complex facilities and those in rheumatology shortage areas (Table).

Conclusion: In 2016, quality of care among Veterans with RA (as measured by the proportion receiving a DMARD) who receive care within VA was equal to or higher than rates for those receiving care in Medicare health maintenance (HMO) or preferred-provider organization (PPO) settings (76.8% and 77.8%, respectively). It far exceeded rates reported among

Medicare beneficiaries a decade ago. However, Veterans with multimorbidity and older age were less likely to receive a DMARD as were those living in the North Atlantic and Southeast. Specialty rheumatology care plays a vital role in quality of care. Future work should examine approaches to increase the reach of this specialty care to all VA patients and aim to reduce Veteran and system level variation.

Indoleamine-2,3-Dioxygenase in Murine and Human Systemic Lupus Erythematosus

Zev Sthoeger^{1,2}, Amir Sharabi³, Heidy zinger¹, ilan asher⁴ and edna mozes¹, ¹Department of Immunology, The Weizmann institute of Science, Rehovot, Israel, ²Department of Allergy and Clinical Immunology, Kaplan Medical Center,, Rehovot, Israel, ³Department of Rheumatology, Beth Israel Deaconess Medical Center, Boston, MA, ⁴Department of Allergy and Clinical Immunology, Kaplan Medical Center, Rehovot, Israel

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Lupus Erythematosus – Etiology and Pathogenesis I

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Indoleamine-2,3-dioxygenase (IDO) is a tryptophan catabolizing enzyme which plays a role in immune regulation and in the pathogenesis of autoimmune disorders. Increased IDO activity was reported in systemic lupus erythematosus (SLE). The tolerogenic peptide, hCDR1, ameliorates lupus manifestations via the immunomodulation of cytokines and the induction of FOXP3 expressing regulatory T cells [1]. The aim of this study has been to determine the effect of hCDR1 on IDO gene expression in SLE.

Methods: (NZBxNZW)F1 female mice with established SLE manifestations were treated (10 weekly subcutaneously injections) with hCDR1, control peptide or vehicle alone. The effects on anti-dsDNA antibody titers, proteinuria levels and kidney immunohistology were assessed. Splenocytes were obtained for gene expression studies. Nine Lupus patients were treated for 26 weeks with hCDR1 (5) or vehicle (4) in a Phase II clinical trial by weekly subcutaneous injections [1]. Blood samples were collected, before and after treatment, in PAXgene tubes and frozen until mRNA isolation. Peripheral blood lymphocytes (PBL) of 16 lupus patients and 6 healthy controls were incubated for 48 hours with hCDR1, control peptide or medium alone prior to gene expression assays. Gene expression of IDO and FOXP3 was determined by real-time RT-PCR.

Results: Treatment of (NZBxNZW)F1 SLE afflicted mice with hCDR1 down-regulated significantly IDO gene expression (72.4% and 71% inhibition compared to vehicle, $p=0.0001$ and to control peptide $p=0.05$, respectively). This was associated with a significant reduction of anti-dsDNA antibody titers, proteinuria levels and glomerular immune complex deposits. Similarly, a significant reduction in IDO gene expression was determined in samples of hCDR1 treated lupus patients (57.4% inhibition compared to pretreatment levels, $p=0.0046$). No inhibition of IDO expression was observed in the vehicle treated patients. In agreement, as previously reported, treatment with hCDR1, but not with the vehicle, resulted in a significant decrease of disease activity [1]. Further, hCDR1 significantly reduced, in vitro, IDO gene expression in PBL of lupus patients ($p=0.00017$ and $p=0.021$ compared to medium and to control peptide, respectively). In contrast, hCDR1 up-regulated by more than two folds the expression of FOXP3 gene in PBL of the same lupus patients. hCDR1 did not affect the expression of the latter genes in PBL of healthy controls.

Conclusion: hCDR1 significantly down-regulated IDO gene expression in SLE affected mice and in lupus patients (treated in vivo as well as in vitro). This effect is specific because it was not observed in healthy donors or following treatment with the control peptide. The reduction of IDO gene expression was associated with the beneficial effects of hCDR1. We reported previously that hCDR1 affects various immune pathways and cell types, most importantly, FOXP3 expressing functional T regulatory cells [1]. Our results suggest that the up-regulation of FOXP3 in lupus is not driven by IDO but it is rather controlled by other pathways and cytokines (e.g. TGF- β) that were shown to be induced by hCDR1.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Lupus Erythematosus – Etiology and Pathogenesis I

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: In the phase 2 study JAHH (NCT02708095), treatment with baricitinib (bari), an oral selective Janus kinase 1/2 inhibitor approved for the treatment of RA, resulted in significant improvements in patients with active SLE receiving standard background therapy compared with placebo (PBO).¹ Expression of type I-associated IFN responsive genes (IRGs) is elevated in patients (pts) with SLE.² We developed a robust quantitative assay to measure changes in the IFN signature. We then examined the relationship between the IFN signature and measures of clinical outcome.

Methods: A total of 314 pts were randomized in a 1:1:1 ratio to receive PBO, bari 2- or 4-mg once daily for 24 weeks (Wks) in study JAHH. Total RNA isolated from whole blood collected in PAX gene tubes was analyzed using a multiplex quantitative (qPCR) assay panel of 6 IRGs on the Modaplex at baseline (BL), and Wks 2, 12, and 24. The assay was developed and optimized using RNA samples from 1760 patients with SLE enrolled in phase 3 trials of tabalumab (an anti-B cell activating factor monoclonal antibody),² along with controls from healthy blood donors. The IFN signature assay produced a bimodal distribution.

Results: 70% of pts had an elevated IFN signature at BL. Bari significantly reduced the IFN signature by Wk 24 compared with PBO (2-mg: -20%, 4-mg: -24%, $p \leq 0.05$), with decreases observed as early as Wk 2. In the pts who had a high IFN signature at BL, bari 4-mg significantly reduced the IFN signature at Wk 12 (-24%) and Wk 24 (-23%) compared with PBO ($p \leq 0.01$); decreases were also observed at Wks 12 and 24 with the 2-mg dose, but the difference from PBO was not statistically significant, consistent with a dose-response effect. Bari 4-mg treatment resulted in significant clinical improvement in the resolution of arthritis or rash determined by the SLEDAI-2K.¹ However, the effect of bari on IFN signature reduction (change from BL as well as absolute BL value) did not correlate with SLEDAI-2K-defined clinical improvement at Wk 12 or 24.

Conclusion: A dose-dependent decrease in the IFN signature was observed in bari-treated pts with SLE. Treatment with bari resulted in clinical improvement across various measures of SLE disease activity.¹ Moreover, response was observed with bari regardless of the change in the IFN gene signature. These data suggest that the clinical improvement observed in bari-treated pts with SLE may be the result of bari-mediated effects on multiple cytokine pathways that may include, but are not limited to, IFN signaling.

Marked Immune Cell Subset Changes in Refractory Lupus Patients in a Phase I Trial of Allogenic Mesenchymal Stem Cells

Caroline Wallace Fugle¹, Chungwen Wei², Ignacio Sanz², Zihai Li¹, Chrystal Paulos¹, Megan Wyatt¹, Diane L. Kamen³ and Gary S. Gilkeson⁴, ¹MUSC, Charleston, SC, ²Emory University School of Medicine, Atlanta, GA, ³Medicine/Rheumatology & Immunology, Medical University of South Carolina, Charleston, SC, ⁴Department of Medicine, Medical University of South Carolina, Charleston, SC

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Lupus Erythematosus – Etiology and Pathogenesis I

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Reports of positive effects of allogenic mesenchymal stem cells (MSCs) in treating refractory lupus, from a single center in China, led us to investigate the clinical and immune effect of a single infusion of 1×10^6 MSCs per kg umbilical cord MSCs in a Phase I trial of 6 patients with refractory lupus. We report the immune effects of MSC infusions on 6 patients; 5 met the primary outcome of a Systemic Lupus Response Index-4 (i.e. SRI-4). Clinical responses are submitted separately.

Methods: We assessed B and T cell subsets at Wks 0, 4, 8 and 24 by Flow. We measured levels of TGF β and glycoprotein A repetitions predominant (GARP) in the serum by ELISA as the hypothesized immune effector mechanism of MSCs. B cell assays were performed at Emory; 3 Wk. 8 samples were undeliverable due to winter storms.

Results: B cell subsets were notably affected by MSC infusion with a significant decrease in CD27 IgD double negative B cells (DN) with a concomitant increase in resting naïve B cells (rN) in 4/6 (Fig. 1). Of particular note are the diminishing subsets with an activated phenotype (CD11c+CD21-), including DN2 and activated naïve (aN) B cells. Patient 004 was the single treatment failure and her B cell subsets, with a high percentage of rN B cells and few DN/aN B cells at baseline, did not change. We assessed for changes in Tregs, Th1, Th2, T_{FH} and Th17 subsets. 2/6 patients had increases in Tregs (i.e. patients 001, Fig. 2) and helios+ Tregs (Fig. 2), but there were no major shifts in subsets as seen in B cells. GARP is highly expressed on MSCs and a major regulator of TGF β bioactivity. GARP impacts Treg development, B cell activation and development of autoimmunity. We assessed if MSC infusions impacted serum GARP or TGF β levels. There were significant increases in serum GARP (Fig. 3, $p < 0.01$) and TGF β levels (not shown) following MSCs.

Conclusion: MSC infusions in a Phase I open label trial in refractory lupus led to clinical improvement in 5/6 patients and significant changes in immune cell subsets with a shift from activated B cell subsets to resting naïve B cells. Serum GARP and TGF β levels increased post MSC infusion serving perhaps as the proximate immune effector mediators. A Phase II double blind placebo controlled multi-center trial of UC-MSCs in 81 refractory lupus patients will be starting this summer.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Lupus Erythematosus – Etiology and Pathogenesis I

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Systemic lupus erythematosus (SLE) is a complex autoimmune disease in which 70% of patients experience disfiguring skin inflammation (grouped under the rubric of cutaneous lupus erythematosus (CLE)). Studies have revealed that interferons (IFNs) are important mediators for SLE and CLE, but the mechanisms by which IFNs lead to disease are still poorly understood. We and others have previously identified increased type I IFN expression in non-lesional SLE keratinocytes, but whether alterations in response to IFNs also contribute to disease is unknown. We thus aimed to investigate IFN responses in SLE vs. control keratinocytes and to identify mechanisms by which differential regulation may occur.

Methods: Age and gender-matched control (n=7) and SLE (n=7) keratinocytes were isolated from non-lesional, non-sun exposed 6mm punch skin biopsies from the upper thigh and used at passage 3. All patients gave written, informed consent and were treated according to the Declaration of Helsinki. These keratinocytes were treated with or without 5 ng/mL of IFN α , IFN β , IFN κ , and IFN γ for 6 hours followed by RNA isolation and RNA-sequencing. In-depth analysis of the interferon response was conducted. PITX1 expression in normal and CLE lesional skin was evaluated by immunohistochemistry. Knockdown of PITX1 was used to examine IFN gene expression in the absence of PITX1.

Results: A significant hypersensitive response to IFNs was identified in lupus keratinocytes including genes (*IFIH1*, *STAT1*, and *IRF7*) encompassed in SLE susceptibility loci. In particular, 273 genes in SLE keratinocytes demonstrated a higher effect size ($p=5.8 \times 10^{-32}$); these genes were termed lupus sensitive interferon (LSI) responses. Importantly, 50 LSI response genes were significantly enriched among the dysregulated genes in CLE lesions ($p=1.8 \times 10^{-41}$), confirming their *in vivo* relevance. Binding sites for the transcription factor PITX1 were significantly enriched ($p=2 \times 10^{-4}$) in the LSI genes, suggesting a role for PITX1 in regulation of IFN responses. Indeed, PITX1 expression was increased in CLE lesions, and knockdown of PITX1 expression in N/TERT keratinocytes significantly abrogated interferon response gene expression after type I IFN, but not TNF α stimulation.

Conclusion: SLE patients exhibit increased interferon signatures in their skin secondary to increased production and a robust, skewed IFN response that is regulated by PITX1. Targeting of these exaggerated pathways may prove to be beneficial to prevent and treat hyper inflammatory responses in SLE skin.

Session Date: Monday, October 22, 2018

Session Title: Systemic Lupus Erythematosus – Etiology and Pathogenesis I

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: African-American (AA) ethnicity is associated with a 3-fold higher risk of developing systemic lupus erythematosus (SLE). In addition, there is an increased risk of lupus nephritis (2-fold), high-risk histological features, and resistance to treatment. This may account for the increased mortality rate compared to Caucasian patients, especially in women. In Phase One of the Accelerating Medicines Partnership (AMP) study, we used single-cell RNA sequencing (ssRNA-Seq) on kidney biopsies from patients with active lupus nephritis to identify pathways that were differentially expressed in AA patients.

Methods: Single cells from renal biopsies obtained for clinical purpose for active nephritis were processed using CEL-Seq2. The bioinformatic pipeline to generate the expression levels of unique molecular identifiers (UMIs) from RNA reads has been previously described. We used canonical correlation analysis to identify common sources of variation between AAs and Caucasians. Cell clusters were identified using t-distributed stochastic neighbor embedding (t-SNE). Cluster identity was defined based on the presence of known cell lineage markers, enrichment of known gene set or using publicly available gene expression atlases. Next, we identified differentially expressed genes within each cluster with > 1.5 -

fold change in expression (p <0.05, Bonferroni). Finally, we applied Ingenuity Pathway Analysis (IPA) (QIAGEN Bioinformatics) to identify pathways of interest.

Results: Samples from 16 AA and 13 Caucasian patients were obtained. Of the 3829 sequenced cell libraries, we used 2358 which passed our quality filter for a total of 30155 UMIs. We identified 12 cell clusters: CD4, CD8, B cells, NK, monocytes, myeloid, NKT, distal tubule, proximal tubule, plasma cells, fibroblasts, and cell cycle. We identified 42 unique genes differentially expressed between AAs and Caucasians (Table 1). IPA identified a stronger type 1 interferon signature in AA patients, especially in CD4+ lymphocytes. In Caucasians, we identified selective expression of genes related to macrophage activation and that FKBP5, potential mediator of the immunosuppressant effect of mycophenolate and rapamycin analogues, is preferentially expressed in fibroblasts.

Conclusion: AA lupus nephritis patients have a stronger Type I interferon gene signature in immune and renal cells. In Caucasian patients, infiltrating macrophages have an activated profile and fibroblasts express FKBP5, suggesting a potential mechanism for their better response to immunosuppression. These results indicate that ethnicity may predict a response to both current and upcoming treatments, paving the way for a more personalized approach to treatment in lupus nephritis. Further work in Phase 2 of AMP will confirm and extend these findings.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Lupus Erythematosus – Etiology and Pathogenesis I

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Long QT syndrome (LQTS) is an abnormal QT corrected (QTc) interval prolongation, strongly associated with increased risk of sudden death. Studies have associated LQTS with autoimmune conditions, and evidence points towards a link between inflammation and LQTS. We already demonstrated that LQTS occurs in SLE patients positive to anti-Ro/SSA antibodies, and interference with ventricular repolarization is linearly associated with levels of anti-Ro52/TRIM21 antibodies. However, critical cytokine pathways facilitating the development of LQTS in SLE are still unknown. This study was conducted to evaluate the cytokine milieu in SLE patients with LQTS.

Methods: Consecutive patients fulfilling the 1997 ACR criteria for SLE were included. Patients with a history of ischemic heart disease or implantable pacemakers, and those taking drugs potentially affecting QT interval (except for antimalarials) were excluded. Patients underwent a resting 12-lead ECG recording to measure QTc interval (Bazett's formula). A QTc interval duration >460 msec in women and >440 msec in men was set to define LQTS. Serum cytokine and chemokine levels were measured by multiplex bead array technology.

Results: Sixty-six patients with a mean age of 39±13 years (57 female gender) were included. A LQTS was found in 10 patients (15%), with mean QTc interval of 470±18 msec as compared to 414±23 msec in those with no LQTS. Main clinical and demographic characteristics were similar in both groups, except for a lesser use of antimalarials in patients with LQTS. Disease activity was similar between groups. Anti-Ro/SSA (75±66 U/mL versus 29±44 U/mL; P=0.005) and anti-Ro52/TRIM21 (50±55 U/mL versus 14±30 U/mL; P=0.01) antibody levels were higher in patients with LQTS. Regarding serum cytokines, levels of type I IFN-induced chemokines IP-10 (425±258 pg/mL versus 275±267 pg/mL; P=0.021) and IL-8 (58±52 pg/mL versus 29±24 pg/mL; P=0.039) were significantly higher in patients with LQTS. Notably, anti-Ro/SSA antibody levels were linearly associated with IP-10 (r=0.41, 95%CI 0.18–0.60; P=0.0002) and IL-8 (r=0.31, 0.06–0.52; P=0.005) levels. In addition, anti-Ro52/TRIM21 antibody levels also were linearly correlated with IP-10 (r=0.39, 0.16–0.58; P=0.0005) and IL-8 (r=0.23, -0.02–0.45; P=0.03) levels. Other type I IFN-induced chemokines (MCP-1 and RANTES) were similar between groups.

No differences in the cytokine circuits characterizing Th1 (IFN- γ , IL-2, IL-12, IL-27), Th2 (IL-4, IL-5, IL-13, IL-6), Th17 (IL-17, IL-21, IL-22, IL-6, GM-CSF, IL-23), Th9 (IL-9, IL-4, IL-21, IL-6), Th22 (IL-22, TNF, IL-6, IL-10), Tr1 (IL-10, IFN- γ , IL-27) were found. Additionally, no differences were found in other chemokines (MIP-1 α , SDF-1, IL-18, GRO- α , Eotaxin, MIP-1 β) characteristic of innate immunity.

Conclusion: Our results reinforce the existence of a specific LQTS mediated by anti-Ro/SSA autoantibodies, especially those specifically directed against the antigen Ro52/TRIM21. The interference in ventricular repolarization seems to be driven by proteins from the IFN gene signature, which is in line with the notion that Ro52/TRIM21 antigens are an element of response to type I IFN.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

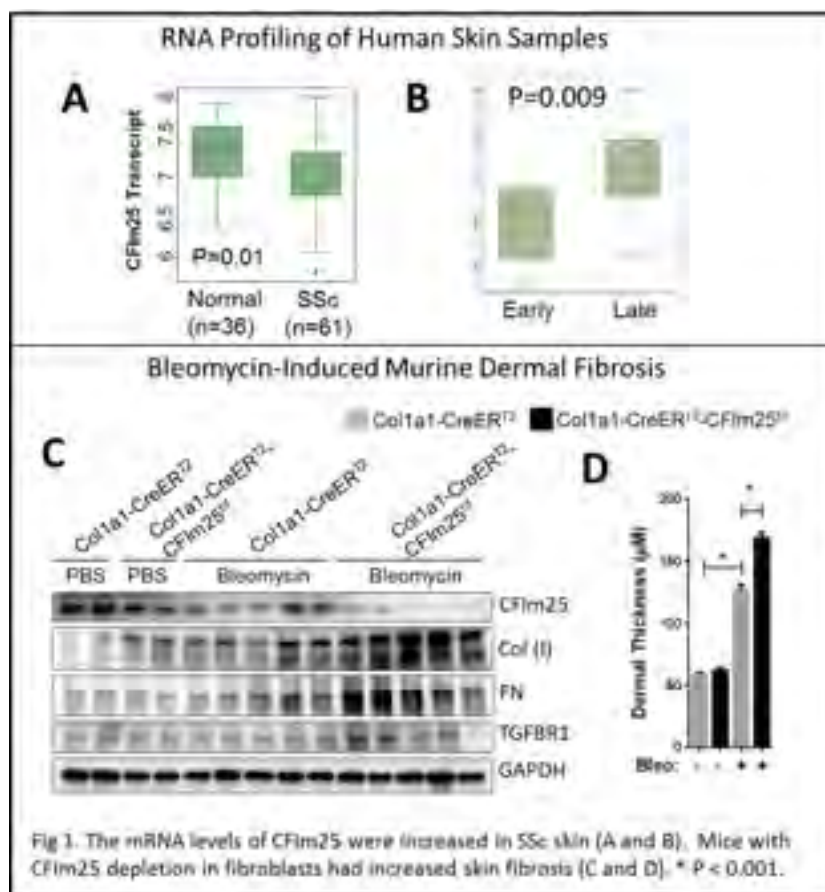

Session Title: Systemic Sclerosis and Related Disorders – Basic Science

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Persistent myfibroblast activation and associated excessive extracellular matrix protein deposition are hallmarks of systemic sclerosis (SSc). However, the mechanisms that account for this excessive fibrotic response remain elusive, hampering development of targeted treatment modalities. Alternative polyadenylation (APA) allows adding poly (A) tail to different polyadenylation sites which gives rise to transcripts with variable 3' UTR length. Cleavage factor Im 25 (CFIm25 – gene name: Nudt21) has been recently identified as a key regulator of APA¹. CFIm25 deletion leads to 3' UTR shortening of key genes involved cell fate determination. A shortened 3' UTR will often lack microRNA binding sites in comparison to its long form, resulting in increased mRNA translation due to evasion of microRNA-mediated gene repression. The goal of this study is to understand the role of CFIM25 and APA in SSc pathogenesis.

Methods: CFIm25 expression and cellular localization was investigated in skin from SSc patients and murine models. RNA sequencing was carried out using control or CFIm25 knock down fibroblasts to determine CFIm25 targets, which were

subsequently verified by Real-time PCR and Western Blot. Finally, bleomycin was administrated subcutaneously in mice with conditional CFIm25 deletion in fibroblasts to determine the effect of CFIm25 repression *in vivo*.

Results: CFIm25 mRNA was down regulated in SSc skin compared to matched controls (Fig 1A). Patients with disease duration < 2 years had significantly lower CFIm25 mRNA levels than the remainder of patients (Fig 1B). Moreover, downregulation of CFIm25 in SSc skin was primarily observed in myofibroblasts in IHC experiments. Global RNA sequencing experiments upon knock down of CFIm25 in normal skin fibroblasts (n=5 per group) resulted in 3' UTR shortening of 971 genes. TGF- β was predicted to be the top upstream regulator of this gene list. Moreover, CFIm25 depletion led to enhanced protein expression of key fibrotic genes, including COL1A1 and TGFBR1. Similarly, these genes showed 3'UTR shortening in SSc skin compared to matched controls (n=10 per group). CFIm25 protein levels were decreased in the skin of bleomycin dermal fibrosis and Tight Skin Mouse I murine models. Finally, conditional CFIm25 deletion in fibroblasts led to exaggerated skin fibrosis upon bleomycin treatment (n=10 per group), as measured by Masson's trichrome staining, collagen I and TGFBR1 Western Blot (Fig 1C), and dermal thickness (Fig 1D).

Conclusion: We link for the first time a recently discovered key RNA processing protein, CFIm25 to 3' UTR shortening and increased transcription/translation of TGF- β regulated profibrotic genes, in dermal fibrosis models and SSc. CFIm25 rescue can be a potential therapeutic target in SSc.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Sclerosis and Related Disorders – Basic Science

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Fibroblast growth factor receptor3 (FGFR3) is a member of the family of 4 different receptors (FGFR1-4) with more than 23 identified ligands FGF1-23. Each FGFR has different isoforms resulting from natural alternative splice variants and hence can bind more than one FGF ligands. Upon binding FGF ligands, fibroblast growth factor receptors (FGFRs) trigger various intracellular signaling pathways to regulate important biological processes.

Methods: Differential expression profiling of dermal cells from SSc patients and healthy volunteers were performed employing GEArray cDNA microarray, qPCR, Western Blot, immunohistochemistry and immunofluorescence analyses. Selective inhibitors in conjunction with knockdown and knockout strategies were used to target FGF9/FGFR3 signaling *in vitro* and *in vivo*. FGFR3/FGF9 target genes were identified by Affymetrix gene arrays. The anti-fibrotic potential of FGF9/FGFR3 inactivation was evaluated in two mouse models of SSc: skin fibrosis induced by bleomycin and tight skin-1 (TSK) mice.

Results: FGFR3, specifically the isoform FGFR3 IIIb, expression was significantly upregulated in the dermis and dermal fibroblasts of SSc patients as compared to healthy volunteers. In contrast, the expression of other members of the FGFR family (FGFR1,2 and 4) was not induced in SSc. FGFR3 IIIb binds only FGF1 and FGF9 and we found significant increase in the levels of FGF9, in contrast to FGF1, in SSc patients as compared to healthy people.

To screen for FGFR3 regulated genes in fibroblasts, which might contribute to the pathogenesis of SSc, FGFR3(Act) mice with constitutive FGFR3 signaling and FGFR3(KO) mice, lacking FGFR3, were differentially screened by Affymetrix gene chips. We found that FGFR3(Act) mice express significantly elevated levels of the profibrotic mediators monocyte chemoattractant protein-1(MCP-1), connective tissue growth factor(CTGF), interleukin-4 receptor α (IL4R α), endothelin-1 (ET-1) and its receptor endothelin-receptor B (EDNRB). Further analyses revealed that FGF9/FGFR3 stimulates the expression of these profibrotic mediators via ERK- and p38-dependent pathways.

Genetic knockout of FGFR3 ameliorates skin fibrosis in TSK mice and in bleomycin-induced fibrosis. TSK or bleomycin-challenged mice displayed reduced dermal thickening, decreased myofibroblast counts and lower hydroxyproline content upon inactivation of FGFR3. Confirming the translational potential of these findings, we demonstrate pharmacological inactivation of FGFR3 by PD173074 could induce the regression of experimental fibrosis in bleomycin-challenged or in TSK mice.

Conclusion: We have identified and characterized FGFR3 signaling as a novel mediator of fibroblast activation and tissue fibrosis in SSc. FGFR3, regulates a network of major profibrotic mediators including CTGF, MCP-1, ET-1 and its receptor EDNRB and IL4R α . Thus targeting of this major upstream regulator would deactivate several profibrotic pathways simultaneously. We could demonstrate successfully that the targeted inhibition of FGFR3 ameliorated fibrosis in different preclinical models of SSc. Our findings may have direct translational implications as FGFR3 inhibitors are currently in development.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Sclerosis and Related Disorders – Basic Science

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30 PM-6:00 PM

Background/Purpose: Persistent myofibroblast activation driving progressive fibrosis is the defining hallmark of systemic sclerosis (SSc). Uniquely, fibrosis in SSc affects the skin, heart, lungs and muscles synchronously, suggesting that pathways shared across multiple target organs could be responsible. However, the nature of the fundamental alteration common to distinct organs affected in SSc patients remains unknown. In order to identify novel therapeutic targets, we sought potential novel mechanisms accounting for multi-organ fibrosis.

Methods: We performed next generation sequencing on skin biopsies from patients with SSc (n=19) and matched healthy controls (n=14). Expression of differentially regulated genes in the skin was investigated by immunohistochemistry. Novel knockout mice were generated and at various ages analyzed for fibrosis. Regulation of morphogen signaling and fibrotic responses was examined in cell culture assays using null fibroblasts.

Results: Unbiased RNAseq transcriptome analysis identified SPAG17 as the most differentially-expressed gene in SSc skin biopsies (-4.18 fold; p< 0.0001). SPAG17 is a primary cilia gene with unknown function, previously linked to human height in GWAS. Levels of SPAG17 mRNA in SSc skin biopsies showed negative correlation with the Modified Rodnan Skin Score; low SPAG17 expression was associated with increased morphogen (Hedgehog, Wnt) activity (elevated Smoothed and Dishevelled1) in the skin. Immunofluorescence analysis of SSc skin biopsies demonstrates marked reduction in SPAG17 expression, and absence of SPAG17 in lesional myofibroblasts. SPAG17-deficient my of ibroblasts had stunted and dysfunctional primary cilia, and showed constitutive activation of Smad pathways. Moreover, loss of SPAG17 rendered

fibroblasts exquisitely sensitive to TGF- β . Since SPAG17 knockout mice generated in our lab die in the perinatal period due to severe lung involvement, we crossed SPAG17^{fl} mice with Sox-Cre mice. The offspring survive into adulthood, and are indistinguishable for their wild type littermates. Remarkably, by 4-6 months of age, SPAG17-deficient mice show notable fibrosis in skin, heart, lungs, kidney and skeletal muscle.

Conclusion: The ciliary gene SPAG17 appears to play a critical role in preventing fibrosis in multiple organs. Loss of SPAG17 renders fibroblasts markedly susceptible to fibrotic stimulation, and is associated with spontaneous scleroderma-like skin changes accompanied by fibrosis in multiple organs. Reduced expression of SPAG17 and consequent ciliary dysfunction and augmented morphogen signaling therefore appear to play a previously unrecognized role in fibrosis and could contribute to the pathogenesis of SSc. SPAG 17 KO mice represent a unique novel disease model phenocopying synchronous fibrosis in multiple organs.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Sclerosis and Related Disorders – Basic Science

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30 PM-6:00 PM

Background/Purpose: Systemic Sclerosis (SSc) is an etiologically mysterious disease, in which adults acquire an inflammatory prodrome with progressive fibrosis of the skin and viscera. In the absence of a strong genetic signature in twin studies (monozygous=dizygous=4% concordance) or genome-wide association studies (only indicative of inflammatory predisposition), it remains unclear as to how dermal fibroblasts from SSc patients maintain a fibrotic synthetic repertoire (FSR) when cultured *ex vivo*. We posited epigenetic regulation of gene expression as a mechanism that “locks in” the aberrant performance of SSc fibroblasts.

Methods: Transcriptomes and epigenomes were profiled by RNA-seq and Assay for Transposase-Accessible Chromatin (ATAC)-seq, respectively, using primary dermal fibroblasts (PDF) established from skin biopsies of healthy controls or SSc patients with diffuse cutaneous involvement. PDFs were further evaluated by targeted epigenomic editing, chromatin immunoprecipitation, protein analysis, and pharmacological strategies. Organ cultures of SSc patient skins were performed to assess therapeutic agents *in vivo*.

Results: RNA-seq revealed that SSc PDFs maintain a strong FSR after many passages in culture (e.g. *COL1A1*, *SERPINH1*). This correlated with specific upregulation of TGF β 2 (but not β 1 or β 3) mRNA and protein expression that was prone to further amplification by TGF β treatment. siRNA knockdown of TGF β 2 silenced the FSR in SSc PDFs. Together, these data suggest an epigenetic mechanism to “lock in” the FSR in SSc, with particular relevance for TGF β 2. ATAC-seq revealed an open chromatin conformation for a sequence-constrained region distal to the *TGFB2* gene in SSc PDFs, with direct correlation between accessibility and TGF β 2 mRNA levels. This element showed a signature for activated enhancers: acetylated H3K27 and occupancy by the histone acetyltransferase (HAT) EP300. CRISPR-based targeted histone acetylation to this enhancer induced TGF β 2 expression, and consequentially TGF β target gene expression (*COL1A1*, *SERPINH1*), in control and SSc PDFs, validating functional enhancer status. In keeping with this result, targeted histone methylation to the *TGFB2* enhancer normalized TGF β 2 expression and the FSR in SSc PDFs. Treatment of SSc PDFs with a HAT inhibitor (HATi) was sufficient to deactivate *TGFB2* enhancer activity, but full epigenetic activation of the enhancer rebounded after drug removal. We posited that this epigenetic memory—analogue to regulation of inflammatory enhancers—might be initiated by inflammatory effectors (e.g. NF- κ B) and enforced by BRD4 recruitment. In support of this hypothesis, we found high NF- κ B and BRD4 occupancy at the TGF β 2 enhancer in SSc PDFs. Treatment with the NF- κ B or BRD4 inhibitor normalized TGF β 2 expression and the FSR, which was now refractory to drug removal. Finally, SSc skin maintained a FSR and dense fibrosis in organ culture. Both parameters were strikingly reversed upon incubation with BRD4 inhibitor for ten days.

Conclusion: These data suggest an epigenetic mechanism for fibrosis in SSc pathogenesis, identify therapeutic targets and biomarkers for use in clinical trials, and inform a new regulatory mechanism of *TGFB2*.

Session Title: Systemic Sclerosis and Related Disorders – Basic Science

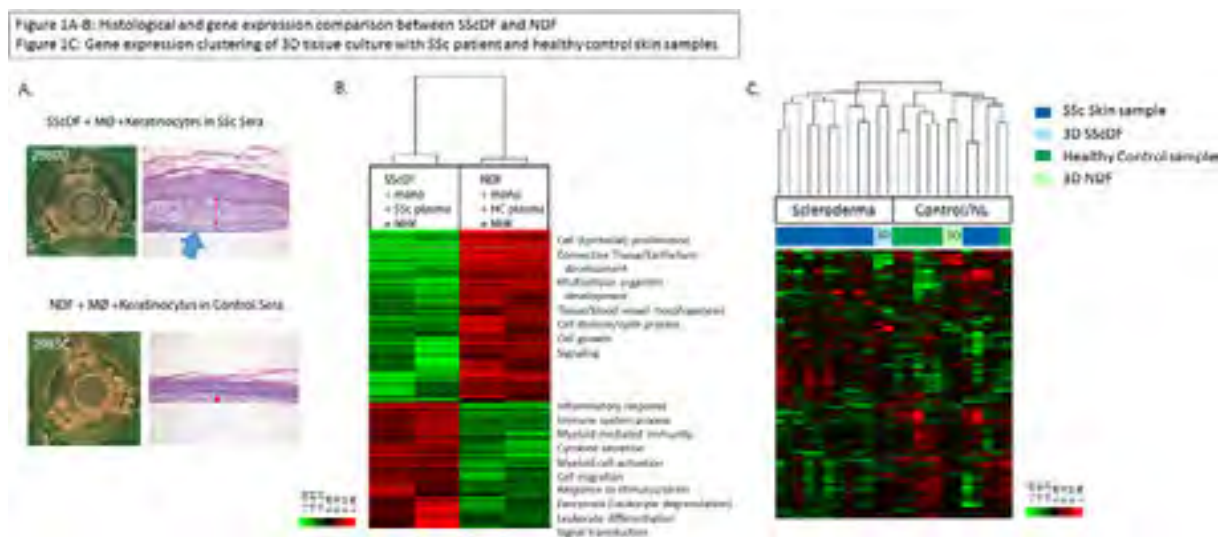

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30 PM-6:00 PM

Background/Purpose: The molecular mechanisms of systemic sclerosis (SSc) have been difficult to study outside of patient samples. Mouse models often lack key features of the disease, and fibroblast cultures show inconsistent results. We have developed an innovative skin-like tissue of SSc, self-assembled Skin Equivalents (sSE), where we study fibroblast behavior in a 3D micro environment with epithelial-dermal crosstalk and immune interaction. Here we investigate the molecular changes in SSc sSE and show that it is molecularly similar to SSc skin biopsies.

Methods: Fibro blasts were isolated from SSc patient skin (SScDF) and normal skin (NDF), expanded and seeded into transwell chambers +/- monocytes. SSc patient-derived plasma and healthy control (HC) plasma were incorporated into the culture media during the polarization period. Normal Human Keratinocytes were seeded at 3 weeks for epithelialization, and tissues were harvested after 5 weeks followed by IHC, atomic force microscopy (AFM), RNA-seq, DNA methylation, and ATAC-seq. Cell supernatants were used for multiplex ELISA analysis.

Results: We created 136 samples of sSE from one SScDF line and one NDF line. H&E staining of SScDF sSE showed increased dermal thickness and stiffness compared to NDF sSE (Fig 1A). Differential expression of the SScDF sSE and

NDF sSE with autologous plasma and monocytes showed increased expression of genes representing pathways involved in inflammatory/immune system response, myeloid-mediated immunity, myeloid cell activation, and leukocyte differentiation (Fig 1B). The upregulated genes in NDF sSE showed typical pathways involved in epithelial proliferation, tissue morphogenesis, and cell growth. Differential expression of the SScDF sSE +/- monocytes found that sSE tissues with monocytes had increased immune response, immune cell proliferation and activation, macrophage migration, and cell chemotaxis. In samples without monocytes, epithelial cell differentiation and collagen processes were upregulated, but the strong immune signal was missing. Additionally, IL6 and IL13 production increased in SScDF supernatant during tissue development and after the polarization period. Also, analysis of gene expression in SScDF sSE by RNA-seq data demonstrated molecular similarity to human SSc patient skin samples and NDF clustered more closely with HC skin samples (Fig1C). Lastly, 3D sSE tissues and 2D monolayer fibroblast cultures have distinct DNA methylation patterns.

Conclusion: There is a hierarchy of drivers in the creation of 3D tissues, with the origin of dermal fibroblasts being the biggest modifier of disease morphology and the addition of monocytes being the next biggest factor in developing the immune response. These 3D sSE tissues consistently replicate the molecular pathways found in SSc skin and allow for a controlled model system of SSc to manipulate and test drug therapy responses.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Sclerosis and Related Disorders – Basic Science

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30 PM-6:00 PM

Background/Purpose: The Retinoic-acid related Orphan Receptor-alpha (ROR α) is a member of the nuclear receptor superfamily and a ligand-dependent transcription factor implicated in a wide range of physiological and pathological processes. Although individual key mediators of fibroblast activation such as TGF β and WNT pathways have been identified, the factors that coordinate the activation and interaction of those pathways remain largely enigmatic. Here, we aim to evaluate the role of ROR α in the pathogenesis of fibrotic diseases.

Methods: Mice carrying *Ror α ^{fl/fl}xCol1a2-CreER* were generated to specifically knockout *Ror α* in fibroblasts in an inducible manner. ROR α was inactivated using the selective inhibitor SR3335. The role of ROR α was investigated in different mouse models: Bleomycin- and TBRI^{CA}-induced dermal fibrosis, bleomycin-induced pulmonary fibrosis, carbon tetrachloride (CCL4)-induced liver fibrosis and in Wnt-10b transgenic mice. The activity of TGF β /SMAD signaling pathway was analyzed by reporter assays. RNA sequencing was performed to determine target genes of ROR α in fibroblasts.

Results: The expression of ROR α was upregulated in fibroblasts in both human and murine fibrotic lung and liver. Activation of canonical Wnt/ β -catenin signaling mimicked the increase of ROR α in fibrosis and potently induced ROR α expression. Reporter assays showed that canonical Wnt ligands induced the transcriptional activity of ROR α , which could be prevented by Wnt signaling antagonists Dickkopf. Inhibition of ROR α signaling by incubation with SR3335 inhibited WNT- and TGF β -dependent myofibroblast differentiation and effectively reduced the release of collagen. Reporter assay demonstrated that SR3335 dramatically inhibited TGF β /SMAD signaling pathway activity. Knockout of ROR α reduced the stimulatory effects of TGF β and WNT on fibroblast activation and collagen release. In contrast, fibroblasts overexpressing ROR α are more susceptible to the profibrotic effects of TGF β and WNT. In addition, fibroblast-specific inactivation of ROR α *in vivo* protected from experimental fibrosis induced by bleomycin injection. Furthermore, treatment with SR3335 effectively reduced Wnt-induced fibrosis *in vivo*. Dermal thickening, myofibroblast differentiation and hydroxyproline

content were all significantly reduced in Wnt10b-tg mice treated with SR3335 as compared to vehicle-treated littermates. Inhibition of ROR α also ameliorated TGF β -dependent fibrosis with potent antifibrotic effects in mice overexpressing TBRI^{CA}. Treatment with SR3335 also reduced bleomycin-induced skin and lung fibrosis and CCL4-induced liver fibrosis.

Conclusion: The present study characterizes ROR α as a key checkpoint of TGF β - and WNT- induced fibroblast activation. ROR α is induced in fibrotic diseases in a WNT-dependent manner to promote TGF β - and WNT-induced fibroblast activation and tissue fibrosis. Targeting of ROR α simultaneously interferes with TGF β - and WNT-signaling as two core pathways in the pathogenesis of fibrotic diseases. The inhibition of those core pathways translates into potent antifibrotic effects across different models and organ systems.

Session Title: Epidemiology and Public Health II: RA Risk: Education, Obesity, Smoking, or Biomarkers?

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30 PM-6:00 PM

Background/Purpose: Lower socio-economic status (SES) has been associated with worse clinical outcomes, reduced functional ability and lower quality of life; however, little is known about the association between SES and the development of RA. A few studies have observed an inverse association between education level, a surrogate marker of SES, and risk of developing RA in Northern European populations. The purpose was to investigate the association between SES on an individual level and risk of developing RA in a Southern European Mediterranean population.

Methods: EPIC is a multicentre, pan-European prospective cohort study of apparently healthy populations. We undertook a nested case-control study to investigate risk factors for RA, by identifying incident RA cases (pre-RA) and matched controls amongst subjects enrolled in four EPIC cohorts in Italy and Spain. The lifestyle, environmental exposure, anthropometric information and blood samples were collected at baseline. Confirmed pre-RA cases were matched with controls by age, sex, centre, and date, time and fasting status at blood collection. The exposure was SES as measured by level of educational attainment categorised as university (referent), secondary school/technical/professional school, primary school completed, and none. The primary outcome was incident RA. Conditional logistic regression (CLR) analysis was adjusted for ACPA seropositivity, smoking status, and presence of shared epitope (SE). A further model also adjusted for other potential confounders, including body mass index (BMI), waist circumference, physical activity, and alcohol intake.

Results: The study sample included 398 individuals of which 99 individuals went on to subsequently develop RA. In this analysis, time to diagnosis (defined as time between date of blood sample and date of diagnosis), was 6.71 years (SD 3.43). A significant positive association was observed with level of educational attainment and RA incidence (secondary/technical vs university: OR 5.60, 95% CI 1.59-19.7, primary school vs university: OR 5.06, 95% CI 1.45-17.6, no education vs university: 7.11, 95% CI 1.37-36.8; p for trend 0.02) independent of ACPA seropositivity, SE and smoking). This association between level of educational attainment and RA incidence was confirmed in the fully adjusted model (secondary/technical vs university: OR 5.52, 95% CI 1.53-19.9, primary school vs university: OR 4.87, 95% CI 1.38-17.1, no education vs university: OR 6.48, 95% CI 1.21-34.6; p for trend 0.02).

Conclusion: Lower educational levels were associated with higher risk of developing RA in a Southern European Mediterranean population. This association was not explained by other established genetic and environmental risk factors for RA.

Session Date: Monday, October 22, 2018

Session Title: Epidemiology and Public Health II: RA Risk: Education, Obesity, Smoking, or Biomarkers?

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30 PM-6:00 PM

Background/Purpose: Being overweight or obese increases the risk of rheumatoid arthritis (RA) among women, particularly among those diagnosed with RA at earlier ages. Abdominal obesity is more associated with visceral fat and inflammation than overall obesity measured by body mass index (BMI). We investigated whether abdominal obesity predicts RA risk in two large prospective cohorts, the Nurses' Health Study (NHS) and Nurses' Health Study II (NHSII).

Methods: We followed 48,919 women in NHS (aged 40-67 years in 1986) and 47,220 women in NHS II (aged 29-48 years in 1993) without RA at baseline. Lifestyle and environmental exposures were collected through biennial questionnaires. Abdominal obesity was measured using waist circumference (WC) reported in 1986, 1996 and 2000 in NHS and 1993 and 2005 in NHS II. The cut off point for abdominal obesity (WC \geq 88 cm) was based on WHO recommendations for women. Incident RA cases were identified using the previously validated connective tissue disease screening questionnaire followed by a medical record review. RA serologic status was determined by positive rheumatoid factor (RF) or anti-citrullinated peptide antibodies (ACPA) in the medical record. Using pooled data from the two cohorts, we estimated hazard ratios (HR) for RA risk using time-varying *Cox proportional hazards* models. We repeated analyses restricted to young and middle aged women (age \leq 55 years) based on our pre-specified hypothesis.

Results: During 28 years of follow-up, we identified 803 incident RA cases (505 in NHS, 298 in NHSII). Women with WC $>$ 88 cm had increased RA risk compared with women with WC $<$ 88 cm (Table). The multivariable adjusted HR was 1.27 (95% CI: 1.10-1.47). Further adjustment for BMI attenuated the association. Consistently, BMI was also associated with risk of RA (HR were 1.48 with 95% CI: 1.24-1.77) for BMI \geq 30 kg/m² compared to BMI $<$ 25 kg/m². Stratified analyses by serostatus demonstrated that the association of WC with RA risk was stronger for seropositive RA than for seronegative RA. Among young and middle aged women (age \leq 55 years), abdominal obesity increased risk of all RA by 65%, and by 94% for seropositive RA. After further adjusting for BMI, abdominal obesity remained associated with risk of seropositive RA (HR 1.51, 95% CI :1.01-2.25).

Conclusion: In this prospective cohort study of women followed up to 28 years, abdominal obesity was significantly associated with increased risk of developing RA. Abdominal obesity conferred the greatest risk for seropositive RA among women \leq 55 years old independent of BMI.

Table. Hazard ratios (95% CI) for RA by waist circumference (WC) in Nurses' Health Study (NHS, 1986-2014) and Nurses' Health Study II (NHS II, 1993-2013)

	All age groups			Age \leq 55 years		
	WC \leq 88 cm	WC $>$ 88 cm	p value	WC \leq 88 cm	WC $>$ 88 cm	p value
All RA						
Case/person-years	488/1,756,204	315/842,074		177/822,620	100/258,601

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Epidemiology and Public Health II: RA Risk: Education, Obesity, Smoking, or Biomarkers?

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30 PM-6:00 PM

Background/Purpose: Adiponectin, acytokine mainly produced by the adipose tissue, plays an important role in several metabolic and inflammatory processes. In obese subjects, serum adiponectin levels are surprisingly low and they associate with a higher risk for metabolic diseases, including type 2 diabetes. On the contrary, adiponectin levels are increased in serum and synovia of subjects with established RA. By exploiting a longitudinal study enrolling more than 4000 obese subjects, we aim to determine if serum adiponectin levels are a risk factor for the development of RA in obese subjects.

Methods: The Swedish Obese Subjects (SOS) study is a longitudinal controlled trial on the effect of bariatric surgery on the incidence of obesity-related diseases. It includes 4047 obese subjects whereof 2010 underwent bariatric surgery and 2037 constituted the matched control group. SOS study participants who developed RA were identified by searching the Swedish National Patient Register. Eleven subjects with prevalent RA at baseline are excluded by the analyses. Patients were followed up until diagnosis of RA, death, migration or end of follow-up (December 2016). Total adiponectin was measured using the Quantikine ELISA kit from Quantikine ELISA kit from Bio-Techne (Minneapolis, MN, USA).

Results: Adiponectin measurement at baseline was available for 3691 subjects. Among those subjects, 82 subjects developed RA during a follow up for up to 29 years. High serum adiponectin levels at baseline were associated with the incidence of RA, independently of bariatric surgery, sex, age, body-mass index, smoking, and C-reactive protein and erythrocyte sedimentation rate levels (adjusted Hazard Ratio HR per 10 µg/mL adiponectin 1.70, 95% confidence interval CI 1.12-2.60, P value=0.01). When stratifying the population according to the median of baseline adiponectin, subjects with adiponectin greater than 6.8 µg/mL had a higher risk to develop RA during follow up (log-rank P 0.028, unadjusted HR 1.64, 95% CI 1.05-2.56, P=0.03, Figure 1).

Conclusion: In a large cohort of obese subjects followed up for up to 29 years, serum adiponectin levels were associated with the incidence of RA years before the onset of clinical signs. The association between adiponectin and the incidence of RA is independent of other risk factors, including C-reactive protein, smoking and bariatric surgery.

Bariatric Surgery Does Not Affect the Incidence of Rheumatoid Arthritis in Obese Subjects

Yuan Zhang¹, Cristina Maglio², Anna Rudin³ and Lena Carlsson⁴, ¹Dep. of Rheumatology and Inflammation Research, The Sahlgrenska Academy at University of Gothenburg, Gothenburg, Sweden, ²Dep. of Rheumatology and Inflammation Research and Wallenberg Centre for Molecular and Translational Medicine, The Sahlgrenska Academy at University of Gothenburg, Gothenburg, Sweden, ³Dept of Rheumatology and Inflammation Research, The Sahlgrenska Academy at University of Gothenburg, Gothenburg, Sweden, ⁴Department of Molecular and Clinical Medicine, The Sahlgrenska Academy at University of Gothenburg, Gothenburg, Sweden

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Epidemiology and Public Health II: RA Risk: Education, Obesity, Smoking, or Biomarkers?

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30 PM-6:00 PM

Background/Purpose: Obesity is among the risk factors for rheumatoid arthritis (RA). Bariatric surgery is an effective treatment to achieve weight loss and to prevent obesity-related diseases, such as type 2 diabetes¹. Bariatric surgery-induced weight loss in subjects with RA has been associated with a lower disease activity, a decrease in inflammatory markers and a lower use of disease-modifying antirheumatic drugs². However, the effect of bariatric surgery on the prevention of RA is not known. We have previously shown that bariatric surgery reduces the risk of gouty arthritis and psoriasis in obese subjects^{3,4}. By exploiting a longitudinal study enrolling more than 4000 obese subjects, we aim to determine if bariatric surgery prevents the incidence of RA.

Methods: The Swedish Obese Subjects (SOS) study is a longitudinal controlled trial on the effect of bariatric surgery on the incidence of obesity-related diseases. It includes 4047 obese subjects: 2010 underwent bariatric surgery and 2037 constituted the matched control group. Seven Swedish local ethics review boards approved the study protocol. SOS study participants who developed RA were identified by searching the Swedish National Patient Register. Eleven subjects with

prevalent RA at baseline are excluded by the analyses. Patients were followed up until diagnosis of RA, death, migration or end of follow-up (December 2016).

Results: During a follow up for up to 29 years, 92 subjects developed RA. Fifty-one individuals (55%) had a seropositive RA. Forty-seven subjects (2.3%) developed RA in the surgery group compared to 45 subjects (2.2%) in the control group. Bariatric surgery was not associated with the incidence of RA during follow up(log-rank $P=0.88$; unadjusted Hazard Ratio-HR 1.03, 95% Confidence Interval-CI 0.69-1.55, $P=0.88$, Figure 1). Similar results were obtained if only subjects with seropositive RA were included in the analysis. Adjustment for confounding factors did not affect the results (HR for bariatric surgery after adjustment for confounding factors 0.95, 95% CI 0.60-1.50, $P=0.82$). Smoking habit, as well as baseline serum levels of C-reactive protein and erythrocyte sedimentation rate, but not female sex or body-mass index, were associated with the risk of developing RA in this obese population.

Conclusion: In a large cohort of obese subjects followed up for up to 29 years, bariatric surgery does not affect the incidence of RA years.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Epidemiology and Public Health II: RA Risk: Education, Obesity, Smoking, or Biomarkers?

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30 PM-6:00 PM

Background/Purpose: Compared to never smoking, past and current smoking are both associated with increased risk of seropositive rheumatoid arthritis (RA). Thus, smoking cessation may delay or even prevent RA, but previous investigations were limited for definitive conclusions by short follow-up. Therefore, we investigated the impact and timing of smoking cessation on RA risk using two large prospective cohorts with lengthy follow-up.

Methods: We investigated smoking cessation and RA risk in the Nurses' Health Study (NHS, 1976-2014) and the NHS II (1989-2015). Smoking exposure data and covariates were obtained prospectively by biennial surveys. Women self-reported RA and medical record review confirmed RA by ACR criteria. Serologic status of RA was validated by rheumatoid factor (RF) and/or anti-cyclic citrullinated peptide (anti-CCP) by chart review. Using pooled data, Cox regression estimated HRs and 95% CIs for RA phenotypes (seropositive, seronegative) by smoking status and years since cessation adjusting for

Figure. Among the subset of past smokers (reference: 0-2 years since quitting), restricted cubic spline curves showing hazard ratios and 95% confidence bounds for seropositive and seronegative rheumatoid arthritis by years since quitting smoking. P values are for linear relation. Curves are adjusted for the covariates listed in the Table.

Methods: We performed a retrospective cohort study of CCP+ individuals seen at a US tertiary care system between 2003-2016 who were without classifiable rheumatic disease including RA per 2010 ACR/EULAR criteria by medical record review within one month of initial positive CCP. Incident RA by ACR/EULAR criteria and date of diagnosis were identified and confirmed independently by two rheumatologists through medical record review. We investigated the risk of

Table. Multivariable hazard ratios for progression to rheumatoid arthritis among patients with CCP positivity (n=340)

	Cases/person-years	Multivariable HR (95% CI)
CCP level		
>1 to 2x ULN	14/509	1.00 (Ref)
>2 to 3x ULN	10/147	2.81 (1.24, 6.37)
>3x ULN	49/314	6.18 (3.40, 11.3)
Age (continuous, per year)	73/1047	1.00 (0.98, 1.01)
Male	17/359	1.00 (Ref)
Female	56/687	1.84 (1.06, 3.19)
BMI <30 kg/m ²	51/734	1.00 (Ref)
BMI ≥30 kg/m ²	22/312	0.60 (0.54, 1.51)
Not current smoker	59/918	1.00 (Ref)
Current smoker	14/129	1.68 (0.92, 3.09)

BMI, body mass index; CCP, cyclic citrullinated peptide; CI, confidence interval; HR, hazard ratio; ULN, upper limit of normal.

progression to RA overall and stratified by CCP level (low: >1 to 2 times upper limit of normal [x ULN]; medium: >2 to 3x ULN; high: >3x ULN). We used multivariable Cox regression to evaluate the effect of CCP level on RA risk.

Results: We identified 340 CCP+ patients who at baseline were without RA or other rheumatic disease; 66% of the patients were female, and mean age was 55.0 years (SD 15.3). The most common indication for checking initial CCP was arthralgia (74%) followed by lung disease (10%). There were 73 (22%) patients who developed incident RA during 1047 person-years of follow-up. Absolute risk of progression to RA increased with higher CCP level (**Figure**), with 50% of patients progressing to RA by 5 years of follow-up. Compared to low CCP, medium (HR 2.73, 95% CI 1.21, 6.16) and high (HR 6.21, 95% CI 3.42, 11.3) CCP levels were strongly associated with progression to RA (**Table**). Women had increased risk of progression to RA (HR 1.75, 95% CI 1.01, 3.01) independent of CCP level, age, smoking, and BMI. Checking initial CCP for arthralgia was strongly predictive of progression to RA (HR 6.08, 95% CI 1.91, 19.3) compared to other indications.

Conclusion: In this study of CCP+ patients without RA identified through a US tertiary care system, RA risk increased substantially with increasing CCP level. This study provides support for close monitoring for development of RA among patients with CCP+ as well as the need for identifying strategies to mitigate this risk.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases I: DADA2, Cardiac Sarcoid, Cancer Immunotherapy

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: The deficiency of adenosine deaminase 2 (DADA2) was initially described in 2014 in 2 reports: one emphasizing early-onset lacunar strokes, livedoid rash and intermittent fevers; the second focusing on patients with early-onset polyarteritis nodosa. Since then, there have been reports of antibody deficiency, pure red cell aplasia and cytopenias. We now present clinical follow-up on 38 patients evaluated at the National Institutes of Health (NIH).

Patients and Methods: All 38 patients were enrolled in an IRB approved study at the NIH. Sequencing of *ADA2* (formerly known as *CECR1*), the gene encoding ADA2 (adenosine deaminase 2), was obtained on all patients. Clinical, laboratory, and radiographic testing were obtained at each visit.

Results: 35 patients had germline biallelic mutations in *ADA2*. In 3 symptomatic siblings with low ADA2 serum levels, only one mutation has been found thus far. Serum ADA2 levels were obtained in 32 patients. The mean level was 45.4% of age-matched controls (range 36.7-61.6%). 25/36 patients reported recurrent fevers. 24 (66%) patients had a history of at least one stroke, with 18 having ischemic strokes in small vessel distribution, 1 having only hemorrhagic strokes and 5 having both. The average age at the time of the first stroke was 6.2 years (range 5 months-24 years). The average number of strokes was 3 (range 1-11). Skin manifestations were found in 32 (84%) of patients and included livedo in 28, cutaneous polyarteritis nodosa in 22, and Raynaud's in 8. Abdominal ultrasound revealed hepatomegaly in 18 patients (74%) and splenomegaly in 22 patients (58%). Portal hypertension was observed in 7 patients (18%). Abdominal MRA was abnormal in 7 patients, revealing arteritis and aneurysms. Significant peripheral vasculopathy was seen in 3 patients, one requiring amputation of gangrenous digits. Systemic hypertension was observed in 10 patients (26%), with one patient developing posterior reversible encephalopathy syndrome (PRES) in relation to hypertension. Prolonged QT was noted in 5 patients (13%).

Laboratory evaluation revealed hypogammaglobulinemia, especially IgM, in 27 patients (71%). Specific antibody response to vaccines were inadequate in 5 of 16 patients tested. Lymphocyte phenotyping revealed arrested B cell class switching in 22 of 26 patients (85%) tested. 25/38 (66%) demonstrated hematologic abnormalities including anemia, leukopenia, lymphopenia and/or thrombocytopenia with 7 patients developing pancytopenia and 1 patient with pure red cell aplasia. Three patients had bone marrow failure and underwent bone marrow transplantation, with two patients requiring a second transplant.

Conclusion: The spectrum of DADA2 continues to expand to include ischemic and hemorrhagic strokes, skin findings, portal and systemic hypertension, hematologic abnormalities, vascular pathology, immune deficiency and bone marrow failure. As the phenotypic presentation is likely to continue to expand, it is important to investigate any new complaints. In addition, it is important to monitor patients closely as their phenotypic presentation can change with time.

Treatment of Cardiac Sarcoidosis: A Comparative Study of Steroids Alone Versus Steroids Associated with Immunosuppressive Drugs

Thomas Ballul¹, Raphaël Borie¹, Bruno Crestani¹, Eric Daugas¹, Vincent Descamps¹, Philippe Dieude¹, Antoine Dossier¹, Fabrice Extramiana¹, Thomas Papo¹ and Karim Sacre², ¹Université Paris-Diderot, Paris, France, ²Bichat Hospital, Paris Diderot University, Paris, France

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases I: DADA2, Cardiac Sarcoid, Cancer Immunotherapy

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30 PM-6:00 PM

Background/Purpose: To analyze the efficacy of steroids and immunosuppressive drugs in the prevention of relapse in cardiac sarcoidosis.

Methods: In this monocentric retrospective study, all consecutive patients with histologically proven sarcoidosis hospitalized from January 2012 to December 2016 were considered. All patients admitted for treatment of symptomatic cardiac sarcoidosis (CS) were included. Patients received either steroids or steroids plus immunosuppressive (IS) drugs for CS treatment. The efficacy of each treatment strategy (steroids vs steroids + IS) was assessed by the cardiac relapses rate during follow up.

Results: 326 consecutive patients with histologically proven sarcoidosis were screened. Among them, 36(11%) were admitted for symptomatic cardiac sarcoidosis (20 (55.5%) men, median age at diagnosis 48.5 [22.8-76]). 24 patients received steroids and 12 received steroids + IS (azathioprine n=5, methotrexate n=5, cyclophosphamide n=2). Over a median follow up of 3.6 [1-15.2] years, 13 (36.1%) patients suffered a cardiac relapse including third degree heart block (n=3), reduced left ventricular ejection fraction <50% (n=3), left ventricular dyskinesia (n=2) and ventricular tachycardia (n=2). The rate of cardiac relapse was 45.8% in the steroids group and 16.7% in the steroid + IS group (p=0.048). The median time to relapse did not significantly differ between groups (1.5 [0.5-6.8] vs 1.5 [1-3.2] years). Severe infection occurred in 4 patients under steroids alone and in 2 patients under steroids+ IS therapy (p=ns)

Conclusion: In cardiac sarcoidosis relapses occur frequently. The association of steroids with immunosuppressive drugs appears to reduce the risk of cardiac relapse, as compared to steroids alone.

Characteristic of patients

	All (n=36)	Steroids (n=24)	Steroids and IS (n=12)	p

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases I: DADA2, Cardiac Sarcoid, Cancer Immunotherapy

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30 PM-6:00 PM

Background/Purpose: Cardiac sarcoidosis has been noted in 2-7% of patients with sarcoidosis. However, the incidence is >20% based on necropsy data. Given the poor yield of biopsy due to patchy involvement of the disease, the diagnosis of cardiac sarcoidosis has increasingly favored the use of 18F-fluorodeoxyglucose positron emission tomography/computed tomography (18-FDG PET/CT) and gadolinium enhanced cardiac magnetic resonance imaging (CMR) scans. To date, there is little data to suggest the optimal dose and duration of corticosteroids and steroid-sparing agents, and the efficacy of these agents on cardiac sarcoidosis. We aimed to study whether patients on steroids for presumed or proven cardiac sarcoidosis had fewer ventricular arrhythmias as recorded on Implantable Cardiac Defibrillator (ICD) monitoring.

Methods: We completed a retrospective review of patients diagnosed with cardiac sarcoidosis between June 1, 2006 and June 1, 2016 at our institution. Patients with evidence of cardiac involvement on either 18 FDG-PET/CT, CMR, or endomyocardial biopsy (EMB) were selected. We evaluated the effect of corticosteroids on FDG-PET/CT and performed paired T test analysis on the number of ventricular tachycardia (VT) and non-sustained ventricular tachycardia (NSVT) events for 3 months in patients on and off high dose corticosteroids (prednisone >30 mg).

Results: We identified 1,298 patients diagnosed with sarcoidosis of whom 59 met inclusion criteria for a diagnosis of presumed or proven cardiac sarcoidosis. Among 59 patients, 19 had EMB of whom 8 were positive for sarcoidosis. 25 patients had serial 18-FDG PET/CT before and after treatment with corticosteroids. Of those, 12 (48%) had complete resolution after corticosteroids, 7 (28.0%) had partial resolution, 4 (16.0%) had increased uptake after corticosteroids, and 2 (1%) had negative serial 18-FDG PET/CT scans. There was a higher mean number of VT events during the corticosteroid free period compared to the high dose corticosteroid treatment period, though not statistically significant (21 vs 1 event, p=0.2, n=16). A similar trend was seen in the number of NSVT events (372 vs 7 events, p=0.3, n=16).

Conclusion: Our data suggests that treatment of presumed cardiac sarcoidosis with corticosteroids shows improvement in hypermetabolic activity on 18 FDG-PET/CT. Although our observations are limited due to a small sample size, we found a trend towards improvement in ventricular arrhythmias while on corticosteroids. Given the difficulty in diagnosing cardiac sarcoidosis by biopsy, treatment of cardiac sarcoid purely based on imaging findings should be considered. Future prospective trials are needed to validate our findings.

Table 1: Total number of patients who had ventricular tachycardia or non-sustained ventricular tachycardia events while receiving any of the following treatments

	No. patients	n (%) with any event
Off steroids		
Ventricular tachycardia	34	17 (50.0)
Non-sustained ventricular tachycardia	35	16 (45.7)
Steroids > 30mg		
Ventricular tachycardia	24	8 (33.3)
Non-sustained ventricular tachycardia	23	5 (21.7)
Steroids < 30mg		
Ventricular tachycardia	21	7 (33.3)
Non-sustained ventricular tachycardia	21	11 (52.4)
Steroid sparing agent		
Ventricular tachycardia	21	6 (31.6)
Non-sustained ventricular tachycardia	19	8 (42.1)

Markovic⁴ and Uma Thanarajasingam⁵, ¹Internal Medicine, Mayo Clinic, Rochester, MN, ²Health Sciences Research, Mayo Clinic College of Medicine and Science, Rochester, MN, ³Oncology, Mayo Clinic, Rochester, MN, ⁴Department of Medicine and Oncology, Mayo Clinic, Rochester, MN, ⁵Department of Rheumatology, Mayo Clinic, Rochester, MN

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases I: DADA2, Cardiac Sarcoid, Cancer Immunotherapy

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30 PM-6:00 PM

Background/Purpose: Rheumatologists are increasingly called upon to manage the autoimmune side effects of immune-checkpoint inhibitors (ICIs). However, these new entities are poorly understood and treatment often relies upon retrospective studies and expert opinion. The objective of this study is to describe the prevalence, clinical presentation, and management of a large cohort of patients with rheumatic immune-related adverse effects (Rh-irAEs) from immune checkpoint inhibitor therapy.

Methods: From a database of all patients who received any immune-checkpoint inhibitor at the Mayo Clinic Rochester, Minnesota campus between January 1st, 2011 and March 1st, 2018, we identified those with Rh-irAEs using diagnostic codes, search terms, and manual chart review.

Results: Of the 1,293 patients who received any checkpoint inhibitor, 43 were clinically diagnosed with Rh-irAEs. Eighteen patients with Rh-irAEs who received ICI therapy elsewhere were also analyzed. Clinical syndromes included inflammatory

arthritis (IA) (n=37, prevalence 2%), myopathy (n=10, 0.8%), and connective tissue disease (CTD) (n=14, 0.7%). IA was most commonly polyarticular and 28 patients (76%) required glucocorticoids. Mean treatment duration was 20 weeks (SD 23 weeks). Seven of these patients (19%) also received disease-modifying drugs and 3 patients (8%) required discontinuation of ICI therapy. Myopathy was treated with glucocorticoids in all cases for a mean duration of 15 weeks (SD 17 weeks) and led to two deaths and permanent ICI discontinuation in 9 patients (90%). CTD included cases of sicca syndrome, systemic sclerosis, and vasculitis. Nine of these patients (64%) were treated with glucocorticoids for a mean duration of 31 weeks (SD 30 weeks) and 3 patients (21%) had complete resolution of their Rh-irAE symptoms.

Conclusion: This study represents the largest cohort of Rh-irAEs to date. Most patients required long courses of treatment with only a minority achieving complete symptom resolution. Prospective, multicenter studies are necessary to determine the optimal management of these emerging disorders and further define immunologic phenotypes.

Figure 1. Time of Rh-irAE symptom onset after starting ICI therapy.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

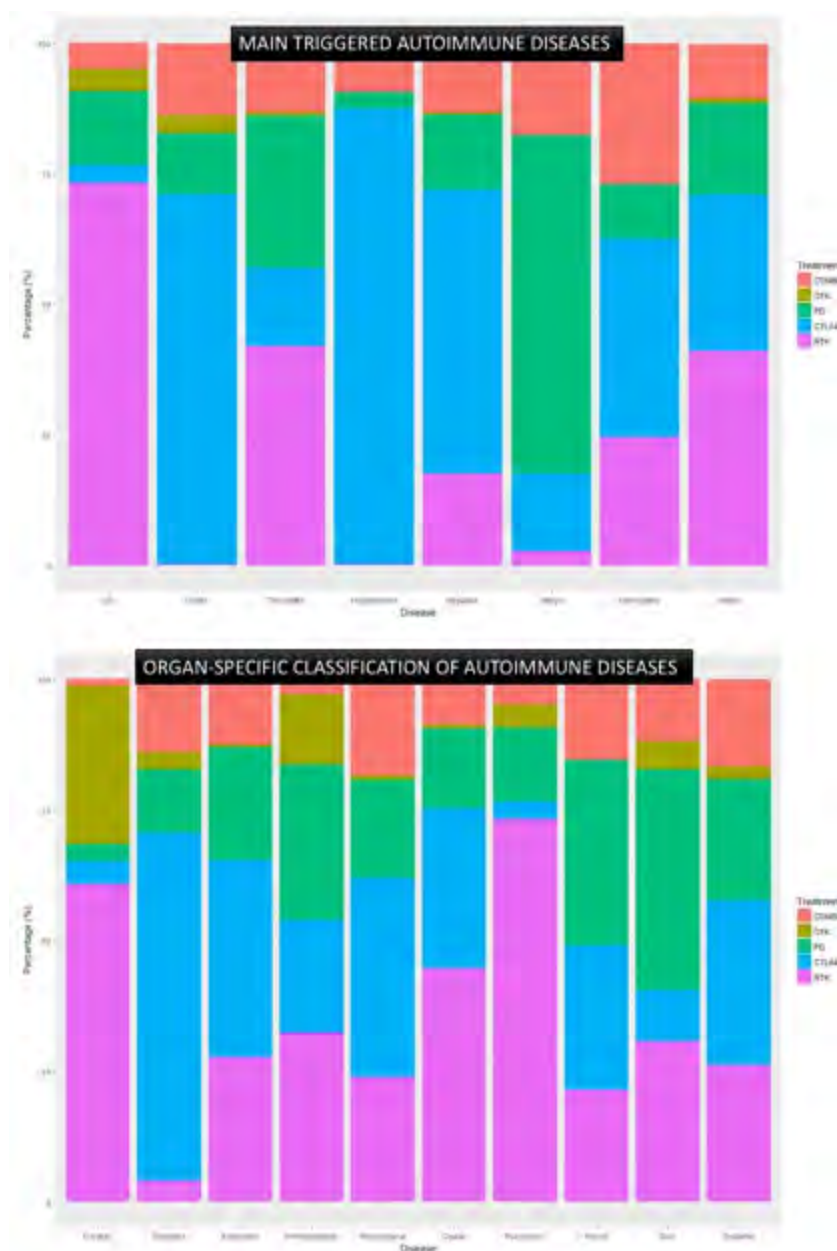

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases I: DADA2, Cardiac Sarcoid, Cancer Immunotherapy

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30 PM-6:00 PM

Background/Purpose: The scenario of biological-triggered autoimmune diseases has dramatically changed in recent years due to the increasing use of biologics in patients with solid cancers.

Methods: In 2006, the SEMI Spanish Study Group on Autoimmune Diseases (GEAS) created the BIOGEAS project, including the BIOGEAS systematic review of the literature (articles published until January 1st 2018) using the terms of the main groups of cancer immunotherapies that were crossed with autoimmune diseases using MedDRA terms (MedDRAVR 15.0). The autoimmune basis of the reported adverse event was defined according to the fulfilment of the corresponding international criteria, biopsy-proven histopathology, positive autoantibodies and/or resolution after corticosteroid treatment.

Results: We identified 6158 patients who developed 6288 autoimmune adverse events in patients with solid (n=5849) and haematological (n=309) neoplasia. The two main groups of cancer immunotherapies involved included checkpoint inhibitors in 3844 (mainly the CTL4 inhibitor ipilimumab in 1973 cases and the PD1 inhibitors pembrolizumab and nivolumab in 712 and 700 cases, respectively) and tyrosinekinase (TK) inhibitors in 2443 cases (mainly erlotinib and imatinib in 499 and 437 cases, respectively). Organ-specific classification of triggered autoimmune diseases included endocrine (n=1723), digestive (n=1591), pulmonary (n=1337), cutaneous (n=531), systemic/rheumatic (n=331), cardiac (n=304), neurological (n=218), ocular (n=150), haematological (n=38) and renal (n=69) autoimmune diseases. **Figure** shows distribution of the main pharmacological groups according to the most frequently-reported individual autoimmune diseases and to their classification by organ/system. The main organ-specific patterns of association (> 50% of cases related to a specific pharmacological pathway) are interstitial lung disease in patients treated with drugs targeting TK receptor; colitis, hepatitis and hypophysitis in those treated with CTL4 inhibitors; and vitiligo in those treated with drugs targeting the PD/PD-1 pathway.

Conclusion: More than 6000 cases of autoimmune diseases triggered by cancer immunotherapies have been reported. A multidisciplinary approach is essential, with a central role for the specialist in autoimmune diseases who should get used to managing not only spontaneous autoimmune diseases, but also the increasing number of biological-induced autoimmune diseases that may be forecast.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases I: DADA2, Cardiac Sarcoid, Cancer Immunotherapy

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30 PM-6:00 PM

Background/Purpose: Rheumatic immune-related adverse events (irAEs) from PD-1 inhibitor immune checkpoint immunotherapy can not only lead to cessation of immunotherapy, but also can be disabling and can also persist beyond cessation. Currently no biomarker can predict rheumatic irAEs. However, it is known that oncological response to PD-1 inhibitor therapy is predicted by pre-treatment neutrophil to lymphocyte ratio (NLR) and given that rheumatic irAEs are strongly associated with an oncological response to PD-1 inhibitor therapy, it therefore stands to reason that rheumatic irAEs and NLR prior to therapy might be associated, though this is currently unknown.

Methods: We examined the relationship between NLR and the development of rheumatic irAEs in all patients first treated with a PD-1 inhibitor in our center prior to January 1, 2017, as identified by hospital pharmacy dispensing records. Patients were included if a NLR could be calculated from a complete blood count performed at the institutional laboratory within two weeks prior to commencing treatment; this was subsequently log-transformed. The relationship between NLR and the development of rheumatic irAEs was assessed using the two-tailed Fisher's Exact Test, with NLR cut-point determined using recursive partitioning algorithm. Treatment efficacy was examined using oncological response, with responders defined as those who achieved at least partial response. The relationship between oncological response and NLR was also examined using identical methodology. Analysis was performed using R 3.5.0 and the rpart package.

Results: Out of the 211 patients included in the study, 15 developed a rheumatic irAE. The median age was 66 years and median treatment duration was 19 months. The primary cancer was melanoma in 91 patients (41%) and non-small cell lung cancer in 82 patients (39%). Nivolumab was used in 127 patients (57%). The log-NLR cut-point of 1.7 (untransformed = 5.5), as determined by recursive partitioning, is comparable to similar cut-points used in previous studies. Using this cut-point, there was a statistically significant association between lower log-NLR and the development of rheumatic irAEs ($p = 0.007$). At the same cut-point, there was also a statistically significant relationship between lower log-NLR and oncological response to therapy ($p < 0.001$).

Conclusion: Lower pre-treatment NLR prospectively predicts the development of rheumatic irAEs in our cohort, using methodology comparable to previous studies demonstrating the relationship between NLR and oncological response. Its promise as a biomarker for rheumatic irAEs should be explored in larger cohorts.

Physician Opioid Prescribing Patterns and Risk for Chronic Opioid Use Among Rheumatoid Arthritis Patients

Yvonne C. Lee¹, Bing Lu², Hongshu Guan³, Jeffrey Greenberg⁴, Joel Kremer⁵ and Daniel Solomon⁶, ¹Northwestern University Feinberg School of Medicine, Chicago, IL, ²Rheumatology Immunology & Allergy, Brigham & Women's Hospital, Boston, MA, ³Division of Rheumatology, Immunology and Allergy, Brigham and Women's Hospital, Boston, MA, ⁴Corrona, LLC, Waltham, MA, ⁵Albany Medical College and The Center for Rheumatology, Albany, NY, ⁶Rheumatology, Brigham and Women's Hospital, Boston, MA

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Pain Mechanisms – Basic and Clinical Science

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30 PM-6:00 PM

Background/Purpose: Experts have implicated physician prescribing rates as a contributing factor to the opioid crisis. However, little is known about heterogeneity in these patterns and its effects on chronic opioid use. Our objectives were to: 1) identify the extent to which US physicians varied in baseline opioid prescribing rates, and 2) determine the implications of physicians' baseline opioid prescribing rates on future probability of chronic opioid use among rheumatoid arthritis (RA) patients.

Methods: Data were obtained from the Corrona Rheumatoid Arthritis Registry. To ensure robust baseline opioid prescribing information, physicians were included in the analyses only if they contributed ≥ 10 RA patients within the first

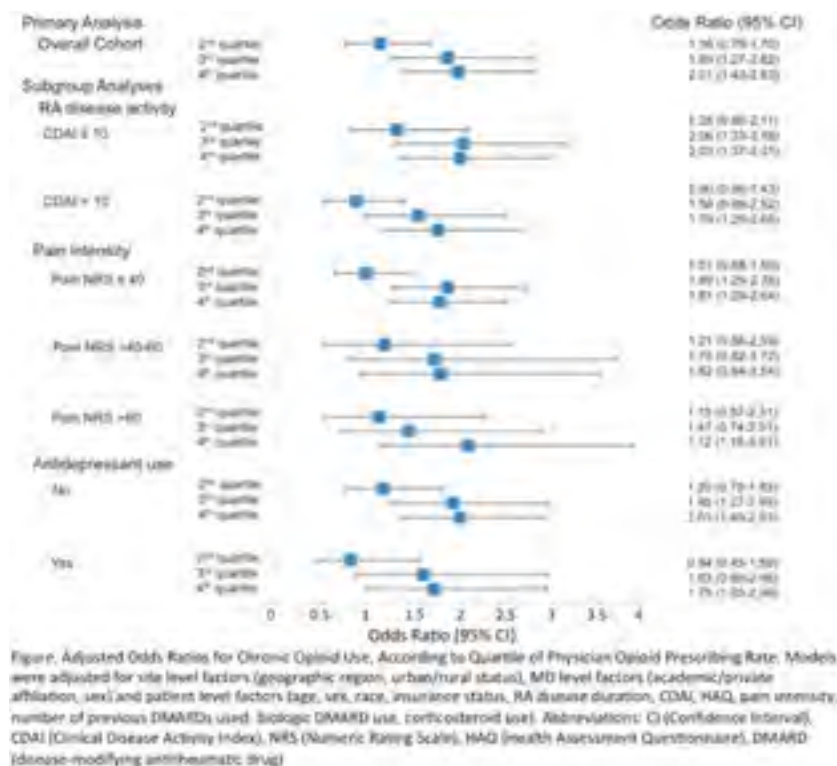

Figure 6. Adjusted Odds Ratios for Chronic Opioid Use, According to Quartile of Physician Opioid Prescribing Rate. Models were adjusted for site level factors (geographic region, urban/rural status), MD level factors (academic/private affiliation, sex) and patient level factors (age, sex, race, insurance status, RA disease duration, CDAI, HAQ, pain intensity, number of previous DMARDs used, biologic DMARD use, corticosteroid use). Abbreviations: CI (Confidence Interval), CDAI (Clinical Disease Activity Index), NRS (Numeric Rating Scale), HAQ (Health Assessment Questionnaire), DMARD (disease-modifying antirheumatic drug).

12 months of participation in the registry. RA patients were included if they: 1) were patients of the included physicians, 2) had ≥ 12 months follow-up, and 3) were not prevalent opioid users at study entry. Baseline opioid prescribing rates were calculated using data from RA patients seen within the first 12 months after a physician began participating in the registry, dividing the number of patients reporting opioid use by the number of patients seen during that year. The baseline opioid prescribing rate was then assessed as the exposure of interest in models that predicted chronic opioid use in patients seen subsequent to the baseline 12 month period. Generalized linear mixed models, controlling for relevant patient, physician and site characteristics, were used to assess the relationship between baseline prescribing rates and future chronic opioid use. Subgroup analyses were done to examine heterogeneity across the following clinical characteristics: 1) disease activity, defined by Clinical Disease Activity Index (CDAI) score ≤ 10 vs. > 10 ; 2) pain intensity (≤ 40 , $> 40-60$, > 60 out of 100); and 3) antidepressant use (yes/no). Interaction terms were used to assess the statistical significance of differences between subgroups.

Results: Among the 148 physicians in the initial cohort, baseline opioid prescribing rates varied from 0-70%, with a median of 27% and interquartile range of 18-37%. Among the 9337 RA patients included in the period after the baseline 12 months, physician opioid prescribing rates during the baseline period were significantly associated with risk for chronic opioid use (ref: lowest quartile; 2nd quartile: OR 1.16, 95% CI 0.79-1.70, 3rd quartile: 1.89, 95% CI 1.27-2.82, 4th quartile: OR 2.01; 95% CI 1.43-2.83) (Figure). No statistically significant differences were noted between subgroups.

Conclusion: Rates of baseline opioid prescribing varied widely. A physician's baseline opioid prescribing rate was a strong predictor of whether a patient would become a chronic opioid user in the future, even after controlling for patient characteristics.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Pain Mechanisms – Basic and Clinical Science

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30 PM-6:00 PM

Background/Purpose: RA patients differ in the degree to which pain interferes with function. To improve function, an understanding of this diversity is needed. Our objectives were to: (1) understand the degree to which pain interfered with specific activities, (2) characterize the distribution of pain intensity that does not interfere with activities (ie, non-interfering pain), and (3) identify characteristics associated with non-interfering pain.

Methods: Data were derived from subjects with rheumatologist-confirmed RA in FORWARD—The National Databank for Rheumatic Diseases. Subjects completed 8 items from the PROMIS Pain Interference Item Bank that asked the degree to which pain interfered with activities (from “not at all” to “very much”). If subjects reported any pain interference, they were asked, “At what level would pain no longer interfere with this activity?” Responses were collected using a 0-10 numeric rating scale (NRS; 10 = severe pain). Internal consistency of non-interfering pain items was assessed using Cronbach’s alpha and item-total correlations to determine if an overall mean of non-interfering pain could be calculated. Multiple linear regression analyses examined associations between non-interfering pain and the following characteristics: age, sex, disease duration, BMI, Rheumatic Disease Comorbidity Index, disability (Health Assessment Questionnaire), pain intensity NRS, fatigue NRS, self-reported current depression, sleep problems NRS, and fibromyalgias (Polysymptomatic Distress Scale).

Results: As of April 2018, 1048 RA patients had completed questionnaires. Pain interference was most common for daily activities (70.1%) and least common for ability to concentrate (46.7%) (Table). The mean level at which pain no longer interfered with activities ranged from 2.7 ± 2.2 for ability to fall/stay asleep to 3.1 ± 2.1 for daily activities. Internal consistency across items was high (Cronbach’s alpha = 0.97). Overall, the mean threshold for non-interfering pain was 2.9 ± 2.0 . Independent predictors of non-interfering pain were greater pain severity ($\beta = 0.21$, $p < 0.0001$) and lower fatigue ($\beta = -0.11$, $p = 0.04$). Other characteristics tested were not statistically significant at alpha = 0.05.

Conclusion: The mean pain level that did not interfere with activities was 3 (on a 0-10 scale) and did not vary depending on activity type. This may suggest that RA patients consider non-interfering pain to be a concept similar across different situations. Factors that may contribute to high non-interfering pain levels include pain and fatigue. Future studies are needed to determine if these associations, particularly that between pain intensity and non-interfering pain, reflect an artifact in rating (eg, patients who rate pain highly may also rate non-interfering pain highly) or underlying pathways that can be targeted to decrease the functional impact of pain.

Table The proportion of RA patients who experience pain interference and the pain level at which pain does not interfere with activities (N = 1048)

Activity ¹	PROMIS Pain Interference Questions % Experienced Pain Interference	Pain Level That Would Not Interfere With Activity	
		Mean \pm SD	Median (IQR)
Daily activities	70.1%	3.1 ± 2.1	3 (2,4)
Work around the house	69.2%	3.1 ± 2.1	3 (2,4)
Household chores	66.9%	3.0 ± 2.1	2 (2,4)
Ability to fall asleep/stay asleep	61.6%	2.7 ± 2.2	2 (1,4)
Ability to work	62.9%	2.9 ± 2.2	2 (1,4)
Enjoyment of life	57.8%	2.8 ± 2.3	2 (1,4)
Social activities	55.2%	3.1 ± 2.1	3 (2,4)
Ability to concentrate	46.7%	2.8 ± 2.1	2 (1,4)

Abbreviation: IQR, interquartile range.

¹ Total number who responded to each question was 1047 for daily activities, 1046 for work around the house and household chores, 1044 for social activities, 1041 for ability to concentrate, 1040 for enjoyment of life, 1039 for fall asleep/stay asleep, and 458 for ability to work; 575 subjects did not answer the latter question because they were retired or otherwise not working.

Michael Stein¹ and Wayne Ray⁵, ¹Department of Medicine, Vanderbilt University Medical Center, Nashville, TN, ²Pediatrics, Vanderbilt University Medical Center, Nashville, TN, ³Department of Biostatistics, Vanderbilt University Medical Center, Nashville, TN, ⁴Anesthesiology, Vanderbilt University Medical Center, Nashville, TN, ⁵Health Policy, Vanderbilt University Medical Center, Nashville, TN

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Pain Mechanisms – Basic and Clinical Science

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30 PM-6:00 PM

Background/Purpose: Hydrocodone, codeine, oxycodone, and tramadol are frequently prescribed for moderate pain in adolescents. However, pharmacokinetic and pharmacodynamic differences between these short-acting opioids could affect their relative safety. Although tramadol, which is both a serotonin/norepinephrine reuptake inhibitor and a μ -opioid agonist, has been considered a safer opioid, limited data support this perception. We aimed to compare the occurrence of opioid-related adverse events for adolescents without cancer or other severe conditions taking commonly prescribed short-acting opioids.

Methods: Retrospective cohort study in Tennessee Medicaid, 1999-2011. We studied Medicaid enrollees 12 to 17 years of age without cancer, other severe conditions or evidence of substance abuse with filled prescriptions for study opioids. Exposure was defined as current or recent use of hydrocodone, codeine, oxycodone, and tramadol. The primary outcome was an emergency department visit, hospital admission, or death adjudicated after review of medical records as plausibly related to opioid use, classified as serious if there was hospitalization or opioid-related escalation of care. Propensity-score adjusted hazard ratios (HRs) were calculated with hydrocodone as the reference category.

Results: The incidence of opioid-related adverse events per 10,000 person-years of opioid exposure was 317.0 for tramadol (47/1,483 person-years), 229.7 for oxycodone (43/1,872), 91.2 for codeine (58/6,359), and 97.5 for hydrocodone (127 events/13,026). The adjusted HR for tramadol was 2.72 (1.84-4.03), with a comparable increase for serious events (HR = 2.92 [1.45-5.88]). Risk for codeine was not significantly increased (HR = 1.35 [0.95-1.90]). The risk for all events was increased for oxycodone (HR = 1.77 [1.17-2.68]), but that for serious events was not (HR = 0.94 [0.32-2.73]). The increased risk for tramadol was consistently present in multiple sensitivity analyses to reduce residual confounding or misclassification and in an analysis with codeine as the reference category (all events: HR = 1.86 [1.16-2.98]; serious events: HR = 2.74 [1.33-5.64]).

Conclusion: In this cohort of adolescents without cancer or other severe conditions prescribed short-acting opioids, the incidence of opioid-related adverse events for tramadol was consistently greater than that for either hydrocodone or codeine, including for the more serious events leading to hospitalization or escalation of care.

¹Boston University School of Medicine, Boston, MA, ²Departments of Anesthesiology and Pharmacology, Columbia University Medical Center, New York, NY, ³University of Iowa, Iowa City, IA, ⁴Epidemiology and Biostatistics, University of California, San Francisco, San Francisco, CA, ⁵University of Alabama Birmingham, Birmingham, AL, ⁶Clinical Epidemiology Research and Training Unit, Boston University School of Medicine, Boston, MA

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Pain Mechanisms – Basic and Clinical Science

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30 PM-6:00 PM

Background/Purpose: Self-reported descriptors of pain in knee osteoarthritis (OA) such as burning and stabbing pain are suggestive of a neuropathic component of pain beyond that of nociceptive pain from structural pathology. However, such descriptors do not necessarily equate to specific pain mechanisms. While there is evidence of proprioceptive and vibration perception abnormalities in knee OA, to date, there have been no studies documenting objective neuropathy involving nociceptive pathways in knee OA. We used the StEP [Scholz, 2009] protocol, which distinguishes neuropathic vs. non-neuropathic pain with feasible bedside evaluations to assess the prevalence of clinical evidence of neuropathy in knee OA.

Methods: The Multicenter Osteoarthritis (MOST) Study is a NIH-funded longitudinal cohort study of persons with or at risk of knee OA. Subjects were evaluated with a peripheral neuropathy screen, and a standardized somatosensory assessment at

the knee with von Frey 2 g and 26 g monofilaments (static allodynia, hypoesthesia), brush (dynamic allodynia), and pinprick (hyperalgesia), each assessed with 4 trials. Abnormal responses were defined as pain (allodynia or hyperalgesia) or no response (hypoesthesia) in $\geq 3/4$ trials. We excluded those with TKR. We evaluated the prevalence of each somatosensory abnormality stratified by # of knees with radiographic knee OA (ROA) and with frequent knee pain (FKP).

Results: There were 1821 participants (mean age 67, mean BMI 30, 62% female, 46% with FKP in either knee, 3.9% with +peripheral neuropathy screen); 722 without ROA (39.6%), 413 with unilateral ROA (22.6%), and 686 with bilateral ROA (37.6%). The prevalence of allodynia, hyperalgesia, and hypoesthesia was $<5\%$ in all groups, regardless of # of knees with ROA or FKP (**Figure**). For those with unilateral ROA or unilateral FKP, the prevalence of abnormalities were similar in the ipsilateral and contralateral knee.

Conclusion: Using standardized bedside assessment tools for the clinical distinction between neuropathic and nociceptive pain, we observed an overall low prevalence of somatosensory changes that would be consistent with neuropathy. However, these changes did not meet the diagnostic threshold criteria of neuropathic pain, and the presence of abnormalities did not differ by # of knees with ROA or FKP, or by laterality. We cannot rule out subclinical neuropathy that could be detected by nerve conduction study or skin biopsy. Nonetheless, we did not find overt evidence of nerve lesion in those with ROA at a greater frequency than those without ROA, and similar findings for FKP vs. no FKP. Further, the prevalence of abnormalities detected did not approach that reported for “neuropathic-like” pain by self-report on Pain Detect. Patient-reported symptoms may not directly reflect underlying mechanisms, highlighting the need for identifying objective means of pain phenotyping to move towards mechanism-based treatments for OA pain.

Relation of Sensitization and Conditioned Pain Modulation to Post-Knee Replacement Pain

Tuhina Neogi¹, Na Wang², Cora E. Lewis³, Michael C. Nevitt⁴ and Laura Frey-Law⁵, ¹Clinical Epidemiology Research and Training Unit, Boston University School of Medicine, Boston, MA, ²Boston University School of Medicine, Boston, MA, ³University of Alabama Birmingham, Birmingham, AL, ⁴Epidemiology and Biostatistics, University of California, San Francisco, San Francisco, CA, ⁵University of Iowa, Iowa City, IA

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Pain Mechanisms – Basic and Clinical Science

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30 PM-6:00 PM

Background/Purpose: Alterations in pain processing, such as pain sensitization and inadequate conditioned pain modulation (CPM), may contribute to the observed pain persistence post-knee replacement (KR) in 20-30% of patients, but studies to date have been conflicting. Further, many studies have been small and comprised only subjects who experienced post-KR pain improvement. It is therefore not known if altered pain processing is present in those with persistent post-KR pain. We undertook a comprehensive evaluation of pain sensitization and CPM in relation to post-KR pain.

Methods: The Multicenter Osteoarthritis MOST Study is a NIH-funded longitudinal cohort of persons with or at high risk of knee OA. We evaluated subjects prior to KR and 12-18 months post-KR with a standardized somatosensory evaluation of mechanical pressure pain thresholds PPT at the wrist and patellae, temporal summation TS at the wrist, and WOMAC pain questionnaires. CPM was assessed post-KR. PPT was assessed with an algometer 1cm² tip, 0.5 Kg/sec as the point at which pressure first changed to slight pain; 3 trials at each anatomic site were averaged. Lower PPT indicates more pain sensitivity, reflecting peripheral sensitization at a site of disease and central sensitization at a site without disease. Temporal summation, indicating central sensitization, was defined by increased pain during repeated mechanical stimulation 1 Hz x 30-sec with a 60 g monofilament. CPM was assessed using the forearm ischemia test. Inadequate CPM was defined as a ratio of <1, indicating lack of increase in post-conditioning stimulus PPT. We evaluated the relation of pre- and post-KR PPT and TS, and of post-KR CPM to post-KR WOMAC pain and to a minimal clinically important difference MCID in WOMAC pain, adjusting for potential confounders.

Results: There were 171 subjects in our study who were seen before and after their KR (mean age 69, 62% female, mean BMI 31). Pre-KR PPT and pre-KR TS were not associated with post-KR WOMAC pain (**Table**). Post-KR TS and inadequate CPM were significantly associated with a worse WOMAC pain score post-KR, and non significantly with lower likelihood of achieving the MCID.

Conclusion: Pre-KR PPT and TS were not associated with post-KR pain levels or pain improvement. Thus, while PPT and TS are associated with pain severity overall in knee OA subjects, they do not adequately predict pain response to KR. Post-KR presence of TS and inadequate CPM were associated with worse pain post-KR, suggesting a role for central altered pain processing in pain persistence post-KR, and provide support for pain phenotyping to guide mechanism-based treatment approaches.

	Post-KR WOMAC Pain		Minimal Clinically Important Difference (MCID) in Post-KR WOMAC Pain **	
	Mean difference in WOMAC Pain* (95% CI)	P-value	OR (95% CI)	P-value
Pre-KR Measures:				
Pre-KR TS	0.11 (-0.31, 0.54)	0.6	0.93 (0.70, 1.24)	0.6
Pre-KR PPT at wrist	-0.19 (-0.59, 0.20)	0.3	1.11 (0.84, 1.47)	0.5
Pre-KR PPT at patella	-0.07 (-0.32, 0.19)	0.6	1.02 (0.84, 1.23)	0.9
Post-KR Measures:				
Post-KR TS	0.82 (0.19, 1.45)	0.01	0.73 (0.44, 1.21)	0.2
Post-KR PPT wrist	-0.21 (-0.63, 0.21)	0.3	0.99 (0.75, 1.31)	0.9
Post-KR PPT patella	-0.15 (-0.45, 0.15)	0.3	1.02 (0.82, 1.26)	0.9
Inadequate CPM (<1)	1.47 (0.26, 2.68)	0.02	0.78 (0.56, 3.00)	0.6

* Mean differences refers to an increase (positive value, indicating worsened pain) or decrease (negative value indicating pain improvement) in WOMAC pain post-KR relative to pre-KR value per unit increase in continuous variables (TS, PPT) or for those with vs. without that feature for dichotomous variables (inadequate CPM)

** Defined as an improvement of at least 5.6/20 (Escobar, et al. 2007)

Analyses were adjusted for age, sex, BMI, depressive symptoms, pain catastrophizing, clinic site, time of clinic assessments relative to KR date

Characterization of the Pharmacology and Pharmacokinetics of Cntx-4975, a High-Purity, Synthetic Trans-Capsaicin in Clinical Development for the Treatment of Moderate to Severe OA Knee Pain

James Campbell, **Randall Stevens** and Peter Hanson, Centrexion Therapeutics, Boston, MA

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Pain Mechanisms – Basic and Clinical Science

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30 PM-6:00 PM

Background/Purpose: CNTX-4975, a highly purified, synthetic *trans*-capsaicin and long-acting, non-opioid analgesic in phase 3 trials for moderate to severe OA knee pain, has demonstrated safety and efficacy in a randomized, phase 2 study. CNTX-4975 targets the transient receptor potential vanilloid 1, producing analgesia via reversible desensitization of end terminals of primary afferent pain fibers. We report pharmacologic and pharmacokinetic (PK) data from preclinical and human studies of CNTX-4975.

Methods: An in vitro pharmacologic study, using human and rat cells, assessed the activity of 10 μ M CNTX-4975 at 113 receptors and 42 enzymes to identify potential off-target effects. In an in vivo rat model, the analgesic efficacy of a single intra-operative instillation of CNTX-4975 (0.075–7.5 mg/mL) in incised rat paws was evaluated by assessing response to thermal stimuli after surgery compared with subcutaneous buprenorphine (50 μ g/kg, 1 hour before test). Tolerability of IA or intra-tendon injections of CNTX-4975 was evaluated in 11 local tolerance studies conducted in rabbits, rats, and dogs using doses (0.12–0.60 mg/mL) that resulted in considerably higher systemic exposures than those investigated in human trials. Phase 1 and 2 human studies assessed efficacy, safety, and PK of CNTX-4975 (0.01–15 mg) across multiple indications, including moderate to severe OA knee pain. PK parameters included peak plasma concentration (C_{max}), systemic exposure (mean area under the curve to last measured time point [AUC_{0-last}]), half-life ($t_{1/2}$), and time to C_{max} (T_{max}).

Results: In the in vitro pharmacology study, CNTX-4975 10 μ M demonstrated activity at 1 benzodiazepine and 1 melatonin receptor. The 10 μ M concentration was up to 2000 times higher than that detected in plasma following the highest dose administered in human studies (15 mg intra-operatively; 2 mg IA). No pharmacologic effects from activity at these receptors are expected with clinical doses of CNTX-4975. In the postsurgical rat pain model, a single intraoperative dose of CNTX-4975 0.25 mg/mL substantially relieved thermal hyperalgesia, and 7.5 mg/mL demonstrated efficacy comparable to buprenorphine; efficacy was sustained for several days to 1 week, depending on the dose. In local tolerance studies, CNTX-4975 was well tolerated, and no local toxicity was observed following a single IA injection of CNTX-4975 into rat knees. In human trials, PK analyses demonstrated rapid absorption of CNTX-4975 following IA knee injection. C_{max} and AUC_{0-last} for CNTX-4975 were linearly related to dose over the range studied and across indications (0.1–15 mg); approximate T_{max} <1 hour was not dose-dependent. Mean $t_{1/2}$ was 0.3–3.6 hours. C_{max} and AUC_{0-last} did not exceed mean values of 2.6 ng/mL and 4 ng•h/mL, respectively.

Conclusion: A single IA injection of CNTX-4975 demonstrated rapid absorption in humans, and was associated with substantial, prolonged efficacy and no local toxicities in preclinical studies. These findings are consistent with the mechanism of action of CNTX-4975 and safety and tolerability results from open-label and randomized, phase 2 clinical trials.

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30 PM-6:00 PM

Treating Rheumatoid Arthritis To Target: Is Low Disease Activity Good Enough?

Background/Purpose: It is now widely recognised that treat-to-target (T2T) principles in rheumatoid arthritis (RA) are effective in achieving optimal disease outcomes. The aim of this study was to examine for differences in outcomes between low (LDAS) and remission (RDAS) disease activity score (DAS) categories, to establish whether LDAS is an acceptable treatment target in RA.

Methods: Data from two consecutive, similarly designed UK multi-centre RA inception cohorts, were used: the Early RA Study (ERAS) and Early RA Network (ERAN). Recruitment figures/median follow up for ERAS and ERAN were 1465/10 years (maximum 25 years), and 1236/6 years (maximum 10 years) respectively. Standard demographic and clinical variables were recorded at baseline and then annually until the end of study follow up. Disease activity was categorised by mean DAS28 score between years 1-5 as remission [mRDAS<2.6] or low [mLDAS 2.6-3.2]; as sustained low/remission DAS (sLDAS/sRDAS) based on DAS persisting in each of the two categories at years 1-2 and as Boolean remission (years 1-2). Change in HAQ and SF36 (physical [PCS] and mental [MCS] components) for each disease activity category were modelled using linear mixed models with time incorporated as a linear spline with change-point at 12 months. Year of onset, age, gender and use of steroids or conventional DMARDs at first visit were included as covariates.

Results: Out of 2701 patients, 468 (17%) were in mRDAS, 284 (11%) in mLDAS in the first five years of disease. Lower proportions had achieved sRDAS (8%), sLDAS (6%) and Boolean (2%) remission (table). Mean age was similar across categories; more women were in low vs remission DAS. Compared to mLDAS or sLDAS, inflammatory markers, DAS, functional (HAQ, PCS) and mental (MCS) scores tended to be better in the mRDAs, sRDAS or Boolean remission categories. Significant differences ($p<0.05$) were noted between the mRDAS and mLDAS between years 1-5 for all outcomes; for sRDAS compared to sLDAS, the difference was significant at one year but not by five years (figure).

Conclusion: This study demonstrates striking differences between remission and low DAS categories, suggesting worse functional and SF36 outcomes over time in the low DAS categories. The findings support that remission should be the primary T2T goal in RA.

Figure. Disease outcomes by DAS category.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Patient Outcomes, Preferences, and Attitudes I: Beliefs and Behaviors

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30 PM-6:00 PM

Background/Purpose: Controlling disease activity in RA using a treat-to-target (T2T) strategy can optimize clinical and patient-important outcomes. Yet, many patients are not familiar with T2T and report medication risk aversion as a major barrier to changing therapy. To improve willingness of patients to escalate treatment, we developed and evaluated an educational, direct-to-patient video intervention that included information relevant to managing RA using a T2T strategy.

Methods: We conducted a controlled, randomized trial of our intervention among US patients with self-reported RA enrolled in the Arthritis Power patient registry. We recruited participants by email, and surveyed their satisfaction with disease control, values about RA medications, decisional conflict about treatment change and willingness to change treatment if/when recommended by their rheumatologist (Table). Intervention group participants were invited to view up to 6 videos (mean duration 2 min each) relevant to T2T; those in the control group viewed vaccination-related videos (mean duration 1:23 min each) unrelated to T2T as an “attention control”. Participants were required to view 3 (intervention) and 2 (control) videos, respectively. The primary outcome, collected using surveys, was patient-reported willingness to change RA treatment, measured by the choice predisposition scale (0-10, anchors: “Not willing at all”; “Extremely willing”) that reflected preference for RA treatment change. We stopped recruitment when 208 (N=104 per group) participants enrolled based on a priori sample size estimation. We compared the difference in pre-post differences in willingness to change RA treatment between the two groups using t-test.

Results: We invited 1264 RA patients by email. We reached our enrollment goal in 8 weeks. Study participants (N=208) were 90% Caucasian, 90% women, with mean (SD) age 50 (11) years, in good health (51%); 52% reported familiarity with T2T. A majority (89%) reported having values that favored RA medications. We observed no differences in baseline socio demographics, patient global assessment of disease activity, health literacy, willingness to change treatment, or decisional conflict (Table). We found a significant improvement in pre-post willingness to change treatment in intervention vs. control participants (0.5 vs 0.01, p=0.01). We calculated an effect size (Glass’s delta) for the intervention of 0.48 (i.e. moderate). Moreover, decisional conflict about treatment change decreased; there was no significant difference in pre-post differences in decision conflict between groups.

Conclusion: This randomized trial testing a novel patient-directed intervention advocating for T2T strategy implementation in RA care increased self-reported willingness to change RA treatment. Further studies are needed to evaluate if this effect is sustained over time and if it translates into actionable behavior change. Table: Patient Demographic, Clinical Characteristics, Values Regarding Rheumatoid Arthritis (RA) Treatment, Decisional Conflict about RA Treatment and Willingness to Change RA Treatment by Group.

Variable	Intervention (N=104)	Control (N=104)	p value
Baseline

Goal Concordance in Rheumatoid Arthritis: Beyond Pain Reduction, Is There Agreement?

Jennifer Barton^{1,2}, Shelia Markwardt², Allison Schue¹, Somnath Saha^{2,3} and Edward H. Yelin⁴, ¹VA Portland Health Care System, Portland, OR, ²Oregon Health & Science University, Portland, OR, ³Medicine, VA Portland Health Care System, Portland, OR, ⁴Medicine/Rheumatology, University of California San Francisco, San Francisco, CA

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Patient Outcomes, Preferences, and Attitudes I: Beliefs and Behaviors

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30 PM-6:00 PM

Background/Purpose: Goal concordance between patients with chronic diseases and their clinicians has been linked to improved outcomes, but not explored in rheumatoid arthritis (RA). Our objective was to assess the extent to which RA patient goals for treatment are concordant with their rheumatologists and to identify correlates of goal concordance.

Methods: Patients meeting 2010 ACR criteria for RA and seen at least once in the prior 12 months at one of two rheumatology clinics (Veterans Affairs Hospital-based or university-based) were enrolled in a cross-sectional survey study. Both enrolled RA patients and their corresponding rheumatology fellow or attending who agreed to participate completed the RA goals measure (ranked top three goals for RA treatment out of eight possible choices) prior to the clinic visit. Patients then completed a longer survey on overall health, medications, demographics, health literacy, adherence and function. Primary outcome was goal concordance defined as the patient's #1 goal being listed among any of the top three listed by the clinician. Differences in baseline patient characteristics by goal concordance were assessed using chi-square or Fisher's exact tests for categorical variables and Mann-Whitney U tests for continuous variables.

Results: A total of 171 patient-clinician dyads were analyzed. Patients were 50% female, 15% Spanish-speaking, and 25% had limited health literacy. "Have less pain" was selected by both in 82% of dyads and "have fewer problems doing daily activities" by 61% (table). The proportion of dyads in which the clinician ranked the patient's #1 goal among the top three was 80%. Given the overwhelming agreement around pain, the proportion of dyads with goal concordance after removing pain, fell to 36%. Goal concordance did not vary by age, gender, race/ethnicity, or health literacy. However, Spanish language was associated with a greater proportion being concordant with clinicians. Of note, 27% of patients ranked "feel less tired" as one of their top three compared to only 6% of clinicians, 12% of patients ranked "improve

mood” compared to 0% of clinicians, and 40% of clinicians ranked “Avoid side effects from medicine” compared with 14% of patients.

Conclusion: Among 171 RA patient and clinician dyads, the majority of patients shared their top goal with their clinicians’ top three, with “have less pain” as the most common goal. Beyond that shared goal, clinicians prioritized avoidance of side effects while patients ranked improved sleep, less fatigue, and improved mood. Tools to facilitate goal elicitation may help improve communication of what matters most to RA patients.

Table. Patient and clinician agreement on treatment goals for rheumatoid arthritis

Goal, N=171 pairs	Selected only by Patient, N (%)	Selected only by Clinician, N (%)	Not selected, N (%)	Selected by both, N (%) ¹
Have less pain	11 (6.4)	17 (9.9)	3 (1.8)	140 (81.9)
Have fewer problems doing daily activities	6 (3.5)	54 (31.6)	6 (3.5)	105 (61.4)
Be able to work outside the home	31 (18.1)	35 (20.5)	93 (54.4)	12 (7.0)
Avoid side effects from medicine	23 (13.5)	69 (40.4)	36 (21.1)	43 (25.1)
Improve sleep	32 (18.7)	6 (3.5)	130 (76.0)	3 (1.8)
Feel less tired	46 (26.9)	10 (5.8)	102 (59.6)	13 (7.6)
Improve mood	21 (12.3)	-	150 (87.7)	-
Not affect ability to have children	7 (4.1)	-	163 (95.3)	1 (0.6)
Other	15 (8.8)	5 (2.9)	151 (88.3)	-

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Patient Outcomes, Preferences, and Attitudes I: Beliefs and Behaviors

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: We evaluated a social networking intervention to help patients with rheumatoid arthritis become active partners in their own care. We developed a closed independent community in Facebook® for patients with rheumatoid arthritis. Three patient advocates with expertise in health communication moderated the Facebook® community.

Methods: In a randomized controlled trial we compared the use of Facebook® as an educational platform providing evidence-based health information and social networking to a static non-participatory website offering the same educational materials as Facebook but without the interactive components of social networking (intervention = Facebook® + website and control = website alone). Inclusion criteria were: (i) adults diagnosed with rheumatoid arthritis by a rheumatologist, and ongoing or prior treatment with traditional disease-modifying antirheumatic drugs or biologic agents, (ii) able to communicate in English; (iii) internet access and a personal email account; (iv) current use of internet-based social media platforms (Facebook® or similar); and (v) disease duration ≤ 10 years. Our primary outcome measures were patients’ disease knowledge, self-efficacy and empowerment. Follow-up assessment were conducted at 3 and 6 months.

Repeated measures ANOVA was used to compare the primary outcome measures between two study groups at 3-month and 6-month follow-up. All analyses were done on an intention-to-treat basis.

Results: 210 patients agreed to participate and completed the baseline questionnaire. After completion of the baseline questionnaire, participants were randomly assigned at 1:1 ratio; 105 were randomized to the intervention arm and 105 were randomized to the control arm. No statistically significant differences between the two study groups were detected at baseline. At the 3-month assessment, 90 patients from the intervention arm and 93 patients from the control arm completed the survey (87% response rate). At the 6-month assessment, 89 patients from the intervention arm and 89 patients from the control arm completed the survey (85% response rate). No statistically significant differences were observed between groups for patient knowledge, self-efficacy, or empowerment at 3 or 6 months. However, the intervention group reported more satisfaction with their perceived peer support compared with the control group at 3 and 6 months. This was reflected in the various subscales including perceived availability of peer support (i.e., peer supporter being present and ready to help), perceived assistance in daily management (i.e., peer supporter assistance in the actions needed to take every day to control the disease and protect the patients' health), social & emotional support (i.e., peer supporter addressing the emotional aspects of living with rheumatoid arthritis), and linkage to clinical care (i.e., peer supporter helping to make effective use of health services).

Conclusion: The perceived receipt of direct and nondirective support was higher in patients using Facebook®, but this was not translated into greater knowledge, self-efficacy or empowerment.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Patient Outcomes, Preferences, and Attitudes I: Beliefs and Behaviors

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30 PM-6:00 PM

Background/Purpose: Disease remission is the ideal treatment target in SLE; when remission cannot be reached, the lowest possible disease activity state should be targeted. Available definitions of remission and low disease activity state (LLDAS) are based on physician's driven clinical data. Little data exist on the effect of remission and LLDAS on the patients' perception of the disease. Our purpose was to evaluate the relationship between the available definitions of remission and LLDAS and the patient's perspective on quality of life (QOL) and disease burden.

Methods: This is a cross-sectional analysis from our database that enrolls adult patients who fulfilled the 1997 ACR criteria for SLE. Disease activity was evaluated with the SELENA-SLEDAI while organ damage with the SLICC/DI. The remission status at last clinic visits was defined according to the European consensus criteria (DORIS), the LLDAS was defined according to the Asian Pacific Lupus Consortium definition. The QOL was assessed by the validated Italian version of the Short-Form-36 (SF36), the disease burden was evaluated by Italian version of the Lupus Impact tracker (LIT) and fatigue by the FACIT score. Patients included in this analysis are categorized according to the categories: clinical remission off treatment (ROFT), LLDAS, active disease.

Results: A total of 194 patients were included in this analysis (96.3% Caucasian, 92.2% female, mean age 45.5±13.4 years, mean disease duration 14.4 ±10.1 years); disease activity was globally low (median SLEDAI: 2, IQR 0-4); 122 patients (62.9%) were on LLDAS, 33 (17.01%) were on ROFT, 41 (21.13%) had some degree of disease activity. SF-36 and LIT scores according to the three groups are reported in table. Patients in remission off treatment have lower disease burden as compared to those with active disease status but the difference didn't reach statistical significance (p=0.3). Though LIT showed lower value also among LLDAS than active disease patients, this was not statistically significant (p=0.8). Fatigue was significantly lower in the remission group with respect to the active (p=0.01) while no differences were observed in SF-36 scores.

	ROFT	LLDAS	active	ROFT vs active	LLDAS vs active
Age (mean \pm SD)	47 \pm 13	46 \pm 12	42 \pm 15.7	p= n.s.	p= n.s.
SLEDAI median (IQR)	2 (0-2)	2 (0-2)	6 (4-8)	p =0.01	p =0.02
SLICC/DI median (IQR)	0.93	1.25 \pm 1.8	1.51 \pm 2.2	p=n.s.	p=n.s.
LIT median (IQR)	21.2 (6.25-35)	20 (7.5-45)	32.5 (7.5-40)	p= n.s.	p=n.s.
PCS median (IQR)	60 (56-68)	63 (56-78)	63 (57-72)	p=n.s.	p=n.s.
MCS median (IQR)	62 (55-67)	64(56-77.5)	61.5 (57-70)	p=n.s.	p=n.s.
FACIT median (IQR))	43 (39-46)	40 (32-46)	39 (30-45)	p=0.01	p=n.s.

Conclusion: in this cohort, PROs seem to be moderately influenced by the disease status as defined according to the clinical definition of remission and LLDAS. The small sample size, the slightly higher damage in the active group, and none to mild variation in disease activity in the three groups could have appeared the association. On the other hand, these results underly the fact that disease burden and quality of life are related to several multifaceted aspects of the disease that are not accurately captured by physician driven instruments. Further prospective studies on larger cohorts are necessary to confirm these data.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Patient Outcomes, Preferences, and Attitudes I: Beliefs and Behaviors

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30 PM-6:00 PM

Background/Purpose: Patients often have to pay for prescription medications out-of-pocket and cost-related non adherence is a recognized problem. The treatment of rheumatoid arthritis is associated with high out-of-pocket cost. Research has shown that while patients may have a desire to discuss medication costs with health care professionals (HCPs) these discussions often do not take place. The objective of this study was to examine the frequency with which out-of-pocket medication costs are discussed and to examine predictors of these discussions between rheumatologists and patients with rheumatoid arthritis (RA) in Canada.

Methods: A cross-sectional online survey was distributed to patients with RA and rheumatologists in Canada. Participant characteristics and medication status were assessed and participants were asked to rate the importance of discussing out-of-pocket medication costs, as well as how often medication costs are discussed between physician and patients. Stepwise, multivariable logistic regression was used to explore the predictors of (1) patients discussing costs with their rheumatologist and, (2) perceived importance of discussing medication cost for patients. Potential predictors included age, sex, income, education, use of biologics, and attitude to shared decision making.

Results: The sample contained 78 patients and 64 rheumatologists. There were no differences in the perceived importance of discussing medication costs between patients and physicians with over 65% of physicians and patients rating it as quite or very important. When asked whether they discuss medication cost during health care encounters, 22% of patients reported never talking about medication cost, whereas no physicians reported never discussing costs with their patients. Among patients who reported never talking about medication cost with their physician, 65% (n= 17) were currently taking and 6% (n=1) had taken a biologic agent in the past. There were no significant differences across responses to having talked about medication cost by income, education, age, or province. In multivariable logistic regression models, the odds of discussing cost among patients who perceived discussing cost with their HCP as 'very important' were 4.5 (p = 0.043) higher than patients who perceived discussing cost as 'neither important nor unimportant' or 'not important'. No other

characteristics were found to be significant predictors of discussing medication cost. No patient characteristics were statistically significant predictors of perceived importance of discussing cost.

Conclusion: Out-of-pocket costs have been shown to affect medication adherence; consequently patients and HCPs should discuss costs in the treatment decision making process. Our findings suggest this does not always happen. Furthermore, medication cost was more likely to be discussed by patients who perceived it as 'very important.' This finding suggests that the onus to initiate discussions about cost is currently on patients, not HCPs). In the absence of any clear predictors of the perceived importance of discussing costs to patients, treatment costs and ability to pay should be discussed routinely, as an important component of shared decision making.

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes III: Diagnosis and Prognosis II

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30 PM-6:00 PM

Background/Purpose: To assess whether the neutrophil-lymphocyte ratio (NLR) can predict those who require disease modifying therapy escalation and hence progression in rheumatoid arthritis (RA).

Methods: Patients with newly diagnosed RA were recruited from the Early Arthritis Clinic at the Royal Adelaide Hospital. Those who were on glucocorticoids at the time of review were excluded. All patients were commenced on methotrexate, sulphasalazine and hydroxychloroquine and were reviewed at regular intervals, and Disease Modifying Anti-Rheumatic Drug (DMARD) therapy was adjusted according to a set algorithm. The NLR, platelet-lymphocyte ratio (PLR) and other markers of disease activity such as the ESR, CRP and DAS 28 were collected as well as current therapy. The primary outcome measure was failure of triple DMARD therapy.

Results: Two-hundred and twenty-two patients met inclusion criteria. The mean age was 54.2 ± 15.4 years with a mean duration of polyarthritis of 22.3 ± 25.0 weeks prior to their first review. Forty-five (20%) of patients had failed triple therapy by one year. The mean NLR was significantly higher in those who failed triple therapy when compared to those that did not (3.7 ± 2.8 vs 2.9 ± 1.5 ; $p=0.02$), however, the PLR was not significantly different (184.1 ± 78.6 vs 171.4 ± 84.5 ; $p=0.41$). The NLR was an independent predictor of treatment failure (OR 2.65, CI 1.23-5.72, $p=0.01$) whilst the PLR, ESR, CRP and DAS-28 ESR were not (p -values 0.41, 0.13, 0.17 and 0.28 respectively).

Conclusion: The NLR is significantly increased in those with treatment failure in RA and outperforms more conventional markers of disease activity. The NLR may be a cheap, objective and reproducible prognostic marker, however, further prospective studies are required to identify the role of the NLR in RA disease management algorithms.

SESSION INFORMATION

Session Date: Monday, October 22, 2018
Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes III: Diagnosis and Prognosis II
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30 PM-6:00 PM

Background/Purpose: Rheumatoid Arthritis (RA) patients in clinical remission may still develop structural damage that has been attributed to ongoing synovial inflammation, sometimes only detectable by ultrasound or MRI. Here, we assess the clinical features, histologic characteristics, and transcriptional profiles of synovium from RA patients in clinical remission undergoing arthroplasty.

Table 1. Baseline Characteristics	Remission (DAS28<2.6) n=22, 15%	Low (DAS28<3.2) n=21, 15%	Moderate (DAS28<5.1) n=77, 53%	High (DAS28>5.1) n=24, 17%
Age at baseline (Years)	62.33±12.1	65.54±10.52	62.87±11.57	62.2±10.28
Sex: Female	73%	76%	91%	88%

Number of Swollen Joints	2.9±3.62	3.48±4.09	6.55±7.84	12.17±9.83
ESR (mm/hr)	5.4±2.91	15.14±12.59	23.03±17.24	30.46±21.56
CRP (mg/dL)	0.72±0.82	1.33±1.39	2.25±3.47	2.09±2.02
Baseline CDAI	12.14±3.46	11.41±6.31	18.82±6.89	37.18±11.88
RADAI Sum	7.78±5.17	8.66±5.61	10.7±8.36	15.54±9.45
RADAI Sum, adjusted	5.76±5.39	4.25±5.48	8.9±8.32	17.96±9.98
DMARD	68%	88%	49%	57%
Non-methotrexate DMARD	18%	18%	27%	10%
Biologics	50%	52%	52%	70%
Steroid	45%	38%	43%	26%

Methods: We studied 144 patients with long-standing RA (median disease duration of 12.5 years) undergoing total hip or knee arthroplasty between 2013 and 2017, and met classification criteria for RA using ACR/EULAR 2010 or 1987 criteria. Baseline data collected included age, sex, comorbidities, duration of disease, and medications. Disease activity was divided into remission (DAS 28 ESR<2.6), low disease activity (≥ 2.6 -3.2), moderate disease activity (≥ 3.2 -5.1), and high disease activity (≥ 5.1) [12]. Synovium was assessed by histologic analysis and RNA-Seq. Statistical analysis was descriptive. Continuous characteristics are summarized by mean \pm standard deviation or median [interquartile range], as appropriate. Categorical variables were compared using Fisher's exact tests.

Results: Of 144 participants, 15% (n=22) met DAS criteria for remission, only 1 was drug free. 17%, 53%, and 15% had high, moderate, and low disease activity at baseline as measured by DAS 28 (TABLE 1). Of the patients in DAS remission: (i) histologic analysis of synovium demonstrated that 45% had moderate to marked lymphocytic infiltrates, 17% had greater than 10% plasma cells, 39% had fibrin deposition, 6% had Russell bodies, 17% had binucleate plasma cells, 17% had neutrophils, and 29% had synovial multinucleated giant cells, all features characteristic of the high inflammatory RA subtype (Figure 1), (ii) RNA-Seq analysis demonstrated that 67% had moderate levels of synovial inflammatory gene expression, and (iii) clinical assessment demonstrated that 36% of all patients in remission prior to surgery, met DAS 28 criteria for flare, 6 weeks after joint replacement.

Conclusion: Remission is uncommon in RA patients with long-standing disease undergoing arthroplasty. Of those in remission, synovium may be characterized by ongoing inflammation, and they remain at risk for flares. The notion that RA burns out and that patients undergoing arthroplasty have inactive disease should be re-evaluated.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes III: Diagnosis and Prognosis II

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30 PM-6:00 PM

Background/Purpose: Small RNAs (sRNAs) are important regulators of biological processes and are potential biomarkers of disease and drug response. We previously found that microbial sRNAs are abundant in human plasma, altered in patients with rheumatoid arthritis (RA) compared to control subjects, and inversely associated with disease activity in RA. The aim of this study was to determine if pre-treatment plasma levels of microbial sRNAs: 1. Predict clinical response to initiation of disease-modifying antirheumatic drugs (DMARD); or 2. Change 6 months after DMARD initiation.

Methods: Plasma samples and clinical data were provided from a longitudinal multi-center study (Treatment Efficacy and Toxicity in Rheumatoid Arthritis Database and Repository). RNA was extracted from plasma of 70 patients with RA before and 6 months after first-time starts of: methotrexate (n=24), adalimumab (n=23), or tocilizumab (n=23). Sequencing was performed using Illumina Next Seq500. Using TIGER, an in-house sRNA analysis pipeline, high quality reads were first aligned to the human genome allowing for 1 mismatch. Remaining reads were aligned to 57 genomes of bacteria previously found to be altered in RA, representative genomes of 207 human microbiome bacteria, 8 fungi, and 167 environmental bacteria. Differential expression of sRNAs and microbial genome counts were performed using DESeq2 with 5% false discovery rate. Benjamini and Hochberg method was used for multiple test correction. Clinical improvement was defined as a decrease in DAS28 score from pre-treatment to 6 months after starting DMARD treatment. Spearman correlation was used to correlate continuous variables.

Results: Baseline total microbial sRNAs were ~3-fold higher (P=0.009) (Figure) among patients whose DAS28 improved after starting a DMARD. Moreover, baseline total microbial sRNA read counts had an AUC=0.75 (P=0.009) for predicting improvement with therapy. Microbial sRNAs (total abundance, genome counts and individual sRNAs) did not significantly

Figure. The abundance of pre-treatment plasma microbial sRNAs was approximately 3-fold higher among those whose DAS28 score improved with initiation of a new DMARD ($P=0.009$). Data are presented as geometric mean and 95% confidence interval.

change after DMARD initiation. On a cross-sectional basis a greater abundance of total microbial RNA reads were associated with lower tender joint count ($P<0.05$), which validated prior observations.

Conclusion: The abundance of plasma microbial sRNAs was predictive of improvement in DAS28 after first-time initiation of a DMARD. Initiation of these drugs did not significantly change the abundance of plasma microbial RNA. Future studies will determine if microbial sRNAs modify host immune responses in RA.

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes III: Diagnosis and Prognosis II

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30 PM-6:00 PM

Background/Purpose: TKA is commonly performed in patients with a history of inflammatory arthritis. These patients are likely at higher risk of complications, from both the underlying disease and immunosuppressive medications. The purpose of this study was to perform a population-based comparison of the risk of postoperative complications between patients with inflammatory arthritis and osteoarthritis.

Methods: A national private insurance database was used to select patients undergoing unilateral primary TKA. Patients were categorized to the inflammatory cohort if they had an ICD diagnosis of inflammatory arthritis as well as treatment with a DMARD, biologic, or SLE-specific medication within the year prior to surgery. Patients with no diagnosis of inflammatory arthritis were assigned to osteoarthritis. Postoperative complications were identified using Reportable CMS Complication Measures. Risk of each complication was compared between cohorts using multivariate logistic regression controlling for age, gender, length of stay, comorbidities, and use of corticosteroids within 3 months prior to TKA.

Mechanical Complications (90d)	2547	1.67	63	2.03	1.07	(0.81, 1.38)	0.63
Infection (30d)	1193	0.82	44	1.43	1.64	(1.17, 2.39)	0.00 *
Readmission (30d)	11584	8.62	385	12.55	1.46	(1.30, 1.63)	0.00 *

Results: 137,550 patients were included; 2.23% met criteria for inflammatory arthritis as described above. Independent of age, gender, LOS, comorbidities, and recent steroid use, inflammatory patients were found to have higher risk of transfusion (OR 1.39, $p < 0.01$), infection (OR 1.64, $p < 0.01$), and readmission (OR 1.46, $p < 0.01$). There were no differences in risk of VTE, medical, or mechanical complications.

Conclusion: Independent of other comorbidities, patients with inflammatory arthritis are at high risk of transfusion, infection, and readmission. Treatment of these patients is likely more costly and efforts should be made to optimize their health and treatment medications prior to TKA to minimize their complication risk. Additionally, these results have important implications for evolving bundled payment models. Hospitals should receive commensurate resources to maintain access to TKA for patients with inflammatory arthritis that are prone to higher resource utilization.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes III: Diagnosis and Prognosis II

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Flares of immune-mediated inflammatory diseases, as Rheumatoid Arthritis (RA) occur unpredictably representing a major burden for patients and clinicians. We aimed to dissect the synovial tissue (ST) features of RA in sustained remission that could predict disease flare once biological treatment is tapered or discontinued.

Methods: 48 RA patients in sustained clinical (DAS<1.6 for at least 9 months) and ultrasound (US) remission (Power Doppler negative) under biological-Disease Modifying Anti-Rheumatic Drug (bDMARD) plus Methotrexate underwent ultrasound guided ST biopsy. ST CD68⁺, CD21⁺, CD3⁺, CD20⁺, CD31⁺ cells and collagen were assessed using immunohistochemistry and Goldner's Trichrome staining, respectively. Some ST samples were digested with liberase and ST macrophages were sorted by FACS-ARIAIII and phenotyped. This included evaluation of the number of CD206 positive and negative anti-inflammatory and pro-inflammatory macrophages, respectively. After study entry, RA were randomly assigned to tapering/discontinuation group (TAP/DISC: tapering for 6 months first and discontinuing bDMARD afterwards) or to the group maintaining the same therapeutic scheme (CONT). Each RA was followed every 3 months to assess the occurrence of disease flare after treatment change for at least 6 months.

Results: At study entry, 29 RA were assigned to TAP/DISC group and 19 to CONT group, respectively. Among the TAP/DISC group, 6(20.7%) and 8/14(57.1%) experienced disease flare after bDMARD tapering only and tapering/discontinuation respectively, whereas 2 (10.5%) of RA of the CONT group experienced disease flare during the follow-up (p=0.31 for RA tapering only and p=0.001 for RA discontinuing b-DMARD). In particular, RA of the TAP/DISC group who experienced disease flare after bDMARD modifications showed, at study entry, higher IHC scores for ST sublining CD68⁺ cells (p=0.02), higher CD31⁺ vessels count (p=0.01) and lower collagen deposition (p=0.04 and p=0.01 in lining and sublining, respectively) compared to RA not experiencing flare. Logistic regression analysis revealed that CD31⁺ vessels count ≥ 12.8 at the time of sustained remission achievement [OR (95%ICs):5.7(1.0-32.1)] and TAP/DISC strategy [OR (95% ICs):5.4(1.3-22.7)] are independent factors associated to disease flare in RA patients in remission. In addition, regardless of the treatment modifications, synovial tissue of RA who experienced disease flare during the follow-up contained higher number of CD206^{neg} pro-inflammatory macrophage subpopulation at the time of sustained remission achievement, as compared to RA who maintained disease remission that showed mostly CD206^{pos} subpopulation (p=0.03).

Conclusion: Disease relapse is a common event in RA patients in sustained remission after b-DMARD discontinuation. The analysis of composition and phenotypes of synovial tissue cells identifies, at the time of remission achievement, RA patients at higher risk of disease flare after treatment discontinuation.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes III: Diagnosis and Prognosis II

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30 PM-6:00 PM

Background/Purpose: Patients with RA had increased risk of cardiovascular disease (CVD). Interleukin33 (IL-33) plays an important role in pathogenesis of RA and development of CVD. Plasma IL-33 level was undetectable in most subjects that limits its utility as CVD biomarker. MicroRNAs (miRNAs) function as post transcription regulators of gene expression. This study aimed to ascertain if dysregulated miRNAs targeting *IL-33* gene expression were associated with subclinical atherosclerosis in early RA patients

Methods: 76 ERA patients were recruited in this 1 year study. Potential miRNAs binding to 3'UTR of *IL-33* gene were predicted by miRanda¹. 10 miRNAs with highest possibility targeting functional sites of *IL-33* gene were quantified in cell free plasma samples by real time PCR. Carotid IMT and plaque were identified using high-resolution B mode ultrasound annually. Carotid plaque (CP+) was defined as a localized thickening >1.2 mm. Plaque progression (PP+) was defined as increased region harboring plaque

Results: miRNA were detected in >80% of subjects. CP were identified in 26/76 (34%) subjects (CP+ group) at baseline. The CP+ group were predominantly male, older, with a higher CRP level and a prevalence of multiple CV risk factors. Plasma level of miR-186-5p was significantly higher in the CP+ (Fig 1). Using multivariate logistic regression, miRNA-186-5p was independent predictor for presence of CP (Table 1). ROC showed that increased miRNA-186-5p expression level could discriminate patients with and without CP [Area under the ROC (AUC):0.658, $p=0.024$]. 73 subject were followed until year 1. 16/73 (22%) subject had plaque progression. Subjects in the PP+ group were older, had higher prevalence of multiple CV risk factors, with lower pain and patient global score at baseline. A higher proportion of them were on conventional synthetic DMARDs. miR-382-5p expression level was significantly higher in subjects in PP+ group (Fig 1). Using multivariate logistic regression, miRNA-382-5p level was an independent predictor for plaque progression (Table 1). ROC analysis showed that miR-382-5p level could discriminate patients with and without PP (AUC was 0.66, $p=0.048$)

Conclusion: Increased expression of miR-186-5p and miR-382-5p was independent predictor for presence & progression of subclinical atherosclerosis. This suggest that circulating miRNA may serve as novel biomarkers for CV risk stratification in ERA patients

Session Title: Rheumatoid Arthritis – Treatments III: New Compounds and Biosimilars

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30 PM-6:00 PM

Background/Purpose: Joint synovium is the main tissue involved in rheumatoid arthritis (RA) lesions. Alpha9 integrin is expressed by synovial tissue lining cells and has been identified as a putative key molecule in the development and exacerbation of RA (Kanayama et al. 2009). ASP5094 is a recombinant humanized anti-human alpha9 integrin IgG1 monoclonal antibody under development for the treatment of RA. A first-in-human study in healthy subjects has demonstrated that single intravenous (IV) ASP5094 doses up to 10 mg/kg had an acceptable safety profile and were well tolerated. The purpose of this study was to establish the safety/tolerability, pharmacokinetics (PK), and pharmacodynamics of ASP5094 in patients with RA on methotrexate (MTX).

Methods: Patients (aged 18–65 years) with RA on a stable regimen (10–25 mg/week) of MTX were eligible for this phase 1, randomized, placebo-controlled, multiple ascending-dose study. Eligible patients were assigned to one of three sequential cohorts to receive increasing IV doses of ASP5094 (1, 3, 10 mg/kg) or placebo every 4 weeks for a total of three doses (Day 1, 29, and 57). A total of 10 patients were assigned to each cohort and randomized 4:1 (ASP5094, n=8; placebo, n=2). The primary objectives were to evaluate the safety, tolerability, and PK of ASP5094 in patients with RA on MTX. Exploratory objectives included the pharmacodynamics of ASP5094, assessed by the alpha9 integrin receptor occupancy rate in neutrophils as a surrogate for alpha9 integrin binding in joints at the level of synoviocytes. Formation of anti-ASP5094 antibodies was assayed using a validated method.

Results: At all dose levels, ASP5094 was well tolerated. No difference was observed between treatment groups in either the nature or frequency of treatment-emergent adverse events (TEAEs) or TEAEs considered related to ASP5094, and no dose-response relationship was observed. Two patients permanently discontinued the study due to possible treatment-related AEs: one patient treated with ASP5094 (1 mg/kg) discontinued due to a mild, intermittent tremor. The other patient, treated with placebo, discontinued due to a mild second-degree atrioventricular block, which resolved the same day. Pharmacokinetic steady state was not reached after three administrations of ASP5094 (regardless of dose level) because of slow elimination. ASP5094 exhibited nonlinear, target-mediated drug disposition pharmacokinetics. A trend of dose-dependent increase in receptor occupancy was observed. Median receptor occupancy was >90% for all ASP5094 doses on Day 1 and was maintained at >80% for approximately 2 weeks after each dose within 1 mg/kg dose cohort. For doses of 3 and 10 mg/kg, median receptor occupancy was maintained by >80% throughout the treatment period until Day 85 and Day 141, respectively. No patient had confirmed positive titers for anti-ASP5094 antibodies.

Conclusion: In this study, multiple IV doses of ASP5094 had an acceptable safety profile and were well tolerated in patients with RA on stable doses of MTX. ASP5094 exhibited a nonlinear PK disposition and demonstrated dose-dependent, high, and prolonged neutrophil alpha9 integrin receptor occupancy rates.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Treatments III: New Compounds and Biosimilars

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30 PM-6:00 PM

Background/Purpose: GP2017, a proposed adalimumab biosimilar, matched reference adalimumab (refADL) in preclinical and pharmacokinetics studies.^{1,2} The confirmatory efficacy and safety study in patients with plaque-type psoriasis demonstrated equivalent efficacy and similar safety of GP2017 and refADL.³ This Phase III study compares efficacy and safety of GP2017 and refADL in patients with moderate-to-severe rheumatoid arthritis (RA) with inadequate response to disease modifying anti-rheumatic drugs, including methotrexate (NCT02744755). The study was designed to demonstrate similar efficacy of GP2017 and refADL over 24 weeks of treatment, and to evaluate long-term safety, immunogenicity and efficacy of GP2017 up to Week (Wk) 48. Data from randomization to Wk 24 are presented.

Methods: Eligible patients were randomized 1:1 to receive 40 mg subcutaneous GP2017 or refADL every other week from Wk 0 to Wk 22. The primary endpoint was change in Disease Activity Score-28 including high-sensitivity C-reactive protein (DAS28-CRP) from baseline at Wk 12. Therapeutic equivalence was confirmed if the 95% confidence intervals (CIs) for the difference in DAS28-CRP change from baseline (BL) at Wk 12 between GP2017 and refADL were completely contained within the predefined equivalence margin of [-0.6,0.6]. Secondary endpoints included time-weighted averaged change in DAS28-CRP from BL to Wk 24, safety and immunogenicity.

Results: In total, 353 patients were randomized to receive GP2017 (n=177) or refADL (n=176). Using a mixed model repeated measures method, mean change from BL at Wk 12 in DAS28-CRP was -2.16 for GP2017 (n=140) and -2.18 for refADL (n=144) ($\Delta=0.02$; 95% CI: -0.24,0.27). Time-weighted averaged change from BL in DAS28-CRP until Wk 24 was -1.85 for GP2017 (n=127) and -1.93 for refADL (n=138) ($\Delta=0.08$; 95% CI: -0.11,0.27). Treatment-emergent adverse events (TEAEs) occurred in 61.6% of patients in GP2017 group and 60.2% of patients in refADL group (Table). Most TEAEs were mild or moderate in severity. Infections and infestations were most common TEAEs, of those mild viral upper respiratory tract infections were reported by 14.7% and 9.1% of patients in GP2017 and refADL groups, respectively. Injection site reactions occurred in 7 (4.0%) and 11 (6.3%) patients in GP2017 and refADL groups. From BL to Wk 24, antidrug antibodies were detected in 21.8% and 24.4% of patients treated with GP2017 and refADL, of which >70% in both groups were neutralizing.

