Arthritis & Rheumatology

AN OFFICIAL JOURNAL OF THE AMERICAN COLLEGE OF RHEUMATOLOGY

ABSTRACT SUPPLEMENT

2019 ACR/ARP Annual Meeting

November 8–13, 2019

Atlanta, GA

American College of Rheumatology
Education • Treatment • Research

Wiley

Accreditation Statement: The American College of Rheumatology is accredited by the Accreditation Council for Continuing Medical Education (ACCME) to provide continuing medical education for physicians.

Designation Statement: The ACR designates this live educational activity for a maximum of *53.25 AMA PRA Category 1 Credits*™. Physicians should claim only the credit commensurate with the extent of their participation in the activity.

International Physicians: International physicians who register as part of a group and require *AMA PRA Category 1 Credit(s)*™ must provide the following information to your tour leader: full name, mailing address, telephone and fax numbers and e-mail address. The information will be used to verify your meeting attendance.

The American Medical Association has an agreement of mutual recognition of continuing medical education credit with the European Union of Medical Specialties. International physicians interested in converting *AMA PRA Category 1 Credit*™ to EACCME credit should contact the UEMS.

Health Professionals: Participants may claim hours to receive a Certificate of Participation for an activity designated for *AMA PRA Category 1 Credit(s)*™.

Disclosure Policy
As an educational provider accredited by the Accreditation Council for Continuing Medical Education, the American College of Rheumatology must ensure balance, independence, objectivity and scientific rigor in all its educational activities. Therefore, all those in a position to control content (e.g., speakers and moderators) participating in an ACR-sponsored activity are required to disclose to the planning committee and audience any financial or other relationships that occurred in the past 12 months. This includes the relationships of spouse/partners. If there are relationships that create a conflict of interest, these must be resolved in accordance with the ACR's CME Resolution of Conflict policy prior to the participation of the individual in the development or presentation of CME content. Relevant relationships include, but are not limited to:

None: Has no relevant financial relationship to disclose.
1. Shareholder
2. Grant/Research Support
3. Employee
4. Ownership Interest (stocks, stock options, or other ownership interest excluding diversified mutual funds)
5. Consulting Fees (e.g., advisory boards)
6. Officer or Board Member
7. Royalties
8. Speaker/Honoraria includes speakers bureau, symposia, and expert witness
9. Other Financial or Material Support

Abstract author disclosures are published online. Any individual who refuses to disclose relevant financial relationships is ineligible to serve as a planning committee member, presenter or author of an ACR CME activity, and cannot have control of, or responsibility for, the development, management, presentation or evaluation of the CME activity.

Abstract Embargo Policy
Accepted abstracts are made available to the public online in advance of the meeting and are published in a special online supplement of our scientific journal, *Arthritis & Rheumatology*. Information contained in those abstracts may not be released until the abstracts appear online. Academic institutions, private organizations, and companies with products whose value may be influenced by information contained in an abstract may issue a press release to coincide with the availability of an ACR abstract on the ACR Abstract website. However, the ACR continues to require that information that goes beyond that contained in the abstract (e.g., discussion of the abstract done as part a scientific presentation or presentation of additional new information that will be available at the time of the meeting) is under embargo until **November 9 at 4:30 PM ET.** Journalists with access to embargoed information also cannot release articles before this time.

Violation of this policy may result in the abstract being withdrawn from the meeting and other measures deemed appropriate. Authors are responsible for notifying colleagues, institutions, communications firms, and all other stakeholders related to the development or promotion of the abstract about this policy. If you have questions about the ACR abstract embargo policy, please contact ACR abstracts staff at abstracts@rheumatology.org.

Media
Credentialed media press attend the Annual Meeting to cover stories for consumer, trade, and other media

outlets and are easily identified by their black press ribbons. Media Press has access to all general sessions and limited access (at the discretion of speakers) to Meet the Professor and Workshop sessions. Media Press may use handheld audio recorders and still cameras (assuming that intellectual property copyrights are respected); moving video recording is also permitted with the advance permission of the presenter(s). This policy refers to credentialed members of the press only. No photos or video are allowed in the Poster Hall without prior permission from the poster presenter. **The exception to this policy is that no photos or video are allowed in the Exhibit Hall.** Press who would like general photos of the Exhibit Hall can obtain these after the meeting from the ACR. Attendees who have questions about the ACR's media policies should contact the ACR public relations department at pr@rheumatology.org.

Photographs and Video Recording Policy
As a courtesy to our presenters, ACR policy does not permit photographs or recordings during educational sessions, including poster sessions. The only exception to this is for registered media, who should review their registration materials for more information.

Abstract Reprint (Reproduction) Policy
Copyright law covers all Annual Meeting abstracts published by the American College of Rheumatology. All rights reserved. No abstracts may be reproduced in any form or by any means without the prior permission of the publisher, except as permitted under section 107 and 108 of the 1976 United States Copyright Act.

For the purposes of this statement, the term **ACR Abstracts** refers to all Annual Meeting abstracts as published in *Arthritis & Rheumatology* and posted online, including the abstracts accepted for presentation during ARP sessions and the late-breaking category.

For the purposes of this statement, the term **ACR Posters** refers to the accepted abstract **POSTER PRESENTATIONS** as presented in the poster hall during the Annual Meeting. **This does not include abstract text published in the online supplement of *Arthritis & Rheumatology*.** All **ACR Posters** are the property of the ACR and the presenting author and cannot be reproduced or distributed without written permission from the ACR and the presenting author.

- For the purposes of this statement, the term "reproduce" includes all forms of reproduction, including, but not limited to, print, electronic and photographed formats.
- For the purposes of this statement, the term "presenting author" refers to the author who is designated as the individual who will present the work during the ACR/ARP Annual Meeting, as identified through the abstract submission process.

Approval Process for ACR Abstracts

- Excerpts or the entirety of **ACR Abstracts** may not be reproduced without the prior written permission of the publisher.
- Permission requests for abstract content and other permission inquiries should be addressed to:

Permissions Department
c/o John Wiley & Sons, Inc.
111 River Street
Hoboken, NJ 07030
Fax: 201-748-6008
wiley.com/go/permissions

- Commercial entities seeking permission to reprint must obtain all materials from the author and/or publisher John Wiley & Sons, Inc. The ACR cannot provide any materials.

Approval Process for ACR Posters

- Reprint requests for the actual poster abstract text published in the *Arthritis & Rheumatology* supplement are considered **ACR Abstracts** and must submitted to Wiley (see approval process above).
- Requests to reproduce individual ACR posters, figures from ACR posters, or booklets of poster presentations (e.g., two or more) must be submitted via e-mail to abstractreprints@rheumatology.org.
- Poster reproduction requests must include the following:
  – Abstract ID Number
  – Abstract Title
  – Presenting Author's Name
  – A copy of Presenting Author's written approval (Please Note: An e-mail approval from Presenting Author is acceptable)

Reproducing ACR Abstracts and Posters for Dissemination Prior to the Annual Meeting

- Requests to reproduce abstracts for dissemination prior to the Annual Meeting *will not be approved*.
- Per the ACR Embargo Policy (see above), academic institutions, private organizations, and companies with products whose value may be influenced by information contained in an abstract may issue a press release to coincide with the availability of an abstract online.
- Permission to issue a press release does not require ACR approval. However, it must comply with the ACR Embargo Policy; violation of this policy may result in the abstract being withdrawn from the meeting or other measures deemed appropriate.
- For more information regarding press releases, please contact the ACR public relations department at pr@rheumatology.org.

Reproducing ACR Abstracts and Posters for Dissemination During the Annual Meeting

Following approval (see approval process above), an exhibiting organization may:

- Following approval (see approval process above), an exhibiting organization may disseminate copies of individual ACR Abstracts from its exhibit space. Booklets of abstracts (e.g., two or more) may not be produced.
- Following approval, an exhibiting organization may disseminate information summaries (title/date/time/poster number) of ACR Abstracts from its exhibit space. Summaries may not reference company or product names. Requests for approval must be submitted in writing to abstractreprints@rheumatology.org.
- Presenting authors may disseminate individual copies of their ACR Poster during their assigned poster presentation time. Dissemination must be limited to the area directly in front of their assigned poster space and may not interfere with other poster presentations.
- An electronic copy of the poster may be provided via a QR code generated by the presenter and included on the poster.

Reproducing ACR Abstracts and ACR Posters for Dissemination After the Annual Meeting

ACR Abstracts

Following approval from Wiley (see approval process above), the ACR permits ACR Abstracts (i.e., all abstract content published in the online supplement) to be reprinted and disseminated following the Annual Meeting.

- Abstracts and booklets of abstracts (e.g., two or more) must include the following statement on the front of the abstract/booklet: *Abstract(s) reprinted from the ACR/ARP Annual Meeting held November 8–13, 2019. The American College of Rheumatology does not guarantee, warrant, or endorse any commercial products or services. Reprinted by (insert name of supporting company).*
- Booklets cannot contain corporate or product logos or any advertisements. No exceptions.

ACR Posters

Following approval from the presenting author and the ACR (see approval process above), copies of actual ACR poster presentations (i.e., images from the poster presentation hung in the poster hall) may be reproduced.

1. Reprint requests for the actual poster abstract text published in the *Arthritis & Rheumatology* supplement are considered **ACR Abstracts** and must submitted to Wiley (see approval process above).

- **IMPORTANT: The ACR does not retain and cannot provide poster presentation images.**
- The following statement must be listed under each Poster reprint: *Reprinted from the ACR/ARP Annual Meeting held November 8–13, 2019. The American College of Rheumatology does not guarantee, warrant, or endorse any commercial products or services. Reprinted by (insert name of supporting company).*

Use of the ACR Name

The names, insignias, logos and acronyms of the ACR, the ARP, and the Rheumatology Research Foundation are proprietary marks. Use of the names in any fashion, by any entity, for any purpose, is prohibited without the express written permission of the American College of Rheumatology.

Use of the ACR Disclosure Key

It is suggested when referencing disclosures in the reprints, that the ACR's disclosure key be added to provide adequate context for abstracts:

None: Has no relevant financial relationship to disclose.

1. Shareholder
2. Grant/Research Support
3. Employee
4. Ownership Interest (stocks, stock options, or other ownership interest excluding diversified mutual funds)
5. Consulting Fees (e.g., advisory boards)
6. Officer or Board Member
7. Royalties
8. Speaker/Honoraria includes speakers' bureau, symposia, and expert witness
9. Other Financial or Material Support

Use of the ACR Scientific Program Content

- Information displayed or presented at all sessions during the Annual Meeting is the property of the ACR or the presenter. Information may not be recorded, photographed, copied, photocopied, transferred to electronic format, reproduced or distributed without the prior written permission of the ACR and the presenter.
- Any use of the program content, which includes but is not limited to oral presentations, audiovisual materials used by speakers and program handouts, without the written consent of the ACR is prohibited.
- This policy applies before, during and after the meeting.
- The ACR will enforce its intellectual property rights and penalize those who infringe upon it.

Interleukin-6 Promotes Osteoclast-like Phenotype in Human Rheumatoid Arthritis Synovial Fibroblasts

Anil Singh,[1] Mahamudul Haque,[1] Bhanupriya Madarampalli,[2] and Salahuddin Ahmed[3], [1]Department of Pharmaceutical Sciences, Washington State University, College of Pharmacy, Spokane, WA, Spokane, WA, [2]University of Washington, Seattle, WA, [3]Department of Pharmaceutical Sciences, Washington State University, College of Pharmacy, Spokane, WA. Division of Rheumatology, University of Washington School of Medicine, Seattle, WA, Spokane, WA

SESSION INFORMATION

Session Date: Sunday, November 10, 2019
Session Title: Cytokines & Cell Trafficking Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is an autoimmune disorder characterized by chronic inflammation and joint destruction caused by pro-inflammatory cytokines. Progressive joint damage is also an outcome of the enhanced osteoclast function in synovial microenvironment mediated by IL-6. However, the molecular mechanisms through which IL-6 propels synovial fibroblasts to contribute to bone loss in RA are not fully characterized.

Methods: Human synovial tissue derived RA synovial fibroblasts (RASFs) were treated with IL-6 and IL-6 receptor (IL-6/IL-6R, 100 ng/ml each) alone or in combination with M-CSF (2 ng/ml) and RANKL (5 ng/ml) for 9 days to study differentiation mechanisms to osteoclast-like precursor cells. Osteoclast-like phenotype of RASFs was confirmed by a Tartrate-resistant acid phosphatase (TRAP) staining method. Osteoclast-like characteristics of RASFs were determined using quantitative RT-PCR or Western immunoblotting for markers such as RANKL, OPG, NFATc1, OSCAR and MITF. Signaling mechanisms that contribute to osteoclastogenesis in RASFs were confirmed by transient small-interfering RNA (siRNA). Effect of IL6/IL-6R was further examined on bone marrow-derived macrophages (BMDM) from 7-week old C57BL/6 mice and compared to M-CSF/RANKL treatment groups.

Results: Treatment of human RASFs with IL-6/IL-6R for 9 days resulted in the phenotypic changes to osteoclast-like features confirmed using TRAP staining ($p< 0.05$; n=3). IL6/IL-6R treatment of RASFs also increased the expression of osteoclast-specific expression of OPG, Cathepsin K, and Cathepsin B, which was comparable to the expression in M-CSF/RANKL-stimulated samples ($p< 0.05$; n=4). The increased TRAP staining and osteoclastogenic factors by IL-6/IL-6R were independent of M-CSF receptor expression in human RASFs. In addition to increasing Cathepsin K, Cathepsin B, and traditional osteoclast-specific markers (MITF, RANKL, and OSCAR), IL-6/IL-6R increased the expression transcription factor ETS2 by 3-5-fold when compared to M-CSF/RANKL-differentiated human RASFs. In vitro studies using mouse BMDMs showed a significantly higher expression of Cathepsin B, OPG, MITF and ETS2 in response to IL-6/IL-6R activation when compared to M-CSF/RANKL treatment group ($p< 0.05$; n=3). Silencing ETS2 expression during human RASF differentiation abrogated IL-6/IL-6R-induced Cathepsin K and Cathepsin B production, and osteoclastogenic features of these synovial cells.

Conclusion: IL-6 uniquely contributes to osteoclast-like phenotype of RASFs by directing the molecular reprogramming in these cells mediated through ETS2. Targeting ETS2 to suppress this phenotypic switch of RASFs to osteoclast-like cells may serve as regulatory mechanism of limiting bone resorption in RA.

Baseline Cytotoxic Gene Expression Associates with Ustekinumab Response in Systemic Lupus Erythematosus

Loqmane Seridi,[1] Matteo Cesaroni,[1] Matthew Loza,[1] Jessica Schreiter,[1] Kristen Sweet,[1] Yevgeniya Orlovsky,[1] Isabelle Baribaud,[1] Ashley Orillion,[1] Peter Lipsky,[2] Ronald van Vollenhoven,[3] Bevra Hahn,[4] George Tsokos,[5] Marc Chevrier,[1] Shawn Rose,[1] Frédéric Baribaud,[1] and Jarrat Jordan[1], [1]Janssen Research & Development, LLC, Spring House, PA, [2]AMPEL BioSolutions, LLC, Charlottesville, VA, [3]Amsterdam Rheumatology and Immunology Center, Amsterdam, Netherlands, [4]University of California, Los Angeles, CA, [5]Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Cytokines & Cell Trafficking Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic Lupus Erythematous (SLE) is a clinically and biologically diverse disease, for which only one new therapy has been approved in the past 60 years. In a phase 2 trial of mild-to-moderate SLE patients, ustekinumab (UST) improved clinical and laboratory measures of disease activity compared with placebo (PBO).[1]We previously reported an association of IFN-g reduction with response to UST,[2]suggesting an impact on the IL12/Th1 axis. To extend these findings, we performed unbiased transcriptomic analysis from baseline whole blood samples to identify genes that discriminate UST responders (UST-R) from non-responders (UST-NR) using the primary endpoint of Systemic Lupus Erythematosus Responder Index (SRI)-4 at week 24 to define response.

Methods: UST was studied in a Ph2 PBO-controlled study of 102 patients with seropositive SLE and active disease despite standard therapy. Patients were randomized 3:2 to receive IV UST 6 mg/kg or placebo followed by subcutaneous injections of UST 90mg or placebo every 8 weeks. Whole blood gene expression at baseline was measured via microarray using RNA samples from 100 patients, as samples from 2 patients failed quality control. An unbiased approach was used to identify gene signatures present at baseline that associate with UST response. Recombinant IL-12 or IL-23 was incubated in vitro with whole blood from 6 healthy donors for 24h and RNA-Seq was performed to determine the effect of these treatments on representative genes comprising the UST response signature.

Results: A non-biased machine learning algorithm identified a 9-gene whole blood signature composed primarily of cytotoxic cell-associated transcripts (PRF1, KLRD1, GZMH, NKG7, GNLY, FGFBP2, TRGC2, TARP, TRGV2) that was enriched at baseline in UST-R vs UST-NR. By Gene Set Variation Analysis, the cytotoxic signature enrichment in UST-NR was less at baseline than both UST-R and a healthy control cohort (P=0.0087, P=0.056, respectively), whereas UST-R cytotoxic gene enrichment was similar to healthy controls (P=0.31). No significant difference in cytotoxic signature enrichment was observed at baseline between PBO responders and PBO non-responders or healthy controls (Figure). Enrichment levels of the cytotoxic gene signature remained stable over time in PBO and UST-NR groups while a trend of decreased cytotoxic signature was observed in UST-R, although never reaching levels seen in UST-NR. To begin to understand the relationship between IL-12 and IL-23, the targets of UST, and the cytotoxic signature, whole blood was stimulated with these cytokines in vitro. Recombinant IL-12, but not IL-23, resulted in increased expression of representative members of this cytotoxic gene signature.

Conclusion: We identified a novel cytotoxic signature in baseline blood samples that associated with UST response in SLE. The observation that IL-12 can increase this signature in vitro and that IL-12 is a robust inducer of cytotoxic cell activity[3] as well as IFN-γ[3] suggests an important role of IL-12 blockade in the mechanism of action of UST in SLE.

Abstract Number: 0003

Pannexin-1 KO Mice Are Unresponsive to Tenofovir Induced Bone Loss

Ane Larrañaga-Vera,[1] Francisco Conesa-Buendia,[2] Bruce Cronstein,[3] and Aranzazu Mediero[2], [1]NYU Langone Health, New York, NY, [2]IIS-FUNDACION JIMENEZ DIAZ, Madrid, Spain, [3]NYU Langone, New York

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Cytokines & Cell Trafficking Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Tenofovir is an anti-retroviral agent commonly used to treat human immunodeficiency virus (HIV)-infected patients as part of the drug regimen known as highly active anti-retroviral therapy (HAART). As many as 15% of patients taking tenofovir develop osteopenia resulting in pathological fractures. Recent studies

in our lab indicate that tenofovir-induced osteopenia is due to reduction of extracellular adenosine resulting from tenofovir-mediated blockade of Pannexin-1, a transporter for ATP which is hydrolysed in the extracellular space to adenosine, and the effect of tenofovir on bone can be reversed by dipyridamole, an agent that blocks adenosine re-uptake. To further confirm this effect we studied the effect tenofovir on bone in Pannexin-1 knockout mice (PANX1KO) mice.

Methods: PANX1KO animals were treated daily with 75mg/Kg of tenofovir, 25 mg/kg tenofovir or both during 4 weeks, after that bone mineral density (BMD) was measured. Additionally, primary osteoclasts were differentiated in the presence of different concentrations of Tenofovir and dipyridamole. The differentiation stage and extracellular ATP levels were studied.

Results: Consistent with previous experiments, tenofovir treatment of extracellular ATP in cultures of wild type (WT) bone marrow-derived primary osteoclasts as well as an increase in osteoclast differentiation. However, the addition of dipyridamole inhibited osteoclast differentiation ($p=0.0068$). The dipyridamole-induced inhibition was reversed with Tenofovir in a dose dependent manner (0.0055). In contrast, osteoclasts from PANX1KO mice did not decrease ATP release when treated with Tenofovir ($p= 0.3292$). Additionally, PANX1KO mice osteoclast differentiation was also inhibited by dipyridamole ($p=0.0005$), which was not reversed by dipyridamole treatment ($p= 0.9756$). In WT mice, Tenofovir treatment reduced bone mineral density by 10% ($p< 0.05$, $n=10$) and this effect was reversed in the animals who received Dipyridamole in addition to Tenofovir. In contrast, tenofovir did not affect bone mineral density in PANX1KO mice ($p >0.99$, $n=4$).

Conclusion: Tenofovir, a commonly used drug, induces osteopenia in many patients. The results presented here support the hypothesis that tenofovir reduces bone density by inhibiting ATP release with subsequent adenosine-mediated inhibition of osteoclast differentiation. These effects can be reversed by treatment with dipyridamole.

AMP Deaminase 2 Surface Expression Counteracting CD73-Driven Generation of Anti-Inflammatory Extracellular Adenosine

Lisa Ehlers,[1] Aditi Kuppe,[1] Cindy Strehl,[1] Marieluise Kirchner,[2] Frank Buttgereit,[3] and Timo Gaber[1], [1]Charite University Hospital Berlin, Berlin, Germany, [2]Max Delbrück Center for Molecular Medicine, BIH Core Facility Proteomics, Berlin, Germany, [3]Charité-Universitätsmedizin Berlin, Berlin, Germany

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Cytokines & Cell Trafficking Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Adenosine and its nucleotides represent crucial immunomodulators in the extracellular environment. ATP and ADP are released from stressed cells in states of inflammation, whereas adenosine serves as a key anti-inflammatory mediator which signalsvia multiple receptors on immune cells. The ectonucleotidases CD39 and CD73 are responsible for the sequential catabolism of ATP to adenosine via AMP, thereby promoting an anti-inflammatory milieu induced by the “adenosine halo”. Great importance has been attributed to these enzymes in the pathogenesis of autoimmune diseases such as RA and as targets in cancer therapy. AMPD2 mediates AMP deamination to IMP, consequently reducing adenosine formation. Here, we postulate that (i) this pathway is also present on

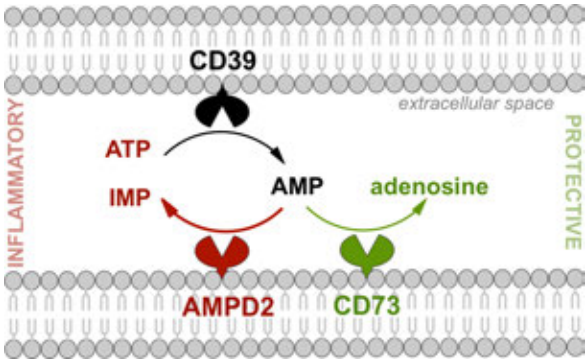

Figure 1. Surface AMPD2 counteracting CD73-driven adenosine generation.

the cell surface of immune cells, and (ii) its predominance may lead to an increased state of inflammation as found in chronic inflammatory diseases (Fig. 1).

Therefore, we analyzed surface AMPD2 expression and its modulation on distinct cell lines and primary immune cells.

Methods: Firstly, AMPD2 surface expression was verified by immunoprecipitation from membrane fractions isolated from cell lines (HEK293 and HMEC1) and CD14+ monocytes analyzed by immunoblot and mass spectrometry. In addition, surface biotinylation of the aforementioned cells was performed. Also, AMPD2 surface expression was evaluated by flow cytometry, analyzing both cell lines (HEK293, HMEC1, THP1, and Jurkat) and primary human immune cells.

Secondly, co-expression of surface AMPD2, CD39 and CD73 on PBMCs was analyzed by flow cytometry directly after isolation as well as after a 24h culture period. Moreover, surface expression was assessed after immunostimulation and Golgi transport inhibition.

Results: AMPD2 surface expression was confirmed by immunoblot and mass spectrometry of (i) precipitated AMPD2 from membrane fractions and (ii) biotinylated surface molecules in HEK293 and HMEC1 as well as CD14+ monocytes. Surface expression was reduced after AMPD2 knockdown in HEK293. AMPD2 was detected on the surface of all examined cell lines, human T cells and monocytes from healthy donors and RA patients by flow cytometric analysis. Flow cytometry revealed a stable surface expression of AMPD2, CD39 and CD73 on lymphocytes after immunostimulation. Golgi transport inhibition slightly reduced AMPD2 surface expression ($p=0.02$), while expression of CD39 and CD73 remained unaffected. However, 24h incubation with substances agonizing TLRs 1, 2, 4, 5, 6, 7, and 8 respectively strongly enhanced the surface expression of AMPD2 ($p< 0.01$) and CD39 ($p< 0.05$) on monocytes, while this effect was attenuated by concomitant incubation with dexamethasone. Agonists of TLRs 3 and 9 did not affect AMPD2 surface expression. CD73 expression was not influenced by immunostimulation. Golgi transport inhibition significantly decreased monocytic AMPD2 surface expression ($p< 0.001$).

Conclusion: We demonstrate AMPD2 surface expression on immune cells for the first time and thereby reveal a novel regulator of the extracellular ATP-adenosine balance. The extracellular conversion of AMP into IMP may constitute a shunt-like mechanism adding to the CD39-CD73 system controlling immunomodulation.

Interferon Kappa Promotes the Development of Psoriasis

Mehrnaz Gharaee-Kermani,[1] Shannon Estadt,[1] Sonya Wolf-Fortune,[1] Johann Gudjonsson,[1] and J. Michelle Kahlenberg[1], [1]University of Michigan, Ann Arbor, MI

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Cytokines & Cell Trafficking Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Psoriasis is a one of the most common chronic inflammatory autoimmune skin diseases characterized by hyperproliferation and abnormal differentiation of keratinocytes and infiltration of inflammatory cells. It affects about 3% of the world's population, with unknown etiology. In psoriasis, a complex network of cytokines and chemokines is produced by various types of immune cells, but keratinocytes also play a key role in pathogenesis. Early infiltration of plasmacytoid dendritic cells and detection of an interferon (IFN) signature occurs in many psoriasis lesions. In addition, deletion of the type I IFN receptor is protective in imiquimod-induced psoriasis. Recently, we described keratinocyte production of IFN-κ as an important source of type I IFN production in the epidermis. We thus wanted to explore the role of IFN-κ in psoriasis.

Methods: We used the well-characterized imiquimod (IMQ) psoriasis model for these studies. 10-week old male and female wild type (WT) and mice transgenic for IFN-κ under the K14 promoter (resulting in only epidermal overexpression) were used (n=5-8 per group). Psoriasis was induced by topical application of IMQ on both ears for 8 consecutive days. Control mice received Vaseline. Animals were monitored daily for ear thickness, lesion severity, and body weight. On day nine, mice were euthanized and disease severity was compared between WT and IFN-κ transgenic mice. Skin inflammation was assessed via H&E staining.

Results: Although both IFN-κ transgenic and WT IMQ treated mice exhibited psoriasis lesions in both ears after 8 days of treatment, the lesion size and thickness was significantly increased in IFN-κ transgenic mice vs. WT for both male and female mice. Interestingly, the difference was more exaggerated in IFN-κ transgenic female mice vs. male mice. H&E staining revealed increased inflammatory cell infiltrates in IMQ treated IFN-κ-TG vs. WT mice. Control mice did not show any sign of inflammation or disease. Ongoing studies are characterizing the differences in cell populations that make up the inflammatory infiltrates in WT vs. IFN-κ transgenic mice.

Conclusion: Overexpression of IFN- κ in the epidermis caused accelerated and increased disease severity after topical application of IMQ. This suggests that overproduction of type I IFNs may impact psoriasis development and there may be a role of targeting IFNs in early disease. Further studies will need to elucidate the specific mechanisms that may be at play.

A Novel Role for Extracellular Sulfatase-2 in Mediating IL-6-induced Adhesion and Migration Molecules in Human Rheumatoid Arthritis Synovial Fibroblasts

Ruby Siegel,[1] and Salahuddin Ahmed[2], [1]Washington State University Spokane, Spokane, WA, [2]Department of Pharmaceutical Sciences, Washington State University, College of Pharmacy, Spokane, WA. Division of Rheumatology, University of Washington School of Medicine, Seattle, WA, Spokane, WA

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Cytokines & Cell Trafficking Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Interleukin-6 (IL-6) promotes synovial hyperplasia by inducing mediators of adhesion, migration and leukocyte infiltration in rheumatoid arthritis (RA). The extracellular enzymes sulfatase-2 (Sulf-2) and sulfatase-1 (Sulf-1) cleave specific sulfate esters from heparan sulfate proteoglycans (HSPGs) which may affect the receptor/ligand binding and signaling of chemokines, cytokines, and growth factors. However, the potential role of sulfatases in IL-6 signaling remain unexplored. The present study evaluated the effect of the sulfatases on IL-6 signaling and induction of effector molecules in human RA synovial fibroblasts (RASFs).

Methods: Human RASFs were serum-starved overnight followed by treatment with 100 ng/ml each of IL-6 and IL-6 receptor (IL-6/IL-6R) for different time periods. Conditioned media and whole cell lysates were collected to determine the expression of adhesion (cadherin-11, ICAM-1) and migration (podoplanin) molecules using qRT-PCR and Western blotting. IL-6/IL-6R-induced MCP-1 release in conditioned media was measured by ELISA. Effect of sulfatases on IL-6/IL-6R stimulation was evaluated by small inhibitory RNA (siRNA) knockdown of Sulf-1 and Sulf-2. RASFs treated with siRNA were stimulated with IL-6/IL-6R for 24 hr for protein studies, or for 30 min to determine signaling mechanisms.

Results: Compared to IL-1β (10 ng/ml) or TNF-α (20 ng/ml), IL-6/IL-6R selectively induced the expression of Sulf-2 by 1.5-fold, without marked change in Sulf-1 expression in human RASFs (n=3). In a time-dependent study (n=3; 0-48 hr), IL-6/IL-6R caused a significant increase in the expression of cadherin-11 (2-fold; $p< 0.01$), podoplanin (2.5-fold; $p< 0.05$) and ICAM-1 (3.5-fold; $p< 0.0001$), and the production of MCP-1 in the conditioned media (2.6-fold; $p< 0.05$). Additionally, IL-6/IL-6R stimulation caused a ~4-fold increase in expression of syndecan-2, a known HSPG target of Sulf-2, in human RASFs ($p< 0.01$; n=3). Interestingly, densitometric analysis of Western blots showed that knockdown of Sulf-2, but not Sulf-1, preferentially reduced IL-6/IL-6R-induced cadherin-11, podoplanin, and ICAM-1 by 35%, 25%, and 30%, respectively ($p< 0.05$; n=3). However, siRNA targeted for both Sulf-2 and Sulf-1 proved effective in reducing IL-6/IL-6R-induced MCP-1 production by 35% and 56%, respectively ($p< 0.01$; n=3). Evaluation of signaling events showed that inhibition of Sulf-2, but not Sulf-1, suppressed IL-6/IL-6R-induced phosphorylation of JAK-1 (Tyr1022) by ~50% while maintaining the expression of SOCS3, a negative regulator of JAK/STAT3 signaling.

Conclusion: Our study identified a novel role of Sulf-2 in facilitating IL-6-induced signaling in RASFs and suggests potential therapeutic value of targeting Sulf-2-dependent pathways in treatment approaches for RA.

Citrullination of Interleukin 6 Augments Its Pro-inflammatory Capacity and Signaling Potency Through Interleukin-6 Receptor in Rheumatoid Arthritis

Chenyang Lu,[1] Ray Ohara,[2] Phillip Campbell,[1] Yuxuan Du,[3] Alexander Stinson,[2] Jonatan Hervoso,[3] Ellen Cealey,[3] David Fox,[4] and **M Amin**[5], [1]The University of Michigan, Ann Arbor, MI, [2]Washington University, St. Louis, MO, [3]the University of Michigan, Ann Arbor, [4]University of Michigan, Ann Arbor, [5]University of Michigan, Ann Arbor, MI

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Cytokines & Cell Trafficking Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is a chronic inflammatory disorder featured by synovial hyperplasia, inflammatory cell infiltration and presence of anti-citrullinated peptide antibodies (ACPAs) in sera. Citrullination, a post-translational modification of arginine to citrulline by peptidylarginine deiminase (PAD), contributes to the development of RA. We have shown that interleukin 6 (IL-6) can be citrullinated and mediates inflammation in RA. Additional experiments were performed to define the receptor for citrullinated IL-6 (citIL-6).

Methods: Recombinant human (rh) IL-6 was incubated with rhPAD4 and the citrullination of IL-6 was verified by liquid chromatography-mass spectrometry (LC-MS). We identified the presence of citIL-6 and ACPAs against citIL-6 in RA synovial fluids (SFs) and sera by performing Western blotting and immunodot blot assay, respectively. In vitro, monocyte (MN) chemotaxis assays were performed with modified Boyden chambers to examine the effect of citIL-6 on MN migration. The role of citIL-6 in RA fibroblast-like synoviocyte (FLS) proliferation and migration was determined using the IncuCyte S3 live-cell analysis system and scratch wound assays. FLS were stimulated with citIL-6 or noncitIL-6 to examine the phosphorylation of signaling molecules by Western blotting without exogenous IL-6 receptor (IL-6R). To define the receptor for citIL-6, RA FLS were transfected with gp130 siRNA or blocked with sarilumab, an IL-6R neutralizing antibody, and signaling molecules were tested by Western blotting after stimulation with citIL-6 or noncitIL-6. In vivo, citIL-6 or noncitIL-6 was injected into mouse knees and joint circumference was measured at 0 hour and 24 hours after injection.

Results: LC-MS confirmed that all of the arginines in rhIL-6 can be citrullinated by rhPAD4. Western blotting showed that citIL-6 was present in the SFs from RA, and immunodot blot assay showed that sera from RA patients but not healthy controls contained ACPAs reactive with citIL-6 but not noncitIL-6. Compared to noncitIL-6, citIL-6 induced more MN migration ($p< 0.001$). We found that citIL-6 induced significantly higher FLS proliferation and migration rates after 24 hours than noncitIL-6. CitIL-6, without exogenous IL-6R, consistently upregulated phosphorylation of Erk1/2, Jnk, and Stat3 in RA FLS while noncitIL-6 did not unless exogenous IL-6R was added. Furthermore, gp130 knock down or monoclonal antibody blockade of the IL-6R abrogated the phosphorylation of Stat3 and Erk1/2 in FLS by both citIL-6 and noncitIL-6, indicating IL-6R and gp130 are necessary for function of both forms of IL-6. The change in mouse knee circumference with citIL-6 injection was approximately 7-fold higher than that with noncitIL-6 injection (0.90 ± 0.13 mm vs 0.13 ± 0.13 mm; $n=14$; $p< 0.05$), indicating that citIL-6 induced much more severe inflammation in mouse knees compared to noncitIL-6.

Conclusion: IL-6 can be citrullinated by PAD, citIL-6 was present in RA SFs, and citIL-6 ACPAs were present in RA sera. CitIL-6 appears to be a more potent ligand of IL-6R and play an important role in the pathogenesis of RA by inducing proliferation as well as migration of FLS and recruitment of monocytes.

CKD-506, a Selective Histone Deacetylase (HDAC) 6 Inhibitor, Regulates Inflammatory Responses Through NF-kB and AP-1 Signaling

Jieun Shin,[1] Nina Ha,[1] Daekwon Bae,[1] Dong-hyeon Suh,[1] Ji-yeon Baek,[1] Jae Hyun Jun,[1] Yong Jae Lee,[1] Young Il Choi,[1] Keun Ho Ryu,[1] Gi Soo Youn,[2] and Jinseu Park[3], [1]CKD Research Institute, Yongin-si, Republic of Korea, [2]Department of Biomedical Science, Hallym University, Chuncheon, Republic of Korea, [3]Department of Biomedical Science, Hallym University, Chuncheon

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Cytokines & Cell Trafficking Poster

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Inhibition of HDAC6 has been proposed beneficial and therapeutic effects in inflammatory diseases. CKD-506, a potent and selective oral HDAC6 inhibitor, has anti-inflammatory and anti-rheumatic effects in arthritis animal models and RA patient samples. Moreover, CKD-506 was generally safe and well tolerated following single and multiple doses in healthy volunteers, and CKD-506 is on clinical investigation to assess the efficacy and safety in patients with rheumatoid arthritis. Herein, we identify the molecular mechanisms of CKD-506 in regulation of inflammation.

Methods: Mouse peritoneal macrophages and Raw264.7 cells were transfected with HDAC6 overexpression vector or pcDNA3.1 vector as control. Cells were cultured in the presence or absence of 0.03~3 μM CKD-506, and the expression and production of inflammatory mediators were determined by RT-PCR and ELISA respectively. For reporter assays, cells were transfected with pNF-kB-luc or pAP-1-luc plasmid and luciferase activity in cell lysates was determined by luminometer. Tubulin acetylation and signaling molecules by CKD-506 in HDAC6 overexpressed cells were checked by immunoblot analysis.

Results: HDAC6 overexpression in both Raw264.7 cells and mouse peritoneal macrophages strongly induced pro-inflammatory mediators such as TNFa, IL-6, IL-1b. However, CKD-506 inhibited the expression and production of TNFa, IL-6, and IL-b at dose dependent manners in HDAC6 overexpressed cells. Moreover, ROS production and NADPH oxidase activity mediated by HDAC6 overexpression were inhibited by CKD-506. In signaling pathway, HDAC6 overexpression strongly induced NF-kB and AP-1 activity and CKD-506 inhibited both signaling pathways. In addition, CKD-506 with methotrexate exhibited better anti-inflammatory effects on macrophages with HDAC6 overexpression.

Conclusion: CKD-506 inhibits inflammatory mediators such as TNFa, IL-6, IL-1b, ROS, and NADPH oxidase activity in HDAC6 overexpressed cells. This anti-inflammatory activities of CKD-506 are mediated through NF-kB and AP-1.

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Cytokines & Cell Trafficking Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is characterized by a wide range of systemic dysfunctions as well as an elevated erythrocyte sedimentation rate. Chemokine CXCL 10 (IP-10) is a chemotactic chemokine for monocytes and T-Lymphocytes and has been studied as a potential biomarker to detect SLE activity. The clinical manifestations of the activity of this disease are difficult to assess for clinicians as there is no high sensitivity blood test available for diagnostic purposes. The aim of this study was to determine if SLE activity in our patients, evaluated using the Systemic Lupus Erythematosus Disease Activity Index (SLEDAI), elevates the expression of IP-10 mRNA in leucocytes, measured as Fold Change using qRT-PCR.

Methods: We recruited SLE female patients, diagnosed according to SLICC 2012 classification criteria. The patients were classified in five groups (Control; n=30, Without Activity (WA); n=30, Mild Activity (Mi A); n=30, Moderate Activity (Mo A); n=30, Severe Activity (SA); n=30) according to SLEDAI results, subsequently blood samples were taken, labeled and transported with all preservation precautions to the Molecular Biology Laboratory where total RNA was extracted from leucocytes and quantified. Primers were designed to amplify a specific region in the exon 2 and 3 of the IP-10 gene and gene expression levels were determined using qRT-PCR. ANOVA test was used to compare the expression of IP-10 mRNA between groups and a Spearman test was used to correlate the SLEDAI with the IP-10 mRNA expression levels.

Results: Overexpression of IP-10 mRNA was observed in the SA group with a Fold Change of 3.0171 (p=0.02), SLEDAI correlates with an increased expression of IP-10 (R=0.9029); Group Mo A was omitted from the analysis due to inconsistent results probably caused by methodological errors.

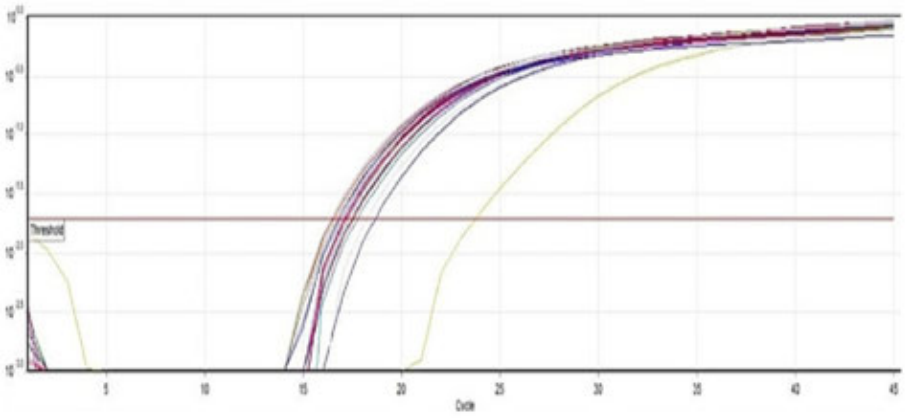

Figure 1. qRT – PCR CTs analysis from IP-10 sequence amplification.

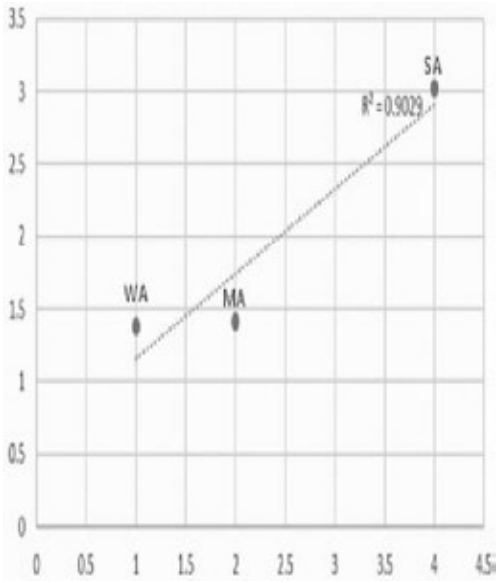

Figure 2. Correlation Activity of SLE with Fold Change $R^2 = 0.9029$ (WA = Without Activity, MA = Mild Activity, SA = Severe Activity)

CTs	Control	Without Activity	Mild Activity	Severe Activity
Fold Change	1	1.381147	1.412124	3.017178

Table 1. Overexpression of IP-10 in different groups

Conclusion: IP-10 mRNA overexpression could be associated with Several Activity of SLE, quantification of IP-10 gene expression has potential as a biomarker to evaluate SLE activity. Complimentary techniques such as IP-10 protein quantification are suggested to confirm our observations.

Roles of Histone Acetyltransferases CBP/p300 and Transcriptional Factor RORα/REV-ERBα Against TNFα-induced CCL2 Expression in RA-FLSs

Ikumi Okumura,[1] Kohsuke Yoshida,[1] Kenta Kaneshiro,[2] Koto Uchida,[3] Arisa Yaekura,[4] Yuto Oketani,[5] Kanta Morii,[1] Koji Tateishi,[6] Yasuhiro Terashima,[6] Yoshiko Kawasaki,[7] Nao Shibanuma,[7] Yoshitada Sakai,[8] and Akira Hashiramoto[1], [1]Kobe University Graduate School of Health Sciences, Kobe, Hyogo, Japan, [2]Kobe University Graduate School of Health Sciences, Osaka, Osaka, Japan, [3]Kobe University Graduate School of Health Sciences, Okayama, Okayama, Japan, [4]Kobe University Graduate School of Health Sciences, Kawanishi, Hyogo, Japan, [5]Kobe University Graduate School of Health Sciences, Himeji, Hyogo, Japan, [6]Kohnan Kakogawa Hospital, Kakogawa, Hyogo, Japan, [7]Kobe Kaisei Hospital, Kobe, Hyogo, Japan, [8]Kobe University Graduate School of Medicine, Kobe, Hyogo, Japan

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Cytokines & Cell Trafficking Poster

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

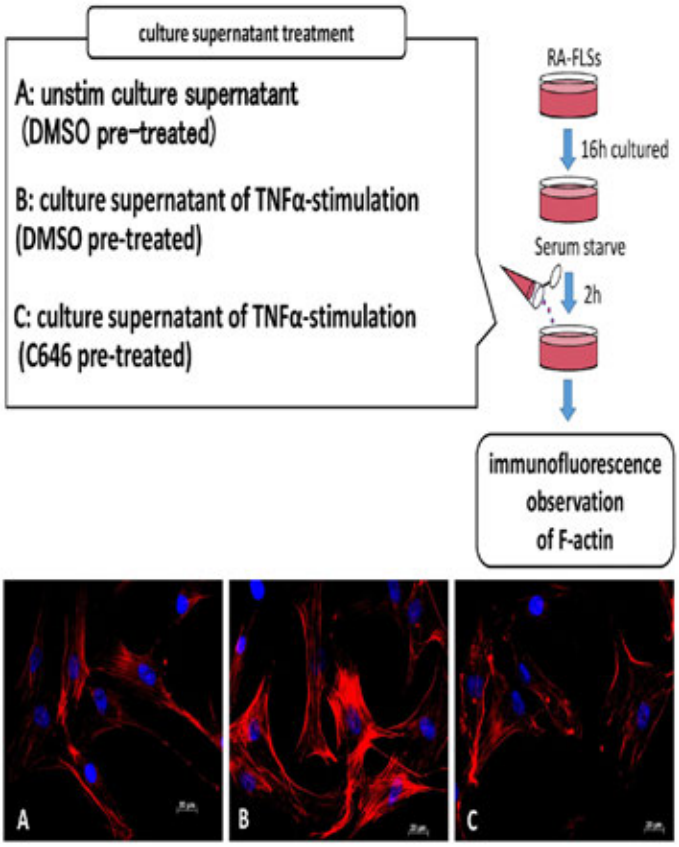

Figure 1. TNFα induced reorganization of the actin cytoskeleton in RA-FLSs (A and B), while C646 significantly inhibited that (C).

Background/Purpose: We have reported that TNFα induced expressions of clock gene*Bmal1*by up-regulating transcriptional activator RORα and down-regulating repressor REV-ERBα in RA fibroblast-like synoviocytes (RA-FLSs), and that histone acetyltransferases CREB binding protein (CBP) and p300 were involved in this process. A chemokine CCL2, associated with cell proliferation and migration of RA-FLSs, is regulated by RORα and REV-ERBα as well as Bmal1. In this study, we investigate the relation between RORα/REV-ERBα, histone acetyltransferases and TNFα-induced CCL2 expression in RA-FLSs.

Methods: To examine the effect of RORα antagonist SR1001 and REV-ERBα agonist GSK4112 on TNFα-induced CCL2 expression, primary cultured RA-FLSs were treated with SR1001 (20μM) and/or GSK4112 (20μM) in the presence of TNFα (10ng/ml) for 24h.

Next, to clarify the role of histone acetyltransferases on TNFα-induced CCL2, cells were incubated with p300/CBP inhibitor C646 or transfected with both p300 and CBP small interfering RNA (siRNA) before stimulation with TNF-α. Thereafter, intracellular CCL2 mRNA and culture supernatant CCL2 were analyzed by qPCR and ELISA, respectively.

To examine the effect of C646 on TNFα-induced cell migration of RA-FLSs, wound healing assay and immunofluorescence observation were performed by using two different culture supernatant of TNFα-stimulation; DMSO pre-treated control and C646 pre-treated one.

Results: TNFα-induced CCL2 expression was strongly inhibited by simultaneous treatment with both SR1001 and GSK4112, as compared with solo treatment of each agents. Further, CCL2 expressions were also suppressed by

pretreatment with C646 and silencing of both*Cbp*and*p300*genes. C646 significantly inhibited both TNFα-induced cell migration and reorganization of the actin cytoskeleton as compared to those with DMSO control (Figure 1).

Conclusion: We newly found that TNFα induced expression of CCL2 through RORα and REV-ERBα, which was associated with CBP/p300 in RA-FLSs, in the same manner as*Bmal1*.

Results propose these molecules as novel therapeutic targets of RA.

Biomarker Changes for Patients with Rheumatoid Arthritis Receiving Tofacitinib with Methotrexate or Glucocorticoids vs Tofacitinib Monotherapy

Julie Lee,[1] Xing Chen,[1] Weidong Zhang,[1] David Martin,[1] Craig Hyde,[1] Tomohiro Hirose,[2] Shweta Shah,[3] and Lori Fitz[1],
[1]Pfizer Inc, Cambridge, MA, [2]Pfizer Japan Inc, Toyko, Japan, [3]Pfizer Inc, Collegeville, PA

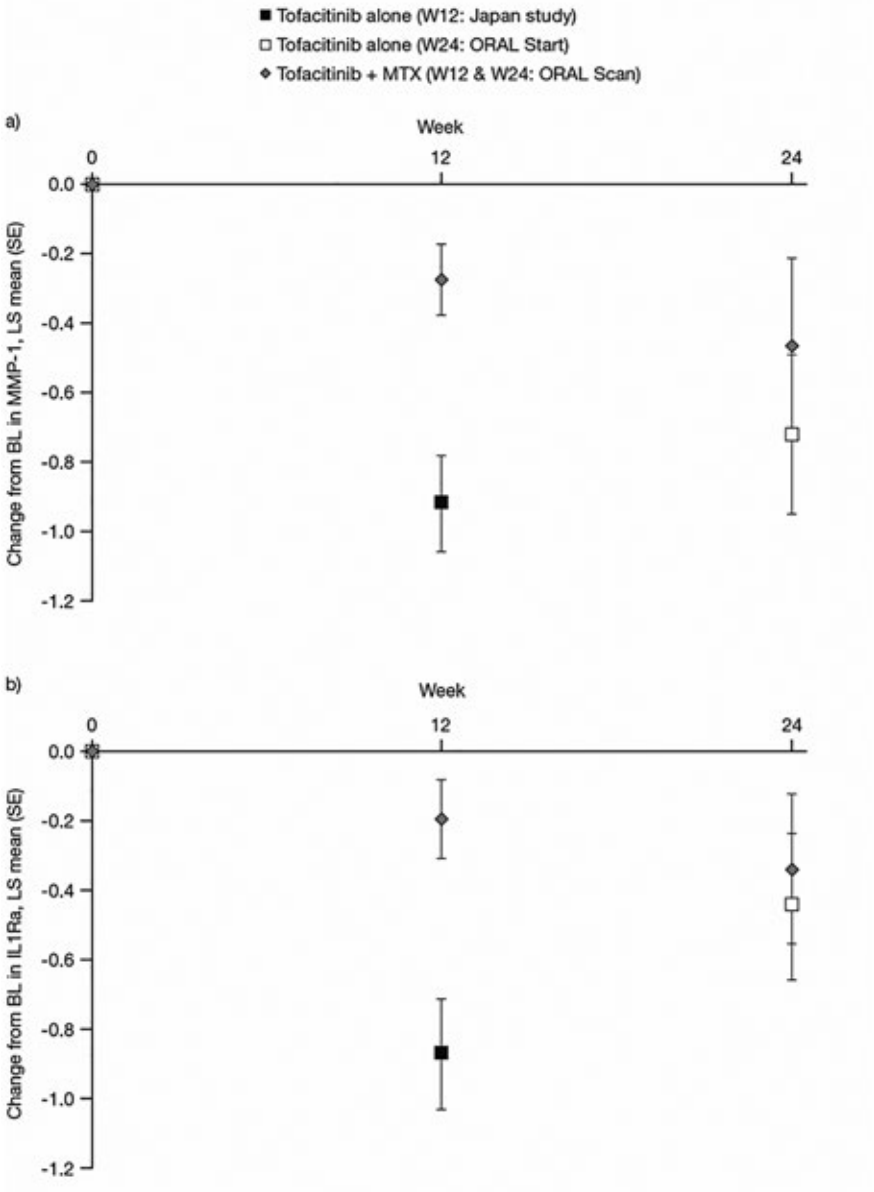
SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Cytokines & Cell Trafficking Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Tofacitinib is an oral Janus kinase inhibitor for the treatment of RA. Herpes zoster (HZ) is more common in patients (pts) with RA vs the general population.[1]HZ risk is increased with tofacitinib use,[2]and seems to further increase with concomitant use of conventional synthetic DMARDs (eg MTX) or glucocorticoids (GC).[3]This increased risk may be linked to treatment-induced IFN suppression,[3]as varicella-zoster virus replication may be limited by IFN activity.[4]We evaluated whether tofacitinib + MTX and/or GC suppressed IFN pathway proteins to a greater extent than tofacitinib alone.

Methods: This post hoc analysis pooled data from 1 Phase (P) 2 (Japan study [NCT00687193]) and 2 P3 (ORAL Scan [NCT00847613]; ORAL Start [NCT01039688]) tofacitinib studies. Serum samples were collected at baseline (BL), Week (W) 12, and/or W24 from pts with RA treated with tofacitinib 5 or 10 mg twice daily alone (Japan study; ORAL Start) or with stable MTX (15–25 mg/week for ≥ 6 weeks; ORAL Scan), and/or GC (≤ 10 mg/day prednisone or equivalent; all studies). A total of 376 proteins associated with cellular/inflammatory processes, including 6 IFN pathway proteins (CXCL9, CXCL10, CXCL11, IL-12, IFNγ, and IL-20), were measured using a homogeneous, solution-based assay (Olink Proseek®Multiplex Assay, Uppsala, Sweden). Protein-level changes at W12 (Japan study; ORAL Scan) and/or W24 (ORAL Scan; ORAL Start) were compared for both regimens using linear regression models. The dependent variable was change from BL in protein levels at W12 or W24. The independent variable was MTX or GC status. Age, gender, GC status (in MTX model), BL protein levels, and tofacitinib dose were covariates. Separate regressions were performed for each study; GC results were combined via meta-analysis using fixed-/random-effect models. Significance was considered at $p < 0.1$ after controlling for false discovery rate (FDR).

Results: In total, 659 samples were obtained from 321 pts. Of the 6 IFN pathway proteins, IFNγ and IL-20 were below the limit of detection. There were no statistical differences between tofacitinib alone vs tofacitinib + MTX and/or GC

Figure 1. Change from BL to W12 and W24 in a) MMP-1 and b) IL1Ra in patients receiving tofacitinib alone or tofacitinib + MTX



BL protein levels were assessed in all studies (Japan study [NCT00687193]; ORAL Scan [NCT00847613]; ORAL Start [NCT01039688]). Data for protein changes at W12 are from the Japan study (tofacitinib alone) and ORAL Scan (tofacitinib + MTX); data for protein changes at W24 are from ORAL Start (tofacitinib alone) and ORAL Scan (tofacitinib + MTX). All groups included patients who may or may not have received concomitant GC. Significance was considered at $p<0.1$ after controlling for FDR. Data quality control included accounting for plate/batch effects and limits of detection, and removal of samples/analytes with excessive missing data. At W12, FDR-adjusted p=0.08 for MMP-1; FDR-adjusted p=0.09 for IL1Ra. At W24, FDR-adjusted p=1.00 for MMP-1; FDR-adjusted p=1.00 for IL1Ra.

BL, baseline; FDR, false discovery rate; GC, glucocorticoids; IL1Ra, interleukin-1 decoy receptor; LS, least squares; MMP 1, matrix metalloproteinase-1; SE, standard error; W, Week

in changes in levels of the 4 detectable IFN pathway proteins (CXCL9, CXCL10, CXCL11, and IL-12) at W12/W24. Significant differences were observed for 2 of 370 other proteins: MMP-1 (FDR-adjusted p = 0.08) and IL1 decoy receptor (IL1Ra; FDR-adjusted p = 0.09); levels were decreased at W12 for tofacitinib + MTX to a greater extent vs tofacitinib alone (Figure 1).

Conclusion: Tofacitinib + MTX and/or GC may not suppress IFN pathway proteins to a greater extent than tofacitinib alone. There were differences at W12 for tofacitinib + MTX vs tofacitinib alone in MMP-1 and IL1Ra, but it is not clear

whether these were due to ethnicity differences in the study populations receiving these treatments (global vs Japan). Analyses of biomarker changes with tofacitinib are ongoing.

Session Date: Sunday, November 10, 2019
Session Title: Cytokines & Cell Trafficking Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: *Chlamydia trachomatis*-induced reactive arthritis (ReA)/ undifferentiated spondyloarthropathy (uSpA) is an immune-mediated situation where development of disease and maintenance of this pathogen remains elusive. The aim of the study was to estimate the peripheral and localized Th1/ Th2/ Th17 cytokine responses in paired synovial fluid (SF) and serum samples in genitourinary ReA/ uSpA patients infected with *C.trachomatis*.

Methods: With hospital ethical permission, ReA/ uSpA (n = 45)/ Rheumatoid Arthritis (RA) (n = 35)/ Osteoarthritis (OA) (n = 35) patients were enrolled following European spondyloarthropathy study group criteria for ReA/ uSpA and American College of Rheumatology for RA; while OA patients were diagnosed on the basis of clinical and radiological findings. Clinical profile of all arthritic patients was recorded and SF and blood (serum) were collected from each patient. Commercially available kits were used for estimation of SF/ serum cytokines and serum chsp60 by Elisa and HLA B27 by PCR in SF DNA. Statistical analysis of data was done by GraphPad Prism software version 5.0 (GraphPad software, La Jolla, CA, USA).

Results: IFN-gamma was significantly ('p' = 0.0003) elevated in the SF of *C.trachomatis*-positive ReA/ uSpA patients while it was non-significant ('p' = 0.06) in serum. IL-4 was significantly higher in SF ('p' = 0.01) and serum ('p' = 0.006)

of*C. trachomatis*-infected ReA/ uSpA patients in comparison to uninfected ReA/ uSpA, RA and OA patients. IL-17 was comparable ('p' = 0.9) in SF and serum of *C.trachomatis*-infected and uninfected ReA/ uSpA patients and RA. SF and serum IFN-gamma were positively correlated ($r = 0.28$; $p < 0.05$); IL-6 and IFN-gamma in SF were also positively correlated ($r = 0.72$; $p < 0.007$) in ReA/ uSpA patients. IFN-gamma was slightly high ('p' > 0.05, non-significant) in chsp60-positive patients while it was low in HLA B27-positive patients with *C. trachomatis*infection.

Conclusion: Synergistic upregulation of IFN-gamma in SF and serum shows Th-1 dominant immune response which is probably mediated by IL-6 in *C.trachomatis*-induced ReA/ uSpA. HLA B27 and chsp60 do not play any significant role during *C.trachomatis*-induced ReA/ uSpA.

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Cytokines & Cell Trafficking Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Primary Sjögren's syndrome (pSS) is a female-predominant autoimmune disease with peak onset in perimenopause. pSS is characterized by severe ocular and oral sicca, leading to reduced quality of life and increased healthcare costs. Minor salivary glands are central to the diagnosis and prognosis of pSS. Although the exact pathogenesis of pSS remains unclear, focal lymphocytic infiltrate, and ultimately, fibrosis of the minor salivary gland, is a key feature of pSS. Mesenchymal stromal cells (MSCs), a cell type with the potential to abrogate inflammation/fibrosis,have been isolated from human minor salivary glands but little is known of their immunobiology. We hypothesize that minor salivary gland-resident MSCs may play a role in pSS pathology. To test this idea, we culture adapted minor salivary gland MSCs and interrogated the hypothesis that treatment with interferon (IFN) γ will have altered immunobiology with and without estrogen treatment.

Methods: All pSS subjects (N=8) fulfilled ACR/EULAR criteria for pSS. Control subjects (N=7) were referred for minor salivary gland biopsy but did not have features or diagnosis of autoimmune disease. MSC cell lines were cultured from minor salivary glands were studied between passages 4 and 6. MSC phenotype was assessed by morphology and flow cytometry using typical MSC surface markers (CD19-,CD45-,HLADR; CD105+,CD90+,CD73+). Estrogen studies were performed on control MSC populations and culture was performed in phenol-free media using charcoal stripped fetal bovine serum. Control MSCs (n=3) were pre-treated for 48 hours with 17 β-estradiol (0.1μM) in the presence or absence of IFN y (25 ng/mL). MSC activity was measured by flow cytometry median fluorescence intensity (MFI) of key mediators of MSC immunobiology including indoleamine 2,3-dioxygenase (IDO), programmed death ligand (PDL)1, and PDL2.

Results: 8 pSS and 7 control MSC cell lines were established with both morphologic and cell marker expression consistent with an MSC phenotype (Figure 1a & Figure 1b). MSCs had minimal expression of CD45, CD19, and HLADR. MSCs had high expression of CD105, CD73, and CD90. Phenotypic cell marker expression did not vary

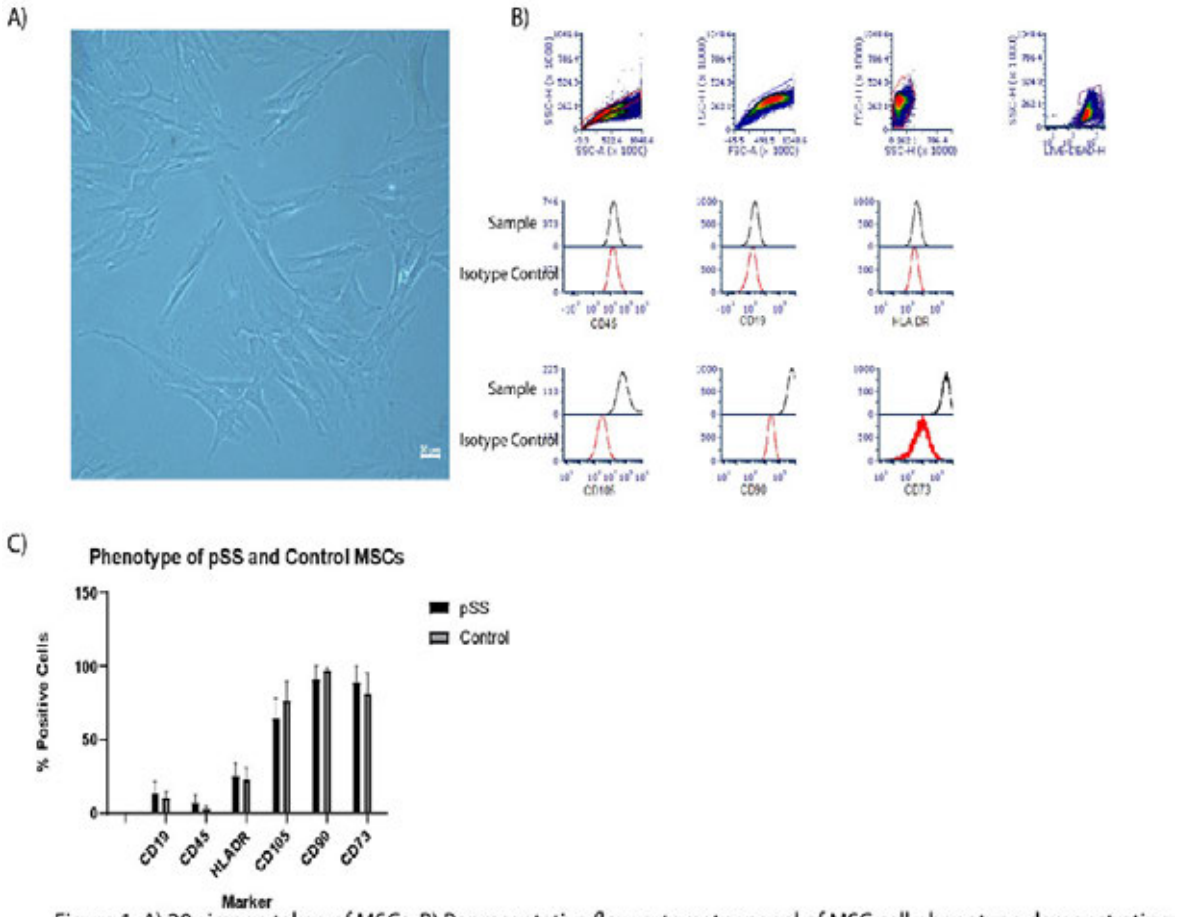

Figure 1. A) 20x image taken of MSCs; B) Representative flow cytometry panel of MSC cell phenotype demonstrating cell populations negative for CD45, CD19, and HLA DR and positive for CD105, CD90, and CD73;
C) Comparison of pSS (n=8) and control (n=7) cell surface markers shows no difference in cell marker expression patterns between these groups.

between pSS and control MSCs (Figure 1c). Control MSCs treated with IFNγ demonstrated increased expression of IDO, PDL1, and PDL2 (Figure 2a & Figure 2b). Estrogen pretreatment did not affect expression of IDO, PDL1, or PDL 2 with or without IFNy licensing.

Conclusion: These results confirm the similarities of MSC phenotype between pSS and controls. Despite increased sicca symptoms around the time of menopause when estrogen is in flux, we did not find that estrogen impacted minor salivary gland MSC immunobiology. Even in the setting IFNγ stimulated MSCs, simulating a high IFN SS-like environment, pulse estrogen exposure did not appear to modify expression of key MSC immunobiology markers. Future investigation will test whether long term pre-conditioning of MSC with estrogens leads to an altered immune plasticity response.

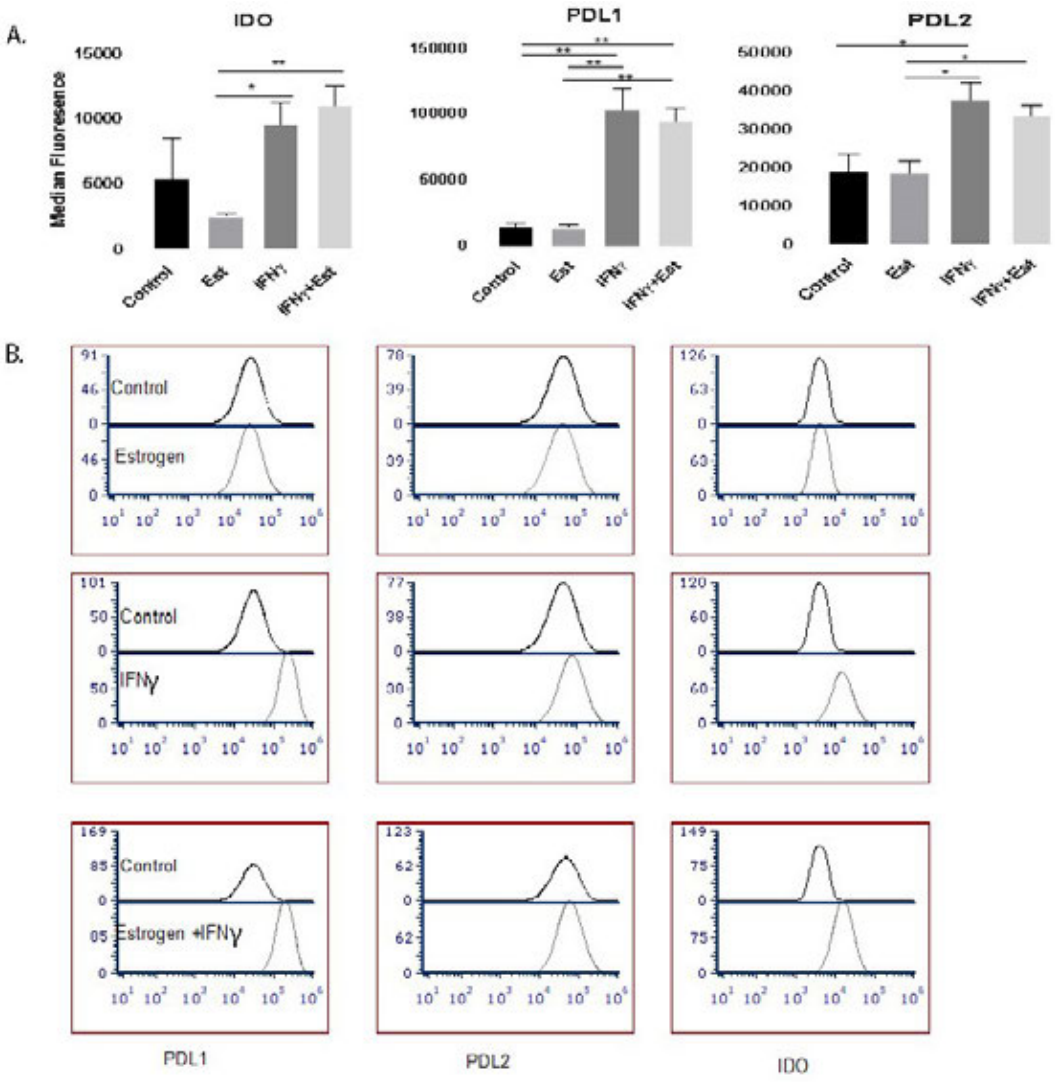

Figure 2. A) IDO, PDL1, and PDL2 have increased median fluoresence after IFNγ licensing. Estrogen treatment does not impace IDO, PDL1, or PDL2 expression (n=3); B) Representative figure demonstrating expression of IDO, PDL1, and PDL2 after treatment with estrogen, IFNγ, or both estrogen and IFNγ. *=p≤0.05; **=p≤0.01.

Sec16A Abnormalities Affect the Intracellular Trafficking of HLA-B27 in the Pathogenesis of Axial Spondyloarthritis

Ayantika Talukdar,[1] Fanxing Zeng,[2] Zhenbo Zhang,[1] and Nigil Haroon[3], [1]University Health Network, Toronto, ON, Canada, [2]University Health Network, Toronto, Canada, [3]Toronto Western Hospital, Krembil Research Institute, University of Toronto, Toronto, ON, Canada

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Cytokines & Cell Trafficking Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Axial Spondyloarthritis (AxSpA) is a chronic inflammatory arthritis, mainly affecting the axial skeleton. HLA-B27 confers the greatest genetic association in AxSpA. Exome sequencing in a multiplex family had revealed that the incidence of AxSpA in individuals with HLA-B27 and the Sec16A mutation was 100%. Sec16A is a protein that plays a major role in the formation of COPII vesicles and trafficking of proteins from ER to plasma membrane via Golgi Complex. We had previously shown that Sec16A abnormalities not only hinder the assembly of COPII vesicles, leading to abnormal intracellular trafficking and ER stress but also it disrupted the HLA-B27 expression. Here, we aim to investigate whether the Sec16A abnormalities affect the intracellular trafficking of HLA-B27, which is associated with the development of AxSpA, differ from those of HLA-B7, which is not associated. In addition, examining the effect of top 10 interacting proteins of Sec16A, previously identified using BioID, by next generation sequencing help us understanding the pathway associated with intracellular trafficking of HLA-B27.

Methods: Sec16A knockout HeLa cells were generated by transfecting these cells with Sec16A CRISPR/Cas9 KO plasmid (h) and Sec16A HDR plasmid (h) according to manufacturer's instructions. KO efficiency was determined by western blotting. The plasmids encoding YFP (Yellow Fluorescent Protein) tagged HLA-B27

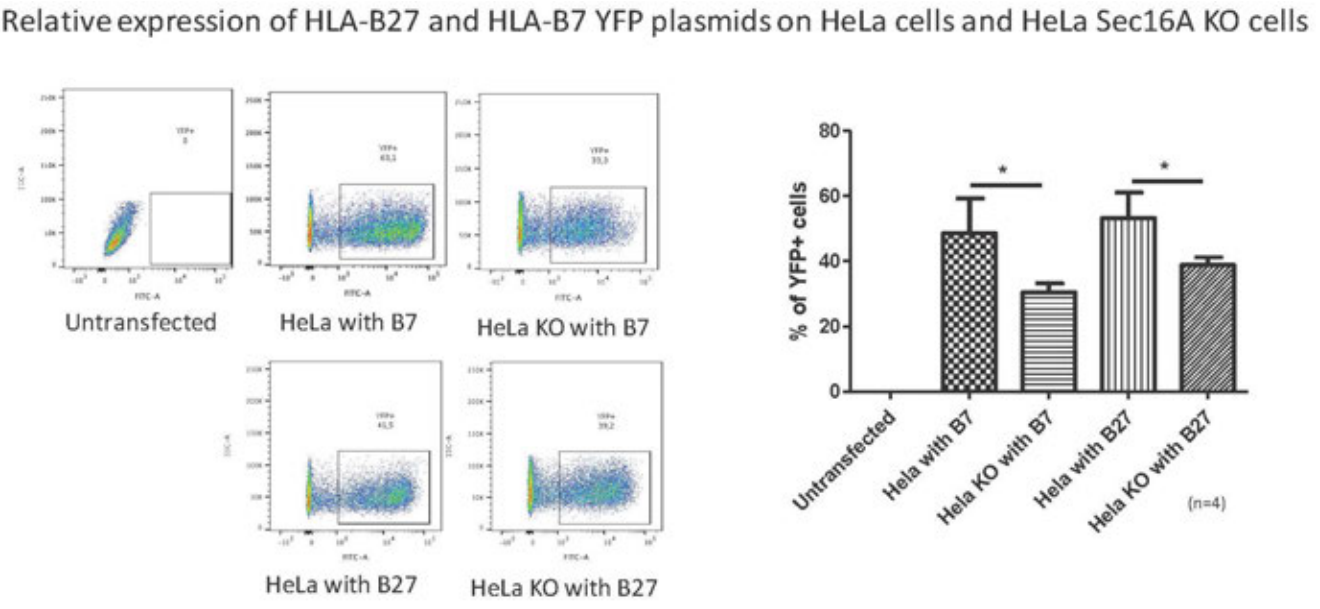

Figure 1.

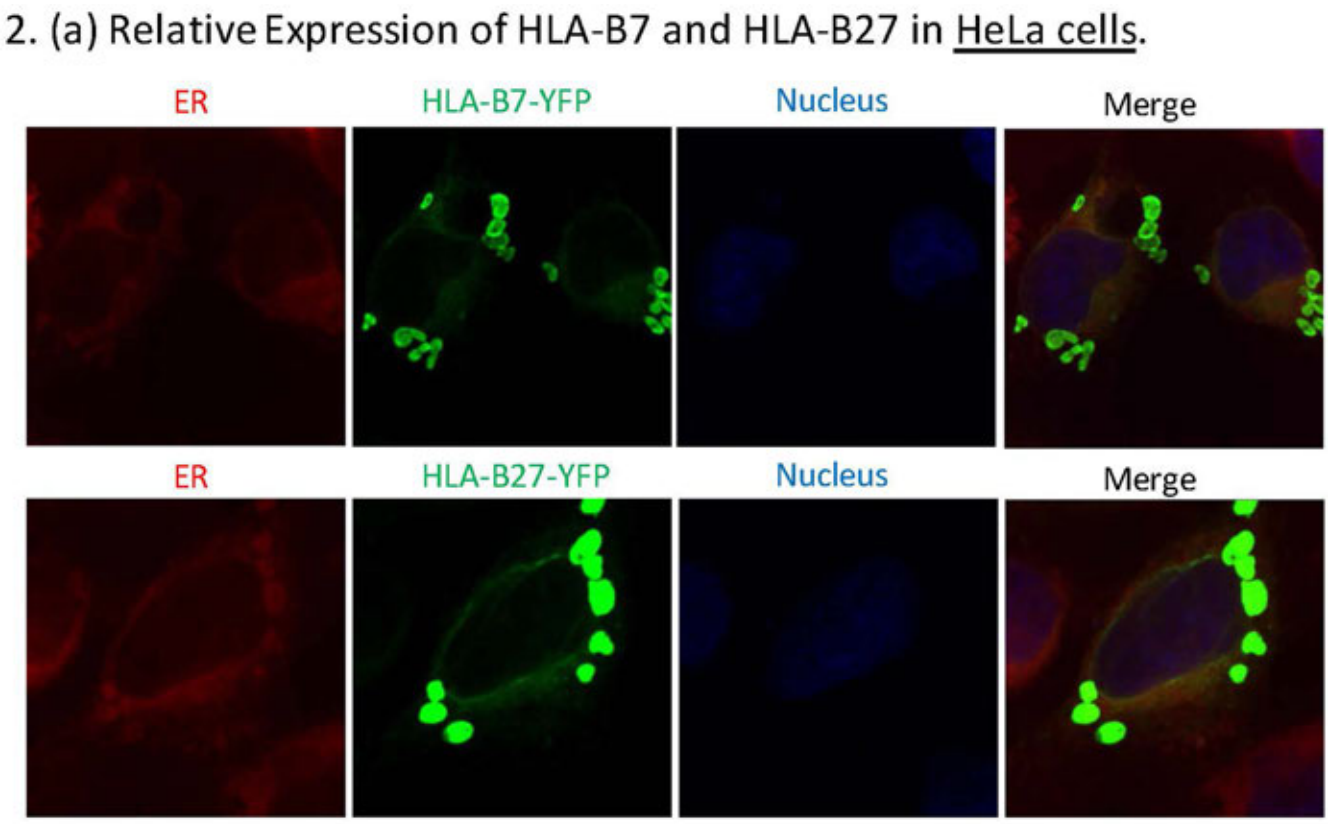

Figure 2.

and HLA-B7 were transfected to HeLa cells and HeLa Sec16A KO cells. The YFP expression of HLA-B7 and HLA-B27 in HeLa cells was assessed by flow cytometry and confocal microscopy at different time points. The real time intracellular trafficking of HLA was monitored using live cell imaging. Also, the expression of properly folded and misfolded HLA-B7 and HLA-B27 were determined using flow cytometry. The top 10 proteins interacting with Sec16A were suppressed using siRNA in C1R-B27 cells and their effect were studied using Next Generation Sequencing.

Results: There was a significant decrease in the expression of both HLA-B7 ($p< 0.05$) and HLA-B27 ($p< 0.05$) in the HeLa Sec16A KO cells compared to wild type cells after transfection. HeLa cells showed an intracellular accumulation of HLA-B27 and HLA-B7 as a result of over expression. On the other hand, we did not observe any such vesicle formation in the HeLa Sec16A KO cells. Sec16 KO cells exhibit an exaggerated unfolded protein response resulting in degradation of the HLA-B proteins. This is also evident from the increased level of intracellular misfolded HLA-B27 and HLA-B7 in the Sec16 KO cells. Using next generation sequencing, we found that Sec16A interacting proteins had an effect in the pathways related to inflammation, ER-to-Golgi vesicle mediated transport and antigen presentation.

Conclusion: Sec16A plays a significant role in the trafficking of HLA-B molecules (HLA-B7 and HLA-B27) irrespective of the subtypes, thereby playing a prospective role in the pathogenesis of AxSpA.

CYR61/TGF-β Axis Promotes Adventitial Fibrosis of Takayasu Arteritis in the IL-17 Mediated Inflammatory Microenvironment

Lili Ma,[1] Xiufang Kong,[2] Xiaomeng Cui,[1] Sifan Wu,[1] Yujiao Wang,[1] and Lindi Jiang[1], [1]Zhongshan hospital, Fudan University, Shanghai, China (People's Republic), [2]University of Michigan & Fudan University, Ann Arbor, MI

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Cytokines & Cell Trafficking Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: As a novel proinflammatory and potential profibrotic factor, the role of CYR61 on the vascular fibrosis of Takayasu arteritis (TA) has not been investigated.

Methods: CYR61 expression was analysed in aortic vessel samples from TA patients and healthy donors by immunohistochemistry tests. The *in vitro*effect of recombinant human CYR61 (rhCYR61) on the proliferation, migration and activity of adventitial fibroblasts (AFs) in the inflammatory microenvironment was studied.

Results: CYR61 showed obviously higher expression in the TA-affected vessel wall. The proliferation of AFs and the synthesis of ECM components such as collagen I, collagen III and fibronectin were stimulated by rhCYR61. rhCYR61 also partly blocked the migration of AFs. The integrin αvβ1 was identified as the membrane receptor of CYR61, and phosphorylation of the Erk1/2 pathway was also identified. Pretreatment with PD98059, an inhibitor of Erk1/2, resulted in a remarkable decline in the mRNA and protein expression of collagens and fibronectin. Furthermore, rhCYR61 upregulated the expression of TGF-β in AFs, and TGF-β siRNA transfection obviously attenuated the profibrotic effect of rhCYR61. Finnally, recombinant human IL-17 (rhIL-17) could promote the expression of CYR61 in AFs, and the combination of rhIL-17 and rhCYR61 dramatically strengthened the synthesis of ECM. The CYR61 monoclonal antibody diminished these effects of rhIL-17 in AFs.

Conclusion: These findings indicated that CYR61/Erk1/2/TGF-β pathway played a profibrotic role in the pathogenesis of TA, and this was enhanced by IL-17 mediated inflammatory environment. Thus, targeting CYR61 may have potential clinical values in the future.

Monoclonal ACPA Promote Synovial Fibroblasts Migration Through a Peptidylarginine Deiminases (PAD) Dependent Pathway

Meng Sun,[1] Bence Rethi,[1] Akilan Krishnamurthy,[2] Vijay Joshua,[3] Alexandra Circiumaru,[1] Aase Hensvold,[1] Marianne Engström,[4] Sergiu-Bogdan Catrina,[5] Johanna Steen,[6] Vivianne Malmström,[3] Caroline Grönwall,[3] Lars Klareskog,[7] Heidi Wähämaa,[1] and Anca Catrina[7], [1]Rheumatology unit Karolinska University Hospital and Karolinska Institutet, Stockholm, Sweden, Stockholm, [2]Rheumatology unit, Department of Medicine, Karolinska University Hospital and Karolinska Institutet, Solna, Stockholm, [3]Rheumatology Unit, Department of Medicine, Karolinska University Hospital and Institutet, Stockholm, Sweden., Stockholm, Sweden, [4]Karolinska Institutet and Karolinska University Hospital, Stockholm, [5]Karolinska Institutet and Karolinska University Hospital, Stockholm, Sweden, [6]Stockholm University, Stockholm, [7]Rheumatology unit Karolinska University Hospital and Karolinska Institutet, Stockholm, Sweden, Stockholm, Sweden

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Cytokines & Cell Trafficking Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Anti-citrullinated protein antibodies (ACPAs) play an important role in rheumatoid arthritis (RA) pathogenesis. ACPAs have different amino acid motif recognition patterns and show cross-reactivity to other protein modifications. We aimed to investigate the effect of different monoclonal ACPAs on RA synovial tissue derived fibroblast-like synoviocytes (FLS).

Methods: FLS were isolated from synovial tissue of RA patients by enzymatic digestion. ACPA and control monoclonal antibodies (mAbs) were derived from single B cells isolated from RA patients. Whole antibodies and F(ab')2 fragments were tested in synovial fibroblast migration (IncuCyte live-cell analysis) and osteoclast formation assays. Blocking experiments were performed with soluble citrullinated proteins in SF migration. The role of mAbs cross-reactivity was tested in fibroblast migration assays using antibodies with distinct cross-reactivities, inhibitors of peptidylarginine deiminases (Cl-amidine and GSK199), histone acetyltransferase (anacardic acid) and histone deacetylase (trichostatin A). Binding patterns of monoclonal ACPAs were tested in synovial biopsies obtained from both healthy donors and RA patients.

Results: Three monoclonal ACPAs (1325:01B09, 14T+:02D09 and14T+:02H12) enhanced fibroblast migration significantly compared to control mAb 1362:01E02-treated samples (mean±SD fold increase of 1.9±0.5, 1.7±0.4 and 1.8±0.6, respectively, $p< 0.05$), whereas the same antibodies showed no effect on osteoclast formation. Clone 1325:01B09 but neither 14T+:02D09 nor 14T+:02H12 is cross reactive with homo-citrullinated and acetylated targets (acetylated histone). The effect of 1325:01B09 on fibroblast migration was completely abolished by Cl-amidine or by pre-incubating the antibody with citrullinated fibrinogen or histone but not by citrullinated enolase or vimentin. Despite the cross-reactivity with acetylated epitopes, neither anacardic acid nor trichostatin A could modulate the 1325:01B09 effect on fibroblast migration. The fibroblast-promoting ACPA clone 1325:01B09 but not the osteoclastogenic 1325:04C03 co-localized with podoplanin-positive fibroblasts in the inflamed rheumatoid synovium. On the contrary to RA samples, healthy synovia were not stained by ACPAs. F(ab')2 fragments of mAbs show similar effects on synovial fibroblast migration, osteoclast formation and a similar tissue binding pattern as the intact antibodies, indicating an Fc-independent mediated effect.

Conclusion: Some but not all ACPA clones could stimulate synovial fibroblast migration through a mechanism that was dependent on protein citrullination but no other protein modifications or FcR binding. Different clones acted on fibroblasts and osteoclasts suggesting unique pathological roles associated with individual ACPA specificities.

Transcription Factor Fli-1 Impacts Lupus Nephritis by Orchestrating CXCL10/CXCR3 Axis

Xuan Wang,[1] Mara Lennard Richard,[1] Tomika Caldwell,[2] Brittany Henry,[2] Tammy Nowling,[2] Jim Oates,[3] Gary Gilkeson,[4] and Xian Zhang[1], [1]Medical University of South Carolina, Charleston, SC, [2]Medical University of South Carolina, Charleston, [3]Division of Rheumatology & Immunology/Medical University of South Carolina, Charleston, SC, [4]Division of Rheumatology & Immunology/Ralph H. Johnson VA Medical Center/Medical University of South Carolina, Charleston, SC

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Cytokines & Cell Trafficking Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Lupus nephritis is a major cause of death in both animal models and human patients. Expression of Fli-1, a member of the Ets family of transcription factors, is implicated in the development of nephritis in murine models ofSLE as well as human lupus nephritis. The increased expression of Fli-1 is significantly associated with new or recurrent lupus nephritis in SLE patients with lupus nephritis compared with SLE without lupus nephritis. Reducing the levels of Fli-1 in two lupus mouse strains significantly decreased renal disease with a profound decrease in infiltrating inflammatory cells and prolonged survival. IFN-gamma Inducible Protein (IP-10), also known as C-X-C motif chemokine 10 (CXCL10), is an inflammatory chemokine belonging to the CXC chemokine family. Overexpression of CXCL10 is associated with clinical lupus nephritis. CXCL10 is chemotactic for inflammatory cells including macrophages, monocytes and activated T and NK cells that express the CXCR3, a receptor for CXCL10. Previous reports demonstrated that CXCR3+ cells are recruited into the inflamed kidneys in murine models of lupus and human patients. In this study, we examinedif Fli-1 impacts lupus nephritis by orchestrating CXCL10/CXCR3 Axis.

Methods: The expression of CXCL10 was measured in kidneys from Fli-1 knockout heterozygous MRL/lpr mice, a murine model of lupus (Fli1+/-; Fli-1 homozygous knockout is embryonic lethal), and wild-type (Fli1+/+) MRL/lpr mice. A murine endothelial cell line, human renal glomerular endothelial cells (HRGEC), and human T cells were used in this study. CXCL10 was measured using commercially available ELISA kits. The specific Fli-1 siRNA was used to knock down the expression of Fli-1 in cells.

Results: CXCL10 protein concentration was significantly higher from kidney homogenates from wild-type MRL/lpr mice compared to the kidney homogenates from Fli-1+/- MRL/lpr mice at the age of 25 weeks (WT, 2,264±376 pg/mg vs Fli-1+/-,1322±129 pg/mg, N=11, $p< 0.05$). CXCL-10 concentrations from mouse endothelial cells transfected with Fli-1 siRNA were significant lower compared to the cells transfected with control siRNA following stimulation with LPS (645.7± 167.1 pg/ml versus 336.2± 93.26 pg/ml at 6 hours, $P< 0.001$; and 1493.75± 392.35 pg/ml versus 540.01± 187.37 pg/ml at 24 hours, $p< 0.001$). The CXCL10 concentrations in supernatant from HRGEC transfected with Fli-1 siRNA and stimulated with LPS or TNF-α were significantly lower 6 and 24 hours post LPS or TNF-α stimulation compared to thosetransfected with control siRNA. Fourteen putative Ets binding sites are identified within a 2900 bp region of the CXCL-10 promoter, and four sites in the promoter showed significant enrichment for Fli-1 specific antibodies compared to normal IgG controls by the chromatin immunoprecipitation (ChIP) assay. We have demonstrated that mutation of the Fli-1 DNA binding domain led to a statistically significant reduction in activation from the CXCR3 promoter when compared to wild-type Fli-1 protein, andacetylationand phosphorylationofFli-1play arole in CXCR3activityin Tcell.

Conclusion: Together, the results implicate that one key factor in Fli-1's impact on lupus nephritis is by modulating theCXCL10/CXCR3 Axis.

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Cytokines & Cell Trafficking Poster

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Higher levels of CXCL10 and CXCL11 in patients with a very early diagnosis of systemic sclerosis (SSc) subsequently shifted to SSc were pointed out (1). An intriguing role of IL-33 in early SSc patients was also previously described (2).

Methods: Serum levels of CXCL-10, CXCL-11 and IL-33 were measured in 30 undifferentiated connective tissue disease at risk for SSc (UCTD-risk-SSc) patients (3), otherwise referred to as very early-early SSc, and 34 healthy controls (HC) by multiplex suspension immunoassay. All UCTD-risk-SSc patients were followed-up for 36 (12-101) months.

Results: Serum levels of CXCL-10, CXCL-11 and IL-33 resulted higher in UCTD-risk-SSc patients as compared to HC (respectively: $p< 0.001$; $p< 0.001$ and $p=0.07$). UCTD-risk-SSc subsequently evolved to SSc showed higher baseline cytokines levels versus patients not evolved (CXCL10: $p=0.05$; $p=0.04$ and IL-33: $p=0.03$). At receiver operating characteristic (ROC) analysis the following cut-off values were able to discriminate patients evolving into SSc (CXCL-10 >34.47 pg/mL, area under the curve (AUC)=0.72, $p=0.02$ with 0.63 sensitivity (SE) and 0.82 specificity (SP); CXCL11 >42.38 pg/mL, AUC=0.73, $p=0.02$ with 0.84 SE and 0.54 SP; IL-33 >8.86 pg/mL, AUC=0.73, $p=0.01$ with 0.89 SE and 0.54 SP). In addition a baseline CXCL-11 value >45.21 pg/mL and IL-33 value >8.86 pg/mL were able to discriminate patients developing an interstitial lung disease (AUC=0.80, $p< 0.001$ with 1.0 SE and 0.56 SP and AUC=0.72, $p=0.05$ with 1.0 SE and 0.53 SP).

Conclusion: We confirmed the previous data on CXCL-10 and CXCL-11 and we first highlighted a potential role of IL-33 in predicting disease evolution.

Inhibition of IkB Kinase-IKK Complex of Canonical NF-κB Pathway in Antiphospholipid Antibody-Mediated Endothelial Cell Activation

Rohan Willis,[1] Elizabeth Papalardo,[1] Mohammad Jamaluddin,[1] Zurina Romay-Penabad,[1] Alvaro Schleh,[1] Allan Brasier,[1] and Emilio B Gonzalez[2], [1]University of Texas Medical Branch, Galveston, TX, [2]University of Texas Medical Branch, Galveston

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Cytokines & Cell Trafficking Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Antiphospholipid antibodies (aPL) activate several target cell types leading to inflammatory damage and thrombosis in the antiphospholipid syndrome (APS). NF-κB activation is essential for inducing this inflammatory phenotype but there is limited information on the role of the canonical vs non-canonical NF-κB activation pathways in APS and the inhibition of these pathways as a possible therapeutic strategy in APS. We sought to determine the efficacy of specific inhibitors of the regulatory IκB kinase complex (IKK), which is responsible for initiating nuclear translocation of NF-κB, in ameliorating the effects of aPL.

Methods: Whole IgG fractions were purified from normal (IgG-NHS) and primary APS (IgG-APS) patients by ammonium sulphate precipitation followed by DEAE sepharose chromatography. Increasing doses of purified whole IgG-APS and control IgG-NHS fractions were used to treat human umbilical vein endothelial cells (HUVEC) (100-400μg/ml). Quantitative RT-PCR was used to measure E-selectin (E-sel), tissue factor(TF), interleukin (IL)-6 and IL-8 mRNA expression and western blot was used to evaluate the time course of NF-κB activation in treated HUVEC identifying various subunits over 4-hours post treatment (at time points 0, 15, 30, 60, 120, 240 and 480 minutes). The effectiveness of specific IKK inhibitors Bay-11-7082 and BMS-345541 were evaluated.

Results: IgG-APS increased pro-inflammatory cytokine expression in a dose dependent manner, with a maximum mRNA fold change ranging from 4-18 times over controls. Over the 4-hour time-course cytoplasmic expression of IκBα decreased and nuclear expression of RelA, p50 (strong) and p52, p105 (weak) subunits increased in response to aPL treatment (peaks at 30 to 60 minutes), indicating strong activation via the canonical NF-kB pathway. BMS and Bay-11 significantly inhibited cytokine expression 2.5 to 3.5 fold in aPL-treated HUVEC.

Conclusion: The canonical NF-kB pathway is essential for aPL-medicated EC activation in at least a portion of APS patients. Accordingly, specific IKK inhibitors may prove useful in ameliorating aPL-mediated inflammation in these patients.

Session Title: Cytokines & Cell Trafficking Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: In previous studies, our group has demonstrated that a synthetic 20 amino acid peptide ("TIFI") with structural similarity to Beta-2-Glycoprotein I Domain V (β2GPI DV) prevents endothelial cell (EC) activation and thrombosis in a mouse model of antiphospholipid syndrome (APS). In order to improve its half-life and decrease its immunogenicity, TIFI was PEGylated but this process proved inefficient, with substantial loss of material during the process. Therefore, we have designed two synthetic peptides that would potentially improve efficiency of PEGylation, TIFI Mut1 and TIFI Mut2, and evaluated their ability to inhibit antiphospholipid antibody (aPL)-mediated EC activation.

Methods: Whole IgG fractions were purified from normal (IgG-NHS) and primary APS (IgG-APS) patients by ammonium sulfate precipitation followed by DEAE sepharose chromatography. A dose of 200μg/ml IgG was used to treat human umbilical vein endothelial cells (HUVEC) alone or after 2 hours pre-incubation with 10μM TIFI WT, Mut1 or

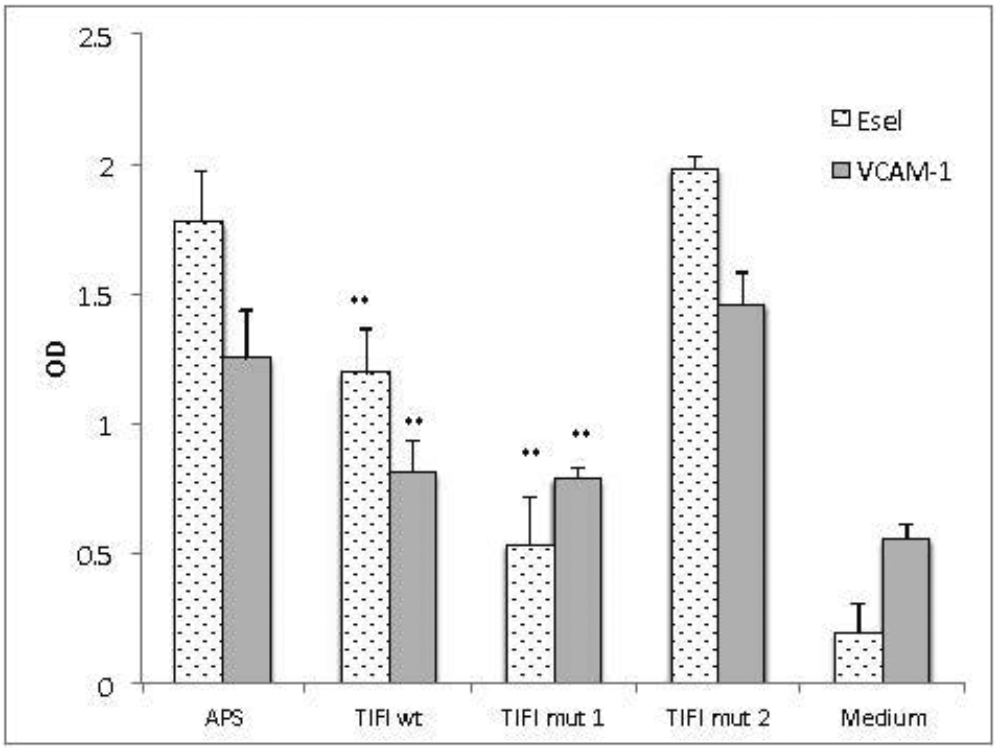

Figure 1. CytoELISA Activity on HUVEC - Effect of non-PEGylated TIFI variants on aPL-mediated cytokine production. **-p<0.001 compared to APS

Mut2. Quantitative RT-PCR was used to measure E-selectin (E-sel), tissue factor (TF), intercellular adhesion molecule-1 (ICAM-1) and vascular cell adhesion molecule-1 (VCAM-1) mRNA expression. VCAM-1 and E-sel cell surface expression was also determined by cytoELISA on fixed ECs treated with IgG ± TIFI variants

Results: TIFI-Mut1 was 1.3-2.3 fold more effective than TIFI-WT in inhibiting aPL-mediated inflammatory cytokine mRNA induction. Similarly, TIFI-Mut 1 was 3 times more effective in limiting cell-surface expression of E-sel compared to TIFI-WT and was equally as effective in limiting VCAM-1 surface expression. TIFI-Mut2 was ineffective at inhibiting aPL activation of HUVECs.

Conclusion: TIFI Mut1 peptide reduces aPL-induced inflammatory cytokine gene expression and cell surface expression significantly, indicating that PEGylation of this peptide variant will likely be effective in an in vivo application.

Immuno-Phenotypic Analysis of Peripheral Blood Mononuclear Cells in Rheumatoid Arthritis Patients Treated with E6011, a Humanized Anti-Fractalkine Monoclonal Antibody

Tomohiro Yamada,[1] Jungo Kakuta,[1] Eri Fusaoka-Nishioka,[1] Jun-ichi Ito,[2] Nobuyuki Yasuda,[3] Tetsu Kawano,[3] and Toshio Imai[3], [1]KAN Research Institute Inc., Kobe, Japan, [2]EISAI Co. Ltd., Tsukuba, Japan, [3]KAN Research Institute, Inc., Kobe, Japan

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Innate Immunity Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Fractalkine (FKN) and its solo receptor CX3CR1 are deeply involved in the pathogenesis of rheumatoid arthritis (RA). FKN is expressed on vascular endothelium, while CX3CR1 is expressed on peripheral blood leukocytes such as monocytes/macrophages, NK cells, effector $CD8^+$T cells and a minor fraction of $CD4^+$T cells. E6011, a novel humanized anti-FKN monoclonal antibody (mAb), is under clinical development in RA. In order to continuously assess the E6011 pharmacodynamics by monitoring the alteration of peripheral blood immune cells, including CX3CR1-expressed cell populations, a series of multi-color flow cytometry (FCM) was conducted before and during the course of the E6011 treatment of active RA patients in phase 2 clinical trial.

Methods: Immuno-phenotypic changes were explored by FCM during the E6011 administration in 190 Japanese RA patients with inadequate response to MTX (NCT02960438). Patient's peripheral blood were drawn into fixative tube (Cyto-Chex® BCT, Streck) at each clinics and thereafter transported to the FCM facility at KAN Research Institute. Inc. within 30 hours after the blood collection to operate the FCM analysis by standardized method. Immuno-phenotyping was carried out by multi colors flow cytometry (BD FACSCantoII™, BD LSRFortessa™, BD Biosciences).

Results: Based on these determined conditions, CX3CR1 expression on monocytes, NK cells and a part of $CD8^+$and $CD4^+$T cells were confirmed in this method. Interestingly, during the E6011 treatment, the proportion of CD16+ monocytes, which highly express CX3CR1 within whole monocytes, were significantly decreased at 2 week after initial treatment from the baseline (E6011 : $p< 0.001$, placebo: $p> 0.48$) and sustained up to 24 week, while that of $CD16^-$monocytes were increased. The reduction of the proportion of NK cells, $CD4^+$and $CD8^+$T cells were not ob-

served, but in some certain populations like CX3CR1-expressed $CD56^+CD16^+$NK cells and terminal differentiated effector $CD8^+$T cells, the percentage of these populations tended to increase from the baseline at 2 week and kept increasing up to 24 week by the E6011 treatment.

Conclusion: Our results indicated that the reduction of $CD16^+$monocytes after initial treatment might be a sensitive pharmacodynamic marker of E6011 exposure, possibly reflecting mechanism of action of E6011, since the $CD16^{+-}$ monocytes are the most abundant $CX3CR1^+$cell population in peripheral blood.

Abstract Number: 0022

Beta-2 Glycoprotein I as a DNA- and NET-binding Protein

Kelsey Gockman,[1] Srilakshmi Yalavarthi,[1] Gautam Sule,[1] Alexandra Morris,[1] Yu Zuo,[2] and Jason Knight[3], [1]University of Michigan, Ann Arbor, MI, [2]University of Texas Southwestern, Dallas, TX, [3]Division of Rheumatology, Department of Internal Medicine, Michigan Medicine, Ann Arbor, MI

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Innate Immunity Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Beta-2 glycoprotein I (β_2GPI) is a prominent autoantigen in antiphospholipid syndrome (APS). As an abundant plasma protein, β_2GPI has variably been suggested to have antioxidant, anticoagulant, and scavenging functions, albeit without a clear consensus regarding its defining role. Many years ago, β_2GPI was shown to be capable of binding cell-free DNA in plasma; however, to our knowledge, this line of investigation was not further pursued. Here, we tested the hypothesis that β_2GPI might bind to not only negatively-charged DNA, but also neutrophil extracellular traps (NETs)—prothrombotic tangles of chromatin and microbicidal proteins extruded from activated neutrophils. We also asked whether β_2GPI-DNA complexes might be detectable*in vivo*, specifically in the blood of patients with APS.

Methods: To induce NET release, control neutrophils were stimulated with either phorbol 12-myristate 13-acetate (PMA) or lipopolysaccharide (LPS) in the presence of human serum as a source of β_2GPI. In parallel, APS neutrophils were cultured in the presence of autologous serum and allowed to undergo spontaneous NET release. To assess a potential direct interaction between β_2GPI and either genomic DNA or purified NETs, we utilized the electrophoretic mobility shift assay (EMSA). Finally, we developed a novel sandwich ELISA to measure plasma concentrations of β_2GPI-DNA complexes in which the capture antibody was specific for β_2GPI and the detection antibody specific for DNA.

Results: By confocal immunofluorescence microscopy, we observed broad decoration of both anuclear neutrophils remnants and NET strands themselves by β2GPI. The pattern of β2GPI decoration of NETs was relatively granular, as compared with linear painting of NETs by neutrophil elastase. β2GPI-decorated NETs were appreciated in the context of PMA-and LPS-stimulated control neutrophils, as well as spontaneous NET release from APS neutrophils. By agarose-gel EMSA, β2GPI triggered dose-dependent electrophoretic retardation of both neutrophil genomic DNA and purified NETs. Using a custom ELISA for β2GPI-DNA complexes, we tested 78 primary-APS plasma samples alongside 41 healthy-control samples. APS plasma demonstrated significantly higher levels of β2GPI-DNA complexes as compared with healthy controls (3.6 μg/ml ± 10 versus 0.57 μg/ml ± 1.6; $p< 0.0001$ by Mann-Whitney test).

Additional analyses are underway to determine whether β2GPI-DNA complexes are associated with particular APS clinical profiles, and the extent to which these complexes are unique to APS versus other inflammatory states.

Conclusion: β_2GPI appears to directly bind both genomic DNA and NETs. In neutrophil cultures, β_2GPI decorates anuclear neutrophil remnants, as well as classic NET strands. Intriguingly, β_2GPI-DNA complexes are on average 6-fold higher in the plasma of patients with primary APS as compared with controls. Future research should endeavor to determine whether β_2GPI is an endogenous DNA scavenger, and the extent to which the β_2GPI-NET association may play a role as an instigator and/or perpetuator of autoimmunity in APS.

Covalent High Molecular Weight HMGB1 Complexes in Muscle Regeneration: Implications in Inflammatory Myopathy

William Willis,[1] Jennifer Petrosino,[2] Giancarlo Valiente,[1] Lai-Chu Wu,[3] and Wael Jarjour[4], [1]The Ohio State University, Columbus, [2]The Ohio State University Wexner Medical Center, Columbus, OH, [3]Ohio State College of Medicine, Columbus, [4]Ohio State College of Medicine, Columbus, OH

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Innate Immunity Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Increased levels of the alarmin high mobility group box one (HMGB1) have been implicated as a possible pathogenic mediator and biomarker for myositis. We have recently published that in response to stress/ inflammation, HMGB1 forms covalent protein complexes (HMGB1c) via transglutaminase-2 (TG2) dependent crosslinking. The purpose of this study is to test the hypothesis that HMGB1c is a driver of skeletal muscle myogenesis and may play a role in the pathogenesis of myositis.

Methods: A combination of in vivo and in vitro studies were used to examine the role of HMGB1c in muscle regeneration. Muscle regeneration and myogenesis were examined in TG2 -/- vs. wild-type mice as well as in mouse C2C12 myoblasts. An in vivo muscle regeneration model using BaCl2 induced injury was used to probe muscle covalent HMGB1 complex expressionand myogenic markers. Samples were analyzed by real time RT-PCR, immunohistochemistry, and western blotting.

Results: HMGB1 formed high molecular weight, heat/denaturing resistant protein complexes (HMGB1c) in differentiating C2C12 cells. Loss of TG2 function via RNAi or genetic ablation reduced HMGB1c formation, impaired C2C12 differentiation, and delayed muscle regeneration in vivo. Impaired muscle regeneration in TG2 -/- mice also correlated with enhanced pro-inflammatory immune cell infiltration and reduced presence of myogenic M2 macrophages.

Conclusion: Our results revealthat TG2 is a novel mediator of myogenesis in vitro and in vivo, which may occur in-part via HMGB1 transamidation and altered pro- to anti-inflammatory transitions during myogenic differentiation. Increased presence of HMGB1c in plasma of myositis patients relative to healthy controls suggests that the crosslinked alarmin could play a role in disease pathogenesis.

Role of Trained Immunity in the Pathogenesis of Erdheim-Chester Disease

Giulio Cavalli,[1] Riccardo Biavasco,[1] Marina Ferrarini,[2] Elisabetta Ferrero,[2] Eugenio Montini,[2] Simone Cenci,[2] Cardaci Simone,[2] and Lorenzo Dagna[1], [1]Vita-Salute San Raffaele University, Milan, Italy, [2]IRCCS San Raffaele Hospital, Milan, Italy

SESSION INFORMATION

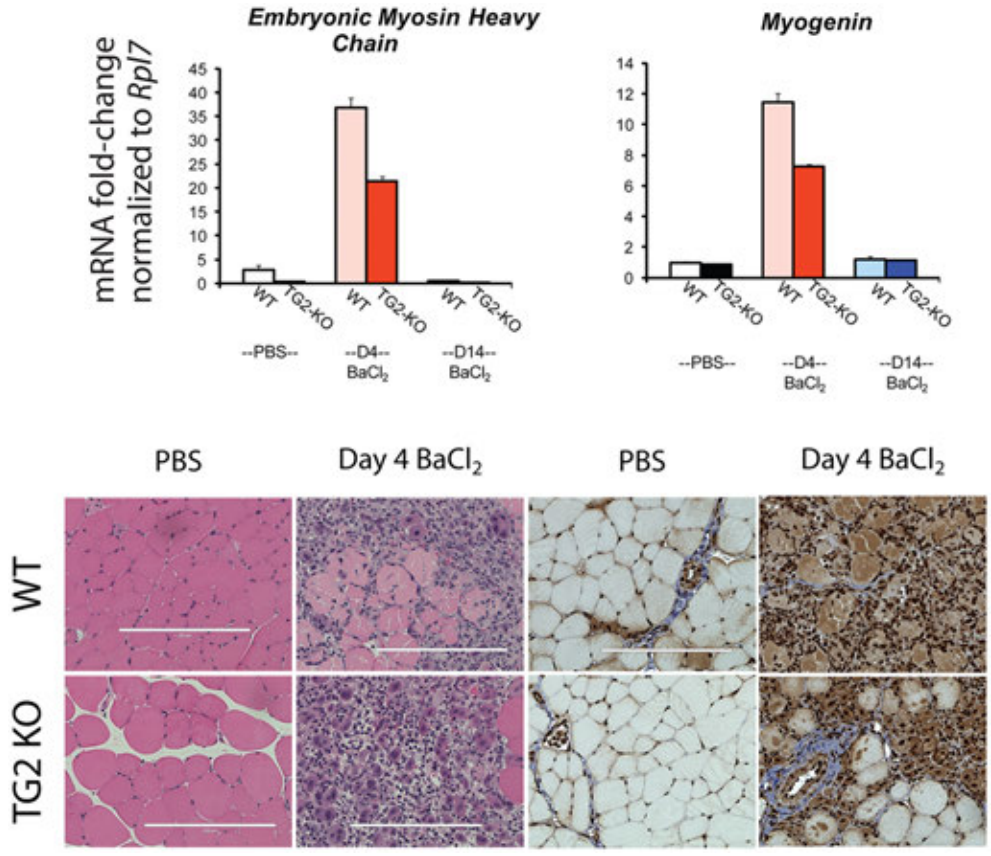
Session Date: Sunday, November 10, 2019

Session Title: Innate Immunity Poster

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Erdheim-Chester disease (ECD) is a chronic inflammatory disease characterized by infiltration of bone and other tissues by foamy macrophages. These cells exhibit activating mutations along the MAPK pathway, most commonly BRAFV600E, and increased production of pro-inflammatory cytokines. Although this dual neoplastic-inflammatory nature of ECD has long fascinated scientists, the mechanistic link between these two features remains elusive. We hypothesized that Trained Immunity (TI), a pro-inflammatory cell program physiologically elicited in monocytes/macrophages upon activation of the MAPK pathway, might represent the missing link between oncogenic transformation and pro-inflammatory activation in ECD. In this study, we aimed at determining the role of



TG2 genetic ablation decreases cytosolic HMGB1 levels, delays regeneration in a BaCl2-induced muscle injury model.

TI in the pathogenesis of ECD, and to evaluate the therapeutic potential of targeting this mechanism for the treatment of ECD.

Methods: We developed innovative models to study ECD pathogenesis*in vitro*and*in vivo*(ectopic expression of BRAFV600E in monocytes and hematopoietic progenitors from healthy donors cultured and/or transplanted into immunocompromised mice), as well as*ex vivo*(3D culture of ECD tissues in bioreactor). Mechanistic features of TI, including typical changes in cell energy metabolism and epigenetics, were investigated by assessing I) cytokine and lactate production; II) mitochondrial respiration with Seahorse flux analyzer; III) glucose and glutamine metabolism with metabolomics analyses; III) chromatin dynamics with ATAC sequencing.

Results: Activation of the MAPK pathway induced by BRAFV600E in ECD macrophages induces changes in the epigenetic landscape, cell energy metabolism, and cytokine production characteristic of TI. In particular, changes in cell energy metabolism of macrophages are characterized by increased glycolysis and glucose and glutamine metabolism. This metabolic rewiring is likely needed to sustain rampant, constitutive production of pro-inflammatory cytokines IL-1β, IL-1α, and IL-6.

Conclusion: A role emerges for TI in the pathogenesis and pro-inflammatory activation of ECD. Since drugs targeting TI programs are already entering the clinical arena, the identification of this mechanism in the pathogenesis of ECD may translate into novel, effective treatment options for ECD patients.

Altered Distribution and Enhanced Osteoclastogenesis of Mucosal-associated Invariant T Cells in Gouty Arthritis

Yong-Wook Park,[1] Young-Nan Cho,[1] Hae-Seong Jeong,[1] Hye-Mi Jin,[1] and Seung-Jung Kee[1], [1]Department of Rheumatology, Chonnam National University Medical School and Hospital, Gwangju, Republic of Korea

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Innate Immunity Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Mucosal-associated invariant T (MAIT) cells are subsets of innate invariant T cells and rapidly produce Th1/Th17 cytokines including interferon (IFN)-γ, tumor necrosis factor (TNF)-α, and interleukin (IL)-17 in an innate-like manner. Accumulating data indicate that MAIT cells play an important role in immune defense against infection or cancer. Furthermore, recent studies have extended knowledge regarding the clinical relevance of MAIT cells to cardiometabolic diseases, including metabolic syndrome, obesity, diabetes mellitus, and cardiovascular disease. Here, we investigate the role of MAIT cells in gouty arthritis (GA), one of metabolic diseases, and their effects on osteoclastogenesis.

Methods: Patients with GA (n = 61), hyperuricemia subjects (n = 11), and healthy controls (n = 30) were enrolled in this study. MAIT cells, cytokines, CD69, programmed death-1 (PD-1), and lymphocyte-activation gene 3 (LAG-3) levels were measured by flow cytometry.*In vitro*osteoclastogenesis experiments were performed using peripheral blood mononuclear cells in the presence of macrophage colony-stimulating factor and receptor activator of nuclear factor kB ligand.

Results: Circulating MAIT cell levels were significantly reduced in GA patients. However, their capacities for IFN-γ, IL-17, and TNF-α production were preserved. Expression levels of CD69, PD-1, and LAG-3 in MAIT cells were found to be elevated in GA patients. In particular, CD69 expression in circulating MAIT cells was increased by stimulation with monosodium urate monohydrate (MSU) crystals, suggesting that deposition of MSU crystal might contribute to MAIT cell activation. Interestingly, MAIT cells were found to be accumulated in synovial fluid and infiltrated into gouty tophus tissues within joints. Furthermore, activated MAIT cells secreted pro-resorptive cytokines (i.e., IL-6, IL-17, and TNF-α) and facilitated osteoclastogenesis.

Conclusion: This study demonstrates that circulating MAIT cells are activated and numerically deficient in GA patients. In addition, MAIT cells have the potential to migrate to inflamed tissues and induce osteoclastogenesis. These findings provide an important role of MAIT cells in the pathogenesis of inflammation and bone destruction in GA patients.

Increased Sodium Accumulation Detected by ^{23}Na-Magnetic Resonance Imaging in Inflamed Knees of Patients with Autoimmune Joint Disease

Emma de Moel,[1] Wouter Teeuwisse,[2] Thomas Huizinga,[3] René Toes,[3] Andrew Webb,[2] and Diane van der Woude[1], [1]Department of Rheumatology, Leiden University Medical Center, Leiden, Netherlands, [2]Department of Radiology, C.J. Gorter Center for High-Field MRI, Leiden University Medical Center, Leiden, Netherlands, [3]Leiden University Medical Center, Leiden, Netherlands

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Innate Immunity Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Salt, or sodium, has recently emerged as a potent factor involved in modulating inflammatory responses. Sodium is implicated as a dietary risk factor for (ACPA-positive) RA[1]and increased sodium concentrations lead to enhanced Th17 cell differentiation[2]. Furthermore, sodium accumulates locally in certain inflamed and sclerotic tissues such as the skin, both in the context of infection and in autoimmunity, as has been shown in scleroderma patients[3]. To clarify whether sodium, as a possible inflammation-enhancing factor, may also accumulate locally in the joints in autoimmune arthritis, we used a state-of-the-art, non-invasive 7-Tesla^{23}Na MRI technique to measure sodium concentrations in inflamed knees of patients with autoimmune joint disease.

Methods: In 8 patients with autoimmune arthritis of the knee (3 JIA, 2 PsA, 2 RA, 1 peripheral SpA) and 11 healthy controls, we measured synovial Na^+content in the (affected) knee with a birdcage double-tuned proton/^{23}Na sodium transmit/receive coil on a 7-Tesla MR system (Philips Healthcare, Best, the Netherlands). Cartilage, synovium, and synovial fluid (in the intra-articular space and synovial bursae) was manually segmented in the proton image in six sagittal slices, after which the volume of interest was transferred to the^{23}Na image for extraction of^{23}Na MR signal intensity. Average Na^+content in mmol/L was calculated by relating^{23}Na MR signal intensity to three agarose standard gels of known Na^+concentration (20, 50, and 100 mmol/L), scanned in tandem with each knee (see Figure 1).

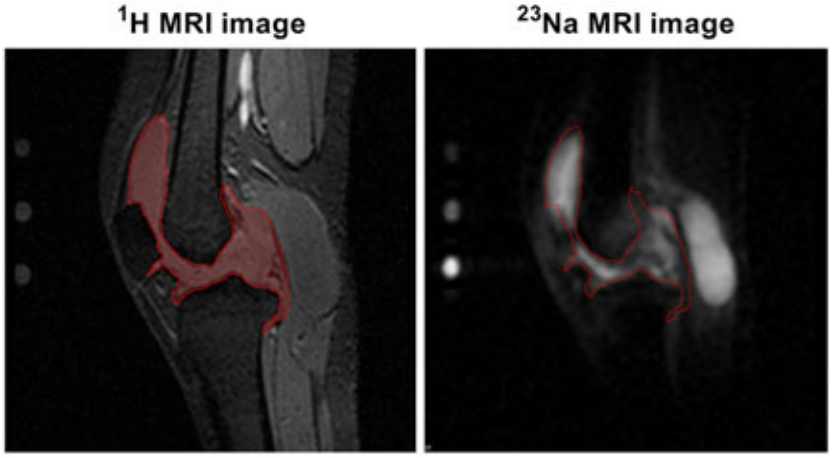

Figure 1. Manual segmentation of a mid-knee sagittal slice of a representative patient. The volume of interest (cartilage, synovium, and synovial fluid in the joint space and synovial bursae) was manually selected in the proton image (left), propagated to adjacent slices, and then transferred to the sodium image (right) for quantification of sodium signal. Cross-sections of three sodium-containing agarose phantom tubes are visible anterior to the knee, from top to bottom: 20, 50, 100 mmol/L sodium. Baker's cysts, as visible in this patient, were not included in the analysis.

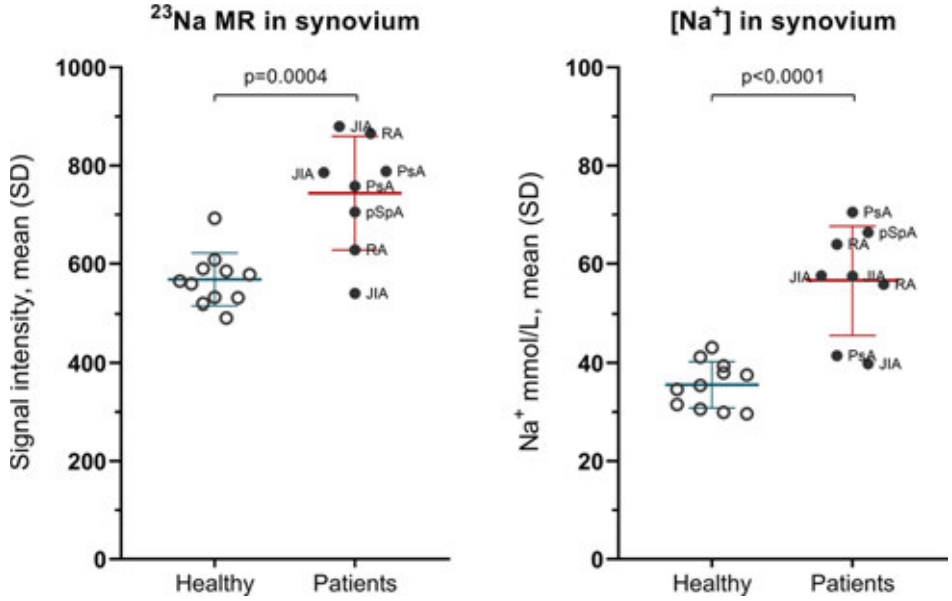

Figure 2 Synovial sodium MR signal intensity (left) and concentration (right) quantified by 23Na-MRI. Each dot, representing one subject, is based on the average of 6 sagittal MRI slices capturing the synovial volume.

Results: ^{23}Na-MRI signal intensity in synovial structures was consistent and reproducible across slices: between slice coefficient of variation in a representative patient was 9.4%.^{23}Na-MRI demonstrated increased^{23}Na MR signal intensity in arthritis knees of patients compared to healthy controls: mean (SD): 744 (116) vs 568 (54), p=0.0004 (Figure 2). When this MR signal intensity was converted to Na^{+}concentration, patients had clearly increased Na^{+}-concentrations compared to controls: mean (SD): 57 (11) vs 36 (5) mmol/L, p< 0.0001. A linear regression with synovial Na^{+}concentration as the outcome indicated that the differences in synovial Na^{+}concentration between patients and healthy controls could not be explained by differences in synovial volume (not shown).

Conclusion: Tissue sodium detection and quantification by 7-Tesla ^{23}Na MRI is feasible and reliable, and indicates significantly higher sodium content in inflamed knees of patients with autoimmune joint disease compared to healthy controls. This suggests that sodium may be involved in modulating inflammation and synovial cell biology. Whether this is specific for chronic autoimmune joint diseases or may be present for more general inflammation remains to be determined.

Altered Inflammatory Response of Macrophages in the Fosl-2 Transgenic Mouse Model of Systemic Sclerosis

Chantal Rufer,[1] **Michal Rudnik**,[1] Siim Uhtjärv,[1] Mara Stellato,[1] Florian Renoux,[2] Oliver Distler,[3] and Gabriela Kania[1], [1]Center of Experimental Rheumatology, Department of Rheumatology, University Hospital Zurich, Zurich, Switzerland, [2]Center of Experimental Rheumatology, Department of Rheumatology, University Hospital Zurich, Zurich, [3]Dept. of Rheumatology, University Hospital Zürich, Zürich, Switzerland, Zürich, Switzerland

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Innate Immunity Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Fos-like 2 (Fosl-2) is a transcription factor belonging to the Fos family of proteins which is part of the AP-1 transcription complex. The Fosl-2 transgenic (tg) mouse model has been shown to develop a similar phenotype to patients with SSc, such as vascular changes, dysregulation of innate and adaptive immunity, and fibrosis of the skin and visceral organs. Although the etiology is yet to be found, various studies have indicated immune cells, such as macrophages, to be important contributors to the pathogenesis of SSc. In this study, we aimed to determine the role of Fosl-2 expression in macrophages.

Methods: Bone marrow from Fosl-2 tg and wild type (wt) mice was isolated and differentiated into macrophages by stimulation with recombinant mouse macrophage colony stimulating factor (M-CSF) (20 ng/ml) for 7 days. The bone marrow-derived macrophages (BMDM) were stimulated with LPS (10 ng/ml) or IL-4 (10 ng/ml) for various time points. Expression of Fosl-2 and cJun was checked by Western blot. Levels of inflammatory cytokines IFN-g (wt n=12, tg n=15), TNF-α (wt n=9, tg n=11), IL-1β (wt n=8, tg n=9), IL-6 (n=7), and anti-inflammatory markers MRC1 (wt n=9, tg n=11) and CCL22 (n=8) were determined by qPCR and ELISA. To assess the production of nitric oxide, BMDM were stimulated with LPS (10 ng/ml) (n=17) or LPS + IFN-g (10 ng/ml) (n=9) and a Griess assay was performed. An arginase assay was conducted to evaluate urea concentration post stimulation (wt n=7, tg n=3).

Results: We observed induction of Fosl-2 after LPS and IL-4 stimulation in wt and Fosl-2 tg BMDM, with the peak of expression at 4 to 6 hours in wt mice. Tg mice show a higher induction of Fosl-2 after LPS stimulation than wt mice. After LPS stimulation, Fosl-2 tg BMDM showed a decreased mRNA expression of IFN-g ($p< 0.0001$), TNF-α ($p=0.0036$), as well as a tendency towards decreased expression of IL-1β. Protein levels of IL-6 and TNF-α appeared to peak around 6h post LPS stimulation and were decreased in tg BMDM compared to wt BMDM ($p=0.0044$ and $p=0.02555$). Fosl-2 tg BMDM were characterized by lower concentrations of NO after LPS stimulation ($p=0.0061$) and further decreased after co-stimulation with IFN-g ($p=0.0118$), in comparison to wt mice. After stimulation with IL-4, when comparing wt to tg BMDM, MRC1 ($p=0.0007$) was downregulated and CCL22 ($p=0.0361$) upregulated.

Conclusion: Our data indicates the involvement of Fosl-2 in the regulation of the inflammatory response of macrophages. Decreased levels of inflammatory cytokines suggest a possible alternative activating phenotype-promoting role of Fosl-2. Alternative activation of macrophages induces fibrosis, thus bringing Fosl-2 and macrophages into the spotlight regarding the development of fibrosis in SSc.

Novel *ExVivo* Model of Septic Arthritis Identifies Role of Neutrophils in Joint Destruction

Kathryn McCall,[1] Caroline Atherton,[2] Neal Millar,[2] Carl Goodyear,[3] Tom Evans,[4] and Iain McInnes[2], [1]Institute of Infection, Immunity & Inflammation, University of Glasgow, Galsgow, United Kingdom, [2]Institute of Infection, Immunity & Inflammation, University of Glasgow, Glasgow, United Kingdom, [3]University of Glasgow, Glasgow, United Kingdom, [4]Institute of Infection, Immunity & Inflammation, University of Glasgow, Glasgow

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Innate Immunity Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Septic arthritis (SA) caused by bacterial species, such as *Staphylococcus aureus*, has high morbidity and mortality[1]. Currently diagnosis is often prolonged and unreliable, with no suitable near-patient biomarkers available[2]. To generate more reliable biomarkers and to understand pathogenesis we sought to develop a novel *ex vivo* system to explore the effect of pathogenic and mutant *Staphylococcus* strains in promoting cartilage degradation.

Methods: Human cartilage explants were obtained from femoral heads being surgically removed following trauma. Explants were infected for 48h with 10^6cfu bacteria from two *Staph. aureus* SA-derived patient isolates (28g & 36v) or with a mutated bacterial strain preventing biofilm formation and adhesion, *Staphylococcus epidermidis* RP62A

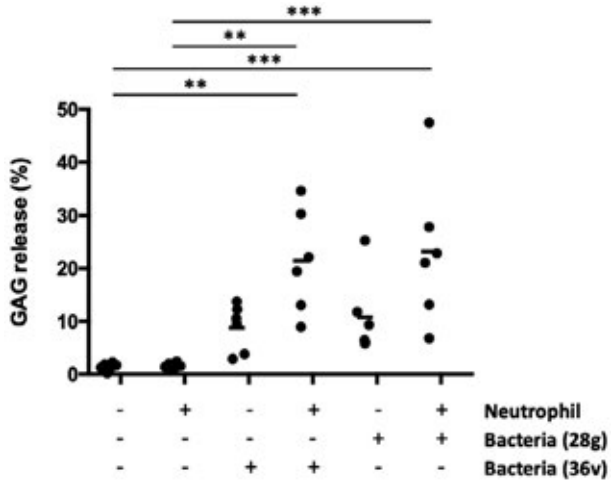

Figure 1 Synovial sodium MR signal intensity (left) and concentration (right) quantified by 23Na-MRI. Each dot, representing one subject, is based on the average of 6 sagittal MRI slices capturing the synovial volume.

wild type strain or RP62A mutated strain. In the final 24h of bacterial infection, neutrophils purified from healthy donor blood were added to explant cultures at 3 x 10^6cells/well. Chondrocyte viability was assessed using CellTracker green CMFDA and propidium iodide. Images were captured using confocal microscopy (LSM880) and cells counted using Imaris software. Structural damage was measured by glycosaminoglycan (GAG) release and statistical analysis performed using GraphPad Prism software.

Results: When cartilage explants were co-cultured with bacteria +/- neutrophils, cell death was significantly increased compared to the negative control or addition of neutrophils alone, (one-way ANOVA, Holm-Sidak's multiple comparisons test, N=3, bacteria - neutrophils $p < 0.05$, bacteria + neutrophils $p < 0.01$). Cartilage breakdown, estimated via GAG release, was induced by*Staph. aureus*alone, whereas it was significantly enhanced upon neutrophil addition in the final 24h of co-culture, Figure 1. Using the model, we investigated the effect of bacterial cell adhesion using a*Staph. epidermidis*adhesion mutant. The mutated strain did not significantly release more GAG compared to the negative control, whereas the wild type strain caused significant damage (2-way ANOVA, Holm-Sidak's multiple comparisons test, N=3, $p < 0.05$). Moreover, the effect of neutrophil stimulation was attenuated when bacteria were unable to adhere to the cartilage.

Conclusion: A co-culture model of septic arthritis has been developed which allows precise examination of the contribution of the host neutrophil response and (mutant) bacterial species to cartilage damage. We used this to define the importance of bacterial adherence to cartilage for subsequent degradation. This novel model will be a valuable tool in understanding pathology and identifying biomarkers of joint infection in the future.

Abstract Number: 0029

Therapeutic Anti-TNF Biologic Agents Exhibit Functional Differences in Blocking TNF-induced Effects on Human Monocytes *In Vitro*

Bohdan Harvey,[1] and Zehra Kaymakcalan[1], [1]AbbVie Bioresearch Center, Worcester, MA

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Innate Immunity Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Therapeutic anti-TNF biologic agents can be distinct in their structure and/or in their binding to TNF. Whether these differences affect the functional properties of these biologics in direct comparison to each other has not been thoroughly investigated. Our objective was to determine the equivalency of all anti-TNF biologic agents approved for RA in preventing a variety of TNF-induced effects on human monocytes *in vitro*.

Methods: Human monocytic U937 NF-kB luciferase reporter cells and human RA PBMC were incubated with 100 ng/mL TNF +/- biologic [adalimumab (ADA), etanercept (ETN), infliximab (IFX), golimumab (GOL) or certolizumab pegol (CZP)] as pre-formed complexes. Surface TNF-RI and –RII levels were monitored by flow cytometry after 1h. Luciferase activity was measured after 4 h. to assess NF-kB activation. After 24 h., U937 cells and CD14+ monocytes from human RA PBMC cultures were analyzed for surface levels of ICAM-1, an adhesion molecule shown to contribute to monocyte migration and arthritis. Apoptosis was assessed using caspase 3/7 fluorescent substrate. Alpha-2,6 sialylation (Sia), a glycosylation modification shown to regulate TNF-RI internalization and apoptosis, was evaluated using FITC-labeled Sambucus nigra lectin (SNA).

Results: Surface levels of TNF-RI and –RII on U937 cells were both reduced by 2.4-fold in presence of TNF. TNF-RI was maintained at baseline levels by 16.7 nM ADA or CZP as pre-formed complexes with TNF; however, those complexes with ETN, IFX or GOL could only preserve a fraction of TNF-RI on the surface (43%, 52% & 62%, respectively). All anti-TNF biologics were equally effective in preventing loss of TNF-RII. TNF stimulation of U937 NF-kB reporter cells led to a 122-fold increase in luciferase activity which was reduced to baseline by only ADA or CZP at a 38 nM conc. Partial inhibition by 65%, 77% or 88% was observed with ETN, IFX or GOL, respectively. TNF-enhanced ICAM-1 surface expression on U937 cells and on CD14+ monocytes from RA PBMC was reduced to baseline by 16.7 nM ADA or CZP, whereas ETN, IFX or GOL were only partially effective (69%, 83% & 86% reduction, respectively). Both ADA:TNF and CZP:TNF complexes also completely inhibited TNF-induced apoptosis in a dose dependent manner unlike ETN, IFX and GOL, which were less effective (42%, 32% & 42% reduction, respectively). According to SNA staining, alpha-2,6 Sia surface levels dropped in presence of TNF specifically on the subset of cells undergoing apoptosis, and this subset was reduced proportionately to the inhibitory properties of anti-TNF biologics on apoptosis.

Conclusion: For each of the conditions tested *in vitro*, many resembling features associated with RA, the pre-formed complexes of ADA:TNF and CZP:TNF were significantly more effective in preventing the TNF-induced effects (decrease of surface TNF-RI and alpha-2,6 Sia; increase in NF-kB activation, ICAM-1 surface levels and apoptosis) on human monocytes than those complexes of TNF with ETN, IFX or GOL. Additional *in vitro* and *in vivo* studies need to be done to further elucidate these mechanistic differences.

Aberrant M1 Polarization of Macrophages in Behcet's Disease

Jing Shi,[1] Xiuhua Wu,[2] Jinjing Liu,[1] Hua Chen,[3] and Wenjie Zheng[1], [1]Peking Union Medical College Hospital, Beijing, China (People's Republic), [2]General Hospital of Tianjin Medical University, Tianjin, China (People's Republic), [3]Department of Rheumatology and Clinical Immunology, Peking Union Medical College Hospital, Clinical Immunology Center, Chinese Academy of Medical Sciences and Peking Union Medical College; The Ministry of Education Key Laboratory, Beijing, China, Beijing, Beijing, China (People's Republic)

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Innate Immunity Poster

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Behcet's disease (BD) is systemic inflammatory vasculitis with unknown *etiology*. As a critical compartment in innate immunity, macrophages may play a role in BD. According to the phenotype and cytokine expression, macrophages can be classified into 2 subtypes, the pro-inflammatory classically activated macrophages (M1) and the anti-inflammatory alternatively activated macrophages (M2). However, the mechanism of how macrophage polarization is involved in BD is yet unidentified. Here we aim to investigate the effect of the BD serum on the phenotype and the functions of macrophages.

Methods: Thirty treatment-naïve active BD patients from our center and 30 gender- and age-matched healthy controls (HC) were included in this study. The monocytes of HC were isolated from PBMCs through $CD14^+$microbeads and further cultured into M0 macrophages. Then the macrophages were polarized to M1 macrophages with LPS and IFNγ, and to M2 macrophages with IL4. Serum from BD patients and HC was applied to the human monocyte-derived macrophages (HMDM). The cell surface markers and the cytokines in the supernatant were detected and compared to the phenotypes of M1 and M2 macrophages. The phagocytosis of different HMDMs was determined by the cellular uptake of Dextran. In order to investigate the effect of different HMDMs on the differentiation of Th1 and Th17 cells, HMDMs were co-cultured with naïve $CD4^+$T cells and the intracellular cytokines as well as the nuclear transcription factor were detected by FACS. Western-blot analysis was performed to detect the expression of JAK1, STAT1 and their phosphorylated forms in the HMDMs when stimulated with BD serum.

Results: Compared to M0 macrophages, BD serum stimulated HMDM had an increased expression of CD86 ($p=0.024$) and a decreased CD163 expression ($p=0.009$). The secretion of IL12 ($p=0.019$) and TNFα ($p=0.0295$) was also increased. The HC serum stimulated HMDM, however, had a similar phenotype with M0 macrophage. All these observations suggested BD serum could promote M1 polarization. BD serum also led to a significant increase in macrophage phagocytosis ($p=0.011$), which was similar with M1 phenotype ($p=0.014$). Moreover, M1 phenotype macrophages and BD serum treated macrophages can both promote naïve $CD4^+$T cells to differentiate into Th1 cells, characterized by increased IFNγ and T-bet (IFNγ: M1 $p=0.037$; M_{BD} $p=0.048$. T-bet: M1 $p=0.0009$; M_{BD} $p=0.0121$). No significant increase of IL17A was noted in both M1 phenotype macrophages as well as BD serum treated macrophages. After stimulating HMDM with BD serum for 5 minutes, the expressions of phosphorylated JAK1 and phosphorylated STAT1 were both elevated ($p_{JAK1}=0.0228$, $p_{STAT1}=0.0101$), indicating a role if JAK1-STAT1 pathway in the BD serum treated macrophage polarization and the pathogenesis of BD.

Conclusion: Serum from patients with BD could promote M1 macrophage polarization via the JAK1-STAT1 pathway, and could also increase the macrophage phagocytosis and drive Th1 differentiation.

Regulation of Neutrophil Extracellular Traps by Apremilast (phosphodiesterase 4 Inhibition)

Shane van Breda,[1] Simona Rossi,[1] and Paul Hasler[2], [1]University Hospital Basel, Department of Biomedicine, Basel, Switzerland, [2]Kantonsspital Aarau, Department of Rheumatology, Aarau, Switzerland

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Innate Immunity Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Increased propensity for neutrophil extracellular trap generation has been described in autoimmune diseases such as rheumatoid arthritis. Neutrophil extracellular traps are thought to contribute to disease propensity. Calcium signalling is known to be important for neutrophil extracellular trap generation. Thus, controlling this calcium signalling pathway may allow for regulation of autoimmune disease pathology. Apremilast is a selective phosphodiesterase 4 inhibitor that is currently approved for the treatment of psoriasis and psoriatic arthritis with a positive phase 3 on Behcet`s disease. Inhibition of phosphodiesterase 4 can elevate cAMP levels, decrease adenylate cyclase levels and thus modulate calcium release and store-operated calcium signalling.We hypothesised that by inhibiting phosphodiesterase 4 with apremilast, calcium release can be controlled and in turn decrease the propensity for neutrophil extracellular trap generation.

Methods: Healthy controlswere recruited at the Blood Bank of the Swiss Red Cross, Basel. Patients matching American College of Rheumatology criteria for rheumatoid arthritis were recruited at the University Hospital of Basel (n = 13).

Whole blood was collected into heparin tubes and neutrophils isolated using Dextran-Ficoll density centrifugation. Neutrophils were resuspended in RPMI + 10mM Hepes and were separately treated with apremilast, PDE7 inhibitor (0.1 - 100uM), rolipram (10 uM) and IBMX (300 uM).

For healthy control neutrophils, PMA (20nM) and calcium ionophore (2.5 uM) were used to induce neutrophil extracellular traps. Spontaneous neutrophil extracellular trap formation was measured for rheumatoid arthritis neutrophils. Samples were fixed, then prepared for immunohistochemistryusing mouse anti-human MPO antibody (Abcam)followed by incubation with goat anti-mouse IgG AF555 (Invitrogen Life Technologies). DNA was counterstained with DAPI. Neutrophil extracellular traps were then quantified using NETQUANT and a Nikon EclipseTi-E.

Treated neutrophils were loaded with DHR123 (25uM) for 15 min at 37°C. Once loaded, ROS production was monitored using a Biotek Synergy H1 Hybrid Reader (Biotek) at 0, 15 and 30 minutes (excitation 485 nm, emission 570 nm). In the case healthy control neutrophils, ROS production was induced using PMA (20nM) while for rheumatoid arthritis neutrophils, spontaneous ROS production was monitored.

Results: Reduction in PMA induced ROS production for healthy control neutrophils when treated with apremilast was observed. A decrease in PMA and calcium ionophore-induced neutrophil extracellular trap generation was also observed. Apremilast treatment of rheumatoid neutrophils also displayed a decrease in spontaneous ROS generation and neutrophil extracellular trap generation. We also investigated the effect of phosphodiesterase 7 inhibition. Interestingly, this displayed an opposite effect to phosphodiesterase 4 inhibition.

Conclusion: By reducing neutrophil extracellular traps through modulation of calcium signalling by phosphodiesterase 4 inhibition, the possibility of controlling neutrophil extracellular trap generation in certain autoimmuneconditions might be possible.

Aberration of Histone Lysine Methylation in Adult-Onset Still's Disease Are Novel Biomarker Candidates Associated with the Disease Activity

Yoshimi Aizaki,[1] Yasuto Araki,[1] Kojiro Sato,[2] and Toshihide Mimura[1], [1]Department of Rheumatology and Applied Immunology, Faculty of Medicine, Saitama Medical University, Saitama, Japan, [2]Division of Rheumatology and Clinical Immunology, Department of Medicine, Jichi Medical University, Tochigi, Japan

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Innate Immunity Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Adult-onset Still's disease (AOSD) is a systemic autoinflammatory disorder characterized by spiking fever, transient rash, arthritis and leukocytosis. Macrophage and neutrophil activation is a hallmark of AOSD. No specific laboratory tests have been known in AOSD. A few serological markers, such as ferritin, CRP, and IL-18, have been used in the clinical settings but their specificity is limited. Although a line of evidence has suggested a genetic contribution to AOSD, the pathogenesis of the disease is still unclear. Non-genetic factors, such as environment, infection and epigenetics, may play pivotal roles in the pathogenesis. Epigenetic mechanisms including posttranslational histone modifications are known to regulate gene expression without altering the genomic sequence. Histone modifications in major rheumatic diseases, such as rheumatoid arthritis, have been investigated, while studies on those in AOSD are limited. From the functional point of view, it is important to analyze the difference of histone modifications in each functional subset of peripheral blood nucleated cells. To examine the pathological condition-specific histone modifications of peripheral white blood cells (WBCs) in AOSD, We have established a novel method for analyzing histone methylation in each subset defined by the surface markers using fluorescence-activated cell sorting (FACS).

Methods: Peripheral WBCs were obtained from patients with active and inactive AOSD and healthy controls (HC). Nine immune cell types were stained with antibodies against surface markers and classified as below: CD4+ T cells, CD8+ T cells, γδT cells, neutrophils, regulatory T cells, B cells, CD14++CD16- monocytes, CD14++CD16+ monocytes and CD14+CD16++ monocytes. All samples were analyzed with a FACSCanto II cytometer. As a quantitative measure of H3K4me3 and H3K27me3, mean fluorescence intensity (MFI) was used. We quantified the serum levels of 10 cytokines (IFN-α, IFN-γ, IL-1β, IL-2, IL-4, IL-6, IL-10, IL-12p70, IL-17A and TNF-α) using multiplex bead array assays and IL-18 using ELISA. The correlation between the level of histone methylation and CRP, ferritin and 11 cytokine levels was examined.

Results: The distinction in H3K27me3 and H3K4me3 MFI levels were observed in several WBC subsets when comparing HC and AOSD. Particularly, histone methylation in neutrophils, B cells, and CD14++CD16- monocytes correlated with the disease activity of AOSD. The levels of serum ferritin, CRP, IFN-γ, IL-2, IL-6 and IL-18 were significantly higher in active AOSD than in inactive AOSD. Histone methylation levels in neutrophils, B cells, or CD14++CD16- monocytes correlated with the levels of either CRP, IFN-γ, IL-2 or IL-18. However, there was no significant correlation between serum ferritin and histone methylation. Focusing on CD14++CD16- monocytes, H3K4me3 MFI levels negatively correlated with the levels of IL-18.

Conclusion: Differences in histone modifications were detected by FACS in different subsets of peripheral WBCs in AOSD patients. Aberrant histone methylations in CD14++CD16- monocytes were associated with the disease activity of AOSD. It is indicated that histone methylation could be a novel biomarker for AOSD.

GS-4875, a First-in-Class TPL2 Inhibitor Suppresses MEK-ERK Inflammatory Signaling and Proinflammatory Cytokine Production in Primary Human Monocytes

Matthew Warr,[1] Angie Hammond,[1] Grace Park,[1] Zhi-Hua Cui,[1] Nathan Wright,[1] and James Taylor[1], [1]Gilead Sciences, Inc., Foster City, CA

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Innate Immunity Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Tumor progression locus 2 (TPL2, also known as MAP3K8) is a mitogen-activated protein kinase kinase kinase and the primary regulator of ERK-mediated gene transcription downstream of multiple proinflammatory stimuli including bacterial products (eg, LPS and bacterial peptidoglycans), damage-associated molecular patterns (DAMPs), TNFα, and IL-1β.[1]TPL2 regulates the expression of several proinflammatory cytokines, including TNFα, IL-1β, IL-6 and IL-8. As TPL2 acts on both the production of and response to TNFα and IL-1β, it acts to amplify proinflammatory signaling. Dysregulated signaling downstream of these inflammatory signals can drive uncontrolled immune cell activation and inflammation, which is associated with multiple chronic inflammatory and autoimmune diseases. As such, TPL2 inhibition represents a strategy to modulate inflammation in a variety of disease settings. We evaluated the effect of a highly selective TPL2 inhibitor (GS-4875) on inflammatory signaling and cytokine production in primary human cells and in an acute inflammation model.

Methods: GS-4875 selectivity was screened using a KINOMEscan™ selectivity assay (ScanMAX, DiscoveRx, San Diego, CA). Cells were precultured with GS-4875 prior to stimulation with LPS, TNFα, or EGF. Lewis rats were dosed orally with 3, 10, 30 or 100 mg/kg doses of GS-4875 or 1 mg/kg dexamethasone followed by IV dosing of 0.01 mg/kg LPS 2 hours later. Animals were bled for plasma at multiple time points between 0 and 5h after compound dosing and plasma concentrations of TNFα and GS-4875 were measured.

Results: GS-4875 inhibits the TPL2 kinase with an IC50 = 1.3 nM with no significant off-target binding activity. GS-4875 selectively inhibited LPS and TNFα-stimulated phosphorylation of TPL2, MEK, and ERK, with little to no inhibition of phosphorylated p38, JNK or p65 observed. Both the RNA production and secretion of TNFα, IL-1β, IL-6, and IL-8 following LPS stimulation in primary human monocytes was similarly inhibited with GS-4875. In monocyte-derived dendritic cells GS-4875 inhibited the secretion of TNFα and IL-6 following LPS stimulation. To confirm TPL2 requirement for inflammatory, but not Ras-mediated (growth factor stimulated) ERK signaling, A431 cells were stimulated with either TNFα or EGF. Although TPL2 inhibition reduced TNFα-stimulated pERK, no effect on ERK activation downstream of EGF was observed. In vivo activity and PK/PD relationship was established using a rat LPS-TNFα model of acute inflammation. GS-4875 treatment showed dose and exposure dependent inhibition of LPS-stimulated TNFα production at all time points with an estimated EC50 (±SD) of 667 ±124 nM. Inhibition of TNFα production at the highest dose tested inhibited TNFα levels at levels equivalent to that of dexamethasone.

Conclusion: This work demonstrates the selective effects of TPL2 inhibition on ERK-mediated signaling and proinflammatory cytokine production and highlights the potential for TPL2 inhibition to treat diseases associated with dysregulated inflammatory signaling and chronic inflammation.

The Role of NFAT5-p65 Complex Enhanceosome in the Inflammatory Responses of Rheumatoid Arthritis Synovial Fibroblasts via TLR4 Signaling

Kunihiko Umekita,[1] Yumi Kariya,[1] Chihiro Iwao,[1] Masatoshi Kimura,[1] Risa Kudo,[1] Yuki Rikitake,[1] Shunichi Miyauchi,[2] and Akihiko Okayama[1], [1]University of Miyazaki, Miyazaki, Japan, [2]University of Miyazaki, Miyazaki

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: RA – Etiology & Pathogenesis Poster I
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Transcription factors belonging to the family of nuclear factors of activated T cells (NFAT) play an essential role in diverse biological processes, such as inflammation, immune response and cell proliferation. Known NFAT5 target genes are involved in the pathogenesis of rheumatoid arthritis (RA), including inflammation promotion and joint destruction. The TLR4 ligands was shown to trigger the activity of NFAT5 in macrophages through the IKK-NF-κB pathway. Some reports indicated that there is an interaction between NF-κB p65 and NFAT5 for the induction of the expression of the target genes of these transcription factors. These findings suggested that NFAT5 might play an important role in not only innate immune but also autoimmune rheumatic disorders. However, it is still not clear whether the TLR4 pathway induces NFAT5-p65 complex enhanceosome activation in RA synovial fibroblasts (RASFs). The aim of this study to investigate the role of NFAT5-p65 enhanceosome in the inflammatory responses of RASFs via TLR4 signaling.

Methods: Human neutrophil-derived lactoferrin (LTF) was used as TLR4 ligand. RASFs were stimulated with LTF, and the expressions of inflammatory cytokines in RASFs were measured. The expression of IL-6, CCL20 and IL-8 mRNA in RASFs was measured using real-time quantitative PCR. The protein levels of IL-6, CCL20 and IL-8 in culture medium was measured by ELISA. To clarify the TLR4 signalling pathway associated with LTF stimulation, a small molecular inhibitor of TLR4 (TAK242) and NF-κB inhibitor were used. The role of nuclear factor of activated T cells 5 (NFAT5) was identified using small interfering RNA. Cerulenin is an inhibitor of fatty acid synthase, which is isolated from *Cephalosporium caerulens*as an antibiotic agent. Cerulenin was reported as one of agents to disrupt the p65-NFAT5-p300 interaction and inhibited the activity of NF-κB. Therefore, to reveal the interaction between NF-κB and NFAT5, cerulenin, which disrupts their interaction, was used.

Results: Stimulation of RASFs with LTF significantly increased the expressions of inflammatory cytokines and chemokines, such as IL-6, CCL20 and IL-8, in RASFs. LTF enhanced the mRNA expressions of these cytokines in RASFs stimulated by TNF-α. TAK242 almost completely inhibited the expressions of inflammatory cytokines and chemokines in RASFs stimulated by LTF. The NF-κB inhibitor partially repressed the expressions of IL-6 and IL-8 mRNAs induced by LTF, but not CCL20 mRNA expression. On the other hand, NFAT5 silencing decreased the expres-

sions of CCL20 and IL-8 mRNAs induced by LTF, but not IL-6 mRNA expression. Cerulenin repressed the expressions of IL-6, CCL20 and IL-8 mRNAs in RASFs treated with LTF or LPS.

Conclusion: NFAT5-p65 enhanceosome might regulate the expressions of LTF-TLR4-responsive genes in RASFs. NFAT5-p65 enhanceosome has potential as novel therapeutic target in the pathogenesis of RA.

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: RA – Etiology & Pathogenesis Poster I
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Our group previously demonstrated that sputum neutrophils from subjects At-Risk for future rheumatoid arthritis (RA) spontaneously form neutrophil extracellular traps with elevated histone H3 (H3) citrullination, which were associated with mucosal inflammation and local anti-citrullinated protein antibody (ACPA) generation (*Okamoto ACR 2018*). Also, enhanced H3 citrullination and functional/metabolomic alterations have been found in peripheral blood CD4 T cells of At-Risk subjects. However, it is unknown in what other cell types elevated H3 citrullination could be observed, and how this phenotype is related to functional alterations in cells. Herein, we explored using mass cytometry and confirmatory flow cytometry H3 citrullination and cytokine/chemokine/metabolomic signatures in peripheral blood immune cells following *ex vivo* toll-like receptor stimulation.

Methods: 13 serum ACPA (+) At-Risk subjects without synovitis, 14 ACPA (+) Early RA patients, and 13 matched healthy controls were included. Freshly drawn whole blood was fixed just after blood draw, or incubated with or without stimulants including LPS and R848 (TLR7/8 agonist) in the presence of protein transport inhibitor for 6 hours and then fixed. Cells were stained with 39 metal conjugated antibodies, and mass cytometry analysis was performed. Batch adjustment was performed before data analysis. Separately, CD14 monocytes were stimulated with R848 after pretreatment with GSK484 (PAD4 inhibitor) or AFM30a (PAD2 inhibitor) to determine effects on H3 citrullination and cytokine production. In addition, CD14 monocytes were cultured on coverslips with stimulant, and immunofluorescence staining was performed to examine H3 citrullination and morphologic changes.

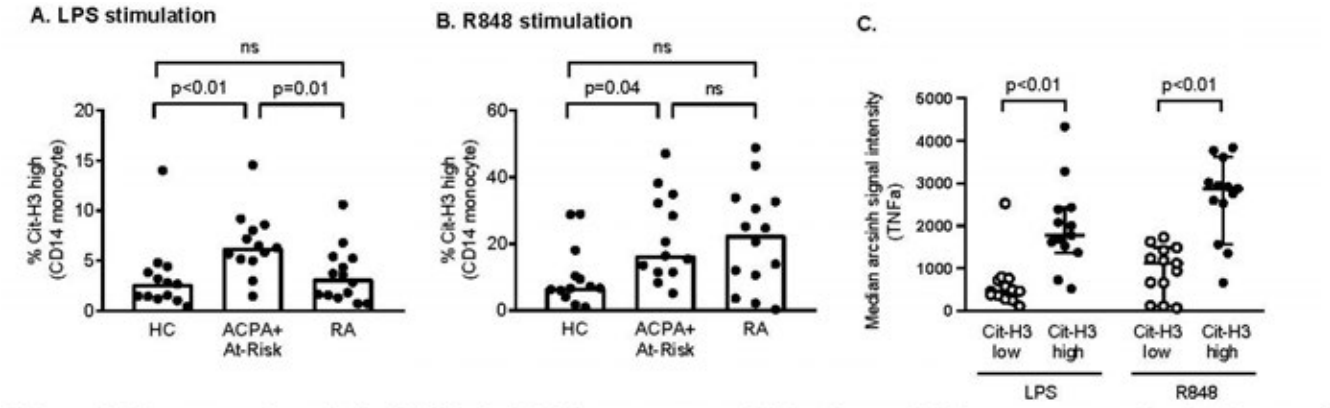

Figure1. Frequencies of cit-H3 high CD14 monocytes following toll-like receptor stimulation and TNFα production in CD14 monocytes. The figure depicts the % of cit-H3 high CD14 monocytes after LPS stimulation (Panel A) and R848 stimulation (Panel B) by mass cytometry. Panel C depicts median arcsinh signal intensity of TNFα in cit-H3 high CD14 monocytes and cit-H3 low CD14 monocytes following LPS and R848 stimulation. P-values were calculated using Kruskal-Wallis test (Panel A and B) and Wilcoxon signed-rank sum test (Panel C), adjusted by Benjamini and Yekutieli method to account for multiple testing. Closed circles=cit-H3 high CD14 monocytes; open circles =cit-H3 low CD14 monocytes.

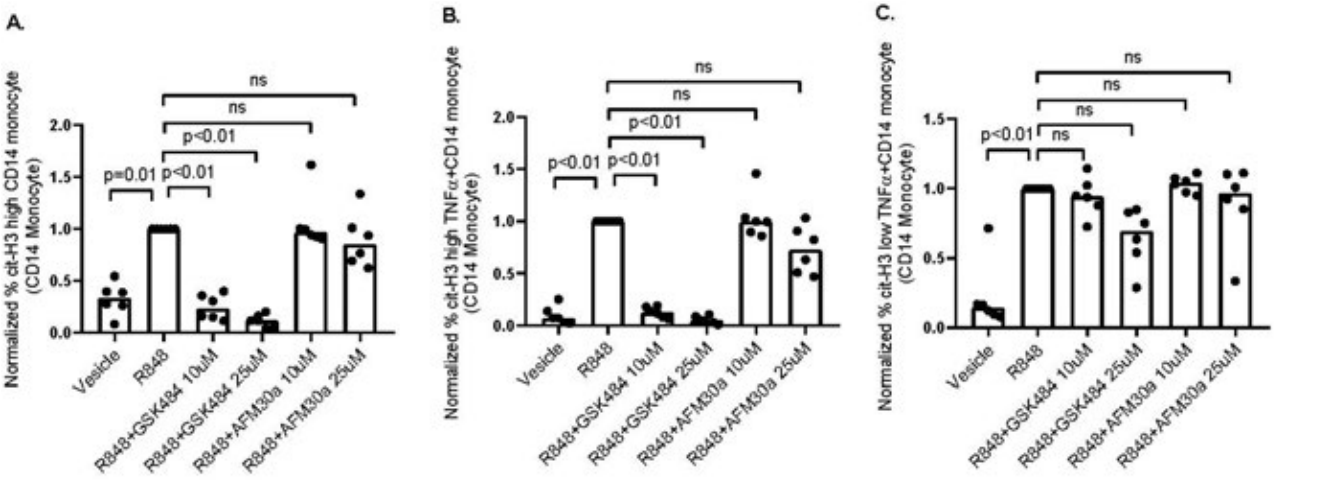

Figure2. H3 citrullination and TNFα production were significantly suppressed by PAD4 inhibitor, but not by PAD2 inhibitor. CD14 monocytes were stimulated with R848 after pretreatment with GSK484 (PAD4 inhibitor) or AFM30a (PAD2 inhibitor) to determine effects on H3 citrullination and TNFα production. The figure depicts the normalized % of cit-H3 high CD14 monocytes (Panel A), cit-H3 high TNFα+ CD14 monocytes (Panel B), and cit-H3 low TNFα+ CD14 monocytes (Panel C) of At-Risk subjects (n=6) by flow cytometry analysis. P-values were calculated using Friedman test and adjusted by Benjamini and Yekutieli method to account for multiple testing.

Results: The % of CD14 monocytes with elevated H3 citrullination following*ex vivo*LPS and R848 stimulation was significantly higher in ACPA (+) At-Risk subjects compared to healthy controls (Figure 1A and 1B). CD14 monocytes in At-Risk subjects with high citrullinated H3 (cit-H3) levels were skewed to produce more TNFα compared to cit-H3 low CD14 monocytes (Figure 1C). H3 citrullination and TNFα production were significantly suppressed by PAD4 inhibitor in cit-H3 high CD14 monocytes, but not by PAD2 inhibitor (Figure 2A and 2B). TNFα production by cit-H3 low CD14 monocytes was not affected by PAD4 or PAD2 inhibitor (Figure 2C). Immunofluorescence staining revealed CD14 monocytes with cit-H3 formed extrusions of DNA with PAD4 co-localization, which was compatible with the development of monocyte extracellular traps (METs).

Conclusion: Peripheral blood CD14 monocytes in subjects At-Risk for RA demonstrate increased cit-H3 expressing MET formation with cytokine skewing to TNFα in a process mediated by PAD4. These finding suggests enhancement of histone H3 citrullination and aberrant TNFα production may play a role in the development of RA. Further studies are needed to determine the role of this phenotype in the generation of ACPA and future development of classified RA.

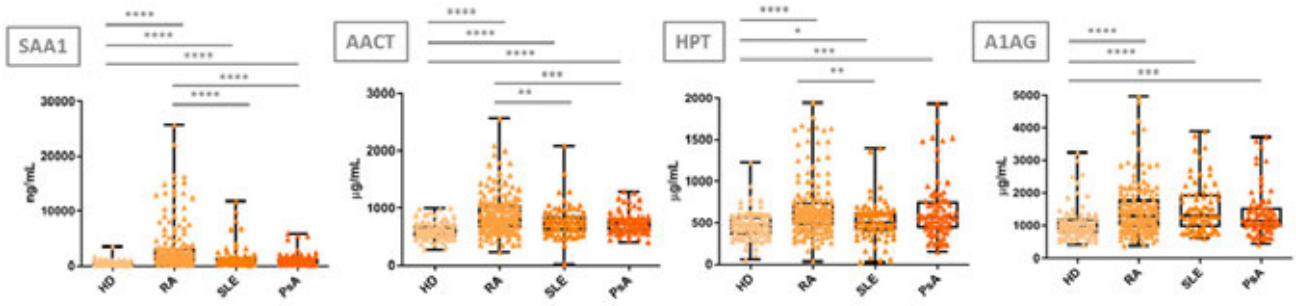
SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: RA – Etiology & Pathogenesis Poster I
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is a long-lasting inflammatory autoimmune disorder that ultimately leads to the destruction of joint architecture. The activity of this disease is measured by the assessment of clinical symptoms (generally using the DAS28). The aim of this study was to find and validate plasma biomarkers able to discriminate patients with different RA activities.

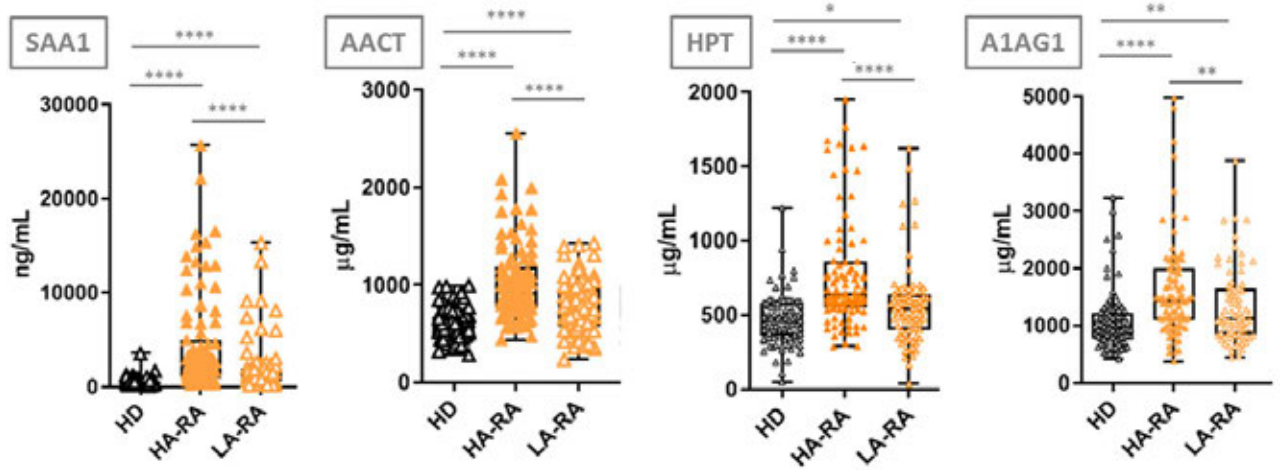
Methods: Plasma samples from patients with different IMIDs (Immune-Mediated Inflammatory Diseases), used in this research belonged to the IMID Consortium. Plasma from RA patients were DAS28-classified as low activity (LA, DAS28: 2,6-3,2) and high activity (HA, DAS28 > 5,1). The study was conducted in three different stages.

Firstly, an initial discovery phase was performed to identify an early panel of proteins with a RA activity differing role. Thus, 80 RA plasma samples (40 LA and 40 HA) were pooled in 8 groups (4 LA and 4 HA). These pools were albumin-depleted, digested, differentially labelled with iTraq 8-plex reagents, combined, desalted using StageTips-C18, HPLC-fractionated and analyzed by shotgun nanoLC-MS/MS. Secondly, the verification of the previously identified possible markers was carried out by a targeted Multiple Reaction Monitoring (MRM) strategy on a QTRAP 5500. Particularly, the same 80 RA plasma samples (40 LA and 40 HA) were individually measured, employing stable isotope-labeled standards (SIS) peptides for absolute protein quantitation. Lastly, the verified proteins were validated by ELISA on additional 420 plasma samples from patients with RA (170), psoriatic arthritis (PsA, 80), systemic lupus erythematosus (SLE, 80) and healthy donors (HD, 90). PsA and SLE patients were used as disease controls.

Results: In the discovery stage, 186 proteins were identified, whereas 11 of these proteins significantly differed between RA patients with LA and HA ($p < 0.05$). A targeted MRM method using SIS peptides was developed for the verification and absolute quantitation of this 11-protein panel on 80 RA plasma samples. A significant increase in the HA condition for Haptoglobin (HPT), Serum Amyloid A1 (SAA1), Alpha-1-antichymotrypsin (AACT) and Alpha-1-acid Glycoprotein 1 (A1AG1) was shown, in accordance with the discovery phase tendency. Equally, the validation results show a significant increase of the 4 verified proteins in HA RA patients from LA RA patients and HD, as well as in LA



SAA1, AACT, HPT and A1AG1 concentrations in plasma from RA, SLE, PsA patients and healthy donors as well as their corresponding significant differences ($p < 0.05$). $p < 0.0001$ (****), $p < 0.001$ (***), $p < 0.01$ (**), $p < 0.05$ (*).



SAA1, AACT, HPT and A1AG1 concentrations in plasma from RA patients with extreme disease activities (LA: low activity; HA: high activity) and healthy donors as well as their corresponding significant differences ($p < 0.05$). $p < 0.0001$ (****), $p < 0.001$ (***), $p < 0.01$ (**), $p < 0.05$ (*).

RA patients from HD, therefore confirming their RA activity monitoring capacity. Furthermore, SAA1 and AACT significantly discriminate among RA, SLE, PsA patients and HD, as well as between RA patients and the related disease controls. Moreover, these proteins are related with the RA process and its effects (inflammation and immune disorder in joints), giving significance to the results obtained.

Conclusion: A three-step proteomic approach (including discovery, verification and validation phases) has been followed for the identification of protein biomarkers for assessing RA disease activity in plasma. A panel of four proteins has been validated as increased in plasma from HA RA patients, and could be useful for the molecular monitoring of the disease, even when they are measured among plasma samples from other IMID patients and/or HD.

Intestinal Microbiota Dynamics in the Progression of Rheumatoid Arthritis

Yanli Tong,[1] Yunqiang Bai,[2] Yi Zhao,[2] Yi Liu,[2] and Yubin Luo[2], [1]Department of Rheumatology and Immunology, West China Hospital, Sichuan University, Chengdu, China (People's Republic), [2]Department of Rheumatology and Immunology, West China Hospital, Sichuan University, Chengdu, Sichuan, China (People's Republic)

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: RA – Etiology & Pathogenesis Poster I
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Intestinal microbial dysbiosis in patients with rheumatoid arthritis (RA) has raised the interest in studying the role of intestinal microbes in the pathogenesis of RA. Animals studies indicate that intestinal microbiota changes prior to the onset of visible inflammatory arthritis. Here, we undertook this study to clarify the intestinal microbiota changes in individuals at high risk for RA with the aim to identify bacteria biomarkers associated with the progression of RA.

Methods: High-risk for RA individuals were defined as having a positive serum antibody for anti-cyclic citrullinated peptide (CCP), without reported arthritis symptoms at the time of enrollment. RA patients were diagnosed according to the American College of Rheumatology (ACR) 2010 classification for RA. Age and gender matched anti-CCP negative healthy individuals were recruited as controls. Individuals having a history of antibiotics treatment in the last six months or other conditions that may affect the study were excluded. The 16S ribosomal RNA of fecal samples from 31 RA patients, 42 high-risk individuals and 38 healthy controls (HC) were sequenced and analyzed.

Results: Alpha diversity analysis showed that the intestinal microbiota communities in high-risk group ("pre" group) had a lower community diversity (Shannon index) than the healthy controls (Fig.1A). Beta diversity using principal coordinate analysis (PCoA) revealed that the intestinal microbiota was significantly different between groups (Fig.1B). Interestingly, we observed that the intestinal microbiota communities dynamically shifted from HCs to high-risk individuals (Pre) to RA patients.

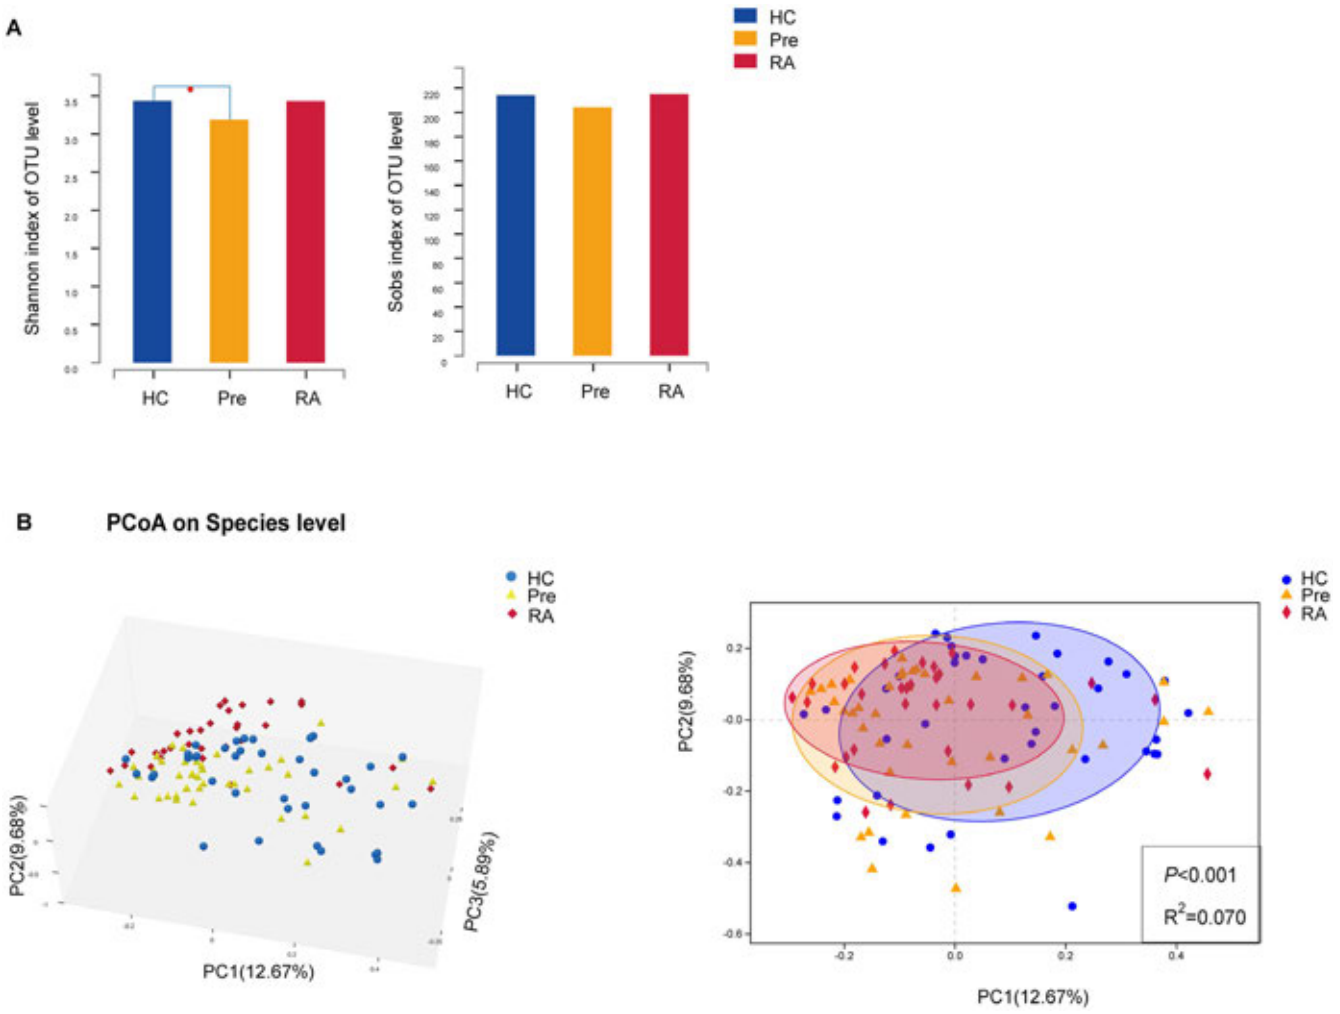

Figure 1. Alpha diversity (A) and beta diversity (B) analysis of the intestinal microbiota communities in rheumatoid arthritis (RA) patients, high-risk individuals for RA (Pre) and healthy controls (HC).

The majority of species (437) were shared by all groups. 35 species were found only in high-risk individuals and RA patients (Fig. 2A). Besides, the abundance of the microflora variant between groups. At the phylum level, the abundance of*Bacteroidetes*gradually decreased from HCs to high-risk individuals to RA patients. The abundance of *Saccharibacteria* were particularly higher in high-risk individuals than in both RA patients and HCs (Fig. 2B). Further to the family level, *Bacteroidaceae*, *Pseudomonadaceae*and*Pasteurellaceae*showed the same trend of gradual reduction from the HCs to high-risk individuals and to RA patients. On the contrary, an enriched abundance of *Streptococcaceae, Lactobacillaceae, Enterococcaceae* and *Leuconostocaceae* were seen in RA patients (Fig. 2C).

To determine taxonomic biomarkers that characterize the differences in the progression of RA, linear discriminant analysis (LDA) analysis was performed (Fig. 3A). We identified potential disease stage specific bacteria. A marker panel of six bacteria species was selected, which had an AUC of 0.78 (95%CI=0.66-0.9) in discriminating RA patients from HCs (Fig. 3B and 3C).

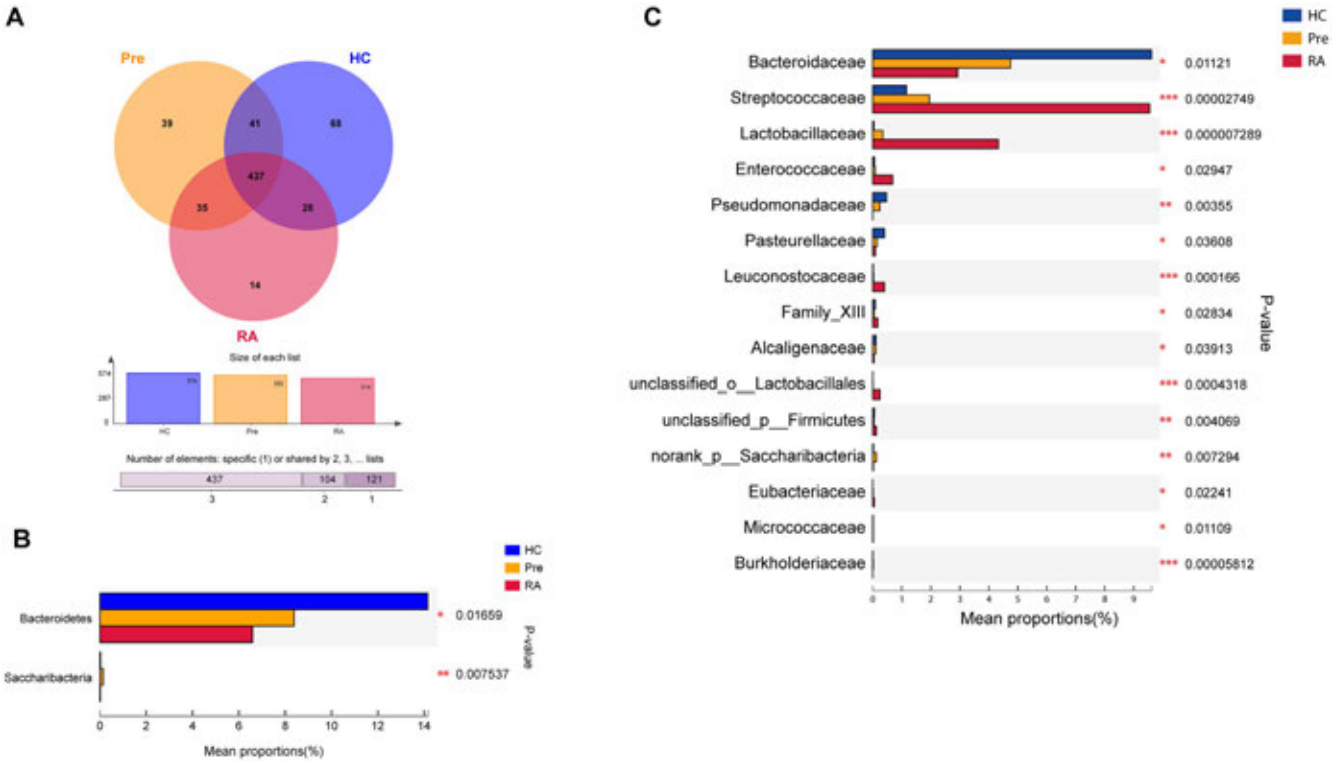

Figure 2 Differential and variant abundance of intestinal bacteria in rheumatoid arthritis (RA) patients, high-risk individuals for RA (Pre) and healthy controls (HC). (A) Venn diagram showing the number of shared and specific species in the three groups of individuals. Bacteria with different abundance in the three groups at the phylum level (B) and the family level (C).

Conclusion: The intestinal microbiota changed gradually during disease progression of human RA. Intestinal dysbiosis occurs prior to the onset of arthritis symptoms in individuals with positive anti-CCP antibody. Identifying the specific microbes characterize individuals at preclinical stage would provide a useful tool for early detection and intervention of RA.

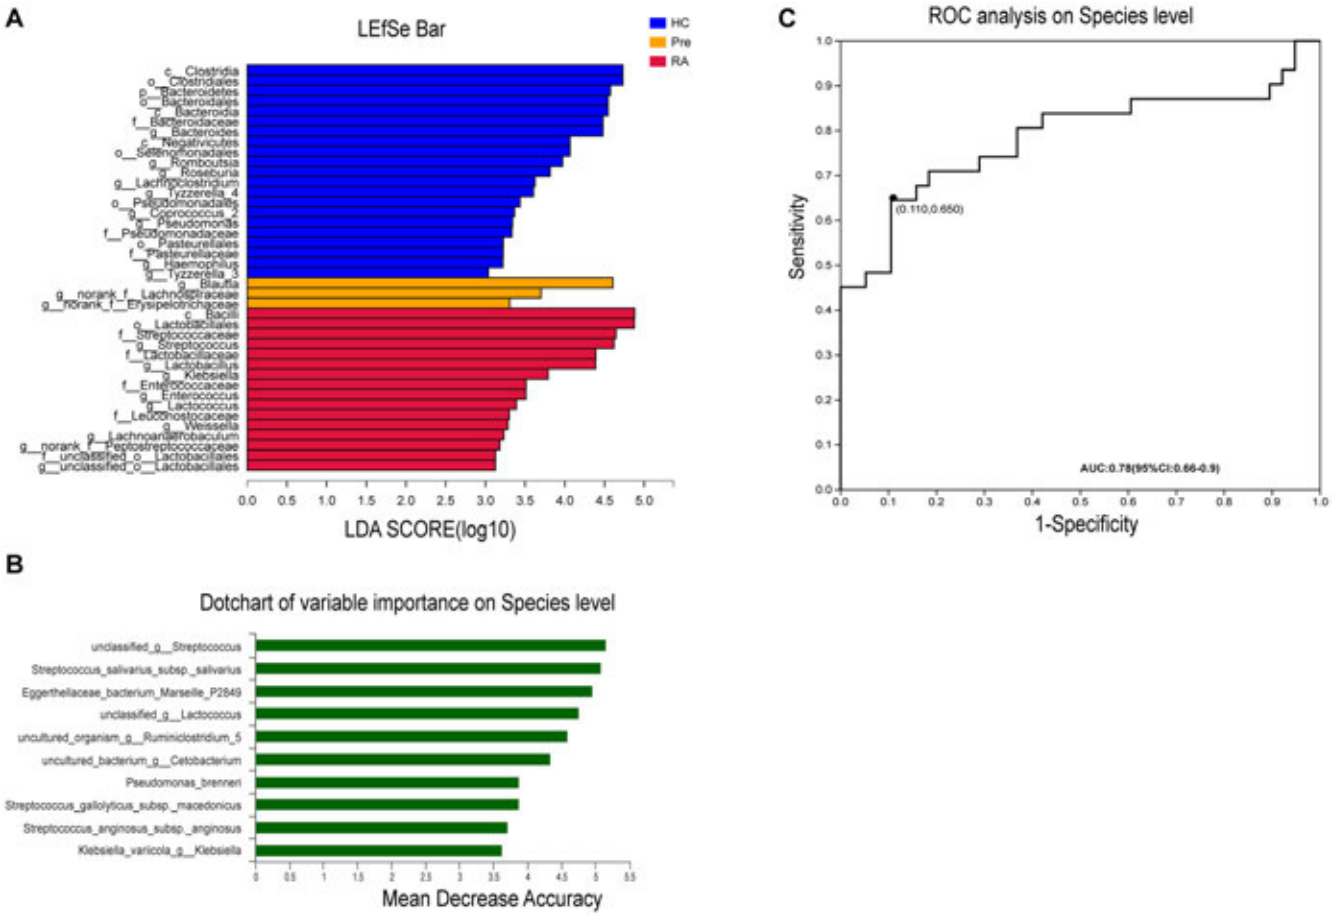

Figure 3 The discriminant taxonomic biomarkers that characterize the stages in the progression of RA. (A) LDA analysis showing the most discriminate bacteria for the specificity of each group. Bacterial marker of six bacteria species (B) yield an AUC of 0.78(95%CI=0.66-0.9) with a specificity of 89% and sensitivity of 65% in discriminating RA patients from healthy controls (C).

Autophagy Receptor Optineurin in Synovial Fibroblasts Plays a Protective Role Against Joint Destruction in Rheumatoid Arthritis

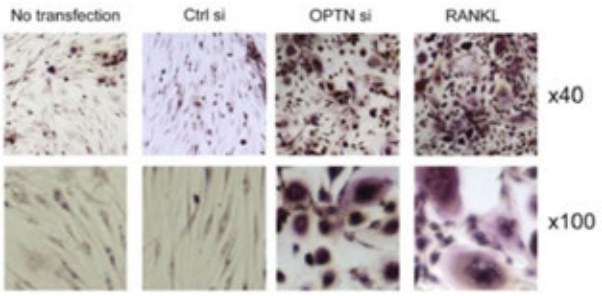
Wen Shi Lee,[1] Masaru Kato,[1] Eri Sugawara,[1] Michihiro Kono,[1] Yuki Kudo,[2] Michihito Kono,[3] Yuichiro Fujieda,[1] Toshiyuki Bohgaki,[1] Olga Amengual,[1] Kenji Oku,[1] Shinsuke Yasuda,[1] and Tatsuya Atsumi[4], [1]Department of Rheumatology, Endocrinology and Nephrology, Faculty of Medicine and Graduate School of Medicine, Hokkaido University, Sapporo, Japan, [2]Hokkaido University Graduate School of Medicine, Sapporo, Japan, [3]Department of Rheumatology, Endocrinology and Nephrology, Faculty of Medicine and Graduate School of Medicine, Hokkaido University, Sapporo, Hokkaido, Japan, [4]Hokkaido University, Sapporo, Japan

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: RA – Etiology & Pathogenesis Poster I
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Joint destructions progress throughout the course of rheumatoid arthritis (RA) without complete remission. Optineurin (OPTN) is an autophagy receptor with multiple functions related to homeostasis of cells and has been reported to negatively regulate osteoclast differentiation *in vivo*. However, the role of OPTN in RA, especially in joint destruction, has been unclear. In this study, we clarify the role of OPTN in the pathogenesis of joint destructions in RA using synovial fibroblasts (RASFs).

Methods: RASFs wereobtained from RA patients who fulfilled theACR 2010 criteria during the knee replacement surgery. RASFs with passages of 4 to 8 were used in this study. RASFs were incubated with pro-inflammatory cytokines and the expression of OPTN was analyzed using quantitative realtime PCR (RT-qPCR) and western blot. RASFs were transfected with siRNA targeting OPTN and the downregulated efficacy was confirmed by RT-qPCR and western blot. The expression of RANKL and osteoprotegerin (OPG) on OPTN-reduced RASFs were analyzed by flow cytometry and RT-qPCR after treatment with TNF-a or IFN-g. CD14+ monocytes isolated from healthy subjects were cocultured with OPTN-reduced RASFs or control RASFs in the presence of M-CSF. RANKL+M-CSF added in cocultured cells were used as positive control. Cocultured cells were stained with Tartrate-Resistant Acid Phosphatase (TRAP). TRAP+ cells with number of nuclei≥3 were considered as osteoclasts. Protein levels of IkBa were analyzed to evaluate the activation of NF-kB signaling. RNA sequencing was performed to analyze further pro-inflammatory/pro-destructive genes regulated by OPTN knockdown. Data within a group were compared using Student's unpaired t-test and data between groups were compared using the analysis of variance (GraphPad Prism). Differences were considered significant if $p < 0.05$.