Conclusion: These data demonstrate equivalent efficacy of proposed adalimumab biosimilar GP2017 and refADL in patients with moderate-to-severe RA. Safety and immunogenicity of GP2017 and refADL were similar and consistent with clinical experience with refADL.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Treatments III: New Compounds and Biosimilars

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30 PM-6:00 PM

Background/Purpose: Patients with rheumatoid arthritis (RA) have lymphocyte dysfunction characterized by deficiency or dysfunction of regulatory T cells (Tregs), which plays crucial roles in immune tolerance. Low dose IL-2 has been reported to promote selectively the expansion of Tregs. This study aimed to investigate the alterations and their clinical significance of the absolute numbers of lymphocyte subpopulations in RA patients and to restore the immunologic balances by low-dose IL-2.

Methods: Absolute number of CD4+CD25+FOXP3+Treg, CD4+IL17+T (Th17) and other subsets in peripheral blood (PB) from 839 patients with RA and 100 healthy donors were characterized by flow cytometry combined with an internal microsphere counting standard. Total 233 of patients were treated with daily subcutaneous injections of 0.5 million IU of human IL-2 for five consecutive days, and then its effects on lymphocyte subpopulations in PB were analyzed.

Results: There was a significant disturbance in lymphocyte subpopulations mainly manifested as the decreased level of Tregs compared with the health controls ($P < 0.05$). Further, Treg values were found to be correlated negatively with DAS28, CRP and tender joint count ($P < 0.05$), suggesting an important role of Tregs in sustained high disease activity. Low dose IL-2 effectively increased the number of Tregs ($P < 0.001$) and re-balance the ratio of Teffs and Tregs ($P < 0.05$), leading to increased clinic symptom partly remission in a rapid way without observed side effects.

Conclusion: Absolute decrease of PB Tregs in patients with RA was associated with continuing disease activation and low dose IL-2, a potential therapeutic candidate, restored decreased Tregs and promoted rapidly remission of patients with RA without over-treatment and evaluated side effects.

Figure 1: Low dose IL-2 modulates lymphocyte subpopulations by selectively expanding Treg cells in patients with RA ($n=235$). Data were presented as median (range) and calculated and compared with Mann-Whitney U test. (A, C) represented changes in absolute number and the percentages of lymphocyte subsets in peripheral blood. (B, D) showed changes in absolute number and the percentages of CD4+T cell subsets. (E) exhibited changes in the ratio of these cells in patients before and after the treatment. * $P < 0.05$; ** $P < 0.01$; *** $P < 0.001$.

Session Title: Rheumatoid Arthritis – Treatments III: New Compounds and Biosimilars

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30 PM-6:00 PM

Background/Purpose: GSK3196165 is a high-affinity anti-GM-CSF cytokine IgG mAb currently in development for RA, with reported efficacy using IV dosing. This study evaluated the efficacy and safety of GSK3196165 dose-ranging in RA.

Methods: 222 adult patients with active, moderate-severe RA per ACR 2010 criteria, ≥ 4 each of swollen and tender joints, DAS28(CRP) ≥ 3.2 and CRP ≥ 5.0 mg/L, were randomized equally to placebo or GSK3196165 22.5 mg, 45 mg, 90 mg, 135 mg or 180 mg SC weekly for 5 injections, then every other week until Week 50 (with blinded/automated escape to the 180 mg dose at Weeks 14 and 26 for non-responders). The primary outcome was the proportion of patients who achieved remission (DAS28 (CRP) < 2.6) at Week 24, with dose selection for further studies at Week 12.

Results: 37 patients were randomised to each treatment group; 150 patients completed the study (Week 62);86/175 (49.1%) eligible patients were escalated to the 180 mg dose after Week 12, and 57/83 (68.7%) patients after Week 24. Patient characteristics were well balanced across the groups. There were more patients in remission at Week 24 in the active groups (e.g. 16% in the 180 mg group, $p=0.134$) than those on placebo group (3%). There was a dose-related treatment effect in change from baseline in DAS28 (CRP) at Week 12, which was also reflected in other clinical endpoints with or without acute-phase reactants (see Table below).

The onset of clinical response across most endpoints was seen at Week 1, but the improvement in the GSK3196165 groups appeared to plateau from approximately Week 6 onwards, maintained to Week 52.

Observed PK exposures were lower than anticipated from previous studies. During the 5 weekly doses, maximum pre-dose concentrations were observed at Week 4 with geometric mean of 1,857 ng/mL (CV_b 176%) with the 180 mg dose, but concentrations dropped unexpectedly after reducing dosing frequency to dosing every two weeks. At Week 12, pre-dose geometric mean concentration was 680 ng/mL (CV_b 124%), which was below the anticipated threshold based on preclinical data for maximum efficacy.

GSK3196165 was well-tolerated, and adverse events were reported similarly across treatment groups. No drug-related SAEs, significant infections and/or pulmonary events were observed.

Conclusion: GSK3196165 has shown dose-related, clinically-meaningful benefit. Following dosing every two weeks, exposure to GSK3196165 was lower than predicted due to increased apparent clearance. Further studies are now required to confirm the additional clinical benefit expected with increased exposure from weekly dosing of GSK3196165 in patients with RA.

This study (NCT02504671) was funded by GSK.

Clinical endpoint at Week 12	Placebo (N=37)	180 mg (N=37)	Difference from placebo (95% CI)
	LS mean change from baseline (SE)

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Treatments III: New Compounds and Biosimilars

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30 PM-6:00 PM

Background/Purpose: Patients with refractory rheumatoid arthritis (RA) have T-cell dysfunction that associates the activation of mTOR that is inhibited by rapamycin, which has been developed as a medication under the generic designation of sirolimus. Recently, we have reported that absolute number of peripheral regulatory T (Treg) cells reduced in RA patients. Since rapamycin has been reported to expand Tregs, in this study, we assessed safety, tolerance, and efficacy of sirolimus for RA treatment.

Figure 1: Sirolimus modulates CD4⁺T cell subsets by selectively expanding Treg cells in patients with RA. Absolute numbers of lymphocyte subpopulations in peripheral blood were analyzed by flow cytometry. Data were presented as median (range) and calculated and compared with Mann-Whitney *U* test. (A-C) shows no significance in the number of Th1, Th2 and Th17 cells between sirolimus groups (*n*=38) and non-sirolimus group (*n*=19). (D) shows patients had a significant increase in the number of Treg cells after 12 and 24 weeks sirolimus treatment compared with that of conventional treatments.

Figure 2: Baseline (conventional) therapies between sirolimus and control group. (A) no differences of prednisone dosage between these two groups. (B-D) lower proportions of the patients achieving methotrexate, leflunomide and hydroxychloroquine, respectively than that in controls (*p* < 0.05).

Methods: We did a double-arm, open-label, and phase 1/2 trial of sirolimus in patients with RA at the Second Hospital of Shanxi Medical University (Taiyuan, Shanxi, China). Eligible participants (aged 18 to 65 years) fulfill the revised the 1987 ACR/EULAR criteria for the classification of RA and did not achieve remission with the conventional treatment over at least 2 years. We excluded patients with allergy or intolerance to sirolimus, with malignant disease or a history of malignancy, or with chronic or severe infection. Patients in control group (*n*=19) were given conventional glucocorticoids and DMARDs treatment. Patients in sirolimus group (*n*=38) were given not only conventional treatment, but also oral sirolimus at a starting dose of 0.5 mg on alternate days for 24 weeks. The demographic features, clinical manifestations

and laboratory indicators were compared before and after the treatment. This trial is registered at Chinese Clinical Trial Registry, number ChiCTR-IPR-17010307.

Results: There was no difference between sirolimus and control group in gender and age ($P > 0.05$). After 24 weeks of the sirolimus treatment, except C-reaction protein, there was a significant decrease in disease activity measures including DAS28, ESR, the number of tender joints and swollen joints ($P < 0.001$). Patients with sirolimus treatment had a significant increase in the number of Tregs and a lower DMARDs usage rate ($P < 0.05$). There was no difference in blood routine, liver and renal functions both before and after the treatment between two groups ($P > 0.05$).

Conclusion: Sirolimus treatment selectively up-regulated Tregs and partly decreased the usage of DMARDs without over-treatment and evaluated side effect. The further study is required to increase the RA patients in sirolimus and conventional treatment groups.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Rheumatoid Arthritis – Treatments III: New Compounds and Biosimilars

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30 PM-6:00 PM

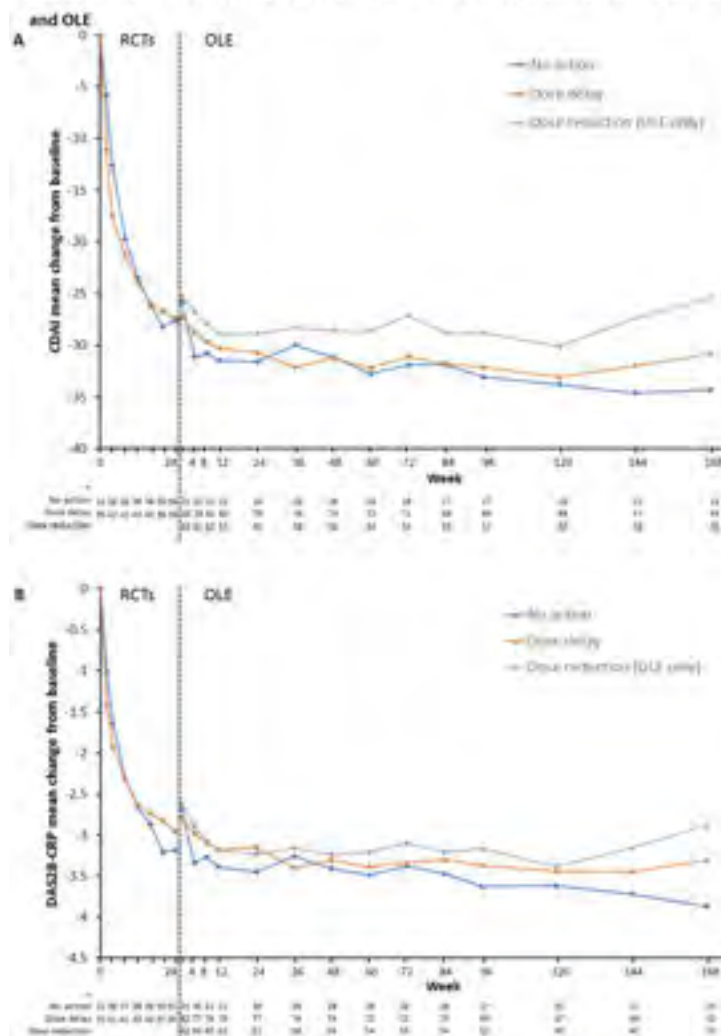

Background/Purpose: In sarilumab randomized controlled trials (RCTs), dose delay and/or reduction was recommended for management of patients who developed neutropenia Grade (G) 3 ($ANC \geq 500$ to $<1000/mm^3$). This posthoc analysis evaluated the impact of sarilumab dose delay/reduction on efficacy and safety in RCTs and open-label extension (OLE: EXTEND).

Methods: In RCTs and OLE, patients who experienced G4 or G3 neutropenia and signs of infection permanently discontinued treatment. Patients with G3 neutropenia (no signs of infection) temporarily (or permanently at investigator discretion) discontinued treatment; patients were retested $\leq 48h$ after recording decreased ANC and before next scheduled dose, and could resume if $ANC \geq 1000/mm^3$. RCTs: patients restarted sarilumab at randomized dose (150 or 200 mg q2w [MOBILITY (NCT01061736)/TARGET (NCT01709578)]; 200 mg q2w [MONARCH (NCT02332590)]). OLE (NCT01146652): patients received sarilumab 200 mg q2w, and restarted sarilumab at 150 mg q2w (per protocol) or 200 mg q2w (investigator discretion); patients requiring dose decrease to 150 mg q2w received that dose for the rest of the study. This analysis included pooled RCT data and OLE data from EXTEND patients enrolling from MOBILITY or TARGET.

Results: Of the 8–11% of patients experiencing $ANC < 1000/mm^3$ at any time (105/1346 [8%] RCT; 147/1353 [11%] OLE), 81/105 [77%] (RCT) and 132/147 [90%] (OLE) were able to continue or reinitiate sarilumab. Of the 81 RCT patients who continued or reinitiated sarilumab, 53% had a dose delay >17 days (i.e. more than one q2w dosing interval) and the remainder continued without interruption. Of 132 OLE patients who continued/reinitiated sarilumab, 82 had dose delay >17 days, 62 had dose reduction, and 31 had no action taken. No meaningful differences in DAS28-CRP or CDAI mean change from baseline over time were observed between patients with $ANC < 1000/mm^3$ who reinitiated sarilumab and those without neutropenia who continued without interruption. Among patients with $ANC < 1000/mm^3$ who continued treatment, no meaningful differences in CDAI or DAS28-CRP mean change from baseline (Figure) were observed in RCT patients with or without dose delay or in OLE patients with no action/dose delay/dose reduction, although some numerical differences were seen. Patients who were neutropenic at any time did not have an increased risk of infections or serious infections (SIEs) (RCT: infections/SIEs 35.9%/2.4% (non-neutropenia) vs 35.8%/1.2% (neutropenia); OLE: 57.8%/8.5% vs 57.6%/8.3%).

Conclusion: The majority of patients in RCTs and OLE who temporarily discontinued treatment with sarilumab due to low ANC were able to continue or reinitiate sarilumab with no apparent clinically meaningful impact on long-term efficacy or safety.

Figure. Effect of dose delay and/or reduction on (A) CDAI and (B) DAS28-CRP change from baseline in RCTs

SESSION INFORMATION

Session Date: Monday, October 22, 2018
Session Title: Systemic Lupus Erythematosus – Clinical II: Renal and Neuropsychiatric Disease in SLE
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: Cognitive dysfunction is a common problem in systemic lupus erythematosus (SLE) but the cause is still unclear; measuring it can be difficult and, as such, treatment options are limited. We examined cognitive function (CF) in a stable SLE group using both behavioural and imaging techniques. Associations for cognitive dysfunction in SLE were also explored.

Methods: 36 stable SLE (SLE 1997 ACR Criteria) and 30 healthy controls (HC) were recruited. Demographics clinical features, psychological questionnaires and blood samples were collected. We compared periventricular hyperintensities (PVH), deep white matter hyperintensities (DWMH), brainstem and basal ganglia features. CF was assessed using selected tests from the CANTAB®, and fMRI was used to examine blood-oxygen-level dependent (BOLD) responses to a working memory and attention task (n-back) and a facial emotional processing task (FERT). The fMRI data was modelled using SPM12. All other data was analysed using SPSS 22.

Results: SLE patients had significantly higher scores for depression and fatigue and they also had higher levels of IL-6, high sensitivity CRP, VCAM-1 and BlyS (Table 1). The SLE group performed significantly worse on a behavioural task of sustained attention ($p=0.002$) but similarly on all other cognitive tasks. They had more and larger perivascular spaces (PVS) in the centrum semiovale (CSO-VRS), $\chi^2=15.50$, $p<0.001$, compared to the HC group. We also found altered BOLD signals compared to the HC group for the n-back task in regions associated with the default mode network during the working memory condition and in the lingual gyrus during the attention condition. For the FERT task, during the sadness condition, differences were also found (Figure 1). The attenuated BOLD signal in the right superior temporal gyrus positively correlated with VCAM-1 ($r=0.53$, $p=0.01$), and SLICC/ACR-DI score ($r_s=0.56$, $p=0.005$). The attenuated BOLD signal in the lingual gyrus positively correlated with the BILAG total score ($r_s=0.45$, $p=0.033$) and IL-6 ($r_s=0.44$, $p=0.036$).

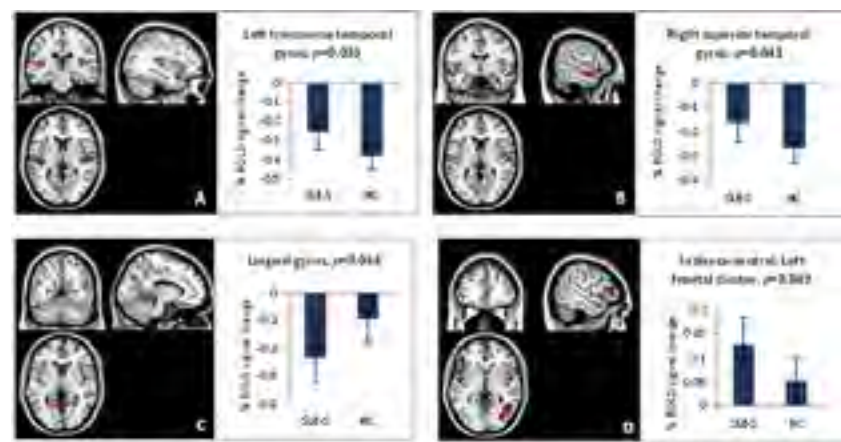

Figure 1: Significantly different BOLD responses to: A & B – the n-back task for the working memory condition in default mode network regions, C – the n-back task for the attention condition in a visual attention area and D – the FERT task for the sadness condition in a cognitive frontal cluster.

Table 1 Differences between the SLE and HC groups for demographic, psychiatric and fatigue characteristics and serological inflammatory markers

Variable	SLE (n=36)	HC (n=30)	p-value
Mean (S.D.), Median (LQ, UQ) or n (%)			
Demographic			
Age (years)	40 (32, 48.75)	32 (27, 46.5)	$p=0.14$
Gender (% female)	34 (94)	30 (100)	$p=0.19$
Handedness (% right-handed)	30 (83)	28 (93)	$p=0.34$
Years in education	16.11 (3.51)	17.97 (3.40)	$p=0.034$

Table. (Cont'd)

Variable	SLE (n=36)	HC (n=30)	p-value
WTAR (IQ)	102.5 (98.25, 108)	111 (105, 114)	<i>p</i> =0.001
Depression			
MADRS	4 (1, 8)	1 (0, 3)	<i>p</i> =0.012
HADS - D	4 (1, 9)	1 (0, 2)	<i>p</i> <0.001
BDI - II	10 (4, 20.25)	3 (0.75, 8)	<i>p</i> =0.002
Anxiety			
HADS - A	6 (3, 10.5)	5 (2, 7)	<i>p</i> =0.08
Fatigue			
FSMC - Motor score	36 (22, 40.5)	14 (11.5, 18.5)	<i>p</i> <0.001
FSMC - Cognitive score	31 (22, 40)	14 (11.5, 18.5)	<i>p</i> <0.001
FSMC - total score	67.5 (44.75, 80.5)	27 (23, 37)	<i>p</i> <0.001
Biomarkers of inflammation and endothelial activation			
hsCRP (mg/l)	1.44 (0.66, 5.06)	0.88 (0.39, 1.39)	<i>p</i> =0.013
IL-6 (pg/ml)	1.67 (0.50, 5.33)	0.50 (0.50, 1.32)	<i>p</i> =0.003
VCAM-1 (ng/ml)	474.93 (194.30)	345.66 (53.79)	<i>p</i> =0.001
VEGF (pg/ml)	66.04 (13.93, 139.60)	45.42 (6.04, 114.93)	<i>p</i> =0.275
BLyS (ng/ml)	0.51 (0.35, 0.71)	0.34 (0.27, 0.39)	<i>p</i> <0.001

WTAR: Weschler Test of Adult Reading; MADRS: Montgomery Asberg Depression Rating Scale; HADS-D: Hospital Anxiety and Depression Scale - Depression score; BDI-II: Becks Depression Inventory - II; HADS-A: Hospital Anxiety and Depression Scale - Anxiety score; FSMC: Fatigue Scale for Motor and Cognitive Functions; hsCRP: High Sensitivity C-Reactive Protein; IL-6: Interleukin 6; VCAM-1: Vascular cell adhesion molecule-1; VEGF: Vascular Endothelial Growth Factor; BLyS: B lymphocyte stimulator

Conclusion: Structural and functional changes related to cognition in SLE may, in part, be influenced by inflammation and aspects of disease including pre-existing damage. Also, the compensatory brain mechanisms used by the SLE group to maintain adequate CF may make SLE patients more susceptible to emotional interference during non-emotional cognitive tasks. Whilst multifactorial in nature, certain aspects of SLE CF may be sensitive to changes in disease status and thus to targeted therapeutic interventions.

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Lupus Erythematosus – Clinical II: Renal and Neuropsychiatric Disease in SLE

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30 PM-6:00 PM

Background/Purpose: Cognitive impairment is common in SLE and impacts quality of life; however, causality is limited by incomplete understanding of neurotoxic mechanisms. Diffusion tensor imaging (DTI) is an advanced MRI technique that assesses white matter integrity (WMI). In an animal model we demonstrated cross-reactive anti-dsDNA/NMDA receptor antibodies (DNRAb) that cause neuron loss, hippocampal dysfunction, and an established behavioral phenotype. In SLE patients, serum DNRAb correlates with poor spatial memory and hippocampal atrophy. We report new associations among serum DNRAb, regional microstructural integrity (DTI) and spatial memory in SLE.

Methods: 19 out of a cohort of 20 adult SLE subjects that met ACR criteria and had no history of CNS insult, well-controlled hypertension, low disease activity and corticosteroid doses (Table), and 14 age/gender matched healthy controls (HC) underwent DTI. A spatial memory task (SMT) assessed both non-spatial object recognition and memory for spatial relations in SLE subjects. Serum DNRAb assays were performed by ELISA with the DWEYS consensus sequence. Fractional anisotropy (FA) maps were compared between SLE and HC, and tract count differences were evaluated (t-test). Regression analysis (Pearson product-moment) assessed correlations between FA maps, serum DNRAb, and spatial memory performance.

Figure 1: Microstructural integrity (FA) in the parahippocampus regions correlates with serum DNRAb titers and performance on a spatial memory test in the SLE subjects.

Figure 2: Connections between the abnormal SLE-related regions visualized with group tractography.

	SLE n=20
Age (years)	41 ± 10.5
Gender: female	18 (90%)
Ethnicity	
Latino/Hispanic	4 (20%)
Asian	1 (5%)
African American	14 (70%)
Caucasian	1 (5%)
Education (years)	13.3 ± 2.4
SLEDAI score	2.3 ± 2.1
SLICC Damage Index score	0.9 ± 1.1
Current medications	
prednisone dose (mg)	2.6 ± 3.7
Hydroxychloroquine	17 (85%)
DMARD*	11 (55%)
Serology	
anti-dsDNA ab +	10 (50%)
anti-Ro/L	16 (70%)
Anti-NMDAR+	9 (45%)
anti-Ribosomal P+	3 (15%)
Anticardiolipin (IgG, M or A)	1 (5%)
Co-morbid disease	
Hypertension	9 (45%)
Coronary artery disease	1 (5%)
Smoking: ever	7 (35%)

Table: Subject characteristics for SLE cohort.

* Disease Modifying Anti-Rheumatic Drug: methotrexate (n=1), azathioprine (n=3), mycophenolatemofetil (n=7)

Results: FA was significantly reduced in 5 discrete regions with abnormal WMI in SLE. FA in the parahippocampal gyrus (PHG) correlated inversely with serum DNRAb and positively with SMT performance (Fig.1). Other regional abnormalities in WM tracts (expressed as % change relative to HC) included: 1) superior longitudinal fasciculus (temporal part) (SLF, -74%), 2) uncinate fasciculus (UF, -86%), 3) cingulum (hippocampus part) (-82%), 4) inferior longitudinal fasciculus (ILF, -99.5%) and inferior frontooccipital fasciculus (IFOF, -100%), and 5) the splenium of the corpus callosum (CC, -48%) ($p < 0.001$) (Fig. 2).

Conclusion: DTI revealed PHG abnormality that correlated with serum DNRAb and SMT performance, suggesting potential roles of these assessments as biomarkers for cognitive impairment. Other discrete regions of decreased WMI, connected by diminished tracts, raise the specter of clinically unrecognized neurodegeneration in quiescent, stable SLE patients without known CNS disease.

Apolipoprotein L1 Risk Variants Associate with Poor Renal Outcomes, Damage Accrual, and Death: A Prospective Ghanaian SLE Cohort

Ashira Blazer¹, Ida Dzifa Dey², Margaret Reynolds³, Festus Ankrah³, Nancyanne Schmidt⁴, Robert M. Clancy⁵ and Jill P. Buyon⁶, ¹Internal Medicine Division of Rheumatology, NYU School of Medicine, New York, NY, ²Department of Medicine, Rheumatology Unit, School of Medicine and Dentistry, University of Ghana, Accra, Ghana, ³Internal Medicine, The University of Ghana, Accra, Ghana, ⁴Internal Medicine, New York University School of Medicine, New York, NY, ⁵NYU School of Medicine, New York, NY, ⁶Rheumatology, NYU School of Medicine, New York, NY

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Lupus Erythematosus – Clinical II: Renal and Neuropsychiatric Disease in SLE

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30 PM-6:00 PM

Background/Purpose: Two Apolipoprotein L1 (APOL1) risk variants (RV), G1 and G2, are enriched in ancestrally African populations due to a conferred superior resistance to *Trypanosoma brucei*. This improved infectious evolutionary fitness comes at the cost of propensity toward progressive renal disease by multiple causes including SLE. In Ghana's Ashanti people, Allelic frequencies for G0, G1, and G2 have been reported at 0.46, 0.49, and 0.13 respectively. Despite their high frequencies, and the established role in SLE nephritis, no study has examined outcomes in a Ghanaian SLE cohort. Accordingly, this prospective study evaluated APOL1 risk traits including renal, damage accrual, and mortality in 101 Ghanaian patients followed at Korle bu Teaching Hospital in Accra, Ghana.

Methods: From 05/2015-04/2018, 101 Ghanaian patients meeting at least 4 ACR criteria for SLE were followed prospectively with data evaluated every six months. DNA was extracted from saliva and patients were stratified by APOL1 genotype as follows: reference allele (G0/G0), RV heterozygote (RV/G0), and RV homozygotes (RV/RV). Sera were shipped to the NYU clinical lab for confirmation of anti-dsDNA. Clinical endpoints included demographics, ACR criteria, SLEDAI score, SLICC damage index, mortality, vital signs, and laboratory values as available.

Results: The frequencies of the G1, and G2 alleles were 0.24, and 0.12 respectively— lower than would be expected given the reported regional frequencies. Subjects were 100% female, with an average age of 32.1 years and disease duration of 2.9 years. There were no differences in demographics across the genotypes. The RV associated with higher BP: 108/71, 108/73, and 120/82 in the G0/G0, RV/G0, and RV/RV groups respectively ($p=0.04$ systolic; 0.009 diastolic). Among those with nephritis, RV/RV carriers presented with higher dipstick proteinuria than G0/G0 and RV/G0 carriers (2.6 vs 1.2 and 1.3 respectively; $p=0.05$; $F=3.1$). While proteinuria responded most robustly to therapy in RV/RVs, it remained higher at each time point compared to the other genotypes ($p=0.002$; $F=5.4$). SLEDAI scores were comparable across the genotypes, however RV/RV carriers had lower dsDNA titers (10.7 IU/mL) than G0/G0 (57.1 IU/mL) and RV/G0 (95.6 IU/mL) carriers ($p: 0.03$). RV homozygosity associated with elevated SLICC damage index: G0/G0 or RV/G0: 0.95 vs RV/RV: 1.7; driven by renal, CVD, and neurologic manifestations G0/G0: 0.46, RV/G0: 0.39, RV/RV: 1.25; ($p=0.03$). There were 5 deaths during the study period: 1 death in the G0/G0 group (ESRD), 1 in the RV/G0 group (post-partum sepsis plus renal), and 3 in the RV/RV group (myocarditis/heart failure; ESRD; unknown). RV carrier status associated with mortality with 25% of the RV/RV group succumbing to disease vs 2% in the G0/G0 and RV/G0 groups ($p=0.003$; $F=6.3$).

Conclusion: Taken together, APOL1 RV associates with renal progression, organ damage accrual, and mortality in this Ghanaian SLE cohort. Despite having poorer outcomes, RV homozygotes exhibited lower dsDNA titers and similar

SLEDAI scores compared to G0/G0 or RV/G0 patients suggesting a genetic effect independent of SLE activity. APOL1 genotyping could have important prognostic implications in ancestrally African SLE patients.

Does Renin Angiotensin System Blockade in Addition to Immunosuppressive Therapy Improve Proteinuria in Acute Lupus Nephritis?

Konstantinos Tselios¹, Dafna D Gladman², Jiandong Su¹ and Murray Urowitz², ¹University of Toronto, Toronto Western Hospital, Toronto, ON, Canada, ²Rheumatology, University of Toronto, Toronto Western Hospital, Toronto, ON, Canada

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Lupus Erythematosus – Clinical II: Renal and Neuropsychiatric Disease in SLE

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30 PM-6:00 PM

Background/Purpose: Angiotensin converting enzyme inhibitors (ACEIs) and angiotensin receptor blockers (ARBs) are currently recommended for patients with lupus nephritis (LN) as an adjunctive therapy for the optimal control of proteinuria. However, that recommendation is mainly extrapolated from studies in diabetes, hypertension and IgA nephropathy with no supportive evidence from patients with LN. The aim of this study was to assess the impact of such treatment on proteinuria in active LN.

Methods: Patients from our long-term longitudinal cohort who were treated with glucocorticosteroids (GCS) and mycophenolate mofetil (MMF, 2-3g/day) or azathioprine (AZA, 2mg/kg) for their first episode of active LN after 2001 were included. They had at least one year of follow-up with visits at 6 and 12 months. Individuals with end-stage renal disease (eGFR \leq 15ml/min/1.73m²) or LN class VI at baseline were excluded. Patients were divided into two groups according to the concurrent treatment with ACEIs/ARBs or not. Demographic, clinical, immunological and therapeutic variables were compared at baseline; cumulative GCS dose and blood pressure at baseline, 6 and 12 months were also assessed. Proteinuria (24h) and eGFR were compared at 6 and 12 months after therapy initiation. Complete renal response was defined as proteinuria $<$ 500mg/day. Statistical analysis was performed with SAS 9.4; $p<0.05$ was considered significant.

Results: One hundred forty three patients were included (77 with concomitant ACEI/ARB treatment and 66 without). There were no significant differences concerning age at LN diagnosis, gender, race, disease duration, SLEDAI-2K and SLICC/Damage Index as well as LN histopathologic class, eGFR and blood pressure at baseline. Severity of proteinuria (2.2 \pm 1.5 vs. 2.1 \pm 1.8g/day, $p=0.78$) and nephrotic syndrome (proteinuria $>$ 3g/day) were also similar (15.6% vs. 18.2%, $p=0.68$). There were no differences in the initial GCS and MMF/AZA doses as well as antimalarial usage. Cumulative GCS dose at 12 months and blood pressure at 6 and 12 months were also comparable. Overall, 55.2% of the patients achieved a complete renal response with a significant mean reduction (60%) in proteinuria at 6 and 12 months. Prevalence of complete renal response, level of proteinuria and eGFR between groups are shown in Table 1.

Table 1 Complete response and level of proteinuria and eGFR over time

	ACEIs/ARBs (+) (n=77)	ACEIs/ARBs (-) (n=66)	P
Complete renal response at 6 months (% , n)	35.1% (27)	50% (33)	
Complete renal response at 12 months (% , n)	49.4% (38)	62.1% (41)	
Proteinuria at baseline (mean \pm SD, g/day)	2.2 \pm 1.5	2.1 \pm 1.8	
Proteinuria at 6 months (mean \pm SD, g/day)	1.2 \pm 1.2	1.1 \pm 1.4	
Proteinuria reduction at 6 months (% from baseline)	45.5%	47.6%	NS
Proteinuria at 12 months (mean \pm SD, g/day)	0.9 \pm 1.0	0.8 \pm 1.3	
Proteinuria reduction at 12 months (% from baseline)	59.1%	61.9%	NS
eGFR (ml/min/1.73m ²) at baseline (mean \pm SD)	92 \pm 38	104 \pm 39	
eGFR (ml/min/1.73m ²) at 12 months (mean \pm SD)	89 \pm 35	107 \pm 34	
Change in eGFR at 12 months (% from baseline)	-3.3%	2.9%	NS

A sub-analysis of the patients who were treated only with MMF (n=81, 51 with concomitant ACEI/ARB treatment and 31 without) yielded similar results.

Conclusion: A majority of patients achieved complete renal response at 12 months without significant differences between groups. Similarly, there was a significant improvement in proteinuria at 6 and 12 months with no significant deterioration of the eGFR and no difference between groups. Renin angiotensin system blockade may not be necessary in the acute phase of LN.

Abstract Number: 1945

Early Prediction of Long-Term Renal Outcomes in Lupus Nephritis Using Hazard Index Equations

Farah Tamirou¹, Meggan Mackay², Maria Dall'Era³, Joanna Fishbein⁴, Kenneth C. Kalunian⁵, Brad H. Rovin⁶ and Frédéric A. Houssiau⁷, ¹Rheumatology Department, Cliniques universitaires Saint-Luc, Brussels, Belgium, ²The Feinstein Institute for Medical Research, Manhasset, NY, ³University of California, San Francisco, San Francisco, CA, ⁴The Feinstein Institute for Medical Research, New York, NY, ⁵University of California San Diego, San Diego, CA, ⁶Division of Nephrology, Ohio State University Medical Center, Columbus, OH, ⁷Pôle de pathologies rhumatismales systémiques et inflammatoires, Institut de Recherche Expérimentale et Clinique, Université catholique de Louvain, Brussels, Belgium

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Systemic Lupus Erythematosus – Clinical II: Renal and Neuropsychiatric Disease in SLE

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30 PM-6:00 PM

Background/Purpose: Early endpoints predicting long-term outcome in lupus nephritis (LN), which could be used as outcome measures in clinical trials, are still debated. Recently, a multicentric study, using an extended international database of prospectively followed LN patients, succeeded in computing equations (hazard index; HI) predicting adverse kidney outcomes, in casu chronic kidney disease (CKD), severe kidney injury (SKI) and renal replacement therapy (RRT). These HI were validated in a replicate cohort. The HI for CKD, SKI and RRT (calculated with data measured at one year) were significantly higher in groups with long-term poor renal outcomes after a follow-up (FU) of ≥ 4 years (Mackay M et al. Arthritis Rheumatol 2016; 68 (suppl.10), abstract 967).

Objectives: To validate the HI for CKD, SKI and RRT in an independent LN cohort followed for ≥ 4 years and to check their validity to predict outcome in patients followed for ≥ 9 years.

Methods: Data from 229 consecutive LN patients followed in a single lupus center were screened. Only those for whom clinical data were available following their first episode of proliferative and/or membranous biopsy-confirmed LN were selected. Serum creatinine and proteinuria at different time points from 102 LN patients followed for ≥ 4 years were analyzed. At last FU, patients were divided according to the presence or absence of CKD, SKI and RRT. Their respective HI, measured at one year, were compared. CKD/SKI were defined as $\geq 30\%/ \geq 50\%$ decrease in eGFR (CKD-EPI equation), compared to the highest value measured within the first year.

Results: As illustrated in the Table, the mean HI for CKD and SKI, measured at one year, were significantly higher in the groups of patients who indeed developed CKD and SKI after a FU of ≥ 4 years compared to those who did not. Importantly, the HI predictive value remained valid after a FU of ≥ 9 years. The mean HI for RRT was higher in patients who developed RRT after ≥ 4 and ≥ 9 years, but the difference was not statistically significant ($p=0.08$ and $p=0.25$, respectively), most likely due to the small numbers of RRT in this series. Of note, clinical (gender, age, mean serum creatinine, mean proteinuria) and pathological (ISN/RPS class) characteristics did not differ at baseline between patients with poor long-term renal outcome compared to the others.

Conclusion: We confirm the validity of the HI equations as early predictors of poor renal outcomes (CKD and SKI after long-term FU). These HI tools could be used as outcome measures in LN clinical trials.

Renal outcome ≥ 4 years (102)	HI at one year (mean \pm SD)	Renal outcome ≥ 9 years (76)	HI at one year (mean \pm SD)
Presence of CKD (21)	0.69 \pm 0.53*	Presence of CKD (18)	0.56 \pm 0.63**
Absence of CKD (81)	0.30 \pm 0.40	Absence of CKD (58)	0.32 \pm 0.36
Presence of SKI (8)	-0.67 \pm 0.36*	Presence of SKI (9)	-0.72 \pm 0.44*
Absence of SKI (94)	-1.20 \pm 0.47	Absence of SKI (67)	-1.22 \pm 0.45
Presence of RRT (5)	-1.74 \pm 0.74	Presence of RRT (6)	-1.87 \pm 0.74
Absence of RRT (97)	-2.33 \pm 0.74	Absence of RRT (70)	-2.28 \pm 0.70

HI : hazard index; figures between brackets correspond to numbers of patients; CKD : chronic kidney disease; SKI : severe kidney injury; RRT : renal replacement therapy; *: $p<0.005$; **: $p<0.05$ (Mann-Whitney U-tests).

Changing the Conversation about Pain: Development and Testing of an Interprofessional Pain CME Applicable for Rheumatologists and Rheumatology Health Professionals

Kim Jones¹, Catriona Buist², Denise Taray³, Rubin Halperin⁴, Mark Stephens³ and Nora Stern⁴, ¹Schools of Nursing and Medicine, Oregon Health & Science University, Portland, OR, ²Anesthesiology and Pain Management, Oregon Health & Science University, Portland, OR, ³Oregon State Pain Management Commission, Portland, OR, ⁴Providence St Joseph Health and Services, Portland, OR

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: ARHP I: Pain, Anxiety, and Depression

Session Type: ARHP Concurrent Abstract Session

Session Time: 4:30 PM-6:00 PM

Background/Purpose: Pain is a near universal symptom of rheumatic diseases. Persistent pain can cause changes in the central and peripheral nervous system transforming pain from a symptom to a chronic illness. Shifting providers' and patients' thinking about "pain as a chronic illness" requires examples of conversations that can be shared between the patient and members of the health care team. The purpose of this project is to overview the development and testing of a novel on-line CME whose goal is to promote optimal patient care and provider satisfaction by 'changing the conversation about pain'.

Methods: From January 2017 to January 2018, the Oregon Pain Management Commission deployed a team, consisting of two clinical pain leaders, a program coordinator (RN) and a producer of online training content, to revise the existing pain module mandated by the State for prescribing providers. An iterative Delphi-type process distilled multiple stakeholders' needs from 13 professional and government organizations into the final modular product.

Results: On January 30, 2018 "Changing the Conversation About Pain" was launched. <http://www.oregon.gov/oha/HPA/CSI-PMC/Pages/module.aspx> By April 1, 1,453 persons had completed the 1.0 CME (476 nurses/nurse practitioners, 108 physicians, 105 dentist, 149 physical therapists, 127 occupational therapists, 79 pharmacists, 22 chiropractors, 13 psychologists and 374 other health professionals). On evaluation, 73% of participants were 'highly committed' to change practice by using alternative communication methodologies with patients and families. Two open fields were available for feedback with comments including:

"Great Insight as to how pain is processed."

"This is by far the most positive and thorough presentation on pain I have ever experienced."

"Gave me language to use when talking with patients that are resistant to everything but pharmacological interventions."

"This module is very informative and helpful for clinicians in understanding complex pain and the available treatment options for patients to benefit from."

Conclusion: Extensive collaboration yielded an interprofessional CME that is thus far well received by a wide range of practicing professionals in addition to mandated providers. The CME is now being rolled out to law enforcement, patient navigators, certified nursing aides coaches, medical coders, health education specialists, and health administrators. These successes are furthering our goal of changing the conversation about pain to empower patients to take a self-management approach to their care.

Do Changes in Pain Sensitization and Depressive Symptoms Mediate the Effect of Extreme Weight Loss on Knee Pain Improvement?

S. Reza Jafarzadeh¹, Tuhina Neogi¹, Joshua J. Stefanik², Margaret M. Clancy¹, Jing-Sheng Li³ and David T. Felson¹,

¹Clinical Epidemiology Research and Training Unit, Boston University School of Medicine, Boston, MA, ²Department of Physical Therapy, University of Delaware, Newark, DE, ³College of Health and Rehabilitation Sciences: Sargent College, Boston University, Boston, MA

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: ARHP I: Pain, Anxiety, and Depression

Session Type: ARHP Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Exposure (X): $\geq 20\%$ Weight Loss

Mediators (M): Change in PPT, CES-D Score

Outcome (Y): $\geq 18\%$ Reduction in WOMAC Pain

Background/Purpose: We previously showed that the one-year effects of weight loss on knee pain reduction were not mediated by changes in structural features of osteoarthritis such as bone marrow lesions and synovitis. We aimed to assess whether the knee pain improvement in these persons could be explained by changes in pain sensitization or depressive symptoms.

Methods: Morbidly obese persons with body mass index ≥ 35 kg/m², from the Nutrition and Weight Management Center who had knee pain on most days of the past month were eligible. Patients were evaluated at baseline, before bariatric surgery or medical weight management, and at one-year. Measurements from both visits included WOMAC pain subscale score, pressure pain threshold (PPT) obtained at index patella and right wrist as an indication of peripheral/central and central sensitization, respectively, and depressive symptoms derived from the Center for Epidemiologic Studies Depression (CES-D) scale. Improvement in pain beyond a minimal clinically important difference (MCID) of 18% (i.e., $\geq 18\%$ reduction) in WOMAC score was defined as the outcome. We defined the exposure as weight loss of $\geq 20\%$ and focused on potential mediator's defined as the change in patella and wrist PPT and CES-D score from baseline to follow-up. For mediation analysis, we fit natural effects models to quantify the magnitude of weight loss effect on pain improvement through a mediator-specific causal pathway; this is the mediating or indirect effect, and the remaining direct effect that is independent of the mediator-specific pathway (Figure 1).

Results: Of 75 study participants, 53% (40/75) lost $\geq 20\%$ body weight by one-year follow-up. Of these 40, 39 (98%) underwent bariatric surgery compared to 23% (8/35) of participants who experienced $<20\%$ weight loss. Pain improvement at MCID level or beyond was observed in 75% (30/40) of those with $\geq 20\%$ weight loss, compared to 34% (12/35) who lost $<20\%$ body weight. Natural direct effect estimates suggested increased odds of pain improvement through changes in patella PPT (odds ratio [OR] = 1.62, 95% CI: 0.89, 2.75), wrist PPT (OR = 1.15, 95% CI: 0.77, 1.77), and CES-D score (OR = 1.22, 95% CI: 0.77, 1.87). However, the bootstrap-based confidence intervals around our reported effect sizes slightly overlapped the null value of 1.

Conclusion: Weight loss-induced knee pain improvement is partially attributable to reduced pain sensitization and to a lesser extent improvement in depressive symptoms.

Beliefs and Preferences for Reducing Sedentary Time in Those with Current or Past Knee Symptoms

Christine Pellegrini^{1,2}, Sara Powell², Chelsea Larsen² and Siobhan Phillips³, ¹Northwestern University Feinberg School of Medicine, Chicago, IL, ²Exercise Science, University of South Carolina, Columbia, SC, ³Preventive Medicine, Northwestern University Feinberg School of Medicine, Chicago, IL

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: ARHP I: Pain, Anxiety, and Depression

Session Type: ARHP Concurrent Abstract Session

Session Time: 4:30 PM-6:00 PM

Background/Purpose: Physical activity is beneficial for those with current or previous knee symptoms, yet few meet federal physical activity guidelines. Reducing sedentary time, which has harmful effects independent of physical activity, may be a more feasible approach to improve the health of this population. The purpose of this study was to identify beliefs about sedentary behavior, barriers to standing, and program preferences in adults with knee pain, knee osteoarthritis (KOA), or total knee replacement (TKR).

Methods: Adults ≥ 50 years with knee pain, KOA, or TKR were recruited via flyers, emails, social media, and healthcare professionals. Participants completed an online survey assessing demographics, pain and function (Patient-Reported Outcomes Measurement Information System [PROMIS]), time spent in moderate-to-strenuous physical activity (MVPA; Godin Leisure Time Exercise Questionnaire) and sitting (Sitting Time Questionnaire), beliefs about sedentary behavior, and preferences for a sedentary behavior reduction program.

Results: A total of 35 participants completed the survey (Table 1). TKR patients were older and experienced less pain than those with knee pain or KOA ($P < 0.05$). Participants self-reported being sedentary 10.1 ± 3.8 hours/day and engaging in

113.7±129.8 minutes/week of MVPA, with no differences between knee groups. The majority of participants own a computer (97.1%) and smartphone (82.9%). Most participants (82.9%) believe that reducing sitting time can improve health, with the majority believing brisk or light walking (91.4%) would be better than standing (65.7%) (Table 2). Over half (54.3%) of participants wish they could sit less. The most common barriers to standing were feeling pain/discomfort (48.6%) and inability to stand while using computer (48.6%) or watching TV (22.9%). Sixty-eight percent of participants were interested in participating in a sedentary reduction program and believed tracking sitting time (71%) and setting goals (67.7%) would be most helpful to reduce sitting time (Table 3).

Conclusion: Adults with knee pain, KOA, and TKR believe reducing sitting time could improve health. These results will help to inform the development of future sedentary reduction interventions tailored to the needs of those with current or past knee symptoms.

Implementation of a Health Diary for Patients with Fibromyalgia

Verónica De Cillis¹, Ayelen Semerano², Adriana Pérez Dávila², Analía Bohr³, Sandra Pelaez⁴ and E. Scheines⁵,

¹Occupational Therapist Service, Hospital de Rehabilitación Manuel Rocca., Buenos Aires, Argentina, ²Hospital de Rehabilitación Manuel Rocca, Buenos Aires, Argentina, ³Rheumatology Section, Hospital de Rehabilitación Manuel Rocca, Buenos Aires, Argentina, ⁴Research Centre of the St.Justine Hospital, Montreal, QC, Canada, ⁵Reumatology, Instituto de Rehabilitación Psicofísica, CABA, Argentina

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: ARHP I: Pain, Anxiety, and Depression

Session Type: ARHP Concurrent Abstract Session

Session Time: 4:30 PM-6:00 PM

Background/Purpose: Fibromyalgia (FM) is a syndrome of central sensitization that encompasses many disorders where the central nervous system amplifies sensory input across many organ systems and results in diverse and varied symptoms such as musculoskeletal pain, alteration of sleep and fatigue. FM has a severe impact on the quality of life of patients, affecting work capacity, activities of daily life, as well as social relationships. There is agreement that first-line treatment should include both pharmacological and non-pharmacological interventions. Among the latter, the completion of a health diary is included as a valuable self-help tool to assess and control symptoms and improve activity levels and quality of life. In the context of this study, we designed a health diary to support self-management in patients with FM. The health diary aimed at changing and adjusting health-related behaviors such as pain management, exercise, and rest through practical hints and self-help activities. The purpose is to explore the effect of the use of a health diary in daily self-management in patients with FM.

Methods: Patients diagnosed with primary FM, referred by the rheumatologist, were included in the study and randomly assigned into two groups. All patients received the health diary with correspondent instructions for its completion. In addition to the completion of the health diary, patients in the experimental group participated in a four-weekly guided counseling and education workshop regarding how to handle chores and health-related behaviors while dealing with FM self-management. The counseling and educational workshop was delivered by two occupational therapists. Patients in both groups completed the FIQ (Fibromyalgia Impact Questionnaire) and a visual analog scale of activity-performance (VAS) at baseline (Mi) and again the visual analog scale one month following the intervention (Mf). Means were calculated to assess the impact of the FM. Instead, the initial and final results of the analog scale were compared using the independent Student T-test. All patients received an email address to ask for support if needed.

Results: 30 women, 34 to 75 years old (M = 56), participated in the study. Participants had a moderate-high FM impact FIQ = 52.14 (18-79.08). In total, 14 patients from the experimental group and 6 patients from the control group completed the health diary. The initial and final averages of the VAS were for the experimental group: personal care Mi = 7.06 - Mf = 8.66 (P = .009); household activities Mi = 5.6 - Mf = 7.3 (P = .010); work Mi = 3.06 - Mf = 3.5 (P = .10); social activity Mi = 3.7 - Mf = 5.2 (P = .002). No statistically significant changes were observed in the group that solely completed the health diary.

Conclusion: The health diary, supported by guided counseling and education delivered through workshops, could be a useful strategy to enhance the implementation of healthy habits in patients with FM. While a tailored healthy diary may be an interesting landscape to self-management, additional support may even reinforce and enhance the promotion and maintenance of healthy habits.

Self-Reported Depression and Anxiety Among US Adults Aged 18-44 Years with Arthritis, National Health Interview Survey 2014-2016

Dana Guglielmo¹, Jennifer M. Hootman², Louise Murphy², Michael Boring³, Kristina Theis², Charles G. Helmick², Kamil E. Barbour² and Patricia Katz⁴, ¹Oak Ridge Institute for Science and Education, Oak Ridge, TN, ²Arthritis Program, Centers for Disease Control and Prevention, Atlanta, GA, ³Cutting Edge Technology and Solutions, Mesa, AZ, ⁴University of California San Francisco, San Francisco, CA

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: ARHP I: Pain, Anxiety, and Depression

Session Type: ARHP Concurrent Abstract Session

Session Time: 4:30 PM-6:00 PM

Background/Purpose: Depression and anxiety are frequent comorbid conditions among adults with arthritis, and are associated with poorer quality of life, reduced adherence and efficacy of arthritis treatment, and suicidal ideation. In the general population, younger adults have a higher prevalence of depression and anxiety than older adults. We analyzed nationally-representative population-based prevalence of self-reported depression and anxiety among 21,318 young adults (aged 18-44 years) with and without arthritis.

Methods: We combined National Health Interview Survey data from 2014, 2015, and 2016. Arthritis was “yes” to: “Have you ever been told by a doctor or other health care professional that you have arthritis, rheumatoid arthritis, gout, lupus, or fibromyalgia?” We classified respondents as having self-reported depression and/or anxiety if they had high or medium frequency (daily, weekly, or monthly) of respective symptoms. Analyses accounted for the complex survey design to make estimates representative of the US civilian, non-institutionalized population. We estimated the unadjusted weighted prevalence (%) with 95% confidence intervals (CI) of depression and anxiety by arthritis and groups defined by selected characteristics.

Results: In 2014-2016, 7.7% of young adults reported arthritis and among them, 29.0% and 48.7% reported depression and anxiety, respectively. Depression prevalence was 2.4 times higher for young adults with arthritis than those without (29.0%; CI=26.0-32.2 vs. 12.3%; CI=11.7-13.0); anxiety prevalence was 1.6 times higher (48.7%; CI=45.5-52.0 vs. 29.6%; CI=28.6-30.6). Among 1,644 young adults with arthritis, depression prevalence was high among those unable to work/disabled and anxiety prevalence was high among those unable to work/disabled and those with 3+ co-occurring chronic conditions (Figure 1). Among those with arthritis and the respective conditions, 32.1% (CI=28.1-36.4) reported taking medications for anxiety and 45.0% (CI=38.7%-51.5%) reported taking medications for depression; for both, medication use was higher compared to those without arthritis (Figure 2).

Conclusion: Self-reported depression and anxiety are common in young adults and considerably more prevalent among those with arthritis than those without. Although there is substantial awareness of depression in adults with arthritis, anxiety prevalence was higher. Health care providers can help arthritis patients by screening for these conditions, especially in younger adults, and referring them to mental health specialists for diagnosis and treatment.

Figure 1. Prevalence of self-reported depression and anxiety among 1,644 US adults aged 18-44 with arthritis for groups defined by selected characteristics, NHIS 2014-2016

*Among nine chronic conditions (asthma, cancer, chronic obstructive pulmonary disease, diabetes, heart disease, hepatitis, hypertension, kidney disease, or stroke), not including arthritis.

†Arthritis-attributable activity limitations, which do not include work limitations.

Abstract Number: 1951

The Effect and Psychosocial Impact of a Longstanding Telephone Peer Counseling Service on Volunteers with Systemic Lupus Erythematosus

Priscilla Toral¹, Melissa T. Flores¹, Roberta Horton¹ and Jillian Rose², ¹Social Work Programs, Hospital for Special Surgery, New York, NY, ²Hospital for Special Surgery, New York, NY

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: ARHP I: Pain, Anxiety, and Depression

Session Type: ARHP Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Studies have demonstrated the value of peer volunteers providing psychosocial support to people living with rheumatic & other chronic conditions. An evaluation was conducted with counselors of a national toll-free phone peer counseling service to assess how their role as helpers affects their psychosocial coping with SLE. Ongoing since 1988, this service provides emotional support for people with SLE & their loved ones. The program has been presented at prior ACR/ARHP, including program users' satisfaction & the impact of a revised curriculum on counselors.

Methods: A 43-item survey with Likert scale & open-ended questions was administered to 11 active peer counselors. The survey captured demographics, satisfaction with their role & examined SLE coping & actions taken since becoming a peer counselor. Surveys were completed electronically.

Results: All (100%) peer counselors completed the survey, with a reach of 44 callers matched from 2017-2018. All respondents were female, 50% identified as White, 30% Black/African-American, 20% Hispanic & 30% other race. Counselors' ages ranged from 30-79, with 30% ages 60-69. Half (50%) were either employed full time/part time, 40% retired & 10% unemployed/receiving disability. Almost half (40%) were single, 91% have SLE & have been a counselor for an average of 12 years.

When asked about satisfaction in their role, 91% indicated being very satisfied. Top reasons for becoming a counselor included an opportunity to help others affected by SLE (100%) & enhancing personal growth/ development (73%). When asked their reasons for continuing as a counselor, 82% identified to meet others impacted by SLE & 73% identified for the support of program staff.

In relation to coping, 64% indicated that they have coped better with SLE since becoming a counselor. Most (73%) reported that they had a better understanding of SLE since becoming a counselor, with 38% very much attributing this to the program. Almost half (46%) reported feeling less depressed since becoming a peer counselor with 60% very much & 40% somewhat crediting their role for this change. Counselors also reported feeling less alone (73%) with 43% very much attributing this to their peer role.

When asked what they find most useful from monthly training seminars, 89% identified group discussion & 78% indicated educational games. When asked if monthly seminars help them to better cope with SLE, 78% agreed & 89% of counselors reported that seminars provide a space for them to reflect on their SLE. Counselors shared the most rewarding part of their role is "educational information that helps me understand SLE better" & "the opportunity to be outside of my own illness & connect with others."

Conclusion: Despite limitations due to a small sample size, results reinforce the two-way flow of psychosocial support received by counselors through their support of callers, ongoing connections with peers & program staff via monthly seminars. Similar to program callers, the counselor role positively impacts volunteers' ability to better cope with SLE & reduces isolation. Findings also highlight the continued relevance of a phone support service to people with SLE and opportunities for further research on volunteer impact of peer-staffed programs.

Abstract Number: 1952

Experimental Tendinopathy Treatment with SM04755, a Topical Small Molecule Inhibitor of the Wnt Pathway

Vishal Deshmukh, Timothy Seo and Yusuf Yazici, Samumed, LLC, San Diego, CA

SESSION INFORMATION

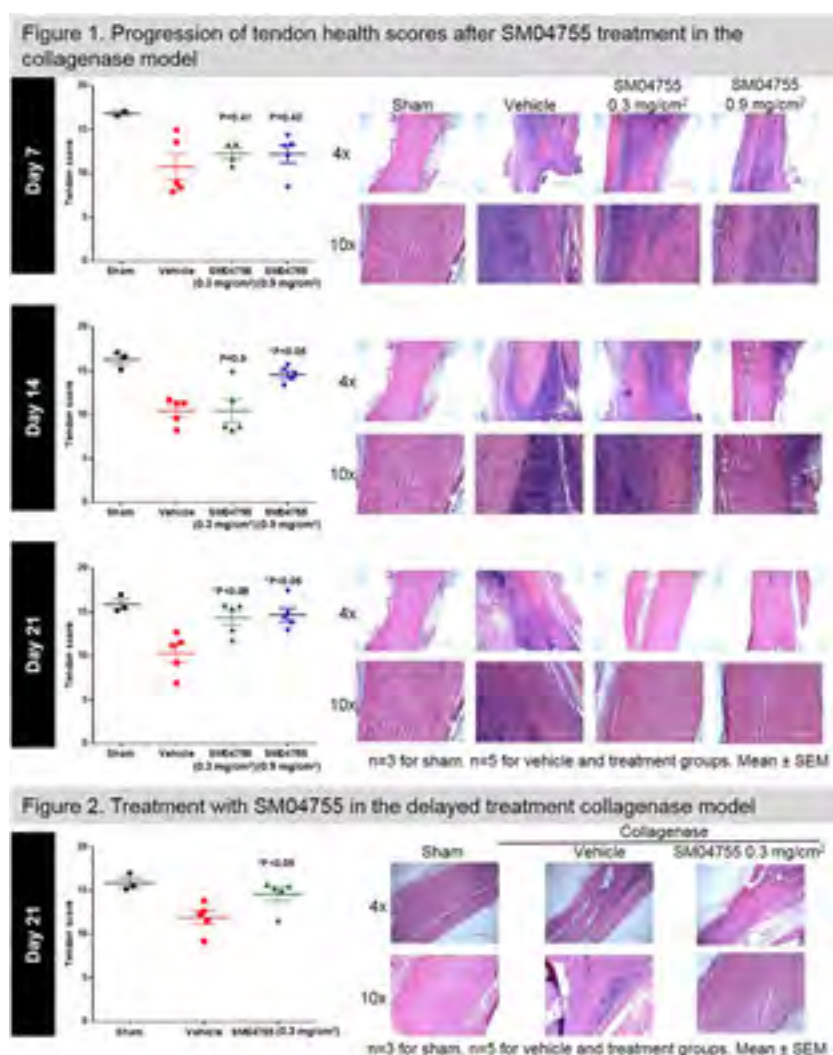

Session Date: Monday, October 22, 2018

Session Title: Orthopedics, Low Back Pain and Rehabilitation – ACR/ARHP

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Tendinopathy is an inflammatory and degenerative disorder caused by injuries and overuse. The Wnt pathway is upregulated in chronic tendinopathy and involved in inflammation, tenocyte differentiation, and fibrosis. SM04755, a novel, topical, small molecule Wnt pathway inhibitor, has previously been shown to inhibit inflammation,

reduce fibrosis, and increase tenocyte differentiation (Deshmukh et al., *Arthritis Rheumatol*, 2016). Two further experiments are presented: 1. SM04755 treatment in an acute dose-response tendinopathy model and 2. SM04755 treatment in a repeat injury/delayed treatment (RIDT) tendinopathy model. These models simulate acute and acute-on-chronic clinical tendinopathy, respectively.

Methods: SM04755 was assessed in rodent Achilles tendinopathy models, induced by intra-tendon collagenase injection (500 µg). In the acute dose response model, a single injection of collagenase or sham per animal on Day -4 was followed on Day 0 by daily topical vehicle, or 0.3 mg/cm² or 0.9 mg/cm² SM04755. Achilles tendons were harvested on Days 7, 14, and 21. In the RIDT model, collagenase injections were given at Days -28 and -14, followed on Day 0 with daily topical vehicle or 0.3 mg/cm² SM04755. Achilles tendons were harvested on Days 7, 14, 21, and 28. Blinded histology analyses scored tendon health based on linearity, tendon cell shape, tendon cell density, inflammation, and hemorrhage (range 5-20). Statistical analyses: one-way ANOVA for multiple group comparisons, t-tests for two group comparisons.

Results: In the acute dose-response model, SM04755 improved tendon health from baseline compared to vehicle as assessed by tendon histology scores. Vehicle scores were 10.77 [±1.46] at Day 7, 10.44 [±0.66] at Day 14, and 10.31 [±1.02] at Day 21. SM04755 (0.3 mg/cm²) scores were 12.30 [±0.62] at Day 7 (NS), 10.45 [±1.29] at Day 14 (NS), and 14.37 [±0.82] at Day 21 (P<0.05). SM04755 (0.9 mg/cm²) scores were 12.22 [±1.02] at Day 7 (NS), 14.57 [±0.41] at Day 14 (P<0.05), and 14.67 [±0.76] at Day 21 (P<0.05) (Fig. 1). In the RIDT model, vehicle scores were 12.35 [±0.30] at Day 7, 10.09 [±0.76] at Day 14, 11.92 [±0.77] at Day 21, and 13.72 [±0.35] at Day 28. SM04755 (0.3 mg/cm²) scores were 11.86 [±2.13] at Day 7 (NS), 9.44 [±0.48] at Day 14 (NS), 14.61 [±0.77] at Day 21 (P<0.05), and 14.93 [±0.46] at Day 28 (NS) (Fig. 2).

Conclusion: In the acute dose-response model, SM04755 (0.3 mg/cm²) showed statistically significant improvements in tendon scores compared to vehicle at Day 21. The 0.9 mg/cm² dose achieved significance at Days 14 and 21, indicating faster response at higher SM04755 dose. In the RIDT model, SM04755 0.3 mg/cm² dose promoted accelerated tendon healing compared to vehicle. Therefore, SM04755 demonstrated accelerated improvement of tendon histology in acute and RIDT models compared to vehicle and has potential as a tendinopathy therapy. Clinical studies are planned.

Randomized Trial on Exercise at Late-Stage after Total Knee Replacement

Sara R. Piva¹, Michael Schneider¹, Charity Moore-Patterson¹, M. Beatriz Catelani¹, Alexandra Gil¹, Brian Klatt², Anthony DiGioia³, Gustavo J. Almeida¹, Samannaaz S. Khoja⁴, Gwendolin Sowa⁵ and James Irrgang¹, ¹Physical Therapy, University of Pittsburgh, Pittsburgh, PA, ²Orthopaedic Surgery, University of Pittsburgh Medical Center, Pittsburgh, PA, ³University of Pittsburgh Medical Center, Pittsburgh, PA, ⁴Department of Physical Therapy, University of Pittsburgh, Pittsburgh, PA, ⁵Physical Medicine and Rehabilitation, University of Pittsburgh Medical Center, Pittsburgh, PA

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Orthopedics, Low Back Pain and Rehabilitation – ACR/ARHP

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Total knee replacement (TKR) improves pain and quality of life; however, the functional limitations that existed for years before surgery tend to persist after surgery. Progressive and intensive exercise programs could resolve these persistent limitations but they are not tolerated by many patients until later stage (>2 months) after surgery. Evidence for the effectiveness of exercise at later stage post-TKR is limited.

The purpose of this study was to compare the effectiveness of later stage exercise programs (outpatient individualized physical therapy [PT] and group classes in community centers) with an usual medical care, at improving physical function and activity, and to explore heterogeneity of treatment effects.

Methods: The study was a 3-arm single-blind randomized clinical trial that enrolled 240 individuals at least 60 years of age, with primary TKR done at least 2 months before, who experienced moderate functional limitations, and were medically cleared to exercise. The 3 study arms were clinic-based PT exercise, community-based group exercise, or usual care (control). The control group continued their usual care whereas the exercise groups participated in supervised exercise programs during 12 weeks.

Physical function was the main outcome and was assessed primarily by the Western Ontario and McMaster Universities Osteoarthritis Index-Physical Function scale (WOMAC-PF), and secondarily by performance-based tests germane to patients with TKR, and additional patient-reported outcomes at 3 and 6 months. The trial was registered in ClinicalTrials.gov, NCT02237911.

Results: All 3 arms demonstrated clinically important improvements. At 3 months, the PT arm showed the most improvement in WOMAC-PF ($p=0.04$). Compared to community arm, the PT arm had greater improvement on performance-based tests (0.1; 95%CI: 0.002, 0.2) and percentage of responders (18% to 24% more in the PT arm). PT arm also had more improvements than control in performance-based tests (0.3, 95%CI: 0.1, 0.4) and percentage of responders (19% to 34% more in PT arm). The community arm improved performance-based tests compared to control (0.2; 95%CI: 0.02, 0.3). Most differences were sustained at 6 months. Exercise was not associated with serious adverse events. Moderator analysis showed significant interactions for obesity, anxiety/depression, and arthritis self-efficacy. Non-obese participants in both exercise arms had more improvements in physical function than the control. For obese participants, those in PT arm appear to experience more improvements than the community arm. Participants without depression/anxiety and high levels of self-efficacy in exercise arms had greater functional recovery compared to control; whereas those in the community arm with depression/anxiety symptoms and low levels of self-efficacy experienced less functional recovery.

Conclusion: This study provides novel evidence about the safety and effectiveness of late-stage intensive rehabilitation post-TKR. Individualized PT provided greater improvements in physical function than community or control arms. Patients and clinicians could benefit from studies to test models to implement late-stage rehabilitation programs post-TKR.

Factors Associated with Overweight or Obesity in Athletes 5 Years after Anterior Cruciate Ligament Injury

Louise Thoma¹, Jessica Johnson², Daniel White³, May Arna Risberg^{4,5} and Lynn Snyder-Mackler², ¹Physical Therapy, University of Delaware, Newark, DE, ²Physical Therapy; Biomechanics and Movement Science, University of Delaware, Newark, DE, ³Department of Physical Therapy, University of Delaware, Newark, DE, ⁴Norwegian Research Center for Active Rehabilitation, Department of Sports Medicine, Norwegian School of Sport Sciences, Oslo, Norway, ⁵Division of Orthopedic Surgery, Oslo University Hospital, Oslo, Norway

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Orthopedics, Low Back Pain and Rehabilitation – ACR/ARHP

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Obesity and knee injury, including anterior cruciate ligament (ACL) rupture, are strong risk factors for the development of knee osteoarthritis. Identifying participant and post-injury characteristics that are associated with obesity after knee injury may help target at risk populations for weight management interventions. The purpose of this study is to examine factors associated with overweight or obesity in athletes 5 years after ACL injury.

Methods: We analyzed data from the Delaware-Oslo ACL Cohort Study, a longitudinal cohort study of athletes after acute ACL rupture from the United States ($n=150$) and Norway ($n=150$). Inclusion criteria were sustaining a unilateral ACL rupture confirmed by MRI and regularly participating in level I/II sports prior to injury. Those with bilateral injuries or significant concomitant injuries were excluded. The outcome of interest was overweight or obesity at the 5-year follow-up. Body mass index (BMI) was calculated from self-reported height and weight, and categorized as Normal ($\text{BMI} < 25 \text{ kg/m}^2$) or Overweight/Obese ($\text{BMI} \geq 25 \text{ kg/m}^2$). Exposures of interest were age (at enrollment), sex, surgical status (ACL reconstruction vs. non-operative rehabilitation), and self-reported knee function at 2-year follow-up (IKDC, International Knee Documentation Committee Subjective Knee Form). We evaluated the association between the exposures and the

Table. Adjusted odds ratios and 95% confidence intervals evaluating the association of exposures with being overweight or obese 5 years after ACL injury			
Exposure	Odds Ratio	95% Confidence Interval	
Age (for each 1 year increase in age)	0.91	0.85	0.98
Sex (Ref = Men)	0.15	0.049	0.46
Surgical status (Ref = ACL reconstruction)	0.23	0.071	0.77
IKDC Score at 2-year follow up (per 1 point increase in IKDC score)	1.02	0.98	1.07

outcome using odds ratios with 95% confidence intervals from logistic regression, mutually adjusting for the other exposures, as well as baseline BMI, country (US vs. Norway).

Results: Of 300 participants enrolled in the study, 215 (72%) completed the 5-year follow up (mean baseline age 27.4 ± 10.1 years, baseline BMI 24.3 ± 3.5 kg/m², 48% women). At 5 years, 49% of the athletes were overweight or obese. Athletes who were older age at baseline, women, and received non-operative treatment had lower odds of being overweight or obese at 5-year follow-up, adjusting for baseline BMI and country (Table). Self-reported knee function at 2-year follow-up was not associated with being overweight or obese at 5-year follow-up.

Conclusion: Athletes who received non-operative treatment, women, and older athletes were less likely to be overweight or obese at 5-year follow-up. Those who undergo ACL reconstruction, men, and younger athletes may be appropriate targets for weight management interventions to prevent weight gain. Further research is needed to confirm these results and evaluate why those who undergo ACL reconstruction have higher odds of being overweight or obese at long-term follow-up.

Race Is Associated with Discharge Disposition after Total Knee Arthroplasty (TKA), Which Is Associated with 90-Day Readmission Rate

Jasvinder A. Singh¹, Michael Kallan² and Said Ibrahim³, ¹Rheumatology, University of Alabama at Birmingham, Birmingham, AL, ²University of Pennsylvania, Philadelphia, PA, ³Cornell University, New York, NY

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Orthopedics, Low Back Pain and Rehabilitation – ACR/ARHP

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: To assess whether race/ethnicity is associated with differences in discharge disposition after elective primary total knee arthroplasty (TKA), and if discharge disposition is associated with 90-day hospital readmission.

Methods: This was an observational cohort study that used the Pennsylvania Health Care Cost Containment Council (PHC4) Database, which includes all patient discharges from 170 non-governmental acute care hospitals in the State of Pennsylvania. We examined the association of race/ethnicity with discharge disposition after elective primary TKA, using multivariable logistic regression models, which were adjusted for patient-level and facility-level variables.

Results: Between 2012 and 2015, there were 107,768 eligible primary TKAs had identifiable race/ethnicity. In study cohort, 7,287 (6.8%) were African-Americans; 63.4% were female, 43.1% were younger than 65 years, 40.2% had private, 3.6% Medicaid and 56.3% Medicare insurance. The 30-, 60- and 90-day readmission rates were 5.3%, 7.5% and 9.4%, respectively. Compared to younger than 65 years, 30-, 60- and 90-day readmission rates were higher in adults 65+ years. *Younger than 65 years.* Compared to whites, African-Americans were more likely to be discharged to skilled nursing facility (SNF) or inpatient rehabilitation facility (IRF), but not home health care, 2.49 (95% CI, 1.42, 4.36), 3.91 (95% CI, 2.17, 7.06) and 1.30 (95% CI, 0.91, 1.88), respectively.

65 years or older. Compared to whites, African-Americans were more likely to be discharged to SNF but not IRF or home health care, 3.30 (95% CI, 1.81, 6.02), 1.64 (95% CI, 0.91, 2.97), and 1.06 (95% CI, 0.68, 1.65), respectively.

Younger than 65 years. Compared to home self-care, discharge to IRF or SNF, but not home health care, were each associated with higher odds ratios of 90-day readmission: 3.62 (95% CI, 2.33, 5.64), 1.91 (95% CI, 1.37, 2.65) and 1.08 (95% CI, 0.96, 1.22), respectively.

65 years or older. Similarly, in multivariable-adjusted model, compared to home self-care, discharge to IRF or SNF, but not home health care, were each associated with higher odds ratios of 90-day readmission: 2.85 (95% CI, 2.25, 3.61), 1.55 (95% CI, 1.27, 1.89) and 0.96 (95% CI, 0.82, 1.12), respectively.

Sensitivity analyses by inverse probability weighting (IPW) method confirmed these findings with minimal accentuation of odds ratios, but no change in significance or interpretation of findings.

Conclusion: African-Americans were more likely than whites to be discharged to IRF and SNF. Discharge to IRF or SNF, but not home health care, were each associated with higher odds ratios of 90-day readmission. These findings indicate that race/ethnicity may predict higher utilization, and further insights into modifiable attributes associated with this higher utilization are needed.

Cohort Effects in Back Pain: The Effect of Changes in Life-Style and Co-Occurring Conditions

Elizabeth M. Badley^{1,2}, Anthony V. Perruccio^{1,2} and Mayilee Canizares², ¹Dalla Lana School of Public Health, University of Toronto, Toronto, ON, Canada, ²Arthritis Program, Krembil Research Institute, University Health Network, Toronto, ON, Canada

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Orthopedics, Low Back Pain and Rehabilitation – ACR/ARHP

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: The goal of this study was to determine a) if the age-trajectory (life course) of back pain differs by birth cohort and b) whether any cohort differences are explained by changes in socio-economic status (SES), lifestyle factors, and the presence of chronic conditions.

Methods: We used biannually collected data from the 1994-2010 Canadian Longitudinal National Population Health Survey: 10,330 participants born from 1925 to 1974 grouped in five 10-year birth cohorts: Pre-World War II, born 1925-1934; World War II generation, born 1935-1944; older baby boomers, born 1945-1954; younger baby boomers, born 1955-64; and generation X, born 1965-74. The outcome was reported back pain as a long term health conditions diagnosed by a health professional. We used multilevel logistic growth models to examine cohort effects in the age-trajectory of back pain adjusting for sex, SES (education, income), lifestyle factors (BMI, physical activity, sedentary behavior, smoking status) and multimorbidity (2+ conditions up to 17).

Results: There was a trajectory of increasing back pain with age up to middle age (50-55 years) and plateauing afterwards. In addition, there were also significant cohort differences ($p < 0.0001$): when compared at the same age, each succeeding recent cohort had higher odds of reporting back pain than those in the earlier cohort. Low education, being a smoker, obesity, and sedentary behavior were associated with increased odds of reporting back pain, but did not substantially affect cohort differences. Addition of multimorbidity to the model significantly and substantially attenuated the cohort differences.

Conclusion: The results suggest that more recent cohorts of Canadian adults are more likely to have back pain and that they report back pain earlier than previous generations. These cohort differences were explained by cohort effects of increasing multimorbidity in more recent generations.¹ These findings are supported by descriptive studies showing high level of multimorbidity in people with back pain,² with important implications for our understanding of back pain and the delivery of healthcare and services.

Kim⁶, ¹Rheumatology, Brigham & Women's Hospital, Boston, MA, ²Division of Pharmacoepidemiology and Pharmacoeconomics, Brigham and Women's Hospital, Harvard Medical School, Boston, MA, ³Orthopedics and Physical Rehabilitation, University of Massachusetts Medical School, Worcester, MA, ⁴Brigham and Women's Hospital, Boston, MA, ⁵Brigham & Women's Hospital and Harvard Medical School, Boston, MA, ⁶Brigham and Women's Hospital, Harvard Medical School, Boston, MA

SESSION INFORMATION

Session Date: Monday, October 22, 2018

Session Title: Orthopedics, Low Back Pain and Rehabilitation – ACR/ARHP

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Elevated hemoglobin A1c (HbA1c) has been associated with a 9-fold increase in wound complications after total joint replacement (TJR). Data suggest that including HbA1c in perioperative screening lowers complications. The CDC recommends perioperative glycemic control as a prevention strategy for infections in patients with and without DM. We aimed to assess how frequently HbA1c was tested prior to TJR in a large claims database.

Methods: Within Medicare Parts A/B/D (2010-2014), we identified patients who were ≥ 65 years old and underwent TJR (hip or knee). The index date was date of TJR; all patients were free of TJR and continuously enrolled in Medicare for ≥ 1 year prior to TJR. We created 4 mutually exclusive groups during the baseline period ranging from 365 to 90 days prior to TJR; 1) non-DM based on no ICD-9 code for DM or DM complications, no claim for insulin or anti-DM medication; 2) DM without medication, based on a diagnosis code for DM but no claim for insulin or non-insulin antidiabetic medication; 3) DM on non-insulin antidiabetic medication; and 4) DM on insulin with or without other antidiabetic medication. The outcome was HbA1c test ordered 90 days prior to TJR. Covariates including age, sex, race, comorbidities, medications, outpatient visits, and number of HbA1c tests, were collected during the baseline period. We calculated the proportion of patients receiving HbA1c or serum glucose test in the 90 days prior to TJR. We used logistic regression with adjustment for covariates to assess characteristics associated with HbA1c testing.

Results: Seventy-two percent were non-DM, 11% DM without medication, 13% DM on non-insulin medications, and 4% DM on insulin. Mean age was 73 -75. Patients with DM had more outpatient visits, and co-morbid diseases compared to those without DM. During the baseline period mean number of HbA1c tests was 0.1 in the non-DM group, 0.8 in DM without medication, 1.1 in DM on non-insulin medications, and 1.3 in DM on insulin. Only 5% of patients without DM had an HbA1c testing within 90 days of TJR, compared to 26% in those with DM not on medication, 39% in DM on non-insulin medications and 43% with DM on insulin. Serum glucose testing was obtained more frequently- 37% of non-DM, and 46-50% of patients with DM. In patients without DM, non-white race and obesity lead to increased HbA1c testing. In patients with DM on no medication, those with DM complications had increased HbA1c testing. For all groups having HbA1c tested in the baseline period was associated with having HbA1c tested prior to TJR (Table).

Conclusion: In this large population based cohort of patients undergoing TJR, HbA1c testing perioperatively occurred in less than half of patients with DM. The presence of diseases co-morbid to DM was not strongly associated with increased screening in the non-DM population. Further study on the utility of perioperative HbA1c monitoring and postoperative outcomes is warranted.

Table: Outcomes in 90 days prior to TJR

	No Diabetes N=335,365	Diabetes		
		Without medication N=49,965	Non-insulin medication N=59,705	Insulin N=20,531

Gene Expression Pathways across Multiple Tissues in Anti-Neutrophil Cytoplasmic Antibody-Associated Vasculitis Reveal Core Pathways of Disease Pathology

Marcia Friedman¹, Donseok Choi^{1,2,3,4}, Steven Planck^{1,4}, James T. Rosenbaum⁵ and Cailin Sibley¹, ¹Oregon Health & Science University, Portland, OR, ²OHSU-PSU School of Public Health, Portland, OR, ³Graduate School of Dentistry, Kyung Hee University, Seoul, Korea, Republic of (South), ⁴Casey Eye Institute, Portland, OR, ⁵Ophthalmology, Oregon Health & Science University and Legacy Devers Eye Institute, Portland, OR

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Genetics, Genomics and Proteomics Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: In recent years, several studies have characterized the gene expression signatures of different tissues affected by ANCA-associated vasculitis (AAV). The purpose of this study is to test the hypothesis that there are commonly preserved disease pathways in all AAV tissues thus far characterized.

Methods: Gene expression data were collected from the three AAV tissues thus far characterized (orbit, peripheral leukocytes, and sinus brushings). The set of differentially up and down-regulated genes from each study were analyzed using the Cytoscape software application with the Reactome FI plugin—this is a pathway-based network analysis system using expert curated knowledge of protein-protein interactions. The pathways data were adjusted for multiple comparisons using a multi-dimensional local false discovery rate (md-lofdr), which estimates the probability of a false discovery of a given pathway in all three tissues analyzed.

Results: Four individual genes were upregulated in all three tissues—*IL1RN*, *TLR2*, *SCL11A1*, and *MMP9*. After multiple comparison adjustments, the network pathway analysis revealed 28 pathways associated with all three tissues. The most strongly associated pathway for all three tissues was the *neutrophil degranulation* pathway (md-lofdr=1.0x10⁻¹²), followed by the *osteoclast differentiation* (md-lofdr=3.8x10⁻⁰⁵), *cell surface interactions at the vascular wall* (md-lofdr=4.2x10⁻⁰⁴), *signaling by interleukins* (md-lofdr=6.1x10⁻⁰⁴), and *phagosome* (md-lofdr=0.003) pathways. There were no downregulated genes or pathways common to all three tissues.

Conclusion: This analysis identified individual genes and pathways of disease common to all AAV tissues thus far characterized. The use of a network pathway analysis allowed us to identify pathologic mechanisms that were not readily apparent in the commonly expressed genes alone. Many of these pathways are consistent with current theories about infectious drivers and the crossroads of innate and adaptive immune mechanisms. In addition, this analysis highlights novel pathways, such as vessel wall interactions and platelet activation, which require further investigation.

Stability of DNA Methylation Signature in Primary RA Synovial Fibroblasts Compared with Cultured Fibroblast-like Synoviocytes

Rizi Ai¹, Deepa Hammaker², Wei Wang³ and Gary S. Firestein⁴, ¹University of California San Diego, La Jolla, CA, ²Medicine, UC San Diego, La Jolla, CA, ³Chemistry and Biochemistry, University of California San Diego, La Jolla, CA, ⁴Medicine, University of California San Diego, La Jolla, CA

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Genetics, Genomics and Proteomics Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is an aggressive immune-mediated joint disease with synovial inflammation and joint destruction. Fibroblast-like synoviocytes (FLS) play a key role in mediating inflammation and joint damage. FLS are usually isolated from enzymatically dispersed synovial tissue and expanded in culture for multiple passages to achieve relatively homogenous population. Epigenetic alteration in RA FLS such as DNA methylation has been demonstrated stable for many passages. One critical question is whether the pathogenic genes altered in later passage FLS reflects the epigenome in situ. Therefore, we studied DNA methylation in the primary (P0) passage synovial fibroblasts (SF) and compared the patterns to late passage cells.

Methods: Genomic DNA from cultured FLS (30 RA, 16 OA) and P0 SF (5 RA, 10 OA) was isolated from synovial tissues obtained at the time of total joint replacement. P0 SF were isolated by enzymatically disaggregating cells and negatively selecting either using anti-CD45 magnetic beads or adherence to plastic. The P0 cells were evaluated by flow cytometry for T cells (RA $1.1 \pm 0.2\%$, OA $0.4 \pm 0.1\%$), B cells (RA 0.2% , OA 0.1%). Methylation levels were measured using Illumina HumanMethylation450 chip. Differentially methylated loci (DMLs) were identified using Welch's *t*-test and mapped to gene promoter regions to define differentially methylated genes (DMGs). The overlapped DMGs were calculated using Hypergeometric test. To compare enriched biological pathways, Ingenuity pathway analysis was applied.

Results: For P0 SF, 18,537 DMLs (difference of β value > 0.1 and q value < 0.05) were identified in 2,756 DMGs. Compared to previously reported 1,714 DMGs in passage 5 (P5), 582 (34.0%) DMGs of P5 were overlapped with DMGs in P0 (p value = $1.32e-149$). 75 differentially methylated pathways were significantly enriched between RA and OA in P0, and 15 of them are overlapped with 52 pathways enriched in P5, such as "Complement System" and "NF- κ B Signaling" associated with immunity and inflammation.

Because the limited number of P0 RA samples may be underpowered, we decreased DML stringency to q value cutoff of 0.1 to allow more DMGs and enriched pathways included. As a result, 26,267 DMLs (difference of β value > 0.1 and q value < 0.1) located on 3,578 DMGs are identified between RA and OA FLS in P5, in which 798 (46.6%) DMGs of P5 were overlapped with DMGs in P0 (p value = $1.04e-241$). In addition, out of 108 significantly enriched pathways between RA and OA in P0, 19 of them are overlapped with pathways enriched in P5. Interestingly, RA-specific pathway "Role of Osteoblasts, Osteoclasts and Chondrocytes in Rheumatoid Arthritis" is overlapped.

Conclusion: In this study, we have compared the DNA methylation signatures in RA between P0 SF and classically prepared P5 FLS. Even though there were differences in cell populations and processing methods, the overlap was highly significant with nearly half of DMGs between RA and OA in P5 FLS can be found in the P0 SF. Despite potential limitations due to sample size and the fact that P0 SF includes several subsets of fibroblasts, the DNA methylation signature of classical RA FLS in established culture are consistent with the patterns observed in SF.

Exome Sequencing Reveals Rare Recessive Mutations in Multiple Genes Including FAS, RAD51B, and ISG15 in a Single Family with Lupus and Suggests a Unique Genetic Model

Jessie Alperin¹, Khader Mustafa², Ola Hijawi², Patrick Coit³, Kenneth Kaufman⁴ and Amr H Sawalha³, ¹University of Michigan Medical System, Ann Arbor, MI, ²Division of Rheumatology, The University of Jordan, Amman, Jordan, ³Division of Rheumatology, University of Michigan, Ann Arbor, MI, ⁴Center for Autoimmune Genomics and Etiology (CAGE), Cincinnati Children's Hospital Medical Center, Cincinnati, OH

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Genetics, Genomics and Proteomics Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Lupus is a complex heterogeneous disease, which can affect almost any organ system. The genetic etiology of lupus is complex, with multiple genetic susceptibility loci identified. Monogenic lupus, caused by a specific single gene defect, is less common but is generally characterized by early disease onset and more severe presentation. The aim of this study was to understand the genetic basis of a consanguineous family with multiple lupus affected siblings in order to gain insights into lupus pathogenesis.

Methods: DNA samples extracted from whole blood were obtained from all members of a family of 13 (11 siblings and their parents) with 3 sisters affected by early-onset lupus with renal and central nervous system complications. Whole exome sequencing was performed for the 3 affected sisters and both parents. Because of strong consanguinity between both parents (first degree cousins both from their paternal and maternal descents), we assumed a recessive genetic model and focused on identifying rare recessive variants in the affected sisters that are present in heterozygous forms in both parents. Variants were filtered for potentially protein damaging effects using SIFT, Polyphen2, MutationTaster, Mutation Assessor, and FATHMM functional prediction algorithms. Sanger sequencing and Sequenom genotyping were used for validation and genotyping all unaffected siblings.

Results: Using whole exome sequencing, we found that each sister has multiple rare recessive mutations, including rare predicted damaging coding mutations in genes such as *FAS*, *RAD51B*, and *ISG15*, involved in apoptosis, DNA damage repair, and interferonopathy, respectively. These recessive genotypes are exceedingly rare in the general population with expected frequencies of ~1, 9, and 3 in 100,000 individuals, respectively. Interestingly, these mutations were mutually exclusive in the affected sisters. While the *ISG15* recessive mutation was not present in any unaffected sibling, homozygosity for the *FAS* and *RAD51B* mutations were not sufficient to explain lupus in the two other affected sisters as some of the unaffected siblings also have these recessive genotypes. Multiple other rare recessive variants enriched in genes related to apoptosis, inflammasome activation, and cell cycle regulation were identified in the affected sisters, suggesting that accumulation of multiple rare recessive variants underlies lupus phenotype in this family. Indeed, calculating genetic risk score using the total of 69 rare recessive variants identified in the affected sisters revealed a significantly higher genetic risk (~2 times) in the affected compared to unaffected siblings.

Conclusion: We describe a unique genetic model in a consanguineous family with lupus whereby the additive effect of a number of rare recessive variants in inflammatory pathways likely contributes to the disease phenotype within the same family.

Session Title: Genetics, Genomics and Proteomics Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Genome-wide association studies of systemic lupus erythematosus (SLE) in Chinese and Korean populations identified striking association with a single nucleotide polymorphism (SNP) rs73366469, located upstream of *GTF2I* gene encoding a transcription factor functional in the immune system. The association of *NCF1* in linkage disequilibrium with rs73366469 has also been reported, and causative association signal of this region requires further study. The *GTF2I-NCF1* region is also associated with Sjögren syndrome (SS) and rheumatoid arthritis (RA) in the Asian populations. However, to our knowledge, association studies with systemic sclerosis (SSc), ANCA-associated vasculitis (AAV), and polymyositis/dermatomyositis (PM/DM) have not been reported. In this study, in addition to confirming association of this SNP with SLE in a Japanese population, we tested its association with clinical phenotypes of SLE. Furthermore, we examined whether the SNP is also associated with SSc, AAV and PM/DM.

Methods: Genotyping of rs73366469 was performed on 842 Japanese SLE patients, 467 SSc patients, 477 AAV patients, 153 PM/DM patients and 934 healthy controls using TaqMan SNP Genotyping Assay. Case-control and case-only association studies were performed by chi-square test. Correction for multiple testing was performed by calculating FDR q values using Benjamini-Hochberg method, and $q < 0.05$ was considered significant. Statistical power was calculated by Power and Sample Size Calculation.

Results: When compared with healthy controls, striking association of rs73366469 C was detected in SLE patients ($p = 9.5 \times 10^{-16}$, $q = 3.7 \times 10^{-14}$, odds ratio [OR] = 2.27) (Table). When the case-only analysis was performed between SLE patients with and without specific clinical phenotypes (central nervous system disorders, renal disorders, presence of anti-dsDNA, anti-Sm or anti-U1-RNP antibodies), significant difference was not observed. When the association was tested in SSc patients, the same C allele was significantly increased in SSc ($p = 0.0028$, $q = 0.012$, OR = 1.47) (Table). Similarly, the association was observed regardless of the clinical phenotypes (lcSSc or dcSSc, presence or absence of anti-centromere, anti-topoisomerase I or anti-U1-RNP antibodies, interstitial lung disease or pulmonary hypertension), significant difference was not observed. In contrast, increase in C allele frequency was not detected in AAV and PM/DM (Table).

Conclusion: Association of *GTF2I* rs73366469 C with SLE was replicated in a Japanese population. In addition, the same allele was found to be associated with SSc. This allele was associated with susceptibility to overall SLE and SSc, but not with specific clinical phenotypes. In contrast, association was not detected in AAV and PM/DM. Taken together with previous reports on RA and SS, *GTF2I* region appears to be associated with susceptibility to multiple, but not all, systemic rheumatic diseases.

Table. Association study of rs73366469 and SLE, SSc, AAV and PM/DM in a Japanese population

	n	Genotype frequency n (%)			C allele frequency (%)	Allelic association (C vs T)			Power calculation (%)
		C/C	C/T	T/T		p	q	OR (95%CI)	
SLE	842	25 (3.0)	250 (29.7)	567 (67.3)	17.8	9.5×10^{-16}	3.7×10^{-14}	2.27 (1.86-2.77)	100

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Genetics, Genomics and Proteomics Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Anti-nuclear autoantibodies are a hallmark of scleroderma with anti-centromere antibody (ACA) recognizing centromeric antigens. ACA-positive patients have longstanding Raynaud's, limited cutaneous disease and increased risk for pulmonary arterial hypertension. We investigated the role of HLA classical genes and alleles on risk for ACA-positive scleroderma in a large collection of patients with scleroderma and genetically matched controls.

Methods: SNP genotypes of 723 scleroderma cases and 5,561 controls, all of European ancestry, were obtained from dbGaP. Classical HLA types were imputed with SNP2HLA using the Type I Diabetes Genetic Consortium reference of 5,225 individuals. Association of HLA classical alleles was tested by a dominant model regression analysis coding the HLA types as numeric values (1 for present, 0 for absent). Regression tests were corrected for genetic dissimilarity by including the top 5 principal components as covariates.

Results: Of the 723 scleroderma cases, 238 (32.9%) were positive for ACA. The most significantly ACA-positive scleroderma-associated HLA allele was *HLA-DRB1*07:01*, which was disease protective (P-value=1.8x10⁻¹⁸, odds ratio

Figure 1: *DRB1*07:01/DQB1*05:01* two-locus analysis for ACA-positive disease risk. Odds ratios are for disease risk relative to individuals with neither allele. Error bars are 95% confidence intervals for the odds ratios.

(OR)=0.11 (95%CI=0.05 to 0.22)). This allele was found in only 3.4% of the ACA-positive cases versus 23.6% of controls and 20.8% of the ACA-negative cases. Regression analysis conditioning on the disease-associated alleles identified *HLA-DQB1*05:01* as the most significantly associated disease risk allele (P-value= 3.3×10^{-08} , OR=2.18 (1.66-2.86)) with additional independent risk effects of *HLA-DQA1*04:01* and *HLA-DQA1*03:01*). A two-locus analysis of the *DQB1*05:01* disease-risk and the *DRB1*07:01* disease-protective alleles suggested the risk effect of *DQB1*05:01* is overridden by the protective effect of *DRB1*07:01*(Figure 1). The odds ratio for ACA-positive disease in individuals carrying both alleles was 0.14, similar to that in individuals carrying *DRB1*07:01* without *DQB1*05:01* (0.15). No effect of *DRB1*07:01* or *DQB1*05:01* was found in the anti-topoisomerase I autoantibody subset (P=0.98 and P=0.054, respectively). For validation, 62 African American ACA-positive cases and 946 matched controls from the Genomic Research in African American Scleroderma Patients (GRASP) Collection, were similarly analyzed. *DQB1*05:01* was associated with disease risk (P= 3.6×10^{-4} , OR=2.68 (1.57-4.58)) and *DRB1*07:01* was protective (P= 8.6×10^{-3} , OR=0.33 (0.13-0.85)) in the African American sample.

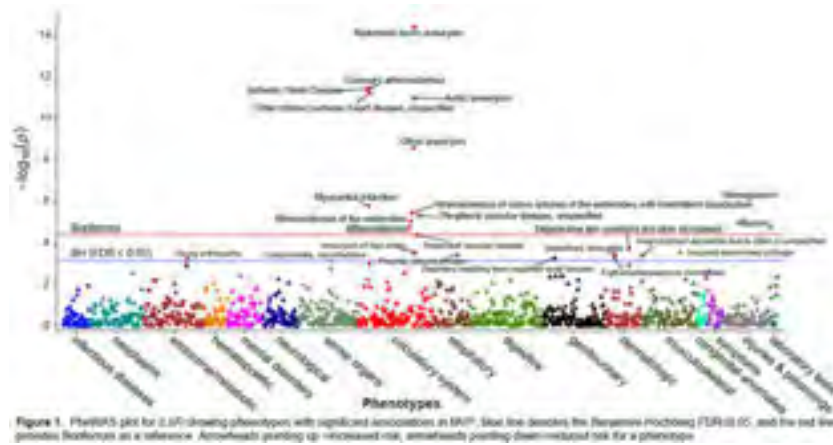

Conclusion: *HLA-DQB1*05:01* is associated with risk and *HLA-DRB1*07:01* is associated with protection for ACA-positive scleroderma. The mechanisms responsible for these effects could be exploited to prevent or treat scleroderma.

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Genetics, Genomics and Proteomics Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Individuals with an interleukin 6 receptor (IL6R) genetic variant not on IL6R blocking therapy have biomarker profiles similar to those treated with IL6R blockers. Individuals with the IL6 variant have impaired IL6 signaling due to reduced IL6Rs; the goal of IL6R blockade is also to impair IL6 signaling by binding to IL6R. This gene-drug pair may therefore facilitate whether the *IL6R* variant has an association with a reduced risk for a phenotype, which in turn can inform which diseases may benefit from treatment with IL6R blockade. To test this hypothesis, we performed a Phenome-Wide Association Study (PheWAS) to screen for associations between an *IL6R* genetic variant and a broad range of phenotypes in the electronic health records (EHR).

Methods: We studied veteran participants in the Veteran's Affairs Million Veteran's Project using genomic data linked to EHR. We extracted all diagnosis codes and mapped them to phenotype groups using published PheWAS methods. Routine laboratory measurements, e.g. complete blood count, were also extracted. A PheWAS was performed by constructing logistic regression models testing associations between the *IL6R* variant (Asp358Ala, rs2228145) and 1,342 phenotype groups; linear regression models were constructed to screen for associations between *IL6R* and 26 routine laboratory measurements. All models were adjusted for age, sex, population stratification, and healthcare utilization. Significance was reported using false discovery rate ≤ 0.05 ; data for Bonferroni adjustments also provided. We replicated findings using freely available online data from the Vanderbilt University Biobank (BioVU) and the UK Biobank, two biobanks with linked genetic and EHR data.

Results: We studied 330,374 participants; the minor allele frequency of the *IL6R* variant was 35.3%. *IL6R* was most strongly associated with a reduced risk of aortic aneurysm phenotypes (OR 0.87-0.90, 95% CI 0.84, 0.93) (Figure). We observed the expected association between *IL6R* and reduced C-reactive protein. We also observed known effects of IL6R blockade from clinical trials, increased hemoglobin. The protective effect of the *IL6R* variant for aortic aneurysm and coronary heart disease was replicated in BioVU and the UK Biobank, respectively.

Conclusion: In this proof of concept study, we demonstrated the application of the PheWAS using large EHR biobanks to potentially inform drug effects. The findings of a protective effect of a single *IL6R* variant with aortic aneurysms corresponded with the newest indication for IL6R blockade for giant cell arteritis, where clinical manifestation is aortic aneurysm.

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Genetics, Genomics and Proteomics Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Epigenetic changes contribute to the pathogenesis of rheumatoid arthritis (RA) and a comprehensive epigenomic characterization of RA fibroblast-like synoviocytes (FLS) has recently been described. As previous studies indicate that energy metabolism is altered in RA FLS, we hypothesize that ChIP mark changes near energy metabolism-related genes would correlate with differences in expression of these genes.

Methods: ChIP-sequencing data, for six different ChIP marks (H3K4me1, H3K4me3, H3K9me3, H3K27ac, H3K27me3, H3K36me3) from publicly available data sets from FLS derived from 11 patients with RA and 11 patients with OA were compared to identify regions with a difference in these histone modifications. Single nearest genes to regions of interest were then utilized for pathway analyses (Gene Ontology Enrichment Analysis, KEGG pathways, PANTHER classification) to determine if particular cellular processes and pathways are associated with these chromatin changes. Pathways associated with energy metabolism were enriched near a ChIP mark change commonly associated with active transcription (H3K4me3) with the use of the whole genome as a reference. To further elucidate these findings, single nearest genes associated with any ChIP mark change and metabolism were utilized for a secondary pathway analysis. Additionally, changes in transcription of genes associated with the ChIP mark changes were assessed using RNA-sequencing data from the same cells used for the ChIP-sequencing analyses.

Results: As per the unbiased pathway analysis, 4 of the 21 pathways significantly associated with changes in H3K4me3 ($p < 0.05$) were associated with energy metabolism with the whole genome used as a background (including glucose 6-phosphate metabolic process, regulation of triglyceride biosynthetic process and arginine metabolic process). 44 different genes involved in energy metabolism were associated with a change in at least one of the ChIP marks. These 44 genes were then used in a KEGG pathway analysis. Glycolysis/Gluconeogenesis was one of the top ranked pathways with 11 out of the 44 genes involved in this pathway (adjusted $p = 2.89 \times 10^{-21}$). Of the 44 genes associated with a change in a ChIP mark, glutaminase (GLS) and the cysteine/glutamate transporter SLC7A11 were two genes with significant differences in expression as per RNA-sequencing data. Of note, both genes were shown to mediate tumor metabolic reprogramming and to promote cancer progression.

Conclusion: This study of RA FLS demonstrated changes in epigenetic marks of genes related to energy metabolism and suggests that these pathways can be critical in RA pathogenesis and be involved in the imprinted aggressive phenotype displayed by RA FLS compared to OA FLS. Additionally, this dataset has the potential to identify RA-specific targets that can be used to develop novel therapeutic agents.

Session Date: Tuesday, October 23, 2018

Session Title: Genetics, Genomics and Proteomics Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The high prevalence of microscopic polyangiitis (MPA) and myeloperoxidase (MPO)-ANCA positive patients as well as frequent occurrence of interstitial lung disease (ILD) constitute unique epidemiological features of ANCA-associated vasculitis (AAV) in the Japanese population. Recent genome-wide association studies in European populations indicated that *HLA-class II* region was most strongly associated with AAV. In the Japanese population, we reported that *HLA-DRB1*09:01* was associated with susceptibility to, and *DRB1*13:02* with protection against, MPA and MPO-ANCA positive AAV (MPO-AAV) in Japan. In this study, we examined whether *HLA-class II* are associated with relapse of MPO-AAV, as well as occurrence of ILD in MPO-AAV, in a Japanese population.

Methods: Relapse rate and time to first relapse were analyzed in 206 MPO-AAV patients, who entered prospective cohort studies of remission maintenance therapy (RemIT-JAV and RemIT-JAV-RPGN) and achieved remission during the observation period. Association of *HLA-DRB1* alleles with relapse rate was tested by chi-square analysis or Fisher exact test, and relapse-free interval was analyzed by log-rank test. Association study with ILD was performed in 297 MPO-AAV patients (126 with ILD and 171 without ILD) and 596 healthy controls. Statistical analyses were conducted using logistic regression analysis under the additive model.

Figure 1.
Kaplan-Meier curves for relapse-free interval in MPO-ANCA positive patients with and without *DRB1*09:01*

Results: Relapse occurred more frequently in the patients with *DRB1*09:01* (*DRB1*09:01* positive: 22/85, 25.9% vs *DRB1*09:01* negative 18/121, 14.9%) (P=0.049, odds ratio [OR] 2.00), and time to relapse was significantly shorter in the patients with *DRB1*09:01* than those without (P=0.048) (Figure 1). Although patients with *DRB1*13:02* showed a tendency towards decreased relapse rate (*DRB1*13:02* positive: 1/16 6.3% vs *DRB1*13:02* negative: 39/190, 20.5%), the difference did not reach statistical significance (P=0.32, OR 0.26), nor did the time to first relapse (P=0.19). When the association of *HLA* alleles was tested between MPO-AAV with ILD and healthy individuals, *DPB1*05:01* and *DRB1*04:05* alleles were significantly decreased in MPO-AAV with ILD (Table 1). Case-case analysis between MPO-AAV patients with and without ILD also showed significant decrease of *DPB1*05:01* in MPO-AAV with ILD (Table 1).

Conclusion: Association of *DRB1*09:01* with relapse in MPO-AAV was observed in a Japanese population. In addition, *HLA-DPB1*05:01* was significantly decreased in MPO-AAV with ILD.

Table 1 Association of *HLA-class II* alleles with interstitial lung disease in MPO-ANCA positive vasculitis

	Allele frequency			vs HC		vs MPO-AAV without ILD	
	MPO-AAV with ILD	MPO-AAV without ILD	HC	P	OR	P	OR

Session Title: Genetics, Genomics and Proteomics Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic autoimmune diseases (SADs) are chronic inflammatory conditions with autoimmune aetiology and many common clinical features, difficulting diagnosis and adequate treatment decisions. Finding new treatments or applying the existing ones in a more effective way is especially hard in SADs due to the heterogeneity of molecular mechanisms within the same disease class. Based on this premise, the first step towards establishing a precision medicine strategy for SADs is to reclassify these conditions at the molecular level, which might result in a more homogenous stratification in terms of pathological molecular pathways. SADs have a multi-factorial predisposition, where the interplay between genetic, epigenetic and environmental conditions is essential in the pathogenesis of the diseases. Thus, in order to capture as many aspects as possible the molecular stratification is performed using multiple layers of information (e.g. genome, transcriptome, methylome or metabolome). Among all available molecular levels of information, the most informative in terms of functionality and dimensionality are transcriptome and methylome, reflecting different aspects of regulation and environmental influence, respectively, giving a wide view of the molecular background.

Methods: We performed an unsupervised integrative clustering analysis to classify SADs patients into subtypes based on genome-wide transcriptome and methylome profiling of ~800 cases distributed across 7 different clinical entities (rheumatoid arthritis, systemic lupus erythematosus, systemic sclerosis, primary Sjögren's syndrome, primary antiphospholipid antibody syndrome, mixed connective tissue disease and undifferentiated connective tissue disease) and ~200 healthy individuals.

Results: Interestingly, patients with different diagnoses were grouped statistically into new groups in terms of molecular functions. These results were replicated in two independent subsets of patients. The new groups of patients are characterized by a major subdivision, where some clusters show an increased inflammatory response and neutrophil degranulation functions, while others are enriched in lymphocyte proliferation and differentiation signatures. This major signal is subdivided into more specific subgroups defined by functional signatures such as type I interferon signaling, complement activation or neural functionalities among others.

Conclusion: This is the first attempt of integrating and characterizing SADS patients based on molecular profiles. The results show that we are able to identify new groups of patients sharing molecular features that do not reflect the clinical diagnoses. This new molecular classification might suppose a first step through precision medicine in SADS.

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Genetics, Genomics and Proteomics Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Because of the low prevalence, only three genome-wide association studies, all from the Caucasian populations, have been reported on ANCA-associated vasculitis (AAV) thus far; therefore, efficient candidate gene studies play an important role. In complex diseases, the majority of single nucleotide polymorphisms (SNPs) associated with disease susceptibility are located in the noncoding region and are suggested to affect gene expression. Recently, long noncoding RNAs (lncRNAs) are strongly implicated in the regulation of gene expression. In this study, we made an attempt to detect SNPs associated with susceptibility to AAV by focusing on candidate lncRNAs selected based on the transcriptome analysis.

Methods: Whole blood transcriptome analysis was conducted on eight patients with AAV and 14 healthy controls (HC). All subjects are Japanese. From the transcriptome data, we selected candidate lncRNAs using two approaches. The first approach took advantage of eQTL (expression quantitative trait loci) SNPs. lncRNAs significantly over- or under-expressed as compared with HC were selected. Then eQTL SNPs associated with expression levels of these lncRNAs were selected as candidate SNPs using GTEx database. In the second approach, in order to more comprehensively capture SNPs with potential relevance, we focused on the SNPs closely located to the candidate lncRNAs. Top 10 lncRNAs were selected based on the fold change (FC) in the expression levels compared with HC. Then SNPs located in the chromosomal regions encompassing the candidate lncRNAs (from 50kb upstream to 50kb downstream) were selected. The candidate SNPs were filtered based on minor allele frequency (>0.1), linkage disequilibrium ($r^2 < 0.6$) and regulome score (< 2). Finally, 96 candidate SNPs associated with 25 lncRNAs were selected for association analysis. Then these SNPs were genotyped in 525 Japanese AAV patients (315 MPA, 108 GPA, 412 MPO-ANCA positive, 70 PR3-ANCA positive) using DigiTag2 or TaqMan SNP genotyping assays, and allele frequencies were compared with 4,394 healthy Japanese controls from our laboratory and Tohoku Medical Megabank Organization (ToMMO).

Results: After quality control, association with AAV were analyzed on 74 SNPs. The SNP rs6958235, located in the upstream region of *ATP6V0E2-AS1*, showed a significant association with MPO-ANCA positive AAV ($P=5.72 \times 10^{-4}$, odd ratio 1.38, 95% confidence interval 1.15-1.65)(Table). The association remained significant after Bonferroni correction ($P_{\text{Bonferroni}}=0.042$). The expression level of *ATP6V0E2-AS1* was downregulated in AAV as compared with HC (FC -4.4).

Conclusion: A SNP rs6958235C located in the upstream region of lncRNA *ATP6V0E2-AS1* was found to be associated with MPO-AAV for the first time. *ATP6V0E2* encodes an isoform of an essential proton pump component that may play a role in the acidification of endosome and lysosome. The functional significance of this SNP requires further study.

Table. Allelic association of rs6958235T>C with AAV subsets in a Japanese population

	n	C allele frequency (%)	$P_{\text{uncorrected}}$	$P_{\text{Bonferroni}}$	OR	95% CI
MPA	315	18.3	1.88E-02	>1	1.29	1.04-1.59
GPA	108	19.4	5.79E-02	>1	1.39	0.99-1.96

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Genetics, Genomics and Proteomics Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic autoimmune diseases (SADs) are chronic inflammatory conditions with autoimmune aetiology and many common clinical features, hampering diagnosis and adequate treatment decisions. Finding new treatments or applying the existing ones in a more effective way is especially hard in SADs due to the heterogeneity of molecular mechanisms within the same disease class. Furthermore, most variants discovered by GWAS locate in non-coding regions, making it difficult for immediate interpretation. An important tool to discover the molecular mechanisms by which SADs- genetic variants exert their risk is the use of Expression Quantitative Trait Loci (eQTL) mapping.

Methods: We performed eQTL analysis using GWAS and RNA-Seq data derived from whole blood samples from ~1100 patients distributed across 7 different clinical entities (rheumatoid arthritis, systemic lupus erythematosus, systemic sclerosis, primary Sjögren's syndrome, primary antiphospholipid antibody syndrome, mixed connective tissue disease and undifferentiated connective tissue disease) and ~300 healthy individuals. All samples analyzed are of European ancestry and form part of the PRECISEADS project dataset. We used matrixEQTL with 8 cofactors to correct for bias introduced by batch, RIN, age, sex, medication, fever, genetic background and blood cell composition.

Results: We show that SADs-associated variants have widespread effects on genome-wide DNA expression levels. By means of stratified and interaction analyses we further show the gender and disease-specific context of SADs-eQTL variants. Importantly > 85% of eQTLs were found in patients but not in healthy subjects and shared across diseases, suggesting how SADs context-specificity works at the molecular level.

Conclusion: Our work serves to illustrate the possible regulatory downstream effects of risk variants and will ultimately inspire the generation of new hypotheses needed to increase our limited understanding on the biology of autoimmunity.

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Genetics, Genomics and Proteomics Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: In recent years there have been tremendous strides in determining the genetic component of complex diseases, not least in Juvenile Idiopathic Arthritis (JIA). We now have 17 genetic loci robustly associated with an increased risk for developing JIA (1). In JIA, like all complex diseases, the regions of the genome harbouring genetic changes are found outside protein coding DNA, in regions of the genome shown to control gene expression, often sited some distance from the closest gene. One of these JIA associated regions, on chromosome 21q22, is labelled with the *RUNX1* gene, although the associated variants are situated over 450kb from the gene. We have previously demonstrated, through Capture HiC analysis, that the genomic region containing the JIA associated variants makes a physical contact with the *RUNX1* promoter. The next challenge in this region, therefore, is to determine how a risk genetic background effects the expression of the gene, contributing to the susceptibility to JIA.

Methods: B-lymphocyte cell lines, containing either a risk or protective JIA genetic background at the 'RUNX1' loci were interrogated for potential causative functional mechanism. Allele specific interactions were investigated using chromosome conformation capture (3C), enhancer activity (H3K4me1) with chromatin immunoprecipitation (ChIP), and the resultant expression of the *RUNX1* gene analysed by qPCR in both stimulated (IL4/anti CD40) and unstimulated cell lines.

Results: The enhancer region associated with JIA interacts with the *RUNX1* promoter in B-cell lines. A stimulation specific effect is observed in B-cell lines harbouring the protective alleles. In this protective context, prior to stimulation *RUNX1* expression is higher than in the risk genotype with enhancer enrichment detected near the proximal promoter. After stimulation the interaction between the enhancer and *RUNX1* promoter is much stronger, and whilst no enhancer enrichment was detected, this increased interaction frequency after stimulation corresponds to a sharp downregulation of *RUNX1* expression. In contrast, the risk genotype showed no stimulation dependant change, maintaining both interaction and expression levels.

Conclusion: 3C and ChIP experiments were performed to investigate genotype and stimulation specific DNA-DNA and DNA-protein interactions and identify correlation with gene expression. These results suggest that the ability for B-cells to switch from relatively high expression of the *RUNX1* transcript to low expression upon stimulation is crucial to an appropriate immune response

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Genetics, Genomics and Proteomics Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Several genetic regions associated with susceptibility to juvenile idiopathic arthritis (JIA), harbour genes involved in the interleukin-2 (IL-2) response which is pivotal in the function of regulatory T cells (T-regs) and their ability to suppress potentially autoimmune effector T cells. Genetically JIA is similar to type 1 diabetes (T1D) which also demonstrates an enrichment of genes related to IL-2 regulation and response. Early clinical trial data has indicated recombinant IL-2 to be successful in enhancing T-regs in T1D. I hypothesise that IL-2 regulation and response is critical to the development of JIA and therefore IL-2 therapy represents an exciting and viable therapeutic option for JIA. We aim to identify a subset of JIA patients who carry a high burden of genetic risk variants in genes related to IL-2 regulation and response, who could then be targeted for IL-2 therapy. Secondly we will link genetics to cellular phenotypes using CyTOF to identify a subset of cells that are most perturbed in JIA and determine the effects of IL-2 on these cellular subsets.

Methods: A weighted genetic risk score (wGRS) was generated using 9 JIA susceptibility SNPs considered to be within or near to genes involved in interleukin (IL-2) regulation and response (1). The IL-2 wGRS was tested in an independent set of UK cases (1435) and controls (5181). The risk of developing JIA was assessed by subtype, using logistic regression. A CyTOF panel containing 33 antibodies targeting markers of T cells and T-regulatory cells was developed and tested in CD3⁺ T cells from two healthy individuals after 12 hour stimulation (anti CD3/CD28 beads plus recombinant IL-2). Cells were stained for all antibodies, Iridium and cisplatin and analysed on the CyTOF Helios. Data will be analysed with traditional biaxial gating as well commercially available packages such as cytokit.

Results: The IL-2 wGRS demonstrated an increased percentage of individuals in the high risk group in the extended oligoarthritis, RF negative and RF positive polyarthritis subtypes suggesting a higher burden of IL-2 related loci. The odds of developing JIA for those in the highest risk group (quintile 5) compared to all others was increased in these subtypes (OR 2.95% CI 1.45-2.76, OR 2.39 95%CI 1.87-3.04, OR 2.14 95% CI 1.49-3.09, respectively). Comparing this to a wGRS generated from JIA susceptibility loci excluding IL-2 related genes shows that this enrichment is specific to the IL-2 wGRS. Biaxial gating of CyTOF data showed increases in activation markers after stimulation (CD25, CD69, CD38 and HLA-DR, decrease CCR7). We demonstrated that our panel can successfully identify traditional CD4⁺ T cell subsets showing differences between stimulated and unstimulated cells and between individuals.

Conclusion: Our analysis has shown that patients with oligoarthritis and polyarthritis have an increased burden of JIA susceptibility variants in genes related to IL-2 regulation and response suggesting these individuals may benefit from IL-2 therapy. Using the CyTOF panel we can now analyse individuals with high and low GRS allowing us to identify cellular subsets which may be altered by these genetic variants.

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Genetics, Genomics and Proteomics Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Immune dysregulation refers to alterations in immune signaling leading to development of autoimmunity, infection and atopic disease. Common variable immunodeficiency (CVID), a prototypic disorder of immune dysregulation, is characterized by hypogammaglobulinemia, recurrent infections, poor vaccine responses and diverse complications, including autoimmunity. Although small subsets of CVID have been linked with various genes, the larger genetic landscape of CVID is unknown. Two closely-related familial disorders of immune dysregulation -- phospholipase C gamma 2 (PLC γ 2) associated antibody deficiency and immune dysregulation (PLAID) and auto inflammatory PLAID (APLAID) -- are caused by dominant mutations in *PLCG2*. These disorders are marked by antibody deficiency and immune dysregulation and are strikingly similar to that observed in CVID. We therefore hypothesized that genetic variants of *PLCG2* influence CVID susceptibility.

Methods: Using a combination of Sanger sequencing and targeted deep resequencing, we examined the coding region of *PLCG2* in 185 CVID patients and 96 local controls. Variant positions were evaluated for evolutionary conservation (GERP++, SiPhy) and the functional effects of missense changes were predicted (PolyPhen2, SIFT, MutationTaster). Distributions of rare, evolutionarily conserved *PLCG2* variants were compared between CVID cases and 37,370 non-Finnish European (NFE) subjects from the Exome Aggregation Consortium using the Sequence Kernel Association Test (SKAT). Effects of *PLCG2* mutations on cell activation were examined by overexpressing mutant constructs in a *PLCG2* deficient DT40 B cell line.

Results: Among 185 CVID cases, we found 12 missense variants of *PLCG2*, including 7 rare and 2 novel variants. All rare variants occurred at evolutionarily conserved sites and were predicted to detrimentally affect protein function. Rare variants were observed in 23 CVID patients (12.4%) and SKAT revealed significant enrichment of rare, evolutionarily conserved *PLCG2* variants in CVID patients compared to the NFE population ($p=5.3E-5$). Overexpression studies revealed alterations in downstream signaling in 7 CVID variants: relative to wild type *PLCG2*, 6 variants lead to basal increases in ERK phosphorylation, while 2 produced enhanced activation following IgM stimulation.

Conclusion: Rare, evolutionarily conserved missense variants of *PLCG2* are significantly associated with CVID. Furthermore, most of the rare *PLCG2* variants found in CVID patients cause abnormal downstream signaling, *in vitro*. Based on these results, we conclude that *PLCG2* influences susceptibility to CVID. Investigations are ongoing to determine whether *PLCG2* mutations predict specific phenotypes or disease courses in CVID.

Resolving the Synovial Fluid Proteome and Peptidome for Disease-Specific Mediators of Inflammatory Arthritis

Shalini Mahendran¹, Eleftherios Diamandis² and Vinod Chandran³, ¹Laboratory Medicine and Pathobiology, University of Toronto, Mount Sinai Hospital, Toronto, ON, Canada, ²Pathology and Laboratory Medicine, University of Toronto, Mount Sinai Hospital, University Health Network, Toronto, ON, Canada, ³Rheumatology, University of Toronto, Toronto Western Hospital, Toronto, ON, Canada

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Genetics, Genomics and Proteomics Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Idiopathic inflammatory arthritis (IA) is a T-cell driven chronic condition characterized an imbalance in cell proliferation and apoptosis leading to significant synovial hyperplasia and degradation of the underlying cartilage and bone. The exact etiology of IA is still poorly understood with studies aimed at delineating the molecular pathways driving loss of immunological tolerance to the body's self-antigens. Naturally, there is a compelling need to identify markers of aberrant immune pathways which may advance current insights into the molecular mechanisms of IA and serve as clinical markers for disease monitoring and treatment responses. Using mass spectrometry (MS), we aim to provide a detailed analysis of the proteome and peptidome of IA synovial fluid (SF).

Methods: SF samples were collected from 10 patients satisfying the 1987 ACR classification criteria for rheumatoid arthritis (RA), 10 patients satisfying CASPAR classification criteria for psoriatic arthritis (PsA) and 10 controls. Samples were investigated under label-free MS-based methods. Proteomic fractions underwent reduction, alkylation, and trypsin digestion while peptidomic fractions were desalted using solid-phase extraction. All samples were subjected to liquid-chromatography tandem MS followed by data extraction using MaxQuant v.1.5.2.8.

Results: Holistic proteome mining identified a total of 419 unique proteins across all 30 SF samples, with a false discovery rate of <1.0%. Non-parametric statistical tests identified 144 IA SF-derived proteins with significant differential expression relative to the control group. Application of filtering criteria resulted in a preliminary list of 5 IA-specific candidate biomarkers, of which MMP3 and neutrophil defensin 3 have been previously investigated. Intracohort comparison of RA and PsA SF proteomes identified 4 novel RA-specific candidates and 2 PsA-specific candidates. Peptidomic profiling of IA SF identified 288 unique peptides arising from 51 unique protein precursors across all SF samples. Differential expression analyses identified peptide fragments of fibrinopeptide A (FpA), a derivative of fibrinogen alpha chain, to be significantly upregulated in IA SF. FpA peptides were predicted to have antimicrobial peptide activity according to a bioinformatic tool. Moreover, KEGG analysis identified *Staphylococcus aureus* infection as a significantly enriched pathway. Taken together,

our peptidomic findings underscore the potential for peptides to elucidate mechanistic pathways related to the etiopathogenesis of IA, including the possible interplay of the microbiome and immune system responses.

Conclusion: Chronic inflammation in IA is orchestrated by a complex network of signaling pathways which are expected to be represented in the protein and peptide expression patterns of SF. The use of high resolution MS facilitates the discovery of key modulators of disease which may ultimately, enable the development of novel therapeutic interventions and minimally-invasive biomarker panels. Verification and validation of chosen candidates in a new set of SF and serum samples, respectively, are currently ongoing.

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Genetics, Genomics and Proteomics Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Diagnosis and monitoring the disease progression of RA is challenging requiring a combination of imaging techniques and blood tests. There is currently no biochemical test for detection of early-stage disease. In this study, we aimed to define a Rheumatoid Arthritis meta-profile and identify biomarkers by leveraging publicly available gene expression data with machine learning approaches.

Methods: We carried out a comprehensive search for publicly available microarray data at NCBI GEO database for whole blood and synovial tissue in Rheumatoid Arthritis and health controls. For the synovium, we collected 13 datasets with 312 biopsy samples. Among them, there were 276 RA samples and 36 healthy tissue biopsies. For whole blood data, we collected 11 datasets with 2,153 samples: 1,394 RA and 759 healthy controls. We computed differential expression using Significance Analysis of Microarrays (SAM) approach. We applied the cutoff of $FDR < 0.05$ and $abs(FC) > 1.2$ to the results to identify significant differentially expressed genes. For pathway analysis we leveraged the gene list enrichment analysis tool ToppGene.

Results: As a result of our analysis we were able to identify 882 genes that were significantly differentially expressed in the synovium between RA patients and healthy controls. Among them we recognized 502 up-regulated and 380 down regulated genes. We confirmed the gene regulation of the immune system process and response, and cell activation and aggregation in both innate and adaptive immune system pathways were involved in RA. As for the whole blood data, we identified 339 significantly differentially expressed genes with 166 up-regulated and 173 down-regulated genes among them. Aiming to determine RA biomarkers we performed a machine learning feature selection procedure to sets of significant genes for both tissues. First, we filtered out genes that cumulatively contribute to the biological variance less than 5%. Then we applied a Variable Selection Using Random Forests (VSURF) approach to the leftovers. Next, we performed a hypergeometric test and found 12 common genes with $p = 0.001$ with 3 common up-regulated genes: Antigen peptide transporter 1 (TAP1), Matrix Metalloproteinase 9 (MMP9), and DNA Damage Regulated Autophagy Modulator 1 (DRAM1), and 2 common down-regulated genes: DDX3Y, MYC. Finally, we built a Random Forest classification model on the synovium data with these 5 genes. We applied 5-fold cross-validation with 10 repeats technique and used Cohen's Kappa statistic as a metric. We obtained Kappa equals 0.61 with sensitivity 0.86 and specificity 0.9 on the testing set. In the final step, we validated the prediction model on the whole blood data, resulting kappa of 0.57 with sensitivity 0.54 and specificity 0.98.

Conclusion: Our computational analysis of public data allowed us to perform a comprehensive in-silico search for biomarkers in Rheumatoid Arthritis. We found three protein coding genes that have the strongest association with RA. Identification of extensive proteins secretion in blood could allow precision phenotyping on even early stages of the disease which could have a positive impact on monitoring disease progression and patient treatment.

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Genetics, Genomics and Proteomics Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Macrophages play an integral role in the progression and persistence of rheumatoid arthritis (RA) through production of degradative enzymes, cytokines, and chemokines and recruitment of additional immune cells which results in progressive joint destruction. We previously demonstrated that naïve mouse joints contain both MHC II⁺ (monocyte-derived) and MHC II⁻ (tissue-resident) macrophages. Interestingly, we have shown that the monocyte-derived macrophages drive inflammation, while the tissue-resident macrophages are involved in resolution of inflammation. Further, we have noticed that CX3CR1 expression dramatically changes during arthritis in both the MHCII⁺ and MHCII⁻ macrophage populations. Thus, we optimized a multi-parameter flow cytometry protocol to isolate four synovial macrophage subsets, delimited by MHCII and CX3CR1 expression, to perform subset-specific transcriptomic analysis.

Methods: We modeled arthritis in mice using an acute, inducible, K/BxN serum transfer induced arthritis (STIA), and a chronic, inducible, collagen-induced arthritis (CIA) in 10-12 week old female C57BL/6 mice. Florescence-activated cell sorting was employed to isolate macrophage subsets via expression of MHC II and CX3CR1 throughout the course of arthritis by FACS. RNA was extracted from sorted macrophage populations and processed for RNA sequencing (RNA-seq).

Results: Analysis of synovial macrophage populations by RNA-seq show that each population has a unique transcriptional profile and identifies a set of genes preferentially expressed in each population that give insight to each population's role at steady state. We then identified patterns in gene expression between two or more populations or shared between all populations to describe the relationship between macrophages. Analysis of synovial macrophage populations over the course of inflammation reveals that each macrophage subset responds differently across the phases of inflammation. At the initiation of inflammation, the CX3CR1/MHCII double positive and MHCII⁺CX3CR1⁻ macrophages show the largest transcriptional response with the peak transcriptional change occurring during the propagation stage in all macrophage populations. However, upon resolution of inflammation, CX3CR1/MHCII double positive and CX3CR1⁺MHCII⁻ macrophages contain a subset of genes that do not return to steady state expression. Macrophage response in our CIA model follows a similar transcriptional pattern to that found in our STIA model, however we do not see a distinct resolution pattern in our macrophage populations.

Conclusion: We conclude that changes in gene expression from synovial macrophage sub-populations over the course of arthritis coincide with the different phases of joint inflammation. This study provides detailed insight into the heterogeneity of synovial macrophage populations and the relationship between tissue resident and monocyte derived macrophage populations during inflammation. The novel pathways identified here provide new insight into potentially useful targets for therapy.

Session Title: Genetics, Genomics and Proteomics Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Behçet's disease is a multisystem disease affecting young adults with variable vessel vasculitis as its underlying pathology. Previous studies in Behçet's disease linked it to the Human Leucocytic antigens (HLA) class I molecules however the use of High-resolution Next Generation Sequencing (NGS) wasn't adopted before for all HLA loci (both class I and II) analysis along with the haplotype analysis. This study aims to identify the Behcet disease susceptibility with class I and II HLA alleles using NGS along with their haplotype analysis to help better understand the disease process and to find a possible association with disease manifestations and severity.

Methods: Sixty patients from specified geographical distribution diagnosed according to the International Study Group (ISG) criteria for Behçet's disease along with 160 normal geographically ethnic-matched controls were typed for the class I HLA alleles and from the control group, 40 control samples were typed for class II HLA alleles.

The work was a part of participation in the 17th International Histocompatibility and Immunogenetics Workshop (IHIWS) in the disease association component during which HLA was typed for patients and 40 control subjects at the allelic level by NGS high resolution typing for 11 loci (HLA-A, B, C, DRB1, DRB3/4/5, DQA1, DQB1, DPA1, DPB1). The control group was then expanded for an additional 120 control subjects typed for HLA class I loci (A, B and C) along with data analysis and haplotype analysis for the results.

Results: Sixty patients were enrolled with mean age 35.28 (± 9.82 years) with 54 males (90%). The main clinical manifestations were oral ulcers (100%), genital ulcers (100%), eye involvement (55%) neurological involvement (28%) and vascular involvement (35%). Furthermore, (33%) had bilateral visual acuity $\leq 6/60$ fulfilling the diagnosis of legal blindness

HLA class I alleles A*68:02:01, B*51:08:01, C*16:02:01 showed highest level of association with Behcet disease patients with an OR = 3 ($p=0.01$) and OR=18.6 ($p<0.0000001$) and OR=6.7 ($p<0.000001$) respectively. As for HLA class I haplotypes HLA class I B*51:08, C*16:02 haplotype was highly associated with susceptibility (OR=17.7, $p<0.000001$). HLA class I B*51 and A*68 were significantly associated with legal blindness (OR=10.1, $p<0.005$) and (OR=8.1, $p=0.023$)

Conclusion: Among the studied Behçet's Patients, HLA-B*51:08:01 is the most frequent susceptibility allele in contrast to other reported populations. Risk of Severe ocular involvement progressing to the blindness of patients was more than 10 folds increased in HLA-B51 positive patients as compared to other patients. HLA-B51 together with HLA-A68 both hold the increased risk of blindness and permanent morbidity in patients with Behcet disease, which if known at diagnosis would modify treatment options in order to salvage the patients' eyesight. Higher resolution analysis of HLA class I alleles and haplotypes specially HLA-B is valuable in knowing susceptibility and aiding in disease control and decreasing ocular morbidity in Behcet disease patients

Session Title: Genetics, Genomics and Proteomics Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The strong genetic contribution of the major histocompatibility complex (MHC) to rheumatoid arthritis (RA) susceptibility has been generally attributed to *HLA-DRB1*. However, due to the high linkage disequilibrium in the MHC region, it is difficult to define the 'real' or/and additional independent genetic risks using the conventional HLA genotyping or chip-based microarray technology.

Methods: To fine map HLA region and identify novel variants contributing to RA, we performed a deep sequencing for entire MHC region for discovery and classical HLA-typing for validation in 2773 subjects of Han ancestry (961 cases and 1812 controls). We analyzed HLA alleles, amino acids, SNPs, and indels across the MHC region to define the association for anti-citrullinated protein antibodies (ACPA)-positive RA.

Results: We identified HLA-DQA1:160D as a novel and the strongest independent genetic risk for anti-citrullinated protein antibodies (ACPA)-positive RA in Han population ($P = 6.16 \times 10^{-36}$, OR=2.29). Further stepwise conditional analysis revealed that DRB1:37N has an independent protective effect on ACPA-positive RA ($P = 5.81 \times 10^{-16}$, OR=0.49). The DQA1:160 coding allele *DQA1*0303* displayed high impact on joint radiographic severity, especially in patients with early disease and smoking ($P = 3.02 \times 10^{-5}$).

Conclusion: We provide the first evidence that *HLA-DQA1*, instead of *HLA-DRB1*, is the strongest and independent genetic risk for ACPA-positive RA in Chinese Han. DRB1:37N is an independent protective factor for ACPA-positive RA. Our study also illustrates the value of MHC deep sequencing for fine mapping disease risk variants in the MHC region.

Transcriptional Perturbation of RA-Risk Enhancer By CRISPR-DEADCAS9 Regulates LONG Range GENE Targets

Kate Duffus¹, Maria Imran², Gisela Orozco³, Helen Ray-Jones², Antony Adamson² and Stephen Eyre⁴, ¹Arthritis Research UK Centre for Genetics and Genomics, University of Manchester, Manchester, United Kingdom, ²University of Manchester, Manchester, United Kingdom, ³Arthritis Research UK, Centre for Genetics and Genomics, Centre for Musculoskeletal Research, Manchester Academic Health Sciences Centre, The University of Manchester, Manchester, United Kingdom, ⁴NIHR Manchester Musculoskeletal Biomedical Research Centre, Manchester University NHS Foundation Trust, Manchester, United Kingdom

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Genetics, Genomics and Proteomics Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Findings from genome wide association studies in complex diseases indicate over 90% of genetic variants associated with risk of developing disease are found outside protein coding regions, suggesting regulation of gene expression is key to disease susceptibility. For rheumatoid arthritis (RA) it has been demonstrated that risk variants are found in gene regulation regions, and are significantly enriched in T-cell specific enhancers. In addition, a significant proportion of associated variants lay some distance from the nearest gene and enhancers may not necessary regulate the closest gene, effectively 'skipping' genes. Using chromatin conformation technology (HiC) we have demonstrated that an enhancer region intronic of the COG6 gene, containing variants associated with RA, make robust physical contact with the promoter of FOXO1, almost 1Mb away on the linear chromosome. COG6 is not an obvious candidate risk gene for RA, whilst FOXO1 is involved in T-cell development and shown to be over expressed in RA synovium. The challenge now is to provide empirical evidence that the enhancer found within COG6 does regulate FOXO1 expression, and how an RA risk genetic background affects this regulation

Use CRISPR-Cas9, to perturb the COG6 intronic enhancer region and measure the downstream effect on the expression of FOXO1.

Methods: We utilised a modified form of the Cas9 enzyme, dead Cas9 (dCas9), that can precisely target DNA, but will not induce a cut. Using the dCas9 attached to either enhancers (p300) or repressors (KRAB) of expression we investigated how perturbation of the enhancer intronic of COG6 changed the expression of FOXO1.

We designed 3 guides across the COG6 enhancer, and transduced a cell line (HEK293) using a lentiviral dCas9 CRISPR system, with either dCas9-KRAB or dCas9-p300 and each of the three guides. We cultured the cells until 70-80%

confluent, GFP sorted the cells and then extracted RNA. A quantitative PCR was performed (QuantStudio) for both COG6 and FOXO1 gene transcript expression and normalised to housekeeping genes.

Results: Up to 90% of HEK cells were transduced with the dCas9 enzyme and guide, and these were sorted by FACS using GFP to sort the top 60%. The 3 guides gave consistently increased levels of FOXO1 expression with the dCas9-p300, compared to both control and dCas9-KRAB ($p=0.02$). This was particularly evident for guide 3, with a 40% increase (p300) and 10% decrease (KRAB) of FOXO1 expression observed. Expression of COG6 was also perturbed, but in a less consistent manner, with both increase and decrease expression for KRAB and p300.

Conclusion: Over 90% of HEK cells were transduced with the dCas9 enzyme and guide, and these were sorted by FACS using GFP to sort the top 60%. The 3 guides gave consistently increased levels of FOXO1 expression with the dCas9-p300, compared to both control and dCas9-KRAB ($p=0.02$). This was particularly evident for guide 3, with a 40% increase (p300) and 10% decrease (KRAB) of FOXO1 expression observed. Expression of COG6 was also perturbed, but in a less consistent manner, with both increase and decrease expression for KRAB and p300.

Session Title: Genetics, Genomics and Proteomics Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is a multi-organ autoimmune disorder with an important genetic component. Genome-wide association studies (GWAS) have linked many single nucleotide polymorphisms (SNPs) to SLE. Recently, Langefeld et al (2017) conducted a large-scale transancestral association study of SLE to identify ancestry-dependent and independent contributions to SLE risk. Here, we take African ancestry (AA) and European ancestry (EA) SLE-associated SNPs, link them to E-Genes and couple those with differentially expressed (DE) genes from SLE patients to develop a better understanding of ancestral-related molecular pathways and novel treatments unique to each ancestral group.

Methods: The GTEx database was used to identify E-Genes from SLE-associated SNPs and their ancestry-specific SNP proxies. Ancestry-specific E-Genes were compared to DE genes from multiple SLE gene expression datasets. For both ancestral groups, E-Gene lists were examined for the significant enrichment of gene ontology (GO) terms, IPA and BIG-C categories, and to predict whether E-Genes were upstream regulators (UPRs). For visualization and clustering analysis, STRING-generated networks of DE E-Genes were imported into Cytoscape and partitioned with the community clustering (GLeay) algorithm via the ClusterMaker2 plugin. Drug candidates targeting E-Genes, DE genes and UPRs were identified using CLUE, REST, API, IPA and STITCH.

Results: Newly predicted E-Genes from the GTEx database were pooled by ancestry. We identified 52 AA-associated and 260 EA-associated SNPs; 1 SNP was shared across ancestries. These SNPs identified 891 distinct E-Genes, which were then compared to SLE DE datasets. We observed differential expression of 516 EA-associated E-Genes enriched in estrogen receptor signaling, neuronal signaling and cholesterol biosynthesis via IPA, and the positive regulation of synaptic transmission by GO-term enrichment. Clustering analysis showed EA E-Gene networks dominated by transcription, RNA processing, glycolysis and immune signaling. Drug candidate comparison identified 77 EA-specific drugs, including hydroxychloroquine and drugs targeting CD40LG and CXCR1/2. For AA, 48 E-Genes were DE in SLE and enriched in IPA categories for T helper cell differentiation and melatonin biosynthesis, and the GO biological process of keratinization. Clustering analysis of the AA E-Genes showed enrichment in PRRs, immune signaling and keratinocyte differentiation. AA-specific drug candidates included HDAC inhibitors, retinoids and inhibitors of IRAK4 and MAP8K4. A total of 46 DE E-Genes were shared between ancestries, with IRF7 upregulated in all SLE datasets. Drugs targeting shared E-Genes included ibrutinib, ruxolitinib and ustekinumab.