Results: OPTN levels were upregulated after TNF-a or IFN-g stimulation at both mRNA and protein levels ($n = 5$, $p < 0.05$). The cell surface expression of RANKL was significantly increased following treatment with TNF-a or IFN-g and the effect was further pronounced in OPTN-reduced RASFs compared with that in control RASFs ($n = 5$, $p < 0.05$). The mRNA levels of RANKL were also increased in OPTN-reduced RASFs ($n = 5$, $p < 0.05$) while OPG levels remained unchanged. CD14+ monocytes cocultured with OPTN-reduced RASFs differentiated more into TRAP+ multinucleated cells (osteoclasts) compared to those cocultured with control RASFs ($n = 4$, $p < 0.05$). IkBa degradation following TNF-a treatment was prolonged in OPTN-reduced RASFs. RNA sequencing detected dysregulation of genes related to cartilage degradation, joint inflammation and bone formation, including MMP-3, CHST15, HAS1 and GATA-3, and the results were confirmed by RT-qPCR.



Representative figure of isolated human CD14+ monocytes cocultured with RASFs.

Conclusion: OPTN may play a protective role in RA with its upregulation when immersing with pro-inflammatory cytokines. Absence of OPTN might worsen RA by generating joint destructive state including increased RANKL expression on RASFs and subsequent osteoclast differentiation.

Role of Sialic Acid in the Aggressive Phenotype of RA FLS

Patricia Oliveira,[1] Brian Pedersen,[1] Nissi Varki,[2] Mark Fuster,[1] Gary Firestein,[3] and Monica Guma[4], [1]UCSD, San Diego, CA, [2]UCSD, San Diego, [3]University of California, San Diego, San Diego, [4]Department of Medicine, School of Medicine. University of California San Diego, La Jolla, United States

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: RA – Etiology & Pathogenesis Poster I
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: A comprehensive epigenomic characterization of rheumatoid arthritis (RA) fibroblast-like synoviocyte (FLS) has recently been described and can help to identify new critical pathways for RA pathogenesis. Two genes involved in sialylation, β-galactoside α2,3-sialyltransferase I (ST3Gal1) and β-galactoside α2,6-sialyltransferase I (ST6Gal1), were found to be significantly associated with changes in epigenetic marks between RA and osteoarthritis (OA) FLS, suggesting a role of this biological process in the aggressive phenotype of RA FLS. Here, we determined whether the amount of sialic acid (Sia) on FLS regulate its phenotype.

Methods: Sia expression in OA and RA synovial tissue was determined by using lectin immunofluorescence (IF). Sialyltransferases (ST) gene expression and Sia expression after TNF or PDGF stimulation in RA FLS were analyzed

by qPCR and by using lectin western blotting (WB),respectively. Migrative (scratch assay) and invasive (matrigel assay) phenotype after PDGF stimulation were evaluated after treatment with neuraminidase (Neu) from *Clostridium perfringens* (25mU/ml for 60 minutes), which cleaves Sia from glycoconjugates, and with an endogenous neuraminidase inhibitor, N-Acetyl-2,3-dehydro-2-deoxyneuraminic acid (NADNA, 100uM). Metalloproteinases (MMP) and IL6 gene expression after TNF and PDGF stimulation was also analyzed after Neu treatment. For arthritis experiments, mice were injected with K/BxN sera on day 0. Lith-O-Asp (a sialyltransferase inhibitor, 3mg/kg) was injected every other day i.p. beginning on day 0 after serum administrationor starting at the peak of arthritis (from day 4). Clinical arthritis scores were serially assessed.

Results: Maackia amurensislectinI and II IF staining was higher in RA synovial lining.PDGF and TNF stimulation increased the expression of ST3Gal1 and ST6Gal1 and total amount of Sia in FLS. Neu treatment decreased the amount of Sia in FLS determined by WB and inhibited not only migration (Neu:26.94±5.4vs. vehicle:22.5±3.4; $p< 0.001$) and invasion (Neu:12.7±1.6 vs. vehicle:24.0±2.5; $p< 0.001$), but also the expression of MMP and IL-6 after TNF and PDGF stimulation. Conversely, NADNA treatment increased the amount of Sia in RA FLS and enhanced both migration (vehicle:32.0±3.1vs. NADNA:16.5±5.0; $p< 0.001$)and invasion (vehicle:27.0±9.3vs. NADNA:39.5±13.6; $p< 0.001$). Finally, Lith-O-Asptreatment significantly decreased arthritis severity. Day 10 scores were 15.16±1.17 and 12.3±1.4($p=0.003$) for vehicle and Lith-O-Asp-treated mice respectively, when mice were treated from day 0, and 15.2±1.2 and 11.3±2.2($p< 0.001$) for vehicle and Lith-O-Asp -treated mice when mice were treated from day 4.

Conclusion: Sia are abundant on vertebrate glycoproteins and mediate a variety of biological phenomena, including migration and invasion. Our results suggest that in FLS, changes in the amounts of Sia likely mediated by changes in expression of ST3Gal1 and/or ST6Gal1, might be key regulator of FLS phenotype and contribute to joint destruction in RA. Modulation of Sia expression could act as disease modifying factor by directly modulating synoviocyte-mediated cartilage destruction.

Inflammation and Neuronal Growth Factors in Rheumatoid Arthritis

Caroline Wasén,[1] Lovisa Leifsdottir,[2] Roda Abdalla,[1] Lina Juzokaite,[1] Karin Andersson,[1] Malin Erlandsson,[1] Marie Kalm,[3] and Maria Bokarewa[1], [1]Department of Rheumatology and Inflammation Research, the Sahlgrenska Academy at University of Gothenburg, Gothenburg, Sweden, Gothenburg, Sweden, [2]Department of Rheumatology and Inflammation Research, the Sahlgrenska Academy at University of Gothenburg, Gothenburg, Sweden, Gotheburg, Sweden, [3]hDepartment of Pharmacology, Institute of Neuroscience and Physiology, University of Gothenburg, Gothenburg, Sweden, Gothenburg, Sweden

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: RA – Etiology & Pathogenesis Poster I
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Depression and cognitive impairment are frequently reported in rheumatoid arthritis (RA). We have recently presented that reduced hippocampus volume may be linked to functional disability and enhanced pain response in patients with RA (Andersson and Wasén et al. 2018). Reduced hippocampus volume and reduced neurogenesis (in hippocampus) was suggested related to insulin-like growth-factor 1 (IGF1) signaling in both RA patients and experimental models.Here, we aim to investigate the relation between growth factors of importance for neuronal growth and inflammation in RA and experimental arthritis.

Methods: Serum of 254 RA patients was analyzed for inflammatory markers IL-1b and IL-6 in addition to growth factors IGF1, brain-derived neurotrophic factor (BNDF) and vascular endothelial growth-factor (VEGF) and compared to the patients' disease activity (DAS28). Mice with collagen-induced arthritis were treated with short hairpin (sh)RNA targeting expression of IGF1 receptor (IGF1R). IBA1$^+$(microglia), DCX$^+$(developing neurons) and serin256-phosphorylated FoxO1$^+$(target of IGF1 signaling) cells in the hippocampal structures dentate gyrus (DG) and cornu ammonis (CA1-3) were identified by immunohistochemistry.

Results: Serum levels of IGF1, BNDF and VEGF all had weak but significant correlations to IL-1b (r= 0.12, 0.20 and 0.19, p= 0.049, 0.0013 and 0.0032, respectively). IGF1 was inversely correlated to IL-6 levels (r= -0.15, p= 0.020) and BNDF was negatively associated with disease activity (r= -0.14, p= 0.038). High serum IGF1 was associated with less expression of IGF1R in human peripheral blood monocytes (r= 0.25 p= 0.023). In IGF1R inhibited mice, the density of IBA1$^+$microglial cells was decreased in DG and CA regions of the hippocampus, indicating reduced local inflammation. The density of pFoxO1$^+$cells was increased in DG (p=0.0046) and CA3 (p=0.0030) when IGF1R was inhibited. The density of pFoxO1$^+$cells in DG and CA3 was positively correlated with serum IGF1 (r= 0.64 and 0.51, p= 0.0006 and 0.0080). However, the density of pFoxO1$^+$cells in DG and CA3 was negatively correlated with the number of DCX$^+$developing neurons (r= -0.46 and -0.65, p= 0.078 and 0.014).

Conclusion: We conclude that systemic inflammation measured as higher disease activity and IL-6 levels were associated with low BNDF, while serum IL-1b may stimulate release of growth factors IGF1, BNDF and VEGF into serum. Inhibition of IGF1R resulted in increased serum levels of IGF1, increased FoxO1 phosphorylation in the hippocampus, but this appeared to be insufficient to rescue neurogenesis.

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: RA – Etiology & Pathogenesis Poster I
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: 1) To analyze the impact of rheumatoid arthritis (RA) in the liver function, 2) To evaluate the impact of obesity and the effect of methotrexate (MTX) and leflunomide (LFN) in the liver alterations.

Methods: Human data: cross-sectional study carried out in 300 RA patients (200 non-obese and 100 obese), 100 obese non-RA and 100 healthy donors (HDs). Clinical and laboratory parameters were analyzed.**In vitro model:** Hep

G2 cells were treated with IgG-ACPAs isolated from RA patients. **Mouse model:** Collagen induced arthritis (CIA) was developed in obese and lean mice. 55 C57Bl/6 mice (4-5 weeks) were used. Forty mice were fed with high fat diet (60%) until reaching 30g (obese) (OB). CIA-OB mice were treated with LFN (10 mg/kg daily) or MTX (3mg/kg three times/week) for 15 days. Liver samples were collected. The expression of genes related to fibrogenesis (TGF-b1, CO-L1A1, a-SMA, TIMP1, MMMP-9, MMP-12), lipid metabolism (PLIN, MCAD, CD36, PPARg, DGAT, LPL), insulin signal (AKT, IRS-1, IRS-2 and GLUT-2), endoplasmic reticulum and oxidative stress (AOX and CHOP) and inflammation (TNF-a, IL-6, MCP-1, CD11c, F4/80) was analyzed.

Results: Within the normal range, the percentage of RA patients with altered levels of hepatic enzymes and albumin was significantly increased. Moreover, these levels were associated with autoimmunity and inflammatory markers. The *in vitro* treatment of HepG2 cells with IgG-ACPAs induced the expression of inflammatory and oxidative stress markers and altered the expression of genes involved in lipid and glucose metabolisms.

On the other hand, RA non-OB patients treated with MTX or LFN did not show any differences in the hepatic subclinical alteration associated with RA. As expected OB non-RA subjects had altered levels of hepatic enzymes. Of note, RA OB patients taking MTX had significant increased levels of hepatic enzymes compared to RA non-OB and OB non-RA patients, suggesting the deleterious effect of MTX in those patients with obesity.

The induction of arthritis in both lean and obese mice elevated inflammatory, endoplasmic reticulum, oxidative stress and fibrogenesis related genes compared to non-disease mice. Supporting the data observed in the human study, treatment of CIA-OB mice with MTX significantly increased the hepatic alteration observed in OB mice. In contrast, LFN reduced genes involved in fibrogenesis, inflammation, endoplasmic reticulum and oxidative stress, suggesting an improvement of the liver function.

Conclusion:

1. RA patients display a subclinical alteration of the hepatic enzymes associated with inflammation and autoimmunity, suggesting that RA might be associated with liver abnormalities induced at least partially by the effect of ACPAs.
2. In mice, the generation of arthritis induced inflammation, fibrosis, endoplasmic reticulum and oxidative stress and an alteration in glucose and lipid metabolisms in the liver.
3. Methotrexate could affect the hepatic function as long as there is a subclinical pre-existent alteration of the liver such as obesity.

Funded by ISCIII (PI17/01316) co-funded with FEDER and Roche Pharma.

Subclinical Oral Inflammation Is Common Across the Spectrum of Oral Findings in Rheumatoid Arthritis Patients, Whereas *Porphyromonas Gingivalis* Antibodies Are Primarily a Marker for Clinical Periodontitis

Sheila Arvikar,[1] Hatice Hasturk,[2] Klemen Strle,[1] Marcy Bolster,[1] Deborah Collier,[1] Alpdogan Kantarci,[2] and Allen Steere[1], [1]Massachusetts General Hospital, Boston, MA, [2]Forsyth, Cambridge, MA

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: RA – Etiology & Pathogenesis Poster I
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Periodontitis and immune responses to periodontal pathogens such as *Porphyromonas gingivalis* (*Pg*) are associated with rheumatoid arthritis (RA) but the mechanisms underlying these connections are incompletely understood. Our goal here was to gain further insights into inflammatory responses linking periodontal and joint inflammation in RA patients.

Methods: Seventy-three subjects underwent full-mouth dental examinations, including 33 RA patients, the majority with early RA (median symptom duration 5.5 months), all meeting 2010 ACR/EULAR criteria, 20 age and gender matched healthy subjects (HS), and 20 chronic periodontitis subjects who lacked RA (non-RA CP). Thirteen inflammatory mediators and matrix metalloproteinases (MMPs) were measured in serum, saliva, gingival crevicular fluid (GCF) and synovial fluid by bead-based multiplex immunoassay. *Pg* DNA in subgingival plaque *Pg* IgG antibodies in serum and were also measured.

Results: Of the 33 RA patients, 30 (91%) received routine dental care, and only one currently smoked. However, on clinical assessment, only 10 of the 33 patients (30%) had healthy periodontium, 13 (39%) had gingivitis, a periodontitis precursor, and 10 (30%) had periodontitis.

Compared with HS and non-RA CP, RA patients had the most elevated serum levels of inflammatory mediators and MMPs, with exception of MMP-3, which was more enriched in the sera of non-RA CP patients ($P < 0.005$ vs. HS). In RA synovial fluid, the Th1-associated mediator, CXCL10, innate immune mediators, IL-6 and IL-8, and MMPs, particularly MMP-1 and MMP-3, were most concentrated compared with serum ($P \leq 0.0001$).

In saliva, the non-RA CP group had greatest concentration of inflammatory mediators, particularly the neutrophil chemoattractant IL-8, and elevated levels of MMPs, especially MMP-1, MMP-8, and MMP-9 ($P < 0.002$). In GCF, a similar inflammatory profile was observed and additionally levels of the anti-inflammatory cytokine IL-10 were significantly lower than in HS. Although values were somewhat lower, RA patients also had elevation of IL-8 in both saliva and GCF ($P=0.02$), and levels of MMP-8, and MMP-9 were also elevated, particularly in saliva ($P < 0.002$). Similar to the non-RA chronic periodontitis group, levels of IL-10 were decreased in GCF of RA patients compared with HS ($P=0.005$). When RA patients were stratified according to dental status (healthy, gingivitis, or periodontitis), there were no significant differences in the levels of inflammatory mediators. In contrast, *Pg* antibodies in serum or *Pg* DNA in subgingival plaque were found only in RA patients with clinical periodontitis.

Conclusion: While RA patients had systemic and joint inflammation, as expected, they also had elevated levels of periodontitis-associated mediators in oral fluids, even in the absence of clinical periodontitis. Levels of IL-8, a chemoattractant for neutrophils, the major effector cell in periodontitis, and MMPs were particularly elevated. Thus, the

oral mucosa may be a common, but often unrecognized, site of extra-articular inflammation in RA. In contrast, *Pg* antibodies and DNA seem to be a marker only for frank periodontitis.

Session Date: Sunday, November 10, 2019

Session Title: RA – Etiology & Pathogenesis Poster I

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is an heterogeneous chronic autoimmune disorder potentially leading to a progressive joint damage with great impact on quality of life. RA pathogenesis is complex and involves environmental factors that trigger disease in genetically susceptible individuals. Extracellular vesicles (EVs) have been described to play an important role in RA pathogenesis and to modulate autoimmune response following environmental exposures, such as air pollution.

Our aim was to evaluate the effects of particulate matter (PM) with aerodynamic diameter ≤ 10 μm (PM10) and ≤ 2.5 μm (PM2.5) on EVs in RA and osteoarthritis (OA) as control.

Methods: Plasma EVs were analyzed by Nanosight and flow cytometry: CD14 (monocyte/macrophage), CD61 (platelet), CD25 (T-reg), human endogenous retrovirus w (HERV-w), human leukocyte antigen G (HLAG). Demographic and clinical data were collected for each patient. Plasma EV concentrations were measured in RA and OA patients and were analyzed by generalized linear regression models. Daily PM concentrations, estimated by Regional Environmental Protection Agency at municipality resolution, were used to assign short-term exposure (mean of the 7 days preceding the evaluation) to each patient.

Results: 12 consecutive patients with RA (median age 68.1, median disease duration 9.3, 12 female, median DAS28 2.25, 5 positive for rheumatoid factors, 6 positive for anti-citrullinated peptide antibodies) and 12 patients with OA (median age 67.1, median disease duration 9.3, 8 female) were enrolled. Analysis of EVs concentration, according to their dimensions, showed a negative association of exosomes (63-92nm) in RA compared to OA ($p< 0.05$). The increase of PM2.5 led to a decrease of CD14+ microvesicles (MV) (β=-0.13; $p< 0.01$) and CD61+ (β=-0.08; p=0.05) in RA, and of HERV-w in OA (β=-0.09; p=0.01). Similar results were observed analyzing PM10 exposure. PM exposure was not observed to modify CD25+ and HLA-G+ MV release both in RA and OA patients (table below). Moreover, we compared plasmatic EVs mean concentration among patients with RA and OA, and we found a significant difference in the two groups in the HERV-w subpopulations (βAR vs βOA = 0.044 vs - 0.091; p = 0.011). In RA patients we also observed a significant association between EVs (CD14+ and HLA-G+ MV) and DAS28 (βCD14+ = 0.03; p = 0.01 and

HLA-G+	-0.01	0.02	0.46	0.00	0.03	0.97

βHLA-G+ = 0.04; p = 0.02). Finally, we observed a negative association between exosomes and C-reactive protein (CRP) (β=-1.99; p=0.03), and a positive association between HERV-w and Erythrocyte Sedimentation Rate (ESR) (β=0.53; p=0.06), and HLA-G+ and ESR (β=0.29; p=0.01).

Conclusion: The results of this pilot study show that PM exposure modulates the release of EVs carrying HLA-G and/or HERV-w in RA patients. This might be interpreted as an attempt of immune system to counteract the perturbation provoked by a pro-inflammatory environmental stimulus. More research is still needed to tie the genetic, epigenetic and environmental factors together and to determine their roles in RA pathogenesis.

Validation of New Genes Identified in a Molecular Bayesian Network of Rheumatoid Arthritis Synovitis

Teresina Laragione,[1] Carolyn Harris,[1] Wenhui Wang,[1] Jun Zhu,[1] and Percio Gulko[1], [1]Icahn School of Medicine at Mount Sinai, New York, NY

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: RA – Etiology & Pathogenesis Poster I
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: We have previously identified new key regulators of Rheumatoid arthritis (RA) synovial pathology using a systems biology approach that combined RA gene expression datasets, epigenomics data, genetics and rodent studies. The RA fibroblast-like synoviocytes (RA-FLS) have a central role in RA pathogenesis and joint damage, and their in vitro invasive properties correlate with in vivo joint damage. In the present study were examine the effect of different key regulators identified in the systems biology study in phenotypes relevant to disease and joint damage.

Methods: RA-FLS cell lines (n=4-6 cell lines per gene) were treated with siRNA smartpool targeting the top key network and subnetwork regulators, and compared with control siRNA. RA-FLS were then examined in different in vitro phenotypes that strongly correlate with joint damage in RA and rodent models of RA. These phenotypes included FLS invasiveness, FLS proliferation, cell adhesion, the wound healing model, and IL-1b-induced expression and production of IL-1b, IL-6, TNFa and MMPs (MMP1, 2, 3 and 14).

Results: Knock down of LOXL2 and NUSAP with siRNA significantly decreased FLS invasiveness by 30% (p=0.03) and 60% (p=0.002), respectively, compared with siRNA control. RA-FLS mobility in the wound healing assay was inhibited by knock down of AKT3, BACH1 and DLX4 (p=0.008). Knock down of TRIM22, an interferon-induced protein involved in innate immunity, decreased the IL-1b-induced release of IL-6 (p=0.03). RA-FLS proliferation and adhesion were not affected by any of the siRNA tested.

Conclusion: This study validated new key regulators identified in our systems biology discovery approach generating potential new understanding of events regulating FLS behavior in RA and potential new targets for the development of new treatments aimed at reducing joint damage.

bDMARD-experienced Filgotinib-treated Patient Samples Exhibit a Partial Reversion to the Peripheral Molecular Profile of a Demographically Matched Healthy Population

Peter Taylor,[1] Emon Elboudwarej,[2] Bryan Downie,[3] Lene Vestergaard,[2] Jinfeng Liu,[2] Amer M. Mirza,[2] and Rachael Hawtin[2], [1]University of Oxford, Oxford, United Kingdom, [2]Gilead Sciences, Inc., Foster City, CA, [3]Gilead Sciences, Inc., Foster Citty, CA

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: RA – Etiology & Pathogenesis Poster I
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Filgotinib (FIL), an oral, selective, Janus Kinase 1 (JAK1) inhibitor was effective in Phase 3 studies of active RA in patients (pts) with inadequate response or intolerance to biologic DMARDs (bDMARD-IR; FINCH-2 ClinicalTrials.gov Identifier: NCT02873936). A proteomic and transcriptomic study was conducted to elucidate the effect of FIL on molecular mechanisms and the underlying pathobiology of RA.

Methods: Whole blood was collected from FINCH-2 RA pts on either a stable dose of placebo + MTX (PBO; n = 148), or once daily FIL 100 mg (n = 153), or 200 mg (n = 148) + MTX at baseline, week 4 and week 12. Samples from demographically matched healthy volunteers (HV; n = 50) were also evaluated. Serum concentrations of 28 cytokines known to be associated with RA pathology were quantified by ELISA-based assays. Globin depleted whole-blood mRNA was sequenced using Illumina HiSeq 2500. Differential gene expression analysis was applied comparing baseline RA pts data to HVs and interpreted into pathways using Gene Set Enrichment Analysis (GSEA). Further, we calculated gene signature (GS) scores using single sample GSEA (ssGSEA) to evaluate a reversion to healthy for Hallmark gene sets that had previously shown the strongest magnitude of FIL-associated effects (Taylor *et al*. EULAR 2019). Each GS was tested (Wilcoxon rank sum) comparing treatment arms with time-paired subjects against HVs. All cytokines and GSs were standardized to HV values. Cytokines and GSs not statistically different between RA pts after treatment and HVs were considered to have "reversed" toward a HV phenotype.

Results: Among 28 cytokines evaluated in baseline RA serum, 18 were significantly different from HV. Of these, 6 (chemokine (C-X-C motif) ligand [CXCL13], chemokine (C-C motif) ligand 2 [CCL2], CCL3, CCL4, IL-18, and Osteocalcin) reversed towards a HV phenotype after FIL treatment (Table 1). In contrast, only IL-18 reached HV levels in PBO treated pts (week 4). Of 15,189 genes with expression data, 3,532 (23%) were significantly increased and 4,408 (29%) significantly decreased in pts with RA relative to HV (false discovery rate < 0.05). The baseline transcriptional profile of RA pts was enriched with pathways implicated in RA pathology, including inflammatory responses and IFN, IL-6, TNFα signalling. Reversal of transcriptional profiles was broadly dose- and time-dependent, with fewer genes differ-

Data presented as median (Q1, Q3). Pathways significantly (unadjusted Wilcoxon test) reduced from baseline are in **bold**.
FIL, filgotinib; HV, healthy volunteer; PBO, placebo; ROS, reactive oxygen species.

entially expressed from HVs after 12 weeks of FIL compared with those receiving PBO. Expression of IFN response genes in pts who received FIL was statistically indistinguishable from HVs after 12 weeks. Interestingly, reactive oxygen species and TNFα signalling did not show this trend of reversal towards HV.

Conclusion: Differences in the peripheral molecular profile were observed between bDMARD-experienced RA pts and HV. While an overall trend toward the non-diseased molecular profile was observed following FIL, only a subset of cytokines and pathways were statistically indistinguishable from HV after 12 weeks. These results support the clinical efficacy of FIL within the bDMARD-experienced population and provide evidence for the reversal of disease activity to a healthier molecular profile in the periphery.

Session Date: Sunday, November 10, 2019
Session Title: RA – Etiology & Pathogenesis Poster I
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Filgotinib (FIL), an oral, selective, Janus Kinase 1 (JAK1) inhibitor was effective in Phase 3 studies of active RA in patients (pts) with inadequate response or intolerance to biologic DMARDs (bDMARD-IR; FINCH-2 ClinicalTrials.gov Identifier: NCT02873936). We evaluated blood and urine biomarkers from FINCH-2 pts to better understand the relationship between molecular drivers of RA and identify any association between biomarkers at baseline and therapeutic response.

Methods: Forty-two cytokines known to be associated with RA pathobiology were quantified by single and multiplexed ELISA at baseline and week 12. The multiplicative interaction between each baseline biomarker (low [≤ median] or high [> median]) and q.d. FIL 100mg (n = 153) or FIL 200 mg (n = 148), relative to placebo (PBO; n = 148), was tested for an effect on week 12 response (ACR-N, ACR20, ACR50, ACR70, DAS28-CRP). The relative concentrations of soluble intercellular adhesion molecule 1 (sICAM1) and serum chemokine (C-X-C motif) ligand (CXCL13) was previously associated with clinical outcomes in pts with RA treated with bDMARDs.[1]We similarly evaluated the therapeutic effect of FIL with sICAM1/CXCL13 ratio (low vs. high) on week 12 clinical responses. Odds ratios (OR) from logistic regression and effect estimates from linear regression models (Wald Chi-Square Test) were reported to assess whether the interaction between biomarker and treatment was associated with clinical response (FDR < 0.20).

Results: Comparing FIL 100 mg pts to PBO, high baseline levels of 8 serum cytokines (Chemokine (C-C motif) ligand 3[CCL3], CXCL10, IL-5, IL-6, IL-18, MMP3, serum amyloid A [SAA] and vascular cell adhesion molecule 1 [VCAM1]) were individually associated with improved ACR response or reduction in RA disease activity (DAS28-CRP) by week 12 (Δ ACRN range [27.5, 79.4]; Δ DAS28-CRP range [-0.70, -0.93]). High baseline serum CRP, CXCL13, and vascular endothelial growth factor A [VEGFA] levels were also associated with improved response to FIL 200 mg (Δ ACRN range [15.4, 32.9]; Δ DAS28-CRP range [-0.79, -1.39]; ACR50 OR range [6.13, 7.10]). Additionally, PBO-treated pts with a low sICAM1/CXCL13 ratio had lower ACR50 response rate compared to pts with high sICAM1/CXCL13 ratio (low vs high ratio Δ = -15.2%). In contrast, FIL treated pts exhibited the opposite effect, where a low sICAM1/CXCL13 ratio led to an increased ACR50 response (FIL 100 mg: low vs high ratio Δ = + 10.7%; FIL 200 mg: low vs high ratio Δ = + 19.9%). Relative to PBO with high sICAM1/CXCL13 ratio, a low sICAM1/CXCL13 ratio was significantly associated with an improved likelihood of ACR50 response to FIL 100 mg and 200 mg respectively at week 12 (OR = 7.40, *P* = 0.001; OR = 5.23, *P* = 0.007). Notably, these significant interactions held for ACR20 and ACR70 in FIL 200 mg (Table).

Table. Interactions of ACR response and CXCL13/sICAM1 ratios in FIL treated RA pts with a low CXCL13/sICAM1 ratio compared with PBO treated pts with high CXCL13/sICAM1 ratio

	Week 12 ACR Response Rate (%)	Low CXCL13/sICAM1 ratio FIL treatment vs high CXCL13/sICAM1 ratio PBO		
		Odds Ratio	95% CI	P Value
ACR 20				
PBO	36.2	n/a	n/a	n/a
FIL 100 mg	68.9	ns	ns	ns
FIL 200 mg	80.6	3.43	1.21, 9.93	0.021
ACR 50				
PBO	24.1	n/a	n/a	n/a
FIL 100 mg	39.3	7.44	1.61, 18.5	0.001
FIL 200 mg	53.7	5.31	2.30, 25.6	0.007
ACR 70				
PBO	10.2	n/a	n/a	n/a
FIL 100 mg	21.3	ns	ns	ns
FIL 200 mg	32.8	9.97	1.97, 60.1	0.007

CI, confidence interval; FIL, filgotinib; n/a, not applicable; ns, not significant; PBO, placebo; sICAM1, soluble intercellular adhesion molecule 1.

Biomarkers at Baseline Table Interactions of ACR response and CXCL13/sICAM1 ratios in FIL treated RA pts with a low CXCL13/sICAM1 ratio compared with PBO treated
pts with high CXCL13/sICAM1 ratio

Conclusion: Individually, high baseline levels of key inflammatory serum cytokines, as well as the presence of a low sICAM1/CXCL13 ratio were each indicative of positive outcomes in these bDMARD-IR RA pts treated with FIL. Further evaluation of these biomarkers alone or in combination may suggest a cytokine profile in RA pts that enriches for the probability of high-end responses to therapy.

Autoreactivity to Acetylated Histones Defines a Subset of RA Patients and Is Associated with Acetyl - Citrulline Anti-Modified Protein Autoantibody (AMPA) Cross-Reactivity

Peter Sahlström,[1] Lisa Liljefors,[1] Vijay Joshua,[2] Natalia Sherina,[1] Radha Thyagarajan,[1] Lena Israelsson,[2] Ragnhild Stålesen,[2] Monika Hansson,[3] Khaled Amara,[2] Ulf Reimer,[4] Leonid Padyukov,[1] Elisabet Svenungsson,[5] Karin Lundberg,[1] Anca Catrina,[3] Lars Klareskog,[3] Vivianne Malmström,[2] and **Caroline Grönwall**[2], [1]Karolinska Institutet, Stockholm, Sweden, [2]Rheumatology Unit, Department of Medicine, Karolinska University Hospital and Institutet, Stockholm, Sweden., Stockholm, Sweden, [3]Rheumatology unit Karolinska University Hospital and Karolinska Institutet, Stockholm, Sweden, Stockholm, Sweden, [4]JPT Peptide Technologies, Berlin, Germany, [5]Division of Rheumatology, Department of Medicine Solna, Karolinska Institutet, Stockholm, Sweden

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: RA – Etiology & Pathogenesis Poster I
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Serum anti-citrullinated protein autoantibodies (ACPA) in rheumatoid arthritis (RA) display reactivity to a variety of cit-autoantigens. Studies of human ACPA mAbs have revealed that individual clones bind multiple cit-epitopes by recognition of consensus motifs. For certain ACPA, this cross-reactivity may extend also to other post-translational modifications (PTMs). Here we investigated anti-modified protein autoantibody (AMPA) reactivity to acetylated epitopes in RA.

Methods: Serum from 402 RA patients, 317 population controls and 160 SLE patients were screened by ELISA for IgG to an acetylated histone 2B peptide ($His2B_{6-22}$(Ac-K12)). IgG values were normalized towards a reference and reactivities to the native lys-peptide were subtracted. Cutoff for positivity was set based on controls (Mean+3 SD Δac-lys: 4.25). ACPA fine-specificity in the RA cohort was assessed by the ISAC antigen microarray, CCP2 by CCPlus assay and RF IgM/G/A by ELiA. In addition, AMPA reactivity to Ac-His2B and $His4_{1-18}$(Ac-K5,8,12,16) peptides were investigated in 295 RA-derived single-cell cloned human mAbs (23 CCP2+ and 272 non-ACPA clones). A mAb-subset was further evaluated using the JPT Histone Code Array. Fisher's exact test, Kruskal-Wallis analysis, and Spearman correlation were used for statistical analysis.

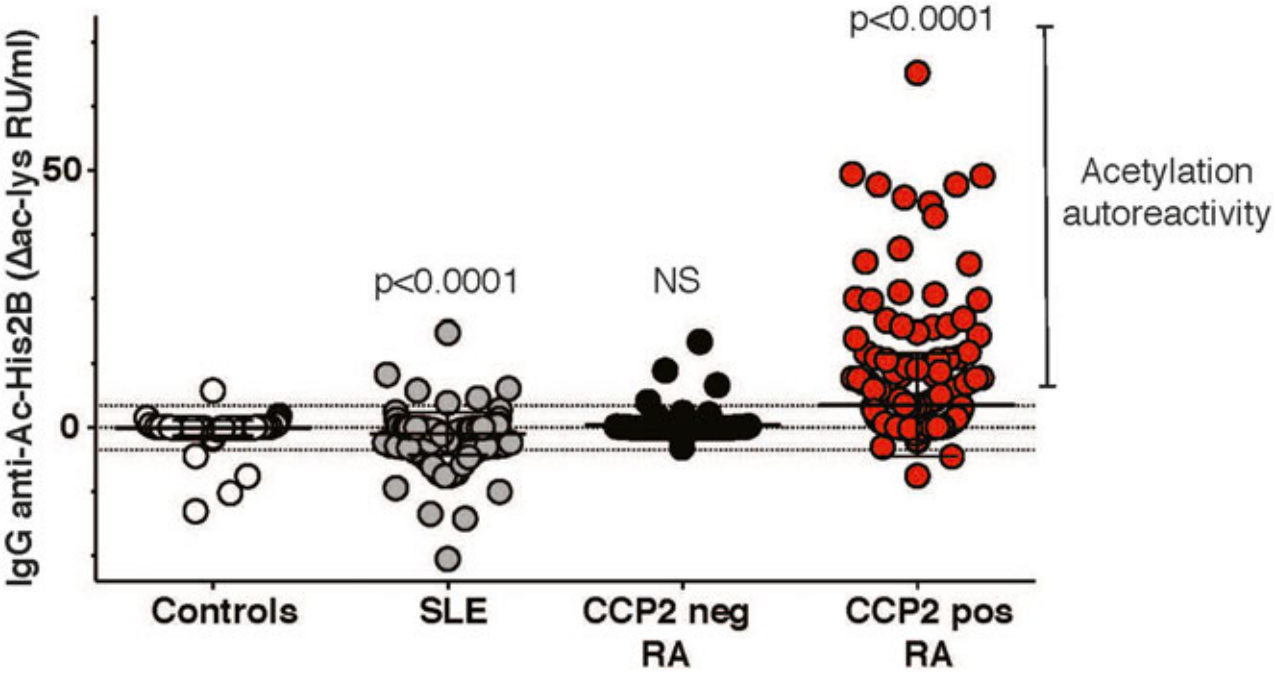
Results: RA patients displayed significant autoreactivity to acetylated histone compared to controls and SLE (Table 1, Fig. 1). Some SLE patients instead had increased reactivity to native His2B. 17% of all RA were positive for IgG anti-Ac-His2B distributing into 23% in the CCP2+ RA subset and 3.2% in CCP2 neg RA, while 0.3% in controls and 3.8% in SLE were positive. The CCP2 neg anti-Ac-His2B pos patients were RF positive and a majority had ACPA fine-specificities. At least one of the positive SLE patients was CCP2 positive. IgG anti-Ac-His2B correlated with IgG anti-CCP2 (R=0.41, p< 0.0001) as well as a range of cit-peptide reactivities (e.g. cit-Vim, cit-Fib, CEP-1). No significant association with DAS28, CRP or shared epitope HLA-DRB1 could be shown. However, levels were increased in smokers (p=0.04; Δac-lys: 3.8±9.6 RU/ml vs 1.9±6.7 RU/ml) and correlated with the number of positive ACPA fine-specificities (R=0.44 p< 0.0001). Among ACPA mAbs, 30% had ac-his reactivity (7/23, derived from 4 different patients and either lung/BAL, synovial plasma cells, or blood memory). None of the non-ACPA mAbs showed any binding. PTM cross-reactivity of these AMPA, and acetyl-lysine consensus motifs, were confirmed by the histone code array. Of note, some ACPA displayed restricted cit-reactivity.

Table 1. Serum IgG autoantibodies to acetylated histone 2B in RA

	Serum IgG anti-Ac-His (Δac-lys) (Mean±SD)		Frequency of IgG anti-Ac-His positivity	
		*p-value**		*p-value**
Controls	-0.1±1.45 RU/ml		0.3% (1/317)	
SLE patients	-1.2±4.18 RU/ml	p<0.0001	3.8% (6/160)	p=0.007
All RA patients	3.2±8.6 RU/ml	p<0.0001	17% (68/402)	p<0.0001
CCP2 neg RA	0.42±2.1 RU/ml	NS	3.2% (4/125)	p=0.03
CCP2 pos RA	4.4±10 RU/ml	p<0.0001	23% (64/277)	p<0.0001

**Compared to healthy population controls; RU=Relative Units*

Figure 1



Conclusion: A subset of ACPA can bind to acetyl-lysine peptides and elevated serum IgG anti-acetylated histone was confirmed in RA patients. We hypothesize that acetyl-autoreactivity in RA is associated with increased levels of cross-reactive AMPA. Notably, while AMPA activity is not restricted to histone motifs, anti-Ac-His may have functional properties by PAD-independent NET-interactions. These novel findings substantially extend our understanding of autoreactivity in RA and provide insight in RA pathogenesis.

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: RA – Etiology & Pathogenesis Poster I
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: 1. To identify and characterize specific immunological, inflammatory and epigenetic determinants involved in the enhanced cardiovascular (CV)-risk present in Rheumatoid Arthritis (RA) patients. 2. To evaluate the effects of biological drugs on the reestablishment of this altered profile.

Methods: Serum samples from 52 healthy donors (HD) and 188 selected RA patients -including 100 patients that had suffered previous CV events and 88 without previous CV events- were studied. Inflammatory and oxidative stress biomolecules and Netosis-derived products were quantified, and the CV-Risk Score was calculated following EULAR recommendations. Carotid intima-media thickness (CIMT) was evaluated as early atherosclerosis marker. miRNnomes were identified using next-generation sequencing miRNA assay. The *in vivo* effects of biologic drugs such as Infliximab (IFX), Tocilizumab (TCZ) and Rituximab (RTX) were evaluated before and after 6 months of therapy in parallel cohorts of 45, 25 and 27 patients, respectively.

Results: Circulating biomolecules related to inflammation -interleukins, chemokines, adhesion molecules-, Netosis -cell-free nucleosomes and elastase- and oxidative stress -lipoperoxides and 8-hydroxy-2'-deoxyguanosine (8-OHdG)- were found coordinately altered in the serum of RA patients. 104 circulating miRNAs were found altered in RA patients. Functional classification (Ingenuity Pathway analysis, IPA) recognized their potential involvement in inflammatory response, immunological and hematological diseases, and correlation analyses established the relationship of a number of them with the biomolecules found altered in RA patients. Non-supervised hard clustering analysis differentiated 3 clusters representing different CV-risk profile groups: a) RA patients with elevated CV-risk score (>9), positive for autoantibodies (RF and ACPAs) and with a high incidence (53 %) of CV events; b) RA patients with medium-low CV-risk score (< 4) but positive for autoantibodies and also with a high incidence (47%) of CV events, thus suggesting a relevant role for autoimmunity in this increased CV-risk; and c) RA patients negative for autoantibodies with medium-low CV-risk score and without previous CV events. Those three phenotypes of RA patients further displayed distinctive and specific molecular shapes. In vivo treatments with IFX, TCZ and RTX reduced disease activity and induced the re-establishment of normal levels in these altered biomolecules in an inhibitor-dependent manner.

Conclusion: 1. Phenotype-based clustering combined with the analysis of molecular profiles might help to define precise CV-risk profiles in RA patients. 2. Specific mediators of autoimmunity, inflammation, oxidative damage and Netosis, along with the miRNAs modulating their expression, coordinately contribute to a higher CV-risk score in RA patients. 3. Biological drugs, most likely though distinctive molecular mechanisms, restore the normal levels of these altered biomolecules, reducing the CV risk in RA patients. Session Title: RA – Etiology & Pathogenesis Poster I

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: The goal of the Accelerating Medicines Partnership (AMP) program is to study synovial tissue from individuals with rheumatoid arthritis (RA) using high-dimensional analyses. During phase 1 of the program, we performed cytometric and transcriptomic analyses of synovial tissues and identified subsets of stromal and immune cells that were enriched in inflamed synovium. For phase 2, we have developed a pipeline to generate parallel single cell transcriptomic, proteomic, and epigenetic datasets of RA synovial cells (**Fig.1**).

Methods: Synovial tissues were obtained from individuals meeting the 2010 ACR criteria for RA and undergoing elective surgical procedures or synovial biopsies. We developed a histologic grading system to guide selection of biopsies with sufficient cell number and quality to apply multiple analytic technologies. Synovial tissues were cryopreserved after acquisition and then thawed and disaggregated. Viable synovial cells from each sample were sorted for subsequent analysis by scRNAseq, CITE-seq (combined scRNAseq and surface proteomics), and scATAC-seq using droplet-based technology (10X Genomics).

Results:

1. Histologic grading informs tissue cellularity. High quality synovial tissues (Grade A) predicted high cell yield (>50,000 cells) and whereas low quality (Grade D) predicted low cell yield (< 1,000 cells).
2. CITE-seq on synovial cells. Optimized cell handling enabled CITE-seq analysis on tissues with as low as 50,000 viable cells. After eliminating low-complexity cells (~5% of cells), we consistently recovered >10,000 high quality cells (>2,000 genes/cell) from each tissue. We tested 83 oligo-conjugated antibodies targeting immune and stromal cell surface markers and identified 61 antibodies with high signal specificity (high K-L divergence within gene-defined clusters) and signal intensity (median non-zero expression). Specificity of proteomic signals were markedly improved through serial titration. Importantly, independently clustering based on either transcriptomic or proteomic data revealed concordant signal that identified 19 distinct immune and stromal cell clusters.
3. Single cell ATAC-seq on synovial cells. We optimized nuclei recovery from synovial cells to enable scATAC-seq analysis from 30,000 viable cells. We demonstrated feasibility of performing scATAC-seq on re-cryopreserved synovial cells to facilitate batched processing. After removing low-read-depth barcodes, we obtained robust scAT-

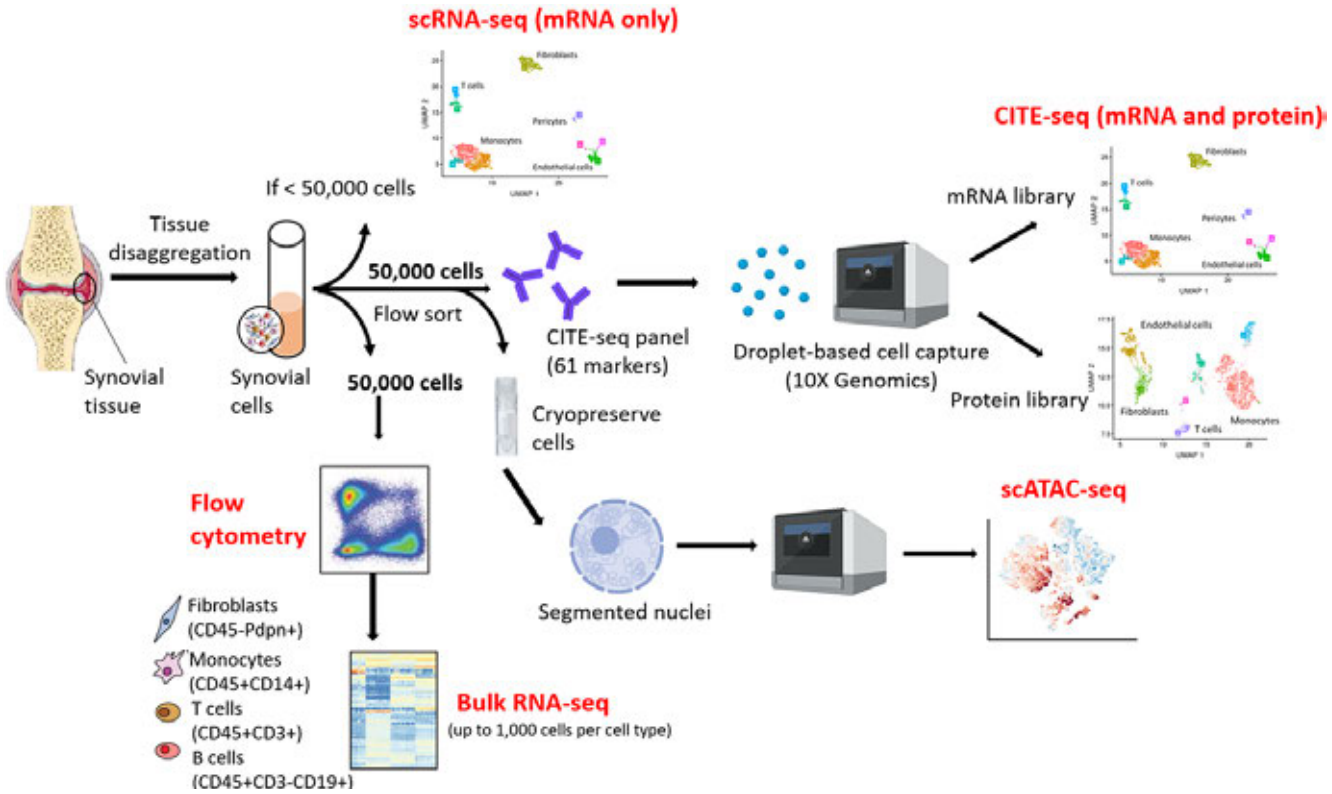

Figure 1. Single cell multiomics analysis of synovial cells.

AC-seq data (>9,000 mapped fragments/nucleus) with high concordance between scATAC-seq with scRNA-seq. We further demonstrated consistent identification of diverse synovial cell types in both once- and twice-cryopreserved synovial cells.

4. Flow Cytometry and bulk RNAseq. A 14-color flow cytometry panel was used to quantify disease-associated cell populations in conjunction with sorting major synovial cell types for low-input RNAseq.

Conclusion: We demonstrate feasibility of implementing multiple single cell profiling techniques in synovial tissue. The collection of multiple modalities of single cell analysis will add new dimensions to our understanding of the cellular pathogenesis of rheumatoid arthritis.

Circulating 25(OH)D, LL-37 and Antimicrobial Protein and Peptide (APP) Levels Are Altered Prior to Onset of Rheumatoid Arthritis

Vidyanand Anaparti,[1] Xiaobo Meng,[1] Hemshekhar Mahadevappa,[1] Irene Smolik,[1] Neeloffer Mookherjee,[1] and Hani El-Gabalawy[1], [1]University of Manitoba, Winnipeg, MB, Canada

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: RA – Etiology & Pathogenesis Poster I
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Epidemiological studies suggest vitamin D deficiency as a potential risk factor for rheumatoid arthritis (RA) development, a chronic autoimmune disorder highly prevalent in indigenous North American (INA) population. Vitamin D improves immune function and protects against infections by inducing the expression of antimicrobial proteins and peptides (APPs) such as LL-37. We therefore profiled the circulating levels of 25-hydroxyvitaminD [25(OH)D], an active metabolite of vitamin D, and APPs in serum samples obtained from a cohort of at-risk first-degree relatives (FDR) of INA RA patients, a subset of whom subsequently developed RA (2010 ACR/EULAR guidelines) and were referred as "progressors".

Methods: 2007 onward, serum samples were collected from at-risk INA FDRs. Anti-citrullinated protein antibodies (ACPA), 25(OH)D, hs-CRP, vitamin-D binding protein (VDBP) and LL-37 (cathelicidin) levels were determined using ELISA and rheumatoid factor (RF) seropositivity was determined by nephelometry. A high-throughput Slow Off-Rate Modified Aptamer (SOMAmer®)-based Protein Array technology (SOMALogic Inc., US) was used for quantification of other APPs.

Results: We demonstrate that seropositive RA patients and FDR had lower 25(OH)D levels compared to ACPA-/FDR ($P< 0.05$, $P< 0.01$ respectively). In contrast, serum LL-37 levels were higher in both study groups compared to ACPA-/FDR ($P = 0.0009$ and $P = 0.0120$ respectively). No difference was observed in LL-37 levels between ACPA+ FDR and RA patients ($P = 0.1090$) Linear regression analysis showed circulating 25(OH)D and LL-37 was inversely associated with anti-CCP antibody levels ($P = 0.005$ and $P = 0.05$ respectively). Longitudinal samples from 14 progressors demonstrated a consistent increase in 25(OH)D, and LL-37 levels at the time they exhibited clinically detectable joint inflammation, without any significant change in VDBP levels. Expression profile of APPs was also significantly altered in progressors at RA onset and at-risk FDRs.

Conclusion: We demonstrate a differential serum abundance in the levels of 25(OH)D and APPs at RA onset in progressors. The interrelationship between vitamin D and these downstream metabolites and their potential role in RA transition requires further investigation.

Cigarette Smoking Has Different Impacts on ACPA and RF Production Depending on Shared Epitope Allele Status in Japanese RA Patients; A Study with the Two Independent Japanese Cohorts (IORRA and KURAMA)

Yuki Ishikawa,[1] Motomu Hashimoto,[2] Katsunori Ikari,[3] Koichiro Ohmura,[4] Masao Tanaka,[4] Hiromu Ito,[4] Atsuo Taniguchi,[3] Hisashi Yamanaka,[3] Tsuneyo Mimori,[4] and Chikashi Terao[5], [1]Joslin Diabes Center, Boston, MA, [2]Department of Advanced Medicine for Rheumatic Diseases, Kyoto University Graduate School of Medicine, Kyoto, Japan, [3]Tokyo Women's Medical University, Tokyo, Japan, [4]Graduate School of Medicine, Kyoto University, Kyoto, Japan, [5]RIKEN, Tokyo, Japan

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: RA – Etiology & Pathogenesis Poster I

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: In rheumatoid arthritis (RA), cigarette smoking affects both rheumatoid factor (RF) and anti-citrullinated cyclic peptide/protein antibody (ACPA) production, but its association in relation to HLA-DRB1 alleles, especially shared epitope (SE) alleles, have been different among different races[1-5]. Furthermore, the impact of cigarette smoking and its cessation on levels of RF and ACPA have not been well documented. We conducted the present study to investigate the impact of cigarette smoking and cessation on RF and ACPA levels in relation to HLA-DRB1 alleles in the largest RA cohorts in Asians.

Methods: A total of 6,239 subjects from two independent Japanese cohorts were enrolled. Their precise smoking histories both before and after the onset of RA were collected in questionnaires. The latest RF and ACPA levels were used (mean disease duration 15.6 years). We defined top quadrant of levels of RF or ACPA as high levels. Associations between smoking status and positivities or high levels of ACPA or RF as well as effects of HLA-DRB1 alleles on the associations were investigated by multiple logistic regression models.

Results: Smoking at onset (SaO) was an independent risk of not only RF and ACPA positivities (RF, odds ratio (OR) 1.52, 95% confidence interval (CI) 1.26-1.85, $p=1.8x10^{-5}$; ACPA, OR 1.39, 95%CI 1.09-1.76, $p=6.8x10^{-3}$), but also high levels of these autoantibodies, especially RF (Figure1; OR 2.06, 95% CI 1.70-2.48, $p=7.4x10^{-14}$; ACPA OR 1.29, 95%CI 1.06-1.57, $p=1.2x10^{-2}$). The larger ORs of RF than ACPA suggests that RF is more sensitive to cigarette smoking than ACPA. The effects of cigarette smoking were significantly larger in males than in females. The patients who quited smoking before onset had no longer significant risks of high autoantibody levels compared to subjects who had never smoked (RF, OR 1.33, p=0.099; ACPA, OR 1.19, p=0.093), and the risk was gradually attenuated depending on cessation years (RF, 0-10 years OR 1.34, 10-20 years OR 1.31, > 20 years OR 0.97; ACPA, 0-10 years OR 1.38, 10-20 years OR 1.01, > 20 years OR 1.12). The effect of smoking on ACPA positivity and its high level was apparent only in the presence of SE alleles, while the effect on RF positivity and its high level was apparent despite the presence of SE alleles (Figure 2 and 3) .

Conclusion: Cigarette smoking especially at RA onset is a significant risk of future high levels of ACPA and RF preferentially in males, and RF is more sensitive to smoking status than ACPA. The effect on ACPA is apparent only in the presence of SE alleles, indicating that an interaction between cigarette smoking and SE alleles affects ACPA production. On the other hand, the effect of cigarette smoking on RF production may be independent of SE alleles. Our study imply a novel potential mechanism of RA pathogenesis.

Autophagy Protein Microtubule-associated Protein 1 Light chain-3B (LC3B) Regulates Joint Inflammation and Destruction in Rheumatoid Arthritis

sangyoun jung,[1] sookon lee,[1] and jinjung choi[1], [1]CHA Bundang Medical Center, Seongnam-si, Kyonggi-do, Republic of Korea

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: RA – Etiology & Pathogenesis Poster I
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Here, we assumed that intracellular autophagy mechanism and its protein microtubule-associated protein 1 light chain-3B (LC3B) play an important role in the synovial fibroblasts of rheumatoid arthritis, and identified it through TNF-α stimulated synovial fibroblasts and animal model of rheumatoid arthritis.

Methods: Mice deficient in microtubule associated protein-1 light chain-3B (LC3B-/-) were induced arthritis by the injection of type II collagen antibody and LPS. The clinical and histologic scores of arthritis and pro-inflammatory cytokines were measured from arthritic mice. Human synovial fibroblasts were obtained from the patients with rheumatoid arthritis. Their autophagic induction and its mechanisms were measured by western blots and ELISA assays after TNF-α treatment.

Results: In the results, we found that the clinical and histologic scores of arthritis and pro-inflammatory cytokines such as TNF-α, IL-1β and IL-6 in joint tissues were significantly decreased in the LC3B-/- arthritic mice compared to wild type littermates. We also identified that autophagy proteins like LC3B were expressed in synovial fibroblasts stimulated with TNF-α, and in this process, the activation of Jun-N terminal kinase (JNK) through reactive oxygen species (ROS) generated by a TNF-α and the expression of early growth response protein-1 (Egr-1) were important to LC3B expression. After knock down of LC3B by siRNA in the TNF-α stimulated synovial fibroblasts, the proliferation, migration and invasion capacities of these cells were significantly reduced and these phenomenons were associated with the decrease of cyclin D1 and vimentin by the increased ROS after autophagy inhibition.

Conclusion: In conclusion, we confirmed that autophagic protein LC3B induced by TNF-α plays an important role in the joint inflammation and destruction of rheumatoid arthritis and suggest this protein as a new therapeutic target in the treatment of rheumatoid arthritis.

Session Title: RA – Etiology & Pathogenesis Poster I

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: To decipher the phenotype of endothelial cells (ECs) derived from circulating progenitors issued from patients with rheumatoid arthritis (RA).

Methods: Proliferation capacities between RA and control ECs was compared using the xCELLigence™ RTCA System. rh-TNFa-induced EC activation was analyzed by adhesion cell expression, VEGF synthesis and stress fiber formation. Angiogenic properties of ECs were assessed *in vitro* by tube formation on Matrigel and migration capacities through VEGF stimulation in modified Boyden chambers, and *in vivo* in a mouse model of tumoral neovascularization. Microarray experiments were then performed on Affymetrix GeneChip® Human Exon 1.0 ST Arrays in ECs issued from 18 RA patients and 11 age and sex-matched healthy controls. Expression of identified candidates was assessed by RT-PCR and western blots in ECs and by immunohistochemistry in the synovium. Their functional importance was then evaluated *in vitro* after gene invalidation by siRNA and adenoviral gene overexpression, and *in vivo* in the mouse model of methyl-BSA-induced arthritis.

Results: RA ECs displayed higher proliferation rate, greater sensitization to TNF-α,with increased VEGF production, ICAM/VCAM expression, and more prominent stress fiber formation, as well as enhanced angiogenic capacities, characterized by accelerated tube formation and increased migration capacities through VEGF stimulation, compared co control ECs. The subcutaneous transplantation of murine colon carcinoma (CT-26) cells with RA ECs in CB17-SCID mice markedly amplified tumor growth and intra-tumoral neovessel density, compared to the transplantation of control ECs.

Supervised microarray analyses identified the NAD-dependent protein deacetylase sirtuin-1 (SIRT1) as a relevant gene candidate. A strikingly decreased SIRT1 gene / protein expression and enzyme activity was detected in RA ECs upon the regulation of miR217 and miR181. A markedly decreased SIRT1 expression was also observed in synovial vessels of RA patients.

Invalidation of SIRT1 with specific siRNA in control ECs was associated with a proliferative and activated profile upon TNFa stimulation, trough the acetylation of p53 and p65, and with the development of proangiogenic capacities through the upregulation of the matricellular protein CYR61. Conditional deletion of SIRT1 in ECs through a Cre-LoxP recombination system increased angiogenesis and worsened signs of arthritis in methyl-BSA-induced arthritis.Conversely, adenoviral overexpression of SIRT1 in RA ECs reversed the activated and proangiogenic phenotype of RA ECs, and activation of SIRT1 with resveratrol alleviated signs of experimental methyl-BSA-induced arthritis.

Conclusion: SIRT1 expression is reduced in synovial vessels of RA patients. SIRT1 invalidation in ECs reproduces the proliferative, activated and proangiogenic profile of RA ECs and exacerbate experimental arthritis. These effects were reversed by SIRT1 activation. These results support the implication of SIRT1 in RA synovial neoangiogenesis and may have direct therapeutic implications, since targeting angiogenesis, and especially SIRT1, might be used as a complementary therapeutic approach in RA.

A Metagenome-wide Association Study of Gut Microbiome Revealed Novel Etiology of Rheumatoid Arthritis in the Japanese Population

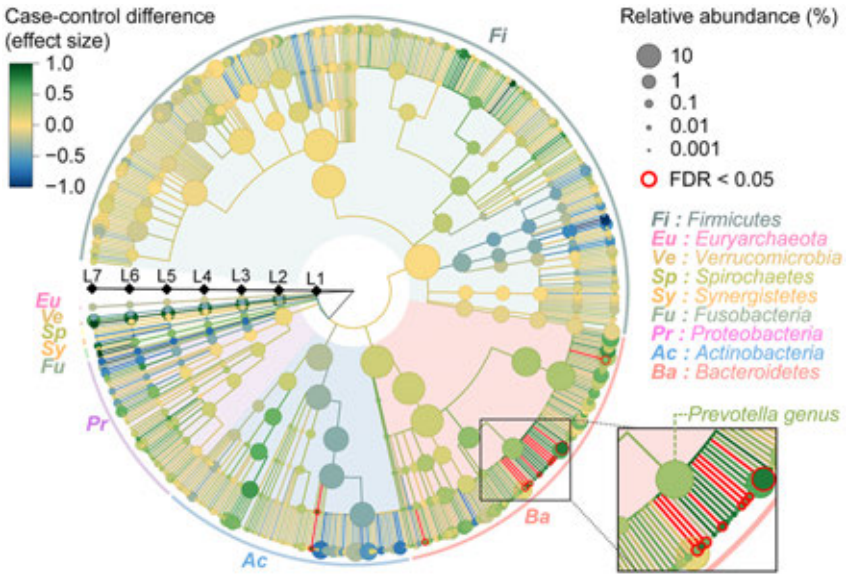
Toshihiro Kishikawa,[1] Yuichi Maeda,[2] Takuro Nii,[1] Daisuke Motooka,[1] Yuki Matsumoto,[1] Masato Matsushita,[3] Hidetoshi Matsuoka,[4] Maiko Yoshimura,[4] Shoji Kawada,[5] Satoru Teshigawara,[4] Eri Oguro,[1] Yasutaka Okita,[4] Keisuke Kawamoto,[5] Shinji Higa,[6] Toru Hirano,[7] Masashi Narazaki,[1] Atsushi Ogata,[5] Yukihiko Saeki,[8] Shota Nakamura,[1] Hidenori Inohara,[1] Atsushi Kumanogoh,[1] Kiyoshi Takeda,[1] and **Yukinori Okada**[1], [1]Osaka University, Suita, Japan, [2]Department of Respiratory Medicine and Clinical Immunology, Osaka University Graduate School of Medicine, Osaka, Japan, [3]Saiseikai Senri Hospital, Suita, Japan, [4]NHO Osaka Minami Medical Center, Kawachinagano, Japan, [5]Daini Osaka Police Hospital, Tennoji-ku, Japan, [6]Osaka Second Police Hospital, Osaka, Japan, [7]Department of Respiratory Medicine and Clinical Immunology, Graduate School of Medicine, Osaka University, Osaka, Japan, [8]NHO Osaka Minami Medical Center, Kawachinagano, Osaka, Japan

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: RA – Etiology & Pathogenesis Poster I
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The causality and pathogenic mechanism of microbiome composition remain elusive in many diseases, including autoimmune diseases such as rheumatoid arthritis (RA). This study aimed to elucidate gut microbiome's role in RA pathology by a comprehensive metagenome-wide association study (MWAS).

Methods: We conducted MWAS of the RA gut microbiome in the Japanese population (n_{case} = 82, $n_{control}$ = 42) by utilizing whole-genome shotgun sequencing of high depth (average 13 Gb per sample). Our MWAS consisted of three major bioinformatic analytic pipelines (phylogenetic analysis, functional gene analysis, and pathway analysis).

Results: Phylogenetic case–control association tests showed high abundance of multiple species belonging to the genus *Prevotella* (but other than previously reported *Prevotella copri*) in the RA case metagenome. The non-linear machine learning method efficiently deconvoluted the case–control phylogenetic discrepancy. Gene functional assessments showed that the abundance of one redox reaction–related gene was significantly decreased in the RA metagenome compared to controls. A variety of biological pathways including those related to metabolism (e.g., fatty acid biosynthesis and glycosaminoglycan degradation) were enriched in the case–control comparison. A population-specific link between the metagenome and host genome was identified by comparing biological pathway enrichment between the RA metagenome and the RA genome-wide association study (GWAS) results. No apparent discrepancy in alpha- or beta-diversities of metagenome was found between RA cases and controls.



Phylogenetic tree. Levels L2–L7 are from the inside layer to the outside layer. The size and color of dots represent relative abundance and effect sizes, respectively. The 12 clades with significant case–control associations ($q < 0.05$) are outlined in red.

Conclusion: Our shotgun sequencing–based MWAS highlights a novel link among the gut microbiome, host genome, and pathology of RA, which contributes to our understanding of the microbiome's role in RA etiology.

Abstract Number: 0055

A Novel Subclass of Intravascular Non-classical, Tissue Resident Synovial Monocyte Is Critical for Rheumatoid Arthritis Pathogenesis

Anna Montgomery,[1] Shang-Yang Chen,[1] Deborah Winter,[2] and **Harris Perlman**[2], [1]Northwestern University, Chicago, [2]Northwestern University Feinberg School of Medicine, Division of Rheumatology, Chicago

SESSION INFORMATION

Session Date: Sunday, November 10, 2019
Session Title: RA – Etiology & Pathogenesis Poster I
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: There are at least three populations of circulating monocytes; classical, intermediate and non-classical. We demonstrated that circulating non-classical monocytes are required for the effector phase of arthritis and spontaneous models of arthritis in mice. While the vast majority of studies on monocytes have focused those in circulation, very little is known about the monocytes in the synovium. The aim of this study was to examine the heterogeneity of tissue monocytes with those circulation and determine their involvement in inflammation.

Methods: NR4A1$^{-/-}$, CX3CR1$^{ERCre.zsGFP}$, CCR2$^{-/-}$, LFA$^{-/-}$ and C57Bl/6 mice were used in all studies. Intravascular and extravascular monocytes were identified using fluorescent anti-CD45 antibody before perfusion. STIA was induced via I.V. KBxN sera. Monocyte populations were quantified by flow cytometry and FACS sorted for RNA-sequencing (RNA seq). Human synovium was obtained from ultrasound guided synovial biopsies and CD45+ cells were FACSorted for single cell RNA seq.

Results: Single cell profiling of CD45^{+}NK1.1^{-}CD3^{-}CD19^{-}Ly6G^{-}CD64^{-}Tim4^{-}CD11b^{+} cells revealed 4 populations of non-classical monocytes that are distinct from circulating non-classical monocytes. We then identified four populations of Ly6C^{lo} monocytes in the joint; 2 intravascular and 2 extravascular cells using 18 color flow cytometry. Similarly, RA patients also display populations of non-classical monocytes using single cell RNA seq of ultrasound guided synovial tissue biopsies. Lineage tracing studies reveal that the origin of extravascular synovial monocytes are from the embryo while the intravascular monocytes are derived post-natally. The NR4A1-/- mice have fewer intravascular monocytes but still retain the extravascular monocytes, while CCR2-/- mice display similar numbers of intravascular non-classical monocytes yet lack the extravascular MHCII^{+} nonclassical monocytes compared to controls. Nonetheless, NR4A1-/- and CCR2-/- mice develop rheumatoid arthritis (RA)-like disease. Moreover, LFA-/- mice fail to have an expansion of the extravascular non-classical monocytes, which correlates with an ability to develop RA-like disease. Clodronate loaded liposomes depletes the intravascular monocytes as well as the extravascular CD177+MHC- nonclassical monocytes. These data suggest that only the loss of extravascular CD177+MHC- nonclassical monocytes but not the intravascular non-classical monocytes and the MHCII+ extravascular non-classical monocytes are essential for the development of RA.

Conclusion: We have identified and described four novel and uncharacterized populations of non-classical monocytes cells in the joint, an intravascular adherent and an extravascular populations. These cells have distinct origins and phenotype from both tissue resident macrophages and circulating non-classical monocytes. Further, the findings presented here strongly suggest the extravascular CD177+ non-classical monocytes are a key effector cells in inflammatory arthritis.

SESSION INFORMATION

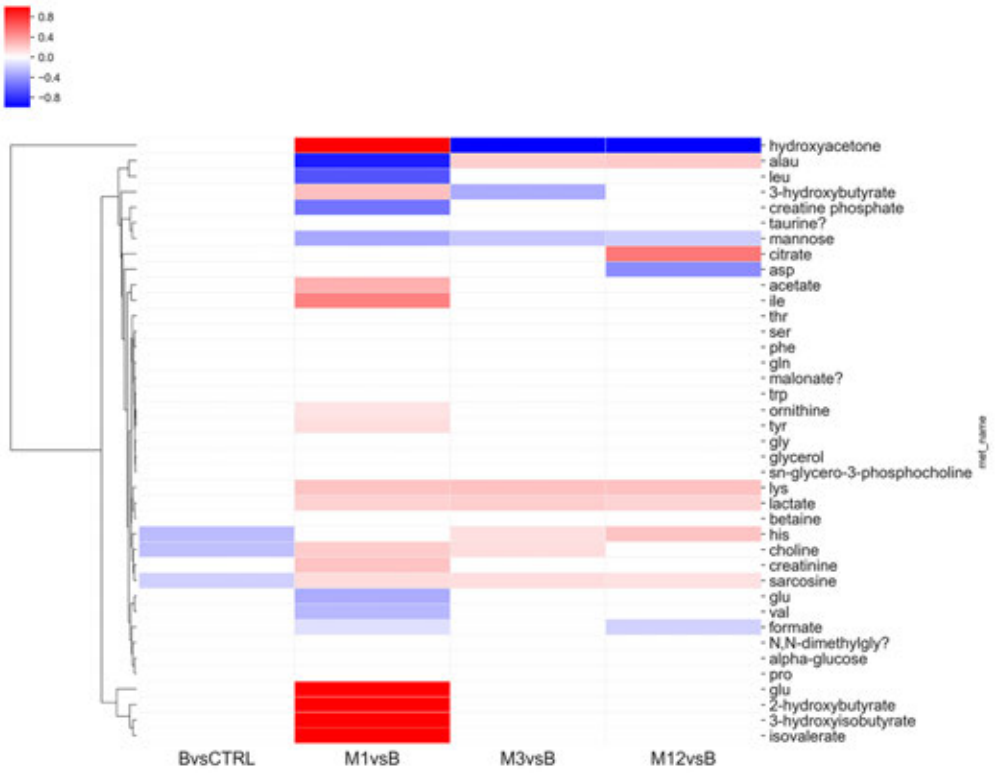
Session Date: Sunday, November 10, 2019

Session Title: RA – Etiology & Pathogenesis Poster I

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Elderly-onset RA (EORA) and polymyalgia rheumatica (PMR) are common rheumatic disease in the elderly and their pathogenesis are still not completely understood. Perturbations caused by in-



flammation can lead to correlated changes in concentrations of certain metabolites. Specifically, choline metabolism is strongly related to inflammation. The objective of this study was to explore metabolomic perturbations profiles in blood, utilizing 1H-nuclear magnetic resonance (NMR) and to relate to arthritic symptoms in the elderly.

Methods: ARTIEL (Arthritis in the Elderly) is a cohort with newly diagnosed arthritis in patients older than 60 years, with blood samples collected at baseline (pre-treatment), 1, 3 and 12 months after treatment, along with physician and patient outcome measures through 12 months. They are compared with randomly control individuals of the same age and gender. A Bruker Avance 700 MHz spectrometer was used to acquire NMR spectra of serum samples. Metabolomics data were pqn-normalized prior to the analysis. We conducted a temporal analysis to determine which metabolites were significantly changed between baseline and control, and between months 1,3,12 and baseline. We also examined the correlation between clinical variables of interest with baseline levels of metabolites. We used the Limma tool in R to conduct the analyses, by fitting linear models to the data, and controlling for the possibly confounding factors age, sex and BMI. False discovery rate was accounted for using the Benjamini-Hochberg method.

Results: 65 patients (average: 75, standard deviation (SD) 7) and 18 controls (average: 75.39, SD, 6.04) were analyzed. Of these, 45 were diagnosed with RA (15 patients were rheumatoid factor positive, 23 were ACPA positive and 5 had erosions at diagnosis) and 20 with PMR. At the start of the study, RA patients had a mean DAS28CRP of 5.7 (SD, 1). In addition, 84% of the patients reported scapular pain, and 56% of the patients reported pelvic pain at baseline. After 12 months of treatment, RA patients had a DAS28CRP of 2.46 (SD, 1). As shown in figure 1, levels of choline, histidine and sarcosine, were lower in arthritis patients than in controls. Of interest, after 1 month of treatment (91% were on glucocorticoids (GC) and 51% were on GC and one DMARD), several metabolites significantly changed respect to baseline (Figure 1). Several metabolites, including lactate, glucose, glutamine, formate and acetate also

significantly correlated with clinical scores at baseline. We did not see any difference in metabolites between RA and PMR population.

Conclusion: Inflammation correlates with significant changes in serum metabolites. Interestingly, choline, a metabolite strongly related to inflammation was significantly lower in arthritic patients than in the control population, suggesting a higher choline uptake and metabolism from inflamed tissues. Metabolite profile dramatically changed after therapy. Further analysis is needed to further understand how inflammation and/or treatment have impact on systemic metabolic profiling, and to define elements of inflammation pathobiology in this population.

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: RA – Etiology & Pathogenesis Poster I
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Interstitial lung disease (ILD) is one of the most significant comorbidities that contributes to the increased mortality observed in patients with rheumatoid arthritis (RA) [1,2]. Although the pathogenesis of ILD associated to RA (RA-ILD) remains poorly defined [2], it is known that vascular tissue plays a crucial role in lung physiology [3]. In this context, a population of cells termed endothelial progenitor cells (EPC) are involved in vasculogenesis and endothelial tissue repair [4]. Previous reports suggest the implication of EPC in different conditions such as RA and idiopathic pulmonary fibrosis (IPF), the most common and destructive ILD [5,6]. Nevertheless, little is known about their specific role in RA-ILD. Accordingly, the purpose of this study was to shed light on the potential role of EPC in RA-ILD pathophysiology.

Methods: Peripheral venous blood was collected from a total of 30 patients (13 with RA-ILD, 5 with RA without ILD and 12 with IPF) as well as 13 healthy controls. All subjects were recruited from the Rheumatology and Pneumology departments of Hospital Universitario Marqués de Valdecilla, Santander, Spain. Quantification of EPC by flow cytometry was analyzed for the expression of surface antigens. The combination of antibodies against the stem cell marker CD34, the immature progenitor marker CD133, the endothelial marker VEGF receptor 2 (CD309) and the common

leukocyte antigen CD45 was used. EPC were considered as $CD34^+$, $CD45^{Low}$, $CD309^+$ and $CD133^+$. All statistical analyses were performed using Prism software 5 (GraphPad).

Results: EPC frequency was significantly increased in RA patients, with and without ILD, and IPF patients when compared to controls ($p< 0.0001$, $p= 0.004$ and $p< 0.0001$, respectively). Nevertheless, patients with RA, in particular those with RA-ILD, showed a lower frequency of EPC than those with IPF ($p=0.009$).

Conclusion: Our results provide evidence for a potential role of EPC in the pathophysiology of RA-ILD disease.

Session Title: RA – Etiology & Pathogenesis Poster I
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Dendritic cells (DC) are specialized antigen-presenting cells (APC) that have a central role in the initiation of immune responses. However, prior studies showed numeric decreases of myeloid (mDC) and plasmacytoid (pDC) DC in RA. This apparent contradiction led us to hypothesize that depletion of these 'canonical' DC is only one manifestation of a more fundamental alteration in this important immunoregulatory compartment in RA and that the overall non-lymphoid APC population ($CD3^-CD19^-$HLA-DR^+) does not decrease due to the appearance

MFI: Median fluorescence intensity

Table 1: Numeric and functional characteristics of DC subsets compared between RA and controls. Numbers in average +-(SD) resp. mean [IQR]
'Candidate nonlymphoid APC' defined as $HLA\text{-}DR^+CD3^-CD19^-CD56^-CD14^{lo}$

Table 1. Enumeration and expression of DR and CCR2 Expression in DC subsets in RA. Enumeration and expression of HLA-DR and CCR2 in DC subsets of Rheumatoid Arthritis patients compared with controls

of anomalous APC phenotypes. We further hypothesized that alterations in DC subsets are associated with clinical aspects of RA including those driving RA-associated cardiovascular disease.

Methods: RA patients enrolled in a cohort study and healthy donors underwent immunophenotyping to define known DC subsets, including $CD1c^+$ mDC, $CD141^+$ mDC and $CD303^+$ pDC in peripheral blood mononuclear cells (PMBCs). We correlated DC subset features with disease characteristics and cardiac function. To screen for non-lymphoid cells with putative APC potential not conforming to conventional DC paradigms we defined 'candidate nonlymphoid APC' ($DR^+CD3^-CD19^-CD56^-$) as a DC superset. We used t-Distributed Stochastic Neighbor Embedding (t-SNE) to categorize the entirety of non-lymphoid APC candidate cells and identify possible novel RA APC subsets.

Results: Circulating $CD1c^+$ frequencies were, as expected, remarkably decreased in RA (mean 1.0% of PBMCs vs controls 2.6%; p=0.009). Mean $CD141^+$ frequencies were 0.1% (RA) vs 0.2%; p=0.019. $CD303^+$ pDC frequencies did not differ (p=0.285). HLA-DR intensity in both myeloid subsets was significantly lower in RA whereas CCR2 intensity was higher in $CD1c^+$ DC. In RA, a lower $CD1c^+$ frequency was associated with lower cardiac index (corr.=-0.54, p=0.008) and CCR2 expression of $CD1c^+$ DC was associated with lower Ejection Fraction (EF) (corr.=-0.70, p=0.001). Interestingly, despite the decrease in canonical DC; the overall frequencies of 'candidate non-lymphoid APC' did not differ (Table 1) suggesting that the declines of canonical DC were compensated for by increases in other populations of this DR^+ DC superset. t-SNE analysis of healthy controls allowed clear categorization with distinct clusters of APC subsets as well as a homogenous cluster of $CD14^-CD16^-CD11c^+$(Figure 2; orange circle). RA t-SNE showed a de-

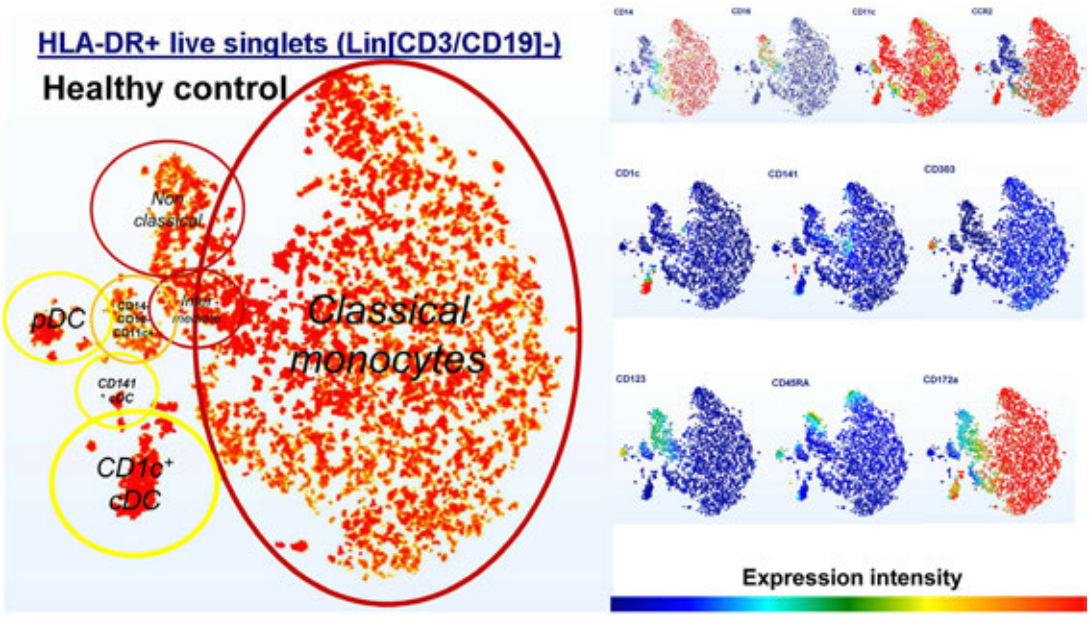

Figure 1. t-SNE representation of non-lymphoid HLA-DR+ cells with APC potential of a healthy donor. Red circles: monocyte populations. Yellow: DC populations. A small homogenous population of CD14-CD16-CD11c+ cells without DC characteristics is shown in orange. Classical monocytes: CD14+CD16+ Intermediate monocytes: CD14+CD16+ Nonclassical monocytes: CD14-CD16+ CD1c+ cDC: CD11c+CD1c+ CD141+ cDC: CD11c+ CD141+ pDC: 11c-CD303+

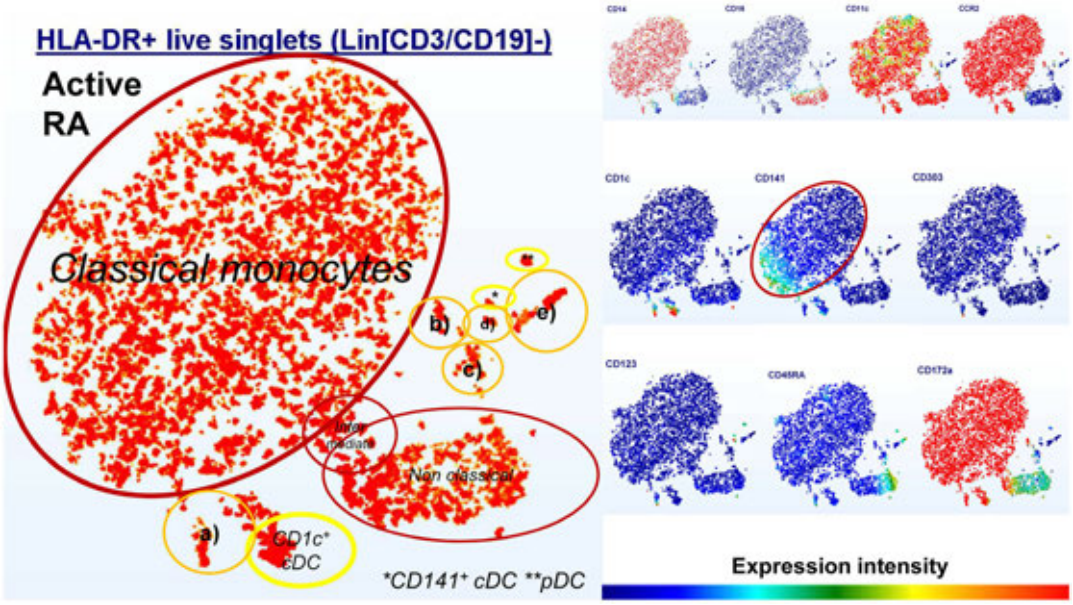

Figure 2. t-SNE representation of non-lymphoid HLA-DR+ cells with APC potential of an RA patient. Red circles: monocyte populations. Yellow: DC populations. Orange: DR+ cells which do not conform to standard DC paradigms but express partial DC markers. a) CD14+ CD1c+ CD141+ CD172a+ CD123+- b) CD14-CD16- 11c+ c) CD14-CD16- CD172a+ d) CD123+ e) CD14- CD16- CD45RA+- Classical monocytes: CD14+CD16+ Intermediate monocytes: CD14+CD16+ Nonclassical monocytes: CD14-CD16+ CD1c+ cDC: CD11c+CD1c+ CD141+ cDC: CD11c+ CD141+ pDC: 11c-CD303+

crease of canonical DC subsets (yellow ellipses) and the appearance of five clusters with some DC features that did not fit accepted definitions (Figure 2a-e)

Conclusion: We found extensive alterations in the DC compartment in RA, including a significant decrease in the major CD1c$^+$ subset and the emergence of anomalous HLA-DR$^+$ non-lymphoid cells with antigen-presenting potential that are candidate DC subsets. The novel subsets included one resembling CD14+ monocyte-derived DC, a subset of which also expressed CD1c in addition to plasmacytoid markers; CD303 and CD123. The remaining populations were distinguished by combinations of CCR2, CD11c, CD123 and CD172a (SIRPα). The association of adverse measures of cardiac function with changes of the DC compartment, including decreases of CD1c$^+$ mDC, emphasize their potential clinical significance.

Evaluation of Potential Mechanisms Underlying the Safety Observations of Filgotinib in Clinical Studies in RA

Julie Di Paolo,[1] Bryan Downie,[2] Amy Meng,[3] Nevena Mollova,[3] Yuanjiang Yu,[3] and Pei Han[3], [1]Gilead Sciences, Foster City, CA, [2]Gilead Sciences, Inc., Foster Citty, CA, [3]Gilead Sciences, Inc., Foster City, CA

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: RA – Etiology & Pathogenesis Poster I
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Inhibition of the Janus kinase-signal transducers and activators of transcription (JAK-STAT) pathway have demonstrated efficacy in immune-mediated diseases and haves been identified as therapeutic targets for the treatment of rheumatoid arthritis (RA). Differences in JAK inhibitor specificity for JAK1, JAK2, JAK3, and TYK2 may influence their safety profiles, but the mechanism is not known. Selective JAK1 inhibition by filgotinib (FIL) may improve the risk-benefit profile by minimizing non-JAK1–related adverse events. JAK2 inhibition is associated with cytopenias, while JAK3 inhibition has been associated with increased risk for opportunistic infections and chronic low-grade inflammation. In clinical trials, FIL did not negatively impact hemoglobin, LDL/HDL ratios, or natural killer (NK) cell counts.[1-3] Here we compare the in vitro profile of JAK inhibitors with different JAK selectivity profiles at clinically relevant doses to calculate the overall kinetics of suppression of erythroid progenitor cell expansion and maturation, NK cell proliferation, and liver X receptor (LXR) agonist-induced cholesteryl ester transfer protein (CETP) expression.

Methods: JAK inhibitors (FIL, FIL metabolite [GS-829845], baricitinib [BARI], tofacitinib [TOFA], and upadacitinib [UPA]) were evaluated in vitro in human cell-based assays: growth of erythroid progenitors from human cord blood CD34$^+$ cells using a HemaTox™ liquid expansion assay, IL-15–induced NK cell proliferation, and LXR agonist-induced CETP expression in the hepatic cell line (HepG2). Using IC_{50}s generated from these assays and the reported human plasma concentrations of the JAK inhibitors from clinical studies,[4-6] we calculated the target coverage for each compound at clinically relevant doses. The activity of FIL in humans was based on a PK-PD modeling algorithm[7] of FIL + GS-829845.

Calculated Inhibition of Cellular Activity at Clinical Exposures (% inhibition over 24h)								
JAK inhibitor	FIL[a]		BARI		TOFA		UPA	
Dose (mg)	100	200	2	4	5	10	15	30
Early erythroid progenitor	18.9	30.5	17.6	38.2	17.6	28.5	31.1	42.4
Mature erythroid progenitor	42.1	50.4	33.0	45.1	36.7	45.0	46.3	54.7
NK cell proliferation	38.9	52.3	51.7	78.9	75.4	86.0	74.2	84.2
Inhibition of LXR agonist-induced CETP expression	17.3	27.4	inactive					

[a]FIL + GS-829845 composite PD effect

Results: In vitro dose-response assay results were obtained for each inhibitor. Based on these results, human exposure data, and modeled PK-PD relationships, FIL 100 mg and FIL 200 mg result in lower calculated cellular inhibition than the other JAK inhibitors at clinical exposures for NK cell proliferation and CETP expression. There was no obvious difference in the effect of FIL on erythroid progenitor cell differentiation or maturation versus the other JAK inhibitors in these experiments.

Conclusion: JAK1 selectivity of FIL resulted in less inhibition of NK cell proliferation compared with BARI, TOFA, and UPA. FIL also reduced LXR agonist-induced CETP expression, while the other inhibitors did not alter these levels. These results provide a potential mechanistic link to the observed reduction of CETP concentration and activity following FIL treatment, and the observed reduction in LDL:HDL in RA patients.[8]

mTORC1-phosphorylated CXCR3^{+}memory B Cells and Their Potential as a New Mode of Action of TNF Inhibitors in RA

Shigeru Iwata,[1] Mingzeng Zhang,[1] Maiko Hajime,[1] Naoaki Ohkubo,[1] Yukihiro Kitanaga,[1] Gulzhan Trimova,[1] Kazuhisa Nakano,[2] Shingo Nakayamada,[1] Kaoru Yamagata,[1] Kei Sakata,[1] and Yoshiya Tanaka[3], [1]The First Department of Internal Medicine, University of Occupational and Environmental Health, Kitakyushu, Japan, Kitakyushu, Japan, [2]The First Department of Internal Medicine, University of Occupational and Environmental Health, Kitakyushu, Japan, Kitakyushu, [3]University of Occupational and Environmental Health Japan, Kitakyushu, Japan

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: RA – Etiology & Pathogenesis Poster I
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: B cells play a crucial role through producing autoantibodies and activating osteoclasts in synovium in rheumatoid arthritis (RA). Recently "Immunometabolism" attract much attention, and mTORC1 is well known as a key player for anabolic change and contributes to B cell activation. However, it remained elusive by which mTORC1 in B cells involved in the pathogenesis of RA.

Methods: PBMCs were obtained from 32 healthy controls (HCs) and 86 patients with RA who were refractory to MTX-treatment and bio-naïve, and analyzed by flow cytometry. In addition, we examined the role of mTORC1 for induction of chemokine receptors on B cells in vitro.

Results: Baseline characteristics of patients with RA in this study were males : females =21:65, age 55.8 years, disease duration 55.8 months, stage I/II/III/ IV:35/33/9/9, MTX dose 13.8mg/week, tender joints 9.1, swollen joints 7.2, DAS28-CRP 4.7, DAS28-ESR 5.4, CDAI 25.9, SDAI 28.2, RF169.6, anti-CCP Abs 336.0, HAQ 1.2. The percentage of $CXCR3^+CD27^+CD19^+$ cells among $CD19^+$ cells decreased in the periphery of patients with RA compared to those of HCs. The level of mTORC1 phosphorylation (p-mTORC1) enhanced in $CXCR3^+CD27^+CD19^+$ cells, but not in $CXCR3^-CD27^+CD19^+$ cells from patients with RA. The level of p-mTORC1 in $CXCR3^+CD27^+CD19^+$ cells were correlated with tender joints, swollen joints, disease activity such as DAS28-CRP, CDAI, SDAI, but not RF and anti-CCP antibodies. We examined the change of percentage of $CXCR3^+CD27^+CD19^+$ cells and the level of p-mTORC1 before and at 1 year after treatment with biologics (37 patients, TNF inhibitors (n=19: adalimumab:11, certolizumab:7, etanercept:1), abatacept (n=16), tocilizumab (n=2)). The percentage of $CXCR3^+CD27^+CD19^+$ cells were recovered and the level of p-mTORC1 decreased selectively in TNF inhibitors treatment group, but not in abatacept treatment group at 1 year. Finally, we examined the role of mTORC1 for induction of chemokine receptor expression on B cells in vitro. Combined stimulation of BCR, CD40L and IFN-γ induced CXCR3 expression on B cells, which were abrogated by mTORC1 inhibitors, Rapamycin. It has been reported that concentration of CXCL10 (IP-10), ligand of CXCR3, increased in RA synovium. We found that TNF-α stimulation induced CXCL10 production from RA patients-derived fibroblast like synoviocytes (FLS), which was abrogated by TNF inhibitors.

Conclusion: Taken together, activation of mTORC1 is involved in the accumulation of CXCR3-positive memory B cells in RA synovium and TNF inhibitors possibly target at this in patients with RA.

Lyn-Deficient Murine Lupus Is Exacerbated by Glucocorticoid-Induced Leucine Zipper (GILZ) Deficiency

Champa Nataraja,[1] Jacqueline Flynn,[1] Wendy Dankers,[1] James Harris,[1] Sarah Jones,[1] and Eric Morand[1], [1]Monash University, Melbourne, Victoria, Australia

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: SLE – Animal Models Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: *Lyn*-deficient mice develop hyperactive B cells, excess IL-6 production, and nephritis. Mice deficient in glucocorticoid-induced leucine zipper (GILZ), an intracellular protein involved in glucocorticoid effects on immunity, also develop spontaneous lupus-like autoimmunity and excess B cell activation (Jones 2016). However, whether GILZ is operative as a suppressor in lupus-prone *Lyn*-/- mice is unknown.

Methods: We compared WT C57Bl/6 mice to *Lyn* knockout (KO) mice and *Lyn*KO mice crossed to a GILZ-deficient background (GILZ- *Lyn* double knock out (DKO)) mice. The effects of GILZ deficiency on *Lyn*KO phenotype, including spleen weight, autoantibodies, nephritis, and cytokines including Type I interferon-induced genes (ISG) were examined.

Results: Lupus-like autoimmunity was increased in GILZ-*Lyn* DKO mice, compared to *Lyn*KO, including increased spleen weight and more severe glomerulonephritis, especially crescents and segmental necrosis. In contrast, serum autoantibodies (dsDNA, Sm, histone, Jo-1, Scl-70, SSA, SSB, U1RNP, Ro52,) were not increased in GILZ-*Lyn* DKO mice compared to *Lyn*KO mice. Serum IL-6, BAFF, IL-17A, IL-18, and TNF were increased in GILZ-*Lyn* DKO mice. A panel of ISG (*ifi44, usp18, oas3, cxcl10, isg15, mx1, irf7, stat1* and *ifit3)* and an overall ISG score were also significantly increased in GILZ-*Lyn* DKO mice.

Conclusion: The *Lyn*KO lupus-prone model was significantly exacerbated by GILZ deficiency, an effect accompanied by evidence of activation of the Type I IFN program. This suggests that endogenous GILZ exerts an inhibitory effect on IFN pathways in this lupus model, and thus that GILZ regulates inflammation in SLE by inhibiting IFN responses downstream of autoantibodies.

Human Gingiva-derived Mesenchymal Stem Cells Are Therapeutic in Lupus Nephritis Through Targeting of CD39-CD73 Signaling Pathway

Song Guo Zheng,[1] Julie Wang,[2] Junlong dang,[3] Nancy Olsen,[4] and Wael Jarjour[1], [1]Ohio State College of Medicine, Columbus, OH, [2]Ohio State University, columbus, [3]Sun Yat-sen University, Guangzhou, [4]Penn State University, Hershey, PA

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: SLE – Animal Models Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Cell specific and cytokine targeted therapeutics have underperformed in systemic lupus erythematosus (SLE) in spite of numerous targets examined and clinical trials conducted. Mesenchymal stem cells (MSCs), especially bone marrow derived MSCs (BMSCs), have emerged as a novel therapy to address the dysregulation in autoimmune diseases because of their immunomodulatory and tissue regeneration properties. Nonetheless, BMSCs have limitations such as heterogeneous cell populations, dysfunction of autologous BMSCs and tumorigenesis. Compared with BMSCs, human gingiva derived MSCs (GMSCs) are superior in regulating immune responses.

Methods: In this study, we prepared gingiva-derived mesenchymal stem cells and adoptively transferred them to NZM2328 mice, a lupus strain that spontaneously develop lupus nephritis with predilection for female mice.

Results: We demonstrate that the adoptively transferred GMSC home to the kidney quickly and have a robust therapeutic effect. Specifically, the administration of GMSCs limits the development of autoantibodies as well as proteinuria, decreases the frequency of plasma cells and lupus nephritis histopathological scores. We further observed that GMSCs directly targeted B cells through suppression of activation and proliferation, plasmocyte differentiation and autoantibody production in an inflammatory milieu. The blockage of CD39-CD73 pathway dramatically abrogated the suppressive capacities of GMSCs in vitro and in vivo and highlights the significance of this signaling pathway in SLE.

Conclusion: Collectively, manipulation of GMSCs provides a promising strategy for the treatment of patients with SLE and other autoimmune diseases.

The Role of the Intestinal Microbiota in Lupus Nephritis

Giancarlo Valiente,[1] Armin Munir,[1] Marcia Hart,[2] Takuma Tsuzuki Wada,[3] Perry Blough,[1] Emma Dalan,[1] William Willis,[1] Lai-Chu Wu,[1] Aharon Freud,[1] and Wael Jarjour[4], [1]The Ohio State University, Columbus, [2]The Ohio State University, Columbia, [3]Department of Rheumatology and Applied Immunology, Faculty of Medicine, Saitama Medical University, Saitama, Japan, [4]Ohio State College of Medicine, Columbus, OH

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: SLE – Animal Models Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The bacterial gut microbiota (GM) exerts substantial influence over the host immune system and dysbiosis of this microbial community has been associated with end-organ damage in chronic inflammatory conditions. The role that pathobionts and GM dysbiosis play in the pathogenesis of systemic lupus erythematosus (SLE) or lupus nephritis (LN) is not fully appreciated. We hypothesized that the GM potently influences the pathogenesis of LN through the induction of host immune processes and that shifts in the bacterial GM would reflect what has been published in lupus patients. This project was focused on the ability of gut dysbiosis to promote kidney damage in a LN mouse model. The pathobiont commensal, segmented filamentous bacteria (SFB), is applied in this study to test this overall hypothesis.

Methods: Using oral gavage, we colonized NZM2410 mice with SFB- or no SFB-fecal homogenates in a sterile vivarium. Colonization was confirmed via repeated fecal DNA PCR analysis using SFB-specific primers. Serum was collected and mice were euthanized at 26 or 30 weeks. The severity of kidney damage was assessed via immunohistochemistry (IHC) and RNA-ISH. Flow cytometry was also performed on small intestinal lamina propria cells. To analyze the makeup of the fecal bacterial metagenome of these mice through 16S rDNA analysis we used Illumina 16S sequencing technology and compared the resulting reads to the Silva fecal bacterial metagenomics database.

Results: We demonstrated that inoculation with SFB was associated with worse renal dysfunction and glomerulonephritis. We also discovered that serum autoantibodies and proinflammatory cytokines were elevated in SFB positive mice versus controls. Initially, we expected to find infiltrating Th17 cells in the kidneys of SFB positive mice. However, while we did not detect intra-renal Th17 cells by immunohistochemistry, we found that SFB positive mice had significantly increased numbers of M2-like F4/80+CD206+ macrophages when compared to SFB negative mice. Lastly, we show that SFB positive NZM2410 mice may harbor intestinal barrier dysfunction. A very recent human LN study also reported related findings. This particular finding suggests a potential mechanism by which commensal bacteria can activate the host immune system.

We identified unique bacterial compositions at multiple taxonomic levels with respect to time of disease and SFB positivity. We also show that many of the taxonomic shifts observed in our study, even within certain genera, are in congruence with lupus-GM human studies. Finally, we identified a particular *Ruminococcus* species group that is enriched in SFB positive versus SFB negative mice. Importantly, this group is significantly enriched in SFB positive mice during late disease versus SFB positive mice at pre-/early disease which suggests a disease activity.

Conclusion: Collectively, the work presented herein helps to address an unfulfilled knowledge gap in autoimmunity. Our findings suggest that changes to the commensal GM may have an important role in renal dysfunction and promoting an overall proinflammatory state in LN. Importantly, this work provides suggestions for novel therapeutic targets that may be useful in treating patients suffering from LN.

Rab4A Controls mTOR Pathway Activation, Pro-inflammatory Lineage Development, and Disease Pathogenesis in Lupus-prone Mice

Nick Huang,[1] Zhiwei Lai,[2] Brandon Wyman,[2] Thomas Winans,[2] Manuel Duarte,[2] Joshua Lewis,[2] Mark Haas,[3] Laurence Morel,[4] and Andras Perl[5], [1]Upstate Medical University, Syracuse, NY, [2]Upstate Medical University, Syracuse, [3]Cedars-Sinai Medical Center, Los Angeles, CA, [4]University of Florida, Gainesville, FL, [5]SUNY Upstate Medical University, Syracuse, NY

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: SLE – Animal Models Poster

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Mouse models of SLE have been indispensable tools for studying disease pathogenesis; however, each model only recapitulates limited aspects of lupus. SLE1.2.3. (TC) mice are mice homozygous for three NZM2410-derive lupus susceptibility loci on the C57Bl/6J background. These mice develop systemic autoimmunity with fatal glomerulonephritis and die typically by 12 months of age. The polymorphic Rab4a locus has been associated with genetic susceptibility and protection from lung disease in SLE patients and has been found to be overexpressed in T cells of patients and mice with SLE. To determine the impact of this gene on disease development, the TC mice has been backcrossed with C57Bl/6 wild-type (WT) mice that carry floxed Rab4A^{Q72L} (TC-FL) alleles or lack Rab4A in T cells (TC-KO).

Methods: Proteinuria was assessed by the Bradford assay. ANA production was measured by ELISA. Mice were sacrificed around 50 weeks of age for analysis via flow cytometry, Seahorse assay and mass spectrometry. Histological scoring for glomerulonephritis (GN) was done blindly by Dr. Mark Haas.

Results: TC mice had increased proteinuria (males 160%, p=0.035, females 230%, p=0.008) over matched controls. Deletion of Rab4A in T cells reduced proteinuria (-50%, p=0.015) in female TC-KO mice relative to TC-FL mice at 21 and 40 weeks of age (TC-FL: 0.85±0.2 mg/ml, n=22; TC-KO: 0.39±0.1 mg/ml; n=12; p=0.041). Similar trends were noted in male mice (TC-FL: 1.01±0.1 mg/ml, TC-KO: 0.79±0.1 mg/ml; p=0.048). ANA production was reduced in male (-70.3%, p=0.009) and female (-24%, p=0.003) TC-KO mice relative to TC mice at 23 weeks of age. GN scores were significantly elevated (425%, p=0.009) in female TC mice compared to WT control at 53 weeks of age. Importantly, TC-KO mice showed a reduction (-40%; p=0.0342) in GN severity over TC-FL mice.

Immunophenotyping unveiled a 45% depletion of CD4$^+$ T cells (p=0.003) and 50% expansion of CD8$^+$ T cells (p=0.016) in TC-KO female mice relative to TC-FL controls. Interestingly, mTORC1 activity in CD4$^+$ was elevated by 100% in TC and by 290% (p=3E-05) in TC-FL mice, an effect that is diminished in TC-KO mice by 47% compared to TL-FL mice (p=0.0395). The same effect was not observed in CD8$^+$ T cells or B cells of TC-KO mice. Additionally, IFNy-producing

Background Model	Genetic modification	Function	Name (in abstract)
C57.Bl6J	WT	Wild type Rab4a	WT
C57.Bl6J	Rab4aQ72L	Constitutively active Rab4a	WT-FL
C57.Bl6J	Rab4aQ72L-CD4Cre	Deletion of Rab4a in CD4$^+$ cells	WT-KO
SLE1.2.3.	WT	Wild type Rab4a	TC
SLE1.2.3.	Rab4aQ72L	Constitutively active Rab4a	TC-FL
SLE1.2.3.	Rab4aQ72L-CD4Cre	Deletion of Rab4a in CD4$^+$ cells	TC-KO

$CD4^+$ T cells were expanded by 370% in TC (p=0.042) and by 310% in TC-FL mice (p=0.025). These proinflammatory cells were depleted by 47% in the TC-KO mice relative to lupus-prone TC mice.

Relative to WT controls, flow cytometry revealed elevated mitochondrial mass (+38%, p=0.0416) and that occurred with a reduction in mitochondrial potential in $CD4^+$ T cells of TC mice (53%, p=0.009). Seahorse metabolic analysis unveiled increased mitochondrial basal respiration (+80%, p=0.024), maximal respiration (+48%, p=0.02), ATP production (+84%, p=0.023) and spare respiratory capacity (+174%, p< 0.001) in $CD8^+$ T cells of TC-WT mice relative to WT controls.

Conclusion: These findings establish how Rab4A promotes mTOR pathway activation, pro-inflammatory T cell lineage development, and disease pathogenesis through its influence on mitochondrial metabolism in SLE. Therefore, inactivation of Rab4A may have therapeutic potential in SLE.

CD6 Modulation Ameliorates Skin and Kidney Disease in a Spontaneous Murine Model of SLE

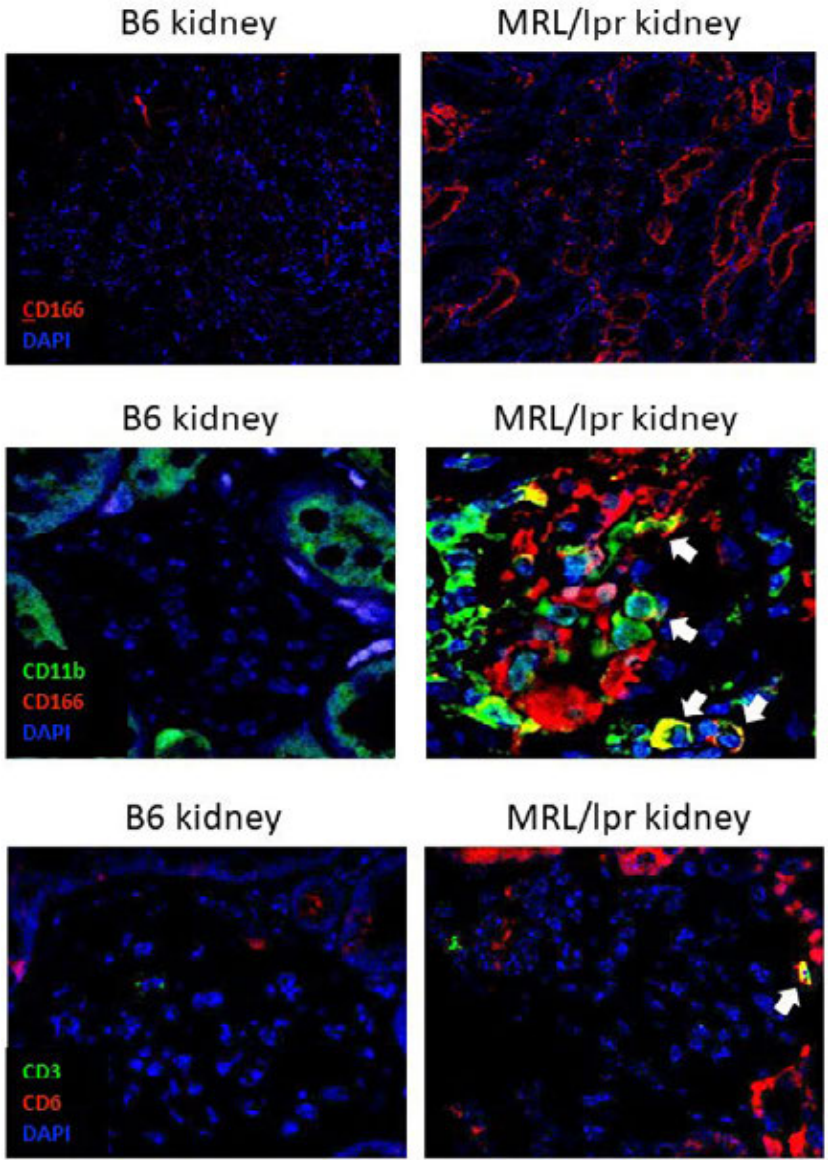
Samantha Chalmers,[1] Sayra Garcia,[1] Rajalakshmy Ayilam Ramachandran,[2] Chandra Mohan,[2] Jeanette Ampudia,[3] Cherie Ng,[3] Stephen Connelly,[3] and Chaim Putterman[4], [1]Albert Einstein College of Medicine, Bronx, NY, [2]University of Houston, Houston, [3]Equillium, Inc, San Diego, CA, [4]Albert Einstein College of Medicine, New York, NY

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: SLE – Animal Models Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: T cells are an important contributor the pathogenesis of SLE and its various end organ manifestations. Thus, they present themselves as potential therapeutic targets; however, the optimal approach to targeting T cells in SLE still remains under investigation. CD6 is a co-stimulatory receptor, predominantly expressed on T cells, that binds to activated leukocyte cell adhesion molecule (ALCAM), a ligand expressed on antigen presentation cells and various epithelial and endothelial tissues. The CD6-ALCAM pathway plays an integral role in modulating T cell activation, proliferation, differentiation and trafficking. In this study, we assessed the expression of CD6 and ALCAM within the context of a murine model of SLE, and then subsequently targeted this signaling axis to determine its role in the pathogenesis of disease.

Methods: The MRL/lpr mouse is a spontaneous murine model of SLE, which exhibits systemic autoimmunity, nephritis, and skin disease. In an initial experiment, 6 month old MRL/lpr mice and B6 kidneys were stained for the presence of both ALCAM and CD6. In a separate experiment, female MRL/lpr mice were aged to 9-10 weeks of age, and then treated with either anti-CD6 monoclonal antibody (60 ug/dose, IP twice per week), isotype control (60 ug/dose, twice per week), or cyclophosphamide (25 mg/kg, once per week). We also included a no treatment group, and a group of MRL/MpJ mice, a congenic healthy control strain. Baseline levels of anti-DNA antibodies, weight, and proteinuria in the MRL/lpr groups were similar. Mice were monitored weekly for proteinuria, lymph node swelling, and macroscopic skin lesions.

Results: MRL/lpr mice at 6 months of age show increased levels of ALCAM expression in their kidneys, both within their tubules and glomeruli, compared to B6 healthy control mice (shown are images representative of 3 mice per



group). Additionally, macrophages infiltrating into the glomeruli of MRL/lpr mice were ALCAM+ (white arrows, top panel) and were paired with a concomitant increase in CD6+ T cell infiltration (white arrows, bottom panel). Consequently, in a separate study, we blocked this signaling axis using a monocolonal antibody for CD6. At 19 weeks of age, mice treated with anti-CD6 show improved proteinuria compared to isotype control mice ($p< 0.05$). MRL/lpr mice develop lymphoproliferative disease which results in abnormally large lymph nodes. Assessing lymphadenopathy at 19 weeks of age, we noted a significant improvement in the anti-CD6 treated mice, compared to the isotype control ($p< 0.05$). MRL/lpr mice also develop severe skin lesions that have similar pathology to cutaneous lupus. Macroscopic scoring of these lesions showed a significant improvement in the skin disease of the anti-CD6 treated mice compared to the isotype control group ($p< 0.05$).

Conclusion: Within a spontaneous model of SLE, anti-CD6 treatment ameliorated multiple end organ pathologies, namely in the kidney and skin, while also significantly reducing the lymphoproliferative phenotype of this model. Overall, these results indicate that targeting the CD6-ALCAM pathway may have promising therapeutic potential for multiple end organ pathologies within SLE.

Upregulated expression of ALCAM (CD166, red), is seen in the tubules of 6 month old MRL/lpr mice, compared to age matched B6 mice (top panel). Looking more closely at the glomeruli, we note ALCAM expression is increased in lupus mice, including on macrophages (CD11b+, white arrows) infiltrating into the glomerulus (middle panel). Finally, CD6+CD3+ T cells are also noted infiltrating the glomeruli of MRL/lpr mice (white arrow, bottom panel). Shown are representative images from 3 mice per group.

Amelioration of Immune Complex-Mediated Glomerulonephritis by CD6 Modulation

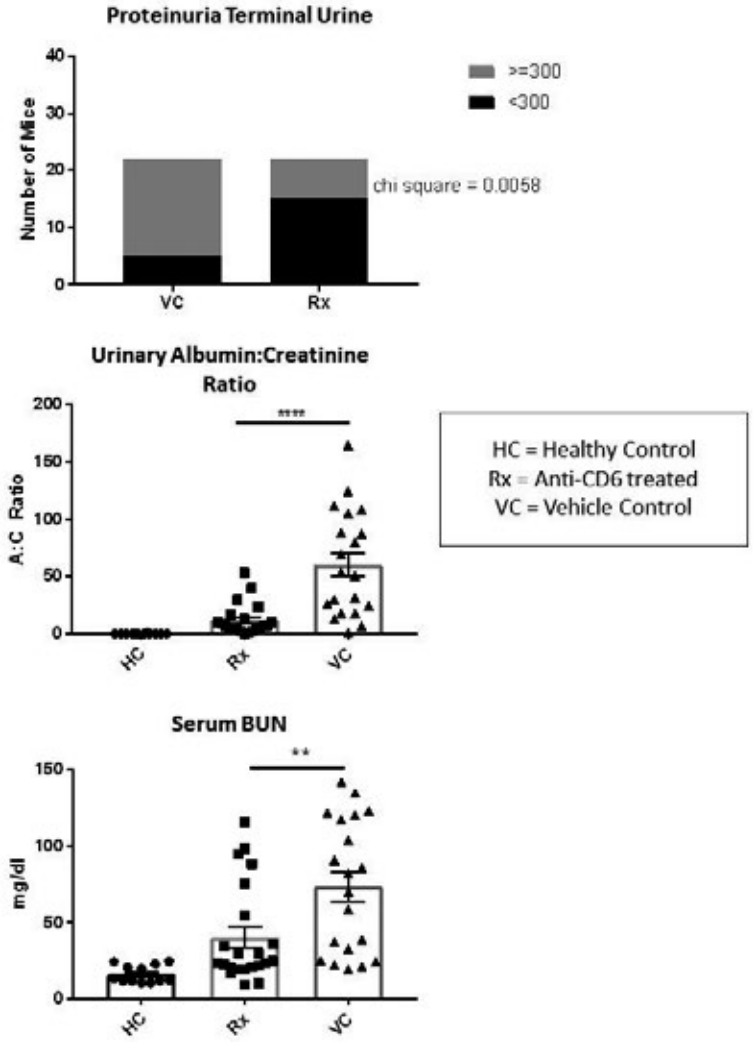
Samantha Chalmers,[1] Sayra Garcia,[1] Jeanette Ampudia,[2] Cherie Ng,[2] Stephen Connelly,[2] and Chaim Putterman[3], [1]Albert Einstein College of Medicine, Bronx, NY, [2]Equillium, Inc, San Diego, CA, [3]Albert Einstein College of Medicine, New York, NY

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: SLE – Animal Models Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: CD6 is a co-stimulatory receptor on T cells, that binds to activated leukocyte cell adhesion molecule (ALCAM), a ligand expressed on antigen presentation cells and epithelial and endothelial tissues. The CD6/ALCAM pathway plays an integral role in modulating T cell activation and trafficking, making this an integral pathway in immuno-inflammation. Increased levels of CD6 are associated with pathogenic T cell responses, suggesting that the CD6/ALCAM pathway is a contributor to disease pathogenesis. T cells are a key cellular mediator in both systemic lupus erythematosus (SLE) and lupus nephritis (LN), as they amplify the autoimmune response and inflammation and contribute to end organ damage. Thus, we designed an experiment to target them via CD6 modulation.

Methods: Nephrotoxic serum nephritis (NTN) is a validated, short-term model of LN. Disease was induced in two separate cohorts of female 129/svJ mice, both aged to 10 weeks. Mice were immunized with rabbit IgG and CFA on day 0 to create mouse anti-rabbit antibodies, which then cross-reacted with nephrotoxic rabbit serum given on day 5, causing an antibody-mediated nephritis similar in pathology to LN. To assess the importance of the CD6/ALCAM pathway in LN pathogenesis, mice were treated 3x per week with an anti-CD6 monoclonal antibody (mAb) (60ug/dose, n=23), or with vehicle control (n=23). Healthy mice (immunized with rabbit IgG, but not given nephrotoxic serum) were also included as a control (n=12). We monitored the progress of kidney disease via proteinuria (uristix), urinary albumin:creatinine ratio, and serum blood urea nitrogen (BUN) to assess the effect of the anti-CD6 treatment on both cohorts. To assess the affect of treatment on immune cell infiltration, flow cytometry, RT-PCR, and immunofluorescent staining was completed at termination.

Results: Mice treated with the anti-CD6 mAb displayed decreased levels of proteinuria ($p< 0.001$) compared to vehicle control mice. This result was confirmed by measuring albumin:creatinine ratios in terminal urine ($p< 0.0001$). We also found a significantly improved BUN ($p< 0.01$) when comparing treated mice to vehicle control mice. To ensure that anti-CD6 treatment did not interfere with the induction of the NTN model, we measured mouse anti-rabbit IgG levels and rabbit anti-mouse glomerular basement membrane (GBM) levels and found no difference between the groups. RT-PCR revealed significantly decreased levels of VCAM and RANTES in the kidneys of treated mice, while



anti-inflammatory IL-10 was increased, compared to control sick mice. Flow cytometry results indicated decreased levels of renal-infiltrating activated T cells (CD4+CD25+CD69+, $p < 0.01$). Immunofluorescent staining and histology results are pending.

Conclusion: Inhibiting the CD6-ALCAM pathway with an anti-CD6 treatment is beneficial in ameliorating the nephritis associated with nephrotoxic antibody administration, an inducible model of lupus nephritis. These results indicate a potentially promising therapeutic option which is more selective than the immunosuppressive therapies currently offered.

Mice treated with a monoclonal antibody to CD6 displayed decreased levels of proteinuria as determined by semi-quantitative uristix (top image), improved urinary albumin:creatinine ratios (middle panel) and lower levels of blood urea nitrogen (BUN; bottom panel), compared to vehicle control treated mice.

Dermal Lymphatic Dysfunction Is Associated with Disease Activity in the MRL/*lpr* Lupus Model

Noa Schwartz,[1] Thomas Li,[2] Susan Chyou,[2] William Shipman,[3] and Theresa Lu[4], [1]Hospital for Special Surgery, New York, NY, [2]Hospital for Special Surgery, New York, [3]Weill Cornell Tri-Institutional MD-PhD Program, New York, NY, [4]Hospital for Special Surgery, Weill Cornell Medicine (Microbiology and Immunology) New York

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: SLE – Animal Models Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Lymphatic vessels are important in limiting the extent and duration of peripheral immune response, both by transporting cellular debris, inflammatory cells and excess interstitial fluid away from the site of inflammation, as well as through the direct modulation of the immune response by the lymphatic endothelial cells (LECs). Disruption in lymphatic function has been implicated in several models of chronic inflammatory diseases, including RA, psoriasis, and IBD. Cutaneous inflammation is a major feature of SLE, and is an important impediment to patients' quality of life. The role of the lymphatic system in SLE, and its contribution to the cutaneous inflammatory phenotype of SLE specifically have not been described to date.

Methods: 7-10 weeks old ('pre-diseased') and 12 weeks old ('diseased') MRL/*lpr* (*lpr*) mice and age-/sex-matched MRL controls were evaluated at baseline, and after exposure to 2000-25000 J/m^2 of ultraviolet radiation (UVR). Lymphatic function was assessed in 2 ways: 1) 'Drainage' - 1μL of 2% evans blue (EB) injected intradermally to the ear, followed by measurement of EB concentration in the draining lymph node (dLN) 1 minute later; or 2) 'Effective clearance' - evaluation of the residual dye concentration in the ear 18-24 hours following EB injection. EB concentration was evaluated by extraction of the dye from the tissue by immersion in formamide, followed by spectrophotometric evaluation of the fluid. Flow cytometry of the contralateral ears and dLNs was performed. Groups were compared with the Mann-Whitney *U* test; data is presented as median (interquartile range), with a two-tailed *p*-value of < 0.05 considered significant.

Results: Lymphatic clearance of EB from the ears of 'diseased' *lpr* mice was significantly impaired compared with controls (2.3-times residual EB in *lpr* ears at 24 hours post-EB injection, compared with controls, $p=0.029$). This difference in effective lymphatic clearance was not observed in 'pre-diseased' mice (0.85 (0.53-0.92) vs. 1 (0.79-1.21) in *lpr* vs. controls, $p=0.8$); indicating a possible association of dermal lymphatic dysfunction with disease activity (Figure 1). Similarly, when cutaneous inflammation was induced by UVR in 'pre-diseased' *lpr* and MRL mice, at 1 month-post UVR the *lpr* mice demonstrated significantly higher numbers of ear LECs than controls (1.42 (1.10-16.25) vs. 1 (0.95-1.05) of LECs per ear, normalized to MRL controls, $p=0.009$), but without the expected corresponding improvement in lymphatic drainage (0.92 (0.50-2.74) vs. 1 (0.57-1.43) EB in dLN, normalized to MRL controls, $p=0.937$); likely indicating a relative dysfunction in the *lpr* lymphatic vessel function.

Conclusion: The lymphatic network has long been known to be important in immune response regulation and tolerance mechanisms. SLE is thought to be the prototypical systemic inflammatory disease, but the role of the lymphatic system was never characterized in this setting. Here we provide evidence of impaired lymphatic function in the *lpr* lupus strain associated with increased disease activity, both due to age and UVR-induced inflammation. These findings may potentially point to a novel focus of study and intervention in this often devastating, yet still elusive disease.

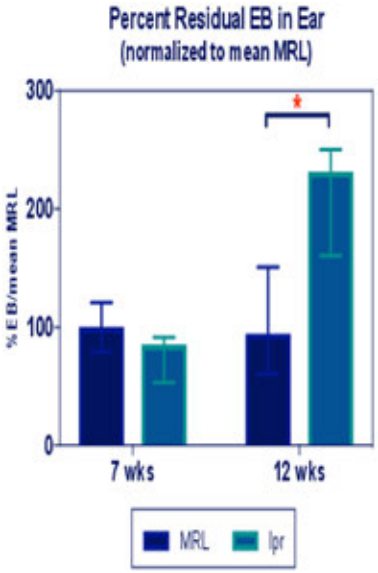

Figure 1. Impaired dermal EB clearance in diseased lpr mice. Quantification of residual EB in ear, 18-24 hours following EB injection. 7 weeks: MRL, n=3; lpr, n=2; 12 weeks: n=4 in both groups. *p<0.05. Bars indicate median with range.

Inactivation of Transaldolase and HRES-1/Rab4 Predisposes to Hepatitis in a Mouse Model of Systemic Lupus Erythematosus

Akshay Patel,[1] Nick Huang,[2] and Andras Perl[3], [1]SUINY Upstate Medical University, Syracuse, NY, [2]Upstate Medical University, Syracuse, NY, [3]SUNY Upstate Medical University, Syracuse, NY

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: SLE – Animal Models Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Deficiency of transaldolase (TAL) in systemic lupus erythematosus (SLE) predisposes to oxidative stress mediated autoimmune hepatitis[1, 2]. Along with TAL, HRES-1/Rab4 (Rab4A), a small GTPase responsible for mitochondrial turnover, is overexpressed in T cells of SLE patients[3] and livers of lupus-prone mice[2]. The expression of Rab4A is dependent on TAL activity[2]. Therefore, we investigated the impact of TAL and Rab4A in pristane-induced and spontaneous models of SLE.

Methods: C57Bl/6J wild-type (WT) mice and strains constitutively lacking TAL (TALKO)[1] or Rab4A in T cells were injected intraperitoneally with pristane (500μL/20g body weight). Mice lacking Rab4A were generated on both C57Bl/6J and lupus-prone SLE1.2.3. backgrounds. The number of inflammatory foci was used as a measurement of lymphocytic inflammation within the mouse livers. Vasculitis measurement[4] was adapted for H&E-stained liver sections. Student's T test was used to test significance; p values < 0.05 were considered significant for hypothesis testing.

Results: Among pristane-injected female mice, TALKO mice had more inflammatory cells relative to WT controls (p=0.0309). C57Bl/6J Rab4ACD4-KO mice had fewer inflammatory foci (p=0.0456), inflammatory cells (p=0.0497), and

SLE Genotype Effects on Female and Male Mice

vasculitis events (p=0.0266) compared to WT controls. The average vasculitis score was also decreased in C57Bl/6J Rab4ACD4-KO animals compared to C57Bl/6J Rab4AWT (p=0.00160) and C57Bl/6J Rab4AQ72L (p=0.0139) animals. The number of inflammatory foci (p=0.0263) and inflammatory cells (p=0.0384) was significantly higher in SLE1.2.3. mice versus C57Bl/6J controls. There was no difference in vasculitis incidents between the two genotypes; the vasculitis score was lower in SLE1.2.3 mice vs. C57Bl/6J (P< 0.0001). Relative to WT C57Bl/6J controls, SLE1.2.3. mice or pristane-injected TALKO male mice failed to show differences in liver inflammation.

Conclusion: Constitutive deletion of TAL or T-cell-specific deletion of Rab4A predisposes to inflammation and vasculitis in the liver, which is also enhanced in lupus-prone mice. These changes were confined to females, which is consistent with a similar gender bias in humans.

Treatment of Lupus-prone MRL-*lpr* Mice with the Mitochondrial Antioxidant MitoQ

Ralph Budd,[1] Karen Fortner,[1] Luz Blanco,[2] Mariana Kaplan,[3] Andras Perl,[4] Iwona Busliewicz,[5] Greg MacPherson,[6] and Mike Murphy[7], [1]The University of Vermont Larner College of Medicine, Burlington, VT, [2]NIH NIAMS, Bethesda, MD, [3]National Institute of Arthritis, Musculoskeletal, and Skin diseases/ National Institutes of Health, Bethesda, [4]SUNY Upstate Medical University, Syracuse, NY, [5]Upstate Medical Center, Syracuse, NY, [6]MitoQ, Aukland, New Zealand, [7]Wellcome MRC Mitochondrial Biology Unit, Cambridge, United Kingdom

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: SLE – Animal Models Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic Lupus Erythematosus (SLE) is characterized by a type I Interferon (IFN-I) gene signature in peripheral blood lymphocytes (PBL), which contain enlarged mitochondria and reactive oxygen species (ROS). SLE patients also manifest an unusual population of CD4-CD8- T cells that arise during homeostatic proliferation of CD8+ T cells. We have previously shown that ROS is sufficient to induce oligomerization of MAVS (**m**itochondrial antiviral stimulator) and type I Interferon (IFN-I) production, both of which was reversible with the mitochondrially targeted antioxidant, MitoQ. In addition, SLE patients manifested spontaneous MAVS oligomerization. CD4-CD8- T cells from MRL-*lpr* mice also manifested spontaneous oligomerization of MAVS and an IFN-I gene signature. Based on these collective observations, we elected to test the therapeutic potential of MitoQ in lupus-prone MRL-*lpr* mice.

Methods: MitoQ was administered in drinking water (200 or 400 mM) to MRL-lpr mice from weaning for the next 11 weeks.

Results: MitoQ produced a reduction in MAVS oligomerization in CD4-CD8- T cells and serum IFN-I. There was no effect on adenopathy or autoantibody production, but MitoQ did result in decreased dermatitis, immune complex deposition in kidneys, and NETosis (Fig. 1).

Conclusion: These findings suggest that SLE may be in part a disorder of mitochondrial dysfunction and ROS production, contributing to MAVS oligomerization and IFN-I stimulation. It also suggests mitochondrially targeted antioxidants as a therapeutic intervention for SLE.

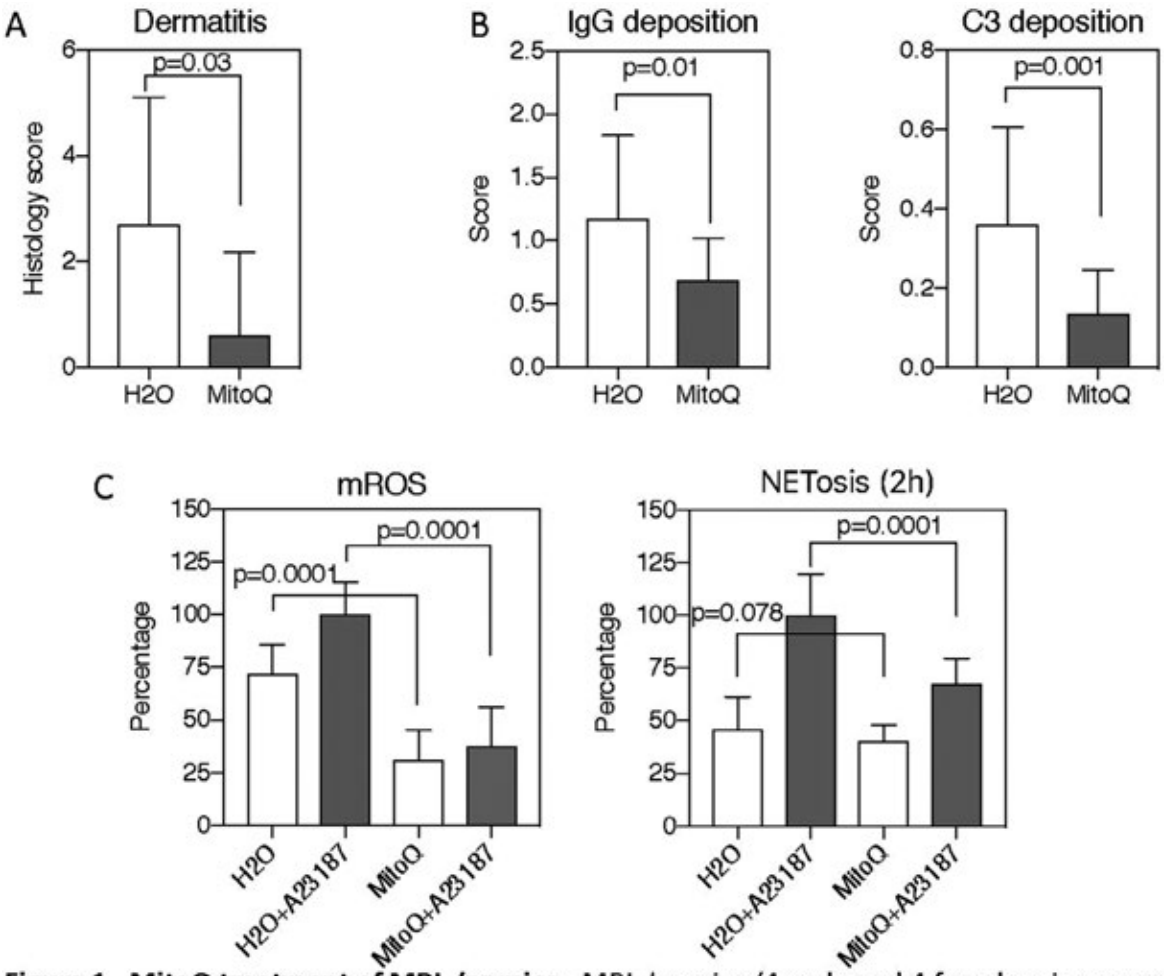

Figure 1. MitoQ treatment of MRL-*lpr* mice. MRL-*lpr* mice (4 male and 4 female mice per group) were administered water alone or MitoQ (200 μM) in drinking water beginning at weaning. After 11 weeks mice were assessed for (A) dermatitis by histologic score, (B) IgG and C3 deposition of kidneys, and (C) neutrophil production of ROS or NET formation without or with A23187 ionophore stimulation.

Angiotensin Receptor Blockers Prevent Loss of Dendritic Complexity in a Lupus Mouse Model of Cognitive Impairment

Lara El Khoury,[1] Nina Kello,[1] Kristiana Hanna,[2] Bruce Volpe,[3] and Betty Diamond[4], [1]Zucker School of Medicine at Hofstra/Northwell, Manhasset, NY, [2]Albany Medical College, Albany, NY, [3]Feinstein Institutes for Medical Research, Manhasset, NY, [4]Feinstein Institutes for Medical Research, Manhasset

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: SLE – Animal Models Poster

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Cognitive dysfunction affects the majority of patients with systemic lupus erythematosus (SLE), however it is grossly under-recognized, the pathogenesis is poorly understood, and no treatments are available. The anti-NMDA receptor (NMDA) antibody, a subset of anti-DNA antibodies cross-reactive with the NMDAR, and termed DNRAbs, has been strongly associated with cognitive dysfunction in both mouse models and humans. In a mouse model, DNRAb-mediated brain pathology proceeds through two stages: excitotoxic neuron loss, followed by persistent neuroinflammation resulting in alteration in neuronal integrity and spatial memory impairment. The renin-angiotensin system is emerging as a promising target in neurodegenerative diseases with angiotensin II as the most neuroactive peptide. We have previously shown that ACE inhibition can preserve and treat the dendritic damage and cognitive impairment that occurs in DNRAb-positive mice. We now tested whether direct inhibition of angiotensin signaling with angiotensin receptor blockers (ARBs) has a similar neuroprotective effect.

Methods: Mice immunized with DNRAbs and then treated with lipopolysaccharide (LPS) to breach the blood brain barrier and allow transient access of antibody to the hippocampus, were studied for loss of neuronal dendritic complexity using Golgi and analyzed using Sholl analysis. Mice received the ARB telmisartan in drinking water or control (regular drinking water) for two weeks, starting one week post LPS.

Results: Dendritic complexity was preserved in DNRAb-positive mice treated with telmisartan compared to those not treated ($p< 0.001$, KS). Moreover, dendritic complexity was considered normal in telmisartan-treated mice when compared to DNRAb-negative mice (not significant, KS).

Conclusion: These findings suggest that angiotensin receptor blockers can preserve neuronal dendritic complexity in the DNRAb mouse model. Future studies looking at microglial activation and spatial memory behavioral deficits are warranted. Angiotensin receptor blockers could be a potential therapeutic target for cognitive impairment in SLE and may serve as an alternative to ACE inhibitors in those that cannot tolerate them.

Inhibition of Nuclear Pore Export Ameliorates Lupus via Modulation of Plasma Cell Generation and Survival

Javier Rangel-Moreno,[1] Maria de la luz Garcia-Hernandez,[2] Teresa Owen,[3] Jennifer Barnard,[3] Bruce Goldman,[3] Christopher Ritchlin,[2] Douglas Widman,[4] Savanna Gornisiewicz,[4] Sharon Tamir,[4] and Jennifer H Anolik[3], [1]University of Rochester Medical center, Rochester, NY, [2]Division of Allergy, Immunology and Rheumatology, Center for Musculoskeletal Research, University of Rochester School of Medicine and Dentistry, Rochester, NY, USA, Rochester, NY, [3]University of Rochester, Rochester, NY, [4]Karyopharm Therapeutics, Newton, MA

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: SLE – Animal Models Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: A major challenge in lupus is the elimination of autoreactive plasma cells, which amplify inflammation at peripheral sites via deposition of autoantibody-self antigen complexes. We previously reported that Selective Inhibitors of Nuclear Export (SINEs), developed to treat malignancies including multiple myeloma, prevented lupus nephritis in lupus prone mice (LPM). SINEs potently reduced spontaneous formation of germinal centers (GC) and generation of autoreactive plasma cells in the spleen of LPM. We hypothesized that SINEs mediate their effect by disrupting NF-kB signaling in stromal cells, compromising migration and positioning of T and B cells, and thus affecting production of GC-derived plasma cells. Furthermore, SINEs may directly target plasma cells in the spleen and bone marrow (BM).

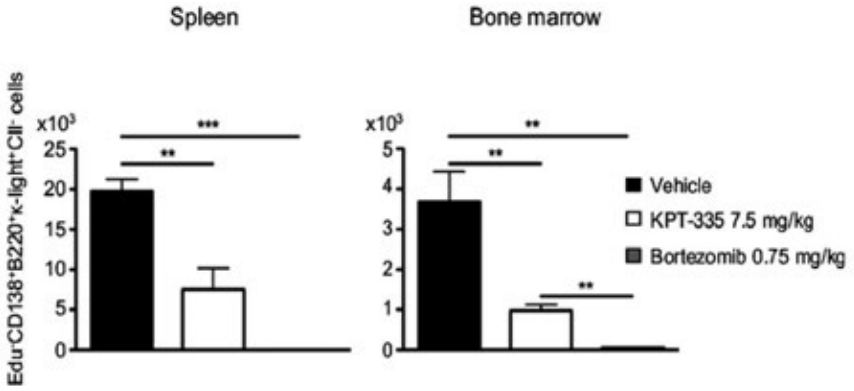

Figure 1. Short-term SINE therapy eliminates long-lived plasma cells in spleen and BM of lupus prone mice. 24 weeks old NZB/NZW female mice with active lupus received 4 i.p. injections of 5-ethynyl-2'-deoxyuridine (Edu, 1 mg/injection) in a period of 2 weeks to label proliferating cells. The following week, two mice cohort received KPT-335 (7.5 mg/kg) or vehicle by gavage, three times a week for one week A third group of mice received 2 ip injections per week of Bortezomib at 7.5 mg/kg. At the end of therapy spleen cells and bone marrow cells were stained with Aqua to eliminate dead cells from analysis, and stained with fluorescent antibodies and Edu. Long lived plasma cells (LLPC) were defined as Aqua⁻ alive cells that did not incorporate Edu, lacked MHC CII and were positive for CD138, B220 and K-light: Aqua⁻Edu⁻CD138⁺B220⁺light⁺CII-. Total number of LLP was calculated based on the number of cells that excluded trypan blue. Stattistically significant differences were calculated by t Test in groups of 8 mice. *: $p = 0.05$, **, $p = 0.005$, ***, $p < 0.0001$.

Methods: We isolated nuclear and cytoplasmic fractions from splenic stromal cells, stimulated with TNFain the presence of SINEs, and evaluated sequestration of NF-kB signaling components in the nuclei by western blot. Fold changes in mRNA expression for stromal cell-derived homeostatic chemokines (HC) were calculated with quantitative PCR. Morphometric analysis of area covered by fluorescent signal revealed the *in vivo* effects of SINEs on splenic HC. Finally, we used flow cytometry to enumerate cycling and non-cycling splenic and BM plasma cells in Edu labelled LPM after short-term therapy with KPT-335 (7.5 mg/kg) or vehicle (n = 8 mice/group).

Results: We demonstrated a significant enrichment for I-kBain the nuclear fraction of stromal cells stimulated with TNFain the presence of SINEs, thus confirming blockade of NF-kB signaling. In addition, fold mRNA expression for CCL19 and CXCL13 - HC that attract CXCR7+T cells and CXCR5+B cells, was significantly reduced in stromal cells incubated with SINEs (Control vs treated, p=0.0028). There was a significant decrease in CXCL13 staining (Control vs treated, p< 0.0001) and the size of follicular dendritic cells networks (Control vs treated, p< 0.0001) in spleens of mice orally treated with KPT-350 at 7.5 mg/kg for 8 weeks (3 administrations/week). As expected, short-term SINE therapy (1 week, 3 administrations/week) caused a two-fold reduction in GC B cells and a significant decrease in T follicular helper cells (Control vs treated, p=0.0043). Of note, short-term SINE therapy caused a global and significant reduction in long-lived plasma cells in spleen (Control vs treated, p=0.004) and BM (Control vs treated, p=0.0071). Unexpectedly, cycling splenic plasmablasts and short-lived plasma cells in the BM were not affected by SINE.

Conclusion: Our data demonstrate that SINEs disrupt NF-kB- dependent production of HC by stromal cells, thus impairing GC formation and compromising autoreactive PC generation. In addition, SINEs have a direct impact on PC survival, including long-lived plasma cells in the BM.

The Single-cell Transcriptomic Landscape of NZB/W Murine Lupus at Early and Late Stages of Disease

Paul Hoover,[1] Tom Eisenhaure,[2] David Lieb,[2] Anne Davidson,[3] and Nir Hacohen[2], [1]Brigham and Women's Hospital, Boston, MA, [2]Broad Institute, Cambridge, MA, [3]Feinstein Institutes for Medical Research, Manhasset

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: SLE – Animal Models Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Lupus nephritis is a complex and heterogeneous disease characterized by infiltrating immune cells in damaged kidney tissue. While mouse models have enabled mechanistic studies of lupus nephritis, immune and kidney cell types and states are incompletely characterized. Thus, shared cells and pathways between mouse and human lupus nephritis remain unrecognized and could provide the basis for targeted studies as well as engineering existing mouse models to better reflect human disease. To provide a comprehensive view of active leukocytes in a common model of mouse lupus nephritis, NZB/W, we measured the transcriptomes of single cells from murine kidneys and as well as spleens at early and late stages of kidney disease.

Methods: NZB/W female mice were generated and followed clinically. Kidneys and spleens from NZB/W mice were harvested for analysis from two 22-week-old non-proteinuric and two 37-week-old proteinuric mice. Single immune and parenchymal cells from digested kidney, and immune cells from spleen, were collected by flow cytometric cell sorting. We used the 10X Chromium 5' kit for single-cell encapsulation into droplets for library generation and next-generation sequencing for ~50,000 reads per cell. After normalization, single-cell transcriptomes passing quality metrics (>500 genes and < 25% mitochondrial content) were analyzed with unsupervised clustering (Seurat 3.0).

Results: We profiled 32,969 single cells collected from kidneys and spleens from NZB/W lupus mice at early and late stages of kidney disease (pre- and proteinuric, 2 mice per disease stage). Using unsupervised transcriptome analysis we discovered 27 distinct cellular clusters. Of these, 15 were immune cell clusters reflecting distinct subsets of T, B, and myeloid cells in both damaged kidney tissue and the spleen; the remaining 12 cell clusters were non-hematopoietic cells reflecting kidney cell types and states in early and late stages of kidney disease. Comparing cells from the same organ type (kidney or spleen) harvested from different mice at identical disease stages revealed highly similar immune and non-hematopoietic cell clusters, indicating reproducibility across animals and minimal batch effect.

Conclusion: By measuring the transcriptomes from single cells collected from damaged murine kidney tissue and spleens at early and late stages of kidney disease (pre-proteinuric and proteinuric), this study provides a comprehensive view of active leukocytes of lupus nephritis in a common model, NZB/W. We discovered 27 distinct murine cellular clusters reflecting multiple T, B, and myeloid cell subsets, as well as non-hematopoietic kidney cells types. We will compare NZB/W immune and kidney cellular clusters to those recently discovered in human lupus nephritis patients by single cell transcriptome profiling (Arazi et. al, Nature Immunology, 2019; Der et. al. Nature Immunology, 2019). We expect to identify new and better understand existing cells and pathways shared between human mouse lupus nephritis. We anticipate this approach can incorporate other common mouse models of lupus nephritis to better understand how each is related to human disease.

Potent Anti-neutrophil Properties of the Natural Compound 6-Gingerol in Models of Lupus and Antiphospholipid Syndrome

Ramadan Ali,[1] Julia Weiner,[1] Alex Gandhi,[1] Shanea Estes,[1] and Jason Knight[2], [1]University of Michigan, Ann Arbor, MI, [2]Division of Rheumatology, Department of Internal Medicine, Michigan Medicine, Ann Arbor, MI

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: SLE – Animal Models Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: 6-gingerol, the major bioactive compound of ginger root, is known to have anti-inflammatory and anti-oxidative effects. Indeed, ginger has been employed for millennia as an herbal supplement in the treatment of inflammatory diseases. Our group recently revealed that 6-gingerol prevents neutrophil extracellular trap (NET) release triggered by either ribonucleoprotein (RNP)/anti-RNP complexes or antiphospholipid antibodies (aPL). Here, we sought to further elucidate the mechanism by which 6-gingerol suppresses NET release, as well as to test its efficacy in lupus-relevant mouse models.

Methods: For in vitro studies, human neutrophils were prepared from healthy volunteers and stimulated with either immune complexes from lupus patients (RNP/anti-RNP) or total IgG fractions from primary APS patients (aPL). Stimulation was in the presence or absence of 6-gingerol and NET release was quantified via the enzymatic activity of NET-associated myeloperoxidase. Phosphodiesterase 4 (PDE4) activity and cyclic AMP (cAMP) levels were measured by chromogenic assays. In vivo, 6-gingerol (10 mg/kg/day) was tested in two models characterized by accelerated NET release: TLR7 agonist-induced lupus (BALB/c mice) and aPL-accelerated inferior vena cava thrombosis (C57BL/6 mice).

Results: As in our previous study, 6-gingerol completely neutralized RNP/anti-RNP- and aPL-mediated NET release at low micromolar concentrations. We further explored mechanisms of aPL-mediated NET release and found that 6-gingerol suppresses normal PDE4 activity, and thereby raises intracellular levels of cAMP. Indeed, the suppressive effects of 6-gingerol could be mitigated by blocking activity of the cAMP-responsive protein kinase A complex. Administration of 6-gingerol to TLR7 agonist-treated mice (model of lupus) resulted in a marked reduction in plasma NET levels, as well as anti-double-stranded DNA and anti-beta-2 glycoprotein I autoantibodies. In a model of APS, 6-gingerol neutralized the acceleration of large-vein thrombosis by human aPL; importantly levels of plasma NET were reduced in the same model.

Conclusion: We demonstrate for the first time that the natural compound 6-gingerol attenuates lupus-relevant NET release in vitro through a mechanism that at least partially depends on inhibition of PDE4. At the same time, administration of 6-gingerol to mice reduces NET release in models of lupus and APS, while also attenuating other disease-relevant activities such as autoantibody formation and large-vein thrombosis.

LILRA3 Promotes Lupus-like Chronic Graft-versus-Host Disease by Expansion of Follicular Helper T Cells and Anti-dsDNA Autoantibodies

Yundi Tang,[1] Yuxuan Wang,[1] Yundong Zou,[1] Mengru Liu,[1] Yan Du,[1] and Jianping Guo[1], [1]Department of Rheumatology and Immunology, Peking University People's Hospital, Beijing, China (People's Republic)

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: SLE – Animal Models Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Leukocyte immunoglobulin-like receptor A3 (LILRA3) is a soluble member of LILR family. We previously reported that *LILRA3* is a novel genetic risk for multiple autoimmune diseases, including systemic lupus erythematosus (SLE). However, it is unclear how LILRA3 contributes to the pathogenesis of SLE. This study was undertaken to examine the *in vivo* role of LILRA3 and its possible mechanism(s) in development of lupus in a chronic graft-versus-host disease (cGVHD) model.

Methods: To functionally study the role of LILRA3 in lupus pathogenesis, we generated a novel *LILRA*3 knock-in (*LILRA3*-KI) mouse and evaluated clinical and immunological phenotypes in the bm12-induced cGVHD model. Human LILRA3 gene (Gene ID: 11026) was inserted into Rosa26 allele in C57BL/6 (B6) mice based on Cas9/sgRNA system. The cGVHD was induced by an intraperitoneal injection of the bm12 donor splenocytes into recipients, either B6 wild-type (B6-WT) or *LILRA3*-KI mice. Mice were assessed for the development of splenomegaly, immune cellular response, autoantibody production, and renal pathology.

Results: Compared with B6-WT recipient mice, the *LILRA3*-KI mice displayed a more pronounced lupus-like phenotype and immune response, which includes an apparent spleen enlargement ($p < 0.001$); expansion of Tfh cells ($p < 0.001$), germinal center (GC) B cells ($p < 0.01$), and plasma B cells ($p < 0.001$); and elevated levels of serum anti-double-stranded DNA IgG autoantibodies ($p < 0.001$).

Conclusion: Our data indicate that LILRA3 promotes lupus-like disease probably through the excessive expansion of Tfh, GC B, and plasma cells, and subsequently leading to an excessive production of anti-dsDNA autoantibodies.

Microglia-Specific Transcriptional Signatures Correlate with Behavioral Deficits in 'Neuropsychiatric Symptoms of Systemic Lupus Erythematosus'

Hadijat Makinde,[1] Elise Mike,[2] Chaim Putterman,[3] Deborah Winter,[4] and Carla Cuda[5], [1]Northwestern University, Chicago, IL, [2]Albert Einstein College of Medicine, Bronx, NY, [3]Albert Einstein College of Medicine, New York, NY, [4]Northwestern University Feinberg School of Medicine, Division of Rheumatology, Chicago, [5]Northwestern University Feinberg School of Medicine, Division of Rheumatology, Chicago, IL

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: SLE – Animal Models Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is a complex autoimmune syndrome affecting multiple organs, including the brain. More than 50% of patients experience neuropsychiatric symptoms of SLE (NPSLE) that often occur early in disease and go undiagnosed. Despite the devastating impact of NPSLE on health-related quality of life, underlying disease mechanisms are unknown. Microglia are the resident innate immune cells of the brain; ac-

cumulating evidence points to microglia as drivers of neurological conditions ranging from neurodevelopmental (autism) to neurodegenerative (Alzheimer's disease, chronic pain) disorders. The recently discovered disease-associated microglia (DAM) subset is enriched for lipid metabolism pathways and phagocytosis-related functions. The vast majority of investigations into microglia, particularly DAM, have occurred in neurodegenerative disease models of Alzheimer's disease, amyotrophic lateral sclerosis and multiple sclerosis. However, very few studies have examined microglia, particularly DAM, in the context of NPSLE. Here, we probed microglia from two NPSLE-prone mouse strains at the transcriptional level to potentially correlate gene signatures with behavioral deficits.

Methods: Mice with caspase 8 flanked by *loxP* sites (*Casp8*$^{fl/fl}$, WT) were bred to mice expressing Cre under the CD11c gene promoter to generate CReCOM (Caspase-8 Removed CD11c-specific Overactive MyD88) mice. B6.*Sle1.Sle3* mice were derived from the introgression of 2 NZM2410-derived susceptibility loci onto non-autoimmune C57BL/6 (B6) mice. 3-4 month old WT and CReCOM mice underwent behavioral testing. Microglia were sorted from mice following behavioral tasks and from 10-12 month old WT, CReCOM, B6 and B6.*Sle1.Sle3* mice for RNA-seq analysis (n=4/group).

Results: CReCOM mice develop an inflammatory disease reminiscent of human SLE and exhibit significant impairment in spatial memory, contextual associative learning, startle response and motor coordination, similar to patients with NPSLE. Likewise, the recently validated B6.Sle1Sle3 NPSLE model exhibits depression-like behavior and significant impairment in spatial and recognition memory, symptoms detected in NPSLE patients. Of the significantly upregulated genes (DESeq2, $p< 0.05$, fold change in expression >1.5) observed in CReCOM (256) and B6.Sle1.Sle3 (214) microglia compared to their respective controls, a common 18-gene 'NPSLE signature' is shared ($p< 2.54x10-4$) and enriched for genes associated with lipid metabolism, scavenger receptor activity and downregulating inflammatory responses and cell chemotaxis processes. NPSLE microglia are also enriched for genes associated with the DAM subset. Moreover, microglial expression of 'NPSLE' and 'DAM' signatures significantly correlate with the severity of behavioral deficits in CReCOM mice.

Conclusion: The discovery of our novel 'NPSLE signature', as well as enrichment of the 'DAM signature', represents the first to connect microglia-specific transcriptional signatures with clinical outcomes in NPSLE-like disease. In future studies, we will assess the penetrance of these signatures to further interrogate how defective microglial function may incite NPSLE.

Effect of Ifnα and Costimulatory Blockade on Brain Infiltration in a Model of 'Neuropsychiatric Symptoms of Systemic Lupus Erythematosus'

Hadijat Makinde,[1] Chirag Raparia,[2] Anne Davidson,[2] and Carla Cuda[3], [1]Northwestern University, Chicago, IL, [2]Feinstein Institutes for Medical Research, Manhasset, [3]Northwestern University Feinberg School of Medicine, Division of Rheumatology, Chicago, IL

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: SLE – Animal Models Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is a complex autoimmune disease that affects many end organs including the brain. Despite a prevalence of over 50% in SLE patients, neuropsychiatric symptoms of SLE (NPSLE) are among the least understood complications. Similar to SLE patients, the lupus-prone NZB/W strain develops NPSLE-like disease that manifests in mood-related disorders and learning impairment. Despite the paucity of data examining underlying mechanisms, accumulating evidence points to microglia, the resident innate immune cells in the brain, as a driver of disease. The cross-talk between infiltrating monocyte-derived macrophages and microglia plays a critical role in directing microglial responses. Evidence shows that IFNα exacerbates systemic disease and induces early lethality in the NZB/W strain in a T cell-mediated manner. In contrast, blocking the CD28/cytotoxic T lymphocyte antigen (CTLA)-4/B7 interaction (using CTLA4Ig) induces disease remission in NZB/W mice in combination with anti-CD40L antibodies and cyclophosphamide. Here, we elucidate the role of IFNα administration and costimulatory blockade on the infiltration of monocyte-derived macrophages and the corresponding microglial responses in NPSLE-like disease.

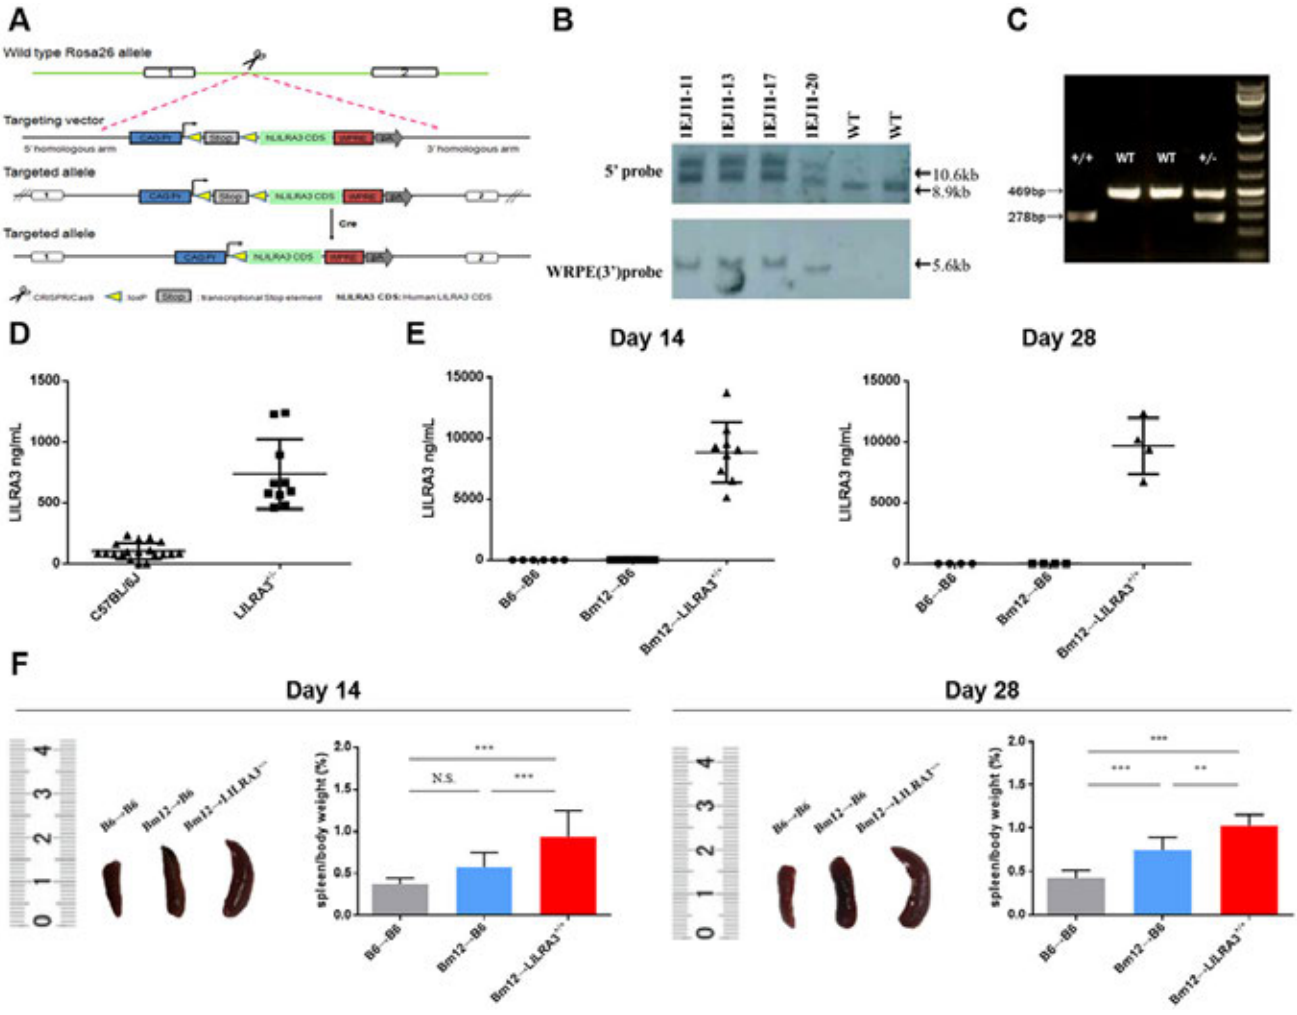

Figure 1. Construction strategy of the LILRA3 knock-in mice. Humanized LILRA3 knock-in (LILRA3-KI) mice were constructed on C57BL/6 background. A full-length sequence of human LILRA3 gene (Gene ID: 11026) was inserted into the C57BL/6 Rosa26 allele based on CRISPR-Cas9 technology (A). LILRA3 expression was confirmed by southern blot (B), PCR (C), and ELISA (D). After cGVHD, serum LILRA3 was highly expressed in bm12→KI mice at both days 14 and 28 (E). The bm12→KI mice showed a significant aggravation of splenomegaly (F). Results from F: data were obtained from 2 independent experiments at day 14 (B6→B6: n=9; bm12→B6: n=12; bm12→KI: n=12). At day 28, data were obtained from a single experiment (B6→B6: n=4; bm12→B6: n=6; bm12→KI: n=4). Data are displayed as mean±SD. ** $p < 0.01$, *** $p < 0.001$.

Methods: One cohort of female NZB/W mice (n= 5) was given a single intravenous injection of adenovirus-IFNα (AD-IFNα) at 12-14 wks of age and tissues were harvested at 18 wks. An additional cohort (n=5) was intraperitoneally injected 3 times/wk for 2 wks with CTLA4Ig/anti-CD40L (costimulatory blockade) at 18-20 wks prior to overt disease and tissues were harvested at 32 wks. Treated animals and age-matched NZB/W control mice were examined for proteinuria and splenic alterations as an indicator of systemic disease. Brain monocytic infiltration was evaluated via flow cytometry as a measure of blood-brain barrier breach. Neurocognitive testing and RNA-seq analysis of sorted microglia are pending.

Results: Mice immunized with AD-IFNα developed proteinuria and splenomegaly, corresponding to an increase in total splenocyte numbers, compared to age-matched control NZB/W mice. In contrast, costimulatory blockade prevented development of proteinuria and splenomegaly compared to their age-matched counterparts. Similar to SLE patients with NPSLE, AD-IFNα-immunized mice showed reduced brain volume compared to age-matched control mice. However, animals placed on the costimulatory blockade treatment showed a trend towards prevention of this brain volume loss compared to age-matched control mice. Furthermore, the increased macrophage infiltration into brains of 18-wk-old AD-IFNα-immunized mice mirrored that found in brains of 32-wk-old NZB/W control mice. Strikingly, costimulatory blockade prevented this infiltration at 32 wks.

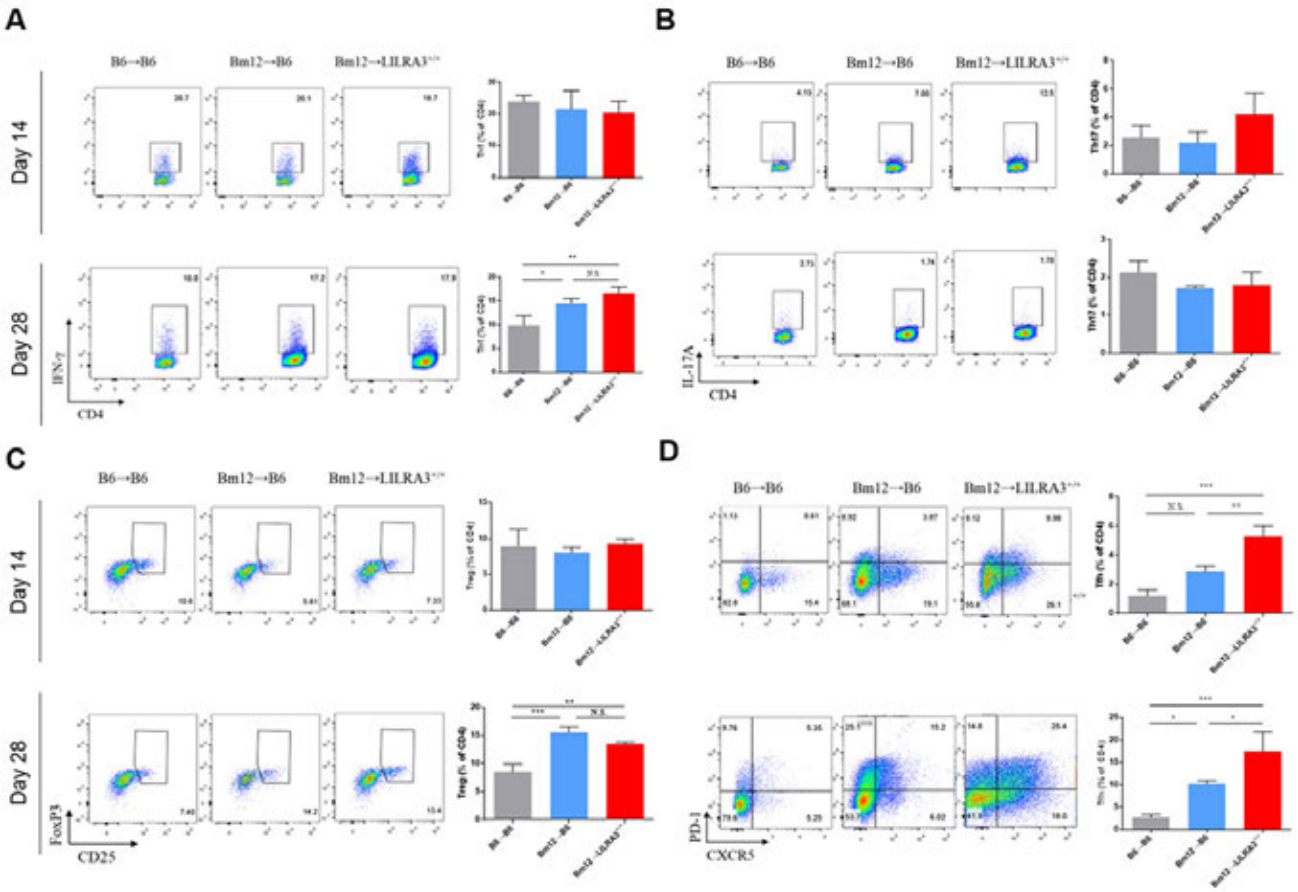

Figure 2. Increased expansion of Tfh cells in LILRA3-KI cGVHD mice. On days 14 and 18, the frequencies of CD4+IFNγ+ Th1 cells (A), CD4+IL-17A+ Th17 cells (B), CD4+CD25+FoxP3+ Tregs (C), and CD4+PD-1+CXCR5+ Tfh cells (D) from splenocytes were determined by flow cytometry. At day 14, data were obtained from 2 independent experiments (B6→B6: n=9; bm12→B6: n=12; bm12→KI: n=12). At day 28, data were obtained from a single experiment (B6→B6: n=4; bm12→B6: n=6; bm12→KI: n=4). Data are displayed as mean±SD. * $p < 0.05$, ** $p < 0.01$, *** $p < 0.001$.

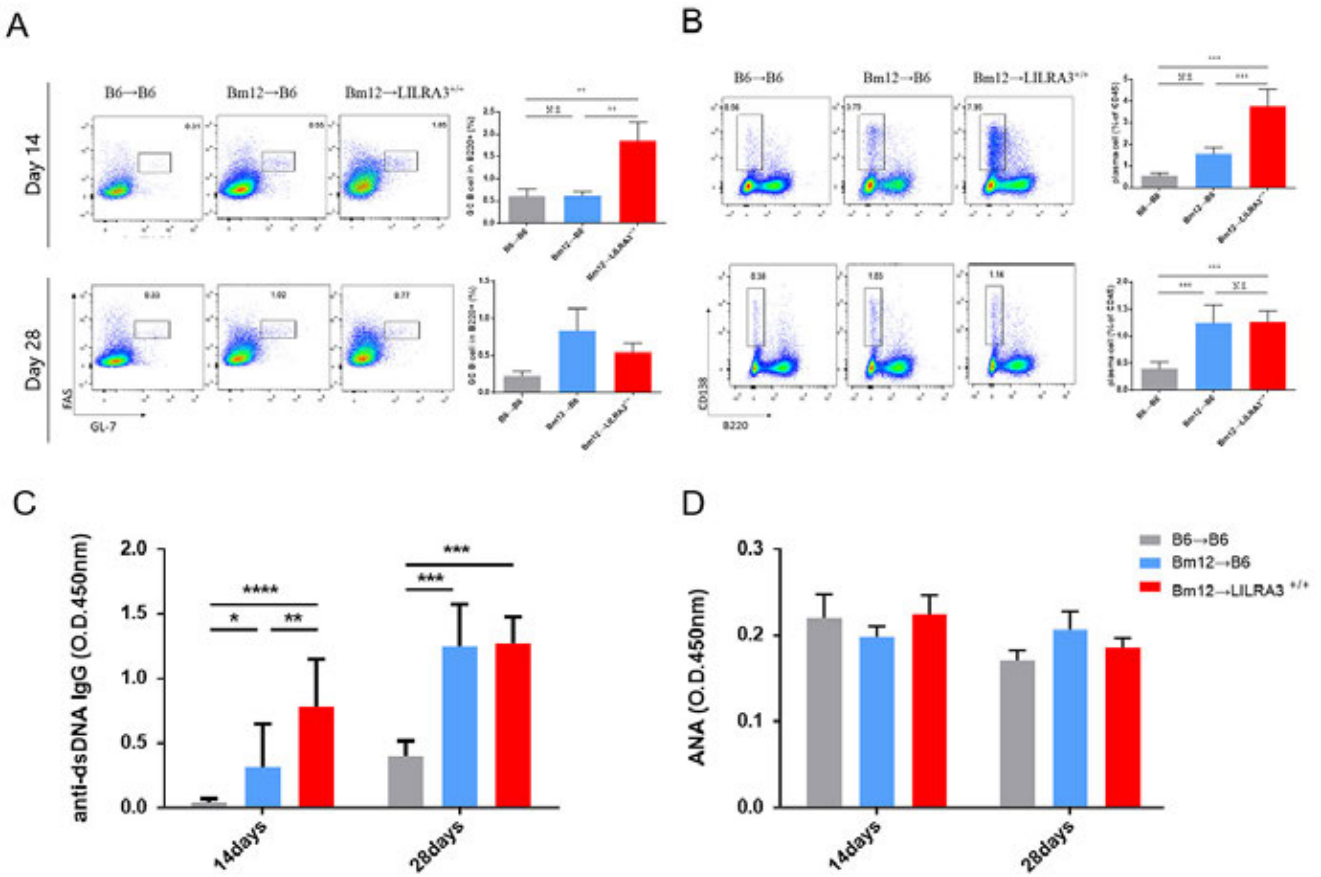

Figure 3. Increased expansion of GC B, plasma cells and anti-dsDNA autoantibody production in LILRA3-KI cGVHD mice. On days 14 and 18, the frequencies of CD19+FAS+GL-7+ GC B cells (A), and CD19+CD138+B220- plasma cells (B) from splenocytes were determined by flow cytometry. Serum levels of anti-dsDNA IgG (C), and ANA (D) were measured by ELISA. At day 14, data were obtained from 2 independent experiments (B6→B6: n=9; bm12→B6: n=12; bm12→KI: n=12). At day 28, data were obtained from a single experiment (B6→B6: n=4; bm12→B6: n=6; bm12→KI: n=4). Data are displayed as mean±SD. ** $p < 0.01$, *** $p < 0.001$.

Conclusion: These data indicate that IFNα accelerates brain macrophage infiltration, potentially impacting repair and regeneration responses of microglia within the injured brain, while costimulatory blockade prevents this insult. Future studies will examine neurocognitive decline and microglial-specific responses to these treatments.

Flux Analysis Reveals Influence of Rab4 Expression on Mitochondrial and Pentose Phosphate Pathway Metabolism of Lupus T Cells

Tamas Faludi,[1] Nick Huang,[1] Manuel Duarte,[2] Joshua Lewis,[2] and Andras Perl[3], [1]Upstate Medical University, Syracuse, NY, [2]Upstate Medical University, Syracuse, [3]SUNY Upstate Medical University, Syracuse, NY

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: SLE – Animal Models Poster

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: HRES-1/Rab4 is a small GTPase enzyme which regulates endosomal trafficking. The protein is overexpressed in T cells of SLE patients (J Immunol. February 15, 2009, 182 (4): 2063-2073) and mice (Ann Rheum Dis. 2014 Oct;73(10):1888-97.), resulting in mitochondrial accumulation through the inhibition of mitophagy (PLoS One. 2014, 9(1): e84392). Since mitochondrial dysfunction in T cells plays an important role in the pathogenesis of SLE, we investigated whether its mouse homologue, Rab4A, regulates metabolism.

Methods: Metabolic flux analysis is an emerging technique capable of offering insight into intracellular metabolism both on an individual metabolite and on a metabolic pathway level (J Ind Microbiol Biotechnol (2015) 42: 317) which makes it a suitable method for the investigation of T cell metabolism.

To study the effects of Rab4A expression in T cells, a site-specific Cre/Lox recombinase system was employed to knock down Rab4A expression in lupus-prone SLE 1.2.3. mice. The metabolic flux of T cells and other lymphocytes was characterized by feeding ^{13}C-stable isotope labeled nutrients, such as glucose or glutamine, to cells in culture and subsequently measuring isotope labeled metabolites using liquid chromatography-mass spectrometry (LC-MS) after the preparation of cell extracts.

Results: The non-oxidative pentose phosphate pathway (PPP) metabolite, sedoheptulose-7-phosphate (S7P) was accumulated in CD4+ T cells (33% elevation, p=0.002) but it was reduced in B cells (24%, p=0.043) of lupus mice. Rab4A deletion in T cells reversed the accumulation of S7P in CD4 T cells in SLE mice (p=0.035).

Mitochondrial tricarboxylic cycle metabolites, glutamate (18% decrease, p=0.029), citrate/isocitrate (37% decrease, p=0.004), alpha-ketoglutarate (32% decrease, p=0.006) and malate (35% decrease, p=0.038) were depleted in CD4+ T cells of SLE mice. Glutamate was also reduced in B cells of SLE mice (7% decrease, p=0.026).

Conclusion: The results suggest that T cell-specific deletion of Rab4A restores the SLE-induced metabolic changes in CD4+ T cells. Therefore, Rab4A may represent a target for correcting T-cell dysfunction in SLE.

Ultraviolet Light Induces Increased T Cell Activation in Lupus-Prone Mice via Type I Interferon-Dependent Inhibition of T Regulatory Cells

Sonya Wolf-Fortune,[1] Shannon Estadt,[1] Jonathan Theros,[1] Tyson Moore,[1] Jason Ellis,[1] Jianhua Liu,[1] Tamra Reed,[1] Chaim Jacob,[1] Johann Gudjonsson,[1] and **J Michelle Kahlenberg**[1], [1]University of Michigan, Ann Arbor, MI

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: SLE – Animal Models Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Ultraviolet (UV) light is a known trigger of skin and possibly systemic inflammation in systemic lupus erythematosus (SLE) patients. Although type I interferons (IFN) are upregulated in SLE skin after UV exposure, the mechanisms to explain increased UVB-induced inflammation remain unclear. Here, we identified the role of type I IFNs in regulating immune cell activation between wild-type and lupus-prone mice following UVB exposure.

Methods: 10-week old female lupus-prone (NZM2328), wild-type (BALB/c) and iNZM mice (which lack a functional type I IFN receptor on NZM2328 background) were treated on their dorsal skin with 100mJ/cm^2 of UVB for 5 con-

secutive days. Following UVB treatment, draining lymph node cell populations were characterized via flow cytometry and suppression assays. Treated skin was examined for changes in expression of type I IFN genes by real-time PCR.

Results: Two weeks following UVB exposure, lupus-prone NZM2328 mice showed an increase in draining lymph node size and expansion of T cell numbers and T cell activation in the draining lymph nodes. B cells were not increased. Neither Balb/c nor iNZM mice demonstrated this change. This T cell activation was preceded by a significant increase in UVB-induced type I IFN expression in the skin of NZM2328 mice compared to BALB/c mice. To explain the rise in T cell activation, T regulatory (T_{reg}) cells were examined. Following UVB exposure, both BALB/c and iNZM mice demonstrated an increase in activated T_{Reg} cells in the draining lymph node 24 hours after the fifth UVB treatment; however, this was not seen in NZM2328 mice. In addition, T_{regs} isolated from NZM2328 mice draining lymph nodes were not functional in a T cell suppression assay. and this was dependent on type I IFNs as Tregs from UVB-treated iNZM demonstrated excellent suppressive capacity, similar to Balb/c mice.

Conclusion: These data suggest that an environment rich in type I IFNs, such as seen in lupus skin, promotes a skewed UVB-mediated T cell response in which activation of T cells is enhanced secondary to a type I IFN-dependent suppression of T_{Reg} cells. Thus, we propose that type I IFNs promote are important for UVB-induced inflammation and may be an effective target for prevention of UVB-mediated flares.

Unique Primed Status of Microglia Under the Systemic Autoimmune Condition of Lupus-Prone Mice

Atsushi Nomura,[1] Daisuke Noto,[2] Goh Murayama,[3] Asako Chiba,[1] and Sachiko Miyake[1], [1]Department of Immunology, Juntendo University School of Medicine, Tokyo, Japan, [2]Juntendo University School of Medicine, Tokyo, Japan, [3]Department of Internal Medicine and Rhumatology, Juntendo University School of Medicine, Tokyo, Japan

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: SLE – Animal Models Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is an autoimmune disease characterized by the production of various autoantibodies. This disease causes disabling neuropsychiatric symptoms even in the absence of apparent inflammation in the central nervous system (CNS), but the mechanisms involved remain unknown. Innate immune-mediated inflammation has attracted attention as a pathogenic mechanism in neuropsychiatric diseases.

Methods: We investigated the CNS of lupus-prone mice focusing on innate immunity. Three strains of lupus-prone mice, FcγRIIB$^{-/-}$*Yaa*, an F1 hybrid of NZB and NZW (NZB/NZW) mice, and MRL/Fas^{lpr} (MRL/lpr) mice were used to analyze CNS immunopathology.

Results: Flow cytometry analysis demonstrated the numbers of brain CD45^{+} cells were increased compared with controls in lupus-prone mice. Upregulation of MHC class I and PDCA1 were observed in microglia and CD11b^{+} myeloid cells of lupus-prone mice, indicating they were activated in response to interferons (IFN). Microglial gene ex-

pression analysis of FcγRIIB$^{-/-}$*Yaa* mice revealed the upregulation of IFN responsive genes and inflammation-related genes including *Axl*, *Clec7a,* and *Itgax*, which were previously reported in neurodegenerative conditions and primed conditions. Upregulated chemokine gene expressions including *Ccl5* and *Cxcl10* were concurrent with increased numbers of T cells and monocytes, especially Ly6C^{lo} monocytes in the CNS. Upregulation of these genes was also observed in NZB/NZW mice, indicating common lupus pathology. The primed status of microglia in FcγRIIB$^{-/-}$*Yaa* mice was also demonstrated by morphological changes such as enlarged cell bodies with hypertrophic processes, and hyper reactivity to lipopolysaccharide. Immunohistochemistry of FcγRIIB$^{-/-}$*Yaa* mice indicated reactive responses of astrocytes and vascular endothelium.

Conclusion: Our data indicated that microglia in lupus exhibit a unique primed phenotype characterized by the upregulated expressions of neurodegeneration-related genes and IFN responsive genes. Interaction with peripheral cells and brain resident cells was presumed to orchestrate neuroinflammation. Targeting innate immune cells, such as microglia and monocytes, may be a promising therapeutic approach for neuropsychiatric SLE.

The Role of Adopter Protein SH3BP2 in a Murine Systemic Lupus Erythematosus Model

Kyoko Kawahara,[1] Tomoyuki Mukai,[2] Akiko Nagasu,[1] Masanori Iseki,[3] Hajime Nagasu,[4] Shoko Tshuji,[1] Takahiko Akagi,[1] Yasuyoshi Ueki,[5] and Yoshitaka Morita[1], [1]Department of Rheumatology, Kawasaki medical School, Kurashiki, Okayama, Japan, [2]Department of Rheumatology, Kawasaki medical School, Kurashiki, Okayama, Okayama, Japan, [3]Department of Immunology and Molecular Genetics, Kawasaki Medical School, Kurashiki, Okayama, Japan, [4]Department of Nephrology and Hypertension, Kawasaki medical School, Kurashiki, Okayama, Japan, [5]Department of Biomedical Sciences and Comprehensive Care Indiana University School of Dentistry, Indianapolis, IN

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: SLE – Animal Models Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: An adaptor protein SH3BP2 (Src homology 3 domain-binding protein 2) is widely expressed in immune cells and controls intracellular signaling pathways, such as Syk, Src, Vav, and PLCγ. In previous reports, SH3BP2 has been reported to regulate the production of antibodies in B cells. We have previously reported that, in a collagen-induced arthritis model, SH3BP2 loss-of-function mutation suppresses antibody production against type II collagen and markedly prevents the development of arthritis (Mukai T, et al. Arthritis Rheumatol 2015). To further investigate the role of SH3BP2 in autoimmune diseases, we examine the effect of SH3BP2 deficiency in a murine systemic lupus erythematosus (SLE) model.

Methods: For the lupus model, we used Fas^{lpr} mice (C57BL6 background), which possess impaired Fas signaling. SH3BP2-deficient mice and Fas^{lpr} mice were crossed to create SH3BP2-deficient Fas^{lpr} double mutant mice. These mice were observed until 35-week old, and then serum, urine, spleen, inguinal lymph nodes, kidney and bone marrow samples were collected. We evaluated proteinuria, splenomegaly, serum anti-dsDNA antibody titer, and histological renal damage. In addition, we analyzed B- and T-cell subsets by flow cytometry.

Results: Wild-type, SH3BP2-deficient, Fas^{lpr}, and SH3BP2-deficient Fas^{lpr} double mutant mice were analyzed. Fas^{lpr} mice exhibited splenomegaly, proliferative glomerulus lesions, and increased anti-dsDNA antibody levels compared to wild-type and Fas^{lpr} mice. All of them were significantly ameliorated by SH3BP2 deficiency. Furthermore, SH3BP2 deficiency suppressed the accumulation of $CD3^+B220^+CD4^-CD8^-$(double negative) T cells in spleen and lymph nodes, which are characteristic of Fas^{lpr} mice.

Conclusion: In the murine lupus model, SH3BP2 deficiency suppressed the development of the autoantibody (anti-dsDNA antibody), organ damage, and the accumulation of double negative T cells in the spleen. SH3BP2 could be a potential therapeutic target for autoimmune diseases.

UV Light Stimulates a Systemic Neutrophil Response Associated with Transient Kidney Injury

Sladjana Skopelja-Gardner,[1] Joyce Tai,[2] Xizhang Sun,[2] Lena Tanaka,[2] Payton Hermanson,[2] and Keith Elkon[2],
[1]University of Washington, Seattle, WA, [2]University of Washington, Seattle

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: SLE – Animal Models Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Sensitivity to ultraviolet B (UVB) light affects ~70% of SLE patients and exacerbates both skin disease and systemic flares, including lupus nephritis (LN). Our findings that neutrophils are the dominant infiltrating immune cell in the skin after exposure to UVB light together with the recent discovery that neutrophil gene signature is the strongest predictor of active SLE disease prompted the hypothesis that *neutrophils are the pathogenic link between UVB light-induced inflammation in the skin and kidney injury in SLE*.

Methods: Mice (C57BL/6J, 3-4mo) were exposed to a single dose of UVB light (500mJ/cm2, 280-320 nm). Skin infiltrating neutrophils in photoactivatable mice (UBC-PA-GFP) were photoconverted with violet light (~415nm) 1 day after UVB light exposure. Individual mice were euthanized on 1, 2, or 6 days after UVB and perfused with saline; non-irradiated mice were used as controls. Immune cells isolated from the skin, bone marrow (BM), blood, lung, and kidney were profiled by flow cytometry. Gene expression was evaluated by QPCR, plasma protein concentration by Legendplex Inflammatory Panel, and proteinuria by Bradford assay.

Results: Acute exposure to UVB light caused a 10-fold increase in neutrophil numbers in the skin, associated with their precipitous egress from the BM and a 5-fold increase in circulating neutrophils. Unexpectedly, UVB light injury in the skin caused neutrophil migration to peripheral organs, including the lung and kidney, with up to 10-fold increase in neutrophil numbers in the kidney. Extensive gene profiling of the skin tissue revealed a broad local cutaneous inflammatory response to UVB light injury, while proteomic analysis of plasma samples identified IL17A as the dominant inflammatory mediator found in circulation 6-24hr after skin exposure to UVB light.

Relevant to SLE pathogenesis, neutrophil infiltration into the kidney was accompanied by endothelial activation and inflammation: increased expression of adhesion molecules VCAM-1 and E-Selectin, as well as inflammatory proteins IL1β, s100A8/9, and s100A6. Moreover, we detected increased early (day 1-2) expression in Ngal and Kim1, markers of kidney injury in LN, as well as elevated urine protein levels, findings indicating that skin exposure to UVB light triggers transient kidney damage. Neutrophils in distal sites late (day 6) after UVB light injury demonstrated two phenotypes: aged CXCR4^{hi} and reverse migrating ICAM1^{hi}CXCR1^{lo}. In the kidney, presence of CXCR4^{hi} neutrophil population followed expression of CXCR4 ligand, CXCL12, another marker of kidney injury. In the photoactivatable mouse model, photoconverted GFP+ skin infiltrating neutrophils were detected in the kidneys of mice one day after UVB light exposure.

Conclusion: Our findings provide several novel insights into the neutrophil response to UVB light: i) localized skin injury triggers systemic neutrophil migration, accompanied by inflammatory response and transient kidney injury and ii) presence of CXCR4^{hi} and ICAM1^{hi}CXCR1^{lo} neutrophil populations in peripheral organs suggests that a subset of activated skin-infiltrating neutrophils has migrated to distal organs via reverse transmigration.

Rab4A Increases Mitochondrial Oxidative Stress and Glutathione Disulfide Accumulation That Underlie Neurobehavioral Changes in Lupus-Prone Mice

Thomas Winans,[1] Tamas Faludi,[2] Brandon Wyman,[1] Nick Huang,[2] Joshua Lewis,[1] Manuel Duarte,[1] Laurence Morel,[3] Frank Middleton,[2] and Andras Perl[4], [1]Upstate Medical University, Syracuse, [2]Upstate Medical University, Syracuse, NY, [3]University of Florida, Gainesville, FL, [4]SUNY Upstate Medical University, Syracuse, NY

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: SLE – Animal Models Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The human GTPase HRES-1/Rab4 has been identified as a susceptibility locus for systemic lupus erythematosus (SLE) and is overexpressed in T cells of SLE patients [1]. HRES-1/Rab4 depletes DRP-1, a mitochondrial protein that initiates mitophagy, thereby increasing the mass of mitochondria [2]. Rab4A is the mouse orthologue of HRES-1/Rab4, which is overexpressed in lupus-prone mice [2]. Therefore, the role of Rab4A in disease pathogenesis has been modeled in Jurkat cells and investigated in lupus-resistant and lupus-prone strains carrying constitutively active Rab4A^{Q72L} alleles or lacking Rab4A in T cells.

Methods: Methods HRES-1/Rab4 was overexpressed in Jurkat cells using a doxycycline-inducible GFP-encoding bi-cistronic expression vector system. Mitochondrial function was assessed by Seahorse metabolic analyzer. The effect of Rab4A was examined in lupus-prone triple congenic SLE123 (SLE) mice and autoimmune resistant C57Bl/6 mice carrying wildtype (WT), constitutive active Rab4AQ72L, or Rab4-deficient alleles (Rab4KO) created through crossing of floxed Rab4AQ72L and CD4Cre mice. Q-Exactive Hybrid Quadrupole-Orbitrap Mass Spectrometer was used for targeted assessment of >800 metabolites. Mouse behavior was evaluated by the elevated plus maze and open field tests. Statistical analyses were performed by Student's T-test or Tukey's HSD ANOVA using GraphPad software and considered significant at $p< 0.05$ for hypothesis testing.

Results: Overexpression of HRES-1/Rab4 led to a significant increase in ATP production (fold change, FC=1.2, p= 0.03), % spare respiratory capacity (FC=1.2, p= 0.002), increased glutathione disulfide (GSSG, FC=4.3, p=0.04) and malondialdehyde (MDA, FC=1.2, p=0.01) in Jurkat cells. The Rab4A^{Q72L} mice traveled a significantly further distance than the WT mice (FC=1.5, p=0.03). The Rab4A^{Q72L} mice also traveled further than the SLE mice, SLE Rab4A^{Q72L} and SLE Rab4A^{Q72L} CD4Cre. Interestingly the deletion of Rab4A in the T cells in SLE mice increased the distance traveled significantly relative to SLE Rab4A^{Q72L} mice (FC=1.7, p=0.01). The Rab4A^{Q72L} mice entered the open arms of the maze more often than WT (FC=1.6, p=0.008). Rab4A^{Q72L} mice entered the open arm significantly more times than all SLE mice. Similar trends were seen in the open field test.