Conclusion: The ancestral SNP-associated E-Genes and gene expression profiles outlined here illustrate fundamental differences in lupus molecular pathways between AA and EA. The results indicate that unique sets of drugs may be particularly effective at treating lupus within each ancestral group.

Rheumatoid Arthritis-Associated Genetic Alteration Defines a New Promoter for Peptidyl Arginine Deiminase 4 Gene

Daniel M. Tóth¹, Timea Ocskó², Tibor T. Glant¹ and Tibor A. Rauch¹, ¹Department of Orthopedic Surgery, Rush University Medical Center, Chicago, IL, ²Orthopedic Surgery, Rush University Medical Center, Chicago, IL

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Genetics, Genomics and Proteomics Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Anti-citrullinated protein antibodies (ACPA) are frequently detected in Rheumatoid Arthritis (RA) patients and used as diagnostic biomarkers at a very early stage of the disease. ACPAs are raised against various peptide epitopes carrying citrullinated arginines generated by peptidyl arginine deiminase (PADI) enzyme family members. PADI4 gene is highly expressed in neutrophils in peripheral blood and also known to citrullinate histone proteins. RA-associated PADI4 single nucleotide polymorphisms (SNPs) do not alter amino acid composition; therefore, it is challenging to explore how they can contribute to RA pathology. We investigated the effect of SNP rs2240335 on transcriptional regulation of PADI4 gene.

Methods: We have investigated the epigenetic landscape of the human chromosome region harboring the *PADI4* gene and focused on histone modifications that predict active promoters. Using 5'RACE method we explored alternative isoform-encoding transcript of PADI4 gene. Quantitative *reverse transcription PCR* was used to explore isoform expression in human tissues. Cellular distribution of a novel short PADI4 isoform was studied by confocal fluorescence microscopy. Short PADI4 isoform's potential catalytic function was tested using *in vitro* transcription and translation system. The disease-associated SNP's effect on transcription was assessed in transient expression studies.

Results: Epigenetic profile analysis around the *PADI4* gene revealed a new promoter region, which proved to be active on bone marrow. We cloned and sequenced the corresponding transcript and designated PADI4-ΔN. PADI4-ΔN is a truncated isoform that only encodes the C-terminal catalytic domain of the enzyme, which is highly expressed in bone marrow sample and neutrophils. PADI4-ΔN was fused to red fluorescent protein (RFP) and overexpressed in cells. Confocal microscopic studies detected the RFP:PADI4-ΔN in cytoplasmic region and nuclei of the transfected cells. Studies addressed to reveal catalytic activity of PADI4-ΔN could not detect any enzymatic activity *in vitro* assays. Transient expression studies revealed that the two allele variants (i.e., G or T at rs2240335 position) can contribute differently to the novel PADI4 promoter activity, which is ultimately reflected by Luciferase activity in cell lysates.

Conclusion: The *PADI4* gene encodes at least three isoforms: (i) the well-characterized full-length isoform, (ii) a C-terminus deleted (PADI4-ΔC) isoform and (iii) the novel N-terminus truncated (PADI4-ΔN) isoform. The newly discovered isoform is not able to catalyze citrullination of vimentin (a well-characterized PADI4 target) and does not affect the enzymatic activity of the full-length isoform in *in vitro* competitive assays. These data suggest that allele variants (at the RA-associated SNP position) primarily alter the physiological ratio of the full-length and truncated PADI4 isoforms, which might lead to RA pathogenesis by an unknown mechanism.

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Genetics, Genomics and Proteomics Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: We have reported that *ABCG2* has an important role in both renal and intestinal urate excretion and these common variants *asrs72552713* (Q126X) and *rs2231142* (Q141K) are risks for gout. Then, we revealed both rare and common non-synonymous *ABCG2* variants are associated with gout susceptibility. In this study, we investigated the effects of rare and common *ABCG2* variants including synonymous, non-synonymous and splice-site variants on gout.

Methods: We sequenced exons of *ABCG2* in 480 patients with gout and 480 healthy controls (Japanese males). Additionally, functional analyses of non-synonymous variants of *ABCG2* were performed. Then, the correlation between urate transport function and scaled C-score of CADDv1.3 (CADD score) was analyzed. Furthermore, we performed Receiver Operating Characteristic (ROC) curve analysis and made selections of variants with altered function of more than 50% compared to wild-type *ABCG2*. In order to assess the effects of common and rare variants on gout susceptibility, we conducted stratified association analyses and multivariate logistic regression analysis.

Results: We identified 5 common and 25 rare exonic or closely situated intronic variants of *ABCG2*. CADD scores demonstrated relationships with the urate transport function significantly ($p=0.014$, $r=-0.539$.) ROC curve analysis demonstrated an area under the curve (AUC) of 0.775. The appropriate cutoff value of CADD score was 15 when we classified variants with mutated function of more than 50% compared to wild-type *ABCG2* (sensitivity=0.88, specificity=0.67.) Therefore, we carried out the downstream analyses of variants with a CADD score greater than 15. Both intronic and synonymous variants showed low CADD scores. Then were moved them on multivariate logistic regression analysis and revealed that rare variants of *ABCG2* significantly increased gout risk and the size effect of these rare variants (odds ratio [OR]=2.7, $p=0.012$) was similar to that of common variants such as Q126X (OR=3.3, $p=4.8 \times 10^{-6}$) and Q141K (OR=2.3, $p=8.6 \times 10^{-16}$).

Conclusion: We confirmed that both common and rare variants of *ABCG2* have independent effects on risk of gout. Our findings help to better understand both eCommon Disease, Common Variantf and eCommon disease, Multiple Rare Variantf hypotheses for the association between *ABCG2* and gout susceptibility. In addition, our *in silico* analyses suggest that there are no important synonymous and splice-site variants of *ABCG2* for the pathogenesis of gout.

A Molecular Bayesian Network for Rheumatoid Arthritis Reveals Multiple Candidate Key Regulators for Disease Severity

Wenhui Wang¹, Amit Lahiri², Teresina Laragione², Jun Zhu¹ and Percio S. Gulko^{2,3}, ¹Genetics and Genomics, Icahn School of Medicine at Mount Sinai, New York, NY, ²Medicine/Rheumatology, Icahn School of Medicine at Mount Sinai, New York, NY, ³Icahn School of Medicine at Mount Sinai, New York, NY

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Genetics, Genomics and Proteomics Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is a common and chronic autoimmune joint disease. RA is pathologically heterogeneous with multiple contributing factors. While there has been a major emphasis in studies of the immune regulatory factors the gene networks regulating the synovial pathology remains incompletely understood. We aimed at establishing a RA synovial tissue gene network to identify new key regulators/driver of the synovial and fibroblast-like synoviocyte (FLS) pathology.

Methods: Several large RA synovial tissue gene expression data sets (GSE48780 and GSE21537, consisting of 83 and 62 synovial biopsies from RA patients, respectively) were used. We used a software suite that we developed, RIMBANet, to construct a Bayesian network model for RA. We computationally estimated cell composition in synovial biopsies (T cells, neutrophils, FLS, macrophages, others).

Results: Immune cell compositions in inflamed and non-inflamed synovial tissues were significantly different, with increased numbers of M1 macrophages in inflamed tissues than in non-inflamed tissues. We adjusted synovial tissue profiling data for cell composition, and combined the two data sets together used in network reconstruction. We identified 7,521 nodes representing expression levels of genes and 8,118 edges representing putative causal relationships between genes. We compared the constructed RA network with well-known interaction databases or canonical pathways, and showed that the RA network overlapped with existing network/pathways significantly better than random networks. Then, we collected a set of RA severity related gene sets from a variety of sources (FLS gene expression, rodent studies, etc) and projected them onto the RA network identified key regulators for disease severity. Top inferred key regulators included DLX4, SEMA3E, LCP1, TRIM22, and ZNF385B. To test whether the inferred key regulators have any impact on RA disease severity, we examined the role of DLX4 in FLS invasiveness, an in vitro phenotype that strongly correlates with joint damage in RA. DLX4 was expressed in RA FLS and its knockdown with siRNA in primary RA FLS significantly reduced FLS invasiveness by 80%.

Conclusion: We here describe a new RA synovial gene network. This study also provides encouraging validation of the new synovial gene network suggesting that it has the potential to lead to the discoveries and of new important genes involved in disease pathogenesis and potentially new targets for treatment.

Abstract Number: 1982

An Integrative Rheumatoid Arthritis Network for Elucidating Molecular Mechanisms Underlying RA Severity

Wenhui Wang¹, Teresina Laragione², Amit Lahiri², Jun Zhu¹ and Percio S. Gulko³, ¹Genetics and Genomics, Icahn School of Medicine at Mount Sinai, New York, NY, ²Medicine/Rheumatology, Icahn School of Medicine at Mount Sinai, New York, NY, ³Icahn School of Medicine at Mount Sinai, New York, NY

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Genetics, Genomics and Proteomics Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is a pathologically heterogeneous disease with multiple contributing factors. Many models have been developed to study RA severity and progression, and several RA severity signatures have been derived. However, the molecular mechanisms underlying these RA severity signatures are not fully understood. For example, Cia25 congenic rat interval regulates arthritis severity. The congenic region is conserved among mouse, rat, and human. However, which gene or genes in the congenic region regulate RA severity and which molecular mechanisms remains incompletely understood. We recently developed a human molecular causal network for RA. We leveraged the RA network to elucidate potential molecular mechanisms that drive RA severity.

Methods: A gene expression signature comparing Cia25 congenic and parental strains was collected. A candidate gene list including HIP1 was derived by comparative genomic analysis of mouse, rat, and human genome and comparing SNPs between Cia25 congenic and parental strains.

Results: Cia25 congenic signature was projected to the human RA network that we constructed. We derived a Cia25 congenic subnetwork by using the signature as seeds and collecting nodes that were within 2 hops from the seeds. We compared the subnetwork with GO biological pathways, and found genes involved in immune response, cell adhesion, and cell migration pathways were significantly enriched in the subnetwork. We further compared transcription factor (TF) binding sites in promoter regions of genes in the subnetwork and known TF binding motifs, and found binding sites for transcription factors BACH1 and BACH2 were enriched in the subnetwork. Bach1 has been shown to regulate osteoclast in mouse models. BACH2 was identified a GWAS as a candidate gene for RA susceptibility. It is worth to note that one of the candidate genes for the Cia25 congenic strain is HIP1. In the RA network, HIP1 was regulated by STK3 and STK3 was a part of Cia25 congenic subnetwork. The HIP1 subnetwork (including genes that can be reached from HIP1 within 3 hops) significantly overlapped with the Cia25 congenic subnetwork, supporting HIP1 as a potential candidate for Cia25 congenic strain. For proof of concept we knockdown HIP1 in human fibroblast-like synoviocytes and detected significantly reduced cell invasiveness.

Conclusion: We used a new RA synovial gene network to help identify new arthritis regulatory genes by integrating complex datasets and show that this strategy led to validation and discovery of new arthritis susceptibility and severity genes.

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Genetics, Genomics and Proteomics Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Myeloid mutations commonly associated to neoplasia in patients who do not meet the diagnostic criteria for myelodysplastic syndrome are coined as clonal hematopoiesis of indeterminate potential (CHIP). CHIP-related mutations are somatic DNA mutations accumulating with aging, being found in approximately 10% of over 65. Chronic inflammation, mirrored by TNF- α -exposure, has been reported to favor the expansion of CHIP-mutant clones, such as TET2- and JAK2-, but recent evidence suggests that CHIP-mutated clones contribute to chronic inflammation, as TET2-mutated myeloid clones manifest a hyper-inflammatory M1 status. We hypothesize that chronic inflammation concurs with age to CHIP-mutation appearance, i.e. they should be more precocious and frequent in rheumatic patients; moreover, CHIP-mutations are associated to more active rheumatic diseases.

Methods: We investigated the peripheral blood and synovial fluid myeloid cells from 4 rheumatoid arthritis (RA), 4 psoriatic arthritis (PsA), and 4 knee osteoarthritis (OA) patients (female 5, median age 73.5 years, range 53-91, median disease duration 10 years, range 7-20). To detect the presence of CHIP-mutations we used a high-throughput sequencing platform (Illumina NextSeq platform) for mutation screening of 78 genes known to be relevant in myelodysplastic diseases.

We evaluated only variants known as pathogenic in COSMIC database, with a population frequency (MAF) < 0.1% described in dbSNP and in 1000 Genome Project.

Results: We found somatic mutations of JAK2, TP53, and TET2 in 2/4 RA patients, GATA2-mutation in 1/4 PsA patients, and a small clone of SF3B1 in 1/4 OA cases. Mutated clones were found both in peripheral blood and synovial fluid of the patients. The patients with CHIP-mutations did not have a more active disease (DAS28-CRP 4.2 ± 0.6 vs 5.1 ± 1.2 ; $p > 0.05$), but 1 RA patient with JAK2-mutation and 1 PsA patient had < 65 years.

Conclusion: Our data suggests that CHIP-mutations are frequent in patients with chronic arthritis, also before 65 years. Understanding the mechanisms connecting somatic mutation-driven clonal hematopoiesis and chronic inflammation will be of great interest not only from a pathogenic point of view, but also in considering possible therapeutic options, such as JAK-inhibitors.

Regulation of Multiple Differentiation Potential in Mesenchymal Stem Cells Via an Intercellular Ca^{2+} Signaling Pathway

Shuang Liu¹, Erika Takemasa² and Masaki Mogi², ¹Dept. Pharmacology,, Ehime University Graduate School of Medicine, Toon-shi, Japan, ²Pharmacology, Ehime University School of Medicine, Toon-shi, Japan

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Osteoarthritis and Joint Biology – Basic Science Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Multipotent mesenchymal stem cells (MSCs) are widely used in regenerative medicine to repair damaged tissues. Regulating Ca^{2+} release-activated Ca^{2+} (CRAC) channel-mediated intercellular Ca^{2+} signaling is critical to the functional modulation of MSCs. CRACM1 in the plasma membrane is an important molecular regulator of the CRAC channel. Our study aimed to elucidate the possible effects of CRAC channel regulation on the multiple differentiation potential of MSCs.

Methods: To increase Ca^{2+} influx, we overexpressed CRACM1 by transfecting pCDNA3-CRACM1 into MSCs (m1-MSCs). Genomic CRACM1-knockout MSCs (m1-ko-MSCs) were prepared using CRISPR/Cas9 technique. YM-58483 was used as a CRAC blocker. The inhibitory effect of YM-58483 was verified by imaging. Wild-type MSCs, m1-MSCs, m1-ko-MSCs, and YM-58483-treated MSCs were differentiated to adipocytes, osteocytes, or chondrocytes. Fatty acid-binding protein 4 was used as an adipocyte biomarker and osteocalcin was used for the detection of osteocytes. Aggrecan was used as a chondrogenic differential marker.

Results: The results suggest YM-58483 inhibited Ca^{2+} influx in MSCs in a dose-dependent manner, as demonstrated by Ca^{2+} imaging of fura-4-loaded cells. Downregulation of CRACM1 function in MSCs suppressed the differentiation of osteocytes, but not of adipocytes. A decrease tendency on the potential of chondrogenic differentiation was observed in intracellular Ca^{2+} -downregulated MSCs compared to wild-type MSCs. Overexpressing CRACM1 had no effect on the differentiation of osteocytes, but suppressed adipogenic and chondrogenic differentiation, while comparing with that observed in wild-type cells.

Conclusion: The results suggest that MSC differentiation potential is related to intercellular Ca^{2+} signaling pathways. In future study, we aim to research the systemic chondrocyte differentiation *in vivo* and, eventually, to carry out experiments in animal models to further contribute to the growing field of regenerative medicine.

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Osteoarthritis and Joint Biology – Basic Science Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Aberrant endochondral bone formation in the physis is a unique bone lesion in neonatal-onset multisystem inflammatory disease (NOMID), also called chronic infantile neurologic cutaneous articular (CINCA), the most severe of the cryopyrin-associated periodic syndrome (CAPS) diseases, which are interleukin 1 β (IL-1 β)-related monogenic auto inflammatory diseases. It is interesting that the pathological features of bone lesions in NOMID / CINCA are similar to those found in patients with fibrous dysplasia, a skeletal disease caused by the gain-of function mutation of the GNAS gene that leads to aberrant activation of the canonical Wnt signal. Since the importance of the Wnt signal in human skeletal development is evidenced by the existence of human diseases caused by abnormalities associated with Wnt receptors, we explored the potential role of IL-1 β on the expression of *WNT* genes and the Wnt antagonist *Dickkopf-1* (*DKK1*).

Methods: The expression of *WNT2*, *3*, *4*, *5A*, *11* and *DKK1* mRNA in fibroblast-like synoviocytes (FLS) was quantified by quantitative PCR. The concentration of DKK1 in supernatant from FLS was determined by ELISA. Additionally, we used TCF reporter transfected in U2OS cell, a cell line that does not express DKK1, to evaluate the activity of the canonical Wnt signal pathway in the presence or absence of the supernatant of cultured FLS treated with or without IL-1 β . Recombinant WNT3A or Lithium chloride (LiCl) was used to activate Wnt signal. Anti-DKK1 antibodies were used to neutralize DKK1 in supernatant from FLS culture.

Results: The mRNA expression of both canonical and non-canonical *WNT* genes as well as *DKK1* was detected in FLS. FLS secreted DKK1 comparable to bone marrow-derived mesenchymal stromal cell. The supernatant of cultured FLS suppressed the luciferase activity of the TCF reporter, and this effect was reduced by its pre-treatment with an anti-DKK1 antibody. Moreover, the supernatant from FLS cultures significantly suppressed the TCF activity induced by WNT3A or LiCl in a dose dependent manner. IL-1 β induced *WNT2* and *5A*, whereas significantly reduced *DKK1* in FLS. Furthermore, the supernatant of FLS cultured with IL-1 β showed a reduced inhibitory effect on TCF activity compared with the supernatant of untreated FLS.

Conclusion: FLS suppress Wnt signal via DKK1 production, and that IL-1 β reduce DKK1 production from the cells and, thereby, activation Wnt signal. Therefore, it is possible that the overproduction of IL-1 β in patients with NOMID/CINCA aberrantly activates the Wnt signal and leads to abnormalities in cartilage and bone differentiation. Our data, consistently with a previous report about fibrous dysplasia, suggest that two distinct genetic mutations in two different diseases lead to similar abnormal activation of the Wnt signal, and, consequently, similar bone lesions.

Adalimumab:TNF Complexes Are Cleared More Efficiently By Human Osteoclasts Than Those with Etanercept through Fc γ -Receptor Binding and Internalization

Bohdan P. Harvey, Joel Cohen-Solal and Zehra Kaymakalan, Biologics, AbbVie Bioresearch Center, Worcester, MA

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Osteoarthritis and Joint Biology – Basic Science Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: TNF-alpha (TNF α) has been shown to contribute to osteoclastogenesis (OCgenesis) independently and in conjunction with M-CSF or RANKL, two key cytokines involved in osteoclast (OC) development. We have previously demonstrated that TNF enhances the kinetics of RANKL-induced human OCgenesis and that its effects are mitigated more effectively by the anti-TNF biologic adalimumab (ADA) as compared to etanercept (ETN). The objective of this study was to determine whether Fc-gamma receptor (Fc γ R)-mediated internalization of the biologic:TNF complexes is a contributing mechanism responsible for the difference in effectiveness between ADA and ETN in preventing TNF-enhanced OCgenesis.

Methods: TNF biologics [ADA and ETN] alone or in preformed complexes with TNF α at 50:1 molar ratio were tested for Fc γ R binding by flow cytometry using CHO stably transfected with human FCGRs (Fc γ RI, Fc γ RIIA, -RIIB, -RIIC, Fc γ RIIIA & -RIIIB). Fc γ R expression and binding of preformed biologic:TNF complexes at 10:1 ratio +/- Fc γ R blocking antibodies to primary human OC precursors (OCP) was evaluated by flow cytometry. Fc γ R-mediated internalization was assessed by monitoring a reduction in OC survival in response to preformed biologic:TNF complexes (25:1 ratio) bound with saporin (ZAP), a ribosome-inactivating toxin, as anti-human Fc IgG Fab conjugate +/- Fc γ R blocking antibodies.

Results: The binding study to CHO (human Fc γ Rs) cell lines showed that monomeric ADA and ETN bind similarly to Fc γ R (highly on high affinity Fc γ R and loosely on low affinity Fc γ Rs) while preformed biologics: TNF complexes bind differently. ADA:TNF complexes bind to low affinity Fc γ R, whereas ETN:TNF keep a monomeric binding profile with no gain of binding to low affinity Fc γ R. OCP were found to express mostly Fc γ RII early in development with predominant binding of only ADA:TNF, not ETN:TNF, to this Fc γ R with additional binding to undefined receptor(s). Despite subsequent increases in Fc γ RI and RIII later on, ADA:TNF still preferentially bound to Fc γ RII on the matured OCP with minimal binding to RIII, whereas ETN:TNF binding was observed only to Fc γ RI. Exposure of OCP to ADA:TNF:ZAP (toxin) complexes led to a significant reduction (4-fold) in mature OC due to complex internalization as compared to human IgG:ZAP+TNF conditions that was partially rescued only with the addition of Fc γ RII blocking antibody. Interestingly, a 1.5-fold reduction in mature OC was observed with ETN:TNF:ZAP.

Conclusion: Our *in vitro* findings demonstrate that human OCP can bind and internalize ADA:TNF complexes more efficiently than ETN:TNF complexes. In addition, this process is partially mediated through Fc γ RII. Clearance of the ADA:TNF complexes may help reduce exposure of the OCP to localized TNF by removing TNF more effectively in the joint environment. Additional *in vivo* analysis need to be done to verify these *in vitro* findings.

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Osteoarthritis and Joint Biology – Basic Science Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Osteoclasts (OC) are bone-resorbing, multinuclear cells that originate from myeloid progenitor cells through repetitive cycles of cell-cell fusion. Dendritic cell-specific transmembrane protein (DCSTAMP) is a transmembrane protein essential for cell-cell fusion and formation of fully functional OC although the molecular mechanisms are not well understood. Utilizing RAW cell lines we previously demonstrated that during OC differentiation, heterogeneity in membrane expression levels of DCSTAMP correlated with efficient cell-cell fusion during multinuclear OC formation. Optimal fusion was observed when DCSTAMP^{low} and DCSTAMP^{high} cells interact. Herein, we examined how complete absence of DC-STAMP in the osteogenic progenitor cells (OCPs) controls their ability to participate in cell-cell fusion events required for efficient multinuclear OC formation.

Methods: We isolated bone marrow macrophages (BMMs) from wild type (WT) and *DCSTAMP* knockout (KO) mice. *DCSTAMP*^{-/-} mice show mild osteopetrosis. To analyze cell-cell fusion, we labeled *DCSTAMP*^{+/+} and *DCSTAMP*^{-/-} BMMs obtained from WT and KO mice, respectively, with red (CellVue® Red) and green (CellVue® Jade) membrane dyes, cultured them with MCSF (30 ng/ml) and RANKL (30 ng/ml), and monitored cell-cell fusion with live cell imaging. Moreover, we examined the expression dynamics and fate of DCSTAMP protein in forming OC employing retroviral-mediated expression of GFP-tagged DCSTAMP protein in *DCSTAMP*^{-/-} cells. In addition, we investigated how DC-STAMP alters expression levels of key osteoclast-related genes in WT and KO cells.

Results: We find that *DCSTAMP*^{-/-} BMMs are incorporated into forming OC, however, *DCSTAMP*^{+/+} cells are essential to initiate cell-cell fusion events. Following retroviral vector-mediated complementation of GFP-tagged DCSTAMP protein expression in *DCSTAMP*^{-/-} BMMs, we noted that during OC formation, DC-STAMP expression level remained high but progressively declined during several rounds of cell-cell fusion and levels were low or absent in mature OCs. Interestingly, we noted that the absence of DC-STAMP did not alter mRNA expression levels of *NEATc1* and other key genes involved in cell-cell fusion and other OC differentiation pathways such as *ACP5*, *CTSK* and *ATP6V0D2*. Unexpectedly we further noted that mRNA expression levels of *ACP5*, and *CTSK* genes were more than 2 fold higher in RANKL activated *DC-STAMP*^{-/-} cells compared to WT cells after 120 hours in culture.

Conclusion: Our findings indicate that DCSTAMP expression levels in OCP are high during the early cell-cell fusion events but progressively decline and are absent or low in mature OCs. While *DCSTAMP*^{-/-} OCPs cannot form multinuclear OCs, they do fuse with *DCSTAMP*^{+/+} OCPs and are incorporated into maturing OCs. These data indicate that DCSTAMP membrane expression is not required for cell-cell fusion in the presence of other cells expressing this molecule. The absence of DCSTAMP in OCPs does not alter *CTSK*, *ACP5*, *ATP6V0D2* mRNA expression levels during early fusion events but these genes were elevated in later stages in KO cells. DC-STAMP may regulate expression of key OC-specific genes in the late stages of OC differentiation.

Session Title: Osteoarthritis and Joint Biology – Basic Science Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Osteoarthritis (OA) is a disease managed rather than cured, with a focus on alleviating its pain. Recent studies show that fucoidans, one of the main therapeutic components of brown algae, are promising candidates to address the symptoms of OA. A wide spectrum of biological activities has been registered in these polysaccharides, however these properties vary between fucoidans from different species. In this study we evaluated the protective effect of different fucoidans on catabolic pathways activated in articular cells.

[illegible]

Results: The production of NO induced by IL-1 β in chondrocytes was attenuated by the three different fucoidans at the lowest dose (5 μ g/ml). Likewise, iNOS expression was significantly reduced by FF5 ($p < 0.05$). Similar results were detected in synoviocytes. IL-1 β -induced Cox-2 expression in chondrocytes were downregulated by FF and FM, however FU failed to modulate its levels. In relation, fucoidans attenuated PGE2 production elicited by IL-1 β , achieving significant reductions with FM5. We also observed all fucoidans, especially FF5, protected chondrocytes against mitochondrial depolarization induced by AA ($p < 0.05$). Subsequently, ROS production was also downregulated by fucoidans. Finally, we activated pro-fibrotic pathways in the synoviocytes by TGF β . Although fucoidans failed to modulate cellular proliferation triggered by TGF β , these polysaccharides down regulated the gene expression of collagen1 and fibronectin as well as α -sma protein expression.

Conclusion: Our results indicate a protective effect of fucoidans against inflammatory and oxidative pathways activated in chondrocytes and synoviocytes. However, we detected that these beneficial activities vary between fucoidans from different species and further studies are warranted.

Session Title: Osteoarthritis and Joint Biology – Basic Science Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Anthrax toxin receptor 1 (ANTXR1) has been known to have relationship with extracellular transmembrane protein deeply associated with the process of bone formation and exert important role in angiogenesis. However, there have been no reports to prove the effects of ANTXR1 on bone metabolism mediated by two types of bone cells, osteoclasts and osteoblasts. The aim of this study is to reveal the role of ANTXR1 in the differentiation and function of osteoclasts and osteoblasts.

Methods: To determine the effect of ANTXR1 on osteoclastogenesis or osteoblast differentiation, we examined TRAP staining, F-actin staining and Pit assay, or ALP and Alizarin Red-mineralization staining, respectively. The mechanism of ANTXR1 by transfection of retrovirus or siRNA analyzed using real-time PCR and western blot analysis. Also, the effect of ANTXR1 on osteoclast-mediated angiogenesis of endothelial cells assessed by in vitro vascular tubule formation assay of human umbilical vein endothelial cells (HUVECs).

Results: Through performing gain- and loss-of-function studies, we found that ANTXR1 positively regulated receptor activator of nuclear factor kappa B ligand (RANKL)-induced osteoclast differentiation and bone resorption with no effects on osteoblast differentiation. During ANTXR1-mediated regulation of osteoclastogenesis, phosphorylation of early signal transducers, c-jun N-terminal kinase (JNK), Akt, and inhibitor of kappa B (IκB) was affected, which in turn alteration of mRNA and protein levels of c-Fos and nuclear factor of activated T cells cytoplasmic 1 (NFATc1). In addition, genetic manipulation of ANTXR1 in bone marrow macrophages (BMMs) modulated the capillary-like tube formation by HUVECs via two kinds of angiogenic factors, matrix metalloproteinase-9 (MMP-9) and vascular endothelial growth factor-A (VEGF-A). These results explained the important role of ANTXR1 in osteoclast differentiation and functional activity, as well as, osteoclast-mediated angiogenesis of endothelial cells.

Conclusion: Taken together, it was proposed that ANTXR1 might be a promising candidate for gene therapy related with bone metabolic diseases and further, have potential to be served as an important biomarker in the research fields of bone metastasis associated with vascularization.

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Osteoarthritis and Joint Biology – Basic Science Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The progressive destruction of osteoarthritic articular cartilage has been attributed to multifactorial cellular events, including increased oxidative modifications in proteins, abnormal inflammatory and catabolic gene expressions and early apoptosis. A plant alkaloid colchicine (Col), leads to down regulation of multiple inflammatory pathways and modulation of innate immunity. A polyphenolic antioxidant luteolin (Lut) has also been reported to have potential chondroprotective effects through inhibition of degradative enzymes and increased gene expression of collagen in animal articular chondrocytes [Kang et al., *Biomol Ther*, 22:239-45, 2014]. We aimed to study the comparative anti-glyco-lipo-oxidative and anti-inflammatory effects of Col and Lut on human osteoarthritic articular chondrocytes (OAC).

Methods: Chondrocytes were isolated from joint cartilage of KL grade 4 OA patients, during total knee arthroplasty as described previously [Naranda et al., *PeerJ*, 5:e3079, 2017]. The alterations in cell counts, viability (MTT (3-(4,5-Dimethylthiazol-2-yl)-2,5-Diphenyltetrazoliumbromide)), the levels of lipid hydroperoxides (LPO), 4-hydroxy-2-nonenal (HNE)-protein adduct and advanced glycoxidation end product (AGE)-protein adduct, osteopontin and proinflammatory cytokines (IL-6, IL-1 β , TNF- α) were studied (ELISA).

Results: Cell viability (MTT) (n=6) and LPO levels (n=3) of primary chondrocytes (30th day after isolation) treated with Col or Lut for 24 h are given in Figure. Lut increased viability at relatively lower concentrations (1 nM-1 μ M). At higher concentrations (50-100 μ M), Lut and Col decreased the viability. Both inhibited LPO levels at 1 nM-1 μ M concentrations, whereas, Lut demonstrated better inhibition compared to Col. Lut diminished HNE-protein adduct levels at concentrations of 1 nM-10 μ M and Col at only 1 μ M concentration. Both compounds also inhibited AGE-protein adduct levels in similar degrees at concentrations of 10 nM-1 μ M. Col strongly blocked the production of IL-1 β in a concentration-dependent manner (1 nM-10 μ M), but not the levels of osteopontin, IL-6 and TNF- α . Lut also significantly attenuated IL-1 β and IL-6 levels in a concentration-dependent manner (1 nM-10 μ M), but had no effect on osteopontin and TNF- α .

Conclusion: Our findings suggest that both Col and Lut might have beneficial effects in OA, mediated at least partly through reduction of oxidative protein degeneration and cytokine release. Although the cytokine inhibition was achieved with both compounds, Lut exhibited more antioxidative efficacy than Col, and probably thus increased viability. (Supported by TUBITAK; The Scientific and Technological Research Council of Turkey, No: 315S012).

Miller⁴ and Anne-Marie Malfait⁵, ¹Biochemistry, Rush University Medical Center, Chicago, IL, ²Internal Medicine, Rush University Medical Center, Chicago, IL, ³Guangzhou Institutes of Biomedicine and Health, Guangzhou, China, ⁴Pharmacology/Medical Humanities and Bioethics, Northwestern University, Chicago, IL, ⁵Biochemistry & Rheumatology, Rush University Medical Center, Chicago, IL

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Osteoarthritis and Joint Biology – Basic Science Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Destabilization of the medial meniscus (DMM) in mice results in experimental osteoarthritis, characterized by progressive joint damage (severe damage by week 12) and associated pain-related behaviors. The purpose of this study was to determine if mice also develop changes in motor coordination and balance by using two assays designed to test these parameters: the balance beam and horizontal ladder.

Methods: A 60-cm long, 6-mm wide square wooden balance beam was elevated 35 cm. Mice were filmed from one end as they crossed the beam. Videos were analyzed for (1) Time (in seconds) the mouse took to cross the beam; (2) Whether or not the mouse used its tail.

We used a 60-cm long horizontal ladder with 4-cm long metal rungs spaced 2 cm apart in a straight line. Mice were filmed from the side as they crossed the ladder. Videos were analyzed for (1) Time (in seconds) the mouse needed to cross the ladder; (2) The number of errors made in placing the right hind paw on a rung.

DMM or sham surgery was performed in the right knee of 10-week old male C57BL/6 mice. Age-matched naïve mice were also used. Twelve or fourteen weeks after surgery, mice were tested on either the beam or ladder.

In addition, two strains of naïve DREADD (Designer Receptor Activated by a Designer Drug) male mice were used, in order to selectively silence either nociceptors (Na_v1.8-Pdi mice) or proprioceptors (PV-Pdi mice) (Ray et al, Science, 333:637, 2011). Mice were injected with either clozapine-N-oxide (CNO) (10 mg/kg, i.p.) or vehicle (PBS) (n=6-10 mice/strain/treatment). One hour post injection, mice were tested by crossing the ladder or beam. The experimenter was blinded to the groups.

Results: Balance beam - Twelve weeks after surgery, DMM mice (n=13) took longer to cross the beam than shams (n=11) (p=0.04), and DMM mice used their tail more often than sham mice while crossing the beam (p=0.03).

Ladder - By week 14 after surgery, DMM mice took longer to cross the ladder compared to naïve mice (n=5/group) (p=0.001), while sham mice were not different from either naïve (p=0.16) or DMM (p=0.1). The number of errors made was not different among the groups at this time point.

On the beam, CNO caused both naïve PV-Pdi (p=0.05) and naïve Na_v1.8-Pdi (p=0.04) mice to take longer to cross the beam compared to PBS, but only PV-Pdi mice showed a difference in tail use when given CNO (p=0.008). Together, this suggests that a mixture of nociceptors and proprioceptors are needed to accomplish the beam task.

On the ladder, naïve PV-Pdi mice given CNO took longer to cross the ladder (p=0.01) and made more errors while crossing (p=0.09) compared to PBS. There was no difference between CNO and PBS in Na_v1.8-Pdi mice, providing evidence that this assay assesses proprioceptive function.

Conclusion: Using two different balance assays, we determined that mice developed impairments following DMM surgery, particularly during the late stage of the model, when joint damage and pain-related behaviors are most apparent. Chemogenetic silencing of proprioceptors but not nociceptors resulted in deficits in the horizontal ladder assay, while the beam test appeared to require both kinds of neurons to accomplish the task depending on the parameter measured.

Abstract Number: 1992

The Effect of 4E-BP1 on Osteoarthritis-Related Gene Expression in TGF- β 1-Stimulated Chondrocytes

Mi Hyun Lee, Ju-Ryoung Kim, Hyun Sook Hwang and Hyun Ah Kim, Hallym University Sacred Heart Hospital, Kyunggi-do, Korea, Republic of (South)

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Osteoarthritis and Joint Biology – Basic Science Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Initiation of protein synthesis is regulated by a repressor of cap-dependent translation, eukaryotic initiation factor 4E-binding protein 1 (4E-BP1), which prevents eukaryotic initiation factor 4E (eIF4E) from participating in the eukaryotic translation apparatus through its binding to eIF4E. In this study we determined whether the control of translational apparatus activity could have an effect on the expression of transforming growth factor-beta 1 (TGF- β 1)-induced catabolic or anabolic genes in primary chondrocytes and be responsible for the pathogenesis of osteoarthritis (OA).

Methods: Human articular chondrocytes were enzymatically isolated from articular cartilage and cultured in monolayer. The relative levels of mRNA and protein were analyzed by real-time quantitative reverse transcription-polymerase chain reaction and Western blot analysis, respectively. Immunoprecipitation (IP) assay was performed to investigate the binding of 4E-BP1 to eIF4E. The total protein synthesis was measured by flow cytometry using protein synthesis assay kit. 4E-BP1 and mTOR genes were knocked down by transfection with small interfering RNAs (siRNAs).

Results: The level of 4EBP-1 was significantly higher in human OA cartilage than normal cartilage. TGF- β 1 increased total protein synthesis, including aggrecan (ACAN) and collagen type II (Col II), together with activation of Akt/mTOR signaling pathway. IP data demonstrated that TGF- β 1 treatment suppressed the interaction of 4E-BP1 and eIF4E. mTOR silencing significantly suppressed ACAN and Col II expressions through decreased level of phosphorylated 4E-BP1 in TGF- β 1-treated chondrocytes. On the other hand, 4E-BP1 knockdown promoted total protein synthesis but suppressed Col II and ACAN expressions with decreased expression of Smad2/3 and Smad4 and increased expression of inhibitory Smad6 and Smad7. Furthermore, knockdown of Smad4 suppressed Col II and ACAN expression whereas increased expressions of Col II and ACAN were observed in Smad6- or Smad7-knocked down chondrocytes

Conclusion: These results demonstrated that TGF- β 1-modulated phosphorylation of 4EBP1 plays a role in the expression of Col II and ACAN through alteration of Smad signaling pathway.

Abstract Number: 1993

Evaluation of Cartilage Degeneration and Osteoarthritis Pain on Female and Male Mouse Model of Osteoarthritis

In Young Park, Jeong-Im Hong, Hyun Sook Hwang and Hyun Ah Kim, Hallym University Sacred Heart Hospital, Kyunggi-do, Korea, Republic of (South)

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Osteoarthritis and Joint Biology – Basic Science Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The prevalence of radiographic and symptomatic osteoarthritis (OA) is higher in women, but in animal study, male mice were more frequently used to explore pathogenesis or drug efficacy. In this study we examined whether gender dimorphism affects cartilage degeneration and pain accompanied by OA in knee joints and the activity of transient receptor potential cation channel subfamily V member 1 (TRPV1) antagonist on joint pain using destabilization of the medial meniscus (DMM)-induced OA mouse model.

Methods: DMM or sham surgery was performed on the right knee of 8-10 week old male and female C57BL/6 mice. Von Frey hair, incapacitance, rotarod, and hot plate tests were conducted to measure the degree of mechanical allodynia, sensorimotor skills, and thermal hyperalgesia in the hind paw, respectively. Degeneration of articular cartilage was assessed by safranin O staining and scored using the Osteoarthritis Research Society International (OARSI) scoring system.

Results: Male mice only showed that at the late stage post DMM surgery, paw withdrawal threshold in von Frey test and response time in hot plate test were significantly decreased relative to the sham control group. However, the pain behavior analysis using in capacitance and rotarod tests revealed no significant difference between female and male DMM group. Histology and OARSI scoring analysis showed that significant difference was not observed in male and female DMM groups. In addition, a TRPV1 antagonist, capsazepin (0.5 and 1.0 mg/kg) significantly reduced DMM-induced pain in male mice but did not in female mice.

Conclusion: These results suggest that DMM-induced pain behaviors and the effects of pain drugs, including TRPV1 antagonist, may be gender-dependent.

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018
Session Title: Osteoarthritis and Joint Biology – Basic Science Poster II
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Hydrogen sulphide (H₂S) is recognized as a therapeutic target in osteoarthritis (OA). Exogenous supplementation with synthetic salts in *in vitro* models of OA has been shown to exert anti-inflammatory effects and results in reduced cartilage degradation. Here we evaluated the effects of an intra-articular treatment with an H₂S-producing compound in an *in vivo* model of OA.

Methods: Experimental OA was induced in the left knees by transecting the medial collateral ligament and removing the medial meniscus. Animals were randomized into 3 groups (6 rats/group). Group 1 (intra-articular sulphide, IS): A single intra-articular injection of GYY4137 (200uM in saline, 50 ul) at day 7. Group 2 (intra-articular control, IC): A single intra-articularly injection of vehicle (saline, 50 ul) at day 7. Group 3 (Surgical control, C): No treatment. Gross evaluation of the animals was performed at days 0 (before surgery), 7, 15 and 40 (euthanasia). Histopathological changes in articular cartilage and synovium were evaluated with the MankinScore (MS) and the Krenn Score (KS), respectively.

Results: At day 7 after surgery animals in all groups had increased left knee perimeter, deep pain levels and showed worse performance in a Rotarod test (number of falls [n#f] and time to 1st fall [t1f], Table 1). At day 40, there was no significant improvement in either of these parameters in groups C or IC (except IC n#f that returned to pre-surgical levels). In IS

Table 1. Number of falls (n#f) within a 5-min period, and time to first fall (s), measured in a Rotarod for animals in the control group (C), the intra-articular control (IC, saline) and the intra-articular sulphide (IS, 200 µM GYY4137), n=6 in each group. #p<0.05 with respect to T0; *p<0.05 with respect to C; †p<0.05 with respect to IC.

Group	Falls per 5 min				Time to 1 st fall (s)			
	T0	T7	T15	T40	T0	T7	T15	T40
C	0.8±0.25	4.20±0.89	4.40±0.88	3.51±0.78	23.3±7.73	33.3±11.88	40.0±5.56	37.80±6.36
IC	1.87±1.88	4.34±1.75	4.17±0.88	3.00±0.88	20.9±7.78	31.67±11.74	38.67±8.56	34.83±5.83
IS	1.13±0.62	4.00±1.55	4.10±0.78	3.00±0.88	18.5±15.8	26.5±10.56	37.0±18.19	38.0±12.04

Table 2. Mankin Score grading of cartilage destruction. C: control group; IC: intra-articular control (saline); IS: intra-articular sulphide (IS, 200 μ M GYY4137); M: medial; L: lateral; TP: tibial plateau; FC: femoral condyle, n=3 in each group. *p<0.05 with respect to C.

Group	Medial compartment	Lateral compartment	MTP	MFC	LTP	LFC	Whole joint
C	5.5 \pm 0.6	4.0 \pm 0.0	12.5 \pm 0.7	17.5 \pm 0.7	4.0 \pm 0.0	4.0 \pm 0.0	8.8 \pm 0.6
IC	10.0 \pm 1.7*	7.5 \pm 4.0	9.7 \pm 6.3	10.5 \pm 1.3	6.7 \pm 4.0	8.0 \pm 1.7	8.7 \pm 2.6
IS	7.0 \pm 1.3*	3.8 \pm 1.7	7.7 \pm 0.6*	6.3 \pm 1.5*	3.0 \pm 0.0	4.5 \pm 3.5	5.7 \pm 2.8

values were significantly improved with respect today 0 and both C and IC groups at days 15 and 40 (Table 1). Also left knee perimeter and deep pain levels had subsided.

Histology showed no significant differences among groups in the lateral tibial plateau (TP) or femoral condyle (FC) separately or in the compartment as a whole. Conversely, MS in the medial compartment were significantly better in the IS group vs the C group, both when considering TP or FC separately, and for the whole compartment (Table 2). No significant differences were found among groups on the Krenn Scores.

Conclusion: Intra-articular H₂S administration (200 μ M GYY4137 in 50 μ l saline) can reduce the severity of cartilage destruction in an *in vivo* model of OA as compared to no treatment or a vehicle control. H₂S also led to a reduction in inflammation and pain levels as demonstrated by gross examination and a performance test. Therefore, hydrogen sulphide is a viable pharmacological candidate for OA treatment and should be further tested, including human clinical trials.

Session Title: Osteoarthritis and Joint Biology – Basic Science Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The major Glycosaminoglycan (GAGs) component of the cartilage ECM are Chondroitin Sulfates (CS) and Keratan sulfates (KS). Heparan Sulfates (HS) are also present in minority in cartilage and very few studies have been done. In general, However, HS act as central functional regulators of cell behavior, principally because of their capacities to interact with several growth factors.

Aim of this study: To characterize the quantity and degree of sulfation of the different GAGs from human normal and osteoarthritic cartilages and to look to the functional properties of HS to bind to growth factors and to induce change on mesenchymal stem cell behavior

Methods: Human samples were harvested from osteoarthritic knee joint (different zones) after TKR and normal counterpart from femoral neck fracture. After extraction, total GAG was quantified by dimethylene blue assay and the proportion of CS, KS and HS were determined following different enzymatic treatments and were normalized to mg of dry tissue. Structure of HS and CS was determined by HPLC analysis. The capacity of the cartilage extracted GAGs to interact

with heparin binding proteins such as FGF-2 and VEGF was evaluated by Elisa- based competition assay with heparin. Finally the effect of GAGs on human mesenchymal stem cell (MSC) was evaluated on adhesion and proliferation assays

Results: 11 OA samples and 7 controlled cartilages were used. Total GAG content was decreased by 1.5 fold in OA compared to normal controls. CS level was the same by KS level was decreased and level of HS decreased by 2 fold. The sulfation pattern of HS shows an increase in the % of di-sulfated disaccharides and a 2 fold decrease in non-sulfated HS. Compared to controls, OA total GAG showed a decrease affinity to FGF-2 binding (less 8 fold) and an increase affinity to VEGF (none in control). Those binding affinities were found to be mainly due to purified HS from OA compared to normal cartilages : FGF-2(2.5 fold decrease) and VEGF (3 fold increase). Interestingly in normal controlled cartilage, presence of CS/KS is able to inhibit HS binding to VEGF, while this inhibitory effect is lost in OA cartilage. Treatment with GAGs from controlled cartilage increased cell adhesion and a 30% increase in the cell numbers of MSC in a dose dependent manner. In the same concentration total GAG from OA did not induced any effect

Conclusion: For the first time, this study showed important effects of HS molecules from OA cartilage on growth factors binding and on cell behavior which may participate to the pathological processes of OA.

Cronstein⁵, ¹Medicine, NYU School of Medicine, New York, NY, ²Department of Medicine, Division of Rheumatology, New York University School of Medicine, New York, NY, ³NYU College of Dentistry, New York City, NY, ⁴Assistant Professor, Basic Science and Craniofacial Biology, NYU College of Dentistry, New York City, NY, ⁵Rheumatology, New York University School of Medicine, Division of Rheumatology, New York, NY

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Osteoarthritis and Joint Biology – Basic Science Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Osteoarthritis (OA) is the most common form of arthritis, affecting nearly 10% of the US population. With age and injury, chondrocytes have diminished mitochondrial content and mitochondrial production of ATP contributing to OA pathogenesis. We have previously reported that chondrocytes release ATP, which is converted extracellularly to adenosine and maintains chondrocyte homeostasis via endogenous stimulation of the A2AR. Injured/ inflamed chondrocytes have lower ATP levels and release less ATP resulting in diminished extracellular adenosine and A2AR stimulation. Mice and humans lacking the capacity to convert extracellular ATP to adenosine (ecto-5' nucleotidase deficient) develop spontaneous OA as do mice lacking A2AR (A2ARKO). We therefore studied the effect of A2AR stimulation on mitochondrial health and function in chondrocytes from WT and A2ARKO mice and in a human chondrocytic cell line.

Methods: A human chondrocyte cell line, T/C28-a2, or neonatal chondrocytes isolated from WT and A2ARKO mice (C57Bl6 background) were grown in culture, treated with IL-1 β (5ng/ml) or medium (4h, 37°C) and during the last hour of incubation, with either medium or the selective A2AR agonist (CGS21680, 1mM). Mitochondrial function was then analyzed by Seahorse Mito Stress Kits using the Seahorse apparatus. Mitochondrial health was assessed by analyzing mean pixel intensity (MPI) of tetramethylrhodamine (TMRM) live cell staining which correlates with reduced collapsibility of mitochondrial membrane potential. Mitochondrial content and ROS burden were assessed in live cell confocal imaging (MitoTracker; MitoSox) and by immunohistochemistry (anti-ATPase Ab; anti-8hydroxyguanosine Ab, 8OHg) in paraffin-embedded tissue from WT and A2ARKO mice.

Results: The mitochondrial membrane potential and mitochondrial content were reduced in A2ARKO chondrocytes compared to WT. In WT chondrocytes mitochondrial content increased after IL-1 β treatment and A2AR stimulation increased mitochondrial membrane potential as well. Histologic staining of knee cartilage for 8OHg, a marker of ROS-induced oxidation in mitochondria, of age-matched WT and A2ARKO mice revealed increased ROS burden in OA (A2ARKO) cartilage. In T/C28-a2 cells, neither IL-1 β nor CGS21680 affected basal O2 consumption rates (OCR), maximal respiratory rate or ATP production but IL-1 β -treated T/C28-a2 cells stimulated by CGS21680 increased all three measures

of mitochondrial function ($p < 0.03$, one-way ANOVA). Membrane potential (measured by TMRM MPI) decreased in T/C28-a2 cells after IL-1 β or CGS treatment alone, but IL-1 β + CGS21680 treatment significantly increased MPI, indicating enhanced mitochondrial health. Mitochondrial content is not significantly modulated by IL-1 β , CGS or IL-1 β +CGS *in vitro*, but IL-1 β treatment significantly increased ROS burden ($p < 0.0001$) and IL-1 β +CGS did not affect ROS-burden in T/C28-a2 cells.

Conclusion: Mitochondrial function and biomass decline with age and after injury and diminished mitochondrial function contributes to the development of OA. A2AR stimulation enhances the function of mitochondria in inflamed chondrocytes and contributes to the maintenance of healthy chondrocytes and cartilage.

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Osteoarthritis and Joint Biology – Basic Science Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: We have recently reported that adenosine A2A receptor (A2AR) knockout mice develop spontaneous osteoarthritis (OA) and intra-articular injection of adenosine prevents OA progression in a rat model of post-traumatic OA. Changes in chondrocyte gene expression in A2AR KO mice are evident in neonatal mice before OA is apparent. A2AR stimulation has previously been shown to regulate expression of NURR-1, a member of the NR4a family of nuclear receptors. There are 3 members of the NR4a family of nuclear receptors Nurr77, Nurr1 and NOR1 which act as transcriptional regulators to diminish binding of NF κ B to its regulatory sites and thereby diminish inflammation. We probed overall expression differences in neonatal chondrocytes from A2AR KO and WT mice and, based on these results, examined the effect of A2AR on NR4a family expression in chondrocytes *in vitro* and *in vivo*.

Methods: Knee cartilage from human OA patients, WT and A2ARKO mice, and from OA mice treated with an intrarticular knee injection (10 μ l) of empty liposome, liposome containing adenosine or CGS21680 (selective A2AR agonist) were examined immunohistologically for expression of Nurr77, Nurr1 and NOR1. mRNA was isolated from chondrocytes from WT and A2ARKO newborn mice and subject to RNAseq analysis. Human chondrocytic cell line TC28a2 was used to study the effect of A2AR agonists on expression of NR4A receptors.

Results: RNAseq analysis revealed alteration in expression of 648 genes, of which 319 were downregulated and 329 upregulated in A2ARKO vs WT chondrocytes. Pathway analysis revealed, among other changes, upregulation of pro-inflammatory and downregulation of extracellular matrix pathways in A2ARKO mice. All 3 of the NR4a genes were downregulated ($p < 0.001$) and a number of pro-inflammatory genes were upregulated (e.g. Nfkb1, Rela and MMP-13 ($p < 0.001$)). By immunohistochemistry NOR1, but not NURR77 or NURR1, is highly expressed in knee chondrocytes in healthy human cartilage and NURR1 is upregulated in human OA cartilage. In OA cartilage of A2ARKO mice there is diminished chondrocyte expression of Nur-77 and increased NURR-1 expression. When studied in a murine obesity model of OA intra-articular injection of liposomal suspensions of CGS21680 promoted NURR-1 expression in OA chondrocytes. When studied *in vitro* in the TC28a2 cell line Nur-77 is present in nuclei and the A2AR agonist stimulated increased nuclear Nur-77, Nurr-1 and Nor-1.

Conclusion: A2AR maintain homeostasis in chondrocytes including maintenance of expression of the anti-inflammatory nuclear receptor Nur-77 in chondrocytes. Diminished Nur-77 expression in OA cartilage likely contributes to OA progression and replacement by Nurr-1 during OA progression is likely insufficient to diminish OA progression but may play a role in A2AR-mediated cartilage repair.

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Osteoarthritis and Joint Biology – Basic Science Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: In osteoarthritis (OA), defects in cellular homeostasis, and in particular in autophagy, are evident and precede joint damage. We have shown that there is a defect in autophagy in OA human chondrocytes and cartilage. Indeed, pharmacological activation of autophagy protects against joint damage. Our working hypothesis is that joint damage in OA could be due to a failure of autophagy that can be detected in the blood and tissue of patients. *Therefore, identifying biomarkers associated with autophagy defects could facilitate the development of personalized therapeutic strategies to prevent OA progression.*

Methods: A comparative analysis of 35 autophagy genes was performed in blood from a Prospective OA Cohort of A Coruña (PROCOAC) of non-OA and knee OA patients. Non-OA patients (Age: 60,13 ± 6,16 years; BMI: 24,65 ± 3,30; Sex: Females/Males; N=30) and Knee OA patients (Age: 68,4 ± 6,07 years; BMI: 29,45 ± 2,86; Sex: Females/Males; N=30, OA grade III-IV) were profiled using PrimePCR autophagy human panel array and analysed using the PrimePCR analysis software (Bio-Rad). Confirmatory studies of the candidate genes were performed in blood and cartilage by using Taqman Technology and immunohistochemistry, respectively. A quantitative proteomic analysis of defective autophagy genes regulated upon deletion of Atg5 in human OA chondrocytes was performed by iTRAQ. Protein identification and quantification were performed using Protein Pilot Software 4.0. Each MS/MS spectrum was searched in the Uniprot/Swissprot database for *Homo sapiens*. Finally, to evaluate the functional consequences of autophagy defects on human chondrocyte homeostasis, pharmacological inhibition of candidate genes was done.

Results: 15 autophagy-related genes were downregulated in blood from knee OA patients compared to non-OA patients (p<0.05). No upregulation was found. although a trend towards upregulation was found for several genes involved in the mTOR signaling pathway. Importantly, key autophagy-related genes, including ATG16L2, ATG12, ATG4B and MAP1LC3B, involved in relevant process including initiating autophagy, phagophore extension and autophagosome formation, were significant downregulated in knee OA patients (p<0.05). Interestingly, HSP90AA1 and HSPA8, chaperone-mediated autophagy genes involved in stress response and protein folding, were significant downregulated (p<0.001). In addition, several regulators of autophagy and apoptosis, such as BNIP3, BCL-2 and BCL2L1 were downregulated (p<0.01). Confirmatory studies for MAP1LC3B and HSP90AA1, showed a significant downregulation (p<0.001) in blood and cartilage from knee OA patients. Remarkably, total proteome screening of human OA chondrocytes with defective autophagy, showed a significant reduction of HSP90AA1(p<0.05). Remarkably, pharmacological inhibition of HSP90 chaperone reduces chondrocyte homeostasis, suggesting that HSP90AA1 might be a potential biomarker associated with defective autophagy in OA.

Conclusion: We identified biomarkers of defective autophagy as a mechanism of central homeostasis, which gives us a general vision of the disease mechanisms linked to OA clinical reality.

Aberrant Expression of the GluN2B N-Methyl D-Aspartate Receptor Subunit in Osteoarthritic Chondrocytes Causes Disease-Associated Changes in Chondrocyte Phenotype through Altered Expression of Core Components of the Chondrocyte Circadian Clock

Maggie Kalev-Zylinska¹, James Hearn¹, Jing Rong¹, Mark Zhu², Jacob Munro³, Jillian Cornish⁴, Nicola Dalbeth¹ and Raewyn Poulsen², ¹University of Auckland, Auckland, New Zealand, ²Medicine, University of Auckland, Auckland, New Zealand, ³Orthopaedics, Auckland City Hospital, Auckland, New Zealand, ⁴Department of Medicine, University of Auckland, Auckland, New Zealand

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Osteoarthritis and Joint Biology – Basic Science Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Circadian clocks are key regulators of cell behaviour. Disruption to cell clocks is implicated in a range of diseases. Expression of two core clock components, *PER2* and *BMAL1*, is altered in chondrocytes in osteoarthritis (OA). Both *in vitro* and *in vivo* studies indicate that this altered expression contributes to OA-associated changes in chondrocyte activity and cartilage loss. Why the chondrocyte clock is altered in OA is unclear. *N*-methyl-D-aspartate receptors (NMDAR) are critical for regulating the more well studied light-sensitive clock present in the hypothalamus. Chondrocytes also express NMDAR and the type of NMDAR expressed changes in OA. The purpose of this study was to determine if NMDAR regulate the chondrocyte clock and if the change in NMDAR expression in OA chondrocytes is responsible for disease-associated changes in the circadian clock and cell phenotype.

Methods: Chondrocytes were isolated from macroscopically-normal (MN) and osteoarthritic cartilage from patients with OA. Cells were treated with NMDAR antagonists or transfected with siRNA targeting NMDAR subunits. The effect on clock gene expression, and chondrocyte phenotypic markers, was assessed by RT-qPCR and ELISA. Effects of GluN2B expression were determined by ectopic expression in the H5 chondrocyte cell line.

Results: In OA chondrocytes, NMDAR inhibition restored *PER2* and *BMAL1* expression to levels similar to MN chondrocytes and resulted in reduced RNA and protein levels of *MMP13* (the major enzyme implicated in the cartilage loss in OA) and *COLX* (type X collagen, a marker of the OA chondrocyte phenotype). Paradoxically, NMDAR inhibition in MN chondrocytes resulted in a similar reduction in *BMAL1* and increase in *PER2*, *BMAL1*, *MMP13* and *COLX* expression as seen in OA. OA chondrocytes expressed both GluN2A and GluN2B NMDAR subunits whereas MN chondrocytes only expressed GluN2A. Knockdown of GluN2A in MN chondrocytes caused OA-associated changes in *PER2*, *BMAL1* and chondrocyte phenotypic marker expression. In OA chondrocytes, GluN2A knockdown further exacerbated disease-associated increases in *PER2*, *MMP13* and *COLX*. Conversely, inhibition or knockdown of GluN2B in OA chondrocytes restored expression of *PER2*, *BMAL1* and phenotypic markers to levels similar to MN chondrocytes. Overexpression of GluN2B in the H5 chondrocyte cell line resulted in a similar reduction in *BMAL1* and increase in *PER2* expression as seen in OA and led to OA-associated changes in phenotypic markers. Knockdown of *PER2* mitigated the effects of GluN2B overexpression on chondrocyte phenotype. Notably, it completely ablated the GluN2B-induced increase in *MMP13* expression. This indicates that GluN2B causes disease-associated changes in chondrocyte phenotype in part, by altering expression of circadian clock components.

Conclusion: NMDAR regulate the chondrocyte clock. Different NMDAR subtypes have different effects on the clock. The change in NMDAR sub-type expression in chondrocytes in OA, (from GluN2A only to GluN2A and GluN2B), may contribute to disease pathogenesis by promoting OA-associated changes in chondrocyte phenotype by altering expression of core clock components.

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Osteoarthritis and Joint Biology – Basic Science Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Almost all cells contain a circadian clock. Cell clocks are key regulators of cell activity and cell differentiation. In osteoarthritis (OA), chondrocytes inappropriately undergo terminal differentiation leading to increased production of cartilage degrading enzymes. Recently, we found expression of two core circadian clock components, *PER2* and *BMAL1*, is altered in chondrocytes in OA. *In vitro* and *in vivo* evidence indicates altered *BMAL1* expression contributes to OA pathology. The purpose of this study was to determine potential causes of the altered *PER2* and *BMAL1* expression in OA, and to investigate the role of *PER2* in regulating chondrocyte behaviour.

Methods: Chondrocytes were isolated from macroscopically normal (MN) and OA cartilage from 12 patients with OA. MN chondrocytes were treated with interleukin-1 β (IL-1 β , 10ng/ml), hydrogen peroxide (100 μ M) or basic calcium phosphate (BCP) crystals (50 μ g/ml) (stimuli previously shown to induce OA-associated changes in chondrocyte phenotype) for up to 48h. Clock gene expression was measured by RT-qPCR. RNAi was used to knockdown *PER2* and chondrocyte phenotypic marker expression was assessed using RT-qPCR and ELISA.

Results: Consistent with previous findings, peak expression of *BMAL1* was lower and peak expression of *PER2* higher in OA compared to MN chondrocytes. In IL-1 β , peroxide or BCP crystal-exposed MN chondrocytes, peak expression of *BMAL1* was also lower, and *PER2* levels remained elevated for longer, compared to untreated cells. IL-1 β , peroxide and BCP-induced changes in disease-associated phenotypic markers (*SOX9*, *ADAMTS5*, *MMP13*) were partially mitigated by knockdown of *PER2*. *PER2* knockdown in OA chondrocytes was associated with restoration of phenotypic marker expression to levels more similar to the non-diseased state. Notably, both RNA and protein levels of *MMP13*, the major enzyme implicated in the cartilage loss in OA, were reduced following *PER2* knockdown in OA chondrocytes.

Conclusion: IL-1 β , peroxide and BCP crystals induce similar changes in the expression of *PER2* and *BMAL1* as occur in OA. Increased *PER2* expression contributes to the induction of OA-associated changes in chondrocyte phenotype following IL-1 β , peroxide and BCP crystal treatment and contributes to the maintenance of the diseased phenotype in OA chondrocytes. Altered expression of *PER2* and *BMAL1* may be a central mechanism by which multiple different risk factors for OA induce disease-associated changes in chondrocyte activity.

Adenosine A2A Receptor Stimulation Regulates Autophagy in Chondrocytes

Benjamin Friedman¹, Carmen Corciulo², Cristina Castro³ and Bruce N. Cronstein¹, ¹Rheumatology, New York University School of Medicine, New York, NY, ²Department of Medicine, Division of Rheumatology, New York University School of Medicine, New York, NY, ³Medicine, NYU School of Medicine, New York, NY

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Osteoarthritis and Joint Biology – Basic Science Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Osteoarthritis (OA) is a debilitating condition characterized by chondrocyte dysfunction and loss of cartilage. Autophagy, a homeostatic process that occurs in times of cellular stress and starvation, is decreased in chondrocytes with aging and OA. The adenosine A2A receptor (A2AR) maintains chondrocyte homeostasis; A2AR knockout (KO) mice spontaneously develop OA. Moreover, intra-articular injection of liposomal preparations of adenosine or an A2AR-specific agonist (CGS12680 (CGS)) in rats with post-traumatic OA (PTOA) or mice with obesity-induced OA prevents development of PTOA and reverses obesity-induced OA. We sought to determine whether adenosine signaling maintains chondrocyte homeostasis, in part, by regulating autophagic flux in chondrocytes.

Methods: Autophagy proteins Beclin-1, p62/SQSTM1, and LC3 were analyzed by western blotting and IF in TC28a2 human chondrocytes $\pm 1\mu\text{M}$ CGS for various times in normal culture and starvation (FBS 10% vs 1%). Chondrocytes were pretreated with autophagy inhibitors hydroxychloroquine (prevents autophagosome destruction by lysosomes, $25\mu\text{M}$, HCQ) and/or 3-methyladenine (blocks autophagy initiation, 3MA, 5mM). Knee joint sections from obese mice treated with adenosine or CGS were analyzed by fluorescent IHC. Autophagy gene expression was determined in differential display analyses comparing wildtype (WT) vs A2AR KO mice and rats with established PTOA treated with intra-articular injections of liposomal CGS or liposomes alone.

Results: Consistent with enhanced autophagy, CGS reduced p62 levels in starved chondrocytes by western blot (4.1 ± 0.7 vs 5.7 ± 0.8 p62/actin, $p < 0.02$). More cells stained diffusely positive for p62 without punctae (less autophagy) in the control vs CGS ($67 \pm 6\%$ vs. $19 \pm 3\%$, $p < 0.0002$). With HCQ added, punctate p62 was more marked and brighter on CGS treatment ($78 \pm 5\%$ vs $13 \pm 4\%$, $p < 0.0001$). Chondrocyte pre-treatment with 3-MA (\pm HCQ) followed by starvation \pm CGS for 1h demonstrated almost complete absence of either p62 or Beclin-1. When studied *in vivo* in OA mouse knees, Beclin-1 was not visible in chondrocytes in normal and obese (OA) mouse controls whereas it was present in all of the chondrocytes in obese mice treated with either CGS or adenosine ($p < 0.0001$). Differential expression analysis of WT vs A2AR KO murine chondrocytes demonstrated significant changes in numerous autophagy genes; e.g. *p62* was elevated in WT mice. Similarly, there were significant changes in autophagy gene expression in PTOA rats given liposomal-CGS vs liposome. Of note the autophagy Atg8-family member *Gabarrap11* that integrates into autophagosomes was increased with CGS-liposome injections (FC +1.75, adj $p = 0.0049$).

Conclusion: These results demonstrate, both *in vitro* and *in vivo*, that A2AR stimulation promotes autophagy, evidenced by decreased p62, increased Beclin-1 and reversal of these effects with autophagy inhibitors. Although the precise mechanism is not known, it is possible that A2AR signaling increases Beclin-1 activity, thereby increasing downstream autophagic flux. This increase in autophagy may contribute to maintaining chondrocyte homeostasis and reversing OA.

Dynamic Compression of Articular Cartilage Explants Increases Formation and Decreases Degradation of Type II Collagen

Amalie Engström^{1,2}, Anne C. Bay-Jensen², Morten A. Karsdal² and Christian S. Thudium², ¹Department of Biomedical Science, University of Copenhagen, København, Denmark, ²Nordic Bioscience, Herlev, Denmark

Session Information

Session Date: Tuesday, October 23, 2018

Background/Purpose: Mechanical loading is recognized as a major factor in initiation and progression of osteoarthritis (OA). Conversely loading is believed to play an essential role in maintaining homeostasis of healthy cartilage. Given the biomechanical function of articular cartilage and the mechanosensitivity of chondrocytes, physiological loading may be of importance in a translational cartilage model and hereby, in development of new OA drug candidates. This study investigated the effect of long-term dynamic *ex vivo* compression on articular cartilage through quantification of type II collagen formation and degradation.

Methods: Full-depth bovine cartilage explants were cultured for 5 weeks. The explants were treated 3 times a week with either OSM [10 ng/mL] and TNF- α [2ng/mL] (O+T), or TGF- β 1 [50 ng/mL]. Untreated samples were included as negative controls (w/o). For each condition, two groups were established; an unloaded group and a group compressed 3 times a week. Compression was applied using Electroforce 5500® (TA Instruments), in a sine wave with a maximum load per cycle of 1 MPa, at 1 Hz frequency for 1200 cycles. Metabolic activity was measured once a week using Alamar Blue. Biomarkers

released to the supernatant were assessed using ELISAs: Pro-C2 and C2M for measurement of type II collagen formation and degradation respectively.

Results: Compression resulted in increased Pro-C2 release throughout the 5 weeks, peaking at week 3 where application of compression without treatment increased the Pro-C2 level 125 % ($p=0.0025$) above the unloaded group. A synergistic effect was observed with compression and TGF- β treatment, increasing the Pro-C2 release by 60% at week 5 ($p=0.0048$) compared to the non-compressed TGF- β treated samples. O+T treatment stimulated a catabolic response in the cartilage explants as shown by the increase in C2M levels. This O+T-induced C2M release was partly blocked by dynamic compression. At week 4, the C2M response was reduced by 61 % ($p=0.0054$) in compressed O+T treated explants compared to the non-compressed O+T treated group.

Conclusion: Long-term dynamic compression induced an increase in type II collagen formation, which was synergistic with the effect of TGF-beta. Furthermore, compression induced a reduction in cytokine-induced type II collagen degradation. In conclusion, compression stimulates formation and attenuates degradation, which may be important when evaluating the mechanisms of different novel drug candidate targeted cartilage metabolism.

Chondrocyte Size in Articular Cartilage As a Marker of Osteoarthritis Severity

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Osteoarthritis and Joint Biology – Basic Science Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Terminal differentiating growth plate chondrocytes are mainly characterized by an increase of their cell size and by the expression of hypertrophic markers such as type X Collagen. Likely, during osteoarthritis (OA) progression, articular chondrocytes acquire a similar protein profile, and, therefore, they have been commonly described as hypertrophic-like chondrocytes. Our aim was to study whether an increase in chondrocyte size may be a feature of the hypertrophic-like phenotype in the articular cartilage (AC) of experimental OA rabbits and in OA human cartilage. The anatomical location of these bigger cells in the deeper zones was also assessed.

Methods: New Zealand female rabbits were randomly assigned to four groups: healthy (n=8), osteoporosis (OP, n=7), OA (n=8) and OA preceded by OP (OPOA, n=8). OP was induced by ovariectomy followed by methylprednisolone administration (1mg/kg/day) during four weeks. OA was induced by anterior cruciate ligament section and partial medial meniscectomy, lasting over a period of 6 weeks. All animals were euthanized and tibias were collected for histological analysis. Cartilage damage and chondrocyte size were assessed in Safranin-O fast green stained sections. Type X Collagen presence was analyzed by immunohistochemistry. Nine human samples were obtained during total knee replacement surgery to perform identical histological studies after the informed consent was gained. Statistical comparisons were performed using Kruskal-Wallis and Mann Whitney tests, whereas correlations were done with Spearman test.

Results: Mankin score showed an increase in cartilage damage in all groups in comparison to healthy rabbits. The most severe cartilage damage was observed in the OPOA group (Healthy: 1.0 (0-1.5), OP: 2.3 (1.5-4.5), OA: 8.0 (7-13), OPOA: 13 (11-16)). Chondrocyte size in OA and OPOA cartilages were greater than that in healthy cartilage, and significantly greater in OPOA vs OA (Healthy: 133.0 (91.1-158.7), OP: 140.7 (119.7-198.3), OA: 180.9 (120.5-266.4), OPOA: 217.4 (183.6-303.5)). However, no differences in the mean chondrocyte size were found between the deepest and in the most superficial regions of the AC in any of the groups analyzed. Chondrocyte size and cartilage damage were significantly and positively correlated ($p < 0.001$, $r = 0.718$). In addition, chondrocyte size was also associated with immunoreactive type X Collagen staining ($p < 0.05$, $r = 0.444$). Regarding human OA cartilage, chondrocyte size also correlated with cartilage damage and with type X Collagen presence ($p < 0.001$, $r = 0.921$ and $p < 0.05$, $r = 0.663$ respectively).

Conclusion: We observed an increase of the chondrocyte size in OA cartilage in relation to an increased cartilage damage. These bigger chondrocytes were homogeneously distributed in the deepest and in the most superficial regions of the AC. A positive correlation was also found between the chondrocyte size and the presence of type X Collagen, both in human and experimental OA cartilage. Our results suggest that chondrocyte size could be a reliable hypertrophic marker of the OA articular cartilage.

Session Date: Tuesday, October 23, 2018

Session Title: Osteoarthritis and Joint Biology – Basic Science Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Osteoarthritis (OA) is a disease which results in the degeneration of articular cartilage. The progression of OA involves inflammation in the early stage of the disease which induces the activation of cartilage-degrading enzymes, such as metalloproteases (MMPs) and aggrecanases (ADAMTSs), through different signaling pathways. Based on the literature, MMP3 can be considered a promising target in OA therapy: in detail, several clinical studies reported an increase of MMP3 level in synovial fluid (SF) in early and advanced OA patients. In our previous work a hyaluronic acid (HA) partial hexadecylamide (HYADD[®]4), contained in the viscosupplement Hymovis[®], was selected as the strongest MMP and hyaluronidase inhibitor among a series of glycosaminoglycans. The objective of these further studies was to confirm the *in vitro* efficacy and selectivity of HYADD[®]4 as MMP inhibitor and to elucidate the mechanism of inhibition through *in silico* studies

Methods: HYADD[®]4 was screened *in vitro* against 10 different human MMPs and other targets. In order to shed light on the mechanism of inhibition, the structural interactions between a HYADD[®]4 oligomer and the crystal structure of MMP3 were evaluated *in silico* by means of molecular modeling studies. Molecular docking and molecular dynamics simulations were performed to propose a hypothetical binding mode of the HYADD[®]4 oligomer on MMP3 and to evaluate the stability of the complex

Results: Among the tested glycosaminoglycans HYADD[®]4 showed the highest inhibition potency against MMP13, MMP8 and MMP3, and no activity against ADAMTS4 and elastase *in vitro*. The molecular modeling results suggest that HYADD[®]4 may behave as a competitive MMP inhibitor, because of its ability to interact with the collagen-binding groove and to participate in the coordination of the catalytic zinc ion of this class of enzymes. Moreover, the hexadecyl side chain in HYADD[®]4 is suitable to fit effectively the enzyme S1' additional pocket, increasing its affinity for MMP3

Conclusion: The HA derivative HYADD[®]4 showed an inhibitory effect on MMP activity *in vitro*; in this study, a specific mechanism for the structural inhibition of MMP3 has been proposed on the basis of molecular simulation studies. A subsequent pivotal clinical trial has been performed to confirm the efficacy of HYADD[®]4 in inhibiting MMP3 activity in the synovial fluid of OA patients in comparison with another viscosupplement based on a different HA chemistry. These findings suggest that the intra-articular administration of HYADD[®]4 (Hymovis[®]) may prevent local cartilage degradation mediated by MMPs

Session Date: Tuesday, October 23, 2018

Session Title: Osteoarthritis and Joint Biology – Basic Science Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Osteoarthritis (OA) is both the most common form of arthritis and a leading cause of chronic disability. Bacterial products, including lipopolysaccharide (LPS), have been suggested as drivers of OA; however, an examination of the microbiota signature of human articular cartilage has not yet been performed.

Methods: Using sterile technique, OA-eroded and OA-intact cartilage was obtained from primary OA knee (intact=21, eroded=21) and hip (intact=33, eroded=34) replacements, OA-free cadaveric control tissue was obtained from the National

Disease Research Interchange (n=30). Age, race, sex, and BMI were not statistically significantly different among groups. 16s rRNA gene deep sequencing was done on an Illumina HiSeq. Operational taxonomic units (OTUs) were assigned using QIIME 1.9 and alpha and beta diversity were calculated. Group OTU differences were identified using Linear Discriminant Analysis Effect Size (LEfSe); LDA log-scores ≥ 2 or ≤ -2 ($p \leq 0.01$) significant, Benjamini-Hochberg FDR q-values were calculated ($q \leq 0.1$ significant). Differences were confirmed with clade-specific qPCR in a separate confirmation cohort (10 eroded, 10 intact, 10 control samples). The Gram status of DNA sequences for each sample was determined and compared.

Results: We found reduced alpha diversity in OA tissue vs. control (control vs. eroded $p=0.009$, control vs. intact $p=0.006$, eroded vs. intact $p=1.0$) and in hip vs. knee (knee-control vs. hip-control $p<0.0001$, knee-OA vs. hip-OA $p<0.0001$). Beta diversity was also different between groups (OA vs. control $p=0.001$, knee-OA vs. hip-OA $p=0.001$, knee-control vs. hip-control $p=0.002$). In group analysis, there were 63 clade differences between OA and control, 35 passed FDR correction; OA was dominated by *Betaproteobacteria* whereas controls characterized by *Actinobacteria* and *Clostridia*. We found 36 differences in knee-OA vs. hip-OA, 8 passing FDR correction. Hip-OA was dominated by *Proteobacteria* including *Rhodocyclaceae*, whereas knees were characterized by *Actinobacteria*. 46 differences were seen in knee-control vs. hip-control. Deep sequencing findings were confirmed by clade-specific qPCR analysis of *Alphaproteobacteria*, *Bacteroides*, *Betaproteobacteria*, *Pseudomonas*, and *Burkholderiales* in a separate confirmation cohort. We noted a shift in OA towards Gram-negative constituent DNA (OA-intact: $37\% \pm 3\%$ vs. control: $27\% \pm 2\%$, $p=0.03$; OA-eroded $38\% \pm 3\%$ vs. control $27\% \pm 2\%$, $p=0.02$, OA-intact vs. OA-eroded N/S).

Conclusion: Our results suggest that bacterial nucleic acid is present in human cartilage samples, and significant diversity and clade differences exist between OA and control tissue, and between hip and knee samples. We identified an increase in nucleic acid from Gram-negative organisms in OA samples, complementary to recent reports of elevated local LPS levels in OA. Further work should be done to confirm our findings and examine the pathogenic role of cartilage microbiota changes in OA.

Session Information

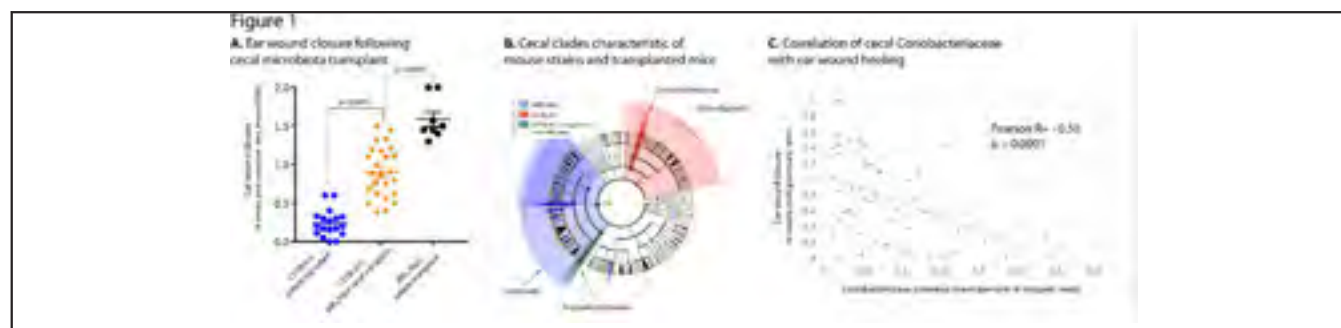

Session Date: Tuesday, October 23, 2018

Session Title: Osteoarthritis and Joint Biology – Basic Science Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: MRL/MpJ mice are substantially protected from developing post-traumatic osteoarthritis (OA), a trait with strong correlation to the ability to heal ear wounds. Previous studies have shown murine ear wound healing to be genetically determined. A powerful role of the gut microbiome in OA has recently been suggested, with dietary

oligofructose supplementation resulting in protection from OA. In this study, we examined whether ear wound healing in MRL mice is associated with gut microbiota changes, and whether microbiome transplantation can transfer this superhealer trait.

Methods: Three-week-old C57BL6/J mice were inoculated by oral gavage with diluted cecal contents from adult male MRL/MpJ mice, or with vehicle control. Six-week-old transplanted B6 mice (n=26), age-matched B6 (n=18) and vehicle control MRL mice (n=8) received a 2mm ear punch. Mice were sacrificed 4 weeks later, final earhole size measured, and DNA extracted from cecal contents. The gut microbiome was characterized by 16s rRNA gene deep sequencing and analyzed using QIIME 1.9.1. Group significance-values and FDR-corrected q-values were calculated in QIIME using Kruskal-Wallis and Benjamini-Hochberg. Characteristic clades of each group were calculated and plotted in LEfSe. Microbiome clades were correlated with earhole closure via Pearson correlation.

Results: As previously reported, MRL ear wounds closed well (earhole closure, mm, MRL: 1.6 ± 0.1 mm mean \pm SEM vs. B6: 0.23 ± 0.04 , $p < 0.0001$). Transplanted B6 mice closed roughly one-half as well as MRL (MRL \rightarrow B6: 0.9 ± 0.06 vs. MRL: 1.6 ± 0.1 , $p < 0.0001$), but significantly more than B6 controls ($p < 0.0001$), (Figure 1A). Microbiome analysis demonstrated several clades that were characteristic of each group (Figure 1B); specifically in MRL and transplanted mice, increases in Lachnospiraceae (B6 mean OTU count 0.05 vs. transplant 4.4 vs. MRL 9.4, $p = 1E-5$, $q = 0.003$), Peptostreptococcaceae (B6 0.28 vs. transplant 0.46 vs. MRL 7.6, $p = 1E-4$, $q = 0.02$), and decreases in Coriobacteriaceae (B6: 10670 vs. transplant: 4982 vs. MRL: 795, $p = 0.0007$, $q = 0.02$) and Erysipelotrichaceae (B6: 0.33, transplant 3.2, MRL 2, $p = 0.002$, $q = 0.05$) were seen. The presence of several clades was highly correlated with earhole closure rates in individual mice, including Coriobacteriaceae (Pearson $R = -0.53$, $p = 3.5E-5$), Figure 1C.

Conclusion: Superhealer MRL mice have substantial differences in gut microbiota composition compared to nonhealer B6 mice. The MRL cartilage healing trait, as measured by earhole closure, is partially transferrable to B6 mice via a gut microbiome transplant, and associated with shifts in specific gut microbiotic taxa. Future work should focus on elucidating the causal mechanism underlying these findings, and further examine the therapeutic potential of gut microbiota modification in treatment of OA.

Session Date: Tuesday, October 23, 2018

Session Title: Osteoarthritis and Joint Biology – Basic Science Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Although hand osteoarthritis (OA) is a worldwide burden, there is no treatment able to cure it. Induced pluripotent stem cells (iPSCs) are considered ideal sources for exploring cell therapies and they have emerged as promising tools for modelling diseases. The advantages of using iPSC lines are unlimited cell source and chondrogenic differentiation potential. However, there are no studies generating iPSCs from patients with hand OA. Therefore, the aim of this study has been to generate iPSC-lines from patients with hand OA and healthy donors, which can be useful for studying the pathogenesis of the disease *in vitro* and for testing new drugs.

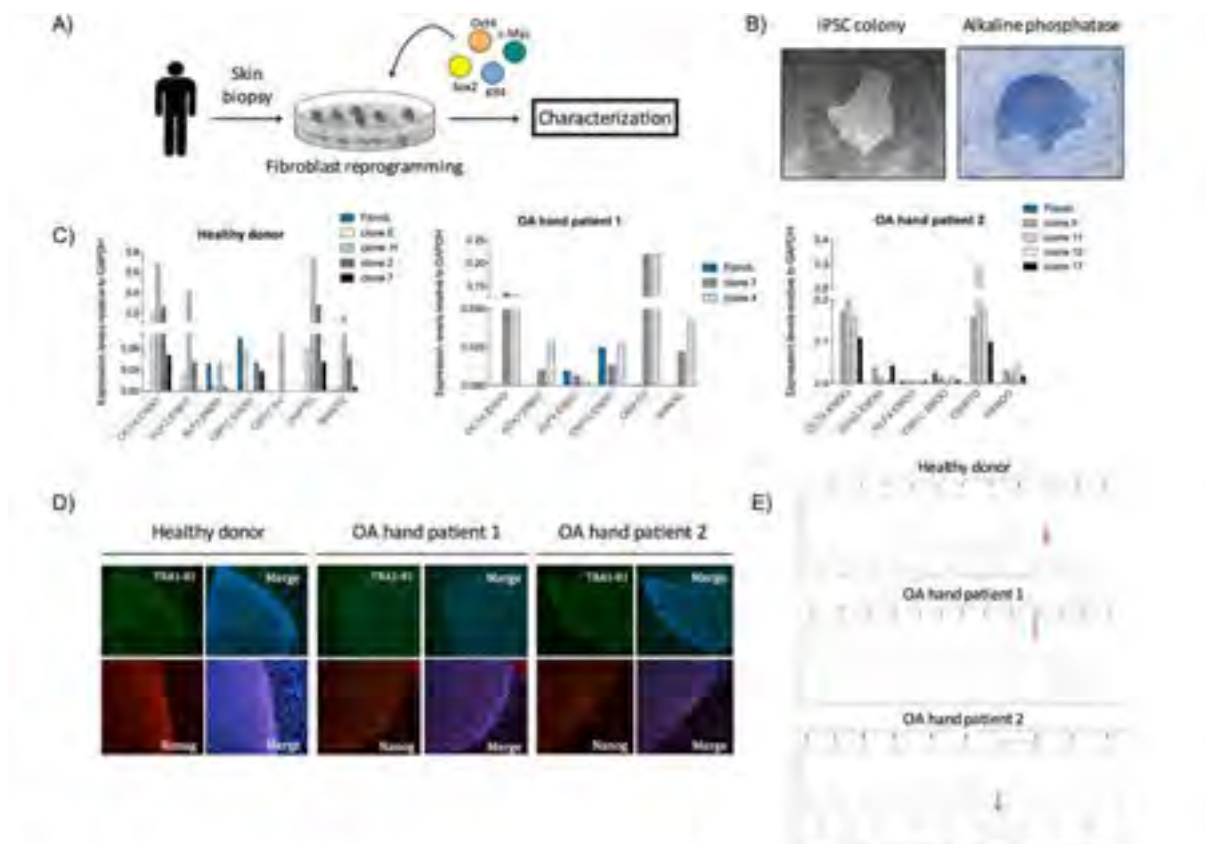

Figure 1. (A) Reprogramming process of the fibroblasts. (B) Left: Bright field image of a representative iPSC colony, Right: Alkaline phosphatase staining. (C) Relative expression levels of the endogenous reprogramming factors (OCT4 ENDO, SOX2 ENDO, KLF4 ENDO, CMYC ENDO) and pluripotency genes (CRIPTO, NANOG). (D) Immunofluorescence images of pluripotency markers of representative iPSC clones. x30 magnification. (E) Sequencing chromatograms. Red arrows point the single nucleotide polymorphism within the ALDH1A2 gene.

Methods: Patients with hand OA (rhizarthrosis) and a healthy control were selected for the study. Fibroblasts from 3mm skin biopsies of these patients were isolated. The transcriptional factors Oct4, Sox2, Klf4 and c-Myc were used for the reprogramming process; which was performed by using the non-integrating method Sendai virus (Fig 1A). Cell lines obtained were morphological, phenotypical and functionally characterized. Furthermore, to evaluate whether these iPSC lines could be used as cellular model of hand OA, presence of single nucleotide polymorphisms (SNPs) within the gene encoding the retinaldehyde dehydrogenase 2 (ALDH1A2) was studied by Sanger sequencing, before and after reprogramming. The variant rs3204689 within the ALDH1A2 gene has been associated with severe OA of the hand (OR=1.46, $p=1.1 \times 10^{-11}$) (Styrkarsdottir *et al.*, 2014).

Results: Fibroblasts were isolated from skin biopsies of two patients with radiographic hand OA and one healthy donor, which presented a normal karyotype:46,XX. Three weeks after reprogramming, embryonic stem cell-like colonies emerged in culture (Fig 1B). These cells showed positivity for alkaline phosphatase activity (Fig 1B) and the pluripotency markers Tra1-81 and Nanog (Fig 1D). Molecular analyses showed high relative expression levels of the pluripotency-related genes OCT4, SOX2, NANOG and CRIPTO in the iPSCs (Fig 1C). These cells were also able to give rise to cells from the three germ layers. Indeed, during mesodermal differentiation, spontaneously beating cardiomyocytes were seen in culture. Regarding SNPs studies, cells from one of the patients with hand OA were homozygous for the at-risk C allele, both before and after reprogramming. Cells obtained from the healthy donor and the second OA hand patient were heterozygous for this variant(Fig 1E).

Conclusion: The reprogramming process using Sendai virus enabled us to generate iPSC lines from patients with hand OA. The presence of the at-risk C allele within the ALDH1A2 gene was maintained after fibroblast reprogramming. The iPSC lines obtained will enable us to model hand OA *in vitro* and to deeper study the role of this genetic variant in the pathogenesis of hand OA.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Osteoarthritis and Joint Biology – Basic Science Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: To investigate the expression of vascular adhesion protein -1 (VAP-1) in joint tissues and serum in knee osteoarthritis (OA) patients and examine whether VAP-1 levels predict increased risk of disease severity or progression of knee OA.

Methods: Baseline serum and synovial fluid VAP-1/semicarbazide-sensitive amine oxidase (SSAO) levels were assessed in cohorts of patients with tibiofemoral medial knee OA and healthy subjects. Standardized fixed-flexion posteroanterior knee radiographs were scored for Kellgren Lawrence (KL) grade (0–4) and medial joint space width (JSW) at the mid-portion of the joint space. Radiographic severity was defined by KL2/3 vs. KL4. Biochemical markers assessed comprised VAP-1/SSAO, IL-1Ra, IL-6, sRAGE, CCL2, CCL4, CD163, hsCRP and MMPs-1,-3,-9. Associations between biomarkers and radiographic severity (logistic regression controlling for covariates) and pain (Spearman correlation) were evaluated.

Results: VAP-1 was locally overexpressed at least 2 fold in the OA synovium based on immunohistochemical, microarray and qRT-PCR analyses compared to controls. Synovial fluid SSAO levels was also significantly higher in OA (107.94±41.42) compared to normals (38.12 ± 22.98 ng/ml; p=0.0001) and inversely associated with radiographic severity. We observed a positive correlation with the levels of SSAO in the synovial fluid and serum of OA patients (r=0.47; p=0.014). However, serum SSAO levels in OA patients were lower than in controls, and inversely correlated with pain and inflammation markers (CRP and soluble RAGE). Serum SSAO levels were also lower in radiographically severe (KL4) OA patients compared to KL2/3. Serum SSAO did not correlate with other markers of inflammation or radiographic joint space narrowing (JSN) over 24 months.

Conclusion: Synovial fluid VAP-1/SSAO levels were elevated in OA and correlate with radiographic severity. However, serum or circulating SSAO levels are lower in OA patients and inversely correlate with pain and inflammation. Serum VAP-1 levels could identify patients at increased risk for knee radiographic severity.

Session Date: Tuesday, October 23, 2018

Session Title: Osteoarthritis and Joint Biology – Basic Science Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Zinc Finger CCHC Domain Containing Protein 6 (ZCCHC6) or Terminal Uridylyltransferase 7 (TUT7) is a member of terminal uridylyltransferase family that mediate terminal uridylation of mRNA or miRNA modulating their expression, stability and biogenesis. Matrix metalloprotease 13 (MMP13) is one of the key protease responsible for the degradation of cartilage extracellular matrix and plays central role in the pathogenesis of osteoarthritis (OA). In the present study we investigated the effect of ZCCHC6 deletion on the expression of MMP13 in human and mouse chondrocytes *in vitro*. We used global *zcchc6* knockout (*zcchc6*^{-/-}) mice to determine the role of *zcchc6* in OA pathogenesis and the regulation of MMP13 expression *in vivo*.

Methods: Human chondrocytes were used for ZCCHC6 knockdown and overexpression experiments. The mouse chondrocytes from *zcchc6*^{-/-} mice and corresponding wild type (*zcchc6*^{+/+}) littermate were used to determine the expression of MMP13 under pathological conditions (stimulation with IL-1 β). The expression of MMP13 mRNA was determined by qPCR using gene specific TaqMan assays and the protein expression levels were determined using Western blotting and ELISA. The *zcchc6*^{-/-} and the *zcchc6*^{+/+} control mice were subjected to destabilization of medial meniscus (DMM) surgery to determine the role of *zcchc6* in OA pathogenesis. The extent of damage to mouse joints was determined by OARSI scoring system.

Results: The expression of ZCCHC6 was upregulated in human normal and OA chondrocytes as well as mouse chondrocytes under pathological conditions. Depletion of ZCCHC6 in human normal and OA chondrocytes resulted in decreased expression of MMP13 at mRNA and protein levels in the presence or absence of IL-1 β . Overexpression of ZCCHC6 in human OA chondrocytes resulted in increased expression of MMP13. The expression of MMP13 was found to be downregulated in the mouse chondrocytes prepared from *zcchc6*^{-/-} mice in comparison to *zcchc6*^{+/+} littermate. Transfection of *zcchc6* in mouse chondrocytes derived from *zcchc6*^{-/-} mice reversed the expression of MMP13. The severity of DMM-induced OA was significantly low in *zcchc6*^{-/-} mice compared to *zcchc6*^{+/+} mice. Furthermore, the expression of MMP13 in *zcchc6*^{-/-} mice joints with DMM surgery was significantly low in comparison to *zcchc6*^{+/+} mice.

Conclusion: In the present study, we demonstrate a novel role of ZCCHC6 in the regulation of MMP13 expression in human and mouse chondrocytes and cartilage. We show here that *zcchc6* deletion has protective effect on the development of OA.

Anti-Endothelial Cell Antibodies in Pediatric Rheumatic Diseases

Rie Karasawa¹, Toshiko Sato¹, Megumi Tanaka¹, Mayumi Tamaki¹, Kazuo Yudoh¹ and James Jarvis², ¹Institute of Medical Science, St. Marianna University School of Medicine, Kawasaki, Japan, ²Pediatrics, University at Buffalo Jacobs School of Medicine & Biomedical Sciences, Buffalo, NY

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Pediatric Rheumatology – Basic Science Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Anti-endothelial cell antibodies (AECA) are antibodies detected in multiple autoimmune and inflammatory diseases. Increased levels of such antibodies may be involved in disease activity and/or the coexistence of vasculitis. Juvenile dermatomyositis (JDM) shows many pathological features of vasculitis. Many autoantibodies detected in JDM have specific clinical and phenotypic associations, but their relationship to disease pathology remains unclear. Juvenile idiopathic arthritis (JIA) is a heterogeneous group of inflammatory diseases. There are no useful autoantibody biomarkers for diagnosis or for characterization of the disease. We aimed to detect target antigens for AECA and to investigate the roles of AECA in both diseases.

Methods: We screened plasma from pediatric rheumatic diseases (3 children with JDM and 2 children with polyarticular JIA) and from healthy children for the presence of AECA by western blotting and two-dimensional electrophoresis (2DE) using proteins extracted from human aortic endothelial cells (HAEC) as the substrate. Selected antigens were positive only in plasma of children with pediatric rheumatic diseases but not in plasma of healthy children. We performed mass spectrometry to identify the candidate antigens from 2DE gels and used ELISA assays to confirm the presence of specific antibodies.

Results: We successfully identified more than 600 proteins that were candidate targets of AECA in JIA and JDM using proteomics. Among these antigens were proteins regulating cellular redox processes. These included peroxiredoxins (Prxs), a family of related antioxidant enzymes. Using ELISA assays, IgG autoantibodies to Prx2 were detected in 12% of the

patients with JDM (n=51) but not in healthy children (n=20). However, 24% of JDM patients with active disease (n=25) had anti-Prx2 antibodies, while these antibodies were absent ($p<0.01$) in JDM patients with inactive disease (n=26). We also noted that 17% of JIA patients with active disease (n=12) had anti-Prx2 antibodies. There was no difference in the frequency of anti-Prx2 antibodies between JIA patients with active disease and those with inactive disease. Another group of antigens that were detected were tropomyosins, a family of actin filament binding proteins, which are categorized into muscle isoforms and non-muscle isoforms. IgG autoantibodies to tropomyosin beta chain (TPM2) were detected in 24% of the patients with JIA (n=17) in contrast to 5% of healthy children (n=20). Interestingly, IgG autoantibodies to TPM2 were detected in 43% of the untreated JIA patients with active disease (n=7) in contrast to 5% ($p<0.05$) of healthy children. On the other hand, 15 % of JDM patients (n=20) had anti-TPM2 antibodies.

Conclusion: IgG antibodies to Prx2 and TPM2 in the proteome of HAEC are present in the children with JDM and with JIA. The measurement of anti-Prx2 antibodies might be useful for evaluation of disease activity in JDM.

Session Title: Pediatric Rheumatology – Basic Science Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: We have found extensive alterations in chromatin accessibility when the CD4+ T cells of children with active polyarticular juvenile idiopathic arthritis (JIA) are compared with cells from healthy children (HC). These differences in chromatin accessibility are strongly linked to differences in transcription. We therefore sought to determine the extent to which chromatin re-organization in JIA CD4+ T cells is influenced by underlying genetic variation.

Methods: Using our previously published whole genome sequencing data from 48 JIA patients, we identified common SNPs that: (1) were found in all JIA patients and (2) had not been identified previously. We categorized the SNPs as loss (LoF) or gain of function (GoF), based on their likely contributions to the regulatory network of CD4+ T cells, using ATAC-seq data to identify regulatory sequences. Using data from the 1000 genomes project, we identified the SNPs that were in linkage disequilibrium with our predicted LoF and GoF SNPs to identify a set of haplotype blocks. Using data from the ENCODE and RoadMap epigenomics projects, we looked for statistical enrichment for informative histone modifications in myeloid and lymphoid cell lines within these haplotype blocks.

Results: *Results* Each of the queried cell lines showed significant enrichment for specific histone marks within the haplotypes of interest. However, findings were most significant within CD4+ T cell subsets, and specifically for histone marks regulating chromatin accessibility. For example, H3K9me3 is a histone mark that is required to maintain chromatin in a condensed state and maintain the identity of terminally differentiated cells. Regions associated with predicted loss of function SNPs were highly enriched for H3K9me3 in CD3+ ($p=7.13E-81$), CD4+ ($p=7.11E-23$) and CD8+ T ($p=9.67E-37$) cell subsets. Predicted gain of function regions were enriched for H3K4me1 marks, an epigenetic signature of poised enhancer function.

Conclusion: We identified novel, predicted genetic risk loci for JIA and identified a strong enrichment for H3K9me3 in T cell subsets. This enrichment was much stronger for regions predicted to be loss of function compared to gain of function. We hypothesize that these genetic variants may alter H3K9me3 localization in JIA, altering the chromatin landscape and leading to the misregulation of transcription.

The Novel G58V Mutation in the TNFRSF1A Gene Identified in a Family with Tumor Necrosis Factor Receptor-Associated Periodic Syndrome (TRAPS) Decreases the Cell Surface Expression of TNFR1

Shoko Tsuji¹, Hidenori Matsuzaki², Tomoyuki Mukai¹, Akiko Nagasu¹, Hiroyasu Hirano¹, Masanori Iseki³, Takahiko Horiuchi⁴, Ryuta Nishikomori⁵ and Yoshitaka Morita¹, ¹Department of Rheumatology, Kawasaki Medical School, Kurashiki, Okayama, Japan, ²Department of Life Sciences, Faculty of Life and Environmental Sciences, Prefectural University of Hiroshima, Hiroshima, Japan, ³Department of Immunology and Molecular Genetics, Kawasaki Medical School, Kurashiki, Okayama, Japan, ⁴Department of Internal Medicine, Kyushu University Beppu Hospital, Beppu, Japan, ⁵Department of Pediatrics, Kyoto University Graduate School of Medicine, Kyoto, Japan

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Pediatric Rheumatology – Basic Science Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: TNF Receptor- Associated Periodic Syndrome (TRAPS) is one of the autoinflammatory diseases characterized by recurrent inflammatory episodes. TRAPS is caused by an autosomal dominant heterozygous mutation in *TNFRSF1A* gene, which encodes tumor necrosis factor receptor 1 (TNFR1). More than 100 heterozygous *TNFRSF1A* mutations have been reported. T50M and Cysteine mutations are recognized as TRAPS mutations, the patients with the mutations develop severe TRAPS phenotypes. On the other hand, R92Q and T61I mutations are known as low-penetrant mutations which cause milder TRAPS phenotypes. The molecular pathogenesis by which the mutant TNFR1 causes TRAPS phenotypes is not yet fully understood. Recently we have identified a novel mutation, G58V (p.G87V) in *TNFRSF1A*, in two individuals in a family with recurrent inflammatory episodes. T61I mutation was also identified in the family. In this study, we examined the effect of the novel G58V mutation on the mutant cells.

Methods: The possible pathogenicity of the G58V mutation was analyzed using the four online prediction tools (SIFT, Polyphen2, PROVEAN and PANTHER). Wild-type (WT) or mutated *TNFRSF1A* (G58V/T61I, G58V, T61I, T50M, R92Q) constructs were generated by cloning. The TNFR1 constructs were transfected into HEK-293 cells. Expression levels of the TNFR1 were examined by western blotting. To analyze cell surface and intracellular expression of TNFR1, we performed the flow cytometric analysis. NF- κ B activation levels at 24 hours after the transfection were measured by the dual-luciferase reporter assay.

Results: The novel G58V mutation was predicted to be a highly damaging amino acid substitution that could affect the function of TNFR1. Expression levels of the WT and mutated TNFR1 proteins are comparable in the whole cell lysates of HEK-293 cells. The cell surface expression of TNFR1 was decreased in the T50M, G58V and G58V/T61I TNFR1-transfected cells compared to WT TNFR1-transfected cells. In contrast, the R92Q and T61I mutation did not affect the expression pattern of TNFR1. NF- κ B promoter activities in the T50M or the G58V TNFR1-expressing cells were significantly decreased compared to those in WT TNFR1-expressing cells (T50M $21.5 \pm 3.6\%$; G58V $34.8 \pm 4.4\%$; G58V/T61I $56.7 \pm 23.9\%$ vs. WT). The R92Q and T61I mutation did not suppress the NF- κ B promoter activities.

Conclusion: The T50M mutation suppressed the cell surface expression of TNFR1 and spontaneous NF- κ B promoter activity in consistent with a previous report (Blood 2006;108:1320-1327). The newly identified G58V mutation exhibited the similar phenotypes to the pathogenic T50M mutation, suggesting that the G58V is one of the responsible mutations causing TRAPS.

Session Date: Tuesday, October 23, 2018

Session Title: Pediatric Rheumatology – Basic Science Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Juvenile-onset systemic lupus erythematosus (JSLE) is characterized by immune cell dysregulation, chronic inflammation and increased cardiovascular risk. JSLE patients have more aggressive disease, major organ involvement and increased standardised mortality ratios compared to adult-onset SLE patients. Our previous findings in adult-onset SLE link immune cell dysregulation with defects in plasma membrane lipids rafts; signalling platforms that facilitate immune cell signalling, activation and effector function. Here we investigate the inter-relationship between immune cell lipid rafts, lipids in the blood (transported by lipoproteins), immune cell function and disease features in JSLE patients.

Methods: Flow cytometry measured metabolic marker expression on 44 immune cell subsets from 39 healthy donors (HCs) and 35 age matched JSLE patients. Analysis of 220 metabolic biomarkers including lipoprotein composition was performed on matching serum. RNA sequencing (seq) and analysis was performed on sorted immune cell subsets from matching samples.

Results: Lipid raft expression on T- and B-cells correlated positively with disease activity ($p=0.0006$ and 0.0006), erythrocyte sedimentation rate ($p=0.026$ and $p=0.015$) and dsDNA titre ($p=0.04$ and 0.0001) and negatively with complement protein C3 ($p=0.002$ and 0.002) supporting the hypothesis that altered metabolism is associated with JSLE pathogenesis. High disease activity was associated with increased levels of pro-atherogenic circulating lipids (very low, intermediate and low density lipoproteins; VLDL, IDL and LDL respectively) and decreased anti-atherogenic circulating lipids (high density lipoproteins; HDL). Immune cell lipid rafts correlated positively with VLDL, IDL and LDL and negatively with HDL suggesting that lipoproteins alter the membrane of immune cells in JSLE. Unsupervised hierarchical clustering based on circulating lipoprotein levels stratified patients into three distinct groups, each characterised by a unique immunological, metabolic and clinical phenotype. Patients in Group 1 had markers associated with increased risk of cardiovascular disease including increased apolipoproteinB:A1 ratio ($p<0.0001$) as well as an increased expression of fats associated with pre-clinical atherosclerotic plaque in adult SLE patients. Receiver operating characteristic curve analysis identified a cut-point value for apolipoproteinB:A1 ratio allowing group identification with 83% sensitivity and 78% specificity, suggesting that this could be used as a predictor of increased cardiovascular risk. Finally, RNAseq analysis from isolated T- and B-cells showed significant differences in cholesterol and glycosphingolipid metabolism genes between the three groups highlighting potential therapeutic targets.

Conclusion: Differences in immune cell lipid metabolism in JSLE could contribute to disease pathogenesis and severity. Regulation of lipid metabolism may provide therapeutic benefit for JSLE patients by reducing both inflammation and atherosclerotic risk. Apolipoprotein measurements in JSLE can be used to pinpoint patients that would benefit from these therapies and/or diets that modify lipid metabolism.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Pediatric Rheumatology – Basic Science Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Macrophage activation syndrome (MAS), a severe complication of pediatric rheumatic disease, is currently classified among the secondary forms of HLH (sHLH). Primary HLH (pHLH) are caused by mutation of genes coding for proteins involved in cytotoxic functions. Mice carrying heterozygous mutations in more than 1 pHLH gene carry a higher risk to develop HLH following viral infection, suggesting that accumulation of partial genetic defects may be relevant in HLH.

Methods: Genes involved in pHLH in MAS in the context of different rheumatic diseases and in sHLH were analyzed, with next generation sequencing (NGS). A targeted resequencing was performed on all patients using a panel including the 7 principal HLH-related genes (*PRF1*, *UNC13d*, *STX11*, *STXBP2*, *Rab27a*, *XIAP*, *SH2D1A*) on MiSeq® and NextSeq550® platforms (Illumina, San Diego, CA); all variants identified were confirmed by Sanger. We took into account variants with an allelic frequency in the global population up to 5% in the dbSNP and Ensembl databases.

Results: We analysed 125 patients: 47 MAS, (40 developed this complication in the context of systemic Juvenile Idiopathic Arthritis (sJIA), and 7 in the context of different rheumatic diseases), 32 sHLH, 22 sJIA (without history of MAS) and 24 with different autoinflammatory diseases (AID). sJIA and AID patients were used as control groups. We identified at least 1 heterozygous variant in one of the pHLH-related genes in 41 patients with a detection rate of 52%, 45% of MAS and 62% of sHLH patients. More than one variant was identified in 37% patients from both groups, with 19% of both MAS and sHLH patients carrying polygenic variants. In control groups, 54% of sJIA and 33% of AID patients carry at least a variant in the analysed genes, while polygenic variants have been detected in 14% and 8% of control patients, respectively. The most involved genes in both MAS and sHLH groups were *PRF1* and *UNC13d*, while variants in *RAB27a* and *XIAP* have been found only in sHLH patients. The most frequent variants identified in both groups were A91V in *PRF1* gene and R928C in *UNC13d* gene. The A91V variant in *PRF1* gene was identified in 19% of both MAS and sHLH patients, while this variant was present, respectively, in only 5% of sJIA and 4% of AID patients. The R928C variant in *UNC13d* gene was identified in 32% of MAS and 18% of sHLH patients, and in the control group in 9% of sJIA and 17% of AID patients. Variants of *PRF1* and *UNC13d* genes were most frequently observed in patients with both MAS and sHLH, while *Rab27a* and *XIAP* variants were more frequent in sHLH. Considering the patients' clinical characteristics, relapse, CNS involvement, ICU admission and death, in sHLH we observed that three of the 6 patients (50%) carrying multiple variants had recurrent episodes of HLH and that two of them (33%) presented a severe disease with exitus.

Conclusion: Monoallelic variants in pHLH-related genes are more frequent in MAS, sHLH and sJIA and less in AID patients, suggesting different molecular mechanisms involved in the diseases. Re-occurrence and severity of disease seem to be more frequent and more severe in patients who carry mutations in two genes in sHLH group. These data may support a polygenic model of sHLH.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Pediatric Rheumatology – Basic Science Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Myositis specific autoantibodies (MSA) and myositis associated autoantibodies (MAA) found in adult and juvenile idiopathic inflammatory myopathies (JIIM) often confer a specific disease phenotype. In adults, the MAA anti-Ro52 is associated with anti-synthetase (ARS) autoantibodies (Abs) and more severe interstitial lung disease

(ILD). However, there are few studies examining the presence or significance of anti-Ro52 Abs in juvenile myositis. The purpose of this study was to define the prevalence and clinical features of anti-Ro52 Abs in a large cohort of patients with JIIM.

Methods: We screened sera from 307 patients with juvenile dermatomyositis (JDM), 26 patients with juvenile polymyositis (JPM), and 44 patients with juvenile connective tissue disease-myositis overlap (JCTM) for anti-Ro52 Abs by ELISA (INOVA, San Diego, CA). Clinical characteristics were compared between myositis patients with and without anti-Ro52 Abs.

Results: Anti-Ro52 Abs were found in 14% of JDM, 12% of JPM, and 18% of JCTM patients. Anti-Ro52 Abs co-existed in 64% of those with ARS ($p<0.001$) and in 31% of those with anti-MDA5 Abs ($p<0.008$). Less than 15% of those with anti-p155/140, -NXP2, -SRP, or -Mi2 Abs and less than 5% of those without an MSA were anti-Ro52+. After controlling for the presence of MSAs in multivariable analysis (including ARS and anti-MDA5), anti-Ro52 Abs were highly associated with ILD (36% vs 4%, $p<0.001$), dyspnea on exertion (59% vs 25% $p<0.001$), and a higher pulmonary score at diagnosis (0.18 vs 0.08 $p=0.004$). Even within the anti-MDA5+ subgroup, Ro52 reactivity was strongly correlated with ILD; 70% (7/10) of those with co-existing anti-Ro52 Abs had ILD compared to 9% (2/22) of those who were Ro52-. Similarly, among ARS+ patients, 100% (9/9) of anti-Ro52+ and only 40% (2/5) of anti-Ro52- patients had ILD. Disease course in anti-Ro52+ patients was more often chronic continuous (78% vs 52% $p=0.05$) and less often monocyclic (3% vs 24% $p=0.02$). Anti-Ro52+ patients were more often ACR functional class 4 (11% vs 4% $p=0.008$) and had a higher mean ACR functional class score at final evaluation (1.7 vs 1.4 $p=0.007$). Anti-Ro52 Abs were associated with an increased total number of medications received (4.8 vs 3.8 $p=0.04$) and anti-Ro52+ patients more often received intravenous pulse steroids (79% vs 52% $p=0.03$). Anti-Ro52+ patients less frequently had a documented remission (5% vs. 27% $p=0.05$). There were no significant differences in the prevalence of HLA DRB1 and DQA1 alleles between Caucasian juvenile myositis patients with and without anti-Ro52 Abs.

Conclusion: Anti-Ro52 Abs are most prevalent in juvenile myositis patients with anti-MDA5 and ARS Abs. Even after adjusting for the presence of MSAs, including anti-MDA5 and anti-ARS Abs, anti-Ro52+ patients were more likely to have ILD and other pulmonary manifestations. Furthermore, anti-Ro52+ patients have more severe disease requiring more intense treatment, less frequent remission, worse functional outcomes, and a frequent chronic disease course. The presence of anti-Ro52 Abs in JIIM may be a significant determinant of disease severity and prognosis, thereby warranting screening JIIM patients for anti-Ro52 Abs.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Pediatric Rheumatology – Basic Science Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: *CXCR4* is a recently identified susceptibility locus for juvenile idiopathic arthritis (JIA). The index single nucleotide polymorphism (SNP) used to identify this locus, rs95338, lies in an intergenic region upstream of the *CXCR4* gene, suggesting that this region has regulatory functions. We sought to gain biological insight into the association between JIA and the *CXCR4* locus by examining the chromatin architecture within this locus, including the presence of epigenetically-marked regulatory elements, in relevant primary cells and cell lines.

Methods: Using the SNP Annotation and Proxy Search from the Broad Institute and standard computational methods, we first defined the linkage disequilibrium (LD) block containing the rs953387 SNP. We used BedTools to query ENCODE and Roadmap Epigenomics data to identify relevant functional epigenetic marks (e.g., H3K4me1/H3K27ac, and CTCF

binding motifs) within the *CXCR4* haplotype. For statistical analysis, each value was compared to the mean and standard deviation of 100 randomly generated files with the same number of peaks as the ENCODE file being examined. In addition, we used quantitative rtPCR analysis to confirm the presence of a non-coding, intergenic RNA transcript that we identified on RNAseq in neutrophils and assess the effects of treatment on expression of this transcript.

Results: The LD block for the rs953387 SNP comprises a genomic region of between 54,236 (r-squared of 0.9) and 69,609 bp (r-squared of 0.8) upstream from the coding region of the *CXCR4* gene. This region contains 154 JIA associated SNPs that we recently identified using whole genome sequencing, in addition to >30 variants catalogued in 1000 Genome Project. Further analysis using ENCODE and Roadmap Epigenomics data demonstrate that the LD block ($r^2 = 0.8$) includes enrichment for H3K4me1 (poised enhancer) peaks compared to randomly generated peaks from hg19 genome in primary CD4+ T-cell lines and primary CD 15+ (neutrophil) cell lines, with the LD containing 12 and 15 peaks respectively. There are 6 H3K27ac (active enhancer) peaks in the LD block from primary CD4+ cell data, which is statistically higher than the random value. CHIPSeq data from neutrophils from our own lab shows multiple H3K4me1 and H3K27ac peaks in this LD block in addition to a noncoding (intergenic) RNA. The non-coding RNA was verified using rtPCR and showed changes in expression levels when neutrophils from children with active JIA were compared to those in clinical remission on medication. Further analysis identified H3K4me1, but not H3K27ac, enrichment in CD14+ monocytes and CD20+ B cells as well as other T- lymphocyte cell lines.

Conclusion: The LD blocking containing the rs953387 SNP lies upstream of the *CXCR4* gene itself and is likely a regulatory region. This region contains enhancer elements in multiple immune cell lines, especially in CD4+ primary T-cells and CD15+ neutrophils as well as an intergenic non-coding RNA. The regulatory function of this region may or may not relate to the *CXCR4* gene itself, as enhancers do not always regulate the nearest gene. These findings corroborate our earlier studies demonstrating that the genetics of JIA impinges almost exclusively on gene regulatory functions.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Pediatric Rheumatology – Basic Science Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Oral microbial dysbiosis of specific organisms such as *Porphyromonas*, *Aggregatibacter*, *Tannerella*, and *Treponema* in dental plaque has been implicated in the pathogenesis of adult rheumatoid arthritis (RA) and periodontitis, while *Neisseria* may play a protective role. Whether oral dysbiosis is also associated with juvenile idiopathic arthritis (JIA) is less clear, as periodontal disease-related organisms are rare in children. Comparing the microbiomes from JIA patients with those of their mothers provide another avenue to explore the role of dysbiosis in arthritis, because healthy children derive much of their microbiome from their mothers. We previously demonstrated increased gingivitis in treated JIA patients compared to healthy children. For this current study, we hypothesized that oral microbial dysbiosis was associated with systemic inflammation, and children with JIA have an altered oral microbiome compared to their mothers. By examining only new-onset JIA patients, the confounding effects of previous treatment should be eliminated.

Methods: Saliva was collected from 14 new-onset, treatment-naïve JIA patients of all JIA subtypes, aged 3-15 years, and their mothers. Subjects who received antibiotics within the previous 3 months were excluded. V3/V4 16S rRNA sequencing was performed on the Illumina MiSeq platform. Sequences were paired and merged using BBMerge. Merged reads were trimmed to remove bases with a Q value <20, and filtered to retain only sequences greater than 400 bp and no more than 1N. Processed reads were classified by comparison to the Human Oral Microbiome 16S Database V15.1. Relative frequencies as percentages of bacterial genera and species were calculated in individual patients and compared to frequencies found in each patient's mother. Paired T-tests and signed rank Wilcoxon tests were performed on all species between probands and mothers; significance level was set at $p = 0.05$.

Results: We assessed all species detected in either probands or mothers. There were no significant differences in the relative frequencies of *Prevotella*, *Neisseria*, *Leptotrichia*, *Fusobacterium*, or *Porphyromonas* species between probands and mothers. *Tannerella forsythia* and *Treponema* species were detected at low relative frequencies in all subjects. *Aggregatibacter actinomycetemcomitans* was not detected in our cohort. With paired T-tests, three species were detected at low frequencies in mothers but not in any probands: *Bacteroidetes* HMT 511, *Veillonellaceae* HMT 155, and *Selenomonas* HMT 134. These species were identified by sequencing only; their functional nature have not been explored. Microbial diversity calculated using Shannon Diversity Index was similar in probands and mothers.

Conclusion: In an inception cohort of new-onset JIA patients, organisms implicated in the pathogenesis of adult RA were not detected at higher frequencies in probands or in their mothers. This is the first study to examine the oral microbiome of untreated JIA patients. Further work to compare the oral microbiota of JIA families against aged-matched healthy family members may elucidate patterns that predispose children to JIA.

Session Title: Pediatric Rheumatology – Basic Science Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: We have previously identified two CD4 pathogenic circulatory subsets in both T effector (CPLs) and T regulatory (iaTreg) compartments that are both HLA-DR⁺, antigen experienced, pro-inflammatory, correlating with disease activity and sharing strong TCR sequence oligoclonality with synovial T cells from JIA patients. Despite being two functionally distinct T cell subsets, their phenotype and association with clinical fate suggests that these functionally discordant subsets may originate from a common precursor. To elucidate the common pathogenic gene drivers and their associated network of pathways within these two pathogenic subsets, we decided to perform next generation RNA sequencing on sorted CPLs and iaTregs and their conventional Teff/Treg counterparts in both the circulation and the synovial micro-environment.

Methods: CPLs were sorted as CD3⁺ CD4⁺ CD14⁻ HLADR⁺ CD25/CD127 Teff gate, and iaTregs were sorted as CD3⁺ CD4⁺ CD14⁻ HLADR⁺ CD25^{hi}/CD127^{low} Treg gate with FACs Aria II from n=16 active JIA PBMCs, n=8 paired JIA SFMCs, and n=8 healthy paediatric PBMCs. As a comparative control, similar HLADR⁻ counterparts were respectively sorted from the same patients. Sorted cells were lysed and extracted for RNA, and cDNA conversion/amplification were then carried out using SMART-seq v4. Libraries are prepared and multiplexed using Nextera XT DNA library preparation kit, and ran on the Illumina HiSeq High output platform.

Results: Comparative differential gene expression (DEG) reveal strong transcriptomic convergence between CPLs and iaTregs as compared with the common pool of Teff and Treg. Phylogenetic analysis indicate the convergence has uncoupled the CPLs or the iaTregs away from their respective original compartments (Teff or Treg) into a common branch point. Restriction in TCR sequence oligoclonality in CPLs/iaTregs versus that of the common Teff/Treg pool reinforce the possibility of a common selection pressure. Pathway enrichment analysis reveal similar dysregulated pathways (IFN-g, PD1, CD28 costimulation) within T cell signalling for both CPLs and iaTregs. Furthermore, Weighted gene correlation network analysis (WGCNA) identified strongly coordinated HLA-DR gene network module and suggests its potential role as the driver of pathogenic T cell subsets away from conventional subsets. Gene set enrichment analysis (GSEA) suggest that HLA-DR module genes are involved in TNFA signalling, inflammatory response, complement, and apoptosis. Global transcription factors gene regulatory network (TF-GRN) analysis identified several key regulatory molecules (FOXP3,

CEBP, SPI and E2F1) driving the convergence of pathogenic CPLs and iaTreg populations. Taken together, we have shown that reveal several layers of mechanism operate to drive the convergence of CPLs and iaTregs, suggesting the possibility of common disease drivers in active JIA patients.

Conclusion: Overall the transcriptomic data indicate strong similarity in both pathogenic populations and underscore a potential mechanistic role of the inflammatory microenvironment in shaping two functionally dichotomic populations.

Session Title: Pediatric Rheumatology – Basic Science Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

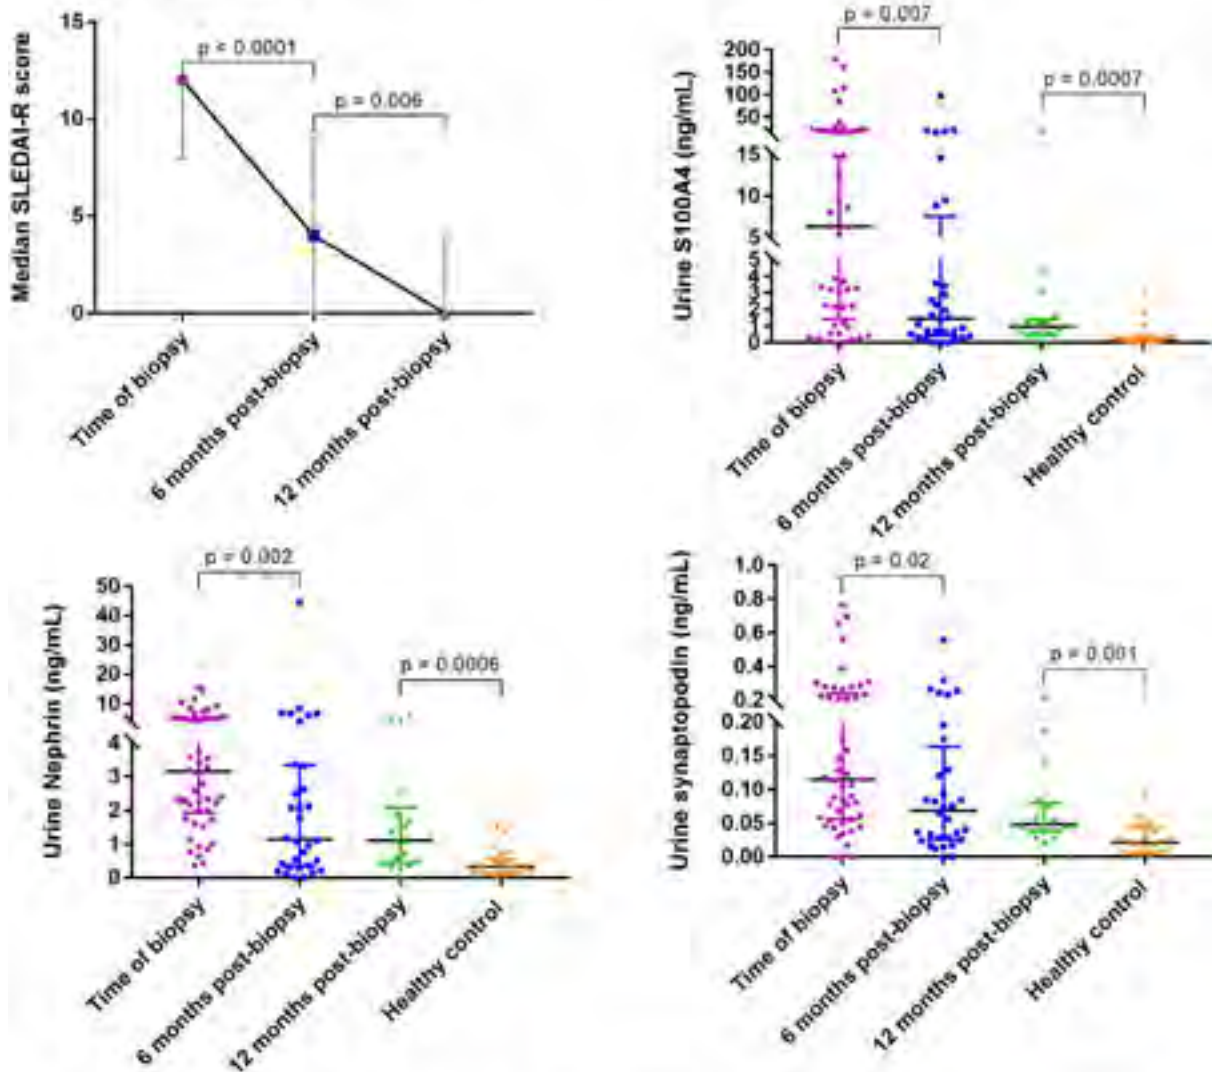

Background/Purpose: We lack accurate clinical tools to identify the degree of active renal inflammation in childhood-onset SLE (cSLE). In this study, we investigated urine S100A4 and podocyte proteins as biomarkers of lupus nephritis (LN) activity with two primary objectives, (1) assessability of candidate urine biomarkers to reflect the NIH activity index (NIH-AI) on renal biopsy and (2) determine whether changes in candidate urine biomarkers correlate with renal clinical disease activity.

Methods: We selected LN patients from an ongoing cSLE registry at Cincinnati Children's Hospital with urine available near time of biopsy and at either six and/or 12-months post-biopsy. Urine levels of S100A4, nephrin and synaptopodin were measured using commercial ELISAs. All patients met ACR classification criteria for SLE. Clinical and laboratory data were collected for patients at each time point. Spearman correlations were performed to assess the relationship between individual biomarkers and both NIH-AI and the renal domain of the SLEDAI (SLEDAI-R). We used the Mann-Whitney U test and Wilcoxon signed-rank test to determine differences in biomarker values at each timepoint.

Results: There were 52, 32 and 18 patients with urine at renal biopsy, six-months and 12-months post-biopsy, respectively. Median urine S100A4, nephrin and synaptopodin levels in the entire cohort decreased from biopsy to six-months post-biopsy (Figure 1), but only urine S100A4 showed a significant decrease within individual patients between biopsy and six-months (median difference: -1.85 ng/mL, $p = 0.01$). There was no significant correlation between NIH-AI and any biomarker when evaluating the entire cohort together at biopsy. Upon stratifying patients by those with urine collected on biopsy day, synaptopodin showed a moderate correlation with NIH-AI ($r_s = 0.47$, $p = 0.027$). Patients with class III/IV LN also had moderate correlation of nephrin with NIH-AI ($r_s = 0.37$, $p = 0.04$). At six-months post-biopsy, there was a moderate correlation between all urine biomarkers and SLEDAI-R, $r_s = 0.48$ ($p = 0.007$) for S100A4, $r_s = 0.53$ ($p = 0.003$) for nephrin and $r_s = 0.47$ ($p = 0.01$) for synaptopodin. Interestingly, the difference in S100A4 and SLEDAI-R levels between 12-months post-biopsy and biopsy showed moderate correlation ($r_s = 0.48$, $p = 0.045$). Patients who had a complete clinical response by six or 12-months, as defined by a SLEDAI-R of zero, had lower S100A4 levels at follow-up than those with an incomplete clinical response ($p = 0.0006$).

Conclusion: While urine synaptopodin and nephrin levels appear to be better indicators of the NIH-AI on renal biopsy, S100A4 or change in S100A4 seems promising as a biomarker of individual clinical response to therapy post-biopsy. It remains to be determined if elevated levels of these biomarkers at follow-up indicate persistent histologic disease activity or poor histologic response to therapy.

Novel Serum Biomarkers Monitor Disease Progression and Response to Change in Corticosteroid Therapy in Children with Juvenile Dermatomyositis

Background/Purpose: Juvenile Dermatomyositis (JDM) is a complex autoimmune disease with varying responses to therapy. Serum protein biomarkers could monitor therapy and test new drugs. The purpose of this pilot study was to identify corticosteroid-responsive serum biomarkers and determine their correlation with differing Myositis Specific Antibodies (MSA) in JDM.

Methods: The CureJM Juvenile Myositis Registry was searched for children diagnosed with definite/probable JDM who had MSA (by immunoprecipitation), and who also had sera available at three time points: 1) before start of treatment, 2) on therapy based on corticosteroids, and 3) when less clinically active and off corticosteroid therapy. Serum samples from JDM patients meeting these criteria (n=8, mean age = 6.8 ± 2.7 years) were tested for 1,300 proteins (SOMAscan proteomics). Data were benchmarked against data from 12 healthy control children, age 6-10, mean age 8.5 ± 1.7 years. To reduce heteroscedasticity the data was log transformed before statistical analysis. A two sample t test with adjustment for multiple testing was performed to compare protein levels between JDM and controls. Statistical analysis was performed with the R language for statistical computing v3.4.2.

Results: In untreated JDM, preliminary data analysis identified 44 elevated proteins and 79 proteins that were decreased compared to controls—adjusted p value of <0.001 . The elevated proteins were primarily immunologic mediators (chemokines, interleukins), confirming previous studies, and included vascular associated proteins such as angiopoietin 2 (novel biomarker), which induces apoptosis of endothelial cells and vascular regression and is an indicator of atherosclerosis. While on prednisone, levels of proteins such as angiopoietin 2, IP10 and myostatin decreased as did levels of CXCL-11, which is regulated by Interferon-beta, a major pro-inflammatory component of JDM. When prednisone was decreased, some of these biomarkers returned to their original levels, prior the treatment, while others stayed low, depending on the MSA of the child. Figure 1 below displays examples of changes in the level of 2 serum biomarkers with therapy.

Conclusion: Specific serum proteins are candidates for consideration as potential biomarkers to monitor response to therapies in children with JDM. Limitations of this pilot study include the low numbers of subjects, which will require validation in additional cohorts.

Figure 1. Two novel JDM serum biomarkers and their longitudinal trajectory with therapy in JDM by MSA. Serum levels of both proteins changed after therapy started and tended to rebound after therapy decreased. The child with MJ and possible U5RNP is the exception; angiopoietin-2 and IL-22 did not return to their original levels after therapy was stopped.

Session Title: Pediatric Rheumatology – Basic Science Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: IL-17 and IL-22 are important cytokines in pathogenesis of spondyloarthropathy. In an IL-23 or IL-22 over-expressing mouse model it was shown that enthesitis is dependent on IL-22. IL-22 is mainly produced by T cells and innate cells. In enthesitis related arthritis (ERA) category of Juvenile arthritis enthesitis is an important clinical feature. As there is no data available on IL-22 in ERA we studied if IL-22 has any role to play in ERA and does it correlate with enthesitis by measuring the frequency of IL-22 producing T cells in blood and synovial fluid.

Methods: Forty patients with JIA-ERA as per ILAR criteria for the diagnosis of JIA were included in the study. Heparinized blood (PB) sample was collected from all cases after consent. While synovial fluid (SF) was collected from only those patients who required therapeutic joint aspiration. The disease activity was assessed by Juvenile spondyloarthropathy disease activity score (JSpADA) and enthesitis score by MASES index. Childhood Health activity score (CHAQ) was done to assess disability. Seven healthy subjects and 8 polyarticular JIA patients were included as control. The disease activity was classified as high if JSpADA score was more than 2.5.

Th1, Th17 and Th22 cell frequency in blood and synovial fluid was measured after stimulating the cells with PMA and Ionomycin for 6 hours and adding secretion inhibitor Brefeldin A 10mg/ml to prevent secretion of cytokines. Later cells were surface stained with anti-human CD3/CD4 antibody for 30 minutes. The cells were fixed and permeabilised with cytofix/cytoperm kit for 20 minutes and then stained with intracellular cytokine PE labeled anti human PerCP-IL22 for 45 minutes. The sample was acquired using FACS Canto II and analyzed using flow Jo software. All analysis was done using non-parametric tests. All frequencies are referred as median(interquartile range).

Results: There were 42 children with ERA of which 35 were male. The mean age for ERA, Polyarticular JIA and healthy controls was 15.45±2.83, 13.62±4.63 and 18 yrs respectively. Thirty-four patients (80%) had arthritis, 28 (66%) had enthesitis and 5 (12%) had uveitis. Mean JSpADA score was 3.85± 1.63.

The frequency of Th1, Th17 and Th22 cells in peripheral blood was similar between patients with ERA, Poly JIA and healthy controls.

In 10 paired samples (PB and SF) the median frequency of Th1 cells were higher in SF (9.3[4.3-19.1] as compared to peripheral blood (2.8 [2.2-3.42]; p<0.02) but the frequency of Th17 (0.4[0.2-1.1] Vs 0.2[0.2-0.325]) and Th22 (0.35[0.2-1.3] Vs 0.25 [0.2- 0.4]) though higher did not reach statistical significance.

The frequency of Th22 cells in PB was higher in children with high disease activity (0.2 [0.1-0.2]) as compared to children with minimally active/inactive disease (0.2[0.1-0.3] p<0.05). However, Th22 cell frequency had no correlation with disability as measured by CHAQ score or presence of enthesitis.

Conclusion: Th22 cells may contribute to inflammation in children with ERA however they do not have any association with enthesitis.

Session Title: Pediatric Rheumatology – Basic Science Poster

Session Type: ACR Poster Session C

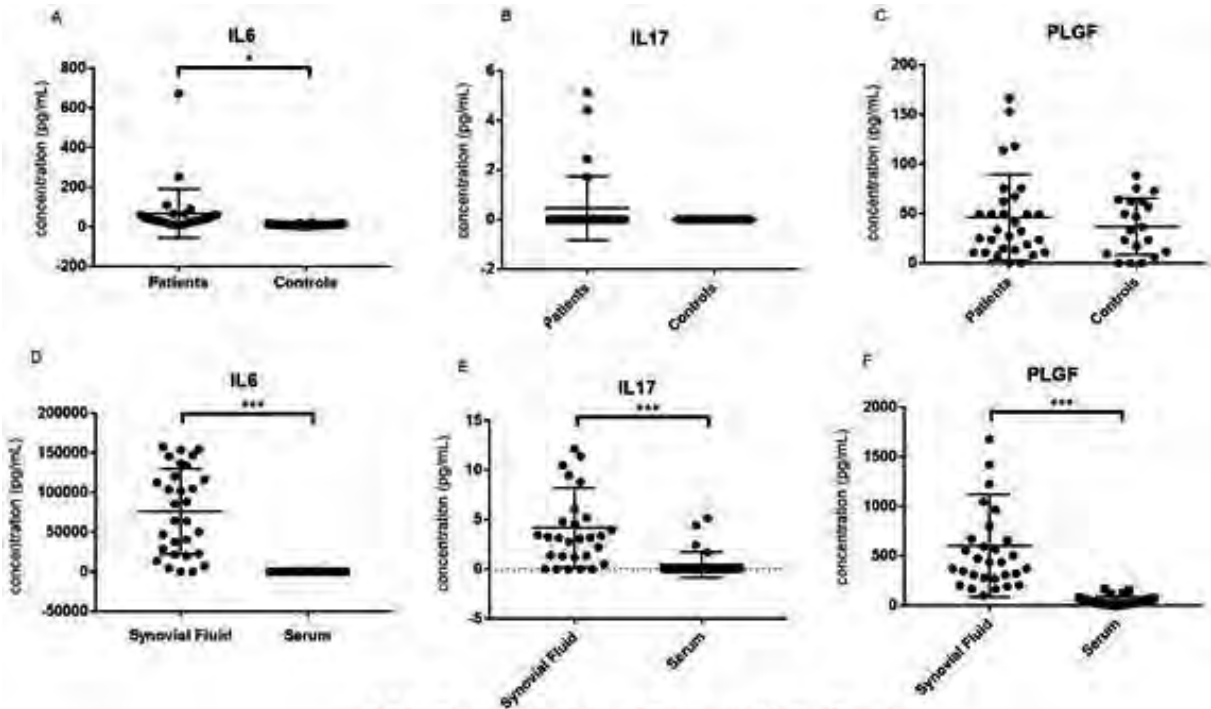

Session Time: 9:00AM-11:00AM

Background/Purpose: F759 mice with single amino-acid substitution in IL-6 receptor gp130 (Y759F) develops features of autoimmune disorders like arthritis, multiple sclerosis due to IL-17A and IL-6 mediated synergistic activation of positive-feedback loop of STAT3 and NF- κ B signaling (inflammation amplifier) in non-immune cells like fibroblasts¹. IL17A activates epiregulin/ErbB1 axis, which in turn triggers activation of multiple growth factors like Placental Growth Factor (PLGF), amphiregulin. These growth factors contribute to this amplification loop in Rheumatoid Arthritis patients² and blocking them abrogates inflammation in animal models³. In this study, we explored the possibility whether this inflammation amplifier loop is playing a role in synovitis of Juvenile Idiopathic Arthritis Enthesitis Related Arthritis (JIA-ERA) by estimating PLGF in sera and synovial fluid(SF) of patients.