The brain metabolomes of Rab4A^{Q72L} mice showed a significant increase in GSSG (FC=1.4, p=0.02) and MDA (FC=1.6, p=0.04). SLE and SLE Rab4A^{Q72L} mice also had more GSSG (SLE: FC=1.5, p=0.04; SLE Rab4A^{Q72L}: FC=1.7, p=0.01) and MDA (SLE: FC=1.9, p=0.12; SLE Rab4A^{Q72L}: FC=2.5, p=0.02) than WT controls.

Conclusion: Activation of Rab4A increases mitochondrial oxidative stress and GSSG accumulation, which apparently underlie neurobehavioral changes in lupus-resistant and lupus-prone mice.

Dysfunction of TRIM21 Promotes Aberrant Plasmablast Differentiation in Systemic Lupus Erythematosus Due to the Reduction of TRIM21-mediated Ubiquitylation of IRF5

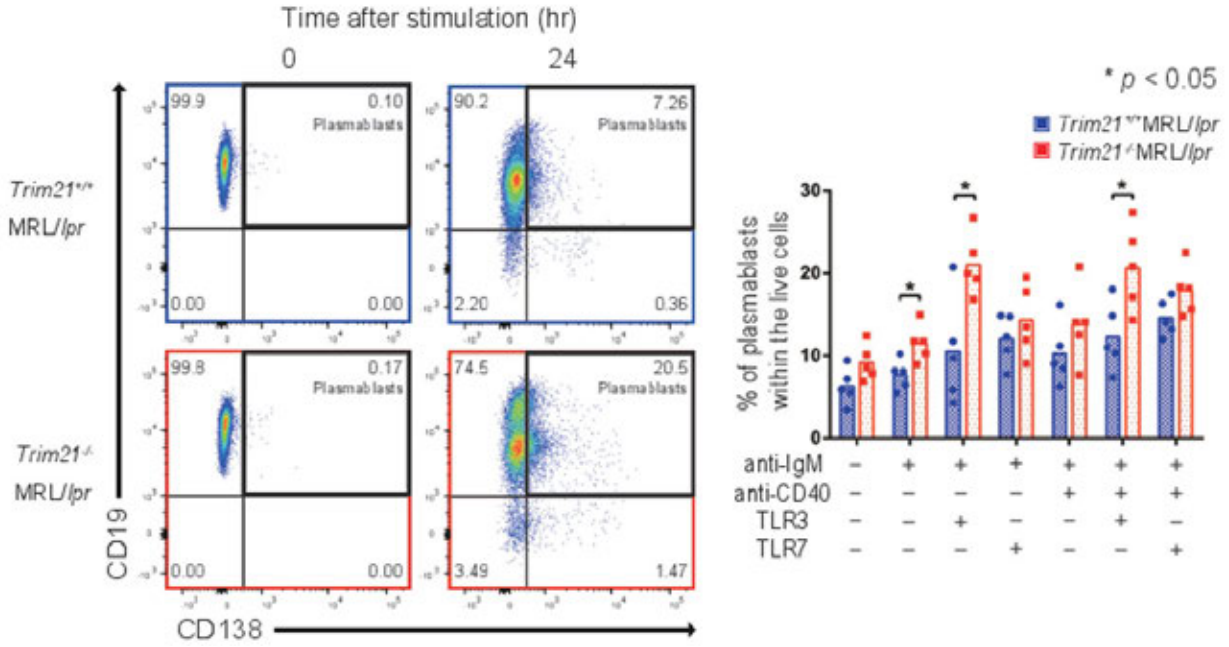
Yosuke Kunishita,[1] Ryusuke Yoshimi,[1] Reikou Kamiyama,[1] Daiga Kishimoto,[1] Koji Yoshida,[1] Eijin Hashimoto,[1] Yumiko Sugiyama,[2] Takaaki Komiya,[1] Natsuki Sakurai,[1] Yohei Kirino,[3] and Hideaki Nakajima[3], [1]Department of Stem Cell and Immune Regulation / Yokohama City University Graduate School of Medicine, Yokohama, Japan, [2]Department of Rheumatic Diseases / Yokohama City University Medical Center, Yokohama, Japan, [3]Department of Stem Cell and Immune Regulation, Yokohama City University Graduate School of Medicine, Yokohama, Japan

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: SLE – Animal Models Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: TRIM21 is a member of the tripartite motif family proteins and is one of the autoantigens which react with anti-SS-A antibody (Ab) present in sera of patients with systemic lupus erythematosus (SLE) and Sjögren's syndrome. Although TRIM21 has been thought to play a role in B-cell proliferation and apoptosis, the role of TRIM21 in SLE pathogenesis is still unknown. Previous studies have shown the data strongly suggesting that TRIM21 can act as a suppressor for autoimmune and inflammatory response and that its dysfunction can cause the pathological state of SLE. Here we examined the pathological role of TRIM21 in SLE using *Trim21*-deficient lupus model mice and B cells from SLE patients.

Methods: *Trim21*-deficient MRL/*lpr* mice were generated by backcrossing *Trim21*-deficient C57BL/6 mice to MRL/*lpr* mice. Urine albumin/creatinine ratio was measured as the urine protein level. Anti-dsDNA and anti-TRIM21 Abs were measured by enzyme-linked immunosorbent assay. CD43-negative resting B cells were isolated from mouse spleens or peripheral blood of SLE patients by magnetic-activated cell sorting and stimulated with several Toll-like

Figure 1. TRIM21 deficiency promotes aberrant B-cell differentiation in MRL/*lpr* mice.



receptor (TLR) ligands. The abilities to differentiate into plasmablasts and to product Ab were examined by flow cytometry and bead-based immunoassay, respectively.

Results: The levels of urine protein and serum anti-dsDNA Ab at 28 weeks of age were significantly higher in *Trim21*-deficient MRL/*lpr* mice as compared to wild-type MRL/*lpr* mice (p = 0.029 and 0.003, respectively). When we stimulated resting B cells from these mice with TLR ligands for 24 hours, B cells from *Trim21*-deficient MRL/*lpr* mice showed significantly higher abilities to differentiate into plasmablasts (Figure 1) and to produce Ab (Figure 2) as compared to wild-type MRL/*lpr* mice. Due to the reduction of TRIM21-mediated ubiquitylation, IRF5 protein expression was increased in *Trim21*-deficient MRL/*lpr* mice (p = 0.021), which correlated with increased plasmablasts generation. B cells from SLE patients with anti-TRIM21 Ab seropositivity also indicated significantly higher ability to differentiate into plasmablasts and to produce Ab as compared with SLE patients without anti-TRIM21 Ab seropositivity or healthy controls (Figure 3).

Conclusion: TRIM21 dysfunction promotes aberrant B-cell differentiation and Ab production in SLE. Anti- TRIM21 Ab may be related to the TRIM21 dysfunction in human SLE pathogenesis. These findings suggest that TRIM21 and anti-TRIM21 Ab can be promising targets for SLE treatment.Figure 1Figure 2Figure 3

Figure 2. TRIM21 deficiency promotes aberrant Ab production in MRL/*lpr* mice.

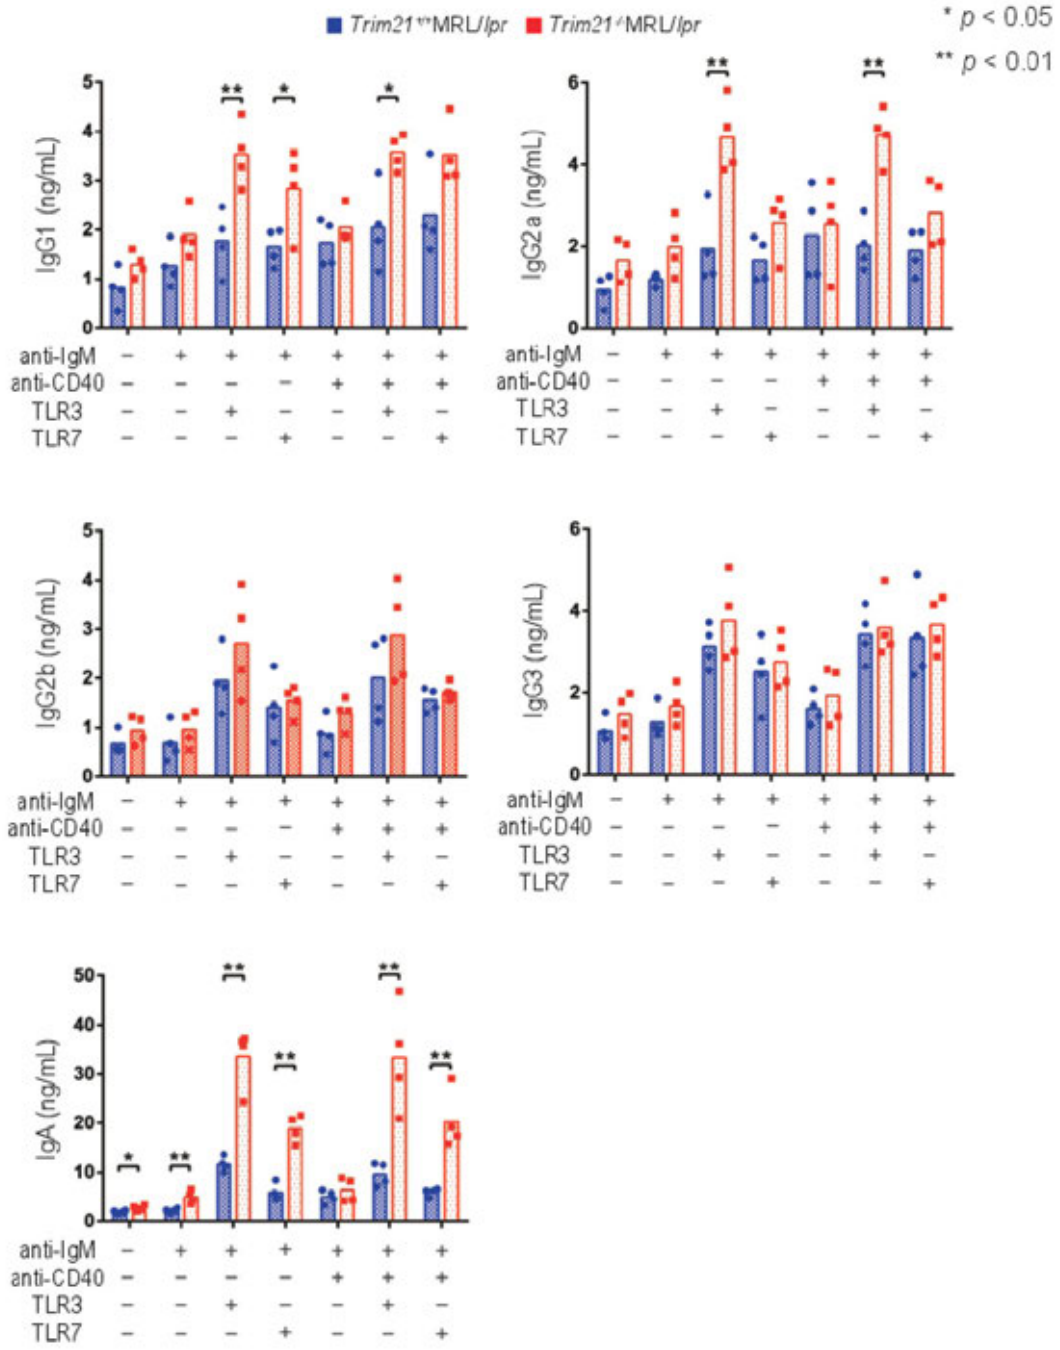


Figure 3. The seropositivity of anti-TRIM21 Ab is related to aberrant B cell differentiation in patients with SLE.

Cenerimod, a Potent and Selective Sphingosine-1-Phosphate Receptor 1 Modulator, Controls Systemic Autoimmunity and Organ Pathology in Mouse Models of Systemic Lupus Erythematosus and Sjögren's Syndrome

Estelle Gerossier,[1] Saba Nayar,[2] Charlotte Smith,[2] Sylvie Froidevaux,[3] Francesca Barone,[2] and **Marianne Martinic**[1], [1]Idorsia Pharmaceuticals Ltd., Allschwil, Basel-Landschaft, Switzerland, [2]Rheumatology Research Group, University of Birmingham, Birmingham, United Kingdom, [3]Idorsia Pharmaceuticals Ltd., Allschwil, Switzerland

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: SLE – Animal Models Poster

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Autoimmune diseases including SLE and SS are characterized by aberrant lymphocyte activation and autoantibody production. This results in systemic manifestations and the formation of tertiary lymphoid structures (TLS) leading to organ pathology, loss of organ function, and poor disease prognosis. SLE and SS are challenging to treat and are associated with mortality or severe disabilities.

Reported here are the proof-of-concept and efficacy of cenerimod, a potent, selective, and orally active sphingosine-1-phosphate receptor 1 ($S1P_1$) modulator, in mouse models of systemic (SLE) and organ-specific (SLE and SS) autoimmunity including TLS formation (SS).

Methods: SLE study: MRL/lpr mice were randomly assigned to either a cenerimod or vehicle group; the study was predefined to end when 20% mortality/morbidity was reached in one group. SS study: Salivary gland inflammation was induced in C57BL/6 (B6) mice by cannulation with replication-deficient adenovirus. B6 mice were therapeutically treated with either cenerimod or vehicle and sacrificed 15 days post cannulation. In both studies, target organs were evaluated for immune cell subsets, inflammatory cytokines, disease-relevant biomarkers, histopathology, and organ function.

Results: In the SLE study, all cenerimod-treated mice remained alive after 10 weeks of treatment, whereas >20% died in the vehicle group. Cenerimod-treated mice had significantly fewer circulating immune cells and immune cell infiltrates in kidneys, brain, and salivary glands. This translated to preserved organ function, with significantly reduced urine albumin concentration, kidney and brain histopathologic score, and local inflammatory milieu. Moreover, anti-dsDNA antibody and systemic BAFF and IFN-α levels were significantly reduced. In the SS study, cenerimod-treated mice displayed significantly reduced lymphocyte infiltration into salivary glands and abrogated expression of genes associated with TLS formation. Cenerimod induced TLS disaggregation and resolution of salivary gland inflammation with concomitant decreases in focus score, lymphoid structure size, and T/B-cell follicular organization, resulting in improved organ function with preserved saliva production.

Conclusion: Together, these data demonstrate that cenerimod treatment significantly ameliorated systemic and organ-specific autoimmunity, resulting in decreased inflammation and preserved organ function in animal models of SLE and SS. These results warrant investigation of cenerimod in autoimmune diseases characterized by systemic lymphocyte activation and organ damage. A phase 2b study evaluating the safety and efficacy of cenerimod in patients with SLE is currently recruiting (NCT03742037).

Selective Inhibition of the Immunoproteasome with KZR-616 Blocks Multiple Cell Signaling Pathways, Plasma Cell Signatures and Myeloid Cell Associated Damage in the NZB/W Lupus Nephritis Model

Tony Muchamuel,[1] Janet Anderl,[1] R Andrea Fan,[1] Henry Johnson,[1] Dustin McMinn,[1] and Christopher Kirk[1], [1]Kezar Life Sciences, South San Francisco, CA

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: SLE – Animal Models Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The immunoproteasome is a distinct class of proteasome found predominantly in immune effector cells and has been shown to play a distinct role in the regulation of the immune cell function. We have previously demonstrated that selective inhibition of the LMP7 and LMP2 subunit of the immunoproteasome with KZR-616 effectively blocks the progression of lupus in the NZB/W mouse model of lupus nephritis (LN), including reducing serum levels of anti-dsDNA antibodies**.** Here we describe changes to global gene expression in the spleens and kidneys of diseased mice following KZR-616 treatment.

Methods: The therapeutic effect of KZR-616 was examined in the NZB/W model of SLE. The degree of proteinuria (0 – 4 scale) was used to evaluate the severity of nephritis. Kidneys were harvested and stained with hematoxylin and eosin and anti-immunoglobulin G (IgG). RNA was extracted from spleens and kidneys of NZB/W mice after 11 weeks of subcutaneous KZR-616 treatment and evaluated by RNA sequencing analysis. Canonical pathways were analyzed using Ingenuity Pathway Analysis software.

Results: KZR-616 administration to mice resulted in selective inhibition of LMP7 and LMP2 by 91% and 71%, respectively, similar to levels of inhibition seen *in vitro* and previously reported data in humans at doses ≥ 30 mg (Lickliter et al. ACR 2017). KZR-616 treatment of diseased mice resulted in complete resolution of proteinuria and an absence of renal IgG deposition compared to vehicle treated animals. Consistent with these findings, we noted decreased gene expression associated with inflammation, the T helper (Th) 1 pathway, Th17 activation, interferon signaling, generation of antibody secreting cells, and plasma cell (PC) differentiation in the spleen. In the kidney, immunoproteasome inhibition abrogated transcripts associated with inflammation, cell and myeloid trafficking into the glomerulus as well as expression of renal ortholog genes previously identified to be differentially expressed in the glomerular and tubulointerstitial compartments in LN patients.

Conclusion: KZR-616 effectively blocks disease progression in a mouse model of SLE by regulating expression of genes that are involved in immune response and effector cell function, PC differentiation and antibody secretion, and glomerular and tubulointerstitial renal pathology. These experimental data support the ongoing clinical evaluation of KZR-616 in patients with LN.

THOR-809: An IL-2 Engineered from an Expanded Genetic Alphabet for the Potential Treatment of Autoimmune Disorders

Jerod Ptacin,[1] Carolina Caffaro,[1] Lina Ma,[1] Ingrid Joseph,[1] David Chen,[1] Taylor Ismaili,[1] Kristine San Jose,[1] Yelena Pavlova,[1] Namit Singh,[1] Lilia Koriazova,[1] Hans Aerni,[1] Michael Pena,[1] Jill Mooney,[1] and Marcos Milla[1], [1]Synthorx, La Jolla, CA

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: CD4+ regulatory T cells (Tregs) play a crucial role in maintaining immune homeostasis. Treg dysfunction is associated with multi-organ autoimmune (AI) and inflammatory-related diseases. Treg-mediated

down-modulation of the immune effector function (Teffs and T helpers) that prevents antigen recall may reset immune tolerance in select AI disorders.

A current focus for therapeutic intervention of autoimmune disorders includes cytokine therapies such as IL-2. Administered at low dose, IL-2 induces limited expansion of CD4+ regulatory T cells (Tregs) and showed therapeutic benefit in chronic graft-versus-host disease (cGVHD) and HCV-induced vasculitis and is currently in clinical investigation for treatment of diverse Tcell-mediated autoimmune disorders. However, the sub-optimal pharmacological properties of IL-2 complicate administration and may limit the efficacy of low dose IL-2 therapy. Multiple IL-2 muteins, most of them consisting of fusions to IgG or its Fc domain, are in pre-clinical and clinical development, to address the pharmacokinetic and pharmacodynamic liabilities of low dose IL-2.

Methods: To engineer an improved IL-2 for autoimmune therapy, we applied our recombinant platform technology that expands the genetic code by adding a new DNA base pair. This allows for optimization of proteins through incorporation of novel amino acids encoded by our new DNA base pair, enabling site-specific modifications that enhance the pharmacological properties of these therapeutics. Here we report on the discovery of a site-specific, covalently-pegylated IL-2 that has substantially improved pharmacologic properties over native IL-2 for expansion of Tregs.

Results: Screening of distinct site-specific PEG-IL-2 conjugates in vitro and in mouse identified THOR-809, which showed significantly improved half-life and sustained exposure. In mouse, THOR-809 preferentially stimulated proliferation of peripheral Tregs relative to Teffs (no expansion) and NK cells (minimal expansion). Expanded Treg populations demonstrated significant upregulation of markers that correlate with Treg suppressive function, including FoxP3, CD25, ICOS and Helios. In Cynomolgus monkey, subcutaneous dosing of THOR-809 demonstrated dose-dependent proliferation and activation of peripheral Tregs with no detectable proliferation of Teffs or NK cells up to 200 mcg/kg. We also show that PEG length and shape influences the half-life and pharmacodynamic response for expansion of Tregs in vivo.

Conclusion: Overall, our results indicate that THOR-809 is an IL-2 tuned for biased activation and expansion of Treg cells, with no activation and expansion of Teff or NK cells. These findings support the development of THOR-809 as a treatment for AI disorders.

KINE-101, a Novel Synthetic Peptide with Potent Regulatory T Cells Activation to Treat Rheumatoid Arthritis

Myun Soo Kim,[1] Sora Lee,[1] Jung Hyun Roh,[1] Jung A Kwon,[1] **Sunyoung Park**,[1] and Daeho Cho[2], [1]KINE SCIENCES Co. Ltd., Seoul, Republic of Korea, [2]Institute of convergence science/Korea university, Seoul, Republic of Korea

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Medical and patient unmet needs still existed in rheumatoid arthritis (RA) global market due to the side effects treated for long duration and sometimes non-response to existing medicines. We developed a novel synthetic peptide, KINE-101 with distinct mode of action to activate the regulatory T (Treg) cells.

Methods: The efficacy of KINE-101 was investigated by collagen-induced arthritis (CIA) mouse model. The activity and differentiation of Treg cells by KINE-101 were determined by FACS analysis using various Treg cells markers. Treg cells depletion study was evaluated using CD25 antibody. Autoantibody production was measured by ELISA and germinal center B cells were stained with B cells markers. Osteoclastogenesis was assessed Safranin O staining using joint tissue section. Preliminary toxicology study was accomplished to confirm the safety of KINE-101.

Results: In CIA model, KINE-101 showed similar efficacy in controlling arthritis index compared to MTX. Surprisingly, activation and differentiation of Treg cells were significantly increased by treatment of KINE-101. The effect of KINE-101 mediated by Treg cells was confirmed by Treg cell depletion study in CIA mouse model. Moreover, collagen type II specific autoantibody production were dramatically decreased and germinal center B cells were inactivated by treatment of KINE-101. Safranin-O staining results show KINE-101 suppresses cartilage damage through inhibiting osteoclastogenesis. No significant toxicological findings were observed as a result of preliminary toxicology study.

Conclusion: We developed a novel synthetic peptide, KINE-101, for the treatment of rheumatoid arthritis. KINE-101 shows high remission of RA symptoms in CIA model by activating Treg cells resulting in reduction of autoantibody production. These results suggest that KINE-101 may serve as a first-in-class therapeutic to control autoimmune diseases with Treg cells regulation.

Type I Interferon Signature Activation in Antiphospholipid Syndrome: Gene Expression Heterogeneity Among Disease Subsets

Irene Cecchi,[1] Massimo Radin,[1] Elena Rubini,[1] Silvia Grazietta Foddai,[1] Ana Suarez,[2] Elisa Menegatti,[1] Dario Roccatello,[1] Savino Sciascia,[3] and Javier Rodriguez Carrio[2], [1]University of Turin, Turin, Italy, [2]University of Oviedo, Oviedo, Spain, [3]Center of Research of Immunopathology and Rare Diseases- Coordinating Center of Piemonte and Valle d'Aosta Network for Rare Diseases, Department of Clinical and Biological Sciences, University of Turin, Torino, Italy

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Type I Interferons (IFN) play a key role in the pathogenesis and evolution of various autoimmune diseases. Previous studies have demonstrated that the expression of a number of genes regulated by type I IFN, the so-called "*IFN signature*", has been related with disease activity and clinical features in systemic lupus erythematosus (SLE) patients and other systemic conditions. However, differences in the degree of activation and gene diversification have been reported among diseases and even at the disease level. To date, a limited number of studies have analysed the IFN signature in antiphospholipid syndrome (APS) setting, both primary (PAPS) and when associated with other autoimmune conditions (secondary APS, SAPS). This study aims to describe the activation and structure of the type I IFN signature among different subsets of APS.

Methods: A total of 116 patients were enrolled, including 19 PAPS patients, 13 SAPS, 75 SLE patients, and 9 antiphospholipid antibodies positive individuals ("*aPL carriers*"). Thirty-two subjects were also recruited as healthy controls (HC).

IFI44, IFI44L, IFI6, MX1 and IRF4 gene expression was determined in whole blood in the entire cohort. Expression levels were normalized to Z-scores and averaged into a global IFN signature. Differences were measured by Kruskal-Wallis tests and associations among genes were studied by cluster and correspondence analyses. Correlations were plotted by network analyses.

Results: A global activation of the type I IFN signature was observed (HC: -0.44±0.08, aPL carriers: -0.38±0.12, PAPS: -0.31±0.80, SAPS: -0.17±0.39, SLE: 0.09±0.80; p(Kruskal-Wallis)< 0.001).Certain heterogeneity was observed among interferon regulated genes (IRG): MX1 being increased in all patient groups (all p< 0.001), whereas IFI44 was only increased in SLE (p< 0.001) and PAPS (p< 0.001), and both IFI44L and IFI6 were increased in SLE (both, p< 0.001) and a trend was observed in SAPS (p=0.060 and p=0.080). By means of an unsupervised analysis, 3 clusters (I to III) were identified, which correlated with clinical status of the patients by correspondence analysis (p< 0.0001, Figure 1a). Network analyses revealed different structures of the IRGs networks among groups, from weaker networks in HC and aPL carriers to stronger degree of correlations among IRGs in SAPS and SLE, thus pointing to diverse

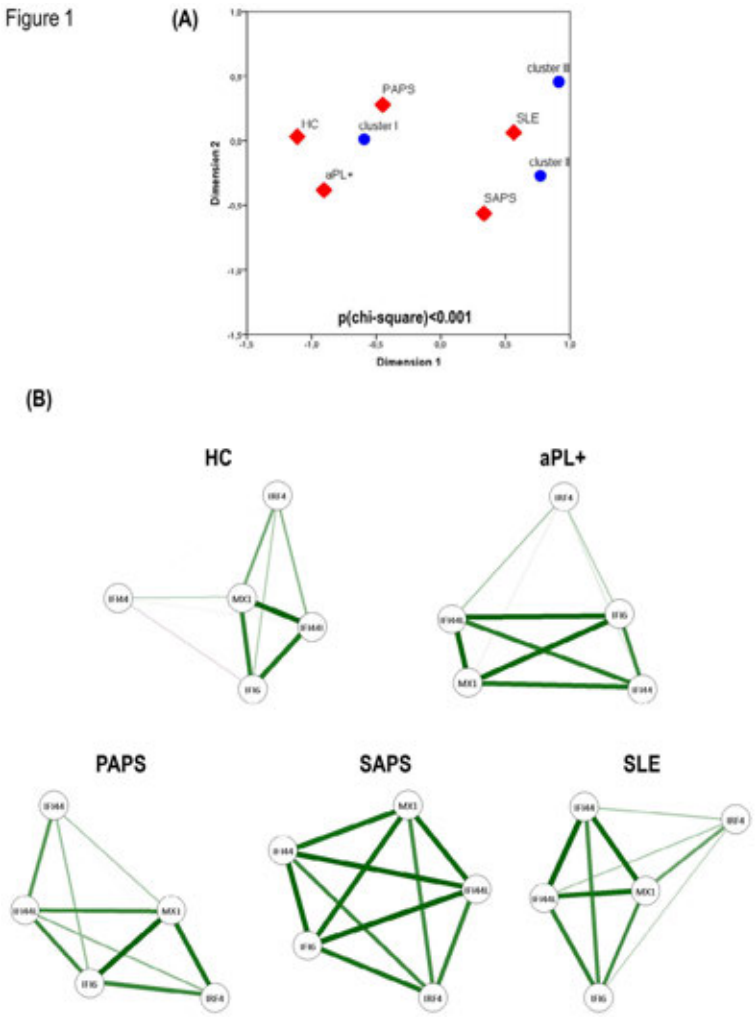

Figure 1. Panel A) Clusters analysis, correlated with clinical status of the patients by correspondence analysis (p<0.0001). Panel B) Network analyses of the interferon regulated genes networks among groups.

expression programs (Figure 1b). Among APS patients (both SAPS and PAPS), the IFN signature was positively associated with anti-phosphatidylserine/prothrombin antibodiesIgG levels (r=0.478, p=0.003), but no associations were observed for the IgM isotype nor with other autoantibodies specificities (all p >0.050). No associations were observed with traditional cardiovascular risk factors or current treatments (all p >0.050).

Conclusion: APS is associated with a broad type I IFN activation, with a notable heterogeneity within the IFN signature structure among clinical subsets.

Difference of Induced CD4+ and Natural Regulatory T Cells in Targeting Inflamed Synovial Tissues in Autoimmune Arthritis

Ximei Zhang,[1] Julie Wang,[2] Nancy Olsen,[3] Wael Jarjour,[4] and Song Guo Zheng[4], [1]Ohio State College of Medicine, Columbus, [2]Ohio State University, columbus, [3]Penn State University, Hershey, PA, [4]Ohio State College of Medicine, Columbus, OH

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Enhanced evidence supports that autoimmune diseases often result from an imbalance between regulatory T cells (Treg**s**) and interleukin-17-producing T helper (Th17) cells. However, under inflammatory arthritic conditions, natural Treg cells (nTregs) lose Foxp3 expression and undergo transdifferentiation into Th17 cells, which has a key role in the pathogenesis of autoimmune arthritis. Our previous data showed that induced iTregs are able to alleviate collagen-induced arthritis(CIA), which inspired us to study the characteristics and functional difference between nTreg and iTreg especially their interaction with inflamed synovial fibroblast cells (ISFs), since ISFs are the most prominent player in both inflammation and joint destruction in rheumatoid arthritis.

Methods: To determine the stability of iTregs or nTregs in the present of ISFs isolated from CIA mice, iTregs or nTregs were co-cultured with ISFs and the expression of Foxp3 and IL-17a was detected by flow cytometry. We also pretreated nTreg and iTreg with ISFs and then compared their suppressive activities against effector T cells. Additionally, iTregs and nTregs were co-cultured with ISFs, and the production of the pro-inflammatory factors TNF-α, IL-6, IL-12, IL-18, IL-1β, IL-11, IL-15, MCP-1, MMPs, as well as anti-inflammatory cytokines IL-10, IL-1R by ISFs were measured by qPCR, the tumor-like biologic behaviors of ISFs were detected by CCK-8 (proliferation) or crystal violet staining (migration and invasion). To determine the function of nTreg and iTregs on ISFs in CIA mice, ISFs isolated from CIA mice treated with nTregs or iTregs were also subjected to detect the expression of the pro-inflammatory factors and observe their tumor-like biologic behaviors. Finally, we also treated colitis mice with nTregs or iTregs that had been pretreated with or without ISFs to determine their difference in treating an inflammatory disease.

Results: iTregs are more stable functional in the presence of ISFs relative to nTregs. iTreg maintained most Foxp3 and less are converted into Th1 and/or Th17 cells when explored with ISFs. Moreover, ISFs treated with iTregs but not nTregs show reduced expression of pro-inflammatory factors and matrix metalloproteinases and suppressed tumor-like biologic behaviors, with lower proliferation, migration and invasion. In line with results in vitro, infusion of iTregs are more functional to reduce the activation of osteoclasts and bone erosion in CIA mice. ISFs isolated from CIA

treated with iTregs also showed reduced expression of pro-inflammatory factors and matrix metalloproteinases and suppressed tumor-like biologic behaviors when compared to treated with nTregs. Adoptive transfer of iTregs that had been pretreated with ISFs are still able to alleviate colitis, while nTreg lost the therapeutic effects on colitis although they are effective if they are not pretreated with ISFs.

Conclusion: iTregs could be more stable and functional than nTregs in the environment of inflammatory synovial tissues in autimmune arthritis. The manipulation of iTreg therapy may provide an advantage strategy in treating patients with rheumatoid arthritis in the future.

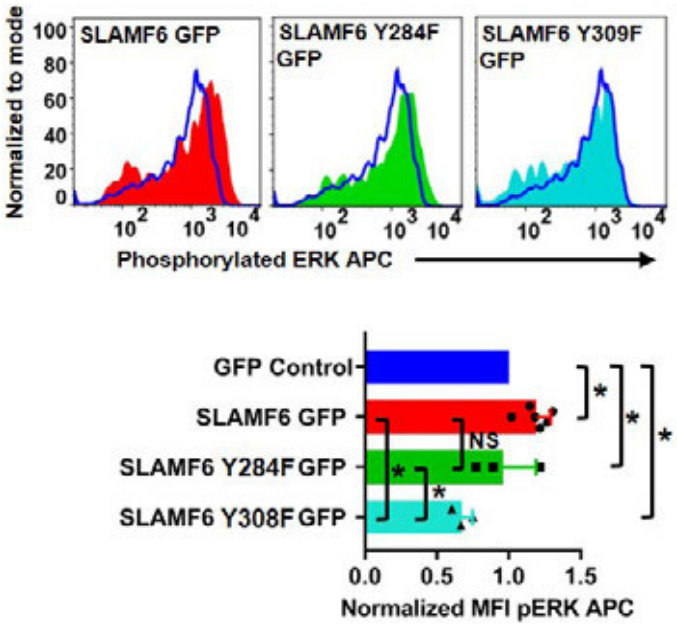
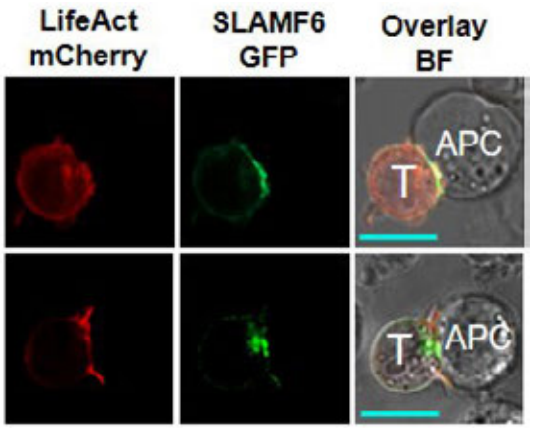
SLAMF6 Clustering Is Required to Augment Autoimmune T Cell Activation

Matthew Dragovich,[1] and Adam Mor[2], [1]Columbia University, New York, NY, [2]Columbia University School of Medicine, New York, NY

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The signaling lymphocytic activation molecule (SLAM) family is encompassed by nine distinct receptors that are hematopoietic restricted. Among these, SLAMF6 is highly expressed in autoimmune T cells and genetic variants have been reported in both rheumatoid arthritis and systemic lupus erythematous. Moreover, previous studies as well as our own data, have suggested that anti-SLAMF6 antibodies can have a therapeutic effect in autoimmunity. However, little is known about the role of SLAMF6, specifically in T cell responses. To utilize SLAMF6 interventional approaches, a better understanding of the biology of this receptor in T cell is required. The goal of this





work is to uncover SLAMF6 downstream signaling and function in the context of neutralizing antibodies (Abs). We hypothesis that the SLAMF6 is a co-stimulatory receptor in T cells and that blocking its function should disrupt T cell receptor (TCR) signaling, specifically in activated autoimmune T cells.

Methods: Primary human T cells were collected from healthy volunteers and from patients with rheumatoid arthritis. Cells were treated with anti-CD3 Abs ± anti-SLAMF6 Abs or anti-CD3 abs ± anti-SLAMF6 monobodies. Cytokine release was measured by ELISA and proliferation was recorded by CFSE dilution assay. SLAMF6 gene was deleted in Jurkat T cells using shRNAs and CRISPR-Cas9, prior to a set of rescue experiments with different versions of mutated SLAMF6 gene. These cells were analyzed by western blot and flow cytometry to illustrate signaling downstream of SLAM6. Confocal microscopy imaging was performed to determine the spatial location of SLAMF6 in the immunological synapse during contact with an antigen presenting cell.

Results: Our experimental data shows that SLAMF6 was obligatory for TCR downstream signaling. Remarkably, SLAMF6 ectodomain was required for its function, yet not for its conscription to the immunological (IS) synapse. Flow-cytometry analysis established that tyrosine 308 of the tail of SLAMF6 was crucial for its ability to augment T cell function (Image 1). Imagining studies revealed that SLAMF6 clustering, with the TCR resulted in a dramatic rise in downstream signaling (Image 2). Mechanistically, we showed that SLAMF6 improved T cell function by increasing T cell adhesivity through activation of the small GTPase Rap1.

Conclusion: We have shown that SLAMF6 ligation via antibodies can deliver a vital co-stimulatory signal to increase TCR activation. This behavior includes increasing cytokine secretion, proliferation,ERK, ZAP70 and AKT phosphorylation and cellular adhesion through Rap1 activation. Our findings propose that during TCR engagement SLAMF6 is transported to the IS independent of its ectodomain where it is engaged by another SLAMF6 molecule through the ectodomain to undergo proper function as a stimulatory co-receptor. SLAMF6 is then deliver a co-stimulatory signal dependent on tyrosine 308 into the T cell. By elucidating the mechanism by which SLAMF6 operates in the TCR pathway, we have provided a model for designing interventional approaches for the treatment of autoimmune diseases where SLAMF6 plays a functional role.

Characteristic histograms of phosphorylated ERK. Jurkat T cells were transfected with GFP control, SLAMF6 GFP, SLAMF6 Y284F GFP and SLAMF6 Y308F GFP then stimulated with CD3 antibodies. After fixation and permeabilization the cells were stained and subjected to flow cytometry. Only GFP positive cells were analyzed for phosphorylated ERK APC. Quantification for a minimum of three independent experiments (n=3-6). *$p<0.05$ for an unpaired student t-test. Images and data were adapted from our publication also titled “SLAMF6 Clustering Is Required to Augment T Cell Activation” in press at PLOS ONE (10.1371/journal.pone.0218109).

Jurkat T cells had been transfected with LifeAct mCherry and SLAMF6 GFP then co-cultured with antigen presenting Raji B cells (APC) (top row) or APCs with SEE (bottom row). Scale bar is 10μm. Images were adapted from our publication also titled “SLAMF6 Clustering Is Required to Augment T Cell Activation” in press at PLOS ONE (10.1371/journal.pone.0218109).

Session Title: T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Despite enormous efforts to develop new therapeutic strategies for treatment of rheumatoid arthritis (RA), the large number of non responding patients to currently available drugs underlies the unmet need to identify new therapeutic targets. Certain $CD4^+$T cell subsets, especially Th17 cells, have been shown to be major drivers of inflammation in patients with RA. The expression of their key transcription factors is controlled by histone modifications which includes acetylation of *lysine residues* mediated by histone deacetylases (HDAC). Indeed, pan HDAC inhibitors have been shown to be a potential therapeutic strategy. However, major side effects limited the clinical use and underline the need of more specific HDAC inhibitors. We therefore addressed the individual role of HDAC1 on the development of collagen-induced arthritis model (CIA).

Methods: Methods: Mice with a T cell specific deletion of HDAC1 (HDAC1cKO) were generated by using the CD-4Cre/LoxP system. Collagen induced arthritis (CIA) was induced at week 8. Animals were scored for paw swelling and grip strength. After 10 weeks, mice were sacrificed and paraffin sections of the affected joints were analysed for histomorphologic signs of inflammation, cartilage and bone destruction. Anti-CII antibody levels were determined by ELISA. Serum samples were analysed for various cytokines by multiplex assays. CCR6 expression in CD4 T cells was analysed by flow cytometry.

Results: To address potential effects of HDAC1 in the pathogenesis of RA, CIA was induced in *HDAC1cKO* mice and *WT* mice. Surprisingly *HDAC1cKO* mice were completely protected from the development of arthritis. In line with the clinical data, histological analysis revealed no signs of inflammation, no bone erosion and no osteoclasts in the joints of *HDAC1cKO* mice. Anti-CII antibodies, including total IgG and igG2c were detected in *HDAC1cKO* and *WT* mice. Surprisingly, IL-17 was significantly decreased in the serum of *HDAC1cKO* mice as compared to *WT* mice, suggesting a role of HDAC1 in the development of Th17 cells. To see whether HDAC1 is involved in the regulation of the chemokine receptor 6 (CCR6), the main marker of Th17 cells, we compared the upregulation of CCR6 in $CD4^+$ T

cells from *WT* and *HDAC1cKO* mice. Indeed, CCR6 could not be upregulated in $CD4^+$ T cells from *HDAC1cKO* mice upon IL-6 *in vitro*. These data support the role of HDAC1 in the regulation of CCR6, an important chemokine receptor, which is necessary for the migration of pathogenic Th17 cells and therefore for the development of arthritis.

Conclusion: Our data show the importance of HDAC1 as a key immune regulator in the pathogenesis of T cell driven collagen induced arthritis. Therefore, it might be considered as an interesting novel therapeutic target in RA.

Negative Immune Checkpoint Molecules on T Regulator Cells Distinguish RA, SLE and Healthy Controls

Barbara Dreo,[1] Barbara Prietl,[2] Selina Kofler,[2] Harald Sourij,[2] Angelika Lackner,[1] Florentine Moazedi-Fuerst,[1] Monica D'Orazio,[1] Martin Stradner,[1] Winfried Graninger,[1] and Hans-Peter Brezinschek[1], [1]Department of Internal Medicine/Division of Rheumatology and Immunology, Graz, Austria, [2]2CBmed GmbH – Center for Biomarker Research in Medicine, Graz, Austria

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: T regulatory cells (Treg) play a crucial role in the regulation of the immune response and therefore are of utmost interest when studying autoimmune diseases, such as rheumatoid arthritis (RA) and systemic lupus erythematosus (SLE). Therefore, targeting specific Treg markers in therapy is now widely discussed. Expression of T cell immunoglobulin 3 (TIM-3) is associated with an enhanced immune suppression and is currently discussed as target in cancer therapy. Fc receptor-like protein 3 (FCLR-3), which regulates Treg proliferation, was shown to be associated with the susceptibility in juvenile RA. Other surface markers, like CD161 enable Treg to produce IL-17A, IFNγ and IL-2, hence promoting inflammation. The aim of this study was to distinguish between RA and SLE using anti-and pro-inflammatory cell markers.

Methods: Peripheral blood samples from 66 patients suffering from RA (mean ± SD; age 60 ± 10 years, female ratio: 0.68, disease duration 18 ± 14 years), 40 SLE patients (age 42 ± 13 years, female ratio 0.85, disease duration 11 ± 13 years) and 72 age-matched healthy participants (age 46 ± 17 years, female ratio 0.68) were drawn over a sampling period of two years. Freshly isolated PBMCs were stained and Treg subsets were identified by the expression of CD25, CD127, FoxP3, CD45RA and CD15 on the surface of $CD3^+CD4^+$ T cells. $CD25^+CD127^+CD45^-$ Treg were further subclassified by the expression of TIM-3 (CD366) and FCLR-3 (CD307c). CD161 was used to identify Th17 type Treg ($CD15S^-CD161^-$) and transitional Treg ($CD15S^-CD161^-$). All cytometric measurements were performed using a standardized BD LSR Fortessa platform.

Results: Transitional Treg ($CD15S^-CD161^-$) were significantly higher ($p < 0.001$) in RA patients compared to the SLE and healthy cohort (40.5 ± 13.4% vs. 28.7 ± 9.6% and 29.7 ± 9.4% respectively). However, differences in the $CD161^+$ Th17 type Treg population could not be detected. Treg expressing TIM-3 were higher in both RA and SLE patients compared to healthy controls (2.8 ± 2.3%, $p = 0.0105$ and 2,.6 ± 1.6%, $p = 0.0031$ vs. 0.8 ± 0.7% respectively), but did not differ between the rheumatic diseases. On the other hand, FCLR-3 positive Treg distinguished RA and SLE

patients (17.8 ± 13.3 vs. 25.3 ± 13.1%, p = 0.0036), as well as SLE patients from healthy controls (16.8 ± 12.9%, p = 0.0112). All findings were not correlated with the disease activity of RA or SLE patients.

Conclusion: Expression of the negative immune checkpoint molecules TIM-3 and FCRL-3 not only distinguish healthy controls from patients suffering from RA or SLE but can be used to differentiate between different autoimmune diseases. These findings indicate that the regulation of the immune response in RA and SLE is triggered by Treg, yet the activation of different Treg subset is disease-specific.

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: T and B cells come together in ectopic lymphoid aggregates in myositis, suggesting that local T:B cell interactions could play a role in disease. T follicular helper cells are increased in circulation in patients with active myositis. We studied circulating Tfh cells from myositis patients using single-cell RNA-sequencing and examined the proximity of Tfh cells to B cells in patient biopsies.

Methods: Tfh cells [$CD3^{+}CXCR5^{+}PD\text{-}1^{+}CXCR3^{neg}$ and $CD3^{+}CXCR5^{+}PD\text{-}1^{+}CXCR3^{pos}$] cells were sorted from peripheral blood and subsets were identified by chemokine markers to designate Tfh1 and Tfh2/17 cell subsets. RNA sequencing was performed on individual cells of (3 controls and 3 myositis patients) using Fluidigm C1 HT platform, and data were analyzed using a pseudo-temporal ordering using Monocle. Biopsies were stained using the OPAL standardized sequential immunofluorescence method for PD-1, CXCR5, CD19, and CD4 in human muscle, and machine learning was used to map proximity of B cells to all T-cells compared with Tfh cells.

Results: We found various subsets within the Tfh pool, corresponding to Tfh1 and Tfh2/17 cells and some cells that looked to be transitioning between states. Tfh2/17 were enriched in myositis patients vs. controls. The Tfh2/17 cells demonstrated a type I interferon signature, while the Tfh1 cells had a type II interferon and proteasome signature. In tissue, we demonstrate Tfh cells in close proximity to B cells in lymphoid aggregates.

Conclusion: Tfh cells are present in myositis biopsies juxtaposed to B cells, suggesting productive T:B interactions in the tissue. Tfh subsets in blood from patients demonstrate distinct pathological signatures when compared to controls.

Session Title: T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Tumor Necrosis Factor (TNF) α is a multifunctional cytokine with pro-inflammatory and anti-inflammatory characteristics. Regulatory T cells (Treg) express a remarkably high level of TNF Receptor 2 (TNFR2). TNFα modulates the proliferation and function of Treg via TNFR2. Recently, a subset of CD4+ Treg termed follicular regulatory T (Tfr) cells has been found in the lymphoid organs and blood of animals and humans. Function of human Tfr in vivo is not well understood, however it has been shown that Tfr cells limit the function of Tfh cells and repress immunoglobulin secretion from B cells in vitro. Altered number and ratio of Tfr in several autoimmune diseases have been reported, indicating that Tfr might contribute the immunological abnormality in these patients. TNF-R2 signaling enhances suppressive activities in Treg, on the other hand it is still unclear whether Tfr response to TNF-α via TNF-R2. We examine the role of TNF-R2 signaling in this new regulatory cell subset.

Methods: We sorted Tfr(CD3+ CD4+ CXCR5+ CD25+ CD127low or CD14-CD4+ CXCR5+ CD25+ CD127low) and Treg(CD3+ CD4+ CXCR5- CD25+ CD127low or CD14- CD4+ CXCR5- CD25+ CD127low) from mononuclear cells of healthy donor using FACS Aria.

We examined the proliferation and suppressive ability of these cells stimulated with an anti- TNF-R2 agonistic antibody in vitro and performed the transcriptome analysis by RNA-seq.

Results: Foxp3 expression was upregulated in both cell types after stimulation with TNFR2 agonists. TNFR2 agonists greatly enhanced proliferation of Tfr and Treg. Although unstimulated Tfr did not suppress expansion of Tconv (CD14-CD4+ CXCR5- CD25- CD127high) or Tfh(CD14- CD4+ CXCR5+ CD25- CD127high), Tfr stimulated with TNFR2 agonists suppressed expansion of these cells. In coculture with naïve B cells and Tfh cells, TNF-R2-stimulated Tfr suppressed differentiation of naïve B cells into antibody-producing cells and production of immunogloblin from B cells. RNA-seq revealed altered transcriptome of these TNF-R2-stimulated cells in co-stilmulatory/inhibitory molecules and known Treg associated genes (i.e. Foxp3, CTLA-4, LAG3, etc.). Tfr and Treg showed mostly similar gene expression flux, however part of genes was differently regulated.

Conclusion: TNFR2 agonist enhanced proliferation and suppressive function in Tfr in vitro assays. It suggests that Tfr response to TNF-R2-stimulation similarly with Treg, however in part RNA-seq data showed different response after TNF-R2-stimulation between Treg and Tfr. TNF-R2 agonist might be one of the therapeutic strategies in autoimmune diseases.

Abstract Number: 0095

IL-21-mediated Suppression of STAT5 Phosphorylation Underlies Treg Depletion and Dysfunction in SLE

Hiroshi Kato,[1] and Andras Perl[1], [1]SUNY Upstate Medical University, Syracuse, NY

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: IL-21 activates mechanistic target of rapamycin (mTOR) complexes 1 and 2 which in turn block regulatory T (Treg)-cell differentiation and function in patients with SLE. While both IL-21 and IL-6 phosphorylate STAT3 in $CD4^+$ T cells cultured under Treg-polarizing conditions, only IL-21 stimulates mTOR and abrogates Treg-cell differentiation in humans (*Arthritis Rheumatol. 2018 Mar;70(3):427-438*). This suggests that IL-21 blocks Treg-cell differentiation through an mTOR-dependent, but STAT3-independent mechanism. However, it remains unclear how IL-21-driven mTOR activation elicits Treg-cell depletion and dysfunction in SLE.

Methods: Naïve $CD4^+$ T cells from 9 pairs of matched SLE and healthy control (HC) subjects were cultured for 24 hours in the presence of anti-CD3/CD28, TGF-β (5 ng/ml), and IL-2 (50 IU/ml) (hereafter designated Treg-polarizing conditions) with or without IL-21 (10 ng/ml). As a control, $CD4^+$ T cells from 3 matched SLE and HC subjects were cultured for 72 hours in the presence of anti-CD3/CD28 and TGF-β (20 ng/ml) with or without IL-2 (100 IU/ml). Expression and phosphorylation of STAT5 at tyrosine 694 were detected by immunoblotting. The signal intensity of phospho-STAT5 was normalized to that of actin. Statistical significance was determined by a two-tailed t-test using GraphPad Prism version 5 software.

Results: IL-2 induced the phosphorylation of STAT5 in CD4+ T cells from patients with SLE ($p< 0.005$). Conversely, IL-21 suppressed STAT5 phosphorylation in naïve CD4+ T cells cultured under Treg-polarizing conditions both in HC and SLE subjects ($p< 0.05$). Following 24 hours of Treg polarization, CD4+ T cells from SLE patients exhibited diminished STAT5 phosphorylation as compared with those from HC subjects ($p< 0.05$).

Conclusion: In light of the essential roles for STAT5 in Treg-cell differentiation, our data suggests that IL-21-mediated suppression of STAT5 phosphorylation underlies the Treg-cell depletion and dysfunction in patients with SLE.

Session Title: T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

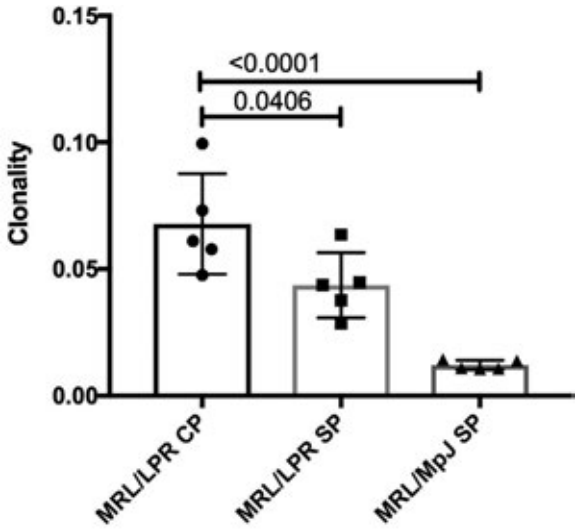

Figure 1A: Sample clonality of MRL/lpr CP T cells, MRL/lpr splenic (SP) T cells, and MRL/MpJ splenic (SP) T cells

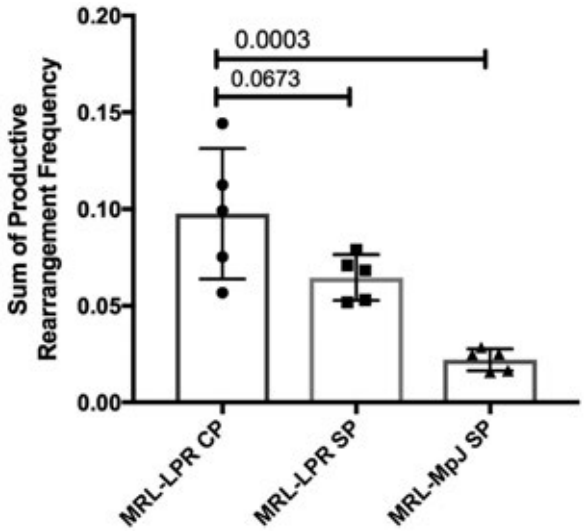

Figure 1B: Abundance of top 10 productive TCR rearrangements for MRL/lpr CP T cells, MRL/lpr splenic (SP) T cells, and MRL/MpJ splenic (SP) T cells

Background/Purpose: Approximately 40% of SLE patients experience neurological and/or psychiatric disorders, including cognitive abnormalities, mood disorders, confusion, psychosis, and seizures. However, the pathogenesis of neuropsychiatric SLE (NPSLE) is complex, and as of yet incompletely understood. We have previously demonstrated that the brain choroid plexus (CP) in the spontaneous MRL/lpr lupus mouse model, a strain which displays affective abnormalities and cognitive dysfunction similar to human NPSLE, is heavily infiltrated with effector T cells. In this study, we investigated T cell receptor (TCR) usage and repertoire diversity in CP infiltrating T cells, to enhance our understanding of this T cell population and its possible contribution to neuropsychiatric disease. In addition, since MRL/lpr mice exhibits T cell proliferation in other parenchymal organs (e.g. lungs and salivary glands), we sought to confirm that the brain T cell infiltration is organ specific.

Methods: Choroid plexuses and spleens were dissected from female MRL/lpr mice (n=5 per group) and MRL/MpJ mice (n=5) (the congenic control) at 16 weeks of age, by which time MRL/lpr mice display profound neurobehavioral deficits. The TCR repertoire was evaluated by isolating genomic DNA from choroid plexus and spleen, and amplifying the CDR3 sequence by multiplex PCR (Adaptive Technologies). The samples were evaluated with the Adaptive Technologies immunoSeq Analyzer and the R package, LymphoSeq.

Results: MRL/lpr CP tissues had significantly increased clonality, derived from the Shannon entropy, as compared to both MRL/lpr and MRL/MpJ splenic tissues ($p = 0.0406$ and $p < 0.0001$ respectively). Similarly, T cells infiltrating the CP demonstrated enhanced oligoclonality, as seen by higher Gini coefficients ($p = 0.0074$ and $p < 0.0001$, respectively, Figure 1A). The abundance of the top 10 productive rearrangements was increased in MRL/lpr CP when compared to the MRL/lpr and MRL/MpJ splenic tissues ($p = 0.0673$ and $p = 0.0003$ respectively), as was the maximum productive frequency (Figure 1B). There was no difference in the gene usage or CDR3 length between the groups. Interestingly, there was an increased sample overlap for tissues originating from the same mouse rather than by organ type.

Conclusion: The results indicate that there is an increased oligoclonal expansion of T cells occurring in the CP of MRL/lpr mice compared to splenic tissues, suggesting antigen-driven brain T cell infiltration and expansion. Further comparative phenotyping of T cells found in different organs (lung, salivary glands, kidney) in the lupus strain is in progress.

Session Title: T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

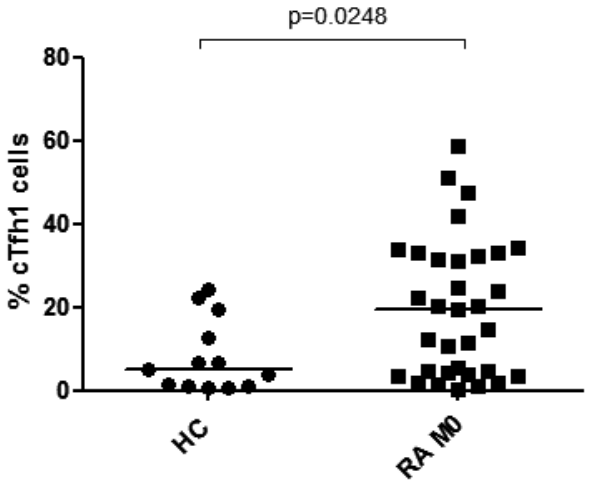

Figure 1 Percentage of cTfh1 cells in RA patients and HC at baseline (M0)

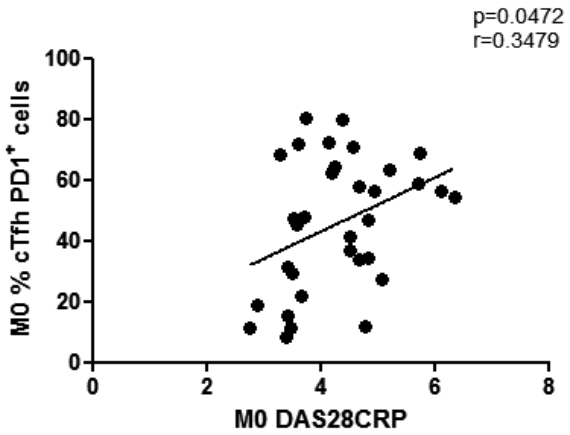

Figure 2 Positive correlation between the percentage of cTfh PD1+ cells and disease activity at baseline (M0)

Background/Purpose: T follicular helper cells (Tfh) constitute a distinct $CD4^+$ helper T-cell subset, promoting B-cell maturation and activation. Circulating Tfh (cTfh) seem to play a critical role in auto-immune diseases. The aim of this study was to analyze cTfh cells involvement in active rheumatoid arthritis (RA), before and after three months of Adalimumab treatment.

Methods: Adalimumab treatment was introduced in biologics-naive RA patients. Disease activity score (DAS) was evaluated at baseline and 3 months later. At baseline, all RA patients have an active disease with a DAS > 3.2 and a corticosteroid treatment > 15 mg per day. All patients vaccinated less than 3 months before Adalimumab initiation were excluded. Three months after Adalimumab initiation, RA patients were classified in responders (R) or non-responders (NR) according to the DAS value (< or > 3.2). cTfh characterization was performed in healthy volunteer controls (HC), and in RA patients before and after 3 months of Adalimumab treatment. Fifteen-color panels of flow cytometry was used to define T helper cells, T regulatory cells, B cells, cTfh cells ($CD3^+CD4^+CD45RA^-CXCR5^+$), effector $PD1^+$ cTfh subset ($CD3^+CD4^+CD45RA^-CXCR5^+$ $PD1^+$), and cTfh1 subset ($CD3^+CD4^+CD45RA^-CXCR5^+CXCR3^+CXCR6^-$). cTfh related cytokine, interleukin 21 (IL21), was also quantified in RA plasma, at baseline and 3 months later.

Results: The results concerned 33 RA patients and 13 HC. Mean age of patients was 58.6 years. Mean RA duration was 8.8 years. Mean DAS value was 4.28. Rheumatoid factors (RF) were positive in 72.7% patients. At baseline, frequency of cTfh1 cells (p=0.0248) (Figure 1), cTfh $PD1^+$ (p=0.004) and IL21 plasma concentration (p=0.003) were higher in RA compared to

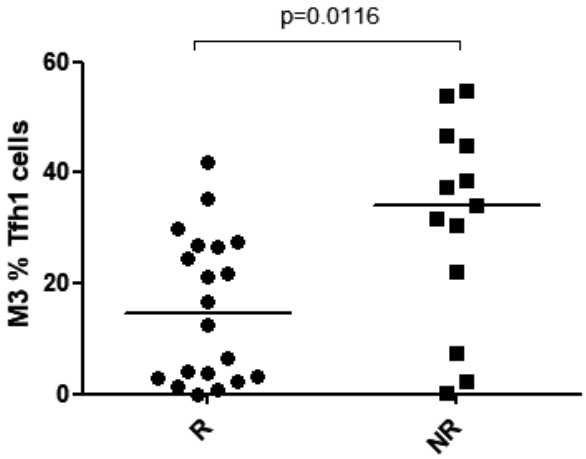

Figure 3 Percentage of cTfh1 cells 3 months after Adalimumab treatment initiation (M3) in responder (R) and non-responder (NR) patients

HC. Moreover, a significant positive correlation was observed between the DAS value, and the percentage of cTfh PD1$^+$ cells (r=0.3479; p=0.0472) (Figure 2) and IL21 plasma concentration (r=0.3755; p=0.0313). After 3 months of treatment, 20 RA patients (60.1%) achieved DAS response. Percentage of cTfh1 was significantly lower in responders than in non-responder patients (p=0.006) (Figure 3). Under treatment, IL21 plasma concentration decreased in all RA patients (p=0.0402).

Conclusion: Our results suggest that cTfh1 cells are involved in RA activation and in a clinical adequate response to adalimumab. Further analysis of these patients is necessary to understand the relationship between cTfh cells, the cTfh1/cTfh2 balance, B cells activation and antibodies production.

Selective Induction of Functional Regulatory T-Cells in Healthy Volunteers by NKTR-358, a Novel IL-2 Conjugate Treg Stimulator, in Development for the Treatment of Autoimmune Diseases

Christie Fanton,[1] Neha Dixit,[1] Suresh Siddhanti,[1] Lin Lu,[1] Daniel Dickerson,[2] Brian Kotzin,[1] and Jonathan Zalevsky[1], [1]Nektar Therapeutics, San Francisco, [2]PRA Health Sciences, Lenexa

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Regulatory T cell (Treg) dysfunction and impaired IL-2 production have been implicated as key immunological defects in multiple autoimmune diseases. Enhanced sensitivity of Tregs to IL-2 supports use of low-dose IL-2 therapy; however, this treatment is limited by short half-life and relatively poor selectivity for stimulation of Tregs versus other conventional T cell (Tcon) subsets and natural killer (NK) cells. NKTR-358 is a polyethylene glycol (PEG) conjugate of recombinant human IL–2 (aldesleukin sequence with no additional amino acid mutation or substitution), and is being developed with the goal to selectively restore Treg numbers and function in autoimmune disease. NKTR-358 demonstrates prolonged biological activity as well as marked and selective stimulation of Tregs in different animal species as compared to native IL-2.

Methods: In this first-in-human, double-blind, single ascending dose study, healthy volunteers received subcutaneous doses of NKTR-358 ranging from 0.3 to 28.0 μg/kg (9 active: 3 placebo per cohort) and were followed for 50 days. The time course and extent of activation and proliferation of Tregs, Tcons, and NK cells were assessed. In addition, suppressive function of Tregs, as well as changes in gene expression and epigenetic markers in peripheral blood lymphocytes were investigated.

Results: All 8 planned cohorts completed dosing. There were no dose-limiting toxicities, serious adverse events, deaths, or clinically significant abnormalities in vital signs, electrocardiograms, or laboratory test values. The primary effect of NKTR–358 was seen on Tregs. In the 3.0 to 28.0 μg/kg dose cohorts, dose-dependent and sustained increases in the absolute numbers, percentages, and proliferation (Ki67+) of circulating FoxP3+CD25^{bright} Tregs were observed. At 28.0 μg/kg, the mean peak increase in numbers of CD25^{bright} Tregs was 17-fold above baseline, and the mean percentage of Ki67+ CD25^{bright} Tregs was 6-fold above baseline. No increases in numbers of CD4+ or CD8+ Tcons were detected and the number of NK cells was increased < 4-fold at the highest dose tested. In addition to increased Treg numbers, expression of Treg activation markers ICOS and CTLA-4 increased at doses ≥20 μg/kg. NKTR-358-induced Tregs maintained their suppressive capacity as shown by the ability to suppress CD4+ Tcon cell proliferation in an *ex vivo* assay. Induction of Treg numbers was further supported by epigenetic analysis of immune cells demonstrating an increase in demethylated FOXP3. Finally, NKTR-358 administration led to dose-dependent induction of genes associated with Treg regulation, such as IDO1 and CD38.

Conclusion: In continuation of results previously reported, single ascending doses of NKTR-358 led to a dose-dependent increase in proliferation of CD25^{bright} Tregs. The induced Tregs displayed functional activity as evidenced by increased levels of activation markers and the capacity to suppress proliferation of Tcons. These clinical results extend previously reported effects of NKTR-358 on selective Treg stimulation and provide strong support for studying NKTR-358 as a new therapeutic in inflammatory and autoimmune diseases, such as systemic lupus.

Session Date: Sunday, November 10, 2019
Session Title: T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Anti-PD-1/PD-L1 checkpoint inhibitor therapies have produced remarkable results in stimulating immune responses against tumors. Checkpoint inhibitor therapy can also trigger a variety of autoimmune responses; however, the mechanisms underlying these immune-related adverse events (IrAEs) remain unclear. Checkpoint inhibitor-related arthritis (CIrA) occurs in ~5% of treated patients, and synovial fluid from these patients provides

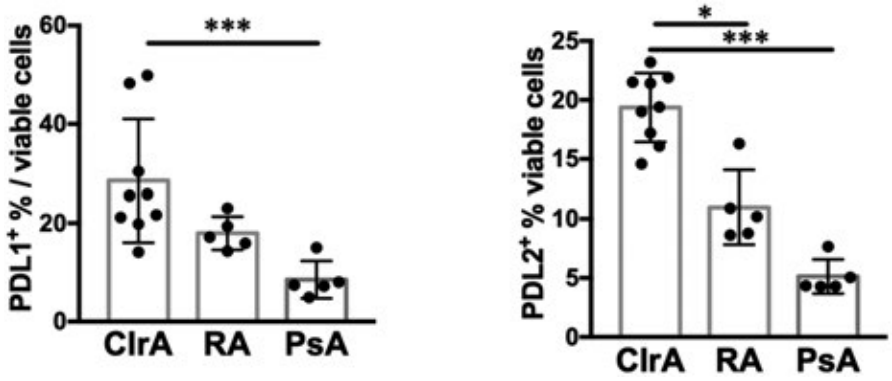

Figure 1. Higher frequencies of PD-L1+ and PD-L2+ cells were found in ClrA.

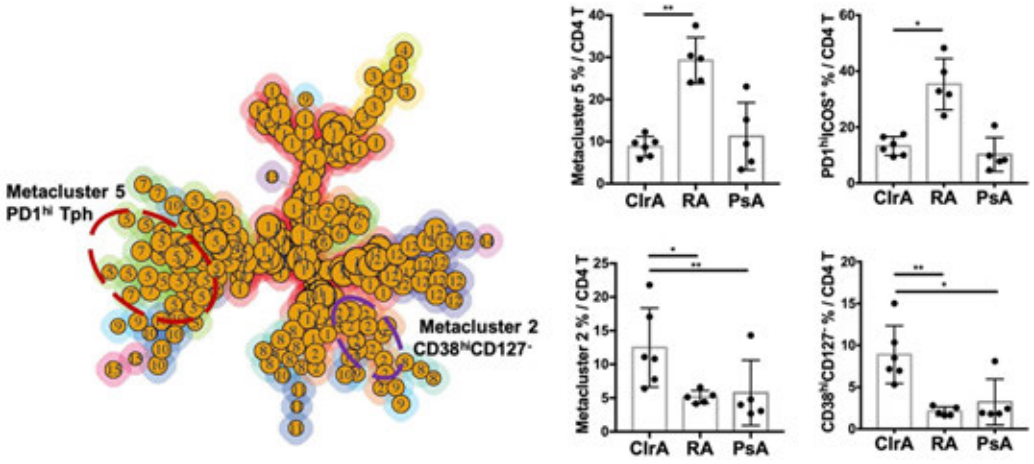

Figure 2. FlowSOM analysis of CD4 T cells revealed expanded PD-1hi Tph cells (CD4 metacluster 5) in RA samples and expanded PD-1+CD38hi CD127- cells (CD4 metacluster 2) in ClrA.

a unique opportunity to study the phenotypes of immune cells from the inflamed site. The extent to which the inflammatory response in ClrA resembles RA or PsA is unknown.

Methods: We conducted detailed immunophenotyping of cryopreserved synovial fluid mononuclear cells (SFMC) from ClrA following anti-PD-1/PD-L1 treatment (n=9), seropositive RA (n=5), and PsA (n=5) patients using a 39-marker mass cytometry (CyTOF) panel. ClrA patients had varied cancers, and 5/9 had mono/oligoarticular arthritis. We identified and custom-conjugated an anti-PD-1 CyTOF antibody using a clone that is not blocked by pembrolizumab or nivolumab, allowing detection of PD-1 in ClrA samples. We used FlowSOM to cluster either CD4 or CD8 T cells into 15 'metaclusters' (cell populations) based on their multi-dimensional phenotypes. We used Kruskal-Wallis or Mann-Whitney tests to identify significantly altered populations ($p< 0.05$), which we confirmed by biaxial gating.

Results: T cells were the most abundant population in ClrA (50% of SFMC. 53% CD4, 40% CD8), followed by monocytes (24%) and NK cells (8%); they were comparable to those in RA and PsA. Cells in ClrA samples showed expression of PD-1 comparable to that in RA and PsA. However, expression of PD-L1 and PD-L2, both frequently expressed on monocytes, was increased in ClrA compared to RA and PsA (Fig. 1, PD-L1: 2.2-fold increased over RA/PsA, $p=0.0021$; PD-L2: 2.4-fold increased over RA/PsA, $p< 0.0001$). FlowSOM analysis of CD4 T cells highlighted distinct cell populations in ClrA and RA. RA samples contained one significantly expanded population (metacluster5, 30% of CD4s in RA, $p=0.006$), which contained PD-1hiICOS+ T peripheral helper (Tph) cells. Tph cells were not expanded in ClrA. In contrast, ClrA samples showed a specific expansion of a distinct population of PD-1+CD38hi

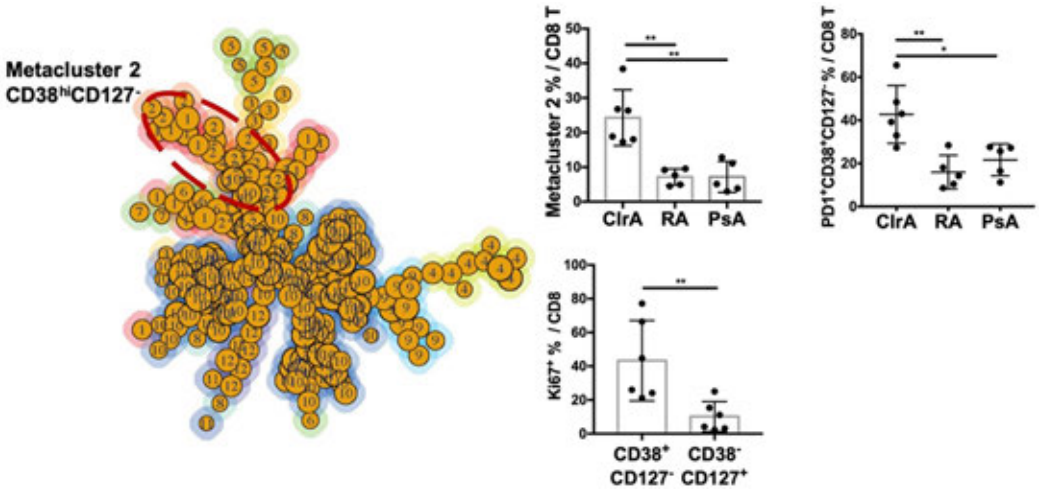

Figure 3. FlowSOM analysis of CD8 T cells revealved the expansion of a PD-1 +CD38hi CD127- population enriched of Ki67+ cells in ClrA.

CD127-cells (metacluster2, 10% of CD4s in ClrA, 2.4-fold increased over RA/PsA, p=0.0047), which we confirmed by biaxial gating (Fig. 2). Interestingly, analysis of CD8 T cells by FlowSOM revealed expansion in ClrA of a CD8 cell population with a similar phenotype to the expanded CD4 population: PD-1+CD38hiCD127-(CD8 metacluster2, 30% in ClrA, 3.4-fold increased over RA/PsA, p=0.0002). Over 40% of PD-1+CD38hi CD127-CD8+T cells in ClrA expressed Ki67, suggesting active proliferation (Fig. 3).

Conclusion: CyTOF analysis of SFMC revealed uniquely expanded CD4 and CD8 T cell populations in ClrA that are not shared with RA or PsA. Both the expanded CD4 and CD8 populations show a PD-1 $^{+}$ CD38 ^{hi} CD127 $^{-}$ phenotype. These cell phenotypes may be directly enhanced by PD-1/PD-L1 blockade and may contribute to the amplified immune response. Functional analysis of these cells may reveal key mechanisms driving CI-associated IrAEs.

Targeting ITK Signaling Ameliorates Collagen-Induced Arthritis via Shifting the Balance Between Th17 and Regulatory Th17 Cells

Ye Chen,[1] Julie Wang,[2] Nancy Olsen,[3] Wael Jarjour,[4] and Song Guo Zheng[4], [1]Ohio State University, Columbus, OH, [2]Ohio State University, columbus, [3]Penn State University, Hershey, PA, [4]Ohio State College of Medicine, Columbus, OH

SESSION INFORMATION

Session Date: Sunday, November 10, 2019
Session Title: T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is a chronic inflammatory disease that cannot be cured and current approaches have some severe side effects. Although the pathogenesis is not completely understood, many studies have suggested that the imbalance between Th17 cells/inflammatory cytokines and suppressive Foxp3+ T regulatory (Treg) cells is associated with the pathogenesis and development in RA progression. IL-2 inducible T cell kinase (ITK) is involved in signaling cascades mediating T-lymphocyte proliferation, differentiation, migration, and pro-inflammatory cytokine pro-

duction. The small molecule BMS509744 covalently binds ITK and inhibits the kinase activity of ITK. In this study, we explored whether BMS509744 regulates Th17/Treg balance and could be an effective in RA therapy.

Methods: DBA/1J mice were immunized with Collagen II and CFA to induce a CIA model. BMS509744 was injected i.p. into the mice on day 30 after immunization. To exam the effects of BMS509744 on Th17 and Treg differentiation and function, naïve CD4+ T cells were isolated from Foxp3^{GFP} mice and cultured under Th17 and Treg polarization condition in the absence or presence of BMS509744. Results were analyzed by using Graphpad Prism 7.0 software. Student t test was used to assess statistical significance between two groups and one-way ANOVA were used to assess statistical significance among multi-groups. *p* values less than 0.05 were considered as statistically significant difference.

Results: In the CIA model, infusion of BMS509744 effectively reduced the severity of arthritis, decreased the histopathology scores, improved bone destruction and down-regulated the expression of inflammatory factor IFN-γ/IL-17A. In addition, infusion of BMS509744 increased ratios of Treg cells in CIA mice. BMS509744 effectively skews naïve T cells to Treg cells under Th17 differentiation condition, and promotes Treg induction and enhances Treg function under Treg polarization condition, and also increases Foxp3 expression across TCR doses under Th17 condition, these effects can be reversed by Foxo1 inhibitor. Moreover, we found that BMS509744 decreased mTOR and Akt activity, resulting in inhibiting the phosphorylation of foxo1 and foxo1 translocation to the cytoplasm. Foxo1 expressed in nuclear can stabilize Foxp3 and inhibit the expression of IL-17A. At last, Foxo1 inhibitors significantly reversed the therapeutic effects of ITK inhibitors in CIA model and reversed effects of ITK inhibitors on the balance of Th17 and Treg in CIA model.

Conclusion: ITK inhibitor BMS509744 inhibits the development of CIA by changing the balance between Th17 and Treg cells via mTOR-AKT-Foxo1 signaling. ITK may be an effective RA therapeutic target.

CD126 Negative CD4+Foxp3+ Cell Represents a Superior Treg Subset in Treating Autoimmune Diseases

Ye Chen,[1] Julie Wang,[2] Nancy Olsen,[3] Wael Jarjour,[4] and Song Guo Zheng[4], [1]Ohio State University, Columbus, OH, [2]Ohio State University, columbus, [3]Penn State University, Hershey, PA, [4]Ohio State College of Medicine, Columbus, OH

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Regulatory T (Treg) cells play an important role in maintaining immunologic homeostasis. Abnormal Treg cells were found in some autoimmune diseases. Transferred natural Treg (nTreg) cells prevents some autoimmune disease but usually, fails to treat established diseases. Several studies demonstrated that natural CD4+CD25+ Foxp3+ Treg (nTreg) could be transdifferentiated into IL-17A-producing cells and lost its function in the presence of pro-inflammatory cytokines. Given IL-6 is an important inflammatory cytokine and IL-6 binds to its receptor (CD126) to exert functional role, whereas some nTreg cells express CD126, we hypothesize that CD126- Foxp3+ cell subsets could be more stable and functional in the inflammatory condition.

Methods: Flow cytometry were used to analyze CD126 expression on nTreg from collagen induced collagen-induced arthritis (CIA). CD126+ and CD126- nTreg were sorted from CIA mice and analyzed the transcript difference via RNA-sequence. These two subsets were cultured *in* the presence of IL-6 to determine the stability. Moreover, we transferred these two subsets into the established colitis model to analyze the function and stability of CD126+ and CD126- nTreg *in vivo.* Results were analyzed by using Graphpad Prism 7.0 software. Student t- test were used to assess statistical significance between two groups and one-way ANOVA was used to assess statistical significance among multi-groups. *p* values less than 0.05 were considered a statistically significant difference.

Results: Compared to normal mice, the proportion of CD126+ nTreg from CIA mice was significantly higher. CD126- nTreg cells express higher immunosuppressive molecule and present stronger function than CD126+ nTreg not only in the normal condition but also in the presence of IL-6. Moreover, CD126- nTreg was stable while CD126+ nTreg lost Foxp3 expression and trans-differentiated into IL-17A producing cells in the presence of IL-6. Impaired IL-6 signaling in CD126- nTreg was the primary mechanism responsible for the stability, in addition, CD126- nTreg exhibited reduced Hif-1a and glucose transporter 1(Slc2a1) expression, which are two key regulators of glycolytic metabolism and play an important role in the balance of Th17 and Treg. Finally, CD126- Tregs is more effective than CD126+ Tregs when transferred to treat colitis model.

Conclusion: CD126- nTreg cells present stronger function and stability even under inflammatory conditions than CD126+ nTreg cells. Our results suggest that manipulation of CD126- nTreg might be a novel strategy for the treatment of autoimmune diseases.

Serine Arginine-Rich Splicing Factor 1 (SRSF1) Restrains IFN-γ and IL-17 Inflammatory Cytokine Production and Its Selective Deficiency in T Cells Exacerbates Experimental Autoimmune Encephalomyelitis (EAE) and Nephrotoxic Nephritis (NTN)

Takayuki Katsuyama,[1] Kotaro Otomo,[1] Hao Li,[2] Michihito Kono,[3] Nobuya Yoshida,[1] George Tsokos,[1] and Vaishali R. Moulton[1], [1]Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA, [2]Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, [3]Department of Rheumatology, Endocrinology and Nephrology, Faculty of Medicine and Graduate School of Medicine, Hokkaido University, Sapporo, Hokkaido, Japan

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: CD4 T helper 1 (Th1) and Th17 cells producing IFN-γ and IL-17 are aberrantly increased and contribute to inflammatory responses in autoimmune diseases including systemic lupus erythematosus (SLE) and multiple sclerosis. Better understanding of the molecules and mechanisms that control these aberrant responses are important to design better therapeutic strategies. By discovery approaches we previously identified the multifunctional protein serine arginine-rich splicing factor 1 (SRSF1) in human T cells, and showed that it controls genes involved in signaling and cytokine production. We further showed that SRSF1 is low in T cells from SLE patients and associates with active disease. We recently generated T cell restricted *Srsf1*-conditional knockout (*Srsf1*-ko) mice. *Srsf1*-ko mice develop T cell hyperactivity, systemic autoimmunity, and inflammation in peripheral organs. While SRSF1 is an

important regulator of gene expression, it is unknown how SRSF1 specifically contributes to CD4 T cell activation/differentiation and resulting inflammation in immune-mediated disease. To this end, we evaluated the role of SRSF1 in the Th1/Th17-dependent experimental autoimmune disease (EAE) and nephrotoxic nephritis (NTN) *in vivo*.

Methods: T cell conditional *Srsf1*-heterozygous (het) and homozygous (ko) knockout mice were generated by crossing *Srsf1*-flox mice with d.*Lck.Cre* mice. Peripheral lymphoid organs were analyzed for immune cell phenotype and stimulated ex vivo with PMA/Ionomycin and analyzed by flow cytometry. Naïve CD4 T cells were cultured for 72h with CD3/CD28 and IL-12 for Th1 differentiation. RNA from in vitro generated effector CD4 T cells from WT and Srsf1-ko (n=3 each) mice was subjected to RNA-sequencing. EAE was induced by injecting mice with myelin oligodendrocyte glycoprotein (MOG) peptide with CFA i.p. on day 0, and pertussis toxin i.p. on day 0 and 2. Body weight (BW) and disease scores were recorded daily for 28 days. To induce NTN, mice were preimmunized with sheep IgG (100μg), and 3 days later, nephrotoxic serum (100μl)was administered intravenously. Mice were euthanized on day 24, and tissues collected for analysis. Kidneys were fixed, processed and evaluated blind for histopathology scoring.

Results: CD4 T cells from the Srsf1-ko mice exhibit an increased activated (CD69hi and CD44hi) phenotype and produce increased amounts of IFN-γ and IL-17 upon e*x vivo* stimulation with PMA/Ionomycin. Increased in vitro Th1 differentiation was observed in CD4 T cells from *Srsf1*-ko mice. RNA-seq revealed an overall elevated T cell activation gene signature, increased inflammatory cytokine genes (IL-17A, IL-17F, IFN-γ, IL-4 and IL-21) and increased representation of the Th1/Th17 differentiation pathways in the ko mice. *Srsf1*-ko mice developed more severe glomerular histopathology scores in NTN and the *Srsf1*-het mice developed more severe EAE as evidenced by clinical disease scores and BW loss.

Conclusion: SRSF1 is a novel regulator of CD4 T cell activation/differentiation, and its deficiency in T cells leads to autoimmunity and target organ damage. Therefore, deficiency of SRSF1 in T cells may represent a molecular defect that contributes to the pathogenesis of autoimmune disease.

Serine Arginine-rich Splicing Factor 1 (SRSF1) Is Indispensable for Homeostasis and Function of Regulatory T Cells

Takayuki Katsuyama,[1] and Vaishali R. Moulton[1], [1]Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Regulatory T cells (Tregs) are pivotal in enforcing immune tolerance to prevent and protect from autoimmunity. Defects in Tregs lead to unchecked immune cell activation and promote autoimmune disease. Numbers and/or function of Tregs are frequently impaired in patients with autoimmune diseases. Therefore, understanding mechanisms and molecules that control Treg homeostasis, stability and function is necessary to better target Tregs in autoimmune disease. Serine/arginine-rich splicing factor 1 (SRSF1) is the prototype member of the highly conserved serine arginine (SR) family of RNA-binding proteins. We previously found that SRSF1 expression levels are decreased in T cells from systemic lupus erythematosus (SLE) patients, and associate with active disease.

In addition, using *Srsf1* T cell-conditional knockout (Srsf1-T cell cko) mice, we have shown that deletion of Srsf1 in T cells leads to systemic autoimmunity and lupus-nephritis in vivo through effector T cell hyperactivity. However, the role of Srsf1 in Tregs is unknown.

Methods: Treg specific *Srsf1* conditional knockout (*Srsf1*-Treg cko) mice were generated by crossing B6.*Srsf1*-flox mice with B6.Foxp3.YFP.*Cre* transgenic mice to delete SRSF1 in FoxP3+ Tregs. Peripheral lymphoid organs were analyzed for immune cell phenotype and function by flow cytometry. Serum autoantibodies were measured by ELISA. Tissues were formalin fixed and processed for histopathology. Apoptosis was assessed by Annexin V/7AAD staining and flow cytometry and expression of Bcl-x genes by RT-qPCR. To assess Treg function, Srsf1-deficient Tregs from *Srsf1*-T cell ko mice were utilized. In vitro co-culture assays were performed with CFSE-labeled conventional T (Tconv) cells followed by measurement of Tconv cell proliferation by flow cytometry. In vivo Treg function was assessed by adoptive transfer of Tregs into B6 mice, followed by induction of colitis by oral dextran sodium sulfate.

Results: *Srsf1*-Treg cko mice develop early fatal systemic autoimmune disease and succumb to disease at 3-4 weeks of age. Mice develop systemic autoimmunity, exhibit increased inflammatory cytokine producing T cells, and inflammatory infiltration in vital organs including the lungs and liver. Tregs are reduced in the peripheral lymphoid tissues and display increased levels of apoptosis. Induced (i) Tregs display skewed ratios of the anti-apoptotic Bcl-xL to pro-apoptotic Bcl-xs isoforms of the Bcl-x apoptosis-related gene with a shift towards the pro-apoptotic isoform. *Srsf1*-deficient Tregs from the *Srsf1*-T cell cko mice exhibit defects in suppressive function assessed by both in vitro and in vivo suppressive function assays. In addition, these Tregs produce proinflammatory cytokines including IFN-γ, IL-17 and IL-4. RNA-seq data analysis of *Srsf1*-deficient Tregs reveals that SRSF1 controls the expression of genes involved in homeostasis, inflammatory cytokines and chemokines.

Conclusion: SRSF1 is a novel regulator of Treg homeostasis and function, and its deficiency in Tregs leads to fatal systemic inflammation and autoimmunity. Therefore, deficiency of SRSF1 in Tregs may represent a molecular defect that contributes to the pathogenesis of systemic autoimmune disease.

Session Title: T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Citrullination of proteins is catalyzed by a family of enzymes called the peptidylarginine deiminases (PADs). While the citrullinated proteins may have physiological roles in differentiation, development, cell death, and gene regulation, the pathological protein citrullination has been associated with a range of diseases in-

cluding rheumatoid arthritis (RA), multiple sclerosis, alzheimer's disease, psoriasis and cancer. Notably, the citrulinated proteins are of interest in the pathology in rheumatid arthritis and the citrullinated proteins were detected in the synovium of RA patients. One of the PAD enzymes, PAD4, was reported to be associated with RA and higher levels of PAD4 expression is reported in the synovium. PAD4 co-localizes with citrullinated proteins in the synovium. We hypothesized that inhibition of PAD4 would be beneficial in the treatment of RA and other autoimmune disorders. Our medicinal chemistry efforts have led to the identification and characterization of a series of novel and selective PAD4 inhibitors. The optimization and development of these inhibitors for a variety of autoimmune disorders is underway

Methods: A variety of approaches including the Structure Based Drug Design (SBDD) was employed to identify the hit series and to optimize the leads. The enzymatic activity of hPAD4, PAD1 and PAD2 was assessed using fluorescence based ammonia release assay. The level of citrullinated histones, which is a direct reflection of PAD4 activity, was measured in human neutrophils by ELISA. The mouse model of collagen-induced arthritis, oxazolone induced colitis and Imiquimod induced psoriasis were used to profile the lead compounds

Results: The lead compound PADi showed an IC_{50} of 190 nM against PAD4 in the biochemical assay. It was selective against PAD1 and PAD2 enzymes. In the human neutrophil-based assay, the compound showed significant inhibition of H3-Histone citrullination with an IC_{50} of 320 nM. PADi showed oral bioavailability of greater than 50% across species. Treatment with PADi showed significant improvement in disease index across the various animal models, with efficacies comparable to the standard of care. In Collagen Induced Arthritis and Oxazolone induced colitis models, 50 mpk (BID, P.O.) dose showed >70% reversal of clinical score, with no effect on body weight. The observed pharmacological benefit was accompanied by reduction of histone citrullination in tissue samples, indicating target engagement. In Imiquimod induced psoriasis model, application of 500 ug of compound topically showed a reduction of psoriatic index with a significant decrease in ear thickness and ear weight.

Conclusion: We have identified and optimized a few novel chemical series of PAD4 inhibitors. One of our lead compound, PADi, a selective PAD4 inhibitor, is efficacious in the disease model of arthritis, colitis by oral administration and in psoriasis by topical application. These results suggest that PAD4 inhibition could be a novel therapeutic strategy against unmet medical needs in autoimmune disorders. Further characterization and advanced pre-clinical studies of PADi is in progress.

Session Title: T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Primary Sjögren's Syndrome (pSS) is a systemic autoimmune disease characterized by lymphocytic infiltration of the salivary and lacrimal glands cells form a large part of the lymphocytic infiltrates observed in salivary and lacrimal gland tissues, particularly in the earlier stages of disease, increasing evidence suggests that Treg cells can suppress and control the autoimmune response to protect the body from autoimmune diseases in humans and in animal models. It is also well known that Treg cells play potent roles in the onset and development of SS, but its roles were controversial. This project aimed to claim its role in pSS by investigating ncRNAs related Treg cell.

Methods: Compared to normal controls, we identified the shared and divergent differentially expressed mRNAs (DEmRNAs), miRNAs (DEmiRNAs) and lncRNAs (DElncRNAs) in salivary glands of pSS and non-pSS sicca cases by RNA-sequencing and bioinformatics analysis. Functional annotation of DEmRNAs were performed. Both cis and trans-target DEmRNAs of DElncRNAs were identified. The target DEmRNAs of DEmiRNAs were identified as well. The DEmiRNA-DEmRNA-DElncRNA interaction network was constructed. QRT-PCR was performed to validate the slected miRNAs, mRNA and lncRNAs in salivary tissues. Dual-Luciferase Report Gene System was used to confirm the target of miRNA. The ratio of Th17 and Treg cells (FOXP3+CD25+ CD4+ T cell) in salivary were identified by flow cytometry.

Results: According to RNA-sequencing, 1523 DEmRNAs, 821 DElncRNAs and 19 DEmiRNAs were detected in salivary gland of pSS group, compared to non-pSS sicca group. 20 DElncRNAs related Treg cell were detected in 20 paired of salivary glands, and lncRNA-Dleu2 was upregulated in pSS salivary gland($p< 0.001$) .After the validation by qRT-PCR, the expression of miR15a/miR16-1 cluster was significant up-regulated in salivary glands of pSS patients ($p< 0.001$), which was negative related with the FOXp3 mRNA, and positive related with lncRNA-DLEU2. According the bioinformatics analysis and references confirmation, miR15a/miR16-1 located in gene of lncRNA- DLEU2, known as a gene cluster. And dual-Luciferase Report Gene System confirmed Foxp3 is the target of miR15a/miR16-1.Flow cytometry confirmed FOXP3+Treg cells were decreased in salivary gland of pSS, which was positive related with the expression of miR15a and miR16-1.

Conclusion: LncRNA- DLEU2-miR15a/miR16-1 might be responsible for the reduced FOXp3+Treg cell in salivary gland of pSS via targeting FOXp3.

Increased T Cell Polyreactivity with Marked Accumulation of TNF-α DP ($CD4^+CD8^+$) in the Synovial Tissue of pre-RA, Arthralgia Subjects

Achilleas Floudas,[1] Douglas Veale,[2] and Ursula Fearon[3], [1]Trinity Biomedical Sciences Institu, DUBLIN, Ireland, [2]EULAR Centre For Arthritis And Rheumatic Diseases and The Conway Institute, Dublin, Ireland, [3]Molecular Rheumatology, Trinity Biomedical Sciences Institute, TCD, Dublin, Ireland

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Effective treatment of Rheumatoid arthritis (RA) patients is achievable within a short window of opportunity following diagnosis. Identification of pathogenic immune mechanisms at a pre-RA stage would greatly benefit our understating of the early events that govern disease progression and help identify new therapeutic targets and early points for therapeutic intervention. Recent studies illustrate the pathogenic effect of increased T cell poly-

reactivity in autoimmunity, such studies in pre-RA arthralgia subjects have been hindered by the rare availability of synovial biopsy samples and minimal synovial cell recovery. In this study, we describe for the first time, polyreactive T cell responses in the synovial tissue of Arthralgia subjects and RA patients.

Methods: Synovial biopsies of RA patients and arthralgia subjects were obtained by key-hole arthsoscopic surgery. Following enzymatic and mechanical digestion of the tissue, a single cell suspension was obtained. Synovial cells and paired PBMC were stimulated *in vitro* and analysed by 15-colour flow cytometric analysis for the identification of T cell pro-inflammatory cytokine responses. Following multiparametric flow-cytometric analysis, SPICE algorithm and Flowsome unsupervised clustering were utilised to examine peripheral blood and synovial tissue T-cell cytokine polyreactivity of arthralgia subject and RA patients and peripheral blood and synovial fluid Tfh responses.

Results: Higher T cell pro-inflammatory cytokine polyreactivity was identified in arthralgia subjects compared to RA patients. Compared to the periphery, synovial tissue T cell polyreactivity is significantly higher with comparable pro-inflammatory cytokine profiles between arthralgia and RA synovial tissue T cells. Flowsome clustering analysis resulted in the identification of novel T cell clusters that exhibit high polyreactivity and an accumulation of DP ($CD4^+CD8^+$) in the synovial tissue of arthralgia subjects and RA patients. Peripheral blood Tfh cell frequency is significantly higher in arthralgia subjects compared to RA patients, with an accumulation of germinal centre like-Tfh T cells in the synovial fluid of established RA.

Conclusion: Polyreactive pro-inflammatory T cell responses pre-date disease onset as demonstrated by the accumulation of polyreactive T cells in the synovial tissue of pre-RA arthralgia subjects. These data highlight a key early pathogenic role for T cell plasticity and the newly, in autoimmunity, described T cell cluster of DP T cells in RA. We are currently investigating transcription factor profiles that govern polyreactivity of these T cell clusters.

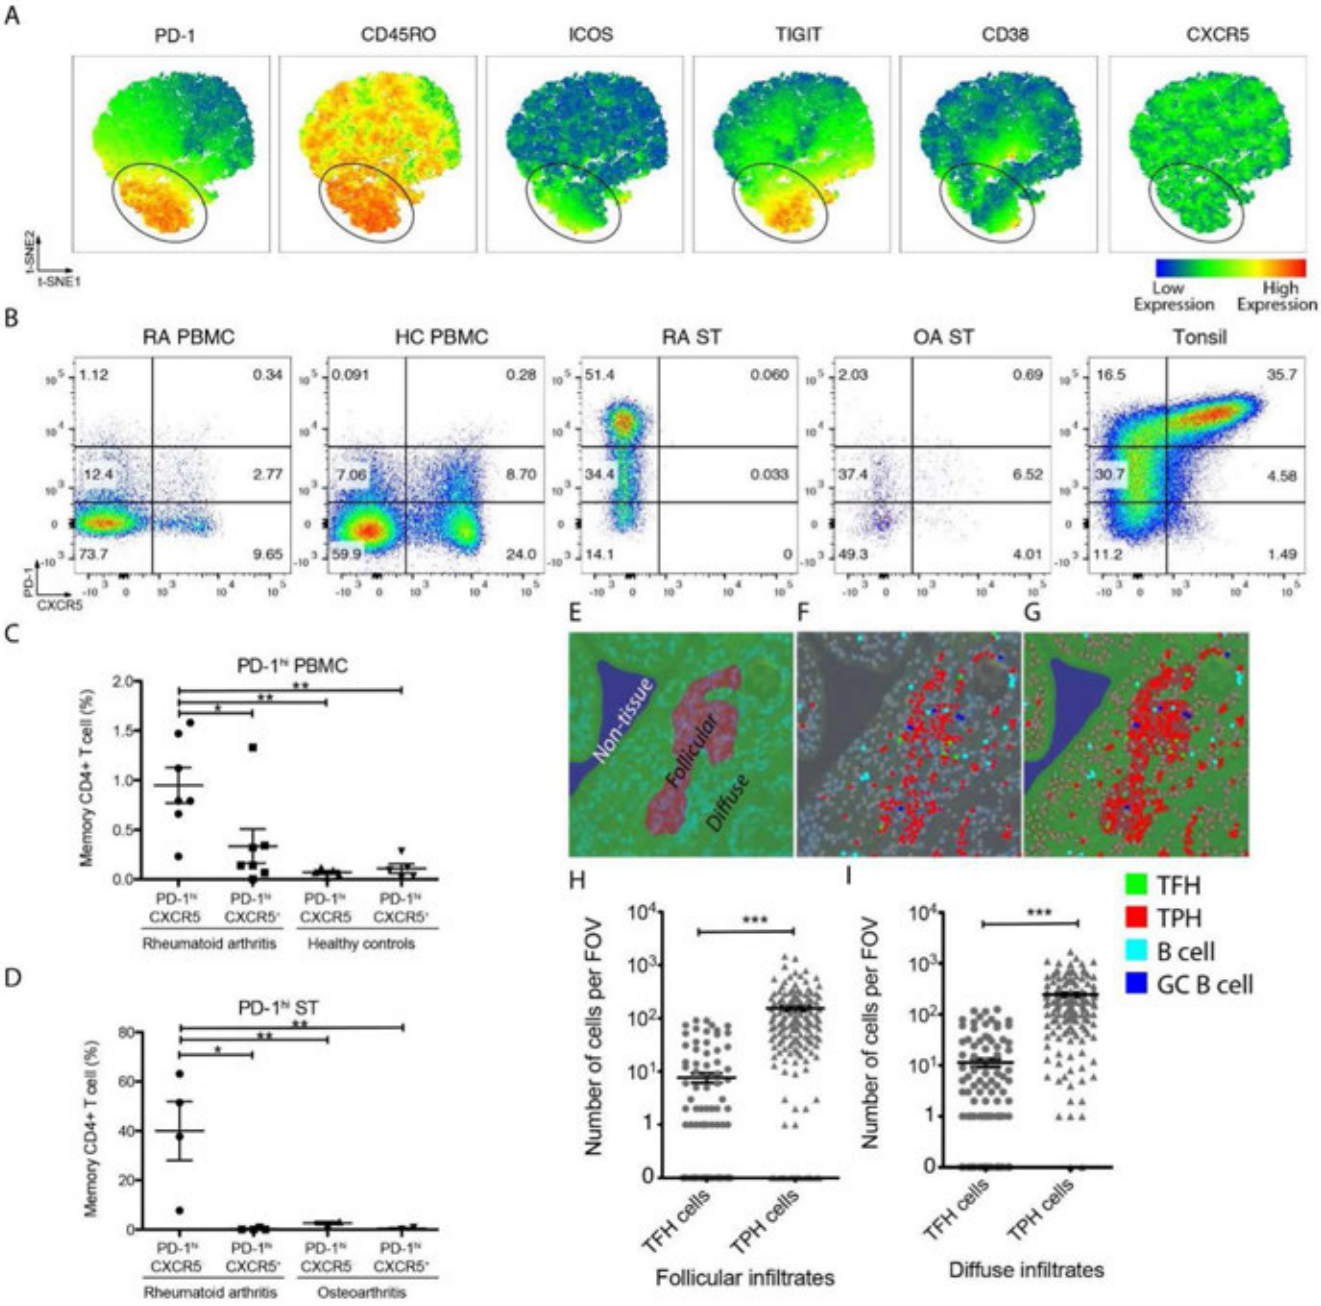
SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Programmed cell death protein 1 (PD-1) expressing T-cells are implicated in the pathogenesis of autoimmune inflammatory diseases such as rheumatoid arthritis (RA). In secondary lymphoid organs, $CXCR5^+$ T follicular helper (TFH) cells secrete IL-21 and provide co-stimulatory signals to germinal centre (GC) B cells, allowing for affinity maturation of antibody responses. Recently a new subset of CXCR5- T-cells, termed T peripheral helper (TPH) cells driving B cell differentiation, have been identified in ectopic lymphoid structures in established RA synovial tissue (ST). Critically, it remains unknown whether TPH cells accumulate in treatment-naïve early RA prior to fully established disease. We aimed to identify TPH cells in treatment naïve early RA patients using flow cytometry (FACS)



and multi-parameter immunofluorescence (IF) microscopy from ST and matched peripheral blood mononuclear cells (PBMCs).

Methods: FACS: Fresh dissociated ST (n=4), and PBMCs (n=7) single cell suspensions were stained with Zombie UV®, CD45RO, PD1, CD3, ICOS, CD8, CD4, CD20, CXCR5, TIGIT and CD38 and analysed using FlowJo 10.5.2.

Histology: 4μm thick RA ST sections were prepared for Opal™ multispectral IF. Primary antibodies for CD45RO, CD20, PD-1 and CXCR5 were sequentially stained, each followed by HRP amplification and specific Opal™ reactive fluorophores. DAPI nuclear staining was performed prior to image acquisition on the Perkin Elmer Vectra 3.0 imaging

system. Images were processed and analyzed using InForm®, a machine learning software package, where the tissue segmentation and TPH and TFH cells quantification was performed.

Results: ST FACS demonstrated T cell infiltration in ST with differential expression of PD-1, CD45RO, ICOS, TIGIT and CD38 (Figure 1A). We observed a higher frequency of PD1hi CXCR5- TPH in RA ST and PBMCs vs. controls (Figure 1B-D). Importantly, no significant difference in TFH frequency was observed in RA and controls. Furthermore, IF identified a 10-fold increase of TPH cells in early RA ST follicular and diffuse regions and identified TPH adjacent to GC B cells (Figure 1E-I).

Conclusion: In this study, we demonstrate, for the first time, the presence and potential role of TPH cells in early RA, with TPH accumulation and close interaction with GC B-cells, potentially contributing to disease pathogenesis and progression. TPH cells may be a novel immune cell target to therapeutic interception of disease progression and warrant further study in early RA.

Session Title: T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Mucosal Associated Invariant T (MAIT) cells express a semi invariant T-cell receptor (TCR) (TCRVα7.2) restricted to MHC related protein 1 (MR1) and are able to be activated by a TCR-independent pathway involving IL-12 and IL-18. As these cytokines are involved in the pathogenesis of Giant Cell Arteritis (GCA), we investigated the role of MAIT cells in GCA.

Methods: Blood samples from 27 GCA patients, as defined by ≥3/5 ACR criteria, were obtained at diagnosis before starting glucocorticoid (GC) and compared with 16 healthy subjects (age >50 years, CRP≤5 mg/L with no infectious, auto-immune or neoplastic disease). A second blood sample was obtained after 3 months of treatment for 20/27

GCA patients. MAIT cells ($CD3^+CD4^-TCR\gamma d^-TCRV\alpha 7.2^+CD161^+$) were quantified and their phenotype analyzed by flow cytometry. For 4 patients and 5 controls, MAIT cells and MAIT depleted $CD161^+$ T cells were sorted using Fluorescent Assisted Cell sorting (FACS), stained with cell trace violet (invitrogen) and cultured with or without anti CD3/CD28 microbeads or IL-12 and IL-18 (50 ng/ml each). Proliferation index was assessed by flow cytometry after 7 days of culture. MAIT ($CD3^+TCRV\alpha 7.2^+IL\text{-}18R^+$) were stained in positive and negative Temporal Artery Biopsies (TAB) by confocal microscopy on a Leica TCS SP8 confocal microscope. Results are expressed as median [interquartile range] and *P* value is the result of Mann Whitney or Wilcoxon ranked tests, as appropriate.

Results: MAIT frequency among circulating αβ-T cells was similar between patients at diagnosis and controls (0.48% [0.15-1.01] vs. 0.47% [0.28-1.13]; *P*=0.63) and not modified after GC-treatment (0.48% [0.15-0.76] vs. 0.43% [0.14-0.88]; *P*=0.51). By contrast, the phenotype of MAIT cells was modified toward a decreased expression in CXCR3 (6.08% [1.57-13.96] vs. 8.33% [6.13-36.66]; *P*=0.048) and an increased expression in IFN-γ (47.7% [31.8-66.7] vs. 31.0% [16.6-38.7]; *P*=0.03) in patients when compared to controls. This difference was not corrected after GC-treatment: from 8.31% [3.90-16.30] to 4.36% [16.40-17.47] (*P*=0.96) for CXCR3 expression and from 39.8% [23.7-61.3] to 42.4% [23.5-63.3] (*P*=0.85) for IFN-γ expression. Functional analyses revealed that MAIT proliferate in the presence of IL-12 and IL-18 without TCR activation, unlike MAIT-depleted $CD161^+$ T cells. Notably, MAIT from GCA patients displayed a stronger proliferation than the one from controls when stimulated with IL-12 and IL-18: proliferation index 3.39 [2.36-7.15] vs. 1.40 [1.20-2.42] (*P*=0.03). MAIT cells ($CD3^+IL\text{-}18R^+TCRV\alpha 7.2^+$ cells) were identified in the arterial wall of 3 positive TABs and absent in 3 negative TAB.

Conclusion: Although MAIT frequency is not modified in the blood of GCA patients, MAIT infiltrate the arterial wall in GCA patient and their functional characteristics are modified toward a pro-inflammatory phenotype: increased IFN-γ expression and stronger proliferation ability in presence of IL-12 and IL-18. As IL-12 and IL-18 are produced by dendritic cells and macrophages in GCA lesions, MAIT cells might be activated by a TCR-independent pathway and play a role in GCA pathogenesis through the production of IFN-γ.

Session Title: T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: CD6, an important regulator of T cell function, interacts with the ligands CD166 and CD318. We previously examined CD318 expression on synovial tissues (STs) and soluble CD318 concentrations in synovial fluids (SFs) of rheumatoid arthritis (RA) patients and demonstrated its potential roles in recruitment and retention of T cells in the RA joints. To further clarify the significance of CD6 in RA, we examined the effects of targeting CD6 in the mouse collagen-induced arthritis (CIA) model, using CD6 knockout mice and CD6 humanized mice that express human CD6 in lieu of mouse CD6 on their T cells.

Methods: We immunized age- and sex-matched WT and CD6 KO mice with a collagen emulsion to induce CIA. Beginning on day 21, CIA clinical scores were recorded by a blinded investigator until day 28. For treatment studies using humanized CD6 mice, we immunized similarly, and injected UMCD6 (a mouse anti-human CD6 IgG) or control IgG on days 7, 14, and 21. We analyzed the joints of the paws for tissue damage, leukocyte infiltration, and local inflammatory cytokine production. We also compared collagen-specific Th1, Th9 and Th17 responses and serum levels of collagen-specific IgG subclasses. Cytokine multiplex assays were used to measure the levels of 32 inflammatory cytokines in homogenates of paw and joint tissues.

Results: CD6 KO mice had markedly lower clinical arthritis scores than WT mice ($p< 0.05$) suggesting that CD6 acts to tune the severity of joint inflammation in CIA. Absence of CD6 reduced 1) collagen-specific Th9 and Th17, but not Th1 responses, 2) many pro-inflammatory joint cytokines, 3) serum levels of collagen-reactive IgG1 and IgG2b, but not IgG2a and IgG3. Significant reductions in joint homogenate hemoglobin (Hb) content in CD6 KO mice were observed compared to WT mice (reduced angiogenesis). Moreover, treating CD6 humanized mice with a mouse anti-human CD6 monoclonal antibody was similarly effective in reducing joint inflammation in CIA as in reducing inflammatory cytokines and chemokines without significantly depleting T cells.

Conclusion: Taken together, these data suggest that CD6 is required for the development of CIA, and that CD6 could be targeted for treating RA.

Bioinformatics Analysis of Transcriptomics Data Reveals That SRSF1 Is a Novel Molecular Brake for the T Cell Activation Program and Controls Key Cytokine Signaling Genes Implicated in Systemic Lupus Erythematosus

Rhea Bhargava,[1] Michelle S. Lee,[2] Takayuki Katsuyama,[3] and Vaishali R. Moulton[3], [1]Beth Israel Deaconess Medical Center Harvard Medical School, Boston, MA, [2]Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, [3]Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: T cells from systemic lupus erythematosus (SLE) patients exhibit a hyperactive phenotype with defects in homeostasis, signaling and cytokine production. By discovery approaches, we previously identified the serine arginine-rich splicing factor 1 (SRSF1) in human T cells and showed that it controls genes involved in sign-

aling and cytokine production. We further showed that SRSF1 expression is decreased in SLE T cells, and associates with worse disease. We recently found that mice with conditional knockout of *Srsf1* in T cells (Srsf1-T cell ko) exhibit T cell hyperactivity, systemic autoimmunity and lupus nephritis. However, little is known about the molecular targets controlled by SRSF1. Our goal is to identify the genes and pathways controlled by SRSF1 in mice and by comparative analysis evaluate if these are implicated in SLE.

Methods: Effector CD4 T (Teff) cells were generated by stimulating naïve CD4 T cells from spleens of *Srsf1*-T cell-ko or control WT (n=3) mice for 72h with CD3/CD28 antibodies. RNA from CD4 Teffs was subjected to RNA-sequencing (R-seq). Data was analyzed for differentially expressed (DE) genes, gene set enrichment, Kyoto encyclopedia of genes and genomes (KEGG) and gene ontology (GO) pathways. Gene expression omnibus (GEO)2R was used to identify a publicly available dataset (GDS4888) from CD4 T cells in patients with active SLE (n=6, SLEDAI range 6-22, ANA and dsDNA positive) and 4 healthy controls. Comparative analysis of mouse (Srsf1-T cell ko) and human (SLE) gene array data was performed using Metascape to identify overlapping gene signatures in SLE patients controlled by SRSF1.

Results: R-seq analysis from CD4 Teff cells of Srsf1-T cell ko mice revealed 608 significant DE genes compared to WT mice at the 2-fold cutoff with $p < 0.05$. In the human SLE CD4 T cells transcriptomics analysis, SRSF1 was confirmed to be significantly downregulated in active SLE patients compared to healthy controls. 290 genes were significantly ($p < 0.05$) changed between patients with active SLE and healthy controls. The top pathways represented in the DE genes in ko mice were cell cycle, Th1 and Th2 differentiation, Th17 differentiation and cytokine-cytokine receptor interaction. Overall the CD4 Teffs showed an elevated T cell activation gene signature. Pathway analysis of the 290 DE genes in SLE patients identified interferon signaling, cytokine production, cytokine receptor interaction, cell migration and lysosomal clearance pathways. Overlapping genes between human and mouse transcriptomics data were analyzed. Specifically, we found 11 genes (CCR1, RHOG, ELL2, IFI16, IFIT3, OAS2, ZER1, PRKD2, RGS3, SAT1, SOCS1) to be significantly altered in active SLE patients, which were regulated by SRSF1 as confirmed by our mouse R-seq analysis.

Conclusion: SRSF1 controls genes involved in T cell homeostasis, activation, cytokine regulation/signaling and differentiation, which are altered in patients with active SLE. Therefore SRSF1 is an important regulator of T cell function and its deficiency may lead to the hyperactive T cell phenotype in active SLE patients. Targeting SRSF1 to correct the aberrant T cell phenotype may lead to novel therapeutics particularly in SLE patients with decreased SRSF1.

The Transcription Factor STAT3 Regulates Pathogenic Th17 Responses in Autoimmune Disease via Noncanonical Roles

Catherine Poholek,[1] Itay Raphael,[2] and Mandy McGeachy[2], [1]UPMC Children's Hospital of Pittsburgh, Pittsburgh, PA, [2]University of Pittsburgh, Pittsburgh, PA

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The Th17 lineage of CD4 T cells drives autoimmune diseases such as RA, SLE, IBD, and MS. The JAK2/STAT3 signaling pathway is required for Th17 fate and cytokine production. DMARDs such as JAK inhibitors and anti-IL-6 mAbs exploit this pathway to treat autoimmune diseases. While deletion of STAT3 is known

to abolish Th17 development, little is known about the role of STAT3 in the maintenance of effector Th17 cells. We generated Th17$^{\Delta STAT3}$ mice that delete STAT3 in Th17 cells after upregulation of IL-17. Thus we examined the functional role of sustained STAT3 expression in Th17 cells during a prototypical Th17-driven autoimmune response in experimental autoimmune encephalomyelitis (EAE).

Methods: IL-17^{cre}ROSA26YFP$^{fl/fl}$ mice were crossed with STAT3$^{fl/fl}$ mice (Th17$^{\Delta STAT3}$) and compared to age and gender matched IL-17^{cre}ROSA26YFP$^{fl/fl}$STAT3$^{fl/+}$ littermate controls (Th17^{ctrl}). Mice were immunized with MOG peptide emulsified with CFA and given pertussis toxin on days 0 and 2. Mice were scored daily for disease severity. Cells were isolated from draining lymph nodes (dLN), blood, and/or central nervous system (CNS) and analyzed by flow cytometry and ELISA. For RNA-Seq, YFP^{+} cells were FACS sorted on day 7 post-immunization and RNA-Seq was performed on an Illumina NextSeq500. Results were analyzed using one-way ANOVA or Student's *t*-test, except for EAE clinical data analyzed by Mann-Whitney test on each day of scoring.

Results: Sustained STAT3 expression in Th17 cells is critical for Th17 pro-inflammatory functions, as Th17$^{\Delta STAT3}$ mice had reduced incidence and severity of EAE compared to controls. Similarly, the number of CD4 T cells and macrophages were reduced in the CNS. While Th17 cells develop early after immunization in Th17$^{\Delta STAT3}$ mice, there was a decline in Th17 cell numbers after STAT3 deletion, beginning at the peak of LN priming (day 10). We performed RNASeq of day 10 dLN YFP^{+}Th17$^{\Delta STAT3}$ and YFP^{+}Th17^{ctrl} cells, which revealed that Th17$^{\Delta STAT3}$ cells had reduced expression of genes associated with cell cycle pathways, and confirmed that YFP^{+}Th17$^{\Delta STAT3}$ cells had increased proportions of cells in G0/G1 phase and decreased proportions of cells in S phase and G2/M. Accordingly, we showed that deletion of STAT3 in Th17 cells resulted in an increase in IL-6-mediated phosphorylation of STAT1, which is known to have anti-proliferative effects. Additionally, Th17 cells showed reduced production of the pro-inflammatory cytokines IL-17, GM-CSF, and IFNγ when stimulated with MOG peptide. Surprisingly, cytokine induction by PMA/ionomycin did not require STAT3, suggesting that STAT3 was functioning in a non-transcriptional role. Furthermore, Th17$^{\Delta STAT3}$ cells had reduced mitochondrial membrane potential, which is required for TCR-activated Ca^{2+} flux.

Conclusion: Expression of STAT3 in effector Th17 cells promotes formation and maintenance of pathogenic autoimmune cells by noncanonical functions of STAT3: by reducing STAT1 activation and anti-proliferative effects, and through maintained mitochondrial membrane potential to drive cytokine production in a TCR-dependent manner.

Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: An important component of the immune tolerance is regulatory T cells (Tregs), which prevents autoimmunity and restrains inflammatory reactions. In Rheumatoid Arthritis (RA), there is a consensus among researchers that Tregs are enriched in the synovial fluid (SF) of individuals with RA. However, despite their synovial

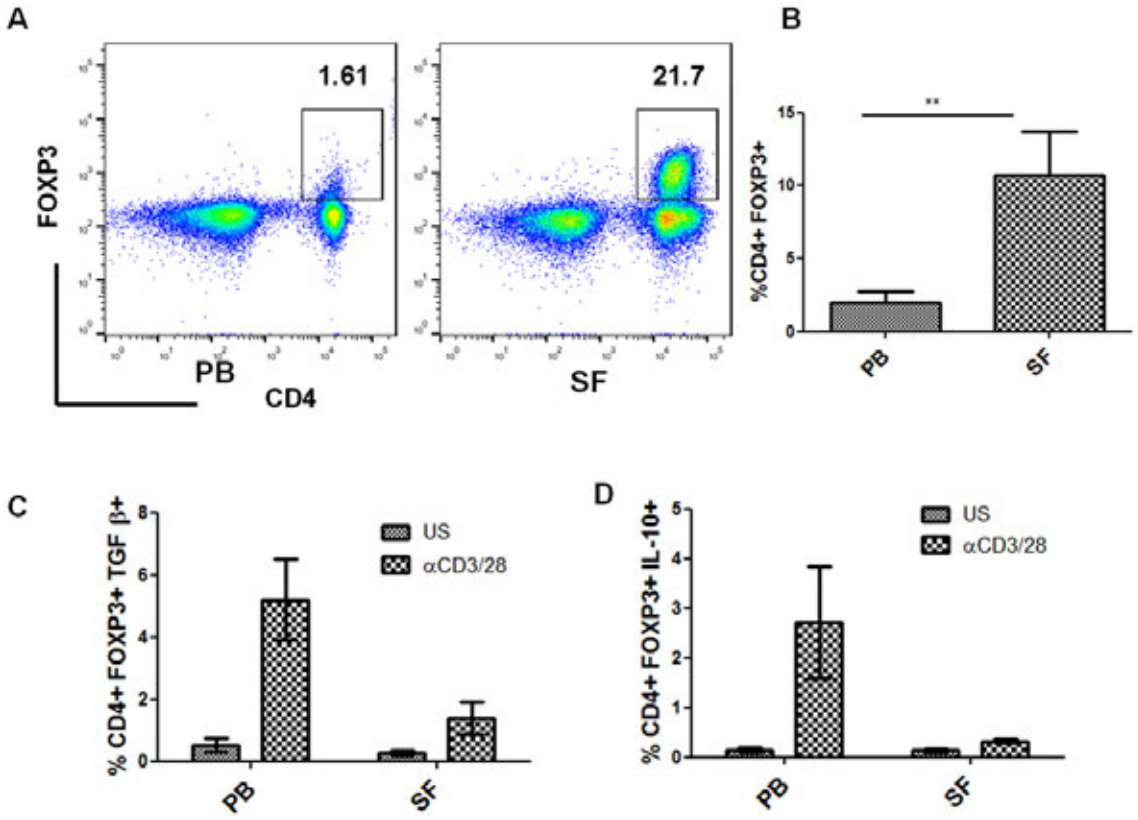

Figure 1: Representative and Cumulative Plots showing Treg frequency in PB and SF of RA patients. Lymphocytes were gated by Forward scatter (FSC) vs. Side Scatter (SSC). Representative dot plots showing CD4+Foxp3+ Tregs in PB (Figure 1A; left panel) and SF (Figure 1A; Right panel) RA patients. Cumulative plots showing frequency of CD4+Foxp3+ cells in PB vs SF in RA patients (Figure 1B; $p<0.05$ is significant). SFMC and PBMC were stimulated . Cumulative plots showing frequency of CD4+Foxp3+IL-10+ cells and CD4+Foxp3+TGFβ+ cells in PB vs SF in RA patients (Figure 1C & D).

accumulation, the synovial inflammation continues in RA suggesting their inability to mediate suppression in the pathogenic site. Recently, our group has shown the enrichment of interleukin-9 (IL-9) producing helper T (Th9) cells in synovial fluid and its positive correlation with disease activity. Therefore, in this study we investigated whether IL-9 plays any role in dysfunctioning of synovial Tregs in RA.

Methods: Mononuclear cells were isolated from peripheral blood (PB) and synovial fluid (SF) of patients with active RA. In vitro stimulation of mononuclear cells was performed by engagement of anti-CD3 and anti-CD28 monoclonal antibodies. We performed IL-9 pathway blocking using a blocking antibody against IL-9 receptor alpha chain. Polychromatic flowcytometry was performed to evaluate the frequencies of IL-10, TGF-β, PD-1 and CTLA-4 positive Tregs (CD4+, CD25+ and FOXP3+).

Results: Treg cells mediate their suppressive function by various ways like contact dependent involving immune inhibitory molecules like programmed cell death protein 1 (PD-1) and contact independent involving suppressive cytokines like IL-10 and TGF-β.We observed that the frequency of $CD4^+$ $FoxP3^+$T cells was significantly higher in the Synovial Fluid (SF) compared to that of Peripheral Blood (PB) from patients. However, Tregs derived from SF are functionally impaired and thus fail to suppress the inflammation at the local site. We observed that *in vitro* stimulation of synovial T cells in presence of IL-9 receptor alpha chain blocking antibody, enhanced the frequency of IL-10 and TGF beta producing Tregs. Also, IL-9 blocking resulted in increase in frequency of PD-1 and CTLA4 expressing Tregs. These observations indicated that IL-9/IL-9 receptor pathway inhibits the suppressive function of synovial fluid derived Tregs. We next checked the effect of recombinant IL-9 on peripheral blood derived Tregs from healthy indi-

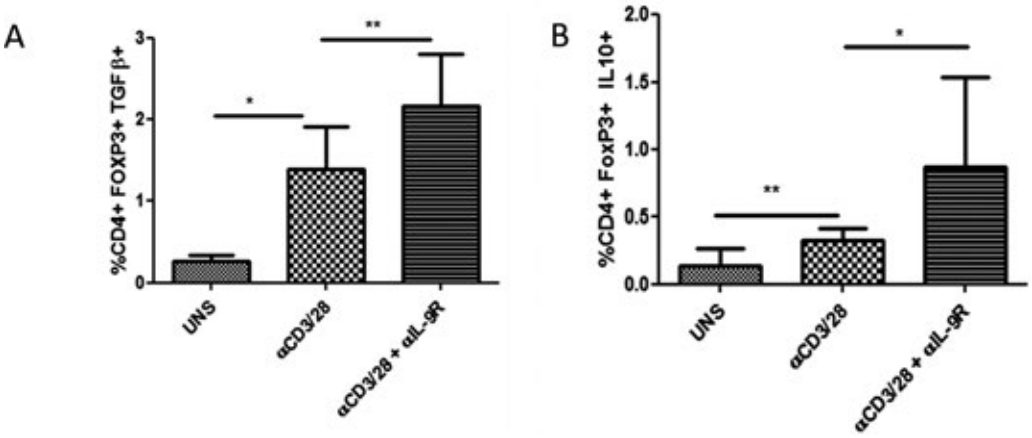

Figure 2: Effect of in vitro blocking IL-9 receptor (IL-9R) on frequency of TGF β and IL10 producing Tregs. Synovial fluid derived mononuclear cells (SMNCs) were stimulated in presence or absence of monoclonal antibody binding to IL-9 receptor alpha . Lymphocytes were gated by Forward scatter (FSC) vs. Side Scatter (SSC).On gated CD4+, the frequency of TGF-β and IL-10 producing Foxp3+ cells were assessed. Cumulative Plots showing frequency of CD4+FOXP3+TGFβ+ (A) and CD4+FOXP3+IL10+(B).

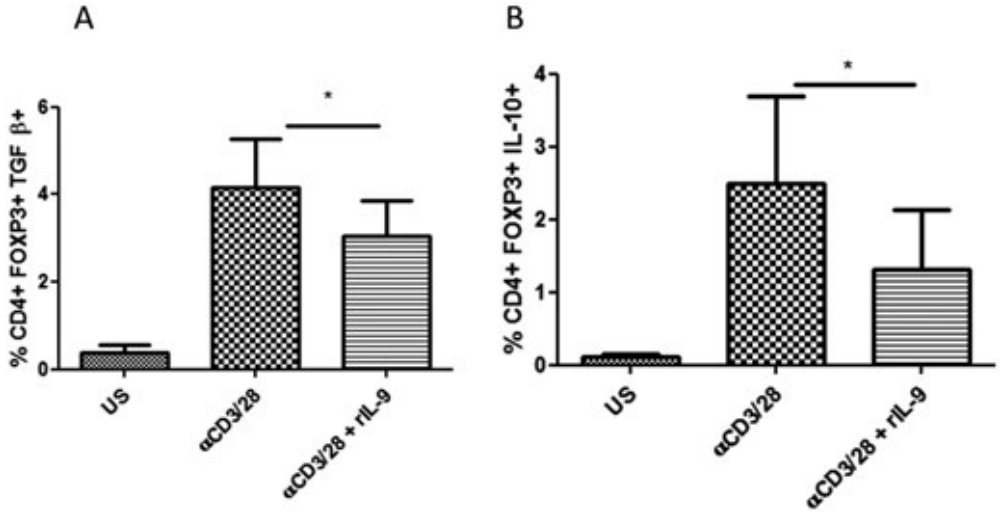

Figure 3. Peripheral blood mononuclear cells (PBMCs) of RA patient were stimulated in presence or absence of recombinant IL-9. On gated CD4+ CD25+ cells, the frequency of TGF-β (A) and IL-10 (B) producing Foxp3+ cells were assessed using Flow cytometry.

viduals. We observed that in vitro stimulation of mononuclear cells in presence of recombinant IL-9 results in reduced frequency of IL-10 and TGF beta producing Tregs, suggesting that IL-9 has negative impact on Tregs.

Conclusion: Our results indicate that IL-9 pathway blocking in RA may contribute in the resolution of inflammation by restoring the Treg function essential for immune tolerance.

In Vitro Characterization of the Effect of Cenerimod, a Potent and Selective Sphingosine 1-Phosphate Receptor 1 ($S1P_1$) Modulator, on $S1P_1$ Receptor Expression, Receptor Internalization, and Migration of Primary Human T Cells in the Presence or Absence of Glucocorticoids

Paulina Kulig,[1] Mark Murphy,[1] and **Marcel Keller**[1], [1]Idorsia Pharmaceuticals Ltd, Allschwil, Switzerland

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Cenerimod is a potent, selective, and orally active sphingosine 1-phosphate receptor 1 ($S1P_1$) modulator that is currently being evaluated in a Phase 2b study in patients with SLE (NCT03742037). $S1P_1$ receptor modulators sequester circulating lymphocytes within lymph nodes, thereby reducing pathogenic autoimmune cells in the blood stream and in inflamed tissues. Extensive clinical experience has become available for the nonselective S1P receptor modulator fingolimod/Gilenya in relapsing forms of multiple sclerosis, supporting therapeutic concept of sphingosine 1-phosphate for the treatment of autoimmune disorders.

In this study, the mode of action of cenerimod was studied in primary human lymphocytes in a series of in vitro experiments including $S1P_1$ receptor internalization and a newly developed real-time migration assay. As glucocorticoids (GC) are frequently used in the treatment of patients with autoimmune disorders including SLE, the influence of GC on $S1P_1$ receptor expression and function were studied.

Methods: Primary human T lymphocytes from healthy donors were isolated from whole blood cultured with different concentrations of cenerimod to measure $S1P_1$ receptor internalization and sphingosine 1-phosphate (S1P)-directed chemotaxis using flow cytometry and real-time migration assays. In a second series of experiments, the effect of different concentrations of GC (prednisolone and dexamethasone) on $S1P_1$ receptor expression was evaluated. Finally, the effect of physiological concentrations of GCs on cenerimod activity in the receptor internalization and migration assay were tested.

Results: *In vitro,* cenerimod led to a dose-dependent internalization of the $S1P_1$ receptor on primary human CD4 and CD8 T lymphocytes. Cenerimod also blocked migration of activated T lymphocytes towards S1P in a concentration-dependent manner, which is in line with the retention of lymphocytes in the lymph node and the reduction of circulating lymphocytes observed in the clinical setting. Culturing of T cells with GC lead to a slight dose dependent decrease of cell surface expression of $S1P_1$ receptor on CD8 and CD4 T lymphocytes. Importantly, physiological concentrations of GC did not affect the activity of cenerimod in the receptor internalization or the migration assay.

Conclusion: These results show that cenerimod by modulating $S1P_1$ blocks T lymphocyte migration towards its natural chemoattractant S1P and demonstrate compatibility of cenerimod and GC.

Session Title: T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Resident memory T cells (TRM) are site-specific memory T cells that take up long-term residence in peripheral tissues and aid in pathogen defense. However, TRM cells can also drive localized, recurrent inflammation. RA and JIA are characterized by recurrent joint inflammation that exhibits a strong tendency to flare at the same sites. We previously created a novel murine model of recurrent, joint-specific inflammation and demonstrated a population of memory T cells with a TRM cell phenotype (CD45+CD3+CD8+CD44+CD62L-CD69hi). Here, we characterize the persistence of these synovial resident memory T cells and their role in arthritis flares.

Methods: Localized arthritis is established by intra-articular (IA) injection of methylated bovine serum albumin (meBSA) or ovalbumin (OVA) with concurrent IL-1beta injections to the footpad to stimulate an immune response. Spontaneous remission occurs after 28 days, but arthritis flares in the original joints when re-stimulated with intraperitoneal meBSA or OVA. To track the site-specific persistence of TRM cells, we labelled synovial T cells using fluorescent reporter mice and IA injection of adeno-associated virus (AAV). To assess the importance of lymphocyte recruitment to an arthritis flare, we treated mice with FTY720, a sphingosine-1 phosphate receptor modulator that sequesters lymphocytes in lymphoid tissues, and evaluated joint inflammation after triggering a flare. Finally, to demonstrate the contribution of synovial TRM cells to the flare response, we locally depleted synovial T cells with a single IA injection of diphtheria toxin into mice with Lck-inducible diphtheria toxin receptors prior to triggering an arthritis flare.

Results: We found that synovial TRM cells persist in previously inflamed joints 8 months after remission and retained their capacity to trigger a flare in a site-specific manner. AAV-labelled TRM cells present in the synovium during remission did not migrate to the contralateral joint. TRM cells enabled joint inflammation by recruiting effector lymphocytes to the joint, and correspondingly localized depletion strongly blunted the capacity to flare arthritis.

Conclusion: Synovial TRM cells persist in arthritic joints and retain their capacity to trigger a site-specific flare after prolonged periods of remission. Our data suggest that synovial resident memory T cells can mediate joint-specific memory in inflammatory arthritis and trigger flares by recruiting circulating lymphocytes, suggesting local depletion of TRM cells as a potential therapeutic strategy.

Session Title: T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: IgG4-related disease (IgG4-RD) is a chronic immune-mediated fibrotic disease often causing multi-organ involvement. We have previously reported the association of SLAMF7+ CD4+ cytotoxic T lymphocytes (CD4+CTLs) with IgG-4RD including their dominance among the CD4 infiltrate in diseased tissues. In the context of chronic viral infections, such as HIV and CMV, CD4+CTL expansions have been observed to parallel those of CD8+CTLs. CD8+CTLs are additionally reported to be relevant to other autoimmune diseases such as Sjogren's syndrome and Celiac disease. To date, no detailed examination of CD8+ CTLs has been reported in the setting of IgG4-RD.

Methods: We used multi-color flow cytometry to quantitate CD8+CTL subsets in the blood of 48 patients with IgG4-RD and explored correlations with disease severity, serum IgG4 levels and CD4+CTL expansions. We used 20 age-matched healthy individuals and 19 sarcoidosis patients without lung parenchymal fibrosis as controls. We performed TCR repertoire analysis and RNA sequencing using Next Generation Sequencing. Diseased tissues were interrogated for CD8+ T cell infiltrates using multi-color immunofluorescence.

Results: $CD28^{Low}$ $CD57^{Hi}$ CD8+CTLs are expanded in the blood of patients with IgG4-RD and correlate with disease severity, serum IgG4 level and expansion of effector CD4+CTLs. The majority of $CD28^{Low}$ $CD57^{Hi}$ CD8+CTLs in the blood have regained CD45RA expression (CD8+ TEMRA) and dominate over CD8+ TEM. In IgG4-RD, CD8+ TEM and CD8+ TEMRA cells are clonally restricted and highly connected to each other. In contrast to cells from healthy individuals, certain TCR V-beta genes are over-represented among $CD28^{Low}$ $CD57^{Hi}$ CD8+CTLs in IgG4-RD, and dominant V-beta genes are shared across different patients. In the context of IgG4-RD, the transcriptome of these cells suggests conditioning by an inflammatory microenvironment (IL-6, TNF-α, and IFN-γ signaling), heightened metabolic activity, increased cell proliferation, and an enhanced capacity to home to damaged tissues. SLAMF7+ CD8+CTLs infiltrate the involved tissues of IgG4-RD patients in high numbers, comparable to those of SLAMF7+ CD4+CTLs. Tissue infiltrating SLAMF7+ CD8+CTLs are composed of both CD8+ TEM and CD8+ TEMRA cells.

Conclusion: $CD28^{Low}$ $CD57^{Hi}$ CD8+CTLs are expanded in the blood of IgG4-RD and correlate with multiple parameters relevant to the mechanism of disease. In contrast to the same cell type from healthy individuals, these CD8+CTLs from IgG4-RD patients appear to be more active, proliferative and tissue-homing. The highly restricted TCR repertoire shows an over-represented V-beta gene usage that is shared across multiple IgG4-RD patients and differs from the V-beta genes used by the the corresponding T cells in healthy individuals. The TCR V-beta usage suggests the possibility that the CD8+CTL responses are targeting shared class I restricted protein antigens across patients in a

disease-specific manner. The accumulation of CD8+CTLs in disease lesions suggest that they may contribute to the pathogenesis of IgG4-RD. (Supported by NIH U19 AI 110495 and UM1 AI144295)

Defective EZH2 Expression Attenuates Treg Differentiation in Rheumatoid Arthritis

Xinyue Xiao,[1] Yueting Li,[2] Hua Chen,[1] and Xuan Zhang[2], [1]Department of Rheumatology and Clinical Immunology, Peking Union Medical College Hospital, Clinical Immunology Center, Chinese Academy of Medical Sciences and Peking Union Medical College; The Ministry of Education Key Laboratory, Beijing, China, Beijing, Beijing, China (People's Republic), [2]Department of Rheumatology and Clinical Immunology, Peking Union Medical College Hospital, Clinical Immunology Center, Chinese Academy of Medical Sciences and Peking Union Medical College; The Ministry of Education Key Laboratory, Beijing, China, Beijing, China (People's Republic)

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: To explore the role of EZH2, a histone methylation regulator, in the pathogenesis of rheumatoid arthritis (RA).

Methods: Forty treatment-naïve patients with active disease and fulfilled the 2010 ACR revised criteria for RA were enrolled in the study.

The expression of EZH2 was further quantified by qPCR, WB, and flow cytometry in T cells. The ability of differentiation, proliferation, and apoptosis of T cells was measured by flow cytometry and qPCR after inhibition of EZH2 through pharmacological inhibitor and siRNA. mTOR signaling pathways were also monitored. The effect of synovial fluid and fibroblast-like synoviocyte (FLS) on EZH2 expression in T cell was determined by flow cytometry and qPCR.

Results: EZH2 expression is lower in PBMC and CD4 + T cells from RA patients. EZH2 inhibition with GSK126 or siRNA ex vivo attenuated the differentiation of naïve T cells into regulatory T cells (Treg). Phenotypically, RA showed decreased Treg frequency in peripheral blood. EZH2 silencing could downregulate SMAD3/4 and increased mTOR expression in vitro. Synovial fluid and FLS from RA patients suppress EZH2 expression in T cells.

Conclusion: Lower expression of EZH2 contributed to decreased Treg differentiation in the CD4+ T cells of RA patients, involved in TGF-β/SMAD signaling and mTOR signaling. The synovial fluid and FLS from RA patients played and role in the reduction of EZH2 expression. Targeting EZH2 might be a potential approach for RA treatment.

The Indole Derivative NecroX Blocks Th17 Cell Differentiation and Fibroblast-like Synoviocytes-mediated Th1/Th17 Responses in Rheumatoid Arthritis

Hyun Jung Yoo,[1] Shin Eui Kang,[2] Ji Hye Lee,[3] Ra Ham Kim,[4] and Yeong-Wook Song[5], [1]Department of Molecular Medicine and Biopharmaceutical Sciences, Graduate School of Convergence Science and Technology and College of Medicine, Seoul National University, Seoul, Repulbic of Korea, Seoul, Republic of Korea, [2]Department of Molecular Medicine and Biopharmaceutical Sciences, Graduate School of Convergence Science and Technology and College of Medicine, Seoul National University, Seoul, Republic of Korea, Seoul, Republic of Korea, [3]Division of Rheumatology, Department of Internal Medicine, Seoul National University Hospital, Seoul, Republic of Korea., Seoul, Republic of Korea, [4]Department of Molecular Medicine and Biopharmaceutical Sciences, Graduate School of Convergence Science and Technology and College of Medicine, Seoul National University, Seoul, Republic of Korea, Seoul, Republic of Korea, [5]Seoul National University Hospital, Seoul, Republic of Korea

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is an autoimmune disease characterized by chronic inflammation of synovium, which causes progressive joint destruction and reduction in quality of life. T-helper-17 (Th17) cells have been implicated to play a crucial role in the development and progression of persistent inflammation. In addition, Th17 cells from patients with early RA induce a pro-inflammatory feedback loop upon RA fibroblast-like synoviocytes (RA-FLS) interaction, including autocrine interleukin (IL)-17A production. NecroX is an inhibitor of necrosis/necroptosis and has been shown to scavenge mitochondrial reactive oxygen and nitrogen species in inflammatory cells, and preventing necrotic cell death against various kinds of oxidative stresses. We aimed to investigate the effects of NecroX on Th17 cell differentiation and T cell – RA-FLS interaction and the production of immune mediators in these interactions.

Methods: RA-FLS were cultured from synovial specimens obtained from RA patients undergoing joint replacement therapy. Inflammatory cytokines/chemokines level was measured by ELISA. Human CD4+ T cells were isolated by magnetic-activated cell sorting from healthy controls and RA patients. Activated naïve CD4+ T cells were pretreated with or without NecroX for Th17 differentiation. The location of phosphorylated signal transducer and activator of transcription 3 (pSTAT3) was detected by immunofluorescence microscope. Human CD4+ T cells were cultured with or without NecroX or co-cultured with RA-FLS by transwell culture system. Th1 or Th17 phenotype was measured by flow cytometry and culture supernatant was collected for analyses of IFN-gamma and IL-17A by ELISA.

Results: NecroX reduced the TNF-alpha induced production of IL-6, CXCL10, MMP-1, 3, 9 and 13 in RA-FLS. When peripheral CD4+ T cells were cultured under Th17 condition, NecroX decreased the population of IL-17+ and CD4+ T cells, and production of IL-17A in dose-dependent manner and also prevented the nuclear translocation of pSTAT3. When RA-FLS were co-cultured with CD4+ T cells, NecroX-7 inhibited RA-FLS-mediated Th1 and Th17 cell expansion both in cell-cell contact-dependent and inflammatory cytokine-dependent manners.

Conclusion: NecroX could be an immune regulator of inflammatory arthritis by suppressing Th17 cell differentiation and RA-FLS activation and inhibiting the pro-inflammatory feedback loop between Th17 cell and RA-FLS. These observations suggest that NecroX might be useful for the development of anti-inflammatory agents.

Polymorphonuclear Neutrophils and Regulatory T Lymphocytes (Treg) Cooperate to Sustain Treg Activity but This Interaction Is Altered in Rheumatoid Arthritis Patients

Maxime Batignes,[1] François Santinon,[1] Marie-Christophe Boissier,[2] Patrice Decker,[1] and **Natacha Bessis**[1], [1]Inserm UMR 1125, University of Paris 13, Sorbonne Paris Cité, Bobigny, France, [2]Assistance Publique-Hôpitaux de Paris (AP-HP), Rheumatology Department, Avicenne Hospital, Bobigny, France

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Regulatory T cells (Treg) are necessary for immune homeostasis but are functionally deficient in inflammatory/autoimmune diseases such as rheumatoid arthritis (RA). On the other hand, polymorphonuclear neutrophils (PMN) are known for their proinflammatory properties and are highly recruited at inflammation sites such as RA joints. However, recent evidences show that PMN exert also immunoregulatory functions. We hypothesized that Treg/PMN interact and that this interaction is dysregulated in RA. We aimed at deciphering the phenotype and activity of both cells upon *in vitro* Treg/PMN co-cultures and characterized the mechanisms involved. Finally, we analyzed the fate of Treg/PMN interaction in RA patients.

Methods: Splenic mouse Treg and bone marrow PMN (C57BL/6 mice) as well as peripheral blood Treg and PMN of healthy donors and RA patients were freshly purified by magnetic sorting. Co-cultures were unstimulated or exposed to anti-CD3/anti-CD28 antibodies and/or LPS. $CD4^+FoxP3^+$ Treg (mouse and human), $Ly6G^+$ (mouse) and $CD66b^+$ (human) PMN were identified by flow cytometry. Cell activation was further studied by flow cytometry using antibodies against CD25, CTLA-4 (Treg) and CD11b, CD39, PD-L1 (PMN). Treg maintenance was evaluated as the frequency of FoxP3 expression among $CD4^+$ cells, and cell proliferation by CFSE staining followed by flow cytometry analysis. In some case, co-cultures were performed using transwell or Tofacitinib (a JAK inhibitor). Cytokine levels were quantified in culture supernatants by ELISA. Collagen-induced arthritis (CIA) was induced by immunization with type II collagen in complete Freund's adjuvant.

Results: Upon co-culture *in vitro* with PMN, Treg proliferated, showed increased maintenance of FoxP3 expression and up-regulated CTLA-4 as well as CD25 compared to Treg cultured alone, only when both Treg and PMN were stimulated. Reciprocally, upon co-culture with Treg, PMN were activated and expressed regulatory molecules, as evidenced by CD11b, CD39 and PD-L1 up-regulation, as compared to PMN cultured alone, when both cell types were stimulated. The co-culture led to higher secretion of MIP-2/IL-8, IL-6 and IL-17. All these effects were abrogated when co-cultures were done using transwell or when blocking JAK-STAT signalling. Most importantly, PMN sustain Treg suppressive effect on effector ($CD4^+FoxP3^-$) T cells (inhibition of cell proliferation). Similar results were observed in co-cultures of PMN/Treg isolated from mice (both naïve and CIA mice) and healthy donors. However, and importantly, we found out that PMN from RA patients were unable to increase CTLA-4 expression on Treg in co-culture, CTLA-4 being involved in Treg suppressive activity.

Conclusion: Our results reveal the existence of a new link between Treg and PMN, leading to an activation of both cell types and a more suppressive phenotype in healthy conditions. Although cell contacts are clearly required, soluble mediators are also involved and probably as a second signal. This is the first demonstration of an effect of PMN

on Treg phenotype. In RA patients, we evidenced a defect in this Treg/PMN cross-talk. This Treg/PMN interaction might unveil new therapeutic targets against RA.

Session Title: T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Polymyositis is a chronic inflammatory myopathy associated with lymphocyte infiltration, especially $CD8^+$T cells to the muscle layer. C protein-induced myositis (CIM) is a murine model of polymyositis (PM). Dexamethasone treatment has an anti-inflammatory effect on polymyositis, but did not improve mitochondrial dysfunction in muscle of CIM mice. In the previous report, mitochondrial function is restored in damaged cells after transfer of mitochondria from human umbilical cord-derived mesenchymal stem cells (UC-MSCs). We investigate whether mitochondrial transplantation may attenuate inflammation and improve mitochondrial dysfunction in CIM model.

Methods: To induce CIM, C57BL/6 mice were immunized with human skeletal muscle C protein fragment. Dexamethasone was administered intraperitoneally at a dose of 0.8 mg/kg/day. Mitochondria from human UC-MSCs were transplanted intravenously on day1 or day7. To evaluate muscle inflammation, ^{18}F-FDG PET/MRI evaluation was performed on day 14. Muscle tissues were stained with hematoxylin and eosin (H&E) for histological evaluation. Pro-inflammatory cytokines were measured by ELISA. The expression of subunits of OXPHOS (oxidative phosphorylation) complexes (I -V) was investigated by immunoblot analysis. To quantitative evaluation of mitochondrial transplantation, the expression of MITO-CO1 and COX4 was evaluated by RT-qPCR.

Results: Mean of histologic summation score of muscles was decreased in day 1 group (0.67 ± 0.60, n = 3), day 7 group (0.75 ± 0.61, n = 10) of mitochondrial transplantation and dexamethasone-treated group (0.5 ± 0.63, n = 10) compared with vehicle (1.5 ± 0.32, n = 7). PET/MRI showed ^{18}F-FDG uptake reduction after mitochondrial transplantation and dexamethasone treatment. IL-6 was reduced in the serum of mitochondrial transplantation and dexamethasone-treated group. However, the protein expression of OXPHOS complex II was increased in day 7 group

of mitochondrial transplantation compared with vehicle or dexamethasone-treated group. As a quantitative evaluation of mitochondrial transplantation, the expression of human mitochondrial encoded gene, MITO-CO1 was increased without altering the expression of COX4, the nuclear-encoded gene in day 7 group of mitochondrial transplantation and these data suggest that isolated mitochondria from human UC-MSC transplanted into CIM mouse muscle.

Conclusion: Mitochondrial transplantation suppressed muscle inflammation and improved the mitochondrial dysfunction through an increase of mitochondrial activity. These findings suggest that mitochondrial transplantation may be used as a new potential therapeutic strategy for inflammatory myopathy.

Session Date: Sunday, November 10, 2019

Session Title: T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Autologous hematopoietic stem cell transplant (autoHSCT) is a highly effective treatment in selected patients with autoimmune diseases. AutoHSCT can induce long-term remission (up to 15 years) with 70-80% progression free survival in patients with relapsed refractory and secondary progressive multiple sclerosis (Muraro 2017) that is superior to standard of care agents in a randomized study (Burt 2019). Likewise, use of autoHSCT in patients with scleroderma achieved superior outcomes in two randomized studies (Tyndall 2014, Sullivan 2018). These impressive results are achieved by eradication of autoreactive immune cells and re-establishment of a self-tolerant immune system, i.e., immune system reset. However, only a small fraction of eligible patients undergo autoHSCT, in part due to toxicity associated with current conditioning protocols. To address these issues, we are developing antibody drug conjugates (ADCs) that selectively target CD45 to eradicate autoimmune cells and enable autoHSCT as a potentially one-time curative treatment for patients with autoimmune disease.

Methods: We generated a novel ADC targeting murine CD45 that was evaluated as a single conditioning agent for murine congenic transplant. This ADC was further evaluated for its ability to eliminate pathogenic host-reactive cells in the context of multiple murine models of autoimmune disease, including MOG-induced experimental autoimmune encephalitis (EAE), proteoglycan-induced arthritis (PGIA), and sclerodermatous graft-vs-host disease (scGVHD). To translate these encouraging pre-clinical data we generated novel anti-human CD45 ADCs that cross react with nonhuman primates (NHP) and evaluated these for the ability to deplete hematopoietic and immune cells in NHPs.

Fig. 1: Administration of CD45-ADC enables autoHSCT and substantially reduces pathology in murine EAE model

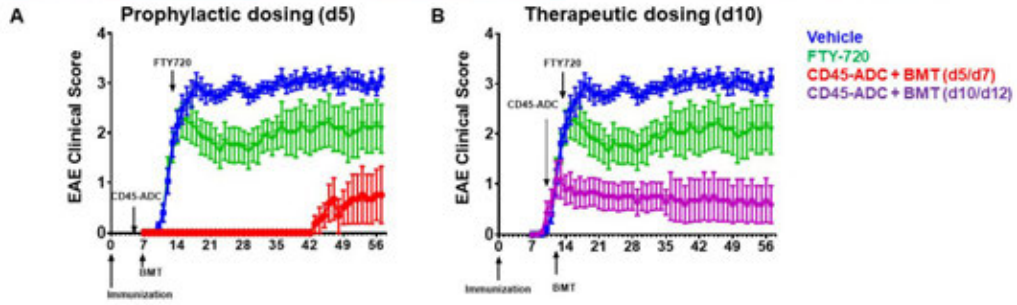

Fig. 1. Administration of CD45-ADC enables autoHSCT and substantially reduces pathology in murine EAE model . Experimental autoimmune encephalitis (EAE) was initiated in C57BL/6 mice via immunization with MOG_{35-55} peptide in complete Freund's adjuvant (CFA) on day 0 with pertussis toxin on days 0 and 1. Groups of immunized mice were conditioned with 3 mg/kg of CD45-ADC on day 5 (**A**) or day 10 (**B**) post-immunization followed by congenic bone marrow transplant ($2x10^7$ BM cells from B6.SJL (CD45.1$^+$)). All animals were scored daily starting at 5 days post immunization. Vehicle (blue) and FTY-720 –treated groups (green) are shown as comparators.

Results: A single-dose of anti-mouse CD45-ADC achieved full myeloablation in recipient mice and enabled full donor chimerism in a congenic mouse transplant model. In EAE, conditioning with anti-mouse CD45-ADC followed by congenic transplant prior to disease onset significantly delayed disease onset and reduced overall disease severity. In active EAE, treatment with anti-mouse CD45-ADC followed by congenic transplant halted progression of disease activity. The disease modifying effect in EAE with anti-mouse CD45-ADC showed comparable efficacy to a traditional conditioning regimen. Evaluation of CD45-ADC in additional autoimmune models of arthritis and scleroderma are ongoing and will be presented. Given these encouraging results we developed an anti-human CD45 ADC that cross-reacts with non-human primates (NHP). Substantial depletion of both lymphocytes and hematopoietic stem cells (HSCs) was observed at well-tolerated doses.

Conclusion: These results suggest that targeted immune depletion with a single treatment of CD45-ADC may be sufficient for auto-HSCT and allow re-establishment of immune tolerance. Targeted CD45-ADCs may represent a safer and better tolerated approach for conditioning patients prior to immune reset through autoHSCT and significantly reduce the side effects associated with current conditioning.

Session Title: T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Animal models of experimental spondyloarthritis (SpA), human genetics and therapies support a central role for adaptive immunity in disease pathogenesis. However, there is very limited data on whether the human enthesis harbours conventional CD4+ and CD8+ T-cells

To investigate whether spinal enthesis including peri-entheseal bone and peripheral blood harboured resident CD4+ and CD8+ conventional T-cells and to evaluate the effects of therapy in blocking the production of pivotal SpA-related cytokines TNF and IL-17A. Additionally, to investigate T cell plasticity via gene expression of Th17 and Treg markers following in vitro induction of entheseal inflammation.

Methods: Healthy interspinous ligament and spinous process with matched blood were harvested from patients undergoing elective surgery for the correction of mechanical spinal defects (n=13). Entheseal soft tissue (EST) and peri-entheseal bone (PEB) were separated and digested. . Following the isolation of CD4+ and CD8+ T-cells lymphocytes from PEB and peripheral blood, the conventional T lymphocytes were investigated using ELISA's and RNA extraction for qRT-PCR to assess T effector cell markers. Cells were stimulated using an anti-CD3/CD2/CD28 beads with and without the presence experimental RORγt inhibitor (RORγti), Tofacitinib, methotrexate (MTX), and phosphodiesterase type 4 inhibitor (PDE4i).

Results: Following stimulation, CD4+ T-cells produced more TNF and IL-17A than CD8+ T-cells ($p< 0.05$), IL-17A was robustly detected in CD4+ but not CD8+ T-cells. TNF and IL-17A production from CD4+ T-cells was effectively inhibited by Tofacitinib ($p< 0.05$), while RORγti only reduced IL-17 secretion highlighting it's specificity in the IL-17A signalling pathway. MTX and PDE4i treated cells had no significant impact on reducing IL-17A production in either cell population. MTX also had no impact on reducing TNF production in either cell population, however PDE4i treated cells did reduce TNF production in both cell populations in blood. CD4+ and CD8+ T-cells showed increased expression of the Treg lineage specific gene FOXP3 compared to DMSO control ($p=0.002$) where PDE4i and methotrexate treatment caused the highest relative expression fold change in CD4+ PEB and CD8+ blood respectively (4.33±0.97, 347.89±347.35). The pleiotropic cytokine TGFβ showed varying results in PEB and blood, with a complete down-regulation in CD4+ PEB and an upregulation in CD8+ Blood, methotrexate treatment caused the highest relative expression fold change (19.66±17.78), which may suggest a Th17 phenotypic shift in PEB and a iTreg shift in CD8

Blood, this is also supported by RORC and IL-6 upregulation in CD4 PEB in PDE4i treated cells (p=0.045 and 0.001 respectively).

Conclusion: This is a novel finding of conventional CD4+ and CD8+ enthesis resident T-cells that exhibit regulatory transcript expression in health. Where TGFβ expression may highlight T cell plasticity, promoting a Th17 phenotype in PEB and iTreg phenotype in blood. Induced IL-17A was robustly inhibited by RORgt inhibition.

Inhibition of Necroptosis Suppresses Muscle Cell Death and Inflammatory Infiltrate, and Improves Muscle Strength in Experimental Polymyositis

Mari Kamiya,[1] Kimito Kawahata,[2] Hitoshi Kohsaka,[1] and Fumitaka Mizoguchi[1], [1]Department of Rheumatology, Graduate School of Medical and Dental Sciences, Tokyo Medical and Dental University (TMDU), Tokyo, Japan, Tokyo, Japan, [2]Rheumatology and Allergology, St. Marianna University School of Medicine, Tokyo, Japan

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: In polymyositis (PM), $CD8^+$ cytotoxic T lymphocytes (CTLs) are assumed to induce muscle cell death. We presumed that the injured muscle cells release pro-inflammatory molecules including damage associated molecular patterns (DAMPs), which would accelerate further CTL-mediated muscle injury. Inhibition of muscle cell death could be a novel therapeutic strategy in PM. We have previously shown that the suppressive effects of perforin deficiency on the severity and incidence of myositis were partial in C protein induced-myositis (CIM), suggesting the involvement of another pathway in addition to the perforin/granzyme pathway. The aims of this study are to clarify the mechanisms of CTL-mediated muscle injury, the pattern of cell death of muscle cells, and the therapeutic effects of inhibition of muscle cell death on *in vitro* and *in vivo* models of PM.

Methods: OT-I CTLs, and their mutants lacking perforin 1 or granzyme B were cocultured with myotubes differentiated from C2C12 cells that were retrovirally transduced with the genes encoding MHC class I ($H2K^b$) and SIINFEKL peptide derived from ovalbumin ($H2K^b$OVA-myotubes) to discern how muscle cell death is mediated *in vitro* by CTL. CIM was used to study the effect of necrostatin-1s (nec1s) on the severity of myositis *in vivo*. The levels of high mobility group box-1 protein (HMGB1), one of the DAMPs, in the supernatant of the coculture and the serum of CIM were measured by ELISA. Muscle biopsy specimens of PM patients were examined with terminal deoxynucleotidyl transferase nick-end labeling (TUNEL) assay, and histologically for the expression of the necroptosis associated proteins including receptor-interacting serine-threonine kinase (RIPK3) and mixed lineage kinase domain-like pseudokinase (MLKL).

Results: OT-I CTLs lacking perforin 1 or granzyme B were as cytotoxic to $H2K^b$OVA-myotubes as wild type OT-I CTLs. Inhibition of Fas ligand by the Fas-Fc chimera protein reduced cytotoxicity of CTLs against the myotubes. The TUNEL assay and time-lapse imaging of cell death visualized by Annexin V and PI revealed that the cell death of

the myotubes was non-apoptotic. The CTL-mediated cell death of myotubes was inhibited by nec1s, a necroptosis inhibitor, or *Ripk3* silencing with siRNA, but not by benzyloxycarbonyl-Val-Ala-Asp-fluoromethylketone, an apoptosis inhibitor. Treatment of myotubes with nec1s inhibited the CTL-induced increase of HMGB1 level in the supernatant of the coculture. Therapeutic administration of nec1s on CIM improved the grip strength of mice and reduced the severity of myositis histologically. The serum level of HMGB1 was lower in nec1s-treated CIM mice compared to that in the untreated mice. Immunohistological staining of muscle tissue of PM patients revealed the expression of Fas, RIPK3, and phosphorylated MLKL on injured muscle cells.

Conclusion: Necroptosis is involved in muscle cell death in PM. Inhibition of necroptosis should be a novel therapeutic strategy in PM.

Blockade of Antigen-specific T Cell Activation by a Non-Depleting Anti-HLA-DR Monoclonal Antibody with a Unique Binding Epitope

Fang Shen,[1] Karen Duffy,[1] Stephane Becart,[2] Robert Kuhn,[1] Melissa Swiecki,[1] Brian Jones,[1] Yawei Li,[1] Jeffrey Hall,[1] Ravi Malaviya,[1] Nathan Felix,[1] Mimi Zhou,[2] Sunil Nagpal,[1] and Navin Rao[1], [1]Janssen R&D, Spring House, PA, [2]Janssen R&D, La Jolla, CA

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The activation of T helper cells requires cognate recognition of antigen-derived peptides presented by Major Compatibility Complex Class II (MHC II) molecules, which are encoded by the human leukocyte antigen gene complex (HLA)-DR, HLA-DP and HLA-DQ genes. Polymorphisms in the HLA-DR beta chain 1 gene *HLADRB1* are highly associated with many autoimmune diseases. The HLA-DRB1 'Shared Epitope' is the single most significant genetic risk factor for Rheumatoid Arthritis. Blockade of the interaction of HLA-DR with the TCR might inhibit activation of autoreactive T cells while preserve protective antigen presentation by other HLA molecules.

Methods: HLA-DR selective binding Fabs were identified from phage display libraries and cloned as IgG2sigma/kappa antibodies. The affinities of the anti-HLA-DR antibodies for HLA-DR1 or DR4 complexes were measured by Surface Plasmon Resonance (SPR). To evaluate the potency of anti-HLA-DR mabs *in vitro*, peptide-specific T cell hybridoma lines were cocultured with APCs expressing HLA-DR1 or DR4. In addition, a mixed lymphocyte reaction (MLR) assay was established via coculture of human CD4+ T cells with bone marrow-derived dendritic cells (BMDC) from human HLA-DR4 transgenic (Tg) mice. To evaluate the efficacy of anti-HLA-DR mabs *in vivo*, human HLA-DR4 Tg mice were immunized with hemagglutinin (HA) peptide and HA-specific T cell expansion was assessed by *ex vivo* stimulation.

Results: DR4B127 is an anti-HLA-DR monoclonal antibody with a 'silent' Fc (lacking effector function). It selectively binds to HLA-DR1 or DR4 in the presence of various antigen peptides (KD=9~146 nM) but does not binds to HLA-DP or HLA-DQ. Its binding epitope does not overlap with the MHC II/TCR interfaces. However, interaction of MHC II/CD4

could be affected. Unlike other anti-HLA-DR antibodies (e.g. L243), the binding of DR4B127 does not cause apoptosis of primary human B cells *in vitro*. Target-mediated internalization is observed for DR4B127 and other HLA-DR-binding antibodies *in vitro,* and internalization efficiency is correlated with binding affinity. DR4B127 dose-dependently inhibits HLA-DR1- or HLA-DR4-restricted, HA peptide-dependent or HLA-DR4-restricted, type II collagen (CII) peptide-dependent activation of T cell hybridoma cells. DR4B127 also inhibits a human T cell/ HLA-DR4 Tg mouse BMDC MLR. DR4B127 demonstrated a short half-life with $t_{1/2}$ < 24h in both HLA-DR4 Tg mice and cyno monkeys. DR4B127 does not deplete B cells in HLA-DR4 Tg mice *in vivo*. However, quick loss of target engagement is observed as over 90% of total HLA-DR epitopes on B cells are not covered by antibody after 24h. Sustained exposure of DR4B127 by repeated dosing is sufficient to inhibit HA-specific T cell expansion *in vivo*, while single dose treatment is not efficacious.

Conclusion: DR4B127 is differentiated from other anti-HLA-DR mabs, demonstrating a unique binding epitope and non-depleting profile. Although short half-life and transient target engagement preclude further development as a therapeutic for autoimmune indications, DR4B127 may have utility as a research tool for selective uptake into HLA-DR-expressing cells.

Session Title: T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Circulating CD4 T cells that express CXCR5 together with PD-1 and/or ICOS are considered as counterparts of bona fide Tfh cells and function as B cell helpers (Simpson N et al, Arthritis Rheum 2010; Craft J, Nat Rev Rheumatol 2012). In addition, circulating CD4+CXCR5+ T cells can be subdivided into three subpopulations: CXCR5+CXCR3+CCR6- (Tfh-Th1), CXCR5+CXCR3-CCR6+ (Tfh-Th17) and CXCR5+CXCR3-CCR6- (Tfh-Th2). Only Tfh-Th17 and Tfh-Th2 but not Thf-Th1 cells seem to provide B cell help. Altered frequencies of circulating Tfh cells (cTfh) and of cTfh cell subpopulations have been associated with autoinmune conditions. We previously described that patients with RA treated with conventional synthetic DMARDs (csDMARDs), demonstrate constitutively altered frequencies of cTfh and cTfh cell subpopulations that are observed not only in patients with an active disease but also in patients who are in remission. Therefore, our objective was to determine if treatment with biological agents (TNF blockers or abatacept) is able to modify the constitutively altered cTfh and cTfh subpopulation numbers, observed in RA patients receiving csDMARDs.

Methods: Peripheral blood was drawn from RA patients receiving csDMARDS (n=35), TNF blockers (n=27: 10 infliximab, 12 etanercept, 3 certolizumab, 2 adalimumab), or abatacept (n=20). For each patient, an age and gender-matched healthy control was also studied (n=82). cTfh and plasmablast frequencies were determined by flow cytometry of freshly isolated PBMCs.

Results: As described, RA patients receiving csDMARDs demonstrated, whether they had an active or inactive disease, an increased frequency of CD4+CXCR5+PD-1^{hi} and CD4+CXCR5+ PD-1^{hi}ICOS+ T cells, together with an increased frequency of circulating plasmablasts. In addition, the frequency of Tfh-Th1 cells was significantly decreased and the frequency of Tfh-Th17 and Tfh-Th2 cells were significantly increased as compared with HC; subsequently, the ratio (Tfh-Th17+Tfh-Th2)/Tfh-Th1 was increased in RA: that is, RA patients demonstrated a higher proportion of Tfh cell subsets bearing a phenotype associated with B cell helping capacity. Interestingly, these alterations were also observed in RA patients treated with TNF blockers, whether they had an active or inactive disease. In contrast, in patients receiving abatacept, the frequencies of cTfh, cTfh cell subpopulations and plasmablasts, were not different from those observed in HC.

Conclusion: Patients with RA receiving csDMARDs or TNF blockers demonstrated a constitutively increased frequency of cTfh cells and an overrepresentation of cTfh subsets bearing a B cell helper phenotype, suggesting that altered germinal center dynamics play a role in RA pathogenesis. Remarkably, in RA patients treated with abatacept these frequencies and ratio were not altered, indicating that costimulation blockade is able to revert the increased generation of Tfh cells in RA; conversely, TNF neutralization does not seem to affect the generation or recirculation of cTfh.

Elevated Proliferative Capacity of CD8+ T Cells in Giant Cell Arteritis

Rosanne Reitsema,[1] Rebeca Hid Cadena,[2] Wayel Abdulahad,[3] Annemieke Boots,[3] Peter Heeringa,[4] and Elisabeth Brouwer[1], [1]Department of Rheumatology and Clinical Immunology, University of Groningen, University Medical Center Groningen, Groningen, Netherlands, [2]Department of Pathology and Medical Biology, University of Groningen, University Medical Center Groningen, Groningen, Netherlands, [3]Department of Rheumatology and Clinical Immunology, University of Groningen, University Medical Center Groningen, Groningen, [4]Department of Pathology and Medical Biology, University of Groningen, University Medical Center Groningen, Groningen

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Giant cell arteritis (GCA) is the most frequent form of systemic vasculitis affecting the large- and medium-sized vessels. The involvement of innate immune cells and CD4+ T cells in the pathogenesis of GCA has been intensively studied. Interestingly, recent findings suggest a role of CD8+ T cells in disease development. However, CD8+ subsets and their functional capacities have not yet been studied in detail. Therefore, this study aims to investigate the phenotype and function of circulating CD8+ T cells in newly diagnosed GCA patients compared to healthy age- and sex- matched controls.

Methods: Newly diagnosed, untreated GCA patients (n=9), diagnosed according to international GCA consensus criteria, and age- and sex-matched healthy controls (HCs, n= 12) were enrolled. Firstly, peripheral blood mononu-

clear cells (PBMCs) were stained with fluorochrome-conjugated antibodies directed against CD3, CD4, CD8, CCR7, CD45RO, Ki-67, CD69 and CD25 and analyzed by flow cytometry. The following differentiation subsets were defined: CD8+ T naive (CD45RO-CCR7+), central memory (T_{CM}, CD45RO+CCR7+), effector memory (T_{EM}, CD45RO+CCR7-) and effector memory re-expressing CD45RA (T_{EMRA}, CD45RO-CCR7-) cells. Secondly, the proliferative capacity of CD8+ T cells was determined in isolated CD3+ T cells by measuring the intensity of cell proliferation dye (CPD) upon 5 days of stimulation with plate-bound anti-CD3 or anti-CD3 plus soluble anti-CD28. Lastly, the proliferative capacity of whole blood sorted CD8+ T naive, T_{EM} and T_{EMRA} cells from two GCA patients in remission and two HCs was determined.

Results: No differences in the proportions of differentiation subsets were present between GCA patients and HCs. A proportional increase of Ki-67 within CD8+ T_{EM} cells was found in GCA patients compared to HCs ($p < 0.01$) suggesting increased homeostatic proliferation in these cells. After stimulation with anti-CD3, the percentage of divided CD8+ T cells was higher in patients than in HCs ($p< 0.05$). After stimulation with both anti-CD3 and anti-CD28, no differences in proliferative capacity were found. Furthermore, a strong positive correlation between the proportion of CD8+ T_{EMRA} cells and the percentage of divided cells upon CD3 stimulation was found in newly diagnosed GCA patients (R=0.8), and not in HCs. Preliminary data from sorted CD8+ differentiation subsets suggest that CD8+ T_{EMRA} cells from GCA patients indeed have a higher proliferative capacity than those from HCs.

Conclusion: This study demonstrated that CD8+ T_{EM} cells show increased homeostatic proliferation in GCA patients compared to HCs. Functional data on proliferative capacity suggest that CD8+ T_{EMRA} cells from GCA patients are more rapidly activated by crosslinking CD3, suggesting either reduced regulation in these patients or more intrinsic threshold changes. This higher proliferative capacity of CD8+ T_{EMRA} cells is contrary to existing literature, since it is well appreciated that the expansion potential of CD8+ T cells decreases from naive T cells to T_{CM} to T_{EM} and T_{EMRA}. The lower activation thresholds for CD8+ T_{EMRA} cells in GCA imply that these cells are not innocent bystanders but contribute to disease progression in GCA.

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Antiphospholipid Syndrome Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Mitochondria are intracellular organelles involved in many biological pathways such as energy supply by oxidative phosphorylation and apoptosis. Mitochondria are considered as derived from the endosymbiosis between an α-proteobacterion and a primitive eukaryotic cell. Mitochondria display molecular features derived from their bacterial origin such as N-formylated peptides or a circular double-stranded DNA with hypomethylated

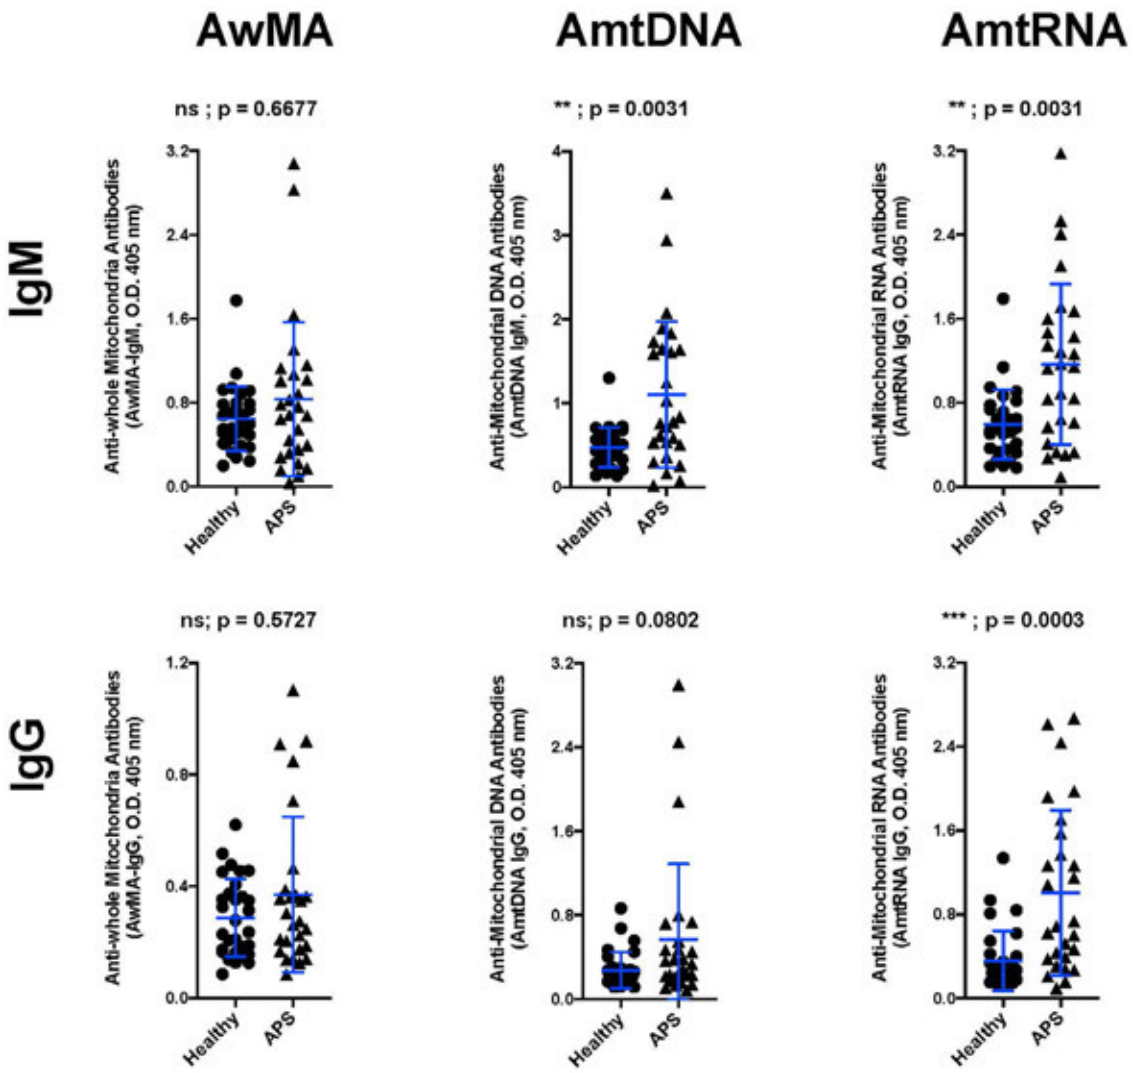

Figure 1. Detection of anti-mitochondrial autoantibodies targeting whole mitochondria (AwMA), mitochondrial DNA (AmtDNA) or RNA (AmtRNA) in healthy donors (n=30) and APS patients (n=27)

CpG motives. When released onto the extracellular milieu upon tissue damage or cell activation, mitochondria may elicit proinflammatory responses through their recognition by the innate immune system. Little is known about interplays between mitochondria and the adaptive immune system, despite descriptions of humoral responses to mitochondria in some diseases. Our laboratory already reported that anti-mitochondrial antibodies (AMA) targeting whole organelles (AwMA), mitochondrial DNA (AmtDNA) or RNA (AmtRNA) are expressed in patients with systemic lupus erythematosus, an autoimmune disease often associated with APS. In this study, we detected AMA in patients with APS and associated their titers with clinical features of APS.

Methods: AwMA, AmtDNA and AmtRNA – IgG and IgM were detected in healthy controls (n=30) and APS patients (n=27) by direct ELISA. All participants agreed to participate to our Systemic Autoimmune Rheumatic Diseases Biobank and Data Base. Demographic and disease characteristic variables were collected according to the standard APS ACTION protocol. Vascular events were defined as arterial, venous or microangiopathic and «any vascular event» was defined as the combination of all types of vascular events Morbidities during pregnancy were defined as spontaneous abortions before the 10^{th} week of pregnancy, miscarriages after the 10^{th} week or premature birth due to eclampsia or preeclampsia before the 34^{th} week and «any pregnancy morbidity» was defined as any combination of one or more items. Kruskall-Wallis and Wilcoxon tests were used to compare groups. Vascular events and morbidities during pregnancy were predicted with logistic regressions.

Table 1. Clinical characteristics of APS patients

Anticardiolipin antibodies (aCL):		
IgG	22	32.99 ± 82.30
IgM		32.82 ± 99.49
Anti-β_2 Glycoprotein I (β_2GPI):		
IgG	25	13.77 ± 28.45
IgM		29.18 ± 114.21
History of vascular events:		
Any	27	22 (81.5)
Arterial		10 (37.0)
Venous		15 (55.6)
History of pregnancy:	12	
History of any pregnancy morbidity		4 (33.3)

Results: AmtDNA-IgM and both AmtRNA IgG and IgM were significantly elevated in APS patients compared to controls. AMA failed to discriminate primary APS (n=7) from secondary APS (n=20). AwMA-IgG were associated with positivity to lupus anticoagulant (p=0.01). While the AMA were not associated with morbidities during pregnancy, AwMA-IgM, AmtDNA-IgG and IgM and AmtRNA-IgM were all associated with reduced history of any thrombotic events (respectively p=0.0447, p=0.0414, p=0.0363 and p=0.0481). AmtDNA-IgM was also associated with reduced arterial vascular events (p=0.0463).

Conclusion: Our findings suggest that AMA are represented within the autoantibody repertoire in APS and that various mitochondrial antigens display different clinical associations in the disease.

Elevated Levels of the Neutrophil Extracellular Trap-binding Protein LILRA3 in Primary Antiphospholipid Syndrome

Hui Shi,[1] Srilakshmi Yalavarthi,[2] Jianping Guo,[3] and Jason Knight[4], [1]University of Michigan, Ann Arbor, [2]University of Michigan, Ann Arbor, MI, [3]Department of Rheumatology and Immunology, Peking University People's Hospital, Beijing, China (People's Republic), [4]Division of Rheumatology, Department of Internal Medicine, Michigan Medicine, Ann Arbor, MI

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Antiphospholipid Syndrome Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The leukocyte immunoglobulin-like receptor A3 (*LILRA3*) gene encodes the only soluble receptor within the LILR family. *LILRA3* polymorphisms have been associated with both rheumatoid arthritis and lupus. Soluble LILRA3 appears to circulate at high levels in patients with rheumatoid arthritis, and has been suggested to have pro-inflammatory functions. Regarding its cellular source, a recent proteomic analysis of neutrophil granules detected LILRA3 as a key component of tertiary granules. To date, the role of LILRA3 in antiphospholipid syndrome (APS) has not been defined. Here, we hypothesized that LILRA3 might be delivered extracellularly via the release of neutrophil extracellular traps (NETs). We also considered whether LILRA3 might function as a NET-binding protein and whether it circulates at high levels in APS patients, where it may promote autoantibody formation or have thromboinflammatory functions.

Methods: LILRA3 expression was assessed in neutrophils of primary APS patients by real-time PCR. Circulating levels of soluble LILRA3 and anti-LILRA3 IgG were measured in primary APS patients and healthy controls by enzyme-linked immunosorbent assay. Electrophoretic mobility shifts assay (EMSA) was performed to determine whether LILRA3 binds neutrophil DNA (the dominant component of NETs). Human neutrophils were activated to release NETs, and co-localization of LILRA3 and NETs was assessed by immunofluorescence microscopy.

Results: Our previous RNA-sequencing of primary APS neutrophils (n=9) revealed ~3-fold upregulation of *LILRA3* in APS patients as compared with matched controls. Here, we verified this overexpression by real-time PCR in an independent cohort of 20 primary APS patients and matched controls (mean 2 fold increase in APS). We also measured LILRA3 protein and anti-LILRA3 IgG in primary APS plasma, and found a positive correlation between LILRA3 protein levels and anti-beta-2 glycoprotein I IgM ($P = 0.009$). Furthermore, as compared with matched controls, primary APS was associated with higher circulating levels of both soluble LILRA3 (1.5 fold) and anti-LILRA3 IgG (1.6 fold), with a positive correlation between the two ($P = 0.041$). To investigate whether LILRA3 might directly interact with NET DNA, LILRA3 was incubated with purified neutrophil genomic DNA and analyzed by EMSA. The addition of 0.25 μM LILRA3 (partial effect) and 1.0 μM (full effect) significantly reduced the migration of genomic DNA (0.1mg/ml) through the agarose gel, suggested a direct interaction between LILRA3 and DNA. Furthermore, by immunofluorescence microscopy, we observed clear co-localization of LILRA3 and NET strands.

Conclusion: We demonstrate for the first time elevated levels of LILRA3 and anti-LILRA3 IgG in patients with primary APS. Furthermore, LILRA3 appears to be a NET-binding protein that can be delivered extracellularly in the context of NETs, where it has potential to play a role in the pathogenesis of APS. Further studies are underway in pursuit of potential thromboinflammatory functions of this NET-binding protein.

Metabolomics Analysis Identifies Biomarkers for APS and Suggests a Potential New Pathway Related to APS Pathogenesis

Chun Li,[1] **Yu Zuo**,[2] Jason Knight,[3] Juan Feng,[4] Xian Wang,[4] David Karp,[5] and Zhanguo Li[6], [1]Peking Univerisity People's Hospital, Beijing, China (People's Republic), [2]University of Texas Southwestern, Dallas, TX, [3]Division of Rheumatology, Department of Internal Medicine, Michigan Medicine, Ann Arbor, MI, [4]Peking University School of Basic Medical Science, Beijing, China (People's Republic), [5]UTSouthwestern Medical Center, Dallas, TX, [6]People's Hospital, Beijing University Medical School, Beijing, China (People's Republic)

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Antiphospholipid Syndrome Poster

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: The metabolic disturbances that underlie antiphospholipid syndrome (**APS**) are currently unknown. The goal of this study was to utilize high-throughput metabolomics screening to identify new biomarkers and dysregulated pathways in primary APS patients.

Methods: Fasting serum samples were collected from 20 primary APS patients and 17 healthy controls. High-throughput metabolomics screening of 247 small molecule metabolites were performed via gas chromatography-coupled mass spectrometry. Multiple variate analysis, principal components analysis, partial least squares discriminant analysis (**PLS-DA**), and pathway analysis were completed. SYTOX Green NETosis assay was performed utilizing freshly-prepared healthy donor neutrophils with various stimulants including normal human IgG, polyclonal antiphospholipid antibodies (**aPL**), sphingosine-1 phosphate (**S1P**), and polyclonal aPL plus various concentrations of S1P.

Results: 50 circulating small molecule metabolites were significantly different between primary APS patients and healthy controls. PLS-DA modeling was performed and demonstrated a clear separation between primary APS patients and healthy controls (**Figure 1**). 15 metabolic molecules that contributed most to the differentiation of primary APS patients and the healthy controls (assessed by variable importance on projection score) had the highest potential to be clinically relevant biomarkers. Pathway analysis revealed that sphingosine metabolism was the most enriched pathway among primary APS patients. Sphingosine metabolism plays paramount roles in membrane biology

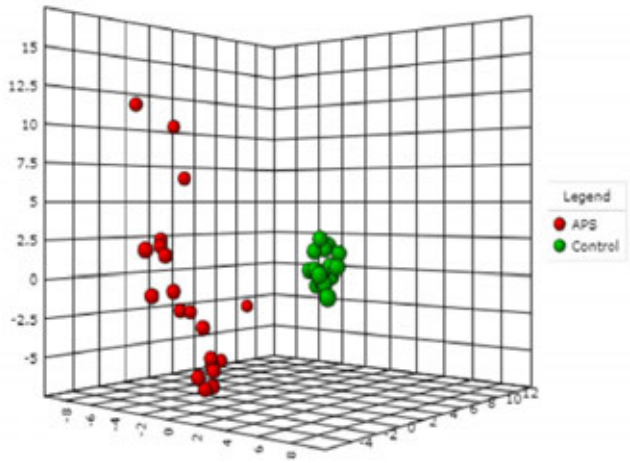

Figure 1. Metabolic analysis of primary APS patients and healthy controls. 3-D PLS-DA modeling to distinguish between APS patients and healthy controls.

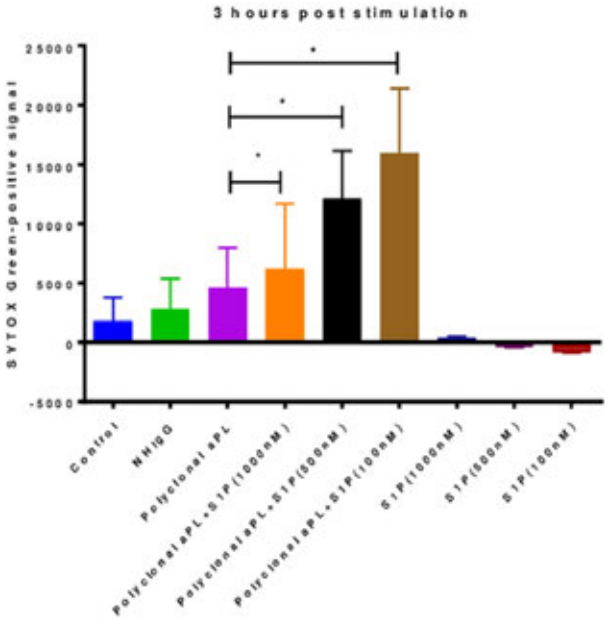

Figure 2. SYTOX Green NETosis Assay on healthy donor neutrophils with various stimulants.

and provides many bioactive metabolites that regulate cellular function. To further elucidate the role of sphingosine metabolism in APS, we examined the effect of S1P (a product of sphingosine metabolism) on aPL-mediated neutrophil extracellular trap release (**NETosis**). aPL-mediated NETosis was significantly potentiated by S1P. Importantly, S1P had no impact on NETosis in the absence of aPL (**Figure 2**).

Conclusion: This study identified metabolomic differences in the serum of primary APS patients and healthy controls. One of the most significant pathways was sphingolipid metabolism. One product of this pathway is S1P, implicated in immunological pathology. The ability of this compound to augment aPL in provoking NETosis suggests a potential role of S1P/S1PR axis in APS pathogenesis.ACR Figure

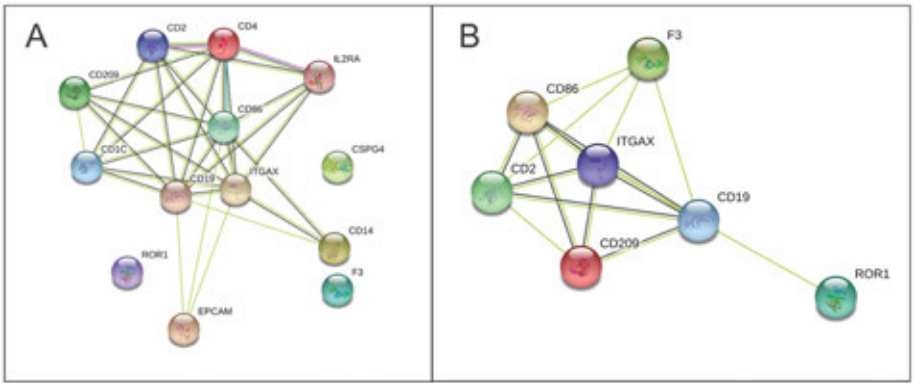
Thrombosis and Obstetric complications	non	13% (2)	14% (1)

Table 1. Patients' clinical characteristics



role in the pathogenesis of APS (1,2), however no data till now has been provided for exosomes, representing small (< 100nm), secreted vesicles of endosomal origin. Recent advances show exosomes to be involved in autoimmune cell-cell communication (3). We hypothesize that markers involved in coagulation, hemostasis and the immune system are enriched on exosomes isolated from APS patients and we aimed to determine their surface marker profiles.