Methods: Sera and Synovial Fluid(SF) of 30 adolescents of JIA-ERA, diagnosed as per ILAR classification, with effusion undergoing therapeutic aspiration were collected and stored between October 2016-April 2018. Disease activity were measured. Levels of IL6, IL17A and PLGF were measured by ELISA. IL6, IL17A and PLGF Kits were procured from BD Biosciences (IL6) and BioLegend Inc.(IL17A and PLGF), San Diego, CA. Sensitivity of the assays were 4.7 picogram(pg)/millilitres(mL), 2 pg/mL and 6.3 pg/mL respectively.

	Healthy Controls	Patients	
	Serum	Serum	Synovial Fluid
N	20	30	
Age (years)*	17.55 \pm 0.58	16.41 \pm 3.35

Duration of Disease (years)*	—	4.31 \pm 1.11	
BASDAI**	—	3.11 \pm 1.96	
ASDAS-CRP**	—	2.96 \pm 0.82	
ESpADA**	—	4.11 \pm 1.36	
CHAQ**	—	1.27 \pm 0.44	
IL6* (pg/mL)*	33.23 \pm 4.56	67.31 \pm 122.72	76167 \pm 53294
IL17A* (pg/mL)*	0.00	0.46 \pm 1.29	4.18 \pm 4.02
PLGF* (pg/mL)*	17.02 \pm 28.48	46.11 \pm 43.18	602.8 \pm 517.61

*BASDAI-CRP, Ankylosing Spondylitis Disease Activity Score using C-Reactive Protein (CRP); BASDAI, Bath Ankylosing Spondylitis Disease Activity Index; CHAQ, Child's Health Activity Questionnaire; ESpADA, Swollen Joint Count/Number of Joints Swollen; IL6, Interleukin 6; IL17A, Interleukin 17A; PLGF, Placental Growth Factor; pg/mL, Picogram/Milliliter
**Rased & Unrased (Rheumatoid)

A,B,C : Comparison of Serum of Patients and Healthy Controls
D, E, F : Comparison of Serum and Synovial Fluid of Patients

Results: The mean age of patients and controls were 16.41 ± 3.35 years and 17.65 ± 0.58 years respectively ($p = 0.11$). Mean duration of disease was 4.31 years. Two third of the patients were on NSAIDS and few were on Disease Modifying Drugs. JSpADA and ASDAS CRP of the patients were 4.11 ± 1.36 , 2.96 ± 0.82 suggesting active disease with moderate disease activity. IL6, IL17A and PLGF were significantly higher in SF as compared to serum ($p < 0.0001$ for each). However, only IL6 was significantly higher in serum of patients as compared to healthy controls (IL6, $p < 0.001$; IL17A, $p = 0.092$; PLGF, $p = 0.655$). Serum IL6 correlates with SF PLGF ($r = 0.460$, $p = 0.01$) and Serum IL17A ($r = 0.443$, $p = 0.01$). However, no correlation of ILs/Growth Factors in SF with disease activity scores were found.

Conclusion: The increased SF levels of IL6, IL17A and PLGF suggest activation of IL6 and IL17A mediated amplification loop in synovial compartment of patients with JIA-ERA. Further study of other growth factors like epiregulin, amphiregulin, norepinephrine is warranted.

Session Title: Pediatric Rheumatology – Basic Science Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Many infants and children with early-onset autoinflammatory diseases are mutation-negative for genetically known autoinflammatory diseases. Recent data suggest a role for Type-I interferon dysregulation in causing autoinflammatory disease phenotypes with clinical features that are distinct from those found in patients with IL-1 mediated autoinflammatory diseases. We assessed an IFN-response-gene signature (IRS), characterized the clinical phenotypes, IFN-related biomarkers and genetic causes.

Methods: We assessed IFN-response gene signatures (IRS) from 63 consecutively evaluated patients who were negative for known autoinflammatory disease-causing mutations. Whole blood gene expression of 28 selected interferon response genes (IRG) was determined by Nanostring and an IFN-score was calculated. Serum levels of 48 cytokines were measured by a multiplex immunoassay. Patients underwent clinical assessments and genetic analyses were performed by whole exome/genome sequencing (WES/WGS).

Results: Of 63 patients tested, 36 had elevated IFN-signatures. Patients with high IRS had higher frequencies of panniculitis (58 vs 0%, $p < 0.0001$), basal ganglia calcifications (45 vs 0%, $p = 0.0043$), interstitial lung disease (ILD) (48 vs 4.8%, $p = 0.0013$), myositis (65 vs 15%, $p = 0.0005$), skin vasculitis (29 vs 7.4%, $p = 0.05$), arterial hypertension (32 vs 3.7%, $p = 0.011$) and liver disease (73 vs 22%, $p = 0.0002$), than patients without an IRS. Of 8 distinct clinical patterns, one group with pulmonary alveolar proteinosis (PAP) and macrophage activation syndrome (MAS) had high IL-18 serum levels. Other groups included 2 patients with novel *LRBA* mutations, 3 patients with a novel *NEMO* splice site mutation, 5 with *de novo* truncating *SAMD9L* mutations, 2 with myositis and anti-MDA5 autoantibodies, 7 with CANDLE-like panniculitis of which 1 had a known *PSMB8* mutations and 2 had novel proteasome mutations in *PSMB8* and in *PSMG2*, respectively. Patients with PAP and MAS, *LRBA*, *NEMO*, *SAMD9L* mutations had overall lower IFN scores and significantly lower USP18 but higher SOCS1 transcript levels compared to CANDLE and SAVI, both negative regulators of IFN signaling.

SOCS1 transcription is regulated through the NF- κ B signaling pathway and SOCS1 expression dysregulation may point to a different origin of the IFN response gene signature compared to CANDLER and SAVI patients. Interestingly, many of these patients with high SOCS1 and lower USP18 levels responded to TNF inhibition. Additionally, patients with high IRS had significantly higher serum levels of IP-10, MIG, MIP1 α , MIP1 β , SCF and GRO α than those with negative IFN scores.

Conclusion: The assessment of patients with IFN signatures revealed distinct clinical pathogenically defined disease subsets. In 3 subgroups of patients, novel monogenic disease-causing mutations were detected. The contribution of SOCS1 and USP18 may assist in delineating different intracellular pathways that lead to the activation of the IFN response gene signature.

Session Date: Tuesday, October 23, 2018

Session Title: Pediatric Rheumatology – Basic Science Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Down syndrome (DS) is a common chromosomal disorder associated with a range of medical & immune abnormalities e.g. increased susceptibility to infections & a high incidence of autoimmune diseases, including Down's Arthritis (DA). Previous work by our group suggests that the prevalence of DA is 18-21 fold greater than JIA, much higher than the previously reported DA prevalence of 8.7/1000. Children with DA most often follow a polyarticular course of disease, with erosive joint damage observed more frequently in this cohort when compared to a cohort of children with JIA. Small joint involvement is frequently observed, again in a significantly greater proportion ($p < 0.01$) of children with DA than expected in a typical JIA cohort. These characteristics suggest that DA may be distinct from JIA, however little is known about the differences in synovial pathology or immunological regulation. Indeed no studies to date have examined immunology and synovial pathology in DA. The objectives of this study were to examine B & T-cell subsets, & cytokine profiles in children with DA & JIA; & to characterise & compare the synovial membrane immunohistochemistry.

Methods: Multicolour flow cytometry was used to analyse the phenotype of B & T cells in PBMCs from 40 children (Healthy Control (HC), JIA, DS, DA). Cells were stained with the following panels; Panel 1 B cells (CD38, CD24, CD20, CD80, CD27, IgM, CD138, CD45, CD19, MHCclassII, BCMA, CD40, CD86, IgD); Panel 2 T cell cytokines analysed after 5 hours PMA/Ionomycin stimulation (CD3, CD8, CD161, IFN- γ , TNF- α , IL-17a, GM-CSF). Flow cytometry data was assessed by FlowJo software analysis.

Synovial tissue was obtained through US guided biopsy & analysed by immunohistochemistry for CD3, CD20, CD68, FVIII (DA n=3; JIA n=6). Synovial Inflammation & lining layer thickness were also scored. Analysis was performed using a semi-quantification scoring method.

Results: Flow cytometry was performed on PBMC samples from 4 distinct groups (n=10 per group); HC (50%F, age 9.2y (2.5-15.6)), JIA (91%F, age 13.2y (8.2-16.1)), DS (45%F, age 6.5y (1-11.9)) & DA (60%F, age 11.4y (3.8-17.8)). All of the children in the DA & JIA cohorts had a polyarticular RF negative pattern of disease.

Analysis revealed that children with DA have a significantly lower number of circulating CD19+CD20+ B cells when compared to children with JIA ($p < 0.05$) & HC ($p < 0.001$). However, children with DA have a greater proportion of memory B cells (CD27+) when compared to children with DS & no arthritis ($p < 0.05$).

IFN- γ & TNF- α production by CD8+/CD8- T cells was greater in DA compared to both JIA (CD8+IFN γ + p<0.001; CD8+TNF α + p<0.01; CD8-IFN γ + p<0.05; CD8-TNF α p<0.05) & HC (CD8+IFN γ + p<0.05; CD8+TNF α + p<0.05; CD8-IFN γ + p<0.05; CD8-TNF α p<0.01).

Examination of synovial tissue demonstrated higher levels of CD3+ cells (p<0.05), Macrophages (p<0.05), CD20+ cells & FVIII in the joints of children with DA.

Conclusion: There are significant differences in B cell populations, cytokine production & immunohistochemical features of synovial tissue in children with DA & JIA. More work is required to verify these results. Preliminary findings may begin to help explain the differences observed in the clinical picture of children with DA & JIA.

Session Date: Tuesday, October 23, 2018

Session Title: Pediatric Rheumatology – Basic Science Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Fibroblast-like synoviocytes (FLS) may play a role in the pathogenesis of Juvenile idiopathic arthritis (JIA) and have chondrogenic potential. Bone morphogenetic proteins (BMP) are necessary for chondrogenesis. We have previously shown increased levels of BMP4 in JIA FLS. Highly conserved antagonists of BMPs regulate signaling in both FLS and chondrocytes (Ch) by binding to BMP ligands but little is known about how these antagonists interact in JIA FLS. To examine regulation of BMP signaling in Ch and FLS, we studied gene expression levels of BMP antagonists gremlin (GREM), chordin (CHRD), noggin (NOG), and follistatin (FST), as well as the expression of these antagonists in Ch cultured in FLS conditioned media.

Methods: RNA was collected from three Ch, CFLS, and JFLS cell lines cultured in their respective media at 6, 12, and 24 hours. Concurrently, RNA was collected from three Ch cell lines cultured in conditioned media from CFLS or JFLS (Ch-CFLS and Ch-JFLS) at the same timepoints. Clariom S microarrays were performed on these samples and log ratios calculated using linear expression values for genes of interest.

Results: In examining the expression levels of BMP antagonists in untreated cells, FST and a follistatin-like antagonist (FSTL5), inhibitors of BMP2, BMP4, and BMP7, are downregulated in CFLS and JFLS respectively compared to Ch. When studying the influence of FLS conditioned media on Ch, FSTL3 was significantly upregulated in Ch-CFLS compared to untreated Ch and Ch-JFLS compared to Ch-CFLS. GREM, a potent inhibitor of BMP2 and BMP4 was significantly upregulated in Ch-CFLS and Ch-JFLS when compared to untreated Ch while CHRD, also an inhibitor of BMP2 and BMP4, was significantly downregulated in Ch-JFLS compared Ch-CFLS.

Conclusion: Our results suggest that untreated Ch favor FST and family members as possible BMP signaling regulators but when cultured in FLS conditioned media, GREM, but not FST or CHRD, is upregulated in both Ch-CFLS and Ch-JFLS. FLS can influence chondrocytes by causing a change in the antagonist the cells use to regulate BMP signaling. Specifically, JFLS can influence Ch to downregulate CHRD and FSTL5 expression compared to Ch-CFLS. Perhaps JFLS, who have higher levels of BMP4 than CFLS, favor a more potent inhibitor like GREM, which is expressed more during late-stage chondrogenesis as opposed to FST, which is favored during earlier chondrogenesis (1).

Session Title: Pediatric Rheumatology – Basic Science Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Neutrophils are key immune cells participating in host defense through several mechanisms, including the formation of neutrophil extracellular traps (NETs). Although beneficial from a host-pathogen perspective, exaggerated NET formation has been linked to inflammation and autoimmunity, including lupus and adult dermatomyositis (DM). However, NETs have not been described in juvenile DM or pediatric overlap syndromes, such as RNP+ myositis. One debilitating manifestation of chronic JDM is calcinosis, the formation of calcium deposits/crystals in soft tissue. Though other crystals, including cholesterol and monosodium urate crystals are known activators of neutrophils, the role of calcium deposits/crystals in neutrophil activation and subsequent cell death is not known. In the current study, we aim to investigate if calcium crystals could mediate NETosis *in vitro*, and to determine the clinical relevance of calcium crystal-mediated NETosis in children with Juvenile Myositis.

Methods: Neutrophils were activated with synthesized calcium crystals and analyzed for NET formation in presence of reactive oxygen species (ROS) inhibitors using immunofluorescence microscopy and ELISA. Markers of neutrophil activation (S100A8/A9, peroxidase activity) and NETs (MPO-DNA complexes) were analyzed in plasma from healthy children (HC, n=20), pediatric lupus (n=10), polymyositis (n=7), JDM patients (n=66), and RNP+ myositis (9). In the Juvenile Myositis population, 74% were female, with a mean age of 11.3 years. The association of NETs with clinical parameters was tested, including disease activity scores (DAS) for skin, muscle and total, the presence of calcinosis as well as Myositis Specific Antibodies (MSA) and Myositis Associated Antibodies (MAA).

Results: Levels of S100A8/A9 and peroxidase activity were markedly elevated in JDM patients as a group ($p<0.01$), as well as in children with RNP+ antibodies ($p=0.005$), indicating systemic neutrophil activation. In children with RNP autoantibodies, S100A8/A9 levels correlated with total disease activity score ($r=0.64$, $p<0.05$) as well as disease activity score in the skin ($r=0.80$, $p<0.001$). No associations were found between NETs and MSA. Consistent with our hypothesis, calcium crystals induced neutrophil activation *in vitro*, with up-regulation of the adhesion molecules CD66b and CD11b on the neutrophil cell surface ($p<0.05$). Further, calcium crystals induced prominent NETosis ($p<0.05$) in a ROS-dependent manner, as determined by fluorimetry and immunofluorescence microscopy. Children with calcinosis had increased levels of circulating NETs as compared to calcinosis-negative children ($p=0.003$) as well as healthy controls ($p=0.02$).

Conclusion: Our results demonstrate a clear contribution of neutrophils in JM pathogenesis, and suggest calcium crystal-driven NETosis is a novel, and potentially therapeutically targetable, mechanism participating in calcinosis-associated pathology. Thus, monitoring neutrophil-derived markers may have significant clinical utility in patients with Juvenile Myositis and skin involvement.

Session Title: Pediatric Rheumatology – Basic Science Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Juvenile idiopathic arthritis (JIA) is the most common rheumatic disease of childhood and has a strong genetic component to disease risk. Genome-wide association studies have been the primary method for understanding genetic risk in complex diseases, including JIA, but they do not fully explain disease inheritance. This study focuses on identifying *de novo* mutations (DNMs) among sporadic oligoarticular and rheumatoid factor-negative (RF-) polyarticular JIA patients that may contribute to disease pathogenesis.

Methods: Whole exome sequencing (WES) and downstream bioinformatic analyses were used to identify rare, nonsynonymous DNMs among 10 oligoarticular or RF- polyarticular JIA patient-parent trios. All cases met either the International League of Associations for Rheumatology (ILAR) or the American College of Rheumatology (ACR) classification for JIA. Analysis of these mutations implicated a role for *DOCK2* in JIA. The impact of *DOCK2* genetic deficiency in C57BL/6 mice on arthritis development and progression was evaluated using the autoantibody-induced, K/BxN serum-transfer model.

Results: Sanger sequencing confirmed 15 nonsynonymous DNMs identified by WES among 8 JIA trios. One DNM was located in *DOCK2*, whose gene product complexes with the gene products of two JIA-associated loci identified by association testing. In mice, *DOCK2* deficiency resulted in decreased clinical measures of disease, while also reducing histopathological features in the forepaws, metacarpophalangeal joints, and knee joints induced by the K/BxN serum-transfer model. *DOCK2* expression drives neutrophil infiltration into the hindpaws that can further exacerbate disease.

Conclusion: DOCK2 is a molecular determinant of autoantibody-induced arthritis that augments disease severity and pathology through a mechanism resulting in neutrophil infiltration. Furthermore, this study demonstrates the value of rare variant detection in understanding the genetic architecture of JIA.

Session Date: Tuesday, October 23, 2018

Session Title: Pediatric Rheumatology – Basic Science Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Kawasaki disease (KD), a predominantly coronary vasculitis of childhood, remains the most common cause of acquired heart disease of childhood in the developed world, and the developing concerns of myocardial damage in the form of cardiac fibrosis amplifies the urgency for a greater understanding both in terms of management and mechanism of this illness. At present, no biomarkers exist for the disease, response to therapy, persistence of inflammation or long term fibrosis; similarly, our understanding of the overall mechanism of the arterial remodeling and myocardial damage in KD is limited. Microwave and magnetic (M²) proteomics is a method whereby accelerated processing of proteins allows for high-throughput sample preparation and isolation of peptides for mass spectrometry. Our hypothesis was that protein biomarkers for vascular and myocardial inflammation would be identifiable in cardiac tissue from mice with a model of KD, that these markers would show response to a therapy such as interleukin-1 (IL-1) inhibition, offering insight into disease mechanisms.

Methods: KD was induced via the established model of lactobacillus casei cell wall extract (LCWE) injection in 4-6 week old male mice. Groups of mice either injected with LCWE alone, LCWE and anakinra, or saline for normal controls. After 2 weeks, mice were sacrificed and aortic root region of the heart was extracted, homogenized and processed. Tissue then underwent mass spectrometry analysis. Probability-based protein database searching of spectra was performed. Data was analyzed for pathway enrichment using STRING and REACTOME pathway analysis.

Results: Several proteins demonstrated multifold elevation in diseased animals as compared to controls, with certain proteins with primarily skeletal muscle and cardiac muscle expression notably elevated and down expressed after therapy. Proteomic analysis demonstrated clustering of diseased (KD) animals apart from controls and anakinra treated animals, which clustered together when analyzed by k-means testing. Preliminary pathway analysis suggests that in KD diseased hearts, there is enrichment for proteins involved in platelet aggregation and activation (p<0.01) and cardiac epithelial to mesenchymal transformation (p=0.04). Anakinra treated animals demonstrate enrichment for wnt signaling and downstream wnt signaling effectors beta-catenin and T cell factor (TCF) (p=0.01).

Conclusion: Potential biomarker proteins for disease activity and response to therapy were found based on the hypothesis of differential protein expression therapy and disease. These proteins require further validation. Overall, anakinra treated animals had a cardiac proteome that was more similar to normal controls than to KD mice. Preliminary pathway analysis suggested pathways for vascular injury and intimal hyperplasia in diseased animals, and induction of a regulatory immune phenotype mediated by wnt/beta-catenin in anakinra treated animals.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Pediatric Rheumatology – Basic Science Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: An atlas of the developing immune system will aid in our understanding of its normal maturation and identification of disease-associated cell subsets. The availability of high dimensional mass cytometry has provided an opportunity for the creation of this reference standard. However, the power available from these big data has not been fully harnessed due to the current focus on specific cell subsets and age groups. There is a critical unmet need for standardized datasets depicting at single cell level and with high dimensionality the entire developmental gradient of the healthy immune system from the neonatal to adult age.

Methods: To address this need, we constructed an immune atlas from the mass cytometry data obtained from the peripheral blood mononuclear cell samples of 113 healthy individuals (cord blood, newborn to adult) using 63 phenotypical and functional immune markers encompassing the major immune lineages. Quality control check and batch effect correction were done before dimensional reduction and clustering to identify the unique cell subsets. Their frequencies across the age categories were presented as 3-D frequency histograms to create the immune landscape. This database and the analytic pipeline were incorporated into a web portal that allows user to interact as well as upload their own data for comparison.

Results: Here, we described EPIC with examples of representative immune subsets over the entire age spectrum. There was a distinct segregation of the naive T cell subset enriched in the cord blood/newborn period from the memory T cell subset enriched in adulthood. The naive IL8+ and TNF α + CD4+ T cells accounted for prominent peaks in the immune landscape during the cord blood/newborn period. In contrast, the memory IFN γ + and TNF α + CD4+ T cells were enriched in adulthood.

Transition developmental milestones were observed in the TNF α + CD4+ T cells where the size of its memory subset would exceed its naive subset at 8 year old. There was a significant reduction and increase in the frequency of the naive and memory TNF α + CD4+ T cells with a Spearman's correlation coefficient, rho, of -0.4662 and 0.4164 respectively (both $p < 0.0001$). A similar intersection was present for the naive and memory regulatory T cell (CD4+, CD25+, Foxp3+, CD152+) subsets at 14 year old with a rho of -0.537 and 0.5034 respectively (both $p < 0.0001$).

Conclusion: A holistic description of the developing immunome was obtained with key developmental milestones in the T cell compartment identified. This atlas has the translational potential of aiding the identification of pathologic immune cell subsets in diseases through its comparison with this reference dataset found in the freely available EPIC web portal.

Serial Serum C4 Concentrations in APPLE Participants With and Without a History of Hypertension

Serial Serum C3 Concentrations in APPLE Participants With and Without a History of Hypertension

Background/Purpose: Chronic systemic inflammation, mediated in part by complement, and inadequate vascular repair mechanisms affect patients with cSLE from a young age and are associated with cardiovascular morbidity. In non-SLE affected patients with cardiovascular disease (CVD) and hypertension, complement levels are increased. In contrast, complement levels are relatively low in SLE when the disease is active. We leveraged data from the Atherosclerosis Prevention in Pediatric Lupus Erythematosus (APPLE) Trial and its cSLE cohort to further investigate the relationship between complement and CVD in SLE. We hypothesized that serial levels of serum C4 and C3 would be higher in patients with hypertension than in those without. We also hypothesized that C4 levels would be influenced by total C4 gene copy number (GCN).

Methods: Clinical data for the three-year study of 221 cSLE patients, plus genomic DNA and plasma samples for 197 patients, were provided by the APPLE repository. Total C4 GCN was measured by TaqMan-based quantitative real time PCR and Southern blot analyses using genomic DNA. Baseline serum C4 levels were compared to total C4 GCN using linear regression. Least-squares regression was used to assess the effect of hypertension, defined by baseline physician-report, on serial serum C4 and C3 protein levels.

Results: A linear relationship was demonstrated between baseline serum C4 levels and total C4 GCN. A one-copy increase in GCN correlated with an increase in serum C4 of 3.28 mg/dL ($p=1.8 \times 10^{-6}$; $R^2=0.12$). Compared to normotensive individuals, individuals with a history of hypertension had significantly higher baseline levels of serum C4 (18.5 mg/dL vs 13.5 mg/dL; $p=4.7 \times 10^{-6}$) and serum C3 (110.7 mg/dL vs 95.7 mg/dL; $p=3.0 \times 10^{-4}$). A history of hypertension had a positive effect on serial serum C4 levels (Figure 1; $p=5.0 \times 10^{-25}$) and serum C3 levels (Figure 2; $p=5.8 \times 10^{-20}$).

Conclusion: In the APPLE Trial, cSLE patients who were hypertensive had significantly higher baseline and serial concentrations of serum C4 and C3 than non-hypertensive cSLE patients. Total C4 GCN directly affected total serum C4 levels. Further elucidating the relationship between complement GCN, serum complement protein levels, and CVD in SLE could allow for more precise real-time interpretation of complement data and may provide an opportunity for early identification of cSLE patients at highest risk for poor cardiovascular outcomes.

Session Title: Pediatric Rheumatology – Basic Science Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Juvenile dermatomyositis (JDM) is a debilitating pediatric autoimmune disease manifesting with characteristic rash and proximal muscle weakness. We investigated signaling abnormalities in immune cell subsets from treatment-naïve JDM patients and healthy controls.

Methods: To delineate signaling abnormalities, mass cytometry coupled with phosphoprotein antibodies was performed with peripheral blood mononuclear cells from seventeen treatment-naïve JDM patients and controls.

Results: The percentages of peripheral NK cells were lower while frequencies of naïve B cells and naïve CD4 T cells were higher in JDM patients than controls. These cell frequency differences were attenuated in paired patient samples with cessation of active disease. A large number of signaling differences were identified in treatment-naïve JDM patients compared to controls. Classification models incorporating feature selection demonstrated that differences in PLCγ2 phosphorylation comprised 10 of the 12 features (i.e., phosphoprotein in a specific immune cell subset) distinguishing the JDM patients from healthy controls. As NK cells represented 5 of these 12 features, further studies focused on the critical PLCγ2 pathway in NK cells which is responsible for stimulating calcium flux and cytotoxic granule movement. No differences were detected in upstream kinases (Itk/Btk, Syk/ZAP70) or total PLCγ2 protein levels. The decreased phosphorylation of NK cell PLCγ2 and downstream MAPKAPK2 was partially attenuated in treatment-naïve JDM patients

with cessation of active disease. Furthermore, suppressed PLC γ 2 phosphorylation in treatment-naïve JDM patient NK cells resulted in decreased calcium flux.

Conclusion: The novel identification of dysregulation of PLC γ 2 phosphorylation and decreased calcium flux in NK cells from treatment-naïve JDM patients provides potential mechanistic insight into JDM pathogenesis.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Pediatric Rheumatology – Basic Science Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: T cells play a critical role in the body's response to pathogens. A naïve T helper (Th0) cell proliferates in response to antigen encounter and is not differentiated. Specific cytokines signal the naïve Th cell to express transcription factors causing differentiation to Th cell lineages, including Th1, Th2, and Th17 lines. Re-activation causes a differentiated effector Th cell to secrete characteristic cytokines, which are IFN γ , IL-5 and IL-13, and IL-17 for Th1, Th2, and Th17 cells respectively. In juvenile idiopathic arthritis (JIA), specific Th cell lineage differentiation and cytokine secretion have not been studied. An *ex vivo* assay was developed in adult human peripheral blood mononuclear cells (pBMCs) wherein mononuclear cells differentiate, re-activate, and then secrete cytokines. We identified a young child with JIA who has a heterozygous mutation in GATA-3, the key transcription factor that drives the Th2 pathway and suppresses the Th1 and Th17 pathways (index patient). In this study, we tested effector Th cell differentiation and cytokine secretion in pBMCs from young children, young children with JIA, and the index patient.

Methods: We enrolled healthy controls, children with seronegative polyarticular or extended oligoarticular JIA, and the index patient. All children were 2-8 years old. PBMCs underwent collection, *ex vivo* differentiation to Th0, Th1, Th2, and Th17 cells, and then re-stimulation. After this, cytokine secretion was measured by enzyme-linked immunosorbent assay. Transcription factor expression and cytokine transcription was assessed by Western blot and quantitative real time polymerase chain reaction. Whole exome sequencing identified the index patient GATA-3 mutation.

Results: Differentiated effector Th cell cultures from children with JIA secrete much higher levels of characteristic cytokines than healthy control children. The Th cell average JIA/control ratios were markedly increased for Th1 (IFN γ , 3.4), Th2 (IL-5, 6.0 and IL-13, 10.3), and Th17 (IL-17, 5.5). The index patient had increased index/control ratios for Th1 (IFN γ , 4.5) and Th17 (IL-17, 3.6) cultures and no change in Th-2 ratios. Surprisingly, the undifferentiated Th0 cells from children with JIA and the index patient secrete IFN γ , with ratios being JIA/control 5.5 and index/control 22.6. The *ex vivo* assay in healthy children produces much lower levels of cytokines than in healthy adults.

Conclusion: Young children produce differentiated effector Th cells that make much less cytokines than adult differentiated effector Th cells. Cultures from children with JIA make more cytokines than cultures from healthy children and are similar to adult cultures. The index patient does not produce differentiated Th2 cells that secrete IL-13 and IL-5, as might be predicted from a GATA-3 mutation. Both the JIA and index patient undifferentiated Th0 cell cultures secrete IFN γ , suggesting a Th1-like phenotype. Mechanisms underlying differences between effector Th cell cultures from young children, children with JIA, the index patient, and adults may reveal fundamental differences in these developmental processes, including limits on the function of the immune system in young children.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Pediatric Rheumatology – Basic Science Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Localized scleroderma (LS) has both inflammatory and fibrotic components affecting skin and underlying tissue. Extent and duration of inflammation during active LS is thought to be the major contributor to long-term disease damage and disability. Identifying the cellular phenotype expressed during active LS would be instrumental to improve outcomes. As a preliminary evaluation, pediatric LS and healthy pediatric control samples were analyzed by mass cytometry by time-of-flight spectrometry (CyTOF). CyTOF uses heavy metal ion tags to mark cells and perform high-dimensional phenotypic and functional analysis on single cells. Our panels focused on monocytes and T cells, respectively, to determine key phenotypic populations in LS samples.

Methods: Paired pediatric LS PBMC samples (n=9 subjects, 18 samples) from individuals with initial active and later inactive disease states and healthy pediatric controls (n=8) were collected (IRB #PRO11060222) and analyzed using CyTOF. Both monocyte and T cell panels of 34 markers each were performed at the Stanford Human Immune Monitoring Center (HIMC) using singlet and viability based analysis. Data was analyzed using SPADE and CITRUS (Cytobank) and Cytosplore software. CITRUS clusters were made from all samples, and cell types were then identified from all levels of the cluster hierarchy that were significantly associated with active LS, inactive LS, and healthy groups. SPADE trees were built using 11 marker calculated cell clusters to define key populations that differed from the subject's active PBMC sample acting as the baseline. Cytosplore software then allowed for sub-analysis of SPADE branches through t-Distributed Stochastic Neighbor Embedding (t-SNE) plots.

Results: CyTOF revealed a dramatic decrease in frequency of monocyte subsets, DC cells (both CD16+/-), and NK cells (CD56+CD16+) in the inactive state. The CD16+CD86+ monocyte subset (M1 phenotype) showed a 3-fold decrease in the inactive state, consistent with our prior LuminexTM findings of the peripheral LS blood signature. Further study of NK subsets shows NK^{CD56bright} cells having a 4-fold increase in the active state and 50% increase in IFN- γ production after lipopolysaccharide (LPS) stimulation. Further CyTOF analysis showed an overall increase in T cell (CD3+) populations in active LS, with decreased T_H1 (CD3+CD4+IFN γ) and Tc1 (CD3+CD8+IFN γ +) populations when transitioning from active to inactive disease state. Granzyme positive cytotoxic T cells (CD8+) were elevated in active LS and when comparing overall LS to healthy controls.

Conclusion: These findings support increased levels of type-1 specific M1 and NK cells during active LS. These cell types are thought to contribute to activation and stimulation of T cells and DCs through IFN γ expression, which would support the elevation of T_H1-like (IFN γ + T_H and Tc) cells and DCs observed in our cohort. Previous work showed that the IFN γ inducible chemokines (CXCL9, CXCL10 and CXCL11) are present during active LS, possibly further polarizing these phenotypes. Further study is ongoing to evaluate these phenotypes in active LS skin, and the association to the PBMC signature.

Session Title: Pediatric Rheumatology – Basic Science Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Downs Arthropathy (DA) is an inflammatory joint condition affecting children with Down syndrome, which is under-recognised, has a delayed diagnoses, resulting in chronic disability. Our clinical research showed an increased risk of arthritis in children with Down syndrome, with the prevalence in Ireland for DA 18-21 times greater than Juvenile idiopathic Arthritis (JIA). Furthermore children with DA had more erosive joint damage compared to JIA. This observed increase in erosive disease suggests that DA synovial fibroblasts (SFC) which reside in the hyperplastic lining layer of the synovium may have a more invasive phenotype, however to date little is known about the underlying mechanisms that drive disease pathogenesis in DA.

The aim of the present study is to compare the function of primary synovial fibroblasts from children with DA vs JIA.

Methods: Synovial tissue biopsies were obtained from children with DA and JIA using ultrasound guided biopsies and assessed histologically for levels of vascularity, lining layer hyperplasia and sub-lining inflammation. Primary synovial fibroblasts were isolated from both DA and JIA and functional comparisons performed at passage 3. DASFC and JIASFC migration was assessed by wound repair scratch assays. Biocoat Matrigel™ Invasion Chambers were used to assess DASFC and JIASFC invasiveness. DASFC and JIASFC bioenergetic activity was assessed using the XFe96-Flux-analyser, where oxygen consumption rate (OCR) and extracellular acidification rate (ECAR), reflecting oxidative phosphorylation and glycolysis respectively were quantified. Further metabolic outputs were assessed following the mitochondrial stress test where cells were treated with oligomycin, FCCP and antimycin A. Finally, glycolytic gene expression was assessed by Real-time PCR.

Results: Synovial tissue analysis demonstrated a marked increase in synovial lining layer hyperplasia in DA vs JIA, with a median lining layer thickness score of 6(3-9) in DA vs 3(2-4) JIA, suggesting a more invasive pannus in DA compared to JIA. An increase in the migration of DASFC compared to JIASFC was observed, an effect paralleled by a significant increase in the invasive capacity of DASFC vs JIASFC. These effects were potentiated in response to TNF α stimulation. Metabolic activity was markedly different in DASFC vs JIASFC, with DASFC displaying increased basal metabolic activity compared to JIASFC. Moreover, following the mitochondrial stress test, a substantial increase in mitochondrial spare reserve capacity was observed in DASFC when compared to JIASFC, suggesting that DASFC have an enhanced ability to respond to sudden changes in the energy demands of the cell. Finally, an increase in metabolic genes HK2 and PDK2 were observed in DASFC vs JIASFC.

Conclusion: This is the first study to demonstrate differences in synovial pathology of children with DA vs JIA, demonstrating a marked increase in the invasive layer of DA synovium compared to JIA. This was paralleled by a significant increase in the migratory, invasive and bioenergetic profile of DASFC vs JIASFC, a phenotype that may contribute to the increased erosive disease observed in DA compared to JIA.

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Etiology and Pathogenesis Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Baricitinib (bari) is an oral selective inhibitor of Janus kinase (JAK) 1 and JAK2. In the phase 3 study RA-BUILD (NCT01721057), once-daily bari yielded significant clinical benefit in patients (pts) with active RA who had inadequate response or intolerance to conventional synthetic DMARDs compared to placebo (PBO).¹ Changes in serum biomarkers² associated with joint tissue remodeling, including synovial remodeling and inflammation (C1M, C3M, and C4M [matrix metalloproteinase-derived fragments of type I, III, and IV collagen, respectively] and ProC3 [N-terminal pro-peptide type III collagen]), cartilage degradation (C2M [derived from type II collagen]), and bone remodeling (CTX-I [C terminal telopeptide of type I collagen] and osteocalcin) were analyzed in a subset (N=240) of these pts.

Methods: Circulating levels of biomarkers from eighty patients per arm (PBO, bari 2- or 4-mg [added to stable background therapy]) were analyzed at baseline (BL), week (Wk) 4, and Wk 12, using a Mixed Model Repeated Measure method to identify markers that are affected by bari longitudinally. Secondly, an analysis of variance was performed to evaluate the relationship between the observed changes in biomarkers at Wks 4 and 12 (grouped as reduction or increase from BL) and the Hybrid ACR response measure (a hybrid of ordinal and continuous versions of ACR scores)³ at the primary endpoint of Wk 12.

Results: Baseline concentrations of biomarkers tested were similar between all three groups. At Wk 4, C1M was reduced by 21% from BL by bari 4-mg compared to PBO (p<0.01); suppression was sustained at Wk 12 (27%, p<0.001). Similarly, at Wk 4, C3M and C4M were reduced by 14% and 12% from BL by bari 4-mg compared to PBO (p<0.001), respectively, and remained reduced by 16% or 11% from BL at Wk 12 (p<0.001). Similar results were observed with bari 2-mg. Bari treatment did not result in appreciable changes compared to PBO for the other biomarkers tested. We further determined the relationship between changes in biomarkers in RA pts and clinical response, as measured by the Hybrid ACR score (Table). In a pooled analysis with all three treatment arms, reduction in C1M, C3M, and C4M by Wks 4 and 12 was associated with significantly greater clinical improvement in the Hybrid ACR response at Wk 12 compared to pts with RA having increased levels of these biomarkers.

Table: Greater clinical improvement, as measured by the Hybrid ACR response,³ observed in patients with a reduction in serum biomarkers

	Week 4			Week 12		
	BM Reduction	BM Increase	Difference	BM Reduction	BM Increase	Difference
C1M	-43.7	26.4	17.3***	-44.4	21.2	-23.2***
C3M	-42.5	28.9	13.6**	-44.2	24.4	-19.8**
C4M	-42.1	29.7	12.5**	-44.7	20.1	-24.6***

Hybrid ACR response measured at Week 12. Data are the mean Hybrid ACR score at Week 12 with patients grouped by a reduction or increase in biomarker change from baseline at Weeks 4 and 12. The estimated mean difference and significance are shown. **p<0.01, ***p<0.001. BM=biomarker; C1M, C3M, and C4M=matrix metalloproteinase-derived fragments of type I, III, and IV collagen, respectively.

Conclusion: A reduction in circulating biomarkers associated with tissue destruction and synovial inflammation in RA pts was observed in bari-treated RA pts, suggesting that bari inhibits key pathological processes at the site of inflammation in RA. Moreover, the decrease in these biomarkers was associated with clinical improvement.

Adenosine Receptors Expression As Predictor of Response to Methotrexate Therapy in Patients with Rheumatoid Arthritis

Ankita Singh¹, Ramnath Misra² and Amita Aggarwal², ¹Sanjay Gandhi Postgraduate Institute of Medical Sciences, Lucknow, India, ²Clinical Immunology, Sanjay Gandhi Postgraduate Institute of Medical Sciences, Lucknow, India

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Etiology and Pathogenesis Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Methotrexate (MTX) is first line of therapy to treat Rheumatoid Arthritis (RA) patients and one third of patients do not respond to this drug. MTX reduces inflammation by increasing extracellular adenosine levels. Adenosine acts via four G-protein coupled adenosine receptors; ADORA1, ADORA2a, ADORA2b and ADORA3. Activation of ADORA2b and ADORA1 leads to pro-inflammatory response, whereas activation of ADORA2a and ADORA3 mediates anti-inflammatory response. MTX also modulates the expression levels of adenosine receptors. Thus, to see if baseline levels of adenosine receptors (ADORA1, ADORA2a, ADORA2b and ADORA3) can predict response to MTX we analysed their levels in whole blood RNA.

Methods: Patients with RA (ACR 2010 criteria), DMARD naïve with active disease (DAS 28 >3.2) were enrolled. Blood samples were collected at baseline before start of MTX. All patients were treated with MTX monotherapy by gradually increasing dose to a maximum of 25mg/week or the maximal tolerated dose. After 4 months of therapy EULAR response was assessed. Adenosine receptors gene expression (ADORA1, ADORA2a, ADORA2b and ADORA3) in the whole blood RNA sample was measured using real time qPCR. HPRT1 was used as a housekeeping gene. The adenosine receptor expression was correlated with response to MTX.

Results: Ninety-nine patients (86.86% females; median age 40 [17-67] years); median duration of disease 24 (2-120) months; median DAS28-CRP 4.48 (3.16-7.63) were enrolled. Among 99 patients 51 were classified as good responders, 28 moderate responders and 20 as non-responders at 4 months. In whole blood RNA, there was predominant expression of ADORA2a and ADORA3 and almost no expression of ADORA1 and ADORA2b. Baseline adenosine receptor expression did not correlate with DAS28 score.

Both adenosine receptors ADORA2a and ADORA3 expression was lower in non-responders (n=20) as compared to good and moderate responders (n=79). However, significant difference was observed only for ADORA3 between good vs non-responder (p=0.03) and moderate vs non-responder (p=0.002). ROC curve analysis showed that ADORA3 with cut-off value of less than -0.21 (Δ Ct) predicted non-response to MTX treatment with a sensitivity of 63.6% and a specificity of 65% (AUC:0.695, p=0.007).

Conclusion: Adenosine receptor A3 (ADORA3) mRNA levels in whole blood may serve as a biomarker for response to MTX.

Abstract Number: 2037

CTLA4 Signaling Down-Regulates Fcγ Receptor I Expression on Circulating Monocytes: A Potential Mechanism of Action of Abatacept for RA

Ryosuke Fukue, Yuka Okazaki and Masataka Kuwana, Department of Allergy Rheumatology, Nippon Medical School Graduate School of Medicine, Tokyo, Japan

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Etiology and Pathogenesis Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Abatacept is a recombinant fusion protein comprising cytotoxic T lymphocyte antigen 4 (CTLA4) and Fc region of immunoglobulin (Ig), which is efficacious against rheumatoid arthritis (RA). Its mechanism of action is believed to be competitive inhibition of T-cell co-stimulation mediated through binding of CD28 to CD80/CD86 on antigen-presenting cells. On the other hand, it has been shown that binding of CTLA4-Ig to CD80/CD86 on monocytes, macrophages, and osteoclast precursors is capable of transmitting intracellular signaling pathways. This signaling is potentially involved in the therapeutic action of abatacept, but detailed mechanisms still remain unclear. This study is aimed to investigate direct effects of CTLA4-Ig on circulating monocytes, which might contribute to its efficacy for suppressing pathogenic process of RA.

Methods: This study enrolled 34 RA patients and 13 controls, including patients with non-inflammatory rheumatic disorders or healthy individuals. Circulating monocytes were isolated from peripheral blood mononuclear cells by negative selection with magnetic-activated cell sorting system, and were cultured in the presence or absence of CTLA4-Ig, CD28-Ig, or Ig alone for 24 hours. In some experiments, anti-CD80, CD86, and/or isotype-matched control monoclonal antibody (mAb) were added in the culture. The recovered cells were subjected to flow cytometry to evaluate expression levels of CD14, CD16, CD32, CD40, CD54, CD62L, CD64, CD80, CD86, CCR2, CXCR2, CD273, CD274, and CD275, and IL-1 β , IL-6, IL-8, IL-10, IL-12p70, IFN γ , MCP-1, TNF α were measured in culture supernatants by multiplex particle-based flow cytometric assay. Expression of candidate molecules was further examined by immunoblots using total cellular extracts of monocytes cultured with CTLA4-Ig or CD28-Ig. Statistical analysis was made using non-parametric Mann-Whitney U test.

Results: In a pilot study using 5 RA patients and 5 controls, we selected CD64, CD80, CD86, CCR2, and CXCR2 as candidate molecules whose expression levels were modulated by CTLA4-Ig stimulation in a fashion different from CD28-Ig stimulation. The validation study involving 20 RA patients and 8 controls demonstrated that treatment with CTLA4-Ig significantly down-regulated expression of CD64 or Fc γ receptor I in circulating monocytes, but stimulation with CD28-Ig had no effect. The CD64 down-regulation induced by CTLA4-Ig was not found in cultures with control Ig alone, and was confirmed by immunoblots. This effect was observed in both RA patients and controls, while CD64 expression levels on circulating monocytes tended to be higher in RA patients compared with controls. Finally, CTLA4-mediated CD64 down-regulation was completely abolished by anti-CD86 mAb, but not by anti-CD80 mAb.

Conclusion: Efficacy of abatacept is associated with a high titer of anti-citrullinated protein antibodies, which form immune complexes and induce activation of monocytes/macrophages through binding to Fc γ receptors. These findings suggest that therapeutic effects of abatacept on RA are mediated, in part, through down-regulation of Fc γ receptor I on circulating monocytes via direct binding to CD86.

Session Title: Rheumatoid Arthritis – Etiology and Pathogenesis Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: In the treatment of rheumatoid arthritis (RA), molecular targeted therapies induced different changes in different immune cell phenotypes. For instance, our previous study showed that abatacept decreased the number of Tfh cells, while TNF inhibitors increased that of Tfh cells. This fact forms the basis for subgroup identification for precision medicine. In this study, we stratified RA patients based on immunophenotyping and investigated the response for targeted therapies.

Figure 1. Statistical cluster analysis based on immune phenotype in RA

Methods: Peripheral blood mononuclear cells were obtained from 224 bio-naive RA patients and 33 healthy individuals. Circulating B, T and dendritic cells were defined based on flow cytometric analysis for human immune system termed “the Human Immunology Project”. Based on these results, RA patients were classified into subgroups by cluster analysis. The human ethics review committee of our university reviewed and approved this study.

Results: The proportions of T effector and activated Tfh cells, but not Th17 and Treg cells, were higher in RA than the age matched control. Likewise, the proportions of B effector cells and plasmacytoid DCs were higher. None of them correlated with disease activity. Cluster analysis (Figure 1) stratified RA patients into 2 groups: patients with less immune abnormality and patients with immune abnormality. The group with immune abnormality was further divided statistically into 3 groups (with high proportions of B effector, Th17, and Tfh cells in all groups): patients with less T cell abnormality (T cell low dependent group), patients with high percentage of Tfh and Treg cells (Tfh/Treg dominant group), and patients with conspicuously high proportion of T effector cells (T effector dominant group). Among these 4 groups, simplified disease activity index (SDAI) and clinical disease activity index (CDAI) components were similar. However, the treatment responses by biologics were different. The number of patients with insufficient response at week 52 was more frequent in T effector dominant group. In addition, TNF inhibitors were numerically more effective in the group with less immune abnormality. In contrast, abatacept had similar efficacies in the group with less immune abnormality and the group with immune abnormality, and tocilizumab had strong efficacy in Tfh/Treg dominant group.

Conclusion: Our study indicates that active RA patients can be divided into four subgroups based on immunophenotype. The identification of immunophenotypic subgroups may enhance treatment effect of molecular targeted drugs and serve as a step towards precision medicine.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Etiology and Pathogenesis Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Myeloid cells – including dendritic cells (DCs), monocytes, and macrophages – are critical to the pathogenesis of rheumatoid arthritis (RA) through production of pro-inflammatory cytokines, recruitment of inflammatory cells, and activation of T cells. Various studies have shown that these cells exhibit activation markers and increased numbers in the joint synovium, but the relationship with the activity of their circulating counterparts has not been fully elucidated. Here, we perform RNA-seq on these *in vivo* cell populations from RA patients in order to compare their genome-wide transcriptional profile within and across individuals.

Methods: We obtained blood samples and ultrasound-guided minimally invasive synovial biopsy tissue (as described in Mandelin et al, *A&R* 2018¹) from RA patients with active disease. Using Fluorescence-Activated Cell Sorting (FACS), we isolated classical monocytes (MHCII+CD14++CD16-), non-classical monocytes (MHCII+CD14+CD16+), and dendritic cells (MHCII+CD1c+) from blood. After processing synovial tissue for single-cell suspension, we isolated macrophages (MHCII+CD14+CD11b+CD206+) and dendritic cells (MHCII+CD1c+) by FACS. We extracted RNA from these cell populations and prepared libraries for RNA-seq. Although the cell numbers were low, particularly for the synovial tissue populations, we have previously demonstrated our ability to reliably generate RNA-seq libraries from sorted populations down to tens of cells. These libraries were sequenced on an Illumina NextSeq 500 and assessed for quality of RNA, sequencing, and gene detection.

Results: For each cell population, we assessed the variability of gene expression across patients. As expected, the DCs were highly variable across individuals: this is likely due to the heterogeneity of subtypes within this population. In circulating monocytes, we observed varying levels of common cytokines and chemokines, such as TNF and CCL1. We also compared gene expression across cell populations to characterize transcriptional signatures that were distinctive to a given cell population. In addition to the genes previously known to be unique to dendritic cells vs. monocytes/macrophages in health, we also identified potential pathogenic factors that varied in their expression across cell types. Finally, to explore the relationship between circulating and tissue cell populations, we asked whether there were pathways that were turned on in the blood prior to extravasation into the synovium. For example, we identified genes that maintained their expression across monocytes and synovial macrophages in RA patients supporting the differentiation of the former into the latter.

Conclusion: Together, these results provide a survey of myeloid cells in the blood and synovial tissue of RA patients. We aim to understand how these cells vary across patients and what clinical variables and medication status influence their transcriptional profile across individuals. Our long-term goal is to use these studies to better understand the underlying mechanisms of pathogenesis and response to current treatments of RA as well as to identify potential targets for future therapies.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Etiology and Pathogenesis Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Galectin-3 (Gal-3) and the co-stimulatory T cell receptor and glycoprotein 4-1BB are both considered important in inflammation and immune responses. This had led to the investigation of Gal-3 inhibitors in fibrotic diseases and agonistic anti-4-1BB antibodies in cancer treatment. We and others have previously shown that galectins are capable of binding to receptors of the TNF superfamily thereby modulating inflammatory signals¹. Purpose: To investigate the interplay between 4-1BB and Gal-3 in rheumatoid arthritis (RA).

Methods: Gal-3 was measured in plasma samples from newly diagnosed, active and treatment-naïve RA (eRA) patients at baseline and after 3 months of aggressive treatment (the OPERA trial, n=97)² and plasma and synovial fluid samples from chronic RA (cRA) patients (n=17) by ELISA. The 28-joint disease activity score with CRP (DAS28CRP) and radiographic damage (i.e. total Sharp score (TSS)) were used to evaluate treatment outcomes over a 2-year period. Plasma samples from age and gender matched healthy controls (HC) (n=48) were also included. Fluorescence polarization analyses were used to evaluate the binding between 4-1BB and Gal-3. Synovial fluid mononuclear cells (SFMCs) from patients with chronic RA (n=8) were cultured for 24 hours, co-incubated with either 4-1BB, 4-1BB ligand, Gal-3, or a combination hereof.

Results: Plasma levels of Gal-3 were increased in eRA (mean: 8.1 ng/ml (CI: 7.6-8.6)) compared to HC (mean: 6.4 ng/ml (5.9-6.9)) ($p < 0.0001$). Gal-3 correlated with DAS28CRP at baseline ($p = 0.27$) ($p < 0.05$). A decrease in Gal-3 levels from baseline to 3 months were significantly correlated with high disease activity after 2 years of treatment evaluated by DAS28CRP ($p = 0.23$) and radiographic damage evaluated by DTSS (0-24 months) ($p = 0.26$) both ($p < 0.05$). After 3 months of intensive treatment, the plasma levels of Gal-3 were still elevated (mean: 8.3 ng/ml (7.8-8.7)) compared with HC ($p < 0.0001$). In cRA, Gal-3 levels in synovial fluid were tripled (mean: 30.9 ng/ml (18.3-43.5)) compared with levels found in plasma (mean: 9.1 ng/ml (7.8-10.4)) ($p < 0.01$). Gal-3 was capable of binding 4-1BB ($K_d = 1.43$ mM (1-1.86 mM)). A mutant Gal-3 (Gal-3 R186S) with severely reduced affinity for endogenous glycans, did not bind to 4-1BB, thus excluding that the 4-1BB and Gal-3 binding is influenced by a protein-protein interaction. Shedding of 4-1BB was increased by addition of Gal-3 ($p < 0.05$). When SFMC cultures were stimulated with a combination of 4-1BBL and Gal-3, the level of MCP-1 decreased by 50% compared to MCP-1 production from untreated cultures and cultures stimulated with either 4-1BBL or Gal-3 separately ($p < 0.05$).

Conclusion: In early RA patients, persistent high plasma levels of Gal-3 during the first 3 months of treatment were associated with lower disease activity and less radiographic progression after 2 years of treatment. Explaining some of these associations, Gal-3 was found to be a new binding partner to 4-1BB, modulating both shedding and function of this receptor in RA. These observations support that Gal-3 is implicated in RA disease pathology at least partly by interacting with the 4-1BB receptor.

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Etiology and Pathogenesis Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Triggering Receptor Expressed on Myeloid cells-1 (TREM-1) is a cell surface receptor expressed mainly on monocytes and neutrophils, known to amplify inflammatory response. We aimed to investigate whether serum level of soluble form of TREM-1 (sTREM-1), which reflects TREM1 activation, is associated with disease activity (DA) features and/or can predict response to biologic agent in rheumatoid arthritis (RA).

Methods: In this ancillary analysis of the Rotation or Change trial in which 300 patients with an inadequate response to a first line anti-TNF agent were randomized to receive either a 2nd anti-TNF treatment or a non-anti-TNF agent, baseline serum level of sTREM-1 was assessed using ELISA kit. Levels of sTREM-1 were compared by non-parametric tests for categorical variables as gender, body mass index (BMI) and Disease Activity Score 28-C reactive protein (DAS28-CRP). Spearman correlation coefficients were calculated between sTREM-1 level and DA measures (DAS28-CRP, CRP level, tender joint count (TJC), swollen joint count (SJC) and patient global assessment (PGA)). Univariable then multivariable logistic regression analyses were used to assess whether baseline sTREM-1 level was associated with EULAR response at 24 weeks (W24) in each group of treatment.

Results: sTREM-1 was available in 272 patients: 83.1% female, mean age (standard deviation) 56.9 (12.2) years, rheumatoid factor (RF) positive in 81.0% and anti-cyclic citrullinated peptide antibody positive in 81.6%. CRP level was >5mg/L in 59.8% patients and mean DAS28-CRP was 4.8 (1.0). W24 good or moderate EULAR response was achieved in 51.9% patients in 2nd anti-TNF group vs 66.9% patients in non-anti-TNF group (p=0.01). sTREM-1 was detectable in all patients with a mean level of 471.1(242.0) pg/mL, was higher in men (585.0 (240.1) pg/mL men, 447.9 (236.3) pg/mL women, p=0.0004) but was not associated with seropositivity status nor BMI. The mean sTREM-1 level was higher in patients with DAS28-CRP>5.1 (542.5 (279.6) pg/mL) than those with DAS28-CRP<5.1 (433.3 (212.5) pg/mL; p<0.01). sTREM-1 was also positively correlated with DAS28-CRP score (R=0.25, p<0.001), due to its correlation with CRP level (R=0.38, p<0.0001), but also to specific assessments of RA (PGA R=0.14 and SJC R=0.20, p<0.05). Mean baseline sTREM-1 levels did not differ between W24 good and moderate EULAR responders vs non-responders (459.9 (217.0) vs 487.6 (275.0)pg/mL overall, 450.8 (210.2) vs 502.7 (291.6) pg/mL in 2nd anti-TNF group and 466.7 (22.7) vs 466.6 (251.7) pg/mL in non-anti-TNF group, all p>0.05), nor between W24 good EULAR responders vs non-responders.

Conclusion: Serum sTREM-1 may be a new DA marker in this large cohort of RA patients. Interestingly, sTREM-1 did not only reflect systemic inflammation (i.e. CRP level) but also clinical joint inflammation, suggesting a specific role in RA synovitis pathogenesis. In this RA population with first anti-TNF treatment failure, sTREM-1 was not associated with W24 EULAR response to treatment.

Immunophenotypic analysis of tissue-resident memory T cells in rheumatoid arthritis

Seokchan Hong¹, Jae Hyung Jung^{1,2}, Jung Sun Lee¹, Jae Bum Won¹, Doo-Ho Lim³, Yong-Gil Kim¹, Chang-Keun Lee¹, and Bin Yoo¹

¹Division of Rheumatology, Department of Internal Medicine, University of Ulsan College of Medicine, Asan Medical Center, Seoul, Korea² Asan Institute for Life Science, Asan Medical Center, Seoul, Korea

³Division of Rheumatology, Department of Internal Medicine, Ulsan University Hospital, Ulsan, Korea

Background/Purpose: Rheumatoid arthritis (RA) is a chronic autoimmune disease that is characterized by an inflammation of the synovial membrane and infiltration of immune cells including T cells into the joints. Recently, discovery of tissue-resident memory T cells (Trm), which reside in peripheral tissue rather than circulation, provides a new avenue in tissue-specific immunity. However, the phenotypes and role of Trm in the patients with RA has not been investigated yet. Thus, we examined the presence and characteristics of Trm in synovial fluid cells in patients with RA.

Methods: Cells with phenotypes of Trm was identified by the expression of CD3, CD8 and CD69 but not CD45RA in the synovial fluid mononuclear cells (SFMCs) of RA patients (n=19). The expression of markers for activation, tissue-residency, pro-inflammatory cytokines and cytotoxic molecules was analyzed with or without IL-15 stimulation.

Results: A substantial portion (mean 54.98%) of the CD8⁺CD45RA⁻ T cells in the SFMCs showed the phenotypes of Trm (CD3⁺CD8⁺CD45RA⁻CD69⁺), and the frequency was significantly increased after stimulation with IL-15 (54.98% vs 79.24%, p<0.0001). The expression of activation markers CD25 and CD38 was similar between CD69⁺ and CD69⁻ CD8 T cells. CD69⁺CD8 T cells had significantly higher expression of chemokine receptor CXCR6 compared to CD69⁻ CD8 T cells (38.2% vs 17.3 %, p=0.017). In addition, CD69⁺CD8 T cells showed higher expression of markers for Trm PD-1 (P<0.001) and CD101 (P=0.07) compared to CD69⁻ CD8 T cells. Proinflammatory cytokines IFN γ (0.15% vs 0.07%, p=0.0056) and TNF α (0.25% vs. 0.10%, p=0.0013) were upregulated in CD69⁺ CD8 T cells compare to their CD69⁻ counterparts. Furthermore, CD69⁺ CD8 T cells were shown to be positive for perforin (mean 35.14%) and granzyme B (mean 46.97%) and its expression was significantly increased after IL-15 stimulation.

Conclusion: These data suggest that the presence of Trm in synovial cells from patients with RA. These cells can produce cytotoxic molecules and thus possibly contribute to tissue damage in RA.

Monocytes and Macrophages of Patients with Rheumatoid Arthritis Respond to Pathologically Increased Ionized Calcium with Proinflammatory Cytokine Production

Supriya Murthy¹, Elisabeth Jaeger¹, Sebastian Jung¹, Kathleen Friedrich², Olga Seifert¹, Christoph Baerwald¹, Matthias Pierer¹ and Manuela Rossol¹, ¹Department of Internal Medicine, Rheumatology, University of Leipzig, Leipzig, Germany, ²Department of Internal Medicine, Rheumatology, University of Leipzig, Germany, Leipzig, Germany

Session Information**Session Date:** Tuesday, October 23, 2018**Session Title:** Rheumatoid Arthritis – Etiology and Pathogenesis Poster III**Session Type:** ACR Poster Session C**Session Time:** 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is an autoimmune disease characterized by synovitis and periarticular bone erosion. Bony erosions and cell necrosis might lead to a local increase in the concentration of extracellular calcium. We have shown in previous studies that increased extracellular calcium activates the Nlrp3 inflammasome of monocytes. Aim of the study was to evaluate the contribution of extracellular calcium to the pathogenesis of rheumatoid arthritis.

Methods: Monocytes from 42 RA patients fulfilling the EULAR/ACR 2010 diagnostic criteria and from 24 age-matched controls were isolated from the peripheral blood using magnetic separation (Miltenyi). Monocytes were differentiated into macrophages for 7 days using human serum. Synovial fluid mononuclear cells (SFMC) and peripheral blood mononuclear cells (PBMC) were isolated using density gradient centrifugation. Cells were stimulated with lipopolysaccharide (LPS) and increasing calcium concentrations (0.9-1.7 mM), and cytokine concentrations were determined in the supernatant by ELISA. Th17 cells were expanded in vitro using a co-culture of CD4⁺ T cells and LPS-activated monocytes. Arthritis was induced in 18 DBA/1 mice using collagen (CIA), 5 DBA/1 mice were used as controls.

Results: The ionized calcium concentration is increased in the synovial fluid of RA patients (n=22) compared to control patients with psoriatic arthritis/ankylosing spondylitis (n=16) (1.1 mM vs. 0.95 mM, p=0.0004) while the ionized calcium concentration in the serum is not different. Blood monocytes from RA patients responded with higher IL-1b, IL-1a, IL-18 and TNF production to an increased calcium concentration (1.7 mM) compared to healthy controls. Importantly, RA monocytes already responded to a calcium concentration of 1.1 mM with a high production of IL-1b, IL-1a and IL-18 whereas control monocytes did not produce cytokines in response to this calcium concentration. SFMCs from RA patients produced even more IL-1b in response to calcium compared to the corresponding blood PBMCs. Monocyte-derived macrophages from RA patients also secreted more IL-1b in response to an increased calcium concentration as well as mouse monocytes/macrophages in the collagen-induced arthritis mouse model. Calcium-induced monocytic IL-1b production correlated with the CIA disease score (r=0.704, p=0.001). The in vitro expansion of Th17 cells, which is in part dependent on monocytic IL-1b production, is also increased when a high calcium concentration is present.

Conclusion: The ionized calcium concentration is increased in the synovial fluid of RA patients, and monocytes/macrophages from RA patients and CIA mice respond with a higher cytokine production to ionized calcium which in turn leads to an increased Th17 expansion. This might point to a contribution of ionized calcium in the pathogenesis of RA.

Session Information**Session Date:** Tuesday, October 23, 2018**Session Title:** Rheumatoid Arthritis – Etiology and Pathogenesis Poster III**Session Type:** ACR Poster Session C**Session Time:** 9:00AM-11:00AM

Background/Purpose: Neutrophils are the most abundant cells in synovial fluid, having all the features of activated cells in rheumatoid arthritis (RA), including prolonged cell survival, increased migratory capacity and the ability to produce high levels of inflammatory mediators. MicroRNAs (miRNA) have recently emerged as a new class of modulators of gene expression, regulating inflammation, degradation of extracellular matrix and invasive behavior of the resident cells in RA.

Purpose: 1) to investigate the miRNA expression pattern in rheumatoid arthritis (RA) neutrophils and its contribution to their pathogenic profile and 2) to analyze the effect of specific autoantibodies or inflammatory components and its modulation by biological therapies.

Methods: Neutrophils were isolated from peripheral blood and paired synovial fluid samples of 40 RA-patients and 40 healthy donors. A microRNA array was performed using nCounter technology. Healthy-neutrophils were treated *in vitro* with antibodies to citrullinated protein antigens (ACPAs) isolated from RA patients and TNF- α or IL-6. *In vitro* treatments of RA-neutrophils with tocilizumab (TCZ) or infliximab (IFX) was carried out. Transfections with the pre-miRNAs miR-223, miR-126 and miR-148 were performed in RA neutrophils. DICER silencing using lentiviral transfection in neutrophils was further carried out.

Results: RA-neutrophils showed a global downregulation of miRNAs and genes involved in miRNA biogenesis, alongside with an upregulation of mRNA targets related to survival, migration and inflammation. Decreased levels of miRNAs and DICER correlated with autoimmunity, inflammation and disease activity. ACPAs and TNF- α decreased the expression of numerous miRNAs and their biogenesis-related genes, and increased their mRNA targets. IFX reversed those effects. Transfections with pre-miRNAs-223, -126 and -148a specifically modulated genes regulating inflammation, survival and migration. DICER depletion influenced the neutrophils' inflammatory profile.

Conclusion: 1) RA-neutrophils exhibit a global low abundance of miRNAs induced by autoantibodies and inflammatory markers, and responsible for their pathogenic activation. 2) miRNA biogenesis is significantly impaired in RA-neutrophils and further associated with a deeper downregulation of miRNAs related to inflammation, migration and survival of synovial neutrophils. 3) Biological therapies such as anti-TNF- α restore miRNA levels, minimizing the inflammatory profile of neutrophils. Supported by the Minister of Health (ISCIII, CP15/0158, PI17/01316, PI15/01333, RIER RD16/0012/0015) cofinanced with FEDER funds.

Session Title: Rheumatoid Arthritis – Etiology and Pathogenesis Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The identification of peripheral blood markers of rheumatoid arthritis-associated interstitial lung disease (RA-ILD) may facilitate an earlier diagnosis and provide insight regarding the pathogenesis of this severe disease complication. Antibodies directed against citrullinated fibrinogen (AhFibA) and the α 36-50Cit and β 60-74Cit peptides exhibiting its immunodominant epitopes are associated with radiographic damages in RA but have not been yet studied in RA-ILD. The aim of this study was to characterize the profile of anti- α 36-50Cit and anti- β 60-74Cit subfamilies of AhFibA in RA-ILD.

Methods: Anti-CCP2, AhFibA and their anti- α 36-50Cit and anti- β 60-74Cit subfamilies were assayed by ELISA in a population of RA-ILD (n=75), RA-noILD (n=75) patients and in a control group of idiopathic pulmonary fibrosis (IPF) patients (n=75). RA was diagnosed according to ACR 1987 and/or ACR/EULAR 2010 criteria. ILD status was assessed with High-resolution computed tomography (HRCT) in all the patients.

Results: Using a 98.5% specificity level, anti-CCP2, AhFibA and their anti- α 36-50Cit and anti- β 60-74C its subfamilies were detected in 66%, 65%, 36% and 62% of RA patients, respectively whereas they were not detected in the majority of IPF patients (1%) (Table 1). No significant difference was observed for the sensibility of the different antibodies for the identification of ILD among RA patients. Anti-CCP2, AhFibA and anti- β 60-74Cit titers were significantly lower in RA-ILD patients compared to RA-noILD patients (Table 1) whereas there was a trend for higher anti- α 36-50Cit autoantibodies ($P=0.145$; ns). Within AhFibA positive RA patients, anti- α 36-50Cit were more frequently observed in those having ILD (66% vs 33, $P=0.013$). In addition, anti- α 36-50Cit antibody titers correlated with those of AhFibA only in RA-ILD patients (Figure 1).

Conclusion: Specific qualitative and quantitative profiles of anti- α 36-50Cit and anti- β 60-74Cit auto antibodies subfamilies of AhFibA are associated with the occurrence of ILD in the context of RA.

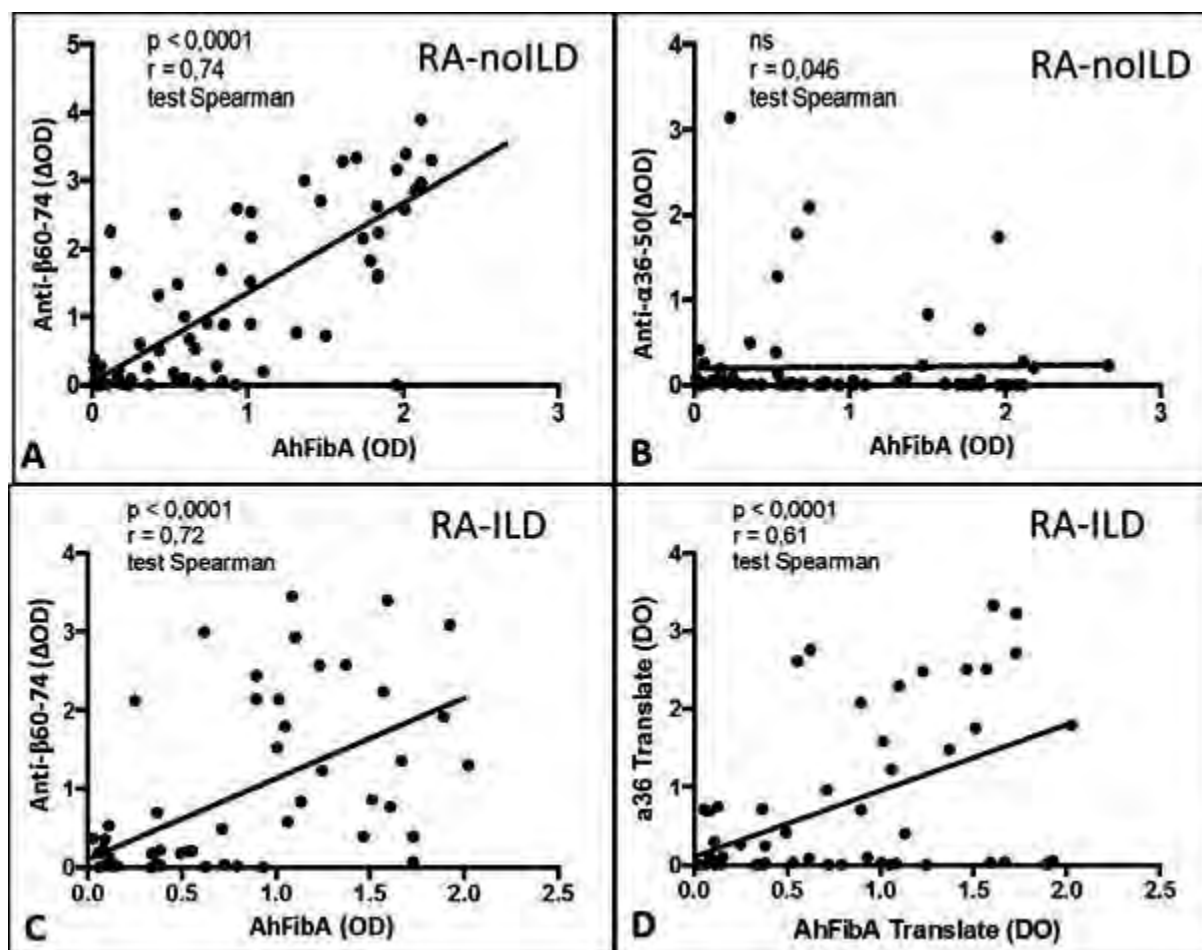

Figure 1. Correlation between AhFibA titers with anti- β 60-74Cit or anti- α 36-50Cit autoantibody titers in RA-noILD population (A and B) and in RA-ILD population (C and D).

Table 1. Distribution of different autoantibodies in the 3 groups (RA-ILD, RA-noILD, IPF). Positivity rate is expressed in number of patients (%), Titers are expressed as median (min-max).

	RA-ILD (n=75)	RA-noILD (n=75)	IPF (n=75)	P value (RA-ILD vs RA-noILD)
Positivity (n,%)				
- anti CCP2	46 (61.3)	53 (70.6)	1 (1.3)	ns

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Etiology and Pathogenesis Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis patients produce a variety of anti-citrullinated protein antibodies (ACPAs) as well as antibodies that bind homocitrullinated and malondialdehyde-acetaldehyde adducted proteins leading to the theory that rheumatoid arthritis antibodies target a range of post-translationally modified proteins. Further, protein modifications may contribute to the loss of immune tolerance in rheumatoid arthritis. However, most rheumatoid arthritis patients also generate antibodies against immunoglobulin G (IgG), called rheumatoid factor (RF), with a high incidence of co-positivity for RF and anti-cyclic citrullinated peptide (CCP) antibodies. While native proteins can be targeted in rheumatoid arthritis, their citrullinated counterparts are often preferentially targeted. IgG is citrullinated in rheumatoid arthritis, but it is not known if native, homocitrullinated, or citrullinated IgG is preferentially bound by autoantibodies. The purpose of this study is to determine if antibodies in rheumatoid arthritis bind to citrulline-containing, homocitrulline-containing, and/or native IgG peptides.

Methods: A high density peptide array was designed to include every possible 12 amino acid peptide in the constant region of the heavy chain of human IgG1, IgG2, IgG3, and IgG4. Serum from control as well as CCP+RF+, CCP-RF+, CCP+RF-, and CCP-RF- rheumatoid arthritis subjects (n=12) was obtained from our biorepository and subjected to the array. Average raw signal intensity for binding of serum IgM and IgG for each category of rheumatoid arthritis subjects was compared to controls to generate a fold increase value for each peptide. Native and citrulline-containing versions of 3 peptides with very high serum IgG binding and also high homology among IgG isotypes were used to detect serum IgG binding for control and CCP+RF+ rheumatoid arthritis subjects (n=40) by enzyme linked immunosorbent assay (ELISA). ELISA results were compared by t test with p<0.05 considered significant.

Results: RF+ subjects (RF+CCP- and RF+CCP+) demonstrate a small elevation in binding of IgM to many native, homocitrulline-containing, and citrulline-containing peptides of the constant region of IgG1, IgG2, IgG3, and IgG4. Serum from the CCP+RF+ group, and no other rheumatoid arthritis group, demonstrated high IgG binding predominantly to citrulline-containing peptides in the constant region of IgG1, IgG2, IgG3, and IgG4. When measured by ELISA, CCP+RF+ subjects had more IgG binding than controls to only 1 of the 3 native IgG peptides, whereas CCP+RF+ subjects had more IgG binding than controls to all 3 of the citrulline-containing versions of the same IgG peptides. Moreover, for the 1 native peptide with increased binding in CCP+RF+ subjects compared to controls, the binding was 3x higher to the citrulline-containing version of that peptide than the native version.

Conclusion: IgG from CCP+RF+ rheumatoid arthritis patients has high binding to citrulline-containing IgG peptides suggesting that rheumatoid factor of the IgG isotype may be an ACPA. These findings support a unified view of autoantibodies in rheumatoid arthritis and may explain how tolerance is broken against IgG.

Session Title: Rheumatoid Arthritis – Etiology and Pathogenesis Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Synovial fluid (SF) provides nutritional support for cartilage and contains numerous catabolic and anabolic cytokines, chemokines and proteins. The precise role of these proteins in joint inflammation and cartilage injury in RA and OA, however, are not well understood. Advances in fluoresce bead based multiplex technology allows the measurement of multiple proteins from volumes < 200 mcL. Easier access to SF can allow investigators to identify patient specific wet biomarkers since most of these key regulatory cytokines in the peripheral blood correlate poorly with those measured simultaneously in the SF.

Table 1: Patient Demographics

	RA	OA
Number of SF Samples	39	13
Number of Patients	26	8
Mean Age	59	64
Gender (F vs M)	19 (73%)/ 7 (27%)	5 (62%)/3 (38%)

Methods: We performed 54 knee aspirations from 26 symptomatic RA and 8 primary OA patients using an external pneumatic compression device and ultrasound guidance. SF was transferred into heparin containing tubes with WBC levels counted by hemacytometer, then samples were centrifuged and cryopreserved within 60 minutes. Levels of 54 separate cytokines/chemokines and proteins were quantitated in batches of 20 using Luminex or ELISA assays. A significant correlation between log-transformed cytokine levels and WBC counts was determined by a $p < 0.05$ using Pearson's product moment between log 10 concentration of specific cytokines and SF WBC levels whereas between group differences was performed using R and SAS programs.

Results: Demographic and clinical features are presented in Table 1. 92% of the OA samples had SF WBC levels < 300 cells/mm³ as did 31% of RA patients. 93% of this RA cohort were receiving prednisone, DMARD or a biologic; yet all had symptomatic knee pain. There was a significant correlation, $p < 0.05$, between all RA and OA patient's SF 10 WBC counts and log concentration of IL-1, IL-1ra, IL-6, MMP-3, MMP 8 and MMP-9 levels, but not with the other cytokines, chemokines, and proteins. Table 2 displays those specific SF proteins which were higher in either RA or OA patients whereas 43 cytokine/chemokine/protein levels did not differ statistically between both groups of patients.

Conclusion: Sufficient SF volumes were obtained using pneumatic external compression and US to measure 54 separate cytokines, chemokines and proteins from cryopreserved samples from all RA and OA patients using multiplex assays. There was a significant correlation between SF WBC levels and 6 different cytokines, chemokines and proteins, but not in 43 others; yet some biomarkers were higher in OA than RA SF samples. Despite SF WBC < 300 levels in OA and well controlled RA patients, the pro-inflammatory catabolic SF profile suggests an ongoing risk for continued cartilage injury.

In Vitro Proof-of-Concept of Pathobiology-Guided Therapy in Immune Mediated Inflammatory Arthritis

Morten Aagaard Nielsen¹, Bent Deleuran^{2,3} and Tue Wenzel Kragstrup^{2,3,4}, ¹Of Biomedicine, Aarhus University, Aarhus, Denmark, ²Department of Biomedicine, Aarhus University, Aarhus, Denmark, ³Department of Rheumatology, Aarhus University Hospital, Aarhus, Denmark, ⁴Randers Regional Hospital, Randers, Denmark

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Etiology and Pathogenesis Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Immune mediated inflammatory arthritis are very heterogeneous diseases including rheumatoid arthritis (RA), psoriatic arthritis (PsA) and spondyloarthritis (SpA). The available biological and targeted synthetic disease-modifying antirheumatic drugs (DMARDs) target very different components of the disease processes. However, how to choose the right treatment for the individual patient is not clear. Characterization of the pathobiological subtypes of immune mediated inflammatory arthritis could provide more specific treatment approaches for each disease. E.g., RA has been proposed to consist of the three synovial phenotypes 1) "lymphocyte", 2) "macrophage", and 3) "fibroblast" and only a subgroup of patients has erosive disease. The objective of this study was to study the effects of different DMARDs on different synovial cell subsets using several human ex vivo models of immune mediated inflammatory arthritis.

Methods: Synovial fluid was obtained from a study population consisting of patients with active rheumatoid arthritis (RA) or peripheral spondyloarthritis (SpA) with at least one swollen joint. The DMARDs used in this study are shown in Table 1. Synovial fluid mononuclear cells (SFMCs) containing primarily synovial monocytes and lymphocytes were cultured for 48 hours (here termed the "*macrophage-lymphocyte model*") and assessed for secretion of monocyte chemoattractant protein-1 (MCP-1) (n=14). Fibroblast-like synovial cells (FLSs) were co-cultured with autologous peripheral blood mononuclear cells (PBMCs) (here termed the "*fibroblast model*") and assessed for secretion of MCP-1 (n=6). SFMCs were cultured for 21 days (here termed the "*osteoclast model*") and assessed for secretion of tartrate-resistant acid phosphatase (TRAP) (n=10). MCP-1 and TRAP were measured by commercially available ELISA kits.

Results: *The macrophage-lymphocyte model;* In SFMCs cultured for 48 hours, all DMARDs except anakinra decreased the production of MCP-1 (all $P < 0.05$). *The osteoclast model;* In SFMCs cultured for 21 days, only the two inhibitors of TNF α adalimumab and etanercept decreased the secretion of TRAP by roughly 25% ($P < 0.01$, $P < 0.001$). *The fibroblast model;* In FLS-PBMC 48 hour co-cultures, only tocilizumab ($P < 0.001$) and the two Janus kinase inhibitors tofacitinib and baricitinib ($P < 0.05$ and $P < 0.05$) decreased the production of MCP-1 by around 50%.

Conclusion: This study reveals differential effects of different DMARDs on different synovial cell subsets using human ex vivo models of immune mediated inflammatory arthritis. Most DMARDs were effective in the "*macrophage-lymphocyte model*", only the two TNF α inhibitors were effective in the "*osteoclast model*", whereas tocilizumab, tofacitinib and baricitinib were superior in the "*fibroblast model*". Studies like this could help guide future studies of personalizing DMARDs to treat immune mediated inflammatory arthritis.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Etiology and Pathogenesis Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is a chronic inflammatory disorder characterized by synovial hyperplasia, progressive joint destruction and the presence of anti-citrullinated peptide antibodies (ACPAs) in sera. Citrullination, a post-translational modification of arginine to citrulline by peptidylarginine deiminase (PAD), contributes to the development of RA. We and others have shown that citrullination can modulate biological roles of key inflammatory molecules in RA. Interleukin 6 (IL-6) is highly expressed in synovial fluids (SFs) and sera of RA patients and plays an important role in RA synovitis. But no information is yet available regarding whether IL-6 is citrullinated in RA.

Methods: Recombinant human (rh) IL-6 was citrullinated by rhPAD4. Liquid chromatography-mass spectrometry (LC-MS) was performed to verify citrullination of IL-6. The role of citrullinated IL-6 (citIL-6) in RA fibroblast-like synoviocytes (FLS) proliferation and migration was determined using the IncuCyte S3 live cell analysis system and scratch wound assays. We performed monocyte (MN) chemotaxis assays using a modified Boyden chamber to examine the effect of citIL-6 on MN migration. To evaluate the arthritogenic properties of citIL-6 *in vivo*, noncitrullinated IL-6 (noncitIL-6) or citIL-

6 was injected into mouse knees and joint circumference was measured at 0 hour and 24 hours after injection. We also identified the presence of citIL-6 and ACPAs against citIL-6 in RA SFs and sera by performing Western blotting and immunodot blot assay, respectively. FLS were stimulated with citIL-6 or noncitIL-6 to examine the phosphorylation of downstream signaling molecules by Western blotting without the addition of exogenous IL-6 receptor (IL-6R).

Results: LC-MS confirmed that all of the arginines in rhIL-6 can be citrullinated by rhPAD4. Both scratch wound assay and live cell imaging analysis showed that FLS proliferation and migration rates were significantly higher in the citIL-6 group compared to the noncitIL-6 group after 24 hours. We also found that citIL-6 induced more MN migration than noncitIL-6 ($p<0.001$). The change in mouse knee circumference with citIL-6 injection was approximately 7-fold higher than that with noncitIL-6 injection (0.90 ± 0.27 mm vs 0.13 ± 0.13 mm; $n=14$; $p<0.05$), indicating that citIL-6 induced much more severe inflammation in mouse knees compared to noncitIL-6. Western blot assays showed that citIL-6 was present in the SFs from RA. Immunodot blot assay showed that sera from RA patients but not healthy controls contained ACPAs react with citIL-6 but not noncitIL-6. CitIL-6, without exogenous IL-6R, upregulated phosphorylation of Erk1/2, Jnk, and Stat3 in RA FLS while noncitIL-6 did not.

Conclusion: IL-6 can be citrullinated by PAD, citIL-6 was present in RA SFs, and citIL-6 ACPAs were present in RA sera. CitIL-6 may play an important role in the pathogenesis of RA by inducing proliferation as well as migration of FLS and recruiting monocytes via a special mechanism that is different from noncitIL-6.

B and T Cell Phenotypes of First Degree Relatives of RA Patients in an Indigenous North American Cohort

Stacy Tanner¹, Christine Zhang², Irene Smolik³, Aaron Marshall² and Hani El-Gabalawy⁴, ¹Rheumatology, University of Manitoba, Winnipeg, MB, Canada, ²Immunology, University of Manitoba, Winnipeg, MB, Canada, ³Arthritis Center, University of Manitoba, Winnipeg, MB, Canada, ⁴University of Manitoba, Winnipeg, MB, Canada

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Etiology and Pathogenesis Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: First degree relatives (FDR) of patients with RA are known to have approximately 4 times increased risk of developing RA and prevalence of RA is increased in Indigenous North Americans (INA) compared to Caucasian populations. To gain insight into immune phenotypes in those with increased risk of developing RA, we phenotyped B and T cell subsets in an INA cohort of FDR, RA patients and healthy controls (HC).

Methods: PBMC's were isolated from FDR's ($n=10$), RA patients ($n=8$) and HC ($n=6$) of INA ethnicity. B cell phenotyping (CD19, CD20, CD27, CD80, CD86, HLA-DR, Ki-67) and CD4 T cell phenotyping (CD3, CD4, CD45RA, CCR7, CXCR5, CXCR3, CCR2, PD-1, ICOS, Ki-67, HLA-DR) was performed by flow cytometry.

Results: FDR's had increased frequency of CD20+27+ B cells (23.1% [IQR 13.8-31.1]) compared to RA patients (10.3% [8.3-12.0]) and seronegative controls (14.4% [9.5-17.9]) shown in Figure 1. The median fluorescence intensity (MFI) of CD27 in FDR was increased compared to HC (1393.5 [IQR1268.1-1530.4] vs 1067.0 [880.5-2334.8]). There were no differences in the expression of CD80, CD86, HLA-DR or Ki-67 amongst memory (CD20+27+) and naïve (CD20+27-) B cell subsets.

Distribution of CD4 T cell subsets (naïve, central memory, effector and terminal effector) between FDR, RA patients and HC was relatively similar. FDRs had double the frequency of PD-1 positive terminal effector memory (TEMRA) cells (9.7% [IQR 2.0-22.6]) compared to HC (4.4% [2.3-7.1]) shown in Figure 2. There was no difference in frequency of CXCR3, CCR2, Ki-67, ICOS or HLA-DR in these subsets amongst FDRs, HCs and RA patients.

Because CXCR5/PD-1+ and CXCR5+/PD-1+ CD4 T cells are efficient in B cell stimulation, we also explored frequency of these T peripheral helper (Tph) and T follicular (Tfh) subsets amongst FDR, HC and RA patients. The Tph subset in the RA patients demonstrated increased ICOS (31.1% vs. 8.5%), Ki-67 (14.1% vs 5.5%), CCR2 (29.2% vs 22.0%), and HLA-DR (13.1% vs 8.0%) compared to FDR's. All participants had similar frequencies of circulating Tfh and Tph subsets.

Conclusion: We found increased frequency of circulating memory B cells in the FDR population compared to unrelated controls. Whether these memory B cells are autoreactive in nature is not yet known. Increased PD-1 positive TEMRA

cells in the FDR population, similar to the RA patients, suggests ongoing antigen experience and CD4 T cell activation in this group of people. Further characterization of regulatory mechanisms which prevent this high-risk group from developing autoimmune disease will be important in understanding the balance between pre-clinical autoimmunity and autoimmune disease.

Session Title: Rheumatoid Arthritis – Etiology and Pathogenesis Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid factors (RFs) are associated with disease activity and joint damage in rheumatoid arthritis (RA) and thought to play a pathogenic role in disease. RFs have been measured for decades by nephelometry and/or solid-phase immunoassay, but these techniques are unable to resolve RF immunoglobulin heavy-chain variable (IGHV) composition at the level of the serum proteome. Here, we have performed the first quantitative mass spectrometry (MS) analysis of serum (secreted) IgH-RF repertoires in RA patients and reveal dynamic patterns of RF production after treatment.

Methods: Serum IgM-RFs from 16 patients with RF-positive newly diagnosed RA were purified by immunoprecipitation (1). IgH-RF V-region peptides were sequenced by LC-MS/MS followed by combined *de novo* amino acid sequencing and database matching using Peaks 8.0 software to determine IGHV composition. Full-scan multiple reaction monitoring (MRM) was used to quantitate expression of individual IGHV sub families in paired serum samples at baseline and after 6 months of tDMARD (n=9) or TNFi (n=7).

Results: High resolution MS sequencing of serum IgH-RFs demonstrated shared germline-encoded oligoclonal patterns with convergent usage of IGHV1-3, 1-69, 3-15, 3-23, 3-64,3-7, 3-74, 4-34, and 5-51 subfamilies, although each patient had an individual IgH-RF peptide expression landscape. Six-month serum RF levels were decreased in 15/16 patients by routine nephelometry and correlated with falling IgH-RF expression levels by MRM/MS ($P < 0.05$ by Spearman rank). Molecular profiling of IgH-RFs by MS proteomics revealed that RF responses in each patient comprised two clonal populations: treatment-responsive (classified as a reduction of $>30\%$ in expression levels), and treatment-resistant (classified as steady, an increase of $>30\%$, or newly emergent) (Figure). Commensurate with global reductions in RF levels after treatment, responsive IgH-RF clones comprised over 2/3rds of the RF clonal repertoire. On the other hand, patients co-expressed sizable numbers of resistant IgH-RF clones indicating molecular heterogeneity of RF responses.

Figure. Responsive (—) and resistant (---) IgH-RFs post-tDMARD

Newly emergent (de novo) clonal populations in treated patients were encoded by IGHV3 subfamilies not expressed at baseline.

Conclusion: RF production in RA is a dynamic, oligoclonal process comprising shared sets of IGHV subfamilies across unrelated patients. While most IgH-RF clonal populations are reduced by conventional therapies, the finding of resistant IgM-RF clones may reflect their production in protected niches in joints or tissues; or differences in selection and clonal expansion by immune complexes. MS-based quantitative proteomics of serum RFs offers a powerful approach for molecular characterisation of these prototypic diagnostic and pathogenic biomarkers in RA.

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Etiology and Pathogenesis Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: We have previously reported in patients with RA abnormal inflammatory T cell responses to an E. coli peptide (dnaJP1) which shares homology with the HLA “shared epitope” as well as with human heat shock protein dnaJ. We hypothesised that these abnormal immune responses are part of pathogenesis, as they may lead to an imbalance in the microbiome and a consequent loss of systemic immune tolerance, through a multistep molecular mimicry mechanism. In an ongoing clinical development program, in which we have completed Phase I and IIa clinical trials and are approaching Phase IIb, we have shown that induction of immune tolerance to dnaJP1 results in clinical improvement in RA and thus represents a promising therapeutic intervention, conceptually similar to the induction of tolerance to an antigen in allergy. Here, we employed a combination of high dimensional cytometry and ngRNA sequencing approaches to dissect the mechanisms associated with clinically relevant induction of immune tolerance.

Methods: Peripheral Blood Mononuclear Cells (PMBCs) were obtained at the end of the Phase II trial (Day168), from clinical responders treated with dnaJP1 (n=6) and clinical non-responders treated with placebo (n=10). The T cell compartment was studied by flow cytometry using specifically designed antibody panels. Flow cytometry results were then analysed by clustering with Multi-Dimensional Automated Reduction and Visualization (MARVis). PD-1 positive and negative Tregs, and Teff were sorted viable and subject to NGRNA seq, which was analysed by gene ontology.

Results: Analysis of the T cell immunomes of dnaJP1 responders and placebo non-responders revealed a subset of CD4+FoxP3+ regulatory T (Treg) cells exclusively in dnaJP1 responders that displayed a higher expression of the inhibitory immune checkpoint receptor, PD-1. The expression of PD-1 contributes to an enhancement of the tolerogenicity of this Treg cell subset by upregulating the production of signature anti-inflammatory cytokines such as TGFβ. In addition, we observed a corresponding reshaping of the effector T (Teff) cell compartment in which the expression of pro-inflammatory cytokines such as IL-17A and IFNγ was downregulated. Importantly, epitope-specific immunotherapy also induced a subset of active antigen-experienced memory T cells (CD4+CD45RO+CD69+) which sustains the tolerogenic immune response by secreting TGFβ. Strikingly, ngRNAseq data confirmed a dichotomous effect of therapy on Treg and Teff subsets, with a prevalence of inflammatory pathways in PD1- Treg, including TNFα production, while, conversely, PD1+ Treg were bona-fide tolerogenic. Teff in RA patients who responded to therapy were characterised by a prevalence of memory and pro-apoptotic pathways.

Conclusion: Our data suggest the presence of a “molecular rheostat” between inflammation and tolerance, which pivots on an unique subset of Treg cells in which the immune checkpoint protein, PD-1 is switched on by the immune therapy.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Etiology and Pathogenesis Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Infiltration of the synovium by mononuclear cells, including monocytes, is one of the main features of RA. Monocytes are the first immune cells which migrate from blood to the site of inflammation leading to tissue destruction due to enhanced pro inflammatory cytokines secretion and overall RA development. It has been shown that abnormalities in miRNA expression are related to inflammatory molecules production by mononuclear cells, however miRNAs have never been fully analysed in monocytes population. The aim of this study was to explore global miRNA and transcriptomic profiling of monocytes from RA patients to predict which aberrantly expressed miRNA can negatively modulate inflammatory molecules.

Methods: Total RNAs from CD14+ monocytes of 12 RA and 10 healthy control (HC) were isolated. The samples were barcoded using Small-RNA-Library-Set for miRNA and simultaneously for RNA-Seq transcriptomic profiling using Illumina HiSeq 2000 platform. Hierarchical clustering was performed to select upregulated miRNAs and significantly downregulated transcripts which are predicted to be the putative target gene of miRNAs. Following computational analysis, selected miRNAs-mRNA candidates were validated using qPCR. Finally, the miRNA candidate was correlated (using Spearman analysis) with clinical parameters including DAS28.

Results: Using next generation sequencing (NGS), we received 10 million reads from each sample. Following computational analysis, we selected 14 specific miRNA candidates which are predicted to target inflammatory mediators out of 188 significantly changed miRNAs in RA monocytes vs HC. Based on the highest scoring in terms of negative correlation ($r = -0.97$, $p = 1.7e-07$, $FDR = 0.04$) and the number of seed regions of miRNA ($n = 5$) binding with the 3'UTR of mRNA, we selected miRNA-146b-3p and its target gene anti-inflammatory retinoic acid receptor alpha (RARA) transcript. In addition, miRNA-146b-3p was 1.12-fold upregulated ($p = 0.02$) compared to HC monocytes. Similarly to NGS studies, qPCR analysis confirmed significantly increased expression of miRNA-146b-3p in RA vs HC monocytes (3.2-fold, $p = 0.01$) and negative correlation between miRNA-146b-3p and RARA expression ($r = -0.39$, $p = 0.031$). In addition, both NGS and qPCR analyses demonstrated negative correlation between miRNA-146b-3p expression and DAS28 score ($r = -0.75$, $p = 0.009$ and $r = -0.62$, $p = 0.034$, respectively).

Conclusion: We have identified a new miRNA candidate miRNA-146b-3p which is predicated to negatively regulate anti-inflammatory RARA transcript that may elucidate an increased inflammatory phenotype of RA monocytes. Supported by 2015/16/S/NZ6/00041 from National Science Centre, Poland and EMBO ST Fellowship.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Etiology and Pathogenesis Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis(RA) is characterized by the presence of auto antibodies like rheumatoid factor (RF), anti-cyclic citrullinated peptide-2 (anti-CCP2), & anti-carbamylated protein (anti-CarP) antibodies. It is currently unclear whether changes in auto antibody levels are associated with disease activity/treatment outcomes and whether they are modified by treatment intensity. Therefore, we investigated whether RA-autoantibody levels associate with disease activity and are affected by treatment intensity.

Methods: In 381 seropositive RA patients in the IMPROVED study¹, we measured at 4 month intervals over the first year of treatment: IgG, IgM, and IgA of anti-CCP2 and anti-CarP, IgM and IgA of RF, and auto antibodies against 4 citrullinated and 2 acetylated peptides. Following initial prednisone and methotrexate (MTX), treatment was escalated or tapered every 4 months according to whether disease activity score<1.6 had been reached. Using generalised estimating equations we investigated whether 1) baseline levels or changes in levels were associated with EULAR response at 4 and 12 months (after correction for baseline determinants), and 2) medication escalation (versus tapering) was associated with a subsequent decrease in levels.

Results: For all 14 auto antibodies, levels decreased significantly in the first 4 months and then rose until 12 months. Good EULAR response at 4 months was preceded by higher baseline levels(mean levels for anti-CCP2 IgG, a representative antibody: good-responders: 814aU/mL; moderate-responders: 490 aU/mL; non-responders: 643 aU/mL), and good responders decreased more in levels 0-4 months than did non/moderate responders(β of 0-4 month change for anti-CCP2: good-responders: -266 aU/mL; moderate-responders: -190 aU/mL; non-responders: -194 aU/mL). However, after correction for multiple testing, this pattern was only significant for 5/14 antibodies. There was no consistent association between EULAR response at 12 months and autoantibody levels or changes. Despite the lack of association with treatment outcomes, levels for most antibodies dropped following treatment escalation, and rose following tapering of treatment. This was best illustrated by the level decrease following the decision at 8 months to restart prednisone(on top of MTX), and rose if MTX was tapered to drug-free (Figure; significant for 12/14 antibodies after correction for multiple testing).

Conclusion: Changes in RA-associated antibody levels over time do not associate with better treatment response, but instead are a reflection of treatment intensity. This suggests that autoantibody levels are modifiable by currently available therapies, but that modifying levels is in itself of limited clinical relevance.

References: ¹Heimans, AR&T 2016, 18:23.

Figure: Levels in arbitrary units (aU/mL) overtime for four (of fourteen) representative antibodies, separated by whether patients restarted prednisone (red) or tapered MTX to drug -free (blue) at 8 months. Dots indicate raw data; lines indicate estimated marginal means (EMMs) calculated by GEE, adjusted for age, gender, disease duration, & smoking status. $p(\Delta)$ -values refer to the difference in the level change over time (i.e.: slope of the lines). Session Title: Rheumatoid Arthritis – Etiology and Pathogenesis Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis is an autoimmune disease characterized by immune cell infiltration in synovial tissue and progressive bone damage. B cells are abundant in the synovial tissue of a subset of RA patients, where they play critical roles in shaping local RA pathogenesis. The unique microenvironment in RA synovial tissue may drive pathogenic B cell function, but current approaches to interrogate single cells rely on disaggregation of tissue with loss of information about the spatial structure and paracrine interactions between cells. To better understand the role of B cells in RA-driven synovial pathogenesis, we are taking the novel approach of examining RNA signatures of B cells isolated from discrete anatomical areas in synovial tissue using laser capture microdissection (LCM).

Methods: Synovial tissue from RA patients was obtained from arthroplasties and immediately flash frozen in OCT freezing medium. 8 µm tissue sections were prepared under strict RNase free conditions. RA synovial sections were stained with anti-CD20 in the presence of three RNase inhibitors at 4°C. Using a PALM MicroBeam Zeiss microscope, individual B cell were marked and catapulted from the tissue section into a cap with adhesive coating. Targeted qPCR for CD19, CD3 and CD14 was performed to assess the specificity of LCM and RNA integrity numbers (RIN) of samples after LCM were quantitated. RNA sequencing was performed on captured B cells using low input SmartSeq2 methodology.

Results: In the presence of three RNase inhibitors, high quality RNA was obtained after cell capture from synovial tissue (RIN values 6.3 ± 0.4). Targeted qPCR for CD19, CD3 and CD14 showed >600-fold enrichment of CD19 transcript in captured B cells. In contrast, CD3 and CD14 were minimally detected. We performed RNA sequencing of captured synovial B cells (400 B cells, n=3). High sensitivity gene detection was achieved with over 11,000 genes at >1 CPM mapped reads. Compared to sequential sections of whole tissue, we observed higher expression of CD138 and Blimp1 in captured B cells suggesting enrichment for antibody secreting cells. Further examination of differential gene expression revealed higher expression of pro-inflammatory cytokines (IL6 400-fold, IFNγ 39-fold, TNF 10-fold) in captured B cells, suggesting that B cells contribute significantly to the pro-inflammatory synovial microenvironment. In addition, captured B cells had higher expression of CD27 and FCRL4, markers for activated memory B cells.

Conclusion: These data suggest that LCM is a valuable tool to interrogate the transcriptome of discrete cell populations in the synovial target tissue. Ongoing studies are underway to further characterize the impact of anatomical region and neighboring cell interactions on cell function.

Citrullination Is Not a Determinant in the Lack of Tolerance to Peptidylarginine Deiminase 2 and 4 in Rheumatoid Arthritis

Pooja Naik¹, Ryan Davis², Jon T. Giles³, Felipe Andrade⁴ and Erika Darrah⁵, ¹Department of Medicine, Division of Rheumatology, Johns Hopkins University School of Medicine, Baltimore, MD, ²Division of Rheumatology, Johns Hopkins University School of Medicine, Baltimore, MD, ³Columbia University, New York, NY, ⁴Medicine/Rheumatology, Johns Hopkins University School of Medicine, Baltimore, MD, ⁵Department of Medicine/Division of Rheumatology, Johns Hopkins University School of Medicine, Baltimore, MD

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Rheumatoid Arthritis – Etiology and Pathogenesis Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Peptidylarginine deiminase (PAD) 2 and 4 are targets of the humoral response in RA. However, the mechanisms by which these enzymes become immunogenic in this disease are still unknown. In addition to catalyzing the conversion of arginine residues to citrulline in a broad range of substrates, these enzymes also autocitrullinate. Since citrullination is a major determinant in the lack of tolerance to autoantigens in RA, we investigated whether PAD2 and PAD4 may also be part of the anti-citrullinated protein autoantibody (ACPA) response in this disease.

Methods: We determined the prevalence of antibodies against auto-citrullinated PAD2 and PAD4 in 184 patients with established RA. ELISA assays were developed to screen sera from RA patients and healthy controls for reactivity to native and citrullinated PADs. Antibody binding to native and citrullinated PADs was compared and confirmed in blocking experiments. Recognition of native vs. citrullinated PAD at the individual level was plotted and analyzed by linear regression.

Results: Anti-native PAD4 and anti-native PAD2 antibodies were present in 42% and 18.5% of patients in the cohort, respectively. Auto antibodies against PAD4 bound similarly to both the native and citrullinated form such that anti-PAD4 levels against the citrullinated form positively correlated with that against the native form (R square = 0.863; $p < 0.0001$). Only two sera were identified that bound exclusively to citrullinated PAD4. Similar results were obtained for binding of auto antibodies to the native and citrullinated forms of PAD2 (R square = 0.908; $p < 0.0001$), with only four sera exclusively binding to citrullinated PAD2. Pre-incubation of sera with native PAD4 or PAD2 in solution significantly reduced antibody binding to the respective citrullinated protein ($p \leq 0.0001$).

Conclusion: Taken together, this study demonstrates that citrullination is not a major determinant in the breach of tolerance to PAD2 and PAD4 in RA. Although PADs are necessary for the production of ACPAs, the data suggest that anti-PAD autoantibodies and ACPAs are likely driven by distinct pathogenic mechanisms.

Session Title: Rheumatoid Arthritis – Etiology and Pathogenesis Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: 1) To identify and characterize the alterations present in the splicing machinery in leukocyte subsets of Rheumatoid Arthritis (RA) patients, and 2) To evaluate their influence on the activity of the disease and its atherothrombotic profile.

Methods: The study was conducted in monocytes, neutrophils and lymphocytes purified from 74 RA patients and 29 healthy donors (HD). By using a microfluidic qPCR array, a set of 45 elements of the splicing machinery were evaluated, including the complete major and minor spliceosome components, and splicing factors with potential pathological role. In parallel, extensive clinical/serological evaluation were carried out. Leukocyte subsets from RA patients were transfected with expression plasmids of selected splicing components, and their effects on cell activity were evaluated. Lastly, leukocyte subsets from HD were incubated with serum from high-activity RA patients and changes promoted in splicing machinery and leukocytes activity were assessed.

Results: A global reduction of spliceosome components in the three leukocyte subsets from RA patients was observed, except for a key minor spliceosome component, RNU4ATAC, which was consistently over-expressed. The levels of those altered components were associated to ACPA positivity, disease activity, and radiological involvement. Correlations with inflammatory mediators, oxidative stress markers and netosis were also demonstrated. Interestingly, eight spliceosome components, including two small nuclear RNA (snRNU) of the major spliceosome (RNU1, RNU5 and U2AF2), the snRNA of the minor spliceosome, RNU4ATAC, and the splicing factors RBM3, RBM17, KHDRS1 and SRSF10 were simultaneously altered in the three leukocyte subtypes. Logistic regression and ROC analyses, including the eight spliceosome components simultaneously altered, identified several signatures as biomarkers of specific RA disease features, being able to: i) discriminate between RA patients and HD; ii) classify patients with high disease activity (DAS28>5.1); iii) recognize patients with radiological involvement; and iv) identify patients showing atheroma plaques.

Mechanistic *in vitro* studies demonstrated the involvement of several spliceosome components in the altered inflammatory profile of RA leukocytes. Likewise, splicing machinery was deregulated by effect of inflammatory/autoimmune mediators present in the serum of RA patients with high disease activity.

Conclusion: 1) We have identified specific alterations in the splicing machinery of leukocytes from RA patients, associated with the activity of the disease, as well as with its inflammatory and atherothrombotic profile. 2) Several signatures involving common altered components of the spliceosome in leukocytes subsets may be used as novel biomarkers for the typification of the disease, avoiding complementary ultrasound or radiological tests. 3) The altered expression of the splicing machinery in leukocytes of RA patients might derive from their autoimmune and proinflammatory profile, which might, in turn, contribute to the clinical shape of the disease.

Session Date: Tuesday, October 23, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Basic Science Poster

Session Type: ACR Poster Session C

Background/Purpose: Psoriatic Arthritis (PsA) affects up to 30% patients with psoriasis and is characterized by wide spread synovio-entheseal inflammation. Physiologically, the human gut microbiota metabolizes dietary fiber into short-chain fatty acids (FA)- which exert anti-inflammatory effects by increasing activity of regulatory T cells (Tregs). Moreover, we have previously shown decreased abundance of *Akkermansia* and *Ruminococcus* and concomitant decrease in medium-chain FA (MCFA) levels in stool of PsA patients. We therefore hypothesized that FA supplementation may have favorable effects on gut microbiome and lead to increase in tolerance, potentially serving as therapeutic target in psoriatic disease.

Methods: Wild type (WT) animals were fed SCFA-rich diet for 14 days followed by 16S rRNA sequencing and microbiota analysis of pellet specimens. We then evaluated effects of MCFA-rich diet in healthy subjects. Peripheral blood and stool samples were collected at days 0, 7 and 14 for 16S rRNA sequencing and FACS. Finally, we conducted a small, prospective, proof-of-principle study in new-onset, drug-naïve psoriatic disease patients (with or without PsA). Each participant received MCFA (1 gm 4 times a day for 6 weeks). Clinical history was obtained at baseline. Skin and joint exam were performed at baseline and follow up. Serum and stool samples were collected at baseline, weeks 3, and 6 for 16S rRNA sequencing and FACS, respectively. Wilcoxon signed-rank test was used to compare differences in Tregs before and after MCFA-rich administration.

Results: SCFA rich diet in WT mice led to statistically significant perturbations in gut bacterial composition 14 days into intervention, with a dramatic increase in commensals (Fig 1A; $p < 0.001$), most notably in *Akkermansia* (Fig 1B). MCFA administration to healthy subjects ($n=7$) also led to significant changes in community structure (Fig 2A; $p=0.03$) and associated increases in circulating Treg cells (Fig 2B; $p < 0.001$). These findings were also observed in psoriatic disease

Figure 1. WT animals stool analysis showing significant alterations of microbiota from day 1 to day 14. (A) Beta diversity plot before and after SCFA administration in WT animals (color coded). (B) Expansion of Akkermansia and Bacteroides on day 14 of SCFA rich diet. DD = Day 1, D7 = Day 7, D14 = Day 14.

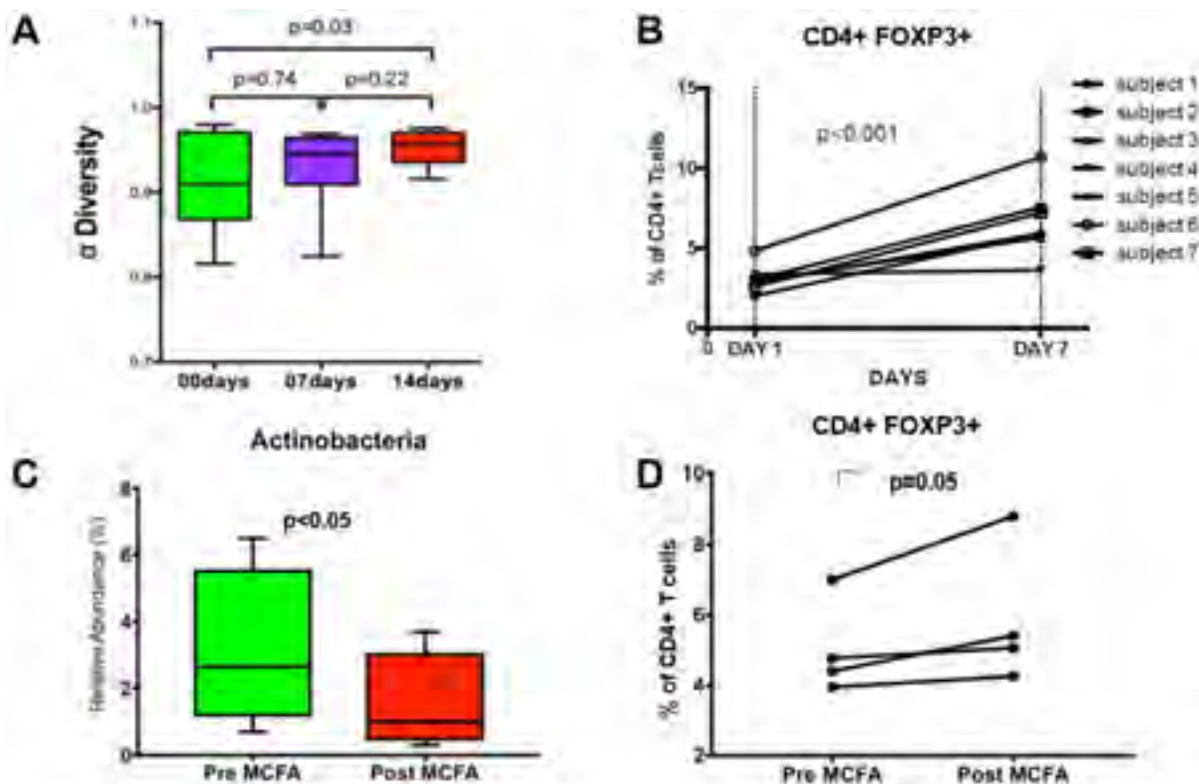

Figure 2. After administration of MCFA in healthy subjects, (A) Changes in α diversity from day 0 to day 14 (p value < 0.05) (B) increased Tregs measured by expression of FoxP3. Psoriatic disease patients after MCFA administration shows (C) decrease in Actinobacteria and (D) increase in Tregs

patients (n=4) showing a significant alteration in specific taxa, including *Actinobacteria* (Fig 2 C; $p<0.05$) and *Mollicutes* ($p=0.09$) and concomitant increase in circulatory Treg cells (Fig 2D)

Conclusion: In both health and psoriatic disease, MCFA supplementation is associated with distinct changes in human gut microbiota composition and peripheral Treg cells. These findings rationalize the need for a larger placebo controlled, prospective trial to study the effects of MCFA in patients with psoriasis and PsA as a potential therapy alone or in combination with DMARDs.

Session Date: Tuesday, October 23, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Basic Science Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The IL-17 axis has been identified as a central pathway in SpA pathogenesis. Targeting this axis in AS and PsA significantly suppresses inflammation and stops bone and cartilage destruction. Retinoic acid receptor related orphan receptor gamma t (ROR γ t) is a transcription factor required for differentiation of IL-17-producing T cells and innate immune cells. We studied the therapeutic effect of a small molecule ROR γ t antagonist on a validated animal model of SpA (*Front Immunol* 2017;8:920).

Methods: Thirty male Lewis rats transgenic for HLA-B*2705, human β 2 microglobulin, and deficiency of the gene *Dazl* (21-3x283-2x17-9, *Arthritis Rheum* 2012;64:2518), 61-90 d old, were injected i.d. with 90 μ g heat-inactivated *M. tuberculosis* in IFA. Starting on d 25, rats were divided into three matched groups and treated with (1) ROR γ t inhibitor, 100 mg/kg daily p.o., (2) vehicle only daily p.o. (disease control), or (3) mAb anti-rat IL-17, 15 mg/kg i.p. twice weekly (treatment control). Clinical measurements included weight, visual scores for arthritis and spondylitis, and hind paw volume by plethysmometry. After 5 wks of treatment, rats were sacrificed for cytokine analysis, skeletal μ CT imaging and histology.

Fig. 1. Hind paw volumes(Δ vehicle only; \circ drug; \square anti-IL-17)

Results: All rats developed ankle swelling and tail spondylitis by d 25. Both ROR γ t inhibitor and anti-IL-17 significantly suppressed arthritis severity and bone damage in the arthritic ankle, compared with vehicle alone (Figs. 1, 2). Additionally, both ROR γ t and IL-17 inhibition were able to reduce damage in the axial skeleton (caudal spine) and in the paws, as measured by μ CT (Fig. 3) and histology.

Fig. 2. Arthritis scores(4 paws)

Fig. 3. μ CT of R tarsus after 5 wk of treatment

Conclusion: The ROR γ t antagonist significantly suppressed clinical signs of arthritis in both the peripheral and axial skeleton in Mtb-induced SpA in B27/h β 2m TG rats. This finding was verified by both μ CT and histologic evaluation of ankle and spine at study termination. These data provide evidence that inhibition of ROR γ t has potential clinical benefit for treatment of spondyloarthritis.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Basic Science Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid Arthritis (RA) and Psoriatic Arthritis (PsA) are chronic joint conditions characterised by persistent inflammation of the synovial tissue (ST). Previous reports suggested less marked synovial lining and fewer infiltrating T cells in PsA compared to RA. Several confounders such as disease duration, treatment, sampling techniques and a predominance of large joints samples may have influenced these findings. Here we aimed at comparing the synovial features of RA/PsA early in the disease and prior to treatment intervention to highlight their histologic and molecular individual characteristics.

Methods: 183 consecutive patients with early (<12 months) treatment-naïve arthritis and active synovitis of at least one joint were recruited as part of the multicentre Pathobiology of Early Arthritis Cohort (PEAC) at the Barts Health NHS Trust and underwent a baseline US-guided synovial biopsy of an actively inflamed joint. ST inflammatory infiltrate was evaluated by H&E and semi-quantitative score (0-4) of the immunostaining for CD68 (macrophages), CD3 (T cells), CD20 (B cells) and CD138 (plasma cells). Patients were classified as: Pauci-immune, CD68 sublining (SL)<2 and/or CD3-CD20-CD138<1; diffuse-myeloid, CD68SL>2, CD20<2 or CD138<2; lympho-myeloid, CD20>2 or CD138>2. RNA sequencing was performed on 93 RA/15 PsA patients.

Results: 144/183 patients met the 2010ACR/EULAR criteria for RA and 39/183 were diagnosed with PsA (32 polyarticular 7 oligoarticular). PsA patients were significantly younger than RA. Comparison of the age-adjusted clinical variables at baseline showed no significant differences between ESR, CRP and DAS28, despite a significantly higher number of tender and swollen joints in RA. ST was retrieved from small joints in 74.4% of PsA and 82% of RA. US score of the biopsied joints showed a significantly higher synovial thickening in the PsA group and comparable power-doppler. Histopathology assessment showed a significantly lower infiltration of B/T lymphocytes, plasma cells and SL-macrophages in psoriatic synovitis. The distribution of synovial pathotypes also differed, as the pauci-immune was the most represented in PsA (43.2%) but the least frequent in RA (24.8%). Only in RA, the pauci-immune pathotype associated with significantly lower ESR, CRP and DAS28 in comparison with lympho-myeloid; these differences remained significant also in a subset of 26 RA subjects age- and gender-matched with PsA patients. Conversely, pathotypes did not define less active disease in PsA. Cellular gene modules analysis showed the expression of neutrophil, eosinophil and mast cell gene-sets in PsA but not RA pauci-immune synovitis. Overall, PsA ST differed from RA with a higher expression of the skin fibroblasts, eosinophils and neutrophils gene-sets. Finally, genes significantly up-regulated in PsA clustered in specific modules including neutrophil recruitment/enrichment and cytoskeleton remodelling.

Conclusion: The demonstration of specific histological and molecular signatures relating to early-untreated PsA and RA will help to shed new light on disease pathogenesis and identify novel therapeutic targets.

Session Date: Tuesday, October 23, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Basic Science Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Ankylosing spondylitis is a chronic inflammatory disease characterized by inflammation of the sacroiliac joints and the spine leading to significant immobility. A subset of patients develops systemic organ involvement including uveitis, interstitial lung fibrosis, and cardiac manifestations. The etiology and pathogenesis of ankylosing spondylitis are incompletely understood, though most patients carry the *HLA-B*27* allele. The objective of this study was to evaluate DNA methylation changes in ankylosing spondylitis with the goal of revealing novel mechanistic insights into this disease.

Methods: Genome-wide DNA methylation analysis was performed in whole blood DNA samples using the Infinium MethylationEPIC array in patients with ankylosing spondylitis compared to age, sex, and ethnicity matched controls with osteoarthritis as a non-inflammatory disease control. We studied 24 patients with ankylosing spondylitis, including 12 patients who carry *HLA-B*27* and 12 patients who are *HLA-B*27* negative. DNA methylation analysis was performed using ‘minfi’ and ‘betareg’ in R environment, and differential DNA methylation was conducted following extensive quality control steps using beta regression with adjusting for technical co-variates as well as blood cell composition in each sample.

Results: We identified a total of 68 differentially methylated sites between ankylosing spondylitis patients and osteoarthritis controls. Of these 31 were hypomethylated and 37 were hypermethylated, representing 21 and 30 genes respectively. Hypomethylated genes found included *HCP5*, which encodes a lncRNA within the MHC region, previously associated with genetic risk for psoriasis and toxic epidermal necrolysis, the transcription factor gene *POU5F1*, *CHD5* which encodes a member of the chromodomain helicase DNA-binding protein family, *PON1* which encodes a member of the paraoxonase enzyme family, and the RAS-signaling related gene *RRAS2*. Hypermethylated genes include GTPase-related genes such as *ARHGAP6*, *RAB11FIP3*, *TBC1D3H*, *TBC1D1*, and *TBCD*. Both *HCP5* and *POU5F1* were hypomethylated in *HLA-B*27* positive compared to *HLA-B*27* negative ankylosing spondylitis patients.

Conclusion: A genome-wide DNA methylation analysis in patients with ankylosing spondylitis found DNA methylation patterns that could provide potential novel insights into this disease. While most DNA methylation changes observed between patients and controls were not dependent upon *HLA-B*27* status, two of the most hypomethylated loci in ankylosing spondylitis were directly linked to *HLA-B*27* positivity. Our findings suggest *HLA-B*27* might play a role in ankylosing spondylitis in part through ‘epigenetic linkage disequilibrium’ inducing epigenetic dysregulation.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Basic Science Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Cardiovascular (CV) disease (mainly due to accelerated atherosclerosis) is one of the main causes of mortality in axial spondyloarthritis (axSpA). The higher incidence of CV risk factors and systemic chronic inflammation increase CV risk in axSpA.¹ This is further enhanced by dysregulated production of adipokines, molecules with key metabolic and immunomodulatory functions. In this regard, low levels of circulating omentin-1, an anti-inflammatory adipokine, have been associated with metabolic dysfunction and CV disease in general population and other conditions different from axSpA.^{2,3} Therefore, the aim of this study was to evaluate the potential role of omentin-1 as a prognostic marker of CV disease in axSpA by assessing its association with subclinical atherosclerosis and CV risk factors in a large cohort of patients, both at the serological and genetic level.

Methods: 299 patients that fulfilled the Assessment of SpondyloArthritis international Society (ASAS) classification criteria for axSpA⁴ and 84 controls were recruited for this study. Clinical data was retrieved from medical records. Serum omentin-1 levels were assessed by ELISA. Carotid US was performed to evaluate the presence of subclinical atherosclerosis. One polymorphism of the gene coding Omentin-1 (*ITLN-1* rs12409609), previously associated with coronary artery disease, was genotyped by TaqMan probes. Statistical analysis of the data was performed using STATA® v. 11.1, adjusting the results by potential confounding factors.

Results: Serum omentin-1 levels were significantly lower in axSpA when compared to controls ($p=0.0001$). Additionally, serum omentin-1 negatively correlated with body mass index ($p=0.002$) and atherogenic index ($p=0.009$) in axSpA. Interestingly, axSpA patients with inflammatory bowel disease exhibited lower omentin-1 serum levels when compared to patients not displaying this extra-articular manifestation ($p=0.005$). Neither serum omentin-1 levels nor *ITLN-1* rs12409609 showed statistically significant association with markers of subclinical atherosclerosis. Likewise, *ITLN-1* rs12409609 did not disclose a statistically significant association with omentin-1 serum levels.

Conclusion: Serum omentin-1 is linked to obesity and adverse lipid profiles in axSpA. Additionally, serum levels of this molecule are associated with the presence of inflammatory bowel disease in axSpA. These data support a role of omentin-1 as a CV risk biomarker in axSpA.

Early Injection of TNF Inhibitor Prevents Spinal Inflammation and Deformity in Curdlan-Induced Spondyloarthritis Animal Model

Doo-Ho Lim¹, Eun-Ju Lee², Seokchan Hong², Yong-Gil Kim², Chang Keun Lee² and Bin Yoo², ¹Division of Rheumatology, Department of Internal Medicine, University of Ulsan College of Medicine, Ulsan University Hospital, Ulsan, Korea, Republic of ^{South}, ²Division of Rheumatology, Department of Internal Medicine, University of Ulsan College of Medicine, Asan Medical Center, Seoul, Korea, Republic of ^{South}

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Basic Science Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: TNF inhibitors are highly efficient in controlling disease activity and improving functional outcomes as well as quality of life in most ankylosing spondylitis patients; however, TNF inhibitors are not sufficiently effective for preventing the progression of consequent spinal damage. Recent clinical studies have shown that early control of disease by using TNF inhibitors prevents spinal damage. This study aimed to investigate the effect of early TNF inhibition on spinal inflammation in murine model of spondyloarthritis.

Methods: We injected curdlan in SKG mice at 8 weeks of age (curdlan group), and administered adalimumab (10 mg/kg) at 3 and 9 weeks after curdlan injection (ADA group). Clinical score of peripheral arthritis was evaluated, and serum cytokines were analyzed at 8 and 14 weeks after curdlan injection. T cell population in the spleen was measured by flow-cytometry. Spinal inflammation and cartilage destruction were evaluated by PET-MRI and histologic examination using H&E and toluidine blue staining. Opal multiplexed immunofluorescence staining for TNF- α , IL-17A, IL-22, and IL-23 was carried out in the spinal tissues at 16 weeks after curdlan injection.

Results: Clinical score of peripheral arthritis was decreased in the ADA group after 1 week of adalimumab injection. Serum levels of TNF- α , IL-17A, IL-22, IL-23, INF-gamma, and IL-6 at 8 weeks showed no significant difference between the two groups. According to splenocytes analysis, frequencies of CD4⁺ T cells, T_H17⁺ cells, and regulatory T cells were not significantly different between the two groups. However, H&E and toluidine blue staining of curdlan group revealed severe inflammatory cell accumulation and intervertebral cartilage destruction in the spinal tissues. ¹⁸F-FDG uptake of thoracic spine level in paravertebral tissue was significantly lower in the ADA group. Also, the densities of TNF- α and IL-17A in immunofluorescent-stained paravertebral tissue were decreased in the ADA group, whereas the serum levels of these cytokines were not significantly different between the two groups at 14 weeks.

Conclusion: Curdlan-induced murine model of spondyloarthritis developed spinal inflammation and consequent cartilage destruction. Early introduction of TNF inhibitor prevented spinal inflammation and deformity in curdlan-induced spondyloarthritis mice via blocking TNF and IL-17A.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Basic Science Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Although human leukocyte antigen (HLA)-B27 is strongly associated with ankylosing spondylitis (AS) and HLA-B27 misfolding induces unfolded protein response (UPR), whether UPR is associated with AS remains controversial. It has been speculated that UPR might occur in more specific immune cells. Since dendritic cells (DCs) are crucial in induction and maintenance of AS in HLA-B27-transgenic rat, and plasmacytoid DCs (pDCs) belong to one type of DCs, we here aim to study the relevance of plasmacytoid DCs (pDCs) in AS and explore if UPR in pDCs contributes to the pathogenesis of AS.

Methods: Peripheral pDCs were isolated from 43 AS patients and 39 controls. The bone marrow (BM) and synovium of inflamed hips from AS patients and controls were obtained. Functional and phenotypic analyses of pDCs and their relationship with UPR was investigated.

Results: We found a significantly higher frequency of pDCs in the peripheral blood, BM and inflamed synovium of hips in AS patients. Functional analysis further revealed that the inflammatory cytokines secreted by isolated peripheral pDCs were significantly increased in AS patients compared with those in normal controls. Remarkably, binding immunoglobulin protein (BIP) and protein kinase RNA-like endoplasmic reticulum kinase (PERK) pathway in UPR were up-regulated in unstimulated pDCs of AS patients. Of note, PERK inhibitor treatment significantly inhibited the enhanced cytokine production by pDCs isolated from peripheral blood of AS patients. Furthermore, the extent of PERK activation was significantly associated with the increased disease severity of AS patients, the increased expression of pDC development marker, FMS-like tyrosine kinase (FLT) 3, and tissue homing marker, chemokine receptor (CCR) 6, of pDCs in AS patients.

Conclusion: Our data uncover that the activation of UPR may occur in pDCs of AS patients. The up-regulated PERK pathway in pDCs not only contributes to the aberrant synovial distribution and enhanced inflammatory function of pDCs in AS patients, but also is associated with systemic disease activity of AS patients.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Basic Science Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Spondyloarthritis (SpA) results in significant pain and loss of function due to inflammation and resulting enthesal/periosteal bone formation. Inhibition of the Janus kinase (JAK)/STAT pathway is being evaluated

clinically as a therapeutic approach in SpA. We studied JAK inhibition in two preclinical models of SpA: the SKG mouse model, in which the IL-23 pathway has been implicated as playing a key role, and rat collagen-induced arthritis (rCIA), an inflammation driven model of bone erosion and aberrant bone formation. In this model, aberrant bone formation increases significantly overtime ⁽¹⁾ and in both models, enthesal/periosteal bone formation is a prominent feature.

Methods: 9-10 week-old SKG mice were injected IP with curdlan at day 0 to synchronize onset of disease. JAKi was delivered beginning at day 0 twice daily by oral gavage for 30 days. rCIA was induced by IP injection of bovine type II collagen in incomplete Freund's adjuvant at days 0 and 6. Treatment with JAKi was initiated at peak inflammation (d17) and continued for 25 days. Clinical and histological scores were used to quantitate inflammation and periosteal/enthesal bone formation was quantitated by histology and microCT. In the SKG model, gene expression at enthesal sites was determined using laser capture microscopy from 2 sites: a reproducible site of periosteal bone formation on the tibia, and inflammatory sites around tail vertebrae at which bone formation did not occur. Whole transcriptome analysis was performed using Affymetrix gene array MTA 1.0.

Results: JAKi suppressed inflammation in both models. Clinical and histologic inflammation scores were significantly decreased by JAKi in SKG mice ($p < 0.05$). Paw volume ($p < 0.001$) and pannus scores ($p < 0.05$) were significantly decreased by JAKi in rCIA. In addition, periosteal/enthesal bone formation at peripheral sites was significantly inhibited in both models by greater than 50% (Figure). In SKG mice, global gene expression analysis of inflamed tissue from entheses identified distinct gene expression patterns at sites of bone formation and sites of inflammation without bone formation. Differentially regulated genes included cartilage and bone markers, such as biglycan and collagen type I alpha 1. IPA upstream regulator analysis identified significant enrichment of major skeletal pathway regulators at sites of periosteal bone formation, including TGF-beta, Wnt3A and AhR, the arylhydrocarbon receptor, implicated in osteoclastogenesis.

Conclusion: Treatment with JAKi suppressed both inflammation and periosteal/enthesal bone formation in two animal models of SpA, accompanied by directed changes in gene expression and activated pathways. These results demonstrate the therapeutic potential of a JAKi in the treatment of SpA, with the possibility of controlling periosteal/enthesal bone formation in these diseases.

Session Date: Tuesday, October 23, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Basic Science Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The measurement of disease activity is mainly dependent on the patient-reported outcome measures in ankylosing spondylitis (AS) patients. Current inflammatory biomarkers have insufficient sensitivity and specificity to assess the disease activity and treatment response, especially after treatment with anti-TNF- α agents. Interleukin (IL)-37 is an anti-inflammatory cytokine, induced by TNF- α , and inhibits the proliferation of Th-17 cells. In AS patients, serum IL-37 level was higher in controls, and associated with CRP level and ESR. We aimed to estimate whether serum IL-37 levels reflect disease activity, and change according to the anti-TNF agent in active AS patients.

Methods: Patients were recruited from the PLANETAS study (NCT01220518). Active AS patients with BASDAI ≥ 4 and visual analogue scale score for spinal pain were ≥ 4 were treated with infliximab originator or infliximab biosimilar, CT-P13. The serum levels of IL-37 were measured at week 0 and week 30 with specific ELISA. Other demographic, laboratory and clinical variables were evaluated simultaneously. Responders were defined as those satisfying Assessment in SpondyloArthritis International Society (ASAS 20/40) response.

Figure 1. Change of Biomarkers After Treatment

Table 1. Change of Biomarkers After Treatment in Non-responders

Variables	ASAS 20 Non-responder (N=15)			ASAS 40 Non-responder (N=21)		
	Baseline	At week 30	P	Baseline	At week 30	P
IL-37 (pg/ml)	189.1 ± 294.2	234.7 ± 170.9	0.40	206.2 ± 278.7	197.3 ± 119.9	0.85
ESR (mm/hr)	34.2 ± 17.9	37.1 ± 16.7	<0.01	39.6 ± 16.3	25.2 ± 12.6	<0.01
CRP (mg/dL)	3.27 ± 4.10	1.39 ± 2.52	0.06	3.01 ± 3.62	1.08 ± 1.99	0.10
BASDAI	6.8 ± 1.2	5.3 ± 1.5	0.31	6.6 ± 1.9	5.0 ± 1.9	<0.01
BASMI	4.3 ± 1.7	4.0 ± 1.7	0.08	4.3 ± 1.7	3.8 ± 1.7	0.02
BASFI	6.8 ± 1.3	6.3 ± 0.9	0.31	6.2 ± 2.2	6.5 ± 1.0	0.04
Patient's Assessment to Pain	69.5 ± 12.1	56.1 ± 22.2	0.08	67.3 ± 13.2	48.3 ± 24.8	<0.01
Physician's Global Assessment	61.1 ± 21.1	56.9 ± 14.9	0.53	60.1 ± 21.1	49.9 ± 19.1	0.06

IL, interleukin; ESR, erythrocyte sedimentation rate; CRP, C-reactive protein; BASDAI, Bath Ankylosing Spondylitis Disease Activity Index; BASMI, Bath Ankylosing Spondylitis Menterology Index; BASFI, Bath Ankylosing Spondylitis Functional Index

Results: Among 250 patients, 50 patients (43 males) agreed to provide their serum samples for further study. The median age of patients was 40 years old (Interquartile range [IQR], 33.8-49.5), and the median BASDAI score was 6.7 (IQR 5.3-7.9). A significant correlation between IL-37 and CRP levels (Spearman's rho $[r]=0.39$, $p<0.01$) and BASDAI ($r=0.31$, $p=0.04$) was observed at the baseline, but not at week 30. When calculating the overall differences (Δ) of parameters between baseline and week 30, Δ IL-37 was correlated with Δ CRP ($r=0.36$, $p=0.02$), Δ BASFI ($r=0.34$, $p=0.02$) and Δ BASDAI ($r=0.32$, $p=0.03$). In ASAS 20/40 responders, all the disease activity markers were significantly improved after 30 weeks of treatment. Notably, most clinical parameters except IL-37 level were decreased in both responders and non-responders. However, there was no change of serum IL-37 level in non-responders. The ROC curves for response revealed that the area under curve (AUC) value for Δ IL-37 (AUC=0.74) was similar to that for Δ ESR (AUC=0.71, $p=0.64$) and superior than that for Δ CRP (AUC=0.54, $p<0.01$).

Conclusion: Serum IL-37 levels correlated with disease activity in active AS patients. Changes in serum IL-37 levels after treatment depends on the clinical response to anti-TNF agents. Further study is required to see if earlier change of IL-37 levels after infliximab infusion can identify patients who are likely to respond to infliximab treatment.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Basic Science Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: A growing body of evidences indicate that the aberrant activation of innate immune systems, occurring in genetically predisposed patients, drives inflammatory processes in Ankylosing Spondylitis (AS). Aim of this study was to evaluate the activation and the functional relevance of inflammasome pathways in patients with AS.

Methods: Intestinal, synovial and bone marrow expression of inflammasome pathways, pyroptosis and IL-1b and IL-18 was evaluated in AS patients. Analysis of organic acid extraction was performed on ileal samples. The expression of the metabolite-sensing receptors GPR43 and GPR109A involved in the regulation of the intestinal inflammasome was also assessed. The role of intestinal dysbiosis in modulating inflammasome activation was also studied in AS patients and HLA-B27 transgenic rats. Inflammasome activation was evaluated in isolated peripheral AS monocytes. The role of LPS, PGE2 and nicotine in inducing monocyte inflammasome activation and the role of inflammasome in modulating IL-23 production and ILC3 expansion was also evaluated.

Results: Activation of inflammasomes was observed in the inflamed gut, synovial and bone marrow samples of AS patients and associated with an increased expression of caspase-1, IL-1b and IL-18. In AS, AIM2 expression was observed in the context of tuft cells and of adherent ileal bacteria. Inflammasome activation in AS gut, was associated with the occurrence of dysbiosis and isolated bacteria from the gut of AS patients induced inflammasome activation on isolated PBMC from healthy controls. Increased pyroptosis was also observed in the gut as demonstrated by the membrane localization of Gasdermin D. Isolated intestinal bacteria from AS ileal samples, significantly modulated inflammasome activation in isolated monocytes. Reduced Short-chain fatty acids concentrations and increased expression of GPR43 and GPR109 were demonstrated in the AS ileal samples. Inflammasome activation was also observed in the inflamed gut of HLA-B27 TG rats and suppressed by antibiotics treatment. Increased expression of NLRP3, NLRC4 and AIM2 was confirmed in AS isolated peripheral monocytes, directly correlated with the ASDAS-CRP, and paralleled by increased serum levels of IL-1b. In in vitro studies, LPS and nicotine strongly activated NLRP3, NLRC4 and AIM2 pathways in AS monocytes. The CC genotype of PTGER4 SNP rs6896969 was associated with a significantly increased activation of inflammasome in AS. Inflammasome activation in AS monocytes was required for the induction of IL-23p19 expression in an IL-1b-dependent way. Finally, inflammasome inhibition blocked IL-23-induced ILC3 expansion.