Methods: Platelet poor plasma was collected from 16 APS patients and 14 aPL negative controls, (7 healthy blood donors (HBDs) and 7 patient controls (PC)) (Table 1). The groups were sex- and age-matched. LA was determined by clotting tests, aCL, anti-β2GPI, aPS/PT were measured with in-house ELISAs (4). Exosomes were isolated using

CD63-labelled magnetic beads and surface protein profile studied with MACSPlex Exosome kit (both from Miltenyi Biotec), for 37 markers (CD1c, CD2, CD3, CD4, CD8, CD9, CD11c, CD14, CD19, CD20, CD24, CD25, CD29, CD31, CD40, CD41b, CD42a, CD44, CD45, CD49e, CD56, CD62P, CD63, CD69, CD81, CD86, CD105, CD146, CD209, CD326, CD133/1, CD142, MCSP, SSEA-4, ROR1, HLA-ABC and HLA-DRDPDQ). All results were normalized against expression of tetraspanin surface proteins e.g. CD9/81/63. Student t-test and $\chi 2$ test were calculated to compare APC median signal intensities between the groups. The database of known and predicted protein interactions STRING 10.5 was used for analysis of interactions between markers.

Results: 7/37 surface markers (CD2, CD11c, CD19, CD86, CD142, CD209 and ROR1) exhibited significantly higher expression in APS patients vs. both control groups (Fig 1). Specifically, CD86+, CD142+ (TF), ROR+ exosomes were found in 44% (7/16), CD2, CD19+, CD209+ in 38% (6/16) and CD11c+ in 31% (5/16) of APS patients, while there was no positive HBD or PC ($p< 0.05$). Using STRING analysis (Fig 2A), we found strongest GO term assigned to analytes APS vs. HBD, to be cell surface receptor signaling pathway, the immune system process, while weaker association was found for regulation of T cell activation. In the KEGG pathway, the strongest association was shown for hematopoietic cell lineage, and less strong for cell adhesion molecules and complement/coagulation cascades. When comparing APS to both control groups (Fig 2B) in the KEGG pathway the association for complement/coagulation cascades was stronger.

Conclusion: Significant differences in exosomal surface markers of APS patients vs. HBD and PC indicate the involvement of the immune system, surface receptor signaling, cell adhesion molecules and complement/coagulation cascades. Profiles of exosomes thus show activated status of immune cells and coagulation cascade in aPL positive patients. Our study also demonstrates that MACSPlex facilitates sensitive multiparametric phenotyping of exosomes in patient plasma.

Is There Clinically Relevant Plasma Interference with ELISA Detection of APS Antibodies? Reproducibility of Serum and Plasma Testing in a Real-World Clinical Setting

Michael Pham,[1] Giovanni Orsolini,[2] Cynthia Crowson,[3] Melissa Snyder,[1] Rajiv Pruthi,[4] and Kevin Moder[5], [1]Mayo Clinic, Rochester, MN, [2]University of Verona, Verona, Italy, [3]Mayo Clinic Rochester, Rochester, [4]Mayo Clinic, Rochester, [5]Mayo Clinic Rochester, rochester, MN

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Antiphospholipid Syndrome Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Traditionally in ELISA detection of APS antibodies, the use of serum is thought to be preferable over plasma according to international consensus bodies. The dilution effects of citrate in the plasma blood draw tube or matrix effects with fibrinogen are some of the cited concerns. However, there is scarcity of clinical data comparing reproducibility of APS antibody detection in serum versus plasma. The purpose of this study was to determine reproducibility of anti-cardiolipin (aCL), beta2-glycoprotein-1 (β2GP1), and phosphatidylserine-prothrombin (aPS-PT) antibody detection between serum and plasma in a real-world clinical setting.

Methods: Patients with clinical serum draws for IgG/IgM aCL, β2GP1, and aPS-PT antibodies were identified, and same-day, platelet-poor citrated plasma samples were obtained for repeat ELISA testing with commercially available ELISA assays. Quantitative levels were determined for each isotype without citrate volume correction and further stratified into Negative (< 15.0 GPL/MPL or U/mL), Weakly Positive (15.0-39.9), or Positive (≥40.0) reference cutoff categories. Median and mean differences along with inter-sample reliability were compared using Wilcoxon paired signed-rank method and kappa coefficients, respectively.

Results: One hundred fifty patients were identified for study with 134 aCL, 110 β2GP1, and 7 aPS-PT serum samples eligible for repeat plasma testing. Mean age was 49±16 years. About 69% were female, 87% were Caucasian, 21% with APS, and 13% with SLE. As shown in Table 1, median differences were generally 0.0 units and mean differences largely falling within 2 units. The differences were technically statistically significant. There was strong inter-sample agreement in reference cutoff category with kappa coefficients ranging from 0.80 to 1.00.

Conclusion: To our knowledge, we present the largest study examining the reproducibility of APS antibodies on paired serum and plasma samples in a real-world clinical setting. Small differences were detected between serum and plasma for aCL and β2GP1 antibodies with similar trends in aPS-PT antibodies. Although the observed differences were statistically significant, the magnitude of the differences was small and the clinical relevance is likely negligible. Moreover, with kappa coefficients of at least 0.80, there was strong inter-sample agreement in reporting negative, weakly positive and positive categories for aCL and β2GP1 antibodies. These results suggest serum and plasma could be used interchangeably for ELISA detection of antiphospholipid antibodies in a clinical setting.

Table 1 – Reproducibility of aCL, β2GP1, and aPS-PT Antibody Levels in Paired Serum versus Plasma

		Quantitative Levels			Agreement to Reference Category
	N Samples	Median Difference (IQR)[1]	Mean Difference (sd)[1]	*p-value*	Weighted κ Coefficient (95% CI)
IgG aCL	134	0.0 (0.0, 0.0)	1.4 (11.8)	<0.05	0.86 (0.78, 0.94)
IgM aCL	134	0.0 (0.0,2.1)	2.1 (9.4)	<0.05	0.85 (0.76, 0.93)
IgG β2GP1	110	0.0 (0.0, 0.0)	0.8 (5.6)	<0.05	1.00 (1.00, 1.00)
IgM β2GP1	110	0.0 (0.0, 0.05)	1.8 (11.6)	<0.05	0.80 (0.68, 0.92)
IgG aPS-PT	7	0.0 (0.0, 0.0)	1.6 (4.3)	>0.10	†
IgM aPS-PT	7	0.0 (-1.4, 0.0)	-0.9 (1.9)	>0.10	†

Anti-Phosphatidylserine Prothrombin Antibodies as a Predictor of the LAC in an All-Comer Population

Michael Pham,[1] Giovanni Orsolini,[2] Cynthia Crowson,[3] Melissa Snyder,[1] Rajiv Pruthi,[4] and Kevin Moder[5], [1]Mayo Clinic, Rochester, MN, [2]University of Verona, Verona, Italy, [3]Mayo Clinic Rochester, Rochester, [4]Mayo Clinic, Rochester, [5]Mayo Clinic Rochester, rochester, MN

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Antiphospholipid Syndrome Poster

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Anti-phosphatidylserine prothrombin antibodies (aPS-PT) are reported to be highly associated with the LAC. Some have suggested a clinically useful role for aPS-PT as a potential surrogate marker for the LAC – especially in the clinical scenario of concurrent anticoagulation where the LAC can have decreased diagnostic performance. However, the studies revealing the aPS-PT and LAC relationship have primarily been carried out on well-established APS and SLE cohorts. Validation studies replicating this relationship in a real-world, all-comer study population are lacking. The purpose of this study was to determine the sensitivity and specificity of aPS-PT to the LAC and other APS serologies in an all-comer population undergoing evaluation for APS and other autoimmune syndromes.

Methods: A cross-section of patients from June 2017 to December 2018 undergoing evaluation for APS across all medical specialties were reviewed for APS testing inclusive of LAC, aPS-PT, anti-cardiolipin (aCL), and anti-β2 glycoprotein-1 (β2GP1). Presence of a LAC was determined by trained hematologists interpreting mixing and neutralization studies. Demographic details were abstracted from the medical record. Cases meeting the SLICC criteria for SLE and the revised Sapporo criteria for APS were enumerated. Sensitivities, specificities, negative-, and positive predictive values with 95% confidence intervals were calculated.

Table 1: Sensitivity and Specificity of IgG and IgM aPS-PT to the LAC and other APS Serologies

	aPS-PT Sensitivity, %		aPS-PT Specificity, %		aPS-PT NPV, %		aPS-PT PPV, %	
	IgG	IgM	IgG	IgM	IgG	IgM	IgG	IgM
LAC	41 (95%CI: 30-53)	54 (41-65)	100 (96-100)	97 (91-100)	65 (56-73)	69 (59-77)	100 (89-100)	95 (84-99)
IgG aCL	53 (28-77)	72 (47-90)	89 (82-94)	80 (72-87)	93 (87-97)	95 (89-98)	39 (20-61)	34 (20-51)
IgM aCL	20 (4-48)	85 (55-98)	84 (76-90)	85 (77-91)	90 (83-95)	98 (94-100)	13 (3-34)	37 (20-56)
IgG β2GP1	58 (33-79)	74 (49-91)	89 (83-94)	80 (72-87)	93 (88-97)	95 (89-98)	44 (24-65)	36 (21-53)
IgM β2GP1	42 (15-72)	100 (72-100)	84 (76-89)	82 (74-88)	94 (88-98)	100 (97-100)	19 (6-38)	31 (17-49)

Abbreviations: LAC = Lupus Anticoagulant, aCL = anti-Cardiolipin, β2GP1 = anti-β2 Glycoprotein-1, aPS-PT = anti-Phosphatidylserine-Prothrombin, NPV = Negative Predictive Value, PPV = Positive Predictive Value

Results: A sample of 166 eligible patients was identified. Mean age was 49±17 years. Seventy-one percent were female, 89% Caucasian, 15% with SLE, and 21% with APS. At time of testing, 18% were on warfarin, 8% on direct factor Xa inhibitors and 1% on low-molecular weight heparin. The aPS-PT was found to be the most specific to the LAC as seen in table 1. Specificity of IgG aPS-PT was 100% (96-100%) and IgM aPS-PT was 97% (91-100%) to the LAC. This corresponds to a positive predictive value for IgG aPS-PT of 100% (89-100%) and IgM aPS-PT of 95% (84-99%). Specificities of aPS-PT to aCL and β2GP1 antibodies were slightly less in the 80% range. In contrast, the sensitivities of aPS-PT to the LAC were only in the 40-50% range.

Conclusion: In our study with an all-comer population undergoing evaluation for APS and other autoimmune syndromes, aPS-PT had high specificity and high positive predictive value to the presence of the LAC. The sensitivity and negative predictive performance of aPS-PT to LAC however was less robust. This study's findings echo similar findings in past studies on APS and SLE cohorts. And, it corroborates the notion that a positive aPS-PT could be a clinically useful marker for the LAC in the general clinical setting.zACR_PSPT LAC association_PDF TABLE

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Antiphospholipid Syndrome Poster

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: The clinical significance of non-canonical anti-phosphatidylserine/prothrombin (aPS/PT) antibodies in antiphospholipid syndrome (APS) is still controversial. This study assessed the prevalence of aPS/PT antibodies, their association with different APS clinical phenotypes and their involvement in the serum and monocytes molecular profiles.

Methods: Forty APS patients and 40 healthy donors were examined. Anti-cardiolipin (aCL), anti-β2GP-I and aPS/PT antibodies (IgG, IgM and IgA isotypes), as well as lupus anticoagulant (LA) were tested. In parallel, monocytes from peripheral blood were purified by positive immunomagnetic selection. Gene expression microarray (Agilent GF112F) and nCounter microRNA expression array (Nanostring) were performed. Separately, a miRNA array in the plasma of those patients was performed, along with the analysis of their inflammatory profile by multiplex assay. Selected

genes and miRNAs found significantly altered and related to the prothrombotic and obstetric pathology in APS were validated in the whole cohort by qPCR. The involvement of the presence and titers of canonical and non-canonical autoantibodies on the altered inflammatory and gene/miRNA profiles were assessed by multiple comparison tests.

Results: aPS/PT antibodies were detected in 11 out of 26 APS patients (42,3%): 6 carriers of the IgM isotype, 1 carrier of IgA isotype, 1 carrier of both IgM and IgA isotypes and 3 carriers of the three isotypes (IgG/IgA/IgM) simultaneously. The 3 isotypes of aPS/PT antibodies were significantly associated with isolated LA positivity. Among them, there was a prevalence of IgM aPS/PT antibodies in thrombotic patients, and of IgA aPS/PT antibodies in patients with obstetric complications. Levels of IgM aPS/PT were significantly different in APS patients with thrombotic manifestations and those with fetal loss.

Inflammatory profile in plasma of APS patients positive for these non-canonical antibodies showed significantly increased levels of a number of pro-inflammatory mediators (IL2, IL4, IL6, INFg, IL8, IL10, IL12, IL17, GM-CSF, MIP1a, MIP1b) in relation to patients positive for canonical antibodies, along with reduced levels of serum miR26a-5p.

Accordingly, monocytes from APS patients positive for aPS/PT displayed slightly distinctive gene/miRNA profiles related to atherosclerosis and thrombosis than those negative for non-canonical antibodies compared with HDs. Moreover, increased IFNg mRNA classified patients positive or negative for aPS/PT antibodies. This IFNg altered expression might be related to the occurrence of obstetrical complications, as observed by its increased expression in aPS/PT positive obstetric patients in relation to thrombotic patients.

Conclusion: Conclusions: Anti-PS/PT antibodies are frequent in primary APS patients positive for other antiphospholipid antibodies, are associated with different clinical features, and confer distinctive molecular profiles. Thus, anti-PS/PT antibodies might constitute a useful serological tool in the diagnosis, phenotypic and molecular characterization of APS patients.

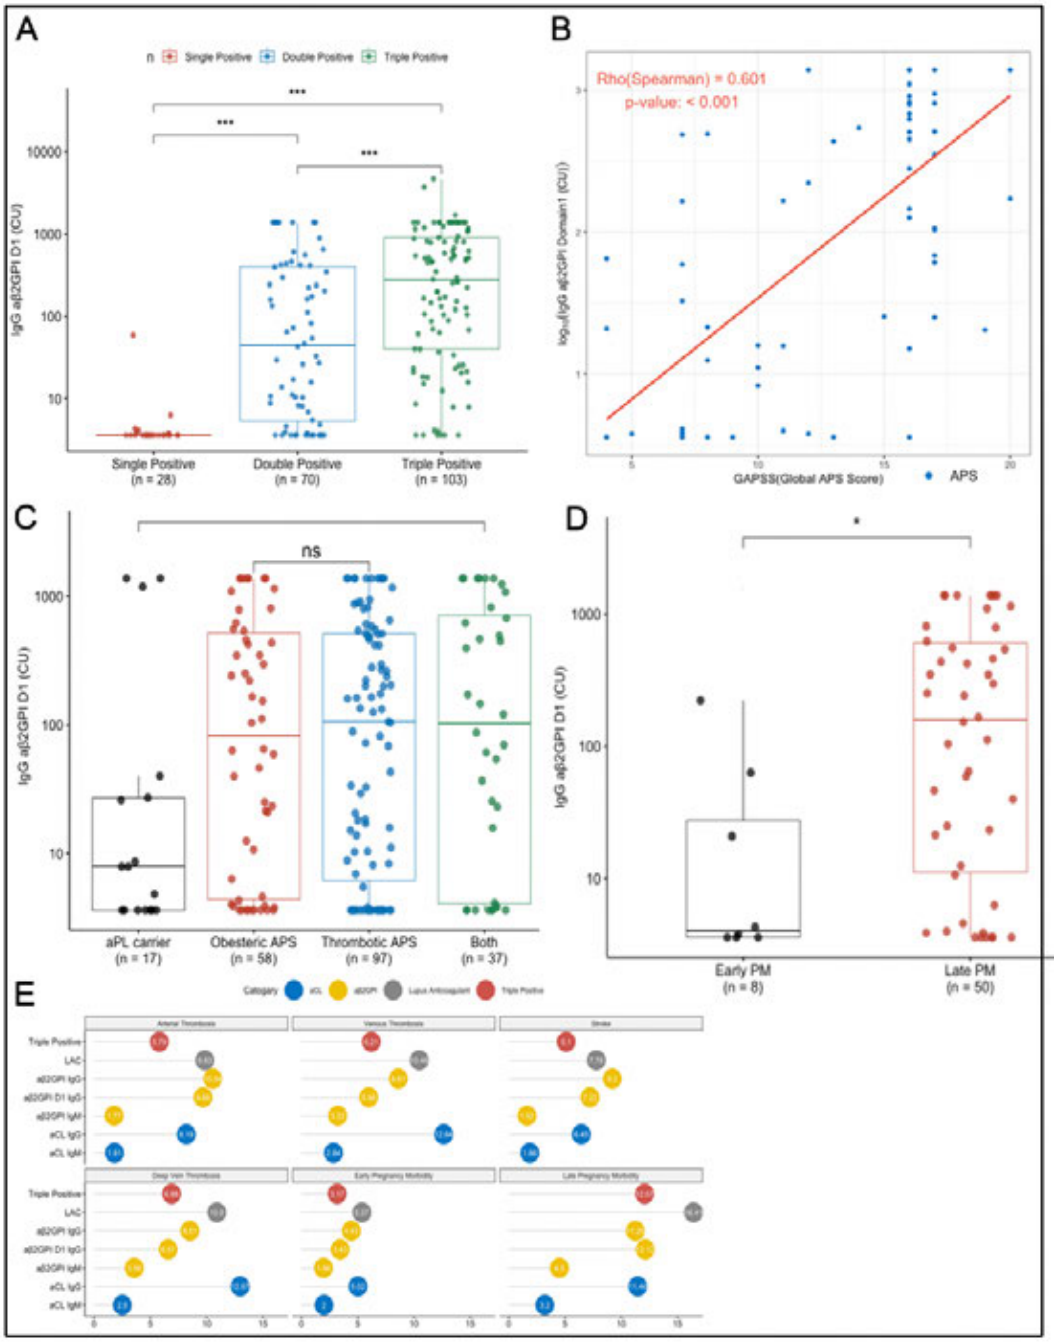
Anti-β2GPI Domain 1 Antibodies Stratify High Risk of Thrombosis and Pregnancy Morbidity in a Large Cohort of Chinese Patients with Antiphospholipid Syndrome

Tingting Liu,[1] Jieyu Gu,[1] Liyan Wan,[1] Gary L. Norman,[2] Hui Shi,[1] and Chengde Yang[1], [1]Department of Rheumatology and Immunology, Ruijin Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, China (People's Republic), [2]INOVA Diagnostics, Inc., CA 92131

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Antiphospholipid Syndrome Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM



Background/Purpose: Anti-β2GPI-Domain 1 (β2GPI -D1) antibodies are currently considered to be a pathogenic subset of anti-β2GPI antibodies and have been strongly associated with thrombosis and pregnancy morbidity in antiphospholipid syndrome (APS) patients. We evaluated the clinical utility of anti-β2GPI-D1 IgG antibody for stratifying the risk of thrombosis and/or pregnancy morbidity (PM) in a cohort of Chinese patients with APS and also assessed its correlation with the Global Anti-Phospholipid Syndrome Score (GAPSS).

Methods: Sera from 192 APS patients, 17 aPL carriers, 193 patients with other systemic autoimmune diseases, and 120 healthy controls were collected and the presence of aCL IgG/IgM, anti-β2GPI IgG/IgM antibodies and anti-β2GPI-D1 IgG were assessed by chemiluminescence assays (CIA). Anti-phosphatidylserine-prothrombin (aPS/PT) IgG and IgM antibodies were detected by commercial ELISA kits.

Results: Anti-β2GPI-D1 IgG antibodies showed high specificity (97.12%) and moderate sensitivity (64.32%) for the diagnosis of APS. Anti-β2GPI-D1 antibody levels were significantly higher in patients with triple aPL positivity and correlated well with the GAPSS. Anti-β2GPI-D1 antibody presented with a higher prevalence and higher titers in patients with late pregnancy morbidity (≥10 wks) and thrombosis compared to those with early pregnancy (< 10 wks) morbidity. Higher anti-β2GP1-D1 antibody titers effectively distinguished APS from other autoimmune diseases.

Conclusion: This study suggests a predictive role of anti-β2GPI-D1 IgG antibodies as a strong risk factor for both thrombotic and obstetric APS (OAPS), especially for late adverse pregnancy outcomes.

Anti-β2GPI-D1 IgG antibodies act as a strong risk factor for both thrombotic and obstetric APS (OAPS), especially for late adverse pregnancy outcomes.

'Non-criteria' Antiphospholipid Antibodies Add Value to Antiphospholipid Syndrome Diagnoses in a Large Chinese Cohort

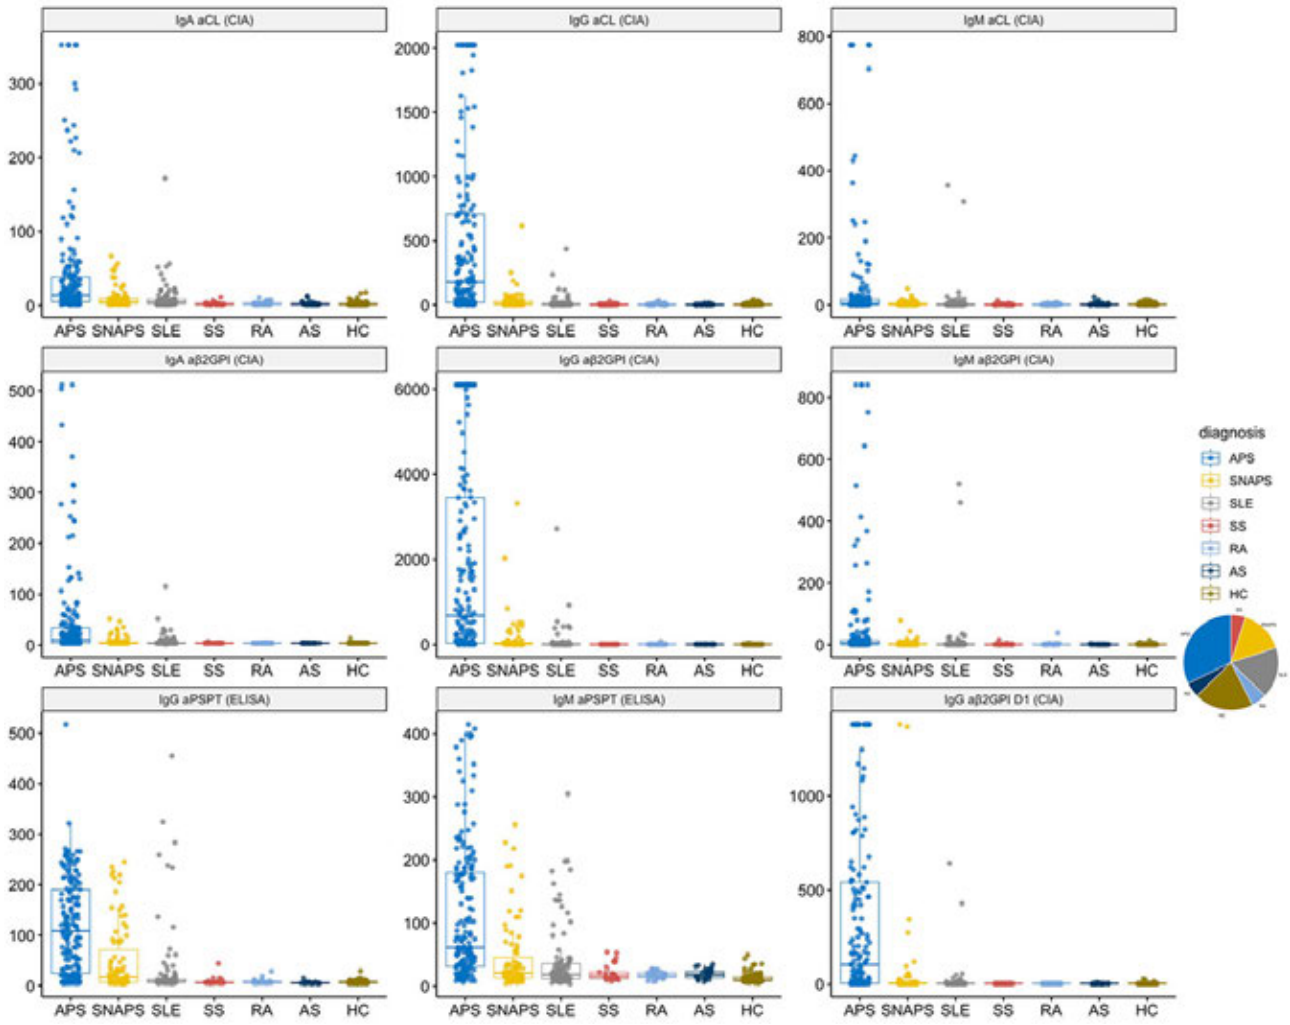
Jieyu Gu,[1] Tingting Liu,[1] Liyan Wan,[1] Gary L. Norman,[2] Chengde Yang,[1] and Hui Shi[3], [1]Department of Rheumatology and Immunology, Ruijin Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, China (People's Republic), [2]INOVA Diagnostics, Inc., CA 92131, [3]University of Michigan, Ann Arbor, MI

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Antiphospholipid Syndrome Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

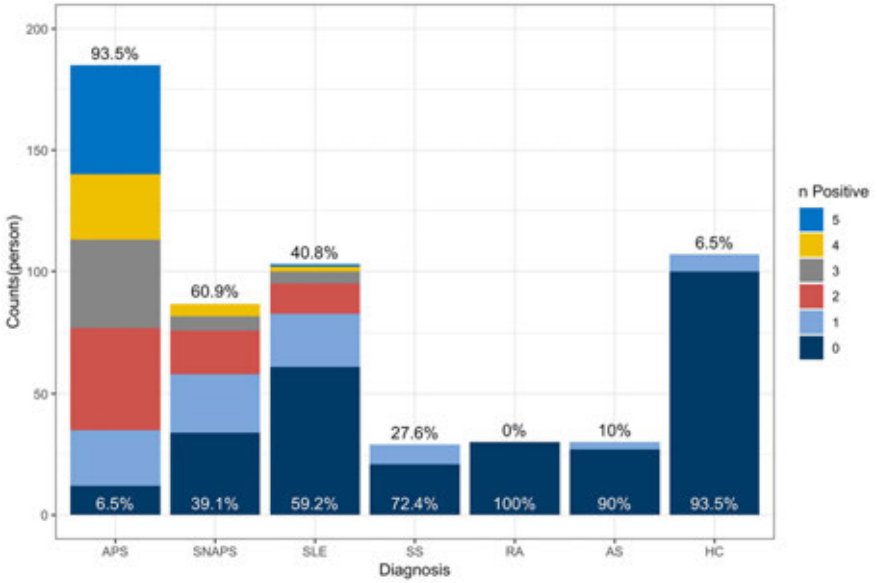
Background/Purpose: The laboratory criteria used in the 2006 Sydney Classification criteria for antiphospholipid syndrome (APS) which is widely used in clinical practice, includes IgG/IgM isotypes of anti-cardiolipin antibodies (aCL), IgG/IgM isotypes of anti β2-glycoprotein I antibodies (aβ2GPI) and lupus anticoagulant (LAC), but there stands a group of patients tagged as seronegative-APS (SNAPS) with clinical manifestation prompting APS but persistent negative criteria antiphospholipid antibodies. Since these patients are at risk of developing recurrent thrombosis and pregnancy morbidities as the APS patients are, it is of great importance to distinguish these patients, meanwhile necessary clinical intervention or preventive measures should be carried out to minimize losses due to the disease. This study aims to assess the value of non-criteria antiphospholipid antibodies in SNAPS patients.

Methods: 192 APS patients fulfilling the 2006 Sydney classification criteria, 90 SNAPS patients, 193 disease control with other autoimmune diseases and 120 healthy controls were included in the survey. A total of 10 different aPLs were tested in the cohort using commercial kits, including 5 non-criteria aPLs: IgG/IgM anti-phosphatidylserine/prothrombin antibodies (aPS/PT), IgA aCL, IgA aβ2GPI, IgG anti-β2GPI Domain 1 (aβ2GPI D1).

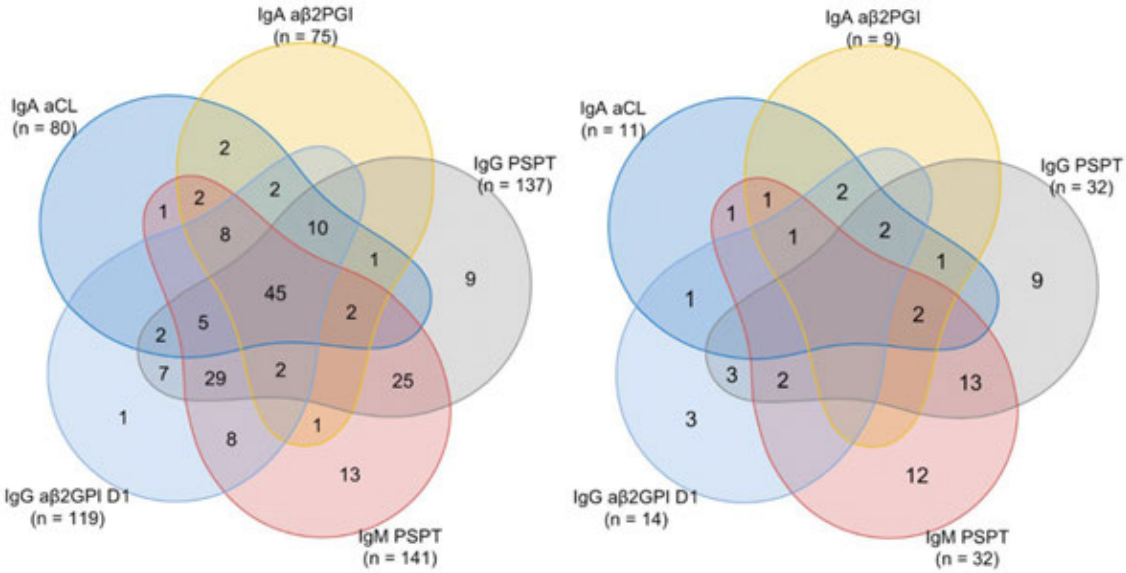
Results: Up to 60.9% SNAPS patients were detected by at least one kind of non-criteria aPLs, and the percentage reaches 93.5% in the APS group. IgG aPS/PT has the biggest Youden Index in classifying APS and SNAPS from the control group, while IgM aPS/PT is a little bit better in sensitivity, just secondary to IgG aβ2GPI. Besides, IgG β2GPI Domain1 is best related with pregnancy morbidities among all the markers. All of the three aforementioned markers can be separately detected in some of the SNAPS patients, while the IgA isotypes of aCL/aβ2GPI tend to appear together with other biomarkers, but they show better diagnostic and prognostic value compared with the IgM



Dot plot of the nine aPL titers among different diagnostic groups, with the box showing the quantile values.



The black percentage above the bars indicates the percentage of patients with any positive non-criteria antibodies while the white percentage on the bottom indicates those without positive non-criteria antibodies.



isotypes of the same aPL. Combined analysis showed better performance of the antibodies profiles with the help of non-criteria aPLs.

Conclusion: SNAPS patients account for a noticeable cohort in the clinical management of thrombotic and obstetric adverse events, and the non-criteria antiphospholipid antibodies help to distinguish a considerable part (40.8%) of these patients in clinical practice.

Numbers in the overlapping region represents the number of patient with specific positive non-criterial aPLs pattern, meanwhile numbers in the non-overlapping region represents the number of patients with single positive non-criterial aPLs. Number in the brackets represents the number of patients in the group with positive outcome of the specific aPL.

Added Clinical Utility of Testing for Extra-Criteria Antibodies Specificities Beyond Sapporo and Sydney Criteria Recommendations

Savino Sciascia,[1] Irene Cecchi,[2] Massimo Radin,[2] Elena Rubini,[2] Silvia Grazietta Foddai,[2] Dario Roccatello,[2] Chelsea Bentow,[3] Andrea Seaman,[3] Carlos Ramirez,[3] and Michael Mahler[3], [1]Center of Research of Immunopathology and Rare Diseases- Coordinating Center of Piemonte and Valle d'Aosta Network for Rare Diseases, Department of Clinical and Biological Sciences, University of Turin, Torino, Italy, [2]University of Turin, Turin, Italy, [3]Inova Diagnostics, San Diego, CA

SESSION INFORMATION

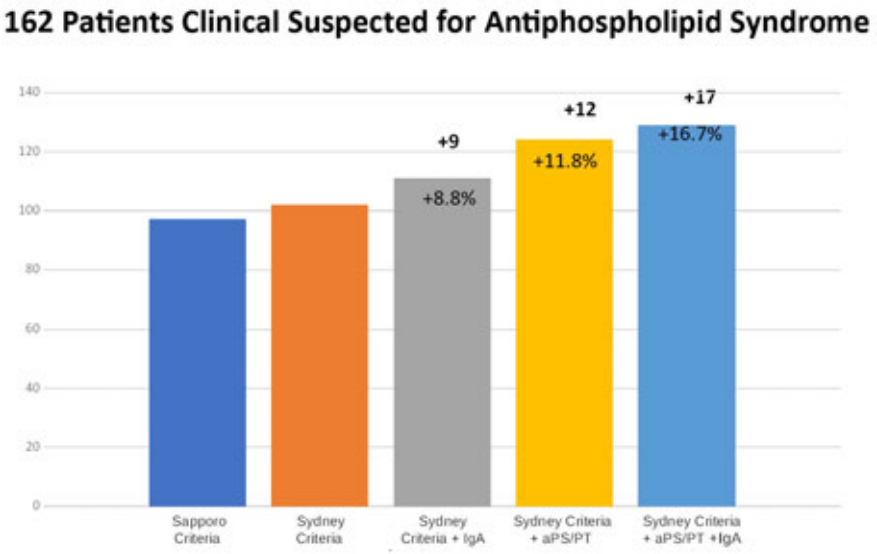
Session Date: Sunday, November 10, 2019

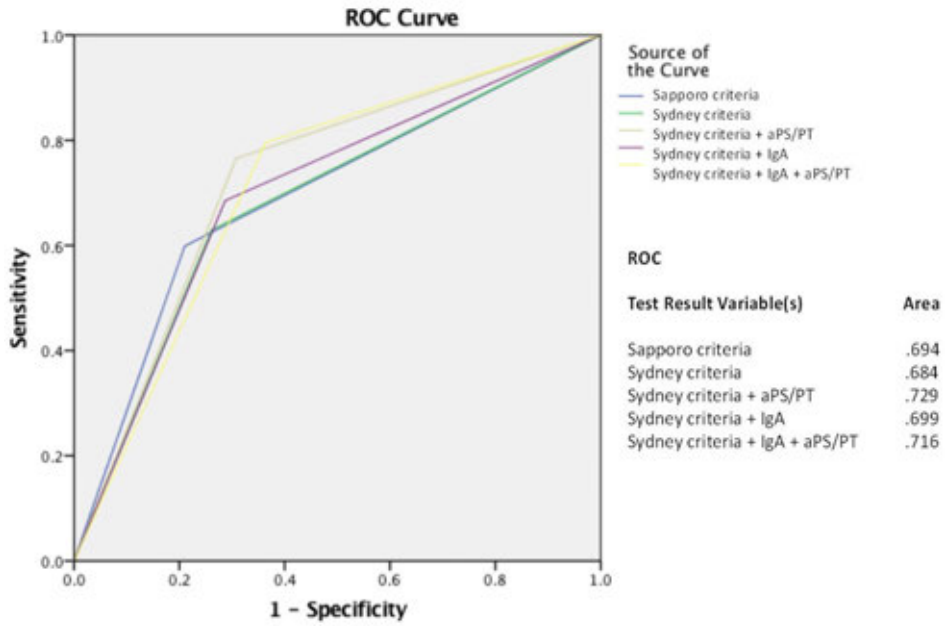
Session Title: Antiphospholipid Syndrome Poster

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: The laboratory diagnostics of antiphospholipid syndrome (APS) takes into account the persistent positivity for anticardiolipin (aCL) and/or anti-β2glycoprotein I (anti-β2GPI) antibodies and/or the presence of lupus anticoagulant (LA). However, testing for extra-criteria antiphospholipid antibodies (aPL) is emerging as a poten-





tial tool to improve diagnostic accuracy in patients suspected for APS. In this study we aimed to evaluate the clinical accuracy of aPL specificities both individually and/or in combination, in a wide cohort of patients suspected for APS [on the basis of the presence of thrombosis and/or pregnancy morbidity (PM-)] in an attempt to identify a panel of tests that may provide the best accuracy for diagnosing APS.

Methods: This study included 277 patients affected by an autoimmune systemic disease (234 women, mean age 44.7 ± 13.9 years). One hundred-forty-four patients suffered at least one thrombotic event or PM as described in the current classification criteria for APS. All patients were tested for LA, aCL, anti-β2GPI and anti-phosphatidylserine/prothrombin (aPS/PT). Testing for aCL, anti-β2GPI, and aPS/PT included IgG/M/A isotypes using a novel particle-based multi-analyte technology (PMAT, Aptiva System, Inova Diagnostics, research use only). Sensitivity, specificity, and predictive values were calculated. The diagnostic accuracy for each combination of tests was assessed by receiver operating characteristic (ROC) curve analysis and their area under the curve (AUC) was calculated.

Results: Six possible combinations of results were derived from testing for 4 aPL (Figure 1). Among them, LA+/aCL+/aβ2GPI+/aPS/PT had the best diagnostic accuracy for APS [AUC 0.73, OR 4.0 (95% CI 1.9-6.0)]. Introducing testing for IgA and aPS/PT in the diagnostic workout of patients for suspected APS improved the diagnostic accuracy up to 16.7% (Figure 2).

Conclusion: Combining LA,aCL, aβ2GPI, and aPS/PT improves the diagnostic power and helps in stratifying the risk for each patient, according to their aPL profile

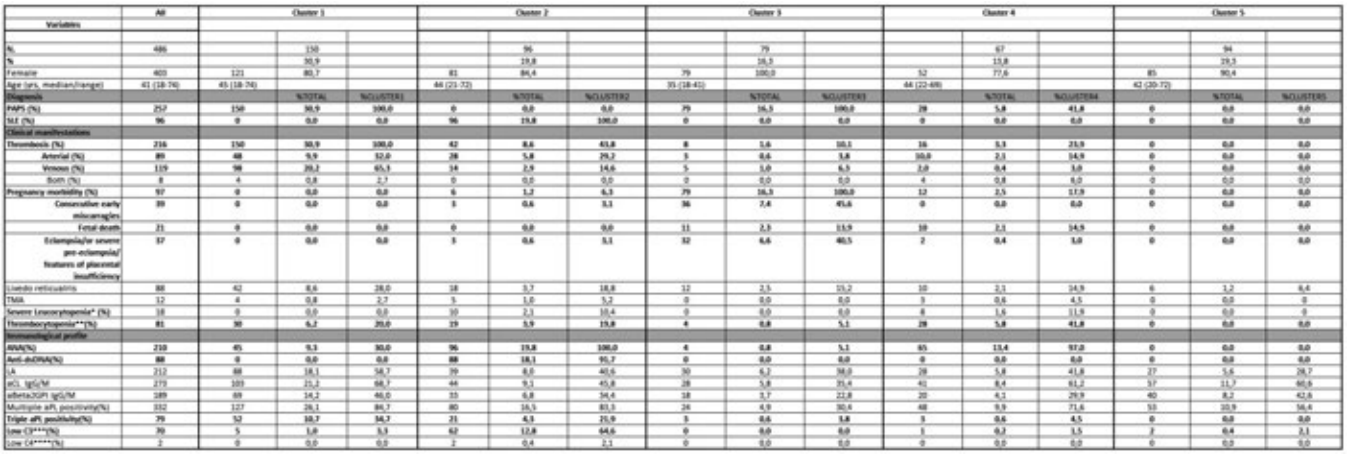
Identifying Phenotypes of Patients with Antiphospholipid Antibodies: Results from a Cluster Analysis in a Large Cohort of Patients

Savino Sciascia,[1] Massimo Radin,[2] Irene Cecchi,[2] Maria Laura Bertolaccini,[3] Tiziana Bertero,[2] Elena Rubini,[2] Antonella Vaccarino,[2] Mario Bazzan,[2] Osvaldo Giachino,[2] Simone Baldovino,[2] Daniela Rossi,[2] Giulio Mengozzi,[2] and Dario Roccatello[2], [1]Center of Research of Immunopathology and Rare Diseases- Coordinating Center of Piemonte and Valle d'Aosta Network for Rare Diseases, Department of Clinical and Biological Sciences, University of Turin, Torino, Italy, [2]University of Turin, Turin, Italy, [3]King's College London, London, United Kingdom

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Antiphospholipid Syndrome Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: In this study, we sought to perform an unsupervised hierarchical clustering analysis in a large cohort of antiphospholipid antibodies (aPL) positive patients, to identify the aggregation of patients into different subgroups sharing common characteristics in terms of clinical and laboratory phenotypes.

Methods: We applied a hierarchical cluster analysis from the multiple correspondence analysis to determine subgroups of patients according to clinical and laboratory characteristics in patients with confirmed aPL positivity who presented to our outpatient clinics 2006 to 2018.



Results: We included in this observational, retrospective, and multicentre study 486 patients (403 [83%] women; median age, 41[18-74] years; mean age, 41.7 years±26) with confirmed aPL. Among those 486 subjects, 5 clusters of patients emerged. Cluster 1 (N=150) presented with thrombotic events (65% with a venous thrombosis) in the absence of a confirmed diagnosis of systemic lupus erythematosus(SLE). Up to 85% of patients from Cluster 1 were positive for more than one aPL, triple aPL positivity was found in 35% of the patients, the highest rate observed among the different subgroups($p< 0.01$). All the patients from Cluster 2 (N=91 patients, 84.4% were female) had a confirmed diagnosis of SLE and presented with ANA positivity. These patients had the highest rate of anti-dsDNA positivity(as high as 92%), and up to 64.6% of them presented hypocomplementemia($p< 0.01$). Cluster 3 included 79 women who suffered from pregnancy morbidity, with consecutive early miscarriages in up to 45.6% of the cases. Multiple aPL positivity was found in 30%, with triple positivity in 3.8%, rates significantly lower when compared to Cluster 1(85% and 35%v.s.30 and 4% for multiple and triple positivity, respectively,$p< 0.01$). Cluster 4 included 67 patients (13.8% of the total), 28(42%) of whom with defined diagnosis of APS. Thrombotic events were observed in 16 out of 67(24%) patients. Patients in this group had the highest rate of cytopenia, with thrombocytopenia as high 42%. None of them had anti-dsDNA antibodies positivity. Multiple aPL positivity was found in 72% of the patients, with triple positivity in 4.5%,rate significantly lower when compared to Cluster 1(85% of multiple aPL and 35% of triple aPL positivity) and Cluster 2(83% for multiple aPL and 22% triple aPL positivity, $p< 0.01$). Cluster 5 included 94 subjects. No subjects in this group had a history of thrombosis or pregnancy morbidity. They were all negative for ANA and anti-dsDNA, with normal leukocytes and platelets count.

Conclusion: This study identified 5 clusters emerging from unsupervised analysis. Clusters 1, 2, 3 and 5 corresponded to well-known entities, such thrombotic Primary APS, Secondary APS, obstetric APS and aPL carriers, respectively. Cluster 4 might represent a bridging condition between patients with pure PAPS and defined SLE, with lower thrombotic risk when compared to Primary APS but higher general features such as ANA and cytopenia (mainly thrombocytopenia), representing a group that might benefit of different therapeutic approaches rather than only counterbalancing the pro-thrombotic status.

Demographic, clinical and laboratory characteristics among the Cluster analysed

Session Title: Antiphospholipid Syndrome Poster

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: APS ACTION "Registry" was created to study the long-term natural history and outcomes of persistently antiphospholipid antibody (aPL)-positive patients with and without other systemic autoimmune diseases (SAID). Our primary objective was to describe baseline demographic, clinical, and laboratory characteristics of patients enrolled since 2010.

Methods: A web-based data capture system is used to store patient demographics and aPL-related medical history. APS ACTION Registry includes adults aged 18 to 60 years with positive aPL, based on the Updated Sapporo APS Classification Criteria, tested on two occasions at least twelve weeks apart within one year prior to enrollment.

Table: Clinical Characteristics of Antiphospholipid Antibody (aPL) Positive Patients in the Antiphospholipid Syndrome Alliance for Clinical Trials and International Networking (APS ACTION) Registry Tested for Three aPL Tests*, Categorized by aPL Profile (n: 668)

Baseline Clinical Characteristics (n: 660)** (Number [%])	LA only Positivity 168 (25%)	Any Single*** aPL Positivity 215 (32%)	Single aPL (excluding LA only) 47 (7%)	Double*** aPL Positivity 167 (25%)	Triple*** aPL Positivity 278 (42%)
Any Vascular thrombosis	123 (73%)	144 (67%)	21 (45%)	113 (68%)	191 (69%)
- Arterial thrombosis	56 (33%)	68 (32%)	12 (26%)	60 (36%)	87 (31%)
- Venous Thrombosis	81 (48%)	92 (43%)	11 (23%)	66 (40%)	130 (47%)
- Small vessel thrombosis	10 (6%)	12 (6%)	2 (4%)	9 (5%)	16 (6%)
- Transient Ischemic Attacks	11 (7%)	13 (6%)	2 (4%)	19 (11%)	20 (7%)
Any Pregnancy Morbidity	61/125 (49%)	75/163 (46%)	14/38 (37%)	55/123 (45%)	77/192 (40%)
- >1 Fetal Death ≥10th week	31 (51%)	39 (52%)	8 (57%)	29 (53%)	43 (56%)
- >1 Preterm Delivery <34th week	12 (20%)	13 (17%)	1 (7%)	14 (25%)	29 (38%)
- 1 or 2 Pre-Emb/Emb Loss <10th week	37 (61%)	45 (60%)	8 (57%)	28 (51%)	34 (44%)
- ≥3 Pre-Emb/Emb Loss <10th week	9 (15%)	14 (19%)	5 (36%)	6 (11%)	6 (8%)
Any Non-Criteria Manifestation	93 (55%)	107 (50%)	14 (30%)	104 (62%)	158 (57%)
- Livedo Reticularis/Racemosa	27 (16%)	28 (13%)	1 (2%)	24 (14%)	32 (12%)
- Persistent Thrombocytopenia	26 (15%)	30 (14%)	4 (9%)	29 (17%)	70 (25%)
- Hemolytic Anemia	9 (5%)	10 (5%)	1 (2%)	7 (4%)	16 (6%)
- Cardiac Valve Disease	11/146 (8%)	12/188 (6%)	1/42 (2%)	12/142 (8%)	32/234 (14%)
- Skin Ulcers	6 (4%)	7 (3%)	1 (2%)	7 (4%)	10 (4%)
- aPL-associated Nephropathy	4/157 (3%)	4/201 (2%)	0	5/160 (3%)	11/256 (4%)
- Cognitive Dysfunction	14 (8%)	17 (8%)	3 (6%)	20 (12%)	33 (12%)
- Multiple Sclerosis-like disease	2 (1%)	3 (1%)	1 (2%)	3 (2%)	0
- Chorea	2 (1%)	2 (1%)	0	4 (2%)	6 (2%)
- Seizure	17 (10%)	21 (10%)	4 (9%)	13 (8%)	23 (8%)
- White Matter Lesions	33/120 (28%)	40/155 (26%)	7/35 (20%)	33/116 (28%)	45/190 (24%)

*Three aPL tested were lupus anticoagulant test [(LA), anticardiolipin antibodies [(aCL), and anti-β_2-Glycoprotein-I antibodies (aβ_2GPI). Only 5/660 (0.8%) of patients had isolated aCL/aβ_2GPI IgA positivity with negative LA and aCL/aβ_2GPI IgG/M

**8 patients had low titer (20-39U) aPL ELISA with negative LA test; thus they were excluded

***: 40U cut-off for aCL and aβ_2GPI IgG/M/A positivity; All groups except LA only and any single aPL were mutually exclusive

Patients are followed every 12±3m with clinical data and blood collection. For this retrospective analysis, we descriptively evaluated the sociodemographic and clinical characteristics of patients overall and in categories by disease manifestation (aPL positive without APS, thrombotic APS, and obstetric APS). We also assessed the clinical characteristics of aPL-positive patients who were tested for all three aPL (lupus anticoagulant [LA] test, anticardiolipin antibody [aCL], and anti-β_2-Glycoprotein-I [aβ_2GPI]) by subgroups based on aPL profiles (LA only, single, double, and triple positivity). Positivity for aCL IgG/M/A and aβ_2GPI IgG/M/A was defined as a titer of ≥40 GPL/MPL/APL units and the highest titer among all test results was taken into consideration during analysis.

Results: As of March 2019, 804 patients were enrolled from 26 centers (mean age: 45 ± 13y; female: 74%; white 68%; and other SAID: 36%). Overall, 172 (21%) were aPL-positive without APS, 453 (56%) thrombotic APS; 73 (9%) purely obstetric APS; and 106 (13%) both thrombotic and obstetric APS. Among thrombotic APS patients, there were slightly higher rates of venous vs arterial thrombosis (62% vs 49%). Slightly higher rates of at least one non-criteria manifestation were observed in APS versus aPL only patients (58% vs 49%). All three aPL were tested in 668 (83%) patients, of whom 278 (42%) were triple positive. While similar frequencies of overall vascular thrombosis, pregnancy morbidity, and non-criteria manifestation were seen across single, double, and triple positivity subgroups, the lowest frequencies were observed in the single aPL positivity (excluding lupus anticoagulant [LA] only) subgroup **(Table).**

Conclusion: One-fifth of APS ACTION patients do not fulfill clinical APS classification criteria; 70% have vascular events; one-fifth have obstetric morbidity; and more than half have at least one non-criteria manifestation. Within single aPL-positivity, LA positivity appears to be an important contributor to aPL-related clinical features. Future prospective analyses, using standardized core laboratory aPL tests, will help better clarify aPL risk profiles.

Abstract Number: 0138

Relationship Between Recurrent Thrombosis and the Antiphospholipid Antibodies Profile in a Cohort of Patients with Antiphospholipid Syndrome

Tomás Urrego,[1] Beatriz Frade-Sosa,[2] Alejandro Hernández,[3] Sebastian Ruiz,[3] Carolina Rua,[4] Julieta Duque,[4] Adriana Vanegas-García,[5] Carlos H Muñoz-Vahos,[5] Luis A González,[5] Gloria Vasquez,[6] and **Jose A Gómez-Puerta**[2], [1]Grupo de Inmunología Celular e Inmunogenética, Universidad de Antioquia, Medellín, Antioquia, Colombia, [2]Rheumatology Department, Hospital Clinic de Barcelona, Barcelona, Catalonia, Spain, [3]Departamento de Medicina Interna, Universidad de Antioquia, Medellín, Antioquia, Colombia, [4]Grupo de Investigación en Trombosis, Medellín, Antioquia, Colombia, [5]Grupo de Reumatología, Universidad de Antioquia, Medellín, Antioquia, Colombia, [6]University of Antioquia, Medellin, Antioquia, Colombia

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Antiphospholipid Syndrome Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Recurrent thrombosis is an uncommon complication of patients with antiphospholipid syndrome (APS), usually related with persistent high levels of antiphospholipid antibodies (aPL), specially classic aPL (anticardiolipin antibodies, aCL or lupus anticoagulant, LA). The role of other aPL, including anti-phosphatidylserine/prothrombin (PS/PT) antibodies, anti B2 glycoprotein 1 (B2GP1) and anti domain 1 against B2GP1 as markers of recurrence in APS, it is less well known. Our aim was to determinate the relationship between the presence of different aPL (criteria and non-criteria aPL) with recurrent thrombosis in a cohort of patients with APS, including patients with primary APS and secondary APS (related with SLE)

Methods: We conducted a prospective single center study including patients with diagnosis of APS (Sidney criteria). A wide panel of aPL antibodies were measured at the moment of study inclusion, then, a prospective follow up was made according daily clinical practice. New thrombotic and non-thrombotic manifestations were recorded during follow-up. Anti-D1 B2GPI antibodies were tested using a chemiluminescent immunoassay (QUANTA Flash, Inova Diagnostics). In addition, anti PS/PT (IgG and IgM), aCL (IgG and IgM) and anti B2GP1 (IgG and IgM) were measured at baseline by ELISA. LA was detected according to International guidelines.

Baseline patient characteristics were summarized using counts and percentages or median and for categorical and continuous variables. Comparison across groups was done using Chi-squared, Fisher's Exact, or Mann–Whitney tests as appropriate. Kaplan–Meier for time to event analysis was used to determine risk factors for thrombotic events during follow-up.

Results: One hundred and sixty eight patients were included, 87% of patients were female with a mean age of 34.0 ± 12.8 years. aPL profile was done in 145 patients with secondary APS and 23 patients primary APS. Clinical follow-up was available in 91 patients. Mean follow-up was 20.6 ± 13.8 months (range 1-46 months). New thrombotic episodes occurred in 8 out of 91 (8.8%) of patients (6 DVT and 2 arterial), 5 of them despite anticoagulation therapy (4 vitamin

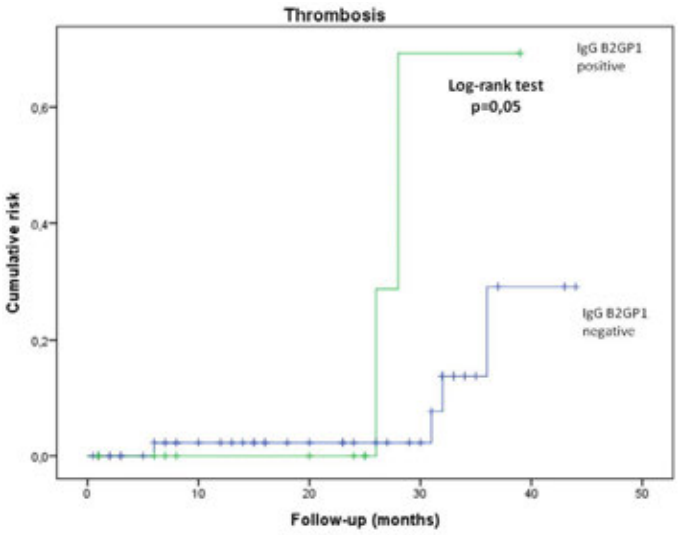

Figure 1. Cumulative risk of thrombosis according IgG B2GP1 antibodies.

K antagonist and 1 Dabigatran).We also documented 6 new episodes of thrombocytopenia and 2 new fetal losses. Overall, anti IgG B2GP1 antibodies were related with recurrent thrombosis (28 vs 7%, p=0,022), arterial thrombosis (6.7 vs 0%, p=0,05) and LA with recurrent thrombocytopenia (12,9 vs 0%, p=0,049). In survival analysis, IgG B2GP1 were related with a significant cumulative risk of thrombosis (Figure). No relationship between non-criteria aPL or triple positivity was found with recurrence. No clinically relevant major or minor bleeding occurred

Conclusion: In our cohort of patients with APS, IgG B2GP1 antibodies were related with recurrent thrombotic events. Given the low rate of new events, a longer follow-up is needed to establish further relationships.

Cumulative risk of thrombosis according IgG B2GP1 antibodies

Antiphospholipid Syndrome Damage Index (DIAPS): Distinct Long-term Kinetic in Primary Antiphospholipid Syndrome and APS Related to SLE

Aline Kühl Torricelli,[1] Michelle Remião Ugolini-Lopes,[1] Eloisa Bonfa,[2] and Danieli Andrade[3], [1]Rheumatology Division - Hospital das Clinicas HCFMUSP, Faculdade de Medicina, Universidade de Sao Paulo (FMUSP), Sao Paulo, Sao Paulo, Brazil, [2]Rheumatology Division, Hospital das Clinicas, Faculdade de Medicina da Universidade de Sao Paulo (HCFMUSP), Sao Paulo, Brazil., Sao Paulo, Sao Paulo, Brazil, [3]Hospital das Clinicas, Faculdade de Medicina, Universidade de São Paulo, Sao Paulo, Brazil

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Antiphospholipid Syndrome Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Antiphospholipid syndrome (APS) is an acquired thrombophilia that affects young productive individuals with permanent damage and negative impact in quality of life. Recently a damage index specific for APS (DIAPS) was developed. There are, however, no data regarding the comparison of its performance and long-term damage in primary antiphospholipid syndrome (PAPS) and APS related to SLE (APS+SLE). The primary purpose of this study was, therefore, to compare the long-term damage in patients with these conditions.

Table 1. Demographic features and damage scores in PAPS and APS related to SLE patients

	PAPS (N=50)	APS+SLE (N=50)	P
Age (years) mean ± SD	47.10±12.4	44.04±10.80	0.19
Female gender N (%)	41 (83%)	44 (88%)	0.57
Diagnostic delay (years) mean ± SD	4.00±4.20	2.54±3.05	0.04
Time of follow up (years) mean ± SD	9.40±3.60	10.94±4.50	0.06
DIAPS at diagnosis mean ± SD	1.72±1.17	0.82±0.96	<0.001
Final DIAPS mean±SD	2.04±1.50	2.24±1.61	0.52
Patients free of damage	2 (4%)	4(16%)	0.67
Δ DIAPS mean ± SD	0.43±0.30	1.22±1.24	<0.001

Table 2. Comparison of damage domains at the end of follow-up of PAPS and APS+SLE

	PAPS n(%)	*APS+SLE* n(%)	P
Peripheral vascular (total)	31(62)	32 (64)	1.00
Deep vein thrombosis	28(55)	29 (56)	1.00
Intermittent claudication	0 (0)	0 (0)	1.00
Tissue loss: minor	2 (4)	0 (0)	0.49
Tissue loss: major	1 (2)	3 (6)	0.61
Vascular venous insufficiency	4 (8)	13 (25)	**0.03**
Pulmonary (total)	9 (18)	15 (30)	0.24
Pulmonary infarction	7 (14)	12 (23)	0.30

Musculoskeletal - Avascular necrosis	1 (2)	4 (8)	0.36
Cutaneous - Chronic cutaneous ulcers	2 (4)	7 (14)	0.15
Gastrointestinal (total)	1 (2)	2 (4)	1.00
Mesenteric thrombosis	1 (2)	1 (2)	1.00
Budd-Chiari syndrome	0 (0)	0 (0)	1.00
Cirrhosis of the liver	0 (0)	1 (2)	1.00
Endocrine (total)	1 (2)	1 (2)	1.00
Suprarenal insufficiency	0 (0)	0 (0)	1.00
Hypopituitarism	1 (2)	0 (0)	1.00
Infertility	0 (0)	1 (2)	1.00

Methods: This is a retrospective analysis of a single tertiary center cohort followed for approximately 10 years, using a standardized prospective electronic chart database. Fifty consecutive PAPS patients age matched with fifty APS+SLE patients were consecutively selected for the study and DIAPS was calculated once-a-year during follow-up. Long term damage and damage kinetics in both groups were compared.

Results: PAPS and APS+SLE had comparable age (47.10±12.4 vs. 44.04±10.80 years, p=0.19) and time of follow-up (9.40±3.60 vs. 10.94±4.50 years, p=0.06). At diagnosis, PAPS group had higher DIAPS than APS+SLE (1.72±1.17 vs. 0.82±0.96, p< 0.001). At the end of 10 years follow-up both groups presented comparable mean damage scores (2.04±1.50 vs. 2.24±1.61, p=0.52). The damage increment throughout the observation period for PAPS was solely 35% whereas for APS+SLE it was gradual, persistent and reached 139% at the end of follow up with a total damage increment for PAPS lower than APS+SLE group (0.43±0.30 vs. 1.22±1.24, p< 0.001). Of note, the frequency of indi-

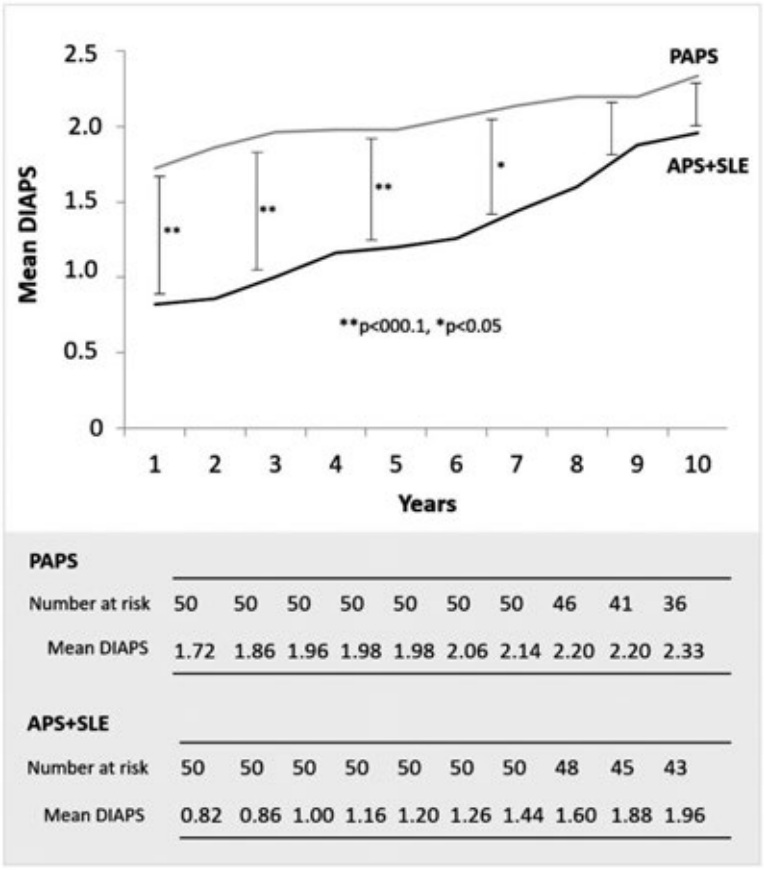

Figure 1. Cumulative incidence of damage along follow-up in PAPS and APS related to SLE

viduals that acquired damage was lower in PAPS than in APS+SLE group (32% vs. 71%, p< 0.001). PAPS had also longer delay in diagnosis than APS+SLE (4.00±4.20 vs. 2.54±3.05 years, p=0.04). This delay was positively correlated to a higher damage score at diagnosis (r=0.36, p< 0.001) in all groups.

Conclusion: We identified a distinct pattern of damage in PAPS and APS related to SLE. Damage in PAPS is an early event while APS+SLE is associated with higher long term damage with a striking increment of damage along the follow-up. Diagnosis delay is correlated with higher damage scores. Damage surveillance requires therefore different approaches for these two conditions.Table 1. Demographic features and damage scores in PAPS and APS related to SLE patients

Abstract Number: 0140

Early Anticoagulation Improves the Long-term Prognosis in Patients with Antiphospholipid Syndrome Associated Portal Vein Thrombosis

Hanxiao You,[1] Jiuliang Zhao,[2] Xinping Tian,[2] Mengtao Li,[3] and Xiaofeng Zeng[2], [1]Department of Rheumatology, Peking Union Medical College Hospital, Peking Union Medical College & Chinese Academy of Medical Science, Beijing, China (People's Republic), [2]Peking Union Medical College Hospital, Beijing, China (People's Republic), [3]Dept. of Rheumatology, Peking Union Medical College Hospital (West Campus), Beijing, China, Beijing, China (People's Republic)

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Antiphospholipid Syndrome Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Portal vein thrombosis (PVT) is a rare and severe clinical phenotype of antiphospholipid syndrome (APS) with a poor prognosis. Anticoagulation therapy is efficient, but is associated with potentially severe side-effects, especially bleeding episodes. The aim of this study was to retrospectively analysis our single center experience on long-term anticoagulation in APS patients presenting a PVT.

Methods: Data of 26 APS patients with PVT from 2012 to 2019 were enrolled. The diagnosis of PVT was made according to the 2009 American College of Liver Diseases (AASLD) criteria. Regular imaging was performed to monitor the outcome of PVT. The hemorrhagic complications and the recurrence of the PVT after anticoagulation withdrawal were also analyzed.

Results: A total of 26 patients with APS-PVT were enrolled, 5 males and 21 females, with an average age of 39±12.65 years, 9 cases (35%) with acute thrombosis, 12 cases (46%) with chronic thrombosis, and 5 cases (19%) with portal vein spongiformity. 14 cases (54%) with portal hypertension, 13 cases (50%) with esophageal varices, 4 cases(15%) with spleen infarction, 6 cases (23%) with gastrointestinal bleeding and 2 cases (8%) with abdominal infection. Triple aPLs positive in 5 cases (19%). 14 cases began anticoagulation therapy immediately after diagnosis of thrombus. 7 patients got thrombus recanalization. 3 patients got recurrence. 5 patients died.

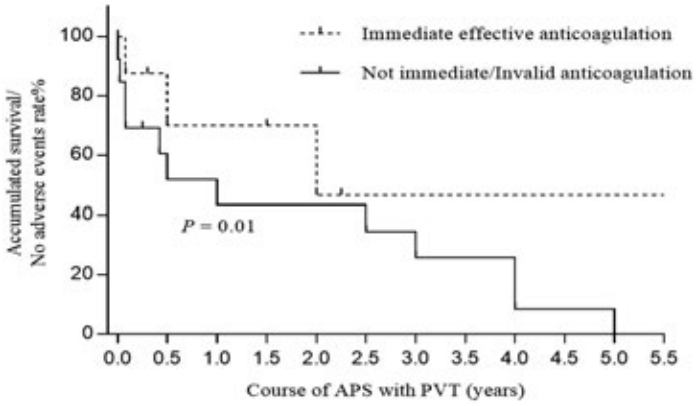

Figure 1 Difference of accumulated survival/no adverse events rate between groups receiving immediate effective anticoagulation and not. Adverse events included recurrent thrombosis, liver cirrhosis and severe portal hypertension complications, such as gastrointestinal bleeding and esophagogastric varices. Effective anticoagulation was defined as sufficient anticoagulant therapy for at least 6 months. Not immediate/invalid anticoagulation was defined as no anticoagulation immediately after the thrombus or course of anticoagulant therapy less than 6 months.

Conclusion: PVT usually had insidious onset with atypical clinical symptoms and easily be misdiagnosed. Early diagnosis and anticoagulation treatment can bring thrombus recanalization thereby significantly improving the prognosis.

Session Title: Antiphospholipid Syndrome Poster

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Women with antiphospholipid syndrome (APS) are at increased risk of recurrent miscarriage, fetal death, placental insufficiency, preeclampsia and fetal growth restriction (FGR). Although treatment improves outcomes, there are still some unsuccessful pregnancies. A multidisciplinary approach with strict monitoring is essential

Table 1. Comparison of clinical and serological features between adverse pregnancy outcomes and successful pregnancies.

*Data available for 29 pregnancies.

Φ Applied only to patients with SLE (n=21).

in order to attain obstetrical success. Our aim is to assess feto-maternal outcomes in Portuguese pregnant women with antiphospholipid syndrome (APS) who received multidisciplinary care and to determine the risk factors for adverse outcomes.

Methods: Pregnant women fulfilling the Sydney classification criteria for definite APS, who attended our specialized Rheumatology and Obstetrics outpatient clinic between 2010 and 2019, were included in this retrospective observational study. Cases of suspected APS not fulfilling the classification criteria were excluded. All pregnancies were followed up by a multidisciplinary team (rheumatologists, obstetricians and nurses). Data was collected from medical records. Adverse Pregnancy Outcomes (APO) were defined as: spontaneous abortion (< 10w), fetal death (≥10w), neonatal death, FGR and delivery prior to 36 weeks of gestation with or without preeclampsia (PE).

Results: A total of 41 pregnancies were identified in 31 women with APS (58% primary; 42% secondary APS). Forty-five percent had thrombotic APS, 42% obstetric APS and 13% mixed APS. Mean age at conception was 33.4 ± 5.2 years; mean disease duration was 6.3 ± 5.3 years. In regard to antiphospholipid antibody (APL) profile, 32%, 24% and 27% of patients were triple, double and single positive, respectively. Although they had fulfilled laboratorial criteria in the past, 17% of patients were negative for all APL at the time of conception. All patients were instructed to receive prophylactic or therapeutic low-molecular-weight heparin combined with low dose aspirin for the duration of pregnancy. Regarding fetal outcomes, there were 3 (7.3%) cases of first-trimester miscarriage, 1 (2.4%) medical abortion and 4 (9.8%) fetal deaths. There were no cases of neonatal death or other fetal malformations. The rate of live births was 80.5%, with a mean gestational age of 37.7 ± 1.7 weeks and mean birth weight of 2853.9 ± 466 g. Most women (64%) delivered by cesarean section. Preterm birth rate was 18% (6 cases), half corresponding to fetus with FGR. Concerning maternal outcomes, there was one single case (2.4%) of PE. There were no cases of eclampsia or HELLP syndrome. Lupus anticoagulant ($p< 0.001$, OR 38) and triple APL ($p=0.008$, OR 8.4) positivity were associated with adverse pregnancy outcomes. In this cohort, no association was found between poor obstetric outcomes and history of thrombosis, presence of SLE or low complement levels (table 1).

Conclusion: In our study, most pregnancies were uneventful. The presence of lupus anticoagulant and triple APL positivity can represent risk factors for adverse outcomes, despite conventional treatment. We reinforce the importance of a multidisciplinary evaluation and surveillance before, during and after pregnancy in women with APS in order to implement early treatment and to optimize fetal-maternal outcomes.

Antiphospholipid Antibodies Prevalence in Women with Late Pregnancy Complication and Low-Risk for Chromosomal Abnormalities

Silvia Grazietta Foddai,[1] Massimo Radin,[1] Elena Rubini,[1] Irene Cecchi,[1] Savino Sciascia,[2] Dario Roccatello,[1] Elisa Menegatti,[1] Silvia Gaito,[1] Luca Marozio,[1] Tilde Manetta,[1] and Giulio Mengozzi[1], [1]University of Turin, Turin, Italy, [2]Center of Research of Immunopathology and Rare Diseases- Coordinating Center of Piemonte and Valle d'Aosta Network for Rare Diseases, Department of Clinical and Biological Sciences, University of Turin, Torino, Italy

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Antiphospholipid Syndrome Poster

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: While current guidelines help defining correct pregnancy standard of care for patients with systemic lupus erythematosus andantiphospholipid syndrome (APS),little is known about the significance of antiphospholipid antibodies (aPL) detection during pregnancy and their association with clinical manifestations of the syndrome in women without history of rheumatic disease.

In this context, we aimed to retrospectively investigate the prevalence of aPL and late-onset pregnancy complications (LO-PC) in a cohort of women with low risk of chromosomal abnormalities.

Methods: For the purpose of this study, we retrospectively collected data from a number of patients ever pregnant attending the S. Anna University Clinic (Turin, Italy) from August 2017 to August 2018, that were found to be negative for triple test and fetal abnormalities and who experienced LO-PC. aPL testing was performed on serum samples derived from pregnancy screening test collected during the fourth month of gestation. aPL detection was performed using both ELISA assay (INOVA Diagnostic) and chemiluminescent immunoassay (INOVA Diagnostic) for the semi-quantitative measurement of antibodies -comprehensive of IgG, IgM, and IgA isotypes for anticardiolipin (aCL) and anti-β2-glycoprotein I (β2GPI), β2GPI domain I, and anti-phosphatidylserine/prothrombin (aPS/PT) IgG and IgM.

	All patients (59)	aPL positive (19)	aPL negative (40)	Chi Square test (p)
Fetal outcomes				
Live births, n (%)	55 (93)	16 (84)	39 (98)	**.007**
Stillbirths, n (%)	4 (7)	3 (16)	1 (3)	.054
IUGR, n (%)	8 (14)	0	8 (20)	N/A
Maternal pregnancy outcomes				
Preeclampsia, n (%)	27 (46)	7 (37)	20 (50)	.9
Eclampsia, n (%)	1 (2)	1 (5)	0	N/A
Gestational diabetes, n (%)	16 (27)	6 (32)	10 (25)	.595
Gestational hypertension, n (%)	32 (54)	12 (63)	20 (50)	.343
HELLP, n (%)	6 (10)	1 (5)	5 (13)	.39
IUGR, n (%)	8 (14)	0	8 (20)	N/A
Obstetric and post-partum complications				
Hypertensive crisis, n (%)	12 (20)	4 (21)	8 (20)	.925
Hemorrhage, n (%)	6 (10)	2 (11)	4 (10)	0.95
Acute renal insufficiency, n (%)	1 (2)	0	1 (3)	N/A
Acute respiratory failure, n (%)	1 (2)	0	1 (3)	N/A
Placental histology				
Malperfusion, n (%)	19 (32)	6 (32)	13 (33)	.943
Fetal thrombotic vasculopathy, n (%)	3 (5)	1 (5)	2 (5)	.965
Subacute villitis, n (%)	1 (2)	0	1 (3)	N/A
Chronic villitis of unknown etiology, n(%)	1 (2)	0	1 (3)	N/A
Subacute deciduitis, n (%)	1 (2)	1 (5)	0	N/A

Results: Fifty-nine patients met the inclusion criteria of the study. Pregnancy complications were as follows: 27 (46%) patients developed preeclampsia, 1 eclampsia, 16 (27%) manifested gestational diabetes, 32 (54%) gestational hypertension, 6 (10%) experienced HELLP syndrome, and 8 (14%) intrauterine growth restriction. Obstetric and post-partum complications were as follows: 12 (20%) patients developed hypertensive crisis, 6(10%) patients developed post-partum hemorrhage, 1 patient developed hypertensive crisis, acute renal failure, and acute respiratory insufficiency concomitantly. Placental histologic examination, when performed, showed that the most frequent histologic finding was placental malperfusion (19 patients, 32%), followed by 3 fetal thrombotic vasculopathy (5%), 1 subacute villitis, 1 subacute deciduitis, and 1 case of chronic villitis of unknown etiology. Nineteen women (32%) were aPL positive, in detail: 15 showed a single positivity (6 aPS/PT IgM, 1 aPS/PT IgG, 8 aCL IgG), 3 double positivity (aCL IgG, aPS/PT IgM), and one triple positivity (aCL IgG, β2GPI IgG, andaPS/PT IgM). Of interest, patients with aPL positivity had significantly lower life births rates (84% vs. 98%, $p< 0.05$). Table 1 shows fetal, maternal outcomes, post-partum complications, and placental histologic findings.

Conclusion: In our experience, the prevalence of aPL in women with LO-PC at low-risk for chromosomal abnormalities was as high as 32%. Our data suggest that testing for both criteria and extra criteria aPL could improve the diagnostic accuracy to identify LO-PC.

Fetal and maternal pregnancy outcomes, obstetric complications and placental findings. aPL means antiphospholipid antibodies; IUGR, intrauterine growth restriction.

Session Title: Antiphospholipid Syndrome Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Antiphospholipid syndrome (APS) is characterized by thromboembolic and obstetric morbidity associated with antiphospholipid antibodies (aPL) in systemic lupus erythematosus (SLE). This study aims to evaluate the prevalence of aPL profile, and identify clinical and genetic risk factors associated with thrombotic and obstetric events in Korean patients with SLE.

Methods: Patients with SLE were enrolled and followed from 1998 to 2018 in Hanyang BAE lupus cohort and were investigated clinical and aPL profile [lupus anticoagulant (LAC), anticardiolipin antibodies (aCL), and anti-β_2-glycoprotein1 antibodies (aβ_2-GP1)]. We genotyped SLE patients using genome-wide association study (GWAS) array (Affymetrix Axiom-KOR, 833K SNPs). To determine risk factors for APS, clinical and genetic variables were analyzed by logistic regression.

Anti-phospholipid antibody	401 (93.7)	77 (97.5)	324 (92.8)	0.20
LAC	222 (51.9)	60 (76.0)	162 (46.4)	<0.01
aCL IgM	156 (36.5)	30 (38.0)	126 (36.1)	0.86
aCL IgG	244 (57.0)	50 (63.3)	194 (55.6)	0.26
aβ2-GPI IgM	80 (18.7)	11 (13.9)	69 (19.8)	0.30
aβ2-GPI IgG	86 (20.1)	24 (30.4)	62 (17.8)	0.02

Results: Among 1,167 SLE patients, 428 (36.7%) had at least one aPL (aPL(+)). In patients with aPL(+) SLE, the number of patients with LAC, aCL and aβ2-GP1 was 223 (52.1%), 297 (69.4%), and 139 (32.5%), respectively. Triple aPL positivity was observed in 70 (16.4%). Among 428 aPL(+) SLE patients, 79 (18.5%) had thrombosis or pregnancy morbidity as clinical criteria of APS, and 42 (9.8%) were satisfied with classification criteria of APS. When comparing the groups with and without thrombosis or pregnancy morbidity in aPL(+) SLE patients, multivariable regression analysis indicated that thrombocytopenia (p=0.04), positivity of LAC (p< 0.01), and positivity of aβ2-GP1 IgG (p=0.02) were associated with the occurrence of thrombosis or pregnancy morbidity in aPL(+) SLE. We identified eight SNPs were associated with development of aPL in SLE patients (p< 5×10-5). We also identified that two genes have significant effects on thrombosis

Table 2. Factors associated with thrombosis or pregnancy morbidity of antiphospholipid antibody-positive systemic lupus erythematosus patients

	Univariate		*Multivariable*	
	OR (95% CI)	*p-value*	*OR (95% CI)*	*p-value*
Sex: female	0.84 (0.37-1.90)	0.67	1.08 (0.43-2.68)	0.87
Age at clinical diagnosis of SLE	0.99 (0.96-1.01)	0.20	1.01 (0.98-1.04)	0.52
Observation period	1.01 (0.97-1.04)	0.76	1.03 (0.98-1.07)	0.23
Arthritis	0.55 (0.34-0.90)	0.02	0.62 (0.36-1.07)	0.08
Neurologic disorder	2.26 (1.11-4.59)	0.02	2.00 (0.90-4.42)	0.09
Lymphopenia	2.44 (1.08-5.55)	0.03	2.33 (0.97-5.57)	0.06
Thrombocytopenia	2.40 (1.46-3.95)	<0.01	1.74 (1.02-2.97)	0.04
Positivity of LAC	3.65 (2.09-6.36)	<0.01	3.91 (2.08-7.33)	<0.01
Positivity of aß2-GP1 IgG	2.02 (1.16-3.51)	0.01	2.04 (1.11-3.75)	0.02

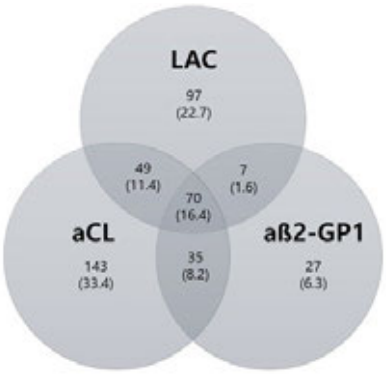

Figure 1. Distribution of antiphospholipid antibody positivity in antiphospholipid antibody-positive in systemic lupus erythematosus patients.
Values are shown number (%).

manifestations in aPL(+) SLE patients (p< 5×10-6). Among them, top gene showed the high risk association with APS(+) SLE (odds ratio=6.2) that influenced on regulation of Wnt pathway and vascular permeability.

Conclusion: In this study, 36.7% of Korean SLE patients showed aPL positivity. Eight SNPs were associated with the development of aPL in SLE, two genes with thrombosis manifestations in aPL(+) SLE, and the top gene with APS(+) SLE. As clinical factors, thrombocytopenia, positivity of LAC, and positivity of aβ_2-GP1 IgG were significantly associated with the occurrence of APS related thrombosis or pregnancy morbidity in aPL(+) SLE. These results may help clinicians to better risk stratify aPL(+) SLE patients.

Antiphospholipid Syndrome-Associated Preeclampsia Is Defined by a Distinct Clinical Phenotype

Shashank Cheemalavagu,[1] Beth Wallace,[2] Wendy Marder,[3] Jason Knight,[4] and Andrew Vreede[5], [1]Department of Internal Medicine, Michigan Medicine, Ann Arbor, MI, [2]Center for Clinical Management Research, VA Ann Arbor Healthcare System; Division of Rheumatology, Department of Internal Medicine, Michigan Medicine, Ann Arbor, MI, [3]Division of Rheumatology, Department of Internal Medicine, Michigan Medicine, Ann Arbor, [4]Division of Rheumatology, Department of Internal Medicine, Michigan Medicine, Ann Arbor, MI, [5]Division of Rheumatology, Department of Internal Medicine, Michigan Medicine; Rheumatology Section, VA Ann Arbor Health System, Ann Arbor, MI

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Antiphospholipid Syndrome Poster

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Antiphospholipid syndrome (APS) significantly increases risk of preeclampsia. It is assumed that APS is associated with a subset of severe preeclampsia, HELLP (Hemolysis; Elevated Liver enzymes; Low Platelet count) syndrome, and that APS-associated preeclampsia presents earlier and with increased severity compared to non-APS associated preeclampsia. However, little data exists that directly compares these groups of patients. Herein we compare clinical characteristics of patients with APS-associated preeclampsia to those of APS-negative preeclampsia patients.

Methods: We used the electronic medical record of a large academic medical system to identify adult APS patients with at least one preeclampsia episode between 2000-2018. APS diagnoses were confirmed using the updated Sapporo APS Classification, and preeclampsia diagnoses (including subsets of severe preeclampsia and HELLP) were classified according to American College of Obstetricians and Gynecologists guidelines. We identified control patients from the same electronic medical record with at least one episode of preeclampsia and negative laboratory testing for antiphospholipid antibodies at the time of the preeclampsia event. Groups were compared with respect to demographic factors, clinical presentation and fetal outcomes (including intrauterine growth restriction, intrauterine fetal demise and infant mortality within the first week of life) using Student's t test and Chi-Square test.

Results: We identified eight APS patients and 29 controls with at least one episode of preeclampsia during the study period (Table 1). APS patients had a mean age of 30 years, 100% were white and BMI was 32 ± 2 (mean ± SD). Controls had similar demographics, with the exception that only 59% of controls were white. Of the eight APS patients, 38% had a pre-existing APS diagnosis (all based on obstetric complications; no thrombotic history), 38% were triple-positive (positive lupus anticoagulant, anti-cardiolipin and anti-β2 glycoprotein antibodies), 38% had at least one prior episode of preeclampsia and 50% had systemic lupus (likely low disease activity based on review of laboratory studies, lack of significant proteinuria, and treatment with few/no lupus medications). Although both groups had similar rates of severe preeclampsia, APS patients were more likely to have preeclampsia associated with at least partial HELLP (75%) compared to non-APS controls (20.7%) (p=0.004). Further, APS patients had more severe liver involvement (p=0.028) and thrombocytopenia (p=0.018). There was a trend for less severe proteinuria in APS-associated preeclampsia (p=0.36). No significant differences were seen in maternal or fetal outcomes, although there was a trend for more frequent intrauterine growth restriction complicating pregnancies of women with APS. Both groups developed preeclampsia at similar gestational ages.

Table 1: Comparison of preeclampsia patients with and without antiphospholipid syndrome

		APS (n=8 patients)	non-APS (n=29 patients)	p
Demographics

[1]Antiphospholipid syndrome

[2]Systemic Lupus Erythematosus

[3]Hemolysis, Elevated Liver Enzymes, and Low Platelets

[4]Intrauterine fetal death

* mean ± SD

** Partial and Complete HELLP

Conclusion: As compared with preeclampsia in the general population, APS-associated preeclampsia has a distinct clinical phenotype, more often presenting in association with HELLP. If verified by other studies, these clinical differences suggest the possibility that distinct disease mechanisms underlie APS-associated preeclampsia.

Development of New International Classification Criteria for Antiphospholipid Syndrome: Phase II Results

Medha Barbhaiya,[1] Stephane Zuily,[2] Yasaman Ahmadzadeh,[3] Raymond Naden,[4] Karen Costenbader,[5] Doruk Erkan,[6] and On Behalf of the New APS Classification Criteria Collaborators[7], [1]Hospital for Special Surgery, Weill Cornell Medicine, New York, NY, [2]Centre Hospitalier Universitaire de Nancy, Nancy, France, [3]N/A, Tehran, Iran, [4]McMaster University, Hamilton, ON, Canada, [5]Brigham and Women's Hospital, Boston, MA, [6]Hospital for Special Surgery, New York City, [7]Hospital for Special Surgery, New York, NY

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Antiphospholipid Syndrome Poster

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: An international multi-disciplinary effort is underway to develop rigorous, new, consensus- and evidence-based classification criteria to identify patients with high likelihood of Antiphospholipid Syndrome (APS) for research purposes. The methodological approach includes four phases: item generation (I); item reduction (II); item weighting and threshold identification (III); and criteria refinement and validation (IV). Phase II aimed to reduce items generated in Phase I to approximately 30 items considered most important for distinguishing APS from other conditions. We previously reported the initial item reduction results reducing 261 Phase I items to 64 high specificity items *(Barbhaiya et al., Arthritis Rheumatol. 2018; 70 [suppl 10])*; here we report overall Phase II results.

Methods: We surveyed the APS Classification steering committee by asking members to rank the 64 previously identified items, using a Likert scale (-5 to +5), based on how specifically each item differentiates APS from other similar conditions (survey A). We ranked each item by mean (+SD) survey score and grouped highest scoring items into independent logical domains (Table). During a face-to-face steering committee meeting, we eliminated low specificity items (score < 1); items overlapping or describing similar concepts were combined. We used nominal group technique (NGT) for problem identification, solution generation, and decision-making via teleconferences to further reduce to approximately 30 items. To more precisely define, cluster, and organize items, we formed domain subcommittees to review literature and come to consensus on the definition, reliability, and precision of each potential criterion. Lastly, we surveyed the steering committee to assess proposed entry criteria and the role of provoking risk factors for macrovascular domain outcomes (survey B).

Results: Mean scores of survey A responses (n: 20) ranged between -1.05 to 4.79. Literature reviews, NGT, and subcommittee discussions reduced 64 items to 27 candidate criteria, which we organized into six independent domains (Table). Survey A results also demonstrated different weights for macrovascular domain outcomes with or without "provoking" thrombosis risk factors. Based on survey B results, we eliminated provoking risk factors with low specificity and, depending on the type of macrovascular domain outcome, 72-89% of the committee members agreed with proposed risk factors and definitions. Following a steering committee consensus to use entry criteria to identify the relevant patient population to whom the classification criteria would be applied, 84% voted in survey B in favor of a time restriction between a positive antiphospholipid antibody test and clinical event as an entry criterion for classification.

Conclusion: Twenty-seven candidate criteria for APS classification were retained and organized into six independent domains using Phase II item reduction techniques. In the next phase, these proposed candidate criteria will be used for real-world case collection and further refined, organized, and weighted so that a preliminary threshold for APS classification can be determined.

Table: Candidate Relative Criteria Based on Phase II of New APS Classification Criteria Development
Candidate Relative Criteria (Laboratory)

• **Domain 1A: Antiphospholipid Antibody Testing- Coagulation-based Functional Assays**
  ○ Lupus Anticoagulant Test
• **Domain 1B: Antiphospholipid Antibody Testing- Solid Phase Assays**
  ○ Anticardiolipin Antibody IgG, Anticardiolipin Antibody IgM
  ○ Anti-β_2-glycoprotein-1 IgG, Anti-β_2-glycoprotein-1 IgM

Candidate Relative Criteria (Clinical)

• **Domain 2: Macrovascular**
  ○ Superficial Vein Thrombosis, Venous Thromboembolism, Arterial Thrombosis, Transient Ischemic Attack
• **Domain 3: Microvascular**
  ○ Livedo Racemosa, Livedoid Vasculopathy, Adrenal Hemorrhage or Plexus Thrombosis, Acute Ischemic Encephalopathy, Cardiac Microvascular Disease, Pulmonary Hemorrhage, Acute aPL Nephropathy, Chronic aPL Nephropathy
• **Domain 4: Obstetric**
  ○ Pregnancy Loss <10w of Gestation, Fetal Death Between 10w to <16w of Gestation, Fetal Death Between 16w to 34w of Gestation, Pre-eclampsia with Severe Features <34w of Gestation, Placental Insufficiency with Severe Features <34w of Gestation
• **Domain 5: Cardiac Valve Disease**
  ○ Non-infectious Valve Vegetation, Thickening
• **Domain 6: Hematologic**:
  ○ Platelet count <20 x 10^9 per liter, Platelet count 20-130 x 10^9 per liter, Platelet count 131-150 x 10^9 per liter

Abstract Number: 0146

Simulated Rheumatology Clinic: Bridging Basic Science and Clinical Application

Rachel Wolfe,[1] Donna Williams,[1] and Jennifer Jackson[1], [1]Wake Forest Baptist Health, Winston-Salem, NC

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Education Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Traditional medical school curricula divided the basic sciences from clinical rotations using a compartmentalized approach, though the need for curricular integration in the preclinical years is now well recognized.[1] Simulation offers learners opportunities for active engagement with basic science knowledge in relevant clinical contexts, thereby enhancing knowledge acquisition.[2] We developed a simulated clinic experience for preclinical medical students to reinforce learning content presented in the rheumatology course.

Methods: Students were divided into groups of 3-4 learners to rotate through a series of 3, 20-minute standardized patient (SP) cases during which they were tasked with performing a targeted history and physical exam. Small groups then had 10 minutes to discuss their findings to develop a differential diagnosis and determine next best step in diagnostic testing for each case. The activity concluded with a large-group debrief with a content expert. Learners' evaluation of the activity was assessed through a voluntary, anonymous online survey.

Results: Twenty-five (18%) learners responded to the survey. Eighty-eight percent (22/25) of respondents found the activity extremely or quite relevant to their role as a future physician. All respondents felt the small-group format and the pace and duration of the learning activity were appropriate. Greater than 90% of respondents found the activity to be extremely or quite effective for reviewing and applying learning content from the rheumatology course, practicing how to approach specific chief complaints, practicing history taking skills, practicing physical exam skills, practicing differential diagnosis formation skills, and practicing creating a diagnostic plan for the cases. Eighty-four percent (21/25) of respondents felt the large group debrief was effective. Twenty out of 24 respondents rated the activity's overall effectiveness as ≥ 8 out of 10.

Conclusion: The simulated rheumatology clinic activity was well received by learners, who rated it as effective for reinforcing and applying concepts discussed in the rheumatology basic science curriculum. Simulation-based activities structured like this one can provide opportunities for clinical applications in other domains of the pre-clinical curriculum. Future directions include evaluating higher-order learning outcomes beyond learner perception.

A Qualitative Study of Factors That Influence Interest in a Career in Pediatric Rheumatology

Nishant Pandya,[1] Cyrus Sholevar,[1] Rosemary Frasso,[2] Dorene Balmer,[3] and **Jay Mehta**[3], [1]Sidney Kimmel Medical College at Jefferson, Philadelphia, PA, [2]Jefferson College of Public Health, Philadelphia, PA, [3]The Children's Hospital of Philadelphia, Philadelphia, PA

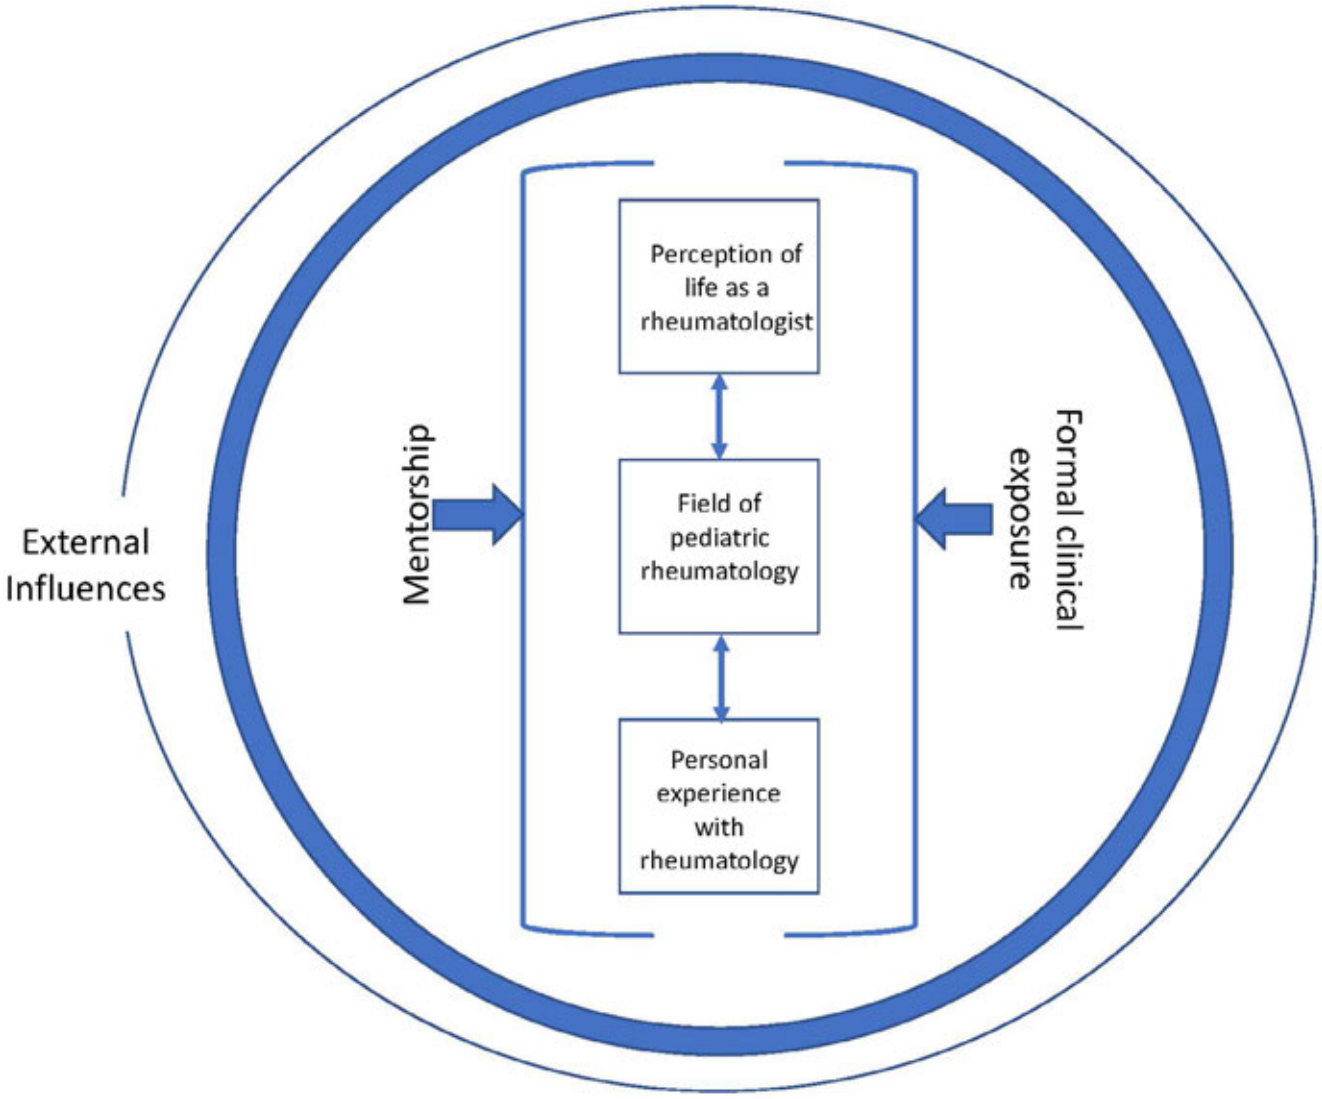
SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Education Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The American Academy of Pediatrics estimates that one-quarter of children with rheumatic disease live over 80 miles from the nearest pediatric rheumatologist. It has been suggested that half of these children receive care from an adult provider. Contributing to this mismatch between children with rheumatic disease and pediatric rheumatology providers is a relative dearth of pediatric residents who choose to enter pediatric rheumatology fellowship. From 2013-2017, between 28-50% of fellowship spots went unfilled each year. Little is known about the factors that influence pediatrics residents to consider a career in rheumatology.

Methods: Semi-structured interviews were conducted with 15 pediatrics residents who were accepted to the ACR Pediatrics Residents Program, which aims to expose pediatrics residents to the ACR Annual Scientific Meeting. Residents were re-interviewed after making their final specialty decision to understand the factors most influential in their decision. Interviews were transcribed and coded. Codes pertaining to influential factors were organized into an explanatory model.

Results: Most residents expressed their interest in pediatric rheumatology growing with formal clinical exposure during residency. Few residents had exposure to this field as medical students. Some residents reported only considering pediatric rheumatology as a career after completing a rotation during residency. Residents stated the evolving research, immunopathology, complex diseases, and long-term patient disease management were desirable aspects of the field. Some residents stated positively viewing pediatric rheumatology as focused on educating and teaching trainees and reported a collegial and friendly atmosphere. Some residents had mentors in pediatric rheumatology and explored research and career opportunities. Few residents mentioned salary, geography, perception of the field by others, or geographic limitations as barriers to considering pediatric rheumatology as a career.

Conclusion: Residents cite a variety of factors influencing their decision to consider pediatric rheumatology as a career. We organized these factors into a model with major influencing factors of 1) perceptions of life as a rheuma-



Explanatory model for influential factors impacting interest in career in pediatric rheumatology

tologist, 2) qualities inherent to the field such as long-term patient relationships and complex immunopathology and 3) personal experience with rheumatology being modified by formal clinical exposure and mentorship, with external influences having a peripheral, but often important, role. Pediatric rheumatology has aspects that are desirable to residents such as its culture, patient-family relationships, and disease processes. Facilitating exposure to pediatric rheumatology during medical school or earlier in residency may help facilitate interest in the field.Model for ACR abstract Explanatory model for influential factors impacting interest in career in pediatric rheumatology

The Combat Rheumatologist: Long Term Professional Outcomes of Graduates from a Tri-Service Military Rheumatology Fellowship Program

Caleb Anderson,[1] Wayne Bailey,[2] and Jess Edison[1], [1]Walter Reed National Military Medical Center, Bethesda, MD, [2]Fort Belvoir Community Hospital/U.S. Army, Bethesda, MD

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Education Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The Walter Reed Army / Walter Reed National Military Medical Center National Capital Consortium (WRNMMC) Rheumatology fellowship program has been in existence since 1973, and in June 2015 graduated its 100th fellow. The military rheumatologist has a unique role and is responsible for leadership as well as rheumatology practice. In an effort to identify the strengths and gaps in the training required of our military rheumatologists, we studied the long-term professional outcome of our graduates. Specifically, we evaluated our graduates' contribution to the advancement of knowledge in the field of rheumatology and medicine, as well as leadership positions held. In an effort to evaluate our graduates' professional military development and contribution to the Defense Health Agency's goal of a medically ready force, we also queried number of deployments, operational tours, and Professional Military Education (PME) participation.

Methods: Email addresses for all graduates of the Walter Reed Army / Walter Reed National Military Medical Center National Capital Consortium Rheumatology fellowship program from 1976 through 2015 were obtained from publicly available registries such as the American College of Rheumatology Annual Directory. An email request was sent to graduates requesting a copy of their curriculum vitae (CV). If no response was received, up to three monthly emails were sent. Data was analyzed for respondents' rank, board certification, hospital committees, professional societies, awards, peer reviewed publications, invited lectures, operational tours, deployments, and PME courses.

Results: Forty-six of 100 contacted graduated fellows provided their CV for review. The highest percentage of respondents were graduates between 2003 and 2015 (26/30). This was the interval chosen for analysis. Twenty one (81%) of respondents were still active duty at the time the survey was taken. The 26 responding graduates had given 415 lectures (16 per graduate), authored 95 peer reviewed publications (3.7 per graduate), and had served on a cumulative total of 95 committees. Seventeen of 26 had been rheumatology service chiefs, four served as assistant department chief, and eighteen (69%) were affiliated with a medical school. Fourteen of the respondents had been deployed with four graduates serving in an operational billet without deployment. Of the 18 Army respondents, three

attended Command and General Staff Intermediate Level Education, six attended Captain's Career Course, two attended Tactical Combat Medical Course, and two attended Brigade Surgeon Course.

Conclusion: Our graduates of the WRNMMC rheumatology fellowship have excelled in medical education and professional development. A gap in completion of PME was noted in the study and led to incorporation of a three week course during fellowship. Overall, scholarly activity, medical education, leadership, and contribution to medical readiness through deployments and operational positions held are among the most consistent findings within the graduates over the previous decade.

Teaching Rare Diseases Through Role Play: Results of an Experimental Workshop About Raynaud Phenomenon

Sébastien Sanges,[1] Sandrine Morell-Dubois,[2] Meryem-Maud Farhat,[3] Morgane Assaraf,[3] Marc LAMBERT,[4] Vincent Sobanski,[3] David Launay,[3] and Eric Hachulla[5], [1]CHRU Lille, Lille, France, [2]Department of Internal Medicine and Clinical Immunology, CHU Lille, University of Lille, Lille, France, [3]CHU Lille, Lille, France, [4]Lille University Hospital, Lille, France, [5]Dept. of Internal Medicine and Clinical Immunology, Hôpital Claude Huriez, University of Lille, Lille, France, Lille, France

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Education Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic autoimmune diseases are mostly taught through theoretical lectures, which do not allow for the acquisition of physical examination skills and semiologic confrontation. We report herein the results of a pilot experiment using role-play to teach how to manage patients with Raynaud phenomenon (RP).

Methods: We developed a workshop that consisted of two 30-minute OSCE (Objective and Structured Clinical Examination) stations. Students were divided into groups of 4 to 5 persons. On each station, 2 students were actors and 2 were observers. After a short briefing, students played a 15-minute scenario and then had a 15-minute debriefing.

The first station simulated the case of a 26-year old woman referred for suspected RP. Students were instructed to perform clinical history taking and physical examination of the patient, formulated relevant diagnosis hypotheses and prescribe any additional necessary exams. Students had to suspect the diagnosis of idiopathic RP. The simulated patient was played by a trained facilitator with expertise on RP.

The second station simulated the case of a 56-year-old woman referred for RP complicated by digital ulcers. Students received the same instructions as before. They had to suspect the diagnosis of systemic sclerosis. The patient role was held by a real patient with systemic sclerosis, followed by the physician who was supervising the station, who had received prior training and who agreed to participate in this training.

At the end of the workshop, the students had to complete a satisfaction questionnaire.

Results: A total of 21 students participated in the workshop and 17 completed the survey. The students were "very satisfied" (Likert 4/4) of this training in 94%. They considered this workshop "not very stressful" (Likert 2/4) and "very formative" (Likert 4/4) in 71%, but "a little short" (Likert 2/4) in 88%. After taking this training, all students felt "a little"

(Likert 3/4, 24%) or “much more comfortable” (Likert 4/4, 76%) to manage patients with idiopathic RP; and “a little” (Likert 3/4, 65%) or “much more comfortable” (Likert 4/4, 35%) to manage patients with systemic sclerosis. All would recommend this workshop to other students.

When asked about the strengths of this training, the students mentioned the benefits of being put in an immersive situation, which allowed for a better acquisition of practical skills (especially physical examination) and a more interactive exchange with teachers; as well as the confrontation with a real patient, which allowed for a better retention of semiologic findings and associated a relational component to this experience. The main weak points reported were its short duration and the stress induced by being observed during the simulation.

Conclusion: This workshop suggests the interest and feasibility on a small group of students of a rare diseases awareness workshop using role-play. The evaluation of its pedagogical efficiency and its generalization on large student promotions are being considered.

Comparison of Debate vs. Lecture to Teach Medical Students Pediatric Rheumatology

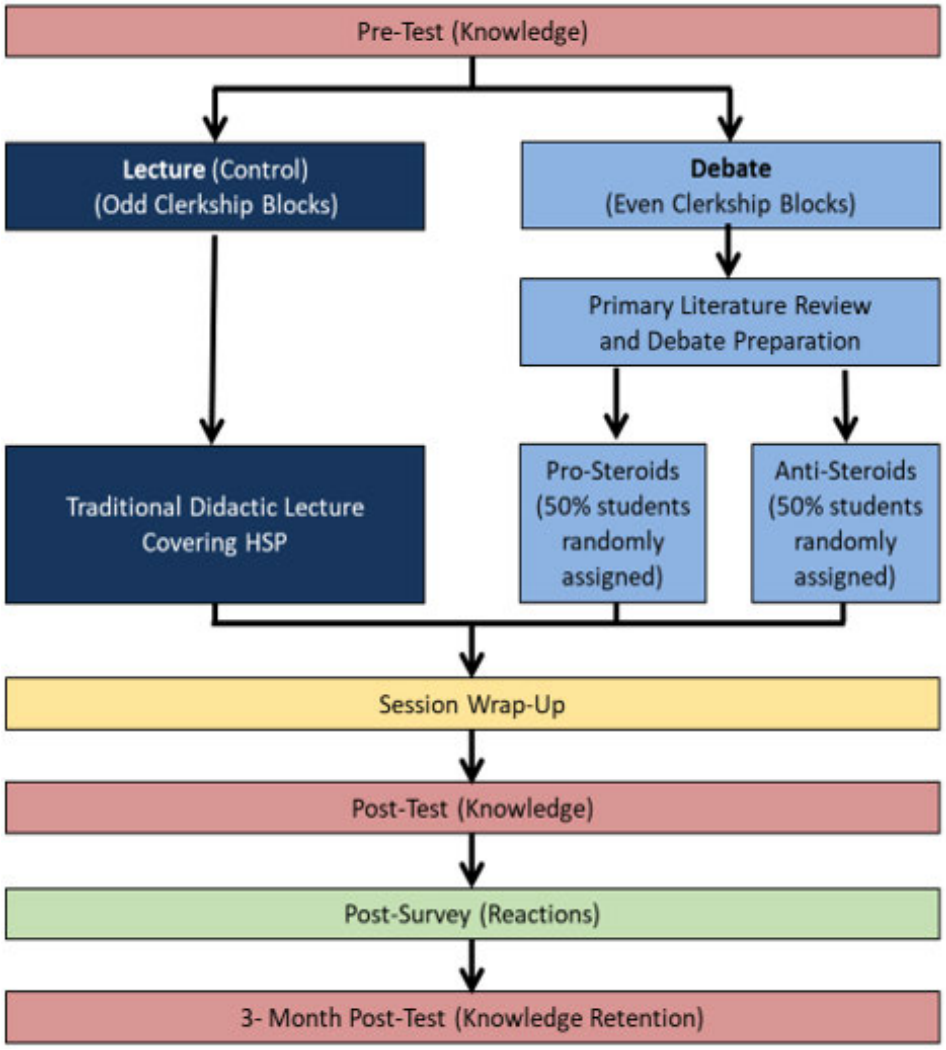
Jodi Dingle,[1] T Brent Graham,[1] Travis Crook,[1] Maya Neeley,[1] Mario Davidson,[2] and Amy Fleming[2], [1]Vanderbilt University Medical Center, Nashville, TN, [2]Vanderbilt University, Nashville, TN

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Education Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Medical students at Vanderbilt receive approximately 25 hours of didactic teaching during their pediatric clerkship. Debate format educational sessions employ active learning principles allowing students opportunities to critically evaluate and articulate evidence to support claims. The aim of our study was for students to participate in a debate of two treatment options for Henoch-Schönlein Purpura (HScP), and evaluate learning outcomes, student engagement, and satisfaction with debate compared to traditional lecture.

Methods: We compared medical students on their pediatrics clerkship participating in a debate to a control group receiving a traditional lecture. Debate group students received a case of a patient with HScP and abdominal pain a week prior to the session. Half of the students were randomly assigned to argue in favor of treatment with steroids and half against steroid treatment. Students were asked to prepare by performing a review of primary literature and then met during their pediatrics clerkship to participate in the debate. The control group received a traditional lecture about HScP. Both groups received same wrap-up presentation reinforcing key concepts. Students completed an identical multiple-choice pre-test before and post-test after the session and a follow-up post-test three months later to assess knowledge retention. Surveys immediately following and three months after the session assessed satisfaction with and the efficacy of the session in promoting active learning and clinically relevant skills.

Results: Both groups showed improvement between the pre- and post-tests, and there was no significant difference in the groups’ post-test scores (n=48, p=0.06). Retention of information on the three-month post-test was not significantly



Study Design

different between the two groups (n=18, p=0.61). More students in the debate group agreed or strongly agreed that they practiced researching a clinical question (n=21 and 27, 81.5% vs 44.4% respectively) and articulating their opinion (77.8% vs 37.0% respectively). More students in the debate group agreed or strongly agreed that they used the research skills they used in this session in the direct care of a patient on the three-month follow up survey (n=8 and 10, 87.5% vs 50% respectively). Students in the lecture group who reported higher satisfaction or increased engagement scored significantly better on the initial post-test (n=27, p=0.004 and p=0.016, respectively). Satisfaction and engagement did not correlate with initial post-test scores in the debate group (n=21, p=0.46 and p=0.29 respectively).

Conclusion: Students learned core knowledge about HScP in both groups as evidenced by similarly improved scores on immediate and three-month post-tests. Participation in the debate allowed students to practice critically appraising literature and articulating their opinion. Debate students' immediate post-test scores were less correlated with their perception of engagement or satisfaction with the session. Future sessions will include a debrief session to help students transfer critical appraisal skills to clinical practice. We are interested in utilizing debates to study tolerance of ambiguity in pediatric rheumatology fellows.

Abstract Number: 0151

Implementation of Recommendations for Prevention of Glucocorticosteroid-Induced Osteoporosis in Hospitalized Patients

Tal Gazitt,[1] Muna Elias,[1] Joy Feld,[1] Idit Lavi,[1] Amir Haddad,[1] Rema Bishara-Garzuzi,[1] Muhanad Abu Elhija,[1] Adi Kibari,[1] and Devy Zisman[2], [1]Carmel Hospital, Haifa, Israel, [2]Carmel Hospital and Ruth and Bruce Rappaport Faculty of Medicine, Technion, Israel, Haifa, Israel

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Education Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Glucocorticosteroid-induced osteoporosis (GIO) is the most common cause of secondary osteoporosis but is under-diagnosed and under-treated. Most professional guidelines recommend as a first step calcium and vitamin D (Ca/VitD) supplementation for patients treated with prednisone ≥ 5-7.5 mg daily or equivalent for ≥ 1-3 months.

Rheumatology inpatient consultations are routinely given by our rheumatology unit with emphasis on smooth transition to outpatient care. The study objectives were to examine the real-life implementation of recommendations for Ca/VitD supplementation in patients anticipated to receive long-term corticosteroid treatment and to assess the impact of standardized academic lecture on guideline implementation.

Methods: All rheumatology inpatient consultations given in 4 internal medicine wards in an academic community-based hospital in 2018 were included in the study. The hospital inpatient database was queried by two independent rheumatologists regarding the total number and content of rheumatology consult notes, doses and indications for steroid treatment where applicable, diagnostic codes, and discharge medications including Ca/VitD for patients prescribed ≥ 7.5 mg/day of prednisone with anticipated treatment for ≥ 1 month. Patients who died during hospitalization and patients hospitalized with diagnostic code of sarcoidosis were excluded from this analysis.

During the month of July 2018, standardized academic lectures on GIO prevention were given by rheumatologists in 3 of the 4 internal medicine wards. The fourth internal medicine ward served as control. The percentage of patients for whom Ca/VitD was both recommended and prescribed and the impact of academic lecture on discharge prescriptions was calculated and compared between the 6-month period before and after the instructional intervention and to the corresponding data in the control internal medicine ward. Variables were compared by Chi Square test or Student's t-test, as appropriate. All tests were 2-sided; $p < 0.05$ was considered statistically significant.

Results: Rheumatology consultations were given to 559 inpatients in 2018, 101 of whom had steroid treatment and should have been treated with Ca/VitD. The mean age of the patients was 64.6±16.1 years, 59.4% female. The main rheumatologic indications for corticosteroid treatment were vasculitis (26.7%), connective tissue disease (22.8%), rheumatoid arthritis (18.8%), and crystal-induced arthropathy (14.9%). In 79.2% of cases, rheumatology consultations specifically recommended Ca/VitD, but only 44.3% of patients were discharged on supplementation. No statistically significant differences were found among the four wards. GIO prevention lecture had no impact on discharge prescriptions.

Conclusion: Real-life implementation of GIO prevention guidelines is poor in internal medicine wards. A collaborative learning program not limited only to academic lectures is recommended as measure of intervention to increase GIO awareness and prevention especially among internal medicine staff.

Abstract Number: 0152

A Shoulder to Lean On: Differences in Shoulder Examinations Between Rheumatology Educators and Fellows

Linett Martirossian,[1] Robert Kalish,[2] Kenneth O'Rourke,[3] Sreelakshmi Panginikkod,[4] and Eugene Kissin[5], [1]Boston University, Boston, MA, [2]Tufts Medical Center, Boston, [3]Maine Health, Maine, [4]University of Massachusetts Memorial Medical Center, Worchester, MA, [5]Boston University Medical Center, Boston, MA

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Education Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The maneuvers to include in a comprehensive shoulder exam are debatable. For rheumatology fellows, rheumatology fellowship program directors (PD) serve as models of competency in performing the musculoskeletal exam. In this pilot study, we investigated exam techniques used by PDs in comparison to rheumatology fellows in their first year of training.

Methods: We recruited 6 rheumatology clinic patients with known causes of shoulder pain to undergo physical exam by 3 rheumatology PDs (32-36 years post medical school), and 3 rheumatology fellows in the first 3 months of training (3-4 years post medical school). Exams were performed in a simulation center with video recording. Exam procedure was not standardized beforehand, but fellows had formal training in shoulder exam both before and during fellowship. Overall diagnosis was noted by participants after each exam. Ultrasound imaging on the day of the exercise and clinical information were used to establish a "gold standard" (GS) diagnosis for each patient.

Videos were reviewed by a 4th PD using a standardized data extraction tool (27 exam techniques) based on a previously published standardized observed clinical exam (OSCE) of the shoulder. Exam findings not included in this tool, as well as total exam duration per room were also recorded.

Table I. Comparison of Program Directors and Trainees in Various Aspects of the Shoulder Exam

	Program Directors	Trainees	P value
% of time arriving at previously established clinical diagnosis	61	33	0.06
Mean % of prespecified exam elements performed*	55	54	0.54
Mean % of neck exam maneuvers performed	58	45	0.03
Mean % of technique measures performed+	75	26	1.7×10^{-11}
Mean time per room	4 min 53 sec.	6 min 24 sec	0.00014

* standardized data extraction tool based on a previously published (OSCE) of the shoulder identifying 27 examination techniques

+ exam technique measures include bilateral palpation, bilateral resisted motion testing, elbows adduction during resisted external rotation, and keeping one of the examiner's hands on the patient's shoulder during passive range of motion determination.

Exam maneuvers employed for each patient, technical methodology of the maneuvers, agreement with GS diagnosis, and duration of each exam were compared between the two groups using the student-t test. Four measures of exam technique assessed for each encounter included bilateral palpation, bilateral resisted motion testing, elbows adducted during resisted external rotation, and keeping one of the examiner's hands on the patient's shoulder during passive range of motion testing.

Results: GS diagnoses were: biceps tendonitis (x2), acromioclavicular joint arthritis, adhesive capsulitis, subacromial bursitis, and fibromyalgia. PDs agreed with the GS diagnosis 61% of the time compared to 33% for fellows. Five exam elements not described in the OSCE tool were noted, all involving the neck.

There was no significant difference in the completed number of prespecified 27 exam elements between PDs and fellows but PDs completed a significantly greater number of cervical spine elements and measures of exam technique then fellows, and spent less time on the exam (Table 1). The Hawkins, Neer, belly press, and horn blower's tests were never performed by any of the PDs.

Conclusion: Exam technique distinguished PDs from fellows most clearly, as did greater attention to exam of the neck for evaluation of shoulder pain. PDs and fellows performed just over half of the exam elements previously described in a shoulder OSCE, and this number did not distinguish the two groups. These results suggest that more emphasis should be placed on exam technique assessment during OSCE examinations in place of performing a greater number of maneuvers.

Abstract Number: 0153

Palliative Care Curriculum in Rheumatology: Teaching Serious Illness Conversations

Marissa Karpoff,[1] Michael George,[2] and Laura Dingfield[1], [1]Hospital at the University of Pennsylvania, Philadelphia, [2]University of Pennsylvania, Philadelphia

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Education Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Palliative care is a specialty that focuses on holistic care, promoting quality of life, and providing an extra layer of support for patients and families alongside traditional medical treatment. While these principles are highly relevant to many patients seen by rheumatologists, palliative care education for rheumatologists has been limited. Our aim was to assess the baseline needs of rheumatologists in our division, present an educational program, and identify opportunities for adaptation and expansion of palliative care education.

Methods: We developed an educational program collaboratively with palliative care that was presented to Rheumatology faculty and fellows at the University of Pennsylvania in the fall of 2018. A needs assessment survey was developed based on well-known palliative care concepts to assess baseline skills and attitudes. A two-hour interactive session was held based on the established and validated "Serious Illness Care Program" created by Ariadne Labs, adapting content to rheumatology. This program includes teaching the "Serious Illness Conversation Guide" – a scripted set of questions to guide clinicians through a conversation that includes 1) setting up the conversation, 2) assessing patient understanding, 3) sharing information, 4) exploring patient goals, fears, strengths, wishes, and 5) closing. The session included a

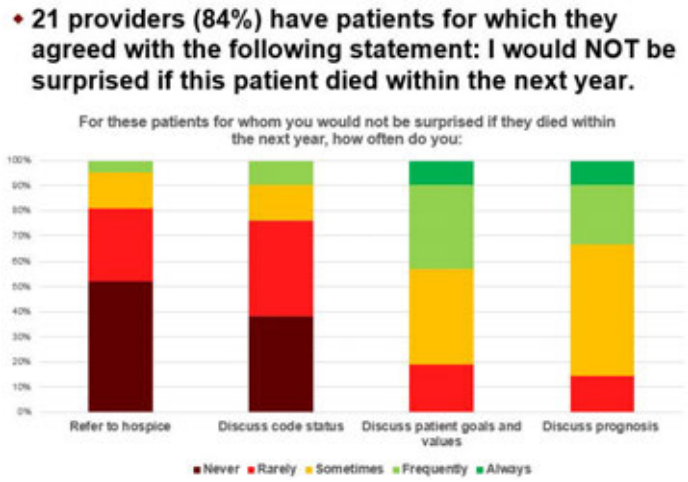

Figure 1.

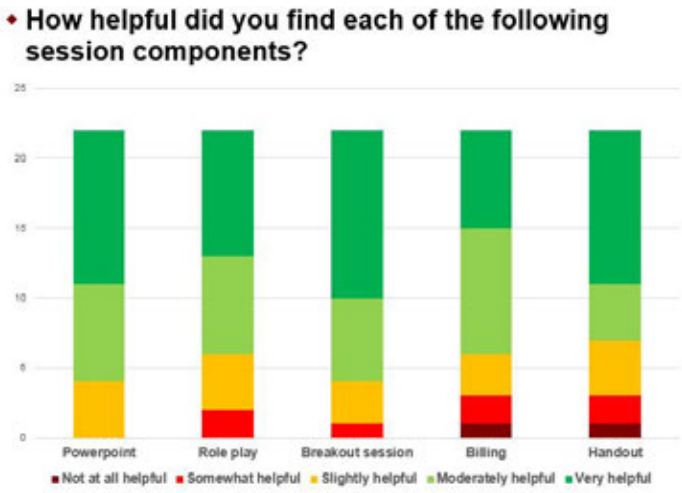

Figure 2.

demonstration of how to utilize the Conversation Guide, break-out sessions to practice conversations led by palliative care specialists using rheumatology-specific cases, and a debrief. Two champions of the program were identified who trialed the guide in clinic over the following four months. All providers received a follow-up survey to evaluate the program.

Results: The needs assessment survey had 25/30 responses. No providers had received previous rheumatology-specific palliative care training and 36% had never received any palliative care training. 21 (84%) reported seeing patients for which they would not be surprised if the patient died within the next year. Few providers referred to hospice or discussed code status, and a minority regularly discussed patient goals/values or prognosis for these patients (Figure 1). Time and uncertainty in prognostication were the most significant barriers to these conversations. The two-hour session was attended by 27 providers. In the follow-up survey, >80% found the program to be interesting, appropriate in length, and appropriate in scope. Each component of the program was favorably rated (Figure 2). Although only two providers were designated as “champions,” 6 providers reported using the Conversation Guide in clinic. Time was the major barrier to using the guide.

Conclusion: This innovation was among the first to adapt a validated palliative care training program to a rheumatology division. The program was highly rated and led to use of the Conversation Guide in clinic. Further adaption of the Conversation Guide to rheumatology specific needs, scheduling changes to allow time for serious illness conversations in clinic, and assessment of benefits to patients are planned.Figure 1.

Abstract Number: 0154

Enhancing Medicine Trainees' Exposure to Gout Diagnosis and Management Through an Interprofessional Approach in the Primary Care Setting

Nicholas Lebedoff,[1] Andrea Barker,[2] Curry L. Koening,[3] Christina Gallop,[4] Kelly Starman,[5] and Michael Battistone[6], [1]University of Utah, Salt Lake City, [2]Salt Lake City Veterans Affairs Medical Center & University of Utah, North Salt Lake, UT, [3]University of Utah Hospital, Salt Lake City, UT, [4]Salt Lake City Veterans Affairs Medical Center & University of Utah, Salt Lake City, [5]Salt Lake City Veterans Affairs Medical Center, Salt Lake City, [6]Salt Lake City Veterans Affairs Medical Center & University of Utah, Salt Lake City, UT

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Education Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Gout is common in primary care, though patients often have inadequate control or are referred to specialists for evaluation and management. This may be due to limited provider time during routine clinic visits, but may also reflect insufficient preparation of primary care providers (PCPs) in health professions education (HPE). Although excellent clinical training in gout is often provided in rheumatology clinics, learners may not effectively translate the lessons learned in the subspecialty context to primary care.

To increase contact between rheumatologist clinical educators and internal medicine (IM) trainees and to strengthen interprofessional and interdisciplinary collaboration in a new teaching and learning environment, a Primary Care Gout Clinic (PC Gout) was established at a Veterans Affairs (VA) Medical Center affiliated with a large academic institution. The primary purpose was to increase IM trainees' exposure to the appropriate evaluation and management of gout; a secondary goal was to improve patient access to specialty services while aligning with current medical home models.

Methods: The PC Gout clinic was initiated in September 2017, by a rheumatologist with primary care support, and a dedicated pharmacist with advanced training in primary care. The clinic is held one half day per week, with trainees (mainly IM) and HPE students regularly assigned. Patients are referred to the clinic from other providers in primary care, the emergency department, inpatient medicine, and other services. Clinic experiences emphasize the importance of treating to uric acid targets, understanding the interactions of gout and urate-lowering therapies (ULTs) with common comorbidities such as chronic kidney disease and congestive heart failure, and the value of care delivery using a model of interprofessional teamwork.

Results: One hundred seventy-two visits have been completed since September 21st, 2017, representing 80 unique patients (77 male, 3 female). Demographics, referral source, and trainee type involved in the encounter are shown in Table 1.

Mean serum uric acid (sUA) level at initial visit was 7.6 mg/dL (0.9 to 13.1). To date, 53 patients (66%) have at least one additional measurement; mean post-treatment sUA is 5.8 mg/dL (2.9-10.5). Figure 1 shows the individual-matched changes in sUA for these patients.

Conclusion: The PC Gout Clinic represents an innovative method of connecting rheumatologist clinical educators with HPE students and trainees and creates a new context for teaching and learning. It embeds the rheumatologist

Table 1 – Patient Demographic and Clinic Information

Abstract Number: 0155

A Prospective, Unblinded, Non-randomized Pilot Study Examining the Effect of a Musculoskeletal Immersion Curriculum for First Year Internal Medicine Residents

Eric Miller,[1] Linh Ngo,[2] Zaki Abou Zahr,[2] Cassedy Mahrer,[3] and Rawad Nasr[3], [1]University of Minnesota, Woodbury, MN, [2]Hennepin Healthcare, Minneapolis, MN, [3]Hennepin Healthcare, Minneapolis

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Education Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Musculoskeletal (MSK) disorders are one of the most common clinic visit complaints. Prior studies evaluating graduate medical training of rheumatology and MSK medicine have shown that a knowledge gap exists in the United States. This gap in knowledge could lead to a delay in medical care and increased healthcare costs. In an attempt to bridge this gap, we designed an introductory curriculum for PGY-1 internal medicine (IM) residents during their first months of residency, aimed at improving knowledge of MSK and rheumatologic conditions, as well as providing early exposure to rheumatology. Our purpose was to assess whether the use of these didactics

Test	Point Range	Mean Change (points)	p-value
Knowledge Exam	0-27	3.68	p<0.001
MSK Exam: Confidence of joint identification	1-5	1.09	p<0.001
MSK Exam: Confidence of assessing joint tenderness	1-5	1.18	p<0.001
MSK Exam: Confidence of assessing joint effusion	1-5	1.45	p<0.001
MSK Exam: Confidence of assessing strength	1-5	1.09	p<0.001
MSK Exam: Confidence of assessing range of motion	1-5	0.86	p<0.001
Rheumatology interest	1-5	0.36	p=0.572

Table 1. Comparing PGY-1 post-test to pre-test scores

Test	Point Range	Mean Difference (points)	p-value
Knowledge Exam	0-27	2.07	p=0.027
MSK Exam: Confidence of joint identification	1-5	0.21	p=0.563
MSK Exam: Confidence of assessing joint tenderness	1-5	0.93	p=0.008
MSK Exam: Confidence of assessing joint effusion	1-5	1.00	p=0.003
MSK Exam: Confidence of assessing strength	1-5	0.86	p=0.002
MSK Exam: Confidence of assessing range of motion	1-5	0.64	p=0.049
Rheumatology interest	1-5	0.29	p=0.390

Table 2. Comparing PGY-1 retention test to PGY-2 control test scores

would: 1) increase rheumatology medical knowledge, 2) result in retention of knowledge, 3) increase confidence of MSK exam skills, and 4) increase rheumatology career interest.

Methods: The study was conducted at Hennepin Healthcare. PGY-1 residents are required to participate in an immersion ambulatory rotation during one of their first three months of residency. We developed a curriculum focused on introductory rheumatology concepts, MSK medicine, and MSK exam that were integrated into their immersion month. We evaluated PGY-1 IM resident knowledge on three separate occasions via a voluntary online test: pre-intervention, post-intervention, and 1-3 months after completing their immersion block (retention test). The test included 27 questions on rheumatology and MSK knowledge, 5 questions on confidence in MSK exam, and one question regarding interest in rheumatology. PGY-2 residents were enrolled as the voluntary comparison control group and completed an identical test to the PGY-1 resident retention test. We provided small gift cards as compensation to increase voluntary

participation. Data was collected and stored on a secure cloud-based program, then analyzed using the student's t-test.

Results: All 22 PGY-1 residents completed the pre- and post-test. Approximately 64% of PGY-1 residents and 64% of PGY-2 residents completed the same retention test. The PGY-1 residents who participated in the rheumatology immersion didactics scored significantly higher on both their post-test and confidence in MSK exam scores (p=< 0.001). There was no significant difference between post-test scores and the retention exam score (p=0.435). The PGY-1 residents also scored significantly higher on their retention test compared to the PGY-2 control group (p=0.027). There was no statistical difference in rheumatology interest either before or after intervention in PGY-1 group or between PGY-1 and PGY-2 groups.

Conclusion: Our pilot study suggests that integrating rheumatology didactics early in residency results in immediate and long-term improvement in rheumatology knowledge and confidence in the MSK exam. The present deficit in rheumatology and MSK medical knowledge, combined with the growing frequency of these conditions in the primary care setting, highlights the importance finding methods to address this gap in knowledge. Our study demonstrates early education in rheumatology and MSK knowledge provides a possible cost-effective solution.

****Not enough time between original session and post-SE assessment to send a second rheuminder

Background/Purpose: Spaced education (SE) and reciprocal peer teaching (RPT) are known to promote knowledge retention and learner engagement. We wanted to understand the educational impact of SE and RPT elements in our rheumatology fellowship core curriculum (CC) but were limited by a small number of learners, insufficient time for test question validation, and difficulty isolating the curricular elements of interest from concurrent educational activities. We developed a novel free recall assessment to analyze knowledge retention from CC sessions in our program to evaluate the impact of SE and RPT.

* Number of fellows present, **Average total number of concepts recalled, ***Average quality score of the concepts recalled

CC = Core Curriculum; SE = Spaced Education; RPT = Reciprocal Peer Teaching

Methods: The SE intervention involved emailing fellows "rheuminder" multiple choice quizzes about key topics covered in CC sessions. There were 19 CC sessions during the pre-SE period. The SE intervention included 11 CC sessions: unique rheuminders were sent about 1 one week after each CC session; 8 rheuminders were re-sent about 1 month later. Pre- and post-SE free recall assessments asked fellows to list every concept they could remember from each CC session over 1 minute. We tallied the total number of concepts listed and scored the quality of each statement according to the following scale: 1 = incorrect or irrelevant; 2 = a general topic that was covered, not an individual learning point; 3 = an individual learning point that is vague or of poor quality; 4 = an individual learning point that is specific and of good quality. Concept quality was independently scored by 2 raters (DL, JG) with discrepancies arbitrated by a third rater (LCS). We defined RPT CC sessions as those in which fellows were required to prepare in advance and teach each other during the session. Non-RPT sessions did not require prep-work and depended on an instructor for content delivery. Both types of sessions occurred throughout the pre and post-SE period. We used student's t-test and Fisher's exact test to analyze the impact of SE (primary analysis) and RPT (secondary analysis) on the average number of concepts recalled and proportions of concept quality.

Results: Metrics on fellow engagement with SE rheuminders are shown in table 1. Data on the number and quality of concepts recalled for each CC topic are shown in table 2. The average number of concepts recalled per session pre- vs. post-SE was 4.21 vs. 3.93 ($p = 0.338$). The quality scores of concepts pre-SE was 1 = 4.9%, 2 = 49.8%, 3 = 32.6%, 4 = 12.7%; post-SE quality was 1 = 5.6%, 2 = 46.5%, 3 = 34.2%, 4 = 13.7% ($p = 0.913$). The average number of concepts recalled per session non-RPT vs. RPT was 4.07 vs. 4.13 ($p = 0.824$). The quality scores of concepts for non-RPT sessions was 1 = 5.4%, 2 = 57.4%, 3 = 27.9%, 4 = 9.3%; quality for RPT sessions was 1 = 4.9%, 2 = 43.2%, 3 = 36.5%, 4 = 15.4% ($p = 0.0148$).

Conclusion: Using a unique free recall assessment, we found that numbers of concepts remembered did not change when analyzed by SE or RPT. However, the quality of concept recall significantly improved for CC sessions employing RPT, and did not change after the SE intervention. These findings suggest that RPT may be more impactful than SE using multiple choice quizzes and offers a unique perspective on the impact of curricular elements within a rheumatology training program.SE Table 2 FINAL Table 2. Data for Each Core Curriculum Session According to Pre- vs. Post-SE and Non-RPT vs RPT

Abstract Number: 0157

We Can Do Better: Evaluating Inpatient Pediatric Rheumatology Inpatient/Consult Service Performance

Katherine Schultz,[1] Britne Gregg,[1] Melissa Klein,[1] Francis Real,[1] and Jennifer Huggins[1], [1]Cincinnati Children's Hospital Medical Center, Cincinnati, OH

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Education Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Analysis of the last five annual program reviews of our fellowship identified repeated concerns raised by both residents and fellows with Rheumatology inpatient rounding and consultation. Thus, one of the specific aims for improvement chosen for our American Council for Graduate Medical Education (ACGME) Self-Study was to obtain feedback regarding our inpatient consult service performance from the Cincinnati Children's Hospital Medical Center (CCHMC) pediatric residents. We know from the adult rheumatology literature that communication,

professionalism, teaching, and pushback have been identified by residents as key measures to evaluate the effectiveness of consultative services. These measures, however, have not been applied to evaluate pediatric rheumatology consultations, and so we modified the existing validated adult survey to 1) determine pediatric resident opinion on the aforementioned areas, and 2) identify areas for improvement.

Methods: Rheumatology consultation patients requiring inpatient admission at CCHMC are primarily admitted to one of the general inpatient teams that is staffed by post graduate year one (PGY-1) through four (PGY-4) residents. Residents on this team from July 2018 through April 2019 were handed and completed a survey during a noon lecture given during the 4-week rotation. Surveys included 6 questions related to the experience and residents' perception of communication, education, etc. All questions were answered on a 5-point Likert scale (not applicable, poor, fair, good, very good, and excellent). The survey was developed by our pediatric rheumatology program director based on a survey described in the adult literature.

Results: 31/38 (82%) of residents completed the survey (75% PGY-1, 23% PGY-2, and 3% PGY-3 or PGY-4). Overall satisfaction with consulting service was good among residents, with 29/31 (94%) of residents reporting "very good" or "excellent satisfaction". Resident opinion on the quality of communication was variable, with 5/31 (16%) reporting "poor" to "good" quality of communication and 26/31 (84%) reporting "very good" or "excellent". The majority of residents reported "very good' or "excellent" professionalism (30/31, 97%). Teaching was also variable, with 6/31 (19%) reporting "poor" to "good" experience. There was little report of pushback, with 31/31 (100%) of residents reporting receiving pushback "rarely" or "never".

Conclusion: Overall, experience with the inpatient consulting service seemed favorable among residents. Areas for improvement included communication and teaching. In regards to communication, more first year residents seemed dissatisfied, which some reporting "poor" or "fair" experiences. Prior investigations through end of year reviews in our program have reported that this dissatisfaction in communication revolves around discussion of rounding times and plans, but further investigation is required to fully illuminate ways to improve this. In regards to teaching, though the majority of responders reported favorably, there were still some who did not have a good experience, and next steps include investigations into ways to improve this.

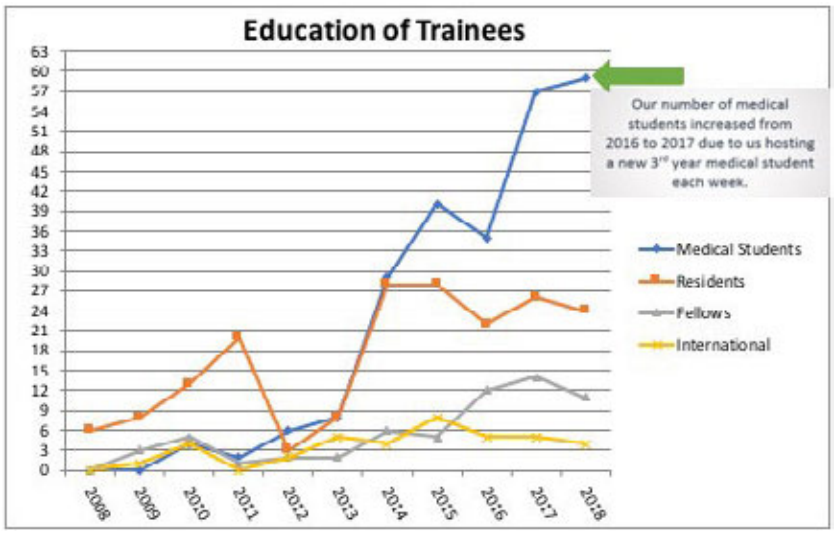
Abstract Number: 0158

Addressing the Pediatric Rheumatology Physician Shortage: Does Early Exposure Matter?

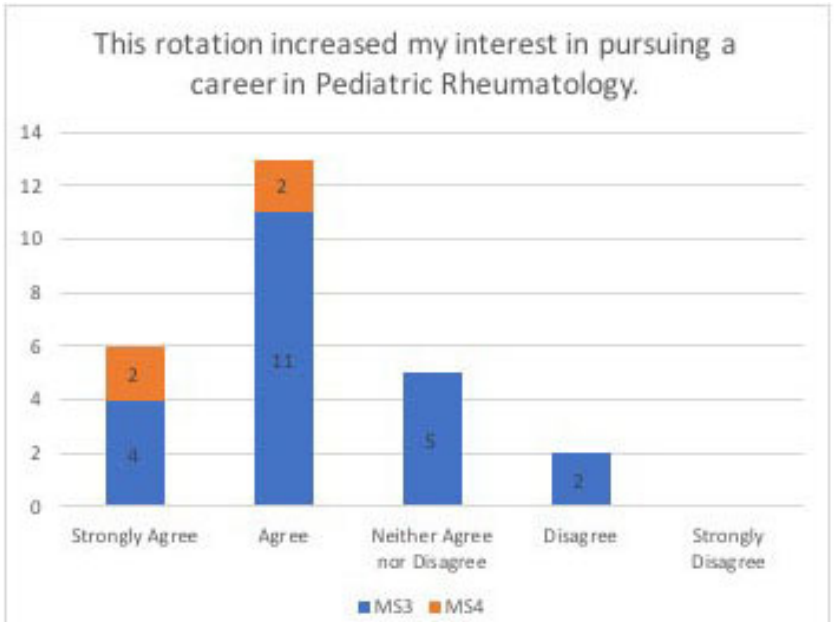
Katherine Schultz,[1] Theresa Hennard,[2] Britne Gregg,[1] Melissa Klein,[1] Francis Real,[1] and Jennifer Huggins[1], [1]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [2]Division of Rheumatology, Cincinnati Children's Hospital and Medical Center, Cincinnati, OH

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Education Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: There is a shortage of pediatric rheumatologists in the United States, with current demands exceeding provider supply by 33%. This disparity is projected to increase to 61% by 2030 as the anticipated work—that is, residents pursuing pediatric rheumatology fellowships—is expected to decline below current rates. Evidence supports that early exposure to rheumatology increases a learner's interest to pursue rheumatology as a career. For



Increase in medical student exposure over 10 year period



Medical student reported interest in pursuing pediatric rheumatology as a career after rotation exposure

example, an adult study demonstrated 35% of current rheumatology fellows identified a clinical rotation as the most influential factor towards choosing their career. Thus we aimed to 1) increase medical students' exposure to pediatric rheumatology at Cincinnati Children's Hospital and Medical Center (CCHMC); and 2) identify how early educational experiences impact learners' self-assessed career plans.

Methods: A multifaceted approach was used to provide clinical experiences in pediatric rheumatology to medical students starting in 2013, initially by conducting lectures at the medical school. Starting in 2016, third year students were offered a one-week outpatient rotation during their pediatric clerkship. Fourth year students were offered 2- or 4-week electives. From July 2018 to April 2019 third- and fourth-year students participating in these rotations were surveyed at the end of their experiences. Beginning in 2018, a survey was by our pediatric rheumatology program based on previous surveys used in the adult literature. The survey included questions related to the impact of the experiences on interest in pursuing pediatric rheumatology as a career rated on a 5-point Likert scale from strongly agree to strongly disagree.

Results: An increased number of medical students participating in pediatric rheumatology experiences occurred as a result of our curriculum (figure 1). Ninety-three percent (27/29) of third- and fourth-year medical students completed the survey in 2018. All students agreed/strongly agreed that the experience was valuable and increased their awareness of pediatric rheumatologic disease. In addition, 65% (19/29) of students agreed/strongly agreed that the rotation increased their interest in pursuing a career in pediatric rheumatology (figure 2).

Conclusion: There is a growing need for pediatric rheumatologists, and early exposure to the specialty may be one strategy to combat the future shortfall. Most medical students that participated in our curriculum reported increased interest in pursuing a career in pediatric rheumatology. Next steps include long-term follow up of participants to evaluate ultimate career choices.Increase in medical student exposure over 10 year periodMedical student reported interest in pursuing pediatric rheumatology as a career after rotation exposure

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Education Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Since 2011, the Veterans Administration (VA) has supported musculoskeletal (MSK) training programs to facilitate provider and trainee MSK education, including a national health professions education (HPE) faculty development course – the MSK Master Educator (ME). The ME program, offered through VA Simulation Learning, Education and Research Network (SimLEARN), was created to teach educators how to systematically train primary care providers and trainees in MSK medicine. The program includes a portable curriculum to be used at ME participants' home institutions. Program development and pilot testing has been previously described. Herein, we describe the long-term effects of the ME training program on the first cohort of learners from 2017-2018.

Methods: The 2.5 day ME program included didactic presentations designed to teach primary care providers how to evaluate and manage shoulder and knee pain, reinforced by a 2-station OSCE. On the final day, participants rotated through an objective structured teaching experience (OSTE) to practice the roles of teacher, student and simulated patient.

Table 1. Demographic and Self-Assessment Information for Master Educator Participants from 2017 to 2018

TABLE 1.
Demographics and Self-Assessment Ratings

Discipline	Primary Care	Rheumatology	Physical Medicine & Rehabilitation	Emergency Medicine	Occupational Medicine, Orthopedics
N (% of total)	17 (49%)	11 (31%)	3 (8%)	2 (6%)	2 (6%)
Years of Experience	> 3	3 to 5	6 to 10	11 to 20	> 20
N (% of total)	7 (20%)	6 (17%)	5 (14%)	11 (31%)	6 (17%)

Anticipated Program Outcomes	Improve personal MSK evaluation & management skills	Improve teaching skills for MSK medicine	Develop an MSK program for practicing providers	Develop an MSK program for trainees
N (% of total)	24 (69%)	31 (89%)	23 (66%)	21 (60%)

Self-Assessment Ratings Variable	Mean pre-course ratings (SD)	Mean post-course ratings (SD)	Mean paired difference (p)
How *important* is it for you to be competent...

Manage shoulder pain (global rating)	4.0 (1.0)	4.7 (0.6)	0.7 (<0.001)
Knee Injection			
Understand indications for a knee injection?	3.9 (1.1)	4.8 (0.6)	0.9 (<0.001)
Perform a knee injection?	3.7 (1.4)	4.6 (0.8)	0.9 (<0.001)
Teach others to perform a knee injection?	3.5 (1.6)	4.4 (0.9)	0.9 (<0.001)

Ratings based on a 5-point scale (1, not at all; 2, slightly; 3, moderately; 4, quite; 5, extremely)

Participant evaluation included written surveys assessing learning goals and perceptions of confidence both before and immediately following the training. In 2019, a follow-up survey was developed. The survey collected information about participants' current work environment and any MSK-related duties that may have changed since participation in the ME program. Additionally, the survey collected perceptions about the ME course content and its importance in preparing participants to teach MSK knowledge to other providers. Individual emails with survey links were sent to 31 ME participants (4 excluded with no active email address).

Table 2. Changes in Local MSK Educational Responsibilities for Master Educator Participants

TABLE 2.
Follow-Up Survey Results

Participant involvement in MSK-related activities before and after the ME program

	Pre-Course N (%)	Post-Course N (%)	Change N (% increase)
Involved in teaching MSK-related content in formal didactic sessions	8 (50)	14 (88)	6 (75)
Level of Learners			
Medical Students	6 (38)	7 (44)	1 (17)
Physician Assistant Students	1 (6)	3 (19)	2 (200)
Nurse Practitioner Residents	2 (13)	3 (19)	1 (50)
Medicine Residents	6 (38)	10 (63)	4 (67)
Medicine Fellows	5 (31)	7 (44)	2 (40)
Practicing Providers	6 (38)	12 (75)	6 (50)
Working in an MSK-related clinical role	12 (75)	13 (81)	1 (8)
Precepting learners in MSK-related clinical experiences	11 (69)	14 (88)	3 (27)

Perceived Program Advantage, Compatibility, and Complexity

	N/A	Not	Slightly	Moderately	Quite	Extremely
How *advantageous* was this approach to teaching primary care providers and/or trainees, over the current approach that was being used at your facility?	1	-	-	-	10	5
How *compatible* was this content for integration into your facility's educational programs to train primary care providers and/or trainees?	-	-	-	3	6	7
How *complex* was this approach to teaching MSK skills to primary care providers and/or trainees?	-	4	4	8	-	-

Results: The ME program was held on 6 occasions from 2017 to 2018. Thirty-five learners participated (29 physicians, 5 nurse practitioners, 1 physician assistant). Demographic information and self-assessments collected immediately before and after the program are presented in Table 1. There was a significant increase in all post-course self-assessments of confidence, including the ability to teach shoulder and knee injections.

Sixteen follow-up surveys were completed in 2019 (52% response rate) by 14 physicians, 1 nurse practitioner and 1 physician assistant. Table 2 includes practice changes for MSK-related educational activities and perceptions of pro-

Table 3. Master Educator Schedule and Program Evaluation

Table 3 - Program Schedule and Rating of Course Elements

How important was each module ***in preparing you to teach*** future MSK content?				
1 – Not at all important	2 – A little important	3 – Moderately important	4 – Quite important	5 – Extremely important

Day 1	Ave (SD)	Day 2	Ave (SD)	Day 3	Ave (SD)

Shoulder Simulated Case Practice	4.9 (0.3)	Knee Simulated Case Practice	4.9 (0.3)		
Shoulder Subacromial Injections *Didactic and task-trainers*	3.9 (1.0)	Knee Intra-articular Injections *Didactic and task-trainers*	4.0 (1.1)		
Review Current Literature in MSK Education	4.4 (0.7)	Objective Structured Clinical Examination (OSCE) *Shoulder & Knee*	4.5 (0.7)		

gram advantage, compatibility and complexity. Participant evaluation of the importance of each ME course elements in preparing them to teach future MSK content are represented in Table 3.

Conclusion: The ME program is a national HPE faculty development course that attracts strong multidisciplinary educators and results in improved self-perception of MSK teaching abilities. Participants have reported an improvement in MSK teaching manifested by an increase in their local educational responsibilities in didactic and clinical settings. The curriculum was rated as advantageous and compatible with local programs, and feasible to integrate. To continue the effectiveness of this program, local institutions should support more educators to participate in this VA sponsored program.

Abstract Number: 0160

Evaluation of ACGME Competencies in a Rheumatology Observed Structured Clinical Examination

Arundathi Jayatilleke,[1] and Al Denio[2], [1]Drexel, Philadelphia, PA, [2]Geisinger, Danville, PA

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Education Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The Pennsylvania Rheumatology Objective Structured Clinical Examination (ROSCE) is an annual assessment of rheumatology fellows' communication skills. Fellows complete several standardized patient (SP) encounters involving complex communication issues within rheumatology. We revised our assessment tools to align with Accreditation Council of Graduate Medical Education (ACGME) internal medicine subspecialty milestone

ICS1-01	listen carefully to patients and caregivers to create rapport and build a therapeutic relationship.
ICS1-02	explain and counsel patients and caregivers about their problems, proposed examinations and treatments, and findings.
ICS1-03	share decision-making in both diagnostic and therapeutic scenarios.
PC1-01	take a comprehensive, accurate history, including review of all available records, on patients with rheumatic symptoms and signs.
PC1-03	understand and use diagnostic tests including, but not limited to, laboratory, imaging, electrodiagnostic and pathologic studies for the evaluation of the patient with rheumatic symptoms and signs.
PC2-01	form comprehensive treatment plan, based on clinical evidence, clinical context, and patient preferences, counsel patients, and assess response to therapy.
PC3-02	understand disease- and treatment-related complications that may lead to long term morbidity, including the consideration for implications of comorbid diseases and the effects of aging.
PROF1-01	demonstrate respectful professional interactions.
PROF1-02	demonstrate respect for patient dignity and autonomy.
PROF3-02	demonstrate compassion and respect to patients.
MK1-03	explain relevant mechanisms of action and potential adverse effects of agents used in the management of patients with rheumatologic conditions.
MK1-05	explain similarities and differences of the clinical presentation and management between adults and children with rheumatic conditions.
MK1-06	form a differential diagnosis for rheumatologic conditions, including consideration of non-rheumatic diseases.
MK1-08	evaluate complex rheumatic diseases in the setting of multiple coexistent conditions, including the effects of aging.
PBLI1-01	identify knowledge or skills gaps to enhance future clinical interactions.

Figure 1. Description of ACGME milestone categories.

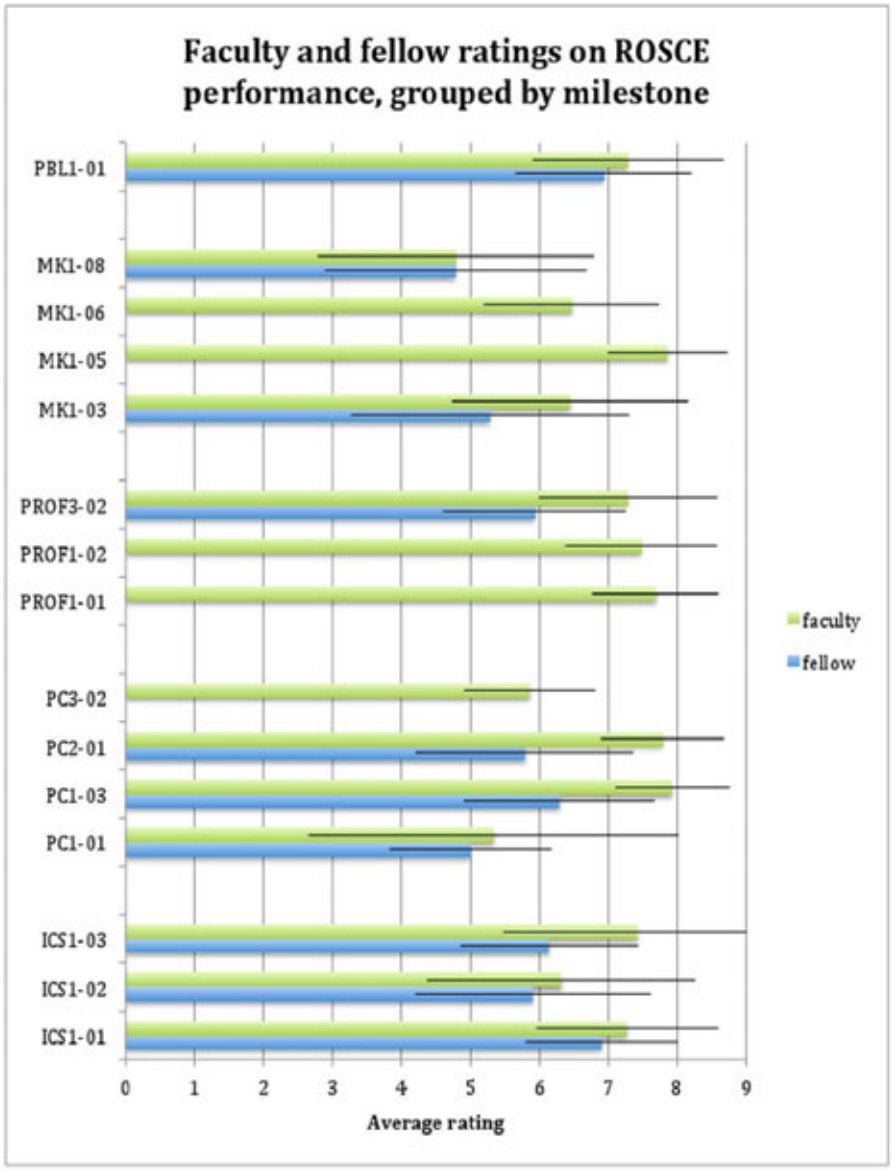

Figure 2. Faculty and fellow ratings on ROSCE performance, grouped by milestone.

areas and compare fellow performance across cases. In this study, we evaluated the comparability of the fellow and faculty ROSCE evaluations within ACGME competency domains.

Methods: 16 trainees from 8 rheumatology programs participated in 7 SP scenarios and were observed by faculty raters. Content validity was determined by consensus of 10 rheumatology fellowship program directors. We recorded faculty and fellow feedback using previously developed 9-point Likert scale instruments. To ensure response process validity, faculty raters were trained on scoring forms prior to the ROSCE; scores were recorded electronically and transferred to Excel for analysis. Fellows completed self-assessment forms afterwards. Items were mapped to milestone categories in the ACGME competencies of medical knowledge (MK), interpersonal and communication skills (ICS), patient care (PC), practice based learning and improvement (PBLI) and professionalism (PROF) (see figure 1). Narrative comments were also recorded.

Results: 16 faculty and 16 fellow feedback forms from 7 ROSCE cases were analyzed. 15 MK, 48 ICS, 9 PC, 1 PBLI, and 26 PROF questions (99 total) were scored across all cases, corresponding to 15 rheumatology milestones.

Overall, average faculty and fellow ratings on milestone categories as well as grouped by competency domains were comparable; however, fellow and faculty ratings were generally poorly correlated except with respect to medical knowledge (r=0.67 for MK1-03, r= 0.70 for MK1-08). Faculty ratings tended to be higher than fellows, most prominently in the MK and PROF domains overall, and in the MK1-03, PROF3-02, PC2-01, and PC1-03 milestones specifically (see figure 2).

Narrative comments from faculty (n=224) largely pertained to use of medical jargon (26%), clarity of explanation (12%), and knowledge base (12%). 24% of fellow comments (n=112) pertained to difficulty of the case, while 33% pertained to areas that they had forgotten during the SP encounter.

Conclusion: Faculty and fellow evaluations of performance were similar in each ACGME competency though fellows tended to self-rate lower than faculty. Correlation between faculty and fellow ratings was generally low, except with regard to more "objective" milestones in medical knowledge; this is likely due to a relatively small spread in ratings of communication skills. We plan to further evaluate validity of our ROSCE and revise our assessments to reflect milestone achievement levels. We hope in future to evaluate correlation of competency evaluation in the ROSCE with program director assessment of fellows.

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Education Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The Veterans Health Affairs (VHA) Simulation Learning, Education and Research Network (SimLEARN) National Simulation Center has developed a portfolio of continuing professional development (CPD) programs to strengthen the skills of primary care providers (PCPs) in the evaluation and management of common musculoskeletal (MSK) conditions. Instituted in 2015, these 2-day courses are held frequently at the SimLEARN Center in Lake Nona, FL, where they are taught by a rotating consortium of national faculty. The purpose of this study was to engage faculty in a systematic process of course evaluation using a structured consensus procedure inform ongoing curriculum development.

Methods: Eleven educators who had taught in the "MSK Clinician" (MSK-C) course at SimLEARN since 2015 were invited to participate in a 3-step Delphi process. Step 1 involved review of the current curriculum, with invitation to suggest additional content. In step 2, each educator rated every item's importance in a curriculum for PCPs, using

1 Not at all important for Primary Care	2 Slightly important for Primary Care	3 Somewhat important for Primary Care	4 Very important for Primary Care	5 Extremely important for Primary Care

Elements of Current Course	Mean Rating (SD)		Consensus to Retain? Mean ≥ 4 SD ≤ 1 (Final Round)
	First Round	Final Round	
Day 1			
Course Introduction/Precourse Assessments	4.1 (1.1)	4.2 (0.8)	Yes
Introduction to Shoulder Exam (Didactic)	4.8 (0.4)	5.0 (0.1)	Yes
Small Group Shoulder Exam Practice (Hands-on)	4.9 (0.3)	5.0 (0.1)	Yes
Shoulder Pathology (Didactic)	4.7 (0.4)	4.9 (0.2)	Yes
Arthrocentesis Basics (Didactic)	4.2 (0.7)	4.2 (0.6)	Yes
Shoulder Injections (Didactic)	4.0 (0.9)	4.1 (0.7)	Yes
Small Group Shoulder Cases (Hands-on)	4.8 (0.4)	4.9 (0.3)	Yes
Shoulder Injections on Task Trainers (Hands-on)	3.5 (1.2)	3.5 (1.2)	No
Day 2			
Shoulder OSCE (Hands-on)	4.2 (1.2)	4.2 (0.1)	Yes
Introduction to Knee Exam (Didactic)	4.8 (0.4)	4.9 (0.3)	Yes
Small Group Knee Exam Practice (Hands-on)	4.9 (0.3)	4.9 (0.3)	Yes
Knee Pathology (Didactic)	4.7 (0.4)	4.8 (0.3)	Yes
Knee Injections (Didactic)	4.0 (0.9)	4.0 (0.8)	Yes
Small Group Knee Cases (Hands-on)	4.8 (0.4)	4.9 (0.3)	Yes
Knee Injections on Task Trainers (Hands-on)	3.6 (1.2)	3.6 (1.1)	No
Knee OSCE (Hands-on)	3.6 (1.2)	3.6 (1.2)	No
Evaluation Feedback and Closing Remarks	4.4 (0.7)	4.5 (0.4)	Yes
Proposed Elements (Additions Only)			
Pain management, specifically non-opioid choices	4.2 (1.2)	4.2 (1.1)	No
Self-care options: specific exercises or resources to describe home therapy	4.2 (0.8)	4.1 (0.6)	Yes
Exercise prescription	3.8 (1.2)	3.4 (1.1)	No
Documentation of the exam, management plan, and procedures	3.6 (1.3)	3.5 (1.1)	No
Comparative efficacy of treatments (PT, steroids, viscosupplementation)	3.8 (0.6)	3.8 (0.6)	No
Back exam	3.9 (1.3)	3.6 (1.3)	No
Back management	3.8 (1.3)	3.5 (1.3)	No
Hip exam	3.9 (1.2)	3.7 (1.2)	No
Him management	3.8 (1.1)	3.6 (1.2)	No
Addition to shoulder exam—Roos maneuver/costoclavicular maneuver (checking for pectoralis minor shortening)	2.2 (0.9)	2.1 (1.0)	No
Addition to knee exam—tracking of the patella	2.8 (1.3)	2.5 (1.2)	No
Newer treatment options for knee injections (beyond steroids and hyaluronic acid), including efficacy data	3.4 (0.9)	3.4 (0.8)	No
Updates from the literature regarding the use of steroid and hyaluronic acid	3.5 (0.8)	3.7 (0.6)	No
Chronic pain medication options in addition to NSAIDS used for chronic MSK pain, with literature regarding efficacy	3.8 (0.8)	3.6 (1.2)	No
Chondromalacia patella, including role of arthroscopy	3.1 (1.1)	3.0 (0.8)	No
Gout (of the knee)	3.3 (0.7)	3.1 (0.7)	No
Tendonitis (of the knee)	3.5 (0.9)	3.3 (0.6)	No
More detailed approach to history of shoulder pain	2.9 (1.5)	2.9 (1.3)	No
Location	3.1 (1.6)	3.3 (1.4)	No
Trauma	3.0 (1.6)	3.0 (1.5)	No
Pain intensity (0-10)	3.0 (1.6)	2.8 (1.5)	No

MSK-C Curriculum Consensus Table Mean Ratings for Step 2 and Step 3

a 5-point Likert scale (1 = not at all important; 5 = extremely important). In the 3rd step, educators were given the groups' average rating for each item, reminded of their own initial rating, and asked to make a final 5-point rating. Individual responses to each step remained anonymous. After the final step, items meeting the predetermined criteria of mean ³4 and standard deviation ≤1 were retained; these items defined group consensus.

Results: Eleven educators (100%; 8 physicians, 2 physician assistants, 1 nurse practitioner) completed all steps of the project.

In step 1, a total of 59 additional elements of the course were proposed by the group, though only one of these—the inclusion of teaching self-care options and specific elements of a home exercise program—met the criteria for consensus. In addition, three of the existing course elements—two sessions for practicing injections using task trainers, and the objective structured clinical examination of the knee—also were not endorsed by consensus.

Mean ratings of all current and proposed course elements in step 2 and step 3 of the consensus process are shown in the Table.

Conclusion: Using a systematic consensus exercise, the faculty of the SimLEARN MSK-C program have critically evaluated the current CPD course, as well as proposed additions to the existing curriculum. This information, combined with participant feedback, other measures of course effectiveness, and ongoing needs assessments conducted by VHA, will help inform the educational and administrative leadership of SimLEARN and give guidance to efforts for continued development of this important national resource.

Abstract Number: 0162

A Shared Mental Model for Teaching and Assessing Examination of the Hand, Wrist, and Elbow in the "Training Rheum" Continuing Professional Development Program

Michael Battistone,[1] Beth Jonas,[2] Janet Bahr,[3] Susan Chrostowski,[4] Anisha Dua,[5] Karina Torralba,[6] Abigail Konopasky,[7] Holly Meyer,[7] and Andrea Barker[8], [1]Salt Lake City Veterans Affairs Medical Center & University of Utah, Salt Lake City, UT, [2]Thurston Arthritis Research Center, Chapel Hill, NC, [3]Gundersen Health System, Onalaska, WI, [4]Rheumatology Associates, Plano, TX, [5]Northwestern University Feinberg School of Medicine, Chicago, IL, [6]Loma Linda University School of Medicine, Loma Linda, CA, [7]Uniformed University of the Health Sciences, Bethesda, MD, [8]Salt Lake City Veterans Affairs Medical Center & University of Utah, North Salt Lake, UT

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Education Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: An increasing number of nurse practitioners (NPs) and physician assistants (PAs) are pursuing careers in rheumatology. To serve their educational interests, the American College of Rheumatology and the American Association of Physician Assistants will launch "The Training Rheum", a 3-day continuing professional development (CPD) course offered August 2019 and January 2020. This program includes instruction in physical exam skills of the hand, wrist, and elbow, reinforced through low-stakes, formative assessment. An interprofessional group of Training Rheum faculty was engaged in a statistically-guided consensus project to develop a useful learning and assessment tool geared to the needs of advanced clinicians new to the practice of rheumatology.

Methods: A literature review was performed to determine physical exam maneuvers of the hand, wrist and elbow that were relevant to informing a clinical diagnosis. Seven faculty involved in the practice and assessment sessions engaged in a 3-step Delphi process. Step 1 involved reviewing the physical exam maneuvers identified in the literature review, and offering suggestions for additional items for the group to consider. In step 2, each faculty member rated every item's importance relative to a curriculum designed for NPs or PAs working in rheumatology, using a

Rating of Items' Importance for NPs and PAs Working In Rheumatology

1 Not at all important for Training Rheum	2 Slightly important for Training Rheum	3 Somewhat important for Training Rheum	4 Very important for Training Rheum	5 Extremely important for Training Rheum

		Mean Rating (s.d.)		Item Retained? (Mean ≥ 4; s.d. ≤ 1)
	Examination Element	**Round 1**	**Round 2**	
1	**Observation**			
	General			
	Inflammation	5.0 (0.0)	5.0 (0.0)	Yes
	Erythema	5.0 (0.0)	5.0 (0.0)	Yes
	Swelling	5.0 (0.0)	5.0 (0.0)	Yes
	Tenderness	5.0 (0.0)	5.0 (0.0)	Yes
	Warmth	5.0 (0.0)	5.0 (0.0)	Yes
	Rashes	4.7 (0.7)	4.7 (0.5)	Yes
	Ulcers	4.6 (0.7)	4.6 (0.7)	Yes
	Scars	3.7 (0.9)	3.7 (0.7)	No
	Muscle atrophy	4.3 (0.7)	4.3 (0.5)	Yes

	Chieropathy	3.7 (1.2)	3.7 (0.9)	No
	Flexion contractures	4.3 (0.9)	4.4 (0.5)	Yes
	Calcinosis	4.1 (0.8)	4.4 (0.5)	Yes
	Digit resorption	3.6 (1.0)	3.4 (0.7)	No
	Nail Signs			
	Pitting	4.7 (0.7)	4.9 (0.3)	Yes
	Onycholysis	4.6 (0.7)	4.7 (0.7)	Yes
	Nailfold capillary changes	4.1 (1.4)	4.1 (1.0)	Yes
	Splinter hemorrhages	4.1 (0.8)	4.1 (0.8)	Yes
	Clubbing	4.0 (0.9)	3.9 (0.6)	No

5-point Likert scale (1 = not at all important; 5 = extremely important). In the third step, faculty were asked to make a final 5-point rating considering the group's overall average rating for each item and their own initial rating. Individual responses to each step remained anonymous. To determine the final consensus checklists, items meeting the predetermined criteria of mean >/= 4 and standard deviation (s.d.) < /= 1 were retained.

Results: All seven faculty members (4 physicians (rheumatologists), 2 NPs, and 1 PA) completed all three Delphi steps. The initial list, including items added in step 1, consisted of 78 elements. The consensus process eliminated

22 items, leaving 53 in the final version of the checklist. Mean ratings of all elements for step 2 and step 3 are shown in Table 1.

All seven faculty members (4 physicians (rheumatologists), 2 NPs, and 1 PA) completed all three Delphi steps.

The initial list, including items added in step 1, consisted of 78 elements. The consensus process eliminated 22 items, leaving 53 in the final version of the checklist.

Mean ratings of all elements for step 2 and step 3 are shown in Table 1.

Conclusion: Using a systematic consensus exercise, an interprofessional group of faculty participating in the "Training Rheum" CPD program has developed a checklist for use in teaching and assessing learners' physical examination of the hand, wrist, and elbow. The next steps will include an evaluation of the effectiveness of this tool, including its response process, internal structure, relation to other variables, and consequences, when used in actual teaching sessions.

Abstract Number: 0163

Workforce Survey: Career Trends of Combined Adult and Pediatric Rheumatology Fellowship Graduates

Kimberly DeQuattro,[1] and **Cuoghi Edens**[2], [1]University of California, San Francisco, San Francisco, CA, [2]University of Chicago, Chicago, IN

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Education Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Future projections deem the rheumatology workforce insufficient to meet patient demand, with certain with catchment areas (micropolitan, rural) already lacking clinicians. Currently there is an inadequate number of pediatric rheumatologists to care for patients, only expected to worsen as the current workforce reaches retirement. Interest in combined adult and pediatric rheumatology training has increased in recent years in concert with medpeds residency applicants and rheumatology fellowship training. One prospect to minimize the workforce gap is to capitalize on physicians trained in both medicine and pediatrics (medpeds) rheumatology who can treat patients of all ages. While combined medpeds rheumatologists exist in clinical practice, the path to this career title has historically not been standardized and there is no governing body to determine this designation. No study has established the number of medpeds rheumatologists in practice, their demographics, practice characteristics, and board certifications of this unique rheumatology workforce.

Methods: Mixed-methods approach of primary and secondary data was used to identify baseline medpeds workforce data. Secondary data derived from query of matriculation, board certification, and practice records of multiple organizations including *Accreditation Council for Graduate Medical Education*, American Board of Pediatrics, American Board of Internal Medicine (ABIM), American Board of Medical Specialties, MedPeds section of American Academy of Pediatrics, and Childhood Arthritis and Rheumatology Research Alliance. Formally medpeds trained rheumatologists were defined as having achieved board certifications in both pediatric and adult medicine and rheumatology. Surveys were used to characterize medpeds physician fellowship training and career experiences. Pediat-

ric rheumatology program directors were queried about past medpeds fellowship trainees. Identified combined medpeds rheumatology fellowship graduates were queried to determine their practice location and type, employment percent (full or part-time), patient population, salary, and board certifications. A similar survey was sent to those who completed a medpeds residency followed by a categorical rheumatology fellowship.

Results: In the United States, there are approximately 5000 rheumatologists, 300 of which are pediatric rheumatologists. Thrirty-four formally trained medpeds rheumatologists were identified in the past 20 years, although the number of dual board-certified rheumatologists is incongruent to this. Additionally, 80 pediatricians were board certified through ABIM in rheumatology in addition to those with combined training. Further survey data collection and analysis is currently ongoing.

Conclusion: Inconsistent data exists on the number of practicing medpeds rheumatologists who care for adult and pediatric patients with rheumatologic conditions. This information is vital to the workforce shortage facing rheumatology, particularly pediatric rheumatology, as medpeds rheumatologists may fill a unique clinical niche and help meet the future provider demand.

Learner Practice Gaps in Osteoporosis: Piloting a Metabolic Bone Disease Curriculum Within a Fracture Liaison Service Framework

Vaneet Sandhu, MBBS,[1] Ajay Kamboj,[1] **Teodor Duro**,[1] Christina Downey, MD,[2] and Karina Torralba[3], [1]Loma Linda University, Loma Linda, CA, [2]Loma Linda University Medical Center, Loma LInda, CA, [3]Loma Linda University School of Medicine, Loma Linda, CA

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Education Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Targeting community level health outcomes is one of the higher aims of medical education. Osteoporosis care gaps are prevalent. Only 23% of women with a fragility fracture have dual energy x-ray absorptiometry (DXA) or pharmacotherapy within 6 months post-fracture. There is also an overreliance on DXA for diagnosis, overlooking a history of fractures, underrecognition of osteoporosis in men, and underutilization of fracture risk assessment (FRAX) to guide therapy. A Fracture Liaison Service (FLS) was established after a local institutional study showed similar care gaps. In the context of experiential learning, a metabolic bone disease (MBD) curriculum was designed within the framework of the FLS for Internal Medicine (IM) residents. (Figure 1,2) Areas of emphasis include disease recognition and risk assessment. The objectives of this study are to determine osteoporosis practice care gaps among residents who have undergone the MBD rotation with the goal to inform educators about areas needing curricular improvement.

Methods: IM residents who completed an MBD rotation April 2018-2019 who provided consent for practice habit review were included in the study. Patient encounters from electronic medical records of women > 65 and men > 70 years of age seen for routine followup visits in continuity clinics May 2018-April 2019 were reviewed. Osteoporosis practice guidelines and nationally-defined patient outcome measures were reviewed by faculty. Six parameters on disease recognition (DXA, FRAX or prior fracture), and risk assessment (steroid exposure, vitamin D level determination; also FRAX) were selected by consensus. Descriptive statistics were utilized. The IM Core Program approved the curriculum as a one week block within a Rheumatology rotation in lieu of an independent 4 week rotation.

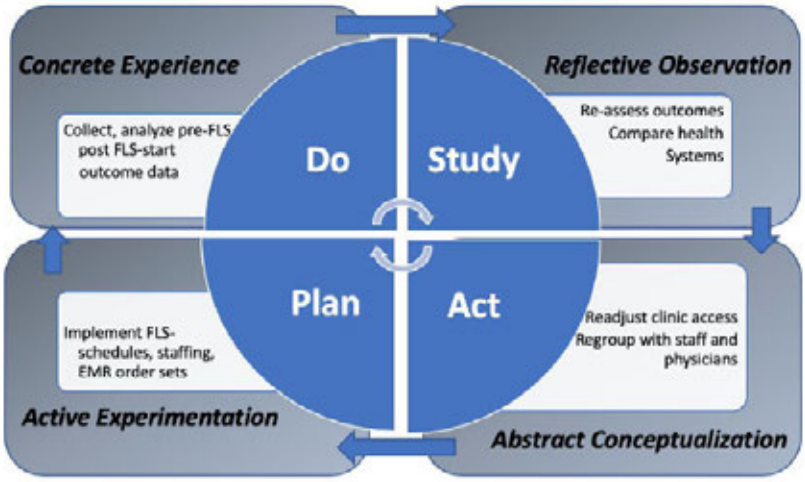

Figure 1. Kolb's Constructivist Theory of Experiential Learning Complements the QI PDSA Cycle

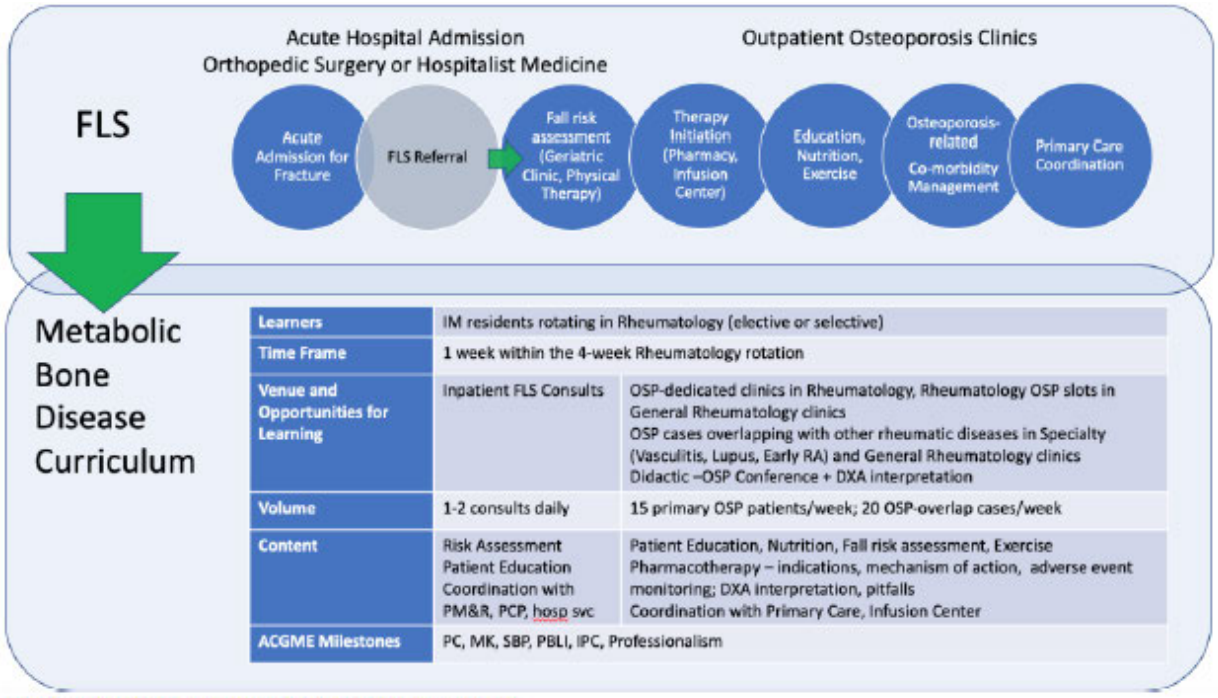

Figure 2. Metabolic Bone Disease Curriculum proposal

Results: 52 residents had gone through the rotation during the designated period of time, and 11 agreed to have a practice review. 2, 6, and 3 were PGY 1, 2, and 3, respectively. 88 charts were reviewed of 54 female and 34 male elderly patient encounters occurring within 3 months of MBD rotation completion. (Figure 3) Fifty (57%) DXAs were ordered by 10 residents. 32 DXAs were completed, and 18 (56%) had osteoporosis. Of these 18 cases, prior fracture was documented in 3 (17%) and long-term steroid use in 4 (22%). No chart had documentation of FRAX. Out of 88 charts, 13 (15%) of patients had a vitamin D level checked within 3 months of provider visit or DXA.

Conclusion: Practice review reveals underutilization of osteoporosis diagnosis and risk assessment strategies. Issues to consider for curricular improvement include reformatting the MBD rotation as a 2-week minimum hands-on rotation providing Orthopedic Surgery, Rheumatology and Endocrinology exposure, and increasing active learning compo-

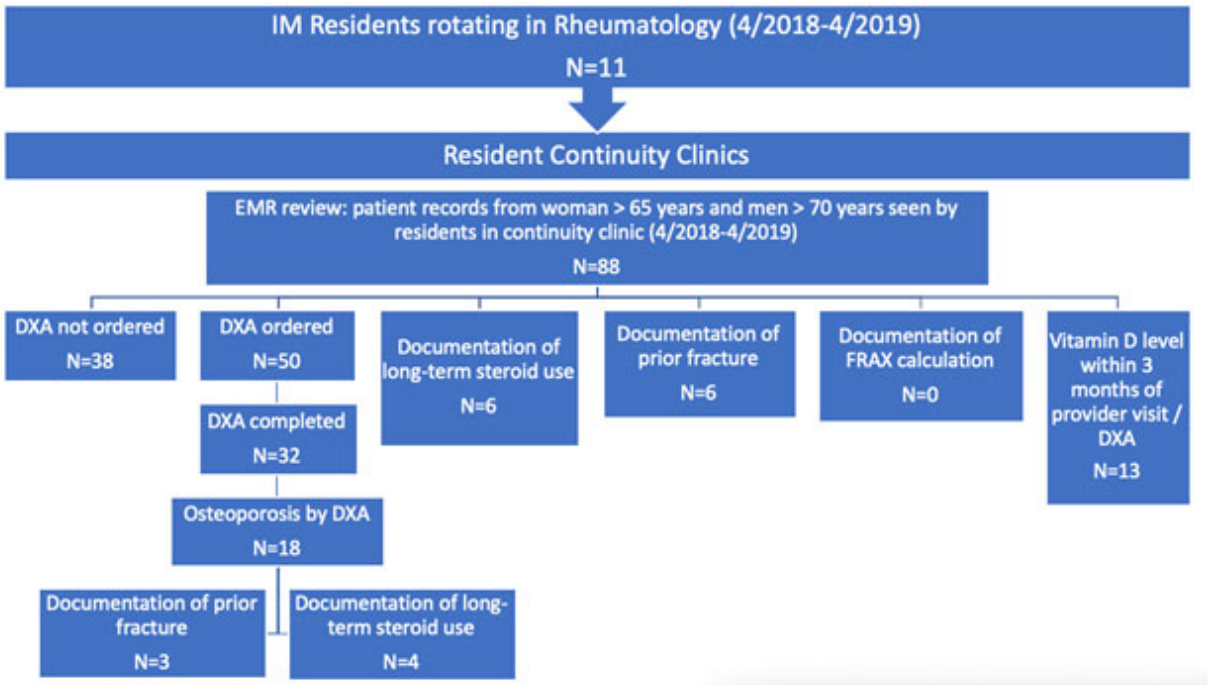

Figure 3. Methodology and Results

nents during the rotation and even throughout the year. The FLS aims to engage primary care physicians, and offering learning opportunities for resident continuity clinic supervising primary care faculty also need to be considered.

Heterogeneity of Strategies and Methods for Assessment of Competences in Rheumatology Training: Results of a Systematic Literature Review to Inform EULAR Points to Consider

Alessia Alunno,[1] Aurelie Najm,[2] Francisca Sivera,[3] Catherine Haines,[4] and Sofia Ramiro[5], [1]Rheumatology Unit, Department of Medicine, University of Perugia, Perugia, Italy, Perugia, Italy, [2]Nantes University Hospital, Nantes, France, [3]Hospital General Universitario de Elda, Elda, Spain, [4]King's College, London, United Kingdom, London, United Kingdom, [5]Department of Rheumatology, Leiden University Medical Center, Leiden, the Netherlands Department of Rheumatology, Zuyderland Medical Center, Heerlen, the Netherlands, Leidin, Netherlands

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Education Poster

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: The structure and content of Rheumatology training programs vary widely among European countries. Harmonization of assessment methods of competences across EULAR countries could contribute to ensure a minimal standard of care. Our objectives were to To summarize the available information on competence assessment methods and strategies in postgraduate medical training in rheumatology and other specialties.

Author, country, year	Humphrey-Murto S, Canada, 2009	Berman JR, USA, 2009	Kissin EY, USA, 2014	Pascual Ramos V, Mexico, 2015
Competence assessed	CanMEDS roles	Clinical skills, communication skills, professionalism	Practical skills (MSUS)	Clinical skills
Tool	DOPS	OSCE	OSCE	OSCE
Comparator tool	A national 10-station OSCE	Rating by program directors	A 76-question MCQ	Theory Test Board Exam (300 MCQ)
Sample size	73	70 (number of participants to year 4 NA)	35	68
Control population	none	none	3 faculty members	3 certified rheumatologists
MERSQI (0-18)	12.5	11	9.5	14.5
Revised tool by Daly et al (1-5)	5	2	5	1
Internal consistency (Cronbach alpha)	not performed	not performed	0.15-0.57	0.83–0.92
Inter-rater reliability	not performed	Correlation between faculty raters not significant	ICC 0.3 between live assessors and assessors on videotapes ICC 0.7 between assessors on videotapes	not performed
Test-retest reliability/intra-rater reliability	not performed	not performed	not performed	OSCE total and partial scores in Year 1 vs Year 2 r=0.80-0.95
Inter-method (or parallel forms) reliability /concurrent validity	DOPS vs OSCE r=0.48	OSCE vs rating by program directors r=0.48	OSCE vs MCQ r =0.52	OSCE total score vs MCQ Study year 1: r=0.203 Study year 2: r=0.436
Feasibility	14 forms per resident to achieve a g coefficient of 0.80	not performed	not performed	not performed
Construct validity	not performed	not performed	OSCE scores significantly discriminated fellows and fellows vs faculty	Significantly higher scores in higher levels of training

MSUS: musculoskeletal ultrasound; DOPS, direct observation of practical skills; OSCE, objective structured clinical examination; MCQ, multiple choice questionnaire; NA, not available; MERSQI, medical education research study quality instrument; ICC, intraclass correlation coefficient

Table 1. Studies addressing assessment of competences in rheumatology

Methods: As part of a EULAR taskforce on the assessment of competences in rheumatology training, a systematic literature review was performed. Two reviewers independently identified eligible studies according to the PIM framework: P (population): trainees, fellows; I (instrument of interest): assessment strategies and methods; M (measurement of properties of interest): validity, discrimination, feasibility. one search for rheumatology and one for related medical specialties and extracted data on assessment methods. Two searches were conducted: (i) for rheumatology, retrieving original studies; (ii) for related medical specialties, retrieving SLRs through which we identified original studies. Risk of bias was assessed using the medical education research study quality instrument (MERSQI).