Conclusion: Inflammasome activation occurs in AS patients and is modulated by a plethora of different tissue-specific and circulating stimuli. Inflammasome drives IL-23p19 production in a IL-1b-dependent mechanism and modulate ILC3 expansion in AS patients possibly representing a future area of therapeutic interventions in AS.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Basic Science Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Angiogenesis is an essential component in the pathogenesis of psoriatic arthritis (PsA). Extracellular matrix metalloproteinase inducer (EMMPRIN) is a multifunctional protein that can enhance angiogenesis by inducing vascular endothelial growth factor (VEGF) and matrix metalloproteinases (MMPs).

Objectives: (a) To assess the concentrations of angiogenic factors in serum of PsA patients in comparison to rheumatoid arthritis (RA) patients and healthy controls. (b) To evaluate the role of EMMPRIN as a mediator of fibroblast-macrophage interactions and angiogenesis in vitro.

Methods: Blood samples were collected from 56 PsA patients with active disease, 41 PsA patients in remission, 33 active RA patients and 33 healthy individuals. Serum levels of EMMPRIN, VEGF, MMP-9, MMP-7, MMP-3, MMP-2, and MMP-

14 were evaluated by Enzyme-Linked Immunosorbent Assay (ELISA). The secreted concentrations of EMMPRIN, VEGF and MMP-9 in a co-culture system of fibroblast (HT1080) and monocyte cell lines (U937 and MonoMac6) were compared to each single cell culture using ELISA. The role of EMMPRIN was demonstrated by the addition of a blocking anti-EMMPRIN antibody to the co-culture. Supernatants derived from single or co-cultures, with or without the addition of anti-EMMPRIN, were applied onto human EaHy926 endothelial cells that were seeded on matrigel® to assess the pro-angiogenic potential of EMMPRIN on tube formation. Statistical analysis: Multiple groups were compared using the one-way ANOVA followed by Bonferroni's multiple comparison post-hoc test, and two groups were compared using the two-tailed unpaired student t test. P values exceeding 0.05 were not considered significant.

Results: PsA patients had significantly elevated levels of serum EMMPRIN, MMP-7, MMP-14 compared to RA patients ($p<0.001$, $p<0.01$ $p<0.01$, respectively) and to controls ($p<0.0001$ $p<0.01$, $p<0.01$ respectively). The levels of VEGF ($p<0.05$), MMP-14 ($p<0.05$), MMP-3 ($p<0.0001$) were higher in PsA patients with active disease compare to patients in remission. MMP-2 levels were significantly higher in both PsA and RA groups compared to controls ($p<0.0001$). Serum concentrations of MMP-9 were significantly lower in RA and PsA patients compared to controls ($p<0.0001$), but no significant difference was noted between the two disease groups.

Secretion of EMMPRIN, VEGF and MMP-9 were synergistically enhanced in the co-culture ($p<0.01$ for the three proteins relative to each of the single cultures). The addition of the blocking anti-EMMPRIN antibody reduced the level of VEGF (1.7-folds, $p<0.001$) and MMP-9 (1.4-folds, $p<0.001$) in the co-culture. Higher number of closed lumens were generated when EaHy926 cells were incubated with supernatants from co-cultured relative to each single culture ($p<0.05$). This number significantly decreased ($p<0.05$) when EMMPRIN was blocked by anti-EMMPRIN antibody.

Conclusion: Our results collectively implicate EMMPRIN as a mediator of fibroblasts-monocytes interactions that regulates angiogenesis, and suggest it may play an important role in the pathogenesis of PsA

Session Date: Tuesday, October 23, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Basic Science Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The NAD⁺-dependent protein/histone deacetylase Sirtuin 1 (SIRT1) acts as an epigenetic regulator and has recently been reported to be involved in the development of murine T_H17 cells. Here, we investigated the role of SIRT1 in polarization of human naïve T-cells in axial Spondyloarthritis (SpA).

Methods: We recruited 23 SpA patients [mean age 45 (±14); 26% female] and 11 healthy controls (HC) [mean age 39 (±11); 55% female]. *In vitro* differentiation of naïve CD4⁺ T cells under T_H17 cell- or regulatory T cell (Treg) polarizing conditions was performed. SIRT1 function was modulated using an inhibitor (Ex-527) or activator (Cay10602) of SIRT1 activity. IL-17 producing Th17 cells, CD25⁺FoxP3⁺ Tregs, and SIRT1 protein levels were measured by flow cytometry.

Results: In SpA patients disease activity measured by Ankylosing Spondylitis Disease Activity Score (ASDAS) correlated positively with T_H17 polarization [$\text{corr}_{\text{coeff}}=0.549$, $p=0.023$], and negatively with Treg polarization [$\text{corr}_{\text{coeff}}=-0.489$, $p=0.064$]. SIRT1 protein levels were higher in SpA patients as compared to HC in naïve CD4⁺ T cells [mean fluorescence intensity, SpA: 1293 (±447) vs. HC: 984 (±410), $p=0.077$] and CD4⁺ memory T cells [SpA: 1528 (±527) vs. HC: 1097 (±510), $p=0.035$].

Modulation of SIRT1 activity with SIRT1 inhibitor (Ex) during T_H17 differentiation in SpA patients decreased the level of T_H17 polarized cells significantly [T_H17: 6.28% (2.89-11.80) vs. T_H17_{Ex}: 3.42 (1.79-8.21), $p\leq0.001$]. Treatment of T_H17 differentiation culture with SIRT1 activator (Cay) showed an enhancing effect on T_H17 polarization [T_H17: 6.28% (2.89-11.80) vs. T_H17_{Cay}: 9.55% (4.17-16.20), $p\leq0.001$].

Conclusion: Our data suggest that the epigenetic regulator SIRT1 is involved in SpA pathogenesis by regulating the potential of naïve T-cells to differentiate towards the T_H17 lineage.

Session Date: Tuesday, October 23, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Basic Science Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: While the exact pathogenesis of psoriatic arthritis (PsA) remains unclear, it is recognised that several environmental factors operate in individuals with genetic susceptibility leading to sustained inflammatory responses. These involve both the innate and adaptive immune system with IL23/IL17 axis playing a central role. One suggested environmental factor is mechanical stress and accordingly, involvement of enthesal sites exposed to maximal biomechanical loading is a common feature of PsA. However, the mechanisms linking mechanical stress/damage at the enthesis/tendon which leads to immune cell activation remains unknown. We aimed to interrogate the role of tendon stromal cells (tenocytes) in the induction of a type 17 response.

Methods: Immunohistochemical staining for CCR6 was performed in paraffin embedded PsA synovial membrane and the presence of CCL20 was quantified in synovial fluid (SF) from PsA and osteoarthritis (OA) patients by ELISA. Healthy tenocytes cultured from hamstring tendons and fibroblast-like synoviocytes (FLS) from PsA patients were stimulated with human IL-1 β (1 ng/ml) and IL-17A (1, 10 and 100 ng/ml). Expression of CCL20 transcript and protein upon stimulation were assessed by qPCR and ELISA, respectively. T cell migration assays were performed with magnetically enriched CD3⁺ cells from peripheral blood of PsA patients and healthy controls using a Transwell system.

Results: We observed an abundance of CCR6 positive cells in PsA synovial membrane and higher levels of CCL20 in SF from PsA patients compared with OA (OA mean \pm -SEM 40.91 \pm -30.06 pg/ml, n=14; PsA 339.5 \pm -100.7 pg/ml, n=39; p<0.0001). Tenocytes were able to upregulate CCL20 transcript (fold change 680.5 \pm -215.2; p<0.0001, n=5) and produce CCL20 (481.8 \pm - 84.26 pg/ml; p<0.0001, n=13), following stimulation with IL-1 β . In this context, the addition of IL-17A induced a synergistic effect with IL-1 β in both tenocytes and PsA FLS. Conditioned media from tenocytes promoted T cell migration.

Conclusion: Activated tendon stromal cells and PsA synovial fibroblasts are able to produce CCL20, a chemokine that binds to CCR6 and is responsible for the recruitment of IL-17 producing cells. In conclusion, our results support a role of the tendon stromal compartment in the development of a type 17 immune response in PsA.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Basic Science Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Psoriatic arthritis is a chronic joint disease clinically associated with psoriasis. Some patients also have signs of inflammatory bowel disease. Enthesitis, inflammation at the attachment sites of ligaments and tendons into the bone, is put forward as key mechanism leading to the clinical manifestations of psoriatic arthritis. One of the leading hypothesis for initiation of disease is that biomechanical stress, together with other initiating factors, plays a role in altering the properties of the anatomic region, thus leading to the development of the disease and its amplification in other compartments of the synovio-entheseal complex.

In this study, we aim to understand early events leading to the onset of psoriatic arthritis, in the presence of distant inflammation in the skin and the intestine.

Methods: Eight-week-old male C57/Bl6 mice were treated with imiquimod cream (IMQ) on a shaved area of the back skin or with dextran sodium sulphate (DSS) dissolved in the drinking water to induce psoriasis-like skin or inflammatory bowel disease-like gut inflammation. Control mice were left untreated. Afterwards, half of the mice were subject to a forced treadmill running protocol to increase biomechanical stress. Control mice with or without IMQ or DSS treatment did not run. Severity of cutaneous or intestinal inflammation was assessed clinically and by histology; knees and paws were evaluated with microCT, histology and immunohistochemistry.

Results: The clinical and histopathologic assessment of skin and intestine sections confirmed that we have successfully induced the two models of inflammation in immune-competent tissues. In both models, signs of systemic inflammation were also present and a significant loss of trabecular bone was indicated by microCT analyses. Signs of synovitis have been detected both for IMQ and DSS protocol, but increased inflammation of the entheses was detected only with the IMQ model. The running protocol appear to affect the joints at the cartilage and the entheseal level.

Conclusion: The presence of cutaneous or intestinal inflammation and the associated bone loss influence the impact of biomechanical stress at the joint level.

Session Date: Tuesday, October 23, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Basic Science Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Non-steroidal anti-inflammatory drugs (NSAIDs) are recommended as first-line drug treatment of spondyloarthritis (SpA) which is frequently associated with inflammatory bowel disease. Biologic disease modifying anti-rheumatic drugs (bDMARDs) should be considered in patients with persistently high disease activity despite conventional treatments. Current recommendation suggests that NSAIDs should only be prescribed if patients are symptomatic due to the potential side effects when administered chronically. However, clinical trial data have suggested that the continuous use of NSAIDs in patients with an elevated CRP results in reduced progression of structural damage in comparison to on-demand use only.

The purpose of this study is to investigate the benefits and harms of NSAIDs when used with bDMARDs on the bony overgrowth and the bowel inflammation in a SpA animal model.

Table 1. Clinical, molecular, and radiologic scores in SKG mice treated with celecoxib and/or etanercept

	Saline (n=8)	Celecoxib (n=9)	ETN (n=14)	Celecoxib+ETN (n=9)
MS score	14.67±2.07	11.11±5.09 (p=0.136)	14±2.94 (p=0.544)	8.25±5.31 (p=0.006)

Tail MPO	5.57E+05±3.5 0E+05	3.58E+05±2.14E +05 (p=0.315)	4.97E+05±2.82E+ 05 (p=0.922)	3.30E+05±2.39E+ 05 (p=0.325)
CT erosion	3.71±2.21	2.13±1.64	6.27±3.97	4.63±4.10
CT osteophyte	5.0±2.0	2.25±1.83	5.27±4.29	1.75±1.39

The numbers shown as mean ± SD. ETN: etanercept. MS: morphology score. MPO: myeloperoxidase. CT: computed tomography. P-value < 0.05 considered significant

Table 2. Clinical and molecular scores of ileitis in SKG mice treated with celecoxib and/or etanercept

	Saline (n=8)	Celecoxib (n=9)	ETN (n=14)	Celecoxib+ETN (n=9)
Ileitis score	2.83±0.75	3.0±1.69 (p=0.254)	4.63±1.41 (p=0.021)	2.75±1.28 (p=0.946)
Bowel length	37.77±5.48	40.54±1.99	42.15±3.39	42.14±3.69
Body weight change	-3.75±1.1	-2.0±0.71	-2.46±0.97	-3.33±0.58
Intestine MPO ROI	1.92E+05±1.36 E+05	2.74E+05±2.60 E+05 (p=0.643)	4.75E+05±3.43 E+05 (p=0.051)	3.08E+05±5.06 E+05 (p=0.728)

The numbers shown as mean ± SD. ETN: etanercept. MPO: myeloperoxidase. P-value < 0.05 considered significant

Table 3. Trabecular and cortical bone mineral densities in SKG mice treated with celecoxib and/or etanercept

	Saline (n=5)	Celecoxib (n=3)	ETN (n=8)	Celecoxib+ETN (n=8)
Cortex BMD	2.01±0.04	1.97±0.02 (p=0.297)	1.87±0.12 (p=0.079)	2.02±0.03 (p=0.884)
Cortex volume	1.02±0.12	1.04±0.09 (p=0.764)	0.93±0.11 (p=0.188)	1.02±0.16 (p=0.942)
Trabeculae BMD	54.74±24.53	82.24±2.59 (p=0.180)	34.16±28.61 (p=0.079)	77.45±55.40 (p=0.770)
Trabeculae volume	0.06±0.03	0.08±0.01 (p=0.227)	0.03±0.03 (p=0.075)	0.06±0.04 (p=0.941)

The numbers shown as mean ± SD. ETN: etanercept. BMD: bone mineral densities. P-value < 0.05 considered significant

Methods: ZAP-70W163C-mutant(SKG) mice were housed under specific pathogen free conditions. All of the mice were injected intraperitoneally with 1,3-glucan (curdlan). Mice were treated with celecoxib and/or etanercept (ETN). Clinical manifestations were scored and the expression of inflammatory molecules were examined. Arthritis, spondylitis, and ileitis were assessed histologically at 8-week experimental end points. A bone mineral density tests (BMD) were conducted as well.

Results: Combination therapy of celecoxib with ETN significantly suppressed the morphology scores(MS) and the infiltration of inflammatory cells in the axial and peripheral joints(Table 1). However, ETN monotherapy did not show any efficacy and celecoxib tended to decrease the disease activity. The expression of myeloperoxidase (MPO) was decreased in peripheral and axial joints by celecoxib but not by ETN. The generation of osteophyte was inhibited by celecoxib but not by ETN in a bone CT. Interestingly, combination therapy of celecoxib with ETN showed an additive effect on the inhibition of new bone formation.

Next, we investigated the effect of celecoxib and ETN on ileitis of the SKG mice(Table 2). Celecoxib did not make any further harmful effects on ileitis, but ETN significantly aggravated the ileitis which was restored with combination therapy with celecoxib. In addition, we looked into a BMD of SKG mice depending on the treatment groups (Table 3). Celecoxib increased BMD while ETN decreased which was compensated by co-use of celecoxib.

Conclusion: These results indicate that celecoxib has beneficial effects on the arthritis, ileitis, and bone mineral density when used with ETN in SKG mice. Further clinical studies are warranted.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Basic Science Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Psoriaticarthritis (PsA) is an inflammatory arthritis occurring in patients with psoriasis. miRNAs are small non coding RNAs whose main function, at a posttranscriptional level, is to modulate the expression of target genes via translation inhibition or mRNA degradation. Several studies have shown links between altered miRNA expression with the pathogenesis of several autoimmune disorders. We demonstrated earlier that miR-21-5p was upregulated in PsA and psoriasis without arthritis (PsC) compared to healthy controls (HC) ($p<0.001$), thus a potential biomarker for PsA. We aimed to determine whether miR-21-5p modulates inflammation in psoriatic disease (PsD = PsA & PsC) through IL-17/IL-23 axis, and determine its role in the treatment response to methotrexate (MTX).

Methods: Serum & whole blood RNA samples were collected from 40 patients with early PsA (<2 years' disease duration and not receiving biologic therapy), 40 patients with psoriasis who have been confirmed by rheumatologist not to develop PsA (PsC >10 years disease duration, not receiving biologic therapy, and matched to PsA patients on age, sex, psoriasis duration, and age of psoriasis onset), and 42 HC(matched to patients based on age, sex). RNA was extracted using the Tempus Spin RNA Isolation Kit. miR-21-5p was validated using droplet digital PCR(ddPCR). miR-21-5p expression was also measured in 30 PsA patients before and after 24 weeks of MTX treatment. Serum levels of IL-17, IL-23, TGFβ1 and CXCL10 were measured by ELISAs from R&D Biosystems kits as per protocols. Descriptive statistics are provided, Spearman correlations were performed.

Results: miR-21-5p was significantly down regulated 24 weeks post-MTX treatment in 30 patients ($p<0.008$), the levels of expression correlated with the actively inflamed joint counts ($r=0.897$, $p<0.0001$). IL-17 levels in PsA & PsC were significantly different from HC ($p= 0.031$), but not different between PsA &PsC. IL-17 levels were down- regulated post treatment and correlated with miR-21-5p ($r=0.559$, $p= 0.0002$), CXCL10 levels ($r=0.485$, $p=0.013$), IL-23 levels ($r=0.429$, $p=0.02$) and negatively correlated with TGFβ1 ($r= -0.449$, $p=0.038$).

Conclusion: In the presence of increased levels of miR-21-5p, IL-17 and IL-23 are upregulated while TGFβ1 is down regulated. When miR-21-5p is decreased IL-17 and IL-23 downregulate, with up regulation of TGFβ1. We have thus determined the role of miR21-5p as a biomarker for inflammation pathway in psoriatic disease and response to methotrexate possibly through modulation of CXCL10 and IL-17. Table 1: Demographic, clinical and relative expression data

Variable	PsA (N=40)	PsC (N=40)	HC (N=42)	P Value
miR-21-5p	122.7 (93.1)	58.5 (36.0)	11.5 (9.6)	<0.001
IL-17	0.5(0.2)	0.5 (0.0)	0.4(0.1)	0.031

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Basic Science Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: MicroRNAs have been shown to play a crucial role during innate or adaptive immune response. Deregulation of miRNAs has been described in several autoimmune or rheumatic diseases including rheumatoid arthritis, inflammatory bowel disease or psoriasis. In spondyloarthritis (SpA), only few studies on miR expression have been reported with highly diverse methodologies and involving small samples of patients. Because T CD4 lymphocytes and monocytes are important cells in SpA pathophysiology, we wanted to assess the miR expression profile in these two cell types sorted from axial SpA (AxSpA) patients.

Methods: Eighty one AxSpA patients were included in this study. Among these patients, 74 fulfilled the ASAS classification criteria (imaging arm) with sacro-iliitis on X-rays (n=56) or objective signs of inflammation on MRI (n=18). Two independent cohorts of 22 and 59 SpA patients were compared to 17 and 38 age and sex-matched controls. Both SpA

patients and controls were recruited from October 2014 to July 2017 in the department of rheumatology at Cochin Hospital in Paris, France. All SpA patients had an active disease despite NSAIDs intake (mean BASDAI score of 49 +/-19 and mean ASDAS score of 3 +/- 0.9), were free of any biologic treatment and were eligible for a TNF-blocker treatment. Seventy-seven percent were HLA-B27 positive. T lymphocytes and monocytes were isolated from PBMC by direct isolation with magnetic microbeads (CD4+ and CD14+). Three-hundred seventy two miRs were screened by q-RT-PCR on the exploratory cohort and only MiRs showing a significant differential expression in the first cohort were analyzed in the validation cohort. An unpaired T-test was used for comparison of miR expression level.

Results: In the exploratory cohort, 51 (CD14+) and 70 miRs (CD4+) were found to be differentially expressed between patients and controls. Among these, 15 miRs (in CD14+), and 12 miRs (in CD4+) were also found deregulated in the validation cohort. These validated miRNAs were found to play a key role in physiological pathways such as NFkB or TGFb, Wnt signalling and monocyte differentiation that have been involved in the pathophysiology of the disease. Neither clinical subphenotypes nor biological parameters were associated with different profiles of miR expression after adjusting for multiple tests. We found a negative correlation between miR-146a-5p level and BASDAI ($r=-0.28$, $p=0.011$) and ASDAS ($r=-0.38$, $p=5.9 \cdot 10^{-4}$) in monocytes.

Conclusion: We found a deregulation of miR expression in monocytes and T CD4 lymphocytes from patients with axial spondyloarthritis, whose consequences could contribute to the pathophysiology of the disease and be of interest for therapeutic perspective. Moreover, identifying biomarkers with the potential of diagnostic signature should help the clinician in daily practice.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Basic Science Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Psoriatic arthritis (PsA) and Psoriasis (PsO) are chronic inflammatory diseases associated with vascular inflammation and increased CVD risk. Few studies have examined vascular inflammatory differences between PsO and PsA and how these differences may impart a different CVD risk profile. We directly investigated the vascular endothelium of patients with PsA, PsO and compared to controls to better understand the inflammatory mechanism(s) that predispose psoriatic patients to CVD risk.

Methods: Twenty patients with psoriatic disease (PD) (mean age 45 years, 55% male, $11.2 \pm 19\%$ body surface area (BSA) involvement) were first compared to 10 matched controls. Next, comparisons were made between PsO ($n = 14$, average age 50 years, 57% male, $11 \pm 22\%$ BSA) and active PsA ($n = 6$, average age 36 years, 50% male, $11 \pm 10\%$ BSA, average 2 – 3 tender/swollen joints per individual). To measure vascular endothelial health, venous endothelial cells were collected from the brachial vein using guidewires inserted through an angiocatheter and isolated with CD146-conjugated magnetic beads. Following collection, endothelial mRNA was isolated, converted to cDNA and inflammatory gene profiling performed by RT-qPCR with Taqman probes and primers. Transcripts were chosen based on *in vitro* gene arrays of human aortic endothelial cells co-stimulated with IL-17 and TNF- α .

Results: PD patients compared to controls showed a trend towards higher levels of hs-CRP (2.4 ± 4 mg/dl vs. 0.8 ± 2 mg/dl, $p = 0.08$) with no overall difference noted between PsA and PsO patients (2.8 ± 2 mg/dl vs. 2.7 ± 4 mg/dl, $p = 0.24$). Transcriptomic profiling of venous endothelial cells comparing PD (PsO and PsA) to controls revealed upregulation of

inflammatory cytokine- and chemokine- associated transcripts (*lymphotoxin beta* [4 - fold], *CCL3* [11 - fold], *CXCL10* [16 - fold], *IL-8* [10 - fold] and *IL-1 β* [4 - fold], $P < 0.05$ for all) and transcripts related to intracellular adhesion (ICAM1 [2.4 - fold] and inflammation *COX-2* [3 - fold], $P < 0.05$). Increased expression of the chemokine *fractalkine* (*CX3CL1* [2.8 - fold], $p < 0.05$) and *lymphotoxin beta* [2 - fold, $p = 0.10$] were found in patients with active PsA compared to PsO. No differences in *CCL3*, *CXCL10*, *IL-8*, *IL-1 β* , *ICAM1* and *COX-2* were seen between PsA and PsO patients.

Conclusion: Endothelial cell pro-inflammatory transcripts are upregulated in patients with active PD compared with controls. Levels of *lymphotoxin beta* and *fractalkine*, a chemokine present in inflamed arthritic synovial tissue, are greater in endothelial cells of patients with PsA than PsO. These findings may underlie increased CVD risk in patients with PD and highlight the inflammatory vascular differences between PsO and PsA.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Basic Science Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The NF- κ B family of transcription factors plays a crucial role in chronic inflammatory diseases and can be activated via two distinct pathways. Non-canonical NF- κ B signaling can be induced by different signals, including transmembrane (tm)TNF ligation to TNF receptor 2 (TNFR2), which is restricted to specific cell types including endothelial cells (EC). Activation of the non-canonical NF- κ B pathway in EC is involved in differentiation into high endothelial venules (HEV), which are specialized lymphoid vessels that play an essential role in the recruitment of B and T lymphocytes into lymph nodes (LN), resulting in LN enlargement. tmTNF transgenic (tg) mice that overexpress tmTNF develop chronic inflammatory features, including arthritis and axial inflammation.

The objective of the current study was to investigate LN size and composition, including stromal cell and lymphocyte subsets in tmTNF tg mice. We hypothesized that overexpression of tmTNF results in increased non-canonical NF- κ B signaling in HEV leading to enlarged LN due to enhanced migration of B and T lymphocytes into LNs.

Methods: Peripheral LN (PLN) and mesenteric LN (MLN) of 7 week old tmTNF tg mice and age-matched wild type (WT) mice were collected and dissected and subsequently analyzed using flow cytometry. Cellular markers were used to distinguish between different (CD31+) EC subsets, including MECA79+ high endothelial cells, and B lymphocytes (CD19+) and T lymphocytes (CD3+).

Results: Lymph nodes of tmTNF tg mice were macroscopically enlarged and had more than two-fold increased total cell numbers when compared to WT mice (tmTNF tg PLN: $23.7 \times 10^6 \pm 7.9 \times 10^6$; MLN: $24.9 \times 10^6 \pm 5.3 \times 10^6$ and WT PLN: $5.2 \times 10^6 \pm 1.0 \times 10^6$; MLN: $10.4 \times 10^6 \pm 4.6 \times 10^6$). The total number of high endothelial cells (HEC) in tmTNF tg mice LN was also increased when compared to WT (tmTNF tg PLN: $2.3 \times 10^3 \pm 0.50 \times 10^3$; MLN: $1.9 \times 10^3 \pm 0.64 \times 10^2$ and WT PLN: 714 ± 393 ; MLN: 1.199 ± 506). In addition, the total amount of capillary endothelial cells (CEC) was increased in tmTNF tg mice (tmTNF tg PLN: 2067 ± 42 ; MLN: 2425 ± 71 and WT PLN: 1097 ± 609 ; MLN: 1327 ± 230). Notably, the ratio between HEC and CEC was also increased in the LN of tmTNF tg mice when compared to WT mice (tmTNF tg PLN: 1.10 ± 0.241 and WT PLN: 0.66 ± 0.006). In addition, total B lymphocyte and T lymphocyte numbers in LN of tmTNF tg mice were strongly increased compared to WT mice (B lymphocytes: tmTNFtg PLN: $10.2 \times 10^6 \pm 3.5 \times 10^6$; MLN: $10.9 \times 10^6 \pm 1.8 \times 10^6$ and WT PLN: $2.8 \times 10^6 \pm 5.8 \times 10^5$; MLN: $5.8 \times 10^6 \pm 2.4 \times 10^6$, T lymphocytes: tmTNFtg PLN: $12.8 \times 10^6 \pm 4.5 \times 10^6$; MLN: $14.2 \times 10^6 \pm 2.8 \times 10^6$ and WT PLN: $2.5 \times 10^6 \pm 3.8 \times 10^5$; MLN: $4.7 \times 10^6 \pm 2.1 \times 10^6$).

Conclusion: Overexpression of tmTNF in mice leads to an increase in LN size which is accompanied by an increase in total HEC and CEC numbers and an increased HEC:CEC ratio. Also, B and T lymphocyte numbers in PLN and MLN were increased. The increase of HEC may be the result of enhanced non-canonical NF- κ B activation in EC, resulting in enhanced recruitment of B and T lymphocytes into LN. Consequently, interfering with non-canonical NF- κ B signaling in EC may be a promising treatment strategy to dampen inflammation in immune-mediated inflammatory diseases, which is the subject of current studies.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Basic Science Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Spondyloarthritis (SpA) is characterized by pathological osteogenesis, inflammation and extensive angiogenesis in inflamed tissues. TNF plays a central role in SpA pathology and transgenic mice that specifically overexpress transmembrane (tm)TNF exhibit features similar to SpA. tmTNF ligation to TNF receptors (TNF-R) in endothelial cells (ECs) can induce signal transduction pathways, that may promote osteogenesis and angiogenesis. Of note, osteogenesis and angiogenesis are coupled by EC differentiation towards a type H (CD31^{hi}endomucin^{hi}) blood vessel phenotype. We investigated the link between pathological osteogenesis, inflammation and angiogenesis in experimental SpA in tmTNF tg mice and the contribution of TNF-R signaling to these processes.

Methods: In this study, tmTNF tg mice, non-tg littermates, and tmTNF tg on either a TNF-RI or TNF-RII deficient background were analyzed for aforementioned SpA features. Cryosections were prepared from vertebrae isolated of these mice at various stages of diseases ranging from 6 weeks till 8 months. Markers to characterize and quantify tissue and cells involved in osteogenesis, angiogenesis and inflammation were analyzed by immune fluorescence confocal microscopy and flow cytometry.

Results: tmTNF tg mice from 6 week onwards contained an increase in type H vessels and osterix⁺ osteoprogenitor cells in the bone diaphysis (osterix mean fluorescence intensity (MFI): 82.8 \pm 7.6) compared to non-tg littermates (MFI: 46 \pm 9.1). These differences in type H vessels and osteogenesis within the vertebrae of tmTNF tg mice were maintained in mice followed up to 8 months. Non-tg littermate vertebrae only exhibited physiological osteogenesis, i.e. in the metaphysis and periosteum. tmTNF tg mice also exhibited ectopic osteogenesis at their entheses, which was not observed in non-tg littermates. Immunostainings demonstrated presence of type H vessels and osterix⁺ osteoprogenitors outside of the bone marrow (BM) at sites of ectopic osteogenesis. This was not observed in non-tg littermates. Interestingly, tmTNF tg mice also displayed altered BM architecture characterized by extensive lymphoid aggregates, which predominantly consisted of B220⁺ B cell aggregates in combination with high endothelial venules (HEV). tmTNF tg mice on a TNF-RI deficient background did not display lymphoid aggregates or HEVs, while tmTNF tg on a TNF-RII deficient background did, although to a lesser extent than tmTNF tg mice, suggesting that particularly TNF-RI-induced signaling events are necessary for the inflammatory phenotype in BM.

Conclusion: tmTNF overexpression in mice results in increased diaphyseal type H vessels and ectopic development of type H vessels associated with enhanced numbers of osteoprogenitors and pathological bone formation. In addition, extensive lymphoid aggregates associated with HEVs develop in the BM. The identification of specialized blood vessels contributing to key features of SpA pathogenesis may reveal potential novel therapeutic targets for SpA.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Basic Science Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: NETosis has been suggested to play a central role in several rheumatology diseases. Nevertheless, this process, and its modulation in therapeutic response has not been described yet in AS patients. Our aims were: 1) to evaluate and characterize the presence of NETosis in AS patients. 2) To explore the relationship among NETosis markers and clinical characteristics of this disease. 3) To analyze the *in vivo* effect of anti-TNF α therapy on NETosis.

Methods: Thirty patients with AS and 32 healthy donors (HDs) were included in a cross-sectional study. Eight AS patients were selected for a six-month longitudinal study of anti-TNF α response. Disease activity was determined by BASDAI index and, CRP and ESR levels; in parallel, plasma inflammatory markers were determined by ELISA kits. Spinal mobility of patients was measured by the BASMI index. *Ex vivo*, spontaneous NETosis generation in purified neutrophils from AS patients and HDs were measured by fluorescence (n=6) and scanning electron (n=3) microscopy after 6 h of incubation. PMA, known to promote NETosis, was used as positive control. DNA extrusion was analyzed by fluorescence microscopy and fluorimetry after SYTOX staining, whereas elastase percentage (NE) was analyzed by fluorescence microscopy after staining of neutrophils with NE antibody. *In vivo*, myeloperoxidase (MPO) and NE protein expression were measured by flow cytometry (FACSCalibur), whereas circulating cell-free DNA and NE levels was examined using fluorimetry after SYTOX staining, and commercial kits, respectively.

Results: Compared to HDs, AS neutrophils showed spontaneous extracellular release of a meshwork of DNA nuclear and granule proteins (NETs), as demonstrated by fluorescence microscopy, fluorimetry, and scanning electron microscopy. Indeed, analysis of DNA fibers staining by SYTOX revealed that NETosis rate was above baseline levels after 6 h of *ex vivo* AS neutrophil incubation as compared to those from HDs ($P<0.05$). Furthermore, higher cell free-DNA levels were observed between AS patients and HDs at 6 h ($P<0.05$). Increased spontaneous NETs production in this pathology was additionally corroborated by the observation of an enhanced percentage of NE-staining cells after 6 h of incubation ($P<0.05$). *In vivo*, higher intracellular NE levels ($P=0.036$), and circulating cell-free DNA levels ($P=0.021$) were also found in AS patients as compared to HDs.

Correlation studies showed that circulating cell-free DNA levels positively correlated with inflammatory markers (i.e. CRP, ESR and TNF α), and with BASMI index. In addition, a positive correlation was found between intracellular NE levels and plasma IL-1 β concentration.

Anti-TNF α treatment of selected AS patients decreased circulating cell-free DNA and NE levels ($p<0.05$), which paralleled the reduction of disease activity.

Conclusion: 1) NETosis is increased in AS patients. 2) Raised NETosis in AS is associated with several markers of inflammation and mobility. 3) Anti-TNF α therapy has a significant effect on NETosis inhibition. Thus, NETosis might act as a key mediator in the etiopathogenesis of AS and have potential for assessment of therapeutic effectiveness in AS patients.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Basic Science Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Ankylosing spondylitis (AS) is a common chronic, systemic, inflammatory disease. Gut microbiome has been reported to play an important role in the homeostasis of human immune system as well as the pathogenesis of AS. In this study, we conducted a research to investigate the differences of gut microbiome between AS patients and healthy controls by the metagenomics approach.

Methods: The fecal sample of 218 AS patients and healthy controls (HCs) were collected and their DNA were extracted. High-throughput sequencing methods with bioinformatics analysis were conducted to reveal the phylogenesis and functional differences of microbiome between AS patients and HCs.

Results: Different species, families and phylum were observed to be enriched in patients and controls. Bacteroidetes was the only phylum enriched in AS patients. Microbiota of intestine from HCs showed more diversity compared to patients. Both Actinobacteria, Firmicutes, Clostridia and Proteobacteria were enriched in HCs. KEGG pathway and module analysis showed that gut microbiota of patients were particularly enriched in the synthesis of LPS and non-mevalonate pathway, which may associate with the regulation of immune system and contribute to the development of disease. Gut microbiome of 27 treated patients who finished one-year follow-up were also sequenced and analyzed. The dysbiosis of the patients were partially restored. The diagnosis model based on gut microbiome information was established and tested, leading to a comparable diagnostic ability to the current criteria.

Conclusion: Dysbiosis of gut microbiota was observed in AS patients compared to HCs. Particular pathway and module enriched in patients such as LPS, may contribute to the pathogenesis of AS. Our study showed that gut microbiome could be used as biomarkers to identify AS patients. Therefore, our findings provide a novel insight of the pathogenesis and diagnosis of AS.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Basic Science Poster

Session Type: ACR Poster Session C

Session Time: 9:00 AM-11:00 AM

Background/Purpose: Psoriatic arthritis (PsA) is an autoimmune disease characterized by the chronic inflammation of the skin and joints. Inflammatory processes translate into changes of the serum protein profiles, including changes in lipoprotein and glycoproteins. Here we investigate the association of plasmatic lipoprotein and glycoprotein profiles with PsA.

Methods: Plasma samples were obtained from 50 PsA patients -classified according to CASPAR - and 50 healthy controls. Lipoprotein and glycoprotein profiles were determined using NMR. For the lipoprotein profiles, VLDL, LDL, IDL and HDL concentration, lipid composition and particle properties were quantified. The glycoprotein profile was decomposed in four reproducible peak regions: LMW, Glyc-B, Glyc-A, Glyc-Lipid and baseline. Association analysis to disease was performed using logistic regression. Classifiers were built using rpart and accuracy was evaluated using ROCs.

Results: We found a significant reduction on cholesterol and triglyceride IDL and LDLs in PsA patients compared to healthy controls ($P < 0.05$). This was accompanied by a reduction also in the particle number for IDL and LDLs ($P < 0.005$). Substantial number of changes were also observed in the plasma glycoprotein patterns, including a decrease of Gly-A and Glyc-Lipid peaks ($P < 0.05$). Using the plasma molecular patterns to predict the presence of PsA, we found a significant classifier for the lipoprotein pattern (ROC (95%CI) = 0.87(0.81-0.94)), and an optimal classifier for the glycoprotein pattern (ROC (95%CI) = 0.91(0.85-0.97)).

Conclusion: Our results support that plasma NMR profiling could be a source of new useful biomarkers for PsA diagnosis and management.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Basic Science Poster

Session Type: ACR Poster Session C

Session Time: 9:00 AM-11:00 AM

Background/Purpose: Psoriatic arthritis (PsA) is characterised by an early vascular phase essential for pannus growth, immune responses and disease progression. Recently, numerous studies have highlighted the emerging importance of endothelial cell metabolism in controlling angiogenesis. Herein, we propose microRNA, miR-125, modulates EC bioenergetics and orchestrates joint angiogenesis as characterised by *ex-vivo* associations, *in-vitro* assays and novel CRISPR/cas9 *in-vivo* zebrafish models.

Methods: MiRNA levels were quantified in synovial tissue by RT-PCR and compared to macroscopic synovial vascularity and immunohistochemical analysis of angiogenic factors (FactorVIII/VEGF/ANG2). ECs (HMVEC) were transfected with anti-miR-125a for 24hr. Angiogenic mechanisms were quantified using tube formation assays, invasion by Transwell matrigel chambers, migration by wound repair and gene expression (PFKFB3, HK2, GSK3A, G6PD by RT-PCR and western blot analysis. Real-time analysis of extracellular acidification rates (ECAR) and oxygen consumption rates (OCR) of anti-125 treated ECs was assessed using the XF-24 Extracellular Flux Analyzer (Seahorse Bioscience). To determine if altered metabolism is observed *ex vivo*, glycolysis/oxidative phosphorylation markers (GAPDH/PKM2/ GLUT1/ATP) were assessed by immunohistochemistry. *In vivo*, miR-125a CRISPR/Cas9-based knock-out zebrafish fluorescent reporter lines were generated and vascular development monitored. Finally, we examined the effect of blocking glycolysis using a small molecule, 3PO, which blocks PFKFB3, in miR-125a^{-/-} ECs and zebrafish embryos.

Results: Synovial expression of miR-125 was significantly decreases in PsA versus OA synovial tissue, levels of which were associated with macroscopic and microscopic synovial vascularity (p<0.05). Decreased expression of miR-125a in HMVEC resulted in increased tube formation, invasion and migration properties (all p<0.05). Inhibition of miR-125 significantly decreased basal, maximal and spare respiratory capacity (p<0.009) with a concurrent decrease in ATP synthesis (p<0.08). Increased glycolysis was further supported by elevation of glycolytic genes, including PFKFB3. Elevated endothelial cell glycolysis was also demonstrated *ex vivo* with vascular synovial expression of glycolytic markers, PKM2, GLUT1 and ATP5B significantly increased in PsA compared to OA controls. 3PO significantly inhibited anti-miR-125a-induced mechanism. Finally, miR-125a^{-/-} embryos displayed increased vascular sprouting, effects normalised by the presence of the glycolytic inhibitor 3PO.

Conclusion: Decreased expression of miR-125 in PsA synovium and *in-vivo* models was strongly associated pro-angiogenic mechanisms. Elevated glycolysis following miR-125 inhibition enabled ECs to meet the increased energy and biosynthetic demands for new vessel formation. Correcting these miRNA deficiencies and their resulting metabolic shift, either by conventional pharmacological or as novel drug targets, may provide therapeutic benefit, especially in early disease.

Bennett², Joel Taurog³ and Robert Colbert⁴, ¹National Institute of Arthritis and Musculoskeletal and Skin Diseases, National Institute of Arthritis and Musculoskeletal and Skin Diseases, National Institutes of Health, Bethesda, MD, ²National Institute of Arthritis and Musculoskeletal and Skin Diseases, National Institutes of Health, Bethesda, MD, ³Dept Int Med-Rheum Dis Div, University of Texas Southwestern Medical Center, Dallas, TX, ⁴National Institute of Arthritis and Musculoskeletal and Skin Diseases, National Institutes of Health, Bethesda, MD

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Basic Science Poster

Session Type: ACR Poster Session C

Session Time: 9:00 AM-11:00 AM

Background/Purpose: Preliminary results suggest that endoplasmic reticulum (ER) aminopeptidase 1 (ERAP1) deficiency partially protects HLA-B27/human b₂m transgenic (B27-Tg) rats from spondyloarthritis (SpA) as evidenced by a reduced frequency of arthritis and orchitis, but not gastrointestinal inflammation. Protection is associated with reduced HLA-B27 misfolding and unfolded protein response (UPR) activation in rat bone marrow macrophages (BMM). Here, we investigated whether ERAP1 deficiency impacts HLA-B27 misfolding-induced IL-23p19 expression in rat BMMs, and/or defective dendritic cell (DC) costimulatory function, both of which have been linked to pathogenesis.

Methods: BMMs from 2-3 month old B27-Tg rats, with ERAP1^{+/+} and ERAP1^{-/-} genotypes were pre-treated with IFN γ (18 hrs) then stimulated with LPS for up to 8 hrs. Relative expression of mRNAs for IL-23p19, BiP, and CHOP were measured by RT-qPCR. Allogeneic DC function was measured using splenic DCs purified from wild type (WT) and B27-Tg rats with ERAP1^{+/+} and ERAP1^{-/-} genotypes using Nycodenz followed by magnetic separation with anti-CD103 (OX62 Ab) microbeads. Resting CD4⁺ T-cells from Dark Agouti (DA) WT rats were purified by negative selection employing a combination of OX33, OX42, 3.2.3, and OX8 antibodies. DCs at 0, 1, 3, 10, 30 ($\times 10^3$) cells were co-cultured with 1×10^5 CD4⁺ T-cells for 5 days; proliferation of T-cells was analyzed by cell counting using IncuCyte.

Results: ERAP1 deficiency reduced LPS-induced IL-23p19 mRNA expression by about 50% ($p < 0.05$) in BMMs from B27-Tg rats, as well as UPR genes BiP and CHOP by 30% ($p < 0.05$). DCs from B27-Tg rats (ERAP1^{+/+}) showed a significant defect in stimulating T-cell proliferation compared to DCs from WT (ERAP1^{+/+}) rats ($p < 0.05$), confirming previous results. However, ERAP1 deficiency did not restore the function of B27-expressing DCs, as there was no improvement in T-cell proliferation.

Conclusion: These results implicate ERAP1 function in modulating aberrant HLA-B27 folding and its effects on IL-23 induction, possibly through UPR activation, in B27-Tg rats. These effects of ERAP1 on HLA-B27 are associated with partial reduction of the experimental SpA phenotype (arthritis and orchitis) but not gastrointestinal inflammation.

Epistasis between HLA-B27 and ERAP1 Affects Gut Microbial Dysbiosis and Arthritis in Experimental Spondyloarthritis

Tejpal Gill¹, Tri Tran¹, Stephen R. Brooks² and Robert Colbert³, ¹National Institute of Arthritis and Musculoskeletal and Skin Diseases, National Institute of Arthritis and Musculoskeletal and Skin Diseases, National Institutes of Health, Bethesda, MD, ²Biodata Mining and Discovery Section, Office of Science and Technology, NIAMS/NIH, Bethesda, MD, ³National Institute of Arthritis and Musculoskeletal and Skin Diseases, National Institutes of Health, Bethesda, MD

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Basic Science Poster

Session Type: ACR Poster Session C

Session Time: 9:00 AM-11:00 AM

Background/Purpose: Common variants in endoplasmic reticulum (ER)-associated aminopeptidase-1 (ERAP1) affect susceptibility to spondyloarthritis (SpA) in HLA-B27-positive human subjects, with loss-of-function/expression conferring protection. Using HLA-B27/human b2-microglobulin transgenic (HLA-B27 TG) rats, an experimental model of SpA, we have preliminary results that ERAP1 deficiency partially protects from the development of arthritis and orchitis, but not gut inflammation. The mechanism(s) underlying the protective effect of ERAP1 loss-of-function remain unknown. Here, we examined the gut microbiota of HLA-B27-TG rats with and without arthritis and with different ERAP1 genotypes, with the goal of identifying arthritis-associated gut microbes.

Methods: Cohorts of HLA-B27-TG rats with 3 ERAP1 genotypes (+/+, +/-, and -/-) were generated by crossing HLA-B27-TG Lewis (LEW) rats with Sprague Dawley (SD) rats carrying 0, 1, or 2 ERAP1 null alleles. The mixed LEW-SD background (SDM) accelerates the onset of arthritis and orchitis, while gut inflammation remains unchanged. Animals were examined 2-3 times per week for the presence of arthritis and orchitis for up to 6 months and then euthanized. Gut inflammation in the cecum and colon was assessed by histological scoring. Microbial profiles were determined using DNA isolated from the cecum luminal contents, with 16S rRNA gene sequencing performed using Illumina MiSeq. Data were quality-filtered using Quantitative Insights Into Microbial Ecology (QIIME 2). Microbe relative frequency was determined at the species level (maximum $> 0.1\%$; $p < 0.05$, $q < 0.1$).

Results: HLA-B27 TG SDM rats with arthritis have a distinct gut microbial signature compared to HLA-B27 TG non-arthritic SDM rats as measured by principal component analysis, despite similar gut histology scores. Moreover, arthritis-associated microbes differ from HLA-B27-associated dysbiotic microbes. Arthritis is associated with a significant loss of microbial alpha diversity, as well as differences in microbial community structure. HLA-B27 TG SDM rats with arthritis have increased *Bacteroides* and *Parabacteroides* at the expense of *Firmicutes*. At the species level, we see an increased relative frequency of certain microbes such as *Akkermansia muciniphila* and *Blautia*, that are often associated with inflammation, whereas other inflammation-associated microbes ([*Prevotella*], *Lachnospiraceae*, [*Ruminococcus*] *gnavus*)

were decreased in comparison with non-arthritic HLA-B27 TG rats. Further analysis based upon different ERAP1 genotypes also revealed ERAP1-associated differences on the microbial diversity and community structure.

Conclusion: In-depth analysis of HLA-B27 TG rats with and without arthritis has revealed the presence of arthritis-associated microbiota, which may explain why only some animals develop arthritis. These distinct arthritis-associated microbial communities will be further tested by microbiota transfer experiments in other genetic backgrounds. These results may provide valuable insights into the relationship between HLA-B27 and ERAP1, and their effects on arthritis and gut inflammation in experimental spondyloarthritis.

Targeting the Voltage-Gated K⁺ Channels: T Cell Targeted Therapies for Spondyloarthritis

Siba P. Raychaudhuri¹, Smriti K. Raychaudhuri² and Heike Wulff³, ¹Rheumatology Section, Sacramento Veterans Affairs Medical Center, Sacramento, CA, ²Rheumatology/Immunology, VA Sacramento Medical Center, Davis, CA, ³Pharmacology, School of Medicine, University of California Davis, Davis, CA

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Basic Science Poster

Session Type: ACR Poster Session C

Session Time: 9:00 AM-11:00 AM

Background/Purpose: TCR (T cell receptor) engagement triggers intracellular Ca⁺⁺ influx through voltage-independent Ca²⁺ channels. This crucial Ca²⁺-influx is only possible by a counterbalancing K⁺ efflux through Kv1.3 and/or KCa3.1. So, these channels are regarded as new targets for immunotherapy: KCa3.1 for acute immune reactions mediated by naïve T cells and Kv1.3 for chronic immune reactions carried by memory T cells. Here we investigated the functional significance of KCa3.1 and Kv1.3 in psoriatic arthritis (PsA) and have used rheumatoid (RA) and osteoarthritis (OA) as controls. To develop K⁺ channel targeted therapies we are working on two small molecules PAP-1 and TRAM-34 which respectively are specific blockers for Kv1.3 and KCa3.1.

Methods: 1. We studied skin tissue, synovial tissue, lymphomononuclear cells (LMNC) from blood and synovial fluid from patients with PsA and RA. In these autoimmune conditions we identified Kv1.3^{high} T cells and determined their phenotypic and functional features. 2. CIA mouse model is a well established tool to study IL-23/IL-17 driven autoimmune arthritis. To determine the functional significance of the KCa3.1 channel CIA was induced in KCa3.1^{-/-} mice and in C57BL/6 wild type mice.

Results: PsA synovial tissues (n=6) were enriched with Kv1.3⁺ T cells compared to osteoarthritis (p<.01). Further we noticed KV1.3 K⁺ channels were functionally active and Kv1.3 current in these T cell could be blocked by PAP-1, a potent small molecule inhibitor of KV1.3 K⁺ channels. 2. KCa3.1^{-/-} mice (n=10) failed to develop clinical evidence of arthritis and did not have histological evidence for joint inflammation. Wild-type C57BL/6 mice developed clinical/histopathological evidence of arthritis. Micro-PET imaging as well confirmed these findings. Compared to KCa3.1^{-/-} mice CD3⁺ T cell proliferation in response to chicken collagen II (CCII) by MTT assay was significantly higher in the C57BL/6 wild type mice (p<.001). 3. *In vitro* studies performed with synovial fluid T cells derived from PsA patients demonstrated that the small molecule Kv1.3 blocker PAP-1 dose-dependently inhibited proliferation and suppressed IL-2 and IL-17.

Conclusion: *In vitro* studies and the *in vivo* model (PET CIA mouse model) have demonstrated critical roles of the Kv1.3 and KCa3.1 potassium ion channels in the pathogenesis of T cell mediated autoimmune arthritis. Synthetic small molecules PAP-1 and TRAM-34 respectively for Kv1.3 and KCa3.1 have already been studied for safety and tolerability and these T cell ion-channels blockers provide a promising therapeutic approach for psoriatic disease and other T cell mediated human autoimmune diseases.

Session Date: Tuesday, October 23, 2018

Session Title: Systemic Lupus Erythematosus – Animal Models Poster

Session Type: ACR Poster Session C

Session Time: 9:00 AM-11:00 AM

Background/Purpose: Response Gene to Complement (RGC)-32 is a cell cycle regulator widely expressed in normal tissues including brain, kidney, spleen, thymus, multiple tumors and in a variety of cell lines. RGC-32 is localized in the cytoplasm and translocates to the nucleus upon upregulation by complement activation, growth factors and cytokines. RGC-32 is induced by TGF- β in fibroblasts, astrocytes and human renal proximal tubular cells and mediates TGF- β dependent profibrotic pathways. In immune cells, RGC-32 is upregulated preferentially in murine and human Th17 cells and promotes their differentiation in vitro and in vivo. Increased expression of IL-17 in kidneys of SLE patients and lupus prone mice is critical for the development of LN. We have previously shown that RGC-32 expression is increased in T cells from SLE patients and in tubules and glomerular infiltrating cells in kidney biopsies of patients with LN. To directly assess whether RGC-32 plays a local role in LN downstream of antibody production, we used the anti-glomerular basement membrane Ab-induced GN (AIGN) model to compare parameters of disease severity in RGC-32 deficient and sufficient mice.

Methods: Wild type (WT) and RGC-32^{-/-} mice were immunized with sheep IgG in Complete Freund's Adjuvant followed by injection of sheep nephrotoxic serum. Mice were monitored for proteinuria and blood urea nitrogen. Kidney histopathology was scored from 0 to 3 based on cellularity, endocapillary and mesangial proliferation, crescent formation, necrosis, fibrosis, tubular casts and dilatation. RGC-32 and IL-17A mRNA expression in kidneys was determined by qRT-PCR. Circulating levels and kidney deposition of mouse anti-sheep IgG were quantitated by ELISA and IF, respectively. Splenic B and T cell responses were characterized by flow cytometry.

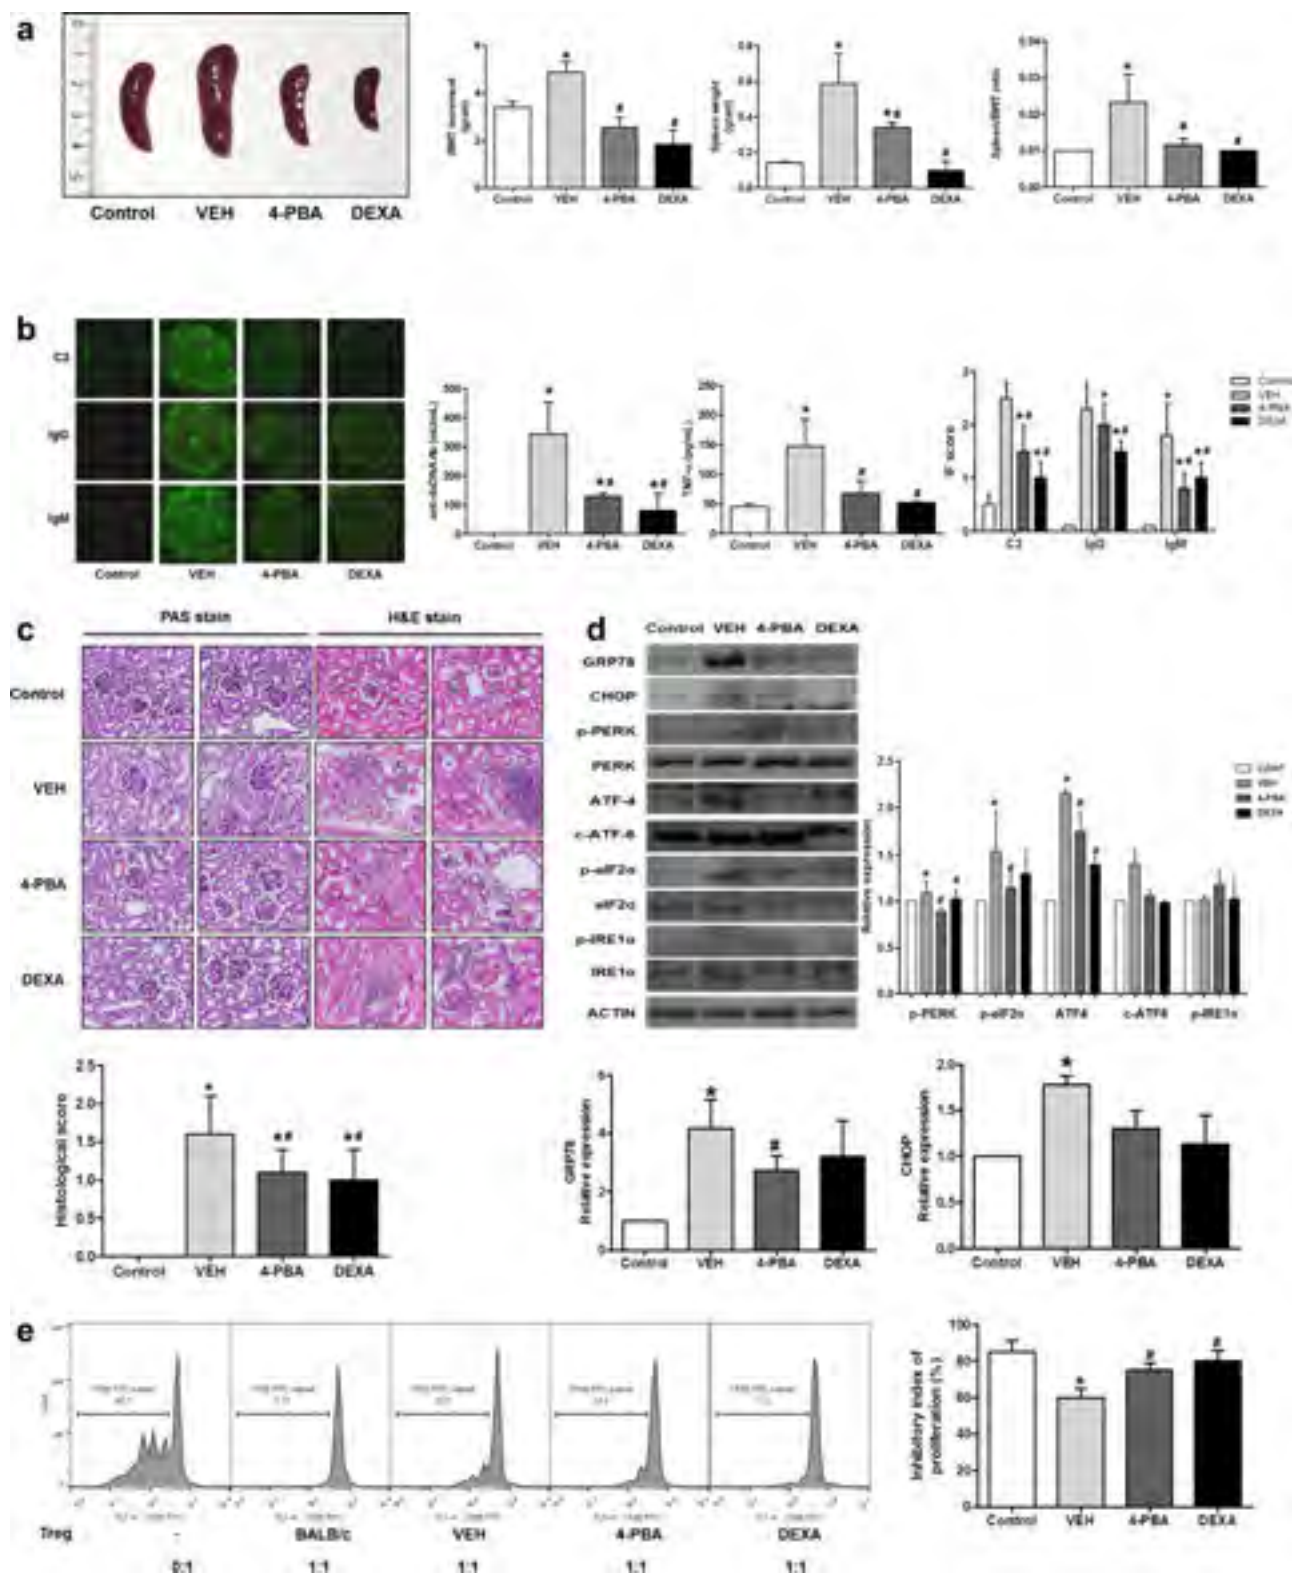

Results: RGC-32 mRNA was significantly upregulated in the kidneys of WT mice with AIGN compared to controls. RGC-32^{-/-} mice displayed an attenuated nephrotoxic injury as demonstrated by significantly decreased proteinuria, a trend for decreased blood urea nitrogen and decreased histopathological glomerular scores. Tubulointerstitial damage did not differ between RGC-32 sufficient and deficient mice. Correlating with RGC-32 expression, IL-17A mRNA expression was upregulated by 3 fold in kidneys of WT mice with AIGN while it was downregulated by 5 fold in RGC-32^{-/-} mice. RGC-32 deficiency did not interfere with the induction of AIGN as mouse anti-sheep IgG titers, percentage of splenic germinal center B cells, plasma cells, effector CD4⁺ T cells, Tregs, IL-17A and IFN- γ secreting cells did not differ between RGC-32^{-/-} and WT mice. Furthermore, kidney deposition of autologous antibodies was comparable between the two groups.

Conclusion: These results suggest that RGC-32 contributes to the pathogenesis of immune complex mediated GN by promoting local IL-17A production and subsequently the development of end-organ damage. These data support further efforts to examine the mechanisms by which RGC-32 modulates local IL-17 expression and enhances kidney damage and suggest that RGC-32 is a potential novel therapeutic target in the treatment of LN.

Session Title: Systemic Lupus Erythematosus – Animal Models Poster

Session Type: ACR Poster Session C

Session Time: 9:00 AM-11:00 AM

Background/Purpose: The purpose of the present study was to investigate whether ER stress inhibition by 4-phenylbutyric acid (4-PBA) ameliorates lupus manifestations in an experimental lupus model and the effect of ER stress inhibition by 4-PBA on the frequency and function of regulatory T cells (Treg).

Methods: A murine lupus model was induced through a 4-week treatment with Resiquimod, a toll-like receptor agonist 7. From the 8th week, the mice were treated with phosphate buffered saline, 4-PBA, and dexamethasone for 4 weeks. The increment of body weight, spleen weight, anti-dsDNA antibody titer, serum cytokines level, and the pathology of glomerulonephritis were analyzed at 12 weeks of age. The population of immune cellular subset, including activated T and B lymphocytes and Treg, and suppressive functions of Treg, were measured.

Results: 4-PBA significantly decreased the level of anti-dsDNA antibodies and serum TNF- α in the murine lupus model. A significant decrease in accumulation of immunoglobulin and glomerulonephritis score was also observed in 4-PBA-treated and dexamethasone-treated mice compared to vehicle-treated group. ER stress inhibition decreased the activated T and B lymphocytes population of splenocytes, but the population of Treg was not significantly different between vehicle group and 4-PBA group. However, a markedly enhanced suppressive capacity of Treg was detected in 4-PBA-treated group.

Conclusion: Our results suggest that ER stress inhibition attenuates disease activity, especially of lupus nephritis, in an experimental model by improving the suppressive capacity of Treg. Thus, reduction of ER stress could be used as a beneficial therapeutic strategy in SLE.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Systemic Lupus Erythematosus – Animal Models Poster

Session Type: ACR Poster Session C

Session Time: 9:00 AM-11:00 AM

Background/Purpose: Lupus nephritis (LN) affects ~70% of systemic lupus erythematosus (SLE) patients and is one of the main contributors to morbidity and mortality. While defective clearance of apoptotic cells (AC), autoantibodies, and type 1 interferons (IFN-I), are strongly implicated in lupus pathogenesis, the precise way that each impacts kidney protection and injury is unknown.

Methods: To investigate mechanisms of kidney injury in a lupus-like disease model, we created C57BL/6 mice with defective clearance of AC (*Mfge8*^{-/-}) and anti-chromatin antibodies (*sle1*) that were also deficient in either C1q [C1q Triple

mutant (C1qTM)] or C3 (C3TM). Kidney injury was evaluated by urine albumin/creatinine ratio (UACR), PAS staining, and immunofluorescence (IF) staining. The effect of IFN-I on disease was studied in C3TM mice by a single injection of an adenovirus expressing IFN α (AdV-IFN α).

Results: *Sle1* mice deficient in MFG-E8 developed significantly higher titers of autoantibodies directed at lupus antigens compared to *sle1* mice alone. When *Mfge8*^{-/-}*Sle1* mice also had C1q or C3 deficiency, a further increase in anti-DNA and other autoantibodies was observed. Both TM strains showed AC accumulation in the kidneys and C1qTM mice had decreased survival. Remarkably, we detected glomerular deposition of C3/C3d in C1qTM and the membrane attack complex (MAC) in C3TM mice. To dissociate the effects of complement on B cells versus effects on the kidney, we studied the impact of defective AC clearance and complement deficiencies on kidney injury in double knockout (DKO) (*Mfge8*^{-/-}*C1q*^{-/-} or *Mfge8*^{-/-}*C3*^{-/-}) mice using Nephrotoxic Nephritis model (NTN). NTN in C1qDKO and C3DKO mice revealed a significantly elevated UACR compared to the single mutants, i.e. worse kidney disease. This effect was independent of antibody deposition in the kidney as similar IgG levels were detected in all NTS-treated strains. IF analyses revealed glomerular C3/C3d deposition in C1qDKO mice and MAC deposition in C3DKO mice. A single injection of AdV-IFN α accelerated kidney damage in C3TM mice, resulting in high anti-dsDNA IgG titers, UACR, renal IgG deposition, and PAS staining.

Conclusion: These findings demonstrate that, in the context of reduced clearance of AC, early complement components have two distinct functions: they prevent enhanced B cell autoreactivity and protect against kidney disease. Increased glomerular C3/C3d deposition in C1qTM and NTN C1qDKO mice suggest activation of the lectin or alternative complement pathways following AC accumulation. Increased MAC deposition in C3TM and NTN C3DKO mice indicates that, in the absence of C3 and presence of AC, a C3-independent mechanism leads to distal complement activation and MAC formation. This effect is further exacerbated by IFN α suggesting a mechanism of disease progression in human SLE in the context of C3 absence and/or consumption. These data prompt models of tissue injury in low complement states that will require assessment in human SLE and provide two distinct perspectives: i) a rationale for targeted therapeutics that are not currently used and ii) a cautionary note about the use of current complement inhibitor therapies.

Session Date: Tuesday, October 23, 2018

Session Title: Systemic Lupus Erythematosus – Animal Models Poster

Session Type: ACR Poster Session C

Session Time: 9:00 AM-11:00 AM

Background/Purpose: Infiltrating macrophages are one of the hallmarks of renal inflammation and kidney damage in lupus nephritis (LN). Surprisingly overexpression of TLR8, but not other endosomal TLRs, was observed in renal macrophages of nephritic NZB/W mice and in LN kidneys. Myeloid cells and neutrophils primarily express TLR8 but as its function differs from mouse to man, its role in autoimmunity remains poorly understood. Recently, TLR8 activation was shown to drive differentiation of T-follicular helper (T_{FH}) cells which are crucial regulators of the germinal-center response and humoral immunity. Herein, we aimed to evaluate the functional consequence of one or two copies of huTLR8 on autoimmunity and renal inflammation in murine SLE.

Methods: NZW/B6, NZW/B6.Yaa and Sle1.Yaa mice expressing 1 (NZW/B6 strains) or 2 (Sle1.Yaa strain) copies of huTLR8 as a BAC transgene (huTR8tg) were generated and followed clinically. HuTLR8 DNA copy number and mRNA expression was confirmed by qDigital and qRT-PCR respectively. 24-week-old huTLR8tg NZW/B6.Yaa mice were administered TL-506 (TLR8-agonist) subcutaneously for 4 weeks and spleens and kidneys were harvested for analysis at 8 weeks. Serum autoantibodies were assessed over time. Spleen weights were assessed and splenocytes, kidney cells and bone marrow cells were characterized by flow cytometric analysis.

Results: A single copy of huTLR8 did not exacerbate clinical disease, however, subcutaneous TLR8-agonist administration appeared to enhance germinal center formation and plasma cell generation in male NZW/B6.Yaa huTLR8tg mice. Strikingly, huTLR8.tg SLE1.Yaa males expressing 2 copies of huTLR8 showed accelerated renal disease and mortality by 4 months of age compared with >9 months in Sle1.Yaa controls. Anti-RNP and anti-cardiolipin antibodies developed by 7-10 weeks of age in both male and female huTLR8.tg mice but maximal titers were the same as in their SLE1.Yaa counterparts. Splenomegaly was observed in both male Sle1.Yaa- ($p<0.001$) and female Sle1-huTLR8.tg mice ($p=0.0013$). Flow cytometric analysis of splenocytes from heterozygous huTLR8.tg SLE1.Yaa males showed an acceleration of memory T cell expansion but similar numbers of germinal center (GC) B cells and T_{FH} cells as their wild type Sle1.Yaa counterparts. By contrast there was a 10 fold increase in splenic myeloid cells compared to their SLE1.Yaa counterparts including macrophages, dendritic cells and neutrophils. Interestingly, aged huTLR8tg SLE1 females often showed distended caeca, intestinal obstruction, cataract, periocular alopecia and blepharitis, indicating a disrupted epithelial and mucosal homeostasis in these mice.

Conclusion: One copy of huTLR8 does not exacerbate lupus in NZW/B6.Yaa mice. One copy of huTLR8 induces splenomegaly with myeloid cell expansion and memory T cell activation in Sle1.Yaa mice, but does not cause B cell expansion or an increase in germinal center cells; two copies of huTLR8 in this strain causes early mortality. Further elucidating how dysregulated TLR8 signaling accelerates disease and disrupts homeostasis is crucial to better understand the role of this TLR in autoimmunity and will facilitate more precise therapeutic targeting.

The Differential Impact of the Abrogation of the Costimulatory Molecule CD137 Ligand on Renal and Cerebral Manifestations in C57BL/6.Fas^{lpr} mice

Anselm Mak¹, Bhushan Dharmadhikari², Lik Wei Wong², Saji Kumar Sreedharan² and Herbert Schwarz², ¹Medicine, Yong Loo Lin School of Medicine, National University of Singapore, Singapore, Singapore, ²Physiology, Yong Loo Lin School of Medicine, National University of Singapore, Singapore, Singapore

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Systemic Lupus Erythematosus – Animal Models Poster

Session Type: ACR Poster Session C

Session Time: 9:00 AM-11:00 AM

Background/Purpose: Costimulatory molecules which mediate cross-talks between leukocytes, have been identified to play a pathogenetic pivotal role in systemic lupus erythematosus (SLE). Abrogation of the costimulatory CD137-CD137 ligand (CD137L) system has previously been shown to worsen systemic lupus erythematosus and yet improve experimental autoimmune encephalitis in murine models. Here, we aimed to investigate the phenotypic effects in dermatological, renal and cerebral manifestations, and the potential alterations of the immunological mechanisms when CD137L was absent in a murine lupus model.

Methods: B6.CD137L^{-/-} and lupus-prone C57BL/6.Fas^{lpr} (B6.lpr) mice were crossed to obtain mice knocked out for the CD137L and Fas genes (DKO mice). The DKO mice were studied and compared with the B6.lpr mice phenotypically regarding survival, dermatitis, glomerulonephritis, cerebral demyelination, microglial activation and hippocampal long-term potentiation (LTP) induced by theta burst stimulation (TBS). Serological studies and the frequency of splenic leukocyte subsets and helper T (Th) cell transcription factors were studied and compared between the DKO and B6.lpr mice (and B6.WT mice where required).

Results: An observation of 22 months involving 226 DKO and 137 B6.lpr mice demonstrated significantly more severe dermatitis (mean±SE unit: 1.03±0.2 vs. 0.37±0.1, $p=0.003$), more frequent proliferative glomerulonephritis (33.3% vs. 7.9%, $p=0.005$) and shorter survival (median± SE survival: 44±4.5 versus 74±3.3 weeks, $p<0.001$) of the DKO mice compared to the B6.lpr mice. Conversely, microglial activation and cerebral demyelination were milder and the synaptic efficacy in terms of hippocampal LTP was superior in the DKO than B6.lpr mice, without affecting the basal synaptic transmission. DKO mice had a significantly higher frequency of splenic Th17 (CD3⁺CD4⁺CD8⁺RoRγt⁺) cells than the B6.lpr and B6.WT mice while the frequencies of Th1 and Th2 cells were comparable between the groups. *In vitro* experiments which involved T-cell stimulation with anti-CD3 did not alter intracellular IL-10 and IL-17 expressions in splenocytes of the DKO and B6.pr mice but a lower proportion of splenic IL-10-producing CD11b⁺ cells were identified in

the DKO mice than in the B6.lpr and B6.WT mice. Serological studies revealed lower serum IL-10 levels in the DKO than in the B6.lpr mice ($p=0.017$).

Conclusion: In the absence of CD137L, higher splenic Th17 and lower IL-10-producing CD11b⁺ frequencies and lower serum IL-10 levels may explain the more severe renal and dermatological pathology of B6.lpr mice, yet this creates an environment in the central nervous system for milder cerebral damage and enhanced long-term synaptic plasticity.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Systemic Lupus Erythematosus – Animal Models Poster

Session Type: ACR Poster Session C

Session Time: 9:00 AM-11:00 AM

Background/Purpose: Diffuse alveolar hemorrhage (DAH) is a life-threatening pulmonary complication of systemic lupus erythematosus. The inciting pathology is thought to be pulmonary capillaritis but the pathogenic cell population(s) that elicits inflammation and tissue destruction remains unclear. Mice treated intraperitoneally with the hydrocarbon pristane develop features of human SLE including autoantibodies, glomerulonephritis and DAH.

We used mass cytometry complemented with studies in informative marrow transplantation and genetic deletions to identify pathogenic cellular populations in DAH.

Methods: Wild-type and transplanted/transgenic mice (6-8 weeks of age) were treated with 0.5 mL of pristane intraperitoneally and analyzed after 2 weeks. Lung sections were analyzed by H&E staining. Lung tissue was digested using collagenase and analyzed by mass cytometry (CyTOF) and flow cytometry.

Results: Mass cytometry using heavy-metal isotopes was superior to fluorescence-based flow cytometry for unambiguous identification of cell subsets in strongly autofluorescent lung tissue digest. Using a 25-antibody mass cytometry panel, we found that alveolar macrophages and eosinophils were significantly reduced in DAH while both Ly6C^{hi} and Ly6C^{lo} monocytes increased markedly. Dendritic cells and interstitial macrophages were minimally affected by pristane treatment. Using bone marrow transplant, we found that the expanded lung monocytes in DAH are bone marrow-derived and differentiate into macrophage-like cells. The incidence of DAH was reduced in Ccr2 (CC-chemokine receptor 2)-deficient mice with impaired monocyte egress from the bone marrow (11/15 in wild-type vs. 3/15 in Ccr2^{-/-}, $p < 0.01$). Furthermore, Irf8 (interferon regulatory factor 8)-deficient mice with absent Ly6C^{hi} monocyte development were strongly protected against the development of DAH (21/25 in wild-type vs. 1/25 in Irf8^{-/-}, $p < 0.001$).

Conclusion: We demonstrate the utility of mass cytometry for unambiguous identification of immune cells in DAH. We found that monocytes infiltrate the lungs in pristane-treated mice and play an essential role in the development of DAH. These findings suggest that monocytes could represent a therapeutic target in SLE-associated human DAH.

Mucosal-Associated Invariant T (MAIT) Cells As a Potential Therapeutic Target for Systemic Lupus Erythematosus

Goh Murayama¹, Asako Chiba², Atsushi Nomura³, Hirofumi Amano¹, Ken Yamaji¹, Naoto Tamura¹ and Sachiko Miyake^{4,5}, ¹Internal Medicine and Rheumatology, Juntendo University School of Medicine, Tokyo, Japan, ²Juntendo Univ Sch of Med, Juntendo University School of Medicine, Tokyo, Japan, ³JUNTENDO UNIVERSITY SCHOOL OF MEDICINE, Tokyo, Japan, ⁴Division of Immunology/NCNP, Natl Institute of Neuroscience, Kodaira Tokyo, Japan, ⁵Immunology, Juntendo University School of Medicine, Tokyo, Japan

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Systemic Lupus Erythematosus – Animal Models Poster

Session Type: ACR Poster Session C

Session Time: 9:00 AM-11:00 AM

Background/Purpose: Mucosal-associated invariant T (MAIT) cells are innate T cells that are restricted by the nonpolymorphic MHC-related molecule-1 (MR1) and express a semi-invariant TCR α chain: V α 7.2-J α 33 in humans and V α 19-J α 33 in mice. Previously, we reported that MAIT cells are activated in patients with systemic lupus erythematosus (SLE) and that the activation state of these cells correlated with disease activity. By using MR1 deficient mice lacking MAIT cells, we revealed that MAIT cells contribute to the disease severity of lupus in Fc γ RIIB^{-/-} *Yaa* mice. In this study, we asked how MAIT cells are involved in the pathogenesis in this lupus model and explored their potential as a therapeutic target for lupus. We also investigated whether MAIT cells infiltrate in the nephritic kidneys of lupus patients.

Methods: Fc γ RIIB^{-/-} *Yaa* mice were crossed to MR1 deficient mice lacking MAIT cells, and disease progression was compared between MR1^{-/-} and MR1^{+/+} Fc γ RIIB^{-/-} *Yaa* mice. The levels of serum anti-dsDNA antibody and urinary albumin were measured. The severity of nephritis was assessed histologically. T and B cell subsets in the spleen and kidneys at 2 months of age were analyzed by using flow cytometry. Fc γ RIIB^{-/-} *Yaa* mice were treated with a suppressive MR1 ligand (MR1L) orally three times weekly for 4 weeks starting at 4 weeks of age. Infiltration of MAIT cells was assessed in kidney biopsy specimens from lupus patients using a confocal microscope.

Results: MAIT cell deficiency improved the disease course of lupus in Fc γ RIIB^{-/-} *Yaa* mice as shown by the increased survival rate, reduced serum anti-dsDNA antibody levels, glomerulonephritis scores and IgG and C3 deposition in glomeruli in MR1^{-/-} Fc γ RIIB^{-/-} *Yaa* mice. MAIT cells enhanced germinal center reaction which was accompanied by the increase of T follicular helper cells, germinal center B and plasma cells and the reduction of T regulatory and T follicular regulatory cells. The presence of MAIT cells enhanced cytokine producing capacity of T and innate-T cells in the spleen and kidneys. Activated MAIT cells were accumulated in the kidneys and produced inflammatory cytokines. Administration of MR1L decreased serum anti-ds DNA antibody levels and reduced germinal center B and plasma cells. The deposition of IgG and C3 in the glomeruli was also reduced in Fc γ RIIB^{-/-} *Yaa* mice treated with MR1L. MAIT cells were accumulated in the nephritic kidneys of lupus patients.

Conclusion: MAIT cells exacerbated the disease severity of lupus by enhancing autoantibody production and tissue inflammation in Fc γ RIIB^{-/-} *Yaa* mice. MAIT cells were found in the nephritic kidneys of lupus patients, suggesting these cells may also contribute to lupus pathogenesis in human patients. As administration of MR1L suppressed the disease course of lupus, MAIT cells hold potential as a new therapeutic target for SLE.

Session Title: Systemic Lupus Erythematosus – Animal Models Poster

Session Type: ACR Poster Session C

Session Time: 9:00 AM-11:00 AM

Background/Purpose: Glucocorticoids (GC) remain the frontline treatment in Systemic Lupus Erythematosus (SLE) despite their predictable metabolic adverse effects. Type I interferons (IFN), produced by TLR7 and TLR9 activated plasmacytoid dendritic cells (pDC), play a critical role in SLE pathogenesis, but are not suppressed by GC. Glucocorticoid-Induced Leucine Zipper (GILZ) is an endogenous anti-inflammatory protein, which regulates T and B cell activation and is suppressed in SLE; whether GILZ regulates type 1 IFN production in SLE is not known. We tested the hypothesis that GILZ inhibits Type I IFN production in SLE.

Methods: We performed *in vitro* analysis on pDC and bone marrow-derived DC (BMDC), and *in vivo* studies, of WT and GILZ^{-/-} mice using stimuli of TLR4 (LPS), TLR7 (Imiquimod), TLR7/8 (Resiquimod) and TLR9 (CpG). IFN was measured using a IFN luciferase assay, ELISA and Luminex. IFN-stimulated gene signatures (ISG) were measured by qPCR. To determine whether GILZ regulates IFN in human SLE, we mined a public gene expression dataset GSE61635. We examined IRF7 and NF- κ B involvement in GILZ effects using ChIP and reporter assays.

Results: GILZ deficiency resulted in increased pDC and BMDC secretion of IFN in response to TLR7, TLR7/8 and TLR9 stimulation. GILZ deficiency was also associated with increased ISG in naïve spleen cells, and TLR-stimulated pDC (Fig 1A) and BMDC of GILZ^{-/-} mice. Correspondingly, increased IFN was seen in GILZ^{-/-} mice in response to TLR7/8 stimulation *in vivo*. In human SLE whole blood, GILZ mRNA was negatively correlated with ISG (*IFI44*, *IFI44L*, *RSAD2*, *IFI27*) (Fig 1B). In BMDC, TLR activation suppressed GILZ, but increased IRF7 expression. CHIP-qPCR showed GILZ enrichment at the IRF7 locus in unstimulated cells, which decreased following TLR7/8/9 activation, indicating direct binding of GILZ to the IRF7 locus as the mechanism through which it regulates IFN α production. In addition, TLR7/8/9-induced NF- κ B activation was suppressed by GILZ, and increased IFN β in GILZ^{-/-} BMDC was inhibited by NF- κ B inhibition.

Conclusion: GILZ is a novel endogenous regulator of Type I IFN production *in vitro*, *in vivo*, and in human SLE, which has direct effects on both IRF7 and NF- κ B and thereby both IFN α and IFN β . This suggests that suppressed GILZ is permissive for IFN activation in SLE, and represents the mechanism through which IFN escapes glucocorticoid suppression.

Session Date: Tuesday, October 23, 2018

Session Title: Systemic Lupus Erythematosus – Animal Models Poster

Session Type: ACR Poster Session C

Session Time: 9:00 AM-11:00 AM

Background/Purpose: Systemic lupus erythematosus (SLE) is a multi-system autoimmune disease associated with B cell hyperactivity driven by dysregulated type I IFN. *Lyn*-deficient mice develop lupus-like autoimmunity due to loss of inhibitory regulation of B cell receptor signalling, resulting in hyperactive B cells, excess IL-6 production, and tissue inflammation. Mice deficient in glucocorticoid-induced leucine zipper (GILZ), an intracellular protein involved in glucocorticoid actions, develop lupus-like autoimmunity and excess B cell activation. GILZ is suppressed in human SLE

(Jones et al., 2016), but the effects of GILZ in murine models of SLE are unknown. We tested the hypothesis that loss of GILZ exacerbates autoimmunity in the *Lyn*-deficient murine model of lupus.

Methods: We crossed GILZ-deficient mice onto a *Lyn*-deficient background (GILZ-*Lyn* double knockout (DKO)) and compared them to WT and *Lyn* KO mice. The effects of GILZ deficiency on spleen weight, nephritis, serum autoantibodies and cytokines, and spleen cell expression of Type I interferon-induced genes (ISG) were examined.

Results: We observed heightened lupus-like autoimmunity in GILZ-*Lyn* DKO mice, compared to *Lyn* KO, that include increased spleen weight ($p=0.041$) and more severe glomerulonephritis, including worse glomerular segmental necrosis ($p=0.0051$) and crescent formation ($p=0.0044$) (Fig 1A-C). Despite this, serum levels of serum autoantibodies against ENAs (dsDNA, histone, Sm, Jo-1, U1RNP, Ro52, ribosomes, and Scl-70) and a panel of serum pro-inflammatory cytokines (BAFF, IL-6, IFN γ , IL-10 and TNF α) measured by Luminex assay were unaffected. In contrast, GILZ deficiency in *Lyn* deficient mice resulted in increased expression of ISG (*ifit44*, *uspi18*, *oas3*, *isg15*, *mx1*, and *irf7*) and an overall ISG signature ($p=0.0023$) (Fig 1D).

Conclusion: In *Lyn* KO lupus-prone mice, GILZ deficiency significantly exacerbated disease expression, accompanied by activation of Type I IFN, despite serum autoantibody titres and pro-inflammatory cytokines being unaffected. This suggests an inhibitory effect of endogenous GILZ on Type I IFN pathways and consequent tissue injury in this model, downstream of autoantibodies. A GILZ-based treatment could be a potential therapeutic strategy in SLE.

Session Title: Systemic Lupus Erythematosus – Animal Models Poster

Session Type: ACR Poster Session C

Session Time: 9:00 AM-11:00 AM

Background/Purpose: While T cells are important for the pathogenesis of systemic lupus erythematosus (SLE) and lupus nephritis, little is known about how T cells function after infiltrating the kidney in the setting of organ damage. The current paradigm suggests that kidney infiltrating T cells (KITs) are activated effector cells contributing to tissue damage and ultimately organ failure. We aim to examine this hypothesis by directly examining KITs.

Methods: KITs and Splenic CD4⁺ and CD8⁺ T cells were isolated from diseased mice in 3 murine models of SLE (MRL/lpr, MRL.TLR9^{-/-} (fas sufficient), and Fc γ RIIB^{-/-}.Yaa). T cells were evaluated for phenotypic, functional, metabolic, and transcriptional profiles as noted in results.

Results: The majority of CD4⁺ and CD8⁺ KITs in all three murine lupus models are not effector cells, as hypothesized, but rather, KITs mimic the “exhausted” phenotype observed in tumor infiltrating T cells. KITs exhibited a significant increase in expression of multiple inhibitory receptors including PD-1, Lag3, and Tim3, and proved highly dysfunctional with reduced cytokine production and proliferative capacity. Mechanistically this was linked directly to metabolic and specifically mitochondrial dysfunction. This phenotype is driven by the expression of an “exhausted” transcriptional signature.

Conclusion: KITs derived from lupus prone mice exhibit a phenotypic and transcriptional signature that is analogous to what has been described in the setting of chronic infection and T cell infiltrates in the tumor microenvironment. Our data reveal that the tissue parenchyma has the capability to suppress T cell responses and limit damage to self. These findings may (1) lend insights into autoimmune related adverse events associated with cancer immunotherapy, which targets T cell exhaustion (2) open novel avenues for the treatment of autoimmunity based on selectively exploiting the exhausted phenotype of tissue-infiltrating T cells and (3) inform on pathophysiologic relationships between parenchymal tissues and infiltrating cells in numerous autoimmune disease states.

Session Date: Tuesday, October 23, 2018

Session Title: Systemic Lupus Erythematosus – Animal Models Poster

Session Type: ACR Poster Session C

Session Time: 9:00 AM-11:00 AM

Background/Purpose: Despite the many lupus patients affected by neuropsychiatric signs and symptoms, the pathogenesis of neuropsychiatric disease in SLE remains unclear. MRL-lpr/lpr mice, a classic mouse model of SLE, presents with neuropsychiatric abnormalities similar to those seen in human disease including cognitive abnormalities and affective deficits. We recently found that MRL-lpr/lpr mice develop tertiary lymphoid structures (a.k.a. ectopic germinal centers) in the brain choroid plexus. Structurally and functionally, tertiary lymphoid structures resemble lymph nodes forming at the site of chronic inflammation to create more localized and specialized immune responses, which may however be detrimental in autoimmune disease. CXCL13 is a key chemokine that drives the formation of lymphoid structures. We studied whether antibody blockade of CXCL13 would prevent brain tertiary lymphoid structure formation and attenuate neuropsychiatric SLE.

Methods: Female MRL-lpr/lpr mice received intraperitoneal injections of a monoclonal anti-CXCL13 antibody, an IgG isotype control antibody, or PBS 3 times weekly for 12 weeks starting at 6-8 weeks of age. During the last week of treatment at 18-20 weeks of age, mice were assessed for cognitive dysfunction (object placement and object recognition tests), and affective deficits (Porsolt forced swim test). Brain tissues were analyzed by histology and immunofluorescent staining.

Results: Anti-CXCL13 mAb treated MRL/lpr mice displayed significant improvement in depression-like behavior as compared to the two control groups, as shown by increased mobility during the forced swim assessment ($p=0.004$). However, cognitive function assessment showed no significant improvements in visuospatial or recognition memory. Preliminary analysis of brain tissue histology showed less choroid plexus lymphocytic infiltration in anti-CXCL13 treated mice. However, there were no apparent differences in systemic disease, as spleen-to-body weight and lymph node-to-body weight ratios, as well as serum IgG anti-double stranded DNA antibody titers, were similar among the groups.

Conclusion: Preventing choroid plexus tertiary lymphoid structure formation by neutralizing CXCL13 attenuates depression-like behavior but not cognitive dysfunction in MRL-lpr/lpr mice. Our results suggest that brain tertiary lymphoid structures play an important role in the pathophysiology of affective deficits, although whether this effect of treatment was limited to the brain remains to be determined. Furthermore, CXCL13 neutralization may be a potential therapeutic strategy to target neuropsychiatric lupus.

Session Date: Tuesday, October 23, 2018

Session Title: Systemic Lupus Erythematosus – Animal Models Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00 AM

Background/Purpose: CD73 is a surface nucleotidase that extends into the extracellular space where it generates adenosine from AMP. By regulating a cell's "purinergic halo," CD73 contributes to the maintenance of immune and vascular homeostasis. Although CD73 is known to be expressed on the surface of T cells, endothelial cells, and myeloid-lineage cells, it has yet to receive intensive study in the context of lupus.

Methods: In C57BL/6 Fas^{lpr/lpr} (B6.lpr) mice, we generated littermates of 3 genotypes: CD73^{+/+}, CD73^{+/-}, and CD73^{-/-}. Autoantibody levels were measured at 16 and 32 weeks of age. At 32 weeks of age, splenocyte activation/polarization and endothelial function were also characterized. In parallel to the B6.lpr studies, we also assessed the role of CD73 in an inducible model of lupus. C57BL/6 mice with no lupus predisposition (CD73^{+/+}, CD73^{+/-}, and CD73^{-/-}) received topical dosing of the TLR7/8 agonist R848 (resiquimod) three times weekly. Autoantibody levels were measured 4 and 8 weeks after the initiation of treatment.

Results: As compared with B6.lpr CD73^{+/+} mice, B6.lpr mice with CD73 deficiency (either partial or complete) demonstrated a greater than 2-fold increase in serum anti-double-stranded-DNA antibodies at both 16 and 32 weeks; this was despite no difference in total IgG levels between groups. Beyond antibodies, CD73-deficient B6.lpr mice demonstrated additional abnormalities in peripheral blood including relative lymphopenia (5-fold decrease), neutropenia (4-fold decrease), and elevated levels of cell-free DNA. In 32-week-old B6.lpr CD73^{+/+} mice, the majority of CD73-positive cells infiltrating spleens were either T cells (CD4⁺ and double-negative) or CD11b⁺Ly6C⁺ monocytes (likely myeloid-derived suppressor cells/MDSCs). In contrast, surface CD73 was not detected on CD8⁺ T cells or granulocytic MDSCs. Endothelial function was measured in the aortas of 32-week-old B6.lpr mice by *ex vivo* exposure of aortic rings to acetylcholine in a wire myography system. As compared with CD73^{+/+} mice, CD73 deficiency resulted in impaired vessel-wall relaxation consistent with decreased nitric oxide production and resultant endothelial dysfunction. In the R848-inducible model of lupus, anti-double-stranded-DNA antibody production was again potentiated by CD73 deficiency. Studies are now underway to comprehensively phenotype the spleens of both mouse models in order to understand the dominant CD73-expressing suppressive cell type in lupus.

Conclusion: These data reveal a protective role for CD73 in lupus autoimmunity and vascular disease, and are consistent with a model whereby a key suppressive cell type (either CD4⁺ regulatory T cells or monocytic MDSCs) wields CD73 and adenosine to suppress B cell function. These data also suggest that novel therapeutic strategies might harness purinergic signaling to limit the damage inflicted by lupus upon organs and blood vessels.

Session Title: Systemic Lupus Erythematosus – Animal Models Poster

Session Type: ACR Poster Session C

Session Time: 9:00 AM-11:00 AM

Background/Purpose: SLE is a heterogeneous autoimmune disease characterized by immune system hyper-activation leading to the production of autoantibodies and immune attack on multiple organs including skin and kidney. Interferon α/β (IFN α/β) alter immune cell populations and are risk factors for SLE. Antibody blockade of the IFN α receptor has demonstrated clinical efficacy in SLE and validates targeting this pathway. JAK1 mediates signaling downstream of IFN α/β , and therefore an inhibitor of JAK1 is anticipated to reduce IFN signaling, normalize immune cell subsets, and improve SLE disease activity. The JAK1 selective inhibitor, filgotinib (FIL) is currently being evaluated in Ph2 studies in cutaneous lupus and Sjogren's syndrome. This work characterizes the disease efficacy and mechanism-of-action of FIL in the NZB/W F1 murine model of lupus.

Methods: FIL was tested in the NZB/W F1 murine model of lupus at two concentrations (0.05% and 0.1%) formulated in chow and administered ad libitum from weeks 28-40. Cyclophosphamide was used as a positive control. Efficacy was determined by proteinuria, renal histopathology, clinical pathology, and survival. Splenic lymphocyte and myeloid subsets

were analyzed by flow cytometry at study termination. Kidney gene expression was determined by qPCR, and serum cytokines by Luminex. An in vitro murine whole blood pSTAT assay and PK were used to establish a PD-PK-efficacy correlation.

Results: In the model, FIL dose-responsively decreased proteinuria and renal inflammation, improved glomerular morphology and renal function, and increased survival. Diseased mice had increased CD11⁺ dendritic cells (DCs), decreased naive T cells, and increased ratio of memory:naive T cell populations versus non-diseased mice. FIL showed a reversal of these cell populations toward non-diseased levels. Consistent with the reduction of inflammation, FIL demonstrated reduction of pro-inflammatory cytokines (e.g., TNF α , IL-6, IL-18, IL12p70, and IL9) and chemokines (e.g., CXCL1, CXCL10, MIP1 β , MCP1 and MCP3), and an increase of IL-4. FIL normalized renal expression of genes for structural damage, apoptosis, complement system, and nucleic acid sensing. Importantly, among the 16 type I interferon signature genes (ISGs) measured, 12 showed a dose-responsive decrease with FIL treatment. Calculated whole blood pSTAT inhibition is consistent with FIL pSTAT coverage achieved in clinical studies.

Conclusion: FIL demonstrated efficacy in reducing disease activity in a murine model of lupus nephritis. This effect was coupled with normalization of splenic cell subsets, ISGs, and cytokines, and provides a mechanistic basis for the evaluation of FIL in the current clinical Phase 2 studies.

NRF2 Downregulates Inflammation and Protects Against Autoimmune Lung Disease in Experimental Lupus

Shuhong Han¹, Haoyang Zhuang¹, Pui Lee², Lijun Yang³ and Westley Reeves^{1,4}, ¹Medicine, University of Florida, Gainesville, FL, ²Harvard Medical School, Boston, MA, ³Pathology, Immunology and laboratory medicine, University of Florida, Gainesville, FL, ⁴Division of Rheumatology & Clinical Immunology, University of Florida, Gainesville, FL

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Systemic Lupus Erythematosus – Animal Models Poster

Session Type: ACR Poster Session C

Session Time: 9:00 AM-11:00 AM

Background/Purpose: The transcription factor nuclear factor erythroid 2-related factor (Nrf2) is a master regulator of genes involved in cellular defense against oxidative and electrophilic stresses. It forms a cytoplasmic complex with the ubiquitin ligase KEAP1 and CUL3, which in unstressed conditions promote the ubiquitin-mediated degradation of Nrf2. Modification of the reactive cysteine residues of KEAP1 by electrophiles or ROS reduces the ubiquitin ligase activity of KEAP1/CUL3, resulting in Nrf2 stabilization and binding to antioxidant response elements (AREs) in the promoters of target genes. As there is functional cross-talk between Nrf2 and NF- κ B mediated inflammatory responses, we hypothesized that Nrf2 might downregulate chronic inflammation in mice with diffuse alveolar hemorrhage (DAH) associated with pristane-induced lupus, a disease driven by macrophages (M ϕ).

Methods: Murine M ϕ subsets were analyzed by flow cytometry and the cell subsets were flow-sorted. Binding of Nrf2 to its target sequence was determined in vitro. Gene expression in sorted M ϕ from pristane or mineral oil (MO) treated mice was determined using RNA-Seq and real-time PCR. Pristane-treated C57BL/6 mice received injections of CDDO-imidazolide every other day, a potent inducer of Nrf2/ARE signaling, or vehicle, starting 3-days after pristane treatment. DAH was assessed on day-14.

Results: M ϕ extracts from pristane-treated B6 mice exhibited lower Nrf2 binding in vitro to AREs vs. extracts from MO-treated controls. RNA-Seq showed that a series of Nrf2-regulated genes involved in the response to oxidative stress were expressed at lower levels in M ϕ from pristane vs. MO-treated mice. Low expression levels were confirmed by real-time PCR and M ϕ from pristane-treated mice had increased mitochondrial superoxide (MitoSox red staining), decreased mitochondrial membrane potential (tetramethylrhodamine staining), and increased cellular ROS (dichlorofluorescein diacetate staining) vs. controls. In vivo injection of CDDO-imidazolide decreased the number of CD11b+Ly6Chi (inflammatory) M ϕ , increased CD11b+CD138+ (pro-resolving) M ϕ , and reversed the pristane-induced changes in mitochondrial superoxide and cellular ROS while restoring mitochondrial membrane potential. Finally, CDDO-imidazolide treatment greatly attenuated the severity of DAH in pristane-treated mice (P<0.0001). A less potent Nrf2 activator, diethylmaleate, also was protective and reduced M ϕ TNF α production.

Conclusion: These observations suggest that oxidative stress is involved in the pathogenesis of chronic inflammation experimental lupus and that pharmacological Nrf2 activation can protect lupus mice from fatal lung hemorrhage.

Session Title: Systemic Lupus Erythematosus – Animal Models Poster

Session Type: ACR Poster Session C

Session Time: 9:00 AM-11:00 AM

Background/Purpose: Lupus nephritis (LN) is a serious manifestation of systemic lupus erythematosus (SLE) that adds substantial morbidity and mortality. Passive transfer of pre-formed nephritogenic antibodies to susceptible mice, or nephrotoxic serum nephritis (NTN), results in immune-mediated nephritis that closely models LN. We have previously shown that the BTK inhibitor BI-BTK-1 reverses the functional and structural kidney disease seen following induction of NTN. In the current study, we elucidated the effects of BI-BTK-1 on various immune cell populations to determine the mechanism of protection, as well as the pathways by which BI-BTK-1 reverses established nephritis. Furthermore, we assessed the effects of early and late withdrawal of treatment on the course of nephritis.

Methods: For induction of NTN, 11-week old 129 mice were immunized with rabbit IgG in CFA, and five days later passively transferred with nephrotoxic rabbit anti-mouse antibodies. To assess the effect of early (starting day 4) and late (starting day 8) treatment with BI-BTK-1 on immune cell infiltration and kidney pathology, we sacrificed BI-BTK-1 or control treated mice on days 7, 10, and 13 (n=5 per group) (Figure 1, "Treatment Delay" experiment). Kidneys were processed for flow cytometry and histology to assess the kinetics of different immune cell populations within the kidney over the course of nephritis. In a separate experiment, we began treating mice with BI-BTK-1 on day 4, and compared the effects of withdrawing treatment early (day 6) and late (day 9) on disease remission and flare (Figure 1, "Treatment Withdrawal" experiment).

A. Effects of treatment delay

B. Effects of treatment withdrawal

Figure 1. Timeline

Results: We found that early treatment with BI-BTK-1 appears to prevent the development of nephritis, and late treatment appears to reverse established disease, in murine NTN. Interestingly, early treatment withdrawal (day 6) resulted in increasing proteinuria comparable to sick control mice. Late withdrawal (day 9), however, provided significant protection against the development of proteinuria and kidney dysfunction (increased BUN) throughout the two week duration of the study ($p < 0.001$ versus sick control, $p < 0.01$ versus early withdrawal). In the treatment delay experiment, flow cytometric analysis revealed a significant reduction of kidney infiltrating M1 (inflammatory) macrophages by day 13 in both early and late treatment, whereas control treated mice exhibited decreased M2 macrophages. Both early and late treated mice had reduced kidney B220+ cells, whereas only mice treated early showed a reduction in neutrophils and CD4+ cells. Renal histology and RT-PCR results are pending.

Conclusion: Our study demonstrates the multiple cell types affected by treatment with BTK inhibition in LN. Furthermore, these results shed light upon the effects of withdrawing treatment, which may eventually have important implication for treatment decisions in human disease.

Topical Endocannabinoid Administration Protects MRL-Lpr/Lpr Mice from Cutaneous Lupus Erythematosus

Samantha Chalmers¹, Sayra Garcia¹, Andrew Draganski¹, Jessica Doerner², Adam Friedman³, Joel Friedman¹ and Chaim Putterman⁴, ¹Albert Einstein College of Medicine, Bronx, NY, ²University of Pennsylvania, Philadelphia, PA, ³Dermatology, GW School of Medicine and Health Sciences, Washington, DC, ⁴Division of Rheumatology, Albert Einstein College of Medicine, Bronx, NY, USA, Bronx, NY

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Systemic Lupus Erythematosus – Animal Models Poster

Session Type: ACR Poster Session C

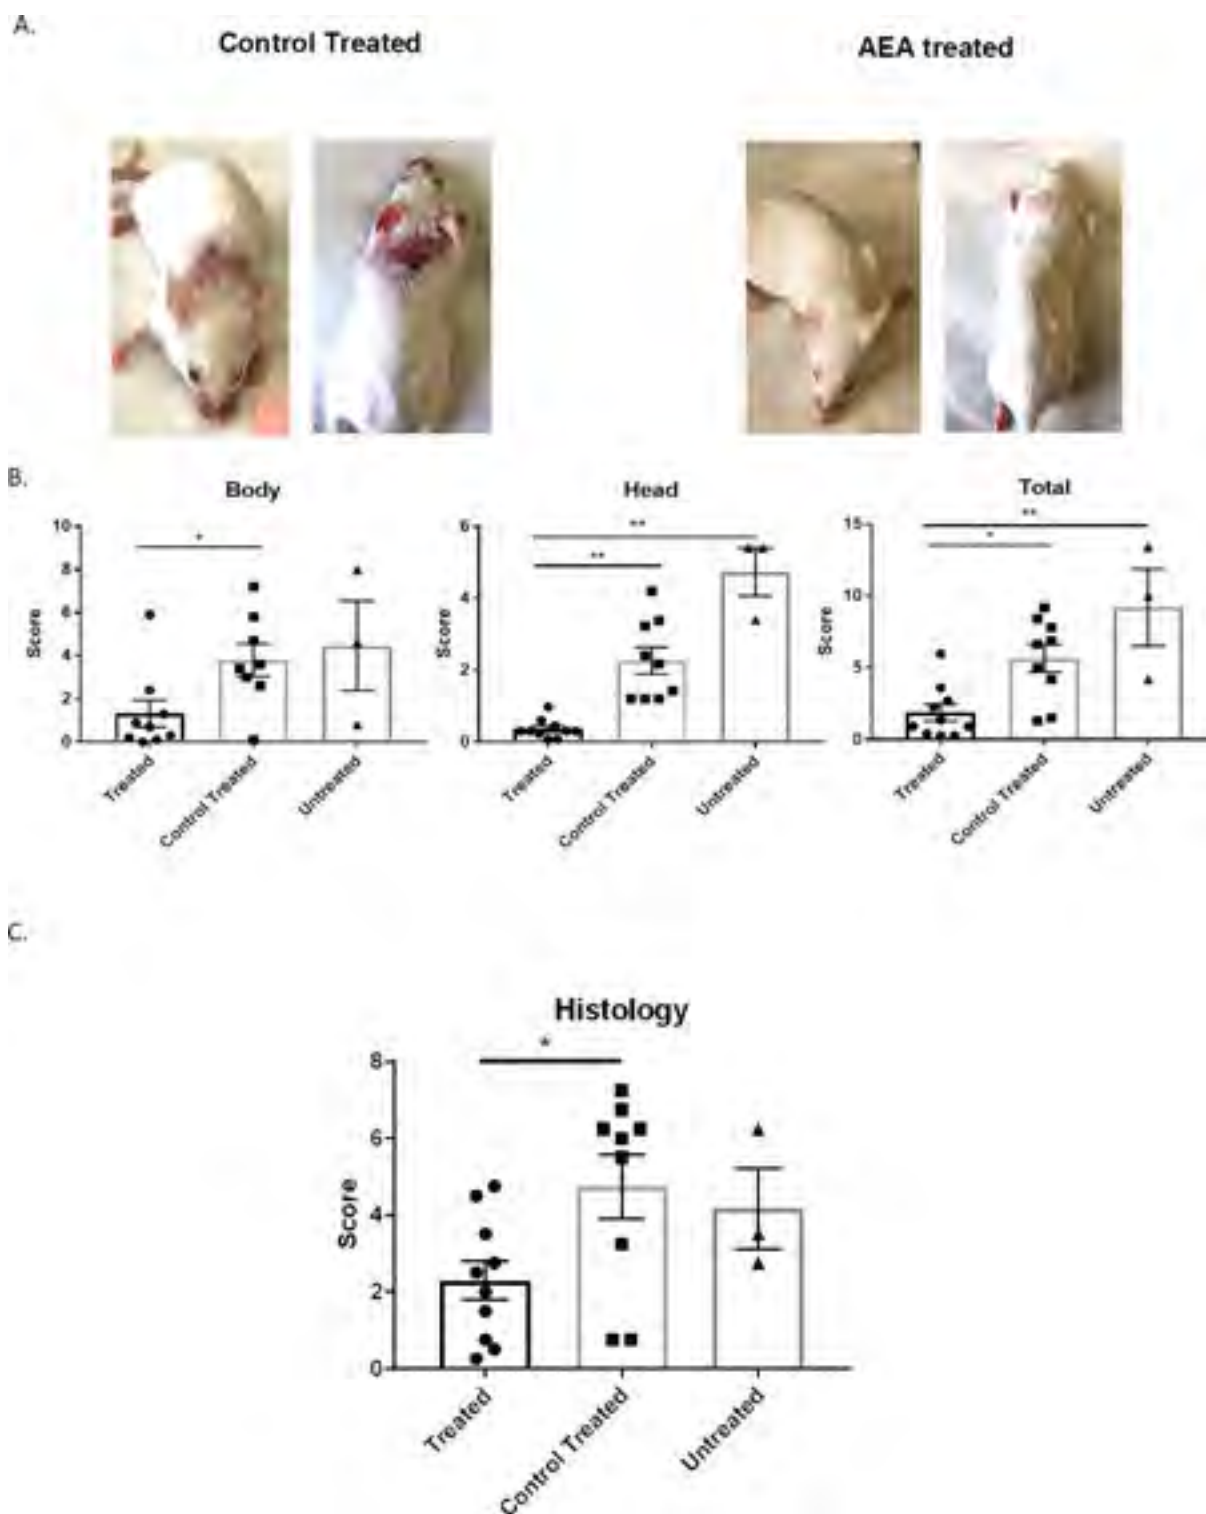

Session Time: 9:00 AM-11:00 AM

Background/Purpose: Cutaneous lupus erythematosus (CLE) affects ~75% of SLE patients and has a profound impact on quality of life. While the morbidity from CLE is significant, effective therapeutic options, including topical therapies, are limited. There is growing evidence that the manipulation of the endocannabinoid system has immunomodulatory activity which could be clinically translated to a broad range of cutaneous and systemic inflammatory diseases, although data is limited specially with respect to topical administration. In this study, local application of anandamide (AEA), a highly lipophilic endocannabinoid, was evaluated in MRL/lpr lupus prone mice, which spontaneously develop skin lesions similar to chronic CLE both clinically and histologically. To overcome known issues with respect to topical delivery of cannabinoids, nanoparticle encapsulation was employed.

Methods: Nanoparticles with 125 nm radius were loaded with 4% AEA (AEA-np) and mixed with coconut oil (25% by weight). Starting at 10 weeks of age, female MRL/lpr mice were treated twice a week with interscapular application of the AEA compound without hair removal. Control groups of mice were treated topically with empty nanoparticles ("control treated") or received only coconut oil ("untreated"). Mice were regularly scored using a validated modified CLASI tool to assess the effect of AEA on cutaneous disease. At 20 weeks of age, mice were sacrificed and the skin harvested for histological analysis.

Results: AEA-np treated mice had significantly improved skin lesions. Interestingly, this improvement was noted both where the nanoparticles were directly applied, as well as the face/snout region. At the time of sacrifice, AEA treated mice had significantly less macroscopic lesions (Figure 1A), which were scored blindly ($p < 0.0001$) (Figure 1B). Moreover, significant histologic improvement was seen as well ($p < 0.05$; Figure 1C). No differences were seen in systemic disease parameters, namely circulating anti-dsDNA antibodies and proteinuria levels. Immunofluorescent staining of skin sections to characterize cellular infiltration and mechanistic studies in vitro are in progress.

Conclusion: Together, these data demonstrate that topical administration with AEA loaded nanoparticles significantly prevents the development of CLE in an established animal model of lupus. Furthermore, this work reinforces and highlights the utility of targeting the endocannabinoid system for autoimmune rheumatic diseases.

Session Date: Tuesday, October 23, 2018

Session Title: Systemic Lupus Erythematosus – Animal Models Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Photosensitivity is a major symptom of lupus, and excessive sunlight can cause skin rashes and flares of disease activity in systemic lupus erythematosus (SLE). Although UV-induced skin inflammation has been widely studied, it remains elusive how UV triggers lupus. A previous study demonstrated that mice lacking the Ro60 autoantigen (Ro60^{-/-}) have increased photosensitivity and spontaneously develop lupus after 6 months of age. Also, it has been shown that lupus patients have elevated levels of type I interferon (IFN). To dissect molecular mechanisms by which UV-induced inflammatory responses are exacerbated in lupus, we combined IFN priming with photosensitive Ro60^{-/-} mice and investigated the effects of UV on lupus-prone skin.

Methods: A recombinant adenovirus encoding IFN- α was administered to 4–5-month-old mice by retro-orbital injection two weeks prior to UV irradiation (IFN priming). Subsequently, mice were irradiated with UVB 250 mJ/cm²/day for three consecutive days. Skin biopsies were taken at four time points and subjected to histological, flow cytometry, and gene expression analyses. Eight groups ($n = 4$ mice per group) were compared: wild type (WT) versus Ro60^{-/-} (C57BL/6 background), male versus female, and with or without IFN priming.

Results: Three consecutive UV exposures caused severe skin damage (erythema and hyperkeratosis) in IFN-primed Ro60^{-/-} females. Gene expression analysis of UV-irradiated skin revealed that many inflammatory genes were differentially upregulated among the 8 mouse groups. Specifically, a combination of IFN priming, Ro60 deficiency, and female gender augmented UV-induced upregulation of *Irf7* (regulator of type I IFN gene induction), *Isg15* (IFN-stimulated gene), and *Ccl2* (chemokine for monocyte recruitment). Consistently, flow cytometry analysis revealed that more inflammatory monocytes (CD45⁺Ly6C^{high}Ly6G^{low}) were recruited to UV-irradiated skin 1 day after the third UV in IFN-primed Ro60^{-/-} females than in IFN-primed WT females. Intriguingly, IFN-primed Ro60^{-/-} females exhibited significantly higher levels of *Ifnar2* (IFN α receptor subunit 2) following UV than their WT counterparts, likely contributing to augmented type I IFN responses.

Conclusion: Inflammatory responses to UV irradiation were augmented in IFN-primed Ro60^{-/-} female, but not in WT, male, or unprimed mice. This female predominance is comparable to that of SLE in humans. Ro60 is an RNA-binding protein and binds to small noncoding RNAs. Lack of Ro60 may disrupt RNA homeostasis and activate RNA sensors and type I IFN pathways. This study provides novel insight into lupus susceptibility factors (IFN priming, Ro60 deficiency, and female gender) that contribute to exacerbation of UV-induced skin inflammation.

Hyaluronic Acid Synthesis Inhibition Blocks Nephritis and Extends Lifespan in Mice Prone to Lupus

Abel Suarez-Fueyo¹, Seung-Ki Kwok², Kayaho Maeda³ and George C Tsokos⁴, ¹Rheumatology, Department of Medicine, Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA, Boston, MA, ²Seoul St. Mary's Hospital, The Catholic University of Korea, Seoul., Seoul, Korea, Republic of (South), ³Rheumatology, Department of Rheumatology, Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA, Boston, MA, ⁴Division of Rheumatology, Department of Medicine, Department of Medicine, Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA, Boston, MA

Session Information**Session Date:** Tuesday, October 23, 2018**Session Title:** Systemic Lupus Erythematosus – Animal Models Poster**Session Type:** ACR Poster Session C**Session Time:** 9:00AM-11:00AM

Background/Purpose: Hyaluronic acid (HA) is a component of the extracellular matrix and is known to be involved in cancer biology. Although evidence suggests that HA plays a role in the expression of kidney pathology in patients with SLE, its function is not fully understood. T cells from patients with SLE express increased amounts of CD44 to which HA binds inducing T cell polarization, adhesion, and migration (J Immunol. 2007, 178:1938-47). In this study, we asked how HA contributes to the expression of lupus pathology and whether it can be targeted therapeutically.

Methods: We analyzed HA expression in kidneys from patients with SLE and a lupus-prone MRL/lpr mice, by using immunohistochemistry. Peripheral blood mononuclear cells (PBMC) from healthy donors were stimulated with anti-CD3/CD28 in the presence or not of HA. 4-Methylumbelliferone (4-MU), an HA synthase inhibitor, was orally administrated to male MRL/lpr starting at the age of 3 months (prevention) or 5 months of age (treatment). In addition, in a third group, 4-MU was administered at the age of 3 months and discontinued at the age of 5 months. At the end of the treatment tissues (kidney and skin) were evaluated by immunohistochemistry, spleen, lymph node and kidney cells were evaluated by flow cytometry.

Results: Kidneys from MRL/lpr and patients with SLE displayed increased accumulation of HA compared to control tissues coinciding with the accumulation of immune cells. MRL/lpr mice which received 4-MU at 3 months of age did not develop any organ inflammation, but discontinuation of treatment resulted in late disease (proteinuria, kidney and skin inflammation) development. Treatment of 5 months old mice that already developed disease halted further progression of the disease with minimal reversal of tissue pathology. Treatment with 4-MU led to increased proportions of Tregs and reduced double negative (DN)T cells, Th17, and Th1 cells both in the spleen and the kidney. Exposure of PBMC from healthy donors to low molecular weight HA *in vitro* while stimulated with anti-CD3/CD28 led to the expansion of DNT cells.

Conclusion: HA expression is increased in tissues in patients with SLE and lupus-prone mice and probably enable the homing and activation of CD44 positive T cells. Inhibition of HA synthesis prevents disease development but fails to reverse established pathology. In addition, HA promotes the generation of CD4⁺CD8⁻CD3⁺ cells which are known to contribute to lupus immunopathology. The development of drugs which prevent the entrance and activation of T cells to tissues should represent novel approaches to prevent relapses in patients with SLE.

Abstract Number: 2103

Using a *Drosophila* Model to Unravel the Genetic Complexity of Systemic Lupus Erythematosus

Nathan Mortimer, Mary Fischer, Ashley Waring and Victoria DeMichel, School of Biological Sciences, Illinois State University, Normal, IL

Session Information**Session Date:** Tuesday, October 23, 2018**Session Title:** Systemic Lupus Erythematosus – Animal Models Poster**Session Type:** ACR Poster Session C**Session Time:** 9:00AM-11:00AM

Background/Purpose: The objective of our research is to understand the genetic architecture and molecular mechanisms that contribute to the development and progression of the autoimmune disease systemic lupus erythematosus (SLE). SLE occurs when the immune system loses self tolerance and triggers a self-directed immune response, often leading to inflammation and tissue damage. Recent evidence demonstrates that both the acquired and innate immune responses are implicated in SLE pathogenesis, however the role of innate immunity is largely understudied. Additionally, while a large number of genes have been linked to SLE, efforts into understanding the basis of the disease have been hindered by this genetic complexity. In order to understand the role of innate immune responses and to unravel the underlying genetics, we have developed a *Drosophila* model of SLE. *Drosophila* provides many advantages for this research, including a wealth of genetic tools, experimental tractability and a highly conserved innate immune response. To develop the SLE model, we have focused on a mutant strain of *Drosophila* which mounts a self-directed cellular inflammation response that results in the damage of self tissue.

Methods: We have characterized the *Drosophila* SLE model using a combination of cell biology approaches including immunofluorescence and cell stains, genetic mapping, and RNA interference mediated reverse genetics.

Results: We find that the *Drosophila* SLE-like phenotype arises from two distinct mutations. The first mutation is a gain of function mutation in the *Drosophila* homolog of Janus Kinase (JAK). Mutations in JAK are linked to a variety of autoimmune diseases including SLE. The second mutation is a loss of function mutation in an enzyme of the N-glycosylation pathway, and accordingly we find that the mutants have decreased N-glycosylation of extracellular matrix (ECM) proteins. Interestingly, altered N-glycosylation is seen in SLE patient samples, and mutations in ECM proteins have been linked to SLE pathogenesis. Additionally, reverse genetics suggests that the *Drosophila* homolog of the SLE-linked integrin gene ITGAM plays a central role in the self tolerance mechanism that is mediated by ECM protein N-glycosylation.

Conclusion: These results demonstrate a high degree of genetic conservation between SLE and our *Drosophila* model. Our data have uncovered a functional link between SLE risk factors, including increased JAK activity, altered N-glycosylation of ECM proteins and decreased integrin receptor signaling, that has not been previously identified in traditional SLE models. This establishes the benefit of our high-throughput and genetically tractable *Drosophila* model to better understand the genetic complexity underlying SLE pathogenesis. Our findings further suggest that additional research into the genetic basis of the *Drosophila* model will likely uncover new SLE genes and provide insight into the molecular interactions between SLE risk factors, and may therefore open new avenues for clinical research or point to new therapeutic strategies.

Session Title: Systemic Lupus Erythematosus – Animal Models Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: NZM2328 mice spontaneously develop glomerulonephritis (GN) and females commonly progress to renal failure. Our previous study showed that acute GN (aGN) and chronic GN (cGN) are two pathological stages, controlled by different genetic loci, and aGN need not progress to cGN. In this study, glomerular and tubular transcriptional profiles were obtained from kidneys of NZM2328 female mice at 8-9, 26, and 36 weeks of age. Transcriptome analysis was employed to characterize the pathologic processes in the separate regions of the affected kidneys to develop better insight into the check points operative in the control of tissue pathology.

Methods: Glomerular and tubular cells were collected separately using Laser Microdissection (LMD) from the same kidneys of NZM2328 female mice at 8-9, 26, and 38 weeks of age. Total RNA from LMD-derived cells were labeled and hybridized on Affymetrix Mouse Genome 430 v2.0 microarrays. LIMMA statistical analyses in R software was used to generate lists of genes with significant differential expression (DE) compared with young mice using a FDR < 0.2 threshold. Weighted gene co-expression network analysis (WGCNA) and module preservation analyses in R were used to find the modules specific for different disease stages. Gene set variation analysis (GSVA) was used to identify the enriched gene clusters in the various GN stages. Upstream regulators(UR) were identified using Ingenuity Pathway Analysis (IPA) combined with LIMMA DE results.

Results: Hierarchical analyses using LIMMA and GSVA showed that glomerular transcriptional profiles from kidney samples can be classified into four distinct groups, normal, aGN, tGN and cGN, which correlated with tissue histology. In contrast, tubular transcriptional profiles from the same kidneys could only be separated into normal and GN, indicating common tubular gene expression profiles across GN stages. Gene clusters generated by WGCNA not only could identify

specific modules for tGN and cGN stages in the glomeruli, but also were able to identify gene modules specific for aGN, tGN and cGN stages in tubular cells. Upstream regulators, such as IL1 β , and Tgf β 1, were found in tGN glomerular modules, indicating that these genes might play an important role in the disease progression from aGN to cGN. However, UR failed to be identified in tubular gene clusters at the aGN or the tGN stage, suggesting that tubular changes at these stages might be related to changes resulting from glomerular insult.

Conclusion: Both hierarchical analysis and GSVA showed that glomeruli expression changes correlated with disease progression. However, tubules exhibited diversity in their gene expression profiles. WGCNA-generated gene clusters and their upstream regulators were identified in glomeruli at the tGN and cGN stages, as well as in tubular cells at the cGN stage. These novel co-expression gene network clusters could provide a basis to identify specific pathways and biomarkers governing the progression through different disease stages in both the glomeruli and tubules of lupus nephritis.

Genetic Analysis of a *Drosophila* Systemic Lupus Erythematosus Model Reveals Lupus Susceptibility Genes

Pooja KR, Brooklynne Thielen, Xavier Hernandez and Nathan Mortimer, School of Biological Sciences, Illinois State University, Normal, IL

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Systemic Lupus Erythematosus – Animal Models Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is a multisystem autoimmune disorder with various immunological abnormalities and a diverse range of clinical symptoms. In contrast to the traditional belief that SLE is solely an adaptive immune disorder, multiple studies of patient samples and mouse models have revealed the involvement of innate immune mechanisms in the initiation of SLE. However, the exact role of innate immunity in SLE pathogenesis is unknown, thus we have developed a new model to understand the genetic complexity of disease development and susceptibility. *Drosophila* is well suited to this research as the innate immune pathways are well conserved between humans and mammals including the JAK-STAT pathway which has been specifically implicated in pathology of SLE in humans. To understand the regulation of the JAK-STAT pathway and its role in SLE, we are utilizing our newly developed *Drosophila* SLE model, which has a gain of function mutation in the *Drosophila* homolog of JAK. Our goal is to identify genes that contribute to the SLE-like phenotype with a particular focus on JAK-STAT signaling.

Methods: To identify genes that modify the *Drosophila* SLE model phenotype, we performed two genetic screens. Forward genetic screening was performed in which 20% of the *Drosophila* genome was screened to look for regions containing genes involved in the autoimmune response in the *Drosophila* SLE model. To understand the role of JAK-STAT signaling in regulating autoimmunity, we conducted a reverse genetic screen in which we tested the role of candidate transcriptional factors in the SLE model autoimmune phenotype. We selected these genes based on previous links to JAK-STAT and then used RNAi to knockdown these genes in immune cells in our *Drosophila* model.

Results: We performed genetic screening and identified novel genes associated with SLE that may regulate conserved transcriptional networks which underlie self-tolerance. Our genetic modifier screen revealed 12 regions that modified the SLE phenotype. We predict that these regions contain genes that function in SLE-associated autoimmune mechanisms. Since our SLE mutant has a gain of function mutation in JAK-STAT, we conducted a reverse genetic screen that focused on understanding of the role of this pathway in autoimmunity. We discovered that RNAi mediated knockdown of candidate transcription factors in mutant immune cells suppressed the phenotype, suggesting that these genes promote JAK-STAT activity.

Conclusion: This study uncovers novel genetic interactions that may play a role in the contribution of the JAK-STAT pathway to SLE pathogenesis. The human homologs of two of our identified JAK-STAT interacting genes, AFF1 and BACH2, have been previously linked to SLE, whereas the others represent putative novel SLE risk factors. Identification of these new genes and genetic interactions will expand our knowledge of the processes which lead to autoimmune disorders, and investigating their molecular role in the *Drosophila* SLE model may well open a new window for the understanding and clinical treatment of this complex disease.

Session Title: Systemic Lupus Erythematosus – Animal Models Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Cognitive dysfunction affects up to 90% of patients with systemic lupus erythematosus (SLE), however it is grossly under-recognized, the pathogenesis is poorly understood and no treatments are available. The anti-NMDAR antibody, a subset of anti-DNA antibodies termed DNRAbs, has been strongly associated with cognitive impairment, notably spatial memory impairment, in both mouse models and humans. In a mouse model, DNRAb-mediated brain pathology proceeds through two stages: excitotoxic neuron loss, followed by persistent neuroinflammation resulting in alteration in neuronal integrity and spatial memory impairment. Microglia-mediated inflammation is generally becoming well accepted as one of the main mediators of neurodegeneration. In our studies we are investigating the mechanisms of long-term neuronal dysfunction mediated by transient exposure to DNRAb. Also, with the emerging yet unknown role of the renin-angiotensin-system, notably angiotensin II, in microglia-mediated neuroinflammation in neurodegenerative diseases, angiotensin-converting enzyme (ACE) inhibition could be an attractive treatment option to test for preserving cognitive impairment through its effects on C1q and C1q's inhibitory receptor, LAIR1.

Methods: Mice immunized with DNRAb and then treated with LPS to breach the blood brain barrier and allow transient access of antibody to the hippocampus, were studied for loss of neuronal dendritic complexity using Golgi and for microglial activation with immunohistochemistry. Spatial memory was assessed with a battery of behavioral tests and CA1 hippocampal neuronal activity was assessed with electrophysiology studies. Microglia were depleted with Colony Stimulating Factor 1 Receptor (CSF1R) inhibitor PLX5622. Mice received centrally acting ACE inhibitor, captopril (or control peripherally acting ACE inhibitor, enalapril), one week after LPS for two weeks. ACE levels in brain tissue was checked before and after treatment. C1q-KO mice and LAIR1-Lyz2-Cre mice were also studied to assess the roles of C1q and LAIR-1 in glia-mediated neuroinflammation.

Results: DNRAb mice had significantly decreased dendritic complexity ($p<0.01$), and impaired spatial memory ($p<0.01$), which was preserved in CSF1R-inhibitor treated mice ($p<0.03$) and in C1q-KO mice. These findings suggest that activated microglia and C1q are critical mediators of DNRAb-associated neuronal damage and spatial memory impairment. We further showed that centrally acting ACE inhibitors can preserve neuronal dendrite complexity ($p<0.03$) and cognitive performance ($p<0.01$) in the mouse model. The effect of captopril was diminished in the LAIR1-Lyz2Cre knockout ($p<0.0001$), signifying that LAIR1 is important in the protective mechanism of captopril.

Conclusion: ACE inhibition may be considered as a safe and promising class of therapeutics in cognitive impairment in SLE and represents a strong candidate for future clinical trials aimed at mitigating cognitive dysfunction. Further studies to understand the mechanism of action of ACE inhibitors are needed.

Lupus-Prone SLE1.2.3. Mice Exhibit Loss of Thymus-Derived CD4⁺CD25⁺Helios⁺ Tregs

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Systemic Lupus Erythematosus – Animal Models Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is a potentially fatal autoimmune disease that is characterized by the production of autoantibodies against nuclear antigens (ANA) and phospholipids (aPL). ANA and aPL production have been found to dependent on activation of complex 1 of the mechanistic target of rapamycin (mTORC1) in several mouse models of SLE (Arthritis Rheumatol. 68:2728-2739, 2016). Mouse models of SLE have been indispensable tools for studying disease pathogenesis, however, each model only recapitulates limited aspects of lupus. SLE1.2.3. mice are mice homozygous for three NZM2410-derive lupus susceptibility loci on the C57Bl/6J background. These mice develop systemic autoimmunity with fatal glomerulonephritis and die typically by 12 months of age. Within the last decade, metabolic pathways have been found to regulate lineage specification in the immune system, many of which have been implicated in disease. Here, we investigated immunometabolic checkpoints of disease pathogenesis in SLE1.2.3 mice.

Methods: SLE1.2.3 mice have been compared to C57Bl/6 wild-type (WT) controls. Mice were matched for age and gender. Splenic tissue were harvested at 30 weeks of age and examined for lineage specification and metabolic changes within the adaptive and innate arms of the immune system via flow cytometry. ANA and aPL were measured as earlier described (Arthritis Rheumatol. 68:2728-2739, 2016). 10,764 immunometabolic parameters were analyzed by flow cytometry and a p-value of less than 0.05 was considered significant for hypothesis testing.

Results: Male and female WT mice produced 0.520 (± 0.042) and 0.670 (± 0.057) μ g of protein per μ L of urine. In contrast, SLE mice had significantly more proteinuria with males and females producing 1.183 (± 0.041 , $p=0.000274$) and 0.906 (± 0.039 , $p=0.0279$) μ g protein per μ L urine. There was also significant elevation of autoantibody production with increases in ANA or anti-cardiolipin by as much as 55-fold. Analysis of the immune system revealed an 18% decrease of CD4⁺ cells ($p=0.02045$). Correspondingly, there was a 22% and 34% increase in CD8⁺ ($p=0.02782$) and CD4⁺CD8⁺ double negative (DN) T cells ($p=0.01505$), respectively. We further found, in male mice, a 31% decrease in CD4⁺Foxp3⁺ Tregs and that mTORC1 activity was decreased by 51% and 39% in regulatory subsets such as CD4⁺Helios⁺ and CD4⁺CD25⁺Helios⁺ Tregs ($p=0.03841$, $p=0.00631$), respectively. In the female mice, mTORC1 activity was decreased in CD4⁺CD152⁺ Tregs decreased by 56% ($p=0.004407$) and mTORC2 activity in CD4⁺CD25⁺ Tregs was decreased by 65% ($p=0.037331$). CD4⁺CD25⁺FoxP3⁺ Tregs were similar in WT and SLE1.2.3 mice.

Conclusion: SLE1.2.3. mice recapitulated lupus pathogenesis which involves ANA and aPL production and glomerulonephritis. Autoantibody production and nephritis has been responsive to mTORC1 blockade with rapamycin. The data suggest that ANA and aPL production may be controlled by mTORC1-dependent development of thymus-derived CD4⁺CD25⁺Helios⁺ Tregs which may serve as targets for therapeutic interventions in SLE.

Session Title: Systemic Lupus Erythematosus – Etiology and Pathogenesis Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: We found in reproducible experiments in which the mice not prone to autoimmune disease were immunized repeatedly with antigen that overstimulation of CD4 T cells led to the development of *ai*CD4 T cell which had undergone TCR revision capable of inducing varieties of autoantibody and antigen-specific CTL *via* antigen cross-presentation, after which they caused SLE (Tsumiyama K et al., 2009). Here we identify *ai*CD4 T cell as DOCK8+CD4 T cell.

Methods: *ai*CD4 T cell was searched by transferring different fractions of CD4 T cells of x12 OVA-immunized BALB/c female mice into naïve mice and tested if autoantibodies were raised, mass spectrometry, and FACS.

Results: We focused CD45RB^{lo} CD122^{lo}PD-1+CD4 T cell as *ai*CD4 T candidate, and its membrane uniquely expressed DOCK8. DOCK8+CD4 T cell was a large lymphocyte with abundant ER and mitochondria, ICOS+ CXCR5- PD1+ Ly6C+ LFA1+, produced increased IFN γ , IL-4, IL-6, IL-17 and IL-21, and its TCR repertoire was deviated. Upon transfer to naïve mice or to the x8OVA-pre-immunized and CD4 T-depleted mice in which CTL was yet immature, DOCK8+CD4 T cells induced SLE, where anti-dsDNA/Sm Ab, glomerulonephritis of WHO IV/V types (Table, upper), skin liquefaction degeneration, splenic periarteriolar fibrosis with amyloid-like deposits classical of Onion-skin lesion, pericholangitis, pneumonitis, thyroiditis, perineuritis and panniculitis developed. Manifestations including kidney disease (Table, lower) were cured by anti-DOCK8 Ab treatment.

Conclusion: We prove the self-organized criticality theory explaining that autoimmunity arises as a natural consequence of routine but exaggerated immune response against antigen when stimulated maximally beyond immune systems self-organized criticality and show that DOCK8+CD4 T cell causes SLE.

Table.

Effect of the transfer of DOCK8+ CD4 T cell to the kidney disease of recipient mice

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Systemic Lupus Erythematosus – Etiology and Pathogenesis Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: During the T cell differentiation, signal transducer and activators of transcription (STAT) family transcription factors play pivotal roles in specifying T cell lineages. T follicular helper (Tfh) cells serve important roles in the development and progression of systemic lupus erythematosus (SLE). To assess the characteristics and mechanisms of differentiation of Tfh cells, we studied the underlying epigenetic modifications by cytokine-induced STAT activation and the phenotype of circulating T helper cells in SLE patients.

Methods: Peripheral blood mononuclear cells from patients with SLE and healthy controls (HC) were analyzed by flow cytometry. The phenotype of circulating T cells was defined based on flow cytometric analysis for human immune system termed “the Human Immunology Project” proposed by NIH/FOCIS. Naive CD4⁺ T cells and memory CD4⁺ T cells were isolated and cultured with T cell receptor (TCR) and various cytokines in vitro. Expression of characteristic markers of Tfh cells and phosphorylation of STATs were analyzed by flow cytometry and qPCR. Histone modifications were evaluated by chromatin immunoprecipitation (ChIP)-PCR. Peripheral blood mononuclear cells from SLE patients and healthy controls were analyzed by flow cytometry and productions of cytokines in serum were tested by cytometric bead array.

Results: Among the immunoregulatory cytokines, IL-12 induced the differentiation of CD4⁺CXCR5⁺CXCR3⁺Bcl-6⁺Tbet⁺IL-21⁺IFN- γ ⁺ T cells, which share features of both Tfh and Th1 cells. The loci of Bcl-6 and Tbet at STAT binding sites were marked by bivalent histone modifications. After IL-12-stimulation, both STAT1 and STAT4 were phosphorylated simultaneously and directly bound on *BCL6* (encoding Bcl-6) and *TBX21* (encoding Tbet) gene loci accompanied by suppression of repressive histone mark trimethylated histone 3 lysine 27. Compared with HCs, the proportion of CD4⁺CXCR5⁺CXCR3⁺CCR6⁺CD69⁺ activated Tfh-Th1-like cells were significantly increased in patients with SLE (mean 0.7 vs 0.4, p=0.02). Levels of serum IL-12 and expression of IL-12 receptors in memory T cells were significantly increased in patients with SLE compared to HCs (p<0.01). Furthermore, the level of pSTAT1, pSTAT4 and Tbet were higher in activated Tfh-Th1-like cells than non-Tfh-Th1 cells (p<0.05).

Conclusion: The findings suggest that IL-12-mediated co-activation of STAT1 and STAT4 alters histone modification, resulting in development of Tfh-Th1-like cells that are characteristically expanded in patients with SLE. This could be one of underlying mechanisms responsible for the pathogenesis of Tfh cells in SLE. Thus, modulation of STAT-mediated gene regulation in Tfh cells potentially offer the opportunities for cell-specific treatment of SLE.

Session Title: Systemic Lupus Erythematosus – Etiology and Pathogenesis Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is a complex, chronic, autoimmune disease. Genome-wide association studies (GWAS) have identified multiple risk SNPs in HLA and non-HLA gene regions. There is evidence that genetics are also important in lupus nephritis (LN) risk. LN is one of the most common and severe manifestations of SLE. The purpose of this study was to determine the association of known SLE risk SNPs with LN in both childhood-onset (cSLE) and adult-onset SLE (aSLE) populations.

Methods: The study population included two tertiary care SLE cohorts; one with cSLE and the other with aSLE. Participants met American College of Rheumatology (ACR) and/or Systemic Lupus International Collaborating Clinics (SLICC) classification criteria for SLE, with prospectively collected clinical and laboratory data. Participants were genotyped on the Illumina MEGA or Omni1 arrays. Principal components were calculated in reference to the 1000 genomes project, and ancestry was genetically inferred. Ungenotyped SNPs were imputed. HLA alleles were imputed in Europeans only. HLA and non-HLA additive SLE weighted genetic risk scores (GRSs) were computed using published SLE GWAS weights. LN was confirmed by renal biopsy as defined by the WHO or the International Society of Nephrology/Renal Pathology Society or diagnosed with renal casts, hematuria, proteinuria, and/or pyuria on two consecutive urinalyses. HLA and non-HLA GRSs were regressed individually and jointly, against LN risk in logistic regression models stratified by cSLE/aSLE cohort and ancestry, adjusted for sex, age of SLE diagnosis, and duration of follow-up. Effect estimates from stratified analyses were meta-analyzed using inverse-variance weighted fixed effects models.