Results: Of the 6,276 articles in rheumatology and 2,265 reviews from other specialties, 4 and 31 original studies were included, respectively. Studies in rheumatology were at variable risk of bias and explored only direct observation of practical skills (DOPS) and objective structured clinical examination (OSCE). Rheumatology OSCEs including clinical, laboratory and imaging stations performed best, with a good to very good internal consistency, and inter-rater reliability. OSCEs correlated fairly to moderately with other assessment tools, including DOPS. Studies on OSCEs on clinical skills in other specialties showed a good to very good inter-rater reliability, while OSCEs on communication skills consistently demonstrated a good to very good internal consistency. Other tools such as multisource feedback

(MSF) and mini-clinical evaluation (mini-CEX) exercise showed a good feasibility and internal consistency, with conflicting data on validity and reliability.

Conclusion: Although there is a consistent body of evidence about assessment of competence in postgraduate medical training in several specialities, data in rheumatology is scarce and this partial picture indicates some conflicting evidence. OSCEs represent an appropriate tool to assess clinical competences and correlate fairly well with other assessment strategies; DOPS, MSF and mini-CEX are other feasible alternatives. This SLR informs the ongoing initiative to formulate EULAR 'points to consider' for the assessment of competences in rheumatology training.

Disclosure: A. Alunno, None; **A. Najm**, None; **F. Sivera**, None; **C. Haines**, None; **S. Ramiro**, None.

Abstract Number: 0166

An Analysis of Inpatient Rheumatology Consults at an Academic Military Medical Center over 16 Years: Do Consults Requests Accurately Reflect the Curriculum and Prepare Fellows for Board Certification and Future Practice?

Caitlin Cruz,[1] and Jess Edison[1], [1]Walter Reed National Military Medical Center, Bethesda, MD

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Education Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Review inpatient rheumatology consults over the last 16 years at a major military academic medical center to analyze trends in rheumatic disease presentation, consultative requests by other services, and a representation of core educational topics for the fellowship curriculum based on medical content categories for the Rheumatology Board Examination.

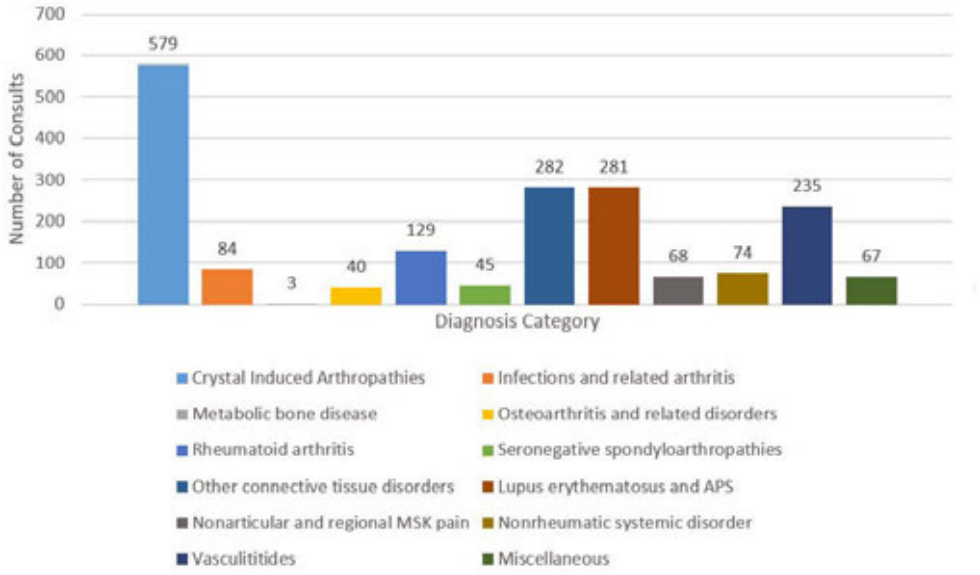

Figure 1. Distribution of rheumatologic disorders evaluated during hospital admission from April 2002 to June 2018.

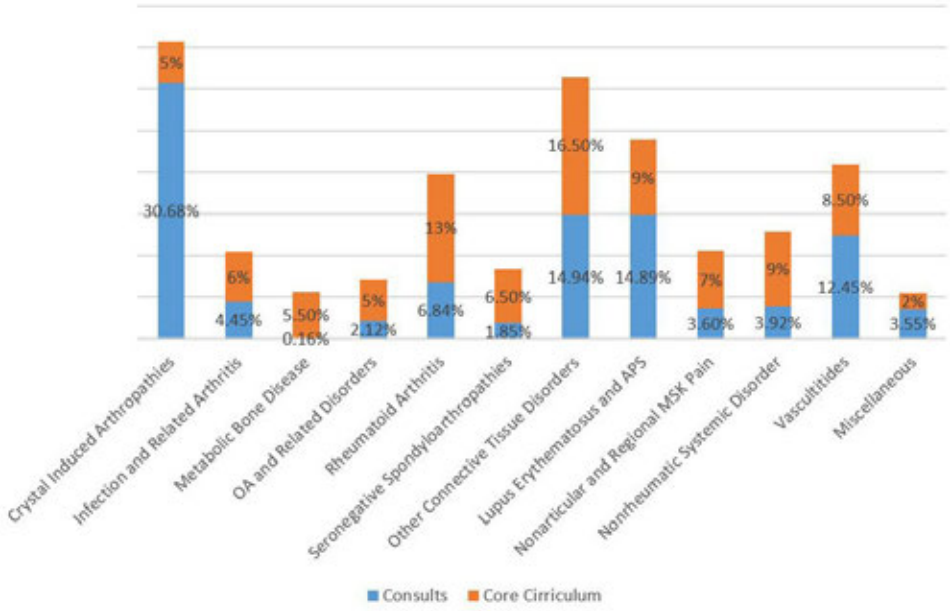

Figure 2. Percentage of consults seen compared to the weighted breakdown of the core curriculum on the board certification examination (based on the 2015 core curriculum outline for rheumatology fellowship program).

Methods: The Rheumatology Fellowship documents every formal inpatient consultation request from any service. The hospital provides services for all active duty, their families, and retirees and inpatients have access to all medical subspecialties. The fellow documents date, reason for consult, and requesting service. Records were categorized by reason for consultation. If the consultation request was unclear, record review was done to determine final rheumatologic diagnosis. Each consultation request was further characterized by diagnoses into pertinent educational core categories as outlined in the 2015 core curriculum outline for rheumatology fellowship program to include: crystal-induced arthropathies, infection and related arthritis, metabolic bone disease, osteoarthritis and related disorders, rheumatoid arthritis, seronegative spondyloarthropathies, other connective tissue disorders, lupus erythematosus and antiphospholipid syndrome, nonarticular and regional musculoskeletal pain, nonrheumatic systemic disorder, vasculititides, and miscellaneous.

Results: From April 2002 until June 2018, a total of 15,0359 adult patients were hospitalized under the care of all inpatient services during this 16-year period. From this population, 1887 consultations were requested for the Rheumatology service. These consultations were completed by 41 fellows over the studied period. Overall 1.25% of admissions required an evaluation by Rheumatology. The most common consult request was evaluation for crystal-induced arthropathies at 30.68% of all consults followed by evaluation for other connective tissue disorders and systemic lupus erythematosus at 14.94% and 14.89% respectively. In comparison to the educational objectives for the board certification examination, crystal-induced arthropathies represents only 5% of tested information while other connective tissue disorders accounts for 16.5% of tested material. For the Rheumatology program, the average fellow evaluated 25 consults per academic year and 46 consults in the 24 months of fellowship.

Conclusion: The adult Rheumatology fellowship at our military academic hospital provides consultation to surgical and medicine services and provides invaluable learning and teaching experiences for the fellowship. As trends in diagnosis and treatment emerge, the fellowship curriculum should continue to change to best prepare future rheumatologists. Continued analysis of the data to identify trends over time can help to optimize graduate medical educational topics at both the residency and fellowship levels as well assist with quality improvement strategies to enhance the curriculum and resources for the future.

Disclosure: C. Cruz, None; **J. Edison**, None.

Bioethics for the Rheumatologist: A Needs-Assessment, Curriculum Development, and Knowledge Assessment of Bioethical Topics for Rheumatology Trainees

Alexandra Saltman,[1] Heather McDonald-Blumer,[2] Lynn Spiegel,[3] and Pier Bryden[4], [1]University of Toronto, Mount Sinai Hospital and Princess Margaret Cancer Centre, Toronto, ON, Canada, [2]University of Toronto and Mount Sinai Hospital, Toronto, ON, Canada, [3]The Hospital for Sick Children, Toronto, ON, Canada, [4]University of Toronto; Sick Kids Hospital, Toronto, ON, Canada

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Education Poster

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: An understanding of bioethics and an ability to apply ethical principles in clinical practice should be key components of postgraduate medical training. However, there is no formal bioethics curriculum for Rheumatology residents at the University of Toronto. Instead, the majority of bioethics education is currently delivered via informal role-modelling by staff physicians. The purpose of this study was to determine whether the implementation of a curriculum tailored to the needs of Rheumatology residents, and delivered centrally at the National Rheumatology Residents' Weekend (NRRW), would increase residents' self-perceived knowledge of, and competency in, bioethical issues in clinical practice.

Methods: A literature review was performed to identify bioethical issues that were relevant to Rheumatology trainees. Cases were developed based on three of these issues for interactive, small-group sessions that were piloted at the NRRW in Toronto in December 2017. A clinician with bioethics expertise delivered a lecture on a framework for evaluating ethical dilemmas. Rheumatology faculty physicians facilitated case-based discussions of three key bioethical issues—medical assisted in dying (MAID), resource allocation, and relationships with industry—using group role-play as a tool for examining different perspectives surrounding these ethical controversies. Residents were given access to all study materials following the sessions. Pre- and post-knowledge surveys were distributed to participating residents to assess their comfort and knowledge with bioethical topics before and after participation in these sessions. Survey results were analyzed using descriptive statistics.

Results: 41% of attendees at the NRRW completed the needs assessment. 46% were PGY4s and 54% were PGY5s. Most residents agreed that formal training in bioethics was very important (29%) or somewhat important (51%) to rheumatology training, but the majority rated their knowledge as low in core bioethical topics. Residents identified: end of life care and MAID (41%), assessing capacity and substitute decision-making (34%), doctor-patient relationships and boundaries (32%), caring for the non-adherent patient (59%), medical resource allocation (51%), and cross-cultural issues (51%) as topics they wished to learn more about. 22% of attendees completed the post-rounds survey. The majority (91%) felt that the case-based sessions improved their knowledge of a core bioethical topic, and that they would feel more comfortable addressing this topic in clinical practice (86%). There were statistically significant improvements in self-perceived knowledge of, and comfort with, a number of core topics, including those not explicitly covered by the case-based sessions.

Conclusion: The design and implementation of a bioethics curriculum relevant to Rheumatology trainees is an effective means of increasing residents' self-perceived understanding of, and engagement with, bioethical issues central

to the practice of Rheumatology. Further study is required to assess whether or not residents retain knowledge of an ethical framework as presented in such a setting and can apply its principles to clinical practice.

Abstract Number: 0168

Development and Usability Testing of Take Charge: An Email Series to Increase Knowledge of Self-Management Skills in People with Lupus

Karin Tse,[1] Lauren Metelski,[1] Reid Dossinger,[1] Mike Donnelly,[1] and **Latifa Boyce**[1], [1]Lupus Foundation of America, Washington, DC

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Education/Community Programs Poster – ARP
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Email may be a promising approach to expose people with lupus, especially newly diagnosed patients, to educational information, tools, and resources on lupus self-management skills. The Lupus Foundation of America developed an educational email series called Take Charge to increase knowledge of self-management skills among newly diagnosed people with lupus. This study aimed to evaluate satisfaction and usability issues with Take Charge to help improve the email series.

Methods: Six emails containing information on lupus self-management skills were distributed weekly to participants affected by lupus. Skills ranged from coping and communications to medication and symptom management. A post-series survey was distributed to users who opened at least one message of series, and semi-structured phone interviews were conducted among a subset of these users to obtain feedback on functionality, content, and design of the email series. The post-series survey measured users' exposure to information on lupus self-management skills during the series and actions taken (self-management skills attempted) after exposure to email content. The phone interviews provided in-depth insight on users' perceptions of the design and branding of the series, and on the clarity, understandability, relevance, and appeal of its contents.

Results: Usability testing was conducted with 13 Take Charge participants (users) —all participants completed the post-series survey and five completed phone interviews. Sixty-nine percent of users reported trying at least one self-management skill presented in the series. Of the six self-management skills presented in the series, 46% of users said they prepared questions for their next doctor's appointment (this was the most attempted skill reported among users). In general, users liked that the series was short, simple, and easy to understand. Users stated that weekly distribution of the emails was an appropriate frequency to prompt them to take action. The email content was also empowering and motivating, particularly the graphics and tone. Users who completed phone interviews could not tell that the series was sent from lupus health educators, which they all thought was an important feature to highlight in the design, especially for newly diagnosed participants. Users recommended the series provide ways to connect with other people with lupus and more in-depth information, such as information on lupus treatment, research, and financing lupus care.

Conclusion: Usability testing for Take Charge provided valuable insight on the use of emails to expose people with lupus to information on lupus self-management skills and prompt them to take action in the management of their care. While user satisfaction was high, usability testing also revealed important issues to enhance the Take Charge

email series. Overall, email series show promise as a feasible method to deliver patient education. Future iterations of Take Charge will be developed and tested for ability to increase knowledge of self-management skills among people with lupus.

Abstract Number: 0169

Wikipedia as a Source of Health Information for the Public: Systematic Analysis of Quality and Readability of 8 Common Rheumatic Diseases Articles

Mosaab Mohameden,[1] Ali Ali,[2] Zi Ying Li,[2] Sehreen Mumtaz,[2] and Candice Reyes Yuvienco[2], [1]University of California San Francisco Fresno, Cincinnati, OH, [2]University of California San Francisco Fresno, Fresno, CA

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Education/Community Programs Poster – ARP
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Wikipedia is the largest open-access online collaborative encyclopedia. Several studies have shown that Wikipedia is one of the most read online source for health information by patients. As of March 2017, the English Wikipedia had over 30,000 medical articles. Data on the quality and readability of rheumatic diseases articles are lacking. At least 36% of the U.S. adults have basic or below basic health literacy; therefore, may face serious challenges in understanding health information. In this study, we aim to systematically analyze the quality of health information and the readability of Wikipedia articles on 8 common rheumatic diseases: osteoarthritis (OA), gout, rheumatoid arthritis (RA), ankylosing spondylitis (AS), psoriatic arthritis (PsA), systemic lupus erythematosus (SLE), scleroderma, and Sjogren's syndrome.

Methods: Quality of health information in the 8 Wikipedia articles was analyzed using DISCERN instrument by 2 independent reviewers trained on this validated scoring system. The readability of articles was evaluated using 7 popular formulas based on the number of sentences, words, syllables, and characters. Medical jargon level was assessed using the De-jargonizer which detects rare medical terms and hence accessibility by the public. Additional data collected include: article views, number of words, and presence of multimedia.

Results: The average DISCERN score for health information quality was found to be 3.5/5. OA article had the highest score of 3.8/5 followed by gout and Sjogren's articles (3.6/5), whereas scleroderma article had the lowest score of 3.2/5. Articles readability ranged from "difficult" to "very difficult" (average grade level: 13th). Scleroderma article was the most difficult to read (college graduate level) whereas gout was the easiest to read (10th-11th grade level). Similarly, the jargon percentage score was highest in scleroderma with 19% rare words used and a general audience suitability score of 73/100. On the other hand, OA article had the lowest jargon percentage (10% rare words) with the highest general audience suitability score of 85/100 followed by gout article with 82/100 score. Page views for the 8 articles between 7/2015-5/2019 was 31,725,957 (average 3,965,744 views per article). Gout article was the most viewed followed by SLE and RA, whereas Sjogren's article was the least viewed. Presence of multimedia averaged 9 images/videos per article with the highest seen in OA article.

Conclusion: Evaluation of 8 common rheumatic diseases articles on Wikipedia revealed a fair quality of health information indicating potentially important shortcomings. The readability level was at college level for most articles making these articles less accessible to the public. There seems to be a positive correlation between disease prevalence and quality of health information as well as the readability scores. Overall, these articles were well viewed and referenced and covered the important aspects of each disease. A more targeted approach and dedicated group effort is needed to improve the quality of information and the readability of these articles.

Abstract Number: 0170

Evaluating an Illustrated Storybook for Children with Juvenile Idiopathic Arthritis

Jimin Lee,[1] Dennis Newhook,[2] Kaylee Eady,[2] and Roman Jurencak[1], [1]Children's Hospital of Eastern Ontario, Ottawa, ON, Canada, [2]CHEO Research Institute, Ottawa, ON, Canada

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Education/Community Programs Poster – ARP
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: While juvenile idiopathic arthritis (JIA) is a common pediatric rheumatic disease, there is a lack of available child-friendly patient education materials. An illustrated storybook on JIA was created by medical students to address this gap. The present study evaluated the storybook for its comprehensibility, appropriateness and acceptability from the perspectives of children with JIA and their parents.

Methods: English-speaking children, aged 4–10 years, diagnosed with JIA in the past 36 months were recruited from a pediatric rheumatology clinic at a tertiary academic centre for this qualitative study. All children met the ILAR classification criteria for JIA. Children and parents were observed reading the storybook aloud and then interviewed using a semi-structured interview guide. Data collection tools were developed through an iterative process involving feedback from external experts and were further refined through piloting. The storybook reading and interviews were audio-recorded and transcribed. The transcripts were then analyzed using conventional content analysis within a qualitative data software, NVivo 11.

Results: Twelve child-parent dyads participated. The average age of children was 6 years and 5 months (4 years 2 months–10 years) and the average time from diagnosis was 19 months (3–32 months). Analysis showed that children comprehended the content of the storybook and understood the emotions portrayed by the story's main characters. Children and parents reported that the story appropriately mirrored their own experiences of JIA. The reading level and book length were deemed acceptable to children aged 5–10, with varying degrees of assistance. Minor revisions were suggested regarding background illustrations, word choices and font.

Three key elements regarding patient education materials were identified: (1) Children were most intrigued by anatomical illustrations and interpreted them according to their own experiences. (2) Non-medical details about the story's main characters helped children relate to the storybook on a personal level. (3) Parents desired not only accurate medical information but also a sense of relief and hope.

Conclusion: The storybook on JIA was considered comprehensible, appropriate and acceptable. The findings informed minor modifications to the present storybook and suggest important elements to consider when creating future pediatric patient education materials.

Abstract Number: 0171

Performance of 2010 ACR/EULAR and 1987 ACR Criteria for Classification of Rheumatoid Arthritis in a Population-based Incidence Cohort, 2010-2014

Elena Myasoedova,[1] John Davis,[1] Eric Matteson,[2] and Cynthia Crowson[3], [1]Mayo Clinic, Rochester, MN, [2]Mayo Clinic College of Medicine and Science, Rochester, Minnesota, USA, Rochester, [3]Mayo Clinic Rochester, Rochester

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Epidemiology & Public Health Poster I: RA
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Previous studies evaluated performance of the 2010 American College of Rheumatology (ACR)/European League against Rheumatism (EULAR) criteria for classification of rheumatoid arthritis (RA) in clinical settings. However, information about performance of these criteria in population-based studies is scarce. We aimed to estimate RA incidence during 2010-2014 using 1987 ACR and the 2010 ACR/EULAR criteria and compare the performance of these criteria sets.

Methods: We evaluated RA incidence in a population-based inception cohort of individuals 18 years of age and older based on fulfillment of the 1987 ACR and the 2010 ACR/EULAR criteria between 1/1/2010 and 12/31/2014. Both rheumatoid factor (RF) and cyclic citrullinated peptide antibody (anti-CCP) were considered for criteria fulfillment. Seropositive was defined as RF and/or anti-CCP positive, and seronegative was defined as neither positive. Incidence rates were estimated and were age-and sex-adjusted to the white population in the US in 2010.

Results: There were 221 patients who first fulfilled 1987 or 2010 criteria for RA in 2010-2014 (216 met 1987 criteria and 175 met 2010 criteria). Table shows RA incidence rates per 100,000 population for the 2010-2014 time period overall and by seropositivity. The estimates for the overall age- and sex-adjusted annual RA incidence were higher

Overall	Female	Male	Total
1987 criteria	54 (45, 63)	29 (22, 35)	42 (36, 47)
2010 criteria	44 (36, 52)	22 (16, 28)	34 (29, 39)
Seropositive			
1987 criteria	33 (27, 40)	16 (11, 21)	25 (20, 29)
2010 criteria	32 (25, 39)	17 (11, 22)	24 (20, 29)
Seronegative			
1987 criteria	20 (15, 26)	13 (8, 18)	17 (13, 20)
2010 criteria	12 (8, 16)	6 (3, 9)	9 (7, 12)

Table 1. Incidence rates per 100,000 population (95% CI) for 2010-2014 by criteria

when 1987 ACR criteria were applied as compared to the 2010 ACR/EULAR criteria due to lower estimates for seronegative patients identified with the 2010 ACR/EULAR criteria. There were a total of 36 seronegative patients who met 1987 ACR criteria but not 2010 ACR/EULAR criteria in 2010-2014. When these patients were compared with the other 47 seronegative patients who met both 1987 ACR and 2010 ACR/EULAR criteria in 2010-2014, patients fulfilling both criteria had higher joint counts ($p< 0.001$) and were more likely to be ever smokers ($p=0.02$). The rest of characteristics of these two groups of seronegative patients were similar, including age at RA incidence, sex, race, body mass index, proportion of patients with prolonged morning stiffness, arthritis in 3 or more joints, arthritis in hand joints, rheumatoid nodules, erosions, abnormal erythrocyte sedimentation rate or C-reactive protein, disease duration >6 weeks. There were no differences between these groups in the proportion of patients started on methotrexate, hydroxychloroquine, sulfasalazine, or other disease-modifying antirheumatic drug (DMARD) as their first DMARD.

Conclusion: The incidence of RA and particularly seronegative RA in population-based studies may be underestimated by 2010 ACR/EULAR criteria as compared to the 1987 ACR criteria for classification of RA. Seronegative RA patients who fulfill 1987 ACR criteria but not 2010 ACR/EULAR criteria have lower joint counts but have otherwise similar RA disease characteristics as patients who fulfilled both sets of criteria.

Abstract Number: 0172

Is the Epidemiology of Rheumatoid Arthritis (RA) Changing? Results from a Population-based Incidence Cohort of RA Patients, 2005-2014

Elena Myasoedova,[1] John Davis,[1] Eric Matteson,[2] and Cynthia Crowson[3], [1]Mayo Clinic, Rochester, MN, [2]Mayo Clinic College of Medicine and Science, Rochester, Minnesota, USA, Rochester, [3]Mayo Clinic Rochester, Rochester

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Epidemiology & Public Health Poster I: RA
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The incidence and prevalence of rheumatoid arthritis (RA) vary substantially between populations in different geographic areas and over time. Recent trends in RA incidence in US populations are unknown. We aimed to examine trends in the incidence of RA from 2005 to 2014 as compared to the previous decades.

Characteristic	Decade of RA incidence			p value
	1985-1994 (N=240)	1995-2004 (N=344)	2005-2014 (N=428)	
Age at RA incidence, years. Mean (SD)	56.6 (16.6)	56.0 (15.5)	55.4 (15.4)	0.736
Female Sex	160 (67%)	240 (70%)	292 (68%)	0.727
Race, white	225 (94%)	321 (93%)	378 (88%)	0.077
Ever smoker at RA incidence	143 (60%)	183 (53%)	186 (43%)	<0.001
BMI≥30 kg/m^2 at RA incidence	57 (24%)	114 (33%)	175 (41%)	<0.001
RF positive	166 (69%)	238 (69%)	217 (51%)	<0.001
Anti-CCP positive in first year after RA incidence	0 (0%)	14/36 (39%)	188/375 (50%)	0.20
Erosion in first year after RA incidence	33 (15%)	65 (19%)	97 (24%)	0.021

Table 1. Patient characteristics by decade of RA incidence

Table 2. Incidence rates by 1987 ACR criteria per 100,000 population (95% CI)

Group	Decade of RA incidence	Female	Male	Total
Overall	1985-1994	48 (40, 56)	31 (24, 38)	40 (34, 45)
	1995-2004	56 (49, 64)	29 (23, 35)	43 (39, 48)
	2005-2014	55 (49, 62)	29 (24, 34)	43 (39, 47)
RF+	1985-1994	33 (27, 40)	23 (17, 29)	28 (23, 32)
	1995-2004	40 (33, 46)	19 (14, 24)	30 (26, 34)
	2005-2014	27 (23, 32)	15 (12, 19)	22 (19, 24)
RF-	1985-1994	15 (11, 19)	8 (5, 12)	12 9, 15)
	1995-2004	17 (13, 21)	10 (7, 14)	14 (11, 16)
	2005-2014	28 (23, 32)	14 (11, 18)	21 (18, 24)

Methods: We evaluated RA incidence trends in a population-based inception cohort of individuals 18 years of age and older who first fulfilled the ACR 1987 classification criteria for RA between 1/1/1985 and 12/31/2014. While both rheumatoid factor (RF) and cyclic citrullinated peptide antibody (anti-CCP) were considered for criteria fulfillment when available, incidence rates were calculated for RF positive vs negative without inclusion of anti-CCP to allow fair comparison of incidence rates over 3 decades during which anti-CCP testing rates were on the rise. Incidence rates were estimated and were age-and sex-adjusted to the white population in the US in 2010. Trends in incidence rates were examined using Poisson regression methods.

Results: The 2005-2014 incidence cohort comprised 428 patients: mean age 55.4 years, 68% female, 51% RF positive, 50% anti-CCP positive (Table 1). There was no statistically significant difference in age at RA incidence, sex distribution or race in 2005-2014 cohort vs 1995-2004 and 1985-1994 cohorts. Smoking rates declined and obesity rates increased from earlier decades to more recent years. Patients in the 2005-2014 cohort were more likely to develop an erosion in the first year of RA incidence as compared to the previous decades.

Table 2 shows RA incidence rates per 100,000 population for 3 most recent decades and by RF status. The overall age- and sex-adjusted annual RA incidence in 2005-2014 was 43/100,000 population with age-adjusted incidence in women 55/100,000 population and 29/100,000 population in men. These estimates were similar to the 1995-2004 decade. There was a decline in the incidence of RF positive RA in 2005-2014 compared to the previous 2 decades ($p=0.006$), with a corresponding increase in RF negative cases ($p< 0.001$, Table 2).

Conclusion: The incidence of RA overall during the 2005-2014 period remained similar to the previous decade. An increase in RF-negative RA disease and decrease in RF positive RA was found using 1987 ACR criteria. Changing prevalence of environmental factors, such as smoking, obesity and others, may have contributed to these trends. Whether these trends represent a changing serological profile of RA requires further investigation.

Abstract Number: 0173

Statin Use Is Associated with Increased Risk of RA in US Population: Results from a Large Nationwide Study

Elena Myasoedova,[1] John Davis,[1] Dennis Asante,[1] Lindsey Sangaralingham,[1] and Cynthia Crowson[2], [1]Mayo Clinic, Rochester, MN, [2]Mayo Clinic Rochester, Rochester

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Epidemiology & Public Health Poster I: RA
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Studies evaluating the effect of statin use on the risk of rheumatoid arthritis (RA) onset have shown conflicting results. Most of these studies evaluated European populations while data from the US are scarce. We aimed to assess the association between statin use and RA occurrence using claims data from the US population.

Methods: For this case-control study, we used OptumLabs Data Warehouse database, a large administrative database of commercially insured and Medicare Advantage beneficiaries, to identify cases of RA and matched controls. Cases were defined as patients with 2 or more diagnoses of RA in 2011-2017 who were ≥18 years old, filled ≥1 prescription for a conventional or biologic disease modifying anti-rheumatic drug or glucocorticoid, and had no diagnoses of RA or relevant therapies during ≥12 months of prior medical/pharmacy coverage. Controls were persons without RA matched 1:1 to RA cases on age, sex, census region and calendar year. Statin use was defined as any filled prescription for a statin medication in the 12 months prior to RA incidence/index date. All patients with available data on statins were used in this analysis. Logistic regression models were used to estimate odds ratios (OR) **with 95% confidence intervals (CI).**

Results: The study included 42,865 cases with RA (mean age 57.6, 74.9% female) and 42,848 matched controls (mean age 57.6, 74.9% female). All patients in both groups had at least 12 months of prior medical/pharmacy coverage during which there were 15,391 (36%) statin users among RA patients and 13,892 (32%) statin users among the matched controls. Statin use was associated with increased risk of RA: unadjusted OR 1.17, 95%CI 1.14-1.20; OR adjusting for age, sex, race, calendar year of RA diagnosis and census region: 1.20, 95%CI 1.16-1.23. When we adjusted for additional comorbidities, including myocardial infarction, congestive heart failure, peripheral vascular disease, cerebrovascular disease, diabetes with or without organ damage, hypothyroidism, liver disease, metastatic cancer, obesity, and renal failure, the association remained statistically significant: OR 1.12, 95%CI 1.09, 1.16. With adjustment for age, sex, race, calendar year of RA diagnosis, census region and Charlson's comorbidity index, we had slightly attenuated but overall similar results: OR 1.08, 95%CI 1.04, 1.11.

Conclusion: This large nationwide study showed increased risk of RA in statin-users vs non-users. The underlying mechanisms for this association require further investigation.

Abstract Number: 0174

Clinical Presentation and Disease Course Evaluation of Mono- and Bilateral Knee Arthritis: Results from the Leiden Early Arthritis Clinic Cohort

Johanna M Maassen,[1] Xanthe ME Matthijssen,[1] Sytske Anne Bergstra,[1] and CF Allaart[1], [1]Department of Rheumatology, Leiden University Medical Center, Leiden, The Netherlands, Leiden, Netherlands

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Epidemiology & Public Health Poster I: RA
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Patients presenting with arthritis in one or both knees propose a challenge regarding diagnosis, prognosis and treatment decisions. The aim of the current study was to characterize patients with knee arthritis who presented to the Leiden EAC and to evaluate the disease course and treatment decisions in the first year of follow-up.

Methods: Patients with arthritis confined to the knee(s) were selected from all patients included in the EAC between 1993 and 2015. Medical files were revised for information on treatment and clinical outcomes. Baseline characteristics were summarized, treatment and outcome was evaluated at 3 and 12 months. Patients were stratified over 4 groups: 1. Early sustained remission (remission at 3 months and no flare in the first year); 2. Late remission (remission at 12 months); 3. Persistent gonarthritis at 12 months; 4. Progression to oligo- or polyarthritis at 12 months. Baseline characteristics were compared between the patients in early sustained remission and the patients with gonarthritis and/or progression at 12 months. The initial medication choices and cumulative treatment within the first year were evaluated.

Results: In total 206 consecutive patients with mono- (174, 85%), and bilateral- (32, 15%) knee arthritis were evaluated. At 12 months, 120 patients could be evaluated: 27 (23%) were in early sustained remission, 41 (34%) were in late remission, 40 (33%) had persistent gonarthritis, and 12 (10%) had progressed to oligo-/poly arthritis. In total 84 (41%) patients were lost to follow-up before 12 months (most likely not progressive or persistent). No differences in baseline characteristics were identified between the patients in early sustained remission vs. the patients with

Table 1. Baseline characteristics – stratified analysis

	Early sustained remission N=27	Persistent gonarthritis/ progression N=52	P-value
Age, years	46.9 (3.6)	44.7 (2.3)	0.60
Female, %	55.6	53.8	0.89
Mono knee, %	14.8	21.2	0.50
RF positive, %	3.7	13.7	0.25
ACPA positive, %	4.8	17.1	0.25
Symptom duration, days	84 (25-84)	92 (41-175)	0.23
DAS	1.8 (0.35)	2.0 (0.15)	0.69
ESR	45 (16-49)	22 (11-48)	0.53

RF: rheumatoid factor; ACPA: anti citrullinated protein antibodies; DAS: disease activity score; ESR: erythrocyte sedimentation rate. P-value comparing the group in "early sustained remission" and the group with "persistent gonarthritis/progression to oligo-/polyarthritis" using Fishers exact test.

Table 2. Cumulative treatment within the first year of follow-up – stratified analysis

Treatment group	Early sustained remission N=27	Late remission N=41	Persistent gonarthritis N=40	Progression to oligo-/polyarthritis N=12	P-value
NSAID only	**12 (44)**	9 (22)	5 (13)	1 (8)	**0.015**
IA corticosteroid injection(s)	**8 (30)**	21 (51)	28 (70)	9 (75)	**0.005**
Prednisone (oral)	1 (4)	4 (10)	1 (3)	2 (17)	0.23
Antibiotics	4 (15)	5 (12)	2 (5)	2 (17)	0.42
csDMARD(s)	2 (7)	6 (15)	11 (28)	**6 (50)**	**0.013**
bDMARD(s)	-	1 (2)	-	-	-
Yttrium	-	-	1 (3)	-	-
Colchicine/Allopurinol	1 (4)	1 (2)	2 (5)	-	0.89

Values are the number (and % of patients within this stratum) of patients ever using drugs from this class within the first year of follow-up. IA: intra articular. p: Comparing the four stratification groups using Fishers exact test.

gonarthritis or oligo-polyarthritis at 12 months (table 1). The initial therapy was similar in all groups (data not shown). During the first year, in 31% patients treatment remained limited to NSAIDs, most often in group 1 (p =0.015). IACs were (also) administered to 46%, mainly in group 2, 3 and 4 (p=0.005). Prednisone was prescribed in 5% of patients. CsDMARDs (and < 1% subsequently a bDMARD) were (also) prescribed in 15% of patients (most frequently in group 4 (p=0.013)). The frequencies of other treatment did not differ between the groups (table 2).

Conclusion: Of 206 consecutive patients with undifferentiated arthritis limited to the knee(s) the majority were in remission or lost to follow up after 12 months. Progression to arthritis in other joints was relatively rare. Baseline characteristics could not predict the disease course at presentation and initial treatment choices suggest that physicians could not either. To timely start appropriate treatment, more research is needed to identify disease characteristics that predict chronicity or progression and identify patients that could profit from early, more effective therapy.

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Epidemiology & Public Health Poster I: RA

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Elevated circulating cytokines are present years before the onset of rheumatoid arthritis (RA). We conducted a prospective cohort study in an at-risk population of anti-cyclic citrullinated peptide (CCP) antibody positive individuals to determine if serum cytokines predict the development of incident inflammatory arthritis (IA).

Table 1. Study population characteristics at baseline by incident IA status, N=137			
Characteristic	**No IA (n=108)**	**Incident IA (n=29)**	**p-value**
Age at baseline, years, mean (SD)	54.5 (13.4)	49.7 (14.9)	0.12
Gender, Female	76 (70.4)	18 (62.1)	0.39
Race/ethnicity, non-Hispanic white	91 (84.3)	21 (72.4)	0.14
Education, > high school	84 (78.5)	25 (86.2)	0.35
Income, > $40,000	76 (76.0)	21 (75.0)	0.91
Shared epitope, positive	49 (45.4)	20 (69.0)	0.02
Smoker, ever	44 (41.1)	11 (37.9)	0.76
All values n% unless otherwise stated.			

Table 2. Hazard ratios for the association of serum cytokines with incident IA (n=29 events)			
	HR	**95% CI**	**p-value**
IL-6	1.27	0.93, 1.74	0.13
IL-8	0.91	0.49, 1.68	0.76
TNF-α	1.97	1.08, 3.58	0.02
Models adjusted for cohort, age at baseline, and shared epitope status.			

Methods: Participants were recruited into the cohort if they were a first degree relative (FDR) of a RA proband or were screened at health fairs. For the present analysis we included n=137 CCP positive participants contributing 508 person-years of follow-up for the appearance of IA (CCP3.1 Inova). During follow-up 29 participants developed IA (defined as having at least 1 joint consistent with RA-like synovitis based on exam), and of those participants 22 were classified as RA by 2010 ACR/EULAR criteria. The concentrations of interleukin (IL)-6, IL-8 and tumor necrosis factor (TNF)-α were quantified from stored serum at baseline and each follow-up visit for a total of n=525 visits. Each of these cytokines and chemokines have previously been implicated in RA pathogenesis. We conducted a survival (i.e. time-to-event) analysis using Cox proportional hazard models with log transformed cytokine concentrations as time-varying predictors and obtained hazard ratios (HRs) and 95% confidence intervals (CIs).

Results: Baseline characteristics by incident IA status are presented in Table 1. Participants who went on to develop IA were significantly more likely to test positive for the shared epitope compared to participants who did not develop IA (p-value = 0.02). We found a significant positive association of serum TNF-α with incident IA risk, adjusting for cohort (FDR or screened), shared epitope status and age at baseline (adjusted HR: 1.97; 95%CI: 1.08, 3.58). The association of IL-6 and IA risk trended in the same direction but did not reach statistical significance (adjusted HR: 1.27; 95%CI: 0.93, 1.74).

Conclusion: In a cohort of DMARD untreated CCP positive individuals, we demonstrated that circulating levels of TNF-α, a potential indicator of systemic inflammation, was positively associated with incident IA. This finding further supports the dysregulation or failure in the ability to resolve inflammation in preclinical RA patients.

The Epidemiology of Rheumatoid Arthritis in the Czech Republic

Jakub Závada,[1] Monika Bezděková,[2] Michal Uher,[3] and Jiří Jarkovský[4], [1]Institute of Rheumatology, Prague, Prague, Czech Republic, [2]Institute of Health Information and Statistics of the Czech Republic, Praha, Hlavni mesto Praha, Czech Republic, [3]Institute of Health Information and Statistics of the Czech Republic, and Institute of Biostatistics and Analyses, Faculty of Medicine, Masaryk University, Brno, Czech Republic, Brno, Czech Republic, [4]Institute of Health Information and Statistics of the Czech Republic, and Institute of Biostatistics and Analyses, Faculty of Medicine, Masaryk University, Brno, Czech Republic, Praha, Hlavni mesto Praha, Czech Republic

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Epidemiology & Public Health Poster I: RA

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: To describe the epidemiology of Rheumatoid Arthritis (RA) in the Czech Republic (CZ)

Methods: We used the administrative database of the National Registry of Reimbursed Health Services (NRRHS) operated by the Czech Institute of Health Information and Statistics (IHIS) to estimate the incidence and prevalence of RA. NRRHS contains all administrative claims data collected for purposes of health system management as part of all public medical insurance plans for the period 2010-17. Data on all Czech citizens seeking healthcare are captured in this billing database, as medical insurance is mandatory in CZ. Cases of RA were identified using the following algorithm: at least 2 physician service claims (over 1 year) with ICD-10 code for RA (M05, M06) as the main diagnosis, with at least 1 of these claims originating from a rheumatologist AND at least one prescription for an oral glucocorticoid, csDMARD or bDMARD. We calculated crude and age and sex–standardized prevalence and incidence rates (with corresponding 95% confidence intervals [95% CIs]) among patients age ≥18 years over the period 2012–2017. The numerator represents all patients with RA, and the denominator represents all persons age >18 years living in CZ for the relevant year for prevalence or persons age >18 years at risk for incidence. Prevalent cases were carried forward for each year. We used a 2-year "run-in" period (2010-2011) to distinguish between incident and prevalent cases, allowing rates to be reported from 2012 onward. All analyses were performed by IHIS using Vertica database and IBM SPSS statistical software, version 25.0.0.1.

Results: As of 2017, there were 86,906 Czechs with RA, corresponding to a cumulative prevalence of 1.01%. Age and sex–standardized RA prevalence for population in 2017 increased over time from 685 (95% confidence interval [95% CI] 679 – 690) per 100,000 population (0.65 %) in 2012 to 1,015 (95% CI 1,008 – 1,022) per 100,000 population (1.01 %) in 2017. Age and sex–standardized incidence per 100,000 population ranged from 118 (95% CI 116 - 121) in 2012 to 80 (95% CI 78-82) in 2017. See table 1. Mean (SD) age at diagnosis was 59 (14) years, and 73% cases were

	Prevalence					Incidence[2]				
Year	No. of RA cases	Population	[1]Crude estimate	Crude %	[2] Standardized rate (95% CI)	No. of new RA cases	Population at risk	[1]Crude estimate	Crude %	[2] Standardized rate (95% CI)
2012	55,616	8,556,018	650	0.65	685 (679–690)	9,604	8,500,402	113	0.11	118 (116–121)
2013	62,673	8,563,023	732	0.73	765 (759–771)	8,077	8,500,350	95	0.10	99 (97–101)
2014	69,703	8,568,015	814	0.81	841 (835–847)	8,198	8,498,312	96	0.10	99 (97–101)
2015	76,061	8,566,285	888	0.89	908 (901–914)	7,633	8,490,224	90	0.09	92 (89–94)
2016	81,806	8,564,814	955	0.96	966 (959–972)	7,298	8,483,008	86	0.09	87 (85–89)
2017	86,906	8,563,563	1,015	1.01	1 015 (1,008–1,022)	6,754	8,476,657	80	0.08	80 (78–82)

RA = rheumatoid arthritis; 95% CI = 95% confidence interval.
[1] Standardized rates are per 100,000 population (age >18) for prevalence and per 100,000 population at risk (age >18) for incidence.
[2] Standardized by age and sex based on population (age >18) of Czech Republic in 2017 for prevalence and population at risk (age >18) of Czech Republic in 2017.

Table 1. Crude and age and sex–standardized prevalence and incidence of RA by year

female. The direction of the time trends in incidence and prevalence were similar across various age groups and both sexes, and the slopes of the curves appeared to be steeper in older individuals.

Conclusion: Over a 6-year period, we observed an increase in RA prevalence over time. This rise may be attributed to the increasing time to ascertain cases, increasing survival, and/or an increase in the aging background population. Incidence appears to decreasing.

Disclaimer: This study was supported by the project of MHCR for conceptual development of research organization 00023728Table 1. Crude and age and sex–standardized prevalence and incidence of RA by year

Early Retirement Attributed to Rheumatoid Arthritis and Its Predictors in Portugal

Mariana Luís,[1] Salomé Garcia,[2] Francisca Guimarães,[3] Manuel António,[4] Ana Fernandes,[5] Filipe Araújo,[6] Rita Cunha,[7] Maura Couto,[8] Ana Pinto,[9] Lígia Silva,[10] Margarida Cruz,[11] Jose Pereira da Silva,[12] and Catia Duarte[13], [1]Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal, [2]Centro Hospitalar São João, Porto, Portugal, [3]Centro Hospitalar do Alto Minho, Ponte de Lima, Portugal, [4]Centro Hospitalar Lisboa Norte, Lisboa, Portugal, [5]Centro Hospitalar do Algarve, Faro, Portugal, [6]Hospital Ortopédico de Sant'Ana, Lisboa, Portugal, [7]Centro Hospitalar Baixo Vouga, Aveiro, Portugal, [8]Centro Hospitalar Tondela-Viseu, Viseu, Portugal, [9]Unidade Local de Saúde da Guarda, Guarda, Portugal, [10]Centro Hospitalar de Trás-os-Montes e Alto Douro, Vila Real, Portugal, [11]Centro Hospitalar do Oeste, Caldas da Rainha, Portugal, [12]Centro Hospitalar Universitario de Coimbra, Coimbra, Coimbra, Portugal, [13]Department of Rheumatology, Centro Hospitalar Universitario de Coimbra, Coimbra, Coimbra, Portugal

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Epidemiology & Public Health Poster I: RA
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Work disability is a common consequence of Rheumatoid Arthritis (RA) with economic implications for both the patient and society. Scarce information is available on the possible causes for early retirement of RA patients in Portugal.

Aim: To evaluate the rate of early retirement due to RA in Portugal. Secondary aim consists in the identification of its main predictors.

Methods: Multicentric retrospective cohort study involving eleven portuguese rheumatology centers, including patients with RA according the ACR/EULAR 2010 or the 1987 ACR Classification Criteria for RA, based on Reuma.pt, the Portuguese Register of Rheumatic Diseases. Patients retired prior to RA diagnosis, never-employed or with missing information on current work status were excluded. Retirement due to RA versus non-retirement were compared using T-test or Chi-2 test as adequate. Variables with $p< 0,05$ in univariate analysis, and other potential predictors selected on clinical and epidemiological grounds, were included in multivariable binary logistic regression, while adjusting for potential confounding or contributing factors.

Results: 3231 patients were included (81,5% female, aged 60,8 ± 13,0 years, mean disease duration 18,0 ± 10,3 years). Until the present time, 37,6% (n=1216) of the patients retired, this being due to RA in 59,6% of the cases. Early retirement due to RA translated into 7 years of active work being lost when compared to patients retired to other

Table 1. Clinical and epidemiological characteristics of the study population.

	Early retired due to RA (n=725)	Non-retired (n=2015)	p
Current age (mean ± SD, years)	67,7 ± 9,73	55,64 ± 11,77	<0,001
Gender (female, %)	84,4	82,4	0,249
Smokers (%)	20,2	30,6	<0,001
Hypertension (%)	38,9	22,9	<0,001
Diabetes mellitus (%)	10,7	5,9	<0,001
Cardiovascular disease (%)	10,0	4,1	<0,001
Age of diagnosis (mean ± SD, years)	44,59 ± 12,24	42,74 ± 12,18	0,001
Disease duration (mean ± SD, years)	24,82 ± 10,38	15,03 ± 8,81	<0,001
Time until diagnosis (mean ± SD, years)	2,67 ± 4,58	2,06 ± 4,12	0,003
Rheumatoid factor (%)	75,9	71,9	0,043
Anti-CCP (%)	73,7	72,6	0,679
Erosive disease (%)	83,9	56,7	<0,001
Occupation type (blue collar, %)	58,1	41,9	<0,001
Educational level (mean ± SD, school-years)	5,00 ± 2,78	8,71 ± 4,49	<0,001

causes (49,6 ± 9,5 vs. 56,6 ± 9,8 years). Compared to patients that are still professionally active, patients retired due to RA were diagnosed later in the disease process (2,7 ± 4,6 vs. 2,0 ± 4,1 years from first symptoms to RA diagnosis, p=0,003), had longer disease duration (24,8 ± 10,4 vs. 15,0 ± 8,8 years at the time of retirement, p< 0,001), were more likely positive for rheumatoid factor (75,9% vs. 71,9%, p=0,043), to present erosive disease (83,9% vs. 56,7%, p< 0,001), have a blue collar occupation (58,1% vs. 41,9%, p< 0,001) and have a lower educational level (5,0 ± 2,8 vs. 8,7 ± 4,5 school-years, p< 0,001). After multivariate analysis, independent predictors for early retirement due to RA were: later diagnosis (OR: 2,23; 95% CI 1,18-4,21/year, p=0,013), erosive disease (OR: 2,21 95% CI 1,54-3,16, p < 0,001), need for biologic therapy (OR: 1,32; 95%CI 1,01-1,73, p=0,045) and lower educational level (OR: 0,83; 95%CI 0,79-0,86/year, p< 0,001). Although a blue collar occupation was associated with a higher prevalence of early retirement, this association does not stand after adjusting for educational level (OR: 0,822; 95% CI 0,654-1,033).

Conclusion: RA itself is the leading cause of early retirement in RA patients, being responsible for the loss of an average of 7 years of work. Late diagnosis, presence of poor prognosis factors (such as erosive disease and the need for biologic therapy) and lower educational level are the main predictors of early retirement associated with RA in Portugal.

Depression: A Common Comorbidity in Rheumatic Diseases. a Case-Control Study

Dionicio Galarza-Delgado,[1] Jose Azpiri-Lopez,[1] Iris Colunga-Pedraza,[1] **Karla Paola Cuellar-Calderon**,[1] Ileana Cecilia Reynosa-Silva,[1] Marielva Castro-Gonzalez,[1] and Carolina Marlene Martinez-Flores[1], [1]Universidad Autonoma de Nuevo Leon, Hospital Universitario "Dr Jose Eleuterio Gonzalez", Monterrey, Nuevo Leon, Mexico

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Epidemiology & Public Health Poster I: RA
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Depression is a frequent comorbidity in rheumatic diseases (RD) and it is associated with chronic pain and long-term medical treatment in these patients. Furthermore, studies have reported the impact of depression in these population and it is consistently associated with the severity and sensitivity to pain, poor treatment outcomes, disease activity and potentially with early mortality. The Patient Health Questionnaire 9 (PHQ-9) is an extensively validated screening tool. It has several advantages: it is more accurate than other screening tools with 88% of sensitivity and 88% specificity, it is self-applied and able to be used by any clinician. Thus, the aim of this study was to determine the prevalence of depression in a group of RD patients and compare it to non-rheumatic controls.

Methods: An observational, cross-sectional study was designed. Patients were recruited at a community educational healthcare conference. Population was divided into two groups: patients with and without RD. A complete history with information about exercise and the PHQ-9 screening tool were performed to every subject. Subjects without RD

Table 1. Demographic Characteristics

were recruited as controls. Descriptive analysis was done using frequencies (%) and median (q25-q75). Comparisons were done using Chi-square and Mann Whitney-U test, considering $p < 0.05$ as significant.

Results: A total of 257 subjects were included. Demographic characteristics are shown in Table 1. Patients with RD have greater scores of PHQ-9 with a median of 7 points (p25-p75, 3-12) than controls with a median of 4 (q25-q75, 1-9) (p= 0.009). In the case group, 83 patients (32.8%) have diagnosis of depression and 61 (25.3%) of the controls (p= 0.016).

Subjects with an inactive lifestyle have a higher prevalence of depression, being sedentary in both groups has an OR 3.246 (IC 1.92 to 5.47), p< 0.001. Sedentarism is highly significant in controls (p < 0.001), but not in RD (p=0.085).

Conclusion: Patients with RD have a higher prevalence of depression than non-rheumatic subjects. An inactive lifestyle was associated with a higher prevalence of depression in both, those with and without RD. The physicians should be aware of it and use screening tools for early detection and provide a multimodal management.

Abstract Number: 0179

The Burden of Comorbidity in Patients with RA, PSA or SPA in a General Practice Registry

Sofia Pazmino,[1] Veerle Stouten,[1] Patrick Verschueren,[2] Pavlos Mamouris,[1] Rene Westhovens,[3] Kurt De Vlam,[2] Delphine Bertrand,[1] Kristien Van der Elst,[2] Bert Vaes,[1] and **Diederik De Cock**[1], [1]KU Leuven, Leuven, Belgium, [2]University Hospital Leuven, Leuven, Belgium, [3]University Hospitals, Leuven, Belgium

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Epidemiology & Public Health Poster I: RA
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis (RA), psoriatic arthritis (PSA) and spondyloarthritis (SPA) are the most common inflammatory rheumatic diseases, associated with a high burden of comorbidities and polypharmacy, especially analgesics. Thus, we compared comorbidity burden and usage of pain-related medication in patient with RA, PSA and SPA versus controls in a general practitioner (GP) setting.

Table 1: Comorbidity incidence rates after a 3-year follow up period

	Crude Incidence Rate of comorbidity per 1000-person years					
	RA n=738	Controls n=2952	SPA n=229	Controls n=916	PSA n=167	Controls n=668
Lung Disease	16.73	13.74	8.98	12.39	10.38	13.43
Cardiovascular disease	24.84	17.31	7.04	6.94	20.29	10.98
Hypertension	29.68	21.97	7.21	13.21	10.58	10.74
Fracture	8.58	9.08	10.18	4.74	7.16	5.18
Depression	7.54	11.53	5.39	6.98	11.10	6.24
Diabetes mellitus	17.84	12.33	3.40	7.70	9.73	7.19
Digestive disease	15.04	13.27	22.46	17.39	11.20	10.24
Malignancies	11.86	20.22	5.05	10.64	17.34	8.69

Crude incidence rate per 1000 is calculated as the number of new cases divided by the total persons years of persons at risk (not having comorbidity at baseline) with a maximum of 3 years of follow-up per person.

Table 2: Prevalent medication use in RA, SPA and PSA patients versus controls

Medication	RA n=738	Controls n=2952	SPA n=229	Controls n=916	PSA n=167	Controls n=668
Glucocorticoids	241(33%)	348(12%)	29(13%)	70(8%)	47(28%)	67(10%)
NSAIDs	455(62%)	1156(39%)	161(70%)	340(37%)	114(68%)	267(40%)
Opioids	164(22%)	366(12%)	46(20%)	71(8%)	30(18%)	64(10%)
Paracetamol	233(32%)	598(20%)	63(28%)	165(18%)	51(31%)	141(21%)

Methods: Data over a 13-year time interval (1999-2012) were obtained from a Flemish GP-based morbidity registration network, called Intego that covers 2% of the Flemish general population. Patients classified on the International Classification of Primary Care (ICPC) codes L88 (rheumatoid/seropositive arthritis) and L99 (musculoskeletal disease other) were selected for this study. Experienced rheumatologists verified if the codes corresponded to a diagnosis of RA/SPA/PSA. Diagnosis date in Intego was considered “baseline”. Per case, 4 controls were selected from all other ICPC codes and matched with cases by age, gender, GP practice, and date of diagnosis. The total comorbidity burden was summarised by calculating the Rheumatic Disease Comorbidity Index (RDCI) score at baseline and after 3 years. RDCI ranges from 0-9, with 9 being the highest comorbidity burden. Incidence rates of comorbidities included in this index were calculated. Prevalent analgesic medication use in RA/SPA/PSA patients versus controls was determined. Mann Whitney and $\chi 2$ tests were used when appropriate.

Results: Over the 13-year period, 738, 229 and 167 patients were included with a diagnosis of RA (mean(SD) age 57.7(17.2), 68% female), SPA (mean(SD) age 40.6(15.1), 50% female) and PSA (mean(SD) age of 47(13.2), 48% female), respectively.

The mean(SD) RDCI at baseline was 1.2(1.4), 0.6(1.0) and 1.0(1.3) for RA, SPA or PSA respectively. After 3 years, the mean(SD) RDCI was 1.5(1.6), 0.8(1.2) and 1.3(1.4) for RA, SPA or PSA respectively. The RDCI differed after 3 years between RA and controls (1.5(1.6) versus 1.4(1.5), p=0.008), and PSA and controls (1.3(1.4) versus 1.0(1.4), p=0.009). In RA, at baseline 58% of individuals had an RDCI score ≥1 (versus 53% controls, p=0.01) and after 3 years, 66% of individuals had an RDCI score ≥1 (versus 60% controls, p=0.004). In SPA, at baseline 36% of individuals had an

RDCI score ≥1 (versus 34% controls, p=0.6) and after 3 years, 45% of individuals had an RDCI score ≥1 (versus 41% controls, p=0.4). In PSA, at baseline 52% of individuals had an RDCI score ≥1 (versus 42% controls, p=0.03) and after 3 years, 60% of individuals had an RDCI score ≥1 (versus 48% controls, p=0.003). Table 1 shows the incidences of selected comorbidities over 3 years. All analgesics were statistically significantly prescribed more in patients with a musculoskeletal disease versus controls (table 2).

Conclusion: This study highlights the issue of multimorbidity in patients with musculoskeletal diseases, especially for individuals with RA and PSA. The high cardiovascular burden is substantial in these two populations. The high prevalence of opioids in 1/5 patients with an inflammatory rheumatic disease is to be noted.

Abstract Number: 0180

Identifying Comorbidities and Seropositivity in Rheumatoid Arthritis Patients Using Single-specialty Electronic Health Record Data

Huifeng Yun,[1] Fenglong Xie,[2] Lang Chen,[1] Shuo Yang,[1] and Jeffrey Curtis[1], [1]University of Alabama at Birmingham, Birmingham, AL, [2]University of Alabama at Birmingham, Birmingham

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Epidemiology & Public Health Poster I: RA
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Comorbidities are associated with worse clinical outcomes among patients with rheumatoid arthritis (RA), as does seropositive disease. Rheumatoid factor (RF) and anti-cyclic citrullinated peptide (CCP) antibody status are often tested at the time of RA diagnosis but may not be repeated and therefore may not appear in a rheumatologists' electronic health record (EHR). Recent ICD10 coding allows discrimination between seropositive (M05) and seronegative (M06) patients, but the validity has not been examined. Moreover, the accuracy of identifying

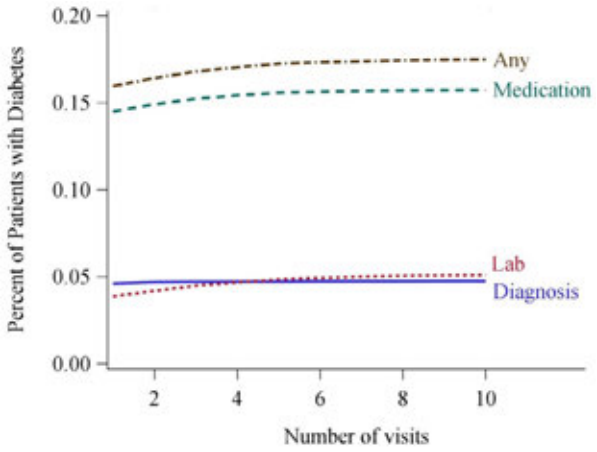

Figure 1. Number of rheumatology visits needed to stabilize diabetes prevalence in the RISE registry.

comorbidities that may not be managed, nor coded, in rheumatologists' EHRs has received little attention. We used a national rheumatology-based EHR registry to examine ICD10 coding to assess the accuracy of seropositive RA classification, and used a confluence of data (diagnoses, drugs, and lab results) to identify diabetes as an example of a common comorbidity that might be relevant for RA.

Methods: Using the ACR's Rheumatology Informatics System for Effectiveness (RISE) EHR-based registry, we created a RA cohort requiring patients to have ≥ 2 rheumatologist visits. Seropositive RA patients were defined as ever have any ICD10 diagnosis code of M05 (i.e. 'with RF'), as well as several permutations of the M05 code (requiring >=2 diagnoses, using the last code, etc). Using RF or anti-CCP lab tests as the gold standard, we calculated sensitivity (Se) and positive predicted value (PPV) based on number of diagnosis codes for RA and different combinations of RF and CCP. We identified diabetes based on ≥ 1ICD9/10 diagnosis code (ICD9: 250.*0, 250.*2; ICD10: E11*); prior prescriptions for diabetes, or elevated laboratory test (hemoglobin A1C ≥ 6.5% or random glucose >200 or fasting glucose ≥ 126mg/dl). We also evaluated the number of physician visits needed to stabilize the prevalence estimate for diabetes.

Results: Among 22,340 eligible RA patients, 5,941 (27%) patients had a lab test for RF (ever), 7,090 (32%) had a test for CCP, and 7,953 (36%) had tests for RF or CCP. Using RF result as the gold standard, the Se for seropositivity using any M05 diagnosis code was 0.86, PPV 0.82; similarly, using CCP as the gold standard, the Se was 0.87 and PPV was 0.68. Combining (RF or CCP), the Se was 0.83 and PPV was 0.83. Requiring additional diagnosis codes, or examining the last code, minimally improved Se and PPV.

Among RA patients with diabetes, 90% were identified as having diabetes medications, 32% by diagnosis codes and 28% by laboratory tests. Diabetes medications by themselves accounted for 51% of all diabetes classification. Using all three types of data, the prevalence of diabetes (17% overall) stabilized after 2 physician visits (Figure 1).

Conclusion: Under ICD10, M05 is a reasonable proxy to identify seropositive RA patients with high sensitivity and positive predictive values. Comorbidities not usually managed by rheumatologists can be identified in a single-specialty EHR like RISE, and identification will be greatly facilitated if specific drugs for those conditions are used.

Disclaimer: This data was supported by the ACR's RISE Registry. However, the views expressed represent those of the authors, not necessarily those of the ACR.Figure 1: Number of rheumatology visits needed to stabilize diabetes prevalence in the RISE registry

Prevalence of Renal Impairment in a US Rheumatoid Arthritis Population

Jon Giles,[1] Lee Simon,[2] Janet Pope,[3] Jim Paik,[4] Michael Grabner,[5] Amanda Quebe,[6] Carol Gaich,[6] Claudia Salinas,[6] and Jeffrey Curtis[7], [1]Division of Rheumatology, Columbia University, New York, NY, [2]SDG LLC, Cambridge, [3]Western University, London, ON, Canada, [4]Eli Lilly & Company, Indianapolis, IN, [5]HealthCore, Inc., Wilmington, DE, [6]Eli Lilly and Company, Indianapolis, IN, [7]University of Alabama at Birmingham, Birmingham, AL

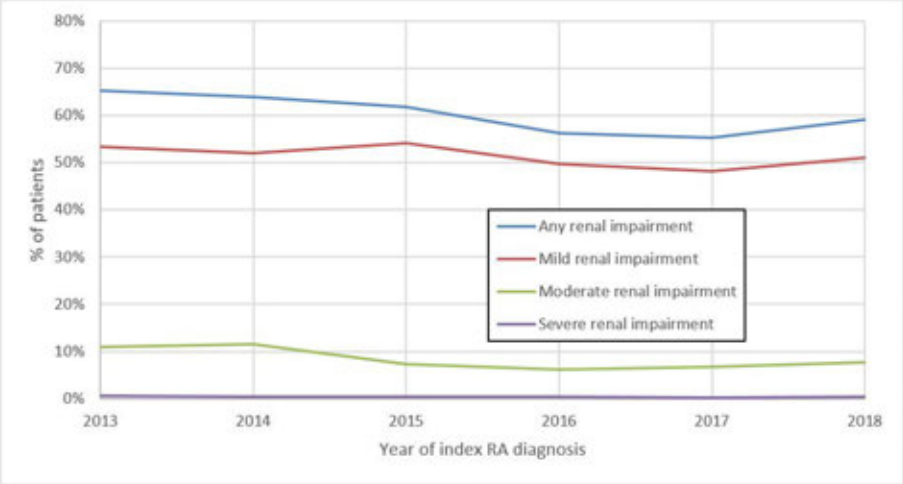
SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Epidemiology & Public Health Poster I: RA
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Table 1. Prevalence of renal impairment overall and by severity category

Severity of renal impairment[a]	All patients[b] (n = 42,173)	Patients treated with advanced therapies[c] (n = 16,197)
Mild (eGFR 60-90 mL/min/1.73m^2), %	52.1	50.9
Moderate (eGFR 30-59 mL/min/1.73m^2), %	9.3	7.0
Severe (eGFR <30 mL/min/1.73m^2), %	0.5	0.3
Overall (any impairment level), %	61.9	58.2

eGFR, estimated glomerular filtration rate; MDRD, Modification of Diet in Renal Disease; SCr, serum creatinine.
[a] MDRD equation: 175 x standardized SCr$^{(-1.154)}$ x age$^{(-0.203)}$ x 0.742 (if female).
[b] With at least 2 SCr laboratory test results available.
[c] Advanced therapies included abatacept, adalimumab, anakinra, certolizumab pegol, etanercept, golimumab, infliximab, rituximab, sarilumab, tocilizumab, and tofacitinib citrate.

Figure 1. Annual prevalence of renal impairment in patients with RA and ≥2 SCr results



Background/Purpose: Clinical management of rheumatoid arthritis (RA) must consider patient renal function, particularly for medications that rely on renal clearance and require dose adjustment or restriction in the presence of renal impairment. However, estimates of the prevalence of renal impairment/chronic kidney disease (CKD) among patients with RA vary widely (5-50%).[1] This study used the Modification of Diet in Renal Disease (MDRD) equation to calculate the prevalence of estimated glomerular filtration rate (eGFR)-based renal impairment among US patients with RA in a commercially insured population, with the goal of providing current real-world data to inform RA treatment decisions in cases where such decisions may be impacted by CKD.

Methods: Claims data from the HealthCore Integrated Research Database (HIRD®) from January 2013 through December 2018 were used. All adult patients with ≥2 claims with diagnosis codes for RA were included in the study, with index date set as the earliest occurrence of an RA claim. All patients had to have ≥2 serum creatinine (SCr) laboratory measurements ≥90 days apart on or after the index date. Prevalence of eGFR-based renal impairment, including by severity category (i.e., mild, moderate, severe; see Table 1 for definitions), was calculated based on the MDRD equation (as race is a component of the MDRD equation, but is not collected in the database, individuals were designated as non-black for purposes of the calculation). Patients with conflicting severity categories based on their

2 SCr measurements were classified into the less-severe category. Possible variations in prevalence for patients on advanced therapies (biologic DMARDs or tofacitinib) were explored in subgroup analysis.

Results: There were 152,090 adult patients with RA identified in the HIRD®, with 128,062 (84%) meeting the criteria for inclusion in the study. Of these, 42,173 (33%) had ≥2 qualifying SCr laboratory results and 16,197 (13%) also initiated advanced RA therapies. Mean age was 56 years; 76% of patients were female. In this population, the estimated prevalence of renal impairment by severity is approximately 52% for mild, 9% for moderate, and < 1% for severe (Table 1). Prevalence was slightly lower among patients initiating advanced therapy. Prevalence remained relatively consistent from 2013 to 2018 (Figure 1).

Conclusion: Among commercially insured US adults with RA with ≥2 SCr results, approximately 7-10% of patients have moderate or severe CKD (eGFR < 60 mL/min/1.73m^2) that might merit dose adjustment of RA medication. Prevalence in this population was stable from 2013 to 2018. While the reported prevalence of renal impairment may tend to underestimate true prevalence due to all patients being covered by commercial insurance, it highlights that renal monitoring, DMARD dose adjustment and potential for drug toxicity remain important considerations for approximately 10% of RA patients.

Comparing the Generalizability of Cardiovascular Risk in Different Rheumatoid Arthritis Cohorts

Fenglong Xie,[1] Cynthia Crowson,[2] Iris Navarro-Millan,[3] Monika Safford,[3] and **Jeffrey Curtis**[4], [1]University of Alabama at Birmingham, Birmingham, [2]Mayo Clinic Rochester, Rochester, [3]Weill Cornell Medicine, New York, [4]University of Alabama at Birmingham, Birmingham, AL

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Epidemiology & Public Health Poster I: RA

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Cardiovascular (CV) risk estimation across diverse rheumatoid arthritis (RA) cohorts may be challenging given potential heterogeneity in comorbidities and widely varying prevalence of CV risk factors. The generalizability of CV risk among younger disabled RA patients enrolled in the Medicare program to similarly-aged patients who are commercially insured is unclear. We aimed to compare CV rates in Medicare and Marketscan to assess comparability.

Methods: Three cohorts of rheumatoid arthritis (RA) patients 40≤ age < 65 years were created using 2006-2016 Medicare and Marketscan claims data respectively. In each dataset, Cohort 1 was defined as ≥2 diagnosis codes for RA occurring 7 -365 days apart with ≥1 diagnosis code from a rheumatologist; Cohort 2 was defined as ≥1 diagnosis code for RA from rheumatologist followed by use of disease-modifying antirheumatic drugs (DMARDS, conventional, biologic or small molecule); Cohort 3 was defined as Cohort 2, plus initiation of a new biologic/tofacitinib, used as a proxy for greater RA disease activity. Other autoimmune diseases, malignancy, past myocardial infarction (MI), or stroke were exclusionary.

Table 1. Distribution of characteristics by RA cohort and by data source

Cohort 2	MI	2.37 (2.23-2.51)	2.24 (2.11-2.38)	1.57 (1.47-1.67)	1.48 (1.39-1.59)
	Stroke	1.65 (1.54-1.76)	1.51 (1.41-1.62)	1.09 (1.02-1.18)	1.03 (0.96-1.12)
	MI or stroke	**2.01 (1.92-2.10)**	**1.88 (1.79-1.97)**	**1.33 (1.27-1.40)**	**1.27 (1.20-1.33)**
Cohort 3	MI	1.65 (1.37-1.99)	1.65 (1.37-1.99)	1.12 (0.91-1.39)	1.10 (0.89-1.36)
	Stroke	1.64 (1.33-2.02)	1.54 (1.25-1.91)	1.09 (0.86-1.38)	1.04 (0.82-1.32)
	MI or stroke	**1.61 (1.41-1.86)**	**1.57 (1.36-1.81)**	**1.09 (0.93-1.27)**	**1.05 (1.89-1.23)**

Note: hazard ratios shown are for Medicare enrollment compared to Marketscan enrollment

* Adjusted for age and sex

** Adjusted for age, sex, diabetes, hypertension, smoking, and other CVD history

*** Adjusted for age, sex, diabetes, hypertension, other CVD history identified using all available data; Obesity, Steroid use, Statin use, all cause hospitalization and number of physician visits identified using one year baseline data

Follow up started at the earliest date of meeting the cohort definition and the requirement of one year of medical and pharmacy coverage and ended at earliest of: 1) a CV outcome (hospitalized MI or stroke, using validated algorithms); 2) end of enrollment 3) age 65 years; 4) end of biologic exposure plus 90 days (cohort 3 only).

Descriptive statistics including standardized mean differences (SMDs) and CV incidence rates (IR) were calculated, and Poisson regression used to generate confidence intervals (CI). Cox regression was used to generate hazard ratio (HR), comparing enrollment in Medicare vs. Marketscan. Models sequentially adjusted for age and sex (model 1); model 1 + diabetes, smoking, hypertension, high CV risk (model 2): and model 2 + a variety of additional risk factors (model 3).

Results: A total of 380,336 RA patients comprised cohort 1 (mean age 53.3 (SD 8.1) years for Medicare and 51.1 (SD 8.8) years for Market Scan, and 21-23% were male). All co-morbidities and medication use were more prevalent in Medicare than Marketscan. Age- and sex-specific IRs were approximately 1.5-2.5-fold greater in Medicare referent to Marketscan. After intermediate adjustment (model 2), RA patients in Medicare in cohort 2 still had higher CV risk (adjusted HR 1.33, 95% CI 1.27-1.40). However, cohort 3 requirements attenuated MI and stroke risk to be negligibly different between Medicare and Marketscan RA patients (adjusted HR 1.09, 95% CI 0.93-1.27).

Conclusion: The rate of CV events varies substantially between different RA cohorts, but multivariable adjustment and careful attention to RA-related features including medication initiation (used as a proxy to reduce heterogeneity in disease activity) can minimize these differences.

Table 2b. Age and sex-specific incidence rates for myocardial infarction (MI) and stroke by RA cohort and data source

Cohort	Outcome	Age	Sex	Medicare			Market Scan		
				Event	Person year	IR(95%CI)	Event	Person year	IR(95%CI)

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Epidemiology & Public Health Poster I: RA

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Data-driven principal component (PC) and cluster analysis has the potential to identify previously unknown patient subgroups within a rheumatoid arthritis (RA) registry to establish prognosis, predict disease trajectory, and help inform treatment. The Brigham and Women's Rheumatoid Arthritis Sequential Study (BRASS), established in 2003, is a single-center, prospective observational registry cohort providing a comprehensive set of clinical disease activity measures in >1400 patients with RA. Our objective was to use PC and cluster analysis of baseline demographic, socio-economic, health and disease characteristics in BRASS to identify and characterize distinct patient clusters in RA.

Methods: Patient variables recorded at entry into BRASS were refined and combined using PC analysis to reduce dimensionality and collinearity. The number of PCs was established by eigenvalue >1, cumulative variance, and interpretability. Patients were clustered using a k-means approach with non-hierarchical, exclusive, and complete clustering, with minimum cluster size 5% of population, and maximum 19 clusters. The final number of clusters was determined according to the cubic clustering criterion and pseudo F.

Results: Analysis of baseline data from 1443 patients identified 41 PCs that capture the fundamental characteristics involved in RA. Cluster analysis distinguished 5 patient clusters. Each cluster reflected a different profile of PCs, and can be described based on overall health, RA disease activity and duration (Table). Key differentiators between clusters include comorbidity PCs (metabolic comorbidities predominate in cluster 1, neurologic in cluster 4, and orthopedic in cluster 5) and patient characteristics/social PCs (greatest number of doctor visits and family history of MI in cluster 3, greatest BMI in cluster 1, highest income in cluster 2, lowest income in cluster 5, and least emotional support in cluster 1).

Conclusion: Data-driven cluster analysis of RA patient characteristics at entry into the BRASS registry identified five distinct patient phenotypes, providing a convenient method to potentially derive novel insights into the multifactorial drivers, commonly co-occurring health conditions, and manifestations of RA. Investigation of longitudinal outcomes in these different clusters in the BRASS registry and validation in an independent dataset is ongoing.

Table. Summary of clusters

	N	Summary descriptor	Patients, %				
					RA duration, years		
			≤1 comorbidity*	CDAI ≤10	<5	5–20	>20
1	108	Health low, RA uncontrolled, shorter RA duration	7%	28%	37%	38%	25%
2	691	Health high, RA controlled, shorter RA duration	59%	43%	46%	37%	17%
3	280	Health high, RA controlled, longer RA duration	48%	46%	24%	45%	31%
4	174	Health low-moderate, moderate RA, moderate RA duration	36%	36%	26%	50%	24%
5	190	Health low, RA uncontrolled, longer RA duration	30%	24%	12%	33%	55%

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Epidemiology & Public Health Poster I: RA
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Some previously published studies suggest that patients with rheumatoid arthritis (RA) are at an increased risk of developing diabetes mellitus. We examined the risk of incident type 2 diabetes mellitus (T2DM) among RA patients compared to four non-RA comparison cohorts.

Methods: Using a large US commercial insurance database, Optum Clinformatics (2005-2017), we identified RA patients based on ≥2 diagnosis codes for RA and use of ≥1 disease-modifying antirheumatic drugs (index date). We selected four comparison cohorts with ≥2 disease-specific diagnosis codes and ≥1 dispensing of disease-specific drugs: 1) general non-RA patients, 2) hypertension, 3) osteoarthritis (OA), and 4) psoriatic arthritis (PsA) patients as an inflammatory arthritis comparison cohort. All study patients were ≥18 years old with 365 days of continuous enrollment prior to the index date. Patients with diabetes diagnosis or use of any anti-diabetic drugs at baseline were excluded. We also excluded patients with RA or PsA from the non-RA, non-PsA cohorts. RA patients were matched to comparator cohorts (except PsA) with age, sex, and index date. Incidence T2DM was defined as a diagnosis of T2DM plus a new dispensing of anti-diabetic drugs within +/- 30 days. Patients were followed up from the day (for the primary analysis) or one year (for the secondary analysis to minimize surveillance bias) after the index date to the earliest event of: 1) occurrence of T2DM, 2) disenrollment, 3) end of data, 4) death, or 5) occurrence of RA or PsA in other cohorts. We used multivariable Cox-proportional hazards model to estimate hazard ratios (HR) of incident T2DM among RA versus each of comparison cohorts, accounting for >40 baseline covariates including demographics, co-morbidities, co-medications, lab ordered, and healthcare utilizations. To validate our results, we selected hip fracture as a positive control outcome since RA is known to increase the risk of hip fracture.

Results: A total of 108,568 RA patients were 1:1 matched to the hypertension, OA, and general non-RA cohorts on age, sex, and index date. 15,055 of PsA patients were identified. Mean age was 55.6 years among RA/general non-RA/hypertension/OA cohort and 77.3% were female. PsA patients had a mean age of 48.6 years and 48.6% were female (Table 1). During the mean 2.4 years of follow-up, we observed 2,091 incident T2DM events in RA patients, 1,828 in the general non-RA cohort, 3,012 in hypertension, 1,802 in OA, and 366 in PsA cohort. The crude incidence rate of T2DM was the lowest in the RA cohort (7.0 per 1,000 person-years) and highest (12.3 per 1,000 person-years) in the hypertension cohort (Table 2). After adjusting for baseline covariates, RA was associated with a 24-35% lower risk of incident T2DM compared to the comparison groups (Figure 1). The secondary analysis showed consistent results. Our positive control outcome analysis showed over 30% increased risk of hip fracture in RA patients compared to the general non-RA, hypertension, and PsA patients (Figure 1).

Conclusion: In this large cohort study with over 10 years of study period, RA patients had a lower rate of incident T2DM compared to the general non-RA, hypertension, OA, and PsA cohorts.

Table 1. Selected baseline characteristics of RA vs. non-RA cohorts

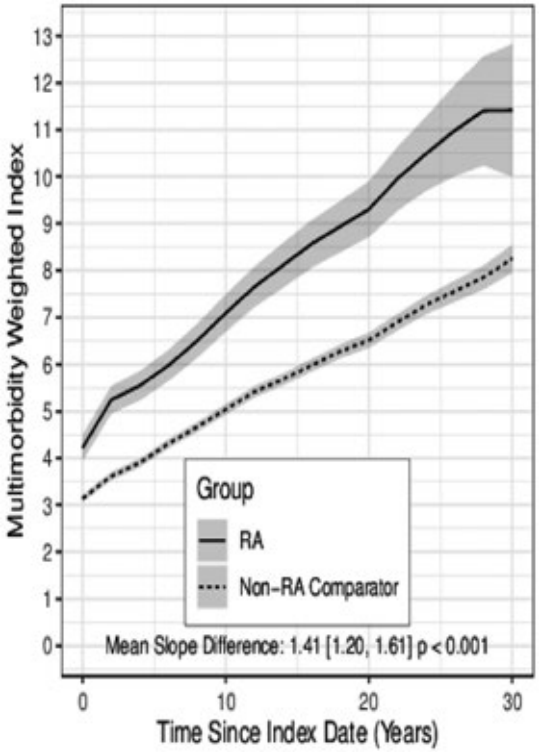
Session Title: Epidemiology & Public Health Poster I: RA

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

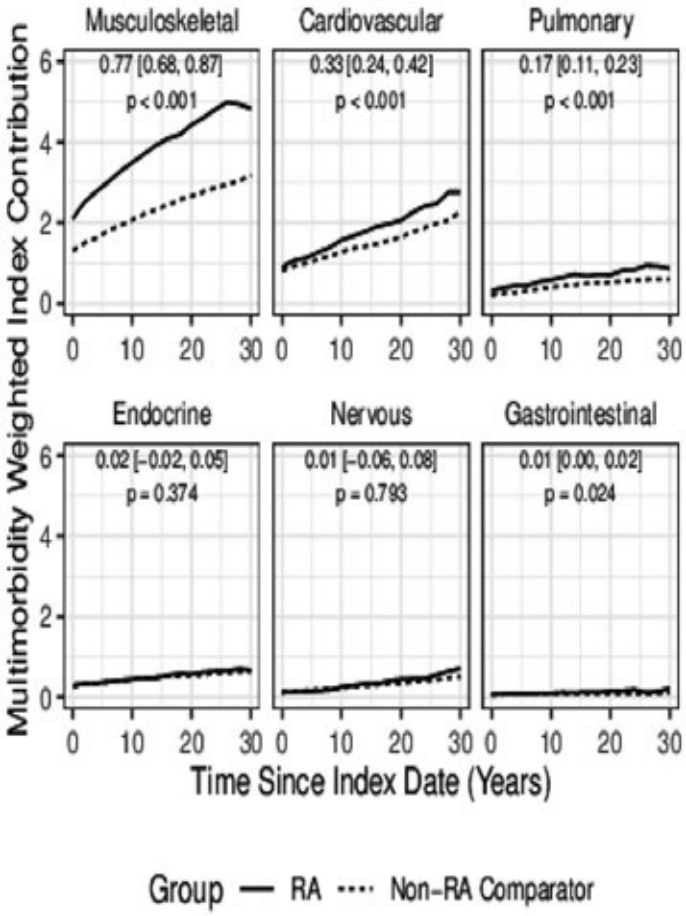
Background/Purpose: Rheumatoid arthritis (RA) patients often suffer from multimorbidity, the coexistence of multiple chronic morbidities. However, little is known about how multimorbidity accrues over time among RA patients compared to similar individuals without RA. Thus, we aimed to describe the longitudinal trajectories of multimorbidity after incident RA and compared to age- and calendar year- matched non-RA comparators, both from a large prospective cohort of female nurses.

Methods: We conducted a prospective cohort study utilizing the Nurses' Health Study, an ongoing (n = 121,700) prospective cohort of female registered nurses that began in 1976. Biennial questionnaires collected information on items such as sociodemographics, anthropometrics, dietary intake, and health conditions. Incident RA and date of



diagnosis were determined by medical record review (all meeting 1987 ACR or 2010 ACR/EULAR classification criteria). For each woman with incident RA, we matched 10 non-RA comparators who had never reported RA at or prior to the index date (time of RA diagnosis) by age and calendar year. To quantify the potentially differential accumulation of multimorbidity over time, we used the validated Multimorbidity-Weighted Index (MWI), previously associated with physical function, mortality, and cognitive decline. We modified the MWI to exclude RA (exposure of interest), analyzing a total of 61 morbidities, each weighted according to their impact on the Short Form-36 physical functioning scale. The conditions included common and rare but debilitating conditions and spanned all organ systems; e.g., musculoskeletal (gout, osteoarthritis, osteoporosis, fractures, joint replacements), cardiovascular, and pulmonary systems. We demonstrated the trajectories of the overall MWI and components of the MWI over time in RA patients and their matched comparators. The between-group difference in trajectories was tested using linear mixed effect models.

Results: We identified 1,007 incident RA patients and matched 10,003 non-RA participants. Both had mean ages of 60 years (SD 10). Need to include mean follow-up time (big strength of the study). Past and current smoking was more common among RA individuals (65%) than comparators (56%). At baseline (**Figure 1**), the MWI was higher for the RA patients (mean 4.2) than matched comparators (mean 3.1). During the follow-up, MWI accrued more rapidly for RA patients than their matched comparators. For each decade, MWI score increased by 1.41 [95% confidence interval (CI) 1.20, 1.61] in RA patients. The largest contributor to the baseline difference and difference in trajectories over time was the musculoskeletal component of the MWI (**Figure 2**). Although similar at baseline, cardiovascular and pulmonary components of the MWI accrued more rapidly over time for the RA patients than the matched comparators.



Conclusion: Women with RA and their non-RA comparators exhibited differential accumulation of multimorbidity after incident RA. Since the MWI concomitantly captures current physical functioning and predicts future physical functioning, cognitive decline, and increased mortality, potential strategies to mitigate the accumulation of multimorbidity in RA patients are urgently needed.

Accumulation of multimorbidity after the index date of RA diagnosis (n=1,007) or matched date for comparators (n=10,003) as quantified by the Multimorbidity Weighted Index.

Accumulation of the major components (musculoskeletal, cardiovascular, pulmonary, endocrine, gastrointestinal, and nervous) of the Multimorbidity Weighted Index after the index date of RA diagnosis (n=1,007) or matched date for comparators (n=10,003)

Asthma, Chronic Obstructive Pulmonary Disease, and Subsequent Risk for Incident Rheumatoid Arthritis Among Women: A Prospective Cohort Study

Julia Ford,[1] Xinyi Liu,[1] Su H. Chu,[2] Bing Lu,[1] Michael Cho,[1] Edwin Silverman,[1] Karen Costenbader,[1] Carlos Camargo,[3] and Jeffrey Sparks[1], [1]Brigham and Women's Hospital, Boston, MA, [2]Brigham and Women's Hospital and Harvard Medical School, Boston, MA, [3]Massachusetts General Hospital, Boston, MA

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Epidemiology & Public Health Poster I: RA
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: While RA patients are known to have excess respiratory morbidity and mortality, less is known about the role of chronic respiratory diseases in the development of RA. Prior studies using retrospective cohort or case-control studies suggest an association between asthma and increased RA risk, but were limited by potential for recall bias and lack of data on smoking and RA serostatus. Chronic obstructive pulmonary disease (COPD) as a risk factor for incident RA has not previously been studied. We investigated whether asthma or COPD are associated with subsequent risk of developing RA, independent of smoking.

Methods: We performed a prospective cohort study investigating asthma, COPD, and incident RA risk in two prospective cohorts, the Nurses' Health Study (NHS, 1988-2014) and NHSII (1991-2015). Self-reported asthma and COPD were confirmed using validated supplemental respiratory questionnaires. Medical record review determined incident RA (meeting 1987 ACR or 2010 ACR/EULAR criteria), serostatus, and date of diagnosis. Covariates including smoking pack-years were self-reported every 2 years. Two separate pooled analyses were performed: 1) asthma as primary exposure, and 2) COPD as primary exposure, each compared to women who never reported asthma or COPD. Cox regression models estimated hazard ratios (HR) and 95% confidence intervals (CI) for RA (overall and by serostatus), adjusting for smoking and other potential confounders. We performed subgroup analyses among never and ever smokers and by age to evaluate possible effect modification for asthma and RA risk by smoking and age.

Table 1. Hazard ratios for incident rheumatoid arthritis according to time-updated asthma, compared to women without asthma or COPD in the Nurses' Health Studies (n=196,409).

	No asthma or COPD	Asthma
	HR (95%CI)	HR (95%CI)
Outcome: All RA		
Cases/person-years	874/3,841,747	100/265,359
Age-adjusted model	1.00 (Ref)	**1.67 (1.35, 2.05)**
Multivariable model*	1.00 (Ref)	**1.53 (1.24, 1.88)**
Outcome: Seropositive RA		
Cases/person-years	562/3,834,291	60/264,341

Multivariable model*	1.00 (Ref)	**1.42 (1.08, 1.86)**
Outcome: Seronegative RA		
Cases/person-years	312/3,833,574	40/264,329
Age-adjusted model	1.00 (Ref)	**1.98 (1.42, 2.76)**
Multivariable model*	1.00 (Ref)	**1.75 (1.25, 2.45)**

*Multivariable model was adjusted for age, questionnaire period, cohort, US geographic region (West, Midwest, Mid-Atlantic, New England, Southeast), median household income (quartile), smoking pack-years (continuous), smoking status (never/past/current), cumulative average physical activity (<3, ≥3 MET-hours/week), parity/breastfeeding in months (nulliparous, parous/<1 month, parous/1-11 months, parous/≥12 months), menopausal status/postmenopausal hormone use (premenopausal, postmenopausal/never, postmenopausal/ever), cumulative average Alternate Healthy Eating Index (quartile), body mass index category (<25.0, 25.0 to <30.0, ≥30.0 kg/m^2), parents smoked in house when growing up (yes/no), lived with smoker (ever/never), and physical exam in the last two years (yes/no).

Table 2. Hazard ratios for incident rheumatoid arthritis according to time-updated COPD, compared to women without asthma or COPD in the Nurses' Health Studies (n=205,153).

	No asthma or COPD	COPD
	HR (95%CI)	HR (95%CI)
Outcome: All RA		
Cases/person-years	1,029/4,337,186	31/47,285
Age-adjusted model	1.00 (Ref)	**2.39 (1.66, 3.43)**
Multivariable model*	1.00 (Ref)	**1.89 (1.31, 2.75)**
Outcome: Seropositive RA		
Cases/person-years	642/4,328,257	21/47,134
Age-adjusted model	1.00 (Ref)	**2.69 (1.73, 4.18)**
Multivariable model*	1.00 (Ref)	**2.07 (1.31, 3.25)**
Outcome: Seronegative RA		
Cases/person-years	387/4,327,740	10/47,121
Age-adjusted model	1.00 (Ref)	**1.93 (1.02, 3.64)**
Multivariable model*	1.00 (Ref)	1.59 (0.83, 3.05)

*Multivariable model was adjusted for age, questionnaire period, cohort, US geographic region (West, Midwest, Mid-Atlantic, New England, Southeast), median household income (quartile), smoking pack-years (continuous), smoking pack-years squared (continuous), smoking status (never/past/current), cumulative average physical activity (<3, ≥3 MET-hours/week), parity/breastfeeding in months (nulliparous, parous/<1 month, parous/1-11 months, parous/≥12 months), menopausal status/postmenopausal hormone use (premenopausal, postmenopausal/never, postmenopausal/ever), cumulative average Alternate Healthy Eating Index (quartile), body mass index category (<25.0, 25.0 to <30.0, ≥30.0 kg/m^2), parents smoked in house when growing up (yes/no), lived with smoker (ever/never), and physical exam in the last two years (yes/no).

Results: We identified 1,060 incident RA cases (63% seropositive) during 4,384,471 person-years of follow-up. In the asthma analysis, the RA incident rate (IR) for 15,148 women with validated asthma was 0.38 per 1000 person-years compared to an IR of 0.23 per 1000 person-years for women without asthma or COPD. Asthma was associated with increased risk for all RA (HR 1.53, 95%CI 1.24, 1.88) compared to no asthma/COPD after adjusting for covariates including continuous pack-years and smoking status (Table 1). Among never-smokers, asthma was associated with increased risk for all RA (HR 1.53, 95%CI 1.14, 2.06) and seronegative RA (HR 1.91, 95%CI 1.22, 2.97), but not seropositive RA. In the COPD analysis, the RA IR for 3,573 women with validated COPD was 0.66 per 1000 person-years. COPD was associated with increased risk of all RA (HR 1.89, 95%CI 1.31, 2.75) and seropositive RA (HR 2.07,

95%CI 1.31, 3.25) after adjusting for covariates including continuous pack-years and smoking status (Table 2). The association of COPD with seropositive RA was most pronounced in the subgroup of ever-smokers who were >55 years old (HR 2.71, 95%CI 1.55,4.76).

Conclusion: In this large prospective cohort study, asthma and COPD were both associated with increased risk for incident RA, independent of smoking status/intensity. Identifying asthma and COPD patients as at-risk populations for RA can help develop prevention and screening strategies as well as provide insight into the role of chronic airway inflammation in RA pathogenesis.

Session Title: Epidemiology & Public Health Poster I: RA

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: JIA-associated uveitis (JIA-U) is the most prevalent extra-articular manifestation of JIA and the most common type of uveitis in children. To date, environmental factors such as smoke exposure, early life infection, pets, breast feeding, residential areas, stressful life events and prematurity have been investigated for potential associations with the development of JIA. Prematurity was found to have a possible correlation with JIA; while in adults, cigarette smoke has been reported to have an association with the onset of uveitis. Our objective is to identify

NOTE: n =number; SD = Standard Deviation; % = Percentage; χ^2 = Chi square value; [a] = Fisher's exact test; * = significant p values

environmental factors (pregnancy history, smoking exposure and initial feeding regimen) and disease characteristics (clinical lab values, disease duration and disease subtype) associated with uveitis development in children with JIA.

Methods: We reviewed records for a JIA cohort comprised of 171 children (120 oligoarticular or polyarticular RF- JIA without uveitis [JIA-no-U], and 51 JIA-U) enrolled in a prospective study on uveitis outcomes who are seen at an outpatient clinic at Cincinnati Children's Hospital. Data collected included JIA and uveitis clinical characteristics, and a baseline ESR at JIA diagnosis. Parents or guardians completed a questionnaire on socio-cultural factors including pregnancy history (fertility treatments, substance use and birth weight), initial feeding regimen and smoke exposure (Figure 1). Means were used to compare JIA-no-U and JIA-U patients using Chi Square (χ2) and T-test.

Results: Of 171 children, mean age was 11 (SD, 5 years), 75% female, 93% Caucasian and 93% non-Hispanic (Table 1). Compared to JIA-no-U, those with JIA-U were more likely to be ANA positive (50.9% vs. 77.8%, p = 0.002), diagnosed with JIA at a younger age (6.7 vs. 4.8 years, p = 0.015), and be of the oligoarticular extended JIA category (24.4%, p = 0.022). ESR (nearest JIA diagnosis) of JIA-no-U and JIA-U children at JIA diagnosis was not significantly

different (22.5 vs. 23.1, p = 0.846). Environmental factors such as initial feeding regimens, pregnancy history and smoke exposure were also not significantly different. A portion of our JIA population report a history of in-vitro fertilization (JIA-no-U: 8 vs. JIA-U: 0, p = 0.050).

Conclusion: Our results are consistent with previous findings suggesting children with JIA-U more commonly have a positive ANA and are diagnosed with JIA at a younger age. In our Midwest regional cohort, we were not able to identify environmental factors significantly-associated with uveitis development in children with JIA. Further, we were not able to confirm associations with smoking or baseline ESR levels. Future studies are needed in a larger cohort to examine environmental factors in relation to healthy controls and JIA-U children, and other reported environmental factors such as birth order, delivery type or family medical history.

The Importance of Diagnosis: Clinical Distinctions Between Adult JIA and RA, and a Characterization of Patients with JIA Reclassified as RA in Adulthood

Kristin Wipfler,[1] Sofia Pedro,[1] Yomei Shaw,[1] Rebecca Schumacher,[1] Teresa Simon,[2] Alyssa Dominique,[3] Adam Reinhardt,[4] and Kaleb Michaud[5], [1]FORWARD, The National Databank for Rheumatic Diseases, Wichita, KS, [2]Bristol-Myers Squibb*, Princeton, NJ, [3]Bristol-Myers Squibb, Princeton, NJ, [4]Children's Hospital & Medical Center & University of Nebraska Medical Center, Omaha, NE, [5]FORWARD, The National Databank for Rheumatic Diseases and University of Nebraska Medical Center, Wichita, KS

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Epidemiology & Public Health Poster I: RA
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Upon transitioning from pediatric to adult care, many patients with JIA are labeled as having RA, despite the two diagnoses being distinct in care and treatment. We investigated differences between adult patients with JIA and those with RA, and between adult patients with JIA who retain their diagnosis and those who are reclassified to RA, in a 20-year observational study.

Methods: Patients enrolled in a large, US-wide longitudinal study of rheumatic disease outcomes from 1998 to 2018 were eligible. Random observations from adults with JIA were analyzed descriptively and matched 1:3 with patients with RA. Matching was performed based on sex, calendar year of observation, and calendar year of diagnosis to produce matching disease duration and treatment era comparisons. Demographics, disease activity and status assessments, medications, co-morbidities and biomarkers were compared using t-tests and Chi-square tests. Logistic regression models for JIA versus RA diagnosis and for JIA diagnosis type were generated using backward elimination at $p < 0.05$.

Results: In the JIA cohort (n=933), 25.8% of patients had physician-confirmed or self-reported JIA and 74.2% had physician-confirmed RA with symptom onset prior to age 16 (Table 1). Nearly all (92.3%) patients with JIA who were given an RA diagnosis had symptoms prior to the terminology change from juvenile RA to a JIA diagnosis, versus 57.7% of other patients with JIA. Biomarkers were identified in a subset of patients: 38.6% of all patients with JIA (n=44) and 68.9% of matched patients with RA (n=135) were RF+ and/or anti-CCP+ (data not shown). After ad-

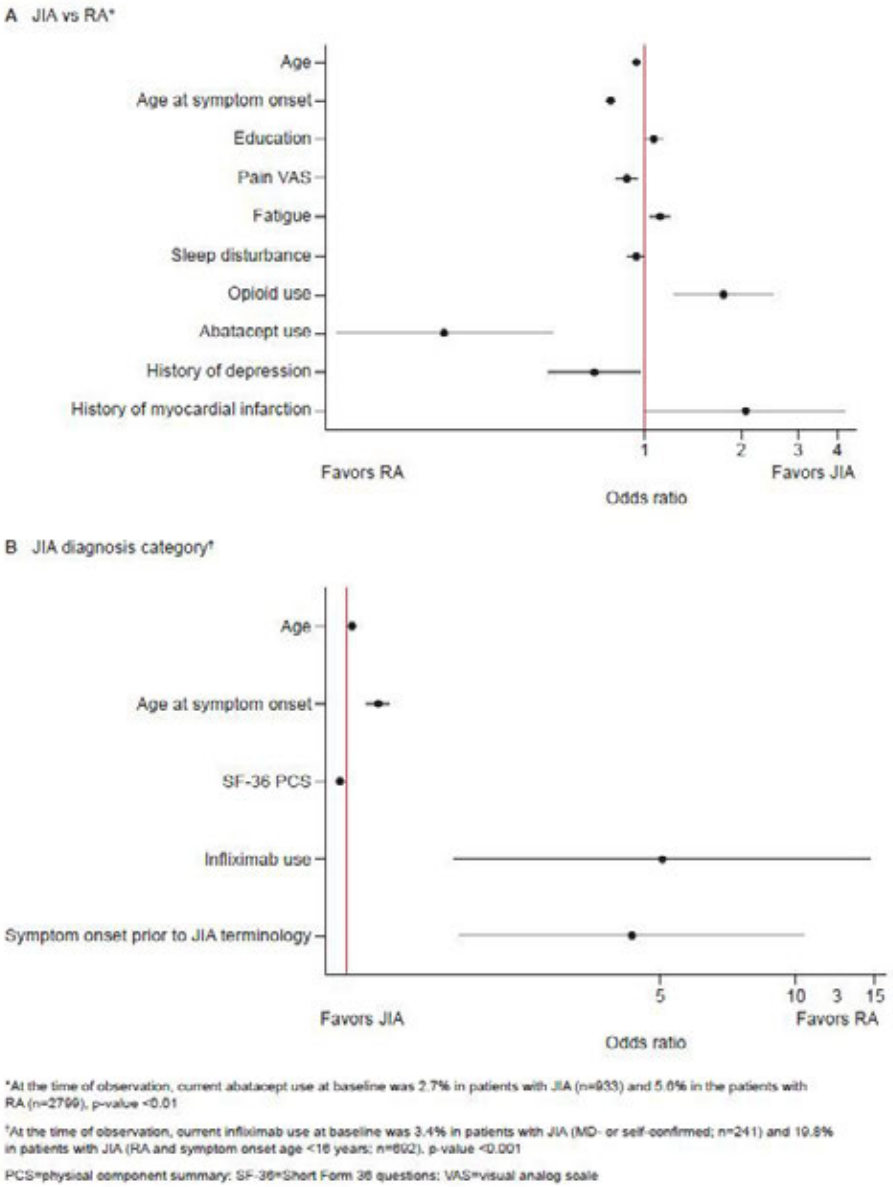
MCS=Mental Component Summary; PCS=Physical Component Summary; SF-36=Short Form-36 questions; TNFi=TNF inhibitor

dressing confounding in logistic regression models, several parameters were associated with JIA (vs RA) diagnosis, including younger age, lower pain and abatacept use, and higher fatigue among others (Figure 1A). In comparing the diagnosis type within the JIA cohort, older age, older age at symptom onset, lower Short Form-36 physical component summary score, symptom onset prior to the JIA terminology change and higher infliximab use were associated with labeling patients with RA in adulthood (Figure 1B).

Figure 1. Odds Ratios of Significant Covariates in Logistic Regression Models for (A) Any JIA vs Matched RA Diagnosis and (B) Retained JIA Label vs Relabeled With RA in Adulthood



*At the time of observation, current abatacept use at baseline was 2.7% in patients with JIA (n=933) and 5.6% in the patients with RA (n=2799), p-value <0.01

†At the time of observation, current infliximab use at baseline was 3.4% in patients with JIA (MD- or self-confirmed; n=241) and 19.8% in patients with JIA (RA and symptom onset age <16 years; n=602), p-value <0.001

PCS=physical component summary; SF-36=Short Form 36 questions; VAS=visual analog scale

Conclusion: Matched adults with JIA or RA had important differences in patient-reported outcomes, medication use and co-morbidities. Diagnoses given to adults with JIA have an important impact on their treatments, as reclassification to RA leads to differences in those treatments, particularly with use of infliximab.

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Epidemiology & Public Health Poster I: RA

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: The prevalence of interstitial lung disease (ILD) among rheumatoid arthritis (RA) patient ranges between 5-10%. ILD leads to high morbidity and mortality in patients with RA and has economic implications. Validation of ILD among patients with RA in administrative datasets will enable future studies to describe clinical courses and treatment patterns on a large scale using real-world data. Therefore, we aimed to validate claims-based algorithms to identify ILD in RA patients.

Methods: We selected RA patients aged ≥65 years who had ≥2 diagnostic codes for RA and ≥1 disease-modifying antirheumatic drugs in Medicare Parts A/B/D linked to the Partners Healthcare electronic medical records from 2012-to 2014. To identify ILD in RA patients, we evaluated 8 claims-based algorithms using a combination of ICD-9 diagnosis codes and procedure codes related to the diagnosis or management of ILD. The algorithms were: (1) ≥1 diagnosis code for ILD by any physician; (2) ≥2 diagnosis codes for ILD by any physician; (3) ≥1 diagnosis code for ILD by any physician and ≥1 procedure code within 6 months from the ILD code; (4) ≥1 diagnosis code for ILD by any physician and ≥1 diagnostic procedure after the ILD diagnosis code; (5) ≥1 diagnosis code for ILD by pulmonologist or rheumatologist; (6) ≥2 diagnostic codes for ILD by pulmonologist or rheumatologist; (7) ≥1 diagnostic code for ILD by pulmonologist or rheumatologist and ≥1 procedure code within 6 months from the ILD code; (8) ≥1 diagnosis of ILD by pulmonologists or rheumatologist and ≥1 relevant diagnostic procedure after the ILD code. We performed manual medical record review and used presence of ILD on the clinical radiology report of chest computerized tomography (CT) scans or lung biopsy as the gold standard. In ambiguous cases of ILD, three rheumatologists and one pulmonologist discussed the case to determine if ILD was present. We calculated the positive predictive value (PPV) of each algorithm as the percentage of ILD confirmed by the gold standard ILD diagnosis over the denominator of patients who had chest CT or lung biopsy data available.

Results: A total of 5,214 RA patients were included in this study. In each algorithm, 181-993 patients were identified. Of those, 40.9-58.0% had adequate records of chest CT or lung biopsy reports. The PPV of algorithm 1 was 43.4% and requiring more than 2 ILD diagnosis codes improved the PPV to 52.0% in algorithm 2. When procedure codes related with the diagnosis or management for ILD was added to diagnostic code (algorithms 3 and 4), PPV did not increase, although the algorithms considering the time sequence between procedure and diagnosis codes improved the PPV slightly. However, the PPV of algorithm 5 (≥1 diagnosis code by pulmonologist or rheumatologist) increased to 61.5%. Requiring more than 2 ILD diagnostic codes by specialists improved the PPV to 72.4% in algorithm 6 (**Table**).

Table. Predictive Values of Proposed Algorithms for Identifying ILD in RA patients

	Algorithm Definition	No. of patients with CT chest or lung biopsy	No. of ILD cases identified	PPV* % (95% CI)
ILD Diagnosis by any physician				
1	≥1 ICD-9 diagnosis of ILD in any position	406	176	43.4 (38.5-48.3)
2	≥2 ICD-9 diagnosis of ILD in any position	248	129	52.0 (45.6-58.4)
3	≥1 ICD-9 diagnosis of ILD in any position and at least one relevant diagnostic procedure within 6 months from the diagnostic code for ILD	373	157	42.1 (37.0-47.3)
4	≥1 ICD-9 diagnosis of ILD in any position and at least one relevant diagnostic procedure† after diagnostic code	303	136	44.9 (39.2-50.7)
ILD Diagnosis by specialist				
5	≥1 ICD-9 diagnosis of ILD in any position by pulmonologist or rheumatologist	166	102	61.5 (53.6-68.9)
6	≥2 ICD-9 diagnosis of ILD in any position by pulmonologist or rheumatologist	105	76	72.4 (62.8-80.7)
7	≥1 ICD-9 diagnosis of ILD in any position by pulmonologist or rheumatologist and at least one relevant diagnostic procedure within 6 months from the diagnostic code for ILD	166	101	60.8 (53.0-68.3)
8	≥1 ICD-9 diagnosis of ILD in any position by pulmonologists or rheumatologist and at least one relevant diagnostic procedure† after diagnostic code	154	94	61.0 (52.9-68.8)

*Gold standard was defined by ILD cases confirmed by chest computerized tomography (CT) or lung biopsy report, and cases with ambiguous ILD on chest CT who were determined to have ILD after adjudication.
†bronchoscopy, biopsy(surgical/transbronchial), chest CT/high resolution CT/positron emission tomography (PET)-CT, pulmonary function testing, oxygen therapy
No.: Number, ILD: interstitial lung disease, PPV: positive predictive value, CI: confidence interval

Conclusion: Among RA patients, the algorithm that required ≥2 ICD-9 diagnosis codes for ILD by pulmonologist or rheumatologist demonstrated adequate PPV of 72.4% to identify ILD. These results demonstrating support the use of the claims-based algorithm for RA-associated ILD for generating more generalizable real-world evidence

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Epidemiology & Public Health Poster I: RA

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Interstitial lung disease (ILD) affects 10-15% of RA patients leading to significant disability and premature mortality. While large administrative datasets have been widely leveraged in outcomes research, the accuracy of algorithms used to identify RA-ILD cases has not been adequately studied. Our objective was to evaluate the accuracy of administrative algorithms for identifying ILD in RA.

Methods: We selected participants in the Veterans Affairs Rheumatoid Arthritis (VARA) registry for detailed medical record review using a stratified sampling technique. Those with ≥2 outpatient or ≥1 inpatient ILD International Classification of Diseases (ICD) codes were reviewed as well as a 10% random sample of those without ILD codes. After standardizing the review process, three rheumatologists abstracted data from clinical notes, imaging/pathology reports, and pulmonary function testing (PFT). 'Stringent' and 'relaxed' ILD definitions based on medical record review were constructed a priori. Administrative data was obtained from the VA Corporate Data Warehouse and included outpatient and inpatient ICD codes, ICD codes from non-VA providers, provider specialty, diagnostic testing (imaging, biopsy, PFTs), and corresponding dates. We tested the algorithms in phases: 1) number and type of encounters, 2) specific ICD codes, 3) provider specialty and diagnostic testing, and 4) exclusion of 'other' ILD. Sensitivity, specificity, positive and negative predictive value (PPV), and agreement (Kappa statistic) with medical record classification were assessed. Analyses accounted for the stratified sampling design using inverse probability weighting. Several sensitivity analyses were completed.

Results: Characteristics of selected participants (n=536) were reflective of the VARA registry (n=2640) and VA population. ILD was confirmed in 182 (stringent) and 203 (relaxed), with pulmonologist diagnosis and chest computed tomography (CT) evidence in the majority. Initially, we identified ≥2 ILD ICD codes from inpatient or outpatient encounters as the best discriminating factors (PPV 65.5%, Kappa 0.70). Optimal ICD codes were ICD-9 515, 516.3, 516.8, and 516.9 and ICD-10 J84.1, J84.89, and J84.9 (PPV 69.5%, Kappa 0.72). Algorithms including a pulmonologist diagnosis, chest CT, PFTs, lung biopsy, or combinations improved performance (PPV 77.4-81.9%, Kappa 0.75). Exclusion of 'other' ILD modestly improved PPV further (78.5-82.9%). In sensitivity analyses, comparisons against even more sensitive ILD reference-standards resulted in PPVs of 82.4-86.3% while other minor algorithm modifications did not significantly affect algorithm performance.

Conclusion: The administrative algorithms identified in this study demonstrate substantial agreement with medical record review in classifying ILD in RA patients, though PPV is limited by the relatively low prevalence of RA-ILD. Optimal algorithms with PPV ≥80-85% contained multiple ILD encounters, specific ICD codes, pulmonologist diagnosis or diagnostic testing, and exclusion of 'other' ILD. These algorithms can be leveraged for RA-ILD outcomes research.

Session Title: Epidemiology & Public Health Poster I: RA

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Cigarette smoke is a known inhalant exposure that contributes substantially to the risk and severity of rheumatoid arthritis (RA). Less is known about the link between other inhalant exposures and RA related factors. The aim of this study was to determine the association between inhalant exposures (occupational, agricultural, and military) with RA-related autoantibodies and severity in U.S. Veterans with RA.

Methods: Participants at 9 sites in the Veterans Affairs Rheumatoid Arthritis (VARA) Registry, a multicenter, longitudinal observational cohort of U.S. Veterans with RA, were mailed surveys assessing occupational, agricultural, and mili-

Table 1. Association of self-reported burn pit exposure with anti-CCP antibody status and concentration by shared epitope status.

Anti-CCP positivity	**OR (95% CI)**	**P value**
Among SE positive	3.06 (1.26, 7.41)	0.01
Among SE negative	1.25 (0.50, 3.10)	0.63
Anti-CCP concentration (log)	**β (95% CI)**	**P value**
Among SE positive	0.67 (0.21, 1.14)	0.005
Among SE negative	-0.20 (-1.13, 0.74)	0.68

Adjusted for age, sex, race, and tobacco use.
Abbreviations: SE, shared epitope; anti-CCP, anti-cyclic citrullinated peptide

Table 2. Association of combined self-reported burn pit exposure and shared epitope status on anti-CCP antibody positivity in RA.		
	Odds Ratio (95% CI)	**P value**
Neither SE nor burn pit	1 (Ref)	-
SE alone	2.78 (1.80, 4.30)	<0.001
Burn pit alone	1.33 (0.56, 3.17)	0.52
SE and burn pit	8.56 (3.46-21.20)	<0.001
Adjusted for age, sex, race, and tobacco use. Abbreviations: SE, shared epitope; anti-CCP, anti-cyclic citrullinated peptide		

tary inhalant exposures. Demographics, disease activity, functional status, and extra-articular features were obtained from the VARA registry database while HLA-DRB1 shared epitope (SE) status, anti-CCP antibodies, and rheumatoid factor (RF) were measured using banked serum from VARA enrollment. Cross sectional associations between self-reported inhalant exposures and RA-related factors (autoantibodies, severity, extra-articular features) were assessed using multivariable linear and logistic regression models adjusting for age, sex, race, and tobacco use. Associations between inhalant exposures and autoantibody status were further examined in models stratified by SE status.

Results: Of 1566 registry participants mailed surveys, 797 returned completed surveys (50.9% response rate). Responders were older, more frequently white, less frequently current smokers, and had better disease activity and functional status. Self-reported occupational dust exposures were present in 67.6%, living or working on a farm in 44.8%, Agent Orange exposure in 29.2%, and military burn pit exposure in 18.6%. Military service periods between 1965-1973 were most common among those self-reporting burn pit exposure, with 19% serving during periods characterized by open-air burn pits on military bases. There were no significant associations between occupational dust, farm, or Agent Orange exposures with RA autoantibodies or disease severity. Self-reported burn pit exposure was significantly associated with anti-CCP positivity (odds ratio [OR] 2.22, 95% CI 1.23-3.99) and higher anti-CCP concentrations (log-transformed; b0.50, 95% CI 0.07-0.93) independent of tobacco use. In analyses stratified by SE status, these associations were limited to individuals with SE alleles (**Table 1**). In models examining combined self-reported burn pit exposure and SE status, those with both risk factors demonstrated a substantially higher risk of anti-CCP positivity (OR 8.56, 95% CI 3.46-21.20) compared to either risk factor in isolation (**Table 2**). Self-reported burn pit exposure was not associated with RF positivity, disease activity, or extra-articular disease.

Conclusion: Self-reported burn pit exposure was associated with anti-CCP antibodies in those with HLA-DRB1 SE alleles independent of, and to a similar degree as tobacco use. While limited by the cross-sectional design and self-report exposure history, these findings suggest that other inhalant exposures may similarly influence RA autoantibody expression and confer risk for RA

A Healthy Plant-Rich Diet and the Risk of Rheumatoid Arthritis in Women

Nathalie Marchand,[1] Shilpa Bhupathiraju,[2] Megu Baden,[2] Jeffrey Sparks,[3] Susan Malspeis,[3] Karen Costenbader,[3] Elizabeth Karlson,[3] and Bing Lu[3], [1]Brigham and Women's Hospital, Boston, [2]Harvard T.H. Chan School of Public Health, Boston, [3]Brigham and Women's Hospital, Boston, MA

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Epidemiology & Public Health Poster I: RA
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Consuming an overall healthy diet has been associated with a reduced risk of developing rheumatoid arthritis (RA), but the impact of consuming a diet rich in healthy plant-based foods and low in unhealthy plant-based foods and animal foods has not been investigated previously. The aim of this study was to examine the association between a healthy plant-rich diet and RA in women.

Methods: We prospectively studied 79,465 women from the Nurses' Health Study (NHS) (1984-2012) and 95,741 women from NHS II (1991-2011), who did not have RA at baseline. Information on health, diet, and lifestyle was collected biennially. A diet score was previously created to define a healthy plant-rich diet with higher intake in fruit, vegetable, whole grain, nut, legume, vegetable, coffee and tea consumption, lower intake in fruit juice, refined grain, potato, sugar-sweetened beverage, sweets and dessert consumption, and lower intake in animal foods (animal fats, dairy, eggs, fish, seafood, meat). Cox proportional hazards models, adjusted for age, smoking, physical activity, hormone use, multivitamin use, parity, and duration of breastfeeding, alcohol and total energy intake, were used to estimate hazard ratios (HR) and 95% confidence intervals (CI). Additional adjustment of BMI in separate models assessed the potential mediation effect. Because type of RA and diagnosis at earlier ages can be indicative of differences in disease prognosis, we further stratified our analyses by age at diagnosis and serostatus (seropositive and seronegative).

Results: Over 3,421,592 person years, 1,091 women developed RA in pooled analyses. In age-adjusted models, women with the highest adherence to a healthy plant-based diet had a decreased risk of RA (quartile 4 vs quartile 1 of dietary intake, HR = 0.82; 95% CI = 0.69-0.97, p trend = 0.01). In multivariable adjusted model, the association was attenuated (HR=0.84; 95% CI = 0.70-1.01, p trend=0.05). Additional adjustment for BMI attenuated the association to null. We did not observe significant associations of a healthy plant-based diet with seropositive and seronegative RA separately in multivariable adjusted models, and did not observe a significant difference among women with age ≤55 years and age >55 years.

Conclusion: Consuming a healthy plant-based diet, rich in whole grains, fruits, vegetables, and nuts, may be associated with a modest reduction in RA risk. BMI may mediate the association. Replication of these findings in other prospective studies are needed to confirm if increased consumption of a healthy plant-based diet leads to reduced risk of RA.

Abstract Number: 0193

Diet as a Risk Factor for Rheumatoid Arthritis

Chelsea Guan,[1] and **Shazia Beg**[2], [1]University of Central Florida, Orlando, [2]University of Central Florida College of Medicine, Orlando

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Epidemiology & Public Health Poster I: RA
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is a chronic, systemic inflammatory disease affecting the joints that typically affects women more than men. An exact cause has yet to be identified, but the disease is thought to manifest due to both genetic and environmental factors. The predominant theory is that RA is an autoimmune disease with en-

vironmental triggers. Recently, diet as a risk factor for RA has become of interest. The objective of this literature review is to determine which dietary factors have an influence on developing RA by examining existing literature on this topic.

Methods: PubMed was searched for relevant articles. Articles that contained a sample size of ≥10, were published in the last 30 years, and were in English were included. A search was built using the following MeSH terms: "rheumatoid arthritis," "risk factors," "diet," "nutritional status," "nutrition therapy," "nutrition assessment," "nutrition disorders," "diet, food, and nutrition," and "nutritional requirements." Each MeSH search included "rheumatoid arthritis" AND "risk factors" AND one of the aforementioned terms. The abstracts were first screened for suitability, and suitable articles were reviewed. Additional relevant articles were found from the references of reviewed articles. A total of 121 articles were reviewed and 53 were included.

Results: Because categorization of each dietary item varied across studies, ensuring consistency among categorization was necessary for data analysis. For example, alcohol intake may refer to only wine, only beer, both wine and beer, depending on the study. Variations in phrasing (e.g. "fruits" sometimes included citrus, other times it was not defined at all), methods of data collection, and cohort chosen were found. Some studies also reported results on RA risk based on RA serostatus. Thus, variation in results across studies is likely multifactorial, including number of cases and region of cohort chosen.

When the variations were considered, moderate alcohol consumption and increased β-cryptoxanthin (a carotenoid) consumption most notably reduced risk of developing RA. Increased coffee consumption may also be a risk factor for developing RA, but more studies are needed to draw conclusions. Fish, protein, red meat, vegetables, fruits, fats, dairy, other vitamins, tea, carbohydrates, legumes, flavonoids, sugary drinks, and sodium intake had variable significance or no significant association with RA risk.

Conclusion: Moderate alcohol consumption and increased β-cryptoxanthin are protective against developing RA. Overall, specific dietary elements and their influence on RA risk is a promising topic, and significant findings may be helpful in preventing the development of RA.

Predicting Remission in Rheumatoid Arthritis: External Validation for Tocilizumab Monotherapy Using Corrona Real World Data

Fredrik Johansson,[1] Jamie Collins,[2] Sara Gale,[3] Hongshu Guan,[4] Seoyoung C. Kim,[5] Elena Losina,[6] David Sontag,[1] Jacklyn Stratton,[4] Huong Trinh,[3] Jeffrey Greenberg,[7] and Daniel Solomon[8], [1]MIT, Cambridge, MA, [2]Brigham and Women's Hospital and Harvard Medical School, Boston, [3]Genentech, San Francisco, CA, [4]Brigham and Women's Hospital, Boston, [5]Brigham and Women's Hospital and Harvard Medical School, Boston, [6]Brigham and Women's Hospital and Harvard Medical School, Boston, MA, [7]Corrona, LLC; NYU School of Medicine, Waltham, MA, [8]Brigham and Women's Hospital, Div. of Rheumatology, Immunology and Allergy, Boston, MA

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Epidemiology & Public Health Poster I: RA
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Predicting remission in rheumatoid arthritis (RA) is an important goal for tailoring therapy. Tocilizumab (TCZ) has been found in randomized controlled trials (RCT) to have similar efficacy when used as mon-

Table 1: Cohort characteristics of RWD and RCT data.
N (%) presented for categorical variables. Median (25th, 75th percentile) for continuous variables.

Variables	RWD (n=452)	RCTs (n=853)
Age (Years)	59.0 (49.0, 67.0)	53.0 (44.0, 61.0)
Sex: Female	370 (82.0%)	680 (79.7%)
Race: White	420 (94.4%)	680 (79.7%)

North America	452 (100.0%)	205 (24.0%)
South America	0 (0.0%)	148 (17.4%)
BMI	28.7 (24.7, 33.7)	26.5 (23.5, 30.5)
HAQ-DI	1.2 (0.6, 1.6)	1.6 (1.1, 2.0)
Disease duration (Years)	10.0 (5.0, 17.0)	1.8 (0.5, 7.3)
Past DMARD / MTX:		
Both No	14 (3.1%)	291 (34.1%)
Both Yes	400 (88.5%)	441 (51.7%)
DMARD Yes / MTX No	38 (8.4%)	121 (14.2%)
Baseline CDAI	21.8 (12.0, 32.6)	40.1 (30.7, 49.4)
Follow-up duration (Weeks)	25.8 (22.7, 28.4)	24.0 (24.0, 24.0)

otherapy or in combination with csDMARDS. We recently derived a remission prediction score for TCZ monotherapy (TCZm) using data from four RCTs to predict remission (CDAI < 2.8) at 24 weeks follow-up (Collins, ARD, 2019). Herein, we describe external validation for the prediction score using "real world data" (RWD) from Corrona.

Methods: We identified patients in the RWD who used TCZm for a minimum of 3 months with at least 1 follow-up visit no later than 9 months after TCZm initiation. Patients starting TCZ in combination with other DMARDs were included if TCZm initiation was within 3 months of first TCZ. We followed patients to determine whether they were in remission (CDAI < 2.8) at the next visit closest to 24 weeks (follow-up) after TCZm initiation. The cohort and remission criteria were chosen to mimic the characteristics of the population in the TCZm RCTs. We compared the performance of prediction models derived in our prior work to an additional baseline model, both in the RCTs and RWD. Each of the 3 models is a logistic regression based on a different selection of variables measured before TCZ initiation (baseline): Model A (variables selected based on odds ratio), Model B (selection based on AIC/BIC) and Model C (baseline CDAI only). We studied both a) application of model parameters learned in the RCTs to RWD, and b) cross-validation of models fit to the RWD. We examined the area under the receiver operating characteristic curve (AUROC) as a measure of discrimination and the calibration slope, comparing predicted remission probability with observed remission.

Results: We identified 453 patients from the RWD (out of 54646) who met the inclusion criteria. The 4 RCTs comprise a total of 853 patients with demographics generally similar to the RWD cohort (see Table 1). The number of patients reaching remission on TCZm by their follow-up visit was 12% (n=53) in RWD vs 15% (n=127) in RCTs. The baseline disease activity and history differed considerably: median CDAI 22 in RWD vs 40 in RCTs, and median RA duration 10 years in RWD vs. 2 years in RCTs. We found that discrimination was as good in RWD given baseline covariates as in the RCTs (see Table 2). The AUROC for Model A trained in RCTs and evaluated in RWD was 0.70 vs. 0.71 in the RCTs, and for Model B 0.69 and 0.65, respectively. The CDAI-only (Model C) achieved AUROC of 0.75 in RWD and 0.59 in RCTs.

Table 2: Internal and external validation of 3 remission prediction models.				
Variables		Model A	Model B	Model C (CDAI only)
Baseline CDAI		✓	✓	✓
Age		✓	✓	
Sex (Female)		✓	✓	
RA disease duration		✓		
Region of the world		✓	✓	
Past DMARD / MTX use		✓	✓	
ESR		✓		
Baseline HAQ-DI		✓	✓	
Baseline Hematocrit		✓		
History of CV disease		✓		
History of diabetes		✓		
Model fit in RCTs (derived in RCT)	AUROC	0.71 (0.67-0.76)	0.65 (0.60-0.69)	0.59 (0.54-0.64)
	AUROC 10-fold CV	0.67 (0.62-0.72)	0.62 (0.57-0.67)	0.59 (0.54-0.64)
	AIC	681.03	702.60	711.82
	BIC	757.01	731.10	721.32
	Calibration slope	1.03	0.95	1.04
Model fit in RWD (derived in RWD)	AUROC	0.79 (0.73-0.84)	0.76 (0.70, 0.82)	0.75 (0.69-0.81)
	AUROC 10-fold CV	0.72 (0.66-0.79)	0.74 (0.68-0.80)	0.75 (0.69-0.81)
	AIC	303.77	296.94	295.00
	BIC	357.25	321.63	303.22
	Calibration slope	1.12	1.13	1.19
Transfer to RWD (derived in RCTs)	AUC	0.70 (0.64-0.77)	0.69 (0.62-0.76)	0.75 (0.69-0.81)
	Calibration slope	1.30	0.95	1.70

Notes: ✓ signifies that a variable was included in the specific model. Transfer refers to a model fit to subjects in the RCTs and evaluated for subjects in the RWD. **Abbreviations:** CDAI, clinical disease activity index, RA, rheumatoid arthritis, DMARD, disease modifying antirheumatic drug, MTX, Methotrexate, ESR, erythrocyte sedimentation rate, HAQ-DI, health assessment Questionnaire without disability index, CV, cardiovascular, RCT, randomized controlled trial, AUROC, area under the receiver operating characteristic curve, 10-fold CV, 10-fold cross-validation, AIC, Akaike information criterion, BIC, Bayesian information criterion, RWD, real-world data.

Conclusion: We found that the remission prediction scores derived in RCTs, based on demographics, baseline disease activity and treatment history, discriminated patients in RWD about as well as in RCTs, despite notable cohort differences in treatment history and disease duration. We found that baseline CDAI alone was highly discriminative in the RWD cohort, but not in the RCTs. We believe that this is because the rapid changes in disease activity in early, untreated RA, characteristic of the RCT cohort, is more unpredictable from previous CDAI only than the slow progression of established RA, as in the RWD cohort. Therefore, we consider models A and B more robust to future changes in treatment practice.

The Clinical Characteristics of Patients with Inflammatory Arthritis and a Persistently Low Alkaline Phosphatase Level in a Veteran Affairs Rheumatology Clinic

Luke Monteagudo,[1] Amy Gravely,[2] Peter Valen,[3] and David Ewart[3], [1]The University of Minnesota, Minneapolis, [2]Minneapolis Veteran Affairs Medical Center, Minneapolis, [3]University of Minnesota School of Medicine/ Minneapolis Veteran Affairs Medical Center, Minneapolis

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Epidemiology & Public Health Poster I: RA
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The biochemical hallmark of hypophosphatasia (HPP) is a low alkaline phosphatase (ALP) level. It is recognized that some forms of HPP present in adulthood and have been associated with common signs and symptoms seen in patients with rheumatic disease, including fatigue, muscle pain, weakness, bone pain, recurrent fracture, joint dislocation, and chondrocalcinosis[1]. The clinical implications of low ALP levels in patients with inflammatory arthritis is not well established.

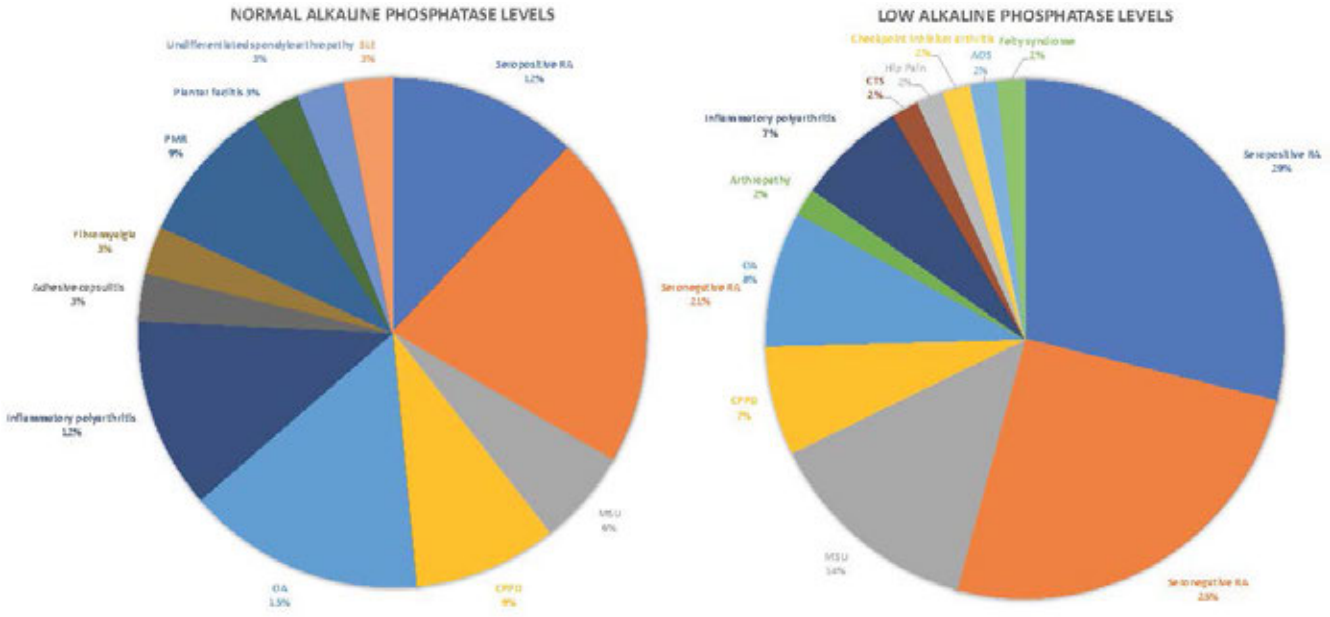

Figure 1. Comparing Diagnoses Between Patients with Normal and Low Alkaline Phosphatase Levels.

Patient Characteristics

yes	16 (31%)	3 (12%)		

Figure 2. Characteristics of Patients with Low and Normal Alkaline Phosphatase Levels.

Purpose: To analyze the clinical features associated with low ALP in patients with inflammatory arthritis in a rheumatology clinic.

Methods: This single center cross-sectional retrospective chart review of patients with low ALP levels and inflammatory arthritis, defined as rheumatoid arthritis (RA) or inflammatory arthritis encounter diagnoses, was performed using the VA electronic medical record. Patients with two or more ALP levels below 40 U/L were compared to patients with consistently normal ALP levels. We excluded patients with co-morbid disease and medications known to cause low ALP levels. The

age, race, rheumatoid factor, anti-citrullinated peptide (anti-CCP) of these two groups were extracted. We looked at the bivariate relationships of these variables, comparing each separately in relation to the group. Clinical diagnoses and pharmacologic history of disease modifying agents and analgesics were extracted and compared between the two groups. Two Sample T test and Pearson's Chi-Square test were used to compare population means and binary variables, respectively.

Results: There was no significant difference in the prevalence of seropositivity or in clinical diagnoses between the two groups, however there was a trend towards patients with low ALP levels having seropositive RA (35% vs 15%, p=0.064). The mean number of disease modifying anti-rheumatic drugs tried was greater in the low ALP group than the control group (1.55 vs 0.92, p= 0.040). Patients in the low ALP group were also older (68 vs 61, p= 0.048). There was no difference in analgesic use between the two groups.

Conclusion: Patients with low ALP and inflammatory arthritis were older and had been tried on a greater number of DMARDs. These findings may suggest that these patients represent a cohort who have disease that is more severe or longstanding. There was no difference in prevalence of seropositive RA or seronegative RA in patients with low ALP levels. However, we did see a trend towards patients with low ALP having seropositive RA. Future work could evaluate for a stronger association between low ALP, RA, gout, pseudogout, and atypical forms of osteoarthritis using a larger sample size to detect this difference.

Risk of Subsequent Atherosclerotic Cardiovascular Disease After the First Unprovoked Venous Thromboembolism in Patients with Rheumatoid Arthritis

Gulsen Ozen,[1] Sofia Pedro,[2] Rebecca Schumacher,[2] Teresa Simon,[3] and Kaleb Michaud[1], [1]University of Nebraska Medical Center, Omaha, NE, [2]Forward, The National Databank for Rheumatic Diseases, Wichita, KS, [3]Bristol-Myers Squibb*, Princeton, NJ

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Epidemiology & Public Health Poster I: RA
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: With the advent of JAK inhibitors has come increased concerns for the risk of venous thromboembolism (VTE), which was already known to be increased in RA due to inflammation. Although it can be potentially a fatal condition, the other adverse outcomes of VTE, particularly the risk of atherosclerotic cardiovascular disease (CVD), are not well-known in RA. As this potential association has clinical implications regarding screening and risk factor modification, we performed a cohort study to determine the risk of subsequent ASCVD in RA patients with unprovoked first VTE.

Methods: RA patients with ≥1 year participation in FORWARD, The National Databank for Rheumatic Diseases, from 1998 through 2018 were assessed for incident nonfatal or fatal ASCVD (myocardial infarction and stroke) validated

Table 1. Baseline characteristics of RA patients with VTE and without any CVD

Variables	Without any CVD, N=25,070	With VTE, N=506	P value

from hospital/death records. We excluded patients with prior VTE/ASCVD and active cancer. Among these patients, we identified patients with first unprovoked VTE (deep venous thrombosis [DVT] and pulmonary emboli [PE] not associated with cancer, recent surgery, hospitalization, fracture, or pregnancy). We calculated event rates and estimated the risk of subsequent ASCVD in patients with incident VTE compared to patients with no history of VTE and ASCVD by using Cox proportional hazards with adjustment for sociodemographics, comorbidities, and RA severity measures.

Table 2. Crude incidence rates and risk of ASCVD in patients with RA by unprovoked VTE

	Events/ patients	Patient-years	Incidence rate (95% CI)*	Unadjusted HR (95% CI)	Adjusted HR† (95% CI)
Patients without VTE or ASCVD	1,283/25,070	147,735	8.68 (8.22-9.17)	-	-
Patients with first unprovoked VTE (no prior ASCVD or VTE)	38/506	16,152	23.53 (17.12-32.33)	2.50 (1.81-3.44)	2.05 (1.43-2.95)
DVT only	21/325	11,150	18.83 (12.28-28.87)	2.03 (1.32-3.12)	1.93 (1.22-3.05)
Pulmonary emboli	17/181	5,002	33.99 (21.13-54.67)	3.78 (2.50-5.70)	2.52 (1.57-4.04)

**Per 1,000 patient-years*
†Adjusted for age, sex, disease duration, socioeconomic status (annual income, insurance, location of residency), ethnicity, smoking, hypertension ,diabetes, comorbidity index, BMI, HAQ, patient global and pain scores, glucocorticoid use DMARDs including MTX, HCQ, TNFi and nonTNFi bDMARDs, NSAIDs, statins, fracture, pulmonary disease, prior count of csDMARDs and bDMARDs, calendar year

Results: In 25,070 RA patients with no VTE or ASCVD and 506 patients with first unprovoked VTE (without prior ASCVD), we identified 1,283 and 38 first ASCVD events during median (IQR) 4.7 (2.4-8.9) years of follow-up. Baseline characteristics of patients with VTE and without any CVD are presented in *Table 1*. Patients with unprovoked VTE had worse RA characteristics (disease duration, HAQ, disease activity, glucocorticoid use) and more frequent traditional CV risk factors (diabetes, hypertension, and obesity). The incidence rate (95% CI) of ASCVD was higher in patients with VTE vs. patients without any CVD (8.68 [8.22-9.17] vs. 23.53 [17.12-32.33] per 1,000 patient-years) (*Table 2*). After multivariable adjustment for baseline differences, we found that patients with an unprovoked VTE had a significantly increased risk of ASCVD (HR [95% CI], 2.05 [1.43-2.95]). The risk increase persisted when we assessed patients with only DVT (HR [95% CI], 1.93 [1.22-3.06]) and the risk in patients with PE was even higher (HR [95% CI], 2.52 [1.57-4.04]) (*Table 2*).

Conclusion: RA patients with unprovoked VTE as the first CVD, even with only DVT, had twofold risk of ASCVD. Future studies are needed to clarify to what extent chronic inflammation and traditional CV risk factors contribute to this association. Nevertheless, RA patients with unprovoked VTE should be evaluated carefully for ASCVD in the presence of concerning symptoms. Also, more vigilant CV risk screening and treatment should be considered in these patients.

Abstract Number: 0197

The Relationship Between Pain and Patient Demographics, Clinical Features, and Health Outcomes in a Cohort of Rheumatoid Arthritis Patients Recruited and Studied Using a Mobile Application

Harriet Dickinson,[1] Yunhao Liu,[2] and **Rachel Williams**[3], [1]GSK, Stevenage, United Kingdom, [2]GSK, Upper providence, [3]GSK, Upper Providence, PA

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Epidemiology & Public Health Poster I: RA
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Pain is one of the most pressing problems for Rheumatoid Arthritis (RA) patients and contributes substantially towards fatigue and disability. Experiences of pain in real world settings may be captured through the use of innovative mobile apps. This study investigates the relationship between pain and patient demographics, clinical features, and health outcomes in a cohort of RA patients recruited via a mobile app.

Methods: A novel mobile app, funded by GSK, known as the PARADE app (PAtient Rheumatoid Arthritis Data from the rEal world) was developed using Apple ResearchKit™ software in 2016. This app obtained informed consent and captured patient demographics, comorbidities, medication use, and PRO instruments - i.e. the Functional Assessment of Chronic Illness Therapy-Fatigue (FACIT-F) and Health Assessment Questionnaire – Disability Index (HAQ-DI). Participants self-reported as being diagnosed with RA and being 18 years or older. A cross-sectional design with week 1 data was used, and Pearson correlations calculated. Pain was measured on a 0 to 10 scale and grouped into: low (0-2), mild (3-5), moderate (6-8) and severe (9-10) pain.

Results: Pain scores were recorded for 421 RA patients; 28.5% of with low pain, 39.0% with mild, 23.3% with moderate, and 9.3% with severe pain, regardless of medication use. Most patients were female (79.1%) and Caucasian (80.5%), however 28.2% of the severe pain group were Hispanic (vs only 9.3% of the low-to-moderate pain group).

Pain score was correlated with tender joint count (correlation r 0.30, $p < .0001$) and degree of morning stiffness (r 0.41, $p < .0001$). The most bothersome RA symptom was joint pain (ranging from 74.2% to 94.9% across pain groups), followed by fatigue (60.8% to 79.3%). Pain was highly correlated with FACIT-F and HAQ-DI scores (r 0.38 and 0.54 respectively, both $p < .0001$). Pain was also correlated with each HAQ-DI subcategory (all $p < .0001$).

Osteoarthritis (OA) was more common in those with moderate pain (34.7%), than low or severe pain (14.2% and 23.1%, respectively). Fibromyalgia was most common in moderate pain patients (36.7%), but less frequent in low and severe pain patients (3.3% and 20.5% respectively). Mood was not associated with pain, and while depression was present in 34.7% of moderate pain patients, it was less common in severe (23.1%) or low (16.7%) pain patients.

Pain medication was frequently used by those with moderate pain (85.7%), but lower levels of use were reported in low (55.0%) or severe (66.7%) pain patients. Conventional Disease-Modifying Anti-Rheumatic Drug (cDMARD) use was common in both low-to-moderate pain groups (61.0% to 68.3%), but only 35.9% in the severe pain subgroup. Biologic DMARDS (bDMARDs) were used by 49.0% of moderate pain patients, but only by 35.9% of severe pain patients.

Conclusion: Pain remains an area of high unmet need in this RA patient cohort. Pain was highly associated with measures of fatigue and disability. However, comorbidities such as OA, fibromyalgia, and depression may be more common in patients with moderate pain than severe or low pain. Patients with severe pain reported lower levels of cDMARD and bDMARD treatment, indicating possible undertreatment of pain in this group.

Assessing Care Quality in Rheumatology Services

Mark Yates,[1] Sam Norton,[1] Alexander MacGregor,[2] Katie Bechman,[3] Sanketh Rampes,[3] and James Galloway[4], [1]Kings College London, London, [2]University of East Anglia, Norwich, United Kingdom, [3]King's College London, London, United Kingdom, [4]Kings College London, London, United Kingdom

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Epidemiology & Public Health Poster I: RA
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

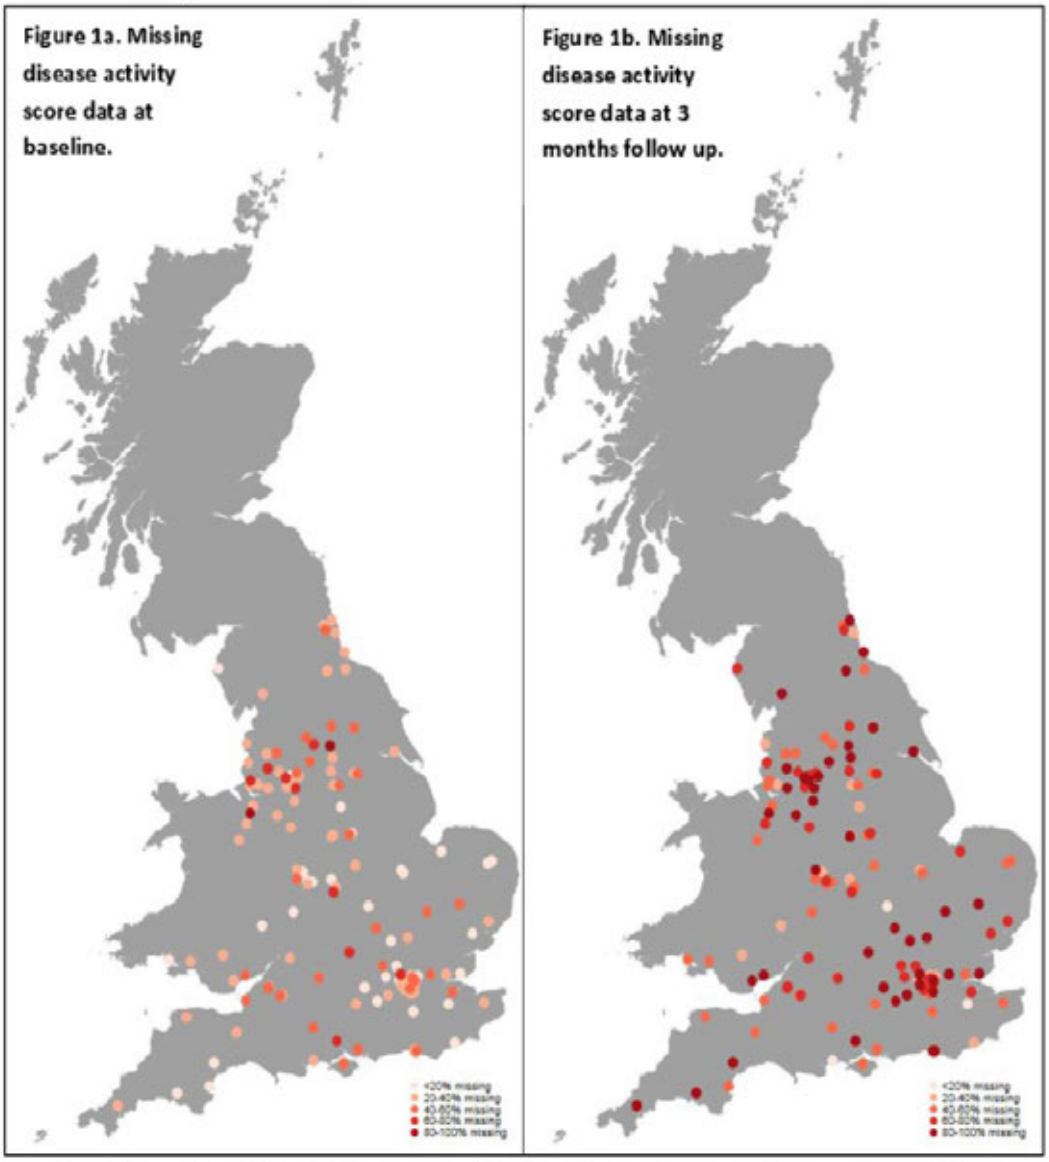
Background/Purpose: There is high-quality evidence that prompt diagnosis and treatment have beneficial impact on outcomes in RA. Current guidelines from both North America and Europe reflect this evidence base. Despite this, there is marked variation in how clinicians follow guidance. We conducted a national survey of practice in England and Wales to assess adherence to guidelines focussing on time to first disease modifying treatment. We have already published from this, demonstrating that over a third of patients experience significant delays. Accepting that data collected outside of a clinical trial or research environment tend to be less complete, we hypothesized that the completeness of data returned would be directly correlated with the quality of care provided.

Table 1. Baseline characteristics, disease activity, and quality of care received stratified by complete and incomplete Das-28 baseline and follow up data.

	Complete DAS-28 data at baseline and follow up	Incomplete DAS-28 data at baseline or follow up	p values
	(N = 1983)	(N = 4222)	
Age, mean (SD)	59.6 (14.2)	57.5 (15.6)	<0.0001
Female	63.8%	63.6%	NS
IMD rank, median (Q1, Q3)	626 (297, 1016)	640 (300, 1022)	NS
White European	91.7%	90.4%	NS
Current Smoker	24.4%	21.2%	0.009
Full time paid employment	36.8%	40.7%	0.008
Seropositive	84.1%	74.3%	<0.0001
DAS-28 at baseline, mean (SD)	5.2 (1.3)	4.9 (1.4)	<0.0001
Symptom duration in days, median (Q1, Q3)	96 (51, 204)	107 (54, 234)	0.003
Referral letter states EIA	90.8%	90.2%	NS
Referral within 3 days	16.0%	17.5%	NS
Review within 21 days	38.8%	36.4%	NS
Treatment within 90 days	70.1%	55.5%	<0.0001

Patients who were positive for RF and/or anti-CCP were considered seropositive. NS = non-significant.

Figure 1. Mapping of departmental proportions of missing disease activity score data at baseline and 3 months follow up.



Departmental proportions of missing disease activity data mapped using the grmap software package in stata 15. Darker colors indicate higher degrees of missing data.

Methods: Data were collected between January 2014 and December 2015 on patients referred to specialist rheumatology services across England and Wales with a suspected diagnosis of inflammatory arthritis. Baseline demographic and clinical details, including a disease activity score (DAS-28), were collected. Patients with a confirmed diagnosis of RA had follow up data collected at three months. Demographic differences in patients with missing DAS-28 data at baseline or three months follow up were tabulated. Departmental proportions of missing DAS-28 data across England and Wales were mapped. A mixed effects logistic regression model adjusted for patient and department level variables was conducted to assess if completeness of baseline DAS-28 data associated with prompt disease modifying treatment commencement.

Results: 6,205 patients diagnosed with RA from 136 rheumatology departments had data, of whom 3,733 (60%) commenced a DMARD within 3 months of referral to specialist rheum care. Disease activity data (measured using

Table 2. Mixed effects logistic modelling of missing DAS-28 data at baseline as a predictor of prompt treatment commencement.

Prompt treatment commencement	Odds Ratio	p values	95% Confidence Interval
Patient level			
Missing baseline DAS-28	0.50	<0.0001	0.41 to 0.60
Age	1.00	0.518	0.99 to 1.00
Gender	1.07	0.447	0.90 to 1.28
In paid work	1.09	0.379	0.90 to 1.32
Socioeconomic position	0.98	0.573	0.92 to 1.05
Smoking status	0.97	0.760	0.79 to 1.18
White European ethnicity	1.03	0.861	0.75 to 1.41
Symptom duration	1.00	0.181	0.99 to 1.00
Seropositive	1.11	0.320	0.90 to 1.37
Department level

Departmental proportion missing follow up DAS-28	0.44	0.105	0.16 to 1.19
Specialist nurse density	1.53	0.041	1.02 to 2.31
Consultant density	0.71	0.031	0.52 to 0.97
Random effect			
Department			
var(_cons)	0.86		0.58 to 1.27

DAS-28) was available for 4,075 (66%) at baseline and 2,341 (38%). Patients with missing DAS-28 data had distinct characteristics to those with complete data, see table 1.

Patients without a baseline DAS-28 score recorded were 50% less likely (odds ratio 0.50, 95%CI 0.41 to 0.60) to commence a DMARD within three months. This effect was independent of all patient level factors included in the analysis. Unit level factors including staff ratios did correspond to data quality, and in particular greater specialist nurse support correlated with higher quality care. See table 2 for further details.

There were broad geographic variations in departmental proportions of missing data, illustrated in figure 1. The departmental proportion of missing DAS-28 data ranged from 0 to 91% at baseline, and 0.1 to 100% at 3 months follow up.

Conclusion: These data from a large national survey demonstrate a clear relationship between the completeness of data collected and the quality of care provided. This supports the view that clinician engagement in quality assessment is likely to be a good surrogate for the quality of care that they are delivering. Measuring quality in healthcare has climbed up the rheumatology community's agenda in the last decade, reflected in the ACR white paper on performance outcome measure in 2016. Data completeness is a simple but useful additional metric as a surrogate for quality.

Obesity and Incident Opioid Use in Rheumatoid Arthritis

Joshua Baker,[1] Sofia Pedro,[2] and Kaleb Michaud[3], [1]University of Pennsylvania, Philadelphia, PA, [2]Forward, The National Databank for Rheumatic Diseases, Wichita, KS, [3]University of Nebraska Medical Center, Omaha, NE

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Epidemiology & Public Health Poster I: RA
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Prevalent chronic use of opioids approximately 17% among patients with rheumatoid arthritis (RA) and has increased over the last decade.(1) Obesity may be a risk factor for chronic opioid use through an association with greater comorbidity, non-inflammatory musculoskeletal disorders, disability, and pain sensitization. We therefore hypothesized a higher rate of use of chronic opioid use in obese patients with RA. We further hypothesized that this relationship would be at least partially explained by worse pain and quality of life scores reported over time in this group.

Methods: RA participants in *Forward*, the National Databank for Rheumatic Diseases, were asked about use of opioid medications on semi-annual surveys between 1999 and 2018. Incident chronic opioid use was defined as new use extending over two contiguous surveys as previously defined. Cox proportional hazards models evaluated associations between body mass index (BMI) category at enrollment and incident chronic opioid use. Initial models considered demographics, smoking, disease duration, and baseline treatments. Subsequent models incorporated time-varying measures depression, pain scores, fibromyalgia severity scores, and physical and mental health status from the SF-36 in order to determine the contribution of these factors to the association between obesity and opioid use.

Results: A total of 25,775 participants were included in this analysis and there were 4,861 incident cases of incident opioid use in 108,864 person-years of follow-up. Higher BMI category was associated a higher risk of incident chron-

Table 1: Risk of chronic opioid use in partially adjusted and fully adjusted models among participants with no data missing for key variables.

	Model 1 *N=19,101 PY= 69,068 Incident Cases 3,345*	**Model 2** *N=19,101 PY= 69,068 Incident Cases 3,345*

BMI Category		
Underweight	1.16 (0.89, 1.50)	1.05 (0.81, 1.36)
Normal	1 (reference)	1 (reference)
Overweight	1.32 (1.21, 1.44)	1.17 (1.07, 1.28)
Obese	1.58 (1.43, 1.74)	1.21 (1.09, 1.34)
Severely Obese	2.11 (1.90, 2.35)	1.26 (1.14, 1.41)

Model 1: Age, sex, race, RA disease duration, smoking, methotrexate use, biologic use, total number of biologics used at baseline.
Model 2: Model 1 plus adjustment for time-varying depression, pain scale, fibromyalgia severity scale, and physical and mental health status.

Table 2: Estimated number of attributable cases of chronic opioid use to obesity based on Model 1.

	N	Predicted 5-year Incidence	Expected Cases at Normal BMI	Cases Attributable to Obesity	% of Cases Explained by Obesity
Underweight	499	120	100	20	0
Normal	8757	1751	1751	0	0
Overweight	8016	1924	1603	321	17%
Obese	4370	1179	874	305	26%
Severely Obese	3152	1040	630	410	39%
All	24794	6004	4958	1046	17%

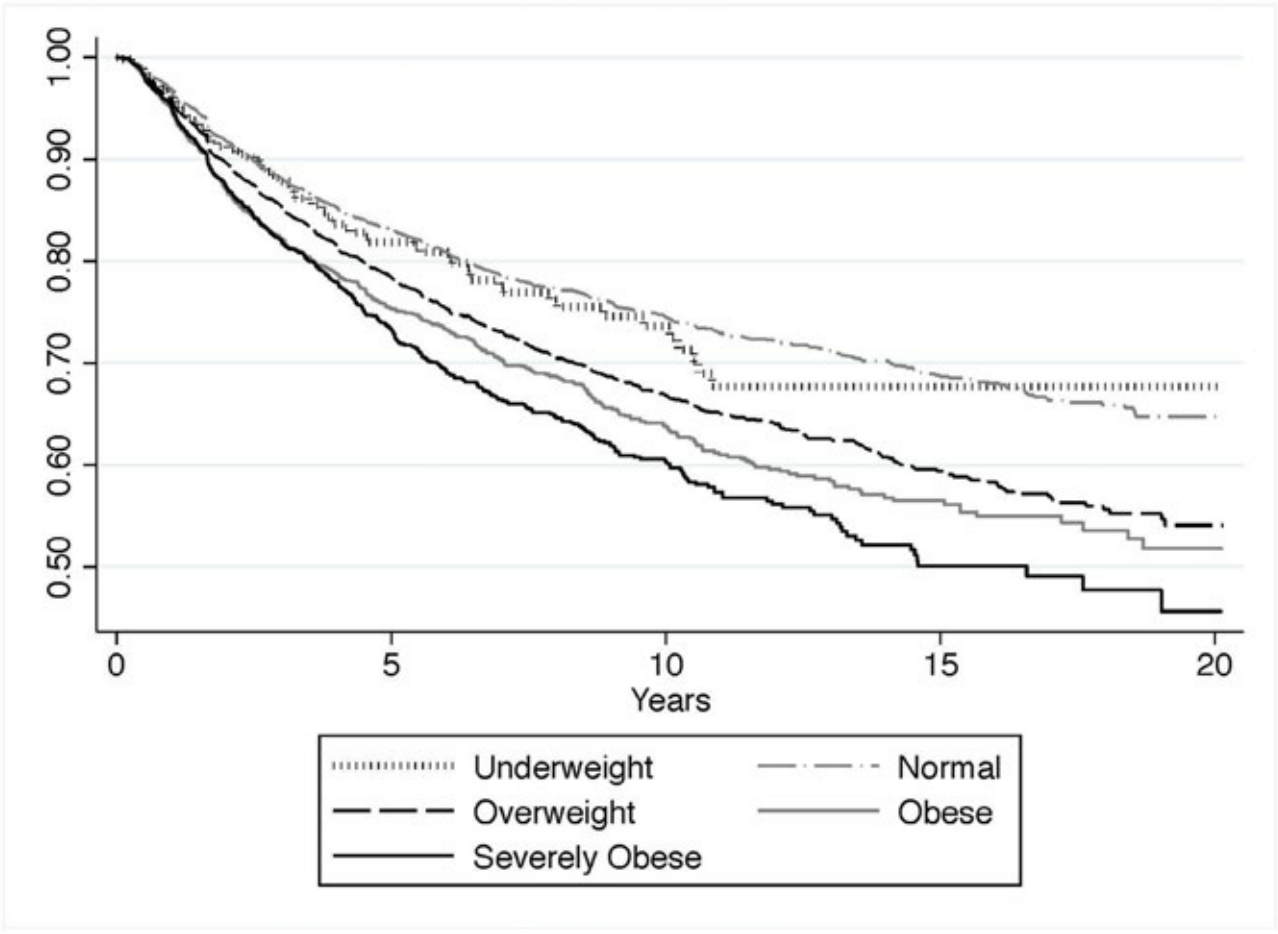

Figure: Survival without use of chronic opioids by BMI category after adjusting for age, sex, race, and smoking status.

ic opioid in a dose-dependent manner. In initial models, severe obesity was associated with a much higher risk of incident use [HR 1.87 (1.72, 2.04) p< 0.0001] compared to normal BMI. Among participants with data for all variables, adjusting for time-varying pain, fibromyalgia, and quality of life scores partially attenuated the relationship (Table 1), suggesting that 69% of the risk was explained by these factors. Based on the absolute incidence at 5 years predicted by Model 1 (Table 2), obesity is expected to account for 39% of use among severely obese individuals. Based on the risk difference of 13%, the prevention or reversal of severe obesity in 8 patients would be expected to prevent one case of chronic opioid use at 5 years.

Conclusion: Obesity is associated with a substantially higher incident chronic use of opioids. This relationship is largely explained by greater reported pain, depression, and poor quality of life over time. Approximately 39% of incident use among severely obese individuals might be attributed to the obesity itself, suggesting a major public health impact on this problem. Interventions to prevent or reduce obesity and related complications could have a substantial impact on chronic use of opioids in this population.

A Validated Text-mining Algorithm to Extract Rheumatoid Arthritis Medication Contained in Format-free Fields of Electronic Medical Records

Tjardo Maarseveen,[1] Thomas Huizinga,[1] Marcel J.T. Reinders,[1] Erik van den Akker,[1] and Rachel Knevel[1], [1]Leiden University Medical Center, Leiden, Netherlands

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Epidemiology & Public Health Poster I: RA
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Rapidly expanding collections of Electronic Medical Records (EMR) form a valuable resource for clinical research. Besides entries with a standardized format, EMRs often also contain free text fields intended for noting specifications of the treatment policy. While these free text fields contain essential information, their free nature makes them hard to parse, as they contain typos or acronyms. As a result, data extraction from EMR is often performed manually, or is performed while excluding the format-free fields. The purpose of this study is to develop and validate a text-mining approach to extract medication prescribed for Rheumatoid Arthritis as contained in format-free fields of an EMR.

Methods: The EMR dataset consisted of 45,012 entries from 2,771 patients that visited the rheumatology outpatient clinic from the Leiden University Medical Centre between 2007 and 2018. We randomly selected 15% and 7,5% of the entries to create a training and test set, with 5,992- and 2,993 entries respectively. The training set was used to design the algorithm, whereas the test set was used as an independent validation of the algorithm's performance of identifying each of the DMARDs and biologicals routinely prescribed for treating RA.

Using methods derived from Natural Language Processing, we developed an algorithm that consecutively performs three tasks: 1. Text pre-formatting 2. Acronym recognition and 3. Typo correction. Text pre-formatting consisted of several simple operations to deal with the most prevalent textual artifacts, including separation of special characters and punctuation sticking to words. Ten independent clinicians compiled acronym lists for each of the routinely prescribed RA medication. Lastly, for typo correction, we employed the Damerau-Levenshtein[1] (DL) distance that determines the similarity between two words by counting the number of single character operations (remove, add, move or replace) required to transform one word into another. Using the training set, we computed for each drug DL distances between all words in the free fields of the EMRs and a particular drug name or its acronym. Using the annotations created in the training set we then determined the DL distance optimally distinguishing between a typo and two similar words with a different meaning.

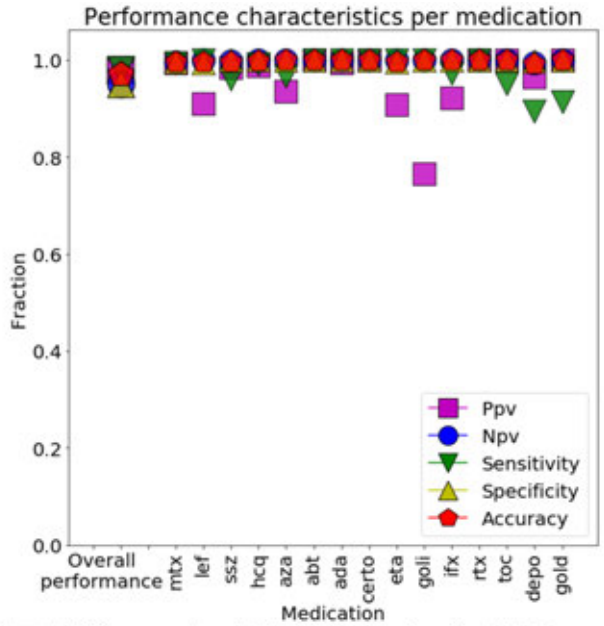

Figure 1: Performance characteristics for the extraction of medication in general and for each medication individually. With the fraction on the Y-scale and the different medications on the X-scale. Where mtx=methotrexate, lef=leflunomide, ssz=sulfasalazine, hcq=hydroxychloroquine, aza=azathioprine, abt=abatacept, ada=adalimumab, certo=certolizumab, eta=etanercept, goli=golimumab, ifx=infliximab, rtx=rituximab, toc=tocilizumab and depo=depomedrol.

Results: Fifteen medications for the treatment of RA were present in our sample (see figure 1). In total, medication was present in 1,789 out of the 2,993 entries. The median DL cutoff for typos was 2 with a standard deviation of 0.96. The overall accuracy of our drug-identification-algorithm was very good per medication in general (0.97) and the individual test characteristics were high: sensitivity=0.98 and specificity=0.95, PPV=0.98, NPV=0.95. Also on an individual drug-level the performance was high: accuracy >=0.99, sensitivity >=0.89 and specificity >=0.99, NPV >=0.99 and PPV >=0.90 for all medication except golimumab.

Conclusion: We developed and validated an algorithm enabling a highly accurate automated extraction of RA medication from format-free fields of Electronic Medical Records.

Identification of Patients with Rheumatoid Arthritis Treated with Biologics Using Standardized Vocabularies

Runsheng Wang,[1] Thomas Falconer,[2] and George Hripcsak[2], [1]Columbia University Medical Center, Division of Rheumatology, New York City, [2]Columbia University Medical Center, Department of Biomedical Informatics, New York City

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Epidemiology & Public Health Poster I: RA

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: To improve efficiency and transportability of observational research, common data models have been developed and maintained to translate data from source vocabularies into standardized vocabularies using vocabulary mapping. The accuracy of mapping International Classification Codes to Systematized Nomenclature of Medicine – Clinical Terms (SNOMED-CT) of rheumatoid arthritis (RA) has been examined at the cohort level, however, its accuracy, in combination with standardized medication coding system RxNorm, has never been examined at the patient level. The objective of this study is to examine the positive predictive value (PPV) of identifying patients with rheumatoid arthritis treated with biologics using Observational Medical Outcomes Partnership (OMOP) common data model.

Methods: NewYork-Presbyterian/Columbia University Irving Medical Center (NYP/CUIMC) EHR has been translated and maintained in OMOP common data model. We searched NYP/CUIMC clinical data warehouse for prevalent cases of patients with rheumatoid arthritis treated with biologics using standardized codes for RA and biologics from 01/01/2013 to 12/31/2018, and excluded patients with other potential indications for biologics. We randomly selected 100 patients from the search result for chart review. We used documentation of a diagnosis of rheumatoid arthritis and a biologics at the index date (+/-4 days) as the gold standard. For patients who had rheumatology visit notes, we examined whether they fulfilled 2010 Rheumatoid Arthritis Classification Criteria.

Results: One hundred and two medical records were identified, and 11 were not accessible. Among the 91 records that were retrieved and examined, 77 patients (84.6%) had a documented RA diagnosis and prescription of biologics, by either rheumatology providers or non-rheumatology providers. Four patients did not have a documented diagnosis of RA, and ten did not have a documented use of biologics. Of the 47 patients who had rheumatology visits, 41 (87.2%) fulfilled the 2010 RA classification criteria.

Conclusion: Using OMOP common data model and standardized vocabularies, we can identify RA patients treated with biologics with a PPV of 84.6% in a single center EHR system.

Session Date: Sunday, November 10, 2019

Session Title: Epidemiology & Public Health Poster I: RA

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Biosimilar use in North America is relatively low, and real-world comparisons of biosimilars and their originator biologics are lacking. We assessed risk factors associated with serious infections in new users of originator infliximab or infliximab biosimilar.

Table 1. Baseline characteristics according to the initial treatment

Characteristic	Originator infliximab (n=2584)	Infliximab biosimilar (n=92)
Female sex (%)	56 (60.9)	1556 (60.2)
Mean age in years, (SD)	48.3 (15.8)	43.9 (15.0)
Age-adjusted CCI score, mean (SD)	1.9 (2.3)	1.4 (2.0)
Past hospitalized infection (%)	5 (5.4)	265 (10.3)
Underline disease indication[1]		
RA	34 (38.2)	546 (22.5)
AS	4 (4.5)	107 (4.4)
Psoriasis/PsA	13 (14.6)	260 (10.7)
IBD	38 (42.7)	1517 (62.4)
Any DMARD use (%)	46 (50.0)	876 (33.9)
Any systemic glucocorticoid use (%)	80 (87.0)	2082 (80.8)
Prior biologic use (%)		
Adalimumab	24 (26.0)	662 (25.6)
Etanercept	8 (8.7)	185 (7.1)
Abatacept	2 (2.2)	27 (1.0)
Certolizumab	3 (3.3)	76 (2.9)
Rituximab	1 (1.1)	25 (1.0)
Tocilizumab	0 (0)	22 (0.9)

[1]Based on the date of diagnosis closest to the start of treatment.
CCI: Charlson comorbidity index; RA: rheumatoid arthritis, AS: ankylosing spondylitis, PsA: psoriatic arthritis, IBD: inflammatory bowel disease, including Crohn's disease and ulcerative colitis.

Methods: We used MarketScan administrative health data to create a cohort of adult new users of infliximab (originator infliximab or infliximab biosimilar), between Jan.-Dec. 2017. The first infusion was the cohort entry date. A 90-day current exposure period was assigned for every infusion and individuals could contribute person-time through the observation period. We assessed frequency and time to first serious infection, defined as those associated with hospitalization. Crude incidence rates were generated to compare infection risk between originator infliximab and infliximab biosimilar. Cox proportional hazards regression models were adjusted to identify risk factors associated with serious infections: current infliximab therapy (originator or biosimilar), age, sex, prior biologic use, prior and current use of DMARDs and systemic glucocorticoids, past hospitalized infection, age-adjusted Charlson comorbidity index (CCI), and underlying conditions (rheumatoid arthritis, ankylosing spondylitis, psoriasis/psoriatic arthritis, Crohn's disease, ulcerative colitis).

Results: We studied 2676 individuals, including 2584 originator infliximab and 92 infliximab biosimilar. Most (60%) were women and the mean age was 44±15 years. Baseline characteristics (stratified by the initial treatment) are presented in Table 1. We identified 115 hospitalized infections during follow-up. Infection rates were 5.5 (95% confidence interval, CI 1.4-22.1) for current infliximab biosimilar and 8.5 (95% CI 7.0-10.3) for originator infliximab. We were unable to identify an association between infliximab therapy and hospitalized infection (adjusted hazard ratio, HR: 0.75, 95%CI 0.18-3.1). Age-adjusted CCI, past hospitalized infection, and prior and current use of glucocorticoids were associated with risk of hospitalized infection (Table 2).

Conclusion: We were unable to detect differences in serious infectious between originator infliximab and infliximab biosimilar. High comorbidity score, occurrence of past infections and use of glucocorticoids were associated with

Table 2. Risk factors associated with hospitalized infections

Variable	HR	95% CI
Infliximab biosimilar	0.75	0.18-3.07
Female sex	0.91	0.61-1.35
Age	0.99	0.98-1.01
Age-adjusted CCI score	1.17	1.07-1.27
Past hospitalized infection	3.69	2.44-5.58
Underline disease indication[1]		
RA	0.23	0.03-1.66
AS	0.48	0.20-1.17

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Epidemiology & Public Health Poster I: RA

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: In North America, biosimilars were approved only relatively recently, and real-world data are few. We described users of infliximab in the US, comparing patient tolerability of biosimilar and originator, in terms of missed doses and discontinuation.

Methods: We used Marketscan® data (Jan-Dec. 2017) to identify adult (age >18) new users of infliximab biosimilar and originator, and switchers from originator to biosimilar. Characteristics (age, sex, comorbidities, medication use) were described. In new users, we assessed missed doses in both the induction (among subjects with >2 months follow-up) and maintenance phases. 'Missed dose' was defined as any gap between infusions beyond recommended intervals

Table 1. Baseline characteristics of new users of infliximab biosimilar and originator, and switchers from originator to biosimilar

Characteristic	Infliximab biosimilar new users (n=112)	Infliximab originator new users (n=3076)	Infliximab biosimilar switchers (n=206)
Female sex, N (%)	69 (61.6)	1848 (60.1)	128 (62.4)
Mean age in years, (SD)	47.3 (15.8)	43.8 (14.9)	52.4 (16.5)
Age-adjusted CCI, mean (SD)	1.9 (2.3)	1.4 (2.1)	1.8 (1.9)
Underline disease[1]			
RA	39 (36.5)	638 (22.2)	69 (35.8)
AS	4 (3.7)	127 (4.4)	9 (4.7)
Psoriasis/PsA	15 (14.0)	300 (10.4)	28 (14.5)
IBD	49 (45.8)	1813 (63.0)	87 (45.1)
Ever DMARDs (%)	53 (47.3)	1024 (33.3)	82 (39.8)
Ever glucocorticoids (%)	95 (84.8)	2424 (78.8)	131 (63.6)
Biologic use (%)			
Adalimumab	32 (28.6)	796 (25.9)	13 (6.3)
Etanercept	11 (9.8)	218 (7.1)	3 (1.5)
Others[2]	8 (7.1)	216 (7.0)	5 (2.4)

[1]Based on the date of diagnosis closest to the start of treatment; 216 missing diagnosis.

[2]Including abatacept, golimumab, certolizumab, tocilizumab, and rituximab.

CCI: Charlson comorbidity index; RA: rheumatoid arthritis, AS: ankylosing spondylitis, PsA: psoriatic arthritis, IBD: inflammatory bowel disease, including Crohn's disease and ulcerative colitis.

Table 2. Factors associated with missed dose and discontinuation during the maintenance phase

	Missed dose		Discontinuation	
Variable	HR	95% CI	HR	95% CI
Infliximab biosimilar	0.32	0.18-3.07	0.82	0.11-6.02
Female sex	1.13	0.61-1.35	0.77	0.41-1.46
Age	1.00	0.98-1.01	0.98	0.96-1.01
Age-adjusted CCI score	1.00	1.07-1.27	1.03	0.85-1.26
Underline disease indication[1]				
RA	1.39	0.88-2.20	1.42	0.32-6.21
AS	1.10	0.53-2.29	0.89	0.25-3.23
Psoriasis/PsA	1.34	0.83-2.17	2.05	0.78-5.33
Past use of DMARD	0.93	0.63-1.35	0.31	0.31-1.64
Past use of systemic glucocorticoid	0.98	0.68-1.42	0.59	0.59-3.41
Any prior biologic use	0.78	0.58-1.06	0.36	0.36-1.37

[1]IBD was the reference category.

(0, 2, and 6 weeks for induction and Q8 weekly for maintenance). Discontinuation (≥ 90-day gap between infusions without restarting therapy) in the maintenance phase was also assessed. We used Cox regression to compare both times to first missed dose and complete discontinuation. All models were adjusted for age, sex, prior use of DMARDs, biologics, and systemic glucocorticoids, comorbidities (Charlson comorbidity index) and underlying disease indication (rheumatoid arthritis, ankylosing spondylitis, psoriasis/psoriatic arthritis, Crohn's disease, and ulcerative colitis).).

Results: We identified 318 users of infliximab biosimilar, including 206 switchers from the originator infliximab (Table 1). Among the 92 new users of infliximab biosimilar with ≥2 months follow-up, the frequency of ≥1 missed dose during induction was 22%, similar to 25% in new users of the originator. For patients completing the induction phase, the adjusted hazard ratio (HR) showed a nonsignificant trend for a longer time to first missing dose in maintenance (adjusted HR 0.33, 95% CI 0.08-1.30, Table 2). We were unable to determine if complete discontinuation differed between the two groups (HR: 0.82; 95% CI: 0.11-6.02).

Conclusion: We documented low use of infliximab use in these US data during 2017; most infliximab biosimilar initiators are switchers from the originator. For previously infliximab-naïve patients, the frequency of ≥1 missed dose during infliximab induction phase was similar in the originator and the biosimilar new users. As the frequency of biosimilar use grows, additional analyses with more follow-up time may help determine if there are differences in persistence between biosimilars and their reference therapy.

Abstract Number: 0204

Real-World Evidence: Clinical and Economic Burden of Anemia, Venous Thromboembolism, and Malignancy Among Rheumatoid Arthritis Patients Switching from First Biologic DMARD to Another Treatment in the US

Robin Dore,[1] Jenya Antonova,[2] Magdaliz Gorritz,[3] Lawrence Chang,[2] Jing He,[3] and Mark Genovese[4], [1]Private practice, Tustin, CA, [2]Gilead Sciences, Foster City, CA, [3]IQVIA, Plymouth meeting, PA, [4]Stanford University, Stanford, CA

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Epidemiology & Public Health Poster I: RA
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: RA patients have an increased risk of malignancy[1] and deep-vein thrombosis and pulmonary embolism (DVT/PE)[2] and high prevalence of anemia.[3] The risks of anemia and malignancy vary by prior DMARD exposure.[1] Comorbidities and treatment side effects may lead to treatment discontinuation and increase healthcare costs. Existing estimates of anemia, DVT, PE, and malignancy are outdated or not specific to patients initiating next treatment after first biologic (b)DMARD. This study aimed to estimate prevalence, incidence, and associated costs of these conditions in RA patients switching from a first bDMARD to another treatment.

Methods: In a US health-plan claims database, we selected adult RA patients (≥2 RA diagnoses ≥30 days apart) who initiated their first bDMARD (1/1/2012–3/31/2017) and switched to another bDMARD or Janus kinase inhibitor (JAKi; index date, ID). Patients had continuous health plan enrollment for 12 months pre-ID and ≥12 months post-ID. The prevalence and incidence of anemia, DVT, PE, DVT or PE, and malignancy (excluding nonmelanoma skin cancer) were assessed by index therapy. Incidence counted patients with new events per 100 patient-years (P100PY) while on treatment. We compared mean per-patient-per-year (PPPY) costs (total, medical, and pharmacy) in patients with and without these conditions.

Results: In 4656 patients who switched from first bDMARD (median age 54 years, 78% female), median RA duration was 1.5 years. Upon discontinuation of the first bDMARD, 46% of patients received a monotherapy (61% TNF-α inhibitor (TNFi), 24% non-TNFi, 15% JAKi), and 54% received a conventional synthetic (cs)DMARD-combination therapy (69% TNFi + csDMARD, 23% non-TNFi + csDMARD, 8% JAKi + csDMARD). The 12-month pre-ID prevalence ranged 14.6–19.8% for anemia, 1.0–2.5% for DVT, 0.7–2.2% for PE, 1.8–3.7% for DVT or PE, and 3.5–8.8% for malignancy (Table 1). Overall, P100PY incidence rates were 6.9 for anemia, 0.7 for DVT, 0.3 for PE, 0.9 for DVT or PE, and 2.0 for malignancy. Incidence rates varied among different treatment classes (Table 2). Total PPPY unadjusted healthcare costs were higher in RA patients with vs without condition: anemia $66,896 vs $53,853; DVT $78,461 vs

Table 1. Prevalence of Anemia, DVT, PE, or Malignancy During Pre-index Period, by Index Treatment

	Pre-index Prevalence				
	Anemia	DVT	PE	DVT or PE	Malignancy
All patients (n=4656)	16.2%	1.7%	0.9%	2.1%	5.2%
Index monotherapy (n=2149)	16.8%	2.0%	1.0%	2.4%	5.4%
TNFi (n=1305)	15.4%	1.8%	0.7%	2.2%	4.4%
Non-TNFi (n=521)	19.8%	1.9%	1.0%	2.3%	8.8%
JAKi (n=323)	17.6%	2.5%	2.2%	3.7%	4.0%
Index combination therapy (n=2507)	15.7%	1.6%	0.8%	1.8%	5.0%
csDMARD + TNFi (n=1740)	16.0%	1.5%	0.7%	1.8%	4.7%
csDMARD + Non-TNFi (n=569)	14.6%	1.9%	1.1%	1.9%	6.5%
csDMARD + JAKi (n=198)	15.7%	1.0%	1.5%	2.0%	3.5%

csDMARD, conventional synthetic DMARD; DVT, deep venous thromboembolism; JAKi, Janus kinase inhibitor; PE, pulmonary embolism; TNFi, TNF-α inhibitor.

Table 2. Incidence Rate (IR) per 100 Patient-years (PYs) of New Anemia, DVT, PE, or Malignancy Patients During Index therapy, by Index Treatment

	Mean treatment duration (months)	Anemia		DVT		PE		DVT or PE		Malignancy	
		IR	PY	IR	PY	IR	PY	IR	PY	IR	PY
All patients	13.2	6.9	4032	0.7	4937	0.3	5001	0.9	4911	2.0	4699
Index monotherapy	9.9	6.6	1410	0.7	1691	0.4	1724	1.1	1679	1.9	1619
TNFi	9.3	6.9	822	0.7	976	0.6	993	1.3	971	1.9	939
Non-TNFi	10.7	5.9	358	1.1	436	0.2	449	1.4	432	1.7	408
JAKi	10.8	6.5	229	0.0	278	0.0	282	0.0	277	2.2	272
Index combination therapy	16.1	7.1	2622	0.7	3246	0.3	3278	0.8	3231	2.1	3080
csDMARD + TNFi	15.5	6.6	1740	0.6	2172	0.3	2187	0.7	2160	2.2	2060
csDMARD + Non-TNFi	17.7	8.5	660	0.7	807	0.1	822	0.9	806	1.6	766
csDMARD + JAKi	16.7	7.2	222	1.1	267	0.4	269	1.1	266	2.8	254

csDMARD, conventional synthetic DMARD; DVT, deep-vein thrombosis; JAKi, Janus kinase inhibitor; PE, pulmonary embolism; TNFi, TNF-α inhibitor

$54,462; PE $99,321 vs $54,483; DVT/PE $88,610 vs $54,305; malignancy $76,741 vs $54,172, all p< 0.001. Cost differences were primarily associated with medical costs (Table 3).

Conclusion: Anemia, DVT, PE, and malignancies affected patients who switched from first bDMARD to another treatment; new cases occurred and varied by treatment received. These conditions were associated with increased unadjusted healthcare costs, primarily driven by medical costs. Future studies are needed to adjust costs by accounting for differences in patient cohorts. The prevalence of these conditions (and the risk of their development as treatment side effects) should be factored into the selection of most optimal treatment.

Table 3. Per-patient-per-year (PPPY) Healthcare costs (USD) During Index Treatment in Patients with and without Anemia, DVT, PE, or Malignancy

	Mean PPPY cost with condition	Mean PPPY cost without condition
Anemia		
Total costs*	$66,896	$53,853
Medical costs*	$32,542	$19,305
Pharmacy costs	$34,353	$34,548
DVT		
Total costs*	$78,461	$54,462
Medical costs*	$48,745	$19,890
Pharmacy costs	$29,716	$34,572
PE		
Total costs*	$99,321	$54,483
Medical costs*	$60,337	$19,962
Pharmacy costs	$38,984	$34,521
DVT/PE		
Total costs*	$88,610	$54,305
Medical costs*	$55,466	$19,756
Pharmacy costs	$33,145	$34,550
Malignancy		
Total costs*	$76,741	$54,172
Medical costs*	$40,172	$19,678
Pharmacy costs	$36,569	$34,493

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Epidemiology & Public Health Poster I: RA
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Marketing of cheaper biosimilar biological agents has created financial incentives for switching from the corresponding originator drugs (=non-medical switch). The economic benefit might potentially be outweighed by extra costs due to patient education or closer monitoring. However, only few studies have previously explored the use of health care resources associated with non-medical switching.[1] In year 2016, Danish national guidelines recommended switch of patients with inflammatory rheumatic diseases treated with originator etanercept (ETA) to biosimilar SB4 in routine care.[2] We aimed to explore if switching lead to increased health care utilization and costs.

Methods: Observational cohort study. Adult patients who switched from ETA to SB4 were identified in the Danish nationwide DANBIO registry. In the National Patient Registry we identified health utilization (hospital admissions/hospital days/outpatient visits/prescription medication use) and comorbidities. Estimation of health utilization included average use and costs one year before/after the switch, changes after the switch, and whether patient characteristics

Figure

Monthly average in-patient and out-patient costs 12 months before and after switch from originator to biosimilar etanercept (n=1620 patients). Black dotted vertical line illustrates time of switch.

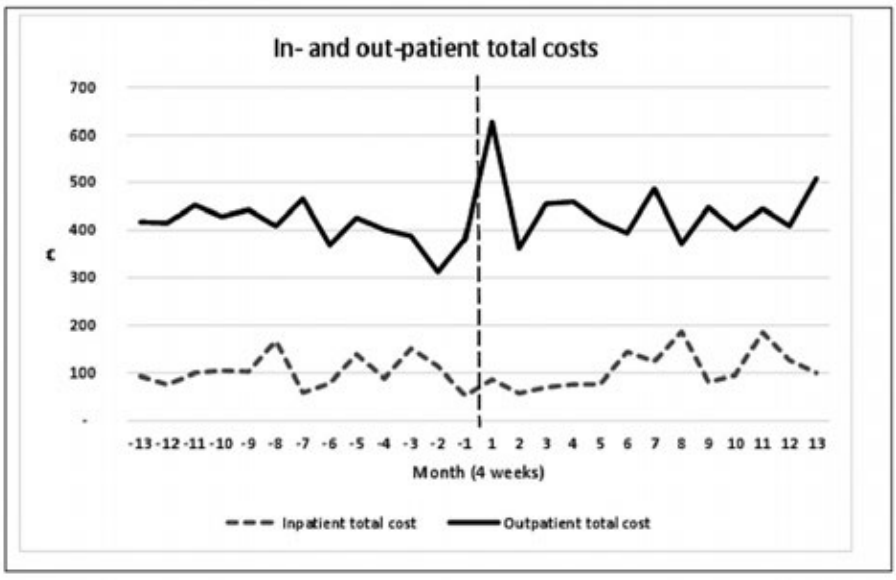

Table 1
A: Health utilization, and B: health costs per patient 12 months before and after switch, unadjusted and adjusted (=predicted)*
N=1620 patients

A. Total health utilization per patient		Unadjusted number, mean (SD)		Adjusted number, mean (95% CI)*	
		Pre-switch	Post-switch	Pre-switch	Post-switch
In-patient services	Number of in-patient admissions	0.25 (0.64)	0.11 (0.40)	0.15 (0.03-0.67)	0.06 (0.01-0.69)

*Predicted costs are for female, 55 years old, not dead in the post-switch period, not withdrawn SB4 within 0-180 days, previous duration of ETA treatment >5 years and with no previous comorbidities
** Defined daily dose of medication total costs (DDD)

affected changes. Analyses were by adjusted 2-step gamma distributed regression models, and for changes over time a GEE model was applied. Impact of comorbidities was explored as interaction terms in the model. Medication costs of ETA and SB4 were not included in model, because these drugs are provided by the hospital department responsible for the therapy and not by private pharmacies.

Results: 1620 patients were included (mean age 55 years(SD 14.7), 40% male). Costs before and after switching were mainly driven by outpatient visits (67% and 72% of all costs, respectively) (Table 1). In general, the adjusted health costs were lower than the unadjusted costs e.g. number of in-patient admissions, hospital days and in-patient costs due to the adjustment for previous comorbidities in the regression (Table 1). Monthly fluctuations of costs were similar before/after switch (Figure). After switching, an increase was observed in the use (8%) and costs (7%) of out-patient services. Number of in-patient days and number of days in hospital decreased (Table 2), but the total number of patients with in-patient services was low (Table 1). Medication costs decreased (5%) (Table 2). Patients with longer ETA treatment duration had increased number of outpatient visits after the switch, higher out-patient total costs and costs related to general practitioners. Higher age (3% per year increase) was associated with higher in-patient total costs related to diseases of the musculoskeletal system and connective tissue diseases. Gender and comorbidities had no impact on costs before and after the switch.

Table 2
A: Changes in health utilization, and B: changes in costs per patient 12 months before and after switch including adjusting variables*

A. Changes in health utilization per patient		After* Exp (estimate), 95% CI	P-value

Medication**	Pain medication, DDD	0.99 (0.96-1.03)	0.702
	Other medication	1.03 (1.00-1.05)	0.051
	Total	1.02 (1.00-1.04)	0.100
B. Changes in health costs per patient		**After* Exp (estimate), 95% CI**	**P-value**
In-patient services	Diseases of musculoskeletal system	0.70 (0.44-1.10)	0.119
	Other diseases	0.81 (0.62-1.05)	0.114
	TOTAL	0.82 (0.65-1.04)	0.100
Out-patient services	Diseases of musculoskeletal system	1.05 (1.00-1.10)	0.057
	Other diseases	**1.24 (1.09-1.41)**	**0.001**
	TOTAL	**1.07 (1.03-1.12)**	**0.001**
Primary sector	General practitioner	1.03 (0.99-1.08)	0.130
	Other practicing specialist	0.97 (0.85-1.10)	0.603
	Physiotherapist, chiropractor, foot specialist	0.97 (0.92-1.02)	0.258
	Other	0.94 (0.88-1.02)	0.140
	TOTAL	0.99 (0.95-1.02)	0.426
Medication	Pain medication	0.98 (0.93-1.03)	0.331
	Other medication	0.95 (0.91-1.00)	0.061
	TOTAL	**0.95 (0.92-0.99)**	**0.019**
TOTAL COSTS		1.04 (0.99-1.09)	0.138

Statistically significant results are marked with bold types
*Adjusted for gender, age, dead in post period, duration of ETA before index date, stopped SB4 treatment within 180 days and comorbidities (WHO chapters) 12-24 months before index date
** Defined daily dose of medication total costs (DDD)

Conclusion: We demonstrated no obvious changes in overall use and costs of health care services following a mandatory non-medical switch from originator to biosimilar etanercept. Longer ETA treatment duration and higher age were associated with increased use and costs of some services.

Abstract Number: 0206

Efficacy of Etanercept on Radiographic Progression in Adult Patients with Rheumatoid Arthritis or Psoriatic Arthritis: Final Results from a German Non-Interventional, Prospective, Multi-Center Study

Siegfried Wassenberg,[1] Thilo Klopsch,[2] Anja Plenske,[3] Silke Behnck-Knoblau,[4] Jürgen Jobst,[4] Pascal Klaus,[4] Thomas Meng,[4] Peter-Andreas Löschmann,[4] and Rolf Rau[5], [1]Centre of Rheumatology, Ratingen, Germany, [2]Internal Medicine Practice, Neubrandenburg, Germany, [3]Pfizer Pharma GmbH, Berlin, Germany, [4]Pfizer Pharma GmbH, Berlin, Berlin, Germany, [5]Dusseldorf, Dusseldorf, Germany

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Epidemiology & Public Health Poster I: RA

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Clinical trials showed that Etanercept (ETN) is highly effective in reducing clinical disease activity and often leading to remission and radiographic non-progression in patients with Rheumatoid Arthritis (RA) or Psoriatic Arthritis (PsA). However, the course of radiographic progression in everyday clinical practice is not known. This German non-interventional study (NIS) assessed radiographic progression in patients with RA or PsA managed in routine outpatient care in private practices with a time interval up to 36 months.

Methods: Throughout the study up to 10 visits (V) were performed (V1 at baseline, V2-7 every 3 months until month 18 – phase 1, V8-10 every 6 months until month 36 – phase 2). Radiographs of hands and feet were taken at baseline (±3 months start of ETN treatment), at month 12 to 18 and/or at months 30-36. All radiographs were scored by 2 blinded readers by the 'van der Heijde modified Total Sharp Score' ($mTSS^{RA}$) for RA patients and the 'van der Heijde modified Total Sharp Score adapted' ($mTSS^{PsA}$) for PsA patients. Additional parameters such as Disease Activity Score (DAS28) and (serious) adverse events were documented.

Results: 1,821 patients were available for the final analysis, 75.7% (N=1,378) were diagnosed as RA and 24.2% (N=440) as PsA patients. The median disease duration at baseline was 4.9 years (range: 0;54 RA) and 8.9 years (0;38 PsA). In RA patients the mean $mTSS^{RA}$ increased from 25.1±42.4 (n=504) at baseline to 26.2±43.6 (n=284) at the end of phase 1 (12-18 months) and to 29.8±48.6 (n=74) at the end of phase 2 (30-36 months). In PsA patients the mean $mTSS^{PsA}$ was 14.7±25.7 (n=166) at baseline, 14.6±23.5 (n=80) at the end of phase 1 and 12.6±23.2 (n=35) at the end of phase 2. Median changes compared to baseline at the end of phase 1 and phase 2 were 0.0, suggesting no radiographic progression on the group level. Calculating normalized progression with yearly intervals about two thirds of the patients showed no radiographic progression after 24 months, i.e. radiographic non-progression defined as a change of $mTSS^{RA/PsA} \leq 0.5$ was observed in 64.2% of RA- and 68.9% of PsA patients after 24 months. The DAS28 decreased from a mean baseline value of 4.6±1.2 (n=1,014) in RA and 4.2±1.1 (n=327) in PsA patients, respectively, to 2.6±1.2 (RA, n=190) and 2.5±1.1 (PsA, n=88) at month 36 indicating an important decrease of disease activity under ETN treatment. Moreover, at month 36, 61.6% of RA and 64.8% of PsA patients were considered to be in remission (DAS< 2.6). A total of 1,993 Treatment Emergent Adverse Events (TEAE) occurred in 849 (46.6%) patients. Most of the AEs were of 'mild' (768 events in 377 patients, 20.7%) or 'moderate' (825 events in 481 patients, 26.4%) severity. 446 patients (24.5%) experienced a total of 753 AEs which were assessed as 'treatment related' to Etanercept (i.e. as adverse drug reactions). 62 out of them in 47 patients (2.6%) were considered to be serious adverse drug reactions.

Conclusion: The final results of this NIS demonstrated that treatment with ETN slows or even stops radiographic progression and reduces disease activity in RA and PsA patients in routine clinical care. The treatment with ETN was well tolerated and no new safety signals were observed.

Abstract Number: 0207

Effects of Successive Switches to Different Biosimilars Infliximab on Immunogenicity in Chronic Inflammatory Diseases in Daily Clinical Practice

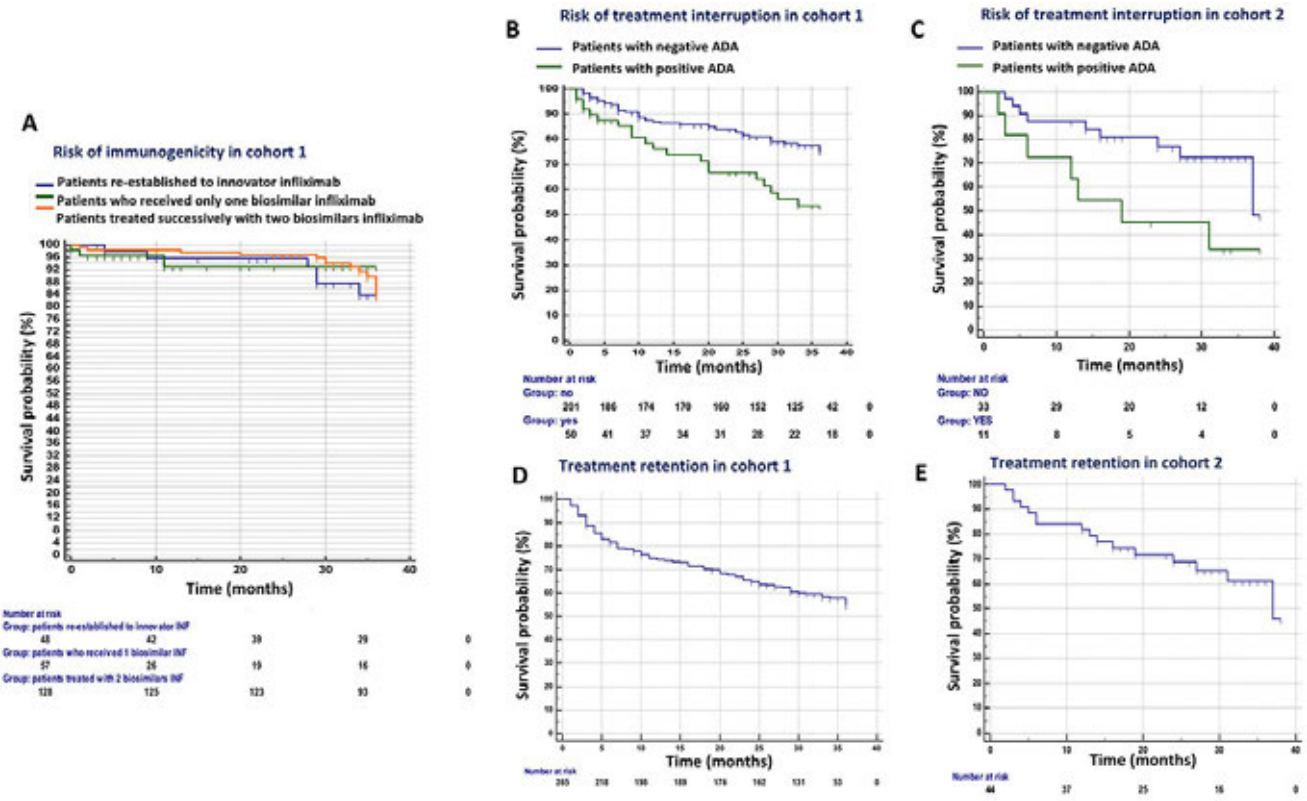
Ambre Lauret,[1] Anna Moltó,[1] Vered Abitbol,[2] Loriane Guterlann,[3] Ornella Conort,[3] Francois Chast,[3] Claire Goulvestre,[4] Claire Le Jeunne,[5] Stanislas Chaussade,[2] Christian Roux,[1] Frédéric Batteux,[6] Maxime Dougados,[7] Yannick Allanore,[1] and **Jerome Avouac**[1], [1]Paris Descartes University, Cochin Hospital, Rheumatology department, Paris, France, [2]Paris Descartes University, Cochin Hospital, Gastroenterology department, Paris, France, [3]Paris Descartes University, Cochin Hospital, Department of Pharmacy, paris, France, [4]Paris Descartes University, Cochin Hospital, Immunology Laboratory, Paris, France, [5]Paris Descartes University, Cochin Hospital, Internal Medicine department, Paris, France, [6]Paris Descartes University, Cochin Hospital, Immunology Laborator, Paris, France, [7]Cochin Hospital, Paris, France

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Epidemiology & Public Health Poster I: RA
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: To determine whether the successive switches from innovator infliximab to a first then a second biosimilar infliximab, or from a first to a second infliximab biosimilar, increase the risk of immunogenicity during a 3-year observation period.

Methods: This is a usual care study performed in the Rheumatology, Gastroenterology and Internal Medicine departments of Cochin Hospital, Paris, France. Two independent cohorts were constituted; Cohort 1 included patients on maintenance therapy with the original treatment who successively switched to CT-P13 in October-December 2015 then to SB2 in December 2017. Cohort 2 included biologic-naïve patients who received CT-P13 starting from November 2015 before being switched to SB2 in December 2017.The end of the observation period was December 2018. Immunogenicity was defined by the detection of positive anti-drug antibodies (ADA >10 ng/mL), at least at two consecutive time points.

Results: Cohort 1 consisted on 265 patients on maintenance therapy with innovator infliximab who switched to CT-P13. Then, 140 patients switched to SB2, 26 remained treated with CT-P13, and innovator infliximab was re-established in 55 patients. 30 patients (16 females) had positive ADA at baseline visit (11.3%), before the switch to CT-P13. These patients were more likely to have a BMI >30 (45% vs. 17%, p< 0.001) and received less innovator infliximab infusions (28±20 vs. 40±25 infusions, p=0.012) than patients without ADA. Among the 235 ADA-free patients at baseline, 20 patients developed ADA during the observation period, corresponding to a rate of 3 for 100 patient years. The mean time to positive ADA detection was 21±14 months (range: 1-37 months). Kaplan Meyer curve illustrating immunogenicity-free survival showed no influence of the number of biosimilars infliximab received on immunogenicity (Figure 1A). Cohort 2 consisted of 44 biologic-naïve patients who initiated CT-P13. Among these patients,



29 switched to SB2, 4 remained treated with CT-P13 and 11 discontinued the treatment before the second switch. 11/44 (25%) patients developed ADA during the observation period, corresponding to a rate of 14 for 100 patients years. Only a single patient developed ADA after the switch to SB2. The mean time to positive ADA detection was 13±11 months (range: 1-31 months). The risk of treatment discontinuation was significantly higher in patients with positive ADA in both cohorts (cohort 1: Hazard Ratio, HR: 2.37, 95% CI 1.38-4.05, p=0.002 and cohort 2: HR: 2.79, 95% CI 1.04-7.52, p=0.042) (Figure 1B-C).Predictors of immunogenicity were only identified in cohort 2: a BMI >30 at baseline visit and mean infliximab through levels < 2 mg/mL from baseline visit to ADA detection were predictive of the development of ADA with HR (95% CI) of 5.54 (1.30-23.65) and 5.53 (1.30-23.43), respectively. The retention rate of infliximab was 58% (154/265) in cohort 1 and 66% (29/44) in cohort 2 at the end of observation period (Figure 1D-E).

Conclusion: Immunogenicity was not favored by switches to biosimilars infliximab in our study. Thus, immunogenicity does not constitute a barrier to interchangeability between biosimilars infliximab in chronic inflammatory diseases.

Kaplan Meyer Survival Analyses. Risk of immunogenicity according to the number of biosimilars infliximab received (A); risk of treatment interruption according to the presence of anti-drug antibodies (ADA) in cohort 1 (B) and 2 (C); and treatment retention within the observation period in cohort 1 (D) and 2 (E)

Abstract Number: 0208

Self-Reported Sleep Disturbances in Rheumatoid Arthritis (RA)

Patricia Katz,[1] Sofia Pedro,[2] and Kaleb Michaud[3], [1]University of California, San Francisco, san francisco, CA, [2]FORWARD, The National Databank for Rheumatic Diseases, Wichita, KS, [3]FORWARD, The National Databank for Rheumatic Diseases and University of Nebraska Medical Center, Wichita, KS

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Epidemiology & Public Health Poster I: RA – ARP
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Sleep disturbances (SD) are reported to be common in RA but relatively few studies have addressed the issue. We examined the frequency and severity of self-reported poor sleep quality, symptoms of restless leg syndrome (RLS), and risk of obstructive sleep apnea (OSA) among individuals with RA, and identified predictors of SD.

Methods: Data were from FORWARD, the National Data Bank for Rheumatic Diseases, for which participants complete questionnaires every 6 months. In one questionnaire, items querying symptoms of RLS, the STOP-BANG questionnaire, a validated measure of OSA risk, physician diagnoses of OSA and RLS, and the Medical Outcomes Study Sleep Scale (MOS-S) were included. The MOS-S yields 5 subscales; results are shown here only for one (Sleep Problems Index I, SPI-I, sleep quality). was also included. Frequencies of reports of OSA risk, RLS symptoms were tabulated. Bivariate regression analyses identified predictors of OSA and RLS (logistic regression) and SPI-I scores (linear regression). Potential predictors included age, sex, race, education, smoking, Rheumatic Disease Comorbidity Index (RDCI)1, low income, obesity (BMI ≥ 30 kg/m2 and < 35), morbid obesity (BMI ≥ 35), RA duration, prednisone

Table 1. Subject characteristics (n = 2623)

	Mean ± SD or % (n)		Mean ± SD or % (n)
Demographic, general health		RA-specific	
Age, years	67.2 ± 11.3	RA duration, years	23.0 ± 11.3
Female	82.7 (2168)	Pain rating (0 – 10)	3.2 ± 2.5
White	93.4 (2449)	Fatigue rating (0 – 10)	3.8 ± 2.9
Current smoker	3.6 (94)	RA Disease Activity Index (RADAI)	2.2 ± 1.5
BMI	28.2 ± 6.7	Prednisone use	25.2 (657)
Obese (BMI≥30)	32.8 (861)	Mean prednisone dose (mgs)	7.6 ± 11.5
COPD	7.9 (208)	Biologic use	51.5 (1349)
Rheumatic Disease Comorbidity Index (RDCI; 0 – 9)	2.1 ± 1.7		
Sleep			
Mean hours	6.8 ± 1.5		
Sleep Problem Index I	33.4 ± 18.9		

Table 2. Self-reported sleep conditions

	Sleep apnea				Restless legs syndrome		
	Diagnosed				Diagnosed		
At risk based on self-report	No	Yes	Total	At risk based on self-report	No	Yes	Total
No	77.3 (2027)	8.7 (227)	85.9 (2254)	No	71.4 (1821)	2.6 (66)	74.0 (1887)
Yes	6.9 (181)	7.2 (188)	14.1 (369)	Yes	17.1 (436)	8.9 (227)	26.0 (663)
Total	84.2 (2208)	15.8 (415)		Total	88.5 (2257)	11.5 (293)	

Table 3. Significant independent predictors of sleep disturbances

	High risk for OSA*	RLS symptoms*	Sleep Problems Index I † (model 1)	Sleep Problems Index I † (model 2)
Age	(ns)	(ns)	-0.2 (.01)	-0.2 (<.0001)
Female	0.5 (0.4, 0.7)	(ns)	2.8 (.0009)	3.2 (.0001)
Low income	(ns)	(ns)	2.0 (.0083)	2.0 (.008)
Obese (BMI 30 – 35)	2.1 (1.6, 2.8)	(ns)	(ns)	(ns)
Morbid obesity (BMI ≥35)	3.4 (2.5, 4.6)	1.3 (1.03, 1.7)	(ns)	(ns)
Current smoking	1.8 (1.1, 3.1)	(ns)	4.4 (.01)	3.7 (.03)
RDCI	1.2 (1.1, 1.3)	(ns)	1.1 (<.0001)	0.9 (<.0001)
RA duration	(ns)	(ns)	-0.1 (.005)	-0.1 (.006)
RADAI	1.3 (1.2, 1.4)	1.3 (1.2, 1.3)	5.8 (<.0001)	5.3 (<.0001)
High risk OSA	---	---	---	7.1 (<.0001)
RLS symptoms	---	---	---	4.2 (<.0001)

* Tabled values are odds ratio (95% CI) from multiple logistic regression analyses
† Tabled values are beta (p-value) from multiple linear regression analysis. Higher scores reflect greater sleep problems

and other medication use, and RA disease activity (Rheumatoid Arthritis Disease Activity Index, RADAI). Variables significant in the bivariate analyses were included in multivariate regression analyses.

Results: Subject characteristics are shown in Table 1 (n = 2623). 16% reported physician-diagnosed OSA, and 14% were at high risk of OSA based on self-reported symptoms (Table 2), compared to 2-4% in the general population. Only half at high risk had an OSA diagnosis. 12% reported physician-diagnosed RLS, and 26% reported RLS symptoms, compared to ~10% in the general population. Only one third with RLS symptoms reported a physician diagnosis. Mean SPI-I was 33.4 (±18.9), ~0.5 standard deviation worse than a population sample mean. Independent predictors of high risk of OSA were male sex, obesity, current smoking, RDCI, and disease activity (Table 3). Predic-

tors of RLS symptoms were morbid obesity and disease activity. Worse scores on SPI-I were associated with younger age, female sex, smoking, higher RDCI, shorter RA duration, and greater disease activity. OSA and RLS symptoms were also independently associated with SPI-I scores.

Conclusion: Symptoms of both OSA and RLS were more common in RA than in the population; self-reported sleep quality was also worse. Some predictors of SDs were similar to predictors in the population (e.g., age, obesity), but disease activity was also consistently associated with SD. Research in RA has linked SDs to worse outcomes. Previous research in other conditions suggests that SDs might also be a cause of increased disease activity through heighted inflammation. Further research is needed to tease out disease-specific causes and effects of SD in RA.

Joint Overuse in Patients with Rheumatoid Arthritis

Daisuke Kobayashi,[1] Sachimi Amao,[2] Satoshi Ito,[3] Kiyoshi Nakazono,[3] Hajime Ishikawa,[4] and Ichiei Narita[1], [1]Division of Clinical Nephrology and Rheumatology, Niigata University, Niigata, Niigata, Japan, [2]Nursing department, Niigata Rheumatic Center, Shibata, Japan, [3]Department of Rheumatology, Niigata Rheumatic Center, Shibata, Japan, [4]Department of Rheumatology, Niigata Rheumatic Center, Shibata, Niigata, Japan

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Epidemiology & Public Health Poster I: RA – ARP
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The development of drug therapies for rheumatoid arthritis (RA), and control of synovitis has now become easier. However, once patients are relieved of pain, they become physically more active and sometimes overuse their joints. Such overuse can result in progression of joint deformity, joint destruction, and in some cases, tendon rupture. However, the actual situation of joint overuse in RA patients remains insufficiently recognized. Here we analyzed the clinical characteristics of such patients who had overused their joints.

Methods: In-depth history taking about joint overuse and physical examinations were performed prospectively for 3148 consecutive patients with RA who visited our outpatient department between August 2016 and October 2016. The patients who satisfied the following inclusion criteria were diagnosed as having joint overuse: (i) met the 2010 American College of Rheumatology/European League against Rheumatism criteria for RA, (ii) had experienced preceding events that exerted a strain on the joints, and (iii) had joint pain and/or swelling of the strained joints. Patients who were suspected of having other conditions such as infection, trauma, pseudogout, and gout were excluded. Among the patients, 41 (10 men and 31 women) were diagnosed as

having joint overuse. The patients' clinical features and laboratory data before they developed joint overuse were collected from their medical records. As comparative controls, we selected 123 age- and sex-matched contemporary patients with RA who had no joint overuse from among 3148 patients. Comparisons between the parameters at different time points were performed using the Friedman test, and a post hoc analysis was performed using the Wilcoxon signed-rank test with Holm correction. The data were expressed as median (interquartile range).

Results: Forty-one patients with a mean age of 62.0 years (range, 54.0–69.0 years) were diagnosed as having joint overuse. The different joints affected by overuse were the wrist (16), hand (thumb and fingers, n = 12), shoulder (4), knee (3), ankle (3), and forefoot (3). The reasons for overuse were occupational in 25 patients, housework in 10, hobbies in 5, and ceremonial occasions in 1. The clinical disease activity index at baseline was 5.00 (2.60–9.00), which increased to 9.00 (6.00–11.3) owing to overuse, and improved to 4.80 (2.20–9.00) at the next visit ($p < 0.001$ and $p < 0.001$, respectively). The 28-joint Disease Activity Score based on erythrocyte sedimentation rate, C-reactive protein, visual analog scale score for pain, and swollen joint count was also elevated transiently. Logistic regression analysis revealed that treatment with biological disease-modifying antirheumatic drugs (bDMARDs; odds ratio [OR], 3.28; 95% confidence interval [CI], 11.32–8.17), low health assessment questionnaire disability index (HAQ-DI; OR, 0.301; 95% CI, 0.11–0.85), and Steinbrocker stage III or IV (OR, 6.89; 95% CI, 2.57–18.5) were significantly associated with the development of joint overuse.

Conclusion: When patients with advanced RA have low HAQ-DI using bDMARDs, they are at risk of joint overuse. Appropriate education would be important for such patients to prevent the overuse.

Abstract Number: 0210

Associations of Clinical Biomarkers with Radiographic Progression of Rheumatoid Arthritis (RA) in African Americans with Early Disease

Emma Astrike-Davis,[1] Rebecca Cleveland,[1] Beth Jonas,[1] and Leigh Callahan[1], [1]Thurston Arthritis Research Center, Chapel Hill, NC

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Epidemiology & Public Health Poster I: RA – ARP
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: To analyze longitudinal data from the Consortium for the Longitudinal Evaluation of African Americans with Early Rheumatoid Arthritis Registry (CLEAR) for the association between biomarkers including the HLA-DRB1 shared epitope (SE), anti-cyclic citrullinated peptide (CCP), and rheumatoid factors IgA and IgM (RFIgA and RFIgM) with changes in radiographic progression from study enrollment (< 2yrs disease duration) to 60-month disease duration. Cross-sectional studies have shown an association between SE, CCP, and RF and disease severity in various cohorts of patients with RA. This study seeks to determine the independent effects of these biomarkers as predictors of radiographic progression among African American patients while controlling for the effects of other comorbidities, socioeconomic factors, age, sex, and RA medication.

Table 1. Baseline Characteristics of the CLEAR Consortium who participated in the 60-month fol

Characteristic	Baseline
Demographics	
Age, Mean (Std Dev)	51.07 (12.3)
Female, N (%)	166 (85.6%)
Months of Disease Duration, Mean (Std Dev)	14.05 (7.2)
Years of Follow up, Mean (Std Dev)	4.09 (0.7)
On Methotrexate and/or Leflunomide, N (%)	125 (64.4%)
Number of Comorbidities (Std Dev)	3.09 (2.2)
BMI, Mean (Std Dev)	31.83 (7.5)
Ever Smoker, N (%)	107 (55.2%)
Biomarkers	
CRP, Mean (Std Dev)	17.21 (42.6)
ACCP Positive, N (%)	227 (64.2%)
RGFIgA Positive, N (%)	248 (70.1%)
RGFIgm Positive, N (%)	257 (72.7%)
Has Shared Epitope, N (%)	150 (42.5%)

Table 2. Radiographic measures over time in the Consortium for the Longitudinal Evaluation of African Americans with Early Rheumatoid Arthritis Registry (CLEAR) (n=194)

	Baseline	60 Months
Radiographic Disease Scores		
Erosion Score, Mean (Std Dev)	1.27 (3.8)	2.12 (7.6)
JSN Score, Mean (Std Dev)	1.79 (5.0)	5.29 (12.6)

Methods: We analyzed data on 194 African American patients with information on biomarkers including SE, CRP, CCP, RFIgA and RFIgM as well as radiographic outcomes including erosion scores and joint space narrowing (JSN) at baseline and after 60 months of disease duration. Radiographic disease progression was determined by increase in disease scores from baseline to 60-month disease duration follow-up, and individuals with severe progression were identified as those in the top worst quintile of disease score increase (Erosion≥1; JSN≥7). Demographics, comorbidities, medications, and measures of SES were also collected at the baseline assessment. Multiple imputation was used to impute missing values. Multivariable multi-level linear and logistic regression models with study site adjusted for as a random effect were used to estimate linear coefficients (β), odds ratios (aOR) and 95% confidence intervals (CI) for disease prevalence and progression in relation to biomarkers at baseline. All models were adjusted for gender, age, BMI, number of comorbidities, cigarette smoking, disease duration at study entry, methotrexate/leflunomide (MTX/LEF) use, education level (< high school [HS] vs ≥ HS), home ownership, professional occupation, as well as simultaneous adjustment for all biomarker predictors.

Table 3. Adjusted[§] associations of predictors of RA joint damage at baseline

	EROSION SCORES				JSN SCORES			
	Baseline Cross-Sectional	Baseline to 5 years Progression			Baseline Cross-Sectional	Baseline to 5 years Progression

No, Mean (Std Dev)	1.44 (0.67)	Erosion Score increased <1	104/41		No, Mean (Std Dev)	1.78 (9.3)	Erosion Score increased <1	113/41
Yes, Mean (Std Dev)	1.09 (0.63)	Erosion Score increased ≥1	39/10		Yes, Mean (Std Dev)	2.51 (8.8)	Erosion Score increased ≥1	30/10
Estimate (95% CI)	-0.35 (-2.20,1.50)	Odds Ratio (95% CI)	1.36 (0.31-5.90)		Estimate (95% CI)	0.73 (-1.85,3.31)	Odds Ratio (95% CI)	0.87 (0.15-4.90)
Has Shared Epitope		Has Shared Epitope	Cases/Controls		Has Shared Epitope		Has Shared Epitope	Cases/Controls
No, Mean (Std Dev)	0.91 (0.50)	Erosion Score increased <1	57/88		No, Mean (Std Dev)	2.20 (7.0)	Erosion Score increased <1	58/95
Yes, Mean (Std Dev)	1.63 (0.56)	Erosion Score increased ≥1	22/27		Yes, Mean (Std Dev)	2.09 (7.8)	Erosion Score increased ≥1	21/20
Estimate (95% CI)	0.72 (-0.39,1.83)	Odds Ratio (95% CI)	1.15 (0.56-2.36)		Estimate (95% CI)	-0.12 (-1.60,1.37)	Odds Ratio (95% CI)	1.71 (0.80-3.66)

[§]Adjusted for age, sex, BMI, use of Methotrexate/Leflunomide, ever smoking, number of comorbidities, education, home ownership, occupation; study site adjusted for as a random effect

[‡]All biomarkers simultaneously adjusted in models

Results: At baseline the mean age was 51 years, 86% were female, average RA disease duration was 14.05 months, and 64.4% patients were on MTX/LEF (Table 1). Radiographic measures at baseline and 60 months are shown in Table 2. Beta estimates for the cross-sectional association between baseline biomarkers and baseline radiographic measures are shown in Table 3. Also in Table 3 are odds ratios for the association between baseline biomarkers of interest and severe radiographic progression. Results did not indicate an association of CCP, RF, or SE with severe radiographic progression in this cohort.

Conclusion: Our findings show modest associations between biomarkers and radiographic severity in cross-sectional analyses. However, when analyzing biomarker predictors of radiographic progression, CCP, RFIgM, RFIgA, and SE are not significantly associated with disease progression in African Americans over a 60-month disease duration with early RA. Future larger longitudinal studies are needed to confirm our results.

Session Date: Sunday, November 10, 2019

Session Title: Fibromyalgia & Other Clinical Pain Syndromes Poster

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: The management of fibromyalgia is difficult, combining pharmacological and non-drug treatments, including massage. Its pathophysiology, still poorly understood, is complex, including muscle anomalies with reduced ATP and microcirculation. To date, only superficial massages have been tested in fibromyalgia. Deep haptic massage, used in athletes, have an action on muscle structures by reaching the free nerve endings present in

the muscle and to ensure a “gate control” of the pain. The purpose of this pilot study was to evaluate the effects of deep haptic massage in fibromyalgia.

Methods: Preliminary monocentric open ended prospective study from october 2015 to november 2017.

Inclusion criteria : women, 18 to 65 years, fibromyalgia by ACR criteria, with a White Spread Index (WPI) ≥ 7 and severity score (SS) ≥ 5 or WPI between 3 and 6 and SS ≥ 9, with stable treatment for 1 month without modification expected within the next 6 months.

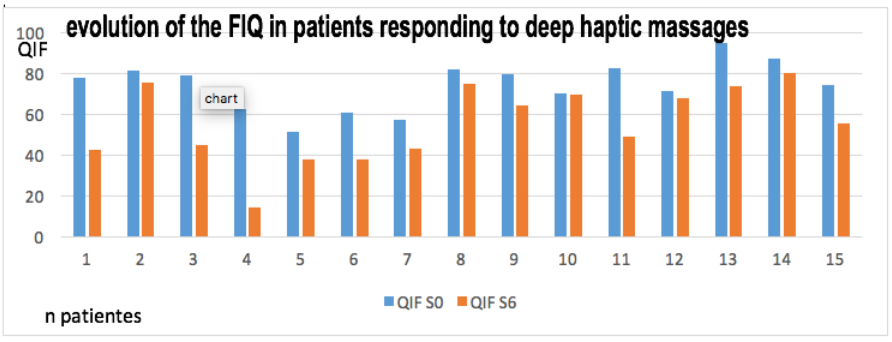
Non inclusion criteria : pregnant women, chronic inflammatory rheumatism, infection disease, individualized psychiatric pathology, severe visceral impairment, non-drug combination therapy, skin lesions contraindicating massages.

Intervention : 2 sessions of deep haptic massage of 30 minutes per week for 6 weeks.

Evaluation at week 0 (S0), S6, S12 and S24. Main evaluation criteria at S6 : fibromyalgia Impact Questionnaire (FIQ). Secondary criteria FIQ to S12 and S24 and sub-items from FIQ to S6, S12 and S24. EVA patient and physician satisfaction at S6, S12 and S24. The analysis of the evolution of the FIQ score carried out using a T Test for a sample.

Results: 21 patients were included (1 study discharge at 3 months), including an age median of 53 (47-57), medians WPI 15 (13-18) and SS 9 (8-11). The average FIQ was from 68.8±16.1 to S0, 60.1±16à S6, 65.7±18.8 à S12 and 68.4±14.5 to 6 months. An average variation between S0 and S6 of -8 percent (ns). No change in sub-items of the FIQ is not significant. The medians of EVA satisfaction at S6 for the patient and physician were similar, respectively 7,5/10 and 6/10. At 3 and 6 months from the massage, EVA satisfaction decreases in a similar way in patients and doctors (5/10 and 4.5/10 respectively). In a subgroup of 14 patients “deep haptic massage reponders”, there is an average variation between S0 and S6 of -26 percents (FIQ means : S0 : 74.03±12.8; S6 : 55.37±19.7).

	J0/J45 (n=21)	J0/J90 (n=21)	J0/J180 (n=20)
Score QIF moyenne	-7,7 (-25,8 - 11,9) *p 0,1293*	2,4 (-19,5 – 12,4) *p 0,5389*	-1,5 (-10,7 – 8,1) *p 0,7538*



Evolution of QIF in patients responding to deep haptic massages

Conclusion: In our study, deep haptic massage does not appear to be effective in the management of fibromyalgia. Nevertheless, positive effects in a subgroup representing more than 50 percents of patients encourage further investigation on a larger scale.

Utility of Mood Disorders Questionnaire in Fibromyalgia: Data from the Cleveland Clinic Fibromyalgia Registry

Carmen Gota,[1] Sahar Kaouk,[2] Kinanah Yaseen,[1] Nilamba Jhala,[1] and William Wilke[3], [1]Cleveland Clinic, Cleveland, OH, [2]University of Dayton, Gates Mills, OH, [3]Cleveland Clinic, Richmond Heights, OH

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Fibromyalgia & Other Clinical Pain Syndromes Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with comorbid fibromyalgia syndrome (FMS) and bipolar disorder (BD) were found to have more severe FMS. The Mood disorders questionnaire (MDQ), a self-reported inventory of lifetime history of manic and hypomanic symptoms has been proposed as a screening tool for BD, but its specificity for BD has been controversial. We evaluated the relationship between MDQ and a history of self-reported prior clinical diagnosis of BD.

Methods: Consecutive patients diagnosed clinically with FMS were enrolled and demographic, socioeconomic and clinical data were collected. Patients completed the following standardized questionnaires; for depression PHQ-9 (patient health questionnaire), anxiety GAD-7 (generalized anxiety disorder questionnaire), disability HAQ-DI (health assessment questionnaire disability index), PDI (pain disability index), PSD (polysymptomatic distress scale/fibromyalgianess scale), WPI (widespread pain index), SS (symptom severity scale), FIQ (fibromyalgia impact questionnaire).

Results: We enrolled 430 patients with FMS who completed the MDQ and also reported a history of psychiatric evaluation, of which 118 (27.5%) had bipolar disorder by either MDQ or prior psychiatric diagnosis. The mean age was 43.3 (12.0), 89.3% female and 87.7% met the ACR 2010 criteria for FMS. The mean MDQ was 3.9 (3.3) and 20.9% had an MDQ >=7. A psychiatric diagnosis of BD was made in 59 (13.7%) of patients; 6.7% (29%) had a BD diagnosis by psychiatry and an MDQ of < 7. Thirty patients (7%) had a diagnosis of BD both by MDQ and psychiatry. Correlation between MDQ and a past psychiatric diagnosis of BD was low, r= 0.293 (p< 0.005). The sensitivity of an MDQ ³7 for a prior diagnosis of BD was 42.4% and the specificity was 13.5%. Patients with MDQ³ 7 had significantly higher scores on depression and anxiety as well as higher fibromyalgianess, fibromyalgia severity and disability scores (Table 1). We performed three separate linear regression analyses to predict FMS severity measured by FIQ from depression (PHQ-9), anxiety (GAD-7) and bipolar disorder determined by MDQ, psychiatric diagnosis or both. Depression and anxiety but not a positive screen for BD either by MDQ, prior clinical diagnosis of BD or either, remained independent predictors of FIQ variance.

Conclusion: The utility of MDQ as a screening tool for BD in patients with FMS, as well as the impact of a psychiatric diagnosis of BD on FMS measures and severity, needs to be further evaluated. Nevertheless, patients with high MDQ scores seem to have more severe depressive and anxiety symptoms and score higher on FMS measures of severity and impact.

Abstract Number: 0213

Relationship Between a History of Abuse and Fibromyalgia Symptoms and Severity: Data from the Cleveland Clinic Fibromyalgia Registry

Carmen Gota,[1] Sahar Kaouk,[2] Kinanah Yaseen,[1] Nilamba Jhala,[1] and William Wilke[3], [1]Cleveland Clinic, Cleveland, OH, [2]University of Dayton, Gates Mills, OH, [3]Cleveland Clinic, Richmond Heights, OH

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Fibromyalgia & Other Clinical Pain Syndromes Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: It has been proposed that the fibromyalgia syndrome (FMS) phenotype is determined by genetic factors, lack of physical exercise, mood disorders, maladaptive pain responses, and both current and past stressors, including a history of abuse. In this study we examined the predictive role of a history of abuse on FMS severity measures, and the association between self-reported abuse and socioeconomic status, symptoms, psychiatric comorbidities, and disability.

Methods: All consecutive patients clinically diagnosed with FMS who answered the question 'Do you have a history of abuse?" were enrolled. Patients' characteristics were compared between those who reported a history of abuse and those how did not. Linear regression analysis was performed to determine the predictive effect of a history of abuse on fibromyalgia impact questionnaire and fibromyalgianess scale, used as FMS severity measures.

Results: We enrolled 593 consecutive patients with FMS, mean age 43.8 (12.3), 87% female, of which 85.2% met the ACR 2010 criteria. A history of abuse was reported by 223 patients, sexual abuse by 125 (56.5%), physical abuse by 155 (69.5%) and both by 78 (34.9%). Fibromyalgia patients with a history of abuse had worse socioeconomical status as measured by higher percentages of single and divorced patients, lower education level, lack of private insurance and greater reliance on Medicare and Medicaid, lower employment rates, and higher disability compared with those without abuse. A higher prevalence of personal and family history of psychiatric comorbidity was found in patients with a history of abuse. Fibromyalgia severity scores, including fibromyalgianess scale, pain disability index, fibromyalgia impact questionnaire and the health assessment disability index were all higher in patients with FMS and a history abuse compare to those without abuse (Table 1). A linear regression model predictied 46% of FMS severity measured by fibromyalgia impact questionnaire variability, $p< 0.0005$, from abuse, exercise, non-refreshing sleep, current stressors, depression and anxiety (Table 2). A similar model, $p< 0.0005$, predicted 32% of fibromyalgianess scale variability (Table 3).

Conclusion: Our results suggest that stressors such as abuse have a wide range of detrimental effects on FMS. We recommend that abuse should be inquired about in all patients evaluated for FMS as this may give more clarity to the nature and severity of the FMS presentation and prompt the need for psychological interventions.

How Well Do Visual Analogue Scales Used in the Fibromyalgia Impact Questionnaire (FIQ) Correlate with Other Measures of Pain, Fatigue, Sleep, Sleep Disturbance, Anxiety and Depression in Patients with Fibromyalgia

Carmen Gota,[1] Sahar Kaouk,[2] Kinanah Yaseen,[1] Nilamba Jhala,[1] and William Wilke[3], [1]Cleveland Clinic, Cleveland, OH, [2]University of Dayton, Gates Mills, OH, [3]Cleveland Clinic, Richmond Heights, OH

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Fibromyalgia & Other Clinical Pain Syndromes Poster

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Fibromyalgia syndrome (FMS), is a biopsychosocial condition characterized by widespread pain, fatigue, non-refreshing sleep, and various degrees of anxiety and/or depressive symptoms. Visual analogue scales (VAS) for pain, fatigue, sleep, anxiety, depression, are patient reported, uni-dimensional continuous scales, widely used in FMS as measures of symptom intensity and as outcome measures in drug trials. There is limited data on how well these VAS scales correlate with other "alternative measures" of pain, fatigue, sleep, anxiety and depression and with global measures of FMS severity and impact.

Table 1: Pearson correlations between VAS pain, VAS fatigue, VAS waking up unrefreshed, VAS anxiety and "alternate measures" of sleep, pain, anxiety and depression (WPI, ESS, hours of sleep, GAD-7 , PHQ-9) and FMS measures of severity and impact: PSD, FIQ, HAQ-DI and PDI.

Variable	VAS fatigue	VAS waking up unrefreshed	VAS depression	VAS anxiety	WPI	Hours of sleep	ESS	PHQ-9	GAD-7	SS	FIQ	PSD	HAQDI	PDI

VAS Visual analogue scale, ESS Epworth sleepiness scale, GAD-7 Generalized anxiety disorder scale, PHQ-9 Patient health questionnaire 9, WPI Widespread pain index, SS Symptom severity scale, PSD Polysymptomatic distress scale /Fibromyalgiaeness scale, FIQ Fibromyalgia impact questionnaire, HAQ-DI Health assessment questionnaire disability index , PDI Pain disability index

*P<0.000, **p<0.05 NS-not statistically significant

Methods: Consecutive patients diagnosed clinically with FMS were enrolled. Patients completed the following VAS scales: VAS pain, VAS fatigue, VAS waking up unrefreshed, VAS anxiety and VAS depression. As " alternative measures" we used: for pain the Widespread pain index (WPI), for sleep the mean hours of sleep per night and the Epworth sleepiness scale (ESS), for anxiety the Generalized anxiety disorder questionnaire (GAD-7) and for depression the Patient health questionnaire (PHQ-9). The following severity/impact measures were used: Fibromyalgia impact questionnaire (FIQ), the Polysymptomatic distress scale/Fibromyalgianess scale (PSD), calculated as the sum of the Widespread pain index (WPI) and Symptom severity scale (SS), the Health assessment questionnaire (HAQ-DI), and the Pain disability index (PDI). Pearson correlation, r was used to measure two-way linear association between two continuous variables; strong correlations are defined as r ³ 0.7, moderate r ³ 0.5, < 07, weak ³ 03,< 05, and very weak r < 0.3.

Results: We enrolled 763 consecutive patients, 82.4% who met the ACR 2010 criteria for FMS. Patients had the following characteristics: 86.6% were female, 80.3% white, age 44.3 (12.4), PHQ-9 12.7 (8.0), GAD-7 8.8 (6.3), VAS pain 7.1 (2.1), VAS fatigue 7.8 (2.1), VAS waking up rested 7.7 (2.4), VAS anxiety 5.1 (3.3), VAS depression 4.5 (3.3), WPI 11.9 (4.3), hours slept per night 5.9 (2.1), ESS 9.5 (5.6), GAD-7 8.8 (6.3), PHQ-9 12.7 (6.3), FIQ 61.7 (20.3), PSD 20.8 (17.0), PDI 5.5 (2.3), HAQ-DI 1.0 (0.6). Correlations between variables are presented in Table 1.

Conclusion: We found that VAS pain and WPI are poorly correlated with each other which suggests that they cannot be used interchangeably and probably both should be used when characterizing the pain of FMS patients.

The very poor correlation of VAS waking up unrefreshed with daytime sleepiness measured by ESS and the mean hours of sleep per night, suggests that a more complex and multidimensional measure of sleep is needed to characterize sleep in FMS patients.

The VAS measures of depression and anxiety had moderate and strong correlations with the alternative measures, PHQ-9 and respectively GAD-7, which indicates VAS depression and anxiety can be used as quick measures of current depressive and anxiety symptoms.

Many studiers of FMS severity report only the FIQ total score and use only the VAS components for more specific measures. This analysis suggests that if alternative measures of specific symptoms rather than VAS FIQ components are used, results and/or conclusions may be different.

Opioid Treatment Pattern in a Community Based Rheumatology Clinic

Reema Andrade,[1] Paula Roe - Prior,[2] Oanh Doan,[2] and Julio Ramos[2], [1]The Wright Center For Graduate Medical Education, Crofton, MD, [2]The Wright Center For Graduate Medical Education, Scranton, PA

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Fibromyalgia & Other Clinical Pain Syndromes Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatologic pain, especially fibromyalgia, is difficult to treat. While Nonsteroidal anti-inflammatory drugs (NSAIDs) are traditionally prescribed as the first line treatment for fibromyalgia, when patients are unable to tolerate, or the pain persists, or when other treatment modalities have failed, opioids have been prescribed.

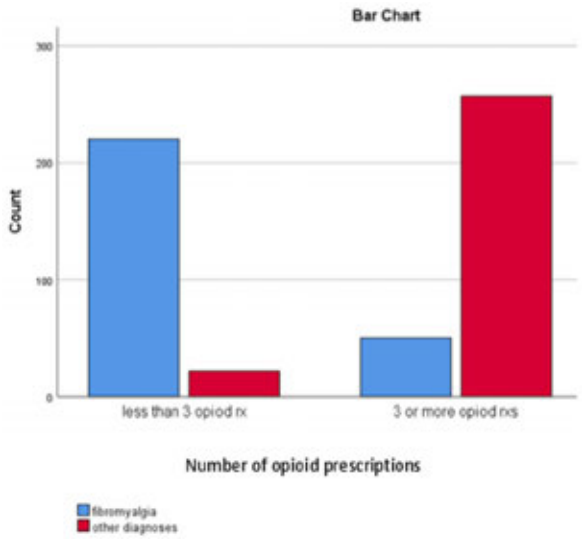

Table 1. Primary diagnosis and Number of opioid prescription ≥ 3

Primary Diagnosis		
Fibromaylgia	Other	No diagnosis
51 (16.4%)	258 (83.0%)	2 (0.6%)
χ^2 =26.65 , p<0.001		

Table 2. Type of opioid and number of opoid prescription ≥ 3

	Weak	Strong	Statistical Significance
Fibromyalgia	7 (14%)	43 (86%)	X^2 =187.25 , p< 0.001
Other	48 (18.7%)	209 (81.3%)	χ^2 = 0.623 , p= 0.43
Total	55	263	

BASDAI

Even though the guidelines do not recommend opioids for the routine treatment of pain in rheumatologic conditions, they are frequently used.

Purpose: To identify the rheumatologic diagnosis for which opioids are most frequently prescribed at one community-based outpatient clinic.

Methods: The medical records of 553 patients treated at the rheumatology clinic from January 1, 2016 until December 31, 2017 were reviewed. To be included in the study, the patients had to have received at least one opioid prescription, but only those who received three or more opioid prescriptions were considered to be reliant on opioids for pain control. The variables used for data collection were age, gender, the primary and secondary rheumatology diagnoses, NSAID prescription as well as the number, name and dose of opioid prescribed. Tramadol and codeine were considered weak opioids, while Fentanyl, Morphine, Oxycodone, Hydrocodone were classified as strong opioids.

Results: Fibromyalgia (FM) was the most common patient diagnosis at 49%, the other 51% had a variety of rheumatologic diagnoses with the next most frequent being rheumatoid arthritis 7%, followed by lupus, 3%, then primary osteoarthritis 2%,, and Sjogren's 1.4%(Image1). Data was missing on 4 patients. Fifty-six per cent (n=311) of the sample had received three or more opioid prescriptions. Of those who received three or more opioid prescriptions, 84% had a diagnoses other than FM, a difference that was statistically significant (χ_2 = 302, p < .001)(Table1). When receiving three or more opioids, 86% (n = 43) of the 51 FM patients who were opioid-dependent for pain control had

been prescribed a strong opioid compared to the other diagnoses, 253 (81.4%) of whom were receiving a strong opioid(Table 2).

Conclusion: Although most research on opioid prescription for rheumatologic pain control has found that FM is the most common diagnosis, this was not the case for one community-based clinic. These results may be attributable to differences in prescribing practices in a community clinic versus a tertiary setting where most of the research has been conducted. Or perhaps patient preferences for treatment accounted for the differences. Additionally the disease duration and degree of suffering for our sample could not be ascertained and it may be that this sample was intrinsically different from others who have been studied.

Does Fibromyalgia Change the Evaluation of Spondyloarthritis Activity? A Meta-analysis of Observational Studies

Arthur Beck,[1] Lilian SOLE,[1] Thomas Barnetche,[2] and Pascale Vergne-Salle[1], [1]CHU de LIMOGES, LIMOGES, France, [2]CHU de BORDEAUX, BORDEAUX, France

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Fibromyalgia & Other Clinical Pain Syndromes Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Recent studies evaluated the prevalence of Fibromyalgia (FM) in Spondyloarthritis (SpA) and its impact on disease activity scores, but none meta-analysis exists yet. Therefore, we performed a meta-analysis to evaluate the impact of fibromyalgia on activity scores in SpA.

Methods: We performed a systematic review of the literature until May 2019 using database including: MEDLINE (via PUBMED), EMBASE and abstracts from the ACR and EULAR congresses 2016-2019. We selected observational studies comparing characteristics of SpA patients (defined by ASAS, NY modified or CASPAR criteria) with or without fibromyalgia (defined by ACR 1990, 2011 fibromyalgia criteria or FiRST survey).

Two readers extracted the prevalence of FM in SpA, female ratio, HLAB27 status, disease duration, radiographic sacroiliitis, C-reactive protein (CRP), BASDAI, BASFI, ASDAS-CRP and Quality of Life (QoL).

Statistical analysis determined in each study theeffect size. Data was analyzed using the inverse variance approach.

Results: The literature search identified 433 articles. Finally, 15 studies met the inclusion criteria.

The prevalence of FM in SpA was 17% IC95% [0.12, 0.23] with a significant female ratio of 5.13 IC95%[3.02, 8.70] in SpA with FM.

FM impacted significantly all the activity scores of SpA: BASDAI: OR= 2.18 IC95%[1.45, 2.91]; BASFI: OR= 2.33 IC95%[1.65, 3.02]; ASDAS-CRP: OR= 0.54 IC95%[0.05, 1.02]; AsQoL: OR=5.50 IC95%[4.28, 6.71]

No statistical difference was found concerning HLAB27 status, disease duration and CRP level.

Conclusion: In this meta-analysis, the prevalence of FM in SpA was 17%, whereas 2-8% in general population. The coexistence of FM with SpA led to higher activity scores, including ASDAS-CRP, although CRP trends to be lower in the FM group.

Rheumatologist have to be aware of the association of FM and SpA, activity scores may be biased.

Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Fibromyalgia (FM) is a condition characterized by chronic widespread pain, tender points, fatigue and disturbed sleep rhythm. Some of these symptoms such as fatigue, tender points and diffuse pain seen in patients with spondylarthritis (SpA). Moreover, FM and SpA can coexist creating a diagnostic challenge, particularly in early disease course and influence clinical disease activity assessment. With this cross-sectional study, we aim to estimate the prevalence of FM in SpA and to elaborate its effect on biological treatments.

Methods: FM was identified according to the ACR 2010 diagnostic criteria. SpA patients identified according to rheumatologist using various SpA subsets criteria. A review of the electronic medical files for SpA patients attending the rheumatology outpatient clinic and infusion unit at a major tertiary hospital during the period from June to December 2018 were included. Patients' demographics, disease characteristics were explored. Regarding SpA medications, number, frequency and dose of DMARDs and biological agents were obtained. Continuous variables were reported by their mean and standard deviation (SD) and qualitative variables by frequency and percentage. Statistical significance was set at $p < 0.05$. Statistical analysis was performed using SPSS version 23.

Results: Of the 305 enrolled SpA patients, 43 (14.1%) had FM. Females represents 57.4% of the patients, mean age was 44.07 ± 11.85 years. Arab ethnicity represents most of our cohort 84.9%, the majority were Emirati 64.6%. Smokers were 8.2% and ex-smokers were 3.3%. HLA B27 tested in a sample of 180 patients; it was positive in only 17.8%. Abnormal MRI SIJ bone marrow edema changes were found in 10.8%, while other SIJ changes was seen in additional 20.6%. The prevalence of FM showed no statistically significant difference between axial and peripheral SpA. Patients with SpA and FM have longer disease duration than SpA alone, P= 0.034. Table.1 show demographics and clinical data. Regarding medication, the use of biologics in SpA patients with FM is more frequent than SpA patients without FM (74.4% vs 51.5 % respectively), P= 0.005 (Figure: 1). Interestingly, the likelihood ratio testing showed that SpA patient with Fibromyalgia switch more frequently to another biologics, P= 0.015 (Figure: 2). Cramer's V test showed that there is a high statistically significant (P= 0.002) and very strong association (> 0.25) between presence of Fibromyalgia and multiple switching of biologics in SpA. There was no difference in the exposure to prednisolone nor conventional DMARDs between SpA patients with or without FM, P= 0.64 & 1 respectively.

Conclusion: FM coexistence with SpA might impact clinical evaluation of disease activity and negatively affect measures of treatment response. In our study, SPA patients exposed to more biologics if they have coexisting FM; Moreover, they are more frequent switchers among biologics including TNFi and IL17i.

Effects of Tai Chi versus Aerobic Exercise on Mindfulness in Fibromyalgia

Augustine Lee,[1] Lori Lyn Price,[2] Raveendhara Bannuru,[3] and **Chenchen Wang**[4], [1]Department of Physical Medicine and Rehabilitation, Tufts Medical Center, Tufts University School of Medicine, Boston, MA, [2]Tufts Medical Center, Tufts University, Boston, MA, [3]Tufts Medical Center, Boston, MA, [4]Tufts Medical Center, Boston

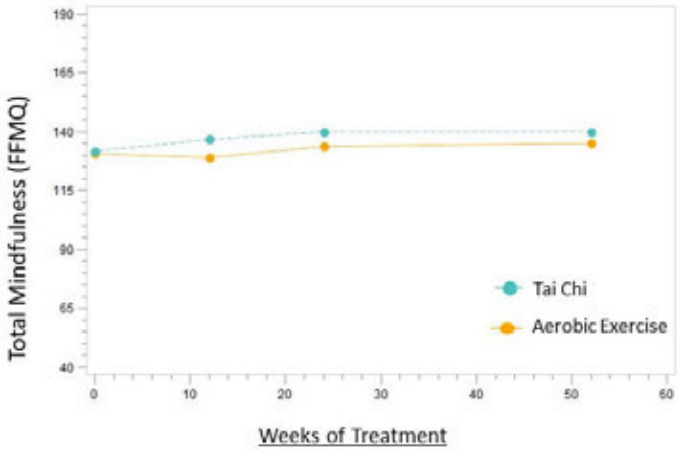
SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Fibromyalgia & Other Clinical Pain Syndromes Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Emerging evidence shows that Tai Chi mind–body practice may result in greater benefits in pain and psychological symptoms of Fibromyalgia (FM). Mindfulness is the ability to maintain a heightened awareness of moment-to-moment experiences without judging or reacting, and its improvement through mind-body

Table. Change in Total Mindfulness Levels After Intervention

Variable	Mean change from baseline (95% CI)		Mean Between group difference (95% CI)	Interaction p- value
	TC (n=151)	AE (n=75)		
Total FFMQ				0.11
Week 12	3.58 (1.08, 6.08)	-1.24 (-4.84, 2.35)	4.8 (0.45, 9.20)	
Week 24	7.27 (4.55, 9.98)	2.50 (-1.46, 6.46)	4.8 (-0.03, 9.57)	
Week 52	5.97(2.63, 9.32)	3.89 (-1.01, 8.79)	2.08 (-3.85, 8.02)	

Table FAST3 indices vs 2011 FM CriteriaTable. Percent agreement and kappa of 3 FAST3 (fibromyalgia assessment screening tool3) indices vs 2011 FM Criteria



practice is widely believed to contribute to the therapeutic benefits of Tai Chi. Observational studies have shown that mindfulness is associated with improved health outcomes among patients with FM. However, little is known about the contribution of mindfulness to the treatment effect of Tai Chi interventions among patients with chronic musculoskeletal pain. Therefore, our purpose was to investigate the effects of Tai Chi mind–body practice compared to aerobic exercise (AE) on mindfulness among adults with FM.

Methods: Secondary analysis of a single-blind trial randomizing adults with FM (ACR 1990 and 2010 Criteria) to either AE (twice per week for 24 weeks) or 1 of 4 Tai Chi intervention groups (once or twice weekly for 12 or 24 weeks). Participants completed the Five Facet Mindfulness Questionnaire (FFMQ) and other health outcome measures before and after intervention. Repeated measures regression models with interaction of evaluation (0, 12, 24, 52 weeks) and treatment group were used to compare change over time in total and facet FFMQ scores between the AE group versus the average of the 4 Tai Chi groups based on the intention to treat principle.

Results: Among 226 randomized participants (mean age 52 years, BMI 30kg/m^2, 92% female, 61% white), baseline mean total FFMQ score was 131.3 ± 20.7. FFMQ significantly improved from Tai Chi at all timepoints (**Table**). However, change in FFMQ from AE did not reach significance. Between group difference for total FFMQ favored Tai Chi at all timepoints and trended toward significance (**Figure**, p=0.11). Similar results were found for the Observing (p=0.11) and Acting-With-Awareness (p=0.18) facets of mindfulness, while the Non-Judging, Describing, and Non-Reacting facets did not significantly improve than from AE (p=0.41 to 0.62).

Conclusion: This is the first study to evaluate the effects of Tai Chi mind–body practice with active exercise in FM. Although Tai Chi significantly improved mindfulness from baseline, these differences did not reach significance when compared to changes from AE group. This suggests that mindfulness may not primarily account for the distinct health benefits from Tai Chi compared with AE shown in prior studies among these patients. Further study is needed to identify underlying mechanisms of effective mind–body interventions to advance treatment-making decisions for clinicians and patients.

AE = Aerobic Exercise; CI= Confidence Interval; FFMQ = Five Facet Mindfulness Questionnaire; total score = 39 to 195, higher scores reflect higher mindfulness; TC= Tai Chi. P≤0.05 was considered statistically significant.

Figure. Change in Mindfulness Between Treatment Groups: FFMQ = Five Facet Mindfulness Questionnaire; total score = 39 to 195, higher scores reflect higher mindfulness. Evaluations were completed at 0, 12, 24, and 52 weeks.

A Fibromyalgia Assessment Screening Tool on a Multidimensional Health Assessment Questionnaire (MDHAQ) Which Does Not Include a Self-Report RADAI Painful Joint Count (RADAI), FAST3nJC, Recognizes Fibromyalgia Similarly to Other FAST3 Indices Which Include a RADAI

Theodore Pincus,[1] Isabel Castrejon,[2] and Joel Block[2], [1]Division of Rheumatology, Rush University Medical Center, Chicago, IL, [2]Rush University Medical Center, Chicago, IL

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Fibromyalgia & Other Clinical Pain Syndromes Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Fibromyalgia (FM) generally is easily recognized, but a diagnosis may be difficult, particularly in patients with secondary FM who have other primary diagnoses. Criteria for FM initially were reported in 1990, and revised in 2010, 2011 and 2016. The 2 most recent criteria are based entirely on patient self-report, which is not collected in most routine clinical care, as multiple patient questionnaires are not feasible in busy clinical settings. MDHAQ/RAPID3 (multi-dimensional health assessment questionnaire/routine assessment of patient index data) is informative in all diseases studied. Cumulative indices based on MDHAQ scales known as FAST3 (fibromyalgia assessment screening tool3) recognize FM at levels of agreement with revised FM criteria of >80% and correlations of >0.80, p< 0.001), and might provide clues to recognize FM in patients with non-rheumatic diseases, as most components of the MDHAQ (as well as the HAQ) appear generic rather than disease-specific, other than a RADAI self-report painful joint count. Therefore, we analyzed a FAST3-nJC (no RADAI JC) index versus 2011 FM criteria as a reference standard, and compared to other FAST3 indices which include a painful RADAI JC.

Methods: All patients with all diagnoses complete an MDHAQ at all visits in routine care at one setting. The self-report questionnaire to recognize the 2011 FM Criteria was added over a 6-month period to be completed by consecutive patients. The MDHAQ includes 0-10 scores for physical function, and pain and patient global visual analog scales (VAS), compiled into 0-30 RAPID3, as well as a 0–10 fatigue VAS, 0–54 self-report painful joint count, and 0–60 symptom checklist. Each MDHAQ scale was analyzed for agreement with FM Criteria according to receiver-operator-characteristic (ROC) curves for area under the curve (AUC). Optimal cut points for each measure were identified, based on specificity and sensitivity, to develop optimal cumulative indices for clues to FM versus the 2011 Criteria as "gold standards."

Results: Among 502 patients with complete data, primary ICD-10 diagnoses were FM in 49, OA in 74, RA in 78, SLE 88 and other rheumatic diseases in 213. Primary or secondary FM was identified in 131 (26%) who met 2011 FM criteria. The 4 MDHAQ scales with the highest AUC vs FM Criteria (0.829-0.889) and optimal cut-points, were symptom

checklist 16/60, RADAI JC 16/54, fatigue VAS 6/10, and pain VAS 6/10. FAST3 0-3 measures were calculated as 0 or 1 based on cut-points for each measure, FM=2 or 3: FAST3-P= symptom checklist+RADAI JC+pain VAS; FAST3-F=symptom checklist+RADAI JC+fatigue VAS; FAST3nJC=symptom checklist+painVAS+fatigue VAS(no RADAI). All FAST3 indices agreed with FM Criteria >80% and kappas were >0.58, indicating good agreement (Table). Lowest agreement was seen for FAST3nJC, expected as FM criteria include a self-report painful joint count, but differences are small.

Table: Baseline Factors Associated with Response to 24-week Treatment

Characteristics	OR* (95% CI)	p-value
Gender, female	1.33 (0.46,3.83)	0.60
Age, yrs	0.98 (0.96,1.01)	0.17
Race		
White	0.77 (0.42,1.43)	0.41
Education		
High School	0.90 (0.21,3.87)	0.88
Living Alone	**0.56 (0.31,1.02)**	**0.06**
BMI, kg/m^2	1.00 (0.96,1.05)	0.97
Duration of Body Pain, yrs	0.98 (0.95,1.02)	0.31
Widespread Pain Index	1.01 (0.93,1.09)	0.83
Symptom Severity	**1.14 (0.99,1.32)**	**0.08**
FIQR	**1.02 (1.01,1.04)**	**0.01**
Patient's Global Assessment	1.00 (0.86,1.16)	0.98
Beck Depression Inventory-II	**1.03 (1.00,1.05)**	**0.05**
HADS Anxiety	1.05 (0.97,1.13)	0.24
HADS Depression	1.04 (0.97,1.12)	0.29
Arthritis Self Efficacy Scale	1.06 (0.92,1.22)	0.45
Coping Skills Questionnaire	**1.19 (0.97,1.46)**	**0.09**
Pittsburgh Sleep Quality Index	0.95 (0.88,1.02)	0.17
6-minute Walk Test, m	1.00 (1.00,1.00)	0.76
Physical Component Score of Short Form-36	1.01 (0.97,1.05)	0.55
Mental Component Score of Short Form-36	**0.97 (0.95,1.00)**	**0.08**
Analgesics	0.84 (0.45,1.60)	0.60
NSAIDs	1.12 (0.48,2.60)	0.80
Narcotics	0.69 (0.38,1.26)	0.22
Hypertension	0.98 (0.52,1.86)	0.95
Diabetes	0.74 (0.26,2.15)	0.54
Heart Disease	1.67 (0.56,4.98)	0.35
Outcome Expectations for Exercise	0.96 (0.64,1.44)	0.85
Tai Chi vs. Aerobic Exercise	1.24 (0.65,2.34)	0.51

*OR = Odds ratio, CI = confidence interval

Conclusion: FAST3nJC had slightly lesser agreement with 2011 and 2016 FM criteria than FAST3-P and FAST3-F but would appear satisfactory to provide clues to recognize FM in patients with non-rheumatic diseases, although a diagnosis of FM ultimately is made by a physician.

Abstract Number: 0220

A Positive Response to Nonpharmacological Therapies in Patients with Fibromyalgia

Raveendhara Bannuru,[1] Michelle Park,[2] Lori Lyn Price,[3] and Chenchen Wang[4], [1]Tufts Medical Center, Boston, MA, [2]Tufts University School of Medicine, Boston, MA, [3]Tufts Medical Center, Tufts University, Boston, MA, [4]Tufts Medical Center, Boston

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Fibromyalgia & Other Clinical Pain Syndromes Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Identifying the factors associated with response to nonpharmacological therapies in patients with fibromyalgia will help personalize treatments and provide information to improve the design and interpretation of future research. We used results from a large comparative effectiveness trial of Tai Chi versus aerobic exercise to investigate baseline characteristics associated with clinical response at 24 weeks in patients with fibromyalgia.

Methods: We analyzed data from a randomized trial which enrolled 226 adults with fibromyalgia as defined by the ACR 1990 and 2010 criteria. Participants were assigned to aerobic exercise (2x/week for 24 weeks) or one of four Tai Chi interventions (1x or 2x/week for 12 or 24 weeks) and followed for 52 weeks. Results from the trial showed that all treatment groups demonstrated improvement in revised fibromyalgia impact questionnaire (FIQR) scores, but the combined Tai Chi groups improved significantly more in FIQR score at 24 weeks than the aerobic exercise group. Although a minimal clinically important difference (MCID) in response has not yet been determined for the FIQR, FIQR scores correlate closely with scores of the original fibromyalgia impact questionnaire (FIQ) ($r=0.88$, $P< 0.001$). Based on the established MCID of the FIQ, we estimated the MCID of the FIQR to be 14% or 8.1 units on a 0-100 scale. We performed a stepwise multivariable analysis to investigate baseline variables associated with positive response (our criteria for entry was univariate $p< 0.10$). Baseline variables included demographics (sex, age, race, education, and whether they live alone) and clinical measurements (BMI, duration of body pain, pain index, symptom severity, FIQR, global assessment, depression, anxiety, self-efficacy, coping skills, sleep quality, 6-minute walk test, physical and mental quality-of-life components of the Short-Form 36, analgesic use, comorbidities, and outcome expectations).

Results: Mean age of the 181 participants with complete data at 24 weeks was 52.3 years, 91.7% were female, average BMI was 30.1 kg/m2, and average duration of body pain was 12.4 years. Mean FIQR at baseline was 55.5. There were 108 participants (60%) who responded to either treatment. When the six variables which were significant ($p< 0.10$) in the univariate analyses were included in the multivariate analysis, only FIQR remained significant (**Table**). Having a higher FIQR score or greater impact of symptoms was significantly associated with clinically meaningful improvement at 24 weeks (**$p = 0.01$**). Response did not significantly differ by treatment.

TABLE 1. FIBROMYALGIA EMERGENCY DEPARTMENT UTILZATION

Age	Total number of visits: N	Percent of visits	Rate of Visits per 100,000 persons	Age (mean)	Total number of admissions to same hospital: N
<17	135	0.82	0.2	13.33	9
18-44	7,475	45.46	6.4	35.1	253
45-64	7,058	42.93	8.4	52.96	365
65-84	1,676	10.19	3.9	71.81	152
85+	98	0.6	1.5	86.93	19
all ages	16,442	100	5.1	46.64	800

TABLE 2: FIBROMYALGIA EMEGENCY UTILIZATION BY GENDER

GENDER	Total number of visits: N	Percent of visits	Rate of Visits per 100,000 persons	Age (mean)	Total number of admissions to same hospital: N	Percentage admissions to same hospital: %
Male	1,020	6.2	0.6	45.21	59	5.80
Female	15,417	93.8	9.4	46.73	742	4.80

Conclusion: Individuals with fibromyalgia who had more severe symptoms seem to experience greater clinical improvement from nonpharmacological interventions such as Tai Chi or aerobic exercise than those who are less impacted by their condition. More studies are warranted to confirm whether other clinical variables may be associated with positive response. These findings will aid in improving the design of future trials for patients with fibromyalgia.

Emergency Department Utilization for Fibromyalgia Patients

Soumyasri Kambhatla,[1] Estefania Gauto-Mariotti,[2] and AUGUSTINE MANADAN[3], [1]John H. Stroger Hospital of Cook County, Chicago, [2]Cook County Health, chicago, [3]Rush University Medical Center, chicago

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Fibromyalgia & Other Clinical Pain Syndromes Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Fibromyalgia (FMS) is a common pain syndrome affecting millions of people in the USA. It is normally managed in the outpatient setting by rheumatologists, pain physicians, and primary care physicians but

some FMS patients seek care in emergency departments (ED). In this abstract, we describe ED visit utilization for patients with FMS based on billing codes.

Methods: Data were abstracted from the National Inpatient Sample Databases. This database is the largest longitudinal collection of inpatient admission and emergency department data in the USA. It is a nationally representative sample from approximately 1000 hospitals. The numbers in the databases are weighted to optimize both national estimates and longitudinal analysis. The databases were searched for ED visits in 2016 with a listed ICD-10 code for fibromyalgia M79.7 as the principal diagnosis. Total number of FMS ED visits, gender, age, number of hospital admissions, and inpatient charges were recorded.

Results: 16,442 ED visits had an ICD-10 FMS code listed as the principal diagnosis in 2016. This is estimated to be 5.1 ED FMS visits per 100,000 persons. The age breakdown was as follows: < 17 =135 (0.82%), 18-44 =7,474 (45.46%), 45-64 = 7,058 (42.93%), and 65-84 =1,676 (10.19%), and ≥85= 98 (0.6%); see table 1. Gender breakdown of ED FMS visits were as follows 15,417 (93.8%) females and 1,020 (6.2%) males; see table 2. Only a small number of ED visits 800/16,442 (4.9%) resulted in an inpatient admission to the same hospital. A similar percentage of females 4.8% and males were admitted 5.8%. The charges for hospital admission were on average $29,431 and had a median of $25,806. This type of analysis is severely limited by the ED's ability to diagnose FMS and the quality of subsequent coding. These numbers may underestimate ED utilization by FMS patients.

Conclusion: This data gives us valuable information on FMS care in the USA. 16,442 visits to EDs were coded with a principal diagnosis of FMS during the year 2016. Females between the ages 18-64 were the most common to seek ED care for FMS. Patients < 18 years, > 84 years and males were the least likely to visit an ED for FMS. Fortunately only a small fraction of these ED visits led to an inpatient admission to the same hospital. Even though the overall number of ED FMS visits was small, there seems to be an opportunity to improve coordination of outpatient care to avoid unnecessary ED visits.

Abstract Number: 0222

Acupuncture for Chronic Musculoskeletal Pain: A Review of Randomized Controlled Trials

Yujuan Zhang,[1] and Chenchen Wang[2], [1]Floating Hospital at Tufts Medical Center, Boston, [2]Tufts Medical Center, Boston

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Fibromyalgia & Other Clinical Pain Syndromes Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Acupuncture has been widely used for pain relief in adults. Evidence on effects of acupuncture for pediatric chronic musculoskeletal pain is scarce. We have reviewed existing randomized controlled trials, expecting to summarize the high-quality evidence of acupuncture on chronic musculoskeletal pain before advocating it in the pediatric population.

Methods: We performed a comprehensive search in MEDLINE as well as reference lists until June 2019. Selection criteria included: chronic musculoskeletal pain, randomized controlled trials, sample size ≥20.

Table 1: Randomized Controlled Trials Evaluating Effects of Acupuncture in Chronic Musculoskeletal Pain*

Author/Year Country	Mean Age (range)	N	Duration (Week)	Intervention(s) [Blinding]	Control(s)	Indication	Author favors acupuncture
Kim E, 2019, Korea	42	106	4	TEA weekly for 4 sessions	Usual Care	chronic neck pain	Yes
Moura CC, 2018, Brazil	47	110	5	eA weekly for 5 sessions (D)	1. Sham 2. Usual care	chronic pain in spinal column	Yes
Seo BK, 2017, Korea	49	54	3	6 sessions of BVA over 3 wks [D]	Sham	chronic low back pain	Yes
Yeh CH, 2015, US	60 (20-82)	61	4	AP weekly for 4 sessions [D]	Sham	chronic low back pain	Yes
Hinman R, 2014 Australia	64	282	12	1. CA 1-2/ week for 12 wks, <=12 sessions [Tr] 2. Laser once weekly for 12 weeks [Tr]	1. Sham 2. Usual care	chronic knee pain	No, pain reduced at 12 weeks, not at 1 year
Vas J, 2014, Spain	51	265	8	AP once weekly for 8 weeks [D]	Sham	chronic pain in spine	Yes
Glazov G, 2014, Australia	57 (18-75)	144	8	1. LD Laser once weekly for 8 weeks [Tr] 2. HD Laser once weekly for 8 weeks [Tr]	Sham Laser	chronic low back pain	Yes
Ferreira LA, 2013, Brazil	32	40	12	Laser 12 sessions over 3 months [D]	Sham laser	temporomandibular dysfunction	Yes
Cho YJ, 2013, Korea	42	130	6	CA twice weekly for >=6 weeks [D]	Sham	low back pain	Yes
Mavrommatis CI, 2012, Greece	62	120	8	Pharm+ CA biweekly for 8 weeks	1. Pharm+ Sham 2. Pharm	Osteoarthritis of knee	Yes
Ahsin S, 2009, Paskistan	51	78	10 days	EA once daily for 10 days	Sham	osteoarthritis of knee	Yes
Haake M, 2007, Germany	26	1162	5	VA Twice a week for 10 sessions [D]	1. Sham 2. Usual care	chronic low back pain	No Similar to sham
Scharf HP, 2006, Germany	62	1039	6	CA 10 sessions over 6 weeks	1. Sham 2. Usual care	osteoarthritis of knee	No Similar to sham
Witt C, 2005, Germany	64	300	8	CA 12 sessions over 8 weeks	1. Sham 2. Usual care	osteoarthritis of knee	Yes, more effective than sham
Assefi NP, 2005, Afghanistan	46	96	12	CA twice weekly for 12 weeks [D]	1. Unrelated point CA* 2. Sham 3. Simulated+	fibromyalgia	No Similar to sham
Kleinhenz J, 1999, Germany	33-37	52	4	CA 8 sessions over 4 weeks	Sham	rotator cuff tendinitis	Yes Needling important

TEA: thread-embedding acupuncture; eA: ear acupuncture; BVA: bee venom acupuncture; AP: auricular acupressure; CA: traditional acupuncture; pharm: usual pharmacological therapies (etoricoxib in this trial); LD: low dose; HD: high dose; [D]: double blinding; [Tr]: triple blinding *Unrelated: acupuncture at the points unrelated to fibromyalgia; +Simulated: noninsertive simulated

Results: We identified 16 randomized controlled trials with a total of 4039 subjects met the eligibility criteria. All the subjects were age 18 or older, with most of them middle aged. Number of trials included chronic pain in temporomandibular joint (1), neck (1), back or spine (7), knee (5), fibromyalgia (1) and rotator cuff tendinitis (1). Seven trials used traditional Chinese acupuncture, two used auricular acupressure, two used verum or bee venom acupuncture, one used electro-acupuncture, two used laser with acupuncture, and one used thread-embedding acupuncture. Ten of the 16 trials (62.5%) were either double or triple blinded. Mean treatment duration was 6.6 weeks (range from 10 days to 12 weeks). **Table 1** summarizes the trials evaluating the effect of acupuncture on pain and the authors' conclusions whether the acupuncture therapies were favorable. Of the 16 trials, 12 (75%) reported that the acupuncture therapy was effective compared to a variety of control groups; nine of those trials reported better pain reduction of acpunture s than sham/placebo groups. Among those 10 trials with double or triple blinded design, 7 out of 10 trials (70%) suggested acupuncture favorable. However, 4(25%) suggested that acupuncture was not more effective than the controlled/sham groups. One trial did show a pain reduction in acupuncture groups at 12 weeks but effects did not sustain at 1-year follow up.

Conclusion: Our review showed a mixed result in the effect of acupuncture in pain relief for chronic musculoskeletal pain. The majority of the trials suggested that acupuncture maybe effective beyond the placebo effect. To date, there are no high-quality trials in pediatric population. Rigorous and well-controlled randomized trials in pediatric population are warranted.

Correlation Between Heart Rate Variability Parameters and Circulating Neuropeptides in Fibromyalgia

Laura Aline Martínez-Martínez,[1] Claudia Lerma Gonzalez,[2] María del Carmen Navarro Gonzalez,[3] Oscar Infante Vázquez,[4] Felipe Israel López Trejo,[5] Evelyn Aranda Cano,[5] Alfonso Salgado Aguayo,[3] Daniel Paz Gómez,[3] María Isabel Barrera Villalpando,[6] Luis Silveira,[7] Violeta Higuera Ortiz,[8] Angélica Vargas Guerrero,[5] and Manuel Martínez-Lavín[9], [1]Departamento de Reumatologia del Instituto Nacional de Cardiologia Ignacio Chavez, Mexico City, Mexico, [2]Departamento de Instrumentación del Instituto Nacional de Cardiología Ignacio Chávez, Mexico City, Mexico, [3]Laboratorio de Investigación en Enfermedades Reumáticas del Instituto Nacional de Enfermedades Respiratorias Ismael Cosío Villegas, Mexico City, Mexico, [4]Departamento de Instrumentación del Instituto Nacional de Cardiología Ignacio Chávez, Mexico Ciity, Mexico, [5]Departamento de Reumatología del Instituto Nacional de Cardiología Ignacio Chávez, Mexico City, Mexico, [6]Instituto Nacional de Psiquiatría Ramón de la Fuente Muñiz, Mexico City, Mexico, [7]Departamento de Reumatología, Instituto Nacional de Cardiología "Ignacio Chávez", Ciudad de México, México., Mexico, Mexico, [8]Hospital General de Zona y Medicina Familiar 8 del Instituto Mexicano del Seguro Social, Mexico City, Mexico, [9]Instituto Nacional de Cardiología Ignacio Chávez, Mexico City, Mexico

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Fibromyalgia & Other Clinical Pain Syndromes Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Heart rate variability analyses in fibromyalgia patients have shown changes consistent with sympathetic hyperactivity that theoretically could lead to chronic pain. There is little investigation on dysautonomia associated circulating neuropeptides in fibromyalgia. There are no studies correlating serum neuropeptide levels with heart rate variability parameters. The purpose of this study was to measure dysautonomia-associated serum neuropeptides levels in women with fibromyalgia and in age, sex, body mass index comparable healthy controls. Additionally to correlate neuropeptide levels with heart rate variability parameters and disease severity.

Methods: We studied 23 women with fibromyalgia without comorbid conditions and 15 matched healthy controls. At the time of the study, patients were free from medications that could affect autonomic-related neuropeptide levels. Time domain parameters were extracted from 24 hours heart rate variability recording. All participants filled out the Revised Fibromyalgia Impact Questionnaire (FIQR), Widespread Pain Index (WPI), Symptom Severity Scale (SSS), Polysymptomatic Distress Scale (PDS) and the Small Fiber Neuropathy Symptoms Survey (SFNSS). The following 7 neuropeptides levels were measured using the 7-Plex Human Neuropeptide Magnetic KitMilliplex MAP: aMSH, beta-endorphin, cortisol, neurotensin, orexin, oxytocin and substance P. The protocol was approved by the institution review board and required a written informed consent from participants. Kolmorogov-Smirnov test was used for normality analysis, Student's T test or Mann Whitney U test for comparisons and Pearson or Spearmen test for correlations. SPSS version 23.0 was used for the analyses.

Results: Beta-endorphin (669.24 ± 186.28 vs 541.71 ± 146.26pg/ml, p=0.028) and neurotensin (156.23 ± 58.15 vs 116.64 ± 47.93pg/ml, p=0.016) levels were higher in fibromyalgia patients. Both neuropeptides levels had a negative correlation with heart rate RR interval standard deviation (Rho -0.5 and Rho -0.6, p< 0.05) and with FIQR "tenderness to touch" (Rho -0.4 and Rho -0.4, p< 0.05).

Conclusion: Heart rate variability parameters suggesting sympathetic hyperactivity correlate with circulating beta-endorphin and neurotensin levels in fibromyalgia patients. Future research will define the possible clinical implications of this novel finding.

A Functional Exercise Program Improves Pain and Health Related Quality of Life in Patients with Fibromyalgia: A Randomized Controllel Trial

Giovana Fernandes,[1] Fabio Jennings,[1] Michele Nery,[1] Rebeka Santos,[1] and Jamil Natour[1], [1]Federal University of São Paulo, São Paulo, Brazil

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Fibromyalgia & Other Clinical Pain Syndromes Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Fibromyalgia (FM) is a syndrome characterized mainly by chronic generalized pain that affects the physical fitness and functional capacity of patients. There is increasing evidence of the benefits of physical exercise in improving FM symptoms, making these interventions part of therapeutic arsenal.

Methods: It is a controlled and randomized study, with blind evaluator. A total of 82 female patients with FM were included, with age between 18 and 65 years, randomized into two groups, intervention and control. The intervention group (FEG) performed functional exercise training for 45 minutes twice a week for 14 weeks. The control group (SEG) performed stretching exercises with the same duration and frequency. Evaluation instruments were: VAS - Visual Analogue Scale for pain assessment; FIQ- Fibromyalgia Impact Questionnaire, for assessing health-related quality of life; Time-up and go test for functional performance evaluation; 1RM, for evaluation of muscle strength; Bank of Welss, for the assessment of flexibility; Berg Balance Scale, to evaluate balance; and SF-36 to evaluate general quality of life. Also, the amount of analgesics used during the intervention period was assessed.

Results: 41 patients were randomized to the FEG and 41 patients to the SEG. After intervention, the FEG presented a reduction in pain and an improvement in the quality of life related to the disease, which was statistically significant compared to SEG. Regarding general quality of life, functional capacity, muscle strength, flexibility and balance, there was no difference between the groups.

Conclusion: Functional exercise training proved to be effective in reducing pain and improving the health-related quality of life of patients with FM when compared to stretching exercises.

Abstract Number: 0225

Evaluating Fibromyalgia Symptoms in Transgender Patients

Dana Levit,[1] Jacob Ablin,[1] Valerie Aloush,[1] and Iris Yaish[1], [1]Tel Aviv Sourasky medical center, Tel Aviv, Israel

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Fibromyalgia & Other Clinical Pain Syndromes Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Fibromyalgia Syndrome (FMS), characterized by widespread pain and fatigue, is known to be more prevalent in women, and has frequently been associated with stress is various models. In the current study we have evaluated the prevalence of fibromyalgia symptoms among Transgender men and women, in attempt to correlate such symptoms with gender dysphoria and gender transformation due to hormonal therapy.

Methods: Participants were recruited among patients followed at a specialized transgender clinic at the endocrinology institute of a large tertiary medical center. Participants were at various stages of the process of gender reassignment, including hormonal treatment.

After providing informed consent, participants were asked to answer the Widespread Pain Index (WPI) and the Symptom Severity Scale (SSS), in order to document the presence of symptoms related to the fibromyalgia spectrum and in order to determine the prevalence of fibromyalgia, according to the 2010-2011 diagnostic criteria.

Results: Thirty-six transgender men [Female-to-male (FTM)] and 29 transgender women [Male-to-female (MTF)] answered the questionnaires. Eight individuals form the FTM group met fibromyalgia criteria (22.2%). Only 1 individual from the MTF group met the criteria for fibromyalgia (3.4%). Among FTM individuals, 13 were evaluated both before and after initiating androgen-based hormonal treatment, in order to evaluate the effect of such treatment on symptoms.

Out of 4 individuals fulfilling fibromyalgia criteria before receiving hormonal therapy, 3 remained unchanged when re-evaluated on treatment, while 1 reported alleviation of symptoms. One individual developed fibromyalgia symptoms after 1 year of hormone treatment.

Conclusion: In this preliminary study, Fibromyalgia symptoms were found to be highly prevalent among Transgender men (FTM), at a rate significantly higher than reported in the general population. Fibromyalgia symptoms appeared to be less frequent among Transgender women (MTF).

These results are relevant for professionals treating transgender individuals in the medical or psychological field. Further research into the effects of gender and of hormone treatment on fibromyalgia and chronic pain are indicated.

Abstract Number: 0226

Hypersensitivity Beyond Pain: Hyperacusis and Hyperalgesia of Patients with Fibromyalgia

Roland Staud,[1] **Gabriella Tom**,[1] Melyssa Godfrey,[1] and Michael Robinson[1], [1]University of Florida, Gainesville, FL

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Fibromyalgia & Other Clinical Pain Syndromes Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

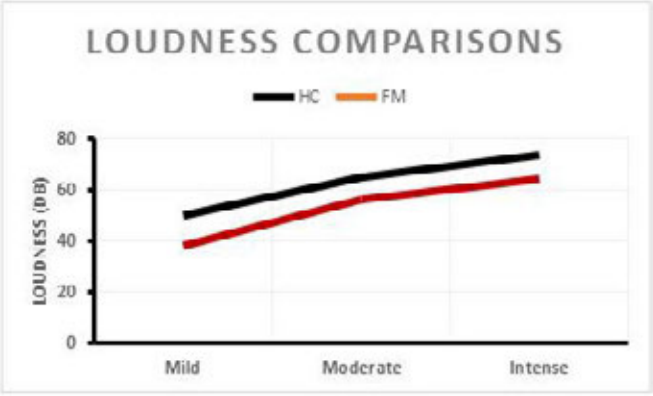
Background/Purpose: Fibromyalgia (FM) is a condition in which patients are afflicted with unexplained chronic musculoskeletal pain, insomnia and fatigue. The underlying mechanisms of this disorder is only partially understood. FM patients frequently report not only hypersensitivities to noxious but also to non-noxious sensations like light touch, sounds, and smells encountered in everyday life. Despite anecdotal reports of unusual sensory sensitivities of FM patients, there has been little or no empirical validation of these complaints in current research. The presence of such sensitivities may contribute to difficulties in function by creating an additional source of stress, anxiety, and fatigue

Hypothesis: Compared to age-sex matched healthy controls (HC), FM patients are not only hypersensitive to A) noxious heat and pressure but also to B) auditory stimuli across 3 different sound intensity levels

Methods: FM subjects fulfilled the 1990 FM Criteria and were not taking pain or psychotropic medications. HC had to be without pain and without any medications. All subjects underwent heat and pressure sensory testing at the hand using sensitivity adjusted stimuli that elicited pain rating of 5 ± 1 VAS (0-10). The subjects underwent auditory threshold testing to ensure normal hearing at frequencies between 1,000 and 4,000 Hz using a GSI 61 Clinical Audiometer. Subsequently, they received auditory stimuli of mixed frequencies at intensities that resulted in mild (12.5 dB, moderate 32.5 dB, and intense (67.5 dB) loudness. All tests were performed in triplicates.

Results: We enrolled 26 HC and 20 FM subjects (all females). Their ages were 52.3 years and 47.5 years, respectively. Avg pain of FM subjects was 4.6 VAS (0-10). Independent t-test demonstrated significantly lower temperature and pressure to achieve 5 VAS for FM subjects than HC (all $p < .001$). A mixed model ANOVA showed that FM subject required significantly less sound intensity (dB) to rate similar loudness compared to HC ($p < .001$). Pearson's product moment correlations demonstrated significant associations between auditory and heat/pressure sensitivity ($p < .05$)

Conclusion: Patients with FM are more sensitive to sensory stimuli in daily life than patients who do not experience chronic pain. Their hypersensitivity, however, seems to extend beyond heat and pressure to auditory and possibly to taste/smell and visual sensations. Our findings suggest that FM patients not only demonstrate hypersensitivity to painful but also auditory stimuli. Furthermore, auditory hypersensitivity predicted heat/pressure pain hypersensitivity. Besides genetic predisposition other factor could explain our findings, specifically the "Cognitive Activation Theory of Stress (CATS)", a theoretical model tying together chronic pain and hyperacusis. CATS postulates that sustained



arousal and lack of appropriate arousal resolution (i.e., restful sleep) can result in dysfunction of the central nervous system. In particular, chronic arousal and lack of restorative sleep, can lead to increased sensitivity to peripheral neural input, resulting in chronic pain and hyperacusis

Sound intensity ratings of FM and HC participants who received auditory stimuli of mixed frequencies that resulted in mild, moderate, and intense loudness. All tests were done in triplicates

Metabolomic and Symptom Comparison in Women With/without Fibromyalgia: A Pilot Study

Victoria Menzies,[1] Angela Starkweather,[2] Yingwei Yao,[3] Timothy Garrett,[4] Debra Lynch-Kelly,[3] Param Patel,[2] and Debra E. Lyon[3], [1]Virginia Commonwealth University School of Nursing, Richmond, VA, [2]University of Connecticut School of Nursing, Storrs, CT, [3]College of Nursing, University of Florida, Gainesville, FL, [4]Southeast Center for Integrated Metabolomics, University of Florida, Gainesville, FL

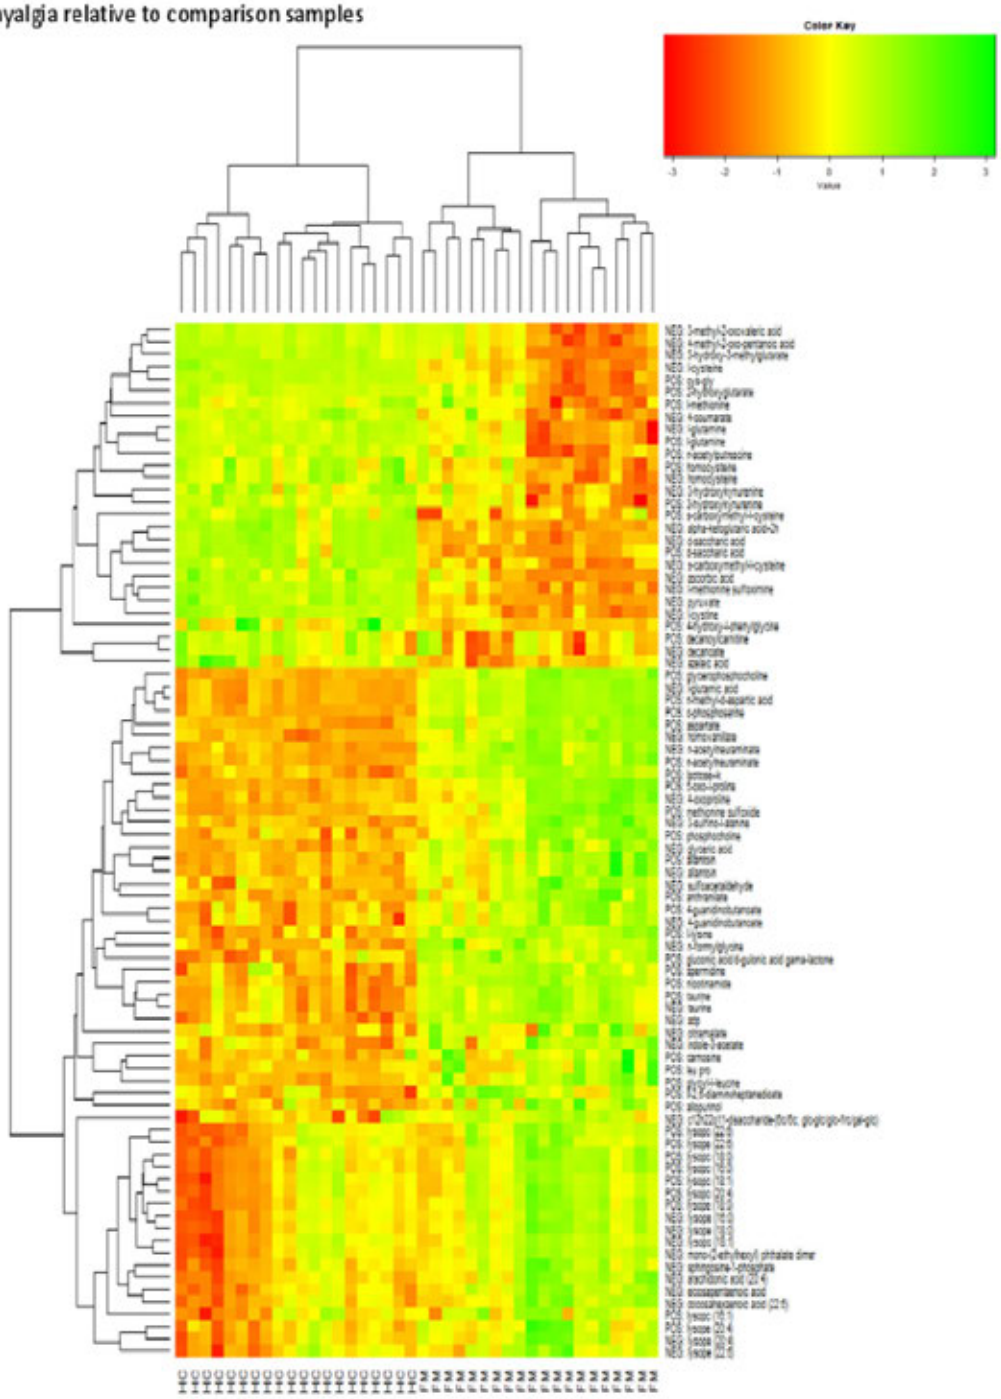
SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Fibromyalgia & Other Clinical Pain Syndromes Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The biological perturbations associated with fibromyalgia (FM) remain unclear. The recognition of objective measures to confirm FM diagnosis have not been identified. The obscurity regarding the pathogenesis of FM underscores the pressing need to enhance understanding of the biological mechanisms that may distinguish patients with FM from individuals without FM. The purpose of this pilot study was to examine levels of global metabolites and relationships among metabolites, symptoms of pain, fatigue and depression in women with FM (*n*=20) and without FM (*n*=20).

Methods: Using a cross-sectional design, we analyzed banked plasma specimens and symptom data from two FM studies and a newly recruited age-matched comparison group. Global metabolomics analysis was performed using state-of-the-art high resolution mass spectrometry coupled with ultra-high performance liquid chromatography. SIMCA-Q software, unsupervised principal component analysis (PCA) and supervised orthogonal partial least-squares discriminant analysis (OPLS-DA) were used to investigate differential metabolite concentrations between groups (fold change; FC >2 or < 0.5). Variable Importance in Projection (VIP) was calculated for each metabolite to provide a quantitative estimation of the discriminatory power of each individual metabolite to classify FM. Means and standard deviations were computed for pain, fatigue and depression scores and metabolite concentrations. Logistic regression analysis was used to compare differences among metabolites and symptoms of pain, fatigue and depression between groups. Pearson correlation coefficients were assessed between significantly differentiated metabolites and symptom severity scores.

Results: Of 1462 significantly differentiated metabolites or unknown compounds between women with and without FM, there were 48 with an FC >2 and VIP >1 and 23 with an FC< 0.5 and VIP >1 (Figure 1). These differential metabolites correctly classified women with FM from women without FM with 100% accuracy (Figure 2). Of the significantly differentiated metabolites between groups, 15 metabolites with FC >2 and 7 metabolites with FC< 0.5 had moderately strong association (r=0.51-0.63) with depressive symptoms in women with FM (Table 1). The metabolite, anthranilate, is associated with the tryptophan/kynurenine pathway, which, when dysregulated is related to depression, a

Figure 1: Statistically significant differential metabolites with FC>2.0 or FC<0.5 in women with fibromyalgia relative to comparison samples



symptom with a prevalence up to 80% in persons with FM. Additional metabolites significantly differentiated between women with FM compared to women without FM were correlated with symptom severity of fatigue (r=0.64-0.86) and pain (r=0.63-0.83), and pain interference (r=0.63-0.86).

Conclusion: The preliminary data presented suggests that metabolomic profiles can be used to classify women with and without FM, with specific metabolite concentrations contributing to symptom severity in women with FM. Future

Abstract Number: 0228

Good Pain, Bad Pain: Illness Perception and Physicians Attitude Towards Rheumatoid Arthritis and Fibromyalgia Patients

Valerie Aloush,[1] Dana Niv,[2] Jacob Ablin,[3] Iris Yaish,[3] Ori Elkayam,[3] and Odelia Elkana[2], [1]Tel Aviv Sourasky medical center, Tel Aviv, [2]Academic College Tel Aviv- Yaffo, Tel Aviv, Israel, [3]Tel Aviv Sourasky medical center, Tel Aviv, Israel

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Fibromyalgia & Other Clinical Pain Syndromes Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis and fibromyalgia are common diagnoses encountered in rheumatology practice. While rheumatoid arthritis is perceived as a valid medical condition and patients receive appropriate consideration and treatment, patients with fibromyalgia do not always get the same recognition for their painful condition. The aim of this study was to examine the physician's illness perceptions of these two rheumatologic disorders, and evaluate how they correlate with their frustration or resistance to admit such patients. We also aimed to check if factors such as physician's empathy and burnout influence illness perceptions and doctor- patient relationship.

Methods: Fifty-two rheumatologists attending one of the two rheumatologic national conferences during the study period were enrolled in the study. Demographic data was registered. Measures collected included the Brief Illness Perception Questionnaire (BIPQ) and the Difficult Doctor- Patient Relation Questionnaire (DDPRQ-10). Both of them were recorded twice, addressing fibromyalgia (FM) and rheumatoid arthritis (RA). Empathy and burnout were assessed by the Jefferson scale of physician empathy (JSPE) and the Shirom–Melamed Vigor Measure (SMVM)/ Shirom-Melamed Burnout Measure (SMBM).

Results: Of 52 physicians included in the study (58% men, mean age 50, mean years of practice 15), 56% were willing to accept fibromyalgia patients whereas 98% will accept rheumatoid arthritis patients. Fibromyalgia was considered a more severe disease than rheumatoid arthritis (FM- BIPQ mean score 58.6, SD 5.5 versus RA-BIPQ mean 49.7 SD 6.5, $p< 0.00$) especially in terms of consequences (beliefs about illness impact on physical, psychological and social functioning), treatment control (belief in cure through treatment), understanding and emotional response generated by the disease. Doctor-patient relationship was perceived more difficult with fibromyalgia patients compared to RA patients (FM-DDPRQ mean score 36.9, SD9.2 versus RA-DDPRQ mean 16.6, SD 7.1, $p< 0.00$). Difficult doctor-patient relationship with FM patients was significantly correlated to the lack of personal patient control over the disease ($p=0.03$), the impact of patient's emotional response ($p=0.01$), and the burden of symptoms perceived as related to fibromyalgia ($p=0.021$). Resistance to accept FM patients was not correlated with illness perception but significantly correlated with higher scores of DDPRQ ($p=0.024$), especially with feeling discomfort towards and during a meeting with a patient with fibromyalgia. No correlation was found between empathy, burnout, years of practice and illness perceptions or willingness to accept fibromyalgia patients.

Conclusion: Fibromyalgia patients were perceived as more difficult than RA patients, with a large burden of symptoms and emotional response and a lack of control on their disease. A high proportion of physicians were reluctant to accept them because they feel emotional/psychological difficulties meeting and coping with these patients. Improving illness understanding and providing coping skills to rheumatologists may improve doctors-patients relationships and outcomes.

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Fibromyalgia & Other Clinical Pain Syndromes Poster

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Fibromyalgia (FM) is a chronic nonarticular pain syndrome of unknown etiology characterized by diffuse muscular pain, fatigue and mood disturbances. Previous studies indicated the absence of skeletal muscle degeneration, regeneration or inflammation. Altered muscle fiber size distribution and decreased capillary density were the only abnormalities reported.

From the clinical point of view some FM symptoms (fatigue, pain, myalgias, trigger points, and stiffness) suggest involvement of the skeletal muscle.

The objective of this study is to determine if there are structural and functional abnormalities in the skeletal muscle in patients with primary FM assessed through a non-invasive multi-modality approach.

Methods: Female patients older than 18 years with primary FM diagnosis (fulfilling 2016 revision to the 2010/2011 ACR criteria), and a group of healthy controls matched by age and gender. Skeletal muscle morpho-structure and function were assessed by the following tests/evaluations: body mass index (BMI), total fat mass and total muscle mass calculated by direct segmental multi-frequency bioelectrical impedance analysis. Cross-sectional measurements of rectus femoris muscle area and tissue echogenicity evaluated by ultrasound and post-processing pixel analysis. Maximum handgrip strength by digital dynamometry, gait speed by 6-meter time walk test, and Fibromyalgia Health Assessment Questionnaire (FHAQ).

Results: Ninety-four FM patients and 140 healthy controls were included, mean age was 51.8 years +/- 10.8 vs 50.2 +/- 11.3, respectively (p = 0.27). FM patients compared with controls had similar BMI (27.9 kg/m^2 +/- 4.9 vs 26.8 +/- 4.5, p = 0.14), higher total body fat mass (27.8 kg +/- 9.2 vs 25.1 +/- 7.6, p = 0.04); the rectus femoris muscle area was also higher for FM patients (44.6 cm^2 +/- 11.4 vs 41.7 +/- 13.9, p = 0.05); regarding ultrasound tissue echogenicity, FM patients demonstrated higher mean brightness in rectus femoris (157.2 pixels +/- 19.4 vs 149.9 +/- 22.4, p = 0.01); lesser handgrip strength (22.0 kg +/- 6.6 vs 26.2 +/- 5.4 p = 0.0001); slower gait speed (1.14 m/s +/- 0.2 vs 1.3 +/- 0.2 p = 0.0001); and major impairment in daily activities by FHAQ (47% vs 2.90% p = 0.0001).

Conclusion: This non-invasive multimodal evaluation discloses the presence of structural and functional skeletal muscle abnormalities in women with FM. These changes can be attributed to sedentary and hypoactive lifestyle with consequent higher total body fat mass, muscular fat infiltration, and functional impairment of activities of daily living.

Alternatively, these abnormalities may also be an expression of a small-fiber polyneuropathy (myoneurovascular dysregulation). Further studies are required to elucidate its underlying pathological process.

Abstract Number: 0230

Patients with Fibromyalgia Associated with Rheumatoid Arthritis and Patients with Primary Fibromyalgia Differ in Depression, Anxiety, Stress-related Disorders and Events: A Cross-sectional Study

Fabiola Atzeni,[1] Mariateresa Cirillo,[2] Ignazio Francesco Masala,[3] Piercarlo Sarzi-Puttini,[4] and Alessandra Alciati[5], [1]Rheumatology Unit, University of Messina, Messina, Italy., Messina, Italy, [2]Rheumatology Unit, University of Messina, Italy, Messina, Italy, [3]Orthopedic and Trauma Unit, Santissima Trinità Hospital, Cagliari, Italy, Cagliari, Italy, [4]Rheumatology Unit, L.Sacco University Hopsital, Milan, Italy, Milan, Italy, [5]Department of Clinical Neurosciences, Villa San Benedetto Menni, Hermanas Hospitalarias, FoRiPsi, Como, Italy and Humanitas Clinical and Research Center, Rozzano (Milan), Italy., Milan, Italy

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Fibromyalgia & Other Clinical Pain Syndromes Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The aim was to evaluate the differences in depression-, anxiety- and stress-related events and trauma between patients with rheumatoid arthritis + Fibromyalgia [AR+FM] (SFM) and those with primary FM (PFM).

Methods: Study design: observational cross- sectional. Patients were consecutively recruited. The inclusion criteria were an age of 18-70 years; a diagnosis of RA according to the 2010 ACR criteria and FM according to the 1990 and 2016 ACR criteria. Lifetime diagnoses of major depression disorder (MDD), panic disorder (PD) and post-traumatic stress disorder (PTSD), three of the most frequently described psychiatric disorders among FM patients were made by a senior psychiatrist using the Structured Clinical Interview for DSM-5 Axis I Disorders-Clinician Version and a single, cross-sectional assessment. Depressive symptoms were measured using the Zung Self-rating Depression Scale (ZSDS). Childhood trauma was measured using the short form of the Childhood Trauma Questionnaire (CTQ). Stressful events were assessed using the validated Italian version of Paykel's Interview for Recent Life Events, a semi-structured interview investigating 64 life events. Pain was assessed using a VAS. The Italian version of the FIQ was used. Two-sided Fisher or T-test and multivariable logistic regression were performed.

Results: Seventy-seven patients were originally screened, but six were excluded. The final analysis therefore involved 70 patients, all Caucasians: 30 with PFM and 40 with AR+FM. All patients with PFM and 38 (95%) of the 40 with AR+FM were treated for FM symptoms (antidepressants, pregabalin). The rates of lifetime MDD and PD were significantly higher in the PFM patients vs RA+FM (76.7% vs 40%, p =0.003), whereas there was no between-group difference in the rates of PTSD (50% in PFM vs 15% in SFM, p.003). The PFM patients reported significantly higher levels of physical (p=0.020) and sexual abuse (p=0.011) and physical neglect (p< 0.001), whereas there was no between-group difference in the levels of emotional abuse (p=0.912) and neglect (p=0.542); consistently, the proportion of sexually abused (p=0.005) or phsically neglected patients was also higher in the PFM group (p=0.023). The rates of emotional neglect were high in both groups, without any significant difference between them. The vast ma-

jority of AR+FM patients (90%) said that only event occurring in the year preceding the onset of FM was RA, whereas the PFM patients mainly reported non-physical events (36%, particularly the ending of a relationship, or working or financial problems) or no event at all (40%), ($p< 0.001$). Multivariable logistic regression used to identify the factors predicting association of PFM/AR+FM status, showed and association with lifetime major depression, life events preceding the development of FM, and BMI ($p < 0.05$ for all).

Conclusion: The study indicate that psychiatric co-morbidities and predisposing and precipitating environmental factors are different in patients with PFM from those in AR+FM patients, thus suggesting that the putative common pathogenetic condition of sensitisation may develop through different pathways.

Abstract Number: 0231

Duloxetine for Chronic Pain Management in a Tertiary Care Rheumatology Practice: How Patients Are Doing in the Real World

Rupal Shastri,[1] Sonali Khandelwal,[2] and Najia Shakoor[2], [1]Rush University, Chicago, IL, [2]Rush University Medical Center, Chicago, IL

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Fibromyalgia & Other Clinical Pain Syndromes Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Chronic pain is a complicated issue that has received a significant amount of attention. In particular, studies suggesting the role of central sensitization in chronic pain conditions, have supported the utility of centrally acting agents in the management of these conditions. Duloxetine, a selective serotonin and norepinephrine reuptake inhibitor, has central nervous system activity and has been has been approved for these syndromes. It was initially approved in 2004 for treatment of depression and neuropathic pain. In 2008, it use extended to the management of FMS and in 2010 to the treatment of chronic musculoskeletal pain, including OA. The utility of this agent in the "real world" is not clear. Here, we evaluated the trends of duloxetine use in a tertiary care rheumatology practice for chronic pain conditions, with emphasis on length of therapy and improvement in patient-reported outcomes.

Methods: IRB approval was obtained. A single center retrospective study was performed of patients with ICD-10 diagnoses of OA, chronic pain syndromes and FMS who were prescribed duloxetine between 2010 and 2019. Age, sex, ethnicity, dose of medication, length of use and multidimensional health assessment questionnaire (MDHAQ) scores pre and post treatment were recorded. Individuals with any diagnosis of mood disorder were excluded. Chi squared and paired t tests were used to analyze differences in prescribing patterns and improvement in patient reported outcomes.

Results: Of 1700 charts reviewed, 250 met inclusion criteria. Of the patients being prescribed duloxetine, 149 had a primary diagnosis of FMS, 71 had OA and 28 had chronic pain. Results are summarized in the Tables. MDHAQ scores significantly improved with duloxetine use in FMS and OA groups, however there was no significant improvement in scores in the chronic pain group . In addition, there was significant improvement of MDHAQ scores in Caucasian and African American patients prescribed duloxetine, while this improvement was not observed in Hispanics patients. Duloxetine 30 mg daily was the most frequently prescribed dose in each condition. In total, over 54% of the patients continued therapy for over 6 months, with a mean duration of therapy in those that continued as high as 26 months in

Table 1.

Disease	Percent of total patients	Sex M/F	Mean Age (Years)	Continued therapy for 6 months or longer	Mean duration of therapy (Months)	Pretreatment MDHAQ	Posttreatment MDHAQ	P-value for change in MDHAQ
FMS	60%	7/142	50± 14	54%	18.0±18.7	17.9±6.4	16.0±6.6	0.008*
OA	29%	6/66	63±10	56%	26.0±27.8	17.8±5.7	15.4±6.4	0.003*
Chronic pain	11%	6/22	57±11	44%	19.0±23.2	18.0±4.6	16.8±6	0.326

Table 2.

Ethnicity	FMS	OA	Chronic Pain	Pretreatment MDHAQ	Posttreatment MDHAQ	P-value for change in MDHAQ
Caucasian	44%	32%	50%	15.0±5.6	13.1±6.2	0.004*
African American/Black	28%	40%	29%	21.0±4.9	18.0±5.7	0.005*
Hispanic	24%	25%	18%	19.0±5.9	18.4±6.1	0.391

the OA group. In addition, our data suggest that physicians in practice for over 15 years prescribed more duloxetine compared to those in practice less than 15 years ($p< 0.03$).

Conclusion: The results of the current study are supportive of previous clinical trial studies in that patient reported outcomes improve significantly during the period of use of duloxetine. Although this improvement cannot directly be attributed to medication use alone, its potential efficacy is also supported by the continued use of the medication for an extended period of time. Chronic pain syndrome patients did not demonstrate significant improvements, however this may be limited by the small number of patients. Interestingly, improvements varied by ethnicity, and these differences could be evaluated in future studies. Finally, considering differences in prescribing based on years in practice, education for younger professionals on the potential utility of this drug may be warranted.

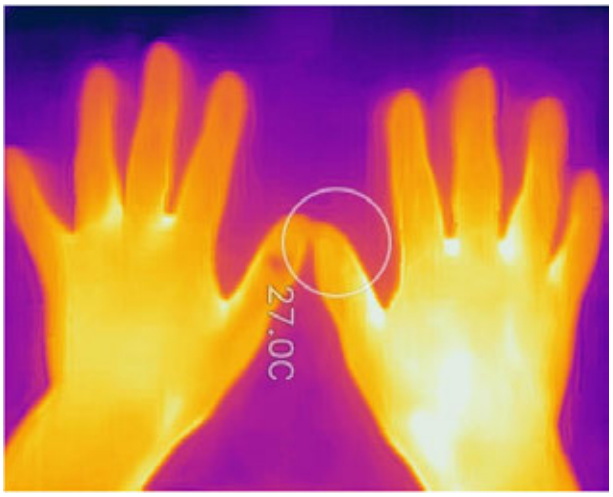
Session Time: 9:00AM–11:00AM



Hands thermography in primary fibromyalgia

Background/Purpose: Fibromyalgia is a diffuse chronic painful disease, with prevalence of 0.5% -12%, with a female:male ratio 3:10. Because of unexplained symptoms, particularly as disability pain, the primary differential diagnosis is inflammatory arthritis. Few studies have evaluated whether digital thermography can differentiate primary from secondary fibromyalgia with arthritis.

Our primary objective was identification of joint inflammation in patients with primary fibromyalgia; secondary objective, to correlate ultrasound findings hand with digital thermography, besides joint exploration of hands.

Methods: We selected patients with primary FM (Criteria ACR 2016) from January-April 2019. We did a clinical, termographic and ultrasound evaluation of the carpal, metacarpophalangeal and proximal interphalangeal joints. The clinical evaluation was made by 2 blinded rheumatologists. For the thermographic evaluation we used a digital photograph of hands at 50 cm perpendicular distance with a thermal camera Flir-One -Pro; for the analysis, the software included in the thermography equipment was used; through the thermal delta of the average temperature of the hand with respect to the joints (we considered an inflamed joint with an increase of > 0.5 ° C). Finally, we did an articular ultrasound of 22 hand joints.

Results: we included 22 patients with primary FM, of whom 3 showed inflammatory changes by thermography, the median age of these patients was 54 years (IQR 7.5) and median of BMI 23.1 (IQR 1.9). All patients had negative rheumatoid factor and anti-CCP, median erythrosedimentation rate 34 (IQR 15). With ultrasound 2 patients had joint effusion, 3 synovitis and 11 synovial hypertrophy, only 1 patient had the three features. We did not find any correlation between thermography and ultrasound ($p = 0.9$). Articular examination showed poor concordance between inflammed and painful joints (Kappa < 0.4); although with certain correlation in left (kappa 0.42) and right carpal inflammation (kappa 0.49), as well as left (kappa 0.43) and right carpal pain (kappa 0.7).

Conclusion: In patients with primary fibromyalgia without joint pain, the use of tools such as digital thermography does not provide information for ruling out inflammatory arthropathy.

Intensive CBT Is Effective in the Treatment of Significant Functional Impairment and Psychological Distress Found in Fibromyalgia: But Can We Improve Depressive Symptoms?

Barbara Bruce,[1] Madeleine Allman,[2] **Jessica Gehin**,[1] Loretta Oliphant,[1] Fernando Rivera,[1] and Andy Abril[1], [1]Mayo Clinic, Jacksonville, FL, [2]Baylor College of Medicine, Houston, TX

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Fibromyalgia & Other Clinical Pain Syndromes Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The study was designed to evaluate the effectiveness and durability of an intensive cognitive behavioral intervention on functioning and depression in patients with Fibromyalgia (FM). Despite significant statistical improvements observed in functional status and level of depression, high rates of depression remained at follow-up. Analyses were designed to determine why depression rates remained high in order to identify more effective interventions

Methods: The patients included in the study were 141 adults with a diagnosis of FM who participated in an intensive two day treatment program for FM provided at a tertiary medical center. The Center for Epidemiologic Studies of Depression Scale (CES-D) and the FM Impact Questionnaire-Revised (FIQR) were completed at the time of admission to the 2-day structured FM Treatment Program and at 3 and 6 month follow-up. The FM Treatment Program is a cognitive behavioral treatment program that focuses upon strategies to decrease central sensitization including management tools to decrease pain, fatigue, assist with sleep disturbance and improve cognitive issues associated with FM. Strategies of behavioral activation, exercise, sleep hygiene and cognitive strategies are integral aspects of the treatment program.

Results: Table 1 contains demographic information for the sample. As seen, patients were majority (85.1%) female and the average age was 52.26 years. Table 2 shows statistically significant improvements ($p < 0.001$) in depression levels (CES-D) and functional status (FIQR) at both 3 and 6 month follow up. 79.4% of patients met the clinical threshold for depression at intake. Following intervention, 52.5% and 53.9% of patients met the clinical threshold for depression at 3 and 6 month follow-up, respectively. As in Table 2, there was a significant effect of treatment on each of the CES-D subscales (Negative Affect: $p=.002$, Positive Affect: $p=.002$, Somatic Symptoms: $p < .0001$, Interpersonal Distress: $p=.019$). Of 20 CES-D items, 14 were significantly improved by treatment ($p < .05$). 6 items did not change significantly after treatment: 'I felt depressed,' 'I felt hopeful about the future,' 'I felt lonely,' 'People were unfriendly,' 'I

Oxytocin Attenuates Tactile Allodynia in Experimental Fibromyalgia Rats

Hiroyuki Takahashi,[1] Kazumasa Kuki,[1] Johji Nomura,[1] and Tsunefumi Kobayashi[1], [1]TEIJIN PHARMA LIMITED, Tokyo, Japan

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Fibromyalgia & Other Clinical Pain Syndromes Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Fibromyalgia is a chronic disease characterized by widespread musculoskeletal pain throughout the body accompanied by fatigue, sleep, and memory issues, but there are no effective drugs in clinical. Oxytocin is synthesized within the paraventricular nucleus and supraoptic nucleus of the hypothalamus, and well known to facilitate the parturition and suckling. In addition to these pharmacological effects, oxytocin has been reported to have antinociceptive effect on neuropathic pain. However, the effect of oxytocin on fibromyalgia has not been reported. In this study, we examined the effect of oxytocin using experimental fibromyalgia model rats.

Methods: SD rats were exposed to repeated cold stress (23°C for 2 h and -3°C for 2 h for 5 cycles, -3°C for 4 h for 1 cycle; for 5 days) in the automatically controlled chamber. Two days after repeated cold stress, rats were intranasally treated with vehicle or oxytocin (25 μL/body), or orally treated with Pregabalin. Mechanical sensitivity was assessed by von Frey filament at 1 and 3 h after treatment. Corticosterone and ACTH in plasma were measured.

Results: Repeated cold stress induced significant tactile allodynia in rats. Pregabalin a drug used for fibromyalgia, significantly improved allodynia at 1 and 3 h after treatment. Intranasal oxytocin significantly attenuated allodynia in a dose-dependent manner. Plasma ACTH and corticosterone were decreased in repeated cold stress rats. Intranasal oxytocin inhibited the decreases in plasma ACTH and corticosterone levels, but pregabalin failed.

Conclusion: This is the first report showing that oxytocin attenuates tactile allodynia in fibromyalgia model. Intranasal oxytocin is expected to be therapeutic option for fibromyalgia.

Muscle Pressure Correlates with Pain Levels in Fibromyalgia Patients and Muscle Tension May Be the Cause of Their Pain

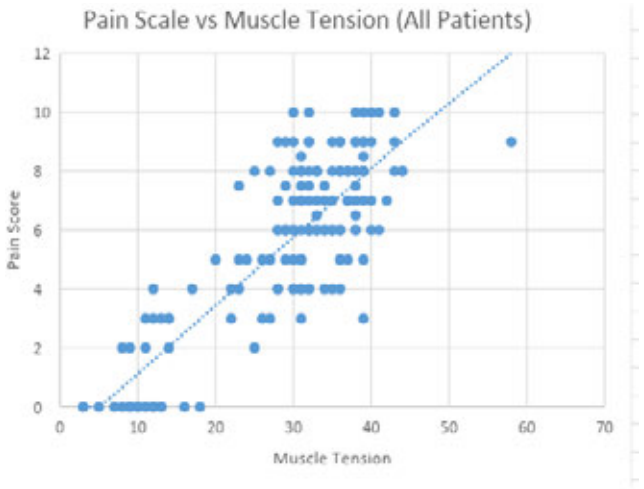
Alexandra Katz Small,[1] Ben Small,[2] Josephine Anilao,[2] Jessica Polyak Wokurka,[3] and Robert Katz[4], [1]Rush University Medical Center, Chicago, [2]Rheumatology Associates, Chicago, IL, [3]Rheumatology Associates, Chicago, [4]Rush University Medical Center, Chicago, IL

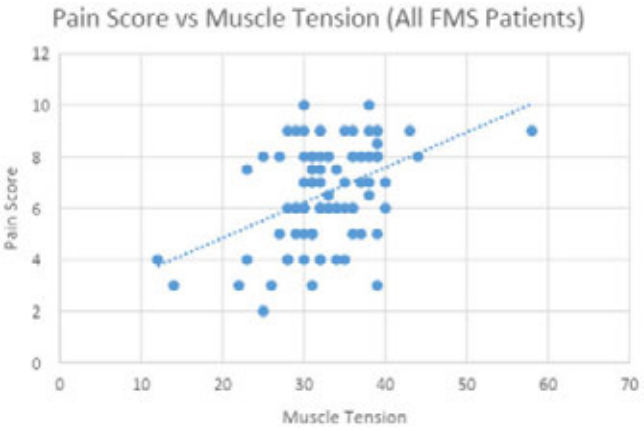
SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Fibromyalgia & Other Clinical Pain Syndromes Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

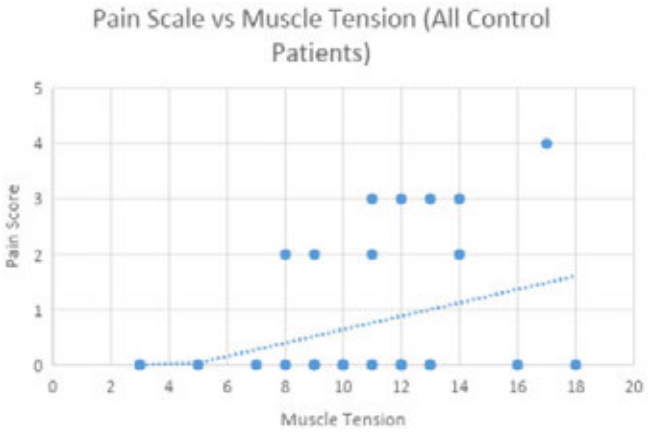
Background/Purpose: Previous research has found that muscle pressure as measured by a pressure gauge is three times higher in the trapezius muscle in fibromyalgia patients compared with non-fibromyalgia controls. We evaluated patients with fibromyalgia to determine whether there is a correlation between pain scores based on visual analog scale (VAS) 0 to 10 and the muscle pressure.

Methods: Patients signed a consent form if they were willing to have a muscle pressure measured by inserting a 22-gauge needle into the left trapezius muscle. After consent from patient, a trained nurse or physician experienced in determining muscle pressure performed the procedure and found the muscle pressure in mmHg. The muscle pressure was then correlated with the pain score of 0 to 10.

Results: For this analysis, all subjects (N=180) - regardless of diagnoses - were combined together in order to assess the correlation between the muscle tension and pain scale scores. Subjects had a median age of 47 years (range 20- 75 years), 81% were female. 79% had a diagnosis of fibromyalgia syndrome (FMS), followed by 7% having a diagnosis of rheumatoid arthritis. FMS patients had a median age of 49 years (range 20 to 75 years); 84.5% were female and 15.5 % male. In the non-FMS group (non-FMS rheumatic disease patients and controls) the median age was 45 years (range 24 to 68 years); and 68.4% were females and 31.6 % males. 142 patients had fibromyalgia and their mean (SD) pain score was 6.6 (1.84) on a 0-10 VAS. The mean (SD) pain score in the non-FMS subjects was 0.7 (1.26). The mean (SD) total population pain score was 5.5 (2.91). The calculated Pearson correlation coefficient for muscle tension vs pain scale for 175 subjects was 0.8312 (R-squared 0.6909; p-value < 0.0001). This indicates a highly significant association between subject's muscle tension and pain scores.







Conclusion: These findings demonstrate that muscle pressure directly correlates with pain scores, and this provides further evidence that muscle pressure may be the cause of much of the pain in fibromyalgia. Attempts to reduce muscle pressure with medication or other treatments could be successful in reducing pain in patients with fibromyalgia.

Abstract Number: 0236

Repeat Muscle Pressures Measured in Fibromyalgia Patients and Compared with Pain Scores

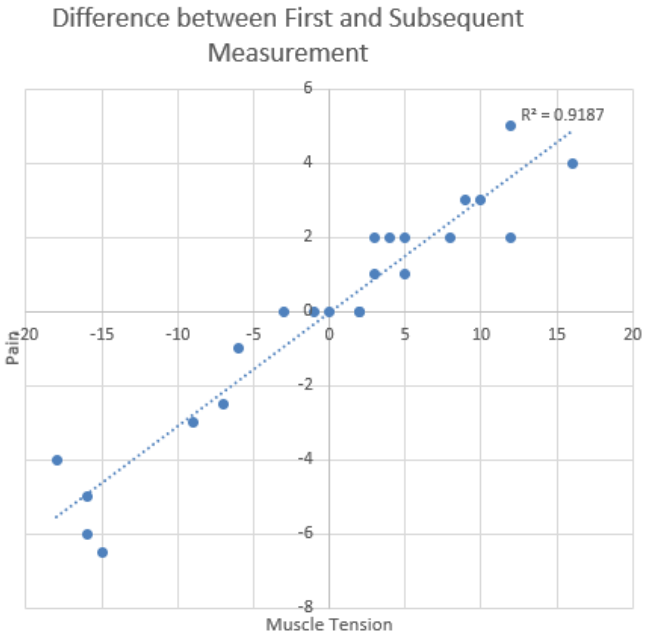
Alexandra Katz Small,[1] Ben Small,[2] and Robert Katz[3], [1]Rush University Medical Center, Chicago, [2]Rheumatology Associates, Chicago, IL, [3]Rush University Medical Center, Chicago, IL

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Fibromyalgia & Other Clinical Pain Syndromes Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Patients meeting the ACR criteria for the diagnosis of fibromyalgia were evaluated for intramuscular pressure using a pressure gauge from a trained physician or nurse. Some of these patients had a repeat muscle pressure determined using the same technique of measuring intramuscular pressure. The visual analog scale pain scores were compared and correlated with the muscle pressures.

Methods: Patients filled out a consent form after agreeing to have a repeat muscle pressure performed. A nurse or physician trained in measuring muscle pressures inserted a 22-gauge needle into the trapezius muscle, injected 0.3 cc of saline, and determined the muscle pressure using a pressure gauge. The pain score was correlated with the muscle pressure.

Results: Twenty three patients had a repeat muscle pressure done on a subsequent office visit after having an initial muscle pressure determined using the pressure gauge. The mean (SD) change in patients' muscle pressure and pain was 0 (9.81) mmHg and -0.04 (3.14). Although some patients showed improvement in muscle tension and/or pain score between visits, and some worsened, 19/23 (83%) of patients' change in both scales was in a consistent direction (both scales showed improvement or both scales showed worsening or both scales showed no change). In addition, when the change in muscle tension was correlated with the change in pain score, the resulting Pearson correlation coefficient was 0.9585 (R-squared 0.9187; p-value < 0.0001), indicating a very strong association between



the two values. The closer a correlation coefficient or R-squared is to 1, the stronger the relationship (with 1 being a perfect correlation between two variables).

Conclusion: The data show that those patients who had less pain at a subsequent office visit also had lower muscle pressure, whereas those patients who had a similar pain score based on the visual analog scale had a muscle pressure in the same range as the initial muscle pressure determination.

These findings further demonstrate that muscle pressure correlates strongly with pain scores, and this provides additional evidence that muscle pressure may be the cause of much of the pain in fibromyalgia. Attempts to reduce muscle pressure with medication or other treatments could be successful in reducing pain in patients with fibromyalgia.

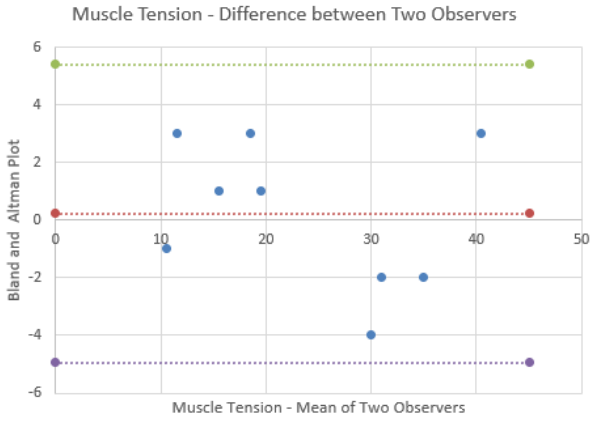
Abstract Number: 0237

Determination of Muscle Pressure in Patients with Fibromyalgia by Two Examiners; The Examiners Get Similar Results

Alexandra Katz Small,[1] Ben Small,[2] Jessica Polyak Wokurka,[2] and Robert Katz[3], [1]Rush University Medical Center, Chicago, [2]Rheumatology Associates, Chicago, IL, [3]Rush University Medical Center, Chicago, IL

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Fibromyalgia & Other Clinical Pain Syndromes Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Muscle pressure is increased in fibromyalgia as measured by a pressure gauge with a needle inserted into the trapezius muscle. We attempted to evaluate whether different examiners found the same muscle pressure using the recommended technique.



Green line = upper Bland and Altman limit of agreement
Red line = indicates the mean difference between Observer 1 and Observer 2
Purple line = lower Bland and Altman limit of agreement

Methods: Two nurses and two physicians separately determined the muscle pressure on fibromyalgia patients who met the ACR criteria for the diagnosis. A needle was inserted at a 45 degree angle up to ½ inch into the left trapezius muscle, 0.3 cc of saline was injected, and the pressure was determined using a manometer. A paired t-test and a Bland-Altman analysis were used to assess the agreement between the two professionals' muscle pressure measurements.

Results: Nine fibromyalgia patients had two muscle pressure evaluations performed by different professionals. Two rheumatology nurses, one rheumatologist and one rheumatology fellow performed the examinations. Visual analog scales were determined based on patient evaluation, and the muscle pressure was measured in mmHg. The mean (SD) of the differences between the pairs of professionals' scores was 0.2 (2.59), and this difference was determined to be insignificant (p = 0.803). Per the Bland-Altman analysis, the 95% limits of agreement are -4.9525 to 5.3970, and all the pair differences fell within these limits, indicating a high level of agreement between the data obtained by the nurses and physicians in determining the muscle pressure in fibromyalgia patients.

Conclusion: This study demonstrates that there is strong agreement - or reproducibility - between the muscle pressures measured by trained rheumatology professionals. Therefore, the measurement of muscle pressure is a reliable indicator of muscle tension in fibromyalgia patients and is a technique that is relatively easy to teach.

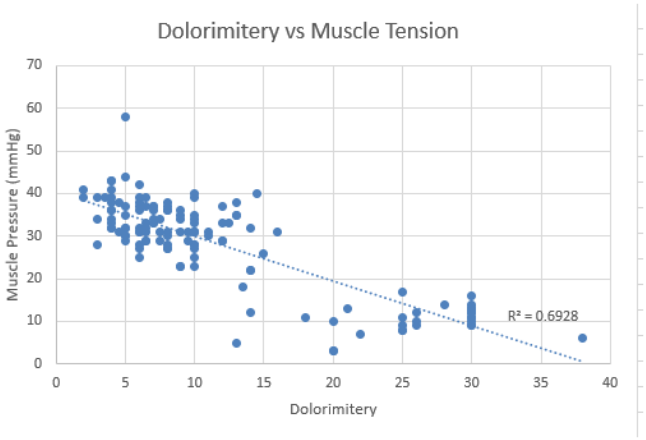
Muscle Pressure as Measured by a Manometer Correlates with Dolorimetry in Patients with Fibromyalgia

Alexandra Katz Small,[1] Ben Small,[2] Jessica Polyak Wokurka,[2] and Robert Katz[3], [1]Rush University Medical Center, Chicago, [2]Rheumatology Associates, Chicago, IL, [3]Rush University Medical Center, Chicago, IL

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Fibromyalgia & Other Clinical Pain Syndromes Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM



Background/Purpose: Muscle pressure is elevated in fibromyalgia patients compared to controls. We have demonstrated this finding in previous studies. We wanted to determine whether a noninvasive measure such as dolorimetry correlates with muscle pressure and would be a surrogate measure for muscle tension and tightness.

Methods: Patients meeting the 2010 ACR criteria for the diagnosis of fibromyalgia syndrome (FMS) signed a consent form if they were willing to have muscle pressure obtained. The pressure was determined using a manometer inserted into the left trapezius muscle by trained rheumatologists and rheumatology nurse clinicians. Dolorimetry was used to assess the amount of muscle tenderness resulting in moderate pain. A 60-pound dolorimetry gauge was used to apply pressure to the trapezius muscle, and the patient indicated when pain intensity became moderately intense.

Results: For this analysis, all subjects (N=133) - regardless of diagnoses - were combined together in order to assess the correlation between the muscle pressure and pain scale scores. Subjects had a median age of 51 years (range 20 - 75 years), 81% were female. 77% had a diagnosis of fibromyalgia. FMS patients had a median age of 52 years (range 20 to 75 years); 85.3% were female and 14.7 % male. In the non-FMS group the median age was 47 years (range 24 to 68 years); and 64.5% were females and 35.5 % males. 102 patients had fibromyalgia and their mean (SD) dolorimetry score was 8.0 (4.36). The mean (SD) dolorimetry score in the non-FMS subjects was 25.2 (5.42). The mean (SD) total population dolorimetry score and muscle tension were 12.0 (12.0) and 27.8 (27.85), respectively. The calculated Pearson correlation coefficient for muscle tension vs pain scale for 133 subjects was -0.8323 (R-squared 0.6928; p-value < 0.0001). This indicates a highly significant association between muscle tension and subject's dolorimetry scores.

Conclusion: Dolorimetry correlates with muscle pressure in patients with fibromyalgia. Dolorimetry indicates the amount of muscle tenderness present. It could be used as a surrogate measure for muscle pressure in patients with fibromyalgia

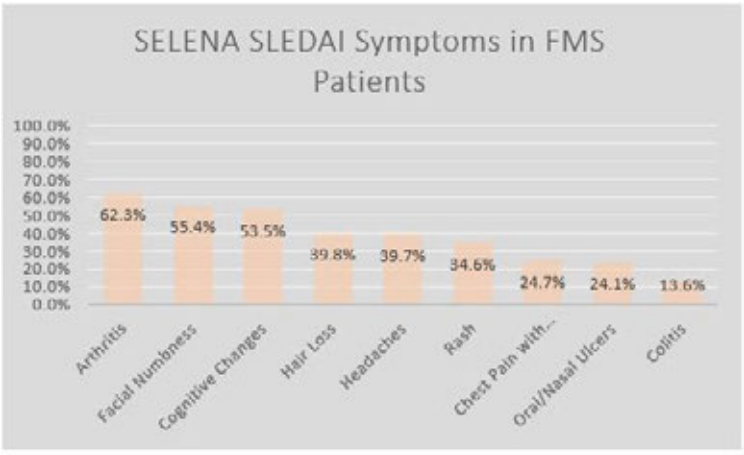
The SELENA SLEDAI Is an Imperfect Measure of Lupus Disease Activity in Patients with Concomitant Fibromyalgia

Robert Katz,[1] Jessica Polyak Wokurka,[2] and Ben Small[2], [1]Rush University Medical Center, Chicago, IL, [2]Rheumatology Associates, Chicago, IL



SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Fibromyalgia & Other Clinical Pain Syndromes Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The SELENA-SLEDAI is a tool for measuring the activity of systemic lupus. It is frequently used in clinical drug trials, but what is the value of this index in patients with lupus and concomitant fibromyalgia?

Methods: Patients were given an office questionnaire in which many of the SELENA-SLEDAI symptoms were listed.

Results: The fibromyalgia syndrome and non-fibromyalgia syndrome rheumatic disease groups did not significantly differ in age or education. In the fibromyalgia syndrome group, there were 191 patients (160 females and 31 males). In the control non-fibromyalgia syndrome rheumatic disease group, there were 130 patients (82 females and 48 males). The mean age for the fibromyalgia patients was 5

Analyzing the fibromyalgia syndrome sample, the SELENA-SLEDAI results were “arthritis” 119 patients (62.3%): cognitive changes 102 patients (53.5%); severe persistent headaches 74 patients (39.7%); hair loss 76 patients (39.8%); oral or nasal ulcers 46 patients (24.1%); facial numbness 106 patients (55.4%); chest pain with deep breathing 47 patients (24.7%); colitis 26 patients (13.6%); rash 66 patients (34.6%).

Conclusion: Patients with fibromyalgia frequently report symptoms that are part of the SELENA-SLEDAI disease activity scale. Therefore, patients with concomitant fibromyalgia and lupus may report these symptoms more commonly, and they may appear to be more resistant to treatment.

This has an important impact on clinical drug trials because the inclusion of patients with lupus and fibromyalgia together can lead to an apparent lack of efficacy for a new drug. In an evaluation of lupus patients by Wolfe, et al in 2014, of those given a diagnosis of lupus by a rheumatologist, 31% also met the criteria for fibromyalgia, based on the 2010 ACR criteria for the diagnosis.

New lupus treatments may appear to be ineffective, when actually they could be quite valuable if concomitant fibromyalgia is excluded. Using the SELENA-SLEDAI as an instrument for assessing lupus disease activity may be confounded by patients also having concomitant fibromyalgia.

Whom Do Patients with Fibromyalgia Turn to for Emotional Support?

Robert Katz,[1] Jessica Polyak Wokurka,[2] and Ben Small[2], [1]Rush University Medical Center, Chicago, IL, [2]Rheumatology Associates, Chicago, IL

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Fibromyalgia & Other Clinical Pain Syndromes Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Fibromyalgia patients often have intense symptoms, especially pain and fatigue. We asked them in an in-office questionnaire whom they turn to for emotional support.

Methods: One hundred and fifteen fibromyalgia patients completed the questionnaire concerning emotional support.

Results: See Chart

Conclusion: Fibromyalgia patients most often find emotional support from their spouse (63%), but also frequently from friends (57%). They less commonly turn to professional support (21%) for their stressful symptoms. Fibromyalgia likely puts a significant strain on relationships and quite possibly fibromyalgia patients should be encouraged to receive professional support. Rheumatologists should help fibromyalgia patients find professional help for the emotional stress of their somatic symptoms.

FMS		%	Rheumatic Disease Controls

Abstract Number: 0241

Comparing Patients with Fibromyalgia Syndrome with Non-Fibromyalgia Rheumatic Disease Patients Regarding Exercise

Robert Katz,[1] and Jessica Polyak Wokurka[2], [1]Rush University Medical Center, Chicago, IL, [2]Rheumatology Associates, Chicago

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Fibromyalgia & Other Clinical Pain Syndromes Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Exercise is reported to help patients with the fibromyalgia syndrome (FMS). We wanted to know whether FMS patients, compared to non-FMS rheumatic disease patients, did try to exercise regularly and whether they felt they benefited from it.

Methods: We administered an in-office questionnaire to 191 FMS patients meeting the 2010 ACR criteria and 130 non-FMS rheumatic disease patients. Patients were asked about whether they exercise, what type of exercise they did, the duration and frequency, and whether they felt that exercise helped their symptoms.

Results: 77.4% of the FMS patients exercise compared to 89.2% of the non-FMS rheumatic disease patients ($p< 0.007$). With respect to whether the exercise helped their symptoms, non-FMS rheumatic disease patient benefited more. The mean VAS for pain improvement (0-10) was 6.19 in the non-FMS group, compared with 4.64 for FMS patients ($p< 0001$). The mean improvement in energy (VAS 0-10) for non-FMS patient was 7.08, vs 4.92 in the FMS group ($p< 0001$). The mean improvement in sleep (VAS 0-10) was 6.78 in non-FMS patients and 4.77 in FMS patients ($p< 0001$). Patients exercised using different methods including using a stationary bike, an outdoor bike, running outside or on the treadmill, walking, swimming, muscle strengthening, yoga, stretching. Although walking was the most common activity chosen by the FMS and non-FMS groups, there was no significant difference between the types of exercise in the two groups. Also exercise frequency and duration did not differ statistically between the two groups.

Conclusion: In this study there was no impact, good or bad, on pain, in fibromyalgia patients who exercised. There was also no improvement in energy or sleep related to exercise in fibromyalgia patients. On the other hand, non-fibromyalgia rheumatic disease patients did benefit from exercise in terms of pain, energy and sleep.

It is unclear why fibromyalgia patients don't respond to exercise favorably. Possibly they do not feel they can exercise vigorously and don't become physically fit. But for whatever reason, we did not find that exercise benefits fibromyalgia patients.

The Effectiveness of Medications for Fibromyalgia Based on Patient Experiences

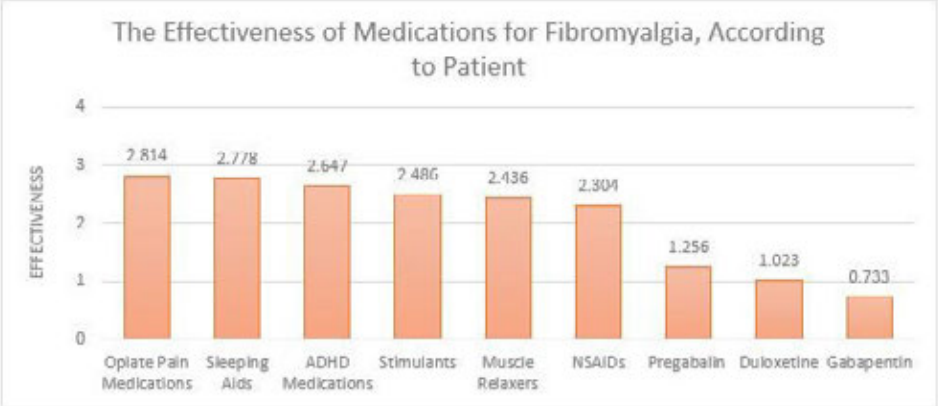
Robert Katz,[1] Jessica Polyak Wokurka,[2] and Ben Small[2], [1]Rush University Medical Center, Chicago, IL, [2]Rheumatology Associates, Chicago, IL

SESSION INFORMATION

Session Date: Sunday, November 10, 2019
Session Title: Fibromyalgia & Other Clinical Pain Syndromes Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: To assess patients' global assessment of frequently used treatments for the fibromyalgia syndrome (FMS), we asked patients with fibromyalgia to rank medications they have tried for their effectiveness.

Methods: 95 patients (mean age of 50.5) diagnosed with fibromyalgia based on the 2011 ACR criteria, 88 females and 7 males, completed an in-office questionnaire regarding the effectiveness of various medications often used to treat fibromyalgia. The study ranked 9 medications, which include Pregablin, Gabapentin, Duloxetine, Muscle Relax-



Medications	Patient	Mean
Opiate Pain Medications	70	2.814
Sleeping Aids	72	2.778
ADHD Medications	34	2.647
Stimulants	35	2.486
Muscle Relaxers	78	2.436
NSAIDs	81	2.304
Pregabalin	43	1.256
Duloxetine	44	1.023
Gabapentin	30	0.733

ants, Sleep Aids, Stimulants, ADHD Medications, Opiate Pain Medications, and NSAIDS. Patients rated the medications using this scale: 1=minimally helpful, 2=somewhat helpful, 3=moderately helpful, 4=very helpful.

Results: The three medications that were most positively rated by patients were opiate pain meds (mean=2.8), medications to improve sleep (mean= 2.8), and ADHD stimulants for fibro fog symptoms (mean=2.6).

The medications with the lowest effectiveness ratings by fibromyalgia patients included: gabapentin (mean=0.73); duloxetine (mean=1.02); pregabalin (mean=1.26). 59.1% of FMS patients reported little or no help from pregabalin, and 83.3 % found gabapentin to be little help.

Conclusion: Fibromyalgia patients rated the effectiveness of various medications that they tried. Pain medication, sleep aids and stimulants given for the attention deficit component of fibro fog were judged by patients to be the most helpful.

Abstract Number: 0243

Concomitant Fibromyalgia in Patients with Other Rheumatic Diseases and Response to Treatment

Robert Katz,[1] Jessica Polyak Wokurka,[2] and Ben Small[2], [1]Rush University Medical Center, Chicago, IL, [2]Rheumatology Associates, Chicago, IL

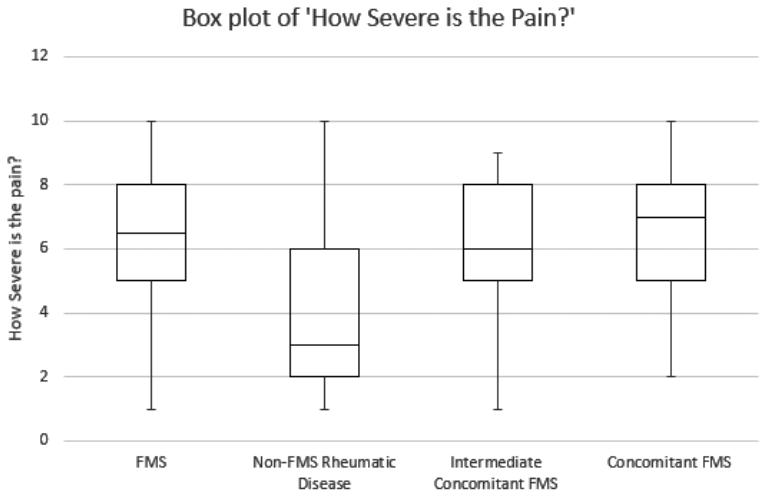
SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Fibromyalgia & Other Clinical Pain Syndromes Poster
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

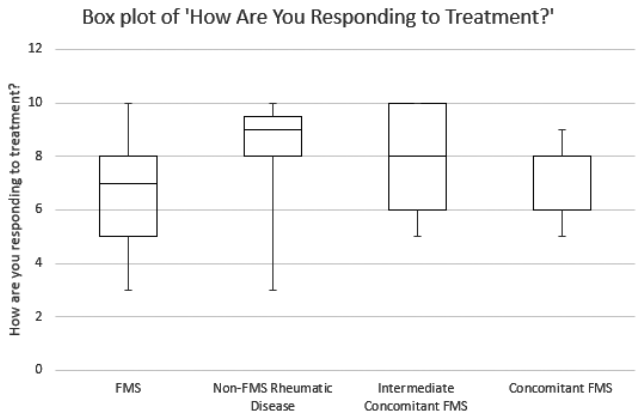
Background/Purpose: Some rheumatic disease patients have concomitant fibromyalgia. We wanted to determine treatment response in patients with and without concomitant fibromyalgia.

Methods: Patients were diagnosed by a rheumatologist. All patients also filled out a form to determine the presence of fibromyalgia based on the 2012 modifications of the ACR approved criteria for the diagnosis. The cut-off point was for the diagnosis of fibromyalgia was 12 or more points on a 1 to 31-point scale. Summarized counts and percentages of sex by derived DX group and for the total

- Descriptive statistics (N, mean, SD, median, min, max, etc) for the FMS score by derived DX group and for the total
- Descriptive statistics (N, mean, SD, median, min, max, etc) for the responses to “How are you responding to tx” by DX group and for the total but also summary of the counts and percentages of the number of patients having each tx score (1, 2, 3, etc).
- A Kruskall-Wallis test to compare all 4 dx groups’ pain score and also the tx response score.
- Upon confirming that there’s indeed a difference between all 4 groups for both scores, comparisons were done, using the Mann-Whitney test and the Bonferroni correction

Results: There were 503 patients analyzed in this study; 75% were female and 25% were male. Of these, 108/503 (22%) had FMS diagnosis, 273/503 (54%) were determined to have other rheumatic diseases but no concomitant





FMS (FMS score < 10), 39/503 (8%) were determined to have other rheumatic diseases and potential FMS (FMS score 10 or 11), and 83/503 (17%) were determined to have other rheumatic diseases and concomitant FMS (FMS score > 11). See table below for a summary of these patients' pain scores and response to treatment scores.

The Kruskall-Wallis test for both scores and showed a significant difference between the 4 diagnosis groups for the pain score ($p < 0.0001$) and the response to treatment score ($p < 0.0001$), indicating that indeed there are differences in pain sensation and response to treatment between the 4 diagnosis groups. When multiple comparisons were performed, the ones that were statistically significantly different for the pain score were

Concomitant FMS vs No Concomitant FMS ($p < 0.0001$)

No Concomitant FMS vs FMS ($p < 0.0001$)

No Concomitant FMS vs Intermediate/potential Concomitant FMS ($p < 0.0001$)

This means that there are significant differences between each of those pairs of dx groups in terms of the pain score. One can conclude from this that having FMS or Concomitant FMS seems to be associated with higher pain scores.

Conclusion: Those patients who scored 12 or more points on the ACR diagnostic criteria scale were diagnosed with having fibromyalgia. Some patients scored 10 to 12 on that scale and were considered to be intermediate in the

How are you responding to tx?				
N	21	39	5	7
Mean	6.4	8.3	7.8	7.1
SD	2.06	1.72	2.28	1.57
Median	7	9	8	8
Min	3	3	5	5
Max	10	10	10	9

determination of a fibromyalgia diagnosis. Patients with inflammatory rheumatic diseases in addition to fibromyalgia (concomitant fibromyalgia) were evaluated for treatment response based on a visual analog scale.

There was a clear difference in patients' response to therapy in those rheumatic disease patients who had concomitant fibromyalgia and those that do not.

Real-World Evidence Associated with the Treatment of Systemic Lupus Erythematosus in the USA, UK, France, and Germany: A Structured Review

Jennifer Lofland,[1] Pamela Berry,[2] Feng Pan,[2] Chetan Karyekar,[3] Hannah Guiang,[4] Rebecca McTavish,[4] and Melissa Thompson[4], [1]Janssen Scientific Affairs, LLC, Spring House, PA, [2]Janssen Scientific Affairs, LLC, Horsham, PA, [3]Janssen Global Services, LLC, Horsham, PA, [4]Cornerstone Research Group, Inc, Burlington, ON, Canada

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Health Services Research Poster I – ACR/ARP
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: SLE is an autoimmune multi-system disease characterized by flares and more rarely remissions. Emerging biologic therapies for SLE are expected to change the treatment landscape. A study was conducted to: (1) review the safety and efficacy outcomes associated with treatment of SLE in the real world; (2) compare results of real-world studies with those of randomized controlled trials (RCTs) and their extension studies; (3) understand real-world patterns of medication use. Searches focused on belimumab, as it is the only biologic agent approved for the treatment of SLE.[1]

Methods: A targeted literature search was conducted in MEDLINE on Jan 2, 2019, with no limitations for publication year. A total of 546 articles underwent title and abstract screening to identify English-language real-world studies of belimumab conducted in USA, UK, France, and Germany. Long-term extension studies for belimumab were identified in a separate systematic literature review of RCTs.

Results: Real-world studies showed reduced disease activity after belimumab treatment in 51% and 77% of patients with SLE at 6 months and 1 year, respectively. In comparison, RCTs of belimumab treatment showed similar

efficacy for this endpoint at 6 months (44%–57%) and lower efficacy at one year (43%–58%). Reductions in disease activity were maintained over 7 years of follow-up in long-term extension studies.

The real-world studies additionally showed that belimumab treatment led to reductions in corticosteroid dosages (24%–58% at 6 months) and discontinuation of corticosteroids in up to 11% of patients with SLE. Similar reductions in corticosteroid dosages and discontinuations were seen in long-term extension studies for up to 7 years. In contrast, claims data showed no effect of belimumab treatment on the number of patients taking corticosteroids.

Numerous reasons for discontinuation of belimumab were reported in the real-world studies, such as patient request, ineffective medication, disease progression, infection, no clinical response, adverse events (AEs), or disease persistence. In contrast, discontinuation was primarily due to AEs in RCTs and withdrawal in the long-term extension studies. Claims data showed that discontinuation of belimumab typically occurred within 6 months of treatment initiation. Rates of AEs remained stable over the course of therapy in the long-term extension studies, with infections being most common.

Conclusion: The current study found that real-world studies of belimumab show similar or better reductions in disease activity vs those observed in RCTs and that these reductions are maintained during long-term treatment. Real-world studies also showed that belimumab is associated with reductions in corticosteroid dosages and even discontinuation of corticosteroid use, two important outcomes for patients with SLE. Longer follow-up of more detailed real-world studies would further improve the understanding of outcomes of belimumab and other biologic therapies in the treatment of SLE.

Abstract Number: 0245

Comorbidities, Health Care Utilization, and Cost of Care in Systematic Lupus Erythematous Increase with Disease Severity During 1 Year Before and After Diagnosis: A Real-World Cohort Study in the United States, 2004–2015

Miao Jiang,[1] Aimee Near,[2] Barnabas Desta,[1] Xia Wang,[1] and Edward Hammond[1], [1]AstraZeneca, Gaithersburg, MD, [2]IQVIA, Durham, NC

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Health Services Research Poster I – ACR/ARP
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is associated with high economic burden. This real-world study assessed health care resource utilization (HRU) and costs in a US cohort of patients with newly diagnosed SLE.

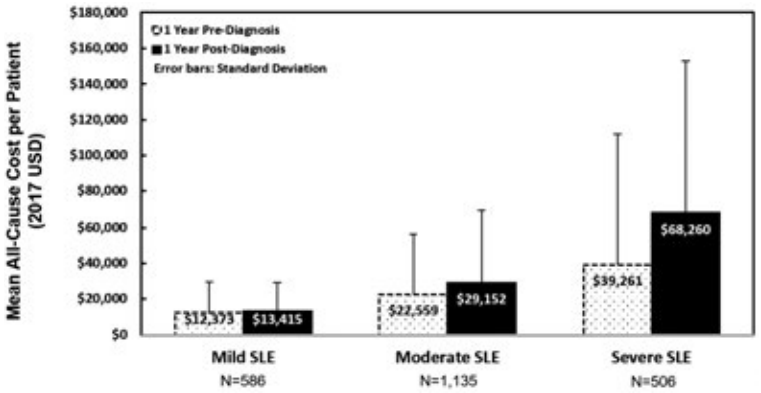

Figure. Mean All-Cause Health Care Costs per Patient by Disease Severity Among Patients With Newly Diagnosed SLE 1 Year Before and After Diagnosis; United States 2005–2014.

Methods: Using linked Truven Health MarketScan® commercial claims data and IQVIA's GE Centricity electronic medical record (EMR) database, we identified patients ≥18 years old with SLE diagnosis (index) between January 1, 2005 and December 31, 2014, with no prior SLE or lupus nephritis diagnosis 1 year pre-index, who had ≥1 year of continuous enrollment pre- and post-index date. Disease severity was classified as mild, moderate, or severe over 1 year post diagnosis using claims-based algorithms, which combined SLE diagnosis, disease activities/SLE-related conditions, medications, and health services use,[1] supplemented with EMR. HRU and costs (2017 US$) were reported over 1 year pre and post diagnosis. All-cause costs were evaluated with a generalized linear model, adjusting for demographics, clinical characteristics, Charlson comorbidity index, and pre-index cost.

Results: In total, 2,227 patients with SLE were included in this analysis; 586 (26.3%) with mild, 1,135 (51.0%) with moderate, and 506 (22.7%) with severe SLE. Mean (SD) age was 50.2 (13.0) years, 90.6% female, and 54.4% White. Patients were prescribed corticosteroids (76.1%), hydroxychloroquine (59.7%), methotrexate (14.7%), and biologics (2.7%).

Patients with moderate/severe SLE had more comorbid disease during the year before SLE diagnosis; 26.5% of severe patients had ≥3 Charlson comorbidities compared with 13.8% moderate and 6.1% mild SLE. Moderate/severe patients also had significantly higher mean per-patient costs 1 year before SLE diagnosis, representing a 1.8- and 3.2-fold increase, respectively, vs mild SLE (mild $12,373 [SD $17,171], moderate $22,559 [SD $33,674], severe $39,261 [SD $72,768]; $P< 0.0001$).

During the first year after SLE diagnosis, the proportion of patients with ≥1 inpatient stay increased with SLE severity (mild 12.8%, moderate 22.4%, severe 51.2%; $P< 0.0001$), as did the average hospital stay days (0.47 [SD 1.69], 1.31 [SD 3.69], 5.52 [SD 12.33], respectively; $P< 0.0001$). Similarly, the proportion of patients with ≥1 ED visit increased with disease severity (mild 26.8%, moderate 41.3%, severe 57.9%; $P< 0.0001$).

Moderate/severe patients had 2.2- and 5.1-fold higher health care costs, respectively, vs mild SLE (average yearly cost: mild $13,415 [SD $15,707], moderate $29,512 [SD $40,466], severe $68,260 [SD $84,712]; $P< 0.0001$; **Figure**). Adjusted cost ratio (95% CI) was 1.81 (1.65, 1.98) for moderate vs mild SLE and 4.24 (3.80, 4.73) for severe vs mild SLE.

Conclusion: Prior to SLE diagnosis, health care costs increase with disease severity. For patients with newly diagnosed moderate/severe SLE, total all-cause health care costs during the first year after diagnosis are significantly higher (4.2- and 1.8-fold increase, respectively) compared with mild SLE. This pattern of increased health care costs

is also observed during the year before SLE diagnosis. Earlier diagnosis may ensure better health care outcomes and lower associated costs.

Smoking Exposure in Pack-Years Predicts Cutaneous Manifestations of Lupus

Nnenna Ezeh,[1] Trevor McKown,[1] Shivani Garg,[1] and Christie Bartels[1], [1]University of Wisconsin School of Medicine and Public Health, Madison, WI

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Health Services Research Poster I – ACR/ARP
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Patients of color are more likely to have systemic lupus erythematosus (SLE) and a smoking history. Prior literature notes that both smoking and race impact odds of cutaneous manifestations. Thus, we examined the impact of cumulative smoking and race on cutaneous manifestations of SLE.

Methods: For this cohort study, electronic health records at an academic center were manually abstracted to include adult patients meeting ACR 1997 or SLICC 2012 classification criteria and with at least one ambulatory rheumatology encounter with an SLE ICD- 9 or 10 code from 2003 - 2016. Our cohort included 632 consecutive SLE patients; 552 met ACR and 80 met SLICC SLE criteria only. The primary outcomes were ACR or SLICC cutaneous criteria and SLICC Damage Index (DI) cutaneous criteria. The primary explanatory variable was smoking exposure defined as low (< 5 pack-years), medium (5-10 pack-years), and high (>10 pack-years), compared to nonsmokers. Covariates included age category at diagnosis (early onset < 18 years old, 18-50 years, or late onset >50 years), sex, and race. Analysis was performed using multivariate logistic regression to calculate odds ratios and 95% confidence intervals (OR, (95% CI)).

Results: Among 632 SLE patients, mean age was 42 ±14 years, 91% female, 82% white, and 40% were ever smokers**.** Figure 1 compares age at SLE diagnosis of ever smokers and never smokers. Never smokers were on average younger with a wider age distribution observed among ever smokers. Patients with low smoking exposure were nine times more likely to develop any mucocutaneous manifestations (OR 9.0, (1.2, 67.7)), four times more likely to meet any SLICC cutaneous criteria (OR 3.7, (1.3, 10.6)), and twice as likely to meet ACR cutaneous criteria (OR 2.0 (1.0, 3.8)) compared to non-smokers (Table 1). Patients with medium smoking exposure were twice as likely to meet acute cutaneous SLICC criteria (OR 2.3, (1.1, 5.1)), whereas those with high smoking exposure had two-fold higher odds of discoid lupus (OR 2.1, (1.1, 4.1)). Chronic cutaneous SLICC criteria and SLICC DI cutaneous criteria showed linear pack-year trends that met significance with high smoking exposure (OR 2.2, (1.2, 4.2) and OR 4.2, (0.9, 9.2) respectively). Patients of color had increased risk for alopecia, discoid lupus, chronic cutaneous lupus, and DI skin damage. Limitations included sample size and just 18% patients of color.

Table 1. Multivariate odds ratios & 95% CI of cutaneous lupus by smoking exposure in pack-years

	Acute SLICC Cutaneous	Chronic SLICC Cutaneous	Any SLICC Cutaneous	Any ACR Cutaneous	Any Muco-cutaneous *	Any SLICC-DI Skin Damage

Black	**0.4 (0.2, 0.6)**	1.8 (0.97, 3.4)	0.9 (0.5, 1.8)	**0.5 (0.3, 0.8)**	0.7 (0.4, 1.6)	**2.6 (1.1, 5.9)**
Other	0.6 (0.3, 1.1)	**3.6 (1.6, 8.1)**	0.6 (0.3, 1.5)	0.5 (0.3, 1.4)	0.5 (0.2, 1.2)	2.2 (0.6, 8.2)

*Any Mucocutaneous included any SLICC or ACR cutaneous or mucosal criteria.

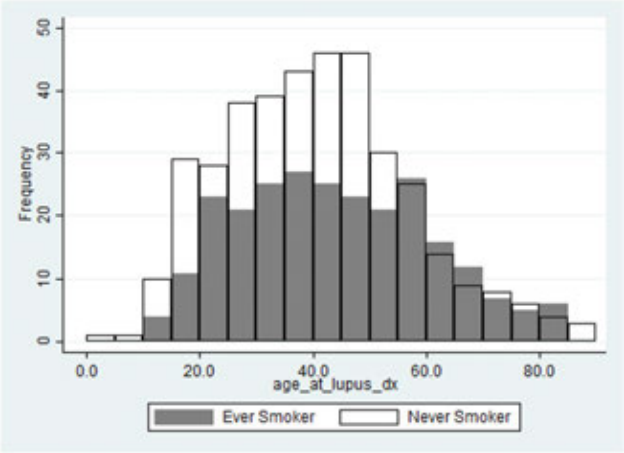

Figure 1. Frequency of ages at SLE diagnosis for SLE ever smokers compared to never smokers.

Conclusion: Any smoking exposure was an independent risk factor for nearly all cutaneous manifestations of SLE, whereas high smoking exposure and patients of color had significantly increased risk of chronic cutaneous manifestations and persistent skin damage. Findings suggest a dose relationship between smoking exposure and cutaneous manifestations/damage, making cessation an important strategy to potentially reduce disparities and improve cutaneous outcomes in SLE.

*Patients who have been referred to rheumatology, but have not had an appointment or missed their first appointment with rheumatology
**Ophthalmology is included as one of the providers. 2 providers represent a provider in addition to Ophthalmology

Background/Purpose: To determine health literacy, medication adherence, and quality of life (QOL) of uveitis patients in order to understand how to deliver better and improved quality of care given uveitis patients' multidisciplinary needs.

Methods: We performed a cross-sectional quality improvement study of uveitis patients treated at an outpatient ophthalmology clinic at a 953-bed county hospital in Atlanta, Georgia. A prospective assessment of health literacy using the Short Assessment of Health Literacy survey (SAHL), adherence using the Beliefs about Medicine Questionnaire (BMQ), and QOL using the 12-item Short Form Health Survey (SF-12) were obtained from 60 consecutive patients, as well as baseline data on uveitis diagnosis and etiology.

Results: Demographics: 57% of patients were women and 80% identified as Black. 42% of patients had schooling beyond high school. 32% of patients earned < $5,000 in annual household income, and 79% earned < $30,000. 27% of patients were uninsured.

Uveitis description and etiology: 70% of cases were bilateral and 43% were anterior in location. 25% were infectious etiologies and 51% were related to inflammatory disease or markers.

Health Literacy: 43% of patients had poor health literacy. Mean SAHL was significantly lower for those with less schooling ($p< 0.0001$).

Beliefs about Medicines: Mean necessity scores (3.7/5) were higher than concerns scores (3.2/5). Necessity scores were higher for multiple providers ($p=0.0220$) as well as those co-managed by rheumatology ($p=0.0275$). Concerns scores were higher ($p=0.0076$) for patients co-managed by rheumatology.

Quality of Life (QOL): Uveitis patients scored lower than the general US population for physical ($p< 0.0001$) and mental QOL ($p=0.002$). Physical QOL was lower for patients co-managed by rheumatology ($p=0.0174$), those managed by multiple providers ($p=0.0318$), or those on immune modifying therapy ($p=0.0345$).

Conclusion: Uveitis patients reported many barriers to care, have significantly poorer QOL compared to normal subjects, and have poor health literacy. Despite strong perceptions of treatment necessity there were also treatment concerns. Rheumatology patients have worse physical QOL but indicated increased adherence. Co-management with other specialties and patient education may be beneficial in improving medication adherence and QOL.

Adherence to Biologic Disease-modifying Anti-rheumatic Drugs (DMARDs) —a Comparison of Long-term Adherence Among Patients with Various Inflammatory Conditions by Primary Dispensing Channel

Caroline Swift,[1] **Yvonne Viteri**,[2] Gail Bridges,[3] Mary Dorholt,[4] and Monal Kohli[5], [1]Express Scripts, St. Louis, MO, [2]Accredo, Northvale, NJ, [3]Accredo, Memphis, TN, [4]Accredo, Maple Grove, MN, [5]Express Scripts, Franklin Lakes, NJ

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Health Services Research Poster I – ACR/ARP
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Medication adherence to biologic DMARDs has been associated with optimal clinical outcomes. Adherence varies with primary dispensing channel among rheumatoid arthritis patients. Prior studies have primarily focused on individual inflammatory conditions. This research compared adherence among patients diagnosed with rheumatoid arthritis, psoriatic arthritis, ankylosing spondylitis or a combination of these conditions over a two-year follow-up period by primary dispensing channel.

Methods: A retrospective cohort analysis of patients continuously eligible for pharmacy/medical benefits, with biologic DMARD claims and corresponding diagnoses for rheumatoid arthritis, psoriatic arthritis, ankylosing spondylitis or a combination of these diagnoses. Dispensing channel was determined by a threshold of 75% of biologic DMARD therapy through a 2-year follow-up period. Adherence was calculated using medication possession ratio during each 1-year period of analysis. Adherent patients were defined as those whose biologic DMARD adherence was at least 80%. Patients were classified as new or continuous users based on 6 months prior to index biologic DMARD claim. Patients were matched between channels based on age, gender, new or continuous use, and diagnosed condition using propensity score matching. Logistic regression was used to assess impact of dispensing channel and to control for age, gender, new or continuous use, diagnosed condition, and comorbidity burden in year one. Year two adherence results also controlled for year one adherence behavior.

Results: Final sample included 2,436 patients on biologic DMARD therapy meeting selection criteria, with an index prescription between July 1 and December 31, 2015. Likelihood of adherence was found to be significantly lower during the first year of follow-up among patients primarily filling their biologic DMARD through retail compared to specialty pharmacy (37.6% [95% CI: 23.7%-48.9%] lower compared to our specialty pharmacy, and 29.0% [95% CI: 10.6%-43.7%] lower compared to other specialty pharmacy). Average adherence, based on MPR, was lower in the second year for all channels, and no significant difference in the change in average adherence was found ($p > 0.05$). Likelihood of adherence in the second year of analysis was influenced by adherence behavior in the first year, with adherent patients in the first year being 11 times more likely to be adherent in the second year (aOR=11.18, 95% CI: 9.09-13.73).

Conclusion: Among patients with diverse inflammatory condition diagnoses, those using specialty pharmacy as primary dispensing channel for biologic DMARDs have higher adherence in the first year of measurement after controlling for other factors influencing adherence. Adherence in the second year was lower for all channels; however, dispensing channel does not appear to impact the magnitude of change in adherence between years. Given that the largest single predictor of adherence in the second year is prior adherence, choice of primary dispensing channel during the first year of therapy should be considered upon starting or continuing biologic DMARD therapy for patients with inflammatory conditions.

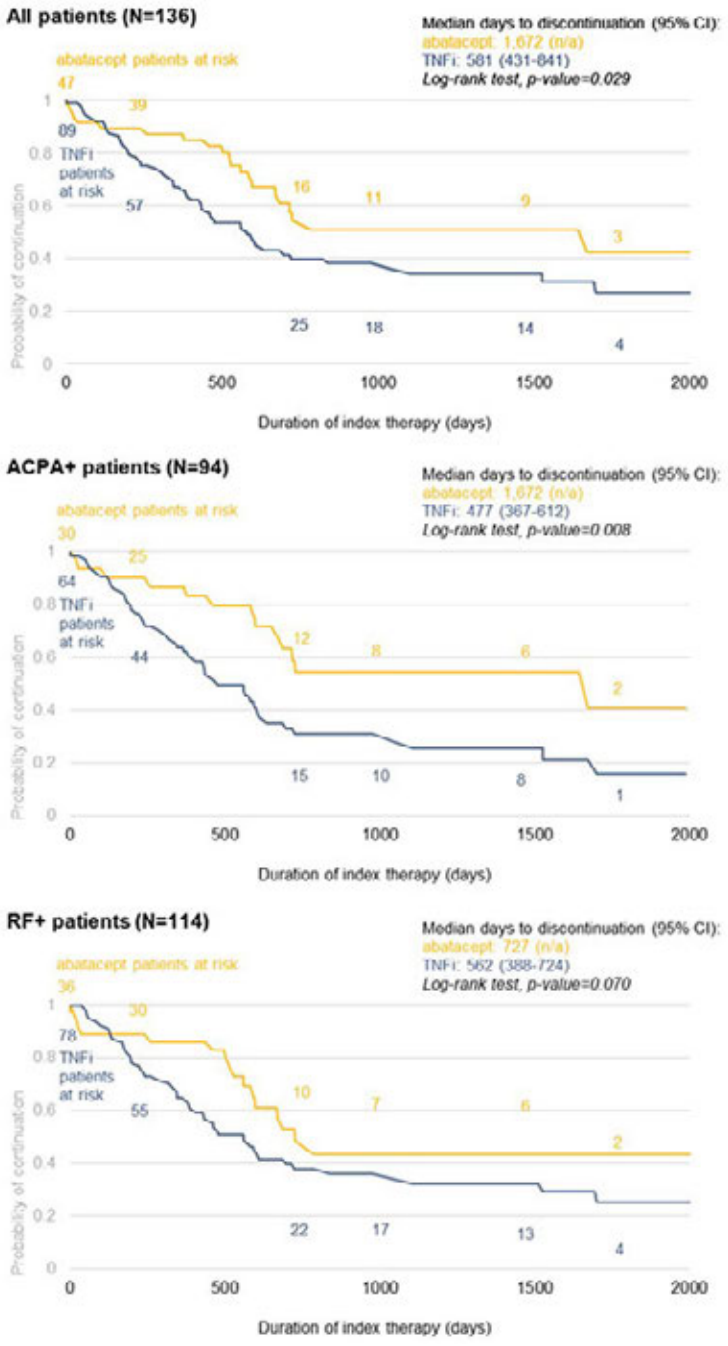
Background/Purpose: Abatacept is recommended as first-line biologic therapy in adult patients with moderate to severe RA. We aimed to assess real-world 1-year treatment persistence in early-line abatacept versus TNFi treated RA patients who were ACPA+ and RF+, which predict poorer functional and radiographic outcomes.

Methods: As part of a multicenter retrospective medical record review of adult RA patients with poor prognostic factors, patients were treated with abatacept or TNFi as the first biologic treatment at participating clinics (defined as early line) and had ACPA positivity, RF positivity, increased CRP, elevated ESR, or joint erosions. This analysis only included ACPA+ and/or RF+ patients. Patients in the TNFi group were treated with adalimumab, etanercept, infliximab (and biosimilars), certolizumab pegol, or golimumab. Data were collected ≥1 year from treatment initiation (8/9/11-11/14/16). Patients with Crohn's disease, ankylosing spondylitis, ulcerative colitis, psoriatic arthritis, or anal fistula were excluded. Demographic, disease, and treatment data (start, stop, reason for discontinuation) were abstracted. Treatment persistence (continuation of index treatment with gap ≤60 days) at 1 year and time to discontinuation were reported. Multivariate logistic and Cox modeling with forward selection compared abatacept and TNFi 1-year persistence, risk of overall discontinuation, and discontinuation for disease progression, controlling for demographic and clinical characteristics (age, sex, Charlson comorbidity index (CCI), RA duration), baseline utilization, and clinic. Analyses will be repeated when >300 patients are recruited.

Results: Data on 136 patients (47 abatacept, 89 TNFi) were available at the time of analysis (Table 1). Abatacept patients were older than TNFi patients. There were no significant differences in gender, CCI, or duration of treatment at the clinic. Risk of discontinuation was lower in abatacept vs. TNFi overall (p=0.029) and for both ACPA+ (p=0.008) and RF+ (p=0.070) patients. Median time to discontinuation for ACPA+ and RF+ patients was 1,672 and 727 days for abatacept vs. 477 and 562 days for TNFi, respectively (Figure 1). At 1 year, 83% of abatacept vs. 64% of TNFi patients were persistent (p=0.021) (Table 1). Adjusted risk of discontinuation was higher in TNFi patients, although not statistically significant (Table 2). Odds of 1-year persistence was lower in TNFi than abatacept patients, but not statistically significant (Table 2). TNFi patients were at significantly higher risk of discontinuing index treatment due to disease progression.

Figure 1 Time to discontinuation of index treatment



Conclusion: In this analysis of ACPA+ and RF+ RA patients, unadjusted analyses demonstrate these patients are significantly more likely to be persistent to abatacept than TNFi at 1 year in a real-world setting. Abatacept patients also experienced a longer time to discontinuation than the TNFi cohort, which may be explained by the significantly lower proportion of patients discontinuing abatacept due to disease progression. Perhaps due to limited sample size, the adjusted comparison of abatacept and TNFi persistence is not significant, however, numeric trends are consistent.

Table 2 Adjusted persistence and discontinuation of index treatment

	Persistence at 12 months: OR (95% CI)	*p*-value	Risk of all-cause discontinuation: HR (95% CI)	*p*-value	Risk of discontinuation for disease progression: HR (95% CI)	*p*-value
Age, years	1.033 (0.998 - 1.069)	0.064	0.998 (0.979 - 1.017)	0.822	0.988 (0.960 - 1.017)	0.425

CCI	1.246 (0.802 - 1.934)	0.328	0.995 (0.796 - 1.243)	0.963	1.054 (0.753 - 1.476)	0.758
Anti-CCP and RF status						
Positive anti-CCP only vs dual positive	2.812 (0.712 - 11.107)	0.140	0.493 (0.228 - 1.069)	0.073	0.337 (0.077 - 1.479)	0.149
Positive RF only vs dual positive	2.607 (0.996 - 6.826)	0.051	0.495 (0.281 - 0.871)	0.015	0.507 (0.221 - 1.164)	0.109
TNFi vs. Abatacept	0.559 (0.217 - 1.439)	0.228	1.525 (0.897 - 2.594)	0.119	3.759 (1.289 -10.966)	0.015

The initial models included age, gender, CCI, ACPA and RF status, and cohort as independent variables. We then used a forward selection method to include additional significant covariates ($p<0.05$) in the final models. The following covariates were considered: time from RA diagnosis to index, number of physician office visits (1-year pre-index), number of hospitalizations (1-year pre-index), and clinic site. None of those covariates were significant and therefore were not included.

Treatment Patterns, Dose Change, and Treatment Discontinuation in RA Patients Switching from First Biologic DMARD to Another Treatment in the US

Robin Dore,[1] Jenya Antonova,[2] Chakkarin Burudpakdee,[3] Lawrence Chang,[2] Jing He,[4] and Mark Genovese[5], [1]Private practice, Tustin, CA, [2]Gilead Sciences, Foster City, CA, [3]IQVIA, Falls Church, VA, [4]IQVIA, Plymouth meeting, PA, [5]Stanford University, Stanford, CA

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Health Services Research Poster I – ACR/ARP
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: For RA patients not meeting their treat-to-target goals despite treatment with their first biologic (b)DMARD, ACR guidelines recommend switching to a different bDMARD or Janus kinase inhibitor (JAKi).[1] Shorter treatment duration was reported for TNF-α inhibitors (TNFi) than non-TNFi bDMARDs;[2,3] little data exist for JAKi. Understanding treatment and dosing patterns and persistency among treatment classes can optimize next-treatment selection in RA patients switching from initial bDMARD to another treatment.

Methods: In a US health-plan claims database, we identified adult RA patients who initiated a bDMARD (1/1/2012–3/31/2017) and switched (index date) to another bDMARD or JAKi (as monotherapy or in combination with a conventional synthetic [cs]DMARD). Patients had ≥2 RA diagnoses ≥30 days apart and 12-month pre- and ≥12-month post-ID continuous enrollment. Treatment patterns before and after the switch were assessed. Index-treatment dose modifications (≥10% daily-dose increase or decrease) were evaluated. Persistency was evaluated as the risk of treatment discontinuation (via Cox proportional hazards models) – among all, within index monotherapy, within index combination therapy.

Results: A total of 4656 patients switched from a first (pre-index) bDMARD to another (index) treatment (78% female, median age 54 years, RA duration 1.5 years). As pre-index bDMARD, 90.0% of patients used TNFi. Upon changing

Table 1. Prior (Pre-Index) Treatments by Subsequent (Index) bDMARD (n=4656)

	Index TNFi (n=3045, 65%)	Index non-TNFi bDMARD (n=1090, 23%)	Index JAKi (n=521, 11%)	Total (n=4656, 100%)
Prior bDMARD – TNFi	2843 (68%)	940 (22%)	407 (10%)	4190 (100%)
Prior bDMARD – non-TNFi	202 (43%)	150 (32%)	114 (25%)	466 (100%)

Table 2. Dose Change (Increase or Decrease) and Time to Dose Change, by Index Treatment

	% of patients with dose increase within:			Time to dose increase, days	% of patients with dose decrease within:			Time to dose decrease, days
	3 months	6 months	12 months		3 months	6 months	12 months	
All patients (n=4656)	4.6%	8.8%	12.0%	196	3.3%	4.5%	5.6%	207
Index monotherapy (n=2149)	5.6%	8.7%	11.0%	164	3.4%	4.4%	5.3%	160
TNFi (n=1305)	3.7%	6.5%	8.9%	173	3.9%	4.4%	5.4%	134
Non-TNFi (n=521)	13.7%	18.6%	20.2%	111	4.3%	7.0%	8.2%	195
JAKi (n=323)	0.6%*	2.5%*	5.3%*	351*	0.0%*	0.3%*	0.6%*	239
Index combination therapy (n=2507)	3.8%	8.9%	12.8%	218	3.2%	4.5%	5.9%	238
TNFi + csDMARD (n=1740)	2.3%	7.6%	11.6%	215	3.0%	4.1%	5.1%	223
Non-TNFi + csDMARD (n=569)	9.4%	15.1%	18.9%	178	4.9%	7.6%	10.5%	247
JAKi + csDMARD (n=198)	1.0%†	2.0%†	6.6%†	444†	0.0%†	0.0%†	0.5%†	541†

*p<0.001 for JAKi vs. bDMARD within monotherapy.
†p<0.05 for JAKi vs. bDMARD within combination therapy.

treatment, 65.4% started another TNFi, 23.4% non-TNFi, and 11.2% JAKi. Most (68%) patients on pre-index TNFi cycled to another TNFi, 22% switched to a non-TNFi, and 10% switched to JAKi. Patients with non-TNFi as first bDMARD switched to TNFi (43%), another non-TNFi (32%), or JAKi (25%; Table 1).

Within 3, 6, and 12 months, the percentages of patients with dose increase ranged: 0.6–6.6% JAKi, 2.3–11.6% TNFi, 9.4–20.2% non-TNFi; dose decrease: 0–0.6% JAKi, 3.0–5.4% TNFi, 4.3–10.5% non-TNFi. Time to dose change was longer in JAKi than in bDMARD treatments (Table 2).

Patients were significantly more likely to discontinue monotherapy than combination therapy (hazard ratio [HR]=2.0). Within monotherapy, patients were more likely to discontinue TNFi than JAKi (HR=1.25). Within combination therapy, TNFi + csDMARD where more likely to be discontinued than JAKi + csDMARD (HR=1.31). In all models, discontinuation risk increased in patients with unknown vs commercial types of insurance (overall HR=1.62, monotherapy HR=1.72, combination therapy HR=1.54); treatment discontinuation risk increased with shortened duration of RA (HR=0.92 for all) and increased number of concomitant medications (HR=1.02 for all; Table 3).

Conclusion: For RA patients switching from first bDMARD to another treatment, TNFi was the most common drug class before and after switch. After switch, JAKi demonstrated higher treatment persistency than TNFi. Dose increases were most common in non-TNFi, followed by TNFi, and least common in JAKi.

Session Title: Health Services Research Poster I – ACR/ARP
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Biosimilars have enabled some US institutions and payers to achieve significant financial savings after implementing a formulary change from the reference biologic. However, within integrated delivery networks (IDN), health-systems, and outpatient practices, there are short-term administrative costs to clinically implement such a change and additional labor associated with formulary management. The objective of this study is to assess the long-term financial implications of implementing a formulary change from a reference biologic to a biosimilar when considering the short-term costs incurred in select, chronic rheumatologic conditions.

Methods: We evaluated the short- and long-term costs of implementing a formulary change from reference to biosimilar etanercept for the treatment of RA, JIA, and AS from a US IDN perspective over a 5-year time horizon. The number of existing and new patients to be treated with etanercept was calculated based on a hypothetical population of 1 million (M) within an IDN, taking into consideration population growth, etanercept treatment patterns, and incidence/prevalence rates of RA, JIA, and AS derived from the literature (see data table for population inputs). For the price of biosimilar etanercept, a base case discount from reference etanercept was estimated from US market experience with biosimilars in general using Average Sales Price data from the Centers for Medicare and Medicaid Services. For patients switching from reference etanercept, the biosimilar market share was assumed to be 95% in year 1 and 100% by year 5. Initial short-term administrative costs to implement a formulary change vary by institution, so three different scenarios (low: $50,000; medium: $100,000; and high: $200,000) were explored. Labor costs to implement a switch included nurse time for additional patient education and pharmacist time to manage non-formulary requests.

Results: For this hypothetical population of 1 M patients within an IDN, a total of 1,331 (0.1%) patients were treated with etanercept for all three indications by year 5. When considering short-term administrative costs, the total non-pharmacy costs of implementing a formulary conversion program over 5 years was $55,518, $105,518, and $205,518 for the low, medium, and high administrative cost scenarios, respectively. When considering pharmacy cost savings within this particular model, the total 5-year savings were $62.4 M, $62.4 M, and $62.3 M for the low, medium, and high administrative cost scenarios, respectively ($10,076, $10,067, and $10,049 savings per switched patient per year on average).

Conclusion: Substantial cost savings may be realized in the long term for an institution when changing the formulary from the reference etanercept to a biosimilar etanercept, even when factoring the short-term administrative costs and labor associated with managing a formulary change within a relatively small population.

Treatment Sequences, Effectiveness, and Costs of Tumor Necrosis Factor Inhibitor Cycling Compared with Swapping to a Novel Disease-modifying Anti-rheumatic Drug in Rheumatoid Arthritis Patients

Aliza Karpes,[1] Zhigang Duan,[2] Hui Zhao,[2] Lincy Lal,[3] Wenyaw Chan,[3] Maria E. Suárez-Almazor,[4] Sharon Giordano,[2] John Swint,[3] and **Maria Lopez-Olivo**[2], [1]School of Public Health, The University of Texas Health Science Center at Houston, Dallas, TX, [2]The University of Texas, MD Anderson Cancer Center, Houston, TX, [3]School of Public Health, The University of Texas Health Science Center at Houston, Houston, TX, [4]Department of Rheumatology/Clinical Immunology, The University of Texas MD Anderson Cancer Center, Houston, TX, USA, Houston, TX

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Health Services Research Poster I – ACR/ARP
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: To evaluate the sequences of therapeutic drugs used by rheumatoid arthritis (RA) patients whose initial tumor necrosis factor inhibitor (TNFi) therapy failed, as well as mean time to therapy discontinuation and costs of TNFi and non-TNFi drugs.

Methods: Using the IBM MarketScan Research Databases, we analyzed claims of adult RA patients who switched to their second biological or targeted disease-modifying antirheumatic drug between January 2008 and December 2015. We determined the most common treatment sequences and estimated the time to therapy discontinuation. We compared drug and other health care costs between adherent and non-adherent patients.

Results: Among 10,442 RA patients identified, 36.5% swapped to a non-TNFi drug, most commonly (54.2%) abatacept. The remaining 63.5% switched to a cycling regimen (second TNFi), most commonly adalimumab (41.2%). For subsequent lines of therapy, non-TNFi drugs were more common. Patients who swapped were significantly older and sicker than those who cycled ($p < 0.001$). Survival analysis showed a longer time to discontinuation for second-line non-TNFi drugs than for TNFi (median 471 days compared with 370 days, $p < 0.001$), but no difference in subsequent lines of therapy. Although non-TNFi drugs were less expensive for adherent patients, cycling was associated with lower costs overall.

Conclusion: Although patients are more likely to cycle to a second TNFi than swap, those who swap to a non-TNFi drug are more likely to persist with the second-line therapy. However, cycling appears to be the less costly strategy.

Abstract Number: 0253

A Systematic Review and Meta-analysis of Observational Studies Reporting on the Use of Checkpoint Inhibitors in Patients with Cancer and Pre-existing Autoimmune Disease

Maria Lopez-Olivo,[1] Noha Abdel-Wahab,[1] and Maria E. Suárez-Almazor[2], [1]The University of Texas, MD Anderson Cancer Center, Houston, TX, [2]Department of Rheumatology/Clinical Immunology, The University of Texas MD Anderson Cancer Center, Houston, TX, USA, Houston, TX

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Health Services Research Poster I – ACR/ARP
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Immune checkpoint inhibitors (ICI) are increasingly used in the treatment of cancer. To date, no clinical trials exist evaluating the use of ICI in patients with autoimmune disease. Therefore, we have systematically reviewed observational studies reporting the outcomes of cancer patients with pre-existing autoimmune disease to determine the frequency of flares, *de novo* immune-related adverse events (irAEs), and deaths.