Results: The cohorts included 421 with cSLE and 878 with aSLE. The mean age of diagnosis of patients with cSLE was 12.9 years (SD=3.2), 82% were female and 41% had LN. Among the aSLE patients, the mean age of diagnosis was 30.2 years (SD=13.1), 89% were female and 39% had LN. Genotyping and imputation resulted in 11.5M SNPs with minor allele frequency ≥ 0.01 and imputation quality ≥ 0.9 . Meta-analyses demonstrated that increasing non-HLA GRS was significantly associated with increased LN risk (OR = 1.27; 95% CI: 1.11, 1.45, $p = 0.0005$). The strongest effect was observed among Europeans with cSLE (OR = 1.60; 95% CI: 1.08, 2.35, $p = 0.018$), whereas in those with aSLE the association was positive but not significant (OR=1.12; 95% CI: 0.91, 1.37, $p = 0.291$). HLA-GRS was not significantly associated with increased LN risk in meta-analysis of all Europeans, yet was significant in Europeans with cSLE (OR = 2.14; 95% CI: 1.00, 4.59; $p = 0.0499$). This association was insignificant in Europeans with aSLE (OR = 1.03; 95% CI: 0.56, 1.90; $p = 0.923$).

Conclusion We found a significant association between non-HLA SLE genetic risk SNPs and LN in our cohort of children and adults with SLE. We found that the effects were strongest among the childhood-onset SLE patients of European ancestry. The HLA risk alleles were also associated with LN risk, but did not reach statistical significance. Futures studies will include additional SLE cohorts.

IFN β Affects Osteogenesis-Adipogenesis Axis in SLE Bone Marrow

Lin Gao, Mary O'Connell, Jennifer Anolik and R. John Looney, Medicine- Allergy, Immunology and Rheumatology, University of Rochester Medical Center, Rochester, NY

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Systemic Lupus Erythematosus – Etiology and Pathogenesis Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: SLE patients are especially vulnerable to corticosteroid induced avascular necrosis. While it is appreciated that multiple factors contribute to AVN, the bone-fat axis in bone marrow is critical. The goals of this project are to examine the mechanisms by which MSC differentiation was affected in SLE and to develop targeted therapies to mitigate this risk. In SLE, type I interferons are key drivers of chronic inflammation, and thus might be a predisposing factor for avascular necrosis. Our recently published data demonstrate that SLE bone marrow MSC produce increased quantities of IFN β . Moreover, SLE BMSC production of IFN β is based on a positive feedback loop involving the innate signaling molecule Mitochondrial Antiviral Signaling (MAVS) protein and that this pathway contributes to human SLE BMSCs senescence associated secretory phenotype (SASP). Here we set out to investigate the differentiation defects of SLE BM-MSCs and the potential intervention approaches.

Methods: The SLE patients recruited in this proposal satisfy the ACR classification criteria for SLE. BM MSCs were isolated with Ficoll centrifugation (1.073 g/ml) and phenotyped using flow cytometry. *In vitro* studies included real-time PCR, western blotting.

Results: Our data suggested heterogeneity in SLE patients based on IFN β level in blood serum. About 3/4 SLE patients had increased levels of IFN β (mean= 2.30pg/ml) compared to healthy controls (mean=0.11pg/ml). Moreover, serum levels of IFN β protein correlated with IFN β mRNA in BM-MSCs ($R^2 = 0.8$, $p<0.05$). We compared 6 age paired BM aspirates from healthy controls and SLE patients. BM-MSCs from SLE patients and healthy controls were isolated and cultured. The MSC surface markers are positive for CD73, CD90 and CD105, but negative for CD34 and CD45 in both healthy and SLE BM-MSCs culture. SLE BM-MSCs display significantly decreased osteogenesis markers, such as ALP (6 folds, $p<0.05$), RUNX2 (8 folds, $p<0.05$), OCN (4 folds, $p<0.05$) and BSP (4 folds, $p<0.05$). However, when adipogenesis markers were evaluated, increased C/EBP delta (7 fold, $p<0.05$), PPARG (4 fold, $p<0.05$), Fabp4 (5 fold, $p<0.05$) and Adiponectin (5 fold, $p<0.05$) were found. Because transcription factor Runx2 is a critical regulator for osteogenesis and C/EBP delta is required for early adipogenesis, we then investigated the correlation between IFN β gene expression and these two transcription factors. The results suggested that Runx2 is negatively correlated with IFN β ($R^2 = 0.78$, $p<0.05$); while C/EBP delta positively correlated with IFN β ($R^2 = 0.89$, $p<0.05$). When BM-MSCs from healthy controls were treated with IFN β , reduced ALP (12 folds, $p<0.05$), RUNX2 (11 folds, $p<0.05$), OCN (8 folds, $p<0.05$) and BSP (7 folds, $p<0.05$) were observed. In contrast to osteogenesis markers, IFN β up-regulated adipogenesis markers C/EBP delta (6 folds, $p<0.05$). Taken together, our data indicate a role of IFN β in osteogenesis-adipogenesis axis in SLE.

Conclusion: IFN-I signature is an important feature of SLE. Our present work suggests that IFN β affects osteogenesis-adipogenesis axis. By revealing the essential role of IFN β on SLE BM-MSC differentiation, our study shed light on SLE pathogenesis and provides a new potential therapeutic target for SLE treatment.

IFN-Gene Expression Is Elevated in Subacute Cutaneous Lupus Erythematosus and DLE and Decreases with Treatment in DLE

Stephanie Lazar¹, Rajaie Namas², Celine C. Berthier³ and Michelle Kahlenberg⁴, ¹Internal Medicine, University of Michigan, Ann Arbor, MI, ²Rheumatology, Cleveland Clinic Abu Dhabi, Abu Dhabi, United Arab Emirates, ³Nephrology, Division of Nephrology, University of Michigan Medical Center, Ann Arbor, MI, ⁴Internal Medicine, Rheumatology, University of Michigan, Ann Arbor, MI

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Systemic Lupus Erythematosus – Etiology and Pathogenesis Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with SLE have increased type I IFN-regulated gene expression in peripheral blood, which has been correlated with systemic disease activity. IFN-regulated gene expression is increased in patients with cutaneous lupus erythematosus (CLE) in peripheral blood and target tissue, including skin samples from chronic cutaneous lupus erythematosus (CCLE) and DLE. The pattern of IFN-induced protein regulation, or IFN-signature, has been shown to correlate with lymphocytic infiltrates in skin and to correlate with disease manifestations of lupus, linking it to pathogenesis of disease. These findings have led to clinical trials of a variety of targeted therapies for treatment of CLE, including antibodies inhibiting B-cells and type I IFN signaling. The current study aimed to measure expression of type-I IFN-regulated genes on skin biopsies from subacute cutaneous lupus erythematosus (SCLE), DLE, and normal control patients to calculate IFN-activity scores as a measure of cutaneous IFN exposure. Patient's IFN-activity scores were compared with serologic tests and medication use at the time of biopsy to determine what factors influence cutaneous IFN-regulated gene expression.

Methods: Skin samples were collected from 47 patients with DLE, 43 patients with SCLE, and 13 healthy controls. Gene expression was evaluated via ST2.1 microarray. Expression level of five genes were translated into cumulative IFN score. Based on Feng et al. 2006, the IFN score was calculated using summation of standardized expression levels from each of the 5 genes for each sample. Each gene score was standardized to the correlating IFN-regulated gene in the control group ((mean IFN-inducible gene SLE- mean IFN-inducible gene control)/standard deviation IFN-inducible gene control). Clinical factors including autoimmune serology results and medication use at time of biopsy were based on chart review. Data was analyzed using two-tailed t-test with reported p-values.

Results: Both SCLE and DLE showed increased IFN gene expression compared to controls (p-value <0.01) and SCLE was increased compared to DLE (p-value <0.05). ANA, anti-Ro, and anti-dsDNA positivity did not correlate with cutaneous IFN gene expression. Decreased IFN-gene expression was correlated with use of hydroxychloroquine and/or prednisone in patients with DLE (p-value <0.01), but showed no difference in SCLE.

Conclusion: IFN-regulated gene expression is elevated in SCLE and DLE and decreases with medication use in DLE. Autoimmune serology did not correlate with IFN gene expression in the skin in the current study. SCLE patients may require alternative therapies to target IFN-driven pathology in the skin.

Abstract Number: 2113

Identification of RNASE2 As a Novel Lupus Candidate Gene

Yang Xu, Xiaojun Tang and **Xuebing Feng**, Department of Rheumatology, The Affiliated Drum Tower Hospital of Nanjing University Medical School, Nanjing, China

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Systemic Lupus Erythematosus – Etiology and Pathogenesis Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Although many factors have been implicated to be involved in the development of systemic lupus erythematosus (SLE), the pathogenesis of this prototypical autoimmune disease has not yet been fully clarified. Here we are aimed to search for new candidate genes that contribute to SLE disease activity.

Methods: A microarray approach using the Affymetrix HUGO chip was employed for the determination of differentially expressed mRNA profiles between active SLE patients (with SLEDAI score > 8) and normal subjects. The expression of screened key genes was then verified by real-time quantitative polymerase chain reaction (RT-PCR) in peripheral blood mononuclear cells (PBMCs) from 69 SLE patients, 43 normal subjects and 40 patients with other connective tissue diseases. Clinical data of SLE patients were collected to analyze for the relationship with gene expression levels. To identify the cell type involved in specific gene production, monocytes, lymphocytes, eosinophils, neutrophils, T cells and B cells were separated from peripheral blood by flow sorting, and measured for the gene expression by RT-PCR.

Results: Gene chip analysis revealed 750 down-regulated and 597 up-regulated genes in SLE patients, among which RNASE2 (ribonuclease A2), a gene rarely reported previously and highly expressed in SLE group (fold change 6.27, $p = 3 \times 10^{-7}$), was selected for further study. RT-PCR confirmed that RNASE2 mRNA expression was elevated in PBMCs from

SLE patients compared with that from normal subjects as well as patients with primary Sjögren's syndrome or rheumatoid arthritis (Figure 1). RNASE2 mRNA level was positively correlated with SLEDAI score ($r = 0.36$, $p < 0.01$), BILAG score ($r = 0.38$, $p < 0.01$) and level of 24 hour proteinuria ($r = 0.40$, $p < 0.01$). In addition, the expression level of RNASE2 was related to serum total immunoglobulin G level ($r = 0.25$, $p < 0.05$) and elevated in anti-Sm positive group and anti-dsDNA positive group (both $p < 0.01$). The cell types mainly involved in RNASE2 production were quite different between normal subjects and SLE patients, which were neutrophils and monocytes respectively.

Conclusion: RNASE2 is highly expressed in monocytes from SLE patients, and correlated with disease activity as well as autoantibody levels. Such insight into SLE pathogenesis may suggest a novel therapeutic target for the disease in the future.

Session Date: Tuesday, October 23, 2018

Session Title: Systemic Lupus Erythematosus – Etiology and Pathogenesis Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Photosensitivity, defined as increased cutaneous erythema and inflammation after ultraviolet light (UV) exposure, is a hallmark of patients with systemic lupus erythematosus (SLE), cutaneous lupus erythematosus (CLE), and many other autoimmune conditions with skin involvement. Type I interferons (IFNs) are increased in SLE and CLE skin and contribute to a propensity for inflammatory responses by keratinocytes. We have identified IFN κ as a keratinocyte-expressed type I IFN whose expression is elevated in non-lesional SLE keratinocytes, which suggests that it may contribute to the propensity for inflammation in SLE skin. Apoptosis of keratinocytes is thought to be a central pathologic response that contributes to increased photosensitivity. However, the contribution of type I IFNs, including IFN κ , to apoptosis after UVB exposure is unknown. We thus examined the role of IFN κ in regulating UVB-induced keratinocyte apoptosis in order to determine whether type I IFNs contribute to photosensitivity predisposition.

Methods: Age and gender-matched control (n=5) and SLE (n=5) keratinocytes were isolated from non-lesional, non-sun exposed 6mm punch skin biopsies from the upper thigh and used at passages 3-5 for study. All patients gave written, informed consent and were treated according to the Declaration of Helsinki. IFN κ -/- N/TERT keratinocytes were generated via CRISPR/Cas9. N/TERTs overexpressing IFN κ were generated via nucleofection of an IFN κ expressing plasmid followed by selection in G418. Primary keratinocytes and N/TERT keratinocyte lines were treated with or without 50mJ/cm² UVB followed by TUNEL staining 8 hours after UVB treatment. In some cases, baricitinib was used to block IFN signaling prior to UVB treatment.

Results: As expected, we identified increased apoptosis in CLE lesional skin vs. normal skin, especially in the basal keratinocyte layer. Importantly, SLE non-lesional keratinocytes displayed increased apoptosis vs. healthy control keratinocytes after UVB treatment. This apoptotic process was dependent on IFN κ as deletion of this protein resulted in significantly diminished TUNEL staining after UVB exposure. Further, chronic overexpression of IFN κ in N/TERT keratinocytes also induced increased apoptosis after UVB. Finally, treatment of SLE and healthy control non-lesional keratinocytes with baricitinib to block IFN signaling significantly diminished UVB-mediated apoptosis.

Conclusion: IFN κ expression serves as a regulator of apoptotic responses to UVB in keratinocytes. In SLE non-lesional skin, chronic overexpression of IFN κ predisposes to increased apoptosis after UVB exposure, which leads to increased autoantigen exposure, cytokine/chemokine production, and inflammatory cell recruitment. This increased inflammatory response likely results in the enhanced UV-triggered erythema and skin eruptions in SLE patients. Downregulation of IFN κ may serve as an excellent, specific target to prevent photosensitivity in SLE patients.

Session Title: Systemic Lupus Erythematosus – Etiology and Pathogenesis Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is a multifactorial disease with genetic and environmental risk factors, and heterogeneous manifestations that encompass a wide range of disease severity. Long-term outcomes for

Figure. Clinical lab measures associated with SLE demonstrate three distinct clusters. The x-axis represents dimension one and the y-axis represents dimension two of the k-means clustering algorithm.

Table. Percentage of individuals carrying 1-2 copies of the listed allele of each significant SNP by cluster (p<0.05)

SNP	Gene	Cluster 1	Cluster 2	Cluster 3	p-value	FDR-adjusted p-value
rs3024503 (T)	ILF3	53%	4%	23%	0.001	0.10
rs10774625 (T)	ATXN2	83%	33%	53%	0.004	0.20
rs2327832 (C)		32%	11%	28%	0.007	0.22
rs2248612 (T)	SLE	68%	82%	70%	0.006	0.22
rs48234 (C)	LOC101287204	41%	38%	57%	0.01	0.22
rs1299652 (C)	TNFRSF7/ATP16B	18%	9%	11%	0.02	0.22
rs14603023 (T)	PHLDB1	77%	62%	60%	0.02	0.22
rs3748079 (A)	ITPR3	28%	27%	48%	0.02	0.26
rs7726159 (T)	FEZF1	63%	62%	64%	0.04	0.41

individual patients are difficult to predict. Little is known about why an affected individual might develop a particular SLE phenotype. Previous studies have used phenotype-mapping approaches to identify subtypes of SLE using genome-wide association studies and gene expression data; however, studies integrating both genetic and clinical data to identify SLE phenotypes using bioinformatics analyses remain limited.

Methods: We characterized subgroups of patients using sociodemographic, clinical and genetic data from previously collected genetic cohorts and electronic health record (EHR) data for 195 individuals with SLE. Single nucleotide polymorphisms (SNPs) were typed on the ImmunoChip. We included 95 variants previously associated with SLE risk. Variables extracted from the EHR included age, sex, race, ethnicity, age at diagnosis, and disease-associated laboratories: complement C3 and C4, SSA, SSB, RNP, anti-Smith, and anti-dsDNA. We first performed K-means clustering using all lab measures on the top N eigenvectors from principal component analysis determined using a bootstrap resampling strategy. We then used Chi-squared and ANOVA tests to examine whether demographic, clinical, and genetic variables were associated with each cluster.

Results: 91% of patients were female; 47% were white, 13% African-American, 15% Asian, and 24% other/mixed race. Results demonstrated three distinct stable clusters (stability score>0.80) (Figure). Cluster 1 (n=91) was characterized as predominately white, non-Hispanic/Latino patients with higher age of onset ($p<0.05$). Cluster 2 (n=47) was significantly more likely to have + anti-dsDNA, + SSB, + RNP, and + anti-Smith antibodies ($p<0.05$). Cluster 3 (n=55) had a significantly higher percentage of abnormal C3 and C4 levels, + SSA, and lower age of onset ($p<0.05$). Nine SNPs were associated with the clusters but did not remain significant after multiple testing correction (Table).

Conclusion: Unsupervised clustering using sociodemographic and clinical variables derived from the EHR and genetic data identified three distinct subgroups of individuals with SLE. Future work will further define these genotype-phenotype clusters and perform validation studies in additional cohorts with more statistical power. Our findings may assist in identifying disease treatments for SLE using a more personalized approach.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Systemic Lupus Erythematosus – Etiology and Pathogenesis Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Neutrophil extracellular traps (NETs) are composed of decondensed DNA that is released during an active cell death program is known as NETosis. To date, fluorescence microscopy is the accepted method for quantification of NETs. However, this method is subjective, time consuming and yields low numbers of polymorphonuclear cells (PMNs) analyzed per sample. NETs contribute to pathogenesis of systemic lupus erythematosus (SLE) but the effects of disease activity on NETosis has not been adequately explored.

Methods: Herein, we describe a flow cytometry-based assay for detection of NETosis within mixed cell populations and applied it to quantify NETting PMNs in SLE.

Results: Using plasma membrane-impermeable DNA-binding dye, SYTOX Orange (SO), we found that cell-appendent DNA of NETting PMNs were positive for SO and DAPI (Fig.1A-B). The combination of optimally diluted antibody and

nucleic acid dyes required no washing and yielded low background fluorescence on flow cytometry (Fig. 1C-D). We then validated the assay by comparing with time-lapse live cell fluorescence microscopy and determined very good correlation ($r = 0.90$, $P < 0.001$), intra- and inter-assay variances, 3.98% and 4.66%, respectively. Significant correlations were found for NETosis from whole blood (WB) and purified PMNs ($r = 0.79$, $P < 0.001$). We examined PMA-induced NETosis in peripheral PMNs from SLE patients and controls and in bone marrow (BM) PMNs from multiple murine models (Fig 2A-C). However, most of the recruited SLE patients examined were on immunosuppressive therapy with quiescent disease activity (Table 1), which may have consequences for PMN activation (Fig. 2A). Therefore, we went on to examine NET formation in BM PMNs from young female lupus-prone mice. Stimulation with PMA resulted in an increase in the frequency of NETting BM PMNs, which was augmented in *Sle1* mice, compared to B6 controls (Fig. 2B). An analysis of BM PMNs across all lupus-prone mice (*Sle1*, *Sle1*Tg7 and *Sle1*23) showed an increase in NETosis in severe-lupus prone *Sle1*23 mice compared to the milder lupus-prone *Sle1* strain (Fig. 2C).

Conclusion: This NETosis flow cytometry-based assay is observer-independent and allows for rapid assessment of a large number of PMNs in mixed cell populations. Disease activity may prime PMNs and lead to aberrant NETosis in SLE.

Figure 1. Visualizing and Quantifying NET-DNA in mixed cell populations.

Session Title: Systemic Lupus Erythematosus – Etiology and Pathogenesis Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: About 20-40% of lupus patients suffer from diffuse neuropsychiatric manifestations of SLE, including cognitive impairment and depression. Although the pathogenesis is not well understood, brain barrier disruption and pro-inflammatory signaling within the brain parenchyma are thought to play an important role in disease development. Fingolimod, approved for the treatment of multiple sclerosis, functionally antagonizes sphingosine-1-phosphate (S1P) receptors and reduces the circulation of auto-reactive lymphocytes. In the CNS, fingolimod exerts a neuro-protective role, reducing pro-inflammatory cytokines and promoting brain barrier integrity. We have previously shown that fingolimod treatment reduces leukocyte infiltration of the choroid plexus in MRL/lpr mice and significantly attenuates cognitive dysfunction and depressive-like behavior. Here, we aimed to determine the effects of fingolimod on glial cells and pro-inflammatory cytokine signaling.

Methods: Ten-week-old female MRL/lpr mice were treated three times weekly with fingolimod (3 mg/kg) or vehicle alone (n=10/group) by intraperitoneal injection. After 10 weeks of treatment, brain cell suspensions generated from one hemisphere were analyzed by flow cytometry, and CD11b-positive CD64-positive CD45-low microglia, GFAP-positive astrocytes, and CD31-positive endothelial cells were sorted for RNA sequencing. Cortex and hippocampus samples were dissected from the other hemisphere of each brain and snap frozen for analysis of gene and protein expression.

Results: Flow cytometry revealed significant reductions in infiltrating leukocyte populations, including T cells, B cells, macrophages, neutrophils, eosinophils, and NK cells in fingolimod-treated mice. There was also a significant decrease in the number and/or activation of parenchymal cells, including microglia and astrocytes. Surprisingly, quantification of cytokine levels from cortical samples revealed a significant increase in IL-1a, IFN γ , IFN β , and IL-12p70 in fingolimod-treated mice when compared with control mice. Similarly, increased expression of IL-1a, IL-1b, and MCP-1 was present in the hippocampi of treated mice. RNA sequencing results in the sorted cell populations are pending.

Conclusion: Fingolimod treatment reduces infiltration of leukocytes from the periphery into the CNS. Despite an unexpected increase in the expression of several brain cytokines with fingolimod treatment, the neurobehavioral deficits manifested by the MRL/lpr lupus strain were significantly attenuated. Our results highlight the complex role of the S1P signaling axis in the pathogenesis of neuropsychiatric SLE.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Systemic Lupus Erythematosus – Etiology and Pathogenesis Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is an autoimmune rheumatic disease characterised by increased cardiovascular risk, with a 5-20 fold increased risk for venous thromboembolism (VTE) compared to the general population. Antiphospholipid antibodies (aPL) constitute a major risk factor for thrombosis in patients with SLE, who frequently also have antiphospholipid syndrome (APS). The protein C pathway has a key role in the regulation of haemostasis and inflammation and could be pivotal in the development of thrombosis in patients with SLE regardless of aPL. APS patients with VTE have been shown to have increased acquired resistance to protein C (APCr) associated with a high prevalence of anti-protein C antibodies (aPC). The role of aPC and APCr in patients with SLE, especially aPL negative (-), is less clear. The aim of this ongoing study is to determine the prevalence of aPC in association with APCr and thrombosis in aPL/APS- patients with SLE.

Methods: Sixty-one consecutively attending patients with SLE, classified according to the revised ACR criteria, have so far been enrolled and subdivided as follow: thrombotic APS (APS; n=15), aPL positive (+) no thrombosis (aPL+/T-; n=17), aPL- with a history of thrombosis (aPL-/T+; n=8), aPL- without a history of thrombosis (aPL-/T-; n=21). Patients with heritable thrombophilia were excluded. aPC levels were determined by in-house ELISA. APCr was determined using thrombin generation (TG) and was measured as %inhibition of endogenous thrombin potential by exogenous recombinant human activated protein C (rhAPC) or by Protac (specific protein C activator) for activation of endogenous protein C.

Results: In this ongoing study, aPC were detected in 44% of patients (APS: 53.3%, aPL+/T-: 47%, aPL-/T-: 48%, aPL-/T+ : 25%; p=NS). aPL+ had higher aPC levels compared to aPL- patients (median (IQR) = 36.7 (24.7-51.8) vs 26.1 (17.3-37.6) U/mL, p=0.04). Positivity to aPC was significantly associated with resistance to both rhAPC (p=0.01) and activation of endogenous protein C (p<0.001). APCr prevalence was similar in aPL+ (54%) and aPL- (45%) patients. Resistance to rhAPC was associated with resistance to activation of protein C (p=0.02), but was less frequently detected (30% vs 48% of all cases), especially in aPL- patients (13.8% vs 43.8% in aPL+; p=0.01). In comparison, resistance to rhAPC was higher in aPL+ compared to aPL- (p=0.02). There were no correlations with demographics or disease activity (assessed by BILAG-2004 or SLEDAI-2K). APCr and aPC positivity were less frequent in patients with a history of rash or serositis (p=0.01 and p=0.02 respectively).

Conclusion: aPC levels and resistance to exogenous APC were higher in aPL+ than aPL- patients. aPC were also detectable in aPL- patients with SLE, and were associated with APCr *in vitro*. In aPL- patients resistance to activation of protein C was more frequent than resistance to exogenous APC, suggesting a possible defect in the activation of protein C. Predictive clinical-pathophysiological models based on aPC-profile and APCr assays might offer an important tool for identification and management of patients with SLE at increased thrombotic risk independent of classical cardiovascular risk factors and aPL.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Systemic Lupus Erythematosus – Etiology and Pathogenesis Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: In subjects with lupus nephritis (LN), tissue injury due to local immune activation involving persistently activated macrophages in the renal parenchyma is limited by non-classical natural killer (NK) cells. This protective pathway, based on a genetic effect related to the NK ligand Human Leukocyte Antigen (HLA)-C, was recently shown to limit activation of macrophages and dendritic cells by immune stimuli in vitro. A risk phenotype of HLA Class I, termed the Lys variant, or the C2 epitope or Asn80Lys, rs17408553, leads to a hypo-responsive NK cell which is secondary to high affinity of ligand by variant and an inhibitory NK receptor. The clinical impact of these pathways is understudied; the aim of this study, therefore, is to evaluate associations of clinical outcomes among subjects carrying the risk genotype in two cohorts of SLE patients.

Methods: Patients were included if there was confirmation of a diagnosis of SLE as per the ACR and access to chart review along with DNA for genotyping. There were 2 patient subsets: 96 lupus nephritis (LN) patients who were selected from SLE cohorts from the ALMS trial (27 LN) and the NYU Specimen and Matched Phenotype Linked Evaluation (SAMPLE, 69 LN), and the second subgroup was SLE absent lupus nephritis (NN) (SAMPLE, 33 NN). LN were adjudicated for response to induction therapy and DNA specimens were genotyped at rs17408553 using a Pyrosequencing assay (ADS9525-RS) and the result is reported as minor allelic frequency (MAF). While pyrosequencing is performed in the usual way, it is noteworthy that the PCR fragment of HLA-C containing the rs17408553 SNP was designed to exclude the very similar HLA-B gene by the specificity of the PCR primers, which can be monitored by one nucleic acid that differs between HLA-C and HLA-B within the PCR amplicon.

Results: Demographic characteristics of LN and NN were matched for age, gender, and ethnicity. LN biopsies encompassed all ISN/RPS classes, the majority of which were proliferative forms. For LN, 35% had hypertension, 47% had nephrotic range proteinuria, and a majority were given an induction therapy consisting of steroids plus mycophenolate mofetil. At six months, 14 LN patients were non-responders, 8 were partial responders and 74 were complete responders. For MAF at rs17408553, the C2 allele was enriched in LN patients compared to controls (0.45 vs 0.37, SLE (LN+NN) vs control; OR 1.40, P=0.01). However, for a comparison of LN and NN, the frequencies of C2 were found to be similar (0.45 vs 0.45, LN vs NN, P=1). While LN spot prot/cr ratios were similar in C1/C1 and C2/N groups at the end of induction (3.86 ± 3.02 vs 4.64 ± 3.30 , P=0.52), there was an association of an increase in variant allele and LN patients with no response at induction (0.73 vs 0.41, LN non-response vs LN response, P=0.0149). The association of variant at HLA-C and subjects with non-response was observed in both LN cohorts (ALMS trial and SAMPLE).

Conclusion: Using two distinct and well-characterized cohorts, there was an association of variant at HLA-C and subjects with non-response to induction therapy. These data support the speculation that hypo-responsive NK cells adversely influence the course of nephritis.

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

CD47-Signal Regulatory Protein-Alpha Interaction Potentiates Proinflammatory Response in Systemic Lupus Erythematosus.

Background/Purpose: Systemic lupus erythematosus (SLE) is a chronic inflammatory disease mediated by unbalanced activation of innate and adaptive immune cells with subsequent uncontrolled inflammation and organ damages. An important regulatory receptor on monocyte is signal regulatory protein alpha (SIRP-alpha) that interact with CD47. This study was aimed to investigate as to whether CD47 contributes to altered proinflammatory response in SLE.

Methods: Expression of CD47 and SIRP- α on peripheral blood mononuclear cells (PBMCs) from SLE patients and healthy controls (HCs) were examined using flow cytometry analysis. Effect of SLE serum, recombinant interferon (IFN)- α , and tumor necrosis factor (TNF)- α on CD47 expression was investigated. Monocytes and THP1 cells were stimulated with lipopolysaccharide (LPS) with or without pretreatment with anti-CD47 antibody, and TNF- α production and mitogen-activated protein kinase (MAPK) and NF κ B signaling were examined. Sera from HCs and SLE patients were screened for autoantibodies directed against CD47 using ELISA.

Results: A total of 25 patients and 16 healthy controls (HCs) were enrolled. CD47 expression on monocytes was higher in SLE patients vs. HCs ($p < 0.001$) and it correlated with SLE disease activity (Spearman rho = 0.467, $p = 0.019$). CD47 expression was upregulated by serum from SLE patients with higher disease activity and exogenous IFN- α but not by exogenous TNF- α . Pretreatment of monocytes with anti-CD47 antibody potentiated TNF- α production in response to LPS by 16.1 folds as compared to 8.5 folds after stimulation with LPS alone, whereas no to little TNF- α was produced after treatment with anti-CD47 alone. CD47 activation induced MAPK but not NF κ B signaling. Finally, autoantibodies against CD47 were detected in 30.7% of SLE patients.

Conclusion: To the best of our knowledge, this report is the first to show that CD47 expression is upregulated during active SLE and potentiates proinflammatory response in SLE. Targeting CD47-SIRP- α interaction might offer a novel therapeutic opportunity in SLE treatment.

Figure. A. CD47 expression on monocytes correlated with disease activity. B. CD47 on monocytes was upregulated after treatment with serum from patients with low ($n=6$) and higher ($n=4$) disease activity or healthy controls (HC). C. Monocytes were pretreated with anti-CD47 antibody and were stimulated with LPS (3 ng/mL) for 5 hours and TNF- α production was measured.

Session Title: Systemic Lupus Erythematosus – Etiology and Pathogenesis Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Despite recent advancements in immunosuppressive therapies, lupus nephritis (LN) remains one of the most severe organ manifestations in systemic lupus erythematosus (SLE). High type I interferon (IFN) is a heritable

risk for SLE, and previous studies have suggested a link between high IFN and lupus nephritis. However, little is known about the relationships between high levels of IFN and the subtypes of LN, and whether IFN plays a critical role in the pathogenesis of LN.

Methods: We studied 221 European-American SLE patients and measured IFN in sera by performing WISH IFN bioassay as described previously. Subtypes of LN were confirmed by renal biopsy review. Complement, anti-dsDNA and other serological parameters were measured in the clinical laboratory, and standard clinical cut-offs were used to define a positive result. mRNA in situ hybridization was performed to detect IFN induced gene (IIG) expression and plasmacytoid dendritic cells in LN kidney biopsies, and Visiopharm analysis software was used for quantitative analysis. Real-time PCR was performed to measure pro-apoptotic gene expressions in human podocyte cell lines. Non-parametric analyses were used unless otherwise mentioned.

Results: Proliferative LN was significantly more common among patients with high serum type I IFN compared to patients with low levels of IFN ($p<0.001$, OR=3.0, Fisher's exact test). Notably, IFN level was significantly higher in active proliferative LN compared to inactive proliferative LN ($p<0.001$), and these findings were independent of complements and anti-dsDNA antibody levels. mRNA in situ hybridization showed increased expression of IIG accompanying plasmacytoid dendritic cell infiltration in active proliferative LN kidneys. In vitro experiments demonstrated that type I IFN induced pro-apoptotic gene expression in human podocyte cell lines.

Conclusion: Our data support an association between type I IFN and active proliferative lupus nephritis that is independent of conventional parameters such as complements and anti-dsDNA antibodies, suggesting that IFN is involved in renal pathogenesis. These data also suggest that IFN could predict renal disease activity or the future risk of developing LN, especially proliferative LN in SLE patients.

CD38 over-Expression in CD8 Positive Cells Defines a Group of Patients with SLE Prone to Infections

Lama Mulki¹, Abel Suarez-Fueyo¹, Eri Katsuyama¹, Vasileios C. Kyttaris¹ and George C. Tsokos², ¹Rheumatology, Department of Medicine, Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA, Boston, MA, ²Division of Rheumatology, Department of Medicine, Department of Medicine, Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA, Boston, MA

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Systemic Lupus Erythematosus – Etiology and Pathogenesis Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: It has been previously shown by our laboratory that CD38 gene expression is increased in the peripheral blood T cell from patients with SLE. The purpose of the current study is to further investigate the overexpression of CD38 in T cells from patients with SLE and seek correlations with clinical parameters.

Methods: T cells CD38 surface expression was analyzed from patients with SLE (n=37) by flow cytometry. Student T-test was used for statistical analyses. The relationship of CD38 surface expression and clinical parameters from patients with SLE (SLE disease activity, medications, infections rate) was analyzed using Pearson's or chi-squared test. Data is expressed as mean \pm SEM.

Results: CD38 surface expression was found to be higher in SLE CD8⁺ T cells ($30\% \pm 3$, n=37) compared to normal controls ($18.7\% \pm 1$, n=18, $p<0.001$) but not in SLE CD4⁺ T cells ($36.8\% \pm 3$, n=18) vs. ($36.9\% \pm 2.3$, n=36, p ns) respectively. Interestingly, within SLE patients, CD38 levels of expression identified two subpopulations of CD8⁺ cells those with high ($>\text{mean}+2\text{SD}$ of normal values) and those with low expression. Patients with SLE who expressed a higher percentages of CD8⁺CD38⁺ cells were more prone to infections ($p<0.0001$) most of which were of viral origin. Also, they had low WBC counts ($p<0.01$). We did not notice a correlation with disease activity or exposure to prednisone. Interestingly, none of the patients with high percentages of CD8⁺CD38⁺ cells were receiving Mycophenolate whereas 6 of

16 with low percentages were receiving Mycophenolate. In 12 patients with SLE patients, CD8⁺CD38⁺ cells were evaluated repeatedly over time but we failed to detect significant variation or association with disease activity.

Conclusion: We have identified a subpopulation of patients with SLE who have higher percentages of CD8⁺CD38⁺ cells and increased rates of infections. We propose that CD38 expression on CD8⁺ T cells can be used as a biomarker to identify patients with SLE who have an increased risk of infections.

Session Date: Tuesday, October 23, 2018

Session Title: Systemic Lupus Erythematosus – Etiology and Pathogenesis Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Arthritis is a common manifestation of SLE but the inflammatory and immune cells that infiltrate synovium and the signaling pathways activated are not well understood. Previous work delineated an IFN signature in lupus arthritis but not rheumatoid arthritis (RA) or osteoarthritis (OA)¹. A multi-pronged bioinformatic approach was utilized to analyze gene expression from RA, OA and lupus arthritis (LA) samples to gain insight into the precise pathogenic mechanisms involved.

Methods: Initial analyses examined genes that were similar and different between non-inflammatory OA, LA and RA synovial biopsy samples following LIMMA differential expression (DE) analysis or Weighted Gene Co-expression Network Analysis (WGCNA) followed by interrogation with cell type specific gene signatures using I-ScopeTM and validated by Gene Set Variation Analysis (GSVA). Genes were functionally characterized using BIG-CTM and pathways elucidated using the upstream regulator (UPR) and canonical pathway functions of IPA^O.

Results: From BIG-CTM and I-ScopeTM analysis, lupus synovitis has a clear gene signature of activated antigen presenting cells including dendritic cells, inflammatory myeloid cells, activated CD4⁺ and CD8⁺ T cells, activated B cells as well as pre- and post- switch plasma cells/plasma blasts as indicated by IgM, IgD and IgG1 heavy chain genes. The presence of both Igk and Igl as well as numerous VL genes indicates the polyclonal nature of the infiltrate. Analysis of gene expression indicated no inflammatory infiltrate in OA and that RA is dominated by activated T and B cell signatures. IPA analysis tools examining canonical pathways and UPRs revealed the role of Sphingosine-1 phosphate receptor and numerous chemokine pathways that may mediate lymphocyte organization and/or recruitment into lupus synovium. In addition, IPA elucidated ongoing signaling induced by inflammatory cytokines. Moreover, signaling pathways including NF-kB, NF-AT and mTOR were evident as well as proliferation and proteasome activity. Important differences were observed in gene expression from lupus compared to RA synovitis, including tendencies of less enrichment of Th17 and T_{cytotoxic}, less frequent enrichment of T_{FH} and increased enrichment of myeloid populations. In addition, IPA UPR analysis indicated ongoing signaling by TNF, IFNg, IFNa, CD40L, IL6, IL1b, IL15, IL21 and IL27 in lupus synovitis.

Conclusion: Bioinformatic analysis of gene expression patterns in lupus synovitis indicate trafficking and potential *in situ* activation and differentiation of immune cells during pathogenesis of LA. Interestingly, a more prominent myeloid signature is present in LA compared with RA, that might provide a unique target of therapeutic intervention.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Systemic Lupus Erythematosus – Etiology and Pathogenesis Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Infections are a major contributor to lupus disease. We have previously demonstrated that bacterial amyloid curli, produced by E.coli, can accelerate disease in mouse models of lupus. Interestingly curli incorporates extracellular DNA, which in turn can be both adjuvant and a self-antigen in lupus. Finally, uropathogenic E. coli (UPEC) is responsible for majority of urinary tract infections in SLE.

Methods: Based on our previous results, we hypothesize that exposure to UPEC triggers anti-curli/eDNA antibodies and curli/eDNA complexes can trigger the innate immune system. We investigated 98 lupus patients who met at least 4 SLICC criteria. Results were compared to 54 age, sex and race matched healthy controls. We tested the production of anti-curli/DNA complex for both IgG and IgA subclasses. We then correlated the levels of anti-curli/DNA antibodies with clinical parameters. Finally, we treated human neutrophils with curli/eDNA complexes.

Results: We found that curli/eDNA induces neutrophil extracellular traps in a ROS manner. Anti-curli/eDNA IgG levels were detected in lupus and controls plasma and the levels correlated with persistent bacteriuria ($p < 0.05$) and disease flares in lupus patients. In addition, anti-curli/eDNA antibodies could bind to DNA demonstrating a potential molecular mimicry mechanism in lupus. IgA anti-curli/eDNA levels were higher ($p < 0.01$) in lupus donors compared to controls.

Conclusion: We conclude curli/eDNA complexes can activate the innate and adaptive immune system and could be a mechanism to sustaining disease in lupus.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Systemic Lupus Erythematosus – Etiology and Pathogenesis Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: ANAs are almost always present in systemic lupus erythematosus (SLE), but they are also present in ~12-20% of the population. A positive ANA (ANA+) can precede the onset of SLE, but for the vast majority the clinical consequences are unknown. In animal models, naturally occurring ANAs can protect against renal disease. The genetics of SLE are well established but those of ANA+ are poorly defined. We hypothesized that ANA+ is associated with increased risk of SLE-like phenotypes and that ANA+ and SLE share the same genetic structure.

associations were GWAS significant, but 118 SNPs had a $P < 1 \times 10^{-5}$. None of these SNPs were previously associated with SLE but mapped to loci (*VAV3*, *NCOA1*, *LOC285696*, *ADAMTS19*, *RPS12*, *CYP2R1*, *KKR1* and *CACNG2*) associated with immune thyroiditis, nephropathies, cancer, vitamin D levels, metabolic and psychiatric phenotypes (Fig. 2).

Conclusion: We found that ANA+ inpatients without SLE had the expected association with other autoimmune disorders; however, there was an unexpected association with reduced risk of renal and hypertension phenotypes. There was no strong overlap in the genetic structure of SLE and ANA+.

Session Title: Systemic Lupus Erythematosus – Etiology and Pathogenesis Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Follicular helper T cells (Tfh) cells in lupus help shape the germinal center (GC) response by delivering contact-dependent and soluble signals, including the cytokines IFN- γ and IL-21. In conventional immune responses, synthesis of Tfh-cell cytokines is regulated by the transcription factors STAT4, T-bet, and Bcl6, although their regulation in lupus is not known. To answer this question, we examined the differential expression of these transcription factors in splenic Tfh cells prior to onset of disease, after immune cell activation but before end organ disease onset, and then in later severe disease in lupus-prone B6.*Sle1.Yaa* mice. We also assess applicability to human lupus.

Methods: Spleens were harvested from 2, 4 and 6 months old B6.*Sle1.Yaa* mice. Transcription factor (T-bet and Bcl6) and cytokine production were assessed by intercellular flow cytometry. Cells were stimulated with PMA and ionomycin, and Tfh (CD4⁺CD44^{hi}Ly6c^{lo}PSGL-1^{lo}CXCR5^{hi}PD-1^{hi}) and Th1 (CD4⁺CD44^{hi}Ly6c^{hi}PSGL-1^{hi}) cells were stained for IL-21 and IFN- γ . Phosphorylation STAT4 in Tfh and Th1 cells were analyzed by flow cytometry after stimulation by IFN- α or IL-12 for 20 minutes in DMEM medium with 1% serum.

Twenty-eight SLE patients from age 18 to 75 years and twenty age-matched healthy control were enrolled in this study. All SLE patients had fulfilled the revised disease criteria of the American College of Rheumatology 1997. Disease activity was assessed with the SLE Disease Activity Index 2000 (SLEDAI2K). Mononuclear cells from the peripheral blood samples were isolated using Ficoll-Paque density gradient media and rested suspended in DMEM medium with 10% serum overnight. Phosphorylation STAT4 in circulating Follicular helper-like T cells (CD4⁺CD45RA⁻CXCR5^{hi}PD1^{hi}CCR7^{lo}) and CD4⁺ T memory cells (CD4⁺CD45RA⁻CXCR5^{hi}PD1^{lo}CCR7^{hi}) were analyzed by flow cytometry after stimulation by IFN- α or IL-12 for 20 minutes in DMEM medium with 1% serum.

Results: We determined that GC Tfh cells produced IL-21 and IFN- γ at similar rates during these three stages of disease; however, Tfh-cell STAT4 activity increased while Bcl6 and T-bet expression declined as disease progressed, suggesting a role of STAT4 in driving T-cell dependent GC B-cell maturation responses in murine lupus.

We found that circulating Tfh and circulating CD4⁺ T memory cells from patients secreted IL-21 and IFN- γ after stimulation. We next examined STAT4 activity these cells, after IFN- α and IL-12 stimulation *in vitro*, in comparison to cells from healthy controls. STAT4 phosphorylation, as an indicator of STAT4-mediated nuclear translocation, was more robust upon IFN- α than IL-12 stimulation, by contrast to canonical STAT4 phosphorylation driven by IL-12 in Th1 cells. Furthermore, the STAT4 phosphorylation correlated to greater disease activity (SLEDAI2K).

Conclusion: Our study indicates that as disease progresses in mice and humans with lupus, Tfh-cells and circulating CD4⁺ T memory cells are robustly responsive to STAT4-guided gene expression, which plays an important role in driving pathologic cytokine production in sustaining moderate and late stage disease activity.

Session Title: Systemic Lupus Erythematosus – Etiology and Pathogenesis Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Reliable non-invasive biomarkers for lupus nephritis (LN) are lacking. We investigated two adhesion molecules as urinary biomarkers in LN, i.e. vascular cell adhesion molecule 1 (VCAM-1) and activated leukocyte cell adhesion molecule (ALCAM), the latter also known as cluster of differentiation 166 (CD166).

Methods: Patients with systemic lupus erythematosus (SLE) (n=111, all female) and non-SLE population based controls (n=99, all female) were included. At inclusion, we assessed renal activity using the renal descriptors of the SLE disease activity index 2000 (SLEDAI-2K) and the renal domain of the British Isles Lupus Assessment Group (BILAG) index. Renal BILAG was not assessed in patients with end-stage renal disease (n=2). Urine and plasma VCAM-1 and urine ALCAM levels in samples obtained from patients and controls at the time of inclusion were estimated using enzyme-linked immunosorbent assay. Urine VCAM-1 and ALCAM levels were next adjusted by urine creatinine. For comparisons, we used the Mann-Whitney *U* test.

Results: In comparative analysis between SLE patients and controls, we observed higher urine VCAM-1 levels (P=0.001) and a trend towards higher plasma VCAM-1 concentrations (P=0.051) in SLE patients, but urine levels of ALCAM did not differ between the two groups. Furthermore, urinary VCAM-1/creatinine and ALCAM/creatinine ratio levels were higher in SLE patients (P<0.001 for both). We next conducted comparative analysis between SLE patients with current renal activity (renal BILAG A–C; n=10) and SLE patients with no current renal activity or no history of renal involvement (renal BILAG D–E; n=98). In this analysis, plasma VCAM-1 and urine ALCAM levels were higher in patients with active renal SLE (P=0.007 and P=0.009, respectively), but urine VCAM-1 levels were not found to differ. Urinary VCAM-1/creatinine and ALCAM/creatinine ratio levels were higher in SLE patients with renal activity (P=0.029 and P=0.001, respectively). Finally, we compared SLE patients with a renal SLEDAI-2K>0 (n=31) with SLE patients with renal SLEDAI-2K=0 (n=80). Here, plasma VCAM-1 concentrations were higher in patients with renal SLEDAI-2K>0 (P=0.018), but urine levels of VCAM-1 and ALCAM did not differ. However, both urinary VCAM-1/creatinine and urinary ALCAM/creatinine ratio levels were higher in SLE patients with renal SLEDAI-2K>0 (P=0.023 and P=0.006, respectively).

Conclusion: A role of VCAM-1 in SLE and LN is implicated. While VCAM-1 appears to reflect SLE disease state, ALCAM might have particular importance in renal SLE. After correction for creatinine, urine levels of both VCAM-1 and ALCAM showed ability to distinguish between SLE patients with active renal involvement compared to SLE patients with quiescent nephritis or no nephritis history.

The Effect of miRNA-21 Overexpression on the Aberrant T Follicular Helper Cells Differentiation in Systemic Lupus Erythematosus

Ming Zhao¹, Xiaofei Gao², Jiali Wu³, Limin Liu¹, Haijing Wu² and Qianjin Lu¹, ¹Department of Dermatology, The Second Xiangya Hospital of Central South University, Changsha, China, ²The Second Xiangya Hospital of Central South University, Changsha, China, ³Department of Dermatology, The Second Xiangya Hospital of Central South University, Changsha, China

Session Information**Session Date:** Tuesday, October 23, 2018**Session Title:** Systemic Lupus Erythematosus – Etiology and Pathogenesis Poster III**Session Type:** ACR Poster Session C**Session Time:** 9:00AM-11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is an autoimmune disease that is characterized by a large number of autoantibodies and multiple organs damage. T follicular helper (Tfh) cell is a subtype of CD4⁺T cells that is characterized by high expression of CXCR5, ICOS, PD-1, Bcl-6 and IL-21, and assisting B cells to produce antibodies. Previous studies have reported increased numbers of circulating Tfh cells in patients with SLE, which play an important role in the development and progression of SLE. However, the mechanism of abnormal differentiation of Tfh cells in SLE is not yet clear. Numerous studies have reported that microRNAs (miRNAs) were involved in the differentiation and function-related genes regulation of various immune cells, contributing to autoimmune diseases. In this study, we investigated the role of miRNA-21 (miR-21) in regulating the aberrant differentiation of Tfh cells in SLE patients.

Methods: This study was approved by the ethical committee of the Second Xiangya Hospital of Central South University and written informed consent was obtained from all subjects. 24 SLE patients and 24 healthy controls were recruited. CD4⁺ T cells and naive CD4⁺ T cells were isolated by magnetic beads. All patients fulfilled at least 4 of the SLE classification criteria of the American College of Rheumatology. RT-qPCR were used to detect miR-21 and genes expression. Naive CD4⁺ T cells were transfected with miR-21 Agomir or Agomir negative control, and were induced to differentiate into Tfh cells under Tfh cells polarized-condition. SLE CD4⁺ T cells were transfected with miR-21 Antagomir or Antagomir negative control, and then were stimulated by anti-CD3/CD28. The percentage of Tfh cells was detected by flow cytometry. Western blot were used to detect the protein expression level of FOXP1 gene. Student's t-test for equality of means was used to compare values. P-values < 0.05 were considered as significant.

Results: Compared with healthy controls, the expression of miR-21, CXCR5, PD1, BCL6 and IL21 in CD4⁺ T cells of SLE patients was significantly increased (P<0.001). miR-21 expression levels positively correlated with SLEDAI scores in SLE patients. Compared with Agomir negative control, the percentage of Tfh cells was significantly increased in naive CD4⁺ T cells transfected with miR-21 Agomir under Tfh cells polarized-condition, and the expression levels of miR-21, CXCR5, PD1, BCL6 and IL21 were up-regulated significantly. Compared with Antagomir negative control, the percentage of Tfh cells was reduced in SLE CD4⁺ T cells transfected with miR-21 Antagomir, and the expression levels of miR-21, CXCR5, PD1, BCL6 and IL21 were also decreased significantly. The protein level of FOXP1, a negative regulator of Tfh cells differentiation, was significantly decreased in CD4⁺ T cells of healthy controls transfected with Agomir and was increased in CD4⁺ T cells of SLE patients transfected with miR-21 Antagomir compared with negative controls respectively.

Conclusion: miR-21 expression was increased in CD4⁺ T cells of SLE patients, which contributes to the aberrantly increased Tfh cells in SLE patients.

Abstract Number: 2129

Precipitating Anti-dsDNA Peptide Repertoires in Lupus

Jing Jing Wang¹, Alexander Colella¹, Dimitra Beroukas², Tim Chataway³ and Tom Gordon^{1,4}, ¹Immunology, Flinders University, Adelaide, Australia, ²Immunology, SA Pathology, Adelaide, AR, Australia, ³Proteomic Facility, Flinders University, Adelaide, Australia, ⁴Immunology SA Pathology, Adelaide, Australia

Session Information**Session Date:** Tuesday, October 23, 2018**Session Title:** Systemic Lupus Erythematosus – Etiology and Pathogenesis Poster III**Session Type:** ACR Poster Session C**Session Time:** 9:00AM-11:00AM

Background/Purpose: Anti-double-stranded (ds)DNA autoantibodies are prototypic serological markers of systemic lupus erythematosus (SLE) but little is known about their immunoglobulin variable (IgV) region composition at the level of the secreted (serum) proteome. Here, we use a novel proteomic workflow based on de novo database mass spectrometric sequencing of anti-dsDNA precipitins to analyse IgV subfamily expression and mutational signatures of high-affinity, precipitating anti-dsDNA responses.

Methods: Anti-dsDNA antibodies were purified from serum precipitins reactions prepared by agarose gel immunodiffusion between circular plasmid dsDNA and SLE serum from eight patients testing positive for anti-dsDNA by Farr

radioimmunoassays (RIA). Microgram amounts of precipitating anti-dsDNA Igs were separated by SDS-PAGE, and in-gel tryptic and chymotryptic digests were performed on the heavy (H) and light (L)-chain bands and peptides were subjected to nano-high performance liquid chromatography-mass spectrometry followed by combined de novo amino acid sequencing and database matching using Peaks 8.0 software utilising ImMunoGeneTics (IMGT) and Uniprot databases. L-chain complementarity determining region 3 (CDR3) peptides were used as biomarkers to track serum anti-dsDNA clonotypes using quantitative multiple reaction monitoring (MRM).

Results: Serum anti-dsDNA proteomes were oligoclonal with shared (public) expression of IgG heavy chain variable region (IGHV) and kappa chain variable region (IGKV) subfamilies. IgV peptide maps from eight subjects showed extensive public and random (private) amino acid replacement mutations with prominent arginine substitutions across H- and L-chains. Shared sets of LCDR3 peptides specified by arginine substitutions were sequenced from the dominantly expressed IGKV3-20 subfamily, with changes in expression levels of a clonal L-chain CDR3 peptide by quantitative MRM paralleling the rise and fall of anti-dsDNA levels by Farr RIA. The heavily mutated IgV peptide signatures of precipitating anti-dsDNA autoantibody proteomes reflect the strong selective forces that shape humoral anti-dsDNA responses in germinal centres.

Conclusion: This first comprehensive proteomic analysis of precipitating anti-dsDNA IgV peptide repertoires in lupus serum offers a fresh approach for characterising and monitoring anti-dsDNA clonal populations with MS precision and accuracy, and for comparing their molecular signatures with other high-throughput “omics” technologies. Direct sequencing of agarose gel precipitins using microlitre volumes of stored sera streamlines the antibody sequencing workflow and is generalisable to other precipitating serum antibodies.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Systemic Lupus Erythematosus – Etiology and Pathogenesis Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Lupus nephritis (LN) afflicts 12-69% lupus patients. Even with the best available therapies, complete response is achieved in only 10-85% of patients. The risk of nephritis and its poor outcomes is significantly higher in blacks. To gain better understanding of the pathogenesis specific for LN, biopsy samples from LN and other glomerulopathies (controls) were evaluated for differential gene expression levels.

Methods: Patients with LN meeting ACR SLE criteria and controls consented to donate additional samples during a clinically indicated renal biopsy. Forty-one LN and 8 control samples were analyzed after rRNA was depleted from total RNA. Libraries were prepared and sequenced with Illumina HiSeq2500 and mapped onto the human genome. Differentially expressed genes (DEG) were selected by DESeq2. Signaling Pathway Impact Analysis identified pathways enriched for DEGs that were mapped to the Reactome database. Key transcripts were correlated with clinical and histologic measures. LN samples were scored using the NIH activity (AI) and chronicity indices (CI).

Results:

Demographics and glomerular involvement are listed in Table 1.

Pathways enriched for DEGs were only identified for those driven by interferon (IFN): a/b signaling, IFN signaling, and cytokine signaling. Transcripts that overlapped between all 3 of these pathways are presented in Figs. 1 and 2. Interferon pathway expression levels were increased in LN compared to controls for DEG identified transcripts. Key pathways were consistent with or without HIV-infected controls compared to LN. Expression levels for interferon induced transcripts (IIGTs) were persistently elevated in LN patients as compared to controls regardless of degree of LN activity or chronicity (represented by NIHA1 high (score>8, range 0-17) vs. low and NIHCI high (score>4, range 2-10) vs. low.

Conclusion: IIGTs are differentially upregulated in LN compared to controls. Within LN, IIGTs are not markedly different between high and low levels of histologic activity or damage. The observation that interferon persists in low activity and high damage LN biopsy samples may represent an opportunity to improve response and outcomes using agents that selectively target IFN pathways.

Prevalence of Systemic Lupus Erythematosus (SLE) and Associated Comorbidities in the 2011-2015 Medicare Population

Suying Li, Tingting Gong, Yi Peng, Kimberly M. Nieman and David T. Gilbertson, Minneapolis Medical Research Foundation, Chronic Disease Research Group, Minneapolis, MN

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Epidemiology and Public Health Poster III: SLE, SSc, APS, PsA, and Other Rheumatic Diseases

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Prevalence of systemic lupus erythematosus (SLE) has been estimated in different US regions. An estimate based on the 2005 US population showed SLE affecting 161,000-322,000 adults (Helmick et al., 2008). We aimed to update estimates of SLE prevalence and associated comorbidity in the US Medicare population.

Methods: We used the 2010-2015 20% Medicare sample data. For each year (2011-2015), we required patients to have Medicare Parts A/B coverage, not have Medicare Advantage, and be alive for the entire preceding year and through the first day of the year. Using ICD-9 diagnosis code 710.0 and ICD-10 codes M32.1, M32.8, and M32.9 (for 2015), we defined SLE by presence of a diagnosis code on ≥ 1 inpatient or ≥ 2 outpatient claims separated by ≥ 30 days. The baseline period, 1 year before each SLE cohort year, was used to define comorbid conditions including: anemia, chronic kidney disease (CKD), end-stage renal disease (ESRD), glomerulonephritis (GN), rheumatoid arthritis (RA), etc. SLE prevalence was reported as the number of SLE patients per 1000 Medicare population.

Results: We included ~6 million Medicare beneficiaries each year. Demographics and baseline characteristics were similar across years. In the 2015 cohort (Table 1), SLE patient mean age was 63.7 (± 14.9) years, 89.4% were female, 21.9% were black; comorbidity percentages were 32.5% anemia, 26.0% CKD, 7.1% ESRD, and 17.9% RA. Non-SLE patient mean age was 72.3 (± 12.6) years, 56.9% were female, 9.4% were black; comorbidity percentages were 13.8% anemia, 11.3% CKD, 1.2% ESRD, and 1.9% RA. Average SLE prevalence was 3.4 (Table 2). Prevalence was higher for ages <45 years, women, and black patients, and for patients with baseline conditions. For example in 2014, SLE prevalence in patients with the following conditions was 37.6, GN; 31.6, RA; 20.5, ESRD; 13.6, psoriatic arthritis; 11.1, Crohn disease; and 10.5, liver disease.

Conclusion: Average SLE prevalence was 3.4 per 1000 Medicare beneficiaries. Prevalence in patients with kidney-related diseases or arthritis was 3-10 times the average. These results underscore the need for effective treatment and management of comorbid conditions and of SLE in the aging Medicare population.

All-Cause Mortality, Hospitalization, and Systemic Lupus Erythematosus (SLE) Related Complications in 2011-2015 Medicare Beneficiaries with SLE

Suying Li, Yi Peng, Tingting Gong, Kimberly M. Nieman and David T. Gilbertson, Minneapolis Medical Research Foundation, Chronic Disease Research Group, Minneapolis, MN

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Epidemiology and Public Health Poster III: SLE, SSc, APS, PsA, and Other Rheumatic Diseases

Session Type: ACR Poster Session C

Session Time: 9:00 AM-11:00 AM

Background/Purpose: Patients with systemic lupus erythematosus (SLE) are at higher risk of complications such as heart attack and renal disease. We aimed to estimate all-cause mortality, all-cause hospitalization, and SLE-related complications in US Medicare patients with SLE, 2011-2015.

Methods: We identified SLE patients during 2010-2015 in the 20% Medicare sample, requiring Medicare Parts A/B coverage, no Medicare Advantage, and being alive for the entire preceding year and through the SLE index date. Using ICD-9 diagnosis code 710.0 and ICD-10 codes M32.1, M32.8, and M32.9 (for 2015), we defined SLE by presence of a diagnosis code on ≥ 1 inpatient or ≥ 2 outpatient claims separated by ≥ 30 days. The first SLE claim date during 2011-2015 was defined as the SLE index date. Chronic kidney disease (CKD) or end-stage renal disease (ESRD) before the SLE index date was identified. Follow-up was from the SLE index date until death, end of Medicare coverage, or December 31, 2015. Outcomes included all-cause death, all-cause first hospitalization, hospitalization due to myocardial infarction (MI)

or stroke, CKD defined from all claim sources, or ESRD. Unadjusted mortality and event rates are reported as number of deaths or events per 100 patient-years.

Results: We identified 38,669 Medicare beneficiaries with SLE during 2011-2015. Mean age was 63.6 (± 14.8) years, 87.5% were female, 72.5% were white, and 20.4% were black. The mean and median follow-up was 2.9 years and the maximum was 5 years after the SLE index date. Unadjusted results are presented in Table 1 overall and by sex. Overall all-cause mortality was 8.17 (7.61%) during the first year and 6.41 (18.34%) during 5 years. In the first year of follow-up, the overall all-cause hospitalization rate was 48.81; rates were 1.79 due to MI and 3.88 due to stroke. Incidence of CKD was 11.93, and incidence of ESRD was 0.81. Within 5 years, 1.73% of SLE patients developed ESRD and 2.68% developed shingles. Compared with women with SLE in 5-year follow-up, men were more likely to die (25.72% vs. 17.28%), be admitted for MI (5.44% vs. 3.71%) or stroke (9.01% vs. 7.49%), and develop CKD (25.99% vs. 20.19%) or ESRD (2.39% vs. 1.63%).

Table 1. All-cause death and complications in 2011-2015 Medicare patients with SLE

Outcomes		Total Patients	In 1-year follow-up			In 5-year follow-up		
			N of Event	% of Event	Rate per 100 patient-year	N of Event	% of Event	Rate per 100 patient-year
All-cause death	All	38,669	2941	7.61	8.17	7,091	18.34	6.41
	Male	4,817	577	11.98	13.21	1,240	25.74	9.80
	Female	33,852	2364	6.98	7.48	5,851	17.28	5.97
All-cause hospitalization	All	38,669	13727	35.50	48.81	22,224	57.47	33.56
	Male	4,817	1898	39.40	57.22	2,879	59.77	38.38
	Female	33,852	11829	34.94	47.68	19,345	57.15	32.95
MI hospitalization	All	38,669	638	1.65	1.79	1,517	3.92	1.40
	Male	4,817	120	2.49	2.78	262	5.44	2.12
	Female	33,852	518	1.53	1.65	1,255	3.71	1.30
Stroke hospitalization	All	38,669	1369	3.54	3.88	2,970	7.68	2.80
	Male	4,817	234	4.86	5.50	434	9.01	3.63
	Female	33,852	1135	3.35	3.65	2,536	7.49	2.70
CKD ^	All	27,573	2923	10.60	11.93	5,736	20.80	8.12
	Male	2,897	418	14.43	16.85	753	25.99	11.23
	Female	24,676	2505	10.15	11.37	4,983	20.19	7.80
Incidence of ESRD ^ ^	All	36,336	272	0.75	0.81	627	1.73	0.61
	Male	4,386	50	1.14	1.26	105	2.39	0.92
	Female	31,950	222	0.69	0.75	522	1.63	0.57
Shingles	All	38,669	533	1.38	1.49	1,038	2.68	0.96
	Male	4,817	61	1.27	1.41	110	2.28	0.88
	Female	33,852	472	1.39	1.51	928	2.74	0.97

^ Excluded those CKD patients defined before SLE index date.

^ ^ Excluded ESRD patients developed before SLE index date.

Conclusion: Medicare beneficiaries with SLE experienced high mortality and SLE-related complications, including MI, stroke, renal disease, and shingles. Effective SLE treatment and prevention of SLE-related complications are needed in the aging Medicare population.

AxSpA, axial spondyloarthritis; PsA, psoriatic arthritis; RA, rheumatoid arthritis; VAS, visual analog scale.

* All values are presented as mean (SD) unless otherwise stated.

[†] $P < 0.05$ for comparison between patients with RA vs PsA or RA vs axSpA.

[‡] $P < 0.05$ for the overall distribution across categories of patients with RA vs PsA or RA vs axSpA.

Background/Purpose: Rheumatoid arthritis (RA), psoriatic arthritis (PsA), and axial spondyloarthritis (axSpA) are 3 common inflammatory rheumatic diseases that can lead to deformities and joint destruction; however, more research has been performed to characterize symptom presentation and the impact of disease burden on patients with RA compared with PsA and axSpA. Additionally, few studies have compared disease burden across patients with RA, PsA, and axSpA because there are limited disease measures that are directly comparable across all 3 diseases. The objective of this study was to compare the disease burden of patients diagnosed with RA, PsA, or axSpA enrolled in the US-based Corrona RA and PsA/SpA Registries.

Methods: This study included adult patients with RA enrolled in the Corrona RA Registry and those with PsA or axSpA enrolled in the Corrona PsA/SpA Registry between March 2013 and March 2018. Patient demographics, clinical characteristics, and disease activity measures collected at registry enrollment were compared between patients with RA vs PsA and patients with RA vs axSpA using t tests or Wilcoxon rank-sum tests for continuous variables and χ^2 or Fisher's exact tests for categorical variables.

Results: A total of 11,350 patients with RA, 2003 with PsA, and 495 with axSpA were included. Patients with RA were older than those with PsA or axSpA (58.4 vs 53.6 and 47.6 years, respectively); a higher proportion of patients with RA were female (77% vs 52% and 36%) and a lower proportion were white (86% vs 94% and 93%) compared with patients with PsA or axSpA. Patients with PsA or axSpA had longer symptom duration (11.2 and 16.7 years) and disease duration (8.4 and 9.8 years) compared with those with RA (9.4 and 7.6 years, respectively) (Table). Patients with RA had a mean physician global assessment score comparable to that of patients with axSpA (27.3 vs 25.5) and higher than that of patients

with PsA (18.6) (**Table**). Patients with axSpA had higher mean patient-reported pain, fatigue, and patient global assessment scores than those with RA (46.1 vs 39.5, 48.3 vs 43.4, and 50.2 vs 36.9, respectively), whereas patients with PsA had a comparable pain score (38.9 vs 39.5), lower fatigue score (41.1 vs 43.4), and higher patient global assessment score (43.2 vs 36.9) than those with RA (**Table**). Higher proportions of patients with PsA or axSpA reported experiencing ≥ 30 minutes of morning stiffness compared with those with RA (65% and 71% vs 62%) (**Table**).

Conclusion: The results of this real-world study indicate that, from a patient perspective, patients with PsA and axSpA have a disease burden comparable to or greater than patients with RA; however, the disease burden of PsA and axSpA may not be as well recognized in clinical practice compared with that of RA. These results provide important insights for physicians into the impacts of RA, PsA, and axSpA from a patient perspective and highlight the need to better understand disease burden in patients with PsA and axSpA.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Epidemiology and Public Health Poster III: SLE, SSs, APS, PsA, and Other Rheumatic Diseases

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Psoriatic Arthritis (PsA) is a progressive and often destructive joint disease that causes pain, swelling and joint stiffness, and can lead to an impaired quality of life. As psoriasis commonly precedes PsA, people with psoriasis provide an important population for studying the effect of modifiable risk factors in the development of PsA.

Methods: Incident cases of psoriasis, diagnosed between 1998 and 2014, were identified from the UK Clinical Practice Research Datalink. The association between baseline psoriasis severity, smoking, alcohol consumption and body mass index (BMI), after adjustment for potential confounders, and development of PsA was assessed using generalised additive

models. In addition, the possible non-linear and cumulative/lagged risks associated with change in BMI during follow-up were investigated using distributed lag non-linear models.

Results: The base population consisted of 90,189 incident cases of psoriasis (42% males, mean age 51), of which 1409 developed PsA after the record of their psoriasis diagnosis. Significant increases in the risk of developing PsA were observed for BMIs of 25.0-29.9 (OR_{adj} 1.79 (CI₉₅ 1.46 - 2.19)), 30.0-34.9 (OR_{adj} 2.10 (CI₉₅ 1.67 - 2.63)), and ≥ 35.0 (OR_{adj} 2.68 (CI₉₅ 2.09 - 3.43)) compared to <25.0 . Increased risks of developing PsA were associated with having severe psoriasis: OR_{adj} 3.40 (CI₉₅ 2.83 - 4.08) and alcohol consumption: OR_{adj} 1.13 (CI₉₅ 0.7275 - 1.7047), OR_{adj} 1.46 (CI₉₅ 1.08 - 1.97) and OR_{adj} 0.77 (CI₉₅ 0.46 - 1.29) for ex-, current and heavy drinkers respectively, compared to non-drinkers. Associations with smoking were not significant: OR_{adj} 0.95 (CI₉₅ 0.78 - 1.15) and OR_{adj} 0.87 (CI₉₅ 0.70 - 1.07) for past and current smokers respectively, compared to non-smokers.

A BMI risk calculator was produced to demonstrate the effects of reductions in BMI on (cumulative) risk of developing PsA (Figure 1). For example, reducing BMI over a 10-year period (linearly) was associated with a reduction in the risk of developing PsA when compared to BMI remaining constant over the same period.

Conclusion: The findings from this study add to the growing evidence that severity of psoriasis, alcohol use and increased BMI are associated with an increased risk of PsA in people with psoriasis. Using measurements of BMI over time allowed us to quantify the burden of continuing weight gain on the risk of PsA and, for the first time, we have shown that reducing BMI over time results in a reduction in the risk of PsA. As PsA affects around 20% of people with psoriasis, weight reduction amongst those who are obese may have the potential to greatly reduce their risk of PsA in addition to providing additional health benefits.

Figure 1- Risk calculator for BMI and developing PsA, representing the changes in risk associated with a linear change in BMI vs constant BMI over a 10 year period. Positive changes (shown in red) indicate an increase in risk with negative changes (in green) indicating reduced risk.

Identification of Psoriatic Arthritis Using an Administrative Claims-Based Algorithm

Julia Ford¹, Lindsey A. MacFarlane¹, Angela Tong² and Seoyoung C. Kim^{1,3}, ¹Rheumatology, Brigham and Women's Hospital, Boston, MA, ²Division of Pharmacoepidemiology and Pharmacoeconomics, Brigham and Women's Hospital, Harvard Medical School, Boston, MA, ³Division of Pharmacoepidemiology, Brigham and Women's Hospital, Boston, MA

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Epidemiology and Public Health Poster III: SLE, SSc, APS, PsA, and Other Rheumatic Diseases

Session Type: ACR Poster Session C

Session Time: 9:00 AM-11:00 AM

Background/Purpose: Psoriatic arthritis (PsA) is an inflammatory arthritis that can present variably in patients with or without psoriasis. The ability to accurately identify PsA in the large electronic healthcare database is critical for epidemiological studies of this disease. This study aimed to develop and validate a claims-based algorithm to identify patients with PsA.

Methods: We used data from the Partners Healthcare electronic medical record linked to Medicare claims in 2012. We developed 4 claims-based algorithms to identify cases of PsA: 1) ≥ 2 International Classification of Diseases, Ninth Revision (ICD-9) codes for PsA (696.0), at least one by a rheumatologist; 2) ≥ 2 ICD-9 codes for PsA by any physician and ≥ 1 claims for PsA-related medication, including biologic and non-biologic disease modifying anti-rheumatic drugs; 3) ≥ 2 ICD-9 codes for PsA and ≥ 1 ICD-9 codes for psoriasis (696.1) by any physician; and 4) ≥ 2 ICD-9 codes for PsA and no more than one ICD-9 code for rheumatoid arthritis (RA; 714.0). The ICD-9 codes were all separated by ≥ 7 days but < 365 days. In algorithms 1, 3, and 4, the index date was defined as the date of the diagnosis code for PsA that occurred second; in algorithm 2, the index date was defined as whichever event (ICD-9 code or medication claim) occurred third. PsA cases defined by the algorithms were confirmed by medical record review, with diagnosis of PsA documented in the clinical record by the treating physician considered as the gold standard. Positive predictive value (PPV) and 95% confidence intervals (CI) of the algorithms were calculated.

Results: The 4 algorithms identified 281, 261, 224, and 216 records respectively, however around 40% had adequate data (defined below) and were included. The PPV of the algorithms ranged from 86.6-90.5% (Table).

Conclusion: Our records suggest that a claims-based algorithm utilizing two or more diagnosis codes for PsA alone, or in combination with a diagnosis for psoriasis, no more than one diagnosis code for RA, or linked to a PsA-related medication, can accurately identify cases of PsA in the claims database.

Table. Positive predictive value of algorithms.

Algorithm	Records identified n	Records with adequate data* n (%)	Confirmed PsA per treating physician n	PPV of algorithm % (95% CI)
≥2 ICD-9 codes for PsA, at least one by rheumatologist	281	134 (47.6)	116	86.6 (79.6, 91.8)
≥2 ICD-9 codes for PsA AND ≥1 medication claim	261	113 (43.3)	98	86.7 (79.1, 92.4)
≥2 ICD-9 codes for PsA AND ≥1 ICD-9 code for psoriasis	224	95 (42.4)	86	90.5 (82.8, 95.6)
≥2 ICD-9 codes for PsA AND no more than 1 ICD-9 code for RA	216	104 (48.1)	93	89.4 (81.9, 94.6)

* Defined as clinic notes that discuss or address diagnosis of PsA within 6 months of the index date.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Epidemiology and Public Health Poster III: SLE, SSc, APS, PsA, and Other Rheumatic Diseases

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Psoriatic arthritis (PsA) is an inflammatory musculoskeletal disease that affects about 30% of psoriasis patients, and can lead to significant joint damage and disability. Results from mortality studies are inconsistent. The aims of this study were: 1) to estimate the trends in mortality rates among PsA patients over calendar time 2) to estimate cause-specific mortality rates.

Methods: Patients are evaluated at the initial clinic visit and subsequently every 6-12 months according to a standard protocol. The prospectively collected data are stored in a web-based database and included demographics, personal and family medical history, smoking and alcohol drinking habits, medications, skin and musculoskeletal disease activity, imaging, and laboratory findings. Information on patient deaths and causes of death was collected prospectively and through linkage with the provincial cancer and death registries, through telephone interviews and correspondence with family physicians and patients' relatives, and through daily checks of death notices in the newspaper. Death certificates, and admission letters were used, where possible, to verify patient deaths and to identify the primary cause of death. Standardized mortality ratios (SMRs) were computed with reference to the Ontario population and were calculated overall, by age, and by sex. Causes of death were recorded by ICD9 and ICD10 codes. Cause-specific SMRs were also computed.

Results: Among 1490 patients followed over 14675 patient-years, there were 225 (15%) confirmed deaths among 111 female and 114 male individuals. The overall standardized mortality ratio was 0.92 (95% confidence interval [CI] 0.81-1.05), the sex specific SMRs were 1.08 (95% CI 0.89-1.30) for females and 0.80 (95% CI 0.66-0.97) for males. The age-specific SMRs were of 3.36 (95% CI 1.61-6.18) for those 20-39 years of age, and 0.97 (95% CI 0.68-1.34), 0.88 (95% CI 0.73-1.06) and 0.86 (95% CI 0.66-1.11) for 40-59, 60-79 and above 80 years of age respectively. Major causes of death included malignant neoplasms (n=61; SMR=0.97 [95% CI 0.72-1.28]), acute myocardial infarction (n=32; SMR=1.11 [95% CI 0.74-1.58]), and pneumonia (n=14; SMR=2.46 [95% CI 1.27-4.31]).

Figure 1: Unadjusted standardized mortality ratios. Overall rates in 1490 study patients, as well as sex-specific rates

Table 1: Characteristics of the study patients at first presentation

	Overall (n=1490)	Alive (n=1265)	Deceased (n=225)
Age, mean \pm SD years	44.5 (13.2)	42.8 (12.5)	54.3 (12.8)
Age at Psoriasis onset, mean \pm SD years	28.7 (14.7)	27.5 (13.9)	35.4 (17.2)
Age at PsA onset, mean \pm SD years	38.2 (13.7)	37.1 (13.3)	44.2 (14.5)
PsA duration, mean \pm SD years	6.3 (7.8)	5.6 (7.1)	10.2 (10.6)
Follow up duration, mean \pm SD years	10.4 (9.7)	10.4 (9.7)	8.7 (8.7)
Smoking ever, n(%)	663 (44%)	579 (46%)	84 (37%)
Sex, n (%)			
* Female	660 (44%)	549 (43%)	111 (49%)
Alcohol consumption, n(%)

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Epidemiology and Public Health Poster III: SLE, SSc, APS, PsA, and Other Rheumatic Diseases

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Antiphospholipid Syndrome (APS) is a systemic autoimmune disease characterized by thrombotic and/or obstetrical manifestations mediated by antiphospholipid antibodies (aPL). By now, no population-based study was performed to assess the epidemiology of APS. Incidence and prevalence of primary APS (PAPS) are therefore unknown. The aim of this study was to evaluate the prevalence during the year 2013 and incidence for the period 2011-2015 of vascular PAPS in the adult population in a 40 kilometers long prealpine valley in northern Italy. The population was 101.477 inhabitants in 2013. The only easy access to the valley is from the main city of the area, where the only Rheumatology referral tertiary Center is located. Therefore, this valley is ideal for epidemiological studies by matching different sources for patients' identification. The search for PAPS cases was restricted to adults below the age of 50, since this is supposed to be the age period for the onset of "true" vascular PAPS.

Methods: We identified adult individuals of 18-50 years of age living in the study area. Patients with thrombotic events were identified by three sources: 1) hospital discharge codes using keywords (deep vein thrombosis, pulmonary embolism, myocardial infarction, ischemic stroke); 2) General Practitioners working in the study area; 3) patients with definite diagnosis of vascular PAPS already followed-up in the tertiary Rheumatology Center. Patients were classified as PAPS if aPL positivity was confirmed overtime.

Table 1. Incidence rates of antiphospholipid antibody syndrome per 100,000 inhabitants in younger adult population (18-50 years) between 2011 and 2015. The 95% confidence intervals (CI) are reported in parenthesis.

	INCIDENCE	
	Number of cases	Incidence (95% CI) per 100,000
OVERALL		
Males + Females	5	3.7 (1.7-7.1)
Males	5	4.0 (1.5-9.4)
Females	4	3.4 (0.9-8.6)
VENOUS THROMBOSIS		
Males + Females	4	1.7 (0.5-4.3)
Males	1	0.6 (0.0-4.5)
Females	3	2.6 (0.5-7.3)
CEREBROVASCULAR ACCIDENTS		
Males + Females	4	1.7 (0.5-4.3)
Males	3	2.4 (0.5-7.1)
Females	1	0.9 (0.0-4.0)
MYOCARDIAL INFARCTION		
Males + Females	1	0.6 (0.0-2.3)
Males	1	0.6 (0.0-4.5)
Females	0	—

Results: We identified 47 patients with venous events during the period 2011-2015. Twenty-seven out of 47 (57%) were tested for aPL, 5/27(19%) resulted to be positive. Regarding arterial events, 36 patients had stroke and 33/36 (92%) were tested for aPL, 4/33 (12%) were positive. Sixty-four patients with myocardial infarction (MI) were observed: 14/64 (22%) were tested for aPL, 2/14 (14%) were positive. Prevalence was estimated to be 22,9 (CI 95% 11,4-41,0) per 100.000 inhabitants in 2013. Table 1 shows the incidence figures of vascular PAPS. We also calculated the “historical” incidence of APS in the 10 years before our study period (2001-2010), yielding a value of 1,2 (CI 95% 0,4-2,6) per 100.000 inhabitants. By comparing the two incidence values (1,2 vs 3,7), we can assume a better diagnostic sensitivity over the years and increasing awareness of PAPS as a cause of thrombosis in younger patients.

Conclusion: This is the first population-based epidemiological study assessing the prevalence and incidence of PAPS in adult population below the age of 50. According to the prevalence estimates, PAPS can be classified as a “rare disease”. This study identified a gap in the diagnostic work-up, as nearly 50% and 80% of patients with venous thrombosis and MI were not tested for aPL. We are currently contacting patients who were tested for a PL in order to refine the epidemiological evaluation.

Abstract Number: 2138

Real-World Evaluation of Treatment Patterns of Methotrexate Users in Psoriatic Arthritis

Brian Ung¹, Dionne Hines², Sandhya Mehta¹, Corey Pelletier¹, Xin Wang² and Rolin Wade², ¹Celgene Corporation, Summit, NJ, ²IQVIA, Durham, NC

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Epidemiology and Public Health Poster III: SLE, SSc, APS, PsA, and Other Rheumatic Diseases

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Methotrexate (MTX) is commonly used to treat psoriatic arthritis (PsA), yet data supporting its effectiveness in PsA are limited. This analysis describes real-world dosing, treatment patterns, and administration modifications in PsA patients initiating MTX.

Methods: Adults with PsA were selected if they initiated MTX (index date) between January 1, 2012, and September 30, 2016, had ≥ 12 months pre- and post-index continuous enrollment in the IQVIATM PharMetricsPlus real-world data adjudicated claims database, and had no history of systemic disease-modifying PsA therapies 12 months pre-index. Concomitant drug use with known MTX interactions was captured along with rates of MTX discontinuation, switch, initiation of combination therapy, and changes to dose and/or administration. Concomitant drug use was defined as ≥ 7 days' supply overlap. Discontinuation was defined as a ≥ 60 -day lapse in therapy. Switching was defined as the presence of a new therapy, with a < 60 -day MTX overlap and MTX discontinuation. Combination therapy was defined as the addition of a PsA agent to MTX, with a ≥ 60 -day overlap. Patients were followed for 12 months after their index date.

Results: A total of 2,105 MTX patients were included. Mean (SD) age was 48.0 (10.3) years and 51% were male. Mean follow-up was 30.1 months. During the pre-index period, 48.2%, 54.9%, and 51.5% used topical steroids, systemic steroids, and non-steroidal anti-inflammatory drugs, respectively. Rates of comorbidities that could increase patients' risk of MTX toxicity were hyperlipidemia (33.5%), diabetes (13.3%), and obesity (13.9%). Other comorbidities included osteoarthritis (54.7%), hypertension (33.2%), and fibromyalgia (17.9%). More than half of MTX patients (56.5%) had a concomitant prescription with known MTX interaction. Mean (SD) duration of MTX monotherapy was 186.0 days (129.7). During

12-Month MTX Treatment Patterns in Patients With a Diagnosis of PsA

Treatment Pattern, n (%)	MTX N=2,105
Discontinuation (≥ 60 -day refill gap)	999 (47.5)
Switch	146 (6.9)
Combination	351 (16.7)
No modification	609 (28.9)

follow-up, 57.6% of patients had ≥ 1 increase in dose and 31.6% had ≥ 1 decrease in dose, while 108 (5.1%) patients changed from oral to subcutaneous injection. Discontinuation was the most frequent treatment modification, followed by combination therapy (Table). Mean (SD) time to discontinuation, switch, and combination therapy was 99.8 days (75.5), 112.2 (60.0) days, and 150.8 (84.7) days, respectively.

Conclusion: During follow-up, half of the MTX users discontinued therapy, had concomitant therapy with known MTX interactions, and had at least 1 increase in MTX dose. More research is needed to better understand the impact of treatment patterns on healthcare outcomes among PsA patients initiating treatment with MTX.

Retrospective Study: Association of Hydroxychloroquine Use and Hemolytic Anemia in Patients with Low Levels of Glucose-6-Phosphate Dehydrogenase (G6PD)

Mateo Mejia Saldarriaga¹, Ivan Emil Ramirez de Oleo¹ and Beverly Johnson^{2,3}, ¹Internal Medicine, Jacobi Medical Center, Bronx, NY, ²Jacobi Medical Center, Albert Einstein College of Medicine, Bronx, NY, ³Rheumatology, Albert Einstein College of Medicine, Bronx, NY

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Epidemiology and Public Health Poster III: SLE, SSc, APS, PsA, and Other Rheumatic Diseases

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Glucose-6-phosphate dehydrogenase deficiency (G6PD) is linked to hemolytic anemia with certain medications and is the most common enzyme deficiency worldwide. Clinical hemolysis and severity of disease depends on the genotype of G6PD, which also has a different geographic distribution, with the most severe risk of hemolysis in the Mediterranean variant. Although the American College of Rheumatology does not recommend routine testing for G6PD prior to initiation of Hydroxychloroquine (HCQ), the package insert for HCQ does recommend careful use in G6PD deficient patients due to potential for hemolysis. A recent retrospective study from Duke assessed 11 G6PD deficient African American patients exposed to HCQ over 700 months cumulative exposure with no cases of hemolysis during medication exposure. Authors recommended against the routine measure of G6PD levels or withholding therapy with HCQ in African Americans given these results. However, the study population was mainly African American and had minor representation of other ethnicities.

Methods: Eligible subjects in our large, urban medical center were identified using clinical looking glass software from January 1st, 1997 to January 1st, 2018. Data was collected using the institutional EMR. Case records were analyzed for G6PD deficiency, HCQ use, length of exposure to HCQ, demographic characteristics and laboratory evidence of hemolysis.

Results: 5264 patients were prescribed HCQ during the pre specified interval, of which 49.5% (2605 patients) were screened for G6PD deficiency. Of the screened patients, 36 were found to be G6PD deficient. After chart review, 18 G6PD deficient patients were found to be exposed to HCQ. The mean age of the patients was 48 years (SD 14.1, range 18-66), 11 were female, the most common race was African American (n=10) and Hispanic (n=5), and the most common diagnosis was lupus (n=7), followed by rheumatoid arthritis (n=5). The mean exposure time was 32.8 months (SD 30.3, range 2-114 months), with a total cumulative exposure of 591 months. No evidence of hemolysis was found, either by clinical or laboratory criteria.

Conclusion: 5264 patients were prescribed HCQ during the prespecified interval, of which 49.5% (2605 patients) were screened for G6PD deficiency. Of the screened patients, 36 were found to be G6PD deficient. After chart review, 18 G6PD deficient patients were found to be exposed to HCQ. The mean age of the patients was 48 years (SD 14.1, range 18-66), 11 were female, the most common race was African American (n=10) and Hispanic (n=5), and the most common diagnosis was lupus (n=7), followed by rheumatoid arthritis (n=5). The mean exposure time was 32.8 months (SD 30.3, range 2-114 months), with a total cumulative exposure of 591 months. No evidence of hemolysis was found, either by clinical or laboratory criteria.

Association of Hydroxychloroquine Use and Incident Atrial Fibrillation in Rheumatoid Arthritis: A Retrospective Study

Alisha Gupta¹, Aditya Joshi¹, Omar Saleem¹, Mary Chester-Wasko² and Tarun S. Sharma³, ¹Internal Medicine, Allegheny General Hospital, Pittsburgh, PA, ²Allegheny Health Network, Pittsburgh, PA, ³Rheumatology, Lupus Center of Excellence, Allegheny Health Network, Pittsburgh, PA

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Epidemiology and Public Health Poster III: SLE, SSc, APS, PsA, and Other Rheumatic Diseases

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Hydroxychloroquine (HCQ) is a derivative of quinidine, a class 1 a anti-arrhythmic agent used to prevent ventricular arrhythmias and recurrent atrial fibrillation (AFib). AFib occurs more commonly in patients with rheumatoid arthritis (RA) compared to the general population. HCQ is commonly used to treat mild RA. This study examines the association of HCQ use and AFib or ventricular arrhythmias in RA.

Methods: A retrospective cohort of adult RA (ICD10: M05 and M06) patients at a tertiary academic rheumatology practice from Dec 1,2014 to May 30,2017 excluding patients with prevalent AFib was constructed. Patients were categorized as HCQ users versus nonusers. Primary outcome was incident AFib adjudicated by electronic health record (EHR) review and EKG confirmation. AFib events occurring in the first year of observation were considered prevalent AFib to allow for a run-in period and exclude prevalent cases more reliably. Secondary outcome was incident ventricular arrhythmias- a composite of ventricular tachycardia (VT), ventricular fibrillation (VF), torsades and sudden cardiac death (SCD) adjudicated similarly. Multivariate regression analysis was performed to estimate the association between HCQ exposure and development of incident AFib, after adjusting for relevant confounders, including demographics (age, sex, ethnicity), AFib-related co-morbidities (BMI, smoking, alcohol use, chronic obstructive pulmonary disease, obstructive sleep apnea, hypertension, coronary artery disease, heart failure, diabetes, cerebrovascular accident and transient ischemic attack, peripheral vascular disease, thyroid disorder, chronic kidney disease and liver dysfunction), anti-arrhythmic medication use (beta-blockers, calcium channel blockers, flecainide, digoxin, amiodarone), and autoimmune serologies. Sub-group analysis was performed on patients age >65yrs (given higher risk of AFib).

Results: Our study included 5697 patients with RA, including 1304 HCQ users. During the observation period, 28 incident AFib events occurred in HCQ users and 54 in non-users. Unadjusted odds ratio (OR) was calculated at 1.76 (95% CI 1.11-2.80, p=0.02), and multivariable logistic regression analysis showed an OR of 2.07 (95% CI 1.30-3.30, p=0.002) for incident AFib. Three incident ventricular arrhythmias occurred in HCQ users and 7 in non-users, all were VT, with OR of 1.44 (95% CI 0.37-5.59, p=0.59). In the age>65 yrs sub-group analysis, OR was 1.99 (95% CI 1.18-3.38, p=0.01).

Table 1: Risk of incident AFib according to HCQ use

Variable	HCQ users (N=1304)	HCQ non-users (n=4393)
Age (yrs)	62.4±13.3	65.4±13.7
Female sex	1058 (81%)	3277 (75%)
Caucasian	1164 (89.3%)	3829 (87.2%)
BMI (kg/m2)	29.8±7.3	29.7±7.1
Smoking (ever)	713 (55%)	2220 (51%)
Alcohol user	504 (39%)	1610 (38%)
Anti-arrhythmic medication use	162 (12.4%)	87 (1.9%)
HTN	380 (29%)	1490 (34%)
COPD	2 (0.1%)	2 (0.1%)
OSA	80 (6%)	94 (0.01%)
CAD	52 (4%)	98 (2.2%)
Heart failure	32 (2.4%)	112 (2.5%)
Diabetes	118 (9%)	606 (13.8%)
CVA/TIA	9 (0.6%)	84 (1.9%)
Thyroid disorder	7 (0.5%)	15 (0.3%)
Liver dysfunction	40 (3%)	118 (2.7%)
CKD	44 (3.3%)	210 (4.8%)
PVD	13 (0.9%)	66 (1.5%)
Incident AFib	28 (2.2%)	54 (1.2%)
Unadjusted Odds Ratio	1.76 (95 % CI 1.11-2.80, p=0.02)	
Adjusted Odds Ratio	2.07 (95% CI 1.30-3.30, p=0.002)	

Conclusion: In this exploratory study, HCQ use was associated with a 2 times higher risk of AFib in RA patients. These preliminary results need to be confirmed in larger studies given HCQ's otherwise favorable effect on cardiovascular disease risk profile in multiple previous studies.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Epidemiology and Public Health Poster III: SLE, SSc, APS, PsA, and Other Rheumatic Diseases

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: A Glucocorticoid Toxicity Index app (GTI 2.0) is now used as a clinical trial outcome measure in adults, but glucocorticoid (GC) toxicity issues in children differ from those relevant to adults in a number of respects. We sought to design a pediatric GTI (pGTI) for use as an outcome measure in clinical trials and other settings to assess the impact of treatment interventions on GC toxicity.

Method: Sixteen experts from 7 subspecialties participated. Six were from the U.S. and 10 from Europe, Canada, or New Zealand. Group consensus methods and multi-criteria decision analysis (MCDA) were employed. The pGTI consists of a Composite Index and a Specific List. Toxicities included in the Composite GTI occur commonly and may vary with GC exposure. The Composite GTI reflects GC toxicity with the potential to change over time: to worsen if GC doses increase, or to improve if successful GC sparing is achieved. The Composite pGTI was evaluated by application to paper cases derived from real-life cases. Weights for individual items of the Composite pGTI were assigned through MCDA, facilitated by 1000 Minds software. Similar MCDA approaches were used in the development of the adult GTI and ACR/EULAR Classification Criteria for several rheumatic diseases (RA, SLE, SSc). In contrast, the Specific List describes clinical events that are less common but often severe and typically not reversible by GC reduction. Items of the Specific List are not weighted but rather recorded as a cumulative index of glucocorticoid-related damage.

Results: The complexity of longitudinal GC toxicity assessment in children lends itself well to app technology, which offers significant advantages in ease of calculation. The impact of normally-anticipated growth on several pGTI domains poses particular challenges addressed effectively by app technology. The pGTI Composite Index consists of 10 toxicity domains: body mass index (BMI), growth, glucose tolerance, lipid metabolism, systolic blood pressure, bone mineral density, GC-induced myopathy, skin toxicity, neuropsychiatric impact, and infections. Weighting of items of the Composite GTI permits the calculation of cumulative and aggregate scores. The pGTI weights improvement in GC toxicity within a given domain as highly as worsening: improvements yield negative toxicity scores; worsening, positive scores. As an example, an increase in BMI of >2 but <5 BMI units is associated with an increase in the cumulative GTI of +21 points. In contrast, decline in BMI to a corresponding degree is associated with a reduction in that domain of -21 points. All pGTI scores are calculated based on a change in toxicity between two visits rather than an absolute score at one point in time. The Specific List is designed to capture GC toxicity not included in the Composite GTI. The Specific List includes six additional domains addressing features of GC toxicity such as pubertal delay/sex hormone access interruption, ocular toxicity (cataracts, central serous retinopathy), and bone health (osteonecrosis).

Conclusion: We describe the development and initial evaluation of a comprehensive, weighted index for the assessment of GC toxicity. A pGTI app will be available in the autumn of 2018.

Exposure to Disease Modifying Antirheumatic Drugs during Pregnancy in Women with Inflammatory Arthritis and the Risk of Serious Maternal Infection: A Population-Based Cohort Study

Mary A. De Vera^{1,2,3}, Nicole W. Tsao^{1,2,3}, Eric C. Sayre² and Alyssa Howren^{1,2,3}, ¹Faculty of Pharmaceutical Sciences, University of British Columbia, Vancouver, BC, Canada, ²Arthritis Research Canada, Richmond, BC, Canada, ³Collaboration for Outcomes Research and Evaluation (CORE), Vancouver, BC, Canada

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Epidemiology and Public Health Poster III: SLE, SSc, APS, PsA, and Other Rheumatic Diseases

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Infection risk is one of the concerns regarding therapy with conventional disease modifying antirheumatic drugs (csDMARDs) and to our knowledge no research has examined this concern in pregnancy. Our objective was to evaluate the association between exposure to csDMARD during pregnancy and risk of serious infections in women with inflammatory arthritis (IA).

Methods: Linking population-based administrative data on all physician visits, hospital admissions, and all dispensed medications to a provincial perinatal registry, we conducted a retrospective cohort study from 01/01/2002 and 12/31/2012. Unique to this registry is detailed information on antenatal, intrapartum, and postpartum maternal and infant outcomes as well as valid information on date of conception. We created a pregnancy cohort of women with IA using a case definition of 2 outpatient physician ICD9 codes within 2 months and less than 2 years apart for rheumatoid arthritis, systemic autoimmune rheumatic diseases, and other IA. We categorized csDMARDs according to accepted compatibility with pregnancy: **Group 1** - antimalarials, cyclosporine, gold, sulfasalazine; and **Group 2** - azathioprine, chlorambucil, cyclophosphamide, leflunomide, methotrexate, minocycline, mycophenolate mofetil, penicillamine. We ascertained exposure during pregnancy as binary use (yes/no) overall and according to the most recent trimester. Serious maternal infection outcomes were those requiring hospitalization during the first 42 days post-partum. We used Poisson regression models to evaluate the association between csDMARD during pregnancy and serious maternal infections, adjusting for baseline covariates.

Results: There were 485 pregnancies in 405 women, and 5,764 pregnancies in 4,168 women in the csDMARDs exposed and unexposed groups, respectively, during the study period (**Table 1**). We identified 3.5%, 3.9%, and 4.0% of mothers with serious infections in unexposed pregnancies and those exposed to Group 1 and 2 csDMARDs, respectively. As shown in **Table 2**, there were no associations with csDMARDs use during pregnancy and serious infections in mothers when considering overall exposure (adjusted odds ratio [OR], 0.96; 95% confidence interval [CI], 0.60 to 1.54) or according to trimester. Findings persisted in sub-analyses according to csDMARD groups.

Conclusion: We found no association with exposure to csDMARDs during pregnancy and serious maternal infections among women with IA. These findings have implications for informing women with IA who are pregnant or planning to become pregnant.

Table 1. Characteristics of pregnant women with inflammatory arthritis exposed and unexposed to csDMARDs preconception and during pregnancy

Characteristics	Exposed to csDMARDs N (%) 405 women 485 pregnancies	Unexposed to csDMARDs N (%) 4,168 women 5,764 pregnancies

Abstract Number: 2143

Lymphoproliferative Malignancy in Psoriatic Arthritis and the Role of Systemic Immunosuppressive Therapies

Linh Truong¹ and Maida Wong², ¹Internal Medicine, University of California, Irvine, Orange, CA, ²Division of Rheumatology, University of California, Irvine, Orange, CA

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Epidemiology and Public Health Poster III: SLE, SSc, APS, PsA, and Other Rheumatic Diseases

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Psoriatic arthritis (PsA) is a systemic inflammatory disease that can have musculoskeletal (PsA-MsK) or concurrent MsK and skin (PsA-MsK/skin) manifestations, and the skin disease has the same clinical features as that of psoriasis (PsO). Such autoimmune diseases have been related to increased lymphoproliferative disease risk, which is thought to be due to continual exposure of systemic immunosuppressive therapies and abnormal immune activation. Such risk is well established in PsO, but is unclear in PsA. Also, the use of immunosuppressants has been a conflicting predictor in the development of malignancy. This study was undertaken to investigate the lymphoproliferative risk among patients with PsA-MsK/skin, PsA-MsK, and PsO and in relation to systemic immunosuppressive therapies, including tumor necrosis factor inhibitor (TNFi) and methotrexate (MTX).

Methods: A multicenter retrospective study involving four Veterans (VA) Hospitals in Southern California was performed (n=930,802). Patients with PsA-MsK/skin (n=18,339), PsA-MsK (n=9,437), and PsO (n=15,951) were assembled using the ICD 9 and 10 coding from 2000 to 2017. Each cohort member was linked to ICD-9 and ICD-10 codes for a diagnosis of lymphoma and leukemia. The Odds Ratio (OR) for developing any lymphoproliferative malignancy was calculated and the prevalence for individual lymphoma and leukemia subtypes were compared among the cohorts. A sample of patients with PsA-MsK/skin (n=42), PsA-MsK (n=57), and PsO (n=50) at Long Beach VA Hospital (VALB) and their use of TNFi and MTX therapy were analyzed in relation to their risk for developing malignancy, with the use of therapy defined as being \geq 12 months of exposure.

Results: In the PsA-MsK/skin, PsA-MsK, and PsO groups, the prevalence of lymphoma and leukemia was 0.25%, 0.66%, and 3.70%, respectively. The most common lymphoproliferative malignancy among all three groups was Non-Hodgkin's lymphoma, with diffuse large B-cell lymphoma as the most prevalent subtype. Patients with PsA-MsK/skin have the lowest risk for developing lymphoproliferative cancer (OR 0.15), followed by those with PsA-MsK (OR 0.37) and PsO (OR 2.27; $p < 0.001$ in all groups). In the VALB cohort, twice as many PsA-MsK/skin patients received combination TNFi and MTX therapy compared to PsA-MsK patients, and almost no PsO patients received systemic immunosuppressants (47.6%, 24.6%, 4.0%; $p < 0.001$).

Conclusion: The subtypes of lymphoproliferative cancers were similarly distributed among patients with PsA and PsO. PsA patients have an unexpectedly low prevalence and low risk in developing lymphoproliferative cancers in comparison to PsO patients. One explanation is that aggressive management of PsA with systemic immunosuppression successfully controls autoimmune inflammatory processes and reduces the risk of developing malignancy. These findings also imply that, perhaps, biologics may not induce malignancy as suggested by other studies. Additional studies are needed to elucidate lymphoproliferative cancer risk in relation to disease activity and inflammatory markers in the future.

Abstract Number: 2144

Epidemiological Characteristics of Psoriatic Arthritis: A Nationwide Study of Inpatient Hospitalisations in 2014

Vagishwari Murugesan and Jennifer Tran, Internal Medicine, Medstar Washington Hospital Center, Washington, DC

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Epidemiology and Public Health Poster III: SLE, SSx, APS, PsA, and Other Rheumatic Diseases

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Psoriatic arthritis is a seronegative inflammatory arthritis associated with Psoriasis. Using the National Inpatient Sample (NIS) we studied the epidemiological characteristics of inpatient admissions using the ICD 9 Code 6460.00 in the year 2014.

Methods: The NIS is a nationally representative sample of 20% of all non-federal hospitals in the USA with information from approximately 1000 hospitals pertaining to records from 7 million inpatient hospital admissions. The epidemiological characteristics we studied were age, gender, payer (Medicare/Medicaid/private insurance/uninsured), patient residence (large central metro, suburbs, medium and small metro and rural areas) and region (northeast, mid-west, southern and west) and associated co-morbidities: hypertension, diabetes, heart failure, chronic kidney disease, osteoarthritis & heart failure. Multiple linear regression was used to analyze factors that were associated with psoriatic arthritis.

Results: For 2014, from a total of nearly 7 million records (7,071,762), there were 775 admissions for psoriatic arthritis as the primary diagnosis (0.16%) which translated to 0.2 admissions per 100,000 persons. The majority of admissions were in the age group of 45 – 64 years (37.4 %) followed by 18-44 age group (30.9%). There was no gender difference males

(52.9%) and females (47.1%) [$p<0.4$]. The total aggregate costs were \$30,851,867 for 2014 amounting to a mean of \$10,728 per admission. Medicare remained the highest payer (36.7%) followed by private insurance (33.5%) and finally Medicaid (21.9%). Patients from a 27.7% patients were from a large central metro and medium and small sized metro and an equal percentage of 27.7% were from a medium sized metro. 26.4% % of patients were from the suburbs and whereas only 18% were from a rural area. The southern region accounted for majority of admissions (34.%) followed by northeast region(25.1%).21.2% were from Midwest and Western region had only 19.3% of all admissions. The mean length of stay (LOS) was 4.4 ± 0.3 days. By multivariate regression the following co-morbidities were noted to be associated with psoriatic arthritis: Hypertension ($p<0.001$), CKD ($p<0.001$), Osteoarthritis ($p<0.001$), Diabetes ($p<0.001$) and Heart failure ($p<0.001$)

Conclusion: While psoriatic arthritis inpatient admissions only account for 0.2 per 100,000 persons, it places a significant burden on cost and length of stay and is independently associated with hypertension, CKD, osteoarthritis, diabetes and heart failure.

Increased Risk of Heart Failure with Prolonged Use of Hydroxychloroquine in Patients with Rheumatoid Arthritis

Elena Myasoedova¹, Reto Kurmann², Cynthia S. Crowson³, John M. Davis III¹ and Rekha Mankad², ¹Division of Rheumatology, Mayo Clinic College of Medicine and Science, Rochester, MN, ²Cardiovascular Diseases, Mayo Clinic College of Medicine and Science, Rochester, MN, ³Health Sciences Research, Mayo Clinic College of Medicine and Science, Rochester, MN

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Epidemiology and Public Health Poster III: SLE, SSc, APS, PsA, and Other Rheumatic Diseases

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Hydroxychloroquine(HCQ) is commonly prescribed for patients with rheumatoid arthritis (RA).Cardiotoxicity is a rare but potentially life-threatening side effect of HCQ and may present as a cardiomyopathy resulting in congestive heart failure (HF).The evidence of cardiotoxicity associated with the use of HCQ largely relies on case reports and case series while large cohort studies on the subject are lacking. In this population-based cohort study, we aimed to examine the association between exposure to HCQ and incidence of HF in patients with RA.

Methods: A population-based incidence cohort of RA patients aged ≥ 18 years (1987 ACR criteria first met between 1/1/1980 and 1/1/2008) with no history of HF was followed until onset of HF (defined by Framingham criteria), death, or 1/1/2008. We collected data on RA characteristics, cardiovascular (CV) risk factors including current smoking, obesity, hypertension, antihypertensive use, dyslipidemia, diabetes mellitus, and the presence of coronary heart disease (CHD) defined as any of the following: angina pectoris, coronary artery disease, myocardial infarction (including silent events), and coronary revascularization procedures (i.e., coronary artery bypass graft, percutaneous angioplasty/stenting, and atherectomy).

Results: The study included 795 RA patients [mean age 55.3 years, 69% women, 66% rheumatoid factor (RF)-positive]. During the mean follow-up of 9.7 years, 92 patients developed HF. There was no overall increase in risk of HF in patients who used HCQ at any time during the follow up (HR 0.9, 95%CI 0.6-1.4) or in current users of HCQ vs non-users (HR 1.0, 95%CI 0.5-1.8).However, compared to non-users, patients with RA who used HCQ for>14 years had over 3-fold increase in risk of developing HF (HR 3.61; 95%CI1.23-10.63). The association remained statistically significant when additionally adjusting for corticosteroid use ($p=0.036$), CV risk factors and CHD ($p=0.049$). The association remained significant in the subset of patients without CHD when censoring those who develop CHD during follow-up ($p=0.038$). HCQ users were equally likely to develop HF with preserved or reduced ejection fraction.

Conclusion: Prolonged use of HCQ in RA is associated with increased risk of incident HF. Underlying mechanisms for this association require further elucidation.

A Meta-Analysis of the Prevalence and Risk Factors for Retinal Toxicity in Rheumatologic Patients on Hydroxychloroquine Therapy

Amanda Worme¹, Leonardo Tamariz², Ana Palacio², Zsuzsanna Nemeth³ and Mathew Farbman⁴, ¹Internal Medicine, University of Miami Miller School of Medicine at Holy Cross Hospital, Fort Lauderdale, FL, ²Internal Medicine, University of Miami Miller School of Medicine, Miami, FL, ³Health Informatics, University of Miami Miller School of Medicine, Miami, FL, ⁴Rheumatology, University of Miami Miller School of Medicine at Holy Cross Hospital, Fort Lauderdale, FL

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Epidemiology and Public Health Poster III: SLE, SSs, APS, PsA, and Other Rheumatic Diseases

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: HCQ is one of the most common DMARD(s) used in treatment of several rheumatologic diseases, including RA and SLE. Although rare, retinal toxicity remains the most feared adverse effect related to HCQ use because it can result in blindness. We conducted a meta-analysis to evaluate the prevalence and risk factors of retinal toxicity in rheumatologic patients on HCQ therapy.

Methods: We searched PubMed, MEDLINE, Scopus, Embase and Cochrane databases (January 1990 to January 2018) supplemented by manual searches of bibliographies of key relevant articles. We selected for all observational studies in which patients were on HCQ therapy for treatment of a rheumatologic disease, and HCQ retinopathy was evaluated. We calculated the pooled prevalence with the corresponding 95% confidence interval (CI) using the fixed effects method and performed a meta-regression to evaluate the variables that could affect the prevalence.

Results: After removal of duplicates, our search strategy found 328 studies. Of the 109 studies reviewed, 7 studies met our eligibility criteria, of which 6 studies had appropriate data for quantitative analysis. Of the studies included, 2 were cohort and 4 were nested case-control, comprising of 4112 evaluable patients. The pooled prevalence of HCQ retinopathy was 6% (95%CI 2-10). We found no statistical association ($p > 0.05$) between the prevalence of retinopathy and the well-known risk factors associated with development of retinopathy, including duration of HCQ use, cumulative dose and daily dose.

Conclusion: Although HCQ use is infrequently associated with retinopathy, the prevalence is higher than previously documented. Larger studies are needed to better power for the meta-regression of risk factors associated with developing HCQ retinopathy. Ophthalmologic screening should continue to be an important part of the evaluation for all rheumatological patients on HCQ therapy.

Figures/Tables:

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Epidemiology and Public Health Poster III: SLE, SSc, APS, PsA, and Other Rheumatic Diseases

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Current cigarette smoking and recent cessation (within 4 years), compared to no smoking or remote cessation, have been associated with increased anti-dsDNA+ SLE risk among women. SLE-specific cytokines and chemokines have been found to be increased prior to diagnosis. We conducted cross-sectional analyses to investigate whether current smoking was associated with concentrations of SLE-associated cytokines including B lymphocyte stimulator (BLyS), stem cell factor (SCF), interferon-inducible protein-10 (IP-10), and interferon-alpha (IFN α) within a general population of women at risk of SLE.

Methods: The Nurses' Health Study (NHS, n=121,700) and NHSII (n=116,429) cohorts were begun in 1976 and 1989, respectively, and collected detailed exposure and outcome data biennially. In 1988- 1989, ~25% participants donated a blood sample. We identified 1177 women without SLE with banked plasma samples and smoking exposure data prior to the blood draw. We tested for presence of ANA (by Hep2IF), and anti-dsDNA and extractable nuclear antigens (ENAs; anti-Ro, anti-La, anti-Sm and anti-RNP, by ELISAs). Samples were tested by ELISA for BLyS, SCF, IP10, and IFN α . Each passed quality control [QC] using blinded split samples. We adjusted for inter-batch variation using common QC samples. Cytokine/chemokine concentrations were natural log-transformed to improve normality. We assessed relationships between smoking and biomarker concentrations using general linear regression for BLyS and SCF. Tobit regression was employed for IP-10 and IFN α due to a high proportion below the threshold of detection (165[14%] and 754 [64%]).

Results: Mean age at blood draw was 56 (SD 10); 64% of women were White, 36% Black; 15% were current/recent smokers. No association was found between current/recent smoking (vs. never or >4 years past) and ANA/dsDNA/ENA positivity (multivariable-adjusted OR 1.11 [95% CI 0.77, 1.60]). Current/recent smoking was associated with increasing circulating log BLyS (β [SE] = 0.10 [0.03], p<0.0001) and log IFN α (β [SE] = 1.15[0.52], p=0.03), but not SCF or IP-10 compared to never/distant smoking (**Table**). When restricted to the 295 women with ANA+, dsDNA+ or ENA+, the relationship between current/recent smoking and log BLyS was stronger.

Conclusion: Current smoking was associated with elevated BLyS, but not SCF-1 or IP-10, among women without SLE. BLyS is responsible for B-cell survival and maturation and has been reported to be elevated in the lungs of smokers. In stimulating the production of BLyS, smoking may accelerate onset or severity of autoantibody-positive SLE.

	Log BLyS				Log SCF			
	Age-adjusted β (SE)	p	Multivariable- adjusted β (SE)**	p	Age- adjusted β (SE)	p	Multivariable- adjusted β (SE)**	p
A. General Linear Regression Analyses: NHS and NHSII Current Smoking* vs. Past or Never Smoking and Continuous Concentrations of SLE-Associated Biomarkers, Log BLyS and Log SCF-1 among women without SLE								
Current Smoking* among all women (n=1177)	0.09 (0.03)	0.0006	0.10 (0.03)	0.0002	-0.04 (0.02)	0.12	-0.01 (0.02)	0.60
Current Smoking* among ANA/dsDNA/ ENA+ women (n=295)	0.19 (0.05)	0.0003	0.21 (0.05)	< 0.0001	-0.09 (0.08)	0.30	-0.09 (0.10)	0.34
Log IP-10				Log IFNα				
	Age-adjusted β (SE)	p	Multivariable-adjusted β (SE)**	p	Age- adjusted β (SE)	p	Multivariable- adjusted β (SE)**	p
B. Tobit Analyses***: Current Smoking* vs. Past or Never Smoking and Continuous Concentrations of SLE-Associated Biomarkers, IP-10 and Log IFNα								
Current Smoking* among all women (n=1177)	0.12 (0.13)	0.36	0.10 (0.13)	0.43	1.37 (0.52)	0.009	1.15 (0.52)	0.03
Current Smoking* among ANA/dsDNA/ ENA+ women (n=295)	-0.04 (0.24)	0.88	-0.03 (0.25)	0.91	1.98 (1.03)	0.05	1.57 (1.04)	0.13

* Current smoking: includes those who quit within past 4 years of blood draw as risk of SLE continued to be elevated among recent quitters in past analyses.

** Multivariable analyses: adjusted for age, race, body mass index, alcohol intake, history of depression (additional adjustment for oral contraceptive use, menopausal status, postmenopausal hormone use did not affect estimates)

*** Tobit analysis is a method that allows for maximum usage of cytokines/chemokines if there are many undetectable values.

Prevalence and Incidence of FMF in Germany – Results of the First Retrospective Analysis of Representative Claims Data

Ivan Foeldvari¹, Katharina Boehm², Thomas Kramps² and Lukas Mayerhoff³, ¹Hamburg Centre for Pediatric Rheumatology, Hamburg, Germany, ²Novartis Pharma GmbH, Nuremberg, Germany, ³Elsevier GmbH, Munich, Germany

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Epidemiology and Public Health Poster III: SLE, SSc, APS, PsA, and Other Rheumatic Diseases

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Familial Mediterranean fever (FMF) is a rare hereditary autoinflammatory disease that predominantly affects, but is not limited to, persons of Middle Eastern ancestry. In Germany, roughly 10% of the general population has Mediterranean roots or migrated from the area of the Silk Road and may therefore be at risk of developing FMF. To our knowledge, epidemiologic data on FMF in Germany remain limited and no analyses of corresponding claims data have been published previously. The aim of this study was to explore the epidemiology of FMF in Germany and to describe demographic characteristics of the affected population.

Methods: We analyzed the database of the Institute for Applied Health Research Berlin (InGef). This database contains a representative subset of anonymized claims based on about 4 million members of the statutory health insurance (SHI) in Germany (overall about 73 million members). Individuals included in this analysis had to be continuously observable between 01-JAN-2012 and 31-DEC-2017. Prevalence and incidence were calculated for two years, 2014 and 2015. FMF patients were identified by ICD codes E85.0 (familial Mediterranean fever) and M14.4 (amyloid arthropathy).

Results: A total of 383 (11.99/100,000) prevalent FMF patients were identified, of whom 111 (28.98%) were < 18 years of age. Adults constituted 71.02% of prevalent cases. Females represented 48.65% of the pediatric population and 49.26% of the adult population. Also, 138 (4.23/100,000) incident cases were observed with a lower number of pediatric patients (47

or 34.06%) than adults (91 or 65.94%) and balanced proportions of males and females. Median age of incident patients was 30 years.

		FMF cases (2014-2015)			
		Prevalent		Incident	
Sex	Age	N	%	N	%
Female	< 18	54	14.10	24	17.39
	≥ 18	134	34.99	41	29.71
Male	< 18	57	14.88	23	16.67
	≥ 18	138	36.03	50	36.23
Total	all	383	100	138	100

Associated rheumatic conditions diagnosed most frequently were juvenile arthritis, rheumatoid arthritis, and spondyloarthritis.

Conclusion: Our analysis provides a broad and current picture of FMF in Germany: We find a 2-year prevalence of about 0.012% for FMF across 2014 and 2015, corresponding to an extrapolated population of about 5,800 affected subjects among SHI members in Germany. The observed 2-year incidence of 0.004% in this population corresponds to approximately 2,100 newly diagnosed patients in 2014 and 2015 (i.e. about 1,050 per year). This high number of newly diagnosed patients in the adult population is unique and surprising, given the predominant onset and diagnosis of FMF during childhood reported in other publications. The cross-sectional design and lack of information on ethnic background constitute methodical limitations of this analysis. Future studies would be needed to assess, if awareness and early diagnosis of FMF improve over time.

Assessing the Prevalence of Localized Scleroderma in Childhood Using Administrative Claims Data from the United States

Timothy Beukelman¹, Fenglong Xie² and **Ivan Foeldvari**³, ¹Pediatric Rheumatology, University of Alabama at Birmingham, Birmingham, AL, ²University of Alabama at Birmingham, Birmingham, AL, ³Hamburg Center for Pediatric and Adolescent Rheumatology, Hamburg, Germany

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Epidemiology and Public Health Poster III: SLE, SSs, APS, PsA, and Other Rheumatic Diseases

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Juvenile Localised Scleroderma (jLS) is believed a rare autoimmune disease, which occurs 10 times more often than systemic sclerosis in childhood and is believed to have a prevalence of one per 100 000 children(1). There is no prevalence data published.

Methods: We used Truven MarketScan® commercial insurance claims data from the United States for the years 2010 through 2014, inclusive. MarketScan contains billing records associated with physician office visits, outpatient infusions, and pharmacy claims, among other data, and is intended to be representative of all persons covered by employer-sponsored health insurance in the United States. In each individual calendar year, we identified all persons in the claims data who were less than 16 years old.

Results: The results for each calendar year are shown in the Table. There were approximately 1600-2200 children per year with diagnoses of localized scleroderma and <3% of them had concurrent diagnoses of systemic sclerosis or mixed connective tissue disease. The prevalence estimates in each year ranged from 3.2 to 3.6 per 10,000 children. The proportion of children with localized scleroderma who received methotrexate in each year ranged from 3.2% to 4.4%.

Conclusion: This prevalence data show a higher than expected prevalence compared to the published incidence data with 2.7 per 100 000 to 2.5 children per million per year. We need more prevalence data from other resources to reassure our findings.

Table. The estimated prevalence of juvenile localised Scleroderma in the United States

Year	Total Children (N)	Diagnosis Code for Localized Scleroderma (N)	No Diagnosis Code for Systemic Sclerosis or Mixed Connective Tissue Disease (N)	Use of Methotrexate	Estimated Prevalence per 10,000 Children [95% CI]
2010	5,894,628	2064	2006 / 2064	75 / 2006	3.4 [3.3-3.6]
2011	6,231,475	2269	2222 / 2269	86 / 2222	3.6 [3.4-3.7]
2012	6,278,118	2198	2154 / 2198	68 / 2154	3.4 [3.3-3.6]
2013	4,950,018	1732	1692 / 1732	61 / 1692	3.4 [3.3-3.6]
2014	4,933,523	1620	1588 / 1620	71 / 1588	3.2 [3.1-3.4]

Sam Lim³, Cristina Drenkard⁴ and **Laura Plantinga**⁵, ¹Department of Epidemiology, Emory University, Atlanta, GA, ²Durham Veterans Affairs Medical Center, Durham, NC, ³Emory University School of Medicine, Atlanta, GA, ⁴Medicine/Rheumatology, Emory University, Atlanta, GA, ⁵Department of Medicine, Emory University School of Medicine, Atlanta, GA

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Epidemiology and Public Health Poster III: SLE, SSc, APS, PsA, and Other Rheumatic Diseases

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Lower socioeconomic status (SES) has been shown to be associated with poor physical functioning in systemic lupus erythematosus (SLE) patients; however, previous studies have not used poverty income ratio (PIR), which measures poverty as a ratio of household income to appropriate poverty threshold for household size, as a proxy for SES in this population. Thus, we examined the association of PIR with self-reported physical functioning in a cohort of SLE patients and also whether this association was similar for self-reported physical functioning and a set of complementary measures of physical functioning.

Methods: We used cross-sectional data on 744 participants from the ongoing Georgians Organized Against Lupus (GOAL) cohort, and secondary analyses used data on 56 participants from a GOAL-ancillary pilot study. Primary analyses utilized multivariable linear regression to estimate the association between PIR (categorized as <1.00 (income below the poverty threshold), 1.00-1.99, 2.00-3.99, and ≥4.00 (income 4 times the poverty threshold)) and physical functioning (PF; scaled subscore from Short Form-12 survey; range, 0-100, with higher scores indicating better functioning). Secondary analyses summarized complementary measures of physical functioning as means or percentages by PIR (categorized as <1.00, 1.00-1.99, and ≥2.00).

Results: Overall, the mean age of participants was 48.0 years; 6.7% were male; 80.9% were black; and 37.5%, 21.0%, 29.6% and 12.0% had PIRs of <1.00, 1.00-1.99, 2.00-3.99, and ≥4.00, respectively. The overall mean PF score was 45.8 (36.2, 40.7, 55.5, and 61.2 for PIRs of <1.00, 1.00-1.99, 2.00-3.99, and ≥4.00, respectively). With adjustment, higher PIRs (<1.00, 2.00-3.99, and ≥4.00, respectively, vs. 1.00-1.99) remained associated (β [95% CI]) with higher PF scores (-6.0 [-12.8 to 0.8], 10.9 [3.3 to 18.6], and 16.2 [6.4 to 26.0]). In secondary analyses, higher PIR was consistently associated with better physical functioning across domains, in that participants with higher PIRs, on average, had higher scores for measures of physical performance, were less likely to report difficulty with activities of daily living, and had fewer falls in the prior year. For example, mean Short Physical Performance Battery scores (range, 0-12) were better in those with PIR ≥2.00 compared to those with PIR <1.00 and 1.00-1.99 (10.2 vs. 8.4 and 8.2).

Conclusion: Our results show that higher SES is associated with better physical functioning across multiple domains, warranting further research into multi-component functional assessments to develop individual treatment plans and potentially improve disparities in SLE outcomes.

The Impact of Obesity on SLE Disease Activity

Phildrich Teh¹, Bishoy Zakhary², Arezoo Haghsheenas³ and Vaneet K. Sandhu³, ¹Internal Medicine, University of California, Riverside, Riverside, CA, ²Office of Research, Riverside University Health System, Moreno Valley, CA, ³Division of Rheumatology, Loma Linda University, Loma Linda, CA

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Epidemiology and Public Health Poster III: SLE, SSc, APS, PsA, and Other Rheumatic Diseases

Session Type: ACR Poster Session C

Session Time: 9:00 AM-11:00 AM

Background/Purpose: Obesity is associated with increased disease severity in multiple autoimmune conditions, likely via formation of pro-inflammatory adipokines [1]. However, the role of obesity in systemic lupus erythematosus (SLE) remains controversial. Studies have linked adiposity with a heightened risk of neurocognitive decline, renal impairment, and depressed quality of life – but not disease activity [1-2]. We aimed to reevaluate whether obesity independently associates with higher disease activity in SLE.

Methods: Adult subjects with the diagnosis of SLE according to the Systemic Lupus International Collaborating Clinics criteria were recruited from the longitudinal, multi-ethnic, Southern California Lupus Registry (SCOLR). Sociodemographic and clinical variables were retrospectively collected. Obesity was defined as BMI >30kg/m² and participants were grouped accordingly. Disease activity was ascertained by calculating the SLE Disease Activity Index (SLEDAI). SLEDAI score of <5 and >5 were defined as low and high activity, respectively. Differences in sociodemographic and clinical variables were assessed using t-test and chi-square analyses. Finally, a multivariate regression model was utilized to determine the independent association between obesity and SLEDAI.

Results: 137 patients were included: 48 Caucasian (35%), 49 Hispanic (36%), 17 Asian (12%), and 23 African-American (17%). Mean age was 42.1± 15.4 years and 51 patients (37%) met criteria for obesity. Using univariate analysis (Table 1), increased BMI was significantly associated with SLEDAI ($P = 0.023$), but also sex ($P = 0.040$) and current steroid use ($P = 0.019$). Therefore, a multivariate regression model was utilized. After adjusting for age, sex, current steroid use, disease duration, and presence of nephritis, obesity remained independently associated with lupus activity ($OR\ 1.051$, $P = 0.048$) (Table 2).

Conclusion: In contrast with prior studies, we observed an independent association between obesity and higher disease activity in SLE. This positive data, which is likely attributable to our more heterogeneous population compared to other studies, identifies obesity as a potential treatment target for improving SLE outcomes.

Session Title: Epidemiology and Public Health Poster III: SLE, SSc, APS, PsA, and Other Rheumatic Diseases

Session Type: ACR Poster Session C

Session Time: 9:00 AM-11:00 AM

Background/Purpose: Systemic Lupus Erythematosus is a systemic autoimmune disease that has diverse manifestations that can occur over a long period of time. The complexity of the disease and its varied presentation makes identification of patients with SLE difficult. A better understanding of disease presentation based on clinical aspects of disease could support earlier identification of disease, personalized treatment, improve identification of patients for clinical trials, and support research into the genetic and environmental mechanisms of SLE. EHR data presents a rich source of information,

Table 2. Comparison of ACR and SLICC criteria and rate of detection of individual criteria in EHR data as well as overall success of the algorithms in the detection of "definite lupus". (Note that patients were initially on least 4 of 5 criteria for ACR)

Data Types		ACR Criteria	Detected in EHR	SLICC Criteria	Detected in EHR
ICD9/10	Clinical Criteria	Malar Rash	101/255	Acute Cutaneous Lupus	425/435
ICD9/10		Photosensitivity	26/332	Chronic Cutaneous Lupus	141/146
ICD9/10		Discoid Rash	70/97	Oral Ulcers	46/281
ICD9/10		Oral Ulcers	46/281	Synovitis (Arthritis)	161/472
ICD9/10		Arthritis	161/472	Serositis	115/221
ICD9/10		Serositis	115/221	Renal Disorder	118/182
ICD9/10		Renal Disorder	105/166	Neurologic Disorder	59/205
ICD9/10		Neurologic Disorder	11/16	Lymphopenia	369/308
Lab		Hematological Disorders	453/454	Hemolytic Anemia	4/5
Lab				Thrombocytopenia	453/454
ICD9/10	Immunologic Criteria			Alopecia	3/96
Lab				Anti-dsDNA Antibodies	79/109
Lab		Immunological Disorders	327/377	Anti-phospholipid Antibodies	84/131
Lab				Anti-Smith Antibodies	79/109
Lab		Anti-Nuclear Antibodies	259/433	Anti-Nuclear Antibodies	259/433
Lab				Low Complement	368/500
Lab				Direct Coombs' Test	2/12
		Patients Satisfying at least 4 Criteria	308/513	Patients Satisfying at least 4 Criteria	467/513

but no detection algorithms have been developed based on “phenotypic” descriptors of SLE. We examined whether the ACR and SLICC classification criteria could be a foundation for the development of such algorithms to detect patients with SLE in EHR data.

Methods: We identified 513 patients with known SLE in a physician validated registry, the Chicago Lupus Database (CLD), whose medical records were also in the Northwestern Medicine Electronic Data Warehouse (NMEDW). We developed algorithms based on ACR and SLICC classification criteria using diagnosis codes (ICD9/ICD10) and lab results to determine whether patients met the same classification criteria in both the CLD and the NMEDW (see Table 1 for criteria). To be classified with SLE, both ACR and SLICC require patients to meet 4 or more criteria, but SLICC also requires 1 clinical and at least 1 immunologic criteria and 4 or more criteria.

Results: As shown in Table 1, of the 513 patients with physician validated SLE present in the CLD who satisfied both the ACR and SLICC classification criteria, the ACR-based EHR algorithm detected 79% (398/513) as having SLE, while the SLICC-based algorithm detected 91% (467/513).

Conclusion: Both ACR- and SLICC-based EHR algorithms detect a significant proportion of patients in the CLD that were classified as having definite SLE. The SLICC-based algorithm had a higher detection rate, likely due to the inclusion of more laboratory parameters in the criteria set and differences in the skin parameter identification, compared to ACR. Our algorithms were developed using only structured data. Both algorithms will likely be improved by using of natural language processing that can probe free-text physician notes for concepts that align with the classification criteria (such as arthritis or renal biopsy results) that were difficult to detect using only diagnosis codes and lab results.

The Effect of Socioeconomic Status on Treatment Outcomes in Lupus Nephritis: Private Versus Public Insurance

Arezoo Haghsheenas¹, Philrich Teh², Kristal Choi³, Abigail Benitez⁴, Lorena Salto³, Mathew Firek⁵, Karina Torralba⁶ and Vaneet K. Sandhu¹, ¹Division of Rheumatology, Loma Linda University, Loma Linda, CA, ²Internal Medicine, University of California, Riverside, Riverside, CA, ³Loma Linda University, Loma Linda, CA, ⁴Rheumatology, Loma Linda University, Loma Linda, CA, ⁵Riverside university health system, Moreno valley, CA, ⁶Loma Linda University Medical Center, Loma Linda, CA

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Epidemiology and Public Health Poster III: SLE, SSc, APS, PsA, and Other Rheumatic Diseases

Session Type: ACR Poster Session C

Session Time: 9:00 AM-11:00 AM

Background/Purpose: Despite therapeutic advancements, lupus nephritis (LN) remains a major cause of mortality among patients with SLE. Loma Linda University Health serves a region in Southern California represented by more individuals below the federal poverty line than the rest of California. As prior studies have demonstrated the impact of socioeconomic status (SES) on long-term outcomes in SLE in their respective counties, we studied the correlation between SES and LN prevalence in our cohort. We further investigated the association between SES, SLE disease activity, and treatment response in a subgroup of LN patients.

Figure1. Correlation between UPC ratio and health coverage

Methods: Adult subjects were recruited from the Southern California Lupus Registry (SCOLR). Sociodemographic data, urine protein to creatinine ratio (UPC), SLEDAI at baseline and 6 months, and insurance type were collected. Using insurance as a surrogate for SES, subjects were divided into 2 groups, public versus private insurance. The prevalence of lupus nephritis was then identified and differences in clinical variables and treatment response in the subgroup were assessed using t-test and chi-square analyses.

Results: 162 SLE patients were recruited. 33% were Caucasian, 36% Hispanic, 11% Asian, and 20% African-American. 42% of patients had public health coverage. After adjusting for age, sex and BMI, SES was independently associated with the prevalence of nephritis ($P = 0.038$) (Table 1).

A subgroup analysis of LN patients demonstrated baseline statistically significant higher UPC in patients with public compared to private insurance ($P = 0.053$) (Figure 1); a similar trend was noted at 6 months. Baseline and 6 month SLEDAI also demonstrated higher numbers among patients with public compared to private insurance (14.91 vs. 11.31; 13.30 vs. 10.42 respectively). No association was detected between medications and insurance type.

Conclusion: SES is associated with greater morbidity in SLE and is a key target for improving outcomes. To our knowledge, this is the first study comparing differences in treatment response to SES in SLE and LN patients in Southern California. In line with prior reports, our findings confirm the association of health insurance with long-term outcomes in SLE and LN. These findings warrant further studies to advocate for change in the healthcare industry to improve long-term outcomes in SLE.

Table 1. Multivariable Analyses Against Prevalence of Lupus Nephritis

	Odds Ratio	P-Value
Age	0.982 (0.955 - 1.009)	0.195
Female	0.993 (0.205 - 4.803)	0.993
BMI	0.968 (0.920 - 1.017)	0.197
Public Health Coverage	2.368 (1.052 - 5.330)	0.038*

Biosimilar Infliximab Treated-Patients with Rheumatoid Arthritis, Psoriatic Arthritis, and Ankylosing Spondylitis in France: Characteristics and Clinical Outcomes

Hubert Marotte¹, Nadir Mammar² and Bruno Fautrel³, ¹University Hospital of Saint Etienne, Saint Etienne, France, ²Pfizer, PARIS, France, ³Institut Pierre Louis d'Epidémiologie et de Santé Publique (iPLESP), UMR S 1136, Sorbonne Université, GRC-UPMC 08, Paris, France

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Epidemiology and Public Health Poster III: SLE, SSC, APS, PsA, and Other Rheumatic Diseases

Session Type: ACR Poster Session C

Session Time: 9:00 AM-11:00 AM

Background/Purpose: CT-P13 was the first monoclonal antibody biosimilar to infliximab (IFX) approved in France. Reflect trial has been set up to evaluate in real life the use of CT-P13 after the introduction of the product in French university hospitals.

Methods: REFLECT is a multicenter, prospective, and observational study. Its objectives are to describe in real-life the patient's (pts) characteristics treated with CT-P13 and the treatment effectiveness. Inclusion criteria were pts (≥ 6 years) with rheumatoid arthritis (RA), axial spondyloarthritis (axSpA), psoriatic arthritis (PsA), or inflammatory bowel disease treated with CT-P13. IFX naive pts (IFXn) or pts having switched from IFX originator to CT-P13 (IFXs) were enrolled. Preliminary results in pts suffering from rheumatic diseases using descriptive statistical analyses from inclusion were reported here.

Results: On December 28th 2017, 627 pts were included by 35 centres and 339 pts with rheumatic diseases were analyzed: 83 were suffering from RA (22.9% males; mean age: 61.7 ± 10.2 ; median time since diagnosis: 13.4 years), 213 axSpA (59.6%; 48.0 ± 13.3 years; 11.5 years respectively), and 43 PsA (37.2%; 53.4 ± 15.1 years; 8.6 years). The majority of pts have been already treated by CT-P13 before inclusion (64.9%, 69.9%, and 77.1% of RA, axSpA, and PsA pts,

respectively); in these pts, the median treatment duration since the first administration of CT-P13 was 8.5 months for RA, 12.9 months for axSpA and 7.9 months for PsA pts. Previous treatments with other bDMARDs other than IFX were observed in 39.2% of RA, 29.9% of AS and 40.0% of PsA pts. Almost half of pts (41.9% of RA, 49.7% of axSpA, and 42.9% of PsA) switched from the originator IFX to CT-P13. At the baseline, the rate of pts in remission was 19 (26.8%), 27 (23.7%), and 14 (45.2%) of RA, axSpA, and PsA pts respectively.

At the first infusion of CT-P13, the median DAS28 score were 4.9 and 2.5 for RA pts in IFXn and INFs pts, and 3.5 and 2.2 for PsA pts respectively. In axSpA pts, the median BASDAI were 5.5 and 2.1 and the median BASFI was 5.1 and 2.8 in IFXn and IFXs pts, respectively. At 6 month follow-up, 48.5% RA pts, 37.7% axSpA pts, were in remission. The median of disease activity scores decreased from the first administration of CT-P13 to 6 month follow-up in IFXn pts and still stable in IFXs pts for RA and axSpA. The analysis of pts suffering from PsA has not been reported due to the small number of patient who had the follow-up at 6 month (6 IFXn pts and 4 IFXs pts).

The safety data are summarized in Table 1.

Conclusion: Preliminary results from this prospective cohort suggest that the treatment with CT-P13 is safe and efficient in both naïve and switched patients. The safety data did not show any new safety concerns.

Table 1: Safety data

	RA N= 83	AxSpA N=213	PsA N=43
Pts with at least one adverse event (AE)	16 (19.3%)	31 (14.6%)	6 (14%)
Pts with at least one serious AE	4 (4.8%)	5 (2.3%)	-
Pts with at least one allergic infusion reaction†	-	3 (1.4%)	-
Pts with at least one infection‡	-	-	1 (2.3%)

† Including acute and delayed hypersensitivity reactions

‡ Including severe infections, tuberculosis, opportunistic infections, hepatitis.

Diagnosis of Systemic Sclerosis in the United Kingdom: An Observational Study Using the Clinical Practice Research Datalink

Alicia Gayle¹, Nils Schoof², Margarida Alves², Deborah Clarke³, Chris Poole¹, Christina Raabe², Prithwiraj Das¹ and Toby Maher⁴, ¹Boehringer Ingelheim Ltd., Bracknell, United Kingdom, ²Boehringer Ingelheim International GmbH, Ingelheim, Germany, ³Department of Medical Affairs, Boehringer Ingelheim Ltd., Bracknell, United Kingdom, ⁴University College London and Royal Brompton Hospital, London, United Kingdom

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Epidemiology and Public Health Poster III: SLE, SSc, APS, PsA, and Other Rheumatic Diseases

Session Type: ACR Poster Session C

Session Time: 9:00 AM-11:00 AM

Background/Purpose: Systemic Sclerosis (SSc) is an autoimmune disease that is characterised by fibroblast dysfunction and excess extracellular matrix deposition that leads to skin thickening and internal organ damage. Patients with SSc often develop interstitial lung disease (ILD) which is currently the leading cause of death. The burden of SSc in the UK is currently unknown. However, it is reported that a high proportion of patients present with advanced disease at diagnosis. The reasons for late diagnosis in SSc are not fully understood, although different routes to diagnosis have been associated with differences in survival. This study aimed to investigate patient characteristics related to first SSc diagnosis in hospital, compared to primary care.