Methods: We searched in 5 electronic databases through August 2018. Study selection, data collection and quality assessment were performed by one investigator and cross-checked by another. A meta-analysis was performed to pool occurrence of flares, *de novo* irAEs, and deaths.

Results: Eleven observational studies were included (868 patients with cancer and preexisting autoimmune disease). Four studies were comparative. All studies included patients with advanced cancer stages. Seven studies reported therapy with PD-1/PD-L1, three CTLA-4, and one both. The mean age of the participants ranged from 54 to 72 years of age. The risk of bias score for cohort studies ranged from four to seven points (out of a maximum of 9). Pooled occurrence of any irAEs (flares or *de novo*) was 55% (95% confidence interval (CI) 44%, 66%); for flares it was 29% (95% CI 11%, 49%), and for *de novo* irAEs 30% (95% CI 24%, 35%). Flares were more commonly reported in patients with rheumatoid arthritis (33%) and psoriasis (20%). Pooled occurrence of deaths was 31% (95% CI 11%, 56%), one due to *de novo* colitis, however none were considered to be related to the pre-existing autoimmune disease. The pooled proportion of permanent discontinuation of the ICI was 12% (95% CI 4%, 24%), and for patients with partial cancer response 25% (95% CI 15%, 36%).

Conclusion: Over 40% of the patients with pre-existing autoimmune disease received ICI blockade with no subsequent flares or *de novo* irAE. These results suggest that ICI can be used in these patients, but careful monitoring is required as close to one third of the patients will experience a flare of their autoimmune disease.

Interstitial Lung Disease Associated Health Care Resource Utilization and Cost in Rheumatoid Arthritis Patients in an Insured Population

Joe Zhuo,[1] Ying Bao,[2] Qian Xia,[2] Aarti Rao,[3] Chidananda Samal,[3] and Sonie Lama[4], [1]Bristol-Myers Squibb, Princeton, NJ, [2]Bristol-Myers Squibb, Lawrenceville, NJ, [3]Mu Sigma, Bangalore, India, [4]BMS, Lawrenceville, NJ

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Health Services Research Poster I – ACR/ARP
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Interstitial lung disease (ILD) is a frequent extraarticular manifestation of rheumatoid arthritis (RA) that imposes substantial economic burden on patients and healthcare systems. However, the impact of the incidence of ILD on healthcare resource utilization (HCRU) and medical cost in RA patients (pts) has not been well documented. The objective of this study was to assess the HCRU and cost attributed to incident ILD in RA pts.

Table 1: Baseline characteristics by cohort

	RA-ILD pts (n=8,214)	RA only pts (n=104,101)	p-value

Urgent care costs	$227.51 ($247.75)	$267.71 ($330.67)	0.2098
Pharmacy costs	$6,364.00 ($12,063.77)	$7,659.26 ($18,245.37)	<.0001
All- cause costs	**$38,898.04 ($71,440.06)**	**$67,843.37 ($120,567.15)**	**<.0001**

Table 3: Comparison of the Change in HealthCare Resource Utilization and Costs Over Time in RA-ILD and RA Only Patients

	RA-ILD pts (n=8,214)	Only RA pts (n=104,101)	p-value
***Difference in number of healthcare services utilized per pt, mean (SD)**			
Inpatient admissions	0.82 (3.30)	0.25 (2.20)	<.0001
Length of stay, days	8.33 (29.13)	1.64 (13.12)	<.0001
Outpatient services	7.68 (23.29)	4.68 (15.89)	<.0001
Emergency visits	0.49 (3.56)	0.18 (3.12)	<.0001
Urgent care visits	-0.01 (0.38)	0.00 (0.30)	0.0048
Pharmacy prescriptions	3.58 (14.52)	5.01 (11.63)	<.0001
All-cause visits	**12.58 (31.61)**	**10.13 (22.42)**	**0.0017**
Difference in costs per patient, mean (SD)			
Inpatient costs	$19,122.83 ($101,609.71)	$3,240.38 ($33,088.83)	<.0001
Outpatient costs	$7,808.52 ($42,668.47)	$3,372.53 ($21,237.32)	<.0001
Emergency costs	$754.83 ($6,009.36)	$244.30 ($3,864.66)	<.0001
Urgent care costs	-$0.31 ($88.27)	$1.21 ($221.04)	0.0034
Pharmacy costs	$1,248.57 ($12,660.92)	$1,632.07 ($9,564.75)	<.0001
All-cause costs	**$28,934.43 ($112,904.91)**	**$8,490.49 ($42,804.70)**	**<.0001**

**Difference = (HCRU or Costs post diagnosis – HCRU or Costs prior diagnosis), positive difference means an increase over time.*

Methods: Adult pts from administrative claims database Optum Clinformatics Data Mart with incident RA (≥2 claims with ICD-9: 714.0 or ICD-10: M05.xxx/ M06.0xx/ M06.8xx /M06.9) between July 2002 to Jun 2018 were included in the analysis. Pts were split into 2 mutually exclusive cohorts of incident RA-ILD pts (Pts having ≥1 ILD diagnosis before and after the chest X-ray/CT scan/Lung Biopsy/Pulmonary Function Test conducted post first RA diagnosis) and RA only patients (no ILD diagnosis in the study period). All-cause healthcare resource use and costs were calculated for the 12 months prior to and 12 months after diagnosis in both cohorts. Statistical differences between the RA-ILD

and RA only cohort were assessed using chi-square and Kruskal-Wallis tests with significance level of 0.05. For the incident RA-ILD cohort, an additional McNemar and Wilcoxon sign rank tests was conducted for the comparion between per and post ILD diagnosis period with significance level of 0.05.

Results: A total of 8,214 incident RA-ILD pts and 104,101 RA only pts were included in the analysis. RA-ILD pts were significantly older, had more comobididities and a lower percentage of female as compared to RA only patients (Table 1). In RA-ILD pts, all healthcare service use including inpatient visits, length of hospital stay, outpatient visits, pharmacy prescriptions increased significantly after the diagnosis of ILD for the RA-ILD cohort, resulting in a 74% increase in all-cause cost. (Table 2) Compared with RA only pts, RA-ILD pts showed a statistically greater increase in overall and all components of healthcare use over the study period (Table 3). The increase of all-cause medical cost was $20,444 higher in RA-ILD pts, primarily driven by the increase in the inpatient and outpatient cost.

Conclusion: RA-ILD pts had a substantial increase in healthcare resource utilization and a nearly doubled medical cost after the diagnosis of ILD. The greater cost was primarily driven by the higher use of inpatient and outpatient service. This indicates the need of more targeted treatment strategy to prevent ILD and improve clinical and economic outcomes of RA-ILD pts.

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Health Services Research Poster I – ACR/ARP
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: In 2018 an international task force published a recommended Treat to Target (T2T) approach to juvenile idiopathic arthritis (JIA) treatment. In February 2019, 17 centers participating in the Pediatric Rheumatology Care and Outcomes Improvement Network (PR-COIN) began a collaborative improvement project using quality

Figure 1. Network aggregate and one example centers' progress on Step 1

Step 1 Standardized assessment and review of components of the clinical juvenile arthritis disease activity score (cJADAS10)

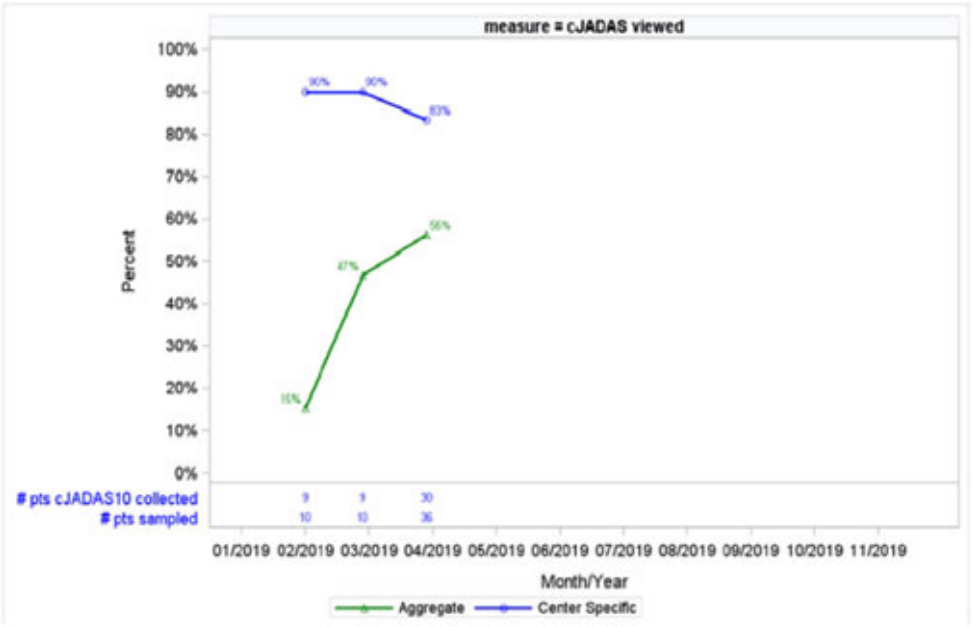

Figure 2. Network aggregate and one example centers' progress on Step 2

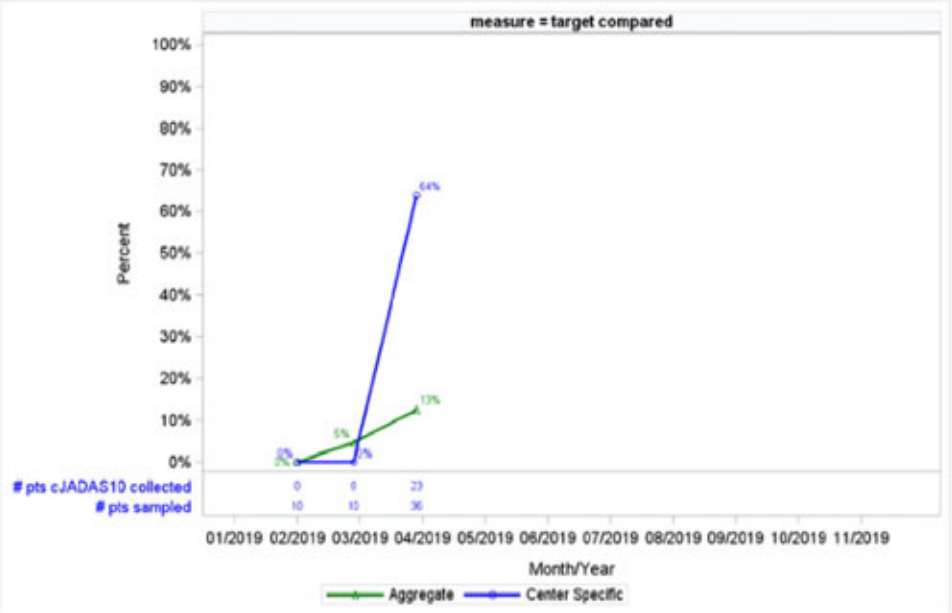
Step 2 Use shared decision making (SDM) concepts to select treatment target with the family and compare it to current disease activity



improvement (QI) methods to test and implement T2T interventions. Based upon published literature and one center pilot experience, PR-COIN designed an approach to introduce interventions to support successful and reliable deployment of three T2T component processes: standardized disease activity assessment, setting a treatment target with patient/family, and use of polyarticular JIA (Poly-JIA) clinical decision support (CDS). Our objective is to implement T2T with high reliability in 80% of PR-COIN centers by October 2019.

Methods: With patient/family partners, PR-COIN co-produced educational materials to train providers on implementation of T2T and to introduce families to the concept. The network adapted an evidence and consensus-based treatment algorithm, and designed a step-by-step implementation plan to support local implementation with a data submission platform to evaluate the interventions. Interactive monthly webinars feature best practices and performance reports, and QI/T2T process coaching. The interventions are being implemented in three steps: 1) standardized assessment and review of components of the clinical juvenile arthritis disease activity score (cJADAS10), including the physician global assessment, active joint count, patient assessment, 2) use shared decision making (SDM) concepts to select treatment target with the family and compare it to current disease activity and 3) use of CDS. Sites progress to the next step once reliable process implementation (>80%) is demonstrated in a representative sample of patients with Poly-JIA.

Results: As of April 2019, 16 centers are participating. All centers completed on-site training, 9/16 (56%) submitted at least one QI tool, and 11/16 (69%) eligible centers submitted performance data. A sample of patient-level data indicate 157/279 (56%) of patients are receiving Step 1 activities (Figure 1). Four of the sixteen centers (25%) are performing Step 1 activities with high reliability and have progressed to Step 2, with 4 / 35 (13%) of sampled patients engaged in SDM to set treatment targets (Figure 2). Figures show aggregate data alongside an example single center performance. Centers are demonstrating progressive improvement over time towards the reliability criteria to full implementation of T2T and performance goals.

Conclusion: Introduction of novel interventions required for fidelity of T2T implementation in pediatric rheumatology clinical practice requires a tiered approach with demonstrated commitment from trained providers, buy-in from leadership, and an identified QI lead. Co-producing support materials with families, infrastructure to support QI, and reliable data submission are key to success. We predict that center-level cJADAS10 improvement will correlate with reliability of the implementation of interventions.

Chronic Musculoskeletal Pain and Its Initial Management in Children, Adolescents and Young Adults in the United States

Debbie Ehrmann Feldman,[1] and Richard Nahin[2], [1]University of Montreal, Montreal, QC, Canada, [2]National Center for Complementary and Integrative Health, National Institutes of Health, Bethesda, MD

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Health Services Research Poster I – ACR/ARP
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Chronic musculoskeletal pain can affect up to 20% of persons under the age of 25 and is a risk factor for persistent chronic musculoskeletal pain in adulthood. Among those who consult a physician, prescribed treatment approaches vary and can be pharmacologic and nonpharmacologic. The goal of this study was to investigate chronic musculoskeletal pain in young people. Specifically we sought to 1) present a portrait of persons with chronic musculoskeletal pain in terms of sex, race/ethnicity, smoking status, and the various diagnoses related to chronic musculoskeletal pain in a representative sample of young Americans; 2) describe the initial clinical management of chronic musculoskeletal pain in this group; and 3) explore factors associated with prescribed treatments.

Methods: We analyzed data from the National Ambulatory Medical Care Survey and National Hospital Ambulatory Medical Care Survey-Out Patient Department (NAMCS) between 2007 and 2015. Visits among persons under the age of 25, with a new chronic musculoskeletal pain condition were identified using pre-determined diagnostic criteria. We documented the following treatment prescriptions: opioids, non-opioid pain medication, physical therapy, counseling and other non-pharmacological treatments. We describe the sample according to sex, age group (< 15 and 15-24), race/ethnicity, payment type for services (serving as a proxy for socioeconomic status), and type of physician (pediatrician, family doctor, specialist). Logistic regression models to determine factors associated with treatment prescription will be calculated.

Results: There were 1,316 initial visits over the 9-year period with a diagnosis of chronic musculoskeletal pain in the NAMCS database for persons under the age of 25, translating into 32,423,549 weighted initial visits, for a frequency of 3.4% of Americans < 25 years of age. Opioid prescription was low for those under the age of 15 years at 1.2% but increased to 13.9% in the 15-24 year old group. Non-opioid pain medications were prescribed in 33.2% of the cases for the younger group and 40.6% in the older group. The proportions prescribed physical therapy, counseling and other nonpharmacological treatments were respectively, 6.3%, 8.3% and 15.4% in those under 15 years and 13.6%, 10.4% and 9.4% in those 15-24 years.

Conclusion: Nearly 3.5% of young Americans consult a physician for a **c**hronic musculoskeletal pain condition. Pharmacologic treatment is used much more than nonpharmacologic treatment, and opioid prescription in the adolescent and young adult group nears estimates of opioid prescription in adults with these problems. Reasons for the low use of nonpharmacologic treatments need to be elucidated.

Alcohol Use Hospitalizations in People with Gout, Osteoarthritis, Rheumatoid Arthritis, Fibromyalgia, and Low Back Pain Are Increasing: A Time-trends Study Using the U.S. National Data

Jasvinder Singh,[1] and john Cleveland[2], [1]University of Alabama Medical Center, Birmingham, [2]University of Alabama at Birmingham, Birmingham, AL

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Health Services Research Poster I – ACR/ARP
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Alcohol abuse and associated mortality is an important public health problem in the U.S. To our knowledge, limited data are available on alcohol use disorder-related hospitalizations in people with common musculoskeletal diseases.

Methods: We used the U.S. National Inpatient Sample (NIS) data from 1998-2014 to examine the rates of alcohol use disorder-related hospitalizations without overdose, detoxification or rehabilitation services, based on the presence of International Classification of Diseases, Ninth or Tenth Revision, Clinical Modification (ICD-9-CM or ICD-10-CM) diagnostic codes for alcohol dependence or abuse in the primary diagnosis position. We assessed five common rheumatic diseases using the respective diagnostic codes in a secondary position: Gout, rheumatoid arthritis (RA), fibromyalgia, osteoarthritis (OA), and low back pain (LBP). Incidence of alcohol use disorder claims was assessed per 100K NIS claims overall.

Results: The incidence of alcohol use disorder-related primary hospitalizations was low in 1998-2000 for the five musculoskeletal conditions and increased over the 19-year study period (**Table1**). The increase was 2-fold higher in people with gout, osteoarthritis or LBP, 2.5-fold for RA versus 3-fold higher in people with fibromyalgia. Rates of alcohol use disorder per 100K total NIS claims showed similar trends, with an increase ranging 3-fold in people with

Table 1. Number of alcohol use disorder as the primary reason for hospitalizations from 1998 to 2016 by five common musculoskeletal diseases

	Gout	OA	Fibromyalgia	RA	Low Back Pain
1998 - 2000	5.69	8.09	1.36	1.82	4.93

% change	106.3%	141.4%	210.8%	91.5%	96.4%

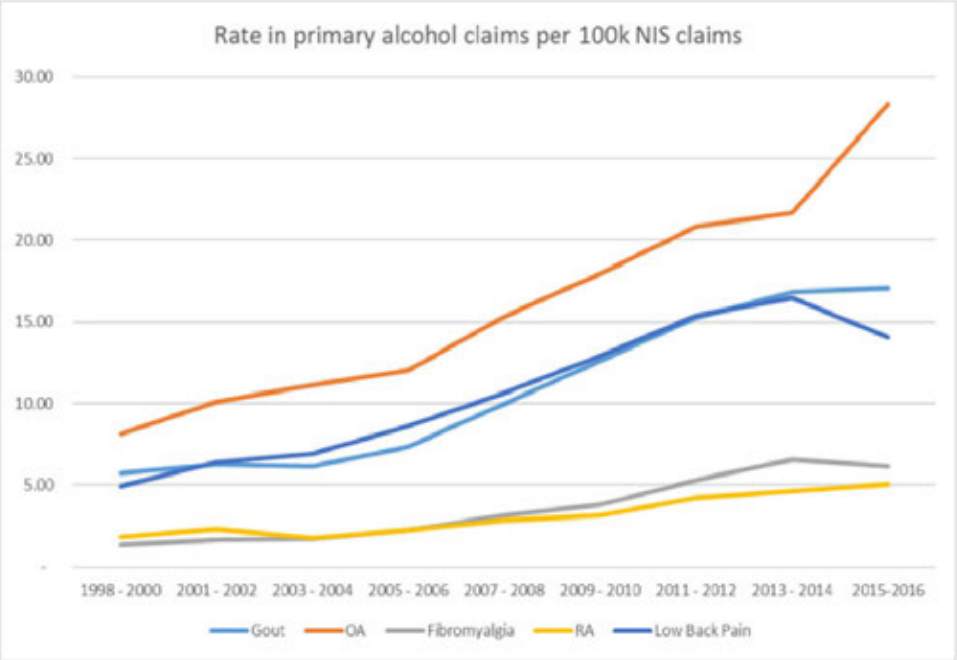

Figure 1. Trends in rates of primary alcohol abuse claims per 100K NIS claims, by five musculoskeletal conditions

gout, osteoarthritis, LBP or RA to 4.5-fold in people with fibromyalgia (**Table 2**). There was a plateauing of alcohol use disorder claims for all conditions except osteoarthritis (**Figure 1**).

Conclusion: The rate of increase in alcohol use disorder hospitalizations occurred in all 5 musculoskeletal conditions, but the rate differed by the condition. Providers need to counsel their patients with these musculoskeletal conditions regarding the risk and impact of alcohol use, in order to prevent associated morbidity and mortality. Findings are also important for policy makers with regards to resource allocation.

Health Services Utilization as Recommended by the American Diabetes Association Among Middle-Aged Patients Disabled with Rheumatoid Arthritis and Diabetes Mellitus

Geyanne Lui,[1] Mangala Rajan,[1] Lisa Kern,[1] Laura Pinheiro,[1] Monika Safford,[1] Jeffrey Curtis,[2] and Iris Navarro-Millan[1], [1]Weill Cornell Medicine, New York, [2]University of Alabama at Birmingham, Birmingham, AL

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Health Services Research Poster I – ACR/ARP
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Medicare beneficiaries who are disabled (coverage by the Social Security Disability Insurance (SSDI)) with rheumatoid arthritis (RA) and diabetes mellitus (DM) and under 65 years of age are complex patients with heavy healthcare use. These young disabled patients cost 31% more than older Medicare patients, but we do not know whether they are receiving the basic standards of diabetes care given their disability and complexities related to also having RA. Our purpose was to assess the standard of care for diabetes measured by health services utilization in patients under 65 years of age who are disabled with RA and DM by race and ethnicity.

Methods: We conducted a longitudinal analysis from 2010– 2014 of patients who were beneficiaries of the SSDI with both RA and DM. RA was defined in 2010 as either 1) two RA diagnoses (ICD9-714.xx) by a rheumatologist between 7 and 365 days apart; OR 2) one RA diagnosis by a rheumatologist and at least 1 prescription for a disease modifying anti-rheumatic drug. DM was defined as one diagnosis from any physician (ICD-9 250.xx) in 2010. Patients were followed for 4 years (2011 – 2014) and outcomes were the testing and visit standards defined by the 2010 American Diabetes Association. We used Poisson models to adjust for age, gender, and Charlson-Deyo Comorbidity Index and examined the differences between racial/ethnic groups.

Results: In 2010, there were 5,380 patients under the age of 65 disabled with RA and DM receiving SSDI benefits. The cohort was 78% female and 61% had 5 or more comorbidities. These patients had high health services utilization with a mean number of visits to the doctor of about 18 visits a year (Table 1). More than half (53.5%) of all patients did not receive a foot exam and almost a quarter (23.3%) did not receive an eye exam in 2011-2014. After multivariable

Table 2. Adjusted Annual Means of Testing and Visits for Standards of Diabetes Care among Medicare SSDI (Disabled) recipients under 65 years with Rheumatoid Arthritis and Diabetes in 2011 - 2014

	Cohort in 2010 followed from 2011 to 2014		
Race/Ethnicity++	White N = 3,281	Black N = 1,119	Hispanic N = 742
Annual mean of HbA1c Tests	2.19 (2.03 - 2.37)	2.14 (1.96 - 2.33)	2.39 (2.18 - 2.61)*
Annual mean of Urine Albuminuria Tests	2.28 (2.10 - 2.48)	2.40 (2.15 - 2.61)	2.80 (2.53 - 3.09)*
Annual mean of Lipid Tests	1.67 (1.54 - 1.81)	1.70 (1.55 - 1.85)	1.96 (1.79 - 2.15)*
Annual mean of eye exams	0.88 (0.79 - 0.98)	1.03 (0.91 - 1.17)*	1.16 (1.12 - 1.32)*
Annual mean of foot exams	1.18 (0.95 - 1.46)	1.04 (0.83 - 1.32)*	1.01 (0.80 - 1.29)*
Annual mean of visits (Evaluation and Management)	19.19 (18.21 - 20.23)	19.15 (18.04 - 20.32)	19.97 (18.76 - 21.25)
Annual mean of visits to rheumatologist	2.69 (2.48 - 2.92)	2.88 (2.63 - 3.14)*	3.08 (2.81 - 3.38)*
Annual mean of visits to primary care†	5.36 (4.81 - 6.21)	5.35 (4.88 - 5.87)	6.03 (5.47 - 6.64)*

+ Poisson model to estimate the counts, adjusted for age, gender, and Charlson-Deyo Comorbidity Index
++ Race/Ethnic category of Other were dropped from the tables to improve readability
*Indicates significant difference with White group, $p<0.05$

adjustment, Hispanic patients had a statistically significant higher annual mean of testing (HbA1c 2.39 vs 2.19, urine albuminuria 2.8 vs 2.28, and lipid 1.96 vs 1.67) than White patients in 2011-2014 (Table 2). Both Hispanic and Black patients had a higher annual mean of eye exams (1.16 and 1.03, respectively, vs 0.88) but lower annual mean of foot exams (1.01 and 1.04, respectively, vs 1.18) than the White patients.

Conclusion: Disabled patients with RA and DM had high utilization of health services and received most of the recommended standard of care for diabetes, which was similar across all racial/ethnic groups. The exception was for eye exams, which was lower among Whites. However, there was low utilization of specialty services related to DM care such as ophthalmology evaluations or foot exams by any physician.

**Patients in the early treatment group-initiated therapy with either an OSM, biologic, or newer OSM within 90 days of the index PsA diagnosis claim. Patients in the delayed/non-treatment group either initiated treatment sometime following the initial 90-day period post-index or did not initiate treatment during the 12-month follow-up period.*

Background/Purpose: The clinical heterogeneity of psoriatic arthritis (PsA) presents a variety of diagnostic and treatment challenges, which may be reflected in the way different health care providers approach the treatment of their patients. Differences in clinical practice between physician specialties may have lasting consequences on patient health outcomes, though there is a dearth of real-world evidence available on the topic.

Objective: To describe treatment patterns and healthcare costs between PsA patients stratified by their treating provider's specialty.

Methods: This study used administrative claims from the IBM® MarketScan® commercial and supplemental Medicare databases from 2014-2017. The sample included patients ≥18 newly diagnosed with PsA (first diagnosis=in-

Note: Annual healthcare costs include medical services (hospitalization, ER visits. Physician office visits, and other outpatient services). Total costs equal all medical services plus all outpatient prescription costs.

Figure 1. Mean Total Annual Healthcare Costs by Provider Group

dex date) with continuous plan enrollment for 12 months both preceding and following index date, an absence of infectious diseases, cancer, and any additional autoimmune disease excluding psoriasis, and an absence of any pharmacologic treatments indicated for PsA during the pre-index period. Patients treated with a medication for PsA were assigned to a physician specialty as observed during the 30-day period preceding the earliest medication claim. Patient not treated with PsA medications within the first 90 days after diagnosis were assigned to the provider listed on their diagnostic index claim. One-year outcomes included medication utilization including switching rates, and healthcare expenditures. Descriptive analyses were conducted by provider specialty and medication and included measures of central tendency and dispersion.

Results: 3,520 patients qualified for the study; the majority were female (56%) with an average age of 49.7. Of all rheumatologist's PsA patients, about two thirds (65%) had early pharmacologic treatment, in contrast to approximately 46% of dermatologist's patients (*p*s < 0.001). Of those with a medication, about 55% of these were prescribed by a rheumatologist; 8% by a dermatologist; < 1% by combination of both; 13% by a primary care provider (PCP); and 24% by others (e.g., pain management, physical medicine & rehab, etc.) (Table 1). Dermatologists were more likely to prescribe a TNFi (73%) compared to remaining provider groups (ranges 33%-48%; *p*s < 0.001) (Table 2). Mean total annual prescription and healthcare expenditures exhibited great variation for all provides, with rheumatologists and dermatologists having similar total costs despite lower prescription costs for rheumatologists (Figure 1).

Conclusion: There is significant variation in the pharmacologic treatment for PsA by different physician specialties. Our findings begin to uncover the impact of rheumatology practice patterns compared to other specialties. While more research is needed to confirm the findings, they highlight potential differences between rheumatologists and other physicians in managing costs and adherence to the recommended clinical guidelines for the management of PSA.

Rheumatoid Arthritis Associated with Longer Hospital Stays in Patients Admitted with Venous Thromboembolism: A Nationwide Analysis 2010-2014

Shraddha Jatwani,[1] Karan Jatwani,[1] and Karan Chugh[1], [1]St. Vincent Evansville, Evansville, [2]Mount Sinai West - St Luke's Hospital, New York

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Health Services Research Poster I – ACR/ARP
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM.

Background/Purpose: Venous thromboembolism (VTE) is a major health problem and can be potentially fatal when complicated by lethal pulmonary embolism (PE). Previous hospital-based studies have reported an increased risk of VTE among hospitalized patients with rheumatoid arthritis (RA), particularly in the first year after admission for RA (1). The relative risk of VTE in patients with RA hospitalized for other causes besides joint surgery was 1.99. (2) Data describing differences in mortality and morbidity of patients with a history of rheumatoid arthritis is limited in current

Table 1: Baseline Characteristics of patients with Venous thromboembolism National Inpatient Sample 2010-2014

literature. In our study, we discuss the potential impact on mortality, length of stay, and cost of hospitalization in patients admitted with VTE with a history of RA.

Methods: We analyzed hospitalizations for VTE (both Deep Venous Thrombosis and PE) among adults in the Nationwide Inpatient Sample (NIS). Patients were stratified into two groups based on the status of RA; using ICD-9 CM diagnostic codes. Descriptive statistics were represented as means/medians for continuous and as frequencies and percentages for categorical variables. A survey weighted multivariate regression analysis was used to adjust for confounders when comparing mortality, length of stay, and total charges.

Results: A total of 1,481,777 admissions with a primary diagnosis of VTE were identified from 2012-2014, and amongst these patients, 33,152 patients had an underlying diagnosis of RA. Patients with underlying RA were older (average age 68.42years vs. 63.19 years), more often females (73.86% vs. 52.16%), and had multiple comorbidities, as described in Table 1. Patients with RA had a significantly longer length of stay (LOS) compared to those without RA (Avg LOS 5.1 days vs. 4.9 days, p value=0.00), but mortality rates were lower in this population (1.67% vs. 2.01%,p value=0.05).

Conclusion: VTE is a major healthcare burden in the US population, and RA has been associated with an increased risk of VTE. Endothelial dysfunction in inflammatory diseases accelerates microvascular thrombosis cascade. Even though RA may not affect the mortality in patients with VTE, this study shows increased morbidity with increased length of stay and cost per hospitalization. Hospitalized RA patients should be evaluated for known risk factors for VTE and should be initiated on VTE prophylaxis at admission unless contraindicated. We also recommend additional analytic studies in other databases to confirm these findings, further quantify the risks, and also develop appropriate monitoring and prophylactic strategy in the hospitalized RA population.

Impact of Rheumatoid Arthritis on Outcomes of Atrial Fibrillation: Results for National Inpatient Sample

Shraddha Jatwani,[1] Karan Chugh,[1] Bikramjit Bindra,[2] and Karan Jatwani[3], [1]St. Vincent Evansville, Evansville, [2]Government Medical College & Hospital, Chandigarh, India, [3]Mount Sinai West - St Luke's Hospital, New York

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Health Services Research Poster I – ACR/ARP
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Atrial Fibrillation (AF) is a common cardiac arrhythmia related to increased cardiovascular morbidity and mortality. There is a significant association of systemic inflammation with the pathogenesis of AF. Several studies have assessed the relationship of AF with Rheumatoid Arthritis (RA) with variable results. Some studies suggest 29-40% higher incidence of AF with RA, while others did not find any increased risk of AF in RA. In this study, we used the National Inpatient Sample (NIS) to assess the impact of RA on demographics, mortality, length of stay, and cost per hospitalization for AF in comparison to non-RA hospitalizations.

Methods: Healthcare Cost and Utilization Project's NIS is the largest all-payer inpatient database in the United States with discharge data from >1200 hospitals, located across the nation. We queried the National Inpatient Sample from 2010-2014 to identify adult hospitalizations for AF with and without RA, using validated ICD-9 CM codes. Logistic regression analysis was used to identify independent associations with in-hospital mortality. Multivariate regression was applied to adjust for confounders.

Results: There were an estimated 43910 adult hospitalizations for AF with a secondary diagnosis of RA, from 2010 to 2014. On univariate analysis, the average age for hospitalizations with AF in the non-RA group was 70.03years, whereas, in the RA group, the average age for was 73.26 years ($p< 0.001$). 72.15% of all hospitalizations with AF & RA were females (significantly higher, p-value < 0.001). Unadjusted logistic regression suggested an increased risk of mortality in patients with AF & RA with an odds ratio of 1.297 (p value=0.01), but after adjusting for confounders, a relative decrease in mortality was identified patients with AF & RA (Adjusted Odds Ratio=0.781; p value=0.025). Unadjusted Linear regression for length of stay (LOS) per hospitalization suggested longer length of stay for patients with AMI & RA (3.837 days vs. 3.41 days, p-value < 0.001), but when adjusted for confounders with multivariate regression, LOS was found to be lower (Coefficient = -0.243; p value< 0.001)

Conclusion: This study reports contemporary data of AF & RA hospitalizations over five years in the United States. It suggests that patients with AF and RA have similar and possibly better outcomes for mortality compared to the

Table 1: Baseline Demographics of hospitalizations for Atrial Fibrillation (AF) without and with underlying Rheumatoid Arthritis (RA)

Outpatient Healthcare Utilization Among Incident Cases of Systemic Sclerosis: Results from a Population-based Cohort (1988-2016)

Caitrin Coffey ,[1] Avneek Singh Sandhu,[2] Cynthia Crowson,[3] Dennis Asante,[1] Eric Matteson,[4] Thomas Osborn,[5] Kenneth Warrington,[6] and Ashima Makol[5], [1]Mayo Clinic, Rochester, MN, [2]kettering health, dayton, OH, [3]Mayo Clinic Rochester, Rochester, [4]Mayo Clinic College of Medicine and Science, Rochester, Minnesota, USA, Rochester, [5]Mayo Clinic Minnesota, rochester, MN, [6]Mayo Clinic Rochester, Rochester, MN

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Health Services Research Poster I – ACR/ARP

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic sclerosis (SSc) is a chronic autoimmune disorder which results in multi-organ dysfunction and high morbidity and mortality. There is limited data on healthcare resource usage in patients with SSc. The purpose of this study was to compare healthcare utilization among incident cases of SSc vs age- and sex-matched comparators without SSc.

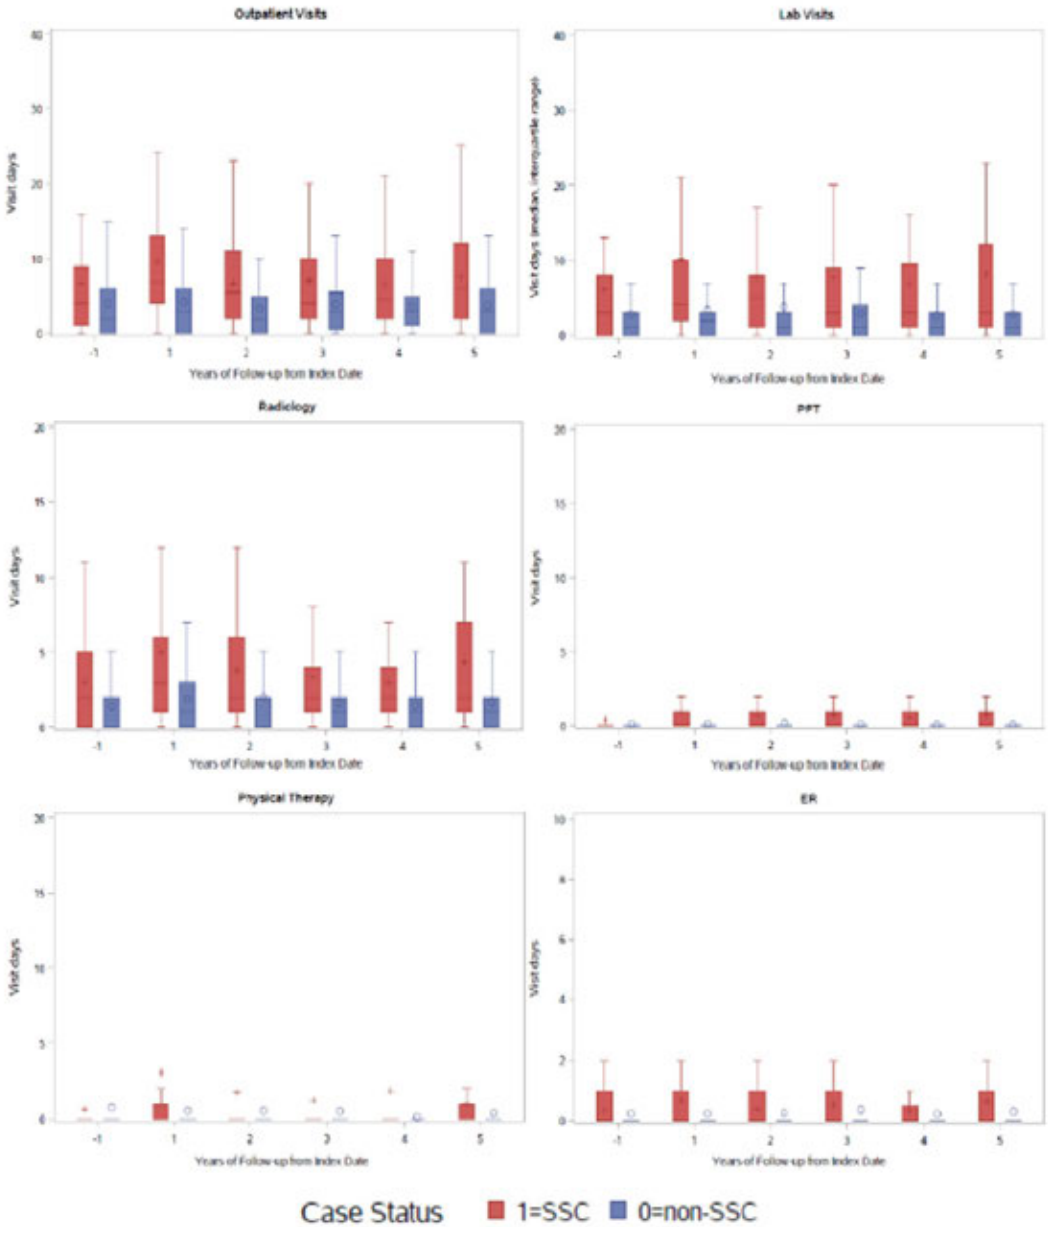
Table. Comparison of outpatient visits, laboratory testing visit-days and imaging visit-days in patients with and without incident systemic sclerosis.

Services	Time Interval (years)	Number of patients, SSc / Non-SSc	SSc Median visit-days (IQR)	Non-SSc Median visit-days (IQR)	Rate Ratio (95% CI)
Outpatient visits	-1-0	69/138	4 (1–9)	2 (0–6)	1.7 (1.1-2.6)
	0-1	69/138	7 (4–13)	3 (0–6)	2.3 (1.7-3.1)
	1-2	66/132	5.5 (2–11)	2 (0–5)	2.1 (1.5-2.9)
	2-3	54/108	4 (2–10)	3 (0.5-5.5-)	1.8 (1.3-2.6)
	3-4	48/96	4.5 (2–10)	3 (1–5)	1.8 (1.3-2.6)
	4-5	43/86	6 (2–12)	3 (0–6)	2.0 (1.4-3.0)
Laboratory testing	-1-0	69/138	3 (0-8)	1 (0-3)	2.1 (1.4–3.3)
	0-1	69/138	4 (2-10)	2 (0–3)	3.0 (2.0–4.6)
	1-2	66/132	5 (1-8)	1 (0–3)	2.0 (1.3–3.2)
	2-3	54/108	3 (1-9)	1 (0–4)	2.6 (1.7–4.3)
	3-4	48/96	3 (1-10)	1 (0–3)	2.7 (1.7–4.1)
	4-5	43/86	3 (1-12)	1 (0–3)	2.9 (1.7–4.7)
Radiology Services	-1-0	69/138	2 (0–5)	0 (0–2)	2.1 (1.6–4.2)
	0-1	69/138	3 (1–6)	1 (0–3)	2.6 (1.8–3.9)
	1-2	66/132	2 (1–6)	0 (0–2)	1.9 (1.8–3.1)
	2-3	54/108	2 (1–4)	1 (0–2)	2.1 (1.3–3.1)
	3-4	48/96	2 (1–4)	1 (0–2)	2.0 (1.3–3.1)
	4-5	43/86	2 (1–7)	1 (0–2)	2.6 (1.6–4.2)

IQR: interquartile range; CI: confidence interval

Methods: A retrospective, population-based cohort of physician-diagnosed patients with SSc in a geographically well-defined area from Jan 1, 1988 to Dec 31, 2016 was assembled. Fulfillment of 2013 ACR/EULAR classification criteria for SSc was ascertained. A 2:1 cohort of age- and sex-matched non-SSc subjects from the same population base was randomly selected for comparison. Outpatient utilization data were obtained beginning 12 months prior to the SSc incidence/index date. Patients were followed until death, migration from the area, or December 31, 2017. A maximum of 5 years following the incidence/index date was used for analysis and the

Figure. Comparison of outpatient visits-days by type of visit between SSc subjects and non-SSc comparators.



ER: Emergency room visit, PFT = Pulmonary function test

follow-up of each matched triple was further truncated at the shortest length of follow-up for any member, to ensure similar periods of observation for SSc cases and non-SSc comparators. Services were summarized as visit-days (number of days at least one service in the category was billed) to avoid overestimation of services provided. Utilization was compared between SSc and non-SSc cohorts using negative binomial and multinomial models.

Results: The cohort included 69 incident SSc cases and 138 non-SSc comparators (mean age of 57 ± 16 years at diagnosis/index, 90% female for both cohorts; 87% [SSc] and 95% [non-SSc] Caucasian). Patients with SSc had the highest utilization of outpatient physician visit-days, laboratory visit-days and combined radiology visit-days during the year of the SSc diagnosis compared with the year prior to diagnosis or years 1 to 4 after diagnosis of SSc (Table, Figure). They also had higher utilization of outpatient physician, laboratory and combined radiology visit-days annually for the year prior to SSc diagnosis and for each of the first 5 years after SSc diagnosis compared to patients without SSc (Table). Rate ratios comparing utilization in patients with and without SSc ranged from 1.8 to 3.0 for all comparisons.

In the year of SSc diagnosis, visit-days specifically for X-rays, computed tomography scan, ultrasound, cardiovascular and gastroenterological testing and procedures, pulmonary function testing, emergency department visit, and physical therapy were higher for SSc subjects than non-SSc comparators, with rate ratios ranging from 2.5 to 13.0. Utilization of magnetic resonance imaging, nuclear medicine imaging, and musculoskeletal procedures were similar between groups in the year of diagnosis.

Conclusion: A higher utilization of outpatient physician visit-days, laboratory visit-days and radiology visit-days was observed among patients with SSc compared to non-SSc subjects throughout 5 years of disease duration, indicating high and continued care needs in this patient population. Highest utilization of services among SSc subjects occurred during the year of SSc diagnosis.

Health Professionals Agreed with Recommendations to Evaluate and Optimize Adherence to Disease-modifying Treatments, but Perceived Feasibility Was Lower: A Study of 357 Physicians and Health Professionals in France

Laure Gossec ,[1] Anna Moltó,[2] Catherine Beauvais,[3] Eric Senbel,[4] René-Marc Flipo,[5] Sophie Pouplin,[6] Christophe Richez,[7] Alain Saraux,[8] Philippe Gaudin,[9] Daniel WENDLING,[10] and Maxime Dougados[11], [1]Sorbonne Université and Hôpital Pitié-Salpêtrière, Paris, France, [2]Paris Descartes University, Cochin Hospital, Rheumatology department, Paris, France, [3]Paris St Antoine University Hospital, Paris, France, [4]Rheumtologist Private Practice, Marseille, France, [5]University of Lille, CHU Lille, department of rheumatology, 59,000 Lille, France, Lille, France, [6]Rouen University Hospital, Rouen, France, [7]Pellegrin Hospital, University Hospital of Bordeaux, Bordeaux, France, [8]CHU de la Cavale-Blanche Brest, Brest, France, [9]Rheumatology Department, CHU Grenoble Alpes Hôpital Sud and GREPI - Université Grenoble Alpes, EA7408, Grenoble - Echirolles, France, [10]Rheumatology, University Teaching Hospital [CHRU], Besançon, France, [11]Cochin Hospital, Paris, France

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Health Services Research Poster I – ACR/ARP
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: In chronic inflammatory rheumatic diseases (CIRDs), including rheumatoid arthritis, spondyloarthritis, connective tissue diseases and crystal-induced arthritis, long-term adherence to disease-modifying drugs (DMARDs) is only moderate. In 2017, a group of 105 experts developed recommendations to facilitate the evaluation and management of non-adherence to DMARDs in daily practice [1]. Five overarching principles and 10 recommendations were developed [1].

The objective of this study was to evaluate the agreement of French rheumatologists and health professionals (HPs) with these recommendations, their perceived feasibility/ ease of application and participants' characteristics linked to perceived feasibility.

Methods: Face-to-face meetings were organized across France in 2018 by the program sponsor (Abbvie) with the support of the program committee. During these meetings, the key data and the recommendations were presented and discussed [1]. Participants then informed on paper, their personal data, agreement (from 1 to 5, where 5 is highest) and perceived feasibility (1-5) for each recommendation. Mean agreement and perceived feasibility were calculated for each recommendation. A univariate and multivariate logistic regression identified the characteristics of the participants who rated feasibility the highest (pooled mean above the median).

Results: A total of 38 meetings were held involving 377 physicians/other HPs: 357 (95%) provided analyzable data. The respondents had an average age of 46 years [standard deviation, SD 13]; 223 (63%) were female. Among the 247 (69%) rheumatologists, one third were hospital based (N=90, 37%). Other HPs were nurses (N=81, 23%) or pharmacists (N=14, 4%). Pooled agreement with the overarching principles was very high (mean 4.4 [0.5]). Agreement with the 10 recommendations was also high: pooled mean 4.3 [0.4]; the recommendation with the lowest agreement (mean 3.9 [0.9]) was recommendation 3 on assessing adherence by complex methods. Perceived feasibility was lower (pooled mean 3.4 [0.5]) with a range of means from 2.8 [0.9] (recommendation 3) to 3.9 [0.9] (recommendation 2: assess adherence by an open-ended question). More than 30% of participants rated the feasibility as low (score 1 or 2) for recommendations 3 and 8 (specific intervention in case of non-adherence). The only factor correlated with

greater perceived feasibility was being a HP other than a rheumatologist: odds ratio 2.52 [95% confidence interval 1.23-5.15], while age, gender and type of exercise were not significant. Thus, perceived feasibility seemed higher among non-physician HPs, which may be due to the selection of HPs with a strong interest on patient education.

Conclusion: French HPs are in agreement with recently-published recommendations for the evaluation and optimization of adherence to DMARDs [1]. However, feasibility was lower, especially with regard to complex evaluation of non-adherence, and targeted interventions. This initiative has contributed to the dissemination of the recommendations; the next step will be their implementation. [1] L. Gossec et al. Joint Bone Spine. 2019;86(1):13-19.

Gaps in Patient Safety Performance in Patients with Immunosuppressive Therapy: Results of Screening for Infections and Vaccination Status in a Large Real-life Cohort

Uta Kiltz ,[1] Aylin Celik,[2] Styliani Tsiami,[1] Björn Bühring,[2] Xenofon Baraliakos,[3] and Jürgen Braun[4], [1]Rheumazentrum Ruhrgebiet/Ruhr University Bochum, Herne, Germany, Herne, Germany, [2]Rheumazentrum Ruhrgebiet and Ruhr-University Bochum, Herne, Germany, [3]Rheumazentrum Ruhrgebiet-Ruhr-University Bochum, Herne, Germany, Herne, Germany, [4]Rheumazentrum Ruhrgebiet/Ruhr University, Herne, Germany

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Health Services Research Poster I – ACR/ARP
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with chronic inflammatory rheumatic diseases (CIRD) are known to have an increased risk of infections compared to the general population. Therefore, prevention of infections by vaccination strategies is mandatory. The aim of this study was to evaluate the vaccination status in patients with CIRD.

Methods: Consecutive patients with CIRD were prospectively recruited. Disease characteristics, vaccination status and screening for latent tuberculosis infection (LTBI) and hepatitis B (hepB) were analyzed. Antibodies against measles and hepB were measured. The vaccination status was assessed by a predefined vaccination score (range 0-26): 3 points for a complete vaccination, 2 points for a basic immunization and 1 point for an incomplete vaccination status for tetanus, diphtheria, poliomyelitis or pertussis. For hepB, pneumococcal, influenza, meningococcal, measles, rubella and varicella 2 points were given for a complete vaccination status and 1 point for an incomplete vaccination status. Finally, patients were categorized into 3 immunization states: low (0-6), moderate (7-13), good (14-20) and high (21-26).

Results: A total of 975 patients with CIRD were included (table 1). All patients on bDMARDs (n=499) were screened for LTBI, and 469 also for hepB (94%). Only 16 patients with LTBI received prophylaxis with isoniazid (3.2%) and only

Complete hepatitis B vaccination status	36 (8,5)	26 (17,9)	13 (9,8)	10 (24,4)	37 (15,9)

Table 1: Patients characteristics of our cohort

All values are given in mean (SD) otherwise indicated

*Physical function was assessed with HAQ except in axSpA patients in whom the BASFI was used.

16 patients with hepatitis B received prophylaxis with lamivudine (3.4%). The mean anti-HBs titer was 251.1±258.1 IU/l. Protective measles specific IgG-antibodies were found in 901 patients (92.4%). No more than 30% of patients had undergone pneumococcal vaccination and less than 20% were protected against hepB and influenza. Although 629 patients had been educated about vaccination strategies (64.5%), only 540 patients could show a vaccination certificate (55.4%). The mean vaccination score was 12.8±4.9 with 5.3% of patients categorized having a low, 24.3% a moderate, 26.1% a good and 1.8% a high score.

Conclusion: Screening for tuberculosis and hepatitis is successfully implemented in clinical routine in Germany but many patients are not sufficiently vaccinated against pneumococci, hepatitis B, influenza and measles. Our vaccination strategy is based on cooperation with GPs. However, this strategy did not seem to work. The overall rate of successful vaccination was low to moderate although patients received professional information about vaccine strategies.

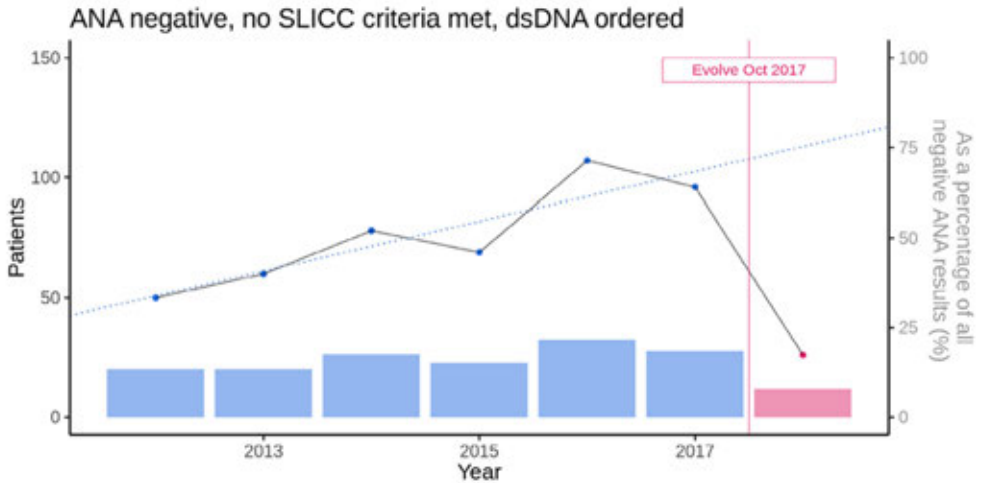
Figure 1. Reduction of anti dsDNA antibody ordering after publication of national recommendation



tive. One recommendation in keeping with international guidelines suggested avoiding ordering anti-double-stranded DNA antibodies (dsDNA) in anti-nuclear antibody (ANA) negative patients unless there was a high clinical suspicion of Systemic Lupus Erythematosus (SLE). Inappropriate anti dsDNA antibody ordering confers a substantial and unnecessary cost on health resources.

We sought to compare ANA and anti dsDNA antibody ordering practices in a large tertiary teaching hospital before and after the Evolve recommendations were promoted.

Methods: Results of ANA and dsDNA testing ordered through the institutional laboratory of a large tertiary teaching hospital between 2012-2018 inclusive were captured, as were data paired to these tests including age, gender and the ordering medical specialty. Analysis was performed on results ordered between January 1 and March 31 of each year. Retrospective chart review of ANA negative patients with dsDNA testing ordered was performed to review the indication for testing and the presence of component clinical criteria from the Systemic Lupus International Collaborating Clinics Classification (SLICC) Criteria for Systemic Lupus Erythematosus.

Results: A total of 24,501 ANA tests were performed between January 1, 2012 and August 16, 2018. Of these, 5216 patients had ANA tests ordered between January 1 and March 31 in any year, with 3071 having returned a negative ANA result and 803 of these having also had a dsDNA ordered (Table 1). The majority of these patients had no history of any SLICC clinical criteria (486, 60.5%). Very few ANA negative patients who did not meet SLICC criteria had positive dsDNA (14, 2.8%) and all were low titre. None of these dsDNA results were relevant to the patient's eventual diagnosis. There was a marked reduction in dsDNA ordering following the promotion of the Evolve recommendations starting October 2017, from 96 patients during January - March 2017 to 28 patients during Januaryy – March 2018 (Figure 1).

Conclusion: A majority of patients who had dsDNA testing ordered despite a negative ANA result had no clinical features of SLE. There has been a marked reduction in the ordering of dsDNA testing in ANA negative

Measuring Advanced/Extended Practice Roles in Arthritis and Musculoskeletal Care in Canada: Stand up and Be Counted Too (2)!

Katie Lundon ,[1] Taucha Inrig,[2] Morag Paton,[1] Rachel Shupak,[2] Carol Kennedy,[2] Mandy McGlynn,[3] and Claire Barber[4], [1]University of Toronto, Toronto, [2]St. Michael's Hospital, Toronto, ON, Canada, [3]UHN, Toronto, [4]University of Calgary, Calgary, Canada

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Health Services Research Poster I – ACR/ARP
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Arthritis and musculoskeletal disorders are the most common chronic health conditions in Canada but there is a critical and growing shortage of rheumatologists relative to the needs of an aging population. Models of care involving advanced or extended role health disciplines practitioners to augment provision of arthritis care are emerging. Research supports these roles, however there are no studies to date documenting the workforce capacity or learning needs of advanced and extended role health disciplines.

Study Objectives

1. To capture descriptive information on the current workforce practices/attributes of advanced or extended role practitioners (ERPs) working in arthritis care in Canada.
2. To determine perceived opportunities and barriers in the pursuit of formal academic/clinical training to support these roles.

Methods: This Pan-Canadian exploratory cross-sectional self-report study was developed and based on the original Stand Up and Be Counted Rheumatologist Workforce Survey.

Data were collected using anonymous, online questionnaires deployed in early 2018 to groups of non-physician health disciplines professionals across Canada with potential to have undertaken formal and informal post-licensure training in arthritis care. Descriptive statistics were generated to describe the demographics and practice information of the sample. Qualitative responses were analyzed using Grounded Theory techniques.

Results: There were 141 respondents; 91 were identified as practising in an extended role capacity. Respondents were further characterized by profession (PT >OT >RN >Chiropractor/Pharmacist) and by their post-licensure training in arthritis care (ACPAC >CPSIA >ACR >Institutional-apprenticeship >ISAEC). Mean age of ERP respondents was 49±9 years, 87% (n=79) were female, and 41% (n=38) of ERPs planned to retire within 5-10 years. Geographic practice sites were Ontario > Alberta > British Columbia > Newfoundland and practice settings were urban academic (46.2%), community (38.5%) and rural (13.2%). Almost 50% (n=45) of ERPs treated patients with inflammatory arthritis. 54% (n=20) of non-ERP respondents had received some form of advanced training but were not deployed as ERPs; almost all 98% (n=89) of ERP respondents had undertaken advanced training. 95% (n=103) of all respondents agreed that formal training is necessary to work as an ERP but only half (n=52) felt that they had sufficient opportunities to pursue training. Barriers to pursuing training are various: from personal, geographic, and patient-care/patient-needs related, to administrative, post-program recognition and financial/remuneration concerns.

Conclusion: No previous studies have assessed the workforce attributes of non-physician, advanced practice arthritis care providers or the perceived need for the training of ERPs working in arthritis/MSK care. It is important to measure the workforce capacity of these health disciplines practitioners as they evolve and integrate into the Canadian healthcare system.

Develop Risk Prediction Model and Drug Withdrawl Road Map Through Pattern Extraction and Data Mining: Create a Master Algorithm from the Smart System of Disease Management (SSDM)

Yan Zhao ,[1] Xiaomei Li,[2] Rong Mu,[3] Xiaoxia Zuo,[4] Hua Wei,[5] Lingli Dong,[6] Shouxin Li,[6] Hongsheng Sun,[7] Guanmin Gao,[8] Lijun Wu,[9] Bing Wu,[10] Yuhua Jia,[11] Hui Xiao,[12] Minghua Xu,[13] Wenyu Zhou,[14] Aichun Chu,[15] Li Dong,[16] Huiqin Yang,[17] Ming Gui,[18] Weiqi Min,[19] Zhenchun Zhang,[20] Ying Pan,[21] Junli Zhang,[22] Jinchang He,[23] Haiying Chen,[24] and Fei Xiao[25], [1]Peking Union Medical College hospital, Beijing, Beijing, China (People's Republic), [2]the First Affiliated Hospital of University of Science and Technology of China, Hefei, China (People's Republic), [3]People's Hospital, Beijing University Medical School, Beijing, China (People's Republic), [4]Xiangya Hospital Centeral South University, Changsha, China (People's Republic), [5]Northern Jiangsu People's Hospital, Yangzhou, China (People's Republic), [6]Tongji Hospital,Tongji Medical Colllege,Huazhong University of Science and Technology, Wuhan, Hubei, China (People's Republic), [7]Shandong Provincial Hospital Affiliated to Shandong University, Jinan, China (People's Republic), [8]the First Affiliated Hospital of Zhengzhou University, Zhengzhou, China (People's Republic), [9]People's Hospital of Xinjiang Uygur Autonomous region, Wulumuqi, Xinjiang, China (People's Republic), [10]Shanghai Gothic Internet Technology Co., Ltd, Shanghai, China (People's Republic), [11]Shanghai Gothic Internet Technology Co., Ltd., Shanghai, Shanghai, China (People's Republic), [12]Shanghai Gothic Internet Technology Co., Ltd, shanghai, Shanghai, China (People's Republic), [13]Affiliated Hospital of Hebei University, Baoding, China (People's Republic), [14]WuHan Fourth Hospital, Wuhan, China (People's Republic), [15]Hubei general hospital, Wuhan, China (People's Republic), [16]Jingzhou Central Hospital, Jingzhou, China (People's Republic), [17]Wuhan NO.1 Hospital, Wuhan, China (People's Republic), [18]The third xiangya hospital of central south university, Changsha, China (People's Republic), [19]Heze municipal hospital, Heze, China (People's Republic), [20]Linyi People's Hospital, Linyi, China (People's Republic), [21]the First Affiliated Hospital of xi'an Jiaotong University, Xi'an, China (People's Republic), [22]Xi'an Fifth Hospital, Xian, China (People's Republic), [23]Panzhihua Central Hospital, Panzhihua, China (People's Republic), [24]The Third Hospital of Hebei Medical University, Shijiazhang, China (People's Republic), [25]Shanghai Gothic Internet Technology Co., Ltd., shanghai, China (People's Republic)

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Health Services Research Poster I – ACR/ARP

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Combination therapy with DMARDs for treating RA is considered as a standard of care. However, certain rates of adverse events (AEs) are unavoidable. The stigma are how to predict the risk and how to define drug withdrawl sequence for optimal risk reductions if AEs persist. The decisions made are always empirical. To develop a risk prediction model and an algorithm for drug withdrawl sequence based on data mining from the SSDM

Methods: SSDM is an interactive mobile disease management tool, including two application systems (APPs) for both the doctors and the patients. The patients can input medical records (including medication and laboratory test results) and perform self-evaluation (DAS28, HAQ) via App. The patients' data synchronizes to mobiles of authorized rheumatologists through cloud and doctors' advices could be delivered. In previous studies, we demonstrated that patients could master SSDM after training.

In order to develop a prediction model and the master algorithm, abnormal white blood cell counts (WBC) and alanine aminotransferase (ALT) elevation were targeted. Data was collected, extracted, validated, and Bayesian networking, data mining, modeling were performed. WBC under 4k/ml is defined as leukocytopenia (LP), over 10k/ml as infection predisposing (IP), and ALT > 40 U/L as ALT elevation.

Results: From Jun 2014 to May 2019, 54,149 RA patients from 587 centers registered in SSDM. 135 different drugs and 1,220 combination therapies are identified. LP happens at 341 and IP at 344, ALT elevation at 325 cases in 752 treatment regiments. Among them, MTX based regiments are 291 types, and the risk ratio (RR) are profiled as prediction model by comparing each AE rate of combination regiment with that of MTX monotherapy (Fig 1). The RR ranges from 0.28 to 6.28. The highest risk combination of prednisone (Pred), leflunomide (LEF), methotrexate (MTX), hydroxychloroquine (HCQ) and Celecoxib (Cel) is selected (RR=6.28) to develop a master algorithm. Figure 2 shows Bayesian network, in which, quartet correlates with 31 different regiments. Based on Bayesian method, the probabilities of LP, IP and ALT elevation are plotted through 64 modeling, and the algorithm for drug withdrawl strategies is generated. Drug withdrawl sequence for LP is HCQ, then Cel, then LEF, then Pred, the risks of LP are reduced by 41%, 22% 36% and 15%, respectively. For IP, withdrawl sequence is Pred, then LEF, then Cel, then HCQ, the risks of IP are reduced by 45%, 28%, 23% and 4%, respectively, For ALT elevation, withdrawl sequence is MTX, then Pred, LEF, then Cel, the risks of ALT elevation are reduced by 48%, 8%, 7% and 6%.

Fig.1 AE rate of combination regiment with that of MTX monotherapy.

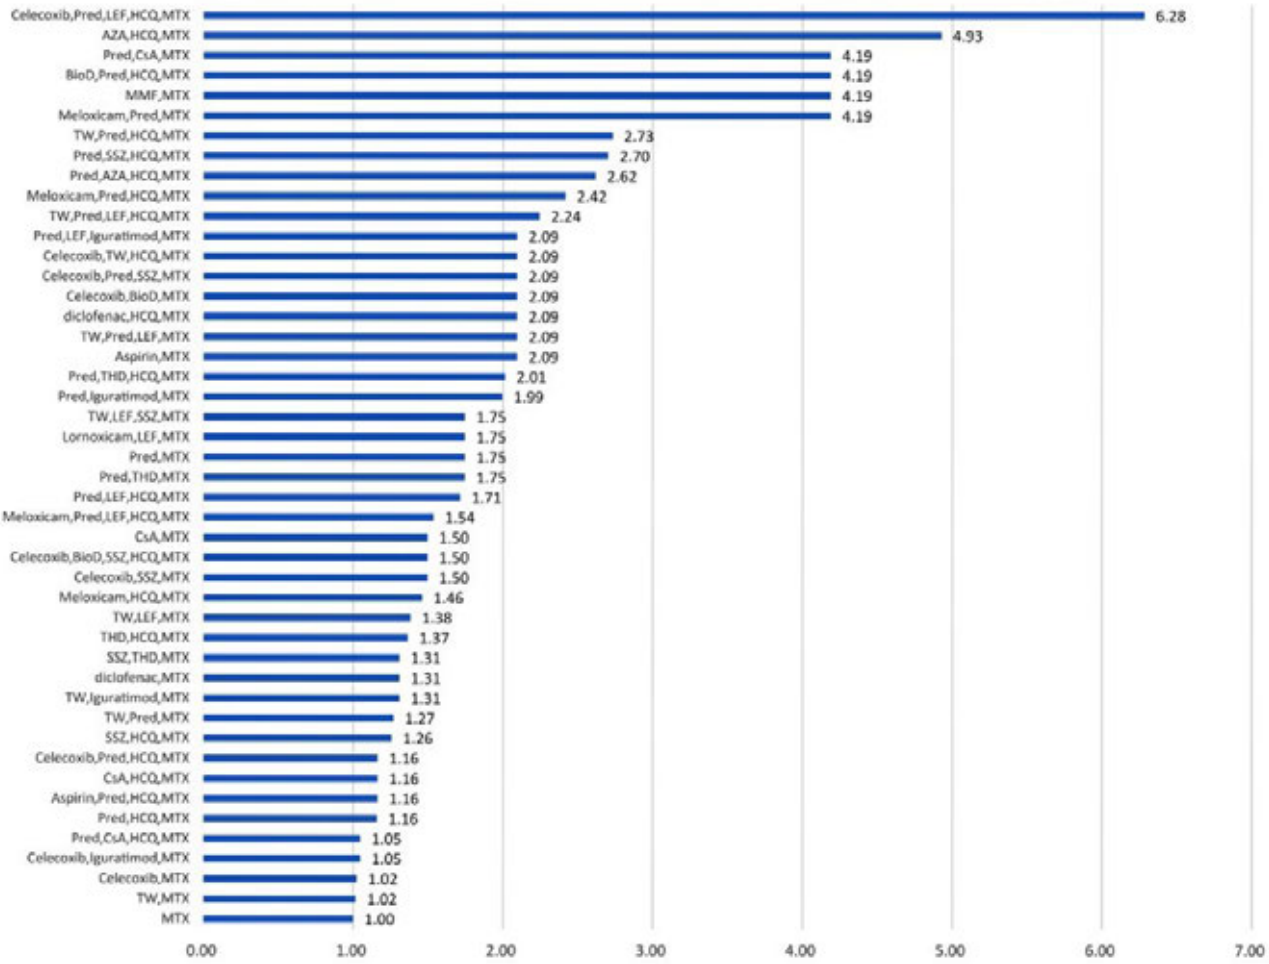

Figure 2. Bayesian network and date processing: Patients number (black as blow) and the rate of LP, IP and ALT elevation in 31 regiments.

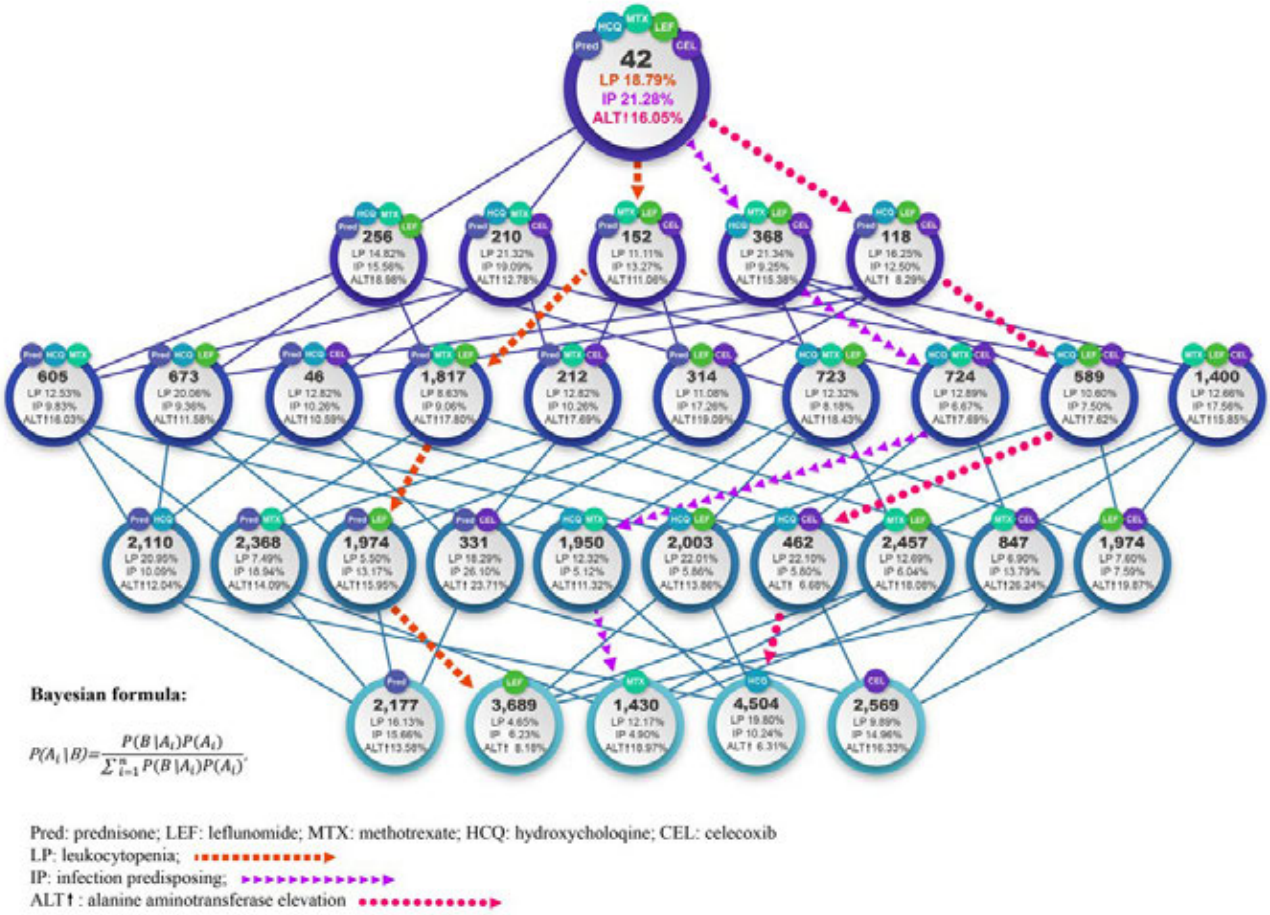

Conclusion: Through patterns extraction, data mining, modeling, and Bayesian networking, a risk prediction model and a master algorithm for drug withdrawl strategy in reduction of AEs are developed, which are expendable and replicatable. Via continuing data inputs and machine leaning, an artificial intelligent system in assisting clinical forecast and decision-making may be achieved with SSDM.

LARS Study: Latin American Rheumatologist Survey

Genessis Maldonado ,[1] Maria Intriago,[1] Enrique Soriano,[2] Letty Moreno,[3] and Carlos Rios[1], [1]Universidad Espiritu Santo, Guayaquil, Ecuador, [2]Rheumatology Section, Internal Medicine Service, Hospital Italiano de Buenos Aires, Argentina., Buenos Aires, Buenos Aires, Argentina, [3]Centro de Reumatología y Rehabilitación, Guayaquil, Ecuador

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Health Services Research Poster I – ACR/ARP
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Currently, Latin America does not have detailed information of rheumatologists in the region based on: education, working conditions, productivity, distribution of time between work activities and job satisfaction.

The purpose of this survey was to provide more information on the rheumatology community in Latin America.

Methods: A digital survey was created using the Google Forms platform, it was approved and endorsed by the scientific committee of PANLAR and later sent to the different rheumatology associations of the region. The data was analyzed in the statistical program SPSS v.23.

Results: 600 surveys of rheumatologists from 23 countries were received. The majority were females (53%). The mean age was 46.8 ± 11.7 [25-78] years, with a majority of mixed race 58%. 63.2% are married, 22.5% are single, 7.8% are divorced, 5.2% in free union and 1.3% are widowed. The mean number of children was 1 [0-7]. Birthplaces included Argentina (25.8%), Brazil (15.8%). The setting of the professional practice after obtaining the title of specialists was: public hospital (36.7%), private (23.8%), private / teaching in a university hospital (12.5%), public / teaching in a university hospital (12.6%), and industry (0.2%). The main place of work was in public / government hospitals by 33.5% followed by private practice 28.8%, private hospital 20.8%, university hospital 15.5%, nonprofit organizations 1% and retired 0.3%. The average of weekly working hours was 37.8 ± 17.7. 87.5% of the sample practices adult rheumatology, 12.7% pediatric rheumatology, 1.5% immunology and 3.5% another specialty. 30.2% had an early arthritis care center at their workplace, 70% had an infusion unit, 56.2% had ultrasound, 48% had a densitometer, 48.7% had a resonator and 78.5% had X-rays. 28.7% have training in ultrasound and 9.5% are in training period, 74.8% have training in reading densitometry and 3% in training period, 52.7% have training in resonance reading and 12.2% in training period. The average satisfaction with practice as a rheumatologist was 5.3/7, career options 4.3/7, geographic location 4.7/7, income 3.5/7, job security 3.7/7, colleagues and co-workers 4.5/7. 33.5% had an annual compensation of < 19,000 US dollars. Only 57.2% have malpractice insurance and 87.5% have medical insurance. 38.2% present at least one clinical comorbidity.

Conclusion: The majority of rheumatologists in the region feel satisfied with their clinical practice. This survey shows a low level of income for the region, however, more data should be obtained. This is the first study of its kind in Latin America, being an initiative for similar projects.

Abstract Number: 0269

Attitudes and Beliefs About Opioid Medications: Determining Treatment Use in Osteoarthritis

Ernest Vina ,[1] Jazmin Dagnino,[1] and C. Kent Kwoh[1], [1]University of Arizona, Tucson, AZ

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Health Services Research Poster I – ACR/ARP
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Table 1. Patient knowledge and attitudes towards opioid medications that may determine opioid medication use (vs. no opioid medication use) in the last 6 months [a]

	Odds Ratio	95% CI
Perception of benefit [b]	2.05*	1.24, 3.41
Perception of risk [b]	0.77	0.52, 1.16
Have family/friends that received opioid medication for OA	7.56*	2.51, 22.77
Have a good understanding of opioid medication treatment	1.71	0.43, 6.86

[a] Logistic regression model adjusted for age, sex, race (White vs. not), education, income, Patient Health Questionnaire-8 (Depression) score, Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) total score, comorbidity score.
[b] OR for a one-point increase in a scale ranging from 1 to 5.
*p<0.05

Background/Purpose: Considering the growing opioid epidemic in the US, it is imperative to have a good understanding of what patient characteristics predict the use of these types of medication. Patients' attitudes and beliefs about treatments may influence perceptions of need and use of health treatments. Their significance as determinants of utilization of opioid medications for osteoarthritis (OA) treatment is unknown, however. The objective of this study is to determine if patient familiarity with and perceptions of efficacy and risk of opioid medications are associated with opioid medication use for OA.

Methods: Participants with chronic, frequent pain due to knee or hip OA were recruited from a university medical center. A self-administered questionnaire was used to determine use of an opioid medication to treat OA in the last 6 months. The questionnaire also assessed patient familiarity with (3 items, yes/no), and perceptions of efficacy (4 items) and risk (3 items) of opioid medications. Responses to perceptions of efficacy and risk question items were based on a five-category ordinal response scale (score 1-5). Items were averaged, with higher values indicating higher perception of efficacy/risk. Chi-squared or t-tests were conducted to determine if the familiarity and perception of efficacy/risk items were associated with opioid treatment use. Logistic regression was used to determine if observed associations persisted after adjustment for sociodemographic and clinical variables.

Results: Our sample consists of 100 participants who had used and 249 who had not used an opioid medication for OA treatment in the last 6 months. Users, compared to non-users, were younger (mean age 62.5 vs. 64.8), less likely to have an Associate's Degree or higher (34.0% vs. 51.0%), and less likely to have ≥$40,000 annual household income (25.5% vs. 45.8%). They also had higher mean WOMAC pain (54.75 vs. 46.76), WOMAC disability (56.64 vs. 44.89), and comorbidity (4.12 vs. 3.23) scores. Opioid medication users were also more likely to have heard about opioids as treatment for OA (95.9% vs. 71.4%), to have family/friends that received a opioid for OA (77.4% vs. 40.4%), and to have a good understanding of what happens after opioid medication treatment (92.2% vs. 64.7%) [all p-values < 0.005]. Mean [SD] perceived efficacy score was higher (3.90 [0.94] vs. 3.27 [0.94], p< 0.005) while perceived risk score was lower (3.20 [1.18] vs. 3.84 [1.07], p< 0.005) among opioid medicine users than non-users. When adjusted for sociodemographic and clinical factors, perception of medication benefit (OR 2.05 [95% CI 1.24, 3.41]) and having family/friends that received the medication for OA (OR 7.56 [95% CI 2.51, 22.77]) remained significantly associated with opioid treatment use (Table 1).

Conclusion: Among patients with knee or hip OA, those who used opioid medications, compared to those who did not, were more familiar with opioids, more likely to believe in their efficacy, and less likely to believe in their risks. Perceived medication efficacy and having family/friends who use the medication were associated with opioid medication use even after controlling for patient sociodemographic and clinical characteristics.

Outcomes of a Fracture Liaison Service at an Academic Health Center

Micah Yu ,[1] Donna Jose,[2] Parke Hudson,[2] Christina Downey,[3] Wesley Phipatanakul,[2] Silvana Giannelli,[2] Kevin Codorniz,[4] and Karina Torralba[5], [1]Loma Linda University Medical Center, loma linda, [2]Loma Linda University, Loma Linda, [3]Loma Linda University Medical Center, Loma LInda, CA, [4]PHudson@llu.edu Loma Linda, [5]Loma Linda University School of Medicine, Loma Linda, CA

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Health Services Research Poster I – ACR/ARP
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Osteoporosis is associated with increased morbidity and mortality. There is a 60% risk of a subsequent fracture for patients who have had one fracture, with vertebral compression fractures having the highest rate of recurrent fragility fracture, and hip fractures being the most common recurrent fracture type at 3 years. Fracture Liaison Services (FLS) are secondary fracture prevention systems that channel hospital-admitted patients to an osteoporosis clinic that have been shown to lower recurrent fracture rates. An FLS at our institution addresses care gaps; a local study showed that up to 90% of fracture patients are never offered screening or treatment for osteoporosis by their primary care physician (PCP). The purpose of this study is to determine the effectiveness of the FLS by analyzing outcome measures related to initiation of treatment, DXA utilization and risk factor assessment.

Methods: Hospital admission data extraction from our Epic® electronic health record (EHR) was done using ICD 10 codes on fragility fracture for pre-FLS data (September 2015-March 2017) and post-FLS (September 2017-February 2019). Chart review was done to retrieve the following data: patient demographics (age, sex, ethnicity), body mass index, weight, height, circumstances of fracture (fragility vs traumatic), anatomic location, prior fractures, primary care provider location, treatment initiation, calcium and vitamin D supplementation, and laboratory data (TSH, PTH, 25-OH-Vitamin D). A 10% improvement in outcome measures related to treatment initiation and DXA utilization were previously set. Percent improvement in these measures, including p-values were calculated, and barriers to care were identified.

Results: Patient demographics, medication initiation, calcium and vitamin D supplementation and risk factor assessment between pre- and post-FLS groups were noted. (Table 1 and 2) Patient populations pre and post-FLS were similar. Overall, a 10% improvement in outcome measures were met except for pharmacotherapy initiation and DXA scan post-fracture. The barrier to medication initiation was most commonly due to reluctance of patients to take medications for prevention of further fractures which typically stems from inability to understand the risk of side effects as compared to the risk of a subsequent fracture.

Out of 92 FLS referrals inpatient, only 27 (29.3%) were adherent with osteoporosis clinic visits. Many patients admitted to the academic medical center are referred from other centers and have outside PCPs, and at an institutional level, primary care services are limited. (Figure 1) A Primary Care Institute was established 2018. It is hoped this would increase patient adherence to visits.

Conclusion: The Fracture Liaison Service met targeted improvements in outcomes in calcium and vitamin D supplementation but not in DXA post-fracture or pharmacotherapy initiation. Improving risk communication physician skills, while necessary, also need to consider patient perspectives on treatment recommendations. Improving access to

Table 1. FLS Patient population demographics and risk factors

	Pre-FLS (N-216)	Post-FLS (N=102)

Who Prescribed Which Osteoporosis Medication to Whom

Jiannong Liu ,[1] Haifebg Guo,[1] Tingting Gong,[1] and Yi Peng[2], [1]Hennepin Healthcare Research Institute, Minneapolis, MN, [2]Chronic Disease Research Group, Hennepin Healthcare Research Institute, Minneapolis, MN

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Health Services Research Poster I – ACR/ARP
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Several osteoporosis (OP) medicines came on the market in the past two decades, each with its own indications. However, there is no clear information on how the medicines were prescribed in the real world. Using Medicare data, we assessed who prescribed which OP medication for what type of patients.

Methods: Using the 2011-2015 Medicare 20% random sample database, we identified patients who initiated an OP medication during a two years period - October 1, 2013, to September 30, 2015, and the specialty of the initial prescribers. OP medications included alendronate, ibandronate (oral and IV formats, separately), risedronate, zoledronic acid, teriparatide, denosumab, raloxifene, and calcitonin; prescriber's specialties included orthopedic, OB/GYN, geriatric, rheumatologic, endocrinologic, internal medicine or family, and "other." Patients were aged ≥65 years at initiation and covered by Medicare Parts A and B for at least 2 years and by Medicare Part D for at least 1 year before initiation. Initiation was defined as first use in the period and no use of the same medicine for at least 1 year before. Patients could be on other OP medications before this initiation. For each medication group, we assessed patient demographics (age, race, sex, and geographic regions), history of fractures (hip, vertebral, other), comorbid conditions, which may be associated with increased fracture risk, and previous OP medication use.

Results: In all, 203,305 patients were included; 4.6% initiated more than one medicine (one by one, not simultaneously) in this period. The largest medication group was denosumab users (123,128), followed by alendronate (50,559) users; the smallest groups were IV ibandronate (548) and teriparatide (3,779) users. Calcitonin users were the oldest (mean age 78.9 years) and denosumab users the youngest (72.8). About 10% of users were men for all medicines except for raloxifene (< 1%) and denosumab (34.5%). More calcitonin and teriparatide users were at high risk of fracture (with previous fracture or more comorbidity) and a large percentage had recent fractures, especially vertebral; more ibandronate and teriparatide users switched from (other) bisphosphonates. OP medication was mostly prescribed by internal/family (47.2%) and "other" (32.1%) doctors. However, this varied by medication; except for high percentages of internal/family and "other" doctors, about 40% of IV bisphosphonates were prescribed by rheumatologists; 10.4%, 18.5%, and 14.8% of teriparatide by orthopedists, rheumatologist, and endocrinologists; 11.8% of raloxifene by OB/GYN; and 11.9% of risedronate by rheumatologists. For details, see Table 1.

Conclusion: This study found that, in the Medicare population, denosumab was prescribed for the most patients and was used by more men; calcitonin was mainly prescribed for older women; calcitonin and teriparatide were prescribed for more patients at high risk of fracture; and OP medications were mainly prescribed by internal/family

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Health Services Research Poster I – ACR/ARP
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Fragility fractures (FF) are a sentinel event in osteoporosis and world-wide only 20% of patients with a FF receive treatment, a large care gap. A 2016-2017 study done at a university-based academic medical center (AMC) found up to 90% of patients admitted for FF did not receive treatment after discharge. A Fracture Liaison Service (FLS) has subsequently been implemented at AMC. The same rheumatologists serve AMC and 20 miles away, Academic Medical Center 2 (AMC2). The objective of this study is to determine the quality of care received by AMC2 FF patients and determine the health disparities among patients seen in these two health systems.

Methods: Medical records of patients with FF who were at least 50 years of age who presented to AMC2 between July 2017 and June 2018 were reviewed. Those with ICD10 codes for FF were reviewed for dual x-ray absorptiometry (DXA) utilization, pharmacotherapy initiation, adequate calcium and vitamin D supplementation. Patient ethnicity and access to AMC2 vs. out of system primary care were also noted.

The objective of this study is to determine factors contributing to gaps in patient care in the AMC2 system with the goal of informing health improvement efforts as part of a Plan-Do-Study-Act (PDSA) cycle. An outcomes comparison between the two medical centers was subsequently done, directed toward socioeconomic status and access to care.

Results: 144 AMC2 patient charts were analyzed. 120 (83%) were female. 36.8% of encounter cases at AMC2 involved Hispanic or Latino patients who were Hispanic or Latino, similar to the ethnicity profile at AMC. 83 (58%) had femoral neck fractures, 13 (9%) had vertebral fractures. 3.47% were subsequently seen at outpatient AMC2 primary care clinics within 6 months post-hospital discharge, 2.96% of which had a post-fracture DXA scan. Similarly, 5% of patients at AMC had a post-fracture DXA completed.

2.78% of AMC2 patients with previous FF were on pharmacologic therapy prior to their ED encounter, vs. 14.4% of AMC patients with prior FF. Though very few patients seen at AMC2 were on treatment for osteoporosis, previous fracture rates were similar: 23% of patients at AMC and 20% at AMC2. At AMC2, 4.1% had osteoporosis treatment after discharge, which was lower than the 10.3% of patients at AMC who were given pharmacotherapy post-fracture.

Table 1. Comparison of Osteoporosis Health Outcomes at AMC (University) and AMC2 (County)

Outcomes	AMC-university	AMC2-county
% Patients on OSP medications prior to FF	8.90%	2.78%
% Treated after discharge	10.30%	4.10%
% Received calcium after discharge	20.8%	12%
% Received vitamin D after discharge	31.2%	21%
Post-fracture DXA	5%	3.47%

At AMC, 20.8% received calcium and 31.25% received vitamin D supplement after discharge. Comparatively, 12% of patients at AMC2 were given calcium and 21% were given vitamin D. (Table 1)

Conclusion: A minority of patients with FF presenting to AMC2 for FF are receiving optimal care post-hospital discharge. Between AMC and AMC 2, the post-fracture treatment rates were disproportionate among FF patients. Similarities in ethnicity remove this as an explanation of disparities in treatment rates. A limitation of this study is the inability to analyze data for patients who leave the AMC2 system post discharge. An FLS would be a good way to improve care and awareness among physicians and patients alike, but the inadequacies of healthcare access will most likely continue to hamper improvement efforts.

Abstract Number: 0273

Bone Health in Lupus: Findings from the Southern California Lupus Registry

Vaneet Sandhu ,[1] and Sara Johnson[2], [1]Loma Linda University, Loma Linda, CA, [2]St George's University, Loma Linda, CA

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Health Services Research Poster I – ACR/ARP
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The association of vitamin D deficiency with SLE is well established. While disease activity can itself cause pathologic bone remodeling and reduced vitamin D, SLE flares often necessitate steroid treatment, which can lead to decreased vitamin D absorption and decreased bone mineral density. Some rheumatologists recommend a goal serum 25(OH)D of 40ng/mL to reduce the probability ratio for a high disease activity score and to also improve urine protein-to-creatinine ratio. In addition, the ACR recommends vitamin D replacement for all patients receiving steroids, irrespective of steroid dose or duration of treatment. The objective of this study is to identify practice care gaps among rheumatologists in their adherence to vitamin D replacement in SLE patients currently on steroid therapy. An additional practice review of evaluating for vitamin D deficiency is noted.

Methods: Data collected from the Southern California Lupus Registry (SCOLR), an academic cohort of 182 patients with SLE, was analyzed. Cross-sectional review of medical records of patients seen from June 2016 to April 2019 included the following data: 1) Current or prior use of systemic steroids, 2) Vitamin D replacement in patients receiving steroid therapy, 3) Evaluation of vitamin D level within 6 months of patient encounter. Independent review was completed on medications prescribed. Abnormal vitamin D level was deemed < 30ng/mL. Descriptive statistics were utilized. This study is approved by the Loma Linda University IRB.

Results: Of 182 patients enrolled in SCOLR, data was available to be analyzed in 176 (Figure 1). Current, prior and never use of steroids was noted in 56 (32%), 73 (41%), 47 (27%), respectively. In patients currently on steroids, vitamin D replacement was provided to 30 (54%).Vitamin D levels were tested in 49/176 (28%) and noted to be abnormal in 27/49 (55%) (Table 1). Contrary to our expectations, patients with current or prior use of systemic steroids did not

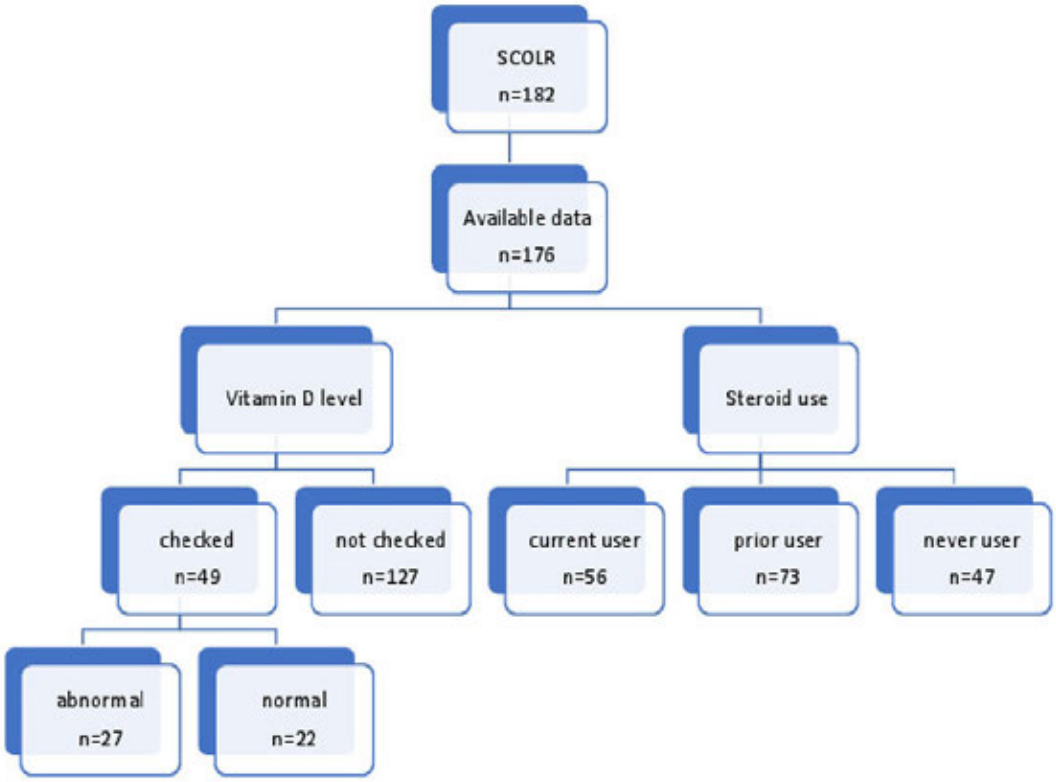

Figure 1. Methodology and Results

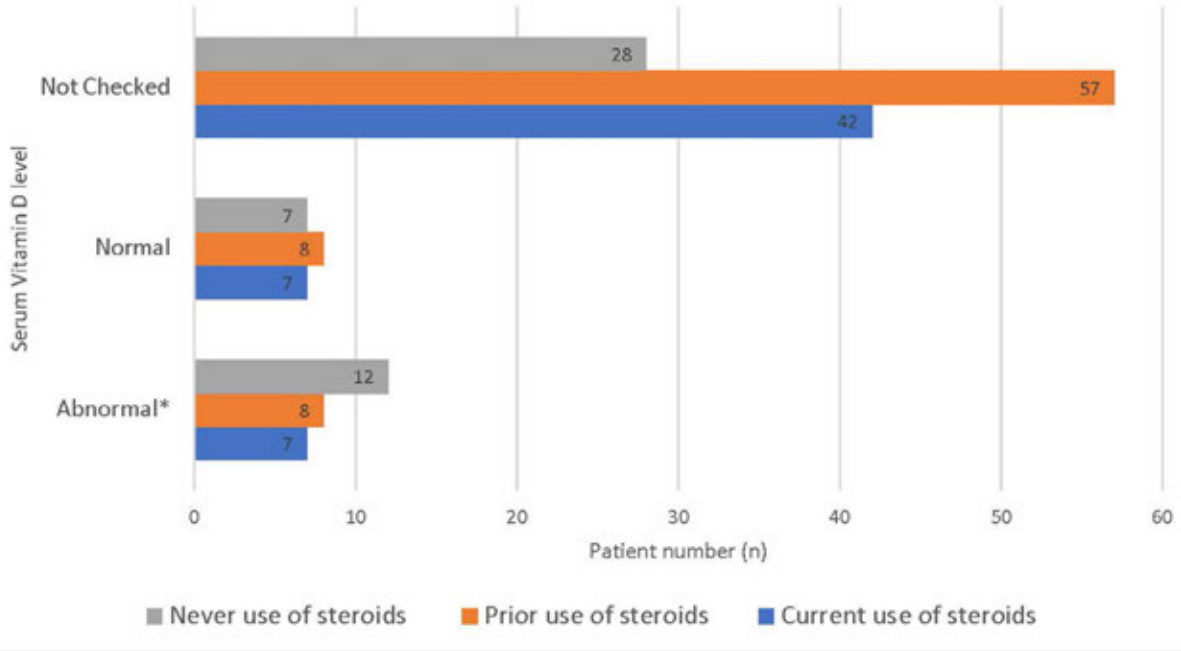
Figure 2. Monitoring serum vitamin D in SLE patients on systemic steroids



** serum 25(OH)D <30ng/mL*

Table 1. Vitamin D level crosstabulation with steroid use

		Vitamin D level		Total
		Normal (n)	Abnormal (n)	
Steroid use	Never user	7	12	19
	Current or prior use of steroids	15	15	30
Total		22	27	49

Pearson Chi^2 test of independence, (χ^2 (df), *p*-value) = 1.07 (1), $p = 0.899$

experience a significantly increased risk of abnormal vitamin D levels (OR 0.583, 95% CI (0.18, 1.89). However, vitamin D level was not checked in 42/56 (24%) patients currently on steroids and 57/73 (78%) patients with prior use of steroids, which limits the ability to formulate more meaningful conclusions.

Conclusion: Rheumatologists are infrequently screening for vitamin D deficiency in SLE. Further, vitamin D supplementation is inadequate in those individuals receiving systemic steroids. We acknowledge our gaps in the power of this study but bring to light the need for increased awareness of bone health in SLE in addition to the appropriate management of such individuals exposed to systemic steroids. With this information, we will plan to implement a best practice advisory warning in the electronic medical record of all individuals receiving steroid therapy to trigger both screening for and treating vitamin D abnormalities. Additional attention is warranted in monitoring and replacing vitamin D a complementary treatment of SLE, which will be the studied further as a continuation of this analysis.

Participation in the Stanford University Chronic Pain Self-Management Program in a Population with a High Prevalence of Arthritis

Dina Jones ,[1] Louise Murphy,[2] Ranjita Misra,[1] Alison Vargovich,[3] Dana Guglielmo,[4] Maura Robinson,[1] Samantha Shawley-Brzoska,[1] Sijin Wen,[1] Megan Burkart,[1] and Richard Vaglienti[1], [1]West Virginia University, Morgantown, WV, [2]Centers for Disease Control and Prevention, Division of Population Health, Atlanta, [3]University at Buffalo - SUNY, Buffalo, NY, [4]Centers for Disease Control and Prevention, Division of Population Health, Atlanta, GA

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Health Services Research Poster I – ACR/ARP
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: In 2016, 1 in 5 US adults reported chronic pain (CP). Osteoarthritis and rheumatoid arthritis are top causes of CP. The Stanford University Chronic Pain Self-Management Program (CPSMP) is a 6-week, low-cost

community-delivered workshop that increases participants' confidence in self-managing their CP. We describe baseline participation in a randomized, wait-list (6 months) controlled trial on CPSMP's short- and longer-term outcomes in West Virginia, a population with a high prevalence of arthritis, CP, opioid deaths, and socio-economic deprivation.

Methods: Community-dwelling adults, aged ≥ 18, with CP of ≥ 3 months, were eligible. Ineligibility criteria were cancer, an open wound, planned surgery in next year, or participation in a similar self-management program in the past year. Participants were recruited from clinics and the community via direct mailings, newspaper articles/advertisements, word-of-mouth, social media, and an electronic patient portal. Baseline data collected included age, sex, arthritis status (yes/no), and pain severity (Stanford Pain Visual Numeric Scale [0=no pain, 10=severe pain]), categorized as no (0), low (1-4), moderate (5-6), or severe (7-10) pain. Participation was the number enrolled divided by the number of eligible participants, multiplied by 100. Barriers to enrollment were identified. Descriptive statistics determined the characteristics of those who enrolled in the study. Statistical tests were conducted to determine if pain severity (categories) varied by: 1) age (Spearman's correlation) or 2) sex and arthritis (Cochran-Mantel-Haenszel tests).

Results: From June 2018 to March 2019, 336 people inquired about the study, 323 (96%) were screened for eligibility, 281 of the 323 (87%) were eligible, and 176 of the 281 enrolled, for a total of 63% participation. Enrollment barriers to participation were: not understanding what CP meant, the stigma associated with having CP, low socioeconomic status, and competing life priorities. At baseline, participants were primarily women (76%); mean age ± SD was 65 ± 13 years (range, 28 to 88). Most participants had arthritis (88%). The mean ± SD, range, and median (interquartile range) pain severity scores were 6.6 ± 1.9, 0-10, and 7.0 (3.0), respectively, with 1% with no pain, 10% mild pain, 39% moderate pain, and 50% with severe pain. Among those with severe pain (n=86), 71% were women and 89% had arthritis. The prevalence of severe pain was lower among older participants (43%, aged ≥ 65) compared to younger ones (61%, aged 18-64) (p=0.006). The distribution of pain severity was similar by sex (p=0.23) or arthritis status (p=0.66).

Conclusion: In a population with multiple challenges, including high arthritis prevalence, participation seemed moderate, possibly due to barriers identified during recruitment. One in 2 trial participants reported severe pain indicating that the recruitment strategy captured individuals in West Virginia with a substantial need for pain management interventions. Because some barriers to trial participation may also be barriers to implementing CPSMP in the community, strategies to increase understanding of CP and reduce its stigma may be important ways to eventually increase CPSMP's reach.

Exercise Is Medicine® in Primary Care Practice: Provider Characteristics and Physical Activity Counseling for Patients with Arthritis, DocStyles, 2018

Dana Guglielmo ,[1] Louise Murphy,[2] Kristina Theis,[1] Charles Helmick,[1] John Omura,[3] and Janet Croft[1], [1]Centers for Disease Control and Prevention, Division of Population Health, Atlanta, GA, [2]Centers for Disease Control and Prevention, Division of Population Health, Atlanta, [3]Centers for Disease Control and Prevention, Division of Nutrition, Physical Activity, and Obesity, Atlanta, GA

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Health Services Research Poster I – ACR/ARP
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Physical activity (PA) can reduce pain, prevent or delay disability, and improve physical functioning and mood in people with arthritis. However, only 36% of US adults with arthritis met the *2008 Physical Activity Guidelines for Americans* aerobic guideline. The American College of Sports Medicine's global initiative, Exercise is Medicine® (EIM), encourages health care providers to perform PA evaluations and refer patients to evidence-based PA programs or fitness professionals to manage chronic conditions, including arthritis. Primary care providers (PCPs) frequently treat rheumatologic conditions and are well positioned to influence patient PA through counseling consistent with EIM guidance. This study examined PA counseling behaviors for patients with arthritis among PCPs, and how adoption of EIM guidance for PA counseling differed across PCP characteristics.

Methods: We analyzed 2018 DocStyles cross-sectional data from 1,389 PCPs (family practitioners, internists, obstetrician/gynecologists [OB/GYNs], and nurse practitioners). PCPs were asked about frequency of assessing and recommending PA to their patients with arthritis, which align with the evaluation and prescription components of EIM guidance, respectively. Responses were classified into three counseling levels: *Does Not Follow, Partially Follows, and Follows* EIM guidance (Table). Prevalence and 95% confidence intervals (CIs) were calculated for each level overall and across selected PCP characteristics. Differences between PCP subgroups were determined using pairwise *t*-tests and linear trends in ordinal variables using orthogonal linear contrasts.

Results: PCPs most commonly reported that they *Follow* EIM guidance for their patients with arthritis (39.7% [95% CI: 37.2-42.3]), while 27.4% (95% CI: 25.0-29.7) *Partially Follow* and nearly a third (32.9% [95% CI: 30.4-35.4]) *Do Not Follow* EIM guidance. Prevalence of PCPs who *Follow* EIM guidance rose with increasing provider age (range: 32.8% among aged 21-39 years to 47.3% among aged > 50 years), years practicing medicine (range: 32.4% among practicing < 10 years to 51.0% among > 30 years), and number of total patients (range: 35.3% among < 75 patients to 46.4% among > 125 patients) and patients with arthritis seen per week (range: 30.2% among 1-9 patients to 56.4% among > 20 patients). Prevalence of PCPs who *Do Not Follow* EIM guidance was highest among OB/GYNs (49.5% [95% CI: 42.2-56.7]), those working in inpatient settings (41.7% [95% CI: 33.8-49.6]), those seeing fewer patients (1-9/week) with arthritis (41.3% [95% CI: 37.4-45.2]), younger providers (21-39 years) (39.9% [95% CI: 34.3-45.5]), those practicing medicine < 10 years (37.8% [95% CI: 32.3-43.4]), or living in the South (37.7% [95% CI: 33.4-42.0]).

Table. Definition of Following Exercise is Medicine® Guidance

		DocStyles: Assess Physical Activity[1] (EIM: Evaluate)	
		Always	Sometimes/Never
DocStyles: Recommend Physical Activity[2] (EIM: Prescribe)	Always	Follows EIM guidance	Partially Follows EIM guidance
	Sometimes/Never	Partially Follows EIM guidance	Does Not Follow EIM guidance

EIM: Exercise is Medicine®

[1]Measured by the question, "When you see patients with arthritis/rheumatic conditions, how often do you ask them about their level of physical activity to assess whether they are sedentary, meeting guidelines (150 minutes per week), or somewhere in between?"

[2]Measured by the question, "When you see patients with arthritis/rheumatic conditions how often do you recommend physical activity/exercise for management of their condition?"

Conclusion: Only about 2-in-5 PCPs *Follow* EIM guidance for PA counseling for patients with arthritis. PCPs who *Do Not Follow* EIM guidance are younger, less experienced, and see fewer patients with arthritis per week compared to PCPs who *Follow* EIM guidance. These PCPs may benefit from additional training and education to help increase their confidence and skills in PA counseling for patients with arthritis.

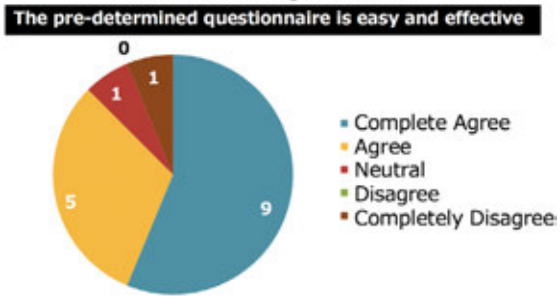
Figure 2. Results of questionnaire about new screening method



cally use pre-determined questionnaires on infections before doctors examine the patients for confirmation. Our aim of this study is to reveal effectiveness of this new method of assessments.

Methods: We retrospectively reviewed charts of patients with RA who received intravenous biologics at St. Luke's International Hospital, Tokyo, Japan from January 2016 to April 2019. We investigated basic demographics, kinds of biologics and other treatments, underlying diseases, incidence of serious infection(SI), and opportunistic infections. SI was defined as bacterial infections requiring intravenous antibiotics, hospitalization, or resulting in death. We calculated the number of scheduled administrations and evaluated results of screening by nurse and doctor's assessment. We compared the number of infections in the new method with those in conventional one. Univariate analysis and Chi-square test were performed. We also asked nurses for their feeling about this new screening method with questionnaire.

Results: We identified 271 cases in total. There are 143 and 128 patients who received intravenous biologics from January 2016 to August 2017 with conventional assessment and from September 2017 to April 2019 with new-style assessment. There are no significant differences in the baseline characteristics and the number of SI between new and conventional methods (7.7% vs 8.6%; p= 0.827)(Table1). New screening method showed high sensitivity (0.98) and specificity (0.89) and there was just 1 case in which doctors postponed biologics even the patient was assessed not to have active infections by nurse (Fig 1). Eighty eight % of nurses answered new method is easy and efficient, and 30% answered time-efficient. (Figure2)

Conclusion: Systematical screening by nurse with pre-determined questionnaires is effective as a screening with high sensitivity and nurses are satisfied with its convenience and time-efficiency. Doctors can carefully see cases in which infections are suspected by nurse. Our new-method of pre-administration assessments can contribute to time-efficient practice without any increasing risk of SI.

Efficacy of a Counselling Program to Promote Physical Activity in People with Inflammatory Arthritis

Linda Li ,[1] Hui Xie,[2] Na Lu,[3] Chris Shaw,[4] Diane Gromala,[4] Catherine L. Backman,[5] Johnathan Tam,[6] Noonan Gregory,[7] Alison Hoens,[1] Anne Townsend,[8] and Lynne Feehan[1], [1]University of British Columbia, Vancouver, BC, Canada, [2]Arthritis Research Canada and Simon Fraser University, Vancouver, BC, Canada, [3]Arthritis Research Canada, Vancouver, BC, Canada, [4]Simon Fraser University, Surrey, BC, Canada, [5]University of British Columbia, Vancouver, Canada, [6]Arthritis Research Canada, Richmond, BC, Canada, [7]Vancouver General Hospital, Vancouver, BC, Canada, [8]Lancaster University, Lancaster, United Kingdom

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Health Services Research Poster I – ACR/ARP
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Being physically active is key to successful management in people with inflammatory arthritis (IA). This study aimed to assess efficacy of a physical activity counselling program, with the use of a Fitbit® and FitViz (a personalized Fitbit-compatible web-based app), for promoting physical activity and improving health outcomes in people with IA.

Methods: Eligible participants had physician-confirmed diagnosis of rheumatoid arthritis (RA) or systematic lupus erythematosus (SLE). After baseline assessment (T0) and stratified randomization by diagnosis, the *Intervention Group (IG)* received standardized education, a Fitbit, access to FitViz, and phone calls from a physical therapist (PT) every 2 weeks to counsel activity goals over an 8-week period. The *Control Group (CG)* received a monthly e-newsletter from the research team. Participants were assessed again at the end of 8 weeks (T1). The primary outcome was time in daily moderate/vigorous physical activity at ≥3 METS and in bouts of ≥10 mins (**3+ MVPA**) measured with a SenseWear® monitor. Secondary outcomes were: 1) daily step count, 2) MVPA at ≥4 METS and in bouts of ≥10 mins (4+ MVPA, reflects purposeful activities), 3) time in sedentary activity in bouts of >20 mins, 4) pain (McGill Pain Questionnaire Short Form), 5) fatigue (Fatigue Severity Scale), and 6) self-management capacity (Partners in Health Scale). We used Analysis of Covariance (ANCOVA) to assess the effect of the intervention on outcome measures at T1 after adjusting for T0. Post-hoc subgroup analysis was done to explore the effect of diagnosis on outcomes.

Results: We recruited 118 participants (*IG*: n=59, 86.4% women; *CG*: n=59, 91.5% women); of those, 83 had RA (*IG*: n=42, 71.2%; *CG*: n=41, 69.5%). Both groups were similar in age [*IG:* 53.5 (SD 14.7) years; *CG*: 53.1 (SD 12.6) years] and body mass index [*IG*: 27.1 (SD 6.5); *CG*: 28.7 (SD 8.9)].The adjusted mean difference in 3+ MVPA was 9.4 mins (95% CI: -0.5, 19.3, p=0.06). A significant effect was found in pain [-0.16 (95% CI: -0.32, -0.01, p=0.04)]. The remaining secondary outcomes improved, but not statistically significant -- step count: 644.1 (95% CI: -103.8, 1,392.0, p=0.09); 4+ MVPA: 0.5 mins (95%CI: -4.6, 5.6, p=0.85); sedentary time: -10.4 mins (95% CI: -53.4, 32.6, p=0.63); fatigue: -0.31 (95% CI: -0.63, 0.00, p=0.05); self-management capacity: 0.13 (95% CI: -0.09, 0.35, p=0.23). Post-hoc analysis revealed a significant effect in 3+ MVPA (13.1; 95% CI: 1.9, 24.3) and pain (-0.25; 95% CI: -0.4, -0.08) in participants with RA, but not those with SLE.

Conclusion: Counselling by a PT has potential to improve physical activity behaviour in people with IA, but further study is needed to understand the intervention effect on different diagnosis. We found a significant improvement in pain, suggesting the intervention might have a positive effect on symptom management.

Improving a SLE-Quality Indicator Tool in an Outpatient Tertiary Care Setting

Jun Chu ,[1] Elaine Poncio,[2] Yenealem Temesgen-Oyelakin,[2] Michael Davis,[3] Isabel Ochoa-Navas,[2] Sarthak Gupta,[4] Zerai Manna,[2] Marquis Chapman,[1] Eileen Chu,[5] Aidan Donnellan,[6] and Sarfaraz Hasni[7], [1]National Institute of Arthritis, Musculoskeletal, and Skin diseases/ National Institutes of Health, Bethesda, [2]NIAMS/NIH, Bethesda, [3]NIAMS/NIH, Bethesda, MD, [4]Systemic Autoimmunity Branch, NIAMS, NIH, Bethesda, [5]National Institutes of Health, Derwood, MD, [6]National Institutes of Health, Bethesda, [7]NIAMS, National Institutes of Health, Bethesda, MD

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Health Services Research Poster I – ACR/ARP
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The care for patients with lupus is complex as they may exhibit multiple concomitant medical and socioeconomic issues. To address all their needs according to the current guidelines is a daunting task in busy outpatient practices. However, incorporating quality indicators in patient care has been found to decrease mortality and morbidity, improve patient satisfaction, and reduce costs. To improve the quality of care following recommendations from published guidelines, ACR, and EULAR, we embarked on a comprehensive quality improvement project by developing a checklist tool that incorporates the major SLE-Quality indicators (SLE-QI).

Methods: The project was launched in October 2017. A SLE-QI checklist detailing quality indicators was created based on published recommendations for standard of care. The checklist included a set of 20 SLE-QIs that address several important aspects of SLE care including diagnosis and disease monitoring, general prevention strategies, screening for comorbidities, drug toxicity monitoring, assessment of renal disease, reproductive health, and quality of life in daily practice. A standardized document template for clinic visits was developed that incorporated these quality indicators. Clinic progress notes were reviewed weekly to determine if these indicators were used and addressed. If SLE-QIs were missing, efforts were made to reach out to providers to address the missing QIs.

Results: At the beginning of the assessment, documentation of SLE-QIs was generally poor and inconsistent. For example, vaccinations was only at 60% compliance while screening for cardiovascular risk was only at 3% compliance. Since documentation was not standardized, it was difficult to assess if SLE-QIs were being done. Implementing SLE-QI in standardized notes resolved these concerns, bringing compliance close to 100% compliance for the 20 identified SLE quality indicators.

Conclusion: Standardized progress notes incorporating QI indicators is a feasible strategy that helps streamline data extraction for future clinical research. Additionally, incorporating patient outcome tools improves the ability to perform treat-to-target strategies for SLE. This ongoing QI project may potentially improve overall patient outcomes and lead to reduce health care costs.

Abstract Number: 0279

Comparison of Carotid Ultrasound and Coronary Artery Calcium Score in Cardiovascular Risk Stratification of Patients with Inflammatory Rheumatic Diseases

Keith Colaco ,[1] Elsie Nguyen,[2] Shadi Akhtari,[3] Paula Harvey,[3] and Lihi Eder[4], [1]University of Toronto, Women's College Hospital, University Health Network, Toronto, ON, Canada, [2]University Health Network, Toronto, ON, Canada, [3]Women's College Hospital, Toronto, ON, Canada, [4]Women's College Hospital and the Department of Medicine, University of Toronto, Toronto, Canada

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Imaging Of Rheumatic Diseases Poster I
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The value of non-invasive vascular imaging for cardiovascular (CV) risk stratification of patients with inflammatory rheumatic diseases is unclear. Measures of atherosclerosis including coronary artery calcification score (CACS) on computerized tomography (CT) scan and both total plaque area (TPA) and carotid intima-media thickness (cIMT) by carotid ultrasound (US) have been reported to improve risk stratification beyond the Framingham Risk Score (FRS). We determined the ability of CACS and US to correctly identify high CV risk patients with inflammatory rheumatic diseases.

Methods: In this cross-sectional study, patients with ankylosing spondylitis (AS), psoriatic arthritis (PsA) and rheumatoid arthritis (RA), who had no history of CV disease, underwent assessment of CV risk factors from July 2017 to March 2019 in a Cardio-Rheumatology clinic. CACS, cIMT and TPA were measured. The correlation between CACS and cIMT, between CACS and TPA, and between cIMT and TPA was assessed by Pearson correlation coefficient.

Table 1. Baseline characteristics of the study population (N = 139)

Variable	Mean ± SD / Frequency (%)
Age (years)	61.2 ± 10.9
Sex: Female (%)	93 (66.9)
Disease duration (years)	13.7 ± 12.0
Tender joint count	1.8 ± 3.5
Swollen joint count	1.0 ± 1.9
DMARDs – current use (%)	117 (84.2)
Use of anti-hypertensive medication (%)	38 (27.3)
BMI (kg/m^2)	28.5 ± 6.0
Current smoker (%)	7 (5.0)
Systolic blood pressure (mmHg)	127.2 ± 17.5
Diastolic blood pressure (mmHg)	78.4 ± 8.8
ESR (mm/hr)	19.6 ± 12.8
CRP (mg/L)	5.2 ± 10.5
Total Cholesterol (mmol/L)	4.9 ± 1.1
LDL cholesterol (mmol/L)	2.7 ± 0.9
HDL cholesterol (mmol/L)	1.6 ± 0.5
Triglycerides (mmol/L)	1.6 ± 1.1
CACS	140.0 ± 400.1
cIMT (mm)	0.665 ± 0.119
TPA (cm^2)	0.079 ± 0.176
Unilateral plaques (%)	30 (21.6)
Bilateral plaques (%)	18 (12.9)

Table 2. Framingham Risk Score categories versus Imaging-based risk groups

Table 2. Framingham Risk Score groups versus imaging-based risk categories

	FRS 10-year CV risk		
	Low risk (<10%) (n=77)	**Intermediate risk (10-19%) (n=34)**	**High risk (≥20%) (n=28)**
US-based risk categories			
Low risk (No plaque and cIMT ≤ 0.9mm) (%)	61 (79.2)	17 (50)	10 (35.7)
Intermediate risk (unilateral plaques) (%)	12 (15.6)	9 (26.5)	8 (28.6)
High risk (bilateral plaques and/or cIMT > 0.9mm) (%)	4 (5.2)	8 (23.5)	10 (35.7)
CACS-based risk categories			
Low risk (CACS=0) (%)	57 (74.0)	11 (32.4)	3 (10.7)
Intermediate risk (0-100) (%)	14 (18.2)	11 (32.4)	12 (42.9)
High risk (>100) (%)	6 (7.8)	12 (35.3)	13 (46.4)
FRS vs. US: Weighted κ = 0.33 FRS vs. CACS: Weighted κ = 0.42			

Table 3. Carotid US versus CACS-based risk categories

	CACS-based risk categories		
US-based risk categories	Low risk (CACS=0) (n=71)	Intermediate risk (0-100) (n=37)	High risk (>100) (n=31)
Low risk (No plaque and cIMT ≤ 0.9mm) (%)	59 (83.1)	20 (54.1)	9 (29.0)
Intermediate risk (unilateral plaques) (%)	10 (14.1)	10 (27.0)	9 (29.0)
High risk (bilateral plaques and/or cIMT > 0.9mm) (%)	2 (2.8)	7 (18.9)	13 (41.9)
Weighted κ = 0.39			

Based on the FRS, patients were classified into low (< 10%), intermediate (10-20%) and high risk categories (>20%). Risk categories for US were defined as low (zero plaque and cIMT< 0.9mm), intermediate (unilateral plaque) and high risk (cIMT >0.9mm and/or bilateral plaques). CACS risk categories were defined as low (CACS=0), intermediate (0-100) and high risk (>100). The weighted Kappa statistic was used to assess agreement between score categories.

Results: 139 patients with RA (49.6%), PsA (37.4%) and AS (12.9%) were assessed (mean age 61.2 ± 10.9 years, 66.9% female) (Table 1). CACS correlated moderately with TPA (r=0.42, p< 0.0001), while there was very weak correlation between CACS and cIMT (r=0.08), and between TPA and cIMT (r=0.14). 29.7% and 16.2% of patients classified into the low and intermediate risk categories based on the FRS had significant atherosclerosis in the carotid (TPA >0) and coronary arteries (CACS >100), respectively (Table 2). 50% of patients in the FRS intermediate risk category were reclassified into an US low risk group, while 35.7% of patients in the FRS high risk category were reclassified into an US low risk group. Importantly, when comparing US and CACS risk categories, 54% of patients in the intermediate CACS risk category were reclassified into a low risk US group (Table 3). There was generally good agreement between the FRS and CACS risk categories in stratifying low and high risk patients, while stratification among intermediate risk patients was poor. Overall, agreement between FRS and US (weighted k = 0.33), CACS and US (weighted k = 0.39), and FRS and CACS (weighted k = 0.42) risk categories was fair to moderate.

Conclusion: There is a moderate agreement between non-invasive carotid vascular and coronary calcium imaging in assessment of atherosclerosis burden in patients with IRDs. The results of the study highlight potential added value of using CACS and TPA in combination with traditional risk scores to improve CV risk stratification.

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Imaging Of Rheumatic Diseases Poster I
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: It has been debated whether treatment outcomes in early RA would be improved by targeting imaging remission, assessed by ultrasound or MRI, in addition to clinical remission. The primary analyses of the ARCTIC and TaSER trials (Haavardsholm et al. *BMJ* 2016; Dale et al. *ARD* 2016) did not show a beneficial effect of adding structured ultrasound assessment to a treat-to-target strategy. However, both studies reported a trend toward less radiographic progression in the ultrasound arm. We aimed to investigate whether an ultrasound-guided strategy would lead to reduced MRI inflammation or structural damage compared to a conventional treat-to-target strategy.

Methods: The ARCTIC trial included 230 DMARD-naïve early RA patients aged 18-75, randomized 1:1 to an ultrasound strategy targeting DAS < 1.6, no swollen joints and no power-Doppler signal in any joint, or a conventional strategy targeting DAS < 1.6 and no swollen joints. All patients were treated by the same DMARD escalation algorithm starting with MTX, then combination therapy MTX/SSZ/HCQ, then biologic DMARD. In the ultrasound arm, treatment was stepped up if indicated by the ultrasound score, overruling the DAS and swollen joint count. MRI of dominant hand was performed at 6 times and scored in chronological order by a blinded reader. MRI acquisitions and scoring were done according to the OMERACT RA MRI Scoring System (Østergaard et al. *J Rheum* 2017). 218 patients (ultrasound n=116, conventional n=102) had MRI at baseline and ≥ 1 follow-up visit, and were analyzed. A combined inflammation score was computed by normalized summation of the synovitis, tenosynovitis and bone marrow edema scores, and a combined damage score by normalized summation of the erosion and joint space narrowing scores (Sundin et al. *J Rheum* 2019). Mean change from baseline to each follow-up was estimated by a linear mixed model adjusted for baseline score, age, gender, center and anti-CCP status. The proportion of patients in each treatment arm with MRI erosive progression after 2 years was calculated, using the smallest detectable change (0.61) as cut-off.

Results: Demographic composition was comparable to the ARCTIC primary sample. There were no statistically significant baseline differences between the arms in either of the combined MRI scores. The mean combined MRI inflammation score decreased during the first year (1-year change in ultrasound arm –64.2 (–71.3; –57.1), conventional arm –59.4 (–66.9; –51.9) p=0.34), and maintained at the same level throughout the 2nd year. There was no significant difference in change from baseline between the study arms at any time (**figure 1a**). The mean combined MRI damage score showed a small increase over time, without any significant difference between study arms (**figure 1b**). In the ultrasound arm 39% of patients had MRI erosive progression vs. 33% in the conventional arm, RR: 1.16 (95% CI 0.81; 1.66), *p*=0.40.

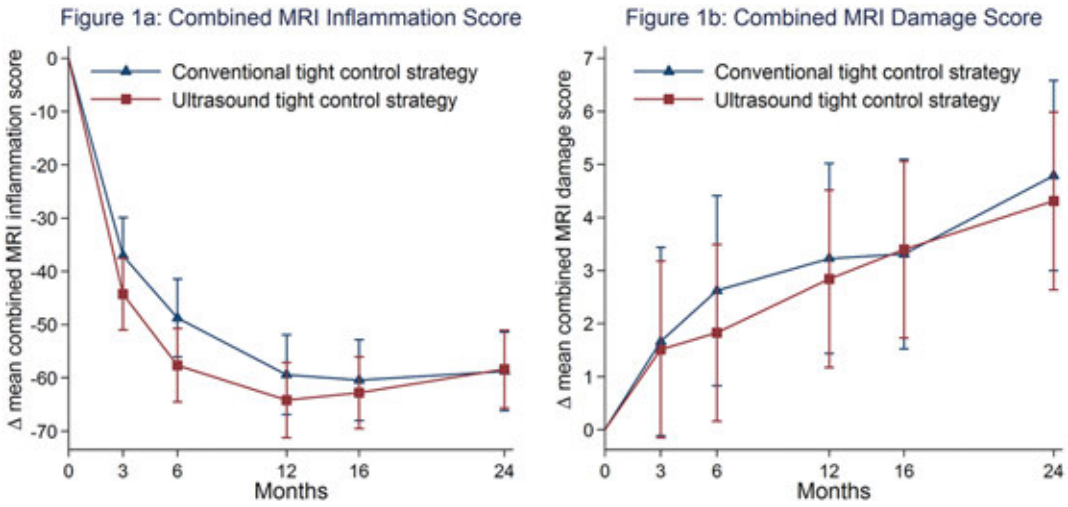

Figure 1 a-b. Change from baseline level to 3, 6, 12, 16 and 24 months of the mean combined MRI inflammation score (range 0-750) and the mean combined MRI damage score (range 0-500). Estimates based on a linear mixed model adjusted for baseline score, age, gender, center and anti-CCP status. Error bars represent 95% CI.

Conclusion: Incorporating ultrasound information in treatment decisions did not lead to reduced MRI inflammation or less structural damage, compared to a conventional treatment strategy. The findings support that systematic use of ultrasound does not provide benefit in treat-to-target follow-up of patients with early RA.

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Imaging Of Rheumatic Diseases Poster I

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: To evaluate the frequency and associations of osteoarthritis (KOA) features on knee ultrasound (KUS) in a community-based cohort study with radiographic and symptomatic data in the same knees.

Table 1. Spearman correlations* between ultrasound (US) features and radiographic (XR) features for RIGHT knees.

KUS Feature (range)	Kellgren-Lawrence Grade (0-4)	Comparable XR feature†
	Spearman correlation p value	*Spearman correlation p value*
Gray scale effusion/synovitis (0-3)	**0.30 (0.16, 0.43) <0.0001**	na
Gray scale synovitis (0-3)	**0.29 (0.15, 0.43) <0.0001**	na
Gray scale effusion (0-1)	**0.16 (0.02, 0.30) 0.0257**	na
Suprapatellar color power Doppler signal (0-3)	**0.14 (0.00, 0.28) 0.0347**	na
Osteophytes, medial (0-3)	**0.62 (0.52, 0.71) <0.0001**	**0.58 (0.50, 0.66) <0.0001**
Osteophytes, lateral (0-3)	**0.54 (0.43, 0.64) <0.0001**	**0.57 (0.46, 0.67) <0.0001**
Meniscal extrusion, medial (0-1, compared with XR medial JSN, 0-3)	**0.42 (0.31, 0.54) <0.0001**	**0.36 (0.23, 0.49) <0.0001**
Meniscal extrusion, lateral (0-1, compared with XR lateral JSN, 0-3)	**0.15 (0.01, 0.29)** 0.0798	0.11 (-0.04, 0.25) 0.1818
Calcium deposition, medial (0-1)	0.08 (-0.06, 0.22) 0.1814	**0.24 (0.07, 0.42) <0.0001**
Calcium deposition, lateral (0-1)	**0.21 (0.08, 0.34) 0.0073**	**0.34 (0.18, 0.50) <0.0001**
Cartilage damage, medial (compared with XR medial JSN, both 0-3)	**0.15 (0.01, 0.28)** 0.0792	0.10 (-0.04, 0.23) 0.1369
Cartilage damage, lateral (to XR lateral JSN, both 0-3)	0.13 (-0.00, 0.27) 0.0526	0.13 (-0.01, 0.27) 0.0570
Popliteal cyst (0-2)	**0.25 (0.11, 0.39) 0.0001**	na

Correlation estimates with 95% confidence intervals (95% CI) excluding the null, and 0.05 p-value level significant statistics for nonzero correlation, are shown in **bold.*

†The feature most comparable to the US feature that was assessed on radiograph (e.g., medial osteophytes on US are compared to medial osteophytes on XR, while US cartilage damage and meniscal extrusion are both compared to XR JSN)

na=not applicable (no comparable XR feature)

Table 2. Spearman correlations* between US features or XR features with KOOS pain subscale scores or sxKOA for RIGHT knees.

KUS Feature (range)	KOOS pain subscale (continuous)	Symptomatic KOA (present/absent)
	Spearman correlation p value†	*Spearman correlation p value*
Gray scale effusion/synovitis (0-3)	0.07 (-0.07, 0.21) 0.3406	0.15 (-0.00, 0.30) 0.0059
Suprapatellar color power Doppler signal (0-3)	0.03 (-0.11, 0.17) 0.6696	0.12 (-0.02, 0.27) 0.4238
Osteophytes, medial (0-3)	**0.34 (0.23, 0.46) <0.0001**	**0.43 (0.32, 0.54) <0.0001**
Osteophytes, lateral (0-3)	**0.22 (0.08, 0.36) 0.0020**	**0.30 (0.16, 0.44) <0.0001**
Meniscal extrusion, medial (0-1)	**0.15 (0.01, 0.29) 0.0371**	**0.26 (0.12, 0.39) 0.0011**
Meniscal extrusion, lateral (0-1)	0.06 (-0.08, 0.20) 0.3963	0.07 (-0.07, 0.20) 0.4181
Calcium deposition, medial (0-1)	-0.05 (-0.18, 0.09) 0.5002	0.03 (-0.11, 0.18) 0.5214
Calcium deposition, lateral (0-1)	-0.10 (-0.24, 0.03) 0.1384	0.06 (-0.09, 0.20) 0.5069
Cartilage damage, medial (0-3)	**0.16 (0.03, 0.29) 0.0263**	**0.15 (0.03, 0.27) 0.0397**
Cartilage damage, lateral (0-3)	0.10 (-0.03, 0.24) 0.1518	0.13 (-0.00, 0.26) 0.0970
Popliteal cyst (0-2)	0.07 (-0.07, 0.21) 0.3310	**0.19 (0.05, 0.33) 0.0096**
Radiographic Features		
Kellgren-Lawrence grade (KLG, 0-4)	**0.25 (0.11, 0.38) 0.0005**	**0.52 (0.43, 0.61) <0.0001**
Osteophytes, medial (0-3)	**0.16 (0.03, 0.30) 0.0217**	**0.33 (0.22, 0.45) <0.0001**
Osteophytes, lateral (0-3)	0.13 (-0.01, 0.27) 0.0671	**0.22 (0.08, 0.36) 0.0008**
Chondrocalcinosis, medial (0-1)	-0.06 (-0.19, 0.07) 0.3968	0.13 (-0.03, 0.28) 0.0782
Chondrocalcinosis, lateral (0-1)	-0.10 (-0.24, 0.04) 0.1623	0.11 (-0.04, 0.26) 0.1214
Joint space narrowing (JSN), medial (0-3)	0.10 (-0.04, 0.24) 0.1554	**0.43 (0.30, 0.55) <0.0001**
Joint space narrowing (JSN), lateral (0-3)	**0.17 (0.02, 0.31) 0.0197**	**0.17 (0.01, 0.33) 0.0054**

Correlation estimates with 95% confidence intervals (95% CI) excluding the null, and 0.05 p-value level significant statistics for nonzero correlation, are shown in **bold.*
†Using modified ridit scores

Methods: A radiology technologist trained in standardized KUS imaging (SSG) scanned both knees in consecutive individuals enrolled in the Johnston County OA Project, using a written protocol. The KUS protocol included 7 views per knee: longitudinal and transverse suprapatellar in 30 degrees flexion (grading for effusion, gray scale synovitis and color power Doppler [CPD]), medial and lateral longitudinal (for osteophytes, meniscal damage, calcium deposition), maximally flexed suprapatellar transverse (for cartilage damage, calcium deposition) and posterior transverse (for popliteal cysts). Each set of images was scored using an atlas by 2 readers (previously shown to be reliable) whose scores were averaged. Radiographs (XR) were scored separately by an expert radiologist (JBR); all readers were blinded to other imaging and clinical data. Radiographic KOA (rKOA) was defined as a Kellgren-Lawrence grade (KLG) of 2 or more; osteophytes and joint space narrowing (JSN) were scored 0-3 using the OARSI atlas. Symptomatic KOA (sxKOA) was defined as rKOA with symptoms experienced in the same knee. Pain was assessed via the Knee Injury and OA Outcome Score (KOOS) pain subscale for each knee. We produced unadjusted Spearman correlations and additionally tested for nonzero correlation using the Cochran-Mantel-Haenszel statistic to describe

associations with each KUS and XR feature and pain. All results shown are for right knees; left knees demonstrated similar patterns.

Results: Participants (n=203) had a mean (±SD) age of 73 ± 8 years and a mean BMI of 29.4 ± 7 kg/m2; about 1/3 were male and 1/3 were African-American. About a third of knees had symptoms and 5% had a history of knee injury. About half of knees met the above definition for rKOA, while almost a quarter met the sxKOA definition. The majority of knees had US evidence (score >0) of at least one of the following: effusion/synovitis, osteophytes, and/or cartilage damage (data not shown). Correlations between US and XR features are shown in Table 1. The strongest correlations were seen for osteophytes (r=0.6); similar correlations were seen between US osteophytes and XR KLG. Correlations for calcium deposition detected by each modality (r=0.2-0.3) were significant. Non-identical constructs such as medial US meniscal extrusion and XR JSN (r=0.4) were also significantly correlated. Medial XR JSN was more closely related to US meniscal extrusion (r=0.4) than to US cartilage damage (r=0.1). Osteophytes by US, compared with XR, had slightly stronger correlations with KOOS pain (Table 2). Medial meniscal extrusion and cartilage damage by US were significantly correlated with KOOS pain while medial JSN by XR was not; all three were correlated with presence of sxKOA.

Conclusion: US assessment of KOA is accessible and reliable and provides information complementary to XR; KUS may provide increased sensitivity for early KOA changes. Future work will further examine the associations between US and radiographic features, including effect modification by key covariates.

Ultrasound Is More Sensitive Compared to Conventional Radiography to Detect Joint Erosions in ACPA-positive Patients with Musculoskeletal Pain

Michael Ziegelasch ,[1] Emma Eloff,[2] Hilde Hammer,[3] Jan Cedergren,[4] Klara Martinsson,[5] Åsa Reckner,[4] Thomas Skogh,[2] and Alf Kastbom[2], [1]Department of Rheumatology, Linkoping, Sweden, [2]Department of Clinical and Experimental Medicine, Linkoping, Sweden, [3]Diakonhjemmet Hospital, Department of Rheumatology, Oslo, Norway, [4]Rheumatology Department, Linkoping, Sweden, [5]Linköping University, Linköping, Sweden

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Imaging Of Rheumatic Diseases Poster I
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Circulating anti-citrullinated protein antibodies (ACPA) are associated with an increased risk of developing rheumatoid arthritis (RA), particularly in patients with erosive disease. We previously showed that erosions detected by ultrasound predict arthritis development in ACPA-positive patients with musculoskeletal (MSK) pain. We now aimed to compare ultrasound with conventional radiography to detect joint erosions during 2 years follow-up of ACPA positive patients with MSK pain.

Methods: We prospectively followed 82 ACPA-positive patients with MSK pain without arthritis at baseline clinical examination. Ultrasound at baseline and after 2 years assessed joint erosions, defined as intraarticular discontinuity

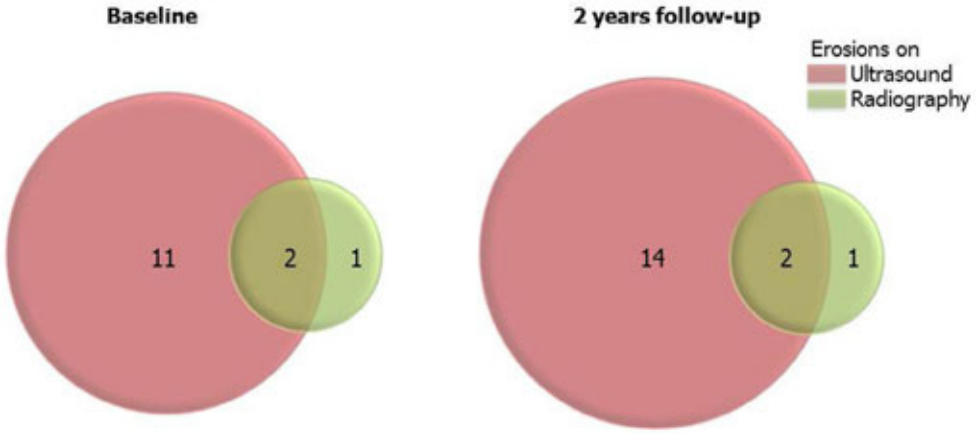

Figure 1. Number of patients with joint erosions according to ultrasound and/or conventional radiography in a cohort of 82 ACPA-positive patients with musculoskeletal pain.

of the bone surface visible in 2 planes, in 36 joints in hands and feet. Radiographs of hands and feet were taken at baseline and after 2 years, and evaluated by experienced radiologists according to clinical routine. In cases where erosions had been identified by the radiologist, and in all cases with indistinct findings as well as the radiographs of all patients with erosions by ultrasound, the radiographs were reevaluated by an experienced rheumatologist to confirm presence of erosions. We used Fisher's exact test to compare the prevalence of erosions as evaluated by ultrasound and radiography.

Results: Baseline joint erosion(s) were detected in 13 (16%) patients by ultrasound and in 3 (4%) patients by conventional radiography (p=0.016, Fig. 1). After 2 years follow-up, 30 of the patients (37%) had developed clinical arthritis. By ultrasound, erosion(s) were detected in 16 patients (19%) and in 3 (4%) by conventional radiography (p=0.018, Fig. 1). During follow-up, the total number of ultrasound erosions had increased from 16 to 20, while radiographic erosions had increased from 3 to 5 (p >0.05). Development of new erosions at 2 years occurred in 8 patients (12%) as evaluated by ultrasound, and in one patient (1%) by radiography (p=0.013) among patients without baseline erosions (by corresponding imaging techniques). In 5 out of the 13 patients (38%) with baseline ultrasound erosions, no further abnormality was detected at 2 years. The corresponding finding concerning radiographic erosion was made in 1 patient.

Conclusion: Ultrasound is more sensitive compared to conventional radiography to detect erosive abnormalities during follow-up of an ACPA-positive at-risk population. To some extent, erosive joint abnormalities show dynamic, and possibly reversible, features in very early phases of RA.

Can Synovial Hypertrophy in the Feet Without Doppler Change During Treatment - Results from a Longitudinal Study of Rheumatoid Arthritis Patients Initiating Biological DMARD

Lene Terslev ,[1] Mikkel Østergaard,[2] Joe Sexton,[3] and Hilde Hammer[4], [1]Copenhagen Center for Arthritis Research, Center for Rheumatology and Spine Diseases, Rigshospitalet, Glostrup, Copenhagen, Denmark, [2]Copenhagen Center for Arthritis Research, University of Copenhagen, Copenhagen, Denmark, [3]Diakonhjemmet Hospital, Dept. of Rheumatology, Oslo, Norway, [4]Diakonhjemmet Hospital, Department of Rheumatology, Oslo, Norway

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Imaging Of Rheumatic Diseases Poster I
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Ultrasound is used to assess disease activity in rheumatoid arthritis (RA). Gray scale (GS) ultrasound shows the synovial hypertrophy (SH) and Doppler the amount of hyperemia. SH Both with and without Doppler change during treatment in the hands– even grade 1. However, SH grade 1 without Doppler is a common finding in the feet of both RA patients and healthy controls. If low grade SH in metatarsophalangeal joints (MTPs) does not have the ability to change during treatment this should be taken in to consideration in the ultrasound evaluation of disease activity and treatment effect in the feet.The aim was to investigate if joints with SH without Doppler activity (Doppler negative SH) in MTPs differ in ability to change during treatment with biological DMARD (bDMARD) as compared to metacarpophalangeal joints (MCPs) in RA patients.

Methods: RA patients initiating biological DMARD treatment were included. US examination was performed at baseline, 3 and 6 months using Siemens Antares US equipment with optimized Doppler settings for slow flow. Bilateral MCP 1-5 and MTP 1-5 were evaluated at each visit. SH and Doppler activity were graded from 0-3 according to the US atlas by Hammer et al. The GS score for SH in Doppler negative joints was registered for the individual joints using

Table 1. The frequency of synovial hypertrophy grades at different time points and the relative frequency of improvement for joints with Doppler negative SH and Doppler positive SH

	SH grade 1				SH grade 2				SH grade 3			
n = total number of joints per grade	MCP (n = 219)		MTP (n=382)		MCP (n=216)		MTP (n=261)		MCP (n=223)		MTP (n=104)

From baseline to 3 months	42%	63%	47%	41%	54%	60%	60%	57%	56%	75%	53%	81%
From baseline to 6 months	38%	66%	36%	43%	67%	70%	62%	55%	63%	88%	74%	76%

SH=synovial hypertrophy, MCP= metacarpophalangeal joints, MTP=metatarsophalangeal joints

GS SH >1 as threshold and were compared to changes in SH score in joints with Doppler activity (Doppler positive SH) in both MCPs and MTPs. Doppler positive was defined as Doppler score ≥1.

Results: 157 patients (83.2% women, 81.3% seropositive for anti-CCP and 75.8% for rheumatoid factor) were included, with a mean (SD) age of 51.5 (13.3) years and disease duration of 9.9 (8.1) years. At baseline, 52.2% used prednisolone (mean (SD) 7.7 (4.6) mg, range 2.5-25mg). The patients had a mean (SD) baseline DAS28 of 4.5 (1.5).1570 MTPs and 1570 MCPs were examined and of these 502 MTPs (32%) had Doppler negative SH and 245 (16%) Doppler positive SH. For MCPs, 251 (16%) had Doppler negative SH and 407(26%) Doppler positive SH. Doppler negative Grade 1 SH were more frequent in MTP than MCP joints and Doppler negative grade 3 SH was rare in MCPs (table 1). The percentage of joints exhibiting a decrease in SH was similar for both MTPs and MCPs, both for joints with Doppler negative SH and Doppler positive SH at baseline. However, adjusting for the grade of SH at baseline, joints with Doppler negative SH appeared to have a somewhat greater tendency towards change. For joints with Doppler negative SH grade 1 at baseline the tendency to change was somewhat lower for MTPs than MCPs (41% vs 63% respectively at 3 months and 43% vs 66% respectively at 6 months follow-up).

Conclusion: Most joints with Doppler negative SH had low grades of SH with the majority having a grade 1 – especially in MTPs. Doppler negative SH in MTPs and MCPs can improve during treatment and exhibit the same tendency to change. For joints with Doppler positive SH, MTPs have the same tendency to change as MCPs except that MTPs with Doppler negative grade 1 SH showed a somewhat lower tendency to change than the corresponding MCPs.

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Imaging Of Rheumatic Diseases Poster I
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Clinical evaluation of synovitis in rheumatoid arthritis (RA) is difficult in obese (O) and overweight patients, due to the fat pad located around the joint, that can over- or under estimate the number of joints regarded as swollen by clinical examination.

Objectives: To compare the level of agreement between the number of joints considered abnormal by Power Doppler ultrasound (PDUS) and clinical examination (swollen joint count (SJC) as component of SDAI) in O (i.e. Body Mass Index (BMI) >30) versus non-obese (NO) (BMI≤30) RA patients.

Methods: RA patients ≥18 years fulfilling 2010 ACR-EULAR criteria, treated with conventional synthetic (cs) or biologic (b) DMARDs were included in the cross-sectional multicenter (13 centers) French observational RABODI study (ClinicalTrials.gov Identifier: NCT03004651). Clinical synovitis was evaluated on 44 joints. ESR and CRP were collected and several composite scores were calculated: SDAI, DAS28, DAS. A standard US examination on 44 joints for the presence of synovial hypertrophy (SH) and PD signal according to the EULAR-OMERACT scoring system was performed in each center by an independent investigator blinded to clinical data. Presence of US synovitis was defined by a SH≥1 and PD signal≥1 on a semi-quantitative scale. Levels of agreement between number of synovitis defined by PDUS and clinical examination were compared in O versus NO patients using Chi2 test, and Kappas (k) and ORs were calculated. A patient was considered "discordant" if ≥1 joint was discordantly classified by PDUS and clinical examination. SDAI was calculated and compared, with SJC defined either by clinical examination or PDUS.

Results: 121 patients were included: mean (SD) age of 58.5 (12.7) years, mean disease duration of 11.1 (9.7) years. 81% were female, 84.3% anti-CCP positive, 63.6% had erosive disease. Mean SDAI was 12,6 (±10,2). 53 (43.8%) had a BMI >30 and 68 (56.2%) ≤30. 59 (48.7%) and 62 (51.2%) had a SDAI≤11 and >11, respectively. 78.5% received csDMARD, 58.7% bDMARD and 40.5% glucocorticoids. The 2 groups were comparable, except for weight (mean (SD) 65.4 (13.5) vs 96.7 (14.7) kg, p< 0.001), some comorbidities (diabetes, asthma and fibromyalgia more frequent in O patients, anemia less frequent), tender joint count (mean 4.04 (±5.23) in NO vs 7.38 (±8.64) in O, p=0.021). Mean

Table: Level of agreement between PDUS synovitis and SJC in obese versus normally weighted RA patients

		BMI <= 30 N=68	BMI > 30 N=53	OR (95%CI)	P*
SDAI (with PDUS) vs. SDAI (with SJC)	Non-Discordant	63	46	1.92 (0.57-6.42)	0.28
	Discordant	5	7		
	Kappa	0.85	0.73		
DAS28 (with PDUS) vs. DAS28 (with SJC)	Non-Discordant	62	47	1.32 (0.4-4.35)	0.64
	Discordant	6	6		
	Kappa	0.81	0.77		
DAS44 (with PDUS) vs. DAS44 (with SJC)	Non-Discordant	63	52	0.24 (0.03-2.14)	0.23
	Discordant	5	1		
	Kappa	0.83	0.96		
PDUS vs. SJC	Non-Discordant	51	35	1.54 (0.7-3.4)	0.28
	Discordant	17	18		
	Kappa	0.50	0.32		

*Chi^2 test

number of clinical synovitis was 2.4 (3.3), and 6.7 (±6.3) by PDUS. Levels of agreement between clinical and PDUS findings were comparable in O vs. NO patients regarding SDAI and other scores (Table). Patients with ≥3 discordant joints was numerically higher in O patients compared to NO (26/53 (49.1%) vs 22/68 (32.4%), p=0.062). Results were similar when overweighted patients (BMI >25) were compared with normally weighted patients (BMI≤25) or when SH≥1 was considered in place of PDUS synovitis. At the joint level, discordance was higher in O patients in some specific joints: MCP4 (p=0.057), wrist (p=0.089).

Conclusion: In RA patients, despite a perceived higher difficulty to clinically detect synovitis (SJ) in O patients, the discrepancy between clinically- and PDUS defined synovitis was not significantly higher than in NO patients, and did not impact the extend of the definition of disease activity level.

Thermal Imaging in Rheumatoid Arthritis: A Comparative Analysis with Ultrasonography and Clinical Joint Assessment

York Kiat Tan ,[1] Cassandra Hong,[1] HuiHua Li,[2] John Carson AllenJr,[3] and Julian Thumboo[1], [1]Department of Rheumatology and Immunology, Singapore General Hospital, Singapore, Singapore, [2]Health Services Research, Singapore General Hospital, Singapore, Singapore, [3]Centre for Quantitative Medicine, Duke-NUS Medical School, Singapore, Singapore

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Imaging Of Rheumatic Diseases Poster I
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The potential of thermal imaging in detecting joint inflammation in rheumatoid arthritis (RA) has not been well studied or compared with other approaches in assessing joint inflammation. Therefore, we aimed

Table 1. Comparing thermographic parameters between joints based on ultrasound findings.

Thermographic Parameter	Mean values within ultrasound category		Difference (95% CI)	P-value
	PD negative	PD positive		
Tmax (°C)	31.2	32.5	1.37 (0.86, 1.87)	**<0.001**
Tmin (°C)	29.3	30.2	0.91 (0.46, 1.36)	**<0.001**
Tavg (°C)	30.1	31.3	1.16 (0.67, 1.64)	**<0.001**
Tmax-min (°C)	1.82	2.29	0.46 (0.28, 0.64)	**<0.001**
	GS negative	GS positive		
Tmax (°C)	31.1	32.2	1.09 (0.67, 1.52)	**<0.001**
Tmin (°C)	29.3	30.0	0.66 (0.32, 1.00)	**<0.001**
Tavg (°C)	30.1	31.0	0.86 (0.47, 1.26)	**<0.001**
Tmax-min (°C)	1.79	2.23	0.45 (0.28, 0.62)	**<0.001**

PD, power Doppler; GS, grey-scale; Tmax, maximum temperature; Tmin, minimum temperature; Tavg, average temperature; Tmax-min, maximum minus minimum temperature.

Table 2. Comparing thermographic parameters and ultrasound scores between joints based on their clinical status.

Thermographic/ ultrasound Parameter	Mean values within Clinical joint category				F-test P-value	Differences (95% CI) S0T0 vs			P-values S0T0 vs		
	S0T0	S0T1	S1T0	S1T1		S0T1	S1T0	S1T1	S0T1	S1T0	S1T1

GS score	0.18	0.31	1.01	1.04	**<0.001**	0.13 (-0.04, 0.29)	0.83 (0.37, 1.29)	0.86 (0.54, 1.18)	0.140	**<0.001**	**<0.001**

S0T0, non-swollen and non-tender; S0T1, non-swollen but tender; S1T0, swollen but non-tender; S1T1, swollen and tender; Tmax, maximum temperature; Tmin, minimum temperature; Tavg, average temperature; Tmax-min, maximum minus minimum temperature; PD, power Doppler; GS, grey-scale.

to gain further insight into the role of thermal imaging in RA by performing a comparative analysis with ultrasound (US) and clinical joint assessment.

Methods: 22 joint (including bilateral wrists, metacarpophalangeal joints, thumbs interphalangeal joints and proximal interphalangeal joints) were studied per patient. At the joint sites, thermographic parameters included maximum (Tmax), minimum (Tmin), average (Tavg) and Tmax minus Tmin (Tmax-min) temperatures, US parameters collected at the same study visit included power Doppler (PD) and grey-scale (GS) joint inflammation (graded semi-quantitatively 0-3), while clinical assessment included joint swelling and tenderness (graded yes=1 or no=0). As imaging findings for different joints in the same patient may not be independent, Generalized Estimating Equations (GEE) analysis was used to (a) compare the differences in mean values of thermographic parameters between joints based on their PD or GS positivity/negativity status (b) compare the differences in mean values of thermographic parameters, US PD and GS scores between joints based on their clinical swelling and tenderness status. Differences in means and 95% CIs were estimated using GEE with robust Huber-White variance estimates.

Results: 814 joints were studied in 37 RA patients with the following baseline characteristics: mean age, 56.5 years; 75.7% female; 75.7% Chinese; mean (SD) disease duration, 30.9 (45.3) months; mean (SD) DAS28, 4.43 (1.12). Comparing joints with PD positivity versus those with PD negativity (table 1), the differences in mean values (95% CI) for thermographic parameters Tmax, Tmin, Tavg and Tmax-min had all attained statistical significance (P-values were all < 0.001). The corresponding differences in mean values (95%CI) for the thermographic parameters comparing joints with GS positivity versus those with GS negativity (table 1) were similarly statistically significant (P-values were all < 0.001). The differences in mean values (95% CI) for PD and GS scores—but not for thermographic parameters—were statistically significant for (a) swollen and tender joints (PD: 0.67 (0.39, 0.96), $P< 0.001$; GS: 0.86 (0.54, 1.18), $P< 0.001$) and (b) swollen and non-tender joints (PD: 0.46 (0.07, 0.84), $P=0.021$; GS: 0.83 (0.37, 1.29), $P< 0.001$) when compared to non-swollen and non-tender joints (table 2)

Conclusion: Thermographic parameters were useful in discriminating between US PD and GS positivity versus negativity status at the RA joints, although they were not useful—unlike ultrasonography—for discriminating between joints based on clinical swelling and tenderness status.

Imaging Neoangiogenesis in Rheumatoid Arthritis (INIRA): Whole-Body Synovial Uptake of a 99mTc-Labelled RGD Peptide Is Highly Correlated with Power Doppler Ultrasound

Laura Attipoe ,[1] Toby Garrood,[2] Sujith Subesinghe,[2] Maria Opena,[2] Cristina Blanco-Gil,[2] Mark Rosser,[3] Gary Cook,[4] and Andrew Cope[5], [1]Rheumatology Dept, King's College London, London, United Kingdom, [2]Rheumatology Dept, Guy's and St Thomas' Hospitals NHS Trust, London, United Kingdom, [3]Serac Life Sciences, Thames Ditton, England, United Kingdom, [4]Nuclear Medicine Dept, Guy's and St Thomas' Hospitals NHS Trust, London, United Kingdom, [5]Academic Rheumatology, King's College London, London, United Kingdom

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Imaging Of Rheumatic Diseases Poster I
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Power doppler ultrasound (PDUS) is superior to clinical examination in the detection of synovitis in patients with rheumatoid arthritis (RA). Although dynamic and cheap it is impractical to scan large numbers of joints in routine clinical settings. MRI, whilst sensitive for synovitis, is expensive, and routine use is limited to targeted joints. Bone scintigraphy produces whole body images but due to lower specificity is not routinely used to detect synovitis

^{99m}Tc-maraciclatide (Serac Healthcare) is a radio-labelled tracer which binds with high affinity to integrin $\alpha_v\beta_3$, a cell-adhesion molecule up-regulated on neoangiogenic blood vessels. It therefore has the potential to image synovial inflammation at the whole-body level. We previously showed in a pilot study that uptake was seen in the inflamed joints of 5 RA patients and that this correlated with PDUS[1]. This study explores correlation with PDUS in a larger groups of patients with a range of disease activities

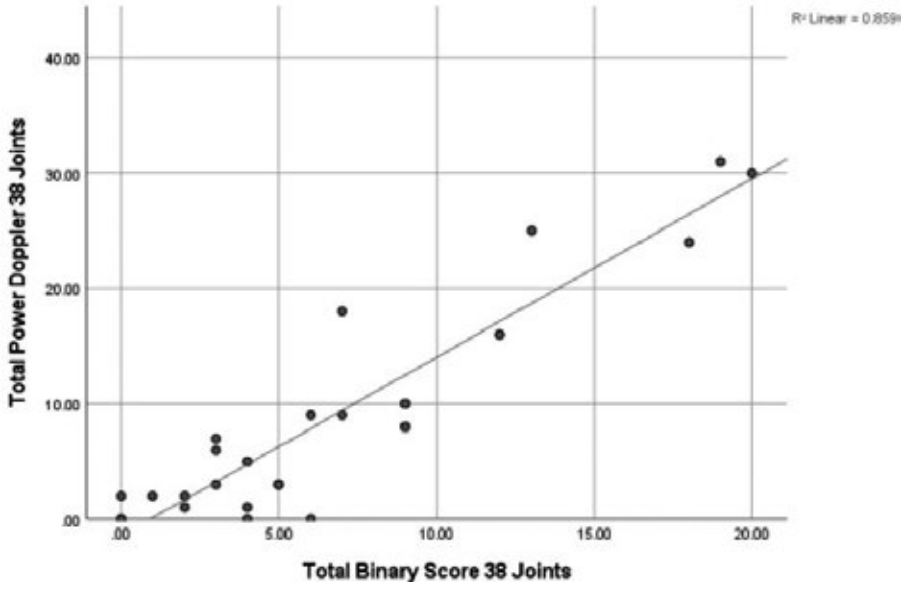

Figure 1. Correlation between total power doppler and 99mTc-maraciclatide binary scores

Methods: 25 patients with RA, fulfilling ACR 2010 classification criteria, were recruited. Patients underwent 66/68 swollen/tender joint counts followed by an ultrasound scan of 38 joints with grey scale (GS) and PD quantification. As per OMERACT guidelines, each joint was scored on a scale of 0-3 for GS and PD with a total score calculated for each patient. Within 3 hours of the ultrasound, patients were injected with 740 MBq of ^{99m}Tc-maraciclatide. Using a

Figure 2. 99mTc-maraciclatide imaging with dedicated hand and foot views

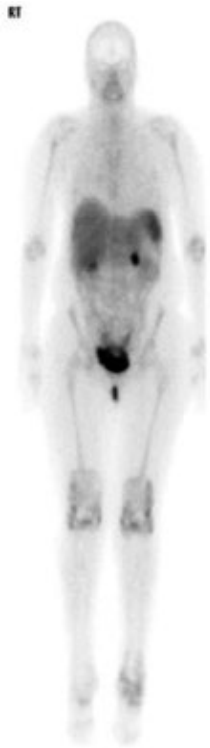

Figure 3. 99mTc-maraciclatide whole body image

gamma camera, whole body planar views and dedicated hand and foot views were taken 2 hours after injection. Acquisition time was 20 minutes for whole body, and 20 minutes for hand and foot views. Nuclear medicine images were scored as positive or negative uptake for each joint (binary score). Binary scores were summed individually to derive a total score for each patient. Ultrasound and ^{99m}Tc-maraciclatide scores were tested for correlation with Pearson's correlation coefficient. Significance was set at $p< 0.05$

Results: Strong correlation was seen between total PDUS and binary scores ($r=0.93$, $r^2=0.86$, $p< 0.001$). In the wrists and ankles ^{99m}Tc-maraciclatide uptake was seen not only in synovitic joints but in inflamed tendons/ tendon sheaths. The imaging procedure was well-tolerated

Conclusion: ^{99m}Tc-maraciclatide uptake was highly correlated with PDUS highlighting its potential as a viable alternative imaging modality. ^{99m}Tc-based planar imaging has the unique capacity to image the whole body and hence the total synovial inflammatory load in a quick acquisition. Furthermore the imaging equipment to perform these scans is already widely available in nuclear imaging departments. Interpretation of scans is also much simpler compared to US and MRI. It could therefore have a role in key decision-making points in pathways for diagnosis, treatment failure, and remission prior to dose tapering. Recruitment is underway to expand the data to a larger group of patients

Ultrasound Evaluation of the Achilles Enthesis in Inflammatory and Non-inflammatory Processes: A Systematic Review

Nancy Desai ,[1] Justin Bucci,[1] and Eugene Kissin[2], [1]Boston Medical Center, Boston, [2]Boston University, Boston, MA

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Imaging Of Rheumatic Diseases Poster I
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Ultrasound (US) evaluation of the Achilles tendon has been utilized to assess involvement at the entheses in the setting various inflammatory, metabolic and mechanical processes. The purpose of this systematic review is to determine if US evaluation has been reported to show different findings at the Achilles enthesis with inflammatory (IT) versus non-inflammatory tendinopathy (NIT).

Methods: We conducted a systematic review of all studies involving US evaluation of IT or NIT (mechanical or metabolic) affecting the Achilles enthesis using the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines. We systematically searched the Embase, PubMed, Medline databases from start until August 2018. One author applied predefined exclusion criteria, excluding poster or conference abstracts, as well as studies without original data, without description of US findings, studies not focused on the Achilles tendon or studies in children. An additional author was utilized to perform secondary review of these articles and any differences were then mitigated by a 3rd reviewing author. Data was extracted from selected articles assessing tendon thickness, Doppler signal and erosions.

Results: Our initial search yielded 574 articles, limited to 174 by initial abstract review and to 46 through full text review. Of these, 30 studies investigated an underlying IT, 14 studies focused on NIT, and 2 articles evaluated both. At the enthesis, the Achilles was abnormally thickened in 12.0% of all patients reported in IT and 29.4% in symptomatic IT groups in comparison to 27.9% of those with NIT and 7.4% of those in the healthy control group. The average Achilles enthesis thickness was 5.24mm in 147 tendons in 4 studies of all patients with underlying IT, 5.65mm in patients from 3 studies focused only on symptomatic tendons in those with IT, compared to 5.72mm in 340 tendons from 6 studies including NIT, and 4.16mm in 243 healthy tendons (5 studies) (Figure 1). NIT increased incidence of Doppler signal at the Achilles enthesis to 28.2% (n=306 tendons, studies = 7, range from 0 to 96.4%) in comparison to 7.6% in IT (n=2746 tendons, studies =24, range 0 to 100%), 12.2% in those with specifically symptomatic IT (n=131 tendons, studies=4, range 1.1 to 100%) and 0.5% for healthy controls (n=953 tendons, studies = 12, range 0 to 6.25%) (Figure 2). Incidence of erosions was similar between IT, 10.9% (n=3108 tendons, studies = 31, range 0.9 to 95.6%) and NIT, 11.1% (n=227 tendons, studies = 5, range 1.2 to 31.1%) and 1.93% in healthy controls (n=973 tendons, studies =12, range 0 to 23.3%) (Figure 3).

Conclusion: Achilles enthesis thickening and even erosions are reported at a similar incidence and degree in both patients with IT and NIT. Surprisingly Doppler signal is more commonly reported in NIT even compared to studies

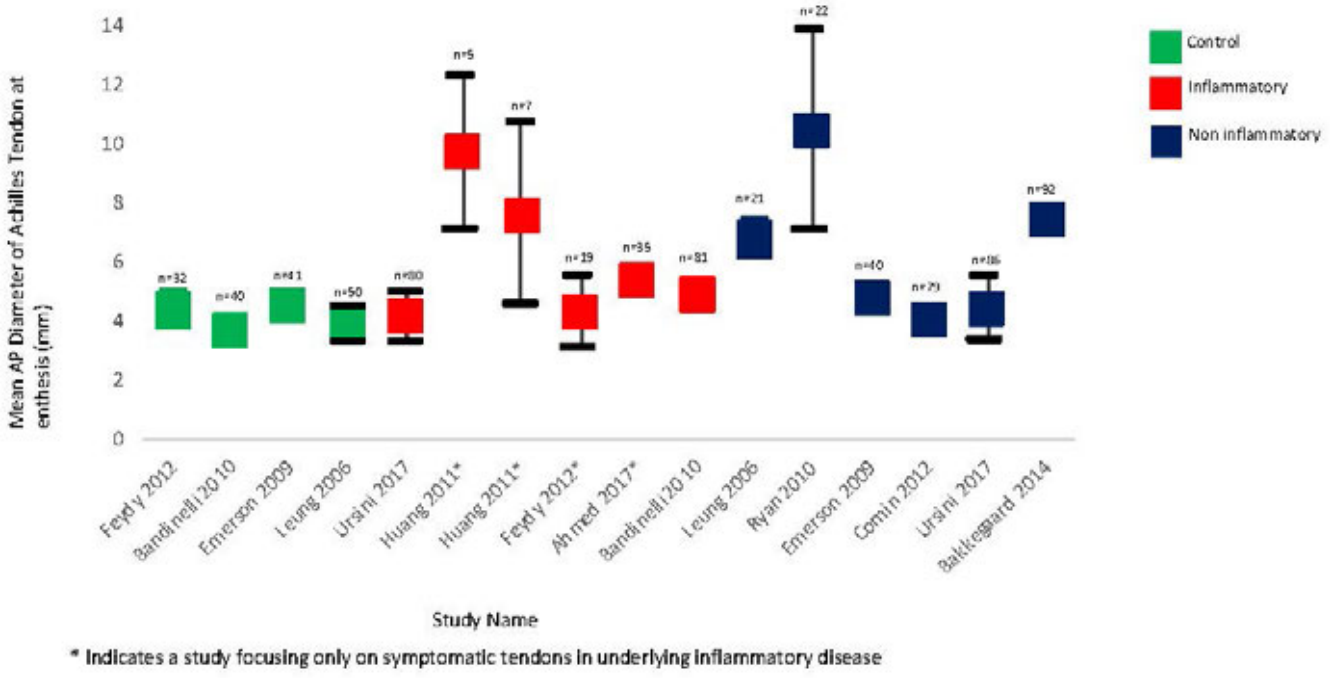

Figure 1. Studies with Increased Thickness Noted at Achilles Enthesis (mm)

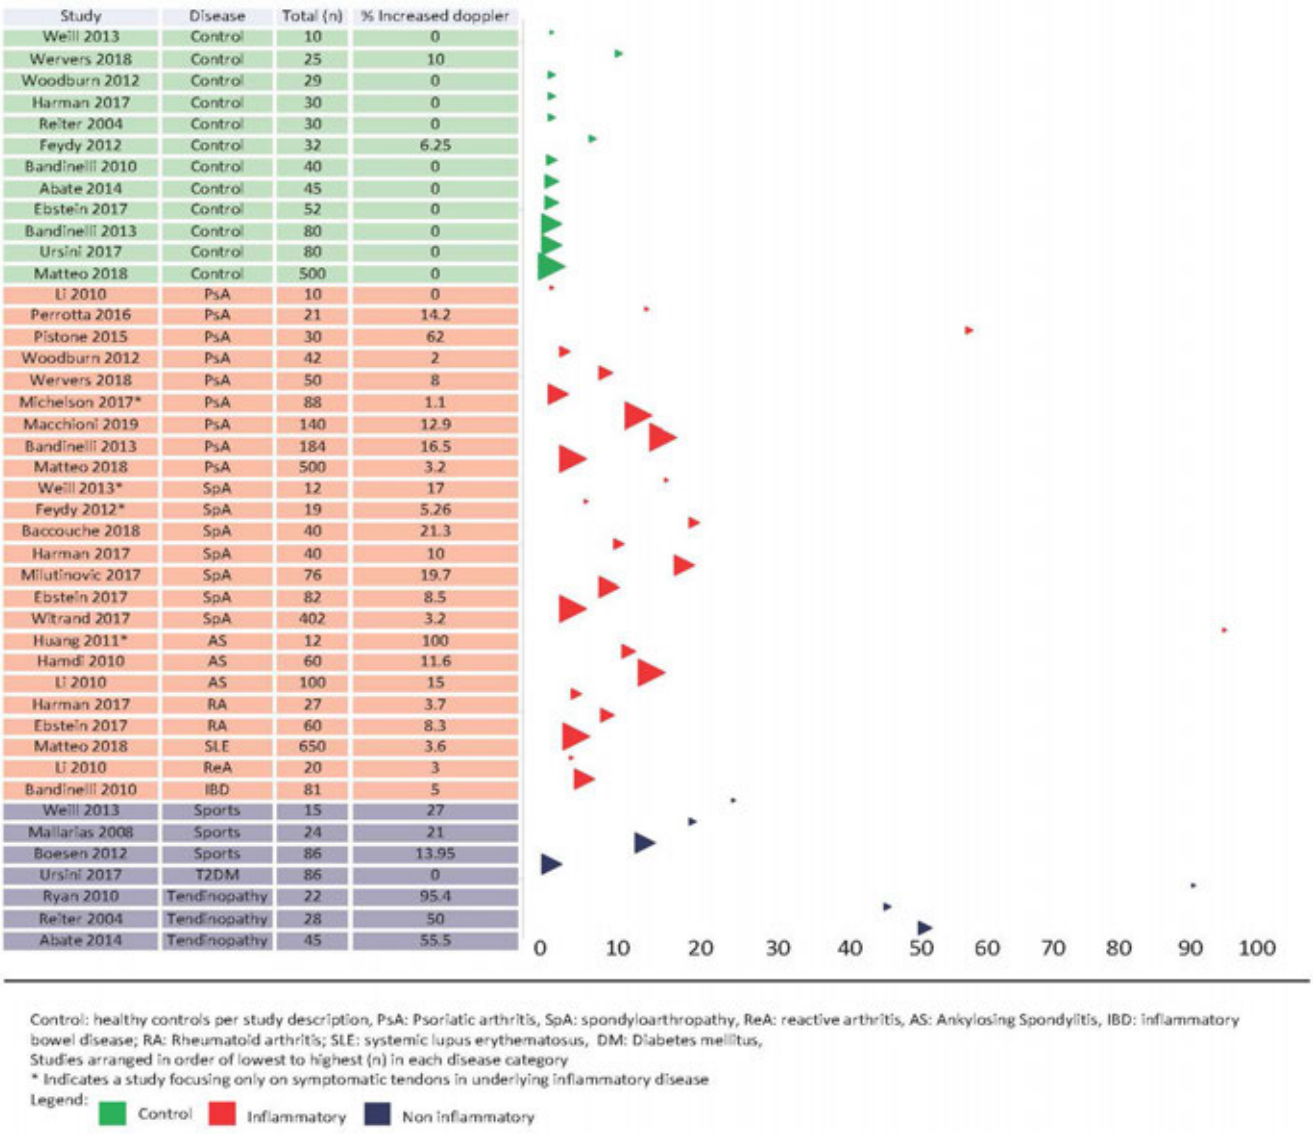

Figure 2. Studies with Doppler Signal Noted at the Achilles Enthesis

looking only at symptomatic tendons with underlying inflammatory conditions. These typical US abnormalities at the Achilles enthesis may not be helpful in distinguishing inflammatory from non-inflammatory causes.

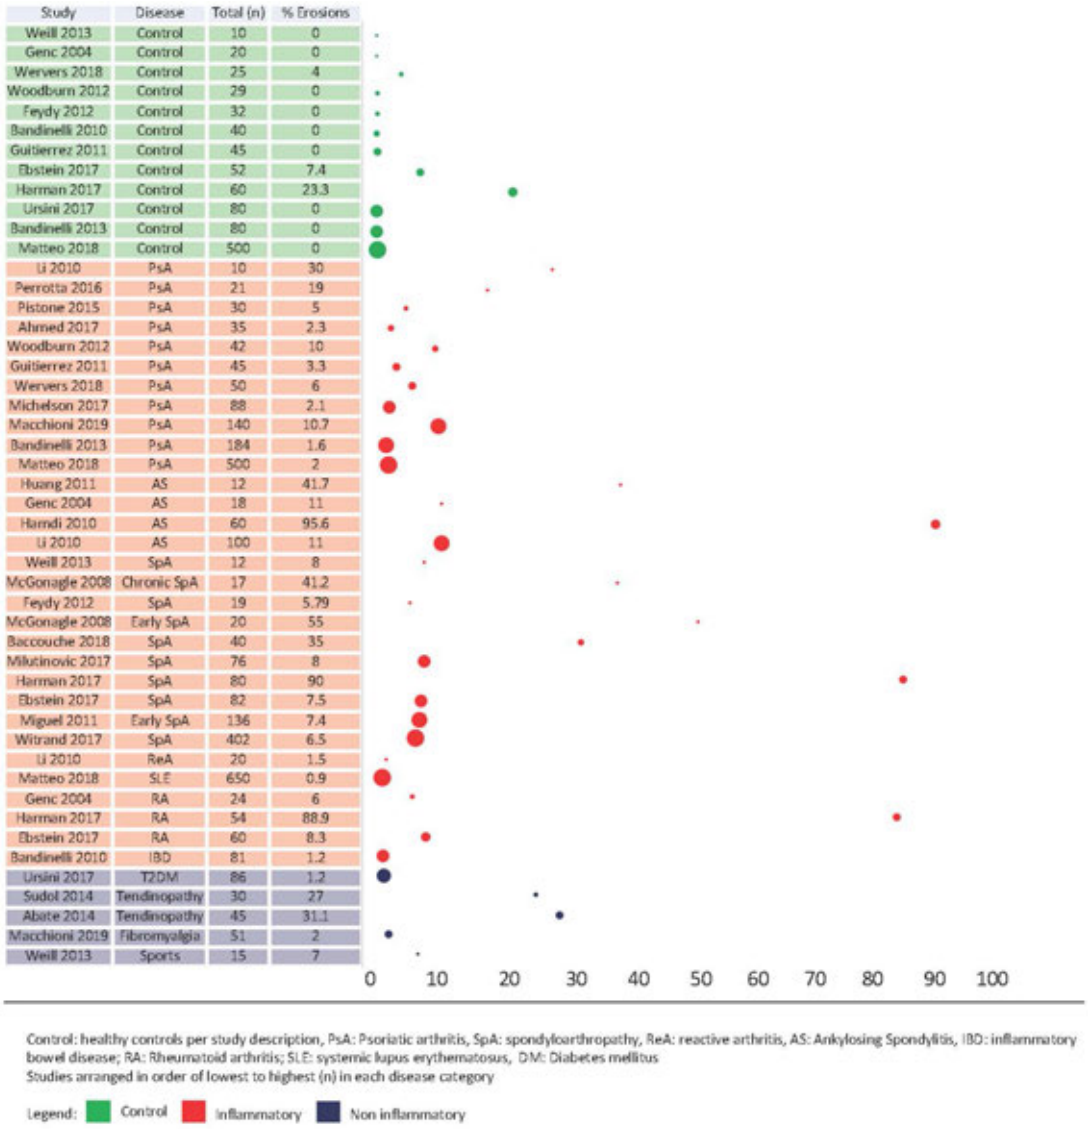

Figure 3. Studies with Erosions Noted at the Achilles Enthesis

Evaluating the Performance of a Single-site Musculoskeletal Ultrasound Clinic Associated with an Academic Rheumatology Practice: Diagnostic and Therapeutic Impact on Patient Care and Survey of Patient and Physician Satisfaction

Nasha Nensey ,[1] and Sobia Hassan[1], [1]Rush University Medical Center, Chicago

SESSION INFORMATION

Session Date: Sunday, November 10, 2019
Session Title: Imaging Of Rheumatic Diseases Poster I
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Growing utilization of musculoskeletal ultrasound (MSUS) for the management of rheumatologic disorders has led to integration of dedicated MSUS clinics in many rheumatology practices. However, there is limited published data on patient/physician satisfaction with such clinics and their clinical impact. This study aimed to analyze the performance of our MSUS clinic by assessing (1) reasons for referral, (2) patient/physician satisfaction and (3) subsequent diagnostic and therapeutic impact.

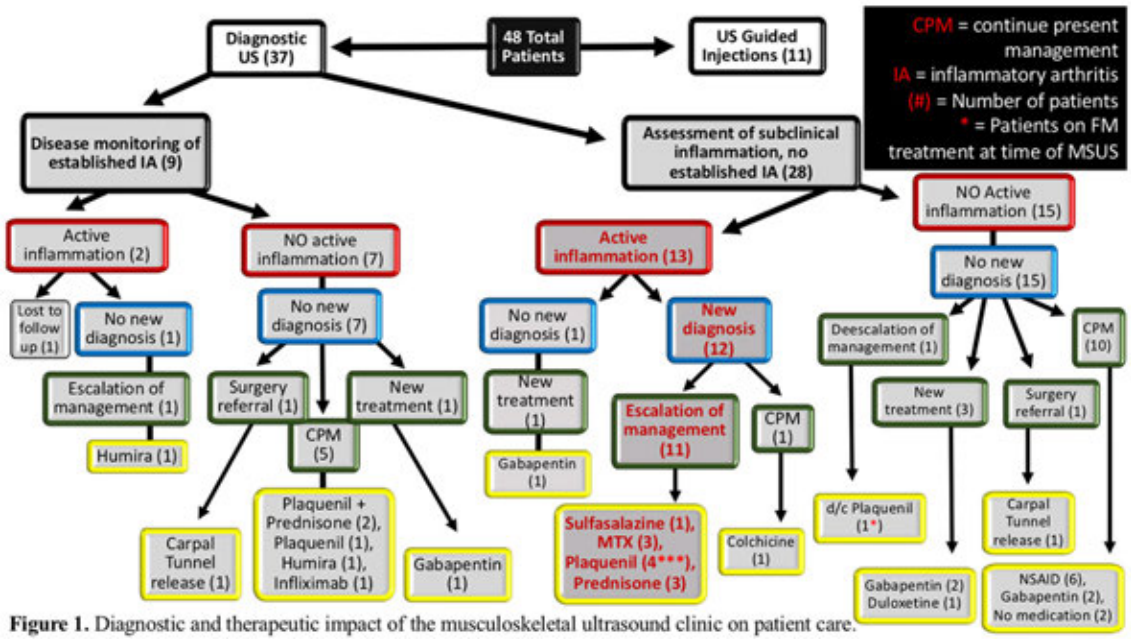

Figure 1. Diagnostic and therapeutic impact of the musculoskeletal ultrasound clinic on patient care.

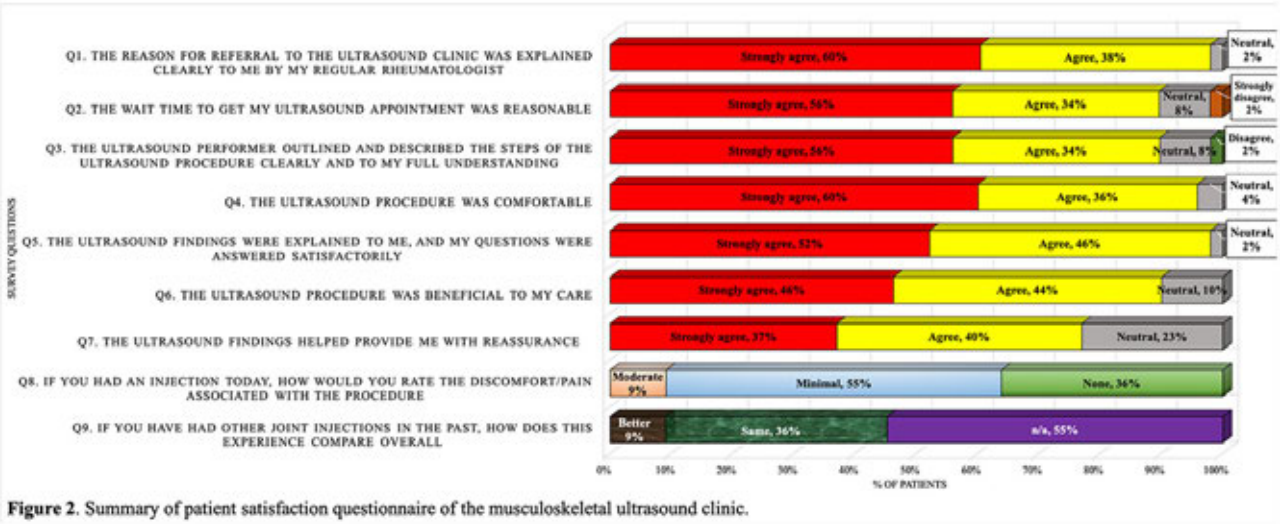

Figure 2. Summary of patient satisfaction questionnaire of the musculoskeletal ultrasound clinic.

Figure 3. Summary of physician questionnaire on satisfaction and perceived utility of the musculoskeletal ultrasound clinic.
(#%): Percentage of physicians with labeled response.

Methods: Patients (pts) and referring rheumatologists anonymously completed and returned a single written in-office questionnaire-based survey, at the end of the visit or study, respectively. For all pts seen for diagnostic MSUS, a retrospective chart review was conducted, and post-MSUS diagnosis and management were documented. Positive MSUS findings, indicative of inflammatory arthritis (IA), were defined as synovitis, tenosynovitis, dactylitis, erosions, synovial thickening or crystal deposition.

Results: Of 48 total pts, seen over 5 months, 23% (n=11) received US guided joint injections and 77% (n=37) had diagnostic US for disease monitoring/management of established IA (n=9) or assessment of subclinical/suspected IA (n=28). Of the 28 pts with suspected IA, 46% (n=13) had MSUS findings of IA, prompting initiation of DMARD (n=8) or prednisone (n=3). Remaining 54% of pts (n=15) had no inflammation on MSUS, leading to de-escalation (n=1) or no escalation of management (n=14). Of 9 pts with established IA, 78% (n=7) showed no active synovitis, with no consequent escalation of management (figure).

The patient survey had 100% response rate, 9.6 mean satisfaction score (1-10 scale) and > 75% positive feedback (strongly agree or agree) for every question (Q); 89-98% explanation of procedure/results (Q1, 3, 5), 89% appointment wait time (Q2), 95% comfort (Q4), 90% benefit to care (Q6), 77% reassurance (Q7). Of pts who received injections, 82% had minimal to no pain, and 100% had similar to improved overall experience, compared to prior injections (figure 2).

Of the 83% (n=10) physician survey response, 100% indicated plan for future referral (figure 3). The most frequent reason given for referral was assessment of subclinical/suspected IA (n=10), followed by US injections (n=9) and disease monitoring (n=4). The majority of physicians (75%, n=3) with experience performing MSUS referred most often (>10 pts/12 months). However, in regards to perceived impact on clinical decision making or benefit to patient care, there was no statistical difference between physicians with more MSUS or rheumatology experience, compared to their less experienced colleagues.

Conclusion: The MSUS clinic was most impactful in the evaluation of patients with subclinical/suspected IA. This group of patients comprised the most referrals to the clinic and 46% of patients had positive US findings, which helped to confirm a new diagnosis of IA. Overall, the MSUS clinic received high patient and physician satisfaction scores and was perceived as beneficial to patient care by both patients and referring rheumatologists.

Session Title: Imaging Of Rheumatic Diseases Poster I

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: The assessment of activity in spondyloarthritis (SpA) and psoriatic arthritis (PsA) involves several domains, including enthesitis. Clinical enthesitis has shown low sensitivity, specificity and reliability. The inclusion of ultrasound (US) can be an objective outcome in the assessment of the disease. Our objective is to assess the prevalence of peripheral US enthesitis using an US score, at patient level, among active SpA and PsA patients

		Total n= 36	AS n=19 (52.8%)	PsA n=10 (27.8%)	nr-axSpA n=7 (19.4%)	p

	≥2	18 (50%)	11 (57.9%)	4 (40%)	3 (42.9%)	0.6
PD MASEI	≥1	29 (80.6%)	15 (78.9%)	9 (90%)	5(71.4%)	0.8
	≥2	21 (58.3%)	12 (63.2%)	5 (50%)	4 (57.1%)	0.8

Table 1. Baseline characteristics of active SpA patients

	Reader 1	Reader 2	Reader 3
ICC reader 1		0.784 (95% CI 0.58 to 0.89)	0.909 (95% CI 0.82 to 0.95)
ICC reader 2	0.784 (95% CI 0.58 to 0.89)		0.855 (95% CI 0.72 to 0.93)
ICC reader 3	0.909 (95% CI 0.82 to 0.95)	0.855 (95% CI 0.72 to 0.93)	

Table 2. Inter-reader reliability

Methods: A cross-sectional study in patients with SpA and PsA active disease (defined as patients who were going to start or switch biological therapy according to physician criteria and in agreement with clinical guidelines) was undertaken. Basal assessment included clinical features, physical examination and laboratory tests. Patients underwent bilateral US examination of peripheral entheses according to the MAdrid Sonographic Enthesitis Index (MASEI). MASEI and OMERACT enthesitis Power Doppler (PD) definitions were checked. Each enthesis was scanned in both the longitudinal and transverse planes, and 5 second videos were recorded for reliability. An inter-reader analysis by three readers was performed. For statistical analysis Mann-Whitney U test, Kruskal-Wallis test and intraclass correlation coefficients (ICCs) were used

Results: 36 patients were included, of whom 19(52.8%) were ankylosing spondylitis (AS) patients, 10(27.8%) PsA, and 7(19.4%) non radiographic axial spondyloarthritis (nr-axSpA). Mean age was 49.8±13.1 years and 18(50%) were females. Mean DAS28 (3.5±1.3), ASDAS (3.7±0.9), BASDAI (5.7±2.2) and CRP values (11.5±12.6) reflect moderate-high disease activity. Demographic and clinical baseline characteristics are shown in Table 1. Mean global MASEI score was 28.1(±9.1) and 30 patients (83.3%) scored ≥18 (proposed cut-off point to diagnose SpA). Abnormal US findings consistent with at least one enthesis showing PD signal (whether using MASEI or OMERACT PD definition) were observed in 29(80.6%) of patients while two or more PD in entheses were observed in 21(58.3%) patients (PD MASEI definition) or 18(50%) patients (PD OMERACT definition), without significant variation among the different SpA subtypes. The sites most commonly affected were the distal patellar, quadriceps and distal Achiles tendon (52.8%, 41.7% and 16.7%, respectively). The inter-reader reliability among the three readers was high (mean ICC of 0.85). Table 2 shows the ICC of every reader pair

Conclusion: Presence of PD enthesitis is found in 80% of patients with active SpA and PsA. This finding is independent of SpA subtype and support the usefulness of PD US in the assessment of enthesitis

---

In Psoriatic Arthritis Patients Considered in Remission by Their Rheumatologist, Can Discordance in Disease Activity Assessment Between Patient and Rheumatologist Be Explained by Residual Inflammation as Measured by Ultrasonographic Examination?