Methods: We carried out a population-based cross-sectional study using data from the Clinical Practice Research Datalink (CPRD) linked to Hospital Episode Statistics (HES). All adult patients with a diagnosis of SSc were identified using International Classification of Diseases-10-Clinical Modification diagnosis codes in hospital records and READ codes in primary care electronic records combined with an adapted version of the EULAR algorithm for defining SSc. Patients were classified into 3 groups: incident SSc, SSc with incident ILD (SSc-ILD), and SSc with other organ involvement (SSc-OOI). Source of diagnosis and patient characteristics were then described.

Results: The study included 606 individuals with incident diagnosis of SSc recorded in either CPRD or HES. Only 1% of patients had a diagnosis code in both primary care and secondary care records. 81% of the cohort were women and the

average age at diagnosis was 61 (SD = 15). 20% of the cohort had SSc-ILD and 63% had SSc-OOI with an overlap of 15%. Patients first diagnosed with SSc in hospital presented higher rates of hospital visits and had a greater proportion of “red-flag” symptoms predictive of SSc (e.g. Raynaud’s or gastrointestinal reflux) prior to SSc diagnosis. Patients with an overlap of SSc-ILD and SSc-OOI tended to be overweight or obese.

Conclusion: Our results provide evidence of differences between patients diagnosed with SSc through UK primary care or secondary/tertiary care routes. These findings should inform the development of initiatives to improve earlier diagnosis of SSc.

Smoking Status Predicts Earlier SLICC Damage Index Progression in a Large SLE Cohort

Trevor McKown¹, Rachna Unnithan¹, Nnenna Ezeh¹, Ting Ye² and Christie M. Bartels¹, ¹Rheumatology/Medicine, University of Wisconsin - Madison, Madison, WI, ²Biostatistics and Medical Informatics, University of Wisconsin - Madison, Madison, WI

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Epidemiology and Public Health Poster III: SLE, SSc, APS, PsA, and Other Rheumatic Diseases

Session Type: ACR Poster Session C

Session Time: 9:00 AM-11:00 AM

Background/Purpose: Tobacco smoking predisposes to certain specific manifestations of systemic lupus erythematosus (SLE); however, less is known about smoking and cumulative organ damage in SLE. Our study aimed to examine the relationship of smoking history and pack-year exposure on rates of end-organ damage in a cohort of SLE patients.

Methods: Observational study in a cohort of 631 consecutive SLE patients at a single academic institution. Patients with at least one ambulatory rheumatology encounter and an ICD-9 or -10 code for SLE between 2008 and 2016 were identified. Electronic health records (EHR) were manually abstracted and patients meeting either ACR1987 or SLICC 2012 classification criteria for SLE were included in analysis. The primary outcomes examined were median time to SLICC damage index (SLICC-DI) increase or death during the study period. The primary explanatory variable was ever-smoking, defined as current or former smoking as ascertained from the EHR. Covariates examined included age at diagnosis, sex, race, ethnicity, area deprivation index (a marker of neighborhood poverty), number of SLE criteria, and SLICC-DI at time of study entry. Kaplan-Meier survival analysis was used to compare time to DI increase between ever-smokers and never-smokers. Multivariate analysis was performed using a Cox proportional hazards model.

Results: Compared to never-smokers, ever-smokers in the cohort were older at SLE diagnosis and at time of entry into the study (44.7 years vs 44.5, $p < 0.01$; 55.9 years vs. 51.9, $p < 0.01$). There were no significant differences in sex (88% female in

ever-smokers vs 92% in never-smokers, $p=0.41$), race (83% white vs 82%, $p=0.25$) or Hispanic ethnicity (5% vs 3%, $p=0.92$). Among 517 patients with SLICC-DI of 0 at the start of observation, the median time to increase in SLICC-DI was 61.7 months in ever-smokers (95% CI, 50.8 - 75.1) and 97.9 months in never-smokers (95% CI, 74.6 - 121.6), as shown in Figure 1. Age at SLE diagnosis (HR 1.03 per year, 95% CI 1.02 - 1.04) and greater than 10 pack-year smoking history (HR 1.43 compared to never-smokers, 95% CI 1.02 - 2.01) were significant predictors of earlier SLICC-DI increase in an adjusted Cox model.

Conclusion: Current or past smoking predicted earlier progression of cumulative organ damage in this cohort of SLE patients, with ever-smokers first developing organ damage about 3 years earlier than never-smokers. Further work is needed to replicate findings in more diverse cohorts, and to examine the effects of tobacco cessation on damage accrual. Figure 1: Kaplan-Meier survival curve showing probability of freedom from SLICC-DI increase by smoking exposure in patients with no previously accrued damage (SLICC-DI = 0) at time of study entry.

Nationwide Estimated Prevalence of SLE: United States Population-Based Study, 2001-2011

KimNgan P. Nguyen¹, Eric Yen², Ning Li³ and Ram R. Singh², ¹David Geffen School of Medicine, UCLA, LOS ANGELES, CA, ²UCLA, Los Angeles, CA, ³Biomathematics, University of California, Los Angeles, Los Angeles, CA

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Epidemiology and Public Health Poster III: SLE, SSc, APS, PsA, and Other Rheumatic Diseases

Session Type: ACR Poster Session C

Session Time: 9:00 AM-11:00 AM

Background/Purpose: In the published literature, the prevalence rates of SLE have widely varied by as much as 12-fold over the years. This is likely due to the variability in study populations (region and race/ethnicity), case definitions (self-report, ICD codes, physician diagnosis, ACR criteria, and SLICC criteria), and case ascertainment sources (case registry, hospital, specialists, laboratory report, US renal database, death certificate, and insurance claims data). Most studies, thus far, covered relatively small population size such as a city, county or state or Medicaid database. To the best of our knowledge, there are no studies on SLE prevalence that cover the total population of the United States (US). Although, elegant reports from 5 CDC registries covering several counties in 5 states provide valuable information on SLE prevalence, there is an important unmet need to estimate the national prevalence of SLE in the US.

Methods: We used ambulatory physician visits in the US derived from the 2001-2011 National Ambulatory Medical Care Survey (NAMCS) and the National Hospital Ambulatory Medical Care Survey (NHAMCS) database to determine encounters that represent SLE, using ICD-9 code 710.0. Using the number of prior visits per patient, we estimated the number of patients with SLE from the visit encounters. STATA was then used to determine the mean proportion and 95% confidence interval.

Results: The overall prevalence rate of SLE is 122/100,000 persons in the US. The annual prevalence of SLE increased from 104.2/100,000 in 2001 to 164.3/100,000 in 2011. The period prevalence of SLE from 2001-2011 is 14-fold higher in females (224/100,000) than males (16/100,000). Non-Hispanic black persons had the highest prevalence of SLE (206/100,000), followed by Hispanics (118/100,000), and non-Hispanic white persons (87/100,000). There were substantial variations in SLE prevalence by geographic regions: persons living in the West had the highest prevalence (143/100,000), followed by South (129/100,000), Northeast (120/100,000), and Midwest (90/100,000).

Conclusion: Analysis of national survey data across the US reveals an increasing trend in the prevalence of SLE over the last decade, which may reflect an increased recognition of SLE, changes in physician's coding practices, or an actual increase in the prevalence. Lack of verification of SLE diagnosis by rheumatologists is a major limitation of this study, especially since there is discordance even among rheumatologists as to what constitutes a diagnosis of lupus. Nevertheless, our data shows regional and demographic differences in SLE prevalence in communities across the US. The female: male ratio of 14:1 in SLE prevalence is higher than in previous studies, which might be due to a lack of recognition of SLE in males by primary care physicians or lack of men visiting clinics that were surveyed by NAMCS or NHAMCS. Like in previous studies, SLE prevalence was higher in black persons than in white persons. Racial/ethnic differences in SLE prevalence may also be due to racial/ethnic differences in individuals who visit clinics that were surveyed or due to lack of entry in the race/ethnicity column by persons of certain race/ethnicity.

Clinical Significance of Anti-Ro52 Antibody in Chinese Patients with Connective Tissue Diseases: A Single-Center Experience

Si Wu, Xiaojun Tang and Xuebing Feng, Department of Rheumatology, The Affiliated Drum Tower Hospital of Nanjing University Medical School, Nanjing, China

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Epidemiology and Public Health Poster III: SLE, SSc, APS, PsA, and Other Rheumatic Diseases

Session Type: ACR Poster Session C

Session Time: 9:00 AM-11:00 AM

Background/Purpose: Autoantibody targeting Ro52 has been implied as a unique antibody with distinct clinical properties. However, its relations with anti-Ro60 antibody and various connective tissue diseases (CTDs) remain to be elucidated.

Methods: Anti-Ro52 and anti-Ro60 antibodies were determined by immunoblotting test. All those who had positive records of anti-Ro52 in Drum Tower Hospital between January 1, 2016 and September 30, 2017 were included in the analysis. Clinical data of hospitalized patients were extracted through chart review and compared with the difference between Ro52+ Ro60- group and Ro52+ Ro60+ group by using chi-square test.

Figure 1. Distribution of Ro52+ Ro60- and Ro52+ Ro60+ in various CTD patients

Results: Totally 4,782 cases were included in this study, among which 3,185 (66.6%) were diagnosis as having CTDs, 1,473 (30.8%) had other diseases and only 124 (2.6%) were healthy. In patients with CTDs, anti-Ro52 was most related to primary Sjögren's syndrome (pSS), systemic lupus erythematosus (SLE), polymyositis/dermatomyositis and rheumatoid arthritis, while in patients with non-CTDs, anti-Ro52 was often seen in those with respiratory, gastrointestinal, neuropsychiatry and urinary diseases. Compared with Ro52+ Ro60+, Ro52+ Ro60- was more frequent in non-CTD patients (42.5% vs. 12.3%, $p < 0.0001$). Distribution of Ro52+ Ro60- and Ro52+ Ro60+ in hospitalized CTD patients was showed in Figure 1. For patients with pSS, Ro52+ Ro60- was associated with a low incidence of mucocutaneous, musculoskeletal, gastrointestinal involvement but a high incidence of cardiopulmonary involvement (all $p < 0.0001$). Meanwhile, SLE patients with Ro52+ Ro60- were found to have less mucocutaneous involvement ($p < 0.001$) but more cardiopulmonary involvement ($p < 0.0001$).

Conclusion: Anti-Ro52 is lack of specific in differentiating CTDs from other diseases, especially when it appears alone. In patients with CTDs, the presence of Ro52+ Ro60- may indicate an increase in cardiopulmonary involvement and a decrease in mucocutaneous involvement.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Epidemiology and Public Health Poster III: SLE, SSc, APS, PsA, and Other Rheumatic Diseases

Session Type: ACR Poster Session C

Session Time: 9:00 AM-11:00 AM

Background/Purpose: To analyse the prevalence of autoimmune diseases (ADs) in Catalonia by using a public big data program (Public Data Analysis for Health Research and Innovation Program, PADRIS)

Methods: We used the health insurance database of the Catalan National Health Insurance (CNHI) which includes all catalan insured population in 2016 (7,483,761 inhabitants). ADs were identified according to the corresponding International Classification of Diseases, Ninth Revision, Clinical Modification (ICD-9-CM) codes. A total of 33

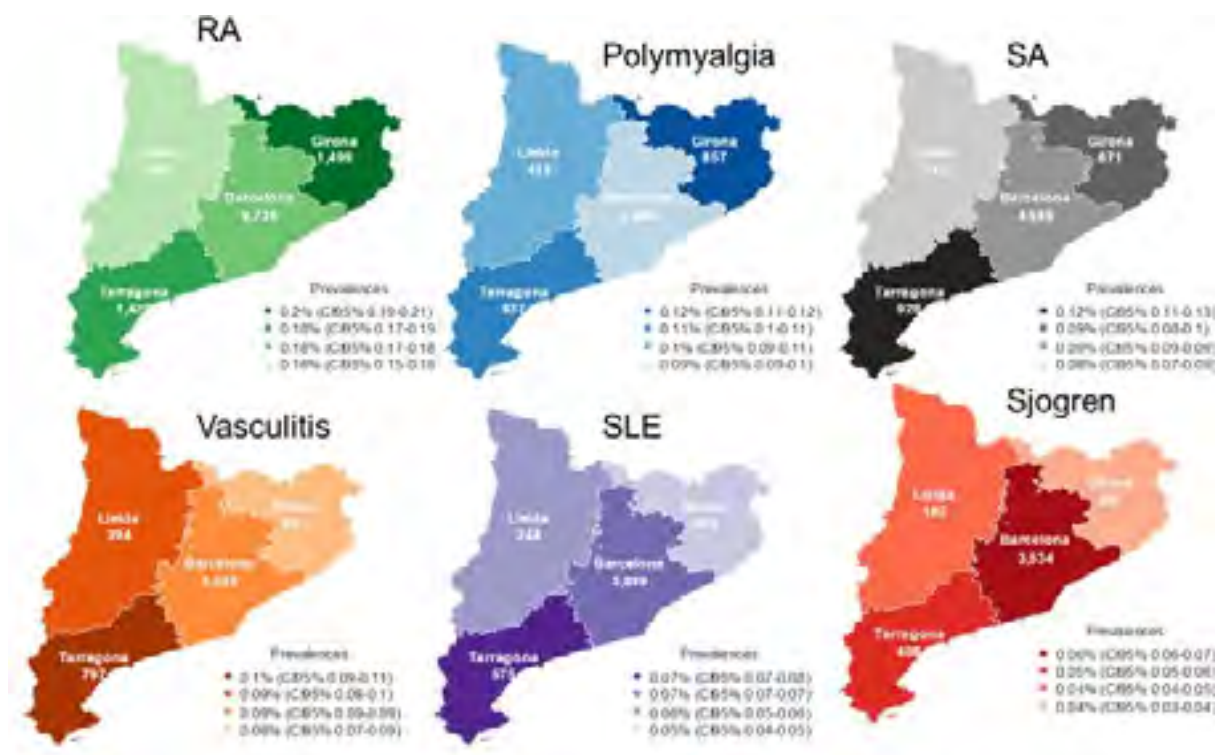

Figure1.

autoimmune diseases were analysed classified in 4 main categories: rheumatic, systemic, organ-specific and immunodeficiency/auto inflammatory. The prevalence of ADs was calculated as the number of ADs patients divided by the total CNHI beneficiaries in the same year (rate per 100,000 persons, 95% confidence intervals -CI-).

Results: In Catalonia, the overall prevalence of ADs was 1,202 per 100,000 persons (95% CI 1,194-1,209); the prevalence was 1,455 (95% CI 1,443-1,467) in women and 939 (95% CI 929-949) in men. ADs were identified as organ-specific (43%), systemic (33%), rheumatic (23%) and immunodeficiency/autoinflammatory (1%) autoimmune diseases. The Top Ten of ADs with the highest prevalence rates included cutaneous psoriasis (282 cases per 100,000), rheumatoid arthritis (178 cases per 100,000), polymyalgia rheumatic (98 cases per 100,000), spondyloarthropathies (92 cases per 100,000), vasculitis (91 cases per 100,000), systemic lupus erythematosus (68 cases per 100,000), Sjögren's syndrome (59 cases per 100,000), celiac disease (58 cases per 100,000), multiple sclerosis (57 cases per 100,000) and psoriatic arthritis (43 cases per 100,000). In 26 (79%) of the 33 ADs, the female:male ratio was higher than 1; the highest ratios were reported for Sjögren's syndrome (10.5), primary biliary cholangitis (5.8), SLE (5.4), systemic sclerosis (3.4) and rheumatoid arthritis (2.6). We found a significant geographical variation in the prevalence of the main diseases (**Figure 1**).

Conclusion: Nearly 90,000 catalans are classified as having an autoimmune disease, representing a prevalence of 1.2% of the total population in Catalonia, a rate that reaches 1.5% in women. We found a different territorial distribution of the main diseases, suggesting a significant influence of geographically-driven determinants in the prevalence of autoimmune diseases.

Effect of the Metabolic Syndrome on Incident Vascular Events and Mortality in Four Rheumatic Diseases: An 8-Year Longitudinal Analysis

Chi Chiu Mok¹, Chiu Sum Chu¹, Ling Yin Ho², Kar Li Chan¹, Sau Mei Tse¹ and Chi Hung To³, ¹Medicine, Tuen Mun Hospital, Hong Kong, Hong Kong, ²Dept of Medicine, Tuen Mun Hospital, Hong Kong SAR, Hong Kong, ³Medicine, Pok Oi Hospital, Hong Kong, Hong Kong

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Epidemiology and Public Health Poster III: SLE, SSc, APS, PsA, and Other Rheumatic Diseases

Session Type: ACR Poster Session C

Session Time: 9:00 AM-11:00 AM

Background/Purpose: To study the effect of the metabolic syndrome (MetS) on incident vascular events and mortality in 4 rheumatic diseases over an 8-years' follow-up.

Methods: Consecutive patients who fulfilled the ACR criteria for SLE, EULAR/ACR criteria for RA, ASAS criteria for SpA and CASPAR criteria for psoriatic arthritis (PSA) were recruited in a 2009/2010. At baseline, patients had the following measurements: body weight, height, waist circumference, blood pressure and fasting blood for assay of glucose and lipid (total cholesterol, HDL and LDL cholesterol, triglyceride). The MetS was defined by the updated joint consensus criteria, using the Asian criteria for central obesity, when $\geq 3/5$ components on waist circumference, blood pressure, triglyceride, HDL and glucose. Patients were followed longitudinally for new vascular events and mortality. Comparison was made between those with and without the MetS at baseline. Cox regression analysis was performed to evaluate the impact of MetS on vascular events and mortality.

Results: 1497 patients were studied (693 RA, 577 SLE, 121 SpA and 106 PSA). The age at entry was highest in RA (53.4 ± 12.0 years) and lowest in SpA patients (39.0 ± 11.9 years). The MetS was present in 137 RA (20%), 85 SLE (15%), 13 SpA (11%) and 39 PSA (37%) patients, respectively. Over 94 months' follow-up, new cardiovascular (acute coronary syndrome or angina) and cerebrovascular (ischemic stroke or transient ischemic attack) events developed in 51 and 29 patients, respectively. The incidence of vascular events (per 100 patient-years) was highest in RA patients (0.84), followed by PSA (0.71), SLE (0.67) and SpA (0.62). There were 99 deaths (12 vascular deaths). The mortality rate (per 100 patient-years) was highest in RA patients (1.04), followed by SLE (0.93), PSA (0.24) and SpA (0.21). Patients with MetS had significantly higher rates of vascular events (9.5% vs 4.8%; $p=0.003$), all-cause mortality (11.4% vs 5.6%; $p<0.001$) and vascular mortality (2.2% vs 0.5%; $p=0.004$) than those without. Cox regression showed that MetS was independently associated with new cardiovascular events (HR 1.98[1.08-3.63]; $p=0.03$) or any vascular events (HR 1.64[1.01-2.66]; $p=0.04$), after adjustment for age, sex, duration of underlying disease, ever smoking, LDL and underlying disease (SLE vs

non-SLE). A diagnosis of SLE was independently associated with new cerebrovascular events in a separate Cox regression model (HR 4.66[1.80-12.1]; $p=0.002$). The MetS, however, was not significantly associated with new cerebrovascular events (HR 1.74[0.76-3.97]; $p=0.19$), all-cause mortality (HR 1.33[0.85-2.07]; $p=0.21$) or vascular mortality (HR 2.91[0.89-9.51; $p=0.08$) after adjustment for the same covariates. Factors independently associated with all-cause mortality were age (HR 1.12[1.10-1.14] per year; $p<0.001$), ever smoking (HR 3.26[1.82-5.84]; $p<0.001$) and SLE (HR 3.18[1.88-5.37]; $p<0.001$).

Conclusion: MetS is common in patients with rheumatic diseases. The presence of the MetS increases the risk of new cardiovascular events in these patients over 8 years, which is independent of the underlying rheumatic disease and other risk factors. The MetS is not independently associated with mortality in these four rheumatic diseases.

Hemophagocytic Syndrome in Adults and Association with Rheumatologic Diagnoses: US National Inpatient Trend over Nine Years

Prakash Paudel¹, Rashmi Dhital² and Dilli Poudel³, ¹Internal Medicine, Berkshire Medical Center, Pittsfield, MA, ²Reading Hospital-Tower Health System, West Reading, PA, ³Internal Medicine, Reading Hospital-Tower Health System, WEST READING, PA

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Epidemiology and Public Health Poster III: SLE, SSc, APS, PsA, and Other Rheumatic Diseases

Session Type: ACR Poster Session C

Session Time: 9:00 AM-11:00 AM

Background/Purpose: Hemophagocytic syndrome (HPS) is a rare fatal condition of excessive immune activation. Association of hemophagocytosis with certain rheumatologic diseases is called macrophage activation syndrome (MAS). We studied the trend of hemophagocytic syndrome and association of rheumatologic conditions over nine years in a large US inpatient database called the Nationwide Inpatient Sample (NIS).

Methods: NIS(2006 – 2014) was used to identify adult hospitalizations ≥ 18 year of age with a listed discharge diagnoses of hemophagocytic syndrome based on ICD-9 diagnosis code 288.4. The code includes multiple white blood cell disorders, including the MAS. Age-and-sex-standardized rates (per 1 million hospitalizations), mortality, mean cost and length of stay (LOS) were calculated for the respective years. Joinpoint regression analysis was used to analyze the yearly trends.

Results: A total of 5679 discharges with the diagnoses of hemophagocytic syndrome were identified among 288.15 million (288,156,693) discharges over nine years (2006-2014).

Hemophagocytic syndrome was more commonly seen in males (57%) vs females (43%) and younger (mean age 45.5 vs 57.1 years). Higher predominance was noted in urban, large and teaching hospital settings. More patients HPS were admitted on emergent basis rather than elective. The trend of hospital discharges for hemophagocytic syndrome was significantly increasing over the years (1.43 per million in 2006 to 44.7 per million in 2014), likely due to increased identification of the entity. Association with rheumatologic conditions as primary diagnoses category was recorded in 3.75% of the total cases of hemophagocytic syndrome. The cost of hospitalization with HPS was \$51,979 vs \$12,340 in those without HPS. Mean LOS remained significantly higher (14.8 days vs 5 days). The mortality and mean cost and LOS with HPS was significantly higher than those without HPS throughout all years (Table 1).

Conclusion: The increasing trend of prevalence and more so in the urban settings may be associated with increasing identification of the condition in inpatient setting. Increased awareness of this rare and fatal condition may help in early identification with an opportunity to better treat with available resources as well as to conduct further studies. The association with specific rheumatologic conditions needs further studies.

Year	2006	2007	2008	2009	2010	2011	2012	2013	2014
Number of cases per million	1.43	4.47	8.56	11.9	11.7	30.1	34.5	33.1	44.7
Mortality percent	10	29.5	28.3	26.5	20.3	27.3	21.9	21.4	22.2
Length of stay (days)	19.1	13.9	18.1	18.3	11	16.5	11.5	14.8	14.9

Session Date: Tuesday, October 23, 2018

Session Title: Epidemiology and Public Health Poster III: SLE, SSs, APS, PsA, and Other Rheumatic Diseases

Session Type: ACR Poster Session C

Session Time: 9:00 AM-11:00 AM

Background/Purpose: Individuals with systemic autoimmune rheumatic diseases (SARDs), including systemic lupus erythematosus (SLE), systemic sclerosis/scleroderma (SSc), Sjogren's syndrome (SjS), dermatomyositis/polymyositis (DM/PM), and systemic vasculitides (SV), experience both physical and psychiatric complications from their disease. Given the high burden of depression and anxiety observed in SLE, the objective of this study was to review the prevalence, incidence, and determinants of depression and anxiety in individuals diagnosed with less common SARDs.

Methods: We conducted a systemic review in MEDLINE, EMBASE, CINAHL, Cochrane Database of Systematic Reviews, and PsycINFO from database inception to March 2018 using terms for all SARDs (SLE, SSs, SjS, DM/PM, SV) combined with terms for "depression" and "anxiety". Inclusion criteria were: 1) observational study design; 2) patients diagnosed with a less common SARD (SSs, SjS, DM/PM, SV); 3) depression and/or anxiety as comorbid outcome; and 4) report relevant estimates (e.g., prevalence proportion, determinants) or sufficient data to allow calculation. Prevalence estimates were pooled using random effects models. Extraction of data on the determinants of depression and anxiety was restricted to studies using multivariate analyses.

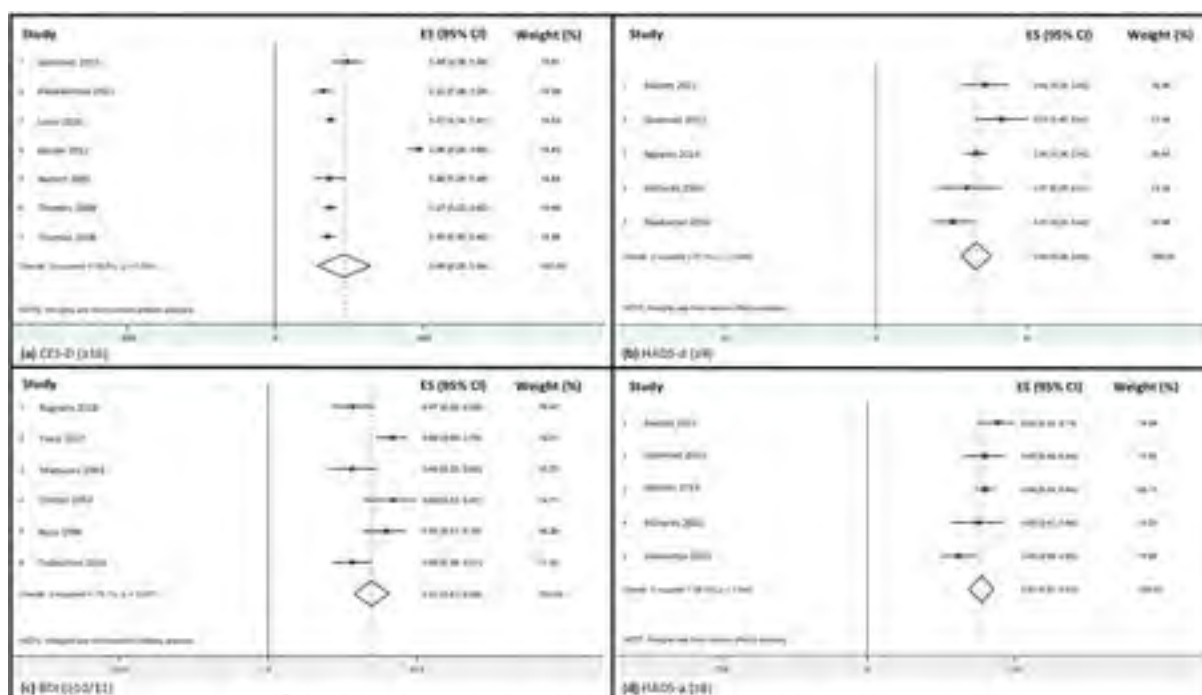

Figure 1. Pooled prevalence estimates (ES) of depression (a-c) and anxiety (d) in systemic sclerosis.

Abb: CI = confidence interval; CES-D = Center for Epidemiologic Studies - Depression scale; HADS-d = Hospital Anxiety and Depression Scale - Depression; BDI = Beck Depression Inventory; HADS-a = Hospital Anxiety and Depression Scale - Anxiety.

Results: Of the 3,059 resultant citations, 65 full-text articles were screened and 42 were included in the final review. Thirty-nine articles reported on the prevalence of depression and estimates ranged from 3-96% in SSc, 7.6-60.9% in SjS, 14.7-26.8% in DM/PM, and 3-64% in SV. The prevalence of anxiety was reported in 17 articles, with estimates ranging from 3-80% in SSc, 4-12.5% in SjS, 39% in DM and 70% in SV. Data available to estimate the pooled prevalence of depression and anxiety according to psychiatric instrument was only available for SSc (Figure 1). The pooled prevalence for depression ranged from 0.40 (95% confidence interval [CI]: 0.34, 0.46) based on the Hospital Anxiety and Depression Scale (HADS) to 0.57 (95% CI: 0.47, 0.66) based on the Beck Depression Inventory and was 0.57 (95% CI: 0.51, 0.63) for anxiety based on the HADS. Two articles evaluated incidence of depression, reporting a 10-year cumulative incidence of 11.1 per 100 in giant cell arteritis ($p < 0.0001$; adjusted hazard ratio [aHR]: 1.37, 95% CI: 1.26, 1.49) and 8.39 per 100 ($p = 0.51$) in granulomatosis with polyangiitis. Significant determinants of depression included disability, pain, tender joints, gastrointestinal symptoms and lung involvement. Determinants of anxiety included disability, pain, and lung involvement.

Conclusion: Our synthesis shows a substantial burden of depression and anxiety in less common SARDs. Findings have implications for raising awareness among health care providers on the importance of these comorbidities among patients with SARDs.

3. College of Pharmacy, Chung-Ang University, Seoul, Republic of Korea
4. Department of Information Statistics, Andong National University, Andong, Republic of Korea

Background/Purpose: Idiopathic inflammatory myopathies (IIMs) are rare rheumatic diseases, and their incidence vary greatly across studies. The aims of this study were to estimate the prevalence and incidence of IIMs in Korea from 2006 to 2016.

Methods: Using data from the Korean National Health Insurance Service (NHIS) between 2004 and 2016, patients with IIMs were identified based on the diagnostic codes including juvenile dermatomyositis (JDM) of M330, dermatomyositis (DM) of M331 or M339, polymyositis (PM) of M332 and registration code of Individual Copayment Beneficiaries Program (ICBP) for rare and intractable disease. The incident cases were captured for patients with an IIM diagnostic code & ICBP code for at least 1 physician visit with a disease-free period for 24 months before the index date.

Results: In Korea, a total of 1,150 patients with IIMs (117 JDM, 521 DM, 512 PM) were observed in 2006, and the number of IIM patients was increased to 2,281 (122 JDM, 1211 DM, 948 PM) by 2016. Considering that the total population of Korea is about 50 million, the prevalence was estimated at 2.3-4.4 (1.0-1.2 for JDM, 1.4-2.9 for DM, 1.4-2.3 for PM) /100,000PY. We identified 218 incident cases of IIM in 2006 (18 JDM, 98 DM, 102 PM) and 237 patients (9 JDM, 114 DM, 114 PM) in 2016, respectively. The incidence rate was estimated at 2.9-4.9 (0.7-1.8 for JDM, 1.8-3.1 for DM, 1.6-3.0 for PM) /1,000,000PY between 2006 and 2016 and it did not reveal any tendency of variation over 10 years. The mean

age (\pm standard deviation) of incident patients with IIM was 54.8(\pm 17.2) years and the percentage of females was 62.8%. Incidence increased with age and peaked among those aged 51-60 years of age.

Conclusion: We report the prevalence and incidence of IIMs in Korea at the nationwide population level. Although the prevalence seems to be increasing recently, the incidence did not reveal any tendency of variation over 10 years.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Epidemiology and Public Health Poster III: SLE, SSc, APS, PsA, and Other Rheumatic Diseases

Session Type: ACR Poster Session C

Session Time: 9:00 AM-11:00 AM

Background/Purpose: EULAR proposes to screen multimorbidities in chronic inflammatory rheumatic diseases. The aim of the study was to assess i) multimorbidities in patients with chronic inflammatory diseases, ii) how patients follow recommendations given after a systematic standardized multimorbidity screening.

Methods: Exams were performed during a 1-day multimorbidity clinic. Diabetes, hypertension, CVD damage, chronic respiratory diseases, osteoporosis and preventive measures were assessed. Advice, complementary exams and prescriptions were provided to patient and general practitioner after this check-up if needed. Patients were called 3 months later to assess the applications of the given recommendations.

Results: Among the 541 patients screened, hypertension was present in 28.1% patients, dyslipidemia in 19.2%, chronic respiratory tract diseases in 12.8% and diabetes in 9.6%. Screening led to the following recommendations: blood pressure monitoring (22.6% patients), dietary advice (56.8%), cardiologist referral (35.5%), intensification of physical activity (27.0%), cancer screening (50.5%), vaccinations (60.6%) and vitamino-calcium supplementation (30.3%). On the 237 patients called back, 72.3% underwent blood pressure monitoring, 58.6% followed dietary advice, 64.4% took vitamino-calcium supplementation, 55.2% had vaccinations done, 52.1% saw a cardiologist, 42.7% increased physical activity and 31.4% performed cancer screening. No specific gender, age, pathology, or psychological factors were associated with adherence to recommendations.

Conclusion: This study underlines the relevance of a systematic screening of multimorbidities in chronic inflammatory rheumatic diseases, and the good patient's adherence rate to the recommendations. Further information will be found after a follow-up visit provided for all the 1200 patients already screened.

The Trend of Utilization of Therapeutic Plasmapheresis Among Select Rheumatologic Diseases

Rashmi Dhital¹, Theresa Lynn², Priyadarshani Sharma², Sijan Basnet³, Prakash Paudel⁴, Swikrit Pyakurel⁵ and Dilli Poudel⁶, ¹Reading Hospital-Tower Health System, West Reading, PA, ²Reading Hospital, West Reading, PA, ³Internal Medicine, Reading Hospital, West Reading, PA, ⁴Internal Medicine, Berkshire Medical Center, Pittsfield, MA, ⁵Universal College of Medical Sciences, Bhairahawa, Nepal, ⁶Internal Medicine, Reading Hospital-Tower Health System, West Reading, PA

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Epidemiology and Public Health Poster III: SLE, SSs, APS, PsA, and Other Rheumatic Diseases

Session Type: ACR Poster Session C

Session Time: 9:00 AM-11:00 AM

Background/Purpose: Therapeutic plasma exchange (TPE) or plasmapheresis is a process in which plasma containing components, including autoantibodies and immune complexes, can be removed from the circulation. The ability to do so makes TPE an option for the treatment of immune-mediated diseases, including many rheumatologic diseases (RDs). In RDs, TPE can help to rapidly decrease the circulating levels of antibodies, while buying time for the immunosuppressive medications to take effect. The aim of our study was to compare the utilization of plasmapheresis among patients with select RDs and to assess the yearly trends in terms of Annual Percentage Change (APC).

Methods: We used National (Nationwide) Inpatient Sample database from the years 2000-2014 to identify inpatients ≥ 18 years with the diagnosis of autoimmune RDs based on ICD-9 codes. We compared the utilization of therapeutic plasmapheresis in RDs with that in Good pasture's syndrome (a rare autoimmune and a prototypical renal disease in which plasmapheresis remains the treatment of choice). Anti-phospholipid syndrome was not used in the analysis due to unavailability of discrete ICD-9 code for the condition. Joinpoint regression analysis software was used to calculate the APC and to determine if the annual change in trend was statistically significant or not.

Results: Among hospitalized adults, the utilization of TPE was much higher in Goodpasture's syndrome compared to any one of the studied RDs. However, a significantly increasing trend was noted among RDs, most notably the anti-neutrophil cytoplasmic antibody (ANCA)-vasculitis and other Vasculitides. The utilization of TPE in Goodpasture's syndrome was ~74,000 per million hospitalizations on 2000 compared to ~94,000 in 2014. Among various RDs, the highest utilization was noted in ANCA associated vasculitis, and the rate doubled from 8000 per million hospitalizations on 2000 to over

16,000 per million on 2014, with an annual increase of 7.27%. Significant increase in trend was also noted among hospitalizations with other Vasculitides (APC of 15.14) (**Figure 1**).

Conclusion: The steady increase in the utilization of TPE for patients with RDs, mostly the ANCA and non-ANCA associated Vasculitides may be reflective of the mounting data suggesting improved outcomes and decreased progression to end-stage renal disease when TPE is used in addition to immunosuppression. While some case reports and controlled trials have demonstrated treatment benefit from plasmapheresis in patients with SLE and IIM, others have found no improvement in clinical course. While plasmapheresis is relatively safe (mortality rate of ~0.05%), the most common adverse reactions are hypocalcaemia, hypovolemia and rarely anaphylactic reaction. Further studies need to be performed to determine the safety and cost-effectiveness of plasmapheresis as a treatment option for RDs.

Abstract Number: 2166

Treatment of Venous Thrombotic Events in Behcet Disease: A Systematic Literature Review

Iustina Janta¹, Roberto González², Tania Gudu³ and Indalecio Monteagudo¹, ¹Rheumatology, Hospital General Universitario Gregorio Marañón, Madrid, Spain, ²Rheumatology, Hospital general Universitario Gregorio Marañón, Madrid, Spain, ³University of Medicine Carol Davila Bucuresti, Romania, Bucuresti, Romania

Figure 1. Flowchart showing the selection of publications that assessed treatment of venous thrombosis in Behcet disease

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Epidemiology and Public Health Poster III: SLE, SSc, APS, PsA, and Other Rheumatic Diseases

Session Type: ACR Poster Session C

Session Time: 9:00 AM-11:00 AM

Background/Purpose: Venous thrombosis (VT) is a serious and potentially life-threatening manifestation of Behcet disease (BD). However, there is little evidence of the management of the VT in BD. To review the treatment used in venous thrombotic events in BD.

Methods: A systematic review was performed according to the PICO approach. Several synonyms for the main components (i.e. Behcet, venous thrombosis, treatment) were used. The literature search was performed in Medline and Embase from databases inception to 1st November 2017. Only articles in English and Latin languages were retained. We excluded abstracts, reviews or letters. From the selected studies, data about the VT, treatment and treatment response were retired using a predefined data collection form.

Results: The literature search resulted in 1552 articles (figure 1). The main reason for article exclusion after full-text review was the lack of description of VT and its treatment. Finally, 26 articles were included in the analysis with a total of 1899 patients. Mean age (standard deviation, SD) was 32.8 (5.6) years and most of them were men (77.7%). The mean (SD) duration time between disease onset and VT onset was evaluated in only 16 articles and was 4.67 (2.9) years. Superficial VT was evaluated in 34.6% articles, involving a number of 29 patients, deep VT in 76.9% articles and 291 patients, cerebral VT in 40.7% articles and 140 patients, inferior or superior cava vein VT in 73.1% articles and 270 patients and Budd-Chiari syndrome in 53.8% articles and 73 patients.

Details of the reported treatments are depicted in table 1. Due to the lack of detailed treatment description, no relationship between the type of treatment and the type of VT could be established. Treatment response was evaluated

Table 1. Treatment for venous thrombosis in Behcet disease as reported in the articles included in the systematic review

Treatment	Number of articles reporting the use of treatment	Number of patients receiving the treatment
	N (%)	N *
Anticoagulant	20 (76.9)	481
Antiplatelet	8 (30.8)	36
Fibrinolytic	4 (15.4)	13
Corticosteroids	20 (76.9)	430
Immunosuppressive/immunomodulatory	23 (88.5)	412
Cyclophosphamide	16 (61.5)	264
Azathioprine	17 (65.4)	732
Cyclosporine A	6 (23.1)	28
Mycophenolate mofetil	1 (3.8)	NR
Interferon alpha	4 (15.4)	5
Methotrexate	5 (19.2)	15
Anti-TNF alpha	4 (15.4)	6
Hydroxychloroquine	1 (3.8)	7
Dapsone	1 (3.8)	1
Thalidomide	2 (7.7)	25
Colchicine	11 (42.3)	114
Surgery	9 (34.6)	9

*Number of patients were reported only as frequencies to avoid the underestimation of percentages (some of the studies only mentioned the treatment, without reporting the number of patients that were prescribed the treatment)

NR: not reported

in 23 (88.5%) articles. A good treatment response, i.e., the thromb resolution was reported in 11 articles, corresponding to 161 patients. Death due to VT was reported in 10 articles (38.5%) and 24 patients. Complications and lack of treatment response were also reported: recurrences, extension or progression of the thromb (11 articles, 450 patients), aneurisms (6 articles, 28 patients), new thrombs (3 articles, 20 patients), post thrombotic complications (3 articles, 38 patients). However, data regarding treatment response were inconstantly reported and the outcomes used for assessing it were very heterogeneous. Therefore, correlations and predictive factors of complications or mortality could not be identified.

Conclusion:

Abstract Number: 2167

Incidence and Baseline Characteristics of Exacerbation in Patients with Interstitial Pneumonia with Autoimmune Features: A Single Center Large-Scale Cross-Sectional Cohort Study

Okinori Murata, Nobuhito Sasaki and Makoto Maemondo, Division of Pulmonary medicine, Allergy, and Rheumatology, Department of Internal Medicine, Iwate Medical University School of Medicine, Morioka, Japan

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Epidemiology and Public Health Poster III: SLE, SSc, APS, PsA, and Other Rheumatic Diseases

Session Type: ACR Poster Session C

Session Time: 9:00 AM-11:00 AM

Background/Purpose: Patients with idiopathic interstitial pneumonia (IIP) may have features of connective tissue diseases (CTDs). The term interstitial pneumonia with autoimmune features (IPAF) has been recently proposed for such patients. A few studies have been reported in prevalence of IPAF which was varied from 7.3% to 34.1% [1, 2]. Factors reported to indicate a poor prognosis in IPAF include age, smoking history, organizing pneumonia pattern in HRCT, anti-RNP antibody positivity, decline in %DLCO and presence of a multi-compartment feature within the morphological domain [2, 3]. To date, however, no study has comprehensively described prevalence of IPAF and factors of exacerbation. The aim of study was to identify of prevalence of IPAF in patients with interstitial lung disease and prognostic factors for exacerbation in patients with IPAF.

Methods: Six hundred and seventy-two patients who visited our department between April 2009 and March 2018 and were evaluated by chest HRCT scan. Then, they were clinically and radiologically diagnosed as having interstitial lung disease (ILD), IIP or connective tissue diseases associated ILD were enrolled. We applied IPAF criteria to these patients. Then, we purified 68 patients. The prognostic factors for exacerbation were prospectively calculated and statistically analyzed using clinical, laboratory and imaging data collected from medical records.

Results: Prevalence of IPAF was 10.1%. Of 68 patients with IPAF, 60% were women and mean age at diagnosis was 64.2 ± 13.8 years old. Mean observation period was 27.1 ± 29.6 months. Exacerbation rate was 25% (n=17). Overall death rate was 5.9% (n=4) and respiratory death rate was 2.9% (n=2). Comparison of characteristics at diagnosis between the exacerbation group and non-exacerbation group showed that the exacerbation group had a significantly elevated rate of smoking, KL-6, and SP-D (P=0.012, 0.0064, and 0.029, respectively).

Conclusion: Our large-scale cross-sectional cohort study identified unique prognostic factors of exacerbation.

Seasonal Variation in Incidence of Polymyalgia Rheumatica: A Population-Based

Shafay Raheel¹, Cynthia S. Crowson² and Eric L. Matteson³, ¹St. Joseph's Hospital, Chicago, IL, ²Health Sciences Research, Mayo Clinic College of Medicine and Science, Rochester, MN, ³Division of Rheumatology, Mayo Clinic College of Medicine and Science, Rochester, MN

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Epidemiology and Public Health Poster III: SLE, SSc, APS, PsA, and Other Rheumatic Diseases

Session Type: ACR Poster Session C

Session Time: 9:00 AM-11:00 AM

Background/Purpose: To determine whether there is a seasonal peak onset of polymyalgia rheumatica (PMR). We examined the seasonal variability of PMR in a geographically-defined population.

Methods: In a geographically defined population, we retrospectively identified all incident cases of PMR between January 1, 1970, and December 31, 2014. Detailed review of all individual medical records was performed. All patients fulfilled EULAR/ACR classification criteria for PMR. Incidence rates were age and sex adjusted to the US white 2010 population. Seasonal variation was compared using quasi-Poisson regression models to account for overdispersion.

Results: The cohort included 786 cases of incident PMR (65% female; mean age 73.3 years). Overall, patients in this cohort were more likely to have incident PMR in the spring season with age- and sex-adjusted incidence rates (per 100,000 population) of 17.2 for spring compared with 13.8 for winter, 15.5 for summer and 15.2 for autumn, but this difference did not reach statistical significance ($p=0.21$). However, subgroup analysis by decade revealed that incidence of PMR was significantly higher ($p=0.013$) in the spring season during 2000-2014 with an age-adjusted and sex-adjusted incidence rate per 100,000 of 21.1 compared with winter (13.6), summer (18.3) and autumn (15.3) [Figure]. Figure. PMR incidence rates by season and decade (1970-79 open circles, 1980-89 squares, 1990-99 filled circles, 2000-14 triangles) among Olmsted County, Minnesota residents in 1970-2014

Conclusion: Incident PMR is more common in the spring season. This pattern is more pronounced in recent years. Further study is needed to understand the potential etiological and clinical significance of this finding.

Temporal Trends in Mortality in Patients Hospitalized for Cerebrovascular Events with Psoriatic Arthritis: Data from the Healthcare Cost and Utilization Project from 2010-2014

Shraddha Jatwani¹, Karan Chugh², Karan Jatwani³, Stuthi Perimbeti⁴, Vivek Modi⁵, Jasleen Kaur⁶ and Rakesh K. Sharma⁷, ¹Department of Internal Medicine, Division of Rheumatology, Henry Ford Allegiance Health, Jackson, MI, ²Division of Pulmonary, Critical Care & Sleep, Wayne State University/Detroit Medical Center, Detroit, MI, ³Department of Internal Medicine, Mount Sinai West - St Luke's Hospital, New York, NY, ⁴Department of Internal Medicine, Mount Sinai West - St Luke's Hospital, NEW YORK, NY, ⁵Department of Internal Medicine, Mount Sinai West - St Luke's Hospital, New York, NY, ⁶Department of Internal Medicine, Wayne State University/Detroit Medical Center, Detroit, MI, ⁷Department of Medicine, Postgraduate Institute of Medical Education & Research, Chandigarh, India

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Epidemiology and Public Health Poster III: SLE, SSc, APS, PsA, and Other Rheumatic Diseases

Session Type: ACR Poster Session C

Session Time: 9:00 AM-11:00 AM

Background/Purpose: Cerebrovascular disease risk is increased in patients of Psoriatic arthritis (PsA), as reported in the literature. Epidemiological studies to assess average annual trends are not available in current literature. Majority of studies are from single centers. Our objectives were to describe the demographics and trends of outcomes for PsA patients admitted with cerebrovascular events in United States.

Methods: We analyzed data from the Healthcare Cost and Utilization Project's (HCUP) National Inpatient Sample (NIS). All hospitalized adult (>18 years) patients between 2010 and 2014 hospitalized for cerebrovascular event (stroke or transient ischemic attack) from NIS database were captured, and stratified into two groups based on secondary diagnosis of PsA, using ICD9 codes. Stata version 15 (College Station, TX) was used to perform the statistical analysis. We analyzed the trends in hospitalization, length of stay, total cost per admission and mortality for cerebrovascular events. Chi-Square test, linear regression and multivariate regression models were used for analysis.

Results: Between 2010 and 2014, 2,255,127 were hospitalized with cerebrovascular events including acute stroke and transient ischemic attack (TIA). 1583 patients were found to have a secondary diagnosis of PsA. Patients admitted with cerebrovascular events and underlying PSA had a mean age of 67.5 ± 0.71 years, which was significantly lower in comparison to general population where mean age was 70.86 ± 0.08 years (p value = 0.00). 50.49% patients were females in patients with PsA. There was no significant difference in rates of overall mortality between the two groups from 2010-2014 (2.99% for patients without PsA and 2.71% for patients with PsA, p value=0.769), and this trend was noted in mortality rates from each year (2010 to 2014).

Conclusion: Patients with PsA were admitted with cerebrovascular events at a younger age compared to their counterparts, suggesting higher burden of comorbidities and inflammation. Compared to previously reported data, there wasn't a significance difference in cerebrovascular mortality in patients with PsA. Decreased risk of mortality possibly reflects early recognition and treatment of PsA, with increased awareness of PsA as well as associated cardiovascular risk. Providers should continue to screen patients with PsA for risk factors associated with cardiovascular and cerebrovascular morbidity and mortality, to improve healthcare outcomes.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Epidemiology and Public Health Poster III – ARHP

Session Type: ACR Poster Session C

Session Time: 9:00 AM-11:00 AM

Background/Purpose: Physical inactivity is prevalent in Systemic Lupus Erythematosus (SLE). Assessment of physical activity (PA) is vital to manage cardiovascular risk factors in SLE. The aim of this cross-sectional correlational design was to explore the relationship between assessments of PA patterns in individuals with SLE using questionnaires covering short- and long-term periods of PA.

Methods: Individuals with SLE (n=148) according to ACR criteria (52±16 years old; BMI: 24.4±4.3 kg/m²; disease duration 22±15 years) were enrolled. The International Physical Activity Questionnaire Short-Form (IPAQ-SF) covering short-term period (last week) and questions from Physical Activity Questionnaire covering long-term period (last 6-12 months) were used. SLAM-R was used to assess disease activity and SLICC-DI to assess organ damage. Spearman rho analysis and p<0.05 was used.

Results: Median SLAM-R was 5 (IQR 6), SLICC was 1 (IQR 3) and IPAQ-SF PA category was moderate. PA on high exertion (days/week) the last 6-month was moderately correlated with IPAQ-SF vigorous activity days/week (r=0.43) and minutes/day (r=0.47) respectively as well as to IPAQ-SF moderate activity days/week (r=0.44). PA (hours/day) the last year was moderately (r=0.47) correlated with IPAQ-SF walking hours/day. Exercise last year was moderately correlated with IPAQ-SF vigorous activity days/week (r=0.46) and minutes/day (r=0.51) respectively as well as to IPAQ-SF vigorous category (r=0.51) and IPAQ-SF total score (r=0.45). Sitting hours/day last 6-month were strongly (r=-0.63) correlated with IPAQ-SF sitting hours/day.

Conclusion: The results indicate that there are moderate-to-strong relationships between short- and long-term period of PA, exercise and sitting behaviours in SLE with mild disease activity and organ damage. Health professionals in clinical practice, therefore, need different questionnaires to capture different time periods of PA patterns.

A 5-Year National Trend in Acute Myocardial Infarction among Hospitalized Patients with Psoriatic Arthritis: Data from National Inpatient Sample

Shraddha Jatwani¹, Karan Chugh², Karan Jatwani³, Vivek Modi⁴ and Jasleen Kaur⁵, ¹Department of Internal Medicine, Division of Rheumatology, Henry Ford Allegiance Health, Jackson, MI, ²Division of Pulmonary, Critical Care & Sleep, Wayne State University/Detroit Medical Center, Detroit, MI, ³Department of Internal Medicine, Mount Sinai West - St Luke's Hospital, New York, NY, ⁴Department of Internal Medicine, Mount Sinai West - St Luke's Hospital, New York, NY, ⁵Department of Internal Medicine, Wayne State University/Detroit Medical Center, Detroit, MI

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Health Services Research Poster III – ACR/ARHP

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 9:00 AM-11:00 AM

Background/Purpose: Psoriatic arthritis (PsA) is associated with an increased risk of cardiovascular morbidity and mortality. The increase in cardiovascular risk evaluated in a meta-analysis on PsA was around 43% for cardiovascular diseases, independently from traditional cardiovascular risk factors. [1] Higher disease activity has been associated with increased rates of mortality. There is limited data on comprehensive nationwide analysis of inpatient mortality in patients admitted for acute myocardial infarction (AMI) with underlying PsA. Our objectives are to describe the demographics & mortality trends for hospitalized patients with AMI with underlying PsA and understand the factors associated with mortality.

Methods: All adult (>18 years) hospitalized patients between 2010 and 2014 from a nationwide inpatient sample (NIS) database were captured. ICD-9 CM codes were used to identify patients with AMI and PsA. NIS is the largest all-payer inpatient care database in the United States with approximately 8 million hospitalizations each year. Descriptive statistics

were represented as means/medians for continuous and as frequencies and percentages for categorical variables. A survey weighted logistic regression model was used to describe inpatient mortality.

Results: From 2010 to 2014 around 2691 patients were hospitalized for AMI with underlying PsA. Mean age of these patients was 63.788 (significantly lower than those without PsA), and 37.98% were females. Most of patients with PsA and AMI were Caucasian (89.7%) and had private insurances (42.65%). There were 52 inpatient deaths in 5 years. Higher age was associated with significantly higher odds of inpatient mortality. But the odds of mortality in patients admitted with AMI with underlying PsA were found to be lower than their counterparts. (OR = .470 \pm 0.145, p value=0.01)

Conclusion: Patients admitted with AMI and underlying PsA are younger in comparison to their counterparts. This could likely reflect cumulative effect of inflammatory burden as well as cardiovascular risk factors. Decrease in odds of cardiovascular mortality associated with PsA possibly reflects increased awareness of cardiovascular risks in patients with PsA as well increase treatment options to control inflammatory burden. Reinforcing and educating involved stakeholders will continue to improve cardiovascular outcomes in patients with PsA

Session Title: Health Services Research Poster III – ACR/ARHP

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 9:00AM-11:00 AM

Background/Purpose: Most patients with RA receive oral glucocorticoids (GC) such as prednisone, despite concerns about safety. We sought to evaluate how primary care physicians (PCPs) use GC to treat RA patients co-managed by rheumatology, and whether PCP perceptions of GC side effects influences willingness to use GC for established RA patients.

Methods: In 2017, we conducted an online, cross-sectional survey of American College of Physicians members, using its Internal Medicine Insider Research Panel. PCPs without subspecialty training spending $\geq 25\%$ time in direct patient care were invited to participate. We developed a vignette featuring a hypothetical 62-year-old woman with RA co-managed by a

Figure 1: Matrix of GC side effects presented to survey participants (N = 244). Participants rated the degree to which two oral GC regimens increased the risk of the below side effects.

Short-term high-dose: 20mg prednisone daily for 2 weeks.

Mean (SD) score 0.73 (0.4)

71% of participants had mean score <1

Long-term low-dose: 5mg prednisone daily for 4 months

Mean (SD) score 0.83 (0.4)

61% of participants had mean score <1

	Not at all (0)	A little (1)	A lot (2)

Diabetes			

rheumatologist, at increased risk for several GC side effects, who presents with severe RA flare. Respondents selected management options from a prepopulated list including laboratory tests, imaging studies, and treatments (GC, NSAIDs, and DMARDs). Participants willing to initiate oral GC were asked how long they would be willing to continue treatment. Participants rated the degree to which two different oral GC regimens increased risk of 11 GC side effects (Fig. 1). Response scores for each regimen were averaged; mean score <1 indicated a PCP thought side effects were unlikely with that regimen. We used multivariable linear regression adjusted for provider and practice characteristics to estimate the association between PCP concern about GC side effects and duration of GC prescribed.

Results: 244 of 557 eligible physicians (44%) completed the survey. Mean age was 51 years (SD 10.6), 35% were female, 74% in non-academic practice, and 51% practiced in a suburban area. In the 6 months prior to the survey, 58% had encountered a patient experiencing RA flare. Most reported patients in their panels had no significant difficulties affording medications or accessing a rheumatologist.

205 respondents (84%) were willing to prescribe oral GC for the hypothetical patient in the vignette. 164 (67%) would prescribe ≥ 20 mg burst/taper of prednisone equivalent; 37 (15%) would prescribe Medrol Dosepak. 124 (51%) were willing to continue GC for ≥ 4 weeks; 53 (22%) were willing to continue for ≥ 6 weeks. Most PCPs perceived GC side effects as unlikely, regardless of regimen (Fig 1). PCP perception of GC side effects did not predict duration of GC prescribed ($p=0.2$ overall, 0.5 short-term high-dose, 0.2 long-term low-dose)

Conclusion: In this national sample, 51% of PCPs were willing to prescribe ≥ 1 month of GC to an RA patient at high risk for GC side effects, despite their perception that their patients have good access to rheumatology care and RA medications. The duration of GC they were willing to prescribe was independent of concern about GC side effects. Poor communication between PCPs and rheumatologists, combined with PCP discomfort managing DMARDs, may contribute to GC overprescribing and thus avoidable side effects

Abstract Number: 2173

Budget Impact of Etanercept Versus Adalimumab for Treatment of Rheumatoid Arthritis in Biologic-Naïve Patients in the United Kingdom

Kateryna Onishchenko¹, Miriam Tarallo², Cinzia Curiale² and Stamatia Theodora Alexopoulos¹, ¹Consulting at McCann Health, London, United Kingdom, ²Pfizer, Rome, Italy

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Health Services Research Poster III – ACR/ARHP

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 9:00 AM-11:00 AM

Background/Purpose: Etanercept and adalimumab are TNF α inhibitors, both indicated in the UK for the treatment of patients with moderate-to-severe active RA who had inadequate response to DMARDs. The objective of this study was to assess the cost impact of etanercept compared to adalimumab when considering dose escalation.

Methods: A budget impact model was developed to assess the drug cost impact of etanercept versus adalimumab, from the perspective of the UK national healthcare payer over a one-year time horizon. The modelled population represented 79,762 patients with RA who were biologic-naïve (previously failed on DMARDs) and who were treated with either etanercept or adalimumab. Clinical inputs in the model included response to treatment (ACR 20% improvement), with patients who did not respond to the initial dose experiencing dose escalation. Applying Phase III trial data, 65% of patients treated with etanercept and 53% of patients treated with adalimumab responded to their initial dose within 3 months. Based on a published systematic literature review, the model assumed a weighted mean of 14.9% of patients who did not respond to the initial dose of adalimumab and subsequently received dose escalation. Dose escalation was not considered for etanercept as it is not specified in the label. Drug costs were taken from published UK sources. Primary model outcomes were the total costs of etanercept versus adalimumab cohorts and net budget impact over one year. Medical writing assistance was provided by Vojislav Pejović, PhD, of Engage Scientific Services, and was sponsored by Pfizer.

Results: Annual drug costs in the adalimumab and etanercept UK cohorts were £768.4 million and £741.4 million, respectively. Treatment with adalimumab resulted in a £27.0 million increased spend compared to the etanercept cohort. Alternative scenarios around dose escalation were explored and were consistent with base case findings.

Conclusion: Treatment with etanercept may yield cost savings versus adalimumab in the UK for biologic-naïve patients with RA, when considering adalimumab dose escalation.

Session Date: Tuesday, October 23, 2018

Session Title: Health Services Research Poster III – ACR/ARHP

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 9:00 AM-11:00 AM

Background/Purpose: Self-reported fracture (fx) history data is frequently used in epidemiological studies of osteoporosis. Self-reported fx data may differ from fx history coded in electronic health records (EHR) due to imperfect patient recall, incomplete communication with clinicians, or lack of a universal EHR. Because both self-reported fx history and EHR data can define phenotypes for clinical research studies, it is important to understand how these 2 data sources compare. Our objective was to compare self-reported fx history using survey data with fx codes from an available EHR dataset.

Methods: Self-reported fx data was derived from the Activating Patients at Risk for Osteoporosis (APROPOS) trial, which recruited participants from the Global Longitudinal study of Osteoporosis in Women (GLOW) cohort. Prior fx data was collected using a survey deployed June - August 2015. Women were asked if they ever had a fx and for each fx type the date of the most recent one. Data on fx recorded in the EHR September 2011 - June 2015 was obtained from Kaiser Permanente Washington Health Research Institute. We excluded skull, toes and fingers fxs. We defined concordance between the EHR and self-reported data if the location of fx was reported to be the same and if the reported dates were within 1 year of each other. Kappa (κ) statistic described the concordance between the 2 sources of fx history. Descriptive statistics evaluated potential factors associated with discordance between the self-reported and EHR-coded fx history.

Results: A total of 133 fxs from 360 women (91% white, mean [SD]) age 74.5(7.5) years, 82% had some college education) were included. There were 35 fxs reported on the survey but not in the EHR and 39 fxs coded in the EHR but not in the survey. Agreement between self-reported and EHR fxs was κ 0.48. Of the discordant fxs, we were more likely to find claims for fxs in EHR referent to self-report among whites (OR=5.5, 95% CI 1.1-27.9), for major osteoporotic fxs (OR=2.8, 95% CI 1.1-7.1), and for fragility fxs that typically require hospitalization (vertebral, hip, femur, pelvis) (OR=3.8, 95% CI 1.3-10.7). Discordance between EHR codes and self-reported fxs did not vary by age, formal education, or health literacy.

Conclusion: There was only modest correlation between self-reported fx history and EHR fx codes. This discrepancy may have implications for clinical and epidemiological studies of fxs suggesting that combining both types of data may be optimal.

Change in Frequency of Arthroplasty Surgery in Rheumatoid Arthritis: A 13-Year Population Health Study

John G. Hanly¹, Lynn Lethbridge² and Chris Skedgel³, ¹Division of Rheumatology, Department of Medicine and Department of Pathology, Queen Elizabeth II Health Sciences Centre and Dalhousie University, Halifax, NS, Canada, ²Nova Scotia Health Authority, Halifax, NS, Canada, ³Dalhousie University, Halifax, NS, Canada

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Health Services Research Poster III – ACR/ARHP

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 9:00 AM-11:00 AM

Background/Purpose: Improvement in the medical management of rheumatoid arthritis (RA) over the past two decades may have reduced the need for arthroplasty surgery but the literature to date has reported inconsistent findings. The objective of our study was to compare the annual frequency of hip, knee and other arthroplasty surgery in a prevalent cohort of RA cases and matched controls over 13 years.

Methods: A retrospective cohort study was performed utilizing administrative healthcare data from approximately 1 million people with access to universal healthcare between 1997 and 2010. RA cases were identified using a previously validated RA case definition in the same dataset (1). Each case was matched by age and sex to 4 randomly selected controls. The annual frequency of arthroplasties in cases and controls was compared. In addition the frequency of coronary artery interventions (bypass grafting, angioplasty and stenting) was used as an additional control. Data included physician billings, hospital discharges and patient registry information using ICD-9 and ICD-10. Statistical analysis used least squares regression t-tests and 2-proportion z-tests.

Results: The number (prevalence) of RA cases per year increased from 3,913 (0.42%) to 4,911 (0.52%) over the study. The mean (SD) age changed from 56.7 (15.9) to 60.1 (14.9) years and the proportion of females from 70.8% to 73.9%. In both the first and last years of the study the frequency of all arthroplasty procedures was higher in cases than controls ($p < 0.001$) (Table). Over time there was a gradual and significant reduction in arthroplasty surgery in RA cases by 51.9% ($p < 0.001$). This was in contrast to controls in whom the frequency of procedures increased by 31.9% ($p = 0.002$) with the exception of hip arthroplasty. For the latter procedure, the frequency decreased by 63% in RA cases ($p < 0.001$) and 35% in controls ($p = 0.617$). In contrast to arthroplasty procedures the frequency of cardiac procedures, which was higher in RA cases in both the first ($p = 0.013$) and final ($p = 0.003$) years of observation, increased in both cases and controls over time although this did not reach statistical significance in either.

Conclusion: There was a striking reduction in arthroplasty surgery in RA cases over 13 years of observation. Lack of similar changes in controls and sustained rates of cardiac procedures over the same time suggests that this was not due to limited surgical access for RA patients. Earlier diagnosis and improved medical treatment of RA are potentially responsible.

Table: Demographics and surgical procedures in RA patients and controls

Demographics	1997		2010	
	RA cases	Controls	RA cases	Controls
Age (SD) in years	56.7 (15.9)	56.7 (15.9)	60.1 (14.9)	60.1 (14.9)
Female (%)	70.8	70.8	73.9	73.9
Surgical procedures	% population undergoing procedure in 1997		% population undergoing procedure in 2010	
	RA cases	Controls	RA cases	Controls
Total arthroplasties	4.78	0.47	2.30	0.62
Hip arthroplasty	1.43	0.20	0.53	0.13
Knee arthroplasty	1.74	0.13	0.81	0.27
Other arthroplasty	1.76	0.13	0.98	0.22
Cardiac procedures	0.36	0.16	0.57	0.29

The Association of Gout with Incident Giant Cell Arteritis in Older Adults

Jasvinder A. Singh and John Cleveland, Rheumatology, University of Alabama at Birmingham, Birmingham, AL

SESSION INFORMATION

Session Date: Tuesday, October 23, 2018

Session Title: Health Services Research Poster III – ACR/ARHP

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 9:00 AM-11:00 AM

Background/Purpose: Giant cell arteritis (GCA) is a vasculitis that affects large and medium sized arteries in people 50 years or older. Gout, the most common inflammatory arthritis in adults, is characterized by the activation of inflammasome and an increased production of pro-inflammatory cytokines, such as IL-1 beta (IL-1 β), IL-6, IL-18 and others, which also play a central role in GCA. Our objective was to assess whether gout in the elderly is associated with a risk of incident GCA.

Methods: We used the 5% Medicare claims data from 2006-2012 for this cohort study. Gout was identified by the presence of two claims for gout at least 4 weeks apart, with International Classification of Diseases, ninth revision, common modification (ICD-9-CM) code of 274.xx. Study outcome was incident GCA, identified by two claims for GCA with an ICD-9-CM code of 446.5, at least 4 weeks apart and an absence of GCA claims in the baseline 365-day period, a valid approach. We used multivariable-adjusted Cox proportional hazard models to assess the association of gout with incident GCA, adjusting for potential confounders/covariates including demographics (age, race, gender), comorbidities (Charlson-Romano comorbidity index), and medications commonly used for cardiac diseases (statins, beta-blockers, diuretics, and angiotensin converting enzyme (ACE)-inhibitors) and gout (allopurinol and febuxostat; Model1).

Results: Among 1,737,027 eligible people in the study cohort, there were 3,004 cases of incident GCA during the follow-up; 2,808 in people without gout and 196 in people with gout. People with gout and incident GCA has a mean duration of gout of 2.2 years prior to the GCA diagnosis (SD, 1.7; median, 1.8; IQR, 0.5, 3.5 years). The crude incidence rate of GCA was 28.0 per 100,000 person-years in people without gout and 63.7 per 100,000 person-years in people with gout. The GCA incidence rate of 28/100,000 in our non-gout population mirrored the incidence rate of 19 to 29/100,000 noted in 50+ year-olds in the three largest population-based studies of GCA. In the main multivariate model, gout was associated with an increased risk of incident GCA, HR was 2.05 (95% CI, 1.82, 2.54; **Table 1**). Women were 2.2-times more likely to have incident GCA compared to men, older age was associated with a higher risk and having 2 or more comorbidities was associated with a 1.7-times HR of incident GCA. Compared to white, black or other race were each associated with 0.6-0.7 times HR of incident GCA (**Table 1**).

Conclusion: Gout was independently associated with 2-fold higher risk of GCA in the older individuals after adjustment for demographics, comorbidity and medications, and the risk could be between 1.4 to 1.9-fold higher risk. Future studies need to confirm this finding and evaluate the underlying mechanism of this novel association.

Session Date: Tuesday, October 23, 2018

Session Title: Health Services Research Poster III – ACR/ARHP

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 9:00 AM-11:00 AM

Background/Purpose: The projections from existing workforce studies in rheumatology vary by a factor of five, largely due to methodological heterogeneity. The purpose of this study was threefold: 1) to summarise the available information on physician workforce modelling, 2) to develop a rheumatology workforce prediction risk-of-bias tool and 3) to apply it to existing studies in rheumatology.

Methods: A systematic literature review (SLR) was performed in key electronic databases (1946-2017) comprising an update of an SLR in rheumatology and a hierarchical SLR in other medical fields. We extracted data on type of model used, details on need, demand and supply factors considered in the model, and other relevant aspects such as regional heterogeneity or uncertainty analyses. Based on the results, key general as well as specific need/demand, and supply factors for workforce calculation in rheumatology were identified and each factor was assigned a risk of bias level (low, moderate, high). The workforce prediction risk of bias tool was developed and applied to existing workforce studies in rheumatology.

Results: In total, 14 studies in rheumatology and 10 studies in other medical fields were included. Studies used a variety of prediction models based on a heterogeneous set of need/demand and/or supply factors. Only two studies attempted empirical validation of the prediction quality of the model. Based on evidence and consensus, the newly developed risk of bias tool includes 21 factors: general factors (e.g. type of the model, stakeholder involvement), need/demand factors (e.g. scope of diseases covered by rheumatologists, morbidity, demography) and supply factors (e.g. time dedicated to clinical work, entry to profession, demographic composition of workforce). The majority of studies revealed high or moderate risk of bias for most of the factors (Table).

Conclusion: The existing evidence on workforce prediction in rheumatology is scarce, heterogeneous and at moderate or high risk of bias. The new risk of bias tool should enable future evaluation of workforce prediction studies. This review informs the EULAR points to consider for the conduction of workforce requirement studies in rheumatology.

Factor	Risk of bias	N of studies
General factors		
Type of model	High: model that was only based on demand or need or supply factors	n=4
	Medium: integrated model that considered demand, need and supply [supply (s)>demand (d)]	n=6
	Low: integrated model that considered demand, need and supply (s<d)	n=4
Need/demand factors		
Projection of population development	High: not considered or only size of population is included	n=6
	Medium: age and/or sex structure and/or other factors were included but using single data source	n=8
	Low: age and/or sex structure and/or other factors were included using more than one source and relying on statistics or national population projections	n=0
Supply factors		
Time spent on clinical (rheumatologic) care	High: not considered in calculation of supply	n=4
	Medium: % of time dedicated to clinical duties was defined without detailed estimation of number, duration, and type of visit (single or multiple data sources) or	n=10
	Low: % of time dedicated to clinical duties was calculated through estimating the number, duration and type of visits, but using single data source	
	Low: % of time dedicated to clinical duties was calculated through estimating the number, duration and type of visits, using more than one data source	n=0

Table. Example of application of the workforce prediction risk of bias tool to rheumatology workforce studies (in total, 21 factors were evaluated)

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Health Services Research Poster III – ACR/ARHP

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 9:00 AM-11:00 AM

Background/Purpose: Technological advancements and a need to improve access to care due to projected workforce shortages have led to a surge in telehealth use over the last 20 years. Clinical video telehealth application to rheumatology (i.e. telerheumatology) has received limited attention, particularly regarding provider perceptions of clinical usefulness. Our objective was to assess rheumatologists' perceptions of and experiences with telehealth and telerheumatology within the Veterans Health Administration (VA), the largest integrated health care system in the U.S.

Methods: A 38-question survey, modeled after a telehealth providers' satisfaction survey (Becevic et al, 2015), was developed through an iterative process by two VA rheumatologists with expertise in telehealth and a social scientist experienced in survey development. The survey assessed VA provider satisfaction with training and information technology support, as well as barriers to using telehealth systems. The survey additionally evaluated perceptions of clinical video telehealth impact on care and appropriate clinical contexts for telehealth visits. VA REDCap was utilized for survey design and online dissemination to 224 VA rheumatologists through the VA Rheumatology Consortium (VARC). Survey responses were analyzed via descriptive statistics.

Results: Forty-five anonymous responses (20% response rate) were collected. Nearly half of the sample identified as female (47%), 33% were between 45-54 years old, and 71% reported working at an academic center. Physicians comprised

96% all respondents. Only 16 providers reported using clinical video telehealth services (36%) and of those, 13 (29%) had practiced telerheumatology. More than half of all respondents agreed that telerheumatology is vital to increasing access to care (59%), and 40% felt it is vital to increasing quality of care in the VA. The majority of providers felt that the greatest barrier to telerheumatology is the inability to perform a physical exam (97%). Respondents indicated that telerheumatology was more helpful for ongoing management of most rheumatic conditions rather than initial evaluation that included establishing a diagnosis (see graph).

Conclusion: A majority of responding VA rheumatologists believe that telerheumatology is vital to increasing access to care in the VA; however, providers feel the suitability of telerheumatology is dependent on the phase of care. Most respondents have never provided telerheumatology care. As remote care technologies are increasingly adopted, continued attention to provider experience and readiness will need to be addressed in order to maintain high-quality, provider- and patient-centric care systems.

Poor Rates of Screening for Retinal Toxicity in Patients on Antimalarial Medications: A Population-Based Study

Ksenia Gukova¹, John M. Esdaile², Hamid Tavakoli³ and J. Antonio Avina-Zubieta^{1,2}, ¹Division of Rheumatology, Department of Medicine, University of British Columbia, Vancouver, BC, Canada, ²Arthritis Research Canada, Richmond, BC, Canada, ³Arthritis Research Canada, Vancouver, BC, Canada

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Health Services Research Poster III – ACR/ARHP

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 9:00 AM-11:00 AM

Background/Purpose: Antimalarial drugs (AM) are commonly used to treat rheumatoid arthritis (RA) and systemic lupus erythematosus (SLE). AM can be associated with retinal toxicity that may result in vision loss. Current US guidelines recommend annual eye screening for all patients with ≥ 5 years of AM exposure. Our objectives were 1) to identify the pattern of retinal screening in patients with RA and SLE under AM therapy, and 2) to evaluate the association of being seen by a rheumatologist and ophthalmologist retinal screening.

Methods: We conducted a population-based study using an administrative health database including the entire population in the province of British Columbia, Canada (over 5 million individuals). Our data included all outpatient and inpatient visits, investigations, procedure codes, demographics, vital statistics and all dispensed medications. We identified RA and SLE cases using a validated algorithm. We created 2 cohorts of AM users: 1) patients who started AM for ≥ 6 consecutive months after disease onset, and 2) a subset of cohort 1, restricted to patients with continuous AM use for ≥ 5 years, allowing gaps of < 6 months.

The unit of measurement was patient-year (PY) of AM use. The primary outcome was the number of PYs in which individuals had an ophthalmology visit with retinal screening (using billing codes for procedures), defined as either 1)

fluorescein angiography of retina, 2) fundus photography, 3) visual field examination, 4) quantitative perimetry examination, 5) anterior segment gonioscopy, or 6) spectral-domain optical coherence tomography.

For objective 2, we created 18-month windows of AM exposure to assess the odds of a retinal screening visit from a previous rheumatologist visit versus not seen by a rheumatologist. We used a generalized linear model with general estimation equation to estimate the odds ratio (OR) of the events.

Results: In cohort 1, we identified 23,868 patients (RA=20,000, SLE=3,868). Among these, 8,119 (34.0%) patients had a history of ≥ 5 years continuous use of AM (cohort 2). The average age in RA patients was 56.2 (SD=15.7) and the average age in SLE patients was 47.3 (SD=14.9). Seventy-three percent of RA patients and 80.0% of SLE patients were female. For cohort 1, we identified a total of 219,355 PYs. Despite guidelines suggesting eye screening every PY of AM use, only 29.7% (65,106) of PYs were associated with retinal screening. For cohort 2, a total of 44,676 PYs of AM exposure were identified with 43.4% (19,393) PYs associated with retinal screening.

For both cohort 1 and 2, there was a significant association between being seen by a rheumatologist and retinal screening (cohort 1: OR 1.63, 95% CI 1.57-1.69, $P<0.0001$; cohort 2: OR 1.46, 95% CI 1.37-1.56, $P<0.0001$).

Conclusion: Overall, this large population-based study demonstrates that only a small proportion of patients under AM therapy undergo for retinal screening as per current guidelines. Our study shows that visits by rheumatologists improve adherence to screening guidelines, however, a huge gap still remains even in a publically funded healthcare system.

Session Date: Tuesday, October 23, 2018

Session Title: Health Services Research Poster III – ACR/ARHP

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 9:00 AM-11:00 AM

Background/Purpose: Research using electronic health records (EHR) may offer advantages over traditional observational studies, including lower costs and greater generalizability to a broader patient population; however, EHR data may be more biased as a result of the high prevalence of missing data. Little research is available that directly evaluates the potential benefits and weaknesses of each study design within a single population. We examined differences in baseline demographics and disease outcomes between RA patients enrolled in a cohort study with more standardized data collection and patients whose data comes purely from the EHR within the same health system. We also compared the availability of measures and prevalence of missing data between the two groups and explored differences in longitudinal predictors of RA disease activity.

Methods: We included individuals with an RA diagnosis (ICD-9 code 714.0) and at least 2 rheumatology clinic visits within 12 months between 2013-2017 from the EHR of a public hospital (n=377 patients, n=2,269 visits). Approximately half were also enrolled in an RA cohort study. In order to examine if longitudinal differences in disease activity were present between cohort and non-cohort groups, mixed effects models were used to evaluate the association between sex, race/ethnicity, age, body mass index (BMI), smoking status and medication on Clinical Disease Activity Index (CDAI) score. Interaction between covariates and participant status (cohort vs. non-cohort) was also assessed.

Results: No significant baseline differences between cohort (n=187) and non-cohort (n=190) participants were found with respect to sex, age, race/ethnicity, smoking status, or disease activity measures (Table). Variables with a higher prevalence of missing data in non-cohort individuals compared to cohort individuals included language (14% vs. 0%), BMI (14% vs. 4%), smoking status (18% vs. 6%), and certain disease activity measures (21-22% vs. 3-6%). Black, non-Hispanic race/ethnicity was associated with a higher CDAI score over the study period compared to white, non-Hispanic individuals in non-cohort participants, while no association was found in cohort participants (p-interaction = 0.07).

Conclusion: Non-cohort participants from the EHR were comparable to a research cohort drawn from the same health system across some variables, but demonstrated more severe disease trajectories in racial/ethnic minorities. While challenges remain given the prevalence of missing data for specific variables in the EHR, utilizing EHR data repositories may inform our understanding of disease trajectories for RA patients who are not adequately captured in research cohorts.

Franklin⁶, ¹Physical Therapy, Arcadia Univ, Glenside, PA, ²Centre for Hip Health and Mobility, Vancouver, BC, Canada, ³Department of Orthopedics, Leiden University Medical Center, Leiden, Netherlands, ⁴Orthopedics, University of Massachusetts Medical School, Worcester, MA, ⁵Orthopedics and Rehabilitation, University of Massachusetts Medical School, Worcester, MA, ⁶Orthopedics and Physical Rehabilitation, University of Massachusetts Medical School, Worcester, MA

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Health Services Research Poster III – ACR/ARHP

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 9:00 AM-11:00 AM

Background/Purpose: Total knee replacement surgery (TKR) for osteoarthritis is a highly prevalent treatment with widely variable functional outcomes. Most patients receive physical therapy (PT) following TKR, but PT practice is variable and associations between specific content and dosage of PT interventions and functional outcomes are unknown. Randomized clinical trials demonstrate functional benefits from specific exercise regimens, but what interventions are implemented in clinical practice are unknown. Details of intervention content and dosage are not routinely available in PT clinical documentation. To carry out a pragmatic study of the effectiveness of real-world PT interventions we set out to develop a secure web-based documentation system for physical therapists (PTs) that would meet four goals: 1) capture PT intervention details including content, dosage, intensity and progression; 2) be used easily by practicing clinicians; 3) provide a treatment summary for use as a daily record; and 4) allow data analysis of intervention factors in a multi-site application for health services research. Such a system would provide consistent metrics for future registries and EHRs to assure complete and comprehensive documentation for research and quality measurement.

Methods: We used an iterative process to develop the data capture system and generate an all-inclusive menu of PT interventions used to treat patients post-TKR. The system required a secure user-friendly computer interface allowing clinical access to input data and designed to facilitate aggregation of data for analysis. The intervention menu was generated in four steps: 1) extraction of interventions from 112 patient records from each patient's final episode of post-TKR care; 2) feasibility testing of the compiled list of interventions by 7 PTs and PT interns from 4 clinics in another geographic region to identify interventions not already included in the list; 3) content review and subsequent revision by 4 national PT post-TKR rehabilitation experts; and 4) review and revision by 2 international PT post-TKR rehabilitation experts.

Results: The final intervention menu includes eight intervention categories (strengthening, flexibility and aerobic exercises, balance and functional training, modalities, manual therapy and patient education). Strengthening exercise is the largest category with 62 exercises. All interventions require input of data including intensity and dosage. The system is deployed in 16 practice sites with 59 PTs and 6 PTAs using the system. Input from a treatment session takes less than 5 minutes. PTs deny difficulty with input. Since deployment of the system two interventions have been added to the original list.

Conclusion: Our findings demonstrate the feasibility of a customized web-based data capture system to collect comprehensive intervention data including the content, intensity and dosage of PT treatments for patients post-TKR. We currently use the system in a study to identify intervention factors associated with positive patient outcomes. The system demonstrates a framework to study PT care in other diagnostic categories to identify "best practice" in PT care.

Defining Alendronate Drug Holidays and Re-Initiation in US Medicare Data

Ayesha Jaleel¹, Jeffrey R. Curtis², Rui Chen², Huifeng Yun³, Phillip J. Foster⁴, Nicole Wright³, Tarun Arora², Amy S. Mudano², Suzanne Cadarette⁵ and Kenneth Saag², ¹Internal Medicine, Baptist Brookwood Health, Birmingham, AL, ²University of Alabama at Birmingham, Birmingham, AL, ³Epidemiology, University of Alabama at Birmingham, Birmingham, AL, ⁴Department of Medicine, Division of Immunology and Rheumatology, University of Alabama at Birmingham, Birmingham, AL, ⁵Leslie Dan Faculty of Pharmacy, University of Toronto, Toronto, ON, Canada

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Health Services Research Poster III – ACR/ARHP

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 9:00 AM-11:00 AM

Background/Purpose: Given alendronate's (ALN) prolonged skeletal retention and emerging safety concerns, the ASBMR task force recommended consideration of a "drug holiday" after 5 years of use. Distinguishing a prolonged gap in intended treatment vs. an intentional drug holiday is often unclear. We sought to estimate the prevalence of potential ALN holidays using two definitions of drug discontinuation, and to evaluate the characteristics of those who restart osteoporosis (OP) therapy after an ALN treatment gap.

Methods: We included only women ALN users (n = 81,287) with a treatment gap in the 2006-2015 US Medicare data, with medical and pharmacy coverage (Medicare parts A, B, and D), and who were at least 80% adherent (MPR) with ALN for ≥ 3 years prior to the gap. We excluded patients with history of cancer, Pagets, Osteogenesis Imperfecta, or systemic hormone therapy. We evaluated the proportion of women with a treatment gap (no prescription claims) for ≥ 6 months and/or ≥ 1 year at which time follow-up began (day 184 and day 366) (index date) until restarting of any OP medication (study end). We used descriptive statistics to characterize women restarting vs. not restarting therapy after a gap of ≥ 1 year.

Results: Using the 6-month gap definition, we identified 35,239 women (43.3% of previously adherent long-term ALN users) who discontinued ALN, of which 6172 (17.5%) restarted on any OP therapy. The median time to restart was 162 days (58, 413.5; 25th and 75th percentile). Half (50%) of the women restarted therapy within a year of stopping, suggesting that a 6-month gap may not truly represent an intended drug holiday. Using a ≥ 1 year gap definition, we identified 27,436 (33.8%) women with a possible drug holiday, of which 2978 (10.9%) restarted OP therapy. The median time to restart was 259 days (92, 512; 25th and 75th percentile). Using the ≥ 1 year definition, restarters and non-restarters differed significantly (p < 0.001) by fracture history (6.9% vs 5.1%), history of previous DXA (21.6% vs. 15.0%), and ≥ 1 rheumatologist or endocrinologist visit (13.8% vs. 8.6%).

Conclusion: Given the large proportion of rapid restarters, a drug holiday gap of only 6-months may not accurately reflect a true drug holiday; a minimum of a 1-year gap appeared more appropriate for defining a likely drug holiday. Increased OP care and history of fractures were associated with OP therapy restart.

Access to Prescription Drugs in Canada: Results from an Online Survey

Nick Bansback^{1,2,3}, Cheryl L. Koehn⁴, Judy Chiu⁵, Melanie Mulder⁶ and Linda Li¹, ¹Arthritis Research Canada, Richmond, BC, Canada, ²University of British Columbia, Vancouver, BC, Canada, ³St Paul's Hospital, Centre for Health Evaluation and Outcomes Sciences, Vancouver, BC, Canada, ⁴Arthritis Consumer Experts, Vancouver, BC, Canada, ⁵Centre for Health Evaluation and Outcome Sciences, Vancouver, BC, Canada, ⁶St Paul's Hospital, Vancouver, BC, Canada

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Health Services Research Poster III – ACR/ARHP

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 9:00 AM-11:00 AM

Background/Purpose: Prescription medications are an important treatment option for patients living with arthritis. However, patients may often not have access to certain medications they hear about in the news, in part because a medication may not meet regulatory or reimbursement criteria, or may not be included in a person's private health insurance drug coverage. The purpose of this study is to understand knowledge about access to prescription medications in Canada.

Methods: A 20-minute pre- post-survey was conducted using a market research panel. The survey asked questions about prescription drug reimbursement coverage (e.g. are they covered in public drug plans and whether it differs across provinces), the regulatory approval process (e.g. what information is used by Health Canada), who pays for a drug covered by the public drug plan and how it is paid for (e.g. new money versus existing money), and the percentage of the cost that is paid by public drug plans, paid directly by the patient, or not filled by older Canadians due to affordability.

Results: A total of 705 Canadians completed the survey. Most respondents were from Ontario (51%), British Columbia (14%), Alberta (11%), and Quebec (11%). Knowledge on the process of prescription drug approval is low. Most respondents were unaware of the type of information is assessed by Health Canada in the approval process (80%) (many thought that price or cost-effectiveness were considered at this stage). Only 55% of respondents knew that certain prescription drugs paid for by the public drug plan may be covered in some parts of Canada but not others, and only 9% knew that federal recommendation and provincial agreement are required before a Health Canada approved prescription drug is covered by public drug plans (91%). Interestingly, 80% of respondents thought new money is allocated to new drugs that are approved (while current practice often requires money to be diverted from existing spending). Respondents also overestimated how much Canadians pay directly for prescription medications, and how many older Canadians did not fill a prescription because of affordability. Participants were motivated to learn more, particularly about costs and accountability in the Canadian health care system.

Conclusion: The general lack of knowledge about regulatory and reimbursement access to prescription medications limits informed dialogue with patients and the public. This includes changes to the approval process of prescription medications and how decisions are made around allocating budgets to certain prescription drugs. We have developed an educational video that seeks to improve this knowledge and engage patients and the public in these important conversations.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Health Services Research Poster III – ACR/ARHP

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 9:00 AM-11:00 AM

Background/Purpose: Diagnosis (dx) of systemic lupus erythematosus (SLE) is made via a combination of clinical and laboratory examinations; the sensitivity and specificity (S&S) of standard diagnostic tests (SDTs) (i.e. ANA and antibodies to dsDNA, Smith, Ro/SSA, La/SSB, centromere, Jo-1, Scl-70, and CCP), are reported to be 83% & 76%, respectively (Putterman et al, 2014). A multivariate assay panel (MAP) combining biomarkers, complement C4d activation products on erythrocytes & B cells, with SDTs, yields improved dx performance with a S&S of 80% & 86%, respectively (Putterman et al, 2014). We evaluated the payer budget impact of SLE dx using MAP compared to SDTs.

Methods: We modeled a health plan of 1 million enrollees, with 0.1% suspected of SLE. SLE dx among suspected SLE patients was 9.2% (Dijkstra et al, 1999). The MAP arm assumed 80% / 20% of suspected SLE patients were tested with MAP/SDTs, compared to 100% SDT testing in SDT arm. Based on improved MAP performance, the hazard ratio for the assumed dx rate compared to SDTs was 1.74, (71, 87, 90, and 91% of the suspected who develop SLE will be diagnosed in years 1 – 4 compared to 53, 75, 84, and 88% with SDTs). Increased MAP performance relative to SDTs should result in earlier dx of SLE, reduction in disease severity at dx, and a longer period of time in less severe disease states (Oglesby et al, 2014) with associated lower costs. Pre-SLE dx claims-based cost data was used to estimate recurring direct costs for

*All 2010 January data for average percent for general medical history, treatment settings, specialty drugs, other risk characteristics, demographics, and other factors based on survey data. Information from Figure 2010. Source: CDC/NCHADS 2010.

undiagnosed patients, and a weighted average of post-dx direct cost data for mild, moderate, and severe SLE were obtained from the literature (Garris, 2014) for SDTs, which was re-weighted to reflect the MAP scenario (Table 1).

Results: Total 4-year pre- and post- dx direct medical cost for suspected SLE patients tested with MAP were \$58,919,462 compared to \$61,174,818 by SDTs (Table 2). Total 4-year average cost savings per suspected SLE patient tested with MAP were \$2,256 (Table 2). Reduced inpatient hospital admissions were the biggest driver of cost savings (\$581,728 in yr 1). In a one-way sensitivity analysis, the percentage of SLE dx among those suspected of SLE and specificity of MAP had the largest impact on average annual cost savings (respective savings of \$16 and \$15 per 1% absolute increase in percentage of SLE among those suspected of SLE and MAP specificity).

Conclusion: Incorporating MAP into SLE dx results in total 4-year direct cost savings of \$2,255,356 (\$2,256 per suspected SLE patient) and year 1 savings of \$711 per suspected SLE patient. Further, by facilitating earlier dx of SLE at a less severe disease state, it is anticipated that MAP will enhance patient outcomes.

Session Date: Tuesday, October 23, 2018

Session Title: Health Services Research Poster III – ACR/ARHP

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 9:00 AM-11:00 AM

Background/Purpose: Rheumatoid arthritis (RA) affects over 1 million Medicare enrollees. Despite the size of this population, costs for RA within Medicare remain poorly understood, especially since biologic DMARDs (bDMARDs) have become an important part of care for RA. Greater insight into the detailed cost to Medicare for patients with RA would be valuable to both policy makers and health care providers, supporting planning for the allocation of limited resources.

Methods: Subjects were Medicare beneficiaries enrolled in the Brigham and Women's Hospital Rheumatoid Arthritis Sequential Study (BRASS). Patient inclusion criteria were age greater than 18 years, DAS28-CRP recorded in the BRASS registry in 2006 or later, and at least 18 consecutive months of available Medicare claims data including prescription drug utilization. Cost and utilization data for inpatient admissions, outpatient care, and physician services were acquired from the Medicare Standard Analytics Files for 2006-2010. Prescription drug utilization data was obtained from the Prescription

Figure 1. Mean Costs of RA-Specific Care

Drug Event file, reflecting Medicare Part D claims. Prescription medication costs were calculated by multiplying utilization by a standardized per unit price for each unique National Drug Code, determined using the Centers for Medicare and Medicaid Services' (CMS) National Average Drug Acquisition Cost (NADAC) Tool or from the lowest per unit price listed on the drugs.com website (if no NADAC cost was available). RA-specific costs were determined by isolating claims with an RA-related ICD-9-CM diagnosis code. RA-specific prescription costs were isolated using a comprehensive list of RA-related medications. Each calendar year in which a patient had Medicare utilization was treated as an independent observation, referred to as a patient-year. All costs were converted to 2015 dollars using the consumer price index medical care component.

Results: 197 individual patients met inclusion criteria, contributing a total of 435 patient years. Mean annual direct cost of all medical care was \$36,643 (95% CI 33,603-39,682). RA-specific care accounted for \$19,216, or 52% of total costs. Within RA-specific care, hospitalizations accounted for 6.3% of costs, outpatient care 25.6%, medications 67.3%, and post-acute care 0.9% (see Figure 1). There was no significant difference in distribution of RA-specific costs across years ($p=0.37$). RA-specific costs were dominated by costs of bDMARDs. The mean annual cost for bDMARDs across the total cohort (bDMARD users and non-users) was \$12,167 (95% CI 10,357-13,976), representing 94.6% of RA-related drug costs and 63.6% of total RA-specific costs.

Conclusion: While bDMARDs have expanded treatment options for RA patients, the cost of bDMARDs is the primary driving factor for the cost of RA-specific care.

Session Title: Health Services Research Poster III – ACR/ARHP

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 9:00 AM-11:00 AM

Background/Purpose: First Nation community consultations identified arthritis as a priority health concern and the need for culturally sensitive health services adapted to community needs. In partnership with the communities, a self-management program, the Arthritis Wellness Program (AWP) was developed to improve the health and well-being of people living with arthritis, in collaboration with family members. We report on the process evaluation of the pilot testing.

Methods: Pilot testing of the AWP was performed twice in each of two on-reserve communities (March 2016 - May 2018). Inclusion criteria: i) arthritis (OA, RA, PsA, AS, or SLE) for > 6 months, ii) age > 19, iii) English speaking, iv) residing on-reserve in one of the two communities and v) having an adult family member or close friend willing to participate. Developed based on initial focus group input with people living with arthritis and family members, health professional interviews, and community consultations, the AWP follows principles of self-management and holistic First Nations approaches to health and wellness. Six evening group sessions were attended by people living with arthritis and a family member, focused on improving understanding of arthritis and treatment options (traditional medicines, medications, nutrition, physical activity), supporting behavior change for healthy lifestyle, learning strategies to cope with the physical, emotional, mental, and spiritual impact of arthritis, improving communication, and optimizing social support.

Results: 29 people with arthritis participated in pilot sessions (21 female, mean age: 56.5 years, range: 22 - 75 years). For nine pairs, both participants had arthritis. 28% had multiple forms of arthritis, RA:55.17%, OA: 68.97%, AS: 10.34%, PsA: 3.45%, SLE: 3.45%, FM: 6.90%. 10.34% were unsure of their diagnosis. All participants had high levels of pain, fatigue, and difficulty coping with activities of daily living due to their arthritis. Attendance for the six sessions ranged from 51 - 81%, mean 67.5%. Overall feedback was positive. Mean ratings (scale of 1-5) for the six group sessions of: usefulness of the group meetings ranged from 4.25 to 4.66, satisfaction with group dynamic: 4.07 – 4.63; satisfaction with amount of information: 4.15 – 4.84. In one-on-one interviews post program, participants appreciated learning more about how to live with arthritis, highly valued the group interaction, and the ability to share with and learn from others with arthritis. Suggestions for enhanced interaction and more hands-on activities were noted. Participants in all four pilot groups wished to continue to interact as a group.

Conclusion: Pilot testing of the AWP revealed it is feasible to deliver to people living with arthritis and family members, and participants were very satisfied with the intervention. The AWP offers support and strategies to help First Nations people live well with their arthritis and encourage effective family support to their loved ones. The AWP is an example of community-based research to improve arthritis care that is culturally sensitive and meets the needs of First Nations communities. Once testing is complete, the AWP will be adopted by the communities for ongoing delivery.

Specialist Link Telephone Advice Cost Effectively Enhances Rheumatology Patient Care in Alberta, Canada

Yolanda Martens-Vanhilst¹, Dianne P. Mosher², Linda Slocombe¹ and Paul MacMullan³, ¹University of Calgary, Calgary, AB, Canada, ²Med, University of Calgary, Calgary, AB, Canada, ³Medicine, Division of Rheumatology, University of Calgary, Calgary, AB, Canada

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Health Services Research Poster III – ACR/ARHP

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 9:00 AM-11:00 AM

Background/Purpose: The Calgary zone of Alberta Health Services serves a population of almost 2 million Canadians over a wide geographical area and is underserved in terms of rheumatology specialists. Furthermore, the quality of referral information is variable, and wait times are prolonged, especially for routine appointments. Thus, there is a high rate of inappropriate use of acute services for patients with rheumatic conditions.

The Division of Rheumatology at the University of Calgary chose to partner with the Primary Care Network Specialist Link telephone advice service (operating 8 am to 5 pm Monday to Friday) to provide real time telephone non-urgent advice to improve efficiency and enhance the co-ordination of patient care delivery.

Methods: The rheumatologists were asked to complete a survey after each phone consult in the initial launch period for the first year. Similarly, Primary Care doctors who had used the service were invited for their feedback. Direct costs, and direct savings were calculated based on the fee for service billing schedule, and a conservative cost effective analysis was performed based on the avoidance of relevant and known direct variable costs only.

Results: Data from a period of 13 months were collected. A total of 209 out of a potential 615 (34%) surveys were received from n=12 rheumatologists. Feedback forms from n=49 individual family physicians were also analysed. 68% of the phone calls avoided an emergency room visit and 46% avoided a consult altogether. Further diagnostic imaging and laboratory testing was avoided after 16% and 15% of calls, respectively. Both specialist and family physicians expressed a satisfaction rating of greater than 90% with mutual collegial support (89%), education (87%) and enhanced patient care (77%) identified as subjective benefits on qualitative analysis, while 29% of calls resulted in management being initiated in the primary care setting before seeing the rheumatologist. Opportunity cost analyses revealed an average net savings of CAN\$133 per phone call.

Conclusion: Empowering primary care doctors to provide care for non-urgent rheumatology patients with the specialist support of real time telephone advice is both efficient and cost effective. Furthermore, improved doctor to doctor communication enhances patient care, improves collegiality and prevents unnecessary use of acute services for patients identified as having a real or potential rheumatic disease.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Health Services Research Poster III – ACR/ARHP

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 9:00 AM-11:00 AM

Background/Purpose: Patients (pts) receiving adalimumab for RA or other indications are offered participation in the AbbVie pt support program (PSP). This analysis assessed clinical outcomes across 4 regional areas for pts in the PASSION study according to PSP participation.

Methods: PASSION was a 78-wk postmarketing, global, observational study that include dpts with moderate to severe RA receiving adalimumab in routine clinical care. Clinical outcomes were evaluated in PSP users and non-users in North America, Eastern Europe, Western Europe, and Oceania. Outcome measures included proportion of pts with low disease activity (LDA), defined for this analysis as Clinical Disease Activity Index (CDAI) ≤ 10 , Disease Activity Score 28(CRP) (DAS28[CRP]) < 3.2 , and Simplified Disease Activity Index (SDAI) ≤ 11 ; remission, defined for this analysis as CDAI ≤ 2.8 , DAS28-CRP < 2.6 , and SDAI ≤ 3.3 ; and HAQ Disability Index Minimum Clinically Important Difference (HAQ-DI MCID, ≥ 0.22 decrease from baseline). Differences between PSP users and non-users for demographics and outcome measures were evaluated using a Chi-square test and differences for baseline (BL) disease activity using a 1-way ANOVA.

Results: Of 1025 pts receiving adalimumab, 499 were PSP users and 526 were PSP non-users. Most BL characteristics were similar for PSP users and PSP non-users for each region, although prior biologic DMARD use was higher in PSP non-users (18%–29%) vs PSP users (0–16%) across regions (significantly higher for Western Europe and Oceania, $P < 0.01$). BL mean disease activity was similar in PSP users and non-users from North America and Western Europe, but higher in PSP users vs PSP non-users from Eastern Europe (CDAI, DAS28[CRP], SDAI, all $P < 0.001$) and Oceania (CDAI, $P < 0.05$). Responder data analyzed by region for PSP users and non-users suggested that greater proportions of pts achieved LDA and remission with continued adalimumab treatment (**Table**). Significantly greater proportions of PSP users vs non-users from Eastern Europe and Oceania achieved LDA and/or remission at some time points ($P < 0.05$). The majority of PSP users and PSP non-users achieved HAQ-DI MCID at all assessed time points across all 4 regions (53%–87% PSP users; 59%–73% PSP non-users).

Conclusion: With continued adalimumab therapy, greater proportions of both PSP users and PSP non-users achieved LDA and remission. Participation vs non-participation in the PSP was associated with greater achievement of LDA and remission in the Eastern Europe and Oceania populations at some time points.

Acknowledgments: AbbVie funded the study, contributed to the design, collection, analysis, and interpretation of the data, and in the writing, review, and approval of the abstract. Medical writing support was provided by Catherine DeBrosse, PhD, and Janet Matsuura, PhD, of Complete Publication Solutions, LLC (North Wales, PA, USA) and was funded by AbbVie.

Use of Smartphones in Collecting Patient Reported Outcomes (PROs): Feasibility of a Study Nested in a US National Cohort

Kaleb Michaud^{1,2}, Sofia Pedro², Madison Grinnell¹ and Rebecca Schumacher², ¹Rheumatology, University of Nebraska Medical Center, Omaha, NE, ²FORWARD, The National Databank for Rheumatic Diseases, Wichita, KS

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Health Services Research Poster III – ACR/ARHP

Background/Purpose: Multiple small studies have demonstrated that patients with rheumatic disease can and are willing to use smartphones to track disease severity. The objective of this study is to examine the engagement of an app that allows collection of PRO and passive phone data, in terms of adherence, flares, timing and predictors of discontinuation.

Methods: Participants were enrollees in Forward, The National Databank for Rheumatic Diseases; 700 were invited in two phases. In Phase I, 2013-2014, 190 patients enrolled, downloaded the app and agreed to respond to daily PROs (pain and function VAS) for the initial 3 months and weekly PROs for the duration (PAS-II). In Phase I, flare questions were triggered if the daily $\Delta\text{VAS} \geq 2.5$ or weekly $\Delta\text{PAS-II} \geq 1.67$. Phase II had 256 participants in 2014-2015 with identical study design but biweekly flare assessment irrespective of PRO.

Correct adherence was computed daily and weekly over the study period to the point of discontinuation defined as no app use \geq month (implementation). Kaplan Meier estimate was used to analyze time to discontinuation and Cox regression for predictors. Confounders included sociodemographic, clinical, passive phone behavior, and seasonal factors. Kappa statistics between PRO and flares were computed to measure agreement.

Results: Of 446 patients, 66% had RA, 89% were female, and baseline age 53 yrs (SD 11) and HAQ-II 1.0 (0.7). Overall, $62 \pm 28\%$ of patients reported daily measures in the app. Daily and weekly correct implementation was $68 \pm 40\%$ and $90 \pm 40\%$. The probability of discontinuation at 6 months was 0.78 and 1 year, 0.64. No differences were found by diagnosis (P 0.92) (Figure). Younger age, pain, and HAQ were significant predictors of discontinuation. Half of Phase I patients reported having ≥ 1 flare (IQ0-3), and Phase II reported ≥ 3 (0-6) flares. By phase, the agreement between flares and PROs was 55% and 65%.

Conclusion: This study revealed good levels of correct adherence which holds promise for passive behavior use in clinical follow-up and patient self-management. Examining predictors of discontinuation of response to smartphone data collection is also important as additional reminders can encourage continued participation.

Table. HR (95% CI) using both definitions in the overall sample.

	Adherence (90 days)	Implementation	Implementation		Persistence at x days
Stats	Daily	Daily	Weekly	x days

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Health Services Research Poster III – ACR/ARHP

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 9:00 AM-11:00 AM

Background/Purpose: When uveitis is believed to be part of an underlying systemic disease or when a systemic treatment is required, a multi-disciplinary approach is usually considered for the optimal management of the patients. The objective of this study was to evaluate the means of collaboration between ophthalmologists (OPHS), internal medicine specialists and rheumatologists (RHEUMS) in the care of patients with non-infectious uveitis.

Methods: A multi-disciplinary (rheumatologist, internist, ophthalmologist) scientific committee built a common questionnaire to evaluate if and how French physicians collaborate in daily practice. Questionnaires were sent to all French ophthalmologists from 24th November 2017 to 6th March, 2018. Each OPH designed the Internist/Rheumatologist he usually works with. Questionnaires were also sent to all members of the CMIO ("*club médecine interne et oeil*"), a French group of internists and ophthalmologists involved in the management of uveitis patients. All mandatory regulatory authorizations were obtained.

Results: A total of 88 physicians completed the questionnaires (37 OPHS, 31 internists, 20 RHEUMS). The physicians' mean age was 44 ± 3 years, 53% were males and 84% was hospital-based (68% in university-hospitals, 30% in general hospitals). Among ophthalmology departments 51% had five or more full-time specialists and 45% showed more than 25 uveitis patients per month in their clinic. OPHS collaborated closely with internal medicine specialists in the management of uveitis patients, but not with RHEUMS. This collaboration took place in the same hospital in 83% of cases, but in a shared setting only in 9%. The means of collaboration were as follows: immediately consecutive appointments (7%), face-to-face meetings (23%), or letters (43%). Diagnostic was mainly done by OPHS alone for B27 positive uveitis or by internists for sarcoidosis. OPHS prescribed and managed the follow-up of corticosteroid treatment, but not of corticosteroid-sparing therapies (immunosuppressant). Answers to the questionnaires were globally consistent between OPHS, internists and RHEUMS

Conclusion: The management of patients with uveitis was mostly organized as collaboration between internal medicine specialists and OPHS, rather than with RHEUMS. Heterogeneous patterns of care were observed. This study may help to define goals to optimize a shared multidisciplinary approach for the management of patients with uveitis.

Safety of Ultrasound-Guided Injections Using Local Puncture Site Sterility

Suzan Jaradat¹, Maheswari Muruganandam², Noelle Rolle², Wilmer Sibbitt Jr³, William Hayward⁴, N. Suzanne Emil³, Monthida Fangtham³, Roderick Fields³ and Arthur Bankhurst³, ¹Internal Medicine, University of New Mexico Health Sciences Center, ALBUQUERQUE, NM, ²University of New Mexico Health Sciences Center, ALBUQUERQUE, NM, ³Rheumatology, University of New Mexico Health Sciences Center, Albuquerque, NM, ⁴The Department of Exercise and Sport Sciences, New Mexico Highlands University, Las Vegas, NM

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Health Services Research Poster III – ACR/ARHP

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 9:00 AM-11:00 AM

Background/Purpose: Ultrasound (US)-guided injections in musculoskeletal medicine typically utilize either local puncture site sterility or conventional surgical sterility. We report on the safety and complications of US-guided injections using local puncture site sterility.

Methods: Local puncture site sterility requires an initial cleansing of the injection site with chlorhexidine antiseptic. The clean, non-sterile US-gel is then placed on the clean, non-sterile US-probe and then both on the skin. Contamination is avoided through use of a longer needle that allows increased distance between the needle puncture site and US-gel-probe (Figure 1A). Under IRB approval, we analyzed 1115 consecutive US-guided corticosteroid injections (in 81.5% females and 18.5% males) to treat predominantly localized osteoarthritis and rheumatoid arthritis. Patient outcomes at 1, 3, 6 and 12 months post-procedure were reviewed for procedural-related complications.

Results: The 1115 US-guided injection procedures consisted of 390 knees (35%), 187 shoulders (17%), 186 carpal tunnels (17%), 120 fingers (interphalangeal and metacarpophalangeal joints, trigger finger) (11%), 47 sacroiliac joints (4.2%), 42 ankles (3.8%), 39 greater trochanteric bursa, (3.5%), 34 wrists (3%), 20 elbows (1.8%), 20 hips (1.8%), 11 popliteal cysts (1%), 11 feet (intertarsal joints) (1%), and 8 toes (interphalangeal and metatarsophalangeal joints (0.7%). Dermal atrophy (Figure 1B) occurred in 51 cases (4.6%), hemorrhage (Figure 2 A) in 1 (0.09%), cellulitis (Figure 2B) in 1 (0.09%), septic joint in 0 (0%), and tendon rupture 0 (0%). All complications resolved with time and proper therapy. The single infection was due to methicillin-sensitive *Staphylococcus aureus* suggesting endogenous contamination from the patient's skin.

Conclusion: US-guided musculoskeletal injections using local puncture site sterility are safe with dermal atrophy being the most common adverse outcome (4.6%). Serious complications, including infection, occur at an incidence less than 0.1% indicating that US-guided injection with local puncture site sterility is an acceptably safe procedural technique.

Figure 1. A. Local puncture site sterility injection. B. Dermal Atrophy after US-guided carpal tunnel injection.

Figure 2. A. Hemarthrosis after US-guided injection. B. Digital cellulitis after US-guided injection.

User Experience with Methotrexate in Managing Inflammatory Arthritis Under the Support of an Interprofessional Arthritis Care Team (UMTX Study)

Diane Tin¹, Marie Craig¹, Carolyn Dittmar², Carter Thorne², Nooshin Samadi¹, Edward Ng² and Aubrey Michael², ¹The Arthritis Program, Southlake Regional Health Centre, Newmarket, ON, Canada, ²Southlake Regional Health Centre, Newmarket, ON, Canada

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Health Services Research Poster III – ACR/ARHP

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 9:00 AM-11:00 AM

Background/Purpose: Methotrexate (MTX) is the cornerstone for the treatment of RA as monotherapy or in combination. While its cost effectiveness in halting the disease is inarguable, many obstacles hinder optimal usage. Myths about MTX, for example, that it is chemotherapy, often lead to fear of side effects and reluctance to accept treatment. While intolerance to MTX has been widely reported, it is known that the subcutaneous administration route is more efficacious than oral and usually better tolerated. Unfortunately, this preferred route is not routinely used based on the belief that self-administration is impractical and unsafe. In our interprofessional arthritis care program, we provide holistic education on disease, medication options and self-management strategies right from the time of diagnosis. Our pharmacists teach subcutaneous self-injection of both MTX and Vitamin B12. In this questionnaire study, we aim to determine patient experience with using MTX with the support of an interprofessional arthritis care team.

Methods: We reviewed and modified, with permission, a survey developed by a national patient advocacy group, adding questions about patient attendance at the interprofessional arthritis care program and whether they have accessed the pharmacist consultation service. The questionnaire, asking for anonymous data only, was administered in hardcopy format to consecutive patients visiting our clinic and the four off-site rheumatologist offices. All patients who have ever used MTX for managing inflammatory arthritis were eligible to participate. Office staff and allied health providers identified eligible participants and provided a study envelope which contained the study participant information letter and the questionnaire. Participants were asked to return the completed questionnaire in a sealed envelope before they left.

Results: Over an 8 week period, a total of 228 completed surveys were received.

Table 1. Study Participants Characteristics (n = 228):

Female	160 (71%)
Age	
< 50 years old	39 (17%)
50 – 70 years old	123 (55%)
> 70 years old	63 (28%)
Diagnosis	
RA	165 (73%)
PsA	30 (13%)
Undifferentiated IA	24 (11%)
Other	7 (3%)
Years since diagnosis	
< 2 years	26 (11%)
2 to 5 years	51 (23%)
5 to 10 years	49 (22%)
> 10 years	99 (44%)
Currently using MTX	162 (75%)
Previously using MTX	54 (25%)
MTX subcutaneous route	163 (73%)
MTX PO route	59 (27%)
MTX dose at least 15mg weekly	84 (49%)
Duration of MTX use	
< 2 years	53 (25%)
2 to 5 years	57 (27%)
5 to 9 years	35 (17%)
> 9 years	65 (31%)
Attended Interprofessional Arthritis Care Program	
Therapeutic education workshop	138 (65%)
Rheumatology clinic/ individual assessment	143 (71%)
Pharmacist consultation	104 (49%)

Over 80% of survey respondents stated they feel MTX helps their arthritis. Only 13% of respondents reported they stopped MTX due to side effects, with nausea and fatigue being most common. It should be noted that 61% of respondents were taking Vitamin B12, with 52% of those using the subcutaneous injection route. Among those using Vitamin B12, 60% believe that it helped reduce the side effects of MTX.

Conclusion: Our survey results suggest long survival of subcutaneous MTX administration. Further study is warranted to explore possible benefits of Vitamin B12 co-prescription and the impact of interprofessional care model on patient experience with MTX use in inflammatory arthritis.

Online Direct-to-Patient Recruitment for Systemic Lupus Erythematosus Results in Rapid Enrollment

June Fujimoto, Lilian Borisov, Kristen Warren and **Robert Terbrueggen**, DxTerity, Rancho Dominguez, CA

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Health Services Research Poster III – ACR/ARHP

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 9:00 AM-11:00 AM

Background/Purpose: For precision medicine to address the dynamic nature of autoimmune diseases, more frequent measurements of disease activity and therapy response are needed. We report on the efficiency of a clinical study with samples sourced directly from participants with Systemic Lupus Erythematosus (SLE), a chronic inflammatory autoimmune disease, recruited entirely through online platforms. Such direct-to-patient recruitment has the added benefit of driving down cost and accelerating the speed at which clinical studies can be conducted.

Methods: We obtained IRB approval to allow for recruitment of SLE participants using online methods (Facebook, 4 bloggers with SLE) and a dedicated webpage (theLIFTstudy.com). Eligible study participants had SLE, were ≥ 18 years of age, lived in the United States, and had access to email and internet. Participants agreed to take online health surveys and self-collect three fingerstick blood samples from home that were returned via US mail for genomic analysis.

Results: Within six weeks, 1,042 SLE participants were recruited, after which time active marketing stopped. In total, over 1,400 participants with SLE (97% women, 3% men) enrolled. Participants with lupus were geographically located across all 50 states, with 17% located in rural areas, similar to the national distribution of 19%.^{1,2} Age Distribution: 0% ≥18-19, 12% ≥20-29; 23% ≥30-39; 30% ≥40-49; 28% ≥50-64; 4% ≥65; 2% unknown. Ethnicity: 72% White, 11% African American, 8% More than One Race, 6% Hispanic/Latino, 1% Native American, 1% Asian.

Channel	Impressions	Click through rate (CTR)	Clicks	Clicks to Email %	# of Emails	Email to Qualified Enrolled %	# Enrolled
Social Platforms	1,423,335	1.4%	19,594,	14%	2,831	38%	1,137
Bloggers			621	70%	436	65%	282
Total							1,419

Study updates allowed for ongoing engagement. A follow-up email sent a year later, requesting an additional fingerstick blood sample, had a 51% open rate, with 88% of the opens agreeing to provide another sample.

Conclusion: An online direct-to-patient process to recruit for an SLE study is an effective model that can help drive down costs in precision medicine. Through the sole use of online platforms, the LIFT study reached its goal of > 1,000 SLE participants enrolled within 6 weeks. The virality of the study enrolled an additional 400 at no additional marketing cost. Online recruitment enabled nationwide participation, with a rural area rate similar to the national distribution, possibly capturing individuals who may normally lack the access and ability to join a traditional SLE study. Bloggers provided an engaged group of patients from which to recruit. Patient engagement to extend participation was also high and may be indicative of the desire for patients to play a more active role in furthering lupus research.

Session Date: Tuesday, October 23, 2018

Session Title: Health Services Research Poster III – ACR/ARHP

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 9:00 AM-11:00 AM

The relative risk of MTX based combinations

Background/Purpose: Adverse events (AE) during treatment in RA patients are unavoidable. Monitoring AEs in real time during long-term treatment is critical for AE detection and rational management. The current AE report system in MedWatch can only collect rare AE, but could not support post marketing vigilance and reevaluation for drugs, especially in real world combination therapy.

To develop and validate SSDM as a new platform for post-marketing vigilance through monitoring AEs with common mono- and combination therapies in treatment of rheumatoid arthritis (RA).

Methods: The SSDM is a mobile App which includes two applications for both physicians and patients. Patients were educated to input the data of lab test records and treatment regimens and perform disease activity evaluation once a month. After data entry, patients can synchronize data to the mobile terminal of their authorized rheumatologist and upload onto cloud, which formed a large patient self-management database.

Results: From Aug 2014 to May 2018, a total of 10,903 RA patients from 480 centers in China were entered in the cohort study. These patients contributed more than 18,823 patient-years (PY) follow-up data. The mean age was 49.29 +/- 16.08 (18 to 99) years and the median disease duration was 27.4 months. The treatment regimens include 11 mono and 39 combination therapies. Taken ALT as an example, the profile of AE of ALT elevation for top ten mono therapy regimens is plot (Figure 1). In the database there are thirty-six MTX based combinations treatment regimens. The specifications of elevation of ALT in MTX combination therapy are drafted based on relative risk ratio comparing with rate in MTX mono therapy (Figure 2). Both AE profiles in mono therapy and specification in combination treatment alerted clinicians for unsafe regimens avoidance and timely adjustment.

Conclusion: The findings show that the AEs may be well collected and described via SSDM database through empowering patient. Rheumatologists are able to monitor the real world profile of adverse events in real time. SSDM is able to assist Rheumatologist in making rational clinical decision. SSDM may serve as new platform for post-marketing vigilance.

Session Date: Tuesday, October 23, 2018

Session Title: Imaging of Rheumatic Diseases Poster III: Other Modalities

Session Type: ACR Poster Session C

Session Time: 9:00 AM-11:00 AM

Background/Purpose: Polymyalgia rheumatica (PMR) is often the presenting manifestation of giant cell arteritis (GCA). Fluorine-18-fluorodeoxyglucose positron emission tomography/computed tomography (PET/CT) scan often discloses the presence of LVV in PMR patients. We aimed to identify predictive factors of a positive PET/CT scan for LVV in patients classified as having isolated PMR.

Methods: A set of consecutive patients with PMR from a single hospital were assessed. All of them underwent PET/CT scan between January 2010 and February 2018 based on clinical considerations. Patients with PMR associated to other diseases, including those with cranial features of GCA, were excluded. The remaining patients were categorized in classic PMR (if fulfilled the 2012 EULAR/ACR classification criteria at disease diagnosis; n=84) or atypical PMR (who did not fulfill these criteria; n=16). Only information on patients with classic PMR was assessed.

Results: The mean age of the 84 patients (50 women) with classic PMR was 71.4±9.2 years. A PET/CT scan was positive in 51(60.7%). Persistence of classic PMR symptoms was the most common reason to perform a PET/CT scan.

	Classic PMR (N=84)		P
	Positive PET/CT (N= 51)	Negative PET/CT (N=33)	
Sex (women), n (%)	31 (62.7)	19 (57.6)	0.64
Age (years), mean \pm SD	70.0 \pm 9.2	73.7 \pm 9.0	0.08
Cardiovascular risk factors, n (%)			
Hypertension	29 (56.9)	24 (72.7)	0.14
Dyslipidemia	18 (35.3)	16 (48.5)	0.23
Diabetes mellitus	10 (19.6)	12 (36.4)	0.08
Current smokers	5 (9.8)	1 (3.0)	0.40
Polymyalgia symptoms, n (%)			
Neck pain	9 (17.6)	9 (27.3)	0.29
Shoulder girdle pain	33 (64.7)	26 (78.8)	0.17
Pelvic girdle pain	44 (86.3)	12 (36.4)	< 0.01
Morning stiffness	11 (21.8)	10 (30.3)	0.44
Unusual symptoms, n (%)			
Inflammatory low back pain	15 (29.4)	3 (9.1)	0.027
Diffuse lower limb pain	27 (52.9)	2 (6.1)	< 0.01
Constitutional symptoms, n (%)			
Fever	2 (3.9)	2 (6.1)	0.64
Asthenia	15 (29.4)	8 (24.2)	0.60
Hypoxemia	4 (7.8)	7 (21.2)	0.08
Weight loss	9 (17.6)	8 (24.2)	0.46
Laboratory markers.			
Hb (g/dL), mean \pm SD	12.7 \pm 1.3	12.2 \pm 1.6	0.09
Platelet count ($\times 10^9/l$), mean \pm SD	281.4 \pm 84.9	263.7 \pm 100.3	0.19
CRP (mg/dL), median [IQR]	2.0 [0.6-4.4]	2.0 [1.1-5.3]	0.28
ESR (mm/1* h), median [IQR]	33.0 [12.0-65.0]	48.0 [29.5-73.0]	0.15
Treatment.			
Glucocorticoids, n (%)	51 (100.0)	33 (100.0)	0.99
Dose of Prednisone (mg), mean \pm SD	12.0 \pm 5.7	12.3 \pm 7.3	0.88
Months of treatment with Prednisone, median [IQR]	4 [1.0-15.0]	7 [2.5-15.5]	0.31
Methotrexate, n (%)	11 (21.8)	4 (12.1)	0.27

Nevertheless, patients with positive PET/CT scan often had unusual symptoms. The best set of predictors of a positive PET/CT scan were bilateral diffuse lower limb pain (OR=8.8, 95% CI 1.7-46.3; p=0.01), pelvic girdle pain (OR=4.9, 95% CI 1.50-16.53; p=0.01) and inflammatory low back pain (OR=4.7, 95% CI 1.03-21.5; p=0.04).

Conclusion: Inflammatory low back pain, pelvic girdle and diffuse lower limb pain are predictors of positive PET/CT scan for LVV in PMR.

Grayson⁴, ¹NIAMS, National Institute of Arthritis, Musculoskeletal and Skin Disease (NIAMS), Bethesda, MD, ²Systemic Autoimmunity Branch, NIAMS, Bethesda, MD, ³Radiology and Imaging Sciences, National Institutes of Health, Bethesda, MD, ⁴National Institute of Arthritis, Musculoskeletal and Skin Disease, National Institutes of Health, Bethesda, MD

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Imaging of Rheumatic Diseases Poster III: Other Modalities

Session Type: ACR Poster Session C

Session Time: 9:00 AM-11:00 AM

Background/Purpose: ^{18}F -fluorodeoxyglucose (FDG) PET may be used to quantify vascular inflammation in large-vessel vasculitis (LVV). Quantitative analysis of arterial FDG uptake has not been standardized. Delayed acquisition time may be advantageous for vascular PET imaging but has not been studied in LVV. Arterial FDG uptake is often normalized to uptake in background tissue; however, the factors that influence tissue-specific distribution of FDG in inflammatory diseases are unknown. The study objective was to identify factors associated with FDG uptake in 1) the large arteries and 2) background tissues (liver, blood pool, spleen) at 1 and 2 hour image acquisition times in a cohort of patients with LVV and comparators.

Methods: Patients with LVV and comparators (systemic inflammatory diseases, healthy controls), were recruited into a prospective observational cohort. Participants underwent either whole body PET-MR at 1 hour acquisition time, PET-CT at 2 hour acquisition time, or both. Arterial uptake was quantified as the sum of mean standardized uptake values (SUV_{max}) for 5 segments of the aorta, carotid, and subclavian arteries. SUV_{mean} values were calculated for each background tissue. Multivariate linear regression models were used to identify associations between tissue-specific FDG uptake and atherosclerosis, vasculitis, and FDG clearance- related factors (see **Table**). The same predictor variables were included in each regression model to facilitate comparisons across different tissues. A p value <0.05 was considered significant.

Results: PET scans were performed at 1 hour (n = 175) and 2 hours (n = 194), with most studies performed sequentially at both time points (n = 145). Age, BMI, and CRP were significantly associated with arterial-FDG uptake at both the 1 and 2 hour time points, with increased effect estimates at 2 hours. Additional vasculitis-related factors (diagnosis, treatment) were also significantly associated with arterial uptake at the 2 hour time point. Factors related to FDG clearance (uptake time, glomerular filtration rate) were significantly associated with FDG uptake in liver and blood pool at 1 hour but were weakly or not associated with FDG uptake at 2 hours. Additional factors were associated with liver and blood pool at 2 hours, but with small effects estimate sizes. Vasculitis-related factors were associated with splenic uptake at 1 and 2 hours.

Conclusion: Tissue-specific factors are associated with FDG distribution in a time-dependent manner. Delayed image acquisition demonstrates stronger associations between arterial FDG uptake and atherosclerosis/vasculitis related factors. The impact of factors related to FDG clearance in background tissues is reduced with delayed imaging. Delayed image acquisition and normalization of arterial FDG uptake to liver or vein is preferable in LVV.

Table: Factors significantly associated with tissue distribution of ^{18}f -fluorodeoxyglucose on positron emission tomography in large-vessel vasculitis at 1 and 2 hour imaging acquisition times

		1-hour Positron Emission Tomography	2-hour Positron Emission Tomography
Target Tissue	Artery	Age ($\beta = 0.09$, $p < 0.01$) BMI ($\beta = 0.28$, $p < 0.01$) CRP ($\beta = 0.05$, $p < 0.01$)	Age ($\beta = 0.20$, $p < 0.01$) BMI ($\beta = 0.41$, $p < 0.01$) CRP ($\beta = 0.12$, $p = 0.01$) Diagnosis ($\beta = 2.06$, $p = 0.04$) Immune Meds ($\beta = 1.65$, $p = 0.01$)
			BMI ($\beta = 0.03$, $p < 0.01$) Age ($\beta = 0.004$, $p = 0.02$) Female ($\beta = 0.08$, $p < 0.01$)
Background Tissue	Liver	BMI ($\beta = 0.02$, $p < 0.01$) GFR ($\beta = -0.002$, $p = 0.03$) Uptake time ($\beta = -0.003$, $p = 0.01$)	BMI ($\beta = 0.03$, $p < 0.01$) Age ($\beta = 0.004$, $p = 0.02$) Female ($\beta = 0.08$, $p < 0.01$)
	Blood Pool	BMI ($\beta = 0.01$, $p < 0.01$) Uptake time ($\beta = -0.005$, $p < 0.01$) GFR ($\beta = -0.003$, $p < 0.01$)	BMI ($\beta = 0.02$, $p < 0.01$) Uptake time ($\beta = -0.003$, $p < 0.01$) Age ($\beta = 0.004$, $p < 0.01$) Fasting Glucose ($\beta = 0.003$, $p < 0.01$) Immune Meds ($\beta = -0.003$, $p < 0.01$)
	Spleen	BMI ($\beta = 0.02$, $p < 0.01$) Diagnosis ($\beta = -0.08$, $p = 0.03$) PGA ($\beta = -0.03$, $p = 0.04$) WBC ($\beta = 0.02$, $p < 0.01$)	BMI ($\beta = 0.03$, $p < 0.01$) Immune Meds ($\beta = -0.09$, $p = 0.01$)

* All of the following variables were included in each regression model:

Atherosclerosis-related factors: Gender (male vs female), Body mass index (BMI), Age in years, Fasting glucose (mg/dL).

Vasculitis-related factors: C-reactive protein (CRP, mg/L), Total white blood cell count (WBC, K/uL), Treatment with immunosuppressants (Immune Meds, Yes vs No), Daily prednisone dose (mg), Physician global assessment (PGA, 0-10 scale), Diagnosis (large-vessel vasculitis vs comparator), Hematocrit (%).

FDG clearance factors: Uptake time (minutes from injection of FDG), Glomerular filtration rate (GFR, ml/minute).

Session Date: Tuesday, October 23, 2018

Session Title: Imaging of Rheumatic Diseases Poster III: Other Modalities

Session Type: ACR Poster Session C

Session Time: 9:00 AM-11:00 AM

Background/Purpose: Giant cell arteritis (GCA) and polymyalgia rheumatica (PMR) are overlapping inflammatory diseases. Large Vessel Vasculitis (LVV) is frequently present in any of the two subsets¹. In some scenarios where complications such as visual loss or stroke are present, treatment with steroids bolus is a common practice. Imaging studies when suspecting LVV are as sensible and more easily available than temporal artery biopsy². ^{18}f -FDG PET/CT is useful to

confirm mural inflammation in extracranial arteries to support diagnosis of LVV. Beside this rationale, some questions still remain unclear regarding the involvement of PET/CT in patients receiving steroids³.

Methods: Multicenter, retrospective, descriptive analysis of 18f-FDG PET/CT in 69 patients who met 2010 ACR criteria for GCA. Demographic data, cumulative GC prior to PET/CT, and vascular territories affected were collected. Patients included were either new diagnosis or those who had previous diagnosis of GCA or PMR, who had a relapse or complicated follow-up. PET/CT scan was reported either positive or negative for LVV for any of 8 major vascular territories: ascending aorta, aortic arch, descending thoracic aorta, abdominal aorta, carotids, subclavian/ brachiocephalic, axillary/humeral and iliac/femoral arteries. Statistic analysis was done with χ^2 with Yates' correction and exact Fischer's test.

Results: Mean age: 72 years \pm 5 yo, 68%, women. Territories mostly affected: thoracic aorta (75%), iliac/femoral arteries (54.2%) and supraaortic vessels (47.9%). In general, GC seemed to be associated with the possibility of a negative PET/CT scan. A subanalysis among patients allowed to classify into 3 groups: (1) no previous steroids (2) previous accumulated GC (3) steroid bolus previous to PET/CT. Group 2, showed a mean accumulated dose of GC 2,908.4 mg \pm 339. A 31.8% of PET/CT scans were negative, interestingly 84% corresponded to the group of patients who had received a steroid bolus prior to the PET/CT (p 0.01) (Table 1).

	Positive PET/CT	Negative PET/CT
Group 1, n= 29	27 (93.1%)	2 (6.9%)
Group 2, n= 27	18(66.7%)	9(33.3%)
Group 3, n=13	2(15.4%)	11(84.6%)

Conclusion: Conclusions: Data from our multicenter cohort of LVV showed that thoracic aorta was the most frequent vessel affected, as expected. When steroid bolus was given, there was a strong association with a negative PET/CT scan, compared with patients who received either a variable dose or any dose of steroids. Our results confirmed something expected beforehand, but not yet described in a large cohort of patients.

Session Title: Imaging of Rheumatic Diseases Poster III: Other Modalities

Session Type: ACR Poster Session C

Session Time: 9:00 AM-11:00 AM

Background/Purpose: To evaluate the impact of 18F-fluorodeoxyglucose PET-CT (FDG-PET/CT) score at baseline, on the therapeutic response to prednisone, in patients with polymyalgia rheumatica (PMR).

Methods: This is a monocentric retrospective study realized at the university hospital of Besancon. We included patients with a diagnosis of PMR meeting the 2012 ACR/EULAR criteria, who had performed a FDG-PET/CT at baseline, between December 2012 and December 2017. Patients were treated with an initial prednisone dose of 0.3 mg/kg a day, progressively decreased following a standardized tapering dose protocol (10% /month). We excluded patients who received

corticosteroids before the FDG-PET/CT, or without baseline FDG-PET/CT. Seventeen specifics previously described hotspots were visually analyzed (1). We realized a semi-quantitative analysis of FDG uptake (4-point score from 0 to 3), following Goerres scoring system (2). Hotspot with 0 indicating no uptake (same as bone); 1, slight uptake; 2, moderate uptake (same as liver); and 3, uptake higher than the liver. It results in a score of 0 to 51. Then we defined two groups of patients according to their resistance to prednisone at 6 months, defined as the reoccurrence of symptoms and/or an increase of systemic inflammation twice during the prednisone tapering.

Results: 30 patients were included: 12 in the group “resistant” and 18 in the group “sensitive”. There were 60% of women, with a mean age of $67,57 \pm 11,63$ years. The mean CRP at baseline was $45,02 \pm 39,59$ mg/L. The mean FDG-PET/CT score at baseline was 18/51. The FDG-PET/CT score baseline was significantly lower in the resistant group (9 vs 23, $p < 0.009$). Resistant patients were younger (60 years vs 74.5 years, $p < 0.008$), and mostly men (66.5% vs 22%, $p < 0.02$). ROC curve shows a predictive threshold of corticoreistance at 9/51 on the PET/CT score at baseline, with 66.67% of sensibility and 83.37 of specificity [AUC: $0,78 \pm 0,08$] Patients with peripheral synovitis had higher PET/CT score baseline ($p = 0.02$).

However, there was no statistically significant difference of CRP at baseline between the two groups (13.75 vs 15, $p < 0.8$), and no correlation between CRP and PET/CT score at baseline ($p = 0.17$). There was no difference concerning the presence of neoplasia (16.5% vs 11%, $p < 1.00$) in the two groups.

Conclusion: These data suggest that higher baseline FDG-PET/CT score is predictive of a better response to prednisone in patients with PMR, with a predictive threshold of corticoreistance lower than 9/51 on FDG-PET/CT score at baseline. Corticoreistant patients seemed to be mostly men and younger, with no significant difference in CRP at baseline.

Active Disease and Follow up 18f-FDG-PET/CT in Patients with Giant Cell Arteritis. Which Treatment Is More Likely to Achieve Remission?

Verena Schönauf¹, Georg Schett², Matthias Englbrecht¹, Juergen Rech³ and Jessica Roth¹, ¹Department of Internal Medicine 3 – Rheumatology and Immunology, Friedrich-Alexander-University Erlangen-Nürnberg, Erlangen, Germany, ²Friedrich-Alexander-University Erlangen-Nuremberg (FAU), Department of Internal Medicine 3 – Rheumatology and Immunology, University Hospital Erlangen, Erlangen, Germany, ³Department of Internal Medicine 3, University of Erlangen-Nuremberg, Erlangen, Germany, Erlangen, Germany

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Imaging of Rheumatic Diseases Poster III: Other Modalities

Session Type: ACR Poster Session C

Session Time: 9:00 AM-11:00 AM

Background/Purpose: Giant cell arteritis is the most common large vessel vasculitis. ¹⁸F-FDG-PET/CT is known to be a useful imaging technique for diagnosing giant cell arteritis. Only a few ¹⁸F-FDG-PET/CT follow up studies with limited number of patients exist. Especially long term immunosuppressive treatment was so far not analyzed. Withdraw of immunosuppressive treatment is normally guided by clinical symptoms and laboratory testing. Under treatment with tocilizumab laboratory testing is not a helpful guiding tool for clinicians. ¹⁸F-FDG-PET/CT follow up investigations might be a useful diagnostic tool to decide if an immunosuppressive treatment is sufficient.

Methods: 28 patients with an active giant cell arteritis were clinically documented and subjected to ¹⁸F-FDG-PET/CT scanning with a Siemens Biograph™ True Point™ PET/CT. Images were evaluated by specialists at the Departments of Nuclear Medicine and Radiology of the University Clinic of Erlangen via a visual grading system. ¹⁸F-FDG-PET/CT scans were graded as active, questionable active and inactive. The scans were graded active when a vascular uptake of the tracer was higher than liver uptake. Additionally we documented the vascular uptake of the tracer applying the PETVAS score by Grayson et. (0-27). All patients received a follow up investigation to evaluate disease activity under immunosuppressive Treatment.

Results: At time of clinically active disease in 22 patients ^{18}F -FDG-PET/CT scans were graded as active and in 6 patients it was graded as questionable active. The mean CRP level was 52 mg/l and the mean PETVAS score was 17.86. The mean time between the first and second scan was 25.61 months. At the time of follow up only in two patients ^{18}F -FDG-PET/CT scans were graded as active, in 13 patients as questionable active and no activity was seen in 13 patients. The mean CRP level at follow up was 9,7 mg/l and the mean PETVAS score was 8.79. Additionally to glucocorticosteroids 19 patients were treated with MTX (67,9%), 8 patients received Tocilizumab and 1 patient received Azathioprin. We couldn't estimate any statistically significant predictors for a follow up PET-CT with no activity (= PETVAS<10) due to the small patient number. Interestingly all 8 patients (100%) with Tocilizumab treatment between the two scans were graded as no activity at follow up and had a PETVAS score <10. While 31,5% (6 patients) treated with MTX still were questionable or active in their ^{18}F -FDG-PET/CT scan (PETVAS>10).

Conclusion: In this follow up study we could show that ^{18}F -FDG-PET/CT scan is a useful tool to estimate clinical remission additionally to clinical parameters and laboratory tests. Interestingly, all patients that received Tocilizumab had visually graded no activity in their ^{18}F -FDG-PET/CT scans (PETVAS<10), while only 68.5% of the patients treated with MTX could achieve a PETVAS<10 at follow up. Larger studies on follow up ^{18}F -FDG-PET/CT especially under Tocilizumab treatment should be done to confirm this result and the stronger immunosuppressive effect of Tocilizumab in comparison to MTX in patients with giant cell arteritis.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Imaging of Rheumatic Diseases Poster III: Other Modalities

Session Type: ACR Poster Session C

Session Time: 9:00 AM-11:00 AM

Background/Purpose: Giant cell arteritis is the most common large vessel vasculitis. ^{18}F -FDG-PET/CT is known to be a useful imaging technique for diagnosing giant cell arteritis. Scarce data exists on ^{18}F -FDG-PET/CT in patients with giant cell arteritis in clinical remission. It was shown that ^{18}F -FDG uptake can persist in patients under immunosuppressive treatment. The decision to withdraw immunosuppressive treatment is normally guided by clinical symptoms and laboratory testing. Under treatment with tocilizumab laboratory testing is not helpful. Therefore ^{18}F -FDG-PET/CT might be an additional investigation method to device between subclinical persisting inflammation and true remission.

Methods: 31 patients with giant cell arteritis in clinical remission were clinically documented and subjected to ^{18}F -FDG-PET/CT scanning with a Siemens BiographTM TruePointTM PET/CT. Images were evaluated by specialists at the Departments of Nuclear Medicine and Radiology of the University Clinic of Erlangen via a visual grading system. ^{18}F -FDG-PET/CT scans were graded as active, questionable active and inactive. The scans were graded active when a vascular uptake of the tracer was higher than liver uptake. Additionally, we documented the vascular uptake of the tracer applying the PETVAS score by Grayson et. (0-27).

Results: Of the 31 patients in clinical remission, two patients presented with a visual active vascular uptake of the tracer in the ^{18}F -FDG-PET/CT scan. 11 patients had a questionable active tracer uptake and 18 patients had no visual vascular uptake of the tracer. The mean PEVAS score of patients with visual active vascular uptake was 16, with patients with questionable uptake was 9.27 and with no vascular uptake was 7.44. Interestingly the patients with active disease had no systemic inflammation markers. One patient was treated with MTX 15 mg/week and 5 mg Prednisolone/day, the other was without treatment. 6 patients of the cohort were treated with Tocilizumab, all of them had visually no tracer uptake and their mean PETVAS score was 8.33. On the other hand patients with Methotrexate were found in all three groups equally distributed with a mean PETVAS score of 9.20.

Conclusion: We showed that 11 patients (35,4%) with clinical remission still had visually questionable active ^{18}F -FDG uptake and 2 patients (6.4%) had visually active ^{18}F -FDG uptake in an ^{18}F -FDG-PET/CT scan. It is not clear whether this subclinical ^{18}F -FDG uptake reflects true activity of the large vessel vasculitis or residual effects due to vascular remodeling. Interestingly all patients under Tocilizumab treatment were in the visual not active group (mean PETVAS=8,33) while patients with MTX were equally distributed among all groups. This result indicates a better immunosuppressive effect of Tocilizumab in comparison to MTX and might be a sign for persisting vasculitis activity in patients with significant ^{18}F -FDG uptake despite clinical Remission.

Session Title: Imaging of Rheumatic Diseases Poster III: Other Modalities

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Polymyositis is a chronic inflammatory myopathy with proximal muscle weakness due to lymphocyte infiltration, especially CD8 + T cells to the muscle layer. C protein-induced myositis (CIM) is a murine model of polymyositis (PM), muscle injury is mediated by C protein-reactive CD8 + T cells. A recent study reported that the serum levels of muscle-derived enzymes were irrelevant to the severity of CIM. In addition, although the histological scoring is the reliable way to assess the severity of CIM, it has limitation to evaluate the inflammation due to focal involvement. The aim of this study was to evaluate the correlation of skeletal muscle inflammation and ^{18}F -fluorodeoxyglucose (FDG) positron emission tomography (PET)/magnetic resonance imaging (MRI) findings in CIM.

Methods: To induce CIM, 8–10-week-old female mice were immunized intradermally with 200 μg C protein fragments emulsified in 200 μg of Freund's complete adjuvant (CFA). Pertussis toxin (0.2 μg) was injected intraperitoneally at the same time.

FDG (300 mCi) was intravenously injected and simultaneous PET/MRI was obtained 60 minutes later by using a hybrid PET/MRI scanner for small animal. On PET/MRI, FDG uptake was measured in the gluteal and thigh muscle, foot pad, and the soft tissue as a background. Maximal target-to-background ratio (TBR) of the muscles was measured as the index for uptake. To monitor disease progression, ^{18}F -FDG PET/MRI evaluation was performed on day 12, day 14 and day 19 after immunization. The next day after imaging, quadriceps, hamstrings and gastrocnemius muscle specimens were harvested. Each muscle tissues were stained with hematoxylin and eosin (H&E). Myositis was graded on a scale of 1–6 according to the histologic severity.

Results: Histological score showed significantly increased in quadriceps, hamstrings and gastrocnemius muscle compared to control mice on day 14 (mean score =1.83; $p = 0.0037$, mean score =2.42; $p = 0.0027$ and mean score =1.583; $p = 0.009$, respectively). Histological scores were higher but not significant in quadriceps, hamstrings and gastrocnemius muscle of CIM on day 12 (mean score =0.58; $p = 0.37$, mean score =0.58; $p = 0.18$ and mean score =1.17; $p = 0.12$, respectively) and on day 19 (mean score =1.00; $p = 0.16$, mean score =0.33; $p = 0.12$ and mean score =1.67; $p = 0.37$, respectively). Mean of histologic summation score of skeletal muscles was 0.77, 1.94, 0.5 ($p = 0.016$, $p = 0.0014$ and $p = 0.12$, respectively) on day 12, 14, 19 in CIM. On PET/MRI, TBR was 1.67 ± 0.51 in control, whereas it was 4.11 ± 1.34 on day 12, 6.34 ± 1.78 on day 14, and 3.93 ± 0.75 on day 19 in CIM model. TBR was correlated with histologic summation score (Spearman's $\rho = 0.954$, $p < 0.0001$).

Conclusion: The findings of FDG PET/MRI appeared to be correlated with the histologic scoring system in CIM model. FDG PET/MRI could be an effective method for quantitative, repetitive, and serial assessment of inflammatory activity in CIM model

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Imaging of Rheumatic Diseases Poster III: Other Modalities

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis(RA) and periodontitis have been suggested to be related, and they share many clinical and pathologic features. Both diseases are chronic inflammatory diseases characterized by the accumulation and persistence of inflammatory infiltrates in local lesions. Patients with RA are more likely to have periodontitis, and some reports said the treatment response to RA was less in patients with periodontitis than those without periodontitis. However, there has been no report investigating the relationship between the degree of periodontitis and the treatment response to RA. And it is said that [18F] fluorodeoxyglucose-positron emission tomography/computed tomography (FDG-PET/CT) can evaluate both the degree of synovitis of RA and periodontitis. The aim of this study was to evaluate the relationship between periodontitis and the treatment response to biologics in RA using FDG-PET/CT.

Methods: Sixty RA patients (14 males, 46 females, average age 58.3(17-80) years) treated with biological therapies were assessed. FDG-PET was performed at baseline and six months after the initiation of biological therapy. The maximum standardized uptake value (SUVmax) was used as a representative value for the assessment of the FDG uptake in periodontal tissue (upper posterior gingival tissue). We also evaluated the DAS28-CRP and several clinical parameters (CRP, ESR, anti-cyclic citrullinated peptide antibody [ACPA], rheumatoid factor [RF], matrix metalloproteinase 3 [MMP-3]). Wilcoxon's signed rank sum test and Spearman's rank correlation test were used to assess the correlation between the periodontal SUVmax and the clinical parameters.

Results: Periodontal SUVmax at baseline had relation with patient age ($r=0.302$, $p=0.009$) and ACPA value ($r=0.265$, $p=0.025$).

After biological therapies, the values for DAS28-CRP, CRP, ESR, and MMP-3 were significantly decreased after 6 months. However, the mean periodontal SUVmax increased from 1.83 to 1.88, indicating no significant change in the periodontal SUVmax after treatment. The ACPA and RF values also did not change markedly after treatment. In contrast, we noted a significantly negative correlation between the baseline periodontal SUVmax and the Δ DAS28-CRP ($r=-0.369$, $p=0.004$).

Conclusion: The baseline periodontal SUVmax had a positive correlation with ACPA value. Biological therapies for RA might not cure periodontitis. In addition, concurrent periodontitis might reduce the response to biological therapies in RA patients.

Atherosclerotic Inflammation in Rheumatoid Arthritis Patients: A Post-Hoc Study Using Fluorodeoxyglucose-Positron Emission Tomography/Computed Tomography

Yukio Yonemoto¹, Masahiro Tachibana², Koichi OKAMURA¹, Takahito SUTO¹, Hideo SAKANE¹, Chisa OKURA¹, Tetsuya Kaneko² and Hirotaka CHIKUDA¹, ¹Orthopaedic Surgery, Gunma University Graduate School of Medicine, MAEBASHI, Japan, ²Orthopaedic Surgery, Gunma University Graduate School of Medicine, Maebashi, Japan

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Imaging of Rheumatic Diseases Poster III: Other Modalities

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) has long been associated with an increased cardiovascular risk, and despite substantial improvements in disease management, its associated mortality remains high. Several reports have suggested that treatment with TNF inhibitors might have a beneficial effect on the cardiovascular risk. However, few studies have quantitatively investigated the relationship between RA and atherosclerotic inflammation. [18F] fluorodeoxyglucose-positron emission tomography (FDG-PET) has been used to assess synovitis in patients with RA and to evaluate the disease activity of RA. In addition, the FDG accumulation has been reported to indicate atherosclerotic inflammation. The aim of this study was to evaluate the relationship between atherosclerotic inflammation and biologics using FDG-PET.

Methods: Sixty RA patients (14 males, 46 females, average age 58.3 [range 17-80] years) treated with biological therapies were assessed. FDG-PET was performed at baseline and six months after the initiation of biological therapy. The carotid FDG uptake was measured by obtaining the standardized uptake values from the carotid of each patient, and the ratio of the carotid to background (blood) activity was determined (TBR). We also evaluated the Disease Activity Score 28 C-reactive protein (DAS28-CRP) and several clinical parameters (CRP, erythrocyte sedimentation rate [ESR], anti-cyclic citrullinated peptide antibody [ACPA], rheumatoid factor [RF], matrix metalloproteinase 3 [MMP-3]). Student's t-test, chi-square test and logistic regression analysis were used to assess the factors influencing the decrease in the TBR.

Results: At six months after starting biological therapies, the values for DAS28-CRP, CRP, ESR, and MMP-3 were significantly decreased. However, the carotid TBR was not significantly improved (1.17 to 1.18). The ACPA and RF values also did not change markedly after treatment. The age, change in the white blood cell count, and carotid TBR at baseline were lower in the decrease TBR group than in increase TBR group. In the logistic regression group, a young age and a low carotid TBR at baseline were factors influencing the decrease in the carotid TBR.

Conclusion: In this study, a young age and a low carotid TBR at baseline were factors influencing the decrease in the carotid TBR. These results suggest that biologics improve not only the disease activity but also atherosclerotic inflammation, especially in young RA patients.

Stamp¹, Nigel Anderson², Fabio Becce³, Maya Rajeswari², Matthew Polson⁴, Olivier Guyen³, Anais Viry³, Chloe Choi², Tracy Kirkbride⁵ and Aamir Raja², ¹University of Otago, Christchurch, New Zealand, ²University of Otago, Christchurch, Christchurch, New Zealand, ³Lausanne University Hospital, Lausanne, Switzerland, ⁴University of Canterbury, Christchurch, New Zealand, ⁵Ara Institute of Canterbury, Christchurch, New Zealand

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Imaging of Rheumatic Diseases Poster III: Other Modalities

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The gold standard for the diagnosis of crystal-related arthritis requires aspiration and visualization of crystals from synovial fluid or tophus material. However, crystal identification may be suboptimal particularly for crystals other than monosodium urate (MSU) which are associated with gout. New imaging modalities such as ultrasound and dual energy CT are increasingly being used to aid in the diagnosis of gout but their role is less well defined in other crystal deposition diseases. The ability to characterise calcium pyrophosphate (CPP) or hydroxyl apatite (HA) crystals using non-invasive imaging would be an advance. The aim of this study was to determine whether we could detect and differentiate between MSU, CPP and HA crystals using novel multi-energy spectral CT (MARS) imaging.

Methods: A finger with a gouty tophus from the Christchurch Cancer Tissue bank and a calcified medial meniscus excised at the time of joint replacement surgery were obtained. The gouty finger was imaged using plain X-ray, DECT and a preclinical MARS scanner. Images of the whole meniscus using plain X-ray and MARS were obtained. MARS imaging of biological specimens and calibration phantoms containing known concentrations of MSU, CPP and HA crystals was performed using energy thresholds of 20, 30, 40 and 50 keV at 80 kVp. Material decomposition was applied to the imaging data to distinguish MSU, CPP and HA crystals. For validation purposes, samples of the crystals were obtained from the meniscus and tophus and examined by x-ray diffraction (XRD) and polarized microscopy respectively.

Results: Plain X-ray of the gouty finger revealed erosions and changes consistent with a tophus (Figure 1a). DECT and MARS both identified MSU crystals, however, MARS was able to detect finer detail (Figure 1b). Within the meniscus plain X-ray identified chondrocalcinosis consistent with CPP crystals while MARS showed a predominance of CPP crystals in the calcified regions in the excised meniscus and in some parts there was a mixture of HA and CPP (Figure 1d). MARS imaging findings of the meniscus were validated using x-ray diffraction of the crystal scrapings.

Conclusion: MARS spectral CT can not only detect and differentiate MSU crystals in a gouty finger but also specifically detect and identify CPP within an osteoarthritic human knee meniscus and distinguish them from HA crystals. There is potential for MARS to become useful in the diagnosis of crystal-related arthropathies including CPPD, gout and calcific tendonitis.

Initial Phase 2 Clinical Data of SEL-212 in Symptomatic Gout Patients: Measurement of Dissolution of Urate Deposits Associated with Monthly Dosing of a Pegylated Uricase (Pegadricase) with Svp-Rapamycin By Dual Energy Computed Tomography

Rehan Azeem¹, Earl Sands¹, Lloyd Johnston², Wesley DeHaan², Alan J. Kivitz³, Takashi Kei Kishimoto², Justin Park¹ and Savvas Nicolaou⁴, ¹Selecta Biosciences, Inc, Watertown, MA, ²Selecta Biosciences, Watertown, MA, ³Altoona Center for Clinical Research, Duncansville, PA, ⁴Radiology, University of British Columbia, Vancouver, BC, Canada

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Imaging of Rheumatic Diseases Poster III: Other Modalities

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Pegylated uricases are therapies for treatment of severe chronic gout, particularly for rapid resolution of tophi. However, uricases are limited by induction of anti-drug antibodies that can compromise efficacy and safety. SEL-212 is a novel combination product consisting of pegadricase (also known as pegsiticase) co-administered with synthetic vaccine particles encapsulating rapamycin (SVP-R). We report initial Phase 2 data on the effect of the intensive lowering of sUA levels by SEL-212 on the dissolution of monosodium urate (MSU) crystals in symptomatic gout patients. Dual-energy computed tomography (DECT) may be used to differentiate urate crystals from calcium by using specific attenuation characteristics, to diagnose gout. DECT uses a computer algorithm to produce color-coded images that render uric acid green, cortical bone blue, and trabecular bone purple. In tophaceous gout patients, DECT may be used for serial volumetric quantification of subclinical tophi to evaluate response to treatment.

Methods: Patients with symptomatic gout (≥ 1 tophus, gout flare within 6 months or gouty arthropathy) and elevated serum uric acid (sUA) ≥ 6 mg/dL were treated with fixed doses of pegadricase (0.2 mg/kg or 0.4 mg/kg) alone or in combination with SVP-Rapamycin (0.05 to 0.15 mg/kg). SEL-212 was infused in 28-day cycles x3 doses followed by challenge with pegadricase alone on 28-day cycles x2 doses, or in 28-day cycles x5 combination doses of SVP-Rapamycin and pegadricase. To investigate changes in uric acid deposits, DECT scans of hand/wrist, feet/ankles, and knees will be performed as an exploratory measure for at least 2 patients in study cohorts which included fixed doses of pegadricase (0.2 mg/kg or 0.4 mg/kg) in combination with SVP-Rapamycin (0.1 to 0.15 mg/kg), during the screening visit, treatment period 3, treatment period 5 or at early termination visit.

DECT images were analyzed by Arthritis Research Canada (ARC) by two DECT Radiologists utilizing a Syngo Via DECT software package.

Results: As of 31 May 2018, an initial DECT scan was performed in 24 patients (143 dosed patients), with 10 patients undergoing a follow-up DECT scan.

The demographics for patients who received a follow-up DECT scan were 44 - 71 years old (mean 57.7 years), male 80%, Black or African American 70%, and Caucasian 30%. Mean BMI at baseline was 31.8 kg/m², with 50% of patients being obese. Mean duration of gout was 6.6 years.

The mean sUA at the screening visit was 8.3 mg/dL. Time between the initial and most recent/follow-up DECT scan ranged from 77 - 147 days (mean 103 days), with a mean change in total urate volume of -1.53 cm³ (range: 0.1 to -11.44 cm³).

Figure 1: DECT Scan Images Showing Reduction of Urate Volume After Exposure to SEL-212

Conclusion: SEL-212 has a significant impact on the reduction of urate deposits in symptomatic gout patients with hyperuricemia as confirmed by DECT.

Session Date: Tuesday, October 23, 2018

Session Title: Imaging of Rheumatic Diseases Poster III: Other Modalities

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Functional decline and reduced quality of life for patients with rheumatoid arthritis (RA) results from chronic changes to joints in patients, including bone erosions and joint space narrowing. Advanced biologic therapies can prevent joint damage progression, and it has been suggested that they can repair bone damage^{1,2}. High resolution peripheral quantitative computed tomography (HR-pQCT) provides measurement of joint space and bone microstructure with high sensitivity and precision. The purpose of this study was to investigate whether HR-pQCT can detect joint damage repair in patients initiating biologic therapies, and whether changes in joint damage are associated with changes in clinical outcomes.

Methods: We recruited 88 participants who met the ACR/EULAR2010 Classification Criteria for RA and were starting on a new biologic agent due to moderate or high disease activity. The 2nd and 3rd MCP joints of the dominant hand were scanned with a HR-pQCT scanner (XtremeCTII, Scanco Medical, 61mm) at 3 and 12 months after initiating the new agent. Participants also underwent a rheumatologist examination for disease activity and self-reported measures of physical (Health Assessment Questionnaire) and hand (DASH Questionnaire) function were collected at these visits, along with the Jebsen hand function test. Joint space volume (JSV) was measured in 3D using an algorithm developed by the SPECTRA collaboration³ (Figure 1). Bone erosion quantification will be completed using a 3D segmentation technique using MIAF-Finger⁴. Individual changes in JSV were classified as increased or decreased if the absolute changes were greater than detection limits based on least significant change.

Results: The cohort was 72.7% female with an average disease activity score (DAS28) of 2.58 at baseline and 2.60 at 9 month follow-up. The average DASH score was decreased to 27.6 from 29.3, while the average HAQ score increased to 0.89 from 0.86. There were no statistically significant changes in clinical results. When compared to detection limits, 73 of

the 84 analyzable joints showed no change in joint space volume, 5 showed an increase and 6 showed a decrease. We found no significant relationships between joint space outcome and disease activity, physical function, or hand function.

Conclusion: In most patients there were no significant changes in joint space as they initiate or change biologic therapies. This may be due to a large detection limit making it difficult to detect changes over a 9 month period. Future erosion analysis will provide further insight on the potential benefits of biologic therapy with regards to the reversibility of bone damage as seen on HR-pQCT.

Session Date: Tuesday, October 23, 2018

Session Title: Imaging of Rheumatic Diseases Poster III: Other Modalities

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Artificial intelligence (AI) techniques including deep learning have been rapidly evolving and shown good performance in many fields over recent years. However, there are few cases that apply these techniques to medical field, since it is difficult to collect dataset for training. In our research, to develop an AI-aided automatic radiographic

scoring system for quantitating degree of bone destruction, we aimed to develop a learning-based model to automatically detect hand joint ankyloses in radiographic images.

Methods: Our method consists three parts: (i) collecting dataset with an annotation tool,(ii) predicting hand joint ankyloses using deep learning, and (iii) visualizing where the model focuses in image. First, to collect and annotate dataset for deep learning efficiently, we developed the annotation tool (Fig. 1). A total of 216 radiographic images of hands were randomly obtained from patients who had visited our division at Keio University Hospital in 2015. Forty-three images were identified as having ankyloses in hand joints including wrist joints, MP joints and PIP/IP joints in agreement with a well-trained rheumatologist and radiologist. In learning phase, images were randomly divided into five sets (fold No. 1 to 5) for 5-fold cross validation. We utilized ResNet[1],a deep learning model for classification of images, to predict hand joint ankyloses. In addition, we visualized where the model focuses in image by using Grad-CAM[2]. The ROC analysis was performed to evaluate performance of the model.

Results: As a performance of detecting hand joint ankyloses, our model presented a precision value of 0.78, recall value of 0.86, and F-measure value of 0.82. Mean area under the ROC curve was 0.90 (Fig. 2). When visualizing the result of the model by Grad-CAM, there were some cases where ankylosis in hand joints in the image contributed to the inference results.

Conclusion: A model based on deep learning to automatically detect hand joint ankyloses in radiographic images was developed with relatively small samples, which suggests that the predictive performance may increase by collecting more training dataset. Our developed model needs to be validated in an independent set of images and tested against other experienced doctors. In the next step of development, we are elaborating a plan for a deep learning-based scoring system to evaluate erosion and joint space narrowing.

Session Date: Tuesday, October 23, 2018

Session Title: Imaging of Rheumatic Diseases Poster III: Other Modalities

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Fluorescence optical imaging (FOI) has been used for assessment of inflammation in the hands and has in several cross sectional studies been compared with US and MRI, but no validated scoring systems exist. The aim was in a longitudinal study to validate a new and clinically feasible FOI scoring system for assessments of synovitis in RA hands by comparison with US and determining its sensitivity to change.

Methods: 46 RA patients eligible for initiation or intensification of disease modifying anti-rheumatic drugs and with ≥ 1 clinically swollen joint in the hand, were included and assessed by FOI, US and clinical assessment at baseline and 6 months. FOI image-sets of both wrists and hands were obtained using a Xiralite system unit. The patients received a bolus of i.v. indocyanine green (ICG) 10 seconds after starting the examination, which obtained 1 image/second for 6 minutes. All FOI images were scored by two readers for synovitis at the wrist, MCP and PIP joint levels in both hands. The novel synovitis scoring is based on the assumption that inflamed tissue would demonstrate a more rapid enhancement than surrounding tissues. For each joint, the images were assessed sequentially from start to peak enhancement. Synovitis was defined as a sharply margined enhancement with clear delineation from surrounding tissues and correct anatomical location, lasting ≥ 3 seconds. The width of the pathology fulfilling these criteria was compared to the width of the joint at the 3rd second of enhancement of that particular joint, and scored 0-3 for synovitis (total range 0–66) The readers were blinded to patient data, but not chronology, and had previously showed a high intra- and inter-reader agreement (ICC:0.70-0.92).

For US assessment, a GE Logiq E9 US unit with a high frequency linear 6-15 ML probe and with Doppler settings optimised for slow flow. Synovitis was scored from 0-3 for grey scale (GS) and Doppler using the OMERACT US synovitis

Table 1. Change in synovitis scores, DAS28, and VAS Global, and their standardized response means, during 6 month of follow-up, for all patients.

All sites - imaging modality (n=46)		Baseline	6.5 months		P	SRM	
FOI	Median [25th-75th]	31	[5-39]	-8.9	[-15.1-7]	<0.01	0.85
	Mean \pm SD	52.0	± 7.8	-7.0	± 6.3		
Grey scale US	Median [25th-75th]	9.2	[6-22]	-9	[-15-3.6]	<0.01	0.88
	Mean \pm SD	55.8	± 14.5	-9.1	± 9.3		
Doppler US	Median [25th-75th]	8	[3-24]	-3.5	[-11.0-3.9]	<0.01	0.82
	Mean \pm SD	9.5	± 8.8	-6.6	± 6.0		
DAS28-CRP	Median [25th-75th]	9.0	[4-5.4]	-2.0	[-3.8-0.5]	<0.01	0.95
	Mean \pm SD	4.2	± 3.3	-1.7	± 1.8		
VAS Global	Median [25th-75th]	48.5	[18-81]	-30	[-62-6.5]	<0.01	1.0
	Mean \pm SD	42.7	± 24.8	-30.0	± 31.7		

P, p-value for Wilcoxon's test for change of paired data between 2 time points; N, number of patients; SRM, standardized response mean; FOI, Fluorescence optical imaging; DAS28, Disease Activity Score for 28 joints, using C-reactive protein; VAS Global, patient global visual analogue scale. Values in brackets are values at 25th and 75th percentiles

scoring system by two trained assessors with a previously documented high intra- and inter-reader agreement (wKappa:0.88-0.95).

Agreement for status and change scores was assessed using single measure intraclass correlation coefficients (ICCs) and Spearman correlation coefficients (rho). Responsiveness was assessed using standardized response mean (SRM)

Results: Baseline scores, change scores and their respective SRMs are presented in table. 1. The mean SRM was good for all parameters

ICC and rho between FOI and US total scores were low for both readers at baseline (range 0.3-0.4) ($p<0.05$), and low to moderate (range 0.31-0.54) ($p<0.01$) for change scores.

Conclusion: A moderate correlation with US for change over time, and good responsiveness, were found for a new FOI scoring system. FOI may potentially prove useful for monitoring RA patients in clinical trials and practice.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Imaging of Rheumatic Diseases Poster III: Other Modalities

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Rituximab (RTX) is an effective and well-tolerated therapeutic option in rheumatoid arthritis (RA) patients with insufficient response to TNF α inhibitors. However, the exact time point of RTX re-therapy often varies and objective parameters (e.g. imaging, such as MRI and/or musculoskeletal ultrasound [US]) are not yet included in the RA treatment strategy [PMID: 28264816]. The aim of this study was to evaluate the ability of the fluorescence optical imaging Xiralite[®] (FOI) to predict RTX re-therapy in RA patients - in comparison to clinical, laboratory and US.

Methods: In this study, n=31 patients with established RA were included and prospectively followed over one year by DAS28, patient's global VAS (0-100 mm), CRP/ESR, US7 score (for synovitis and tenosynovitis in greyscale and power Doppler of the clinically dominant hand/foot; [PMID: 19714611]), and by FOI (phases 1-3 and PrimaVistaMode [PVM]) at baseline (before RTX), and after 3,6, and 12 months. The need for RTX re-therapy was defined according to DAS28 response criteria by EULAR.

Results: Of the included 31 patients (female 77.4%, mean age 60.1 \pm 11.4, mean disease duration 14.9 \pm 7.1 years), n=14 (45.2%) received RTX re-therapy within 12 months: n=3 after 6 months (mths), n=4 after 7 mths, n=5 after 9 mths, and n=2 after 10 mths. In the group with RTX re-therapy, FOI in PVM mode was the only parameter that presented significant increase (beta 0.40, CI 0.08-0.71; $p=0.013$) – compared to the group without re-therapy. In the prediction model via receiver operating characteristic (ROC) analysis, FOI in PVM reached the highest values of all imaging parameters (phases 1-3, US) at baseline for the prediction of re-therapy over one year with an area under the curve (AUC) of 0.64 (OR 0.9, CI 0.79-1.03), however, without significance ($p=0.117$). Patient's VAS and CRP had similar predictive power with AUC of 0.66 each (each $p=ns$).

Conclusion: The FOI Xiralite[®] in PVM is able to discriminate between groups with and without need for RTX re-therapy better than other included imaging parameters. It is able to predict the need for RTX re-therapy with comparable predictive power to patient's VAS and CRP.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Imaging of Rheumatic Diseases Poster III: Other Modalities

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) induces systemic osteoporosis as well as osteoporotic change in the bones having arthritis by RA. Recently immune complex and anti-citrullinated peptide antibody (ACPA) in the blood of patients with RA have been reported to promote bone absorption through activating osteoclast directly (Negishi-Koga T. Nat Commun 2015, Harre U. J Clin Invest 2012). Bone absorption by ACPA is mainly observed in the trabecular bone of the cancellous bone (Lundberg K. Ann Rheum Dis 2016). In the present study, we investigated the effects of ACPA on bone microstructure of the distal radius in the patients with RA using high-resolution peripheral quantitative computed tomography (HR-pQCT).

Methods: Subjects were 95 female patients with DMARDs naïve rheumatoid arthritis without bone erosion (N-group) and 14 female patients with primary osteoporosis (OP-group). The N-group was classified into 52 APCA-negative patients (NN-group, 59 ± 2 y.o.) and 43 APCA-positive patients (PN-group, 58 ± 2 y.o.). For subgroup analyses, 29 subjects in NN-group and 14 subjects in PN-group were selected with excluding active synovitis based on the ultrasonographic findings of the wrist and finger joints. All the patients underwent HR-pQCT in Nagoya Rheumatology Clinic. The bone microstructural parameters to be studied were Tt.vBMD (Total volumetric Bone Mineral Density), Ct(Cortical).vBMD, Tb (Trabecular).vBMD, Tb.Meta.vBMD, Tb.Inn (Inner).vBMD, Tb.N (the number of trabecula), Tb.Th (Thickness), Tb.Sp (Separation), Ct.Th (Thickness), Ct.Po (Porosity), and Ct.PoDm (Pore Diameter).

Results: Significant difference ($p < 0.05$) was observed in averaged left and right Ct.Po (cortical porosity) between NN-group (0.006 ± 0.001) and PN-group (0.010 ± 0.001). In NN-group, the parameters negatively correlated with age were Tt.vBMD, Ct.vBMD, Tb.vBMD, Tb.Meta.vBMD, Tb.Inn.vBMD, Tb.N, and Ct.Th, whereas positively correlated parameters were Ct.Po and Ct.PoDm. PN-group differed from NN-group only in that no significant negative correlation was observed in Tb.Inn.vBMD and Tb.N. These results suggested that ACPA affects the number of trabecula beyond the age-related change. The subgroup analyses excluding the effect of active synovitis represented that the difference between left and right Tb.N was significantly larger in PN-group ($0.154 \pm 0.057/\text{mm}$) than in NN-group ($0.070 \pm 0.014/\text{mm}$) and OP-group ($0.056 \pm 0.037/\text{mm}$) ($p < 0.05$). The results mean ACPA have a left-right asymmetrical effect on the trabecular structure in the distal radius without relation to synovitis, while the pathophysiological mechanisms are not clear.

Conclusion: The results suggested that APCA affects trabecular structure in patients with rheumatoid arthritis independent from the activity of synovitis.

Technetium Tc 99m Tilmanocept: A Targeted Immunodiagnostic Radiopharmaceutical for the Assessment of Synovial Macrophage Activity in Rheumatoid Arthritis

Arash Kardan¹, Allison Kissling², **Bonnie Abbruzzese**², Ahmad Ismail², Rachael Hershey², Carley Hartings², David Ralph², Izabela Gierach², Michael Blue², Hannah Bailey², Christopher Gablemann², Katherine Repp² and Frederick Cope²,

¹Charles F. Kettering Memorial Hospital and Wright State University Boonshoft School of Medicine, Dayton, OH,

²Navidea Biopharmaceuticals, Inc., Dublin, OH

Figure 1. A comparison of Tc 99m tilmanocept imaging in the bilateral hands of a healthy control subject vs. an active RA subject. Imaging was performed at 60 ± 15 minutes and 180 ± 15 minutes post-IV administration of the maximum study dose of 400 μ g tilmanocept radiolabeled with 10 mCi of Tc 99m. No localization was visualized on planar imaging in the healthy control subject. Localization (red circles) to areas of suspected macrophage activity was observed on planar imaging in the bilateral wrists and second MCP of the left hand in the active RA subject. These findings were further observed with greater joint-specific anatomical delineation on SPECT/CT.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Imaging of Rheumatic Diseases Poster III: Other Modalities

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Activated macrophages are a critical component of the inflammatory etiology of RA. It is well established that these macrophages perpetuate joint inflammation and destruction through the release of pro-inflammatory cytokines and chemokines, and that a preponderance of these macrophages express the CD206 marker. Tc 99m tilmanocept selectively targets CD206 with high affinity ($K_D = 2.76 \times 10^{-11}$). In this report, we describe planar and SPECT/CT imaging findings from a clinical study examining the safety and efficacy of intravenously (IV) administered Tc99m tilmanocept in subjects with active RA and healthy controls (HC). These results provide significant insight into the longitudinal quantitative immunodiagnostic potential of tilmanocept in the rheumatological space.

Methods: Subjects with active RA were required to have a clinical diagnosis of moderate to severe RA in accordance with the 2010 ACR/EULAR criteria and a DAS28 score of ≥ 3.2 . HC subjects were required to be deemed clinically free of any inflammatory disease. The images in this report were obtained at 60 ± 15 minutes post-IV administration of the maximum study dose of 400 μ g tilmanocept radiolabeled with 10 mCi of Tc99m. Subjects with active RA underwent static planar imaging of the whole body and bilateral hands followed by additional SPECT/CT in areas of increased radiopharmaceutical uptake. HCs underwent static planar imaging of the whole body and bilateral hands only.

Results: Tc 99m tilmanocept was well-tolerated and no drug-related adverse events were observed. Static planar images of joints in active RA subjects demonstrated significant Tc 99m tilmanocept localization to disease-involved joints of the shoulders, knees, hands, and feet. These findings were further interrogated on SPECT/CT, which revealed greater anatomical delineation of localization specifically to the joint space. Whole body and joint-specific static planar imaging in healthy control subjects failed to demonstrate joint-specific localization.

Conclusion: There are currently no FDA-approved functional imaging modalities for the assessment of macrophage-driven arthropathy in patients with clinically diagnosed active RA. The ability to detect synovial macrophage activity from planar and SPECT/CT imaging makes Tc99m tilmanocept a valuable immunodiagnostic agent for the evaluation of joint-specific inflammation, characterization of joint-level pathobiology, and individualization of treatment. Further studies examining the concordance of tilmanocept uptake with CD206-positive synovial macrophages over time may provide valuable, clinically significant insight into the ability to quantitatively monitor treatment response.

Session Date: Tuesday, October 23, 2018

Session Title: Imaging of Rheumatic Diseases Poster III: Other Modalities

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: High resolution peripheral quantitative computed tomography (HR-pQCT) allows in vivo 3 D imaging of human joint microstructure and joint space width (JSW) at an isotropic resolution of 82µm voxel size. As JSW is regarded a surrogate measure of arthritic disease activity, the HR-pQCT-derived JSW may qualify as an important rheumatologic outcome measure. To date, JSW was reproducibly computed with an ICC of 0.989 in healthy subjects with maintained metacarpophalangeal (MCP) joints. However, data are still lacking on the performance of HR-pQCT-derived JSW measurements in arthropathies with very narrow joint spaces. One of those arthropathies is hemochromatosis arthropathy (HA) which is characterized by excess iron-induced joint destruction and hook-like osteophyte formation. **Objective:** We aimed to determine in patients with HA the 1) feasibility of the HR-pQCT-derived JSW algorithm 2) performance of the JSW-algorithm in this narrow-spaced cohort by assessing failure rates in relation to the corresponding joint space widths 3) JSW cut-off value, below which the JSW algorithm is set to fail and would further require manual re-segmentation.

Methods: MCP of 29 HA patients were imaged on one HR-pQCT system (XtremeCT, Scanco Medical AG). From the images, the mean joint space width (JSW) was semi-automatically computed via an in-house developed and well-validated software as the mean of local 3D widths across the joint space. In case the software failed at the first JSW analysis attempt, each MCP was semi-manually segmented by a trained operator to separate the metacarpal head and phalangeal base and a second JSW-analysis was attempted.

Results: 76.2% of all 84 MCP joint spaces were successfully segmented at the first attempt. 22.6% required semi-manual intervention while in one case the JSW remained undeterminable even after semi-manual correction due to direct contact between the metacarpal and phalangeal bones. MCPs were next subdivided by JSW tertile and failure rates recorded. In MCPs of the lowest tertile software failure rates were highest with 50% failure in MCP2 joints, 44.4% in MCP3 joints, and 22.2% failure rates in MCP4 joints. MCPs ranging in the medium JSW tertile showed 22% (MCP2), 33% (MCP3) and 22% (MCP4) failures rates. Joints with a JSW in highest tertile were all successfully segmentable at the first attempt (0% failure rate). When looking at a JSW-cut-off value, below which the JSW software would fail its segmentation, we observed that in general a mean JSW of <1.4 mm was associated with a high rate of software failure. In MCP 3 and 4 a cut-off of a mean JSW of ≥ 1.41 mm resulted in 100% successfully segmented cases.

Conclusion: Our findings suggest that HR-pQCT-derived JSW quantification in MCP joints is feasible even in arthropathies with known narrow joint spaces such as hemochromatosis arthropathy. Moreover, performance analysis indicated that the software performance seems to be best in the joints belonging to the highest JSW tertile, while joints with a mean JSW of 1.4 mm or smaller seem to fail very likely at the first analysis attempt and do require semi-manual corrections. Further work is needed to assess failure rates in other patient cohorts.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Imaging of Rheumatic Diseases Poster III: Other Modalities

Table 1

		Type of FTT based on MRI n (% of all FTT)		Type of Surgery Performed		
		rFTT	cFTT	RCR	RTSA	Other
AHI	< 7mm	7 (8%)	19 (22%)	0	6	1
	> 7mm	40 (46%)	21 (24%)	14	5	2
Total n		47 (54%)	40 (46%)	14	11	3

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Full-thickness rotator cuff tears (FTT) can be a debilitating cause of shoulder pain and loss of function. Delay in surgical evaluation may result in inoperable changes of the cuff. Advanced imaging involving MRI is often required for diagnosis and provides additional description of the true acuity of the FTT – those with changes of tendon retraction, fatty infiltration, or atrophy are more likely to have a chronic FTT (cFTT) resulting in less successful surgical repair. An acromiohumeral interval (AHI) of < 7mm identified on shoulder x-ray has also been associated with cFTT and less successful surgical treatment. The aim of this study was to determine if x-ray findings of AHI < 7mm was associated with inoperable cFTT in our clinical setting, and could thus be used in place of the more expensive MRI study intriguig initial evaluation of potential FTT into surgical referral vs. medical management.

Methods: Shoulder MRIs performed at the Salt Lake City Veterans Affairs Hospital from March 2017 to March 2018 were identified. Those with a shoulder x-ray within 12 months preceding the MRI were included for review. MRIs were categorized by type of FTT – those potentially repairable without chronic changes (rFTT) and those with changes suggesting inoperability (cFTT). X-rays were then viewed and AHI was calculated. A chi-square analysis was performed on MRI results and AHI > or < 7mm. Finally, charts were reviewed to identify those who received surgical intervention and the type of surgery performed – rotator cuff repair (RCR), reverse total shoulder arthroplasty (RTSA), or other.

Results: 315 shoulder MRIs were identified as having an associated x-ray and included for review. Of those, 87 (28%) had a FTT. Type of FTT and surgery performed are presented in Table 1. There was a significant association between AHI and rFTT or cFTT (chi-square 10.96, p<0.005).

Conclusion: Our findings are consistent with previous reports, where an AHI < 7mm was associated with a FTT that is likely inoperable. Only patients with an AHI > 7mm underwent RCR. We suggest when a FTT is suspected based on clinical exam, the AHI should be measured and if < 7mm, conservative management should be pursued over advanced imaging and surgical referral. This point of triage will hopefully limit unnecessary and expensive imaging where results are unlikely to change initial management, thus improving access to MRI when a delay in care could be detrimental to the patient.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Imaging of Rheumatic Diseases Poster III: Other Modalities

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Primary Sjögren's syndrome (pSS) is a chronic autoimmune disease that affects exocrine glands. It can generate pulmonary compromise due to dysfunction of the glandular epithelium of the airway. To know the prevalence of pulmonary involvement in patients with pSS in our environment; to detail clinical characteristics associated with pulmonary involvement; to compare demographic, clinical, serological and therapeutic characteristics of patients with and without pulmonary involvement in pSS.

Methods: Retrospective descriptive study. Patients diagnosed with pSS (American-European criteria 2002) were included from 2010 to 2017. Abnormal salivary gland biopsy (SGB) was considered to grades III and IV of the Chisholm and Mason classification. Multivariate analyzes were performed comparing pSS with pulmonary involvement versus pSS without this involvement; $p < 0.05$ value was considered statistically significant. The results were analyzed with the software SPSS 19.0.

Results: 197 patients were included, 180 (90%) were women. The mean age at diagnosis was 54 ± 13.62 years. The most frequent symptoms were xerostomia in 166 (83%) patients and xerophthalmia in 178 (89.0%). In 25 (12.5%) patients, pulmonary involvement was diagnosed by high resolution computed tomography (HRCT), 19 (76%) with interstitial lung disease (ILD) and 6 (24%) with bronchiectasis in the absence of DILD; 21 (10.5%) patients had a history of smoking. The most frequent pattern of ILD was nonspecific interstitial pneumonia (NSIP) in 68.4%, followed by lymphocytic interstitial pneumonia (LIN) and usual interstitial pneumonia (UIP) with 15.78% in both groups. Erythrocyte sedimentation rate (ESR) > 50 mm/h was observed at the time of diagnosis in 26 (13.0%) patients, and elevated C-reactive protein (CRP) in 22 (11.0%), median value of 0.06 (RIQ 0-0.39). Anemia was observed in 14 (7.0%) patients, leukopenia in 16 (8.0%) and hypergammaglobulinemia in 47/81 (58.0%). SGB was abnormal in 179 (89.5%), grade III in 75 (37.5%) and IV in 104 (52.0%). Regarding treatment, 61 (30.5%) received hydroxychloroquine, 56 (28.0%) prednisone < 20 mg / day and only 5 (2.5%) prednisone ≥ 20 mg / day. Three (1.5%) patients died during the 7 years of follow-up. In the univariate analysis, it was observed that patients with pSS and pulmonary involvement were associated with greater age at the time of diagnosis (61 ± 10.75 vs 53 ± 13.7 , $p = 0.004$), smoking history (40% vs 4%, $p < 0.001$); ESR > 50 mm/h at diagnosis (36% vs 9.9%, $p = 0.002$), high CRP (36% vs 7.6%, $p < 0.001$), anemia (20% vs 5.3%; $p = 0.02$), greater use of hydroxychloroquine (60% vs 26.9%, $p = 0.002$) and greater use of prednisone at doses > 20 mg / day (12% vs 1.2%, $p = 0.01$) with respect to patients with pSS without pulmonary involvement. In the multivariate analysis, statistical significance was maintained for smoking (OR: 31, 95% CI: 4.513-212.970, $p < 0.001$) and high CRP (OR: 10.49, 95% CI: 1.609-68.405, $p = 0.014$).

Conclusion: The pulmonary involvement in pSS was mainly associated with a history of smoking and was observed more frequently in older patients, with high inflammatory parameters and anemia.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Imaging of Rheumatic Diseases Poster III: Other Modalities

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with ankylosing spondylitis (AS) are at increased risk for cardiovascular disease (CVD), although strategies to detect subclinical CVD are poorly characterized. The aim of this study was to assess left ventricular (LV) systolic and diastolic function by speckle tracking echocardiography (STE) to detect subclinical left ventricular

dysfunction in patients with AS without known CVD. We also tested if CVD activity in AS was associated with lower LV systolic function independently of traditional cardiovascular risk factors.

Methods: Two-dimensional, Doppler, tissue Doppler, and STE assessments were performed in 44 patients with AS (Ankylosing Spondylitis Disease Activity Score (ASDAS-CRP) ≥ 1.3), 20 patients with inactive disease (ASDAS-CRP < 1.3), and 26 healthy controls. AS diagnoses fulfilled the modified New York criteria. None of the enrolled patients or healthy individuals had known cardiac disease. LV systolic function was assessed by ejection fraction (EF) and global longitudinal strain (GLS). LV diastolic function was assessed by septal e' , lateral e' , left atrial maximum volume index (LAVI), average E/e' ratio, and peak tricuspid regurgitation velocity.

Results: Mean patient age was 31-35 years with 91-95% males in all groups. The average disease duration for patients with active and inactive AS was 9 years. LV EF was normal in all patients and controls and did not differ between groups ($p \geq 0.43$). GLS was significantly reduced in active AS patients compared with inactive AS patients (21.9 ± 2.02 vs 24.4 ± 2.73 , $p < 0.0001$) and controls (21.9 ± 2.02 vs 24.0 ± 2.00 , $p = 0.0001$). In multivariate analyses, active AS and increasing levels of disease activity by ASDAS-CRP score were associated with lower GLS after adjustment for other covariables that included age, sex, body mass index, systolic blood pressure, and disease duration. Septal e' and lateral e' were decreased in active AS patients compared with controls (9.30 ± 2.08 vs 10.5 ± 1.78 , $p = 0.01$ and 12.9 ± 2.95 vs 14.9 ± 2.91 , $p = 0.007$), respectively, but not inactive AS patients ($p \geq 0.11$). LAVI was not significantly higher in active AS patients versus controls or inactive AS patients ($p \geq 0.10$). The average E/e' ratio was higher in active AS patients compared with controls (8.13 ± 1.97 vs 7.25 ± 1.10 , $p = 0.04$) but not inactive AS patients ($p = 0.27$). GLS, septal e' and lateral e' , LAVI, and average E/e' did not differ between inactive AS and controls ($p \geq 0.49$). Tricuspid regurgitation did not differ among the three groups, and the velocity was far less than 2.8 m/s generally used as the cut-off for diagnosis of LV diastolic dysfunction.

Conclusion: GLS is significant reduced in Active AS patients compared with Inactive AS patients and healthy controls. Active AS is associated with lower LV systolic myocardial function despite normal LV EF. Patients with Active AS may also have impaired left ventricular diastolic function. Speckle tracking echocardiography may be a useful tool for early detection of impaired LV function in patients with AS. Disease activity in AS was associated with lower LV systolic function independently of traditional cardiovascular risk factors.

Abstract Number: 2216

Detection of Left Ventricular Regional Function in Primary Sjögren's Syndrome Patients without Cardiac Symptoms, As Assessed By Feature Tracking Cardiac Magnetic Resonance Imaging

Atsuma Nishiwaki¹, Natsumi Ikumi², Hitomi Kobayashi^{3,4}, Yasuyuki Kobayashi⁵, Isamu Yokoe⁴, Yosuke Nagasawa⁶, Kaita Sugiyama⁶, Takamasa Nozaki⁶, Mitsuhiro Iwata⁴, Noboru Kitamura⁴ and Masami Takei⁴, ¹Hematology and Rheumatology, Nihon University School of Medicine, Tokyo, Japan, ²Division of Hematology and Rheumatology, Nihon University School of Medicine, Tokyo, Japan, ³Advanced Biomedical Imaging Informatics, St. Marianna University School of Medicine, Kawasaki, Japan, ⁴Division of Hematology and Rheumatology, Nihon University School of Medicine, Tokyo, Japan, ⁵Advanced Biomedical Imaging Informatics, St. Marianna University School of Medicine, Kawasaki, Japan, ⁶Nihon University School of Medicine, Tokyo, Japan

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Imaging of Rheumatic Diseases Poster III: Other Modalities

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The risk of major cardiovascular (CV) events and the long-term CV outcome in patients with primary Sjögren's syndrome (pSS) remain unclear. Myocardial disease is typically clinically silent, only manifesting as myocardial dysfunction after an extended preclinical phase. Feature-tracking (FT) cardiac magnetic resonance (CMR) imaging can reliably be used to assess myocardial function in patients with early dysfunction. Left ventricular (LV) global longitudinal peak systolic strain (GLS) is prognostic of adverse cardiovascular outcomes in various patient populations. Global circumferential peak systolic strain (GCS) is a predictor of congestive heart failure. We sought to measure GLS and GCS using FT-CMR in pSS patients without cardiac symptoms. Furthermore, we aimed to evaluate the association of GLS and GCS with pSS status and severity.

Methods: pSS patients without cardiac symptoms were enrolled. Patients and with no history and/or clinical findings of systemic or pulmonary hypertension, coronary artery disease, valvular heart disease, atrial fibrillation, diabetes mellitus, or dyslipidemia underwent non-contrast CMR. Disease activity was assessed using the EULAR Sjögren's Syndrome Disease Activity Index (ESSDAI). Minor salivary gland biopsy was documented in 85% of patients. Salivary gland biopsy data were classified using the focus score (FS). All subjects underwent evaluation of LV regional function, as measured by FT-CMR. GLS and GCS were calculated in the 16 segments of the whole LV. Group comparisons were made using the Wilcoxon rank sum test, Fisher's exact test, and t-test where appropriate.

Results: We compared 52 patients with pSS (100% women; mean age, 53.2±9.6 years). A total of 11 patients (21%) had Raynaud's phenomenon (RP). The mean of ESSDAI was 2.5±2.6. The GCS in the RP positive group and FS≥2 group decreased more than that in the RP negative group and FS<2 group (p=0.009, p=0.008, respectively). The GCS tended to decrease in the ESSDAI≥4 group compared to the ESSDAI<4 group (p=0.057). Receiver operating characteristic curve analysis showed that GCS reliably detected RP and FS≥2 (area under the curve, 0.75 and 0.72, respectively). GCS in the pSS group was not associated with CV risk factors or other pSS status. GLS in the pSS group was not associated with CV risk factors or pSS status such as RP, FS, ESSDAI.

Conclusion: To our knowledge, this is the first prospective study of LV regional function in pSS and the only study to explore the associations of pSS characteristics with CMR-assessed GCS and GLS. We suggest that RP, FS≥2 and ESSDAI≥4 may predict LV regional dysfunction observed in patients with pSS without cardiac symptoms. We should consider the possibility of subclinical regional function in patients with pSS, even in those with low scores for FS or ESSDAI.

Session Title: Metabolic and Crystal Arthropathies – Basic and Clinical Science Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: There has been an increase in the prevalence of gout over the past two decades, with increasing number of patients presenting at younger age. The clinical characteristics, including comorbidities, concomitant medications, treatment compliance and outcome, have been described in patients with gout, although few studies are available in patients with early onset gout.

Methods: We retrospectively reviewed 327 patients (≥18 years of age) with a diagnosis of gout from 2008 to 2016 using the database of a multispecialty group practice in New England. Patients with ≥ 2 diagnosis of gout per ICD10 code (M10.*) or ICD-9 code (274.xx) recorded on ≥ 2 dates, or 1 diagnosis of gout and ≥ 1 pharmacy prescription of gout-related medications were identified. Patients were classified into age first diagnosed < 30(Group 1), age 30-40 (Group 2) and age >40 (Group 3). All charts of patients with age ≤ 40 by the index date were reviewed, with exclusion of those who did not meet the 2015 ACR/EULAR gout classification criteria or without adequate information. Then, we randomly selected and reviewed 100 out of 7216 patients from Group 3. Clinical characteristics and treatment were compared among the three groups.

Results: We identified 87 patients in Group 1 and 140 patients in Group 2. Patients within Group 1 had significantly higher male/female ratio, body mass index and uric acid level at the time of diagnosis (Table 1). Positive family history of gout was more frequently identified in Group 1. While the prevalence of cardiovascular risk factors was higher in elderly patients, the proportion of patients with hypertension and hyperlipidemia was unexpectedly high within Group 1 (41.4% and 48.3%, respectively). The X-rays of peripheral joints available at the time of gout diagnosis exhibited degenerative changes in 24-47% of patients in different age groups; while erosive changes consistent with gout were found only in few patients. The majority of patients in Group 1 fulfilled the 2012 ACR guidelines for initiating urate lowering therapy (ULT) on the basis of frequency of gout attacks, shown in Table 2. The majority of patients in Group 3 fulfilled the 2012 ACR guidelines for ULT on the basis of chronic kidney disease.

U.L.T, urate lowering therapy, CKD, chronic kidney disease

Conclusion: In our population, patients aged ≤ 40 were less likely to achieve target uric acid levels than older patients. In addition, patients with early onset gout frequently have cardiovascular risk factors. Clinicians should be aware that patients with early onset gout may be an undertreated population at increased risk for recurrent gout and cardiovascular diseases.

Abstract Number: 2218

Use of Anakinra in Hospitalized Patients with Acute Crystalline Arthritis

Jean Liew and Gregory Gardner, Rheumatology, University of Washington, Seattle, WA

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Metabolic and Crystal Arthropathies – Basic and Clinical Science Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:: Medically complex individuals may have contraindications to standard therapies for acute arthritis secondary to gout or calcium pyrophosphate disease (CPPD). Observational studies have demonstrated the rapid efficacy of the IL-1 receptor antagonist, anakinra, on acute arthritis attacks. In this retrospective observational study, we demonstrate the efficacy and safety of anakinra in medically complex, hospitalized patients with acute gout and CPPD arthritis.

Methods: Adult patients treated with anakinra during their admissions from 2014-2017 at two hospitals were identified for inclusion. Charts were reviewed for demographics, comorbidities, serum uric acid level, joint involvement, prior treatment, anakinra dosing, response, and adverse effects, concurrent infections, and surgical interventions. Response to anakinra treatment was determined from review of provider documentation, as well as recorded pain scores on a numeric scale.

Results: We identified 100 individuals accounting for 115 episodes of arthritis. This population was 82% male, with an average age of 60 years. Comorbidities included renal disease (45%) and history of organ transplantation (14%). Twenty-six episodes of arthritis occurred in the perioperative setting. Concurrent infection was present in 29 episodes. Joint involvement was monoarticular in 43 episodes, oligoarticular in 56, and polyarticular in 15; one episode presented as a systemic inflammatory response alone. The most commonly involved joints were the knee, ankle, wrist, first metatarsal-phalangeal joint, elbow, and fingers. Eighty-four episodes of arthritis had partial or complete response to anakinra within four days of treatment initiation; 66 episodes had partial or complete response within one day of anakinra administration. There was only a partial response in seven episodes and no response in six. There was insufficient information to determine the response in 14 episodes. Side effects included three instances of leukopenia.

Conclusion: This is the largest observational study of anakinra use in the inpatient setting for the acute treatment of gout or CPPD arthritis. We demonstrated a rapid response to anakinra, with 75% of episodes significantly improving or completely resolving within four days of the first dose. Overall, anakinra was well tolerated. This data supports the use of this biologic agent even in individuals with infections, as well as perioperative individuals, and immuno suppressed transplant recipients

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Metabolic and Crystal Arthropathies – Basic and Clinical Science Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Gout flare due to rapid urate reduction after initiating urate-lowering therapy (ULT) is one of the major issues in the therapy. International guidelines recommend anti-inflammatory prophylaxis for gout flares during the initiation of ULT and colchicine is widely used. However, colchicine is potentially toxic and caution is advised. In addition, a recent study in Japan suggests stepwise dose increase of febuxostat from 10 to 20 then 40 mg/day is better than fixed-dose febuxostat 40 mg/day and is comparable with colchicine prophylaxis for the prevention of gout flares¹, though the dosage of febuxostat in the US is 40 and 80 mg/day. NC-2500 is a novel potent XOR inhibitor and preclinical studies have shown that multiple doses increase the plasma concentration and enhance the urate-lowering effect of NC-2500 unlike febuxostat. This study aimed to assess the safety, tolerability, pharmacokinetics and pharmacodynamics (PD) profiles of NC-2500 in healthy volunteers.

Methods: A Phase 1, randomized, single-blind, placebo-controlled, single and multiple ascending dose study was conducted. Each cohort consisted of 8 subjects, with 6 receiving NC-2500 and 2 receiving placebo orally. A total of 5 cohorts were studied in the single-dose study (10 mg to 160 mg, fasted conditions) and 4 cohorts were studied in the

multiple-dose study (10 mg to 80 mg, fed conditions). The levels of NC-2500 and uric acid in plasma/serum and urine were assayed at predetermined time points. Safety and tolerability were assessed by physical examination, vital signs, electrocardiography, clinical laboratory tests and adverse events (AEs).

Results: The maximum plasma concentration (C_{max}) and the area under the plasma concentration-time curve (AUC) increased dose-dependently in the single and multiple dose studies. The time to reach the C_{max} was approximately 2.0–3.0 hours for single dose and 3.0–5.0 hours for repeated doses. Following repeated dose, plasma concentrations of NC-2500 increased (AUC 1.4-fold and C_{max} 1.5-fold at a maximum) in comparison with the first dose. NC-2500 was hardly excreted into the urine. The serum uric acid (sUA) levels were reduced after single and repeated administrations of NC-2500. Moreover, in repeated doses, the sUA levels decreased to a target range gradually over the 7 days. The incidence of AEs was similar between NC-2500 and placebo treatments and all AEs were mild in severity.

Conclusion: NC-2500 is expected to have potential to resolve the issues of current ULT by its unique PD profiles. As for safety, NC-2500 was considered safe and well-tolerated. Furthermore, NC-2500 was hardly excreted through the kidneys, which can be a favorable profile for patients with renal impairment, frequently observed in gout.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Metabolic and Crystal Arthropathies – Basic and Clinical Science Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Gout flares may often be self-managed, but there is a paucity of population-based data. The aim of this study was to determine the prevalence of self-reported gout and gout flares, the use of urate-lowering therapy, and the association of gout flares with health-related quality of life (HRQoL) in a large community sample.

Flares	Proportion (%)	SF12 PCS	Effect size	p-val
None	58 (50,66)	45 (43,47)	base	
1	17 (12,24)	42 (38,46)	-3 (-7,2)	0.29
>= 2	25 (18,32)	38 (34,42)	-7 (-11,-2)	0.003
Joint p-val				0.012

Methods: The South Australian Health Omnibus Survey is an annual, face-to-face population-based survey. Data collected in the 2017 survey (n = 2977; 65.3% participation rate) included self-reported medically diagnosed gout, allopurinol use (current, previous, never), the number of gout attacks (flares) in the last 12 months, age, gender, body mass index (BMI), relevant comorbidities, socioeconomic status (Index of Relative Socioeconomic Advantage and Disadvantage score, IRSAD) and HRQoL (SF-12). Allopurinol use was used to determine urate-lowering therapy, as this is mandated first line therapy in Australia. Data were weighted to the Australian Bureau of Statistics 2016 census data to reflect the South Australian population. Only participants 25 years and over (n = 2778) were included in the analysis.

Results: The prevalence of self-reported gout was 6.5% (95% CI: 5.5, 7.5), and was more frequent in males, older age, higher BMI, or lower IRSAD groups (p<0.05 in all cases). There was a higher prevalence of ischaemic heart disease (24%), diabetes mellitus (33%), hypertension (54%) and high cholesterol (40%) among participants with gout than amongst those without gout. Only diabetes remained associated after adjustment for sociodemographic variables (p <0.001).

Amongst gout participants, 37.1% (95% CI 29.6, 45.3) reported currently using allopurinol, while 23.2% (95% CI 16.9, 21.0) reported prior use (38% discontinuation rate). Females were less likely to have ever used allopurinol (p = 0.002) and more likely to have discontinued it (p = 0.029).

Frequent flares (defined as >=2 in the last year) were reported by 25% of participants with gout, but only 51% of this group reported current allopurinol use. Frequent gout flares were also more likely with younger age, higher BMI, or current allopurinol use (p<0.05 in all cases). The frequency of gout flares was associated with a lower physical HRQoL (Table 1).

Conclusion: This is the first study to investigate gout flares using a population-based sample. A quarter of gout participants reported frequent gout flares that were associated with reduced physical HRQoL. Current allopurinol use was associated with frequent gout flares, suggesting undertreated disease and suboptimal use of the drug. Determining predictors of flares and ineffective allopurinol use may identify means of improving treatment and reducing flares. Table 1: HRQoL (SF12) physical component score (PCS) by the frequency of flares among participants with gout, adjusted for sociodemographic variables. Brackets enclose 95% confidence intervals.

Session Title: Metabolic and Crystal Arthropathies – Basic and Clinical Science Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Although increasing age is an important risk factor for development of gout, disease can develop in younger people. The aim of this study was to determine the genetic features of people with early onset gout.

Methods: Participants (n=1,648) with gout according to the 1977 American Rheumatism Association (ARA) classification criteria were recruited from primary and secondary care into the Genetics of Gout in Aotearoa / New Zealand study. All participants had a detailed clinical assessment which included recording of age of onset of first gout presentation. The 10 single nucleotide polymorphisms (SNPs) most strongly associated with serum urate (Köttgen et al, Nature Genetics 2013) were genotyped by the Illumina CoreExome microarray platform. Early onset gout was defined as first presentation before the age of 40 years, consistent with the EULAR gout management guidelines (Richette et al, Ann RheumDis 2017). Genetic associations were also tested in two replication cohorts: Eurogout (n=704) and Ardea clinical trial programme (n=755).

Results:: In the Genetics of Gout in Aotearoa study, there were 712 (43.2%) participants with first gout presentation before 40 years of age. Mean (SD) age of onset was 29 (7) years in the early onset group, and 55 (11) years in the late onset group. In the early onset group, there were significantly more men, higher gout flare frequency, and more tophaceous disease compared with the late onset group. Analysis of the serum urate-associated SNPs, stratified by ancestry, demonstrated no significant associations, with the exception of *ABCG2* rs2231142; the presence of *ABCG2* 141K was associated with early onset gout in participants of Eastern Polynesian ancestry (P=0.002), West Polynesian ancestry (P=0.004) and European ancestry (P<0.001). The association with *ABCG2* 141K persisted after adjustment for sex, highest ever serum urate, tophus, gout flare frequency, serum creatinine and body mass index. Analysis of the replication cohorts confirmed association of early onset gout with *ABCG2*rs2231142 (Figure), but not other serum urate-associated SNPs. Compared with no risk alleles, the meta-analysed odds ratio (95% CI) for *ABCG2* 141K heterozygosity (1 risk allele) was 1.49 (1.27-1.75) and for homozygosity (2 risk alleles) was 2.85 (2.01-4.05).

Conclusion: People with early onset gout have more severe clinical features of disease. In contrast to other serum urate-associated SNPs, *ABCG2* 141K is strongly associated with early onset of gout.

Figure. Forest plot showing association between early onset gout and *ABCG2*. Figure shows meta-analysed allelic odds ratio (95% CI).

Construct Validity of Provisional Remission Criteria for Gout: A Dual Energy CT Study

Nicola Dalbeth¹, Christopher Frampton², Maple Fung³, Scott Baumgartner³, Savvas Nicolaou⁴ and Hyon K. Choi⁵,
¹University of Auckland, Auckland, New Zealand, ²University of Otago, Christchurch, New Zealand, ³Formerly Ardea Biosciences, San Diego, CA, ⁴Radiology, University of British Columbia, Vancouver, BC, Canada, ⁵Division of Rheumatology, Allergy, and Immunology, Massachusetts General Hospital, Boston, MA

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Metabolic and Crystal Arthropathies – Basic and Clinical Science Poster II

Background/Purpose: Provisional domains and definitions for gout remission criteria have been proposed using consensus methodology (de Lautour et al, Arthritis Care Res 2016). These criteria include 5 domains: serum urate, tophus, flares, pain due to gout, and patient global assessment (Table). Dual energy CT (DECT) is an advanced imaging technique that allows color coding and volumetric measurement of urate crystal deposition. The aim of this study was to test the construct validity of the provisional remission criteria by examining the association of each domain and the full remission criteria with DECT urate crystal deposition.

Methods: Patients with gout on allopurinol ≥ 300 mg daily for at least 3 months were prospectively recruited into a multicenter DECT study, using monitored enrollment to include approximately 25% of patients with subcutaneous tophi and 50% with serum urate < 6.0 mg/dL. Participants all fulfilled the 1977 ARA gout classification criteria, and attended a standardized study visit, which recorded gout flare frequency in the preceding 12 months, physical examination for tophus, serum urate, and patient questionnaires. DECT of both hands/wrists, feet/ankles/Achilles, and knees were performed using the second-generation Siemens 128-slice Definition Dual Source scanner, and urate crystal volume was measured by 2 DECT radiologists. The relationship between the DECT urate crystal volume and deposition with each domain as well as with the full remission criteria set (all 5 domains achieved) was analyzed.

Results: With the exception of the pain domain, participants fulfilling each remission domain had lower DECT urate crystal volume than those who did not fulfil the domain (Table). All 5 remission domains were achieved in 23/152 (15.1%) participants. Of those fulfilling the provisional remission criteria, 10/23 (43.5%) had DECT urate crystal deposition, compared with 95/129 (73.6%) of those not fulfilling their mission criteria ($P < 0.001$). The median (range) DECT urate crystal volume was 0.00 (0.00-0.46) cm^3 for those fulfilling the remission criteria, compared with 0.08 (0.00-19.53) cm^3 for those not fulfilling the criteria ($P = 0.002$). In multivariate linear regression (of ranked DECT crystal volume data) and logistic regression models including all 5 remission domains, the serum urate and tophus domains were independently associated with the DECT urate crystal volume and deposition.

Conclusion: In people with gout taking allopurinol, a state of remission defined by the provisional remission criteria is associated with lower DECT urate crystal deposition. Furthermore, those domains most directly related to monosodium urate crystal pathophysiology (serum urate and tophus) are independently associated with urate crystal deposition measured by DECT. Overall, these findings support the construct validity of the provisional gout remission criteria.

Table. DECT crystal volume (cm^3) according to each remission domain and provisional remission criteria. Data are presented as median (range). Results of Mann-Whitney U test analysis are shown.

Domain (definition)	Fulfilled	Not fulfilled	P
Serum urate (< 0.36 mmol/L)	0.03 (0.00-4.63) n=77	0.09 (0.00-19.53) n=75	0.016
Tophus (absence)	0.05 (0.00-1.23) n=104	0.21 (0.00-19.53) n=48	0.001
Flares (none in the last 12 months)	0.05 (0.00-2.57) n=70	0.11 (0.00-19.53) n=82	0.011
Pain due to gout (< 2)	0.07 (0.00-5.11) n=104	0.08 (0.00-19.53) n=48	0.43

Proton Pump Inhibitors and Risk of Calcium Pyrophosphate Deposition (CPPD) in a Population-Based Study

Tuhina Neogi¹, Christine Peloquin¹, Yuqing Zhang^{1,2}, Hyon K. Choi³, Robert Terkeltaub⁴ and David T. Felson¹, ¹Clinical Epidemiology Research and Training Unit, Boston University School of Medicine, Boston, MA, ²Division of Rheumatology, Allergy, and Immunology, Massachusetts General Hospital, Harvard Medical School, Boston, MA, ³Division of Rheumatology, Allergy, and Immunology, Massachusetts General Hospital, Boston, MA, ⁴VA San Diego Healthcare System, San Diego, CA

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Metabolic and Crystal Arthropathies – Basic and Clinical Science Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: There are no therapies available that specifically target CPPD, with treatment limited to symptomatic management. Hypomagnesemia is a recognized risk factor for CPPD, and its treatment has been advocated for CPPD management. Proton pump inhibitors (PPIs) are an under-appreciated cause of hypomagnesemia, and may therefore be an important risk factor for CPPD. We examined the relation of PPI use to the development of CPPD.

Methods: We conducted a time-stratified propensity score(PS)-matched cohort study in The Health Improvement Network (THIN), a general practitioner (GP) EMR database representative of the UK population. Using greedy matching, we matched incident PPI users to incident H2 blocker users by PS (see table) to reduce confounding by indication in 1-year cohort accrual blocks to account for secular trends. We identified incident cases of individuals diagnosed with pseudo gout or chondrocalcinosis (hereafter labelled CPPD) using READ codes from 1995-2015 among those aged 50-89 who were enrolled in a GP practice for ≥ 1 year prior to study entry. We excluded subjects with a gout diagnosis. We compared the risk of incident CPPD among incident PPI users vs. incident users of H2 blockers using Cox proportional hazard models, censoring at time of drug switch, additionally adjusting for the PS model variables. Because of the small number of cases, we also conducted a nested case-control study within the same cohort, matched 1:4 by age and gender using risk-set sampling, evaluating incident use of PPI vs. non-use and vs. H2-blockers prior to incident CPPD.

Results: We identified 81,011 PPI initiators, who were PS-matched 1:1 to H2 blocker initiators, with mean age 66, mean BMI 26.7, 59% female. Overall, covariates were well-balanced in the two groups (SMDs <0.1). There were 118 and 58 incident cases of CPPD among the PPI and H2 blocker initiators, respectively. Incident PPI use was associated with a HR of 1.19 (95% CI 0.86-1.64) of incident CPPD compared with incident H2 blocker use. In the case-control study, when comparing PPI initiators to non-users, the adjusted OR was 1.58 (95% CI 1.39-1.79). When also considering H2 blocker use, the adjusted ORs were elevated for both PPI and H2 blocker users compared with non-users (ORs 1.79 and 1.52, respectively (see Table)); the ratio of ORs for PPI:H2 blocker initiators was similar to PS-matched study HR (ratio of ORs ~ 1.2 ; HR was ~ 1.2).

Conclusion: In this population-based study of GP-recorded CPPD, compared with incident H2 blocker use, incident use of PPIs was associated with a modest but nonsignificant increased risk of CPPD. We were limited by small number of cases. The elevated risk with H2 blocker use may represent residual confounding (e.g., NSAID with gastroprotective use for undiagnosed CPPD) or potentially a true biologic effect, e.g., due to general gastric acid suppression affecting Mg absorption. Nonetheless, the risk appears higher with PPIs than H2 blockers.

PS-matched cohort study:	PPI initiators		H2 Blockers initiators
Subjects (n)	81011		81011
Incident CPPD	118		58
Total Follow-Up Time (person-years (PY))	528978		327609
Mean Follow-up Time (years)	6.53		4.04
Incidence Rate (per 1000 PY)	0.22		0.18
PS-matched HR	1.21 (95% CI 0.88, 1.67)		
PS-matched HR, additionally adjusting for PS model covariates*	1.19 (95% CI 0.86, 1.64)		
Case-control study** 1:	CPPD cases		Controls

Session Title: Metabolic and Crystal Arthropathies – Basic and Clinical Science Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Sex-specific differences in the effect size of genetic variants on serum urate levels have been described, with *SLC2A9* variants having a greater influence on serum urate in women and *ABCG2* variants exerting a greater effect in men. However, it is unclear whether serum urate-associated genetic variants display sex-specific differences in gout risk. The aim of this study was to systematically examine whether serumurate-associated genetic variants differ in their influence on gout risk in men and women.

Methods: This research was conducted using the UK Biobank Resource. Participants of European ethnicity, aged 40-69 years, and with genome-wide genotypes were included. Exclusions were: self-reported sex mismatch with genetic sex, genotyping quality control failure, and related individuals. Gout was defined using a validated definition (self-report of gout or urate-lowering therapy use). The thirty single nucleotide polymorphisms (SNPs) associated with serum urate reported by Köttgen et al (Nature Genetics 2013) were tested for their association with gout in men and women. Gene-sex interactions on gout risk were analysed using logistic regression models that included an interaction term. Age, body mass index, renal failure and diuretic use were included as variables in all models. A further sensitivity analysis was performed by excluding pre-menopausal women. Data are reported at experiment-wide significance ($P < 0.0017$).

Results: Data were available for 359,876 participants, including 7,342 gout cases (2.0%). Gout was present in 6768 (4.1%) men and 574(0.3%) women; odds ratio (95% CI) for men 13.42 (12.32-14.62) compared to women. In the group overall, association of gout at experiment-wide significance was observed for 22 of the 30 serum urate-associated SNPs tested. In men, experiment-wide association was observed for the same 22 SNPs, and in women for four of the 30 SNPs. Evidence for gene-sex interaction was observed for *ABCG2* (rs2231142) and *PDZK1* (rs1471633), with the interaction at *PDZK1* driven by an absence of effect in women and at *ABCG2* by an amplified effect in men (Table). Similar findings were observed in the sensitivity analysis when excluding pre-menopausal women. For the other SNPs tested, including *SLC2A9* (Table), no significant gene-sex interactions were observed.

Conclusion: In a European population, *ABCG2* and *PDZK1* gene-sex interactions exist for gout risk, with serum urate-raising alleles exerting a greater influence on gout risk in men than in women. In contrast, other serum urate-associated variants including *SLC2A9*, do not demonstrate significant gene-sex interactions for gout risk.

Table: Association and interaction between selected serum urate-associated genetic variants and sex for gout risk according to risk allele presence.

Gene	SNP	Serum urate raising allele	Women		Men		Gene-sex interaction* P
			Risk allele absent Referent OR	Risk allele present OR (95% CI)	Risk allele absent OR (95% CI)	Risk allele present OR (95% CI)	
<i>ABCG2</i>	rs2231142	T	1	1.62 (1.35-1.94)	11.99 (10.81-13.30)	28.65 (25.73-31.90)	4.59×10^{-5}
<i>PDZK1</i>	rs1471633	A	1	0.92 (0.77-1.10)	10.54 (9.00-12.34)	13.61 (11.69-15.85)	3.67×10^{-4}
<i>SLC2A9</i>	rs12498742	A	1	4.13 (2.05-8.30)	18.09 (8.85-36.98)	55.62 (27.78-111.37)	0.42

Abbreviations: CI, confidence interval; OR, odds ratio. * Adjusted for body mass index, age, renal failure, diuretic use.

Exploring the Relationship between Gout and Diffuse Idiopathic Skeletal Hyperostosis (DISH): An Epidemiologic and Genetic Study

Michael Corkill¹, Ruth Topless², Adam Worthington³, Robert Mitchell³, Kate Gregory³, Lisa K. Stamp⁴, Matthew Brown⁵, Tony R. Merriman² and Nicola Dalbeth⁶, ¹North Shore Hospital, Auckland, New Zealand, ²University of Otago, Dunedin, New Zealand, ³Waitemata District Health Board, Auckland, New Zealand, ⁴University of Otago, Christchurch, New Zealand, ⁵Translational Genomics Group, Institute of Health and Biomedical Innovation, Queensland University of Technology, Translational Research Institute, Brisbane, Australia, ⁶University of Auckland, Auckland, New Zealand

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Metabolic and Crystal Arthropathies – Basic and Clinical Science Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Gout has been reported to be a risk factor for development of diffuse idiopathic skeletal hyperostosis (DISH), a condition characterized by abnormal bone formation of the soft tissues affecting the spine and also peripheral skeleton. However, it is unknown whether gout has a direct effect on development of DISH or whether this association occurs due to shared risk factors, such as raised body mass index or other features of the metabolic syndrome. The aim of this study was to determine whether gout has a direct effect on the development of DISH.

Methods: Participants in the Genetics of Gout in Aotearoa Study with lateral chest or thoracic spine radiographs were included in this analysis. All participants in this analysis were 30 years or older at the time of the imaging test. Each radiograph was scored for the presence of DISH by a trained rheumatologist or musculoskeletal radiologist. For the purposes of this analysis, DISH was defined as definite and probable DISH, according to the criteria of Ustinger et al, 1985. Participants with imaging features of spondyloarthropathy; spondylosis with osteophytes bridging 2 consecutive vertebrae; or features of DISH and another pathology (primarily disc space narrowing) were not included in the analysis. Genotypes were available for the two major gout-associated single nucleotide polymorphisms (SNPs); *ABCG2* rs2231142 and *SLC2A9*rs734553. Genome-wide genotype data generated on the Illumina CoreExome platform were used to estimate the heritability of DISH using the Genome-wide Complex Trait Analysis (GCTA) tool with prevalence estimates of 41% in Māori and Pacific people and 22% in European (Bateman et al 2018). Clinical and genetic associations with DISH were analysed by logistic regression adjusted by age at recruitment, age at the time of the imaging test, sex and, as appropriate, by metabolic co-morbidity.

Results: The analysis included 816 participants, including 535 (65.6%) with gout. DISH was present in 205/816 (25.1%) of all participants, including 138/453 (30.5%) of those of Polynesian ancestry (Māori or Pacific people) and 67/363 (18.5%) participants of European ancestry. DISH was present in 155/535 (29.0%) participants with gout, and 50/281 (17.8%) participants without gout; unadjusted odds ratio (95% CI) 1.85 (1.29-2.65), $P=7.6 \times 10^{-4}$. However, after adjusting for body mass index, DISH was not associated with gout; adjusted odds ratio (95% CI) 1.28 (0.86-1.91), $P=0.22$. Consistent with this, no association was observed between DISH and the gout-associated *ABCG2* and *SLC2A9* SNPs ($P>0.52$ for all comparisons). The heritability (percent variance in phenotype explained by the genome-wide genotype data) was estimated to be 0.37 (se=0.56) in people of Polynesian ancestry and 0.24 (se=2.1) in people of European ancestry.

Conclusion: DISH is more common in people with gout. Although DISH does demonstrate a heritable component, genetic analysis does not support the hypothesis that gout is causal for DISH. The relationship between gout and DISH is likely due to shared risk factors, particularly raised body mass index and other features of the metabolic syndrome.

Gout and the Risk of Incident Dementia in the Elderly: A Medicare Claims Study

Jasvinder A. Singh¹ and John Cleveland², ¹Rheumatology, University of Alabama at Birmingham, Birmingham, AL, ²University of Alabama at Birmingham, Birmingham, AL

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Metabolic and Crystal Arthropathies – Basic and Clinical Science Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The pursuit of a link between gout/hyperuricemia and dementia has led to contradictory results. Most observational studies, including population-based studies, showed that hyperuricemia was associated with a higher risk of dementia and less cognitive dysfunction, while a few studies found hyperuricemia to be associated with a lower risk of dementia. Recently, a large French population-based study in the elderly (65 years or older) showed that hyperuricemia was associated with a higher risk of dementia and with MRI changes of aging in the brain. Our objective was to assess whether gout in the elderly is associated with a risk of incident dementia.

Methods: We used the 5% Medicare claims data for this observational cohort study. We used multivariable-adjusted Cox proportional hazard models to assess the association of gout with incident dementia, adjusting for potential confounders/covariates including demographics (age, race, gender), comorbidities (Charlson-Romano comorbidity index), and medications commonly used for cardiac diseases (statins, beta-blockers, diuretics, and angiotensin converting enzyme (ACE)-inhibitors) and gout (allopurinol and febuxostat).

Results: In our cohort of 1.71 million Medicare beneficiaries, 111,656 had incident dementia. The crude incidence rates in people without and with gout were 10.9 and 17.9 per 1,000 person-years, respectively. In multivariable-adjusted analyses, gout was independently associated with a significantly higher hazard ratio of incident dementia, with a hazard ratio [HR] of 1.15 (95% CI, 1.12,1.18); sensitivity analyses confirmed the main findings. Compared to age 65 to <75 years, older age groups were associated with 3.5 and 7.8-fold higher hazards of dementia; hazards were also higher for females, Black race or people with higher medical comorbidity.

Subgroup analyses indicated that gout was significantly associated with dementia in patients without key comorbidities (CAD, hyperlipidemia, CVD, diabetes, hypertension) with HR ranging 1.19-1.52, but not in patients with each of these comorbidities, except CAD, with HR 0.99-1.04 (**Table 1**).

Table 1. Association of gout with incident dementia, in pre-defined subgroups by the presence/absence of CAD, hyperlipidemia, CVD, diabetes or hypertension

	Multivariable-adjusted (Model 1)		Multivariable-adjusted (Model 1)	
	HR (95% CI)	P-value	HR (95% CI)	P-value
Gout	No CAD 1.19 (1.15, 1.24)	<.0001	CAD 1.04 (0.99, 1.09)	0.14
Gout	No Hyperlipidemia 1.28 (1.23, 1.33)	<.0001	Hyperlipidemia 1.02 (0.98, 1.07)	0.26
Gout	No CVD 1.19 (1.15, 1.22)	<.0001	CVD 1.00 (0.94, 1.07)	0.99
Gout	No Diabetes 1.23 (1.19, 1.27)	<.0001	Diabetes 0.99 (0.95, 1.05)	0.81
Gout	No Hypertension 1.52 (1.43, 1.60)	<.0001	Hypertension 1.01 (0.97, 1.04)	0.68

Gout*CAD p-value <0.0001; Gout*hyperlipidemia p-value <0.0001; Gout*CVD p-value <0.0001;

Gout*diabetes p-value <0.0001; Gout*hypertension p-value <0.0001.

Conclusion: Gout was independently associated with 17-20% higher risk of incident dementia in the elderly. Future studies need to understand the pathogenic pathways involved in this increased risk.

What Should be the Goals of Gout Therapy? a Patient Perspective

Jasvinder A. Singh, Rheumatology, University of Alabama at Birmingham, Birmingham, AL

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Metabolic and Crystal Arthropathies – Basic and Clinical Science Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: In the absence of any available current evidence, our primary objective was to assess the goals of gout treatment from a patient perspective and secondary objective was to examine any differences by sex.

Methods: A convenience sample of consecutive patients with doctor-diagnosed gout seen at a community-based outpatient clinic were invited at the University of Alabama at Birmingham. All groups answered the key question: What should be the goals of gout treatment? Sex-stratified nominal groups were conducted until saturation was achieved. Responses were collected verbatim, discussed and rank-ordered by each participant.

Results: Thirty-six patients with doctor-diagnosed gout participated in 12 nominal groups, six male only, five female only and one group with both. Mean age was 61.9 years (SD,12.3), mean gout duration was 13.3 years (SD, 12.5), 53% were men, 64% African-American, 42% retired, 47% currently married, 87% were using either allopurinol and/or febuxostat, and 40% had had no gout flares in the last 6 months. Nominal group participants brought up several ideas that mapped to 9 key concepts, which are briefly described in the section below (**Table 1**). The top five treatment goals accounted for 91% of all votes and included: (1) Prevent and better manage flare-ups and improve function (25%); (2) Eliminate flare-ups/disease remission(30%); (3) Diet and activity modification/Lifestyle change (13%); (4) Patient education and public awareness (12%); and (5) Medication management and minimization of side effects (11%). When examining the top-rated concern for each nominal group, the first two goals were nominated by four groups each, diet/activity modification and medication management by 1 group each, and patient education by 3 groups. There were no differences evident by sex in top-ranked treatment goal.

Conclusion: People with gout identified and rank-ordered treatment goals relevant to them. Providers of gout care need to be cognizant of these goals. Disease management concordant with these treatment goals might lead to a more satisfied, informed patient. Clinical trialists should consider inclusion of these outcomes in gout domains due to their relevance to patients with gout.

Table 1. Number of nominal groups with relative ranking of each major theme/concept

	Male groups (n=6)	Female groups (n=5)	All groups (n=12*)	Male groups (n=6)	Female groups (n=5)
	Top theme/concept			Among top 3 themes	
A. Prevent and better manage flare-ups and improve function	2	2	4	4	3
B. Eliminate flare-ups/remission	2	2	4	3	3
C. Diet and activity modification/Lifestyle change	1	0	1	4	2
D. Patient education and public awareness	1	1	3*	2	2
E. Medication management and minimization of side effects	1	0	1	2	2
F. Lowering the serum urate/uric acid	0	0	0	2	1
G. Need for additional Healthcare services	0	0	0	1	1
H. Address the emotional burden of flare-ups	0	0	0	1	0
I. Comorbidity management	0	0	0	1	0

* Included one group with mixed population of both men and women.

Total exceeds possible sum, when there was a more than one major theme/concept tied for the top theme or among the top three themes.

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Metabolic and Crystal Arthropathies – Basic and Clinical Science Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The safety of allopurinol in the setting of chronic kidney disease (CKD) has been a controversial issue for many years. The perceived increased risk of adverse reactions has made many providers hesitant to use allopurinol in the setting of CKD, leading to inadequate control of this highly prevalent malady. Rheumatologists are generally thought to endorse higher doses of allopurinol in CKD than nephrologists. As there is much overlap between the gout and CKD patient populations, this may lead to conflicting messages regarding allopurinol safety and dosing, which may threaten adherence to urate-lowering therapy. These differences may reflect an educational need or areas where improved communication between providers is important.

A script concordance test (SCT) for gout developed by Siaton et al has demonstrated evidence of validity including high reliability (Cronbach's alpha = 0.93), large effect size (Cohen's d = 0.90), and generalizability for use across multiple institutions and learner groups.^{1,2} This study aimed to use the SCT to explore differences between academic nephrologists and rheumatologists regarding the use of allopurinol in the setting of gout and CKD.

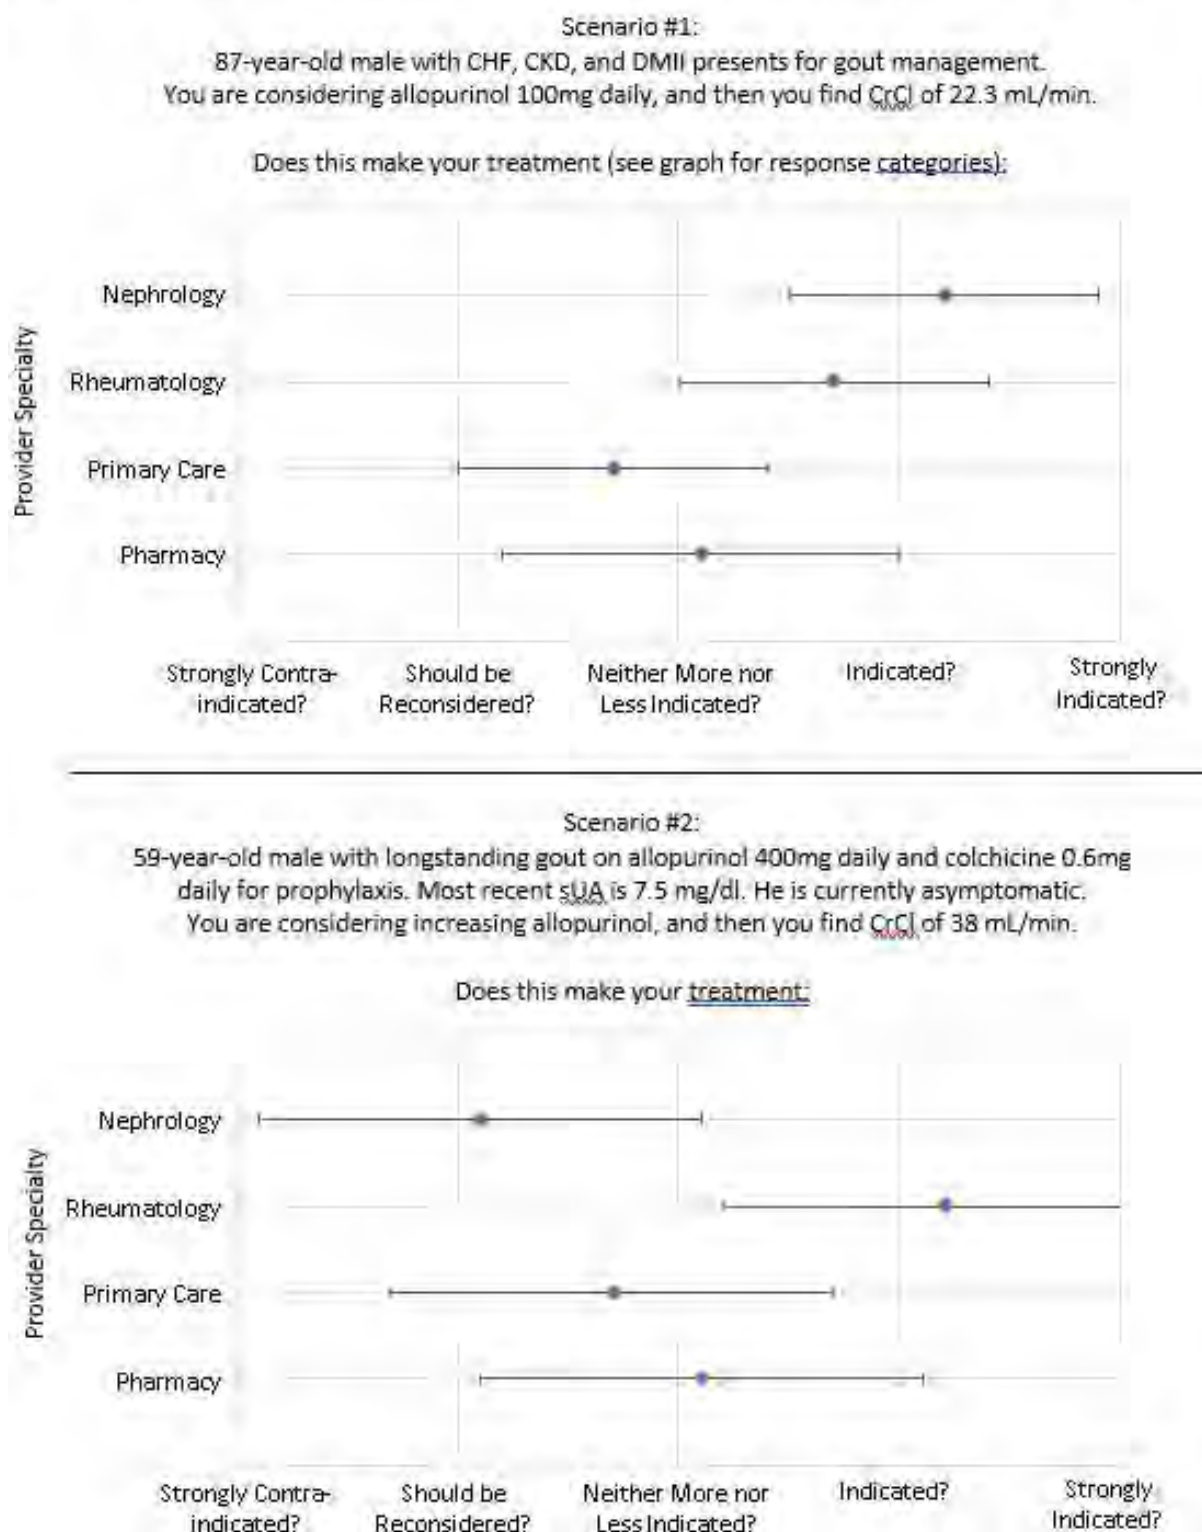

Methods: Using the REDCap online platform, questions from the SCT relevant to the treatment of gout with allopurinol in the setting of CKD were sent via e-mail to attending nephrologists, rheumatologists, primary care providers, and pharmacists associated with training programs of University of Utah. With Excel, response rates were calculated, descriptive statistics were analyzed, and significance of differences in mean responses between specialty groups were examined using 2-tailed Student's t-test.

Results: To date, 38 responses (29%) have been received; details are presented in the Table below:

Specialty	Surveys Sent	Total Responses (Rate)	Rank				
			Instructor	Assistant Professor	Associate Professor	Professor	Other
Nephrology	30	9 (30%)	1	4	1	3	0
Rheumatology	16	10 (63%)	0	3	5	1	1
Primary Care	30	10 (33%)	3	5	1	0	1
Pharmacy	53	9 (17%)	0	0	2	0	7
Total	129	38 (29%)	4	12	9	4	9

Conclusion: Nephrologists were more willing than rheumatologists to start allopurinol at a relatively high dose in CKD (100 mg daily), but were less likely to increase allopurinol to achieve a serum uric acid (sUA) target. This highlights what may be a fundamental disagreement on the mechanism and timing of allopurinol toxicity and the importance of achieving sUA target, where rheumatologists believe it is more dangerous when first being initiated, and nephrologists are less concerned about achieving target sUA in CKD.

Can We Predict Inadequate Response to Allopurinol Dose Escalation? Analysis of a Randomized Controlled Trial

Lisa K. Stamp¹, Peter T. Chapman², Murray Barclay³, Anne Horne⁴, Christopher Frampton¹, Paul Tan⁵, Jill Drake⁶ and Nicola Dalbeth⁵, ¹University of Otago, Christchurch, New Zealand, ²Christchurch Hospital, Christchurch, New Zealand, ³Medicine, University of Otago, Christchurch, New Zealand, ⁴Department of Medicine, University of Auckland, Auckland, New Zealand, ⁵University of Auckland, Auckland, New Zealand, ⁶University of Otago, Christchurch, Christchurch, New Zealand

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Metabolic and Crystal Arthropathies – Basic and Clinical Science Poster II

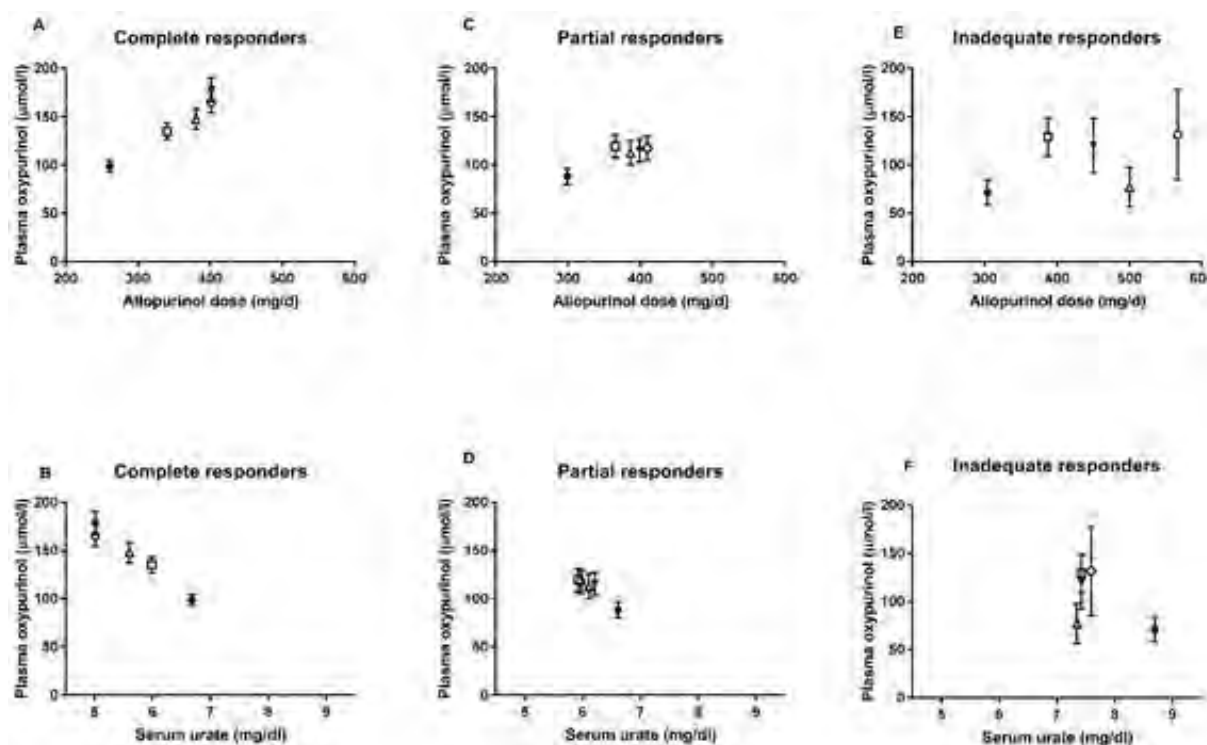

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The two most common causes of inadequate serum urate (SU) lowering with allopurinol are low adherence and under-dosing. Those who are adherent, but do not reach target SU despite allopurinol dose escalation, could be considered to have “inadequate response” to allopurinol. The aim of this study was to investigate the reasons for not reaching target SU and to identify factors that predict response and inadequate response in a randomised controlled trial of allopurinol dose escalation in gout.

Methods: We analysed data from participants in a 24-month open, randomized, controlled, parallel-group, comparative clinical trial. Participants undergoing allopurinol dose escalation were classified as having: *complete response* (CR) –reached target SU at month 9 and 12 of the dose escalation phase **OR** if still dose escalating at month 9 reached target SU by month 12; *partial response* (PR) – reached target at some stage but not fulfilling criteria for CR; or *inadequate response* (IR) – did not reach target SU at anytime. The analysis was designed to minimise the effects of two common causes of inadequate response; low adherence and under-dosing.

Results: Inadequate response was uncommon, occurring in 13/150 (8.7%), compared to 82 (54.7%) CR, and 55 (36.6%) PR. Mean (SEM) SU was higher at the end of the 12-month dose escalation in the IR group compared with both CR and PR groups; 7.6 (0.31) vs. 5.01 (0.06) and 5.97 (0.17) mg/dl respectively ($p<0.001$). There was a relatively linear relationship between increasing allopurinol dose and increasing plasma oxypurinol and between increasing plasma oxypurinol and decreasing SU in the CR group (Figure A and B) over the 12-month dose escalation period. Those with partial response had more static dose and SU levels that were close to the target SU while those with inadequate response had no obvious

relationship between allopurinol dose, plasma oxypurinol and SU (Figure C-E). Using ROC curve analysis, baseline $SU \geq 8\text{mg/dl}$ had a sensitivity of 69.2% and specificity of 85.1% in predicting inadequate response. The OR for an inadequate response if baseline $SU \geq 8\text{mg/dl}$ was 11.7 (95%CI 3.3-41.2). For those with baseline $SU \geq 8\text{mg/dl}$ and baseline allopurinol dose $>200\text{mg/d}$, 7/15 (47%) had an inadequate response.

Conclusion: A minority of people with gout never reach target SU when allopurinol dose is increased in a treat-to-target manner. Approximately half of those with $SU \geq 8\text{mg/dl}$ despite allopurinol $>200\text{mg/d}$ have an inadequate response to dose escalation.

Figure: Relationship between mean allopurinol dose and mean (SEM) plasma oxypurinol and mean serum urate and mean (SEM) plasma oxypurinol in the complete response, partial response, and inadequate response groups at months 0 (●), 3 (□), 6 (Δ), 9 (▼) and 12 (○) of the dose escalation period.

Session Date: Tuesday, October 23, 2018

Session Title: Metabolic and Crystal Arthropathies – Basic and Clinical Science Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: To explore the number of patients on haemodialysis (HD) or peritoneal dialysis (PD) with gout in Canterbury and to determine how many were receiving urate lowering therapy (ULT) and achieving target serum urate (SU).

Methods: Individuals with gout in Canterbury receiving dialysis for at least 90 days on 1st February 2017, 1st January 2016 and 1st January 2015 were identified. Pre-dialysis SU was recorded and SU levels for two days immediately post dialysis were estimated. These estimates were then used to estimate the percentage time serum urate was $<0.36\text{mmol/l}$ using linear interpolation. Results were compared between those on ULT and not on ULT.

Results: 61/216 (28.8%) dialysis patients had gout. Mean age was 61 years (23-84), 46/61 (75.4%) were male and 37/61 (60.7%) were European. 33/61 (54%) were receiving HD. 42/61 (68.9%) were receiving ULT, all allopurinol with a mean (SD) dose of $116.0 \pm 66.9\text{mg/d}$. A total of 936 pre-dialysis serum urate values were available from the 61 people with gout with a median (range) number of tests per participant of 15 (3-42). 46% of participants had a pre-dialysis $SU <0.36\text{mmol/l}$ on less than 25% of occasions and 23% of participants were below target SU on 76-100% of occasions (Figure). There was no significant differences between those receiving HD and PD (median 35.3% vs. 20.0% $p=0.39$) and between those taking ULT and those not on ULT (median 34.5% vs. 27.8% $p=0.55$) in terms of %pre-dialysis urate below target (figure). The mean reduction in SU 24 and 48 hours post HD were 41% and 12% respectively as calculated from the previous study. The percentage time SU was below target two days post HD was only 41%, with no difference in those on or off ULT (43% vs 36%; $p=0.55$).

Conclusion: Gout is a common disease affecting ¼ dialysis patients in Canterbury. The majority of our study patients were receiving ULT with allopurinol. Dialysis alone is insufficient to lower SU and the use of ULT should be considered in those who remain above target SU using a treat to target SU approach.

Figure1:a) Percentage time at target in a) HD vs PD, b) on and off ULT and c) post HD

An Ancestral-Specific Interaction of TRIM46 with a Past-History of Smoking May Influence Gout Risk

Niamh Fanning¹, Tony R. Merriman², Amanda Phipps-Green², John Pearson³, Ruth Topless², Murray Cadzow², Douglas White⁴, Nicola Dalbeth⁵ and **Lisa K. Stamp**⁶, ¹Medicine, University of Otago, Christchurch, Christchurch, New Zealand, ²University of Otago, Dunedin, New Zealand, ³University of Otago, Christchurch, Christchurch, New Zealand, ⁴Department of Rheumatology, Waikato Clinical School, Hamilton, New Zealand, ⁵University of Auckland, Auckland, New Zealand, ⁶University of Otago, Christchurch, New Zealand

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Metabolic and Crystal Arthropathies – Basic and Clinical Science Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Gout is caused by an interplay of genetic and environmental factors. Epidemiological and prospective studies suggest that current-smoking may be protective for developing gout and that smoking cessation may increase risk, although there are conflicting data. The aim of this study was to identify interactions between smoking, genes and the risk of gout.

Methods: New Zealand (NZ) East and West Polynesian and European people with (n=582) or without gout (n=645) genotyped at 10 loci, were compared with 349,748 Europeans from the UK Biobank. The 10 loci were urate-transporter genes (*SLC2A9*, *ABCG2*, *SLC22A11*, *SLC22A12*, *SLC17A1*), gout-associated genes encoding apolipoproteins (*APOA1* and *APOC3*), and loci previously shown to interact with smoking and serum urate (*GCKR*, *TRIM46* and *HNF4G*). Gout was defined by ACR criteria or by self-report and urate-lowering therapy use. Current- and ex-smokers were each compared to never-smokers. The interaction effect on gout between risk allele count and smoking was modelled at each loci and for each population, adjusted for age, gender, alcohol and BMI. Odds ratios (OR) and 95% confidence intervals were calculated. NZ populations were analyzed separately, and combined by meta-analysis, adjusting for genetic admixture using the first 10 principal components generated from genome-wide genotype data. A Bonferroni corrected $p < 0.005$ was used.

Results: An association between ex-smoker status and increased prevalence of gout was observed in NZ [$OR_{meta}=1.61$ (1.21-2.15), $p=0.001$] and UK Biobank [$OR=1.22$ (1.16-1.29), $p=2.2 \times 10^{-14}$] datasets. No association was observed in current-smokers. The only statistically significant interaction between genotype and smoking on gout risk was between ex-smoker status and *rs11264341-TRIM46* C allele in NZ East and West Polynesians [Interaction $OR_{meta}=0.38$ (0.19-0.75), $p=0.0049$], but not in NZ Europeans ($p=0.63$) or the UK Biobank ($p=0.21$). Meta-analysis of *rs11264341-TRIM46* genotype-stratified East and West Polynesian datasets suggests that the risk of gout is higher in ex-smokers without the C allele [$OR_{meta}=4.20$ (1.72-10.26), $p=0.002$] relative to never-smokers without the C allele, but not significantly different in never- or ex-smokers with the C allele [$OR=1.20$ (0.66-2.21), $p=0.55$; and 1.89 [0.92-3.88], $p=0.08$, respectively]. No gout-associated loci interactions were observed for pooled current- and ex-smokers compared to never smokers in the NZ dataset. Interactions influencing gout observed in the UK Biobank dataset were for current smoking with *rs2231142-ABCG2* and *rs670-APOA1* [Interaction $OR=1.17$ (1.00-1.36), $p=0.04$ and 0.79 (0.66-0.95), $p=0.01$, respectively], however these were not significant following Bonferroni correction.

Conclusion: We demonstrate that ex-smokers have higher prevalence of gout than people who have never smoked, and an ancestry-specific interaction between ex-smoker status and *TRIM46* in New Zealanders of Polynesian ancestry. It is unclear how *TRIM46*, a regulator of axonal microtubule organization and neuron polarity, influences risk of gout. There was little evidence of genetic interaction of the loci assessed with smoking and gout.

Prevalence of Gout in the Surviving U.S. Solid Organ Transplant Population

Mark D. Brigham¹, Thilan Tudor¹, Gavin Miyasato¹, Jeffrey D. Kent², Brian LaMoreaux³ and Brian F. Mandell⁴, ¹Trinity Partners, Waltham, MA, ²Medical Affairs, Horizon Pharma USA, Inc, Lake Forest, IL, ³Horizon Pharma USA, Inc, Lake Forest, IL, ⁴Rheumatology, Cleveland Clinic, Cleveland, OH

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Metabolic and Crystal Arthropathies – Basic and Clinical Science Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Although incidence and survival are frequent topics within the solid organ transplant (SOT) literature, there are no recent publications on the total size of the surviving SOT population. Existing studies of gout in SOT have focused on the incident SOT population. This analysis was performed to characterize the prevalent SOT population and the prevalence of gout within it.

Methods: 2017 U.S. population sizes of kidney, heart, liver, and lung recipients were estimated by combining Organ Procurement and Transplantation Network (OPTN) primary transplant cohort sizes (1988-2017) with previously published survival rates for each annual cohort's time since transplant (0-29 yrs), adjusted for recent improvements in 1-5 yr survival. Gout among prevalent SOT patients was assessed via 2 administrative claims databases: Medicare Fee-For-Service Limited Data Set (5% sample) and a commercial claims sample (IQVIATM Real-World Data Adjudicated Claims – US). Definitions used were – SOT: a claim with an SOT procedure code OR any claim with a history of SOT status code; Gout: ≥ 1 claim with any gout diagnosis code. Total gout prevalence was calculated by weighting Medicare and commercially insured patient estimates by OPTN payer distribution.

Results: 637,231 U.S. patients received a primary kidney (393,953), liver (142,186), heart (66,637), or lung (34,455) transplant between 1988 and 2017. An estimated 355,000 (55.8%) recipients were alive in 2017, comprising 233,000 kidney, 78,700 liver, 29,300 heart, and 14,700 lung recipients. Gout was identified in 11% of prevalent SOT patients in 2016. Higher rates of gout were seen in kidney (13%) and heart (13%) recipients compared to liver (6.4%) and lung (5.3%) recipients ($p < 0.0001$ in both datasets).

Conclusion: Hundreds of thousands of U.S. patients are living with an organ transplant today and these numbers are likely to increase. Within the SOT clinical picture, gout is a frequent co-morbidity of which physicians should be aware. This study suggests a markedly higher rate of gout for the most common SOT types (11%) compared to established rates reported for the general population (e.g. 3.9%). Kidney and heart recipients, with the highest rates of gout, bear much of this disease burden.

Activation and Deficiency of Circulating Mucosal-Associated Invariant T Cells in Patients with Gouty Arthritis

Yong-Wook Park¹, Young-Nan Cho², Hye-Mi Jin¹ and Seung-Jung Kee³, ¹Rheumatology, Chonnam National University Medical School and Hospital, Gwangju, Korea, Republic of (South), ²Rheumatology, Chonnam National University Medical School and Hospital, Gwangju, MN, Korea, Republic of (South), ³Laboratory Medicine, Chonnam National University Medical School and Hospital, Gwangju, Korea, Republic of (South)

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Metabolic and Crystal Arthropathies – Basic and Clinical Science Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Mucosal-associated invariant T (MAIT) cells contribute to protection against certain microorganism infections and play an important role in mucosal immunity. Upon antigen recognition, MAIT cells rapidly produce Th1/

Th17 cytokines, including interferon (IFN)- γ , tumor necrosis factor (TNF)- α , and interleukin (IL)-17, in an innate-like manner. MAIT cells are known to play important roles in autoimmunity, infectious diseases and cancers. In addition, severe MAIT cell abnormalities are seen in patients with metabolic disorders (e.g., obesity and type 2 diabetes), suggesting a potential role in these disorders. However, little is known about the role of MAIT cells in gouty arthritis. Here, we examined the level and function of MAIT cells in patients with gouty arthritis.

Methods: The study cohort was composed of 60 patients with gouty arthritis (10 acute gout, 25 intercritical gout, and 25 chronic gout), 11 hyperuricemia subjects, and 30 healthy controls. MAIT cell, cytokine, CD69, programmed death-1 (PD-1), and lymphocyte-activation gene 3 (LAG-3) levels were measured by flow cytometry. In addition, peripheral blood mononuclear cells (PBMCs) were cultured *in vitro* with MSU crystals, and CD69, PD-1, and LAG-3 expression was assessed by flow cytometry.

Results: Circulating MAIT cell levels were significantly reduced in patients with acute, intercritical and chronic gout, but their capacities for IFN- γ , IL-17, or TNF- α production were preserved. Notably, expressions of CD69, PD-1, or LAG-3 in MAIT cells were found to be elevated in patients with gouty arthritis as compared with healthy controls. Freshly isolated PBMCs from healthy donor subjects were stimulated with MSU crystals. MSU crystals induced the expressions of CD69, PD-1, and LAG-3 in MAIT cells. In addition, MAIT cell levels were significantly higher in synovial fluid than in peripheral blood of gouty arthritis patients, suggesting accumulation of MAIT cells in the synovial fluid of gouty arthritis patients.

Conclusion: This study demonstrates that circulating MAIT cells are activated, numerically deficient in gouty arthritis patients. In addition, circulating MAIT cell deficiency in gouty arthritis patients is related to accumulation into synovial fluid. These findings suggest that MAIT cells play an important role in gouty arthritis.

Liver Safety of Febuxostat Compared with Allopurinol in Gout Patients with Fatty Liver Disease

Jung Sun Lee¹, Seokchan Hong², Jebum Won¹, Oh Chan Kwon², Ji Seon Oh², Yong-Gil Kim², Chang Keun Lee² and Bin Yoo², ¹Division of Rheumatology, Department of Internal Medicine,, University of Ulsan College of Medicine, Asan Medical Center, Seoul, Korea, Republic of (South), ²Division of Rheumatology, Department of Internal Medicine, University of Ulsan College of Medicine, Asan Medical Center, Seoul, Korea, Republic of (South)

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Metabolic and Crystal Arthropathies – Basic and Clinical Science Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Although febuxostat has been widely used for lowering uric acid levels because of its renal safety compared with allopurinol, data on the hepatic safety of febuxostat is limited. Therefore, the purpose of this study was to investigate the hepatotoxicity of febuxostat compared with allopurinol in gout patients with fatty liver disease and the clinical factors associated with hepatotoxicity.

Methods: This study involved gout patients exposed to allopurinol or febuxostat and diagnosed with fatty liver based on liver ultrasonography or CT. Hepatotoxicity was defined as follows: (1) elevation of aspartate transaminase (AST)/alanine transaminase (ALT) at least 3 times the upper normal limit for subjects with normal AST/ALT at baseline and (2) doubling of the baseline AST/ALT for subjects with elevated AST/ALT at baseline. The factors associated with hepatotoxicity were evaluated by Cox regression analysis.

Results: Of 134 gout patients with fatty liver disease, 32 patients (23.9%) received febuxostat, and 102 patients (76.1%) received allopurinol. There was no significant difference in the age, BMI, comorbidity, or fatty liver disease severity between patients taking febuxostat and those taking allopurinol. However, the incidence of hepatotoxicity was significantly lower in the febuxostat group than in the allopurinol group (3/32 (9.4%) vs. 36/102 (35.3%), $p = 0.005$). In multivariate analysis, diabetes (HR: 3.549, 95% CI: 1.374–9.165, $p = 0.009$) and the use of colchicine (HR: 9.122, 95% CI: 4.601–18.084, $p < 0.001$) were associated with hepatotoxicity. In contrast, the use of febuxostat was associated with a lower risk of hepatotoxicity (HR: 0.282, 95% CI: 0.086–0.926, $p = 0.037$).

Conclusion: Febuxostat was well tolerated in gout patients with fatty liver disease in terms of hepatotoxicity. Diabetes and the use of colchicine seem to be important factors related to the risk of hepatotoxicity.

Monosodium Urate Deposition Distribution in the Knees, Hands, and Feet of Treated Gout Patients: A Dual-Energy CT Study

Chio Yokose¹, Nicola Dalbeth², Savvas Nicolaou³, Scott Baumgartner⁴, Jia Hu⁵, Maple Fung⁴, F. Joseph Simeone⁶ and Hyon K. Choi¹, ¹Division of Rheumatology, Allergy, and Immunology, Massachusetts General Hospital, Boston, MA, ²University of Auckland, Auckland, New Zealand, ³Radiology, University of British Columbia, Vancouver, BC, Canada, ⁴Formerly Ardea Biosciences, San Diego, CA, ⁵Heron Therapeutics, San Diego, CA, ⁶Department of Radiology, Massachusetts General Hospital, Boston, MA

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Metabolic and Crystal Arthropathies – Basic and Clinical Science Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Prior studies have demonstrated that monosodium urate (MSU) deposits on dual-energy CT (DECT) are commonly found in joints as well as tendons of the feet and ankles of gout patients. However, no study has systematically evaluated the prevalence of MSU deposition in other joints or tendons, particularly in the knee joints. The aim of this study was to determine the prevalence of MSU deposition among multiple sites in the knees, feet/ankles, and hands/wrists among gout patients treated with urate-lowering therapy (ULT).

Methods: Using standardized acquisition protocols, DECT of the bilateral feet/ankles, knees, and hands/wrists were obtained on 153 patients with a known diagnosis of gout and on allopurinol at a dose of at least 300mg daily for at least 3 months. The patients were prospectively recruited as a part of a non-interventional multi-center study conducted in the US and New Zealand. All patients met 1977 ARA gout classification criteria. The presence of MSU deposition was evaluated at 12 sites in the feet/ankles, 4 sites in the knees, and 15 sites in the hands/wrists by two radiologists familiar with DECT interpretation. To account for the larger number of sites in the feet/ankles and hands/wrists, they were then grouped into 4 sub-regions in the feet/ankles (first MTP, other toes, tarsals, tendons) and 3 sub-regions in the hands/wrists (IP joints, MCPs, carpals).

Results: Among 153 gout patients (92% male) with mean duration of allopurinol therapy of 5 years and average allopurinol dose of 333mg daily, mean serum uric acid (SUA) was 6.1mg/dL and 51% of patients had SUA < 6mg/dL. The most commonly involved region was the feet/ankles followed closely by the knees; the hands/wrists had less MSU deposition (61%, 57%, and 23% respectively). The three most commonly affected sub-regions were the lateral tibiofemoral, patellofemoral, and medial tibio femoral compartments of the knees (42%, 39%, and 37% respectively), followed by the first MTP joint (35%) (Table). The prevalence in the cruciate ligaments was similar to that of Achilles tendons (25% and 26%, respectively).

Conclusion: Among patients with gout on ULT, there was a considerable prevalence of MSU deposition in all three compartments and the cruciate ligament of the knee joint. While these findings could reflect the higher frequency of involvement at these sites, they may also reflect larger volume MSU deposits in the knees which takes longer to resolve on ULT. DECT of the knees adds substantial value when assessing MSU burden and response to therapy among treated gout patients.

Table –Prevalence of MSU deposits

Anatomical locations	Prevalence N = 153 patients	Prevalence N = 306 joints
Lateral tibiofemoral compartment	42%	34%
Patellofemoral compartment	39%	32%
Medial tibiofemoral compartment	37%	28%
First MTP	35%	25%
Achilles tendon	26%	19%
Cruciate ligament	25%	17%
Other toes	17%	12%
Tarsals	13%	11%
Carpals	14%	9%
MCPs	7%	5%
Hand IPs	5%	3%

Contemporary Comorbidity Burden of Gout and Hyperuricemia in the US during the Past Decade (National Health And Nutrition Examination Survey [NHANES] 2007-2016)

Michael Chen-Xu¹, Chio Yokose², Michael Pillinger³ and Hyon K. Choi², ¹General Medicine, Wairarapa District Health Board, Masterton, New Zealand, ²Division of Rheumatology, Allergy, and Immunology, Massachusetts General Hospital, Boston, MA, ³Medicine/Rheumatology, NYU School of Medicine, New York, NY

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Metabolic and Crystal Arthropathies – Basic and Clinical Science Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Precise estimates of the comorbidity burden of gout and hyperuricemia are critical as their presence has important implications for the treatment of both gout and hyperuricemia. We therefore estimated the decadal US prevalence of cardiovascular-renal-metabolic comorbidities according to gout and hyperuricemia status, based on the National Health and Nutritional Examination Survey (NHANES) 2007-2016.

Methods: Using data from 26,332 participants (12,793 men and 13,539 women) aged ≥ 20 years old from NHANES 2007-2016, we determined the prevalence (%) of cardiovascular-renal-metabolic comorbidities according to gout and hyperuricemia status. Obesity was defined as body mass index ≥ 30 kg/m². Other comorbidities were defined based on an affirmative answer to a question asking if a physician or a health professional had diagnosed the said comorbidity. Hyperuricemia was defined as a serum urate level >7.0 mg/dL in men and >5.7 mg/dL in women. All statistical analyses were conducted using survey commands of Stata (Version 15.1, Stata Corporation, College Station, Texas) to adjust for clusters and strata of the complex sample design as well as incorporate sample weights. Population estimates (in millions) were calculated as per the NHANES analytic guidelines.

Results: Among gout patients, 69.4% (6.0 million) had hypertension, 55.9% (4.8 million) were obese, 26.5% (2.3 million) had type II diabetes mellitus (T2DM), 22.5% (1.9 million) had chronic kidney disease (CKD) stage ≥ 3 , 19.9% (1.7 million) had nephrolithiasis[†], 11.8% (1.0 million) had a myocardial infarction (MI), 11.1% (1.0 million) had heart failure (HF), and 8.7% (0.7 million) had suffered a stroke over 2007-2016. Among the US adults with both gout and hyperuricemia, 73.9% had hypertension, 60.8% were obese, 28.5% had CKD stage ≥ 3 , 25.0% had T2DM, 18.2% had nephrolithiasis[†], 11.9% had HF, 11.6% had a MI, and 9.3% had suffered a stroke (**Table**). These prevalences were substantially higher compared with individuals without gout or hyperuricemia. Hyperuricemia without gout was also associated with higher prevalences of comorbidities (all P-values < 0.005 , **Table**). Among individuals with gout, the presence of hyperuricemia conferred additional risk for hypertension, CKD and obesity (all P-values < 0.05 , **Table**).

Conclusion: The findings from this recent, nationally-representative sample of US adults highlight that both gout patients and those with hyperuricemia continue to carry a substantial burden of cardiovascular-renal-metabolic comorbidities. These add to the overall disease burden of gout and hyperuricemia to society, and provide support for the consideration of these comorbidities in optimizing gout and hyperuricemia care in the US.

Table. Prevalence of Comorbidities According to Gout and Hyperuricemia* in NHANES 2007-2016

Comorbidities**	Gout		No Gout	
	Hyperuricemia	No Hyperuricemia	Hyperuricemia	No Hyperuricemia
Hypertension	73.9 (68.6, 78.6)	65.4 (60.9, 69.6)	47.6 (45.5, 49.7)	26.3 (25.2, 27.4)
Obesity (BMI ≥ 30 kg/m ²)	60.8 (55.6, 65.7)	51.4 (45.0, 57.7)	56.9 (54.8, 59.0)	30.6 (29.4, 31.8)
CKD Stage ≥ 3 (GFR < 60)	28.5 (24.2, 33.2)	17.5 (14.4, 21.1)	15.8 (14.5, 17.2)	3.2 (3.0, 3.5)
Type 2 diabetes mellitus	25.0 (20.3, 30.4)	25.7 (21.5, 30.5)	13.0 (11.8, 14.2)	7.8 (7.2, 8.3)
Nephrolithiasis [†]	18.2 (14.0, 23.4)	22.0 (17.9, 26.8)	10.2 (9.0, 11.4)	8.5 (8.0, 9.1)

Table . (Cont'd)

Comorbidities**	Gout		No Gout	
	Hyperuricemia	No Hyperuricemia	Hyperuricemia	No Hyperuricemia
Heart Failure	11.9 (8.8, 15.8)	9.8 (7.5, 12.7)	5.0 (4.3, 5.8)	1.4 (1.2, 1.6)
Myocardial Infarction	11.6 (8.7, 15.4)	11.6 (8.9, 15.2)	4.3 (3.7, 5.0)	2.6 (2.3, 3.0)
Stroke	9.3 (6.2, 13.6)	8.0 (6.1, 10.5)	4.3 (3.8, 4.9)	2.2 (2.0, 2.4)

* Hyperuricemia defined as serum urate >7.0mg/dL for males and >5.7mg/dL for women

** Comorbidities were ordered by the descending prevalence of comorbidities among all individuals with gout and hyperuricemia

† Data missing from NHANES 2015-16

Abstract Number: 2237

Prevalence of Urate-Lowering Therapy Use and Target Urate Level Achievement Among Gout Patients in the United States (National Health And Nutrition Examination Survey [NHANES] 2007-2014)

Michael Chen-Xu¹, Chio Yokose², Michael Pillinger³ and Hyon K. Choi², ¹General Medicine, Wairarapa District Health Board, Masterton, New Zealand, ²Division of Rheumatology, Allergy, and Immunology, Massachusetts General Hospital, Boston, MA, ³Medicine/Rheumatology, NYU School of Medicine, New York, NY

Session Information

Session Date: Tuesday, October 23, 2018

Session Title: Metabolic and Crystal Arthropathies – Basic and Clinical Science Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: To determine the latest national prevalence of urate-lowering therapy (ULT) use and achievement of a therapeutic target serum urate level (SUL) in gout patients, and their predictors in the US (National Health and Nutrition Examination Survey [NHANES] 2007-2014).

Methods: Using data from NHANES 2007-2014, we estimated the prevalence of ULT use and achievement of a therapeutic target SUL in patients with gout. During the home interview of NHANES, all participants were asked about a history of health professional- or physician-diagnosed gout and current prescription medications. We defined ULT as taking allopurinol, febuxostat or probenecid, either alone or in combination, and a therapeutic SUL as <6.0 mg/dL. We conducted logistic regression to examine the potential independent associations with purported factors among gout patients.

Results: The prevalence of ULT usage among US gout patients was 32.8% [95% CI 28.3% to 37.6%] in 2007-2014 (39.0% [95% CI 33.6% to 44.7%] among men and 19.4% [95% CI 15.3 to 44.7%] among women). Allopurinol comprised 95.3% [95% CI 92.2% to 98.4%] of ULT usage. Among gout patients, the mean SULs were 5.8 mg/dL [95%CI 5.5 mg/dL to 6.0 mg/dL] among ULT users and 6.9 mg/dL [95% CI 6.7 mg/dL to 7.1 mg/dL] among non-ULT users (mean difference -1.1 mg/dL [95% CI -1.4 mg/dL to -0.8 mg/dL]). Among gout patients, male sex and chronic kidney disease (CKD) were associated with increased fully-adjusted odds of ULT use (**Table 1**). The prevalence of reaching a therapeutic SUL (<6.0 mg/dL) among gout patients was 38.5% [95% CI 35.3% to 41.7%] in 2007-2014 (32.3% [95% CI 28.3% to 36.5%] among men and 52.0% [95% CI 44.8% to 59.1%] among women). Furthermore, among gout patients, ULT use was associated with a fivefold higher odds for reaching a SUL <6.0 mg/dL. By contrast, male sex, obesity, CKD and thiazide diuretic use were associated with a lower fully-adjusted odds for reaching this target SUL (**Table 2**).

Conclusion: These findings from a nationally-representative samples of US adults indicate that 32.8% of US gout patients are receiving ULT. Among gout patients, males, and those with either obesity or CKD are more often receiving ULT. The benefit of ULT among gout patients in achieving this target SUL appears apparent. Male sex, obesity, CKD and thiazide diuretic use were inversely associated with reaching a therapeutic SUL, suggesting a potential need for more aggressive therapy among these groups.

Table 1. Predictors of ULT Use Among US Gout Patients, NHANES 2007-2014*

ULT Use, % (95% CI)	Unadjusted OR (95% CI)	Age- and sex-adjusted OR (95% CI)	Fully-adjusted OR** (95% CI)
---------------------	------------------------	-----------------------------------	------------------------------

Table . (Cont'd)

	ULT Use, % (95% CI)	Unadjusted OR (95% CI)	Age- and sex-adjusted OR (95% CI)	Fully-adjusted OR** (95% CI)
Age ≥ 65	38.0 (31.4, 45.0)	1.53 (0.98, 2.39)	1.71 (1.10, 2.64)	1.59 (0.97, 2.62)
Male	38.8 (33.0, 45.0)	2.66 (1.90, 3.72)	2.85 (2.08, 3.91)	3.22 (2.28, 4.54)
African-Americans	28.3 (22.7, 34.5)	0.78 (0.50, 1.21)	0.89 (0.56, 1.41)	0.85 (0.54, 1.36)
Obesity	34.5 (28.3, 41.2)	1.67 (0.92, 3.06)	1.94 (1.04, 3.60)	2.06 (1.18, 3.61)
CKD Stage ≥3	40.5 (34.2, 47.1)	1.55 (1.06, 2.26)	1.54 (1.04, 2.27)	1.59 (1.04, 2.44)

Session Title: Metabolic and Crystal Arthropathies – Basic and Clinical Science Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Genome-wide association studies (GWAS) have revealed that the large majority of disease-associated single nucleotide polymorphisms (SNPs) are located in the non-coding regions of the genome. Genetic variation in the genomic regulatory landscape likely plays a crucial role in the pathology of disease. Non-coding variants associated with disease can influence the expression of long intergenic non-coding RNAs (lincRNAs), which in turn function in the control of protein-coding gene expression. Here, we investigate the function of two independent serum urate-associated signals in the genomic region of *MAF* (musculoaponeurotic fibrosarcoma oncogene homolog) and cis-located lincRNAs. *MAF* encodes a poorly understood transcription factor and is one of >30 loci associated with serum urate levels by GWAS and also associated with the risk of gout.

Methods: Publicly available databases accessed were serum urate GWAS summary statistics from Köttgen et al (2013), the Contextualize Developmental SNPs using 3D Information (CoDeS3D) algorithm, the NepheQTL database and expression quantitative trait loci (eQTL) data from the Genotype Tissue Expression (GTEx) database. Luciferase, siRNA knockdown assays and quantitative PCR were done in HEK293 cells. Chromatin immunoprecipitation was performed in HEPG2 cells with b-globin and *ABCC6* as negative and positive controls, respectively. Enhancer assays were done in zebrafish using the ZED vector and cloning allele-specific fragments.

Results: Serum urate-associated variants *rs4077450* and *rs4077451* lie within an enhancer that forms long-range interactions with loci encoding lincRNAs *LINC01229* and *MAFTRR*. We demonstrate that *rs4077450* and *rs4077451* can differentially regulate enhancer activity. Serum urate associated variants are also associated with expressed quantitative trait loci (eQTL) in *LINC01229* and *MAFTRR*, which are both strongly co-expressed with the closest protein-coding gene *MAF*. We show that the enhancer region marked by *rs4077450* and *rs4077451* drives expression in the zebrafish pronephros, recapitulating endogenous *MAF* expression. Depletion of *MAFTRR* and *LINC01229* in HEK293 cells leads to increased *MAF* expression.

Conclusion: Collectively, our results are consistent with the hypotheses that serum urate associated variants at the *MAF* locus mediate long-range transcriptional regulation of lincRNAs *LINC01229* and *MAFTRR*, which in turn repress the expression of *MAF*.

Session Title: Metabolic and Crystal Arthropathies – Basic and Clinical Science Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Calcific tendonitis is a frequent cause of shoulder pain. The calcium deposits are composed of carbonated apatite and their origin stays still largely unknown. Our preliminary results showed that calcific deposits are surrounded by chondrocyte-like cells expressing TNAP ((Tissue Nonspecific Alkaline Phosphatase) and ENPP1 (Ectonucleotide pyrophosphatase/phosphodiesterase 1), two key enzymes involved in the mineralization process [1]. The purpose was to study the ability of cells extracted from rotator cuff tendons to produce apatite crystals and to analyze the phenotype of these mineralizing cells.

Methods: Tenocytes were extracted from rotator cuff tendons removed during shoulder total replacement. These cells were first characterized by their gene expression. To evaluate their ability to mineralize, they were cultured in an “osteogenic medium” (OM) containing dexamethasone 10^{-7} M, ascorbic acid 2P (250 μ M) and β -glycerophosphate (10 mM) or in a control medium (DMEM 3%) for 21 days. At 21 days, mineral deposition was assessed by staining with Alizarin red solution. At 21 days, tenocytes total RNA was extracted and quantitative PCRs (qPCRs) were performed after first strand cDNA synthesis. Primers for the following genes were used: Runx2, Sox9, Collagen I, Collagen II, Collagen III, Collagen X, Osteopontin, Osteocalcin, Bone Sialo Protein (BSP), TNAP, ENPP1, Mohawk homeobox (Mkx), Scleraxis (SCX), Tenomodulin (TNMD), Cartilage Oligomeric Matrix Protein (COMP), Aggrecan, Matrix Metalloproteinase 13 (MMP13) and GAPDH. TNAP enzymatic activity was also assessed in the cells at 3, 7, 14 and 21 days.

Results: Tendon samples were obtained from 5 patients (age 69.6 ± 5.13 years). Four were females. Cells extracted from these tendons expressed collagen I, collagen III, Scleraxis and Mkx, as expected for this type of cells. However, TNMD was very weakly expressed and lost after passage 1. These cells were able to mineralize in the OM although no mineralization was observed in the control medium. The mineralized surface was about 15% of surface of the well. qPCR analyses showed a significant increase of TNAP and ENPP1 expression by cells cultured in OM compared to control cells ($p < 0.05$, Mann-Whitney test). Osteoblast markers (Runx2, osteocalcin, osteopontin, BSP) were not increased by the OM. COMP, a chondrocyte marker was significantly increased and there was a trend to an increase of MMP13 and Collagen X suggesting a hypertrophic orientation. In parallel, in the OM, TNAP enzymatic activity started to increase at 7 days and was significantly higher at 14 and 21 days compared to the control medium.

Conclusion: Cells extracted from tendons of the rotator cuff are able to mineralize in an osteogenic medium. The cells expressed genes associated with a chondrocyte phenotype and these results are interesting considering the histological data previously obtained. Further in vitro experiments are necessary to look at the key role of TNAP in the process.

Session Date: Tuesday, October 23, 2018

Session Title: Metabolic and Crystal Arthropathies – Basic and Clinical Science Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Although considered as uncommon, the hip represents one of the possible targets of gout. To date, hip involvement in patients with gout has been poorly investigated by clinical and/or imaging studies. To the best of our knowledge, this is the first study aimed at assessing the prevalence of monosodium urate (MSU) crystal deposits at the hip in patients with gout. The objective of this study is to investigate the prevalence of the US findings indicative of MSU crystal deposits at the hip in consecutive patients with gout, diagnosed according to the 2015 ACR/EULAR classification criteria.

Methods: Inclusion criteria: synovial fluid analysis positive for MSU crystals or presence of subcutaneous tophi at the physical examination.

Exclusion criteria: prior diagnosis of others crystal related arthropathies, such as CPPD or calcium basic phosphate crystal arthritis, highly suggestive findings of CPPD detected at the knee US exam, previous surgical procedures and/or remarkable injuries of the hip. Each patient underwent a bilateral hip and knee US exam. The US exam was carried out using a My Lab Twice US machine (Esaote S.p.A. Genoa, Italy), working with a linear (3-13 MHz) or, when necessary, a convex probe (2-7 MHz). The US abnormalities indicative of MSU crystals deposition were identified according to the OMERACT definitions. At the hip, the following abnormalities were investigated: intra-articular tophi and/or aggregates, double contour (DC) sign over the hyaline cartilage of the femoral head.

Results: Seventy hips, in 35 patients with gout [age (mean±standard deviation) 69.1±11.2; female/male 1/34, disease duration 10.3±10.8 years], were evaluated. The US examination revealed the presence of one or more US findings indicative of MSU crystal deposits in at least one hip in 15 out of 35 patients (42.8%), in 19 out of the 70 hips (27.1%). Tophi were found in at least one hip in 5 out of 35 patients (14.2%), in 6 of the 70 hips (8.5%). Aggregates were detected in at least one hip in 12 out of 35 patients (34.2%), in 12 out of the 70 hips (17.1%). DC sign was found in at least one hip in 5 out of 35 patients (14.2%), in 6 out of the 70 hips (8.5%). Twenty-eight patients were assessed using a linear probe (3-13 MHz) and the remaining 7 patients were studied using a convex probe (2-7 MHz). Figure 1 shows the US findings indicative of MSU crystal deposits at the hip.

Conclusion: These preliminary results show that the prevalence of hip involvement in patients with gout might be underestimated. Further investigations in a larger cohort of patients are needed to explore the clinical and laboratory features associated with hip involvement in patients with gout.

Session Date: Tuesday, October 23, 2018

Session Title: Metabolic and Crystal Arthropathies – Basic and Clinical Science Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: To improve quality of care for patients with gout, two hospitals in the Netherlands initiated a protocolized gout clinic. One clinic adopted a patient-centred (PC-) strategy -emphasizing a shared decision based on serum uric acid (sUA) and patient satisfaction with gout control - and the other clinic adopted a strict sUA (≤ 0.30 mmol/L) target (UA-) strategy, with early combination of xanthine oxidation inhibitors (allopurinol) with uricosurics if the target was not reached and fractional uric acid excretion was below 4% (two modes of action (2MoA)).

Methods: Patients newly diagnosed with gout by the rheumatologist and having a follow-up between 9-15 months after the first visit were included. Co-primary outcomes were the proportion of patients reaching a sUA ≤ 0.36 mmol/L, and the proportion of patients free of flares. Secondary outcomes were the proportion of patients with a sUA ≤ 0.30 mmol/L, requiring treatment intensification beyond allopurinol (and especially 2MoA), and experiencing adverse events. Independent t-tests or chi-square were used to test differences in outcomes between strategies, and logistic regressions to adjust the effect of center on outcomes for baseline confounders.