Marie Moly ,[1] Cédric Lukas,[2] Jacques Morel,[1] Bernard Combe,[3] and Gaël Mouterde[4], [1]CHU Montpellier, Montpellier, France, [2]Rheumatology department, CHU Montpellier, Univ Montpellier, Montpellier, France, [3]CHU Montpellier, Montpellier University, Montpellier, France, [4]CHU Montpellier and Univ Montpellier, Montpellier, France

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Imaging Of Rheumatic Diseases Poster I
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Psoriatic arthritis (PsA) is a heterogeneous disease and its assessment is sometimes difficult. Perception of disease activity by patient and physician is frequently discordant in patients in clinical remission

	N (%)
Ultrasound remission	26 (41.9)
Ultrasound minimal disease activity	44 (71)
Patients with ≥1 grey scale synovitis	55 (88.7)
Patients with ≥1 Power Doppler synovitis	12 (19.4)
Patients with ≥1 grey scale tenosynovitis	15 (24.2)
Patients with ≥1 Power Doppler tenosynovitis	1 (1.6)
Patients with ≥1 grey scale enthesitis lesion (thickness, hypo echogenicity, calcification, enthesophyte, erosion, bursitis)	59 (95.2)
Patients with ≥1 Power Doppler enthesitis	32 (51.6)

Table 1. Ultrasound characteristics of the 62 PsA patients

(1). Ultrasound (US) is an imaging technique, which can detect inflammation in PsA. The aim of our study was to assess whether persistence of disease activity evaluated by the patient, considered in remission by his rheumatologist, was associated with inflammation measured by US.

Methods: We performed a transversal monocentric study. PsA patients were included if they met the CASPAR criteria and were considered in remission by their rheumatologist. Demographic data, characteristics of the disease and treatments were collected. Discordance was defined by a difference between patient's and rheumatologist's global assessment ≥30/100 on a Visual Analogic Scale. An US examination was performed on 50 joints, 28 tendons and 14 entheses by an independent investigator. Synovial or tendon sheath hypertrophy and PD signal were evaluated on a semi-quantitative scale, B Mode and PD signal abnormalities on entheses were searched, according to the EULAR-OMERACT scoring system. US remission was defined by no power Doppler (PD) signal on joints, tendons and entheses and minimal US activity by maximum one PD signal on the same sites. Univariate and multivariate analyses were performed to evaluate factors associated with US abnormalities

Results: Sixty-two PsA patients were included. 40.3% were women, the mean (SD) age was 55 (14) years, 42% were in US remission and 71% in minimal US activity *(Table 1*), 19.4% had ≥1 PD synovitis and 88.7% had a B mode synovitis, 95.2% had a B mode abnormality on entheses and 51.6% had ≥1 PD signal on entheses. Thirty nine percent had a discordant disease activity assessment with their rheumatologist. In univariate analysis, discordance was not associated with US remission (OR=1.71 (95%CI 0.61-4.83), p=0.224) or US minimal disease activity (OR=0.99 (95%CI 0.32-3.05), p=0.602). In multivariate analysis, US remission was independently associated with female gender (OR=3.94 (95%CI 1.20-12.9), p=0.024) and younger age (OR=0.95 (95%CI 0.91-0.99), p=0.027). Minimal US activity was associated with history of enthesis lesion (OR=11.26 (95%CI 1.34-94.93), p=0.026) and age (OR=0.95 (95%CI 0.90-1), p=0.044).

Conclusion: Our study showed persistent inflammation evaluated by US in PsA patients considered in remission by their rheumatologist. However, prevalence of residual inflammation evaluated by US was not higher in patients with self-assessment of their disease discordant from their rheumatologist.

Abstract Number: 0291

Factors Explaining Patient Perspective in Psoriasis and Psoriatic Arthritis: The Role of Inflammation and Structural Damage Detected by Ultrasound

Tania Gudu ,[1] Ilaria Padovano,[1] Hélène Gouze,[2] François Vidal,[1] Emmanuel Mahé,[3] Leire Lara Gonzalez,[4] Alexis Guyot,[4] Philippe Saiag,[4] Isabelle Bourgault Villada,[4] Sophie Ruel-Gagné,[1] Gilles Hayem,[1] Félicie Costantino,[5] Maxime Breban,[6] and Maria-Antonietta D'Agostino[7], [1]Rheumatology Department, APHP, Ambroise Paré Hospital, Boulogne Billancourt, France, [2]Rheumatology Department, APHP, Ambroise Paré Hospital, Bolougne Billancourt, France, [3]Dermatology Department, Victor Dupouy Hospital, Argenteuil, France, [4]Dermatology Department, Ambroise Paré Hospital, Boulogne Billancourt, France, [5]UMR1173, INSERM/Versailles-Saint Quentin University, France Ambroise Paré Hospital [AP-HP] Department of Rheumatology, Boulogne-Billancourt, France, Boulogne Billancourt, France, [6]UMR1173, INSERM/Versailles-Saint Quentin University, France Ambroise Paré Hospital [AP-HP] Department of Rheumatology, Boulogne-Billancourt, France, Boulogne Billancourt, [7]Department of Rheumatology, APHP, Hôpital Ambroise Paré, Paris, France

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Imaging Of Rheumatic Diseases Poster I
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Patient reported outcomes (PROs) reflect patients' opinion on disease activity, impact of disease, quality of life (QoL), disability and are essential in the assessment of PsA patients. PROs may be influenced by several factors other than disease activity and severity. US is an objective tool to evaluate inflammation and structural damage in PsA. This cross-sectional study aimed at evaluating the role of US-detected inflammation (synovitis, tenosynovitis, enthesitis, dactylitis) and structural damage (erosions, enthesophytes, osteophytes and cortical irregularities), according to the OMERACT definitions and scoring [1], to explain PROs in PsA and to compare that to psoriasis (PsO) patients with and without musculoskeletal (MSK) symptoms.

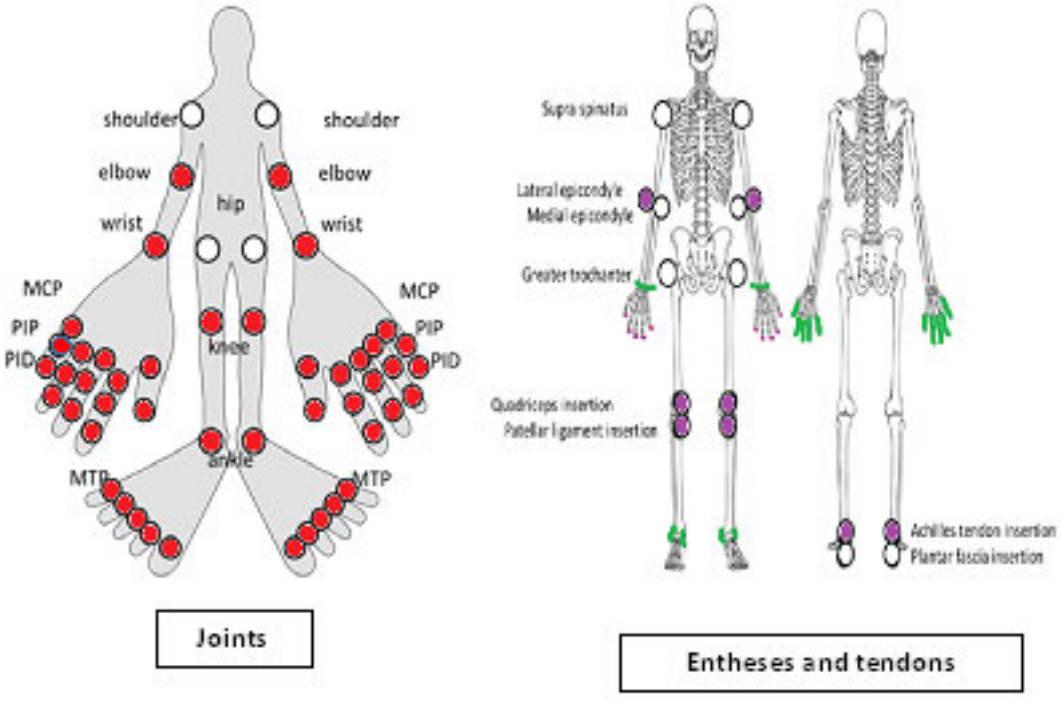

Figure 1. Anatomical sites of US evaluation: joints, entheses and tendons

Table 1. Characteristics of the patients included in the 3 groups: PsA patients, patients with psoriasis with MSK symptoms (symptoPsO) and patients with psoriasis and no MSK symptoms (asymptoPsO) PsA: psoriatic arthritis; PsO: psoriasis; PASI: Psoriasis Area and Severity Index; TJC: total tender joint count; SJC: total swollen joint count; N: number; SD: standard deviation; NRS: numeric rating scale; SF36: Medical Outcome Study Short Form-36; PF: Physical Functioning; RP: Physical Role functioning; BP: Bodily Pain; GH: General Health; VT: Vitality; SF: Social role Functioning; MH: Mental Health; RE: Emotional Role functioning * Number of enthesitis was calculated according to the Spondyloarthritis Research Consortium of Canada (SPARCC) Enthesitis Index

Methods: PsA (CASPAR criteria) [2], PsO with MSK symptoms without fulfilling CASPAR criteria (symptoPsO) and PsO with no MSK symptoms (asymptoPsO) were included. Socio-demographic characteristics, comorbidities, disease duration and treatment were collected. All patients underwent dermatological and rheumatologic assessment: PsO severity, swollen joint count (SJC), tender JC (TJC), number of dactylitis and enthesitis, fibromyalgia criteria; and US evaluation on joints, tendons and entheses as shown in figure 1. PROs were evaluated in all patients: assessment of skin psoriasis and of fatigue on a numeric rating scale (NRS), HAQ and QoL assessed by SF36. Variables were compared across groups (chi square or one-way ANOVA test). Correlations were evaluated using Spearman's test.

Results: One hundred fifty eight patients (54 PsA, 52 symptoPsO and 52 asymptoPsO) with similar socio-demographic characteristics and PsO duration were included (table 1). Most of PsA patients had low/moderate disease activity. With the exception of US enthesophytes, all US changes were significantly higher in PsA, followed by symptoPsO patients.

Across all 3 groups, all PROs correlated mainly with demographic variables, comorbidities, TJC, number of enthesitis, skin severity, depression and fibromyalgia (r=0.29-0.66). SymptoPsO and PsA reported similar scores of fatigue and impact on some QoL domains (vitality, pain, general health, social and mental), significantly higher than asymptoPsO. Only in PsA, HAQ correlated with the total number of US enthesitis (r=0.35, p=0.01) and of joints with ostheophytes/cortical irregularities (r=0.28, p=0.04) as well as the physical function domain of SF36 with the number of joints with ostheophytes/cortical irregularities (r=-0.33, p=0.02).

Conclusion: Quality of life, disability and fatigue were more impaired in PsA and symptoPsO patients than asymptoPsO. In all groups, PROs were mostly associated with socio-demographic characteristics, comorbidities and some clinical variables rather than objective measures such as US changes.

Abstract Number: 0292

Is Shoulder Involvement an Early Feature of Rheumatoid Arthritis in Clinically Suspect Arthralgia? *A Longitudinal Ultrasound Study*

Cleo Rogier ,[1] Pascal de Jong,[2] and Annette van der Helm-van Mil[3], [1]Erasmus Medical Center, Rotterdam, Zuid-Holland, Netherlands, [2]Erasmus MC, Rotterdam, Netherlands, [3]LUMC, Leiden, Zuid-Holland, Netherlands

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Imaging Of Rheumatic Diseases Poster I
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Multiple studies have demonstrated that shoulder involvement is frequent in Rheumatoid Arthritis (RA). Previous research also showed that a swollen shoulder joint has a similar predictive value as small joint involvement for developing RA in patients with undifferentiated arthritis (UA). The phase of clinically suspect arthralgia (CSA) precedes the phase of clinically apparent arthritis; in this phase subclinical tenosynovitis of the hands, visualized with MRI or US, is predictive for developing RA. Given the similarities in predictive values between the shoulder and small joints in UA, and the predictive value of tenosynovitis in CSA, we hypothesized that subclinical tenosynovitis of the shoulder is a predictor for RA development in CSA. Within the shoulder the biceps tendon is the most obvious to investigate, because it passes though the shoulder joint and is covered with a synovial sheet.

Objective: Therefore, the aim of this study is to examine the predictive value of tenosynovitis of the bicep tendon by ultrasound (US) on developing inflammatory arthritis (IA) in CSA patients.

Methods: The SONAR (Sonographic evaluation of hands, shoulders and feet in patients presenting with inflammatory arthralgia to identify subclinical arthritis)-study is a multi-center observational cohort study in which patients were followed on the development of clinically apparent inflammatory arthritis (IA). Visits were done at baseline and every 6 months thereafter. At baseline a US of both shoulders was made. 1-year follow-up data were used. IA was defined as having an arthritis verified by the treating physician. We investigated whether there was a relation between the development of IA and the presence of (1) biceps tenosynovitis (TS); (2) a thickened biceps tendon without power

	Patients that developed IA (n =37)	Patients that did not develop IA (n = 133)	P value
Gender, female, n (%)	30 (81)	110 (83)	0.82
Age, years, mean (SD)	47(12)	44 (12)	0.28
BMI, mean (SD)	27 (5)	28 (5)	0.38
Morning stiffness, minutes median (IQR)	45 (30-90)	30 (15-60)	0.16
TJC44, median (IQR)	5 (3-8)	5 (3-8)	0.81
Shoulder pain, n	0 (0)	9 (6.8)	0.10
SJC44, median (IQR)	0 (0-0)	0 (0-0)	-
ESR, median (IQR)	9 (5-22)	11 (5-21)	0.66
RF-positive, n (%)	12 (34)	34 (26)	0.33
ACPA-positive n (%)	10 (29)	16 (12)	0.019

Abbreviations: BMI: IA: Inflammatory Arthritis, Body Mass Index, TJC44: Tender Joint Count in 44 joints, SCJ44: Swollen Joint Count in 44 joints, , ESR: Erythrocyte sedimentation rate, RF: Rheumatoid Factor, ACPA: Anti-citrullinated Protein Antibody

Table 1. Baseline characteristics (n=170)

	Patients that developed IA, n (%)	Patients that did not develop IA, n (%)	P-value
Bicep tendon TS (n= 164)	5 (15)	14 (11)	0.48
Bicep tendon thickness (n=164)	0 (0)	6 (5)	0.19
Effusion joint (n=157)	0 (0)	0 (0)	-
Subdeltoid bursa effusion (n=159)	3 (9)	26 (21)	0.094

Table 2. Abnormalities identified with US of the shoulders at baseline

Doppler; (3) joint effusion and (4) subdeltoid bursa effusion on US. Reference values for tendon thickness and effusion of the bursa were determined according to Schmidt et al.(1)

Results: A total of 170 patients were included and underwent bilateral US of the shoulder joint. Shoulder symptoms were infrequent (Table 1). After one year 37 patients developed IA (22%). ACPA positivity was associated with the development of IA (Table 1). As presented in Table 2, US abnormalities of the shoulder were infrequent and not associated with IA-development. In particular biceps tenosynovitis was not increased in the patients that developed IA.

Conclusion: Subclinical tenosynovitis of the shoulder is not an early feature of RA in patients with CSA.

Abstract Number: 0293

False Positives in the Ultrasound Diagnosis of Giant Cell Arteritis: Some Diseases Can Also Have Halo Sign

Elisa Fernández ,[1] Irene Monjo,[2] Gema Bonilla,[3] Chamaida Plasencia,[4] Maria-Eugenia Miranda-Carus,[2] Alejandro Balsa,[4] and Eugenio de Miguel[5], [1]Rheumatology Department, La Paz University Hospital, Madrid, Madrid, Spain, [2]FIBHULP-IdiPAZ-Hospital La Paz-Rheumatology, Madrid, Spain, [3]Rheumatology Department, Hospital Universitario La Paz, Madrid, Spain, Madrid, Spain, [4]Immuno-Rheumatology Research Group, IdiPaz & Rheumatology Department. La Paz University Hospital, Madrid, Spain, [5]Rheumatology Department, Hospital Universitario La Paz, Madrid, Spain

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Imaging Of Rheumatic Diseases Poster I
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Giant cell arteritis (GCA) is the most common systemic vasculitis in the elderly. The halo sign is an accepted valid test for the diagnosis of GCA in trained units. However, other conditions can also produce a hypoechoic increase of the arterial wall thickness and mimic the halo sign. Our aim was to describe the frequency and causes of false positives in the diagnosis of GCA by color Doppler ultrasound (CDUS).

Methods: We performed an observational retrospective study of 305 patients with temporal artery CDUS findings compatible with GCA. Their medical records were reviewed to collect demographic, physical examination, clinical and analytical data. The medical diagnosis based on the clinical evolution of the patient during at least 1 year of follow-up was established as the gold standard for definitive diagnosis.

Results: 14 of the 305 included cases (4.6%) were false positives. The characteristics of these 14 patients and their final diagnoses are shown in table 1. 64% were female. The median age was 72 (interquartile range 68-79) years. The median erythrocyte sedimentation rate was 55 (32-110) mm/h, C-reactive protein 15.1 (7.3-100.9) mg/L and hemoglobin 13.3 (11.2-14.1) g/dL. Five patients (36%) fulfilled the 1990 American College of Rheumatology classification criteria. A temporal artery biopsy was performed in 9 patients (64%), with negative results in all of them. Twelve

Table 1. Final diagnoses for false positive halo signs and associated ultrasound findings

Patient	Definitive diagnosis	Biopsy result	Artery involved	Number of arterial branches
1	Non-Hodgkin's T lymphoma	Negative	Temporal	3
2	Narrow-angle glaucoma	No done	Temporal	1
3	Osteomyelitis of the skull base	No done	Temporal	4
4	Polymyalgia rheumatica	Negative	Temporal	2
5	Urinary sepsis	Negative	Temporal	1
6	Polymyalgia rheumatica	Negative	Temporal	1
7	Polymyalgia rheumatica	Negative	Temporal	1
8	Amyloidosis due to multiple mieloma	Negative (deposit of amyloid material)	Temporal	4
9	Atherosclerosis	No done	Axilar	
10	Atherosclerosis	No done	Axilar	
11	Polymyalgia rheumatica	Negative	Temporal	1
12	Atherosclerosis	Negative	Temporal	2
13	ANCA-associated vasculitis	No done	Temporal	2
14	Neurosyphilis	Negative	Temporal	3

patients (86%) had CDUS involvement of the superficial temporal arteries. Five had 1 branch involved (42%), three 2 branches (25%), two 3 branches (17%) and two 4 branches (17%). In addition, two patients (14%) had an isolated halo sign in the axillary arteries, one unilateral and the other bilateral. Regarding the definitive diagnosis, in four patients it was polymyalgia rheumatica (29%), in three atherosclerosis (21%), and there was one case each of non-Hodgkin's Lymphoma type T, osteomyelitis of the skull base, primary amyloidosis associated with multiple myeloma, granulomatosis with polyangiitis, neurosyphilis, urinary sepsis and narrow-angle glaucoma.

Conclusion: CDUS diagnosis of GCA yields a low percentage of false positives. These are attributable either to operator-dependent technical mistakes or to the presence of other medical conditions that alter the US signal of the arterial wall, resulting in a halo sign. The clinician must be aware of the existence of these conditions when interpreting this test, in order to improve the diagnostic accuracy of the CDUS.

Abstract Number: 0294

Tendons Involvement at Early Onset of Gouty Arthritis, Ultrasonographic Study

Ahmed Abogamal ,[1] sameh abdallatif,[2] Maged Hegazy,[2] and khaled Fathy[3], [1]Rheumatology Department, Faculty of Medicine, Al-Azhar University, Egypt, Cairo, Egypt, [2]Al-Azhar faculty of medicine, cairo, Egypt, [3]Ain Shams faculty of medicine, Cairo, Egypt

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Imaging Of Rheumatic Diseases Poster I
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

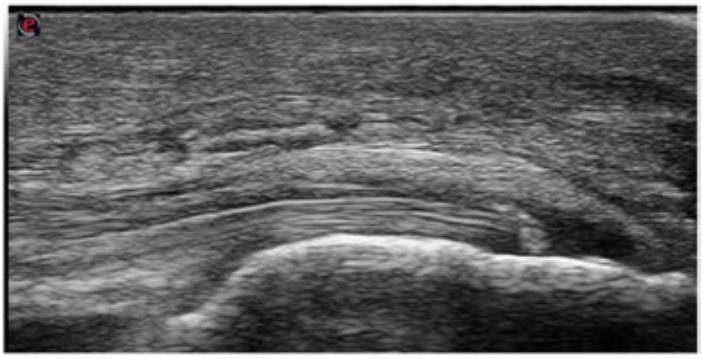
Background/Purpose: Gout is the commonest form of inflammatory arthritis and is caused by the longstanding elevation of serum uric acid levels causing crystal deposits. monosodium urate deposits are the hallmark sign of gouty arthritis, and tendons in many sites represtents a potential target for urate deposits.

Methods: The current study was based on a cross sectional hospital-based survey, conducted among patients presenting at outpatient rheumatology clinics between August 2018- March 2019

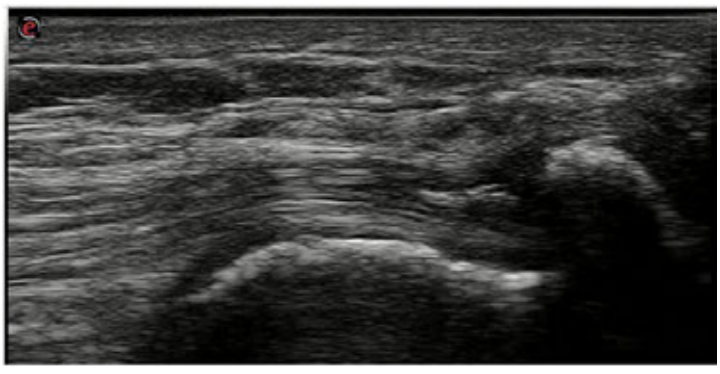
Inclusion criteria: First attack of acute gouty arthritis, diagnosed according to 2015 ACR/EULAR Gout Classification Criteria. Age 45 years or less. Exclusion criteria: Patients with other causes of arthritis, either degenerative or inflammatory. Previous related joint surgery, malalignment, congenital or acquired joint abnormality. Metabolic or endocrinopathies: Diabetes mellitus, dyslipidemia, thyroid dysfunctions. Chronic renal or hepatic diseases.

Grouping: Group I: 65 patients with acute gouty arthritis, Group II: 20 normal subjects as a control group. All patients were subjected to the following: Full clinical assessment, of 5 tendon sites, Achilles, Infrapatellar, Quadriceps, Triceps, and Supraspinatus tendons. Blood assay for serum uric acid level.

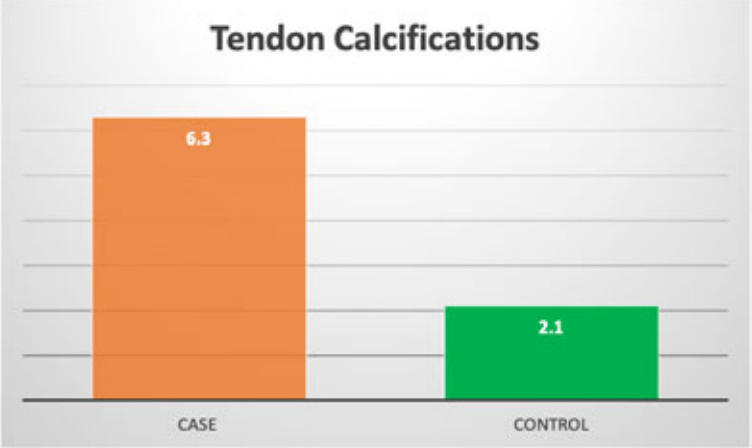
Ultrasonography: was performed for 5 tendon sites; Achilles, infrapatellar ligament, quadriceps, Triceps, supraspinatus tendons. All tendons were evaluated bilaterally according to the EULAR guidelines for performing US in rheumatology. using a scanner with a multi-frequency 12 megahertz linear array transducer (Esaote MYLAB7&General electric Systems; LOGIQU-E). Ultrasonography (US) has been used to detect features of crystal deposits in the tendons, US elementary lesion defined sas intra-tendinous deposits, inhomogeneous, circumscribed, and hyperechoic shadows with or without posterior acoustic shadowing and may be surrounded by a small anechoic halo.



triceps calcification



Achilles Calcification



calcifications in both groups

Results: both groups were matched as regards the age and BMI with no significant difference in means. In the study group; among 650 tendon sites examined by US calcifications were detected in 41 tendon sites 6.3%. 19 at the Achilles tendon unilateral in 13 cases and bilateral in 3 cases, 7 at infrapatellar ligament, 2 at the quadriceps, 7 at the Triceps, and 6 at the supraspinatus tendon. In the other hand clinically, symptomatic tendons presented only in 6 tendon sites with 0.9 %. While in the control group; 190 sites examined by US, and calcifications were detected in 4 sites with 2.1%.

Conclusion: Tendons appears to be involved with the gouty urate deposits, and tendon calcifications could happen and detected early in the course of the disease.

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Imaging Of Rheumatic Diseases Poster I
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The vascularization of salivary glands (SG) in Sjögren's syndrome (SS) has not been extensively studied by imaging methods, and currently no agreement exists on how this should best be evaluated. Color Doppler (CD) ultrasonography (US) might represent a good tool for the assessment of vascularization in SS.

The aim of the exercise of the OMERACT Sjögren US subtask group was to test the reliability of SG vascularization assessment in SS patients using a consensual developed semiquantitative CD US scoring system.

Methods: Nine sonographers participated in the reliability exercise, evaluating the vascularization of bilateral parotid and submandibular glands in 9 SS patients using CD US with previously standardized and optimized Doppler settings. The participants were not allowed to modify the settings while scanning. The superficial lobe of parotid glands was scanned in both longitudinal and transverse plane, while submandibular glands were scanned in longitudinal plane only. A previously agreed four grade semiquantitative score was applied: Grade 0, no visible vascular signals; Grade 1, focal, dispersed vascular signals; Grade 2, diffuse vascular signals detected in less than 50% of the gland; Grade 3, diffuse vascular signals in more than 50% of the gland. Intrareader and interreader reliability of grading SG was determined by Light's weighted kappa analysis.

Results: Light's weighted kappa of intrareader and interreader reliability showed good to excellent agreement. Data are presented in Table 1.

Conclusion: The consensual CD US scoring for the evaluation of SG vascularization in SS showed a good interreader reliability and excellent intrareader reliability. Next step should be further testing for clinical application in a larger group of SS patients and controls. In addition, a potential correlation between SG structural changes seen on B-mode US and vascularization should be studied.

Prevalence of Doppler grades (%) in 9 patients with Sjögren's syndrome	
Grade 0	15.2%
Grade 1	33.8%
Grade 2	44.5%
Grade 3	6.4%
Intrareader reliability (Light's weighted kappa (mean and 95%CI):	
Parotid glands (longitudinal)	0.89 (0.85-0.94)
Parotid glands (transverse)	0.91 (0.83-0.96)
Submandibular glands (longitudinal)	0.72 (0.48-0.87)
All four salivary glands	0.84 (0.73-0.92)
Interreader reliability (Light's weighted kappa (mean and 95%CI):	
Parotid glands (longitudinal)	0.70 (0.61-0.77)
Parotid glands (transverse)	0.76 (0.71-0.81)
Submandibular glands	0.65 (0.57-0.73)
All four salivary glands	0.70 (0.64-0.76)

Legend: CI confidence interval

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Imaging Of Rheumatic Diseases Poster I

Session Type: Poster Session (Sunday)

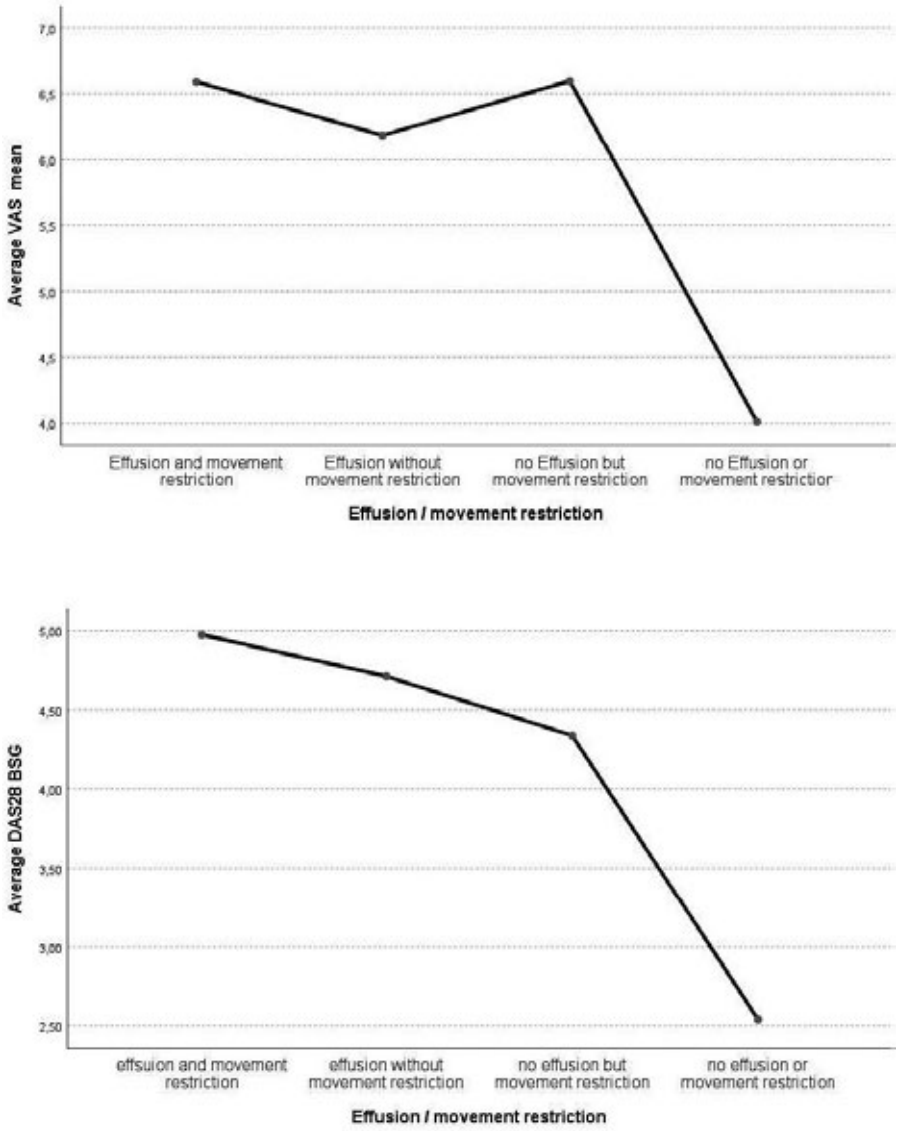
Session Time: 9:00AM–11:00AM

Background/Purpose: Musculoskeletal ultrasound is an important imaging method in the diagnosis of arthritis, especially rheumatoid arthritis (RA). The prevalence of elbow joint arthritis in RA has not yet been specifically investigated sonographically and correlated with the clinical examination and other parameters.

Methods: In 100 patients with RA and 50 patients without rheumatological disease both cubital joints were examined according to the 3 most relevant standard planes (anterior longitudinal humeroradial and humeroulnar as well as posterior longitudinal scans) of the German Society for Ultrasound in Medicine (DEGUM). A complete clinical examination was performed and baseline characteristics (age, sex, etc.), DAS28 and visual analogue scale (VAS) were recorded. Elbow arthritis was defined as joint effusion grade II and/or hyperperfusion of the synovial proliferation. The patients were recruited in the department of Rheumatology of the University Hospital Bonn as well as in the Rheinischen Rheumazentrum Meerbusch. The ultrasound examination was performed by two very experienced physicans (DEGUM level I and DEGUM level II, equals EFSUMB levels). The statistical evaluation was performed with IBM SPSS (Version 25). A p-value < 0.05 was considered significant. The interrater analysis was assesed by Cohen's kappa, as well as by an independent blinded assessor (DEGUM III, equal EFSUMB III).

Results: Mean age was 59.8 years (±SD 15.9) in the RA cohort and 59.8 years (±SD 16.2) in the control group. The RA cohort displayed relevant joint effusion in 54.9%, in 6.9% hypervascularization was visible, whereas in the control group 16% displayed joint effusion and none showed hypervascularization. The mean DAS28 in the RA cohort was 5.3 (±SD 1.1; high activity 56.9% (DAS28 > 5.1), moderate activity 41.1% (DAS28 > 3.2), low activity (DAS28 > 2.6) 2%). The mean VAS in RA patients was 6.41 (±SD 2.3), and 2.42 (± 2.9) in the control group.

In the RA cohort there was a significant correlation between movement restriction (MR) and joint effusion (p-value = 0.001), between DAS28 and MR (p-value = 0.02) and between DAS28 and sonographic joint effusion (p-value = 0.022). The overall collective showed a significant correlation of DAS28 with MR and joint effusion [figure 1].



Graphs elbow study
figure 1 and figure 2

In overall analysis, a highly significant correlation of VAS with MR (p-value 0.001), the presence of joint effusion (p-value 0.001) and the diagnosis of RA (p-value 0.001) was observed.

Interrater analysis showed good agreement with Cohen´s kappa of 0,896 and a highly significant p-value of 0.001.

Conclusion: This is the first study to investigate the prevalence of elbow joint effusion and synovitis in RA patients. It shows, that the prevalence of elbow joint arthritis is high, with over 54% in the RA cohort. Movement restriction is a good indicator of elbow joint arthritis in RA, but not in all RA patients. In the overall analysis of both cohorts, there is a strong correlation between VAS with joint effusion and MR (p-value 0.001) [Figure 2].

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Imaging Of Rheumatic Diseases Poster I

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Psoriatic arthritis (PsA) is an inflammatory disease affecting up to 30% of psoriasis patients. PsA can involve both the peripheral and axial skeleton and manifest with inflammatory and structural changes such as synovitis, tenosynovitis and erosions. Ultrasound (US) and magnetic resonance imaging (MRI) are the leading imaging modalities for peripheral arthritis assessment. However, little is known about the discrepancies between these two modalities in PsA patients. The aim of the study was to evaluate the agreement between US and MRI in the detection of fingers lesions in PsA patients and to evaluate the sensitivity and specificity of US with MRI as gold standard.

Methods: Consecutive PsA patients (all fulfilled the CASPAR criteria) were recruited prospectively. All patients underwent US and MRI assessment of MCP, PIP and DIP joints of one matched hand. The time interval between US and MRI scans was at most 3 days and the US and MRI assessors were blinded to the clinical data. NSAIDs treatment was hold for 3 days before assessment. Agreement between MRI and US was calculated based on absolute agreement and Cohen's Kappa values. Sensitivity and specificity of US was evaluated with MRI as gold standard.

Characteristics	
Age, mean (± s.d)	52.2 (12.9)
Gender, Female, n (%)	36 (60)
BMI, mean (± s.d)	27.7 (4.4)
PSO duration, mean (± s.d)	21.7 (16.5)
PsA duration, mean (± s.d)	10.97 (12.87)
TJC, mean (± s.d)	9.60 (10.72)
SJC, mean (± s.d)	0.95 (1.93)
CRP mg/l, mean (± s.d)	8.50 (9.24)
ESR, mm/h, mean (± s.d)	22.79 (13.38)

DIP (total 240)	97%;K=0.208
Erosions	
MCP (total 300)	98%; K=0.211
PIP (total 300)	98%; K=0.492
DIP (total 240)	98%; K=0.329

Table 3. Agreement and Kappa values between US and MRI

Results: Sixty PsA patients with mean age of 52 years (± 12.9) and female:male ratio of 60%:40% were included (Table 1). Three hundred MCP, 300 PIP and 240 DIP were assessed by US and MRI. The prevalence of synovitis, flexor tenosynivitis and erosions were comparable between the US and MRI assessments (Table 2). Synovitis (19.3% for US and 13.7% for MRI) and flexor tenosynovitis (5.7% for US and 6.3% for MRI) were more prevalent in the MCP joints compared to the PIP and DIP joints in both modalities. Absolute agreement and kappa values between US and MRI were 84%-95% with moderate to substantial kappa values (0.411-0.654), 94%-97% with fair to moderate kappa values for tenosynovitis (0.208-0.468) and 98% with fair to moderate kappa values for erosions (0.211 to 0.492) (Table 3). The sensitivity and specificity of US with MRI for synovitis ranged between 0.5-0.78 and 0.87-0.97 according to the specific type of joint (DIP, PIP and MCP), and for flexor tenosynovitis 0.25-0.47 and 0.97, respectively.

Conclusion: US and MRI have moderate to good agreement for the detection of inflammatory and destructive changes, while the sensitivity is better for synovitis compared to flexor tenoseynovitis.

Abstract Number: 0298

In CCP Positive "At Risk of Rheumatoid Arthritis" Individuals, the Presence of Sub-clinical Synovitis in 4-10joints Universally Results in Clinical Synovitis

Laurence Duquenne ,[1] Kulveer Mankia,[2] Jacqueline Nam,[2] Andrea Di Matteo,[2] Leticia Garcia-Montoya,[2] and Paul Emery[2], [1]Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds, England, United Kingdom, [2]Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Imaging Of Rheumatic Diseases Poster I
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: In a cohort of Anti-Cyclic Citrullinated Peptide Positive (Anti-CCP+) At-Risk of developing inflammatory arthritis (IA) individuals without clinical synovitis, previous univariable analysis showed that the presence of a Power Doppler signal (PD) in at least one joint was predictive of progression (Nam, 2016).

Further analysis is required to examine the influence of the number of joints PD positive on the progression rates and incorporate this data in the already established 2010 ACR/EULAR criteria for Rheumatoid Arthritis (RA), replacing the swollen joint count by the PD positive joint count.

Table 1: Demographic data

	Overall	Progressors	Non-progressors	P-value
N (%)	361	102 (28%)	259 (72%)	/
Mean follow-up (Months (SD))	24.71 (25.96)	19.55 (24.05)	26.75 (24.44)	0.017
High CCP titre	69.2%	92.2%	59.9%	<0.001
Smokers (Ever/Never) Ever smoker	186/142 56.7%	74/24 75.5%	112/118 48.7%	<0.001
Sex ratio (F/M) Women	262/95 72.6%	(190/65) 72.5%	(72/30) 70.6%	0.338
Age (years (SD))	50.95 (13.23)	53.51 (13.28)	49.91 (13.10)	0.021
Alcohol consumption (Unit/week (SD))	7.91 (13.71)	6.21 (9.46)	8.66 (15.20)	0.144
Meet ACR criteria for RA at progression (n/N)	/	80.5% (70/87)	/	/

Objectives:

1. To investigate the association between the number of joints with a Power Doppler signal and progression to IA.
2. To include the PD positive joint count in the 2010 ACR/EULAR criteria for RA to improve prediction in individuals without synovitis.

Methods: Participants were selected by an anti-CCP positive test and a new musculo-skeletal symptom. Individuals with intermittent symptoms or clinical synovitis were excluded.

Using univariable cox regression, we described for the first time the predictive value of the number of joints with a Power Doppler signal.

By replacing the number of swollen joints, with the number of joints PD positive in the 2010 ACR/EULAR criteria for RA, we then analysed IA-free survival curves for participants without clinically swollen joints.

Figure 1: Number of joints with Power Doppler and risks of progression

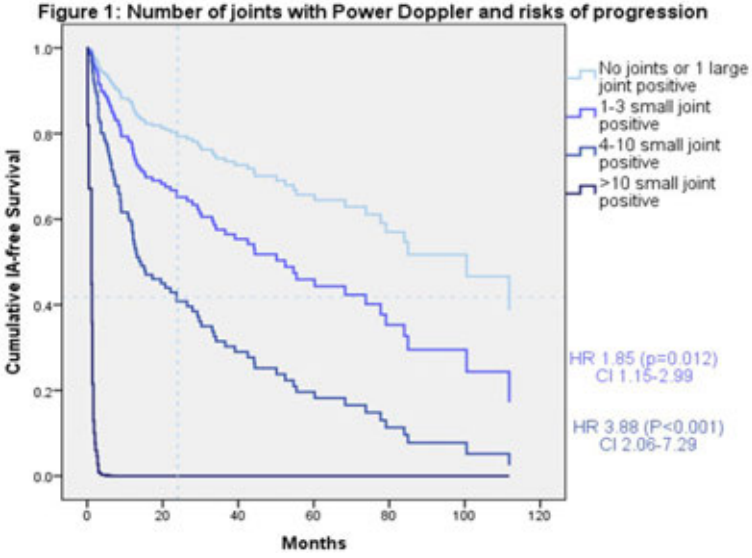

Figure 2: 2010 ACR/EULAR criteria for RA using PD positive joint count in At-Risk of RA individuals

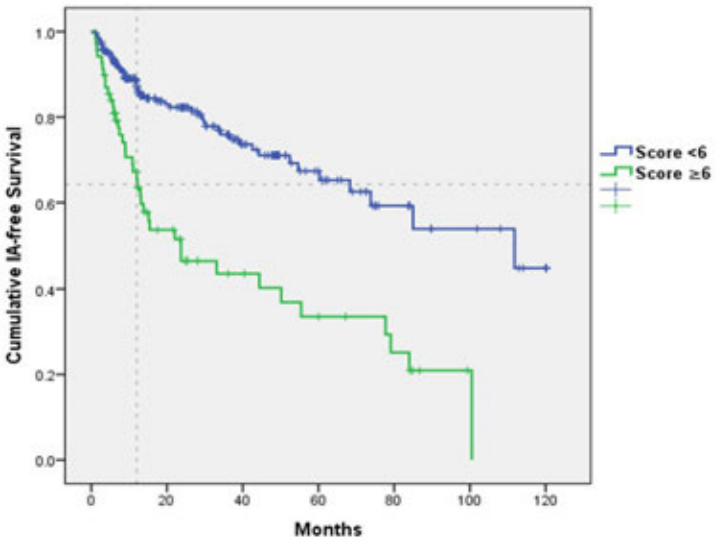

Results: 361 patients were followed for a mean of 24 months (Table 1). Of the 28% of participants who developed IA, 81% met the ACR/EULAR criteria for RA at progression. There were significantly more participants with high anti-CCP titres in the progressor group.

Using Cox univariable analysis, the results show that the probability of developing IA is significantly increased by a Hazard ratio of 1.89 if 1 to 3 small joints present a PD signal (p=0.012), and of 3.81 if 4 to 10 joints are PD positive (p< 0.001) (Figure 1). Furthermore, all participants presenting with 4 to 10 joints progressed, 60% of them in the first 2 years (Figure 1).

Using multivariable analysis and adding CCP titre and inflammatory markers to the PD positive joint count, Hazard Ratio for the probability of progression shows a risk 2.97 times higher (p >0.001, CI 1.96-4.49) for the participants who met the 2010 ACR/EULAR criteria for RA replacing the swollen joint score with the PD positive joint count (Figure 2).

Conclusion:

1. All of the participants with 4 to 10 joints with a Power Doppler Signal progressed to IA (mainly RA), 60% of them in the first 2 years.
2. The predictive value for progression to IA of ultrasound scans is not improved by the addition of CCP titres and inflammatory markers (*when included in the 2010 ACR/EULAR criteria for RA using Power Doppler positive joint count in patient without clinical synovitis*).

Definition of New Ultrasound Enthesophytes Score: Application in a Consecutive Series of IBD Patients

Pierluigi Macchioni,[1] federica Martinis,[2] **Giorgia Citriniti** ,[3] Nicolò Girolimetto,[3] and Carlo Salvarani[4], [1]Azienda USL-IRCCS di Reggio Emilia, Reggio Emilia, [2]Università di Verona, Verona, Italy, [3]Azienda USL-IRCCS di Reggio Emilia, Reggio Emilia, Italy, [4]Division of Rheumatology, Arcispedale Santa Maria Nuova-IRCCS, Reggio Emilia, Italy

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Imaging Of Rheumatic Diseases Poster I
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Recent studies have developed criteria for US definition of entheseal abnormalities (1), however no actual scores are available to determine the extension and severity of enthesophyte growth at patient level.

To evaluate the feasibility of two new scores to measure enthesophytes occurrence and their dimensional changes with time.

Methods: We evaluated 816 enthesis in a consecutive series of 68 IBD patients for the presence and size of enthesophytes. Images were collected at baseline and after 24 months using an Esaote MyLabClass, 18-6 MHz linear multi-frequency transducer both in B-mode and power Doppler-mode. The following sites were evaluated bilaterally: lateral epicondyle of the humerus, distal quadriceps femoris insertion into the patella, inferior pole of the patella, tibial distal insertion of the patellar tendon, calcaneal insertion of the Achilles tendon, and plantar aponeurosis insertion. The presence of enthesophyte was scored dichotomously as present (=1) or absent (=0) for each site and summed up to generate the ARES (Anatomical ReggioEmilia Enthesophytes Score). Enthesophytes were also scored semiquantitatively in a 0-3 scale (0 = absent, 1 = minimal, 2 = discrete, 3 = massive) according to previous studies (2) for each site and summed up to generate RESS (ReggioEmilia Enthesophytes Severity Score). All the stored images were reviewed and scored by 4 rheumatologists (FM, GC, PM, NG) well trained in US examination of enthesis. Four patients were evaluated independently by the 4 ultrasonographers and new ARES and RESS were calculated for each patient. Intraclass correlation coefficients (ICC) were calculated for inter- and intra-observer reliability.

Results: Both intra- and interobserver reliability analyses for presence or absence of enthesophytes showed an excellent ICC for each site. ICC for ARES was excellent for intra and inter observer (Cronbach alfa = 0.930, 95%CI 0.72-0.98 and 0.969, 95% CI 0.942-0.998 respectively). ICC was excellent also for the semiquantitative RESS for almost all the examined sites, but moderate for the plantar fascia (Cronbach alfa = 0.571, 95%CI -0.72-0.89). The total RESS had an excellent ICC both for intra and inter-examiner (Cronbach alfa = 0.963, 95%CI 0.85-0.99 and 0.983, 95%CI 0.913-0.999).

Conclusion: The present study demonstrates that the ARES and RESS scores are easily feasible, highly reproducible and have excellent intra and interobserver reliability.

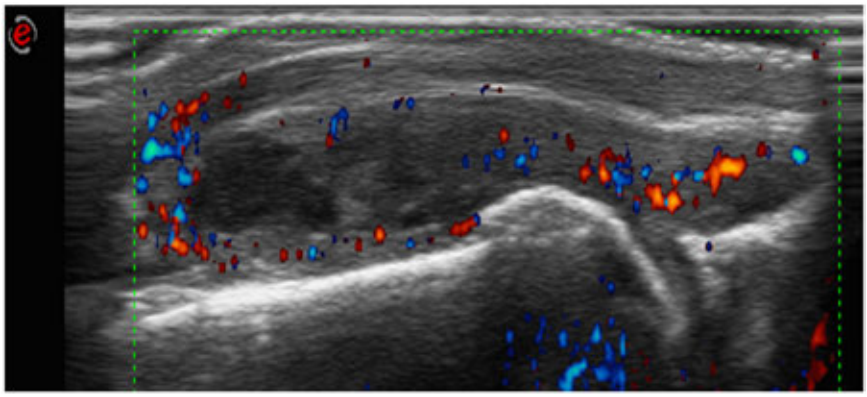
SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Imaging Of Rheumatic Diseases Poster I
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

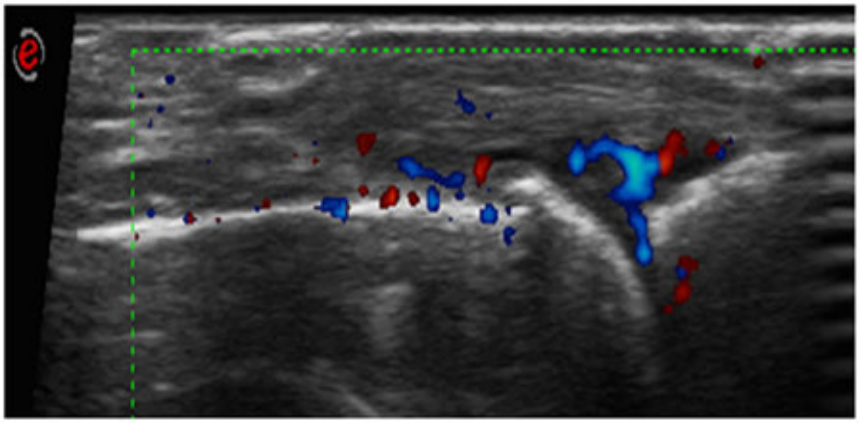
Background/Purpose: Rheumatoid Arthritis (RA) has a synovial ultrasound (US) pattern, while soft tissue involvement is more frequently found in Psoriatic Arthritis (PsA). No previous studies have analyzed if US findings differ between seropositive and seronegative RA patients. The objective is to analyze differences in the ultrasound pattern among patients with seropositive and seronegative RA. To assess if proliferative globular synovitis is associated to seropositive RA.

Methods: Retrospective Analysis. We collected clinical, epidemiological and ultrasound images of patients with RA who met ACR/EULAR 2010 criteria with bilateral carpal and hand ultrasonography carried out during the last five years. Synovial hypertrophy (SH) and Power Doppler signal (PD) in wrist and 1-5 metacarpophalangeal (MCP) were evaluated. We calculated the SH score (sum of the SH degrees of each joint), PD (sum of the PD degrees of each joint) and the total score (sum of the score of SH and PD) for each patient. We also evaluated the presence of proliferative globular synovitis, defined as big synovial hypertrophy with exophytic growth and a convex upper limit

Results: 145 RA patients were collected. 80% were women. Mean age was 59.06 (14.8) years and the mean time of disease evolution was 114.6 (112.8) months. 68.3% were RF positive and 74.5% ACPA positive. Overall, 115 of the 145 (79.3%) patients were seropositive for RF/ACPA. 53.1% had radiographic erosions, 73.1% used conventional synthetic Disease-modifying drugs (DMARDs), 29.7% biological therapy, and 57.2% low doses of corticosteroids (< 5 mg prednisone). The mean DAS28 was 2.81 (1.14), the number of swollen joints was 3 (3.4), and CRP was 0.99 mg/dl (1.6). No significant differences between seropositive and seronegative patients in terms of disease activity (swollen joints count [SJC], tender joint count [TJC], CRP, DAS28), treatment (use of corticosteroids, DMARDs, biological), time of evolution or US scores (SH, PD and total scores) were found. Globular synovitis was present in 71 patients 61.7% and 10.3% (62% and 13.7%) of seropositive and seronegative RA patients, respectively (p< 0.0001). Globally, 75 (51.7%) out of 145 patients had “globular” synovitis by US (Figure 1). 71 out of 75 patients were FR /ACPA positive (95.9%). Only three patients with seronegative RA had this US pattern (p < 0.001). Furthermore, patients with “globular” synovitis had more erosions (72% vs 32.9%, p 0.000), higher SJC (3.3and higher SH and PD scores (p< 0.001).



Globular synovitis in MCP joint of a FR and ACPA positive RA patient. The synovial has an exophytic growth with globular shape and convexity in the upper limit of joint capsule.



Synovitis in MCP joint of a patient with FR and ACPA negative RA. Synovial proliferation is low and the upper limit of the joint capsule has a flat shape.

Conclusion: The presence of proliferative globular synovitis was significantly associated with the presence of RF/ACPA in patients with RA. This US pattern identified a subgroup of RA patients with poor prognosis: more erosions and greater inflammatory activity both at clinical and ultrasound level.

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Imaging Of Rheumatic Diseases Poster I
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Gout is a metabolic disease caused by deposition of monosodium urate (MSU) monohydrate crystals in different tissues. Imaging may be useful to evaluate the extent of MSU deposition, the presence of acute and chronic inflammation, and tissue structural damage. The aim of the current study was to develop evidence-based and expert opinion recommendations for the use of imaging techniques in the diagnosis, monitoring, prognosis and treatment of patients with gout.

Methods: A selected group of experts (rheumatologists, radiologists, rheumatologist sonographers, methodologists and statisticians) from different PANLAR countries were included in the gout imaging task force. Imaging modalities evaluated were: conventional radiography (CR), ultrasound (US), computed tomography (CT), magnetic resonance imaging (MRI) and dual-energy computed tomography (DECT). Seven clinical questions were selected using the Delphi technique with RAND/UCLA modified methodology. Each question was scored in a visual analogue scale from 1 to 9 (1: complete disagreement; 9: complete agreement). With the information obtained, questions were reformulated

Table 1.

Recommendations	Level of evidence	Grade	Level of agreement [&] Task force	Level of agreement [&] Independent committee
1. When clinical diagnosis is doubtful, detection of elementary US lesions defined by OMERACT and/or deposits of MSU by DECT, are sensitive and specific complementary tools for diagnosis of gout.	II	B	9 (100%)	9 (100%)
2. US and DECT have a lower sensitivity for gout diagnosis in patients with less than 2 years of disease duration. However, due to their high specificity, their use is recommended as complementary diagnostic method, regardless time of disease duration.	II	B	8 (100%)	8 (77%)
3. CR and CT show poor sensitivity for gout diagnosis. However, due to its high specificity and low cost, initial evaluation by CR is recommended for all patients with suspected gout, for both differential diagnosis and evaluation of structural damage.	II	B	9 (100%)	8 (92%)
4. MRI and US are valid tools for measurement of synovitis in patients with gout, regardless of disease duration.	III	B	8 (100%)	9 (92%)
5. CR is the choice technique for quantification of structural damage in patients with gout, using the Sharp van der Heijde method modified for this pathology. CT represents an alternative, more sensitive, but more expensive, for evaluation of structural joint damage.	II	B	8 (100%)	8 (85%)
6. US and MRI are alternative tools to detect structural damage in patients with gout. However, currently both techniques do not have a validated scale that allows its quantification. DECT should not be used for detection and quantification of structural damage.	III	B	8 (100%)	8 (77%)
7. US and DECT are the methods of choice to detect and quantify MSU deposits in the different tissues.	III	B	8 (100%)	8 (100%)
8. Current evidence is insufficient to recommend the use of images as a method of follow-up and treatment guidance in patients with gout. However, according to expert opinion, detection of synovitis by US or MRI and/or quantification of deposits of MSU by US or DECT, can be used as complementary tools for monitoring these patients.	IV	D	8 (100%)	8 (92%)

[&]Each question was graduated from 1 to 9 (1: totally disagree; 9: totally agree); median (percentage of response between 7-9)

and re-evaluated using the same scoring system. One question did not reach agreement. Finally, six questions were selected. A systematic literature review was performed using Medline, LILACs, Embase and Cochrane databases from January 1966 to February 2018. The search resulted in a total of 8657 articles, of which 1957 were duplicated. Of the 6700 remaining, 6020 were excluded based on the title and/or summary, leaving 680 for full text review. After that, 639 were excluded, leaving a total of 41 articles as supporting evidence, by two independent reviewers (agreement 97%, kappa 0.91). Recommendations were developed by consensus following similar methodology utilized for clinical question selection. Such recommendations were graded according to levels of evidence from the Oxford Center of Medicine in 2011. Final recommendations were eventually presented to an independent committee including representatives from several PANLAR rheumatologist societies.

Results: Eight recommendations were developed for the use of imaging techniques in the diagnosis, monitoring, prognosis and treatment of patients with gout. The strength of each recommendation was established based on the evidence level as well as rate of agreement. Both gout imaging task force and independent committee agreed with the final recommendations (Table 1).

Conclusion: To the best of our knowledge, these are the first evidence-based and expert opinion recommendations for the use of imaging in patients with gout, providing some guidelines for their use in daily clinical practice.

Abstract Number: 0302

Clinical Impact of a Rheumatology Musculoskeletal Ultrasound Clinic at a U.S. Academic Center

Sarah Chung ,[1] Katherine Wysham,[2] Elizabeth Jernberg,[3] Ingeborg Sacksen,[3] Scott Pollock,[1] and Alison Bays[1], [1]University of Washington Division of Rheumatology, Seattle, WA, [2]Veterans Health Administration Puget Sound, Seattle WA, Seattle, [3]University of Washington Division of Rheumatology, Seattle

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Imaging Of Rheumatic Diseases Poster I
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Routine use of musculoskeletal ultrasound (MSK-US) to aid in clinical decision-making for rheumatology patients is less common in the United States than in Europe, and while MSK-US is widely perceived as additive to the clinical impression, the measured clinical impact is unknown. Our aim was to evaluate diagnostic and therapeutic outcomes of patients with rheumatic disease referred to a rheumatology MSK-US clinic.

Methods: All patients seen at an MSK-US clinic over a 12-week period were reviewed for the study. Subjects referred for non-rheumatologic queries as well as subjects lacking referral documentation were excluded. Data were extracted from the referral documentation, MSK-US clinic notes, and clinic notes from the referring provider pre- and post-US visit (± 6 months). Subjects were categorized into groups pertaining to diagnostic and clinical impact of the MSK-US visit: 1) No diagnostic or clinical impact 2) US findings leading to subsequent clinical action by the referring provider 3) Unknown impact (follow-up data unavailable). All MSK-US examinations were performed using a GE Logiq e ultrasound (GE Healthcare, WI) with 12-L and 18-L transducers. Diagnostic regional MSK exams were performed according to published EULAR protocols, enthesitis exams utilized the Madrid Sonographic Enthesis Index (MASEI), and synovitis exams utilized the ARCTIC protocol (Aiming for Remission in rheumatoid arthritis: a randomized trial examining the benefit of ultrasound in a Clinical Tight Control regimen).

Results: 86 referrals met inclusion criteria. Mean age was 53 ± 14 years, 81% were female, and mean time from referral to US visit was 24 ± 25 days (Table 1). Most referrals were generated from rheumatologists (93%, n=80), and disease activity assessment was the most frequent referral reason (60%, n=51). Overall, MSK-US led to a change in the underlying diagnosis in 28% (n=24) of cases (Table 1). In 58% (n=50) of cases, MSK-US examination led to a subsequent clinical action by the referring provider (Figure 1); the majority of these cases were subjects referred for diagnostic exam or disease activity assessment (Table 1). Discordance between the US visit recommendations and the subsequent referring provider's treatment plan occurred in 11% (n=3) of patients with non-inflammatory US findings.

Conclusion: The most common referral reason in an academic rheumatology MSK-US clinic was for disease activity assessment. MSK-US findings led to a change in the underlying existing rheumatologic diagnosis or clinical impression of the chief complaint in 28% of cases and led to a change in clinical management in 58% of cases. These findings suggest that rheumatologists utilize MSK-US findings to make significant clinical decisions and support the utility of a dedicated MSK-US clinic to aid in the diagnosis and management of patients with rheumatic disease.

Table 1. Cohort characteristics of subjects evaluated in a rheumatology MSK-US clinic over a 12-week period			
		Referral Reason	
	Total Cohort n=86	**Diagnostic/ Disease Activity Assessment*** n=65 (76%)	**Procedure (Injection/Aspiration)** n=21 (24%)
Mean age (years)	53 ± 14	51 ± 13	59 ± 16
Female	70 (81%)	54 (84%)	16 (76%)
Mean time to MSK-US (days)	24 ± 25	21 ± 18	31 ± 38
Referring provider specialty			
Rheumatology	80 (93%)	62 (95%)	18 (86%)
Other	6 (7%)	3 (5%)	3 (14%)
Diagnosis at referral			
Rheumatoid arthritis/JIA	14 (16%)	12 (18%)	2 (10%)
Osteoarthritis/Fibromyalgia	20 (23%)	10 (15%)	10 (48%)
Seronegative inflammatory arthritis	18 (21%)	17 (26%)	1 (5%)
Spondyloarthropathy	15 (17%)	12 (18%)	3 (14%)
Other**	19 (22%)	14 (22%)	5 (24%)
Change in diagnosis***	24 (28%)	22 (34%)	2 (9%)
Change in clinical action****	50 (58%)	49 (75%)	1 (5%)

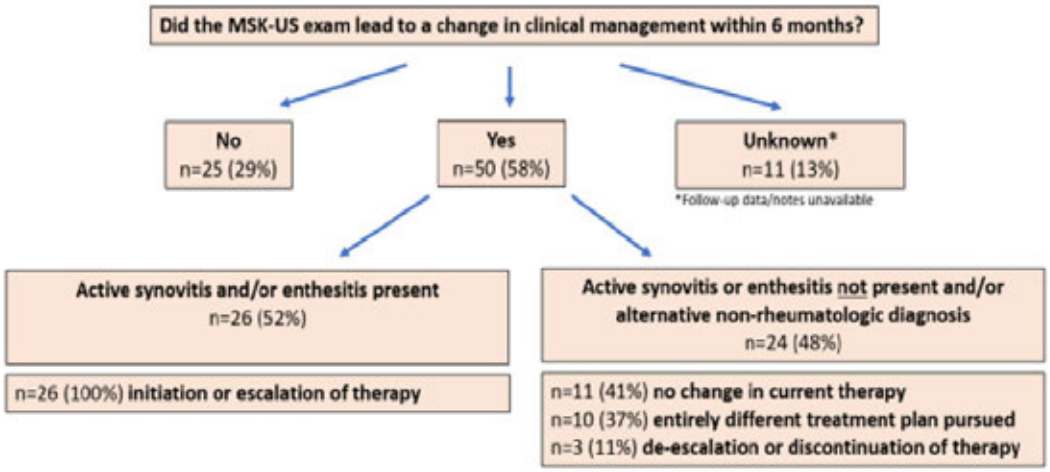
*Refers to diagnostic regional MSK, synovitis, and enthesitis exams

**_Other diagnoses_ refer to the following: systemic lupus erythematosus (SLE), systemic sclerosis (SSc), Sjogren's syndrome (SS), sarcoidosis, anti-neutrophil cytoplasmic antibody (ANCA) vasculitis, polymyalgia rheumatica (PMR), Cogan syndrome, anti-synthetase syndrome, gout, stiff person syndrome, large granular lymphocytic (LGL) leukemia, remitting seronegative symmetric synovitis with pitting edema (RS3PE)

***_Change in diagnosis_ refers to the underlying rheumatologic diagnosis at time of referral and/or the clinical impression of the chief complaint that generated the referral

****_Change in clinical action_ refers to decisions made regarding dosages of current rheumatologic medications, additions/subtractions of medications, referrals to other specialists (i.e. physical therapy, sports medicine), referrals for advanced imaging (i.e. MRI) or specialized tests (i.e. EMG)

Figure 1. Clinical impact of MSK-US exam results on treatment decisions by referring provider, total cohort n=86. No change in clinical management (n=25) includes subjects in whom MSK-US was unable to answer the provider's query as well as subjects in whom there was discordance between the MSK-US visit recommendations and the referring provider's subsequent treatment plan. A change in clinical management (n=50) refers to subjects in whom MSK-US findings led to a subsequent clinical action.



Abstract Number: 0303

Utility of Power Doppler Ultrasound–Detected Synovitis for the Prediction of Flare in Psoriatic Arthritis Patients in Clinical Remission

Johana Zacariaz Hereter ,[1] Josefina Marin,[2] Maria Laura Acosta Felquer,[2] Martin Brom,[3] Javier Rosa,[4] Ricardo Garcia Monaco,[1] and Enrique Soriano[5], [1]Hospital Italiano de Buenos Aires, Ciudad Autonoma de Buenos Aires, Argentina, [2]Hospital Italiano de Buenos Aires, buenos aires, Ciudad Autonoma de Buenos Aires, Argentina, [3]Rheumatology Section, Internal Medicine Service, Hospital Italiano de Buenos Aires, Argentina, Buenos Aires, Ciudad Autonoma de Buenos Aires, Argentina, [4]Rheumatology Section, Internal Medicine Service, Hospital Italiano de Buenos Aires, Argentina, Buenos Aires, Argentina, [5]Rheumatology Section, Internal Medicine Service, Hospital Italiano de Buenos Aires, Argentina., Buenos Aires, Buenos Aires, Argentina

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Imaging Of Rheumatic Diseases Poster I

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Power Doppler ultrasound (PDUS) has been shown to detect subclinical synovitis in psoriatic arthritis (PsA). The aim of this study was to evaluate PDUS features at joint level in patients with PsA in clinical remission and to investigate its value for predicting flares after one year of follow up.

Methods: Consecutive patients with PsA in clinical remission according to the attending rheumatologist and who fulfill minimal disease activity criteria and/or 28-joint Disease Activity Score in remission criteria underwent PDUS examination of 18 joints. All patients were followed up for 12 months. Disease flare was defined as any increase of disease activity generating the need of any of the following: changes in therapy with disease-modifying antirheumatic drugs (DMARD) by the attending rheumatologist: dose increase, switch or addition of a different DMARD, and/or switch or addition of biological therapies.

Results: Sixty patients with PsA in clinical remission (15 [25%] by DAS28, 12 [20%] by MDA, and 33 [55%], by both), were included. Fourteen patients (23%) were receiving biologics (5 as monotherapy and 9 combined with methotrexate (MTX), 27 (45%) were receiving MTX, 2 (3%) sulfasalazine, 1 (2%) leflunamide, and 16 patients were not receiving treatment. 18 (32%) experienced a flare within the next 12 months. Seventeen patients had at least 1 joint with PDUS synovitis at baseline, and 8 (44%) of these had a disease flare during the follow up period compared with only 10 of the 43 patients (21%) without baseline PDUS synovitis (relative risk = 2.1 (95% CI: 0.95 – 4.5; p=0.0698). On logistic regression analysis, PDUS synovitis was associated with short term flares: OR: 4.8, 95% CI: 1.12 - 20.9; p= 0.034), after adjusting for use of biologics, sex, age, disease duration, and baseline disease activity.

In 28 patients without flares a second US was performed within 12 months, in 6 (21%) the PDUS was positive (2 already positive in the first evaluation)

Conclusion: Among patients with PsA in clinical remission, PDUS-detected synovitis was present in around 20% of the patients and was predictor of short-term flares independently of treatment.

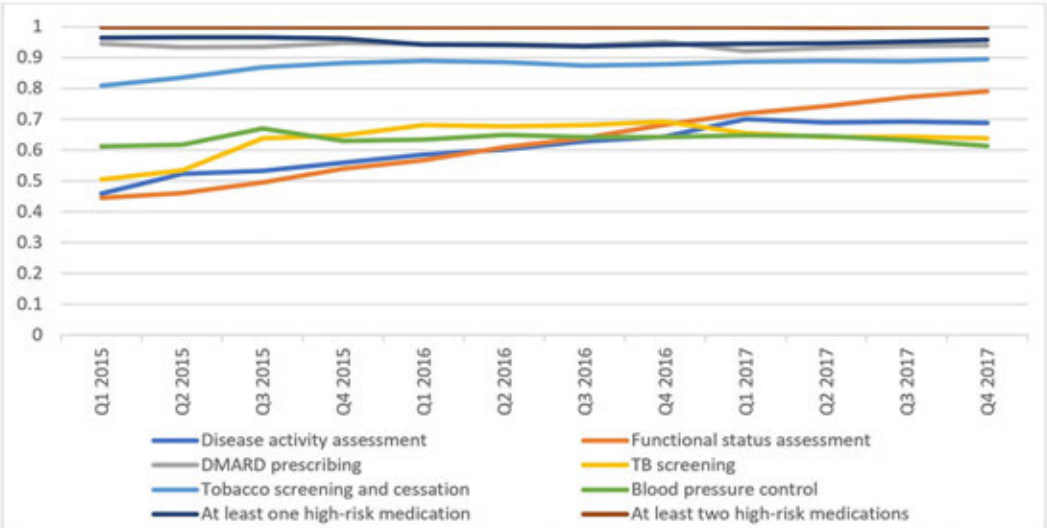
The ACR's Rheumatology Informatics System for Effectiveness (RISE) Demonstrates Improvements in Many Measures of Quality of Care Between 2015 and 2017

Zara Izadi ,[1] Gabriela Schmajuk,[2] Julia Kay,[3] Michael Evans,[1] and Jinoos Yazdany[3], [1]UCSF Division of Rheumatology, San Francisco, [2]UCSF, SFVAMC Division of Rheumatology, San Francisco, CA, [3]UCSF Division of Rheumatology, San Francisco, CA

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Measures Of Healthcare Quality Poster I: Testing, Screening, & Treating
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

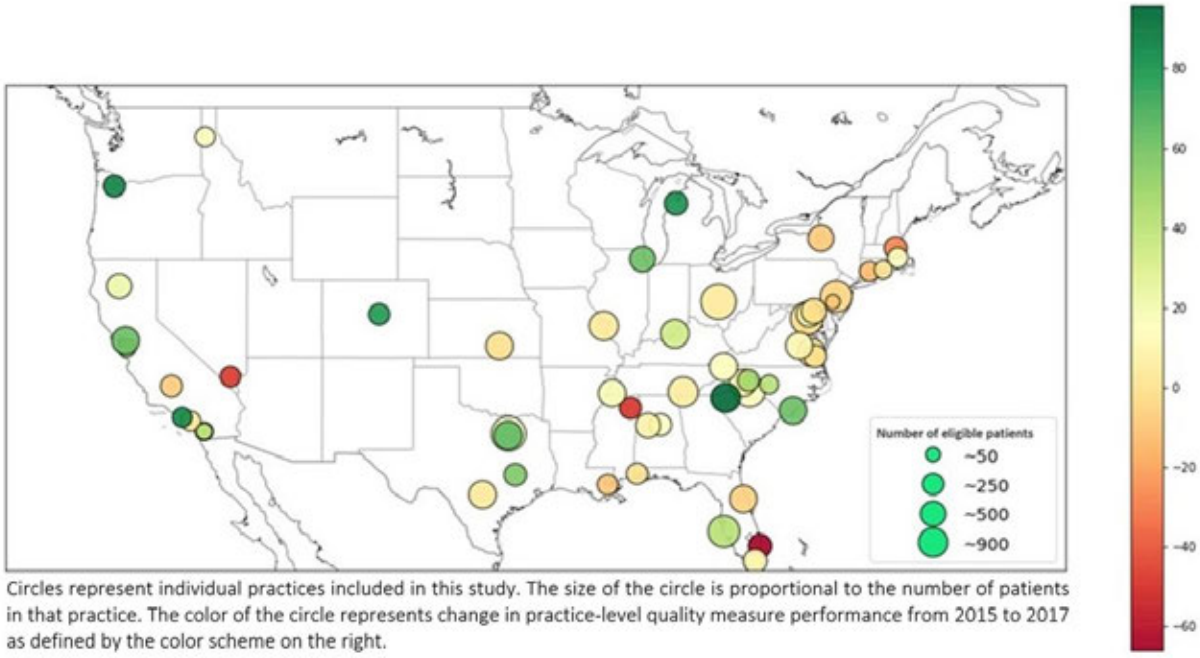
Background/Purpose: The ACR's Rheumatology Informatics System for Effectiveness (RISE) is an EHR-enabled registry that represents over 36% of the U.S. clinical rheumatology workforce and calculates patient-level performance on over 24 quality measures. RISE allows rheumatologists to track their performance on quality measures, but aggregate trends in performance have not been studied. The objectives of our study were to examine changes in performance over time on selected quality measures in patients with RA and assess variations in performance across practices.

Figure 1. Proportion of patients with rheumatoid arthritis meeting the quality measures from 2015 to 2017



Disease activity assessment: Percentage of patients ≥18 years with rheumatoid arthritis (RA) whose disease activity is assessed using a standardized measurement tool at 50% or more encounters for RA with the same clinician during the measurement period; *Functional status assessment:* Percentage of patients ≥18 years with RA whose functional status is assessed using a standardized measurement tool at least once during the measurement period; *DMARD prescribing:* Percentage of patients ≥18 years with active RA who are treated with a DMARD during the measurement period; *TB screening:* Percentage of patients ≥18 years with RA that are newly prescribed a biologic therapy during the measurement period and whose medical record indicates TB testing in the 12 months preceding the biologic prescription; *Tobacco screening and cessation:* Percentage of patients ≥18 years who were screened for tobacco use ≥ 1 time within 24 months AND who received cessation counseling intervention if identified as a tobacco user; *Blood pressure (BP) control:* Percentage of patients 18-85 years of age who had a diagnosis of hypertension and whose BP was adequately controlled (<140/90mmHg) during the measurement period; *Use of high-risk medications in the elderly*: Two rates were reported: a) Percentage of patients ≥66 years who were ordered ≥1 high-risk medication; b) Percentage of patients ≥66 years who were ordered ≥2 different high-risk medications. These are inverse measures but, in this study, they were inverted again such that higher percentages indicated better performance – e.g., a performance of 1% on the inverted measure became 99% in the modified measure.

Figure 2. Variability in within-practice change in measure performance (%) from 2015 to 2017 across states. Measures included: disease activity assessment, functional status assessment and tuberculosis screening.



Circles represent individual practices included in this study. The size of the circle is proportional to the number of patients in that practice. The color of the circle represents change in practice-level quality measure performance from 2015 to 2017 as defined by the color scheme on the right.

Methods: We analyzed data from practices enrolled in RISE between January 1, 2015 and December 31, 2017. Eight quality measures in the areas of RA management (disease activity assessment, functional status assessment, DMARD prescribing, and tuberculosis (TB) screening), and risk reduction (tobacco use screening and cessation, blood pressure (BP) control, and two measures on high risk medication use in elderly) were examined. Practice-level performance was defined as the percentage of eligible patients receiving recommended care for each measure separately. We used hierarchical multivariate linear models to predict change in performance as a function of practice type (single-specialty group practice, multi-specialty group practice, solo practitioner vs. health system), after adjusting for patient demographics, number of providers, EHR vendor and geographic region.

Results: Data from 59,986 patients from 54 practices was examined. Mean age was 62±14 years, 77% were female, 69% were Caucasian, and 81% had private insurance. The most common practice structure was a single-specialty group practice (46%), most practices had 1-4 providers (59.3%), and NextGen was the most commonly used EHR vendor (63%). From 2015 to 2017 there were clinically meaningful and statistically significant changes for disease activity assessment (8.4% per year, $p< 0.001$), functional status assessment (13.9% per year, $p< 0.001$), and TB screening (4.3% per year, $p< 0.001$), but only very modest changes for DMARD prescribing (1.0% per year, $p=0.004$), tobacco screening and cessation (2.9% per year, $p< 0.001$), and BP control (1.6% per year, $p=0.022$) (Figure 1). The degree of change in performance varied considerably across practices and regions (Figure 2). In adjusted analyses, single specialty group practices had the highest rates of improvement on disease activity assessment (12.8% per year), functional status assessment (17.3%) and TB screening (5.7%), while health systems were worsening over time on these measures (-18.5%, -4.2%, -19.3%, respectively; p-value for interaction ≤0.008).

Conclusion: Among practices participating in RISE from 2015 to 2017, aggregated performance, especially on RA-specific measures improved, although we found significant variation in performance over time between practices. These findings suggest that future work to identify workflow patterns leading to high performance or to dramatic improvements in quality are warranted.

Abstract Number: 0305

Naming Is Everything! the Cost of Inappropriate "Lupus Panel" Testing

Caleb Anderson ,[1] Roger Stitt,[2] and Robert O'Brian[1], [1]Walter Reed National Military Medical Center, Bethesda, MD, [2]US Army, Ft Eustis

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Measures Of Healthcare Quality Poster I: Testing, Screening, & Treating
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Greater emphasis has been placed on cost saving measures due to ballooning healthcare cost in the U.S. ACGME now evaluates trainee ability to practice cost conscious care through the systems based practice competency. In the rheumatology clinic at Walter Reed National Military Medical Center (WRNMMC), we observed inappropriate ordering of the so called "lupus panel." The "lupus panel" lab is better known as the lupus anticoagulant test (LAC), which may be associated with the antiphospholipid syndrome (APS) and its clinical features of thromboembolic events and recurrent pregnancy loss. We suspected the misleading name led physicians to order the "lupus panel" to screen for systemic lupus erythematosus (SLE) rather than to evaluate for APS. We retroactively evaluated the rate and cost of inappropriate ordering of the "lupus panel" and found thousands of dollars spent annually on inappropriate ordering. The lab name was changed from "lupus panel" to "lupus anticoagulation panel" based on our recommendation. We then set out to evaluate a change in ordering pattern and resulting cost over a three month period.

Methods: Results of the "Lupus Panel" from 1 January 2015 – 31 December 2015 were collected. The rationale for ordering each test was analyzed in the EMR by two rheumatologists. The test was considered inappropriate if it was

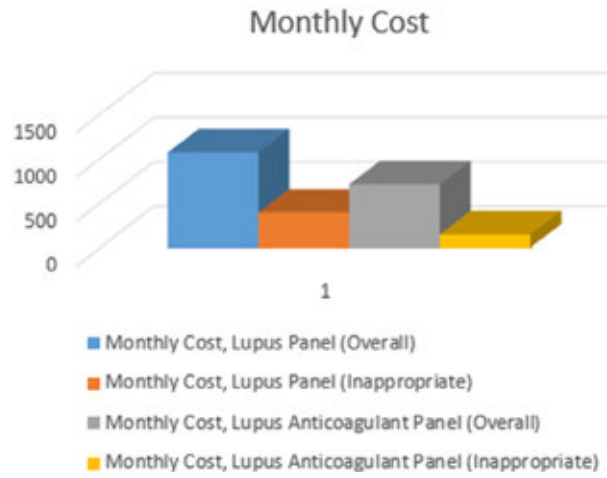

Table One. Monthly cost of total and inappropriate lupus anticoagulant lab tests. Total monthly cost of "lupus panel" was $1072.18, with inappropriate lab tests costing $393.56. Total monthly cost of "lupus anticoagulant panel" was $711.60, with inappropriate lab tests costing $147.79.

ordered for anything other than thrombophilia, initial SLE evaluation by a rheumatologist, or pregnancy loss. The name of the lab was changed to “Lupus Anticoagulant Panel” on 1 April 2018. The ordering pattern from 1 April 2018 – 30 June 2018 was similarly evaluated. The lab processing cost, excluding labor, was estimated by our lab manager. Fisher’s exact test was utilized to evaluate the association between lab name and ordering pattern.

Results: 403 “lupus panel” lab tests were processed in the National Capital Region in 2015, at a rate of 33.6 per month. 148 (37%) samples were considered inappropriate, costing $4,722.68 ($393.56 per month) to process. The three most common reasons for inappropriate testing were musculoskeletal complaints 63 (43%), fatigue 13 (8%), and paresthesias 6 (4%). 65 LAC tests were ordered in the first three months after the name change, at a rate of 22.3 per month. Of the 62 tests that had sufficient documentation to analyze, 14 were considered inappropriate (22.6%). The most common reasons for inappropriate testing were musculoskeletal complaints 6 (43%) and rash 5 (36%). The monthly cost of inappropriate lab tests was $147.79.

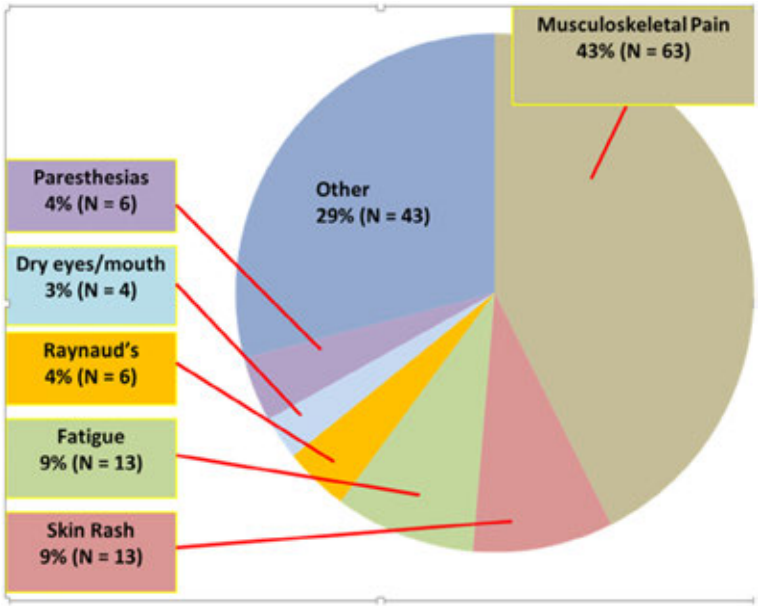

Figure Two: Reasons for inappropriate “lupus anticoagulant panel” testing

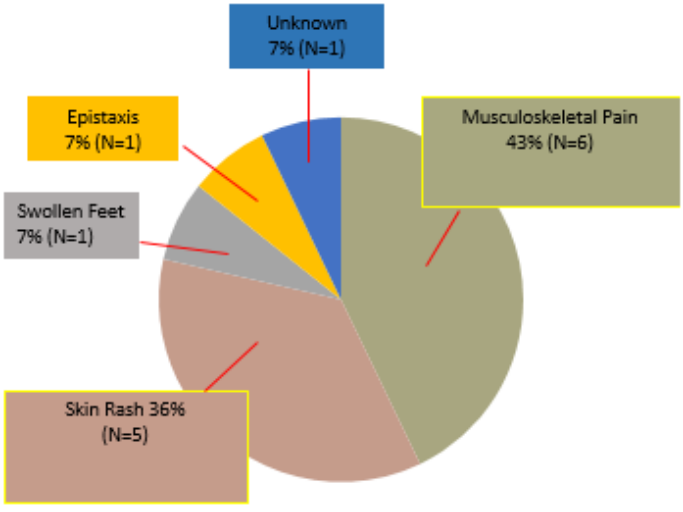

Figure One: Reasons for inappropriate “lupus panel” testing

Conclusion: Inappropriate ordering of the "lupus panel" cost WRNMMC approximately $4,722.68 in lab processing for the calendar year 2015. Changing the name of the lab to better describe the test yielded a significant reduction in the percentage of inappropriate lab tests (37% vs 22.6%, p=0.0318) and reduced annual and monthly cost by approximately $2,949.20 and $245.77, respectively.

Infrequent Screening but High Prevalence of Antinuclear Antibodies in Patients with Neuropsychiatric Disorders

Jihad Ben Gabr ,[1] and Andras Perl[1], [1]SUNY Upstate Medical University, Syracuse, NY

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Measures Of Healthcare Quality Poster I: Testing, Screening, & Treating
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The American College of Rheumatology (ACR) established case definitions of 19 specific neuropsychiatric syndromes seen in patients with systemic lupus erythematosus (SLE) (*1*). Therefore, we evaluated the frequency of antinuclear antibody (ANA) screening by immune that has the greatest sensitivity to detect SLE (*2*).

Methods: This quality improvement project examined the electronic medical records (EMR) of patients diagnosed with 17 neuropsychiatric conditions documented at our institution between 2013 until 2019 (Table 1). Patients with existing SLE have been excluded. ANA testing was done by indirect immunofluorescence using HEp-2 cells as antigen (*2*). Significant ANA titer was defined as titer >1:50. Our findings were compared to published studies in similar patient populations which were available in PubMed for 8/17 conditions. Statistical analysis was performed with chi-square test using GraphPad version 5.0 software.

Results: Table 1 outlines the findings in a total number of 178,585 patients with 17 neuropsychiatric diagnosis in our cohort. ANA was assessed in 19,369 subjects (10.7%). Rates of testing ranged between 6.7% (seizure) and 23.8% (Guillain-Barre syndrome, GBS). Surprisingly, ANA testing was done in 8.9% of patients with psychosis. Each population was evaluated for the numbers of patients who were screened and found to have elevated ANA. Compared to peer-reviewed literature our cohort was larger in number with greater prevalence of positive ANA with the exception of myasthenia gravis, which unveiled similar levels of prevalence.

Conclusion: Up to 80% of SLE manifest a neuropsychiatric disorder, which may benefit from treatment targeting the immune system and inflammation. The prevalence ANA testing was surprisingly low in patients with neuropsychiatric disorders. However, among the tested patients, the prevalence of ANA exceeded those in the literature in 7/8 conditions, which likely reflects a preference for testing in cases where disease manifestations occurred outside the nervous system. Further studies are clearly warranted to substantiate the role of systemic inflammatory diseases, such as SLE, in neuropsychiatric disorders.

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Measures Of Healthcare Quality Poster I: Testing, Screening, & Treating
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Reducing unnecessary laboratory investigations is a health economic priority. Anti-nuclear antibody (ANA) testing is performed as part of the diagnostic work up for autoimmune disease, or in patients with inflammatory or musculoskeletal symptoms. The value of serial ANA testing is unclear, but anecdotal evidence suggests it is frequent. We sought to evaluate the utility of repeated ANA testing in a large tertiary healthcare network, to determine the evidence base for decision support actions.

Methods: The primary endpoint was whether a longitudinal change in ANA resulted in new ANA associated diagnoses. Secondary endpoints included calculation of the total cost associated with repeated testing and the examination of baseline ANA testing behaviours. We retrospectively analysed data from a multi-centre tertiary health network across a 7-year period (March 2011 to July 2018). ANA and other autoimmune test results were obtained from the hospital systems. The laboratory positive ANA cut off of 1:160 was used. Clinical information was sourced from medical records on all patients who had a change in ANA result from negative to positive on repeat testing. The cost of repeated ANA testing was calculated based on the baseline cost to the payer. Descriptive statistics were performed using Stata version 15.

Results: A total of 36,715 ANA tests (excluding 980 cancelled same-day requests) were performed in 28,840 patients. Of these, 14,058 (38.3%) were positive, with females accounting for 9,265 (65.9%, $p< 0.001$). The most frequent ANA patterns were homogenous (47.4%) and nucleolar (23.3%). The distribution of ANA titres was: 1:160 (41.4%), 1:320 (15.3%), 1:640 (13.1%) and 1:1280 (29.2%). 7,875 (21.4%) tests were repeat tests in 4,887 patients, with test frequency in an individual patient ranging from 2-45. Of repeated tests, 79% of results remained the same, while 541 (11.1%) results changed from negative to positive. In the 501 of these in whom medical records were available, a change to positive ANA was associated with a new ANA-associated diagnosis in only 7 cases (2 SLE, 1 scleroderma, 2 undifferentiated connective tissue disease and 2 autoimmune hepatitis), resulting in a positive predictive value of 0.014. When comparing patients with a new diagnosis to those with no new diagnosis, there was no difference between ANA titre, pattern, age, time interval between negative and positive ANA, location or ordering clinician. The direct total cost to the payer of all ANA testing was USD$624,691, of which repeat testing contributed USD$133,990.

Conclusion: Repeat ANA testing was frequent. After a negative result, repeat ANA testing has limited utility in the diagnosis of ANA-associated conditions with a very low positive predictive value, and was associated with excess cost. Clinical alert systems to reduce unnecessary repeat ANA testing may result in significant direct cost savings.

Abstract Number: 0308

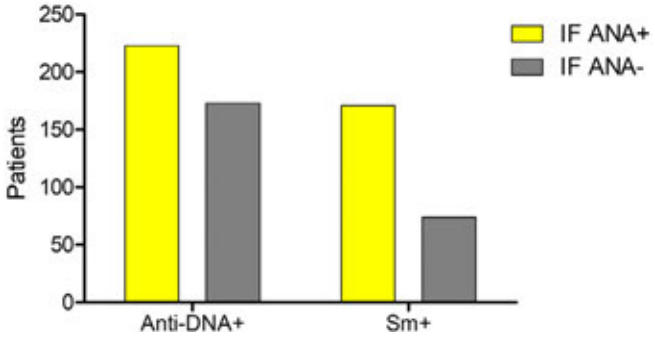
Quality Control of Antinuclear Antibody Detection by Indirect Immunofluorescence and Flow Cytometry-based Recombinant Antigen Assays

Konrad Dziamski ,[1] and Andras Perl[1], [1]SUNY Upstate Medical University, Syracuse, NY

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Measures Of Healthcare Quality Poster I: Testing, Screening, & Treating
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Indirect immunofluorescence (IF) is the recommended initial test for detection of antinuclear antibodies (ANA) by the American College of Rheumatology (*Ann Rheum. Dis* **69**:1420-2), (*Clin. Immunol.* **124**:18-21). Because the staining pattern does not identify the responsible autoantibody, additional testing using Flow Cytometry-

TEST	dsDNA	TEST	Smith
Homogeneous (+)	223	Speckled (+)	171
Homogeneous (-)	173	Speckled (-)	74
Sensitivity (%)	56	Sensitivity (%)	70
Specificity (%)	30	Specificity (%)	44
p value vs Smith	0.0007	p value vs dsDNA	0.0007



Detection of ANA by IF in patients with SLE that have positive anti-DNA or anti-Sm antibodies.

based Recombinant Antigen Assays (FCA) is required. We were interested in assessing the correlation of this method for ANA detection with the results of specific autoantibodies identified by FCA at our institution between 2012-2019.

Methods: 5,474 instances of simultaneous testing with ANA by IF and FCA were identified. All tests were performed in house (SUNY Upstate, Syracuse, NY). Positive autoantibody detection by FCA for dsDNA, anti-Smith, centromere, histone, RNP, Scl-70, SSA, and SSB were individually compared to results of ANA by IF. Sensitivities, specificities, positive and negative predictive values were assessed by 2-tailed Chi-square tests using GraphPad software.

Results: Of 396 positive dsDNA results, 223/396 were associated with a homogeneous pattern and 173/396 were not (sensitivity: 56%; $p< 0.0007$ relative to anti-Smith, $p< 0.0021$ relative to RNP and $p< 0.0001$ to all others). Anti-Smith antibodies had association with speckled pattern in 171/245 instances (70%) while 74/245 (30%) did not (statistical significance only achieved in comparison to dsDNA ($p< 0.0007$ and centromere (0.0009)). There were 562 instances of multiple positive autoantibodies detected by FCA associated with positive IF, and an additional 17 instances of multiple positive autoantibodies associated with negative IF.

Conclusion: This analysis of lupus patients suggests that quality control issues likely exist when IF is used for ANA screening given the high number of negative homogeneous and speckled patterns when compared to positive dsDNA and Sm autoantibody detection by FCA.

Increasing Capacity and Reducing Costs of Rituximab Administration

Zachary Wallace ,[1] Tyler Harkness,[1] Kimberly Blumenthal,[1] Hyon K. Choi,[2] John Stone,[3] and Rochelle Walensky[1],
[1]Massachusetts General Hospital, Boston, [2]Massachusetts General Hospital, Boston, MA, [3]Massachusetts General Hospital Rheumatology Unit, Harvard Medical School, Boston, MA

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Measures Of Healthcare Quality Poster I: Testing, Screening, & Treating
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Rituximab (RTX) is associated with a large cost burden on the healthcare system and treatment delays that often exceed one month because the long infusion duration (>4 hours) limits daily capacity. Time-drive activity-based costing (TDABC) is a novel method to estimate costs that can identify opportunities for economic and process efficiencies. The TDABC approach examines actual time spent with each resource and its per-unit cost. We performed TDABC of RTX administration in rheumatology to identify key cost drivers, project potential cost- and time-saving opportunities, and enable future cost-effectiveness research.

Methods: We implemented TDABC throughout the care pathway (e.g., orders, pharmacy preparation, scheduling, administration) for 26 patients receiving a total of 30 RTX infusions in an academic hospital-based infusion center (IC). The base-case was one treatment cycle which included two 1,000mg RTX infusions administered using standard rates over two visits. We assumed a 23% rebate on drug costs. After collecting base-case data on provider timing, pre-treatment regimens, and infusion rates, we then varied these in sensitivity analyses paying particular attention to varying (1) the drug (biosimilar vs originator), and (2) administration, including the use of subcutaneous (SQ) or rapid (e.g., 90-minute) infusion protocols. We estimated the mean number of RTX infusions per day using 3 months of IC scheduling data and associated visit length (hours) using estimates from TDABC. We then assessed the potential effect of two alternative strategies on annual capacity: a) SQ RTX and b) rapid 2nd infusion protocols. We assumed that SQ RTX would require a 30-minute appointment based on oncology practice.

Results: In the base-case, RTX administration costs $18,840 (**Table 1**), 92% ($17,380) from drug costs; the remaining costs were due to personnel ($780, 4%), non-drug consumables ($60, 0.3%), and space ($630, 3%). In one-way

Infusions	Cost	% of Total
Long (First) Infusion Total		
Drug Costs	$8,690	91%
Personnel Costs	$440	5%
Space Costs	$350	4%
Non-Drug Costs	$30	0.3%
Total Cost	$9,510	100%
Short (Second) Infusion Total		
Drug Costs	$8,690	93%
Personnel Costs	$340	4%
Space Costs	$280	3%
Non-Drug Costs	$30	0.3%
Total Cost	$9,330	100%
Total Base Case Cost	$18,840

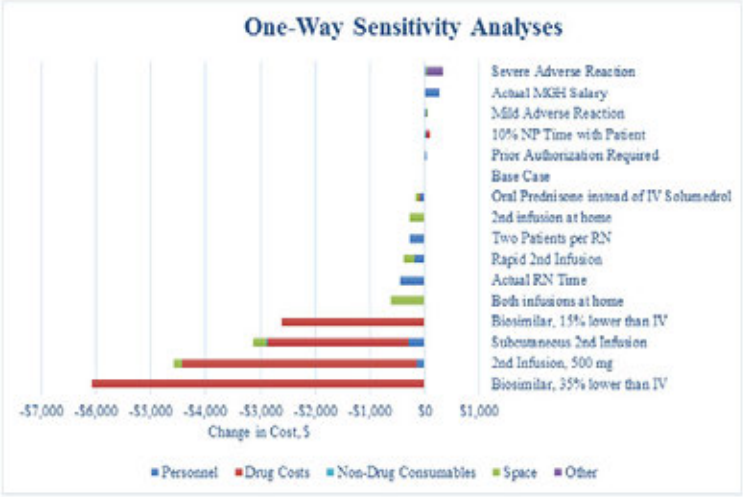
Projected Increases in Capacity



One-Way Sensitivity Analyses Using TDABC

sensitivity analyses (**Figure**), the greatest cost savings were associated with biosimilar RTX at a 35% cost reduction (-$6,080) and substitution of the 2nd dose with SQ RTX (-$3,170). SQ RTX use led to savings on personnel (-$290, -37%), consumable (-$2,640, -15%), and space (-$250, -39%) costs. In a "best case" scenario, when we used IV biosimilar RTX for the 1st dose, SQ RTX for the 2nd dose, assigned two patients per RN, and used oral prednisone (rather than IV solumedrol) as pre-treatment for the 1st dose, total savings reached -$6,350 (-34%). Using SQ RTX would increase the number of RTX treatments available by up to 15 patients per day, a 6-fold increase in capacity (**Table 2**). Using a rapid 2nd infusion would increase the number of RTX treatments available in one day by up to 3, an increase in capacity of 2-fold (**Table 2**).

Conclusion: Using a novel costing method, we found that drug price is the primary driver of the cost of RTX treatment and that varying non-drug factors has minimal impact on overall costs. The ultimate list price of biosimilar RTX may substantially impact the cost of RTX administration on the healthcare system. However, use of biosimilar and SQ RTX may reduce costs by 34% and appreciably increase administration capacity, thereby reducing delays in treatment.

Session Date: Sunday, November 10, 2019

Session Title: Measures Of Healthcare Quality Poster I: Testing, Screening, & Treating

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Biotechnological drugs are a fundamental resource for the treatment (Tx) of rheumatic patients (Pts). Biosimilar drugs are intended to be as effective as the originator product but with a lower cost to healthcare systems.

In our center we promoted a switch from originator infliximab (IFXor) to biosimilar infliximab (CT-P13). We analyzed efficacy, safety, immunogenicity and cost savings of switching.

Methods: Eligible Pts were those older than 18 years old with the diagnosis of rheumatoid arthritis (RA), spondylarthritis (SpA) and psoriatic arthritis (PsA) on Tx with IFXor for at least 6 months and with stable disease activity (DA). In December 2016 all eligible Pts were proposed to switch to CT-P13. At the day of the last Tx with IFXor, informed consent, data and blood samples were collected. On the next Tx day, CT-P13 was administered after standard evaluation of efficacy and safety. Efficacy was measured considering change from baseline in DAS in 28 joints for RA and PsA and in Ankylosing Spondylitis Disease Activity Score (ASDAS) for SpA. Disease worsening was considered when an increase of 1.2 from baseline in DAS28 or an increase of 1.1 in ASDAS occurred. Serum Infliximab levels (sIFX) were dichotomized as low (< 3 µg/mL) and high (>6 µg/mL). Anti-drug antibody (ADA) levels were dichotomized into detectable (>10 ng/ml) or non-detectable (< 10 ng/ml). CT-P13 Tx withdrawal and drug persistence were used as effectiveness outcomes. A cost analysis was done based on the purchasing prices of the 2 drugs at our center.

Table 1. Variation in disease activity of patients switched to biosimilar infliximab (CT-P13). *Median values (IQ)

	Baseline (n=60)	3 months after switch (n=59)	6 months after switch (n=58)	9 months after switch (n=56)	12 months after switch (n=55)	Variation from baseline to 12 months after switch (p-value)
ESR (mm/h)*	15.5 (11-22)	17 (10-30)	15 (10-24)	19 (11-26)	20 (12-35)	4.5
CRP (mg/dL)*	0.18 (0.08-0.59)	0.17 (0.06-0.50)	0.19 (0.11-0.49)	0.20 (0.10-0.63)	0.15 (0.08-0.5)	-0.03
PtGA (0-100)*	30 (20-50)	30 (20-50)	27 (10-50)	30 (10-50)	30 (20-50)	0
PhGA (0-100)*	20 (10-30)	20 (10-30)	15 (0-30)	20 (10-30)	30 (10-40)	10

ESR – Erythrocytes sediment rate; CRP – C-Reactive protein; PtGA – Patient Global assessment; PhGA – Physician global assessment.

Results: During a period of 1 year switch to CT-P13 was performed in 60 Pts for non-medical reasons.

We had a total of 36 Pts with SpA, 16 with RA and 8 with PsA. 65% were females with a median age of 53 years, median disease duration previous to switch of 17 years and median time on IFXor Tx of 8 years.

DA was stable over the observation period and similar to the values observed with IFXor. Median follow-up time was 15 months during which 5 Pts stopped CT-P13. Three Pts had disease worsening, 1 Pt had a minor adverse event (lip edema) and 1 Pt moved to another country. One patient returned to IFXor and the other 3 switched to another drug.

42 switchers had blood samples collected before and after switch. A total of 27 Pts had unaltered sIFX levels and ADA status during follow up.

At baseline, 5 Pts had low sIFX, with no detectable ADAs, that reverted after switch. These Pts had no variation in DA before and after switch.

3 Pts had detectable ADA at baseline with low sIFX levels. After switch, ADAs became negative in 2 of those Pts, with normalization of sIFX. The other Pt kept detectable ADA levels after switch and had a minor elevation of DAS28, based on patient global assessment.

ADAs became positive in 5 Pts after switch. Of these, sIFX changed from high to low accompanied by an elevation of ASDAS in 3 Pts. The other 2 Pts maintained ADA levels detectable with sIFX >3 µg/mL during all the evaluation period.

Apart from the Pts that developed ADAs, no other Pt changed from high to low sIFX.

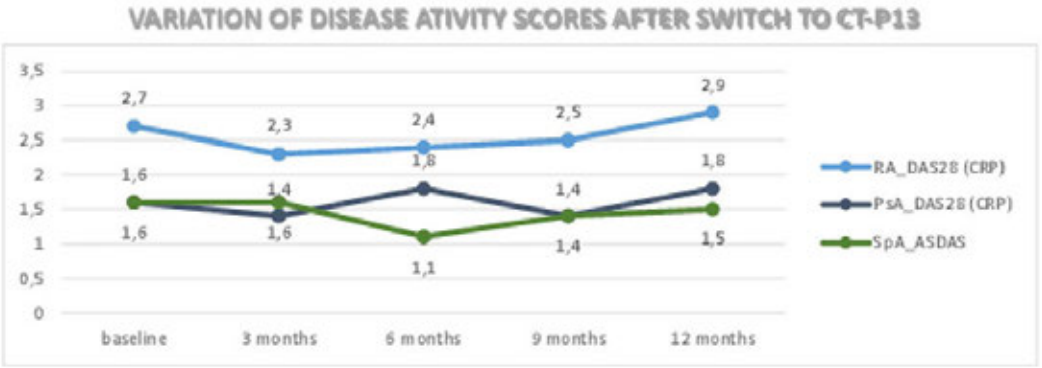

Figure 1. Variation in disease activity of patients switched to biosimilar infliximab (CT-P13). *Median values (IQ)

	RA (n=13)			PsA (n=2)			SpA (n=27)			Total (n=42)		
	Baseline	After switch (3-9 m)	After switch (≥ 12 m)	Baseline	After switch (3-9 m)	After switch (≥ 12 m)	Baseline	After switch (3-9 m)	After switch (≥ 12 m)	Baseline	After switch (3-9 m)	After switch (≥ 12 m)
IFX serum concentration* (µg/mL)	11.5 (9.7)	9.6 (8.9)	7.4 (4.2)	6.9 (2.3)	6.7 (2.3)	6.7 (1.8)	6.1 (3.9)	6.2 (8.1)	5.4 (3.7)	7.6 (6.8)	7.9 (8.9)	6.1 (3.9)
Positive ADA, n/total	2/13	1/13	1/13	0/2	0/2	0/2	1/27	5/27	5/27	3/42	6/42	6/42

Table 2. ADA and sIFX concentration at baseline and after switch. *mean values (SD)

The switch to CT-P13 represented a 26.4 % reduction of costs in the use of IFX Tx in these Pts.

Conclusion: The switch in routine care of a group of RA, SpA and PsA patients from IFXor to CT-P13 did not affect efficacy, safety or immunogenicity and reduced costs in 26.4%.

Documenting Bone Health for Veterans with Rheumatoid Arthritis in an Outpatient Academic Clinic: A Multiphase Quality Improvement Project

Melissa DeFoe ,[1] Rabih Nayfe,[2] Una Makris,[3] Rashmi Arora,[3] and Swathi Reddy[3], [1]VA North Texas Health Care System, Dallas, TX, [2]University of Texas Southwestern Medical Center, Dallas, TX, [3]University of Texas Southwestern Medical Center and the VA North Texas Health Care System, Dallas, TX

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Measures Of Healthcare Quality Poster I: Testing, Screening, & Treating
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid Arthritis (RA) is associated with an increased risk of osteopenia and osteoporosis, which may result in fragility fractures and significant cost and morbidity. Bone density assessments are often overlooked in routine clinical practice, resulting in missed opportunities for early interventions and prevention of disease progression. In the first phase of this multi-phase quality improvement project, a “Bone Health” prompt was added to the RA note template to remind physicians to document bone health status, Fracture Risk Assessment Tool scores, and management. Initial documentation rate of bone health (ie, osteoporosis, osteopenia, normal bone density) was 65%. We found that post-intervention documentation rates improved among residents (70%) and rheumatology fellows (82%). It was unclear whether these changes could be sustained and, importantly, if the intervention would improve the quality of bone health management for RA patients. The aim of this second phase of the project is to evaluate the sustainability of bone health documentation and the impact on clinical management in Veterans with RA in an academic clinic.

Methods: Pre-intervention documentation rates of bone health and appropriate management (defined as evaluation with DEXA or use of pharmacotherapy) were measured by reviewing 50 residents’ (internal medicine, PM&R) and 50

rheumatology fellows' notes from August-October of 2017. The "Bone Health" prompt (intervention) in the note template was implemented in December of 2017. We reviewed 50 resident and 50 fellow notes from January-March of 2019 to evaluate the sustainability of bone health documentation and the rate of appropriate management 12 months after intervention implementation.

Results: One year after the original template intervention was introduced, the post-intervention documentation rate of bone health was sustained in both residents' (88%) and fellows' (82%) notes. For bone health management, in the pre-intervention group, documentation was higher among residents (70%) than fellows (62%). Twelve months after the intervention, rates of documentation of appropriate management dropped among residents (68%) but improved among fellows (74%). Among the Veterans, three had significant medical comorbidities requiring emergency care or discontinuation of therapy, therefore, documenting bone health was less of a priority during these encounters. A subgroup analysis including only Veterans with reduced bone density demonstrated documentation of appropriate management of 84% and 73% in the resident and fellow notes, respectively.

Conclusion: Adding a "Bone Health" prompt demonstrated sustained improvement of assessment over 12 months. As compared to the pre-intervention data, documentation of management of bone disease improved in the fellow group but dropped in the resident group (possibly because they rotate more frequently); however, if Veterans with normal bone density were excluded, documentation of appropriate management improved in both groups. Future projects can evaluate if prompting trainees to document bone health results in fewer fragility fractures.

Timely Glucocorticoid Tapering in Vasculitis: A Need for Improved Knowledge Translation to Limit Toxicity

Arielle Mendel ,[1] Daniel Ennis,[2] Shirley Lake,[3] Simon Carette,[4] and Christian Pagnoux[4], [1]Mount Sinai Hospital, Toronto, ON, Canada, [2]University of Toronto, Toronto, ON, Canada, [3]Division of Rheumatology, Sunnybrook Hospital, Toronto, ON, Canada, [4]Mount Sinai Hospital and University Health Network, Toronto, ON, Canada

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Measures Of Healthcare Quality Poster I: Testing, Screening, & Treating
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: High dose glucocorticoids (GC) are part of the initial treatment of ANCA-associated (AAV) and large vessel vasculitides (LVV). Prompt subsequent tapering limits toxicity. Adherence to tapering recommendations has not been studied. Among patients referred to a tertiary vasculitis clinic for either AAV or LVV, we aimed to determine the frequency of adherence to GC tapering recommendations, barriers to appropriate GC tapering, and possible improvement strategies.

Methods: Consenting new patients assessed July 2017-March 2019 for AAV (including GPA, EGPA, MPA) and LVV (GCA, Takayasu arteritis) were included. Referral specialty, diagnosis, wait time, GC dose and duration were recorded. Patients taking >10 mg prednisone above their target dose based on tapering recommendations were classified as taking 'excessive' GC. Physicians who referred 2 patients in the last year (n=31) were invited to complete a survey to identify barriers to GC tapering and potential solutions.

Results: Of 231 patients referred for AAV/LVV during the study period, 128 (55%) were taking GC at their first visit. Mean prednisone start dose was 53.5 mg (SD 14) and 33/111 (30%) received pulse GC. At the first visit (mean wait time 63 days, SD 31), mean GC dose was 30 mg (SD 18). 35 (27%) patients were taking excessive GC (17 AAV, 18 LVV), 11 of whom had not started tapering entirely. There were no significant differences in referral specialty, diagnosis, or wait times among patients taking 'excessive' vs 'appropriate' doses. Initial GC 'pulses' had been given to 14/31 (45%) of the 'excessive' group patients vs 19/80 (24%) in the 'appropriate' group (NS). 73% of survey respondents (n=14, 93% rheumatologists) felt "very comfortable" tapering GC in GCA, but only 43% and 21% in AAV or Takayasu arteritis, respectively. Challenges with tapering were managing the risk of disease flare (79%) and differentiating active disease from damage (64%). Most (93%) felt that providing GC tapering suggestions at the time of referral would improve timely tapering, and 64% felt reducing wait times would help.

Conclusion: Nearly one third of patients referred for LVV or AAV were taking excessive GC doses at their first visit. There may be a referral bias to our clinic, and excessive GC use may reflect more challenging cases. Providing a GC tapering "action plan" at the time of referral may help to promote timely GC tapering.

Screening and Treating Hyperlipidemia in Patient's on Tofacitinib, Tocilizumab, Sarilumab, and Baricitinib

William Torelli ,[1] James Ross,[2] Thomas Quinn,[2] Kourtney Erickson,[1] Andrea Soliman,[1] and Attiya Harit[3], [1]Lehigh Valley Health Network, Allentown, PA, [2]lehigh valley health network, allentown, [3]lehigh valley health organization, allentown

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Measures Of Healthcare Quality Poster I: Testing, Screening, & Treating
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Background/Purpose: Tofacitinib and baricitinib (JAK inhibitors) are agents used for rheumatoid arthritis (RA), seronegative spondyloarthropathy (SpA), and juvenile idiopathic arthritis (JIA). Tocilizumab and sarilumab are biologics (IL6 inhibitors) for the management of inflammatory arthritis, and giant cell arteritis. Aforementioned drugs elevate total cholesterol and LDL levels. Primary aim is to assess compliance for screening and treatment per guidelines of the American College of Rheumatology (ACR) (ARP Practice Committee, 2017) for hyperlipidemia in patients receiving tofacitinib, tocilizumab, sarilumab, and baricitinib at Lehigh Valley Health Network (LVHN).

Methods: Data reviewed on 146 patients within LVHN, from December 2018 to April 2018. Subjects were retrieved from Epic by searching for orders for the drugs of interest. Manual Chart Review was utilized to determine: age, gender, ethnicity, pathology, medication, steroid dose, additional DMARDs, medication duration, date of drug initiation, previous statin, baseline lipid panel, frequency of lipid screenings, and statin initiated.

Results: Table 1 shows demographic and clinical variables of the charts reviewed. Medications used were the following: tofacitinib (64%), tocilizumab (27%), sarilumab (8%), and baricitinib (0.68%). Patients examined were afflicted with the following disease processes: RA (90%), GCA (4%), SpA (4%), and JIA (2%). Prior to the intervention 29% of patients were on a statin, and 28% had indications for a statin yet were not prescribed one. Additionally, only 17%

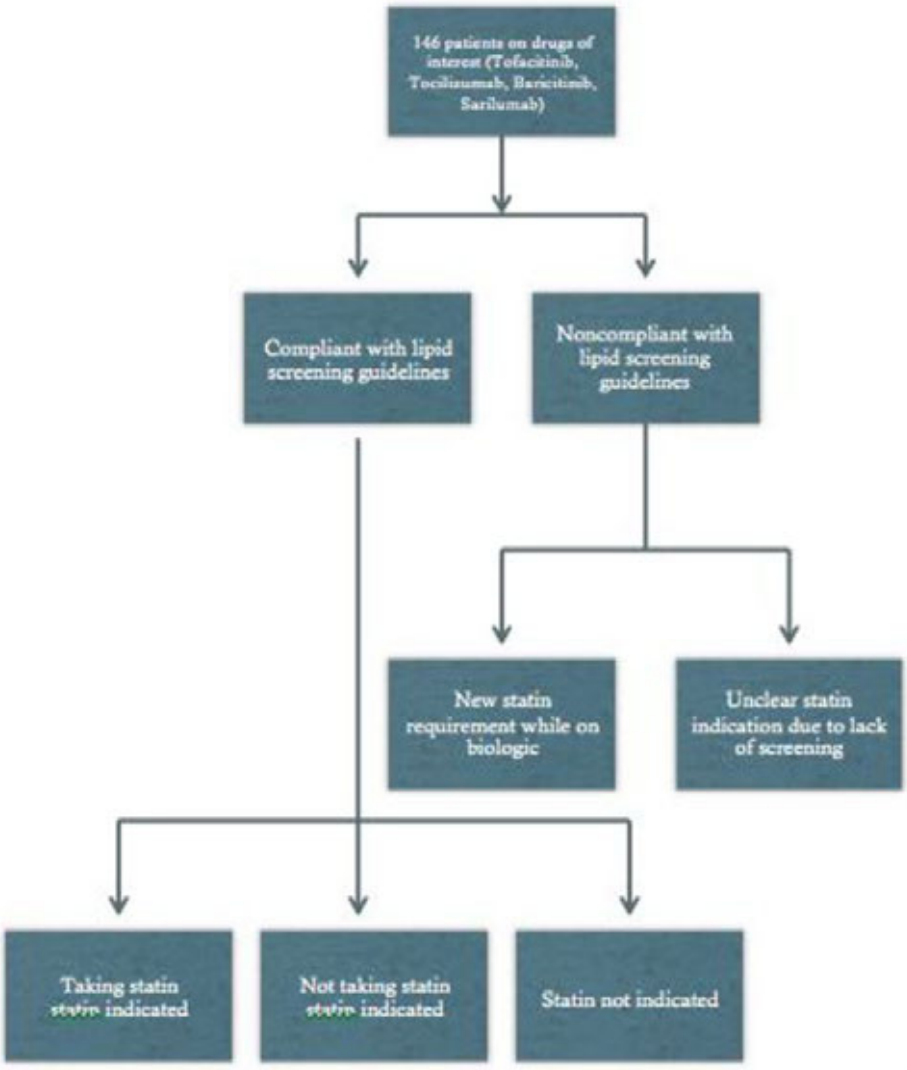

Figure 1.

of patients had a proper baseline lipid screening 4-8 weeks after starting the drug. Only 13% of patient had lipid screenings every 6 months after institution of the drug. Mean age was 56 years old, with 77% female, and average duration on drug of interest was 760.5 days.

Conclusion: According to ACR guidelines, laboratory monitoring for patients on JAK and IL6 inhibition is recommended due to treatment related changes in neutrophils, platelets, lipids, and liver specific enzymes (ARP Practice Committee, 2017). Additionally, British Society for Rheumatology (BSR) advocates for baseline lipid screenings, and rescreening every 3 months (Malaviya, 2014). After analyzing patients in LVHN there is room for improvement. Twenty eight percent of patients in the project have an indication for statin therapy, and are not being treated. Eighty two percent of patients lacked baseline lipid screening 4-8 weeks after starting JAK and IL6 inhibition. An intervention educating rheumatology providers on guidelines for these medications, and options for managing subjects with lipid lowering agents will follow initial data assessment. Data will be re-collected and assessed for improvement in guideline compliance and treatment following the intervention. After the intervention we expect to see increased compliance with lipid screening and management with patients on the drugs of interest within LVHN.

Table 1.

Table 1.		
Demographics	**Drugs**	**Disease Process**
Average Age: 55.8 years	Tocilizumab 27.39% (40)	RA 89.72% (131)
Gender: Female 77.40% (113)	Sarilumab 8.21% (12)	GCA 4.10% (6)
Average days on drug: 760.5 days	Baricitinib 0.684% (1)	SpA 4.10%(6)
Race	Tofacitinib 63.69% (93)	JIA 2.05%(3)

Pre-treatment Screening for Hepatitis B and C Among Users of Biologics or New Synthetic Disease Modifying Drugs: An Analysis Using RISE Data

Jing Li,[1] Julia Kay,[1] Jinoos Yazdany,[1] and **Gabriela Schmajuk** [2], [1]UCSF Division of Rheumatology, San Francisco, CA, [2]UCSF, SFVAMC Division of Rheumatology, San Francisco, CA

SESSION INFORMATION

Session Date: Sunday, November 10, 2019
Session Title: Measures Of Healthcare Quality Poster I: Testing, Screening, & Treating
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Testing for hepatitis B virus (HBV) and hepatitis C virus (HCV) is recommended for patients initiating biologics or new synthetic DMARDs, which can increase the risk of viral hepatitis reactivation. We examined pre-treatment screening for HBV and HCV among practices participating in ACR's RISE registry for patients who were new users of biologics or new synthetic DMARDs.

Methods: Data derived from Rheumatology Informatics System for Effectiveness (RISE), a national EHR-enabled rheumatology registry that passively collects data on all patients seen by participating practices. As of 2017, RISE held validated data from 1,257 providers in 236 practices, representing an estimated 36% of the U.S. clinical rheumatology workforce. Patients included in this study were ≥ 18 years old and had ≥ 1 prescription for a biologic or

Table. Proportion of documented pretreatment screening for HBV and HCV, N (%)

Total N=23,597	HBV*	HCV†	Composite measure (HBV and HCV testing)
No test	18,226 (77.2%)	20,203 (85.6%)	17,732 (75.1%)
Complete testing	1,428 (6.1%)	3,394 (14.4%)	1,373 (3.7%)
Partial testing	3,943 (16.7%)	-	4,992 (21.2%)

* HBV (Hepatitis B virus): Complete testing was defined as documentation of a HBV surface antigen AND HBV core antibody. If an HBV viral load was documented, this counted as an HBV surface antigen. Partial testing included at least one of these tests.
†HCV (Hepatitis C virus): Complete testing was defined as documentation of an HCV antibody or HCV viral load.

new synthetic DMARD between Jan 1 and Dec 31, 2017; the "index date" was defined as the first prescription date. New medication users were identified if they had ≥ 2 visits in the 12 months prior to their index date without any biologic or new small synthetic DMARD use. HBV screening was defined as "complete" if HBV surface antigen AND HBV core antibody were documented or "partial" if only one test was documented; HBV viral load satisfied the HBV surface antigen requirement. HCV screening was defined as having a documented HCV antibody or viral load test. We assessed screening across several windows (before the index date; allowing for a 60-day grace period after the index date; or allowing up to a 1-year grace period after the index date). We assessed practice-level performance for practices reporting on ≥ 20 patients.

Results: 23,597 patients were included from 196 practices. 71.9% were female, mean age of 57.3±14.4 years. 37% were non-white, including 6.9% Hispanic. The most common class of medication was TNFi (62.9%). Overall, only 22.8% patients had any documented HBV screening and 14.4% had any documented HCV screening (Table). Among those with complete testing, most screening was completed prior to the index date (82.6%); 96.9% completed screening by 60 days after the index date. Patterns were similar for HCV screening. Among 168 practices in the practice-level analysis, median performance was 0% (range 0-62.7%) for HBV, 0% (range 0-80.4%) for HCV screening, and 0% (range 0-62.7%) for the composite (HBV and HCV) screening measure.

Conclusion: Only a small proportion of RISE patients who were new users of biologics or new synthetic DMARDs had documented screening for HBV or HCV. It is likely that some patients were tested outside the rheumatology practice and also possible that results are documented in clinical notes or scanned documents, which are not currently accessible for use in electronic clinical quality measures. In order to meet criteria for measures that assess performance of pre-treatment HBV and HCV screening, practices will need to adjust workflows to ensure these patient safety measures are captured consistently in structured fields within the electronic health record.

Disclaimer: This data was supported by the ACR's RISE Registry. However, the views expressed represent those of the authors, not necessarily those of the ACR.

Abstract Number: 0315

Improving the Rate of Tuberculosis Screening Among High Risk Rheumatoid Arthritis Patients on Biologic Agents Using a Proposed Questionnaire

Hamayon Babary ,[1] Suraiya Afroz,[1] John Carter,[1] Yih Lin,[1] Marie O'Brien,[2] Marcos Maldonado,[1] Helen Bateman,[1] Gabriela Montes-Rivera,[1] Grace Berlin,[2] Dan Tseytlin,[2] Madeline MacDonald,[3] Yasmin Ayoubi,[4] Matthew Nguyen,[4] Shalini Setty,[4] Rahul Mhaskar,[4] and Joanne Valeriano-Marcet[1], [1]University of South Florida Division of Rheumatology, Tampa, FL, [2]Lehigh Valley Health Network, Allentown, PA, [3]University of South Florida, College of Medicine, Tampa, FL, [4]University of South Florida College of Medicine, Tampa, FL

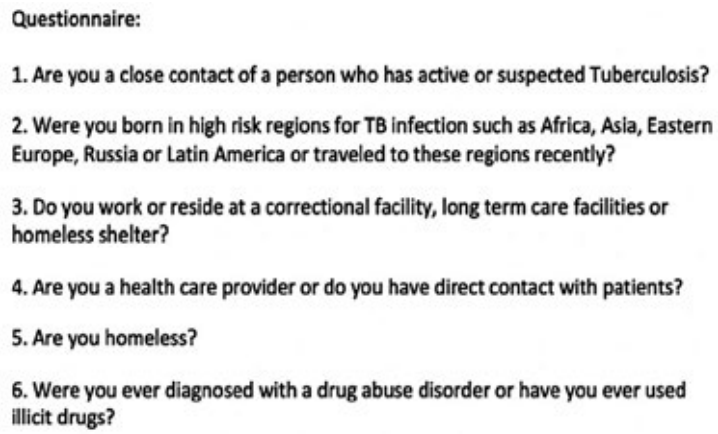
SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Measures Of Healthcare Quality Poster I: Testing, Screening, & Treating
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The use of biologics has transformed the treatment paradigm for RA; however, reactivation of Mycobacterium Tuberculosis is still a concern. Frequent TB screenings without consideration of risk factors can lead to potential clinical dilemmas including indeterminate Interferon-Gamma Release Assays in immunosuppressed patients. Current American College of Rheumatology guidelines recommend annual tuberculosis screening test for high risk patients while on biologics for management of RA. Our goal was to identify the high risk RA patients on biologics (tumor necrosis factor inhibitors, abatacept, IL-6 inhibitors, and tofacitinib)using a guideline based questionnaire and improving the rate of annual Tuberculosis screening among those patients.

Methods: This study was conducted in two large academic centers in Florida and Pennsylvania, which serve a diverse population across multiple clinics. A Plan-Do-Study-Act cycle model was implemented for this project. RA patients chosen for this study were on biologics for more than a year and had a negative baseline interferon-gamma release assay. Chart review was performed to obtain baseline data of how many of these patients were asked high risk questions for Tuberculosis exposure and were screened for Tuberculosis within one year of their visit. Our baseline data was based on one month worth of clinic visits. We put into effect our intervention to improve this rate by educating our Rheumatology providers and creating a questionnaire using American College of Rheumatology guidelines to identify high risk patients (please see attached), which could be easily accessed in our Electronic Medical Record. Post intervention, we gathered data over the course of two months to assess whether there was any improvement in the rate of Tuberculosis screening using the questionnaire.

Results: Our baseline data included 65 patients and postintervention included 175 patients. Analysis of our baseline data revealed that only 4.6% of the time any of the high risk questions were documented in EMR. Post Intervention, our compliance rate using the questionnaire improved to 26.3%. Using the questionnaire we noted an increase in interferon gamma release assay testing from 21 %to 23 % . Moreover, interestingly the rate Tuberculosis conversion to positivity was 0% for all patients in the project.

Conclusion: Our baseline data revealed that we were inadequately identifying high risk patients for Tuberculosis screening. Our post intervention data analysis showed an overall improvement in the rate of appropriate Tuberculosis screening. Despite the slight increase in the percentage of interferon gamma release assays checked in the intervention group, patients were appropriately rescreened based on risk factors. Further intervention such as Electronic Medical Record alerts will be implemented in the future aspects of this study to improve compliance among provid-



Tuberculosis Screening Questionairre

ers.Given the importance of Tuberculosis screening among high risk patients, we want to raise awareness about this quality measure and work towards providing the highest quality of care to our patients.

Implementation of Cardiovascular Screening in Hispanic Patient Population with RA, SLE and PsA

Liliya Gandrabur ,[1] Woo Young Kim,[1] Aditi Sen,[1] Deana Nes,[1] Julia Ash,[1] Amy Wasserman,[1] and Kirk Sperber[1],
[1]Westchester Medical Center, Valhalla, NY

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Measures Of Healthcare Quality Poster I: Testing, Screening, & Treating
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Evidence suggests that the tools used for cardiovascular disease (CVD) risk assessment in the general population underestimate the true risk when they are applied to patients with proatherogenic diseases such as RA, SLE and PsA. High inflammatory state increases atherogenesis and myocardial microvascular abnormalities leading to increased morbidity and mortality risks from cardiovascular (CV) causes. EULAR recommends that it is the rheumatologist who should ensure that CV disease risk assessment and management are performed regularly.[1]

Hispanic population has been underrepresented in the CV risk assessment research. We aimed to identify the RA, SLE and PSA patients' CV risk in clinic with predominantly underserved Hispanic patient population using the Atherosclerotic Cardiovascular Disease (ASCVD) calculator as recommended by the American Heart Association and American College of Cardiology. ASCVD 10-year-risk score of ≥5% is the recommended threshold for statin consideration/initiation. LDL >70 in a diabetic or LDL >190 in a nondiabetic are additional recommendations for statin treatment regardless of the ASCVD 10-year-risk score.[2]

ASCVD Score Data

#	Ethnicity	Age	Sex	Disease	Lipid Total	HDL	LDL	A1C	Diabetes	Smoker	HTN	systolic BP	ASCVD score

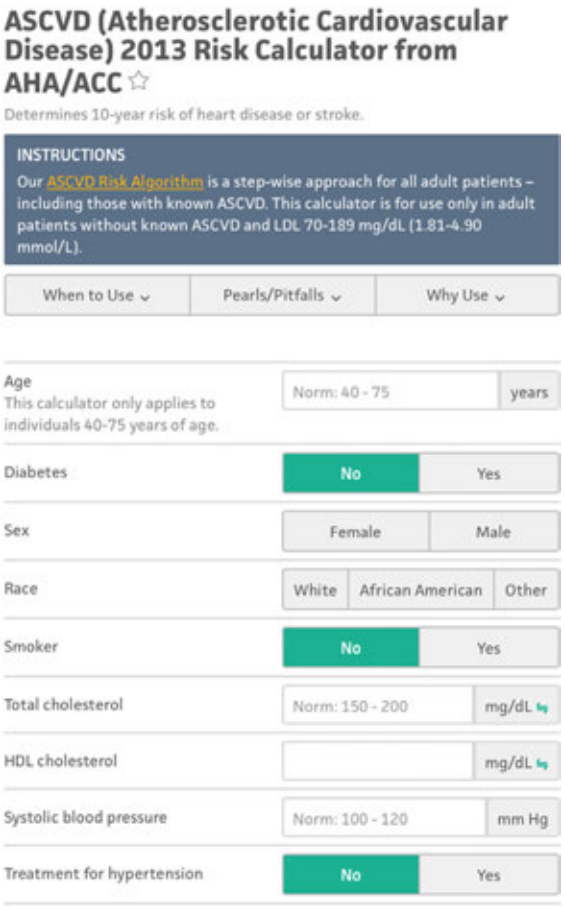
Diabetes with LDL >70
LDL >190
ASCVD score >5%

Table 1

Methods: RA, SLE and PsA patients were assessed during routine follow up visits from 1/2019 to 6/2019. Rheumatology fellows identified patients over the age of 40 who did not have an established diagnosis of CV disease and not treated with lipid lowering therapy. We calculated the ASCVD score based on patients' age, gender, ethnicity, smoking status, systolic blood pressure and antihypertensive treatment, lipid panel (total cholesterol, HDL) by using the *MDCalc Medical Calculator App*. The ASCVD score may also be obtained by going on www.mdcalc.com or tools.acc.org websites.

Results: The ASCVD score was calculated for 53 patients (32 RA, 16 SLE, 5 PsA). Out of these patients, 85% were Hispanic, 6% Caucasian, 7% African American, 2% Asian; 82% were females.We identified 7 (13%) out of 53 rheumatology patients who met the ASCVD criteria for statin initiation. Five (9%) patients had ASCVD score above >5%, 1 patient with diabetes had LDL >70 and 1 patient had LDL level >190. The patients with elevated ASCVD score were all over the age of 60 and carried the diagnosis of RA.

Conclusion: This abstract highlights the importance of CV disease screening in rheumatology clinic to identify patients with the highest risk for life-threatening CV events by calculating the ASCVD score. Thirteen percent of our 53 screened patients satisfied the criteria for statin initiation. Of interest, our study identified 7% of the Hispanic population with autoimmune diseases at risk for CV disease – a population frequently not included in cardiovascular



ASCVD 2013 Risk Calculator from AHA/ACC. Available at: https://www.mdcalc.com/ascvd-atherosclerotic-cardiovascular-disease-2013-risk-calculator-aha-acc Accessed June 4, 2019.

risk assessment studies. Although we have a small sample size, this study demonstrates the ease and feasibility of performing CV risk assessment in clinical practice.

Session Date: Sunday, November 10, 2019

Session Title: Measures Of Healthcare Quality Poster I: Testing, Screening, & Treating

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

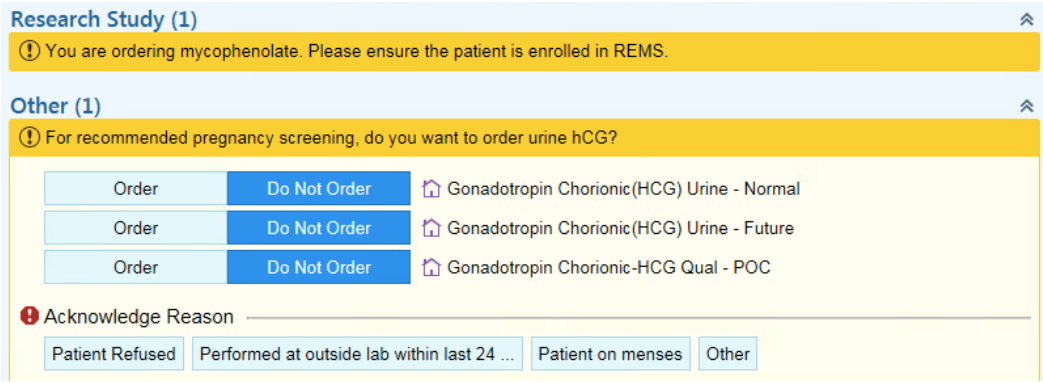

Figure 1. A BPA alert system was implemented in the pediatric rheumatology clinic setting.

Background/Purpose: Mycophenolate is widely prescribed in the rheumatology setting. However, usage of mycophenolate during the first trimester of pregnancy is associated with an increased risk of congenital malformations and miscarriages. The Risk Evaluation and Mitigation Strategy (REMS) from the Food and Drug Administration recommends pregnancy screening at routine follow-up visits. However, there is currently no standardized method of ensuring routine pregnancy screening. After a patient required pregnancy termination due to major fetal abnormalities, this quality improvement project sought to improve physician adherence in pregnancy screening for female patients on mycophenolate.

Methods: This project was conducted in the pediatric rheumatology clinic setting at a single tertiary care center. Female patients age 10 and older prescribed mycophenolate mofetil or mycophenolic acid were included in the study. Process mapping was utilized to identify potential areas of improvement. Two Plan-Do-Study-Act (PDSA) cycles were completed. The identified intervention included leveraging the electronic medical record through the development of a Best Practice Advisory (BPA) tool (Figure 1). The BPA alert was designed to prompt ordering of a urine human chorionic gonadotropin (hCG) test for female patients age 10 and older prescribed mycophenolate. The current PDSA cycle included analysis from March 2018 to March 2019, and missed opportunities for pregnancy screening were identified. A missed opportunity was defined as an encounter where mycophenolate was prescribed but a urine hCG was not ordered within 7 days.

Results: At baseline, pregnancy screening was performed at 11% (8/71) of the encounters where mycophenolate was prescribed. Implementation of the BPA alert resulted in marked improvement in routine pregnancy screening to

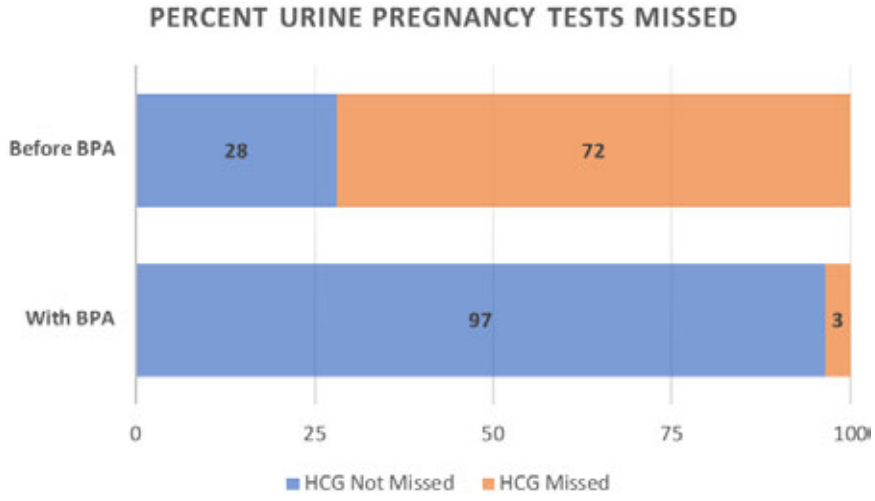

Figure 2. Significant reduction of missed opportunities for routine pregnancy screening after implementation of BPA alert.

79% (114/144, p< 0.00001). An opportunity for routine urine pregnancy screening was missed 72% (51/71) of the time at baseline. Implementation of the BPA alert resulted in reduction of the missed opportunities to 3% (5/144, p< 0.00001), shown in Figure 2. Authorization of a medication refill prior to the next visit was the most common reason for a missed opportunity. Analysis revealed that the BPA alert was not triggered if mycophenolate was prescribed outside a clinic visit.

Conclusion: Pregnancy screening in our female patients of childbearing age on a teratogenic medication is paramount. Effective utilization of an alert system embedded in the electronic medical record resulted in a striking improvement in routine urine pregnancy screening. This systems-based approach provides a sustainable infrastructure for improvement in patient care.

Improving Safe Prescribing of Hydroxychloroquine in a Safety Net Hospital Rheumatology Clinic

Francine Castillo ,[1] Michael Dodge,[1] Jung Hee Noh,[2] Laura Trupin,[1] Jinoos Yazdany,[3] and Sarah Goglin[3], [1]University of California, San Francisco, San Francisco, CA, [2]Zuckerberg San Francisco General Hospital, San Francisco, CA, [3]UCSF Division of Rheumatology, San Francisco, CA

Session Date: Sunday, November 10, 2019
Session Title: Measures Of Healthcare Quality Poster I: Testing, Screening, & Treating
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Hydroxychloroquine (HCQ) prescribing is standard of care for patients with SLE. The main potential side effect is retinal toxicity, especially at higher doses and with prolonged use. In 2016, the American Acad-

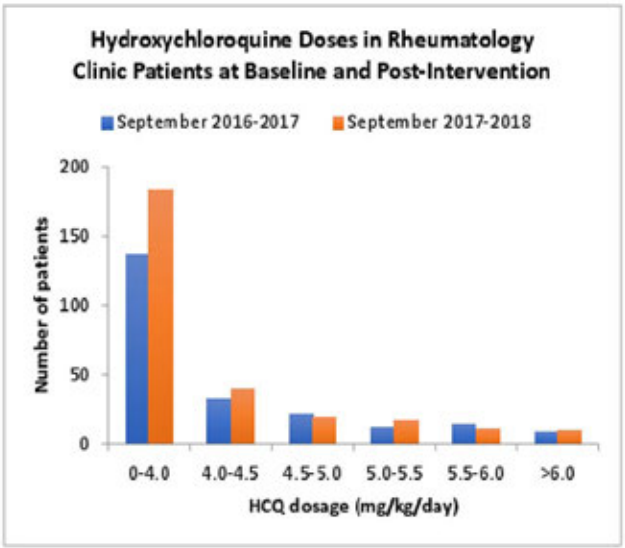

Figure 1. Distribution of hydroxychloroquine doses prescribed to rheumatology clinic patients in the periods prior to and after intervention.

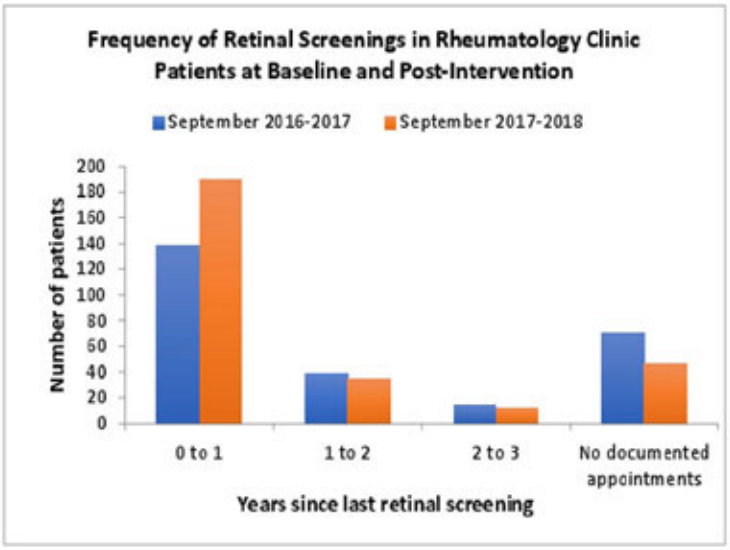

Figure 2. Frequency of retinal screenings among rheumatology clinic patients treated with hydroxychloroquine in the periods prior to and after intervention.

emy of Ophthalmology (AAO) modified its HCQ dosing and screening guidelines to recommend a maximum daily dose of 5 mg/kg of actual body weight and retinal examinations at baseline, then annually after 5 years of taking HCQ. We undertook a quality improvement project in a safety net rheumatology clinic that had two aims: 1) to increase the proportion of patients prescribed hydroxychloroquine at recommended doses from 85% at baseline to 95% and 2) to improve the proportion of patients receiving appropriate retinal screening from 52% at baseline to 80% at one year.

Methods: Using the Institute for Healthcare Improvement's Model for Improvement, we first mapped the existing clinical workflow for HCQ prescribing and monitoring. We developed and applied two process measures to track our progress: the proportion of patients prescribed hydroxychloroquine receiving a dose less than or equal to 5 mg/kg at their last encounter and the proportion of patients prescribed hydroxychloroquine at their last encounter with a retinal screening test over the last 18 months. After identifying baseline values for our two process measures, we worked with clinicians and clinic support staff over four Plan-Do-Study-Act (PDSA) cycles to develop our intervention. The final optimized workflow involved the clinic's nurse using a weekly report to identify patients who were overdue for retinal screening for an ophthalmology referral and to alert physicians whose patients were on a higher than recommended dose of HCQ. In September 2018, we queried the electronic health record again for data on our clinic's adherence rates to AAO guidelines between September 2017 to August 2018 to analyze the impact of our intervention.

Results: The percentage of clinic patients prescribed HCQ at doses less than 5.0 mg/kg daily increased from 84% to 86% during the study period, and the percentage receiving retinal screening increased from 64% to 76%. Of note, only 8 out of the 243 SLE patients on HCQ with a rheumatology office visit in 2018 did not have an ophthalmology appointment scheduled. The remainder of those that did not have retinal screening had an ophthalmology appointment scheduled, but either cancelled or did not appear to their appointments.

Conclusion: Using the Model for Improvement, we were able to develop and integrate an intervention to increase adherence to the AAO recommendations for HCQ dosing and retinal screening measures, although we fell short of our pre-specified improvement goals. Although the intervention has been moderately effective at improving patient safety practices for this drug, efforts are ongoing to further understand barriers to further improvement, including root cause analysis of individual-level and systems-level factors.

A Pragmatic Randomized Trial to Improve Safe Dosing of Hydroxychloroquine

Milena Gianfrancesco ,[1] Sara Murray,[1] Michael Evans,[2] Gabriela Schmajuk,[3] and Jinoos Yazdany[4], [1]University of California, San Francisco, San Francisco, [2]University of California San Francisco, San Francisco, [3]UCSF, SFVAMC Division of Rheumatology, San Francisco, CA, [4]UCSF Division of Rheumatology, San Francisco, CA

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Measures Of Healthcare Quality Poster I: Testing, Screening, & Treating
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Although generally well tolerated, the long-term use of hydroxychloroquine (HCQ) may lead to irreversible and potentially vision-threatening retinal toxicity. The American Academy of Ophthalmology (AAO) issued guidelines in 2011, and again in 2016 that recommended dosing HCQ based on an individual's body weight, and also outlined how and when to screen for retinal toxicity. While providers have been aware of the potential side effects of HCQ for decades, studies have shown that many patients continue to receive higher than recommended doses. We conducted a pragmatic randomized trial to assess the utility of a new e-prescribing (eRX) interface to support appropriate dosing of HCQ.

Methods: Rheumatology providers at a large university health center were randomized into either an intervention (n=12) or control (n=12) group. In the intervention group, providers were presented with an eRX interface which automatically pulled in a patient's weight from the electronic health record each time a new order for HCQ was entered. A suggested HCQ dosage was provided in accordance with the 2016 AAO recommendation, defined as ≤ 5.0 mg/kg (Figure 1). The interface rounded dosage to the nearest half tablet. The control group received no change to the standard ordering interface. Chi-squared tests were used to compare the proportion of all HCQ prescription dosages > 5.0 mg/kg prior to (May 1, 2016-April 30, 2017) and all new orders after eRX implementation (May 1, 2017-April 31, 2019). Mixed effects models were used to examine the association between group assignment and HCQ dosage > 5.0mg/kg, controlling for patient factors and clustering by provider.

Results: A total of 551 patients contributed 1,664 HCQ prescription orders. Most patients were white (62%) and female (87%), with a mean age of 43.2 (+/- 18.5). Prior to the eRX intervention, 69% of HCQ orders were within guidelines across groups. We found no significant difference between groups with respect to the proportion of prescribed dosages > 5.0mg/kg both before and after the eRX implementation (p=0.71 and p=0.45, respectively) (Table 1). After introduction of the eRX interface, the intervention group prescribed 32% of HCQ prescriptions at higher than recommended doses, similar to the control group (29%). The null association remained after controlling for patient level

Table 1. Characteristics of individuals prescribed HCQ before and after implementation of a new eRX interface

	Intervention Group	Control Group	p-value
Patient Characteristics			
Female	191 (89%)	288 (86%)	0.29
Non-white	75 (35%)	136 (40%)	0.19
Age	45.7 (± 15.2)	41.6 (± 20.3)	0.01
*Pre-Intervention (before May 1, 2017)**			
HCQ Dosage (mg/kg)	4.4 (± 1.7)	4.3 (± 1.7)	0.90
Proportion HCQ Doses > 5.0 mg/kg	32%	31%	0.71
*Post Intervention (after May 1, 2017)***			
HCQ Dosage (mg/kg)	4.5 (1.5)	4.5 (1.5)	0.78
Proportion HCQ Doses > 5.0 mg/kg	32%	29%	0.45

*New orders and reorders
**New orders only

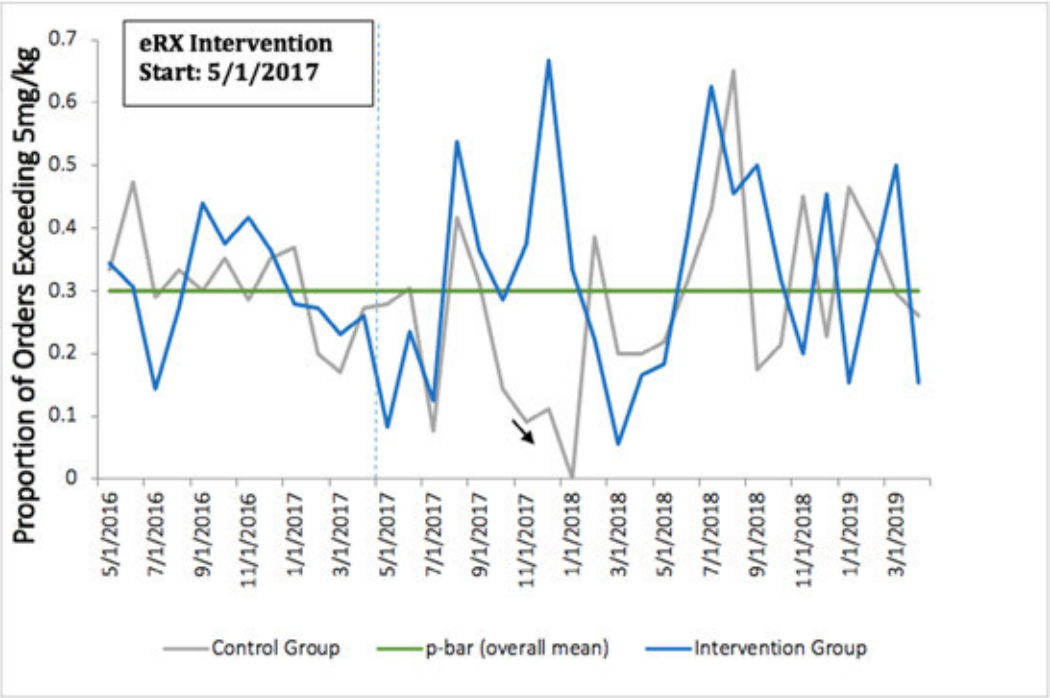

Figure 1. P-Chart demonstrating the proportion of HCQ orders exceeding 5mg/kg over the study period.

factors and clustering by provider. Our control chart also did not show any significant change in prescribing patterns over time (Figure 1).

Conclusion: This study demonstrates that the eRX interface in its current state was insufficient to significantly reduce HCQ dosing to levels recommended in current guidelines. However, the small sample size, rounding of dosage to nearest half tablet, and restriction to new HCQ orders may have limited our ability to detect differences between groups. Additional iterations of the eRX interface should address these issues. Qualitative studies could also help elucidate reasons for lack of improvement, including clinical reasons such as uncertainty about guideline cutpoints or concerns about efficacy, or implementation issues such as the design of the eRX interface and associated workflows.

Background/Purpose: Research has shown potential retinal toxicity rates from HCQ as high as 7.5%. Research suggests toxicity is dose-related. In 2016, the American Academy of Ophthalmology (AAO) issued weight-based guidelines for HCQ dosing recommending that daily dose not exceed 5 mg/kg. Two years into the guideline's release, we analyzed our institution's HCQ prescribing habits and opinions on these guidelines.

Methods: We collected cross-sectional data from all prescribers in rheumatology and dermatology, from all patients with an active hydroxychloroquine prescription in a 20-month period (June 2017 – January 2019). We collected sex and the most current weight. We grouped and compared patients according to weight-based HCQ dose. Concurrently, we constructed and administered a multiple-choice survey to gauge understanding and perceived utility of these guidelines. Survey responses were compared using Fisher's exact test with an assigned p-value < 0.05.

Results: We reviewed 1,128 rheumatology charts. 778 (69%) were prescribed ≤ 5 mg/kg. 80% were female. 277 (25%) were prescribed 5.1 - 6.5 mg/kg. 92% were female. 73 (6%) were prescribed ≥ 6.6 mg/kg. 96% were female. We reviewed 284 dermatology charts. 172 (61%) were prescribed ≤ 5 mg/kg. 71% were female. 77 (27%) were pre-

Figure 1. Hydroxychloroquine dose ≥ 6.6 mg/kg

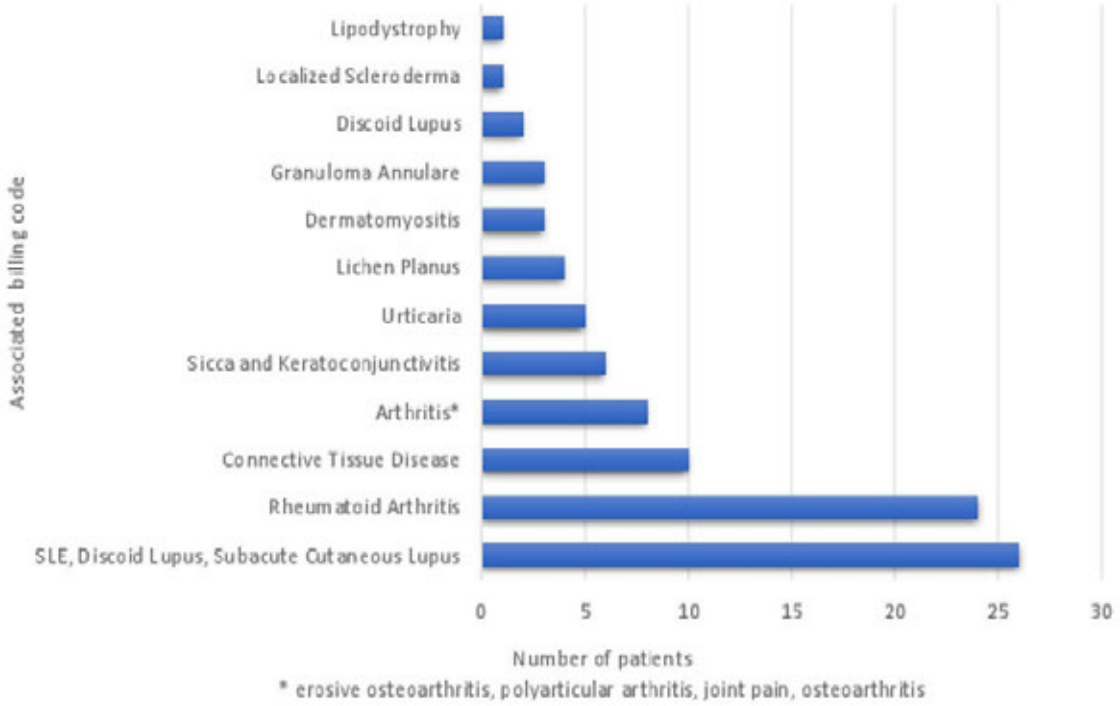

Figure 2. Survey responses

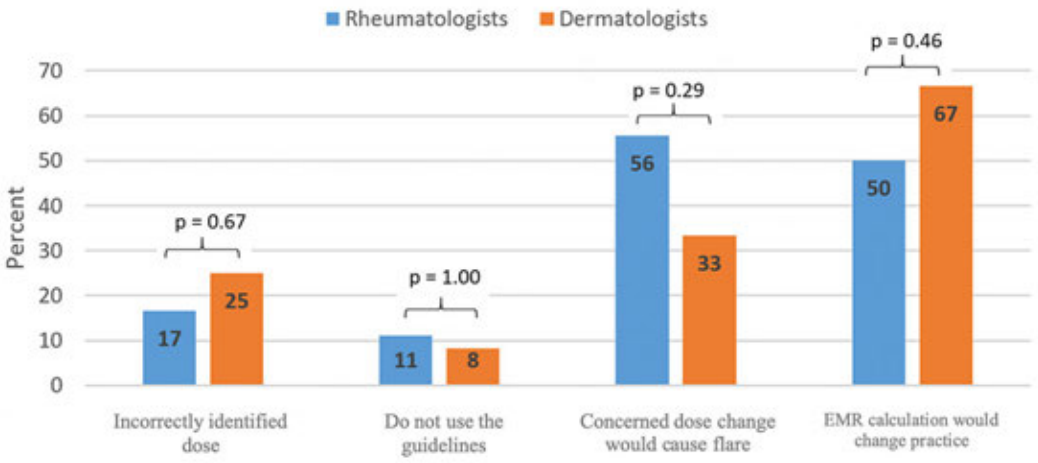

scribed 5.1 - 6.5 mg/kg. 81% were female. 35 (12%) were prescribed ≥ 6.6 mg/kg. 94% were female (Table 1). In rheumatology patients with HCQ dose ≥ 6.6 mg/kg, use was most often for rheumatoid arthritis and systemic lupus erythematosus (SLE). In dermatology patients, indications for this higher dose included SLE, lichen planus, discoid lupus, dermatomyositis, and urticaria (Figure 1). We compiled 18 surveys from rheumatology and 12 surveys from dermatology. 3 (17%)/3 (25%) incorrectly identified the recommended weight-based dose. 2 (11%)/1 (8%) said they did not use these guidelines in their practice. 10 (56%)/4 (33%) were concerned that changing HCQ dose based on these guidelines would lead to disease flares. 9 (50%)/8 (67%) reported that if their electronic medical record (EMR) automatically calculated a weight-based dose that this would change their practice (Figure 2). There were no statistically significant differences in the survey responses between the subspecialties.

Conclusion: Despite prescribers' declared familiarity with the 2016 recommendations regarding weight-based dosing of HCQ, and the belief that they are using these guidelines, HCQ doses often exceeded the recommended daily dose (33%). Survey data suggests that this discordance may be due to concern for causing disease flares. This could also suggest a gap between intended practice and actual practice that could be attributed to guideline misunderstanding or lack of knowledge of these guidelines. Findings are similar in rheumatology and dermatology settings. Smaller patients, and presumably therefore women, are more often prescribed a higher and potentially toxic weight-based dose. Further research should be a combined effort of rheumatology, dermatology and ophthalmology to explore tools, including EMR interventions, for bridging this gap between perceived guideline use and "real-world" implementation.

Abstract Number: 0321

Adherence to Weight-Based Dosing Guidelines in Patients Receiving Hydroxychloroquine for Rheumatoid Arthritis and Systemic Lupus Erythematosus

Tara Skorupa ,[1] and Robert Shmerling[1], [1]Beth Israel Deaconess Medical Center / Harvard Medical School, Boston, MA

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Measures Of Healthcare Quality Poster I: Testing, Screening, & Treating
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Hydroxychloroquine (HCQ) is a commonly prescribed medication for systemic lupus erythematosus (SLE), rheumatoid arthritis (RA) and other rheumatic diseases. However, HCQ may cause retinal toxicity leading to permanent vision loss. The risk of HCQ-related retinopathy correlates with both daily dose and duration of use[1]. In addition to screening ophthalmologic examinations, the most recent guidelines by the American Academy of Ophthalmology recommend limiting the dose of HCQ to 5mg/kg/day of actual body weight[1]. The goal of this study was to determine the proportion of patients in our practice receiving HCQ in compliance with these recommendations.

Methods: We performed a single-center retrospective analysis of 1066 adult patients receiving HCQ for SLE or RA in our rheumatology practice at Beth Israel Deaconess Medical Center between January 1, 2018 and December 1, 2018. To account for "loading dose" adjustments just after beginning the medication, we included only patients who had two rheumatology provider interactions separated by at least 6 months. For patients who stopped taking the drug, the reason for discontinuation was noted but these patients, patients who were lost to follow up, and those who died during the period of study were excluded from the dosing analysis. For each provider interaction, we collected the patient's HCQ dose and weight. We used this data to calculate the daily weight-based dose at each time point.

Results: 830 patients met inclusion criteria: of these, 181 (22%) had weight-based doses above the current recommended dose of 5mg/kg/day. 35 (4%) patients had doses above 6.5mg/kg/day (a cut-off suggested by older guidelines). Of the 81 patients who discontinued HCQ during the period of study, the most commonly cited reasons for discontinuation were medication ineffectiveness (27%), de-escalation of therapy (19%), gastrointestinal side effects (14%), and retinal changes (6%).

Conclusion: At least 2 years after the publication of updated HCQ dosing guidelines, 22% of our patients were taking a dose that was higher than recommended by current guidelines. Further analysis is underway to understand the reason(s) for these finding and to provide feedback that may lead to higher compliance. In addition, we hope to study the impact of these new guidelines on retinal toxicity and the effectiveness of HCQ within our practice.

Hydroxychloroquine Retinal Screening and Dosing in an Unique Rheumatologic Patient Population

Leanna Wise ,[1] Stavros Savvas,[2] and Elizabeth Ortiz[2], [1]LAC+USC/Keck Medicine of USC, Los Angeles, CA, [2]LAC+USC/Keck Medicine of USC, Los Angeles

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Measures Of Healthcare Quality Poster I: Testing, Screening, & Treating
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Hydroxychloroquine (HCQ) is used in many rheumatologic diseases. The American Academy of Ophthalmology (AAO) put forth guidelines in 2012 regarding retinal screening and dosing in regards to HCQ. These include a retinal exam in the first year after initiation of HCQ and a maximum dose of 5mg/kg/day of actual body weight. The Los Angeles County + University of Southern California Medical Center (LAC+USC MC) serves a largely underinsured urban population and is associated with an academic institution. LAC+USC MC utilizes an online third-party system for ophthalmology referrals. Our aim is to evaluate the LAC+USC MC rheumatology clinic's effectiveness at pursuing ophthalmologic care for HCQ patients and adhering to the appropriate dosing recommendations put forward by the AAO.

Methods: This is a retrospective chart review of rheumatology clinic patients prescribed HCQ in the LAC+USC MC rheumatology clinic. Charts of patients with clinic visits between March 2018 and May 2018 were reviewed. Patients were included if they had a clear first-time HCQ initiation date. Gender, age, ethnicity, diagnosis, prescribed dose and recommended weight-based dose of HCQ, and date of ophthalmology referral and exam were noted. Fisher's exact test was used for statistical analysis to see if there was any difference in screening or dosing between different groups of patients.

Results: One hundred and thirty-eight patients qualified for analysis. They were predominantly female (121; 87.7%). Average age was 45.7 (range 18 – 88). Forty-two (30.4%) had lupus, 55 (39.9%) had rheumatoid arthritis, and 41 (29.7) had . Of the 138 patients, 30 (21.7%) received ophthalmologic assessment within the first year of HCQ use. Of the remaining patients who were not screened, 97 patients (89.8%) lacked a timely referral to ophthalmology. Thirty-nine (28.3%) patients were prescribed a HCQ dose higher than the AAO guidelines; the average amount in excess of the recommended dose was 24.3% (range 1-122%). The rheumatoid arthritis patients tended towards lower rates of screening; however, this was not statistically significant.

Conclusion: To our knowledge, this is the first review that has evaluated compliance to AAO recommendations for HCQ retinal screening and dosing in an underserved population at an academic institution. Our findings are congruent with the literature, which demonstrate that providers are not meeting the guidelines for ophthalmologic screening when prescribing HCQ. Additionally, a large proportion of our patients are prescribed more than the recommended HCQ dose. It is important to note that a lowest effective dose of HCQ has not been established for the various rheumatologic conditions for which it is used, and at times, there may be a need for a higher than recommended dose for any particular patient. We hope to use this data to better pinpoint barriers rheumatologists face when following the AAO guidelines. Given our results, possible difficulties include a cumbersome referral system, a lack of knowledge about the guidelines, or difficulty with individualized dosing. Educating providers on AAO guidelines and working with third party referral systems to ensure ease of referrals could help providers meet recommendations.

Abstract Number: 0323

Compliance with Hydroxychloroquine Dosage According to 2016 American Academy of Ophthalmology (AAO) Guidelines: A Study with 6591 Patients

Thein Swe ,[1] and Andras Perl[1], [1]SUNY Upstate Medical University, Syracuse, NY

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Measures Of Healthcare Quality Poster I: Testing, Screening, & Treating

Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Hydroxychloroquine (HCQ) induced retinal toxicity remains a major concern because it can lead to irreversible damage to retinal pigment epithelium and blindness. American Academy of Ophthalmology (AAO) 2016 guidelines recommend to use HCQ at dosages ≤5 mg/kg real body weight to minimize toxicity [1]. Important risk factors for retinal toxicity are daily and cumulative dosage of HCQ, duration of treatment, patient age and concomitant renal or liver diseases [1].

Methods: This is a quality improvement project, a retrospective electronic medical records (EMR) review of patients who have been treated with HCQ since April 2016 through February 2019 at the State University of New York Upstate Medical University. Primary outcome was to identify patients whose dose exceeded the recommended dosage (≤5 mg/kg real body weight) according to 2016 AAO guidelines. Data on cumulative dosages, real body weight, height, age, adherence to the screening ophthalmologic exams within the last 5 years and concomitant renal or liver disease were extracted from EMR. Importantly, we also identified the details of number of patients who were discontinued HCQ use due to retinal toxicity.

Results: A total of 6591 patients on HCQ were identified. The average age was 50 years. Most common indications for HCQ usage were 33% for systemic lupus erythematous, 32% for undifferentiated connective tissue disease, 15.5% for rheumatoid arthritis. 2036/6591 (30.8%) patients were receiving more than 5 mg/kg/day of HCQ. 827/6591 (12.5%) patients had eye exams. Eight patients (0.96%) were diagnosed with HCQ induced retinal toxicity by ophthalmologists (Table 1) and discontinued HCQ. Among eight patients with retinal toxicity, 6 patients were taking > 5 mg/kg/day real body weight of HCQ. Their cumulative dosage ranged from 511 grams to 1,168 grams. Two patients have comorbid chronic kidney disease and two other patients have deranged liver function tests. Their duration of HCQ therapy ranged from 3 years to 8 years. The more than 5 mg/kg/day dosages were associated with increased retinal toxicity {chi-square = 5.378; p=0.02} (Table 2).

Patient	Age (in years)	Daily Dosage	Duration of use	Total Cumulative dose (grams)	Height (feet. inches.)	Weight	Daily mg/kg dosage	Overdose (>5 mg/kg/d real body weight of HCQ) Yes or No	Liver or Renal comorbidities (Present or Absent)
Patient 1	62	400 mg	5 years	730	5 ft	61 kg	6.55	Yes	Absent
Patient 2	32	400 mg	7 years	1,022	5ft 5in	62 kg	6.45	Yes	Absent
Patient 3	73	400 mg	5.5 years	803	5ft 2in	56 kg	7.14	Yes	Present (Deranged liver function tests)
Patient 4	36	400 mg	3.5 years	511	5ft 2 in	60 kg	6.66	Yes	Absent
Patient 5	41	700 mg	3 years	766	5ft 5in	103 kg	6.79	Yes	Absent
Patient 6	68	400 mg	7 years	1,022	5ft	46 kg	8.69	Yes	Present (Chronic kidney disease)
Patient 7	47	400 mg	6.1 years	890	5ft 3in	91 kg	4.39	No	Present (Chronic kidney disease)
Patient 8	62	400 mg	8 years	1,168	4ft 10in	89 kg	4.49	No	Present (Deranged liver function tests)

Table 1. Details of 8 patients who had HCQ induced retinal toxicity.

Table Analyzed	Data 1		
Chi-square			
Chi-square, df	5.378, 1		
P value	0.0204		
One- or two-sided	Two-sided		
Statistically significant? (alpha<0.05)	Yes		
Data analyzed	Number of patients who are taking ≤5 mg/kg of HCQ	Number of patients who are taking >5mg/kg of HCQ	Total
Retinal toxicity +	2	6	8
Retinal toxicity -	4553	2030	6583
Total	4555	2036	6591

Table 2. Chi- Square analysis of HCQ dosage and retinal toxicity

Conclusion: 69.2 % of patients were correctly administered HCQ with dosages based on the 2016 AAO guidelines. Retinal toxicity from HCQ is a rare phenomenon (0.96%) and apparently related to more than 5mg/kg/day of real body weight dosing. It is imperative to adjust the HCQ dosage according to body weight.

Adherence to Guideline Directed Management of Gout Among VA Providers

Kelly Corbitt,[1] **Isis Lopez** ,[2] and David Dillon[3], [1]University of Miami/Jackson Memorial Hospital, Miami, FL, [2]University of Miami/ Jackson Memorial Hospital, Miami, FL, [3]University of Miami/Jackson Memorial Hospital, Miami

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Measures Of Healthcare Quality Poster I: Testing, Screening, & Treating

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Gout is the most common inflammatory arthritis, affecting about 4% of the adult population in the United States. Management is often costly, with estimates around one billion dollars in yearly spending. The American College of Rheumatology recommends serum uric acid level (sUA) less than 6 mg/dL for the appropriate management of gout and prevention of recurrences. Despite the gout-related burden on the general patient population and its impact on the health-care system, guideline-directed management of patients with gout remains inconsistent among general practitioners. The degree to which general practitioners at the Miami VA adhere to guideline-directed management of veterans with gout is unknown – understanding discrepancies in care of veterans with gout

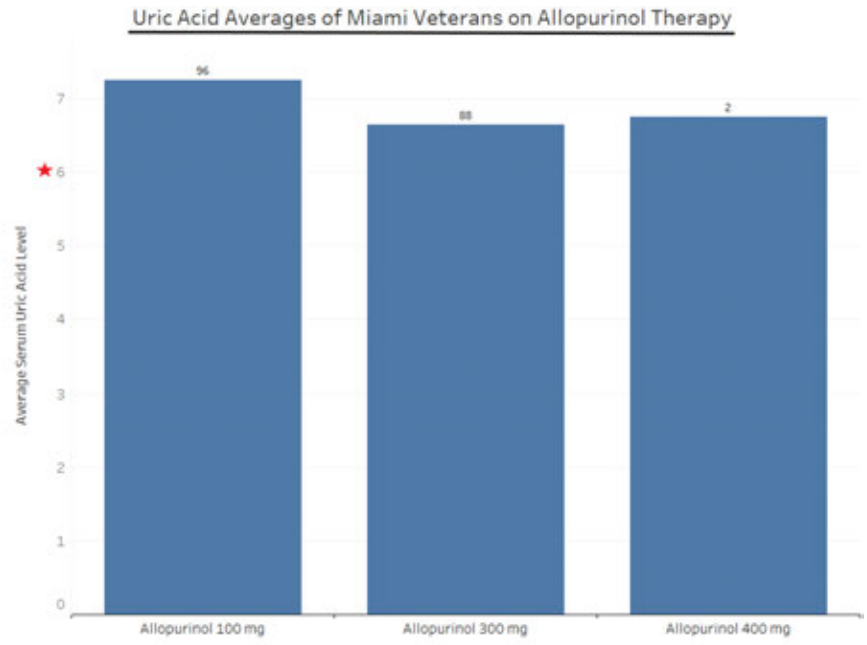

Figure 1. Average Uric Acid levels for varying Allopurinol tablet dosages

can allow us to formulate and implement quality improvement projects to address these deficiencies and standardize care.

Methods: Retrospective chart review of veterans seen at the Miami VA primary care outpatient clinics was performed by searching ICD-9 and ICD-10 codes (274 and M10, respectively) between the years of 2017 to 2018. Patients not seen by a general practitioner within the last year were excluded. The dose of uric acid lowering drugs, as well the value and date of the last serum uric acid level were recorded. Descriptive analysis of these data points was conducted.

Results: We identified 398 veterans with an ICD-9 or 10 diagnosis of gout managed by primary care providers, out of which 186 veterans were prescribed allopurinol. Of the 186 veterans prescribed allopurinol, 96 veterans were on 100 mg daily dosing, 88 veterans on 300 mg daily dosing, and 2 veterans on 400 mg daily dosing. The average sUA of veterans on the 100 mg dosing was 7.24 mg/dL, the average sUA level on the 300 mg dosing was 6.64 mg/dL, and the average sUA on the 400 mg dosing was 6.75 mg/dL.

Among the 398 veterans with a diagnosis of gout, 171 of them had sUA checked in the past year, with an average sUA value of 6.94 mg/dL, irrespective if they were on allopurinol therapy. Of the 186 patients on allopurinol, 36% (67 patients) had no sUA level obtained over a one-year span to assess uric acid lowering response.

Conclusion: Our results reveal that adherence to guideline-directed management of veterans with gout is lacking. We found that a large number of veterans with gout did not have a follow-up sUA level over a one-year span, while

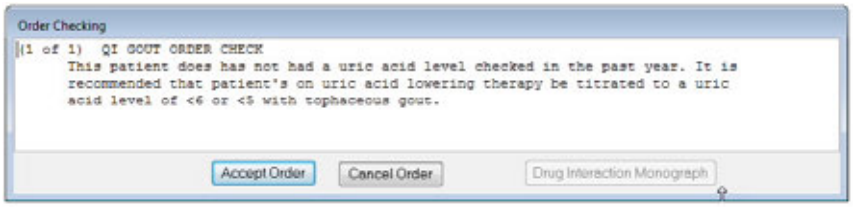

Image 1. Order check prompting primary care provider to order uric acid level

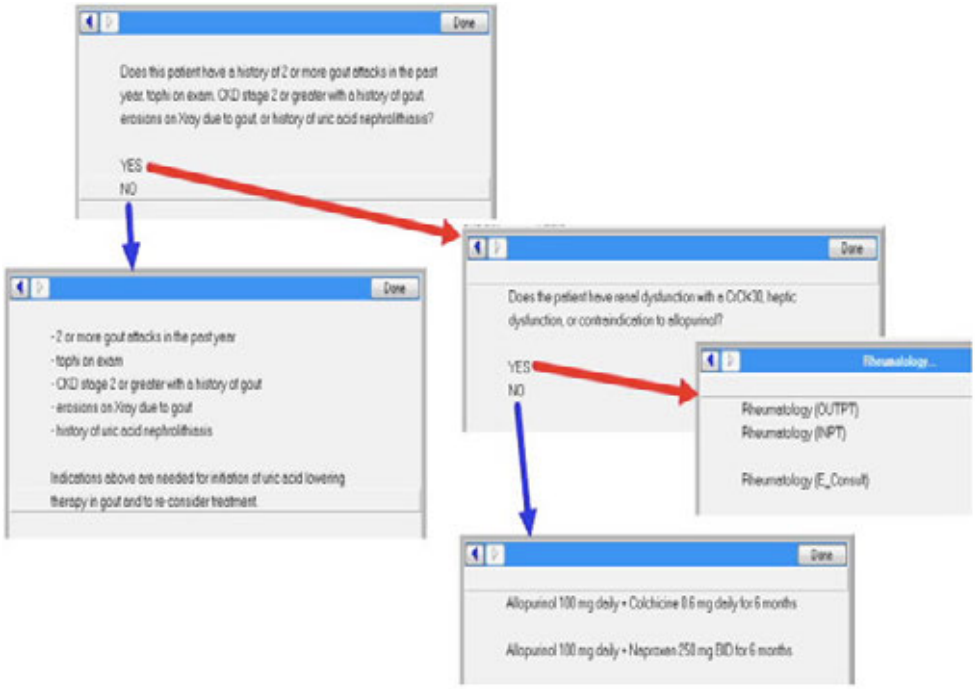

Figure 2. Order set for initiating uric acid lowering therapy for primary care providers

among veterans whose sUA levels were recorded, the average sUA level failed to meet the guideline-accepted sUA level of less than 6 mg/dL, irrespective of allopurinol dosage. In an effort to improve standardization of care for the management of gout among our patients, several quality improvement measures were developed. First, an electronic alert in the VA electronic medical record was created to prompt primary care providers to order a repeat sUA when attempting to place a refill for urate lowering medications if this was not ordered within the year. The goal for sUA level is also displayed via the alert system. An order set has also been developed to assist providers in initiating uric acid lowering agents that includes sUA checks at appropriate intervals. We hope that implementation of these quality improvement measures will lead to improved management of veterans with gout.

Frailty and Sarcopenia in Inflammatory Rheumatic Disease

Elisa Trujillo ,[1] Antonio Aznar,[2] Hiurma Sanchez,[1] Marta Hernandez,[1] Alicia García,[3] and Maria del mar Trujillo Martin[4], [1]Hospital Universitario de Canarias, Santa Cruz de Tenerife, Spain, [2]Hospital Universitario de Canarias, Santa Cruz de Tenerife, Canarias, Spain, [3]Hospital Universitario de Canarias, Santa cruz de Tenerife, [4]Servicio de Evaluación y Planificación, Fundación Canaria de Investigación Sanitaria (FUNCANIS) Red de Investigación en Servicios de Salud en Enfermedades Crónicas (REDISSEC)., Santa Cruz de Tenerife, Spain

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Measures Of Healthcare Quality Poster I: Testing, Screening, & Treating

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Sarcopenia, the loss of skeletal muscle mass, is associated with adverse individual physical and metabolic changes contributing to morbidity and mortality. Sarcopenia is a core component of physical frailty that together impact negatively on an individual's capability to live independently.

Sarcopenia and frailty are important problems among elderly individuals.

Although relationships between sarcopenia and various chronic inflammatory diseases have been shown, the role in rheumatologic disease is currently unknown. The aim of this study was to assess the prevalence of sarcopenia and frailty syndrome in patients with Rheumatoid arthritis (RA) and spondyloarthritis SpA).

Methods: Cross-sectional, observational and descriptive study in patients with RA and SpA (ACR and ASAS criteria) older than 50 years.

-Sarcopenia was defined as per the European Working Group on Sarcopenia in Older People definition as Skeletal muscle mass index (SMI) $\leq$ 8.87 kg/m^2 in men and $\leq$ 6.42 kg/m^2 in women. Body composition analysis was performed using bioelectrical impedance analysis (BIA): fat mass, fat-free mass and predicted skeletal muscle mass were collected. Skeletal muscle mass index (SMI) was calculated by appendicular skeletal muscle mass (sum of predicted muscle mass in all 4 limbs) divided by height squared.

- Fragility was measured according to the 5 criteria proposed by Fried, using the Frail scale, and it was considered fragile to the patient who met at least 3 and prefragiles to those who met at least 2.We applied the Frail Scale and registered data (demographic and diseased related data) using a cross-sectional, observational, and descriptive study design.

Frail scale: Based on five items, reflecting performance, selfreports and common co-morbidities (*Morley JE et al., J Nutr Health Aging. 2012;16(7):601-8*).

Did you feel worn out? or Did you feel tired?

Ability to climb one flight of stairs

Ability to walk 100 m

Self-report of >5% weight los

≤5 of: dementia; heart Disease; depression; arthritis; asthma;bronchitis/ emphysema; diabetes; hypertension; osteoporosis; stroke.

Results: 523 consecutive RA and SpA patients were included, 79.3 %) were female. Mean age was 55.4 years. Patients with spondyloarthritis were 39.3% ankylosing spondylitis, 31.6% psoriasis arthritis, 20.1% undifferentiated spondyloarthritis, 9% spondyloarthritis associated with inflammatory bowel disease.

Mean number of comorbidities was 1.47, with systemic hypertension and obesity as the most frequent ones (32.6 % and 27.1 %, respectively). Polypharmacy was found in 94.2 % and 63.9 % received more than five drugs simultaneously.

RA patients: 21.5 % met frailty criteria (42% in $\geq$ 65 years old patients). SpA patients:18.9% met frailty criterio (37% in $\geq$ 65 years old patients).

Conclusion: Prevalence of frailty in this study was high. Rheumatologists should make an early detection of signs of frailty.

The screenig and early detection of frailty can spur reforms to make routine care less hazardous, can focus on outcomes most relevant to patients and can aid in understanding effectiveness of health care interventions, including at the population level.

Abstract Number: 0326

Cardiac Sarcoidosis Awareness: Are We Underdiagnosing?

Yvonne Lee ,[1] Patil Injean,[1] and Mehrnaz Hojjati[1], [1]Loma Linda University Health, Loma Linda

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Measures Of Healthcare Quality Poster I: Testing, Screening, & Treating
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Sarcoidosis, a multiorgan granulomatous disorder, may involve the heart at any time and often presents with cardiac conduction disturbances, heart failure, and sudden death. 5% of patients with sarcoidosis have clinically significant cardiac involvement and up to 25% of patients have sub-clinical asymptomatic cardiac involvement. The prevalence of cardiac sarcoidosis (CS) may be higher than published statistics. We query the Loma Linda University Medical Center (LLUMC) patient database to investigate.

Methods: A single center retrospective analysis of patients with sarcoidosis from January 2014 to June 2019 at LLUMC was undertaken. Data collected included demographics, specialties involved, diagnostic tests such as cardiac magnetic resonance imaging (CMRI), positron emission tomography (PET) scan, and serologies.

Table 1: Baseline clinical features and initial organ manifestation

Patient Number	Initial organ manifestation of sarcoidosis	Method of sarcoidosis diagnosis	# Organ involvement prior to CS diagnosis?	# Year between diagnosis of sarcoidosis and CS	# Year between cardiac symptoms and diagnosis of CS	Initial Cardiac Manifestation
1	skin	skin biopsy	4	2	14	Heart Failure
2	pulmonary	lung biopsy	2	1	0	Heart Failure
3	skin	node biopsy	6	9	8	AV conduction abnormality
4	unknown	CT scan	1	18	unknown	Heart Failure
5	cardiac	lung biopsy	1	missed diagnosis	missed diagnosis	Heart Failure
6	pulmonary	node biopsy	1	3	3	Heart Failure
7	unknown	skin biopsy	1	9	11	Heart Failure
8	pulmonary	lung biopsy	3	4	1	Heart Failure
9	unknown	unknown	1	unknown	unknown	"stiff heart"
10	hypercalcemia	node biopsy	1	missed diagnosis	missed diagnosis	Heart Failure & AV conduction abnormality
11	pulmonary	node biopsy	4	3	1	Heart Failure
12	cardiac	unknown	3	0	1	AV conduction abnormality
13	gastrointestinal	liver biopsy	2	4	1	Chest Pain
14	cardiac	cardiac MRI	0	1	1	AV conduction abnormality

Table 2 : Methods and specialties involved in cardiac sarcoidosis diagnosis

Method of CS diagnosis	Specialty that suspected diagnosis of CS	After CS diagnosis, was rheumatology involved?	After CS diagnosis, was cardiology involved?	Cardiac MRI	Cardiac PET scan	Left Ventricular Ejection Fraction	EKG
PET scan	rheumatology	yes	yes	N/A	FDG +	15%	normal
Cardiac MRI	internal medicine	yes	yes	scarring	normal	60-65%	Abnormal*
Cardiac biopsy	unknown	yes	yes	N/A	N/A	55-60%	Abnormal*
unknown	rheumatology	yes	no	N/A	N/A	45%	N/A
missed diagnosis	missed diagnosis	missed diagnosis	missed diagnosis	N/A	N/A	35-40%	Abnormal+
unknown	unknown	no	yes	scarring	N/A	25%	normal
Echocardiogram	cardiology	no	yes	N/A	N/A	40%	Abnormal+
Cardiac MRI	unknown	yes	yes	scarring	FDG +	30%	Abnormal*
unknown	unknown	yes	yes	N/A	N/A	65%	Abnormal*+
missed diagnosis	missed diagnosis	missed diagnosis	missed diagnosis	N/A	N/A	50%	Abnormal*+
Cardiac biopsy	cardiology	yes	yes	N/A	N/A	45%	Abnormal*

Cardiac MRI	pulmonology	yes	yes	scarring	FDG +	55-60%	normal
Cardiac MRI	cardiology	no	yes	scarring	normal	70-75%	Abnormal*+

FDG - Fluorine-18-deoxyglucose; N/A – not applicable
* AV conduction abnormality
+ arrhythmia

Results: Out of 496 patients diagnosed with sarcoidosis, 14 patients had CS in accordance with the Heart Rhythm Society diagnostic criteria. The median age was 58, 2:5 male-to-female ratio, and an average body mass index of 30.3 of all 14 patients. 50% patients had Medicare insurance. 42.8% of patients were African American. 71.4% of patients had biopsy proven diagnosis of sarcoidosis. 93% had other sarcoidosis organ involvement at the time of CS diagnosis (Table 1).CS was the only manifestation of sarcoidosis in 1 patient. 0% had another autoimmune disease. The average time between diagnosis of sarcoidosis and CS was 5 years and the average time between cardiac symptoms and diagnosis of CS was 4 years (Table 1). 64% had heart failure, 29% had AV conduction abnormality, and 4 patients had arrhythmias on presentation (Table 1).

14.3% of patients met the diagnostic criteria of CS but the diagnosis was missed. Out of 7 patients diagnosed with CS at LLUMC, cardiologists, rheumatologists, pulmonologist, and internists were the first to suspect diagnosis of CS in 3, 2, 1, and 1 patients, respectively (Table 2). There was an increase in specialty consultations after diagnosis of

Table 3: Serologies

Troponin	CKMB	pro-BNP	Hemoglobin	ESR	CRP
normal	normal	elevated	decreased	normal	normal
elevated	normal	elevated	decreased	elevated	elevated
N/A	normal	Elevated	decreased	elevated	elevated
N/A	N/A	Normal	normal	elevated	elevated
normal	normal	Elevated	decreased	normal	normal
normal	N/A	Elevated	decreased	N/A	N/A
N/A	N/A	N/A	normal	normal	N/A
N/A	N/A	Elevated	decreased	normal	normal
elevated	normal	Elevated	normal	elevated	elevated
elevated	normal	Elevated	decreased	elevated	N/A
normal	N/A	elevated	normal	normal	normal
N/A	N/A	N/A	N/A	N/A	N/A
normal	N/A	N/A	normal	N/A	N/A
normal	N/A	elevated	decreased	normal	normal

CS. Out 14 patients, 93% were followed by cardiology and 57% were followed by rheumatology after the diagnosis of CS; this was an increase from 90% and 14%, respectively. 42.8% had abnormal CMRI and 42.8% had abnormal PET scans. Only 2 patient's diagnosis was confirmed by cardiac biopsy. Additionally, 57% had ejection fraction (EF) reduction only explainable by their CS diagnosis (Table 2).

Most patients with CS had an elevated Pro-BNP (71%), low hemoglobin (61.5%), and/or elevated ESR (45%) at the time of diagnosis (Table 3).

Conclusion: A high clinical suspicion is warranted for prompt diagnosis of CS, since missed diagnosis is possible. Patients with multisystem sarcoidosis involvement should be evaluated for CS. Abnormal EKG followed by low EF or new onset heart failure was the most frequent finding in our cohort of CS at the time of diagnosis. CMRI and PET Scan are useful diagnostic modalities and diagnosis of CS was confirmed in 42.8% of patients using one of these 2 modalities. Serologies are less helpful in diagnosing CS. Cardiologists are at the forefront of diagnosing CS and there needs to be improved rheumatology awareness for screening CS. Multidisciplinary collaboration between subspecialties is important in the diagnosis of CS.

Abstract Number: 0327

Presentation Order Bias in Rheumatology Journals: A Content Analysis

Sarah Stewart ,[1] Greg Gamble,[2] Andrew Grey,[2] and Nicola Dalbeth[2], [1]University of Auckland, Auckland, Auckland, New Zealand, [2]University of Auckland, Auckland, New Zealand

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Measures Of Healthcare Quality Poster I: Testing, Screening, & Treating
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Presentation order can influence the prominence of an academic article. Earlier-listed items or those at the top of tables of contents are more likely to be seen and read, and the serial ordering of articles within a journal issue can influence article citations over many years. The aim of this study was to analyse what rheumatology journals prioritize through the presentation order of research articles within journal issues.

Methods: A content analysis of original articles published in general rheumatology journals from 2013-2018 was undertaken. All included journals produced regular issues, reported original research, and had 2016 Thomas Reuters Impact Factor > 3.0. The following data were extracted: gender of first and last author, country of origin, industry funding, and disease category. Analysis of the overall distribution of article placement within issues was computed using cumulative density function plots and area under the curve (AUC) analysis. The odds ratio (OR) for articles published in one of the first three places of an issue compared with one of the last three places was also calculated. Downloads and altmetrics were analysed.

Results: A total of 6,787 articles were included. There were no differences in presentation order based on gender, country of origin, or industry funding (Figure). However, there were significant differences in presentation order based on disease category (Figure). Articles about rheumatoid arthritis were more likely to be ordered towards the front of an issue ($P < 0.001$), and were more likely to be ordered in the first three places compared to the final three places (OR [95% CI] 5·77 [4·80, 6·92]). In contrast, articles about crystal arthritis, pain syndromes, pediatric rheumatic diseases,

systemic lupus erythematosus, systemic sclerosis, and vasculitis were more likely to be ordered at the end of the issue (P for all < 0.001). Journals presenting content grouped by disease category exhibited greater disease category prioritization compared to journals without disease category content groupings. Articles ordered in the first three places of an issue had higher download rate/article year (rate [95% CI] difference 441.9 [292.9, 591.0]) and mean altmetric scores (mean [95% CI] difference 4.88 [1.62, 8.15]), compared to articles in the last three places.

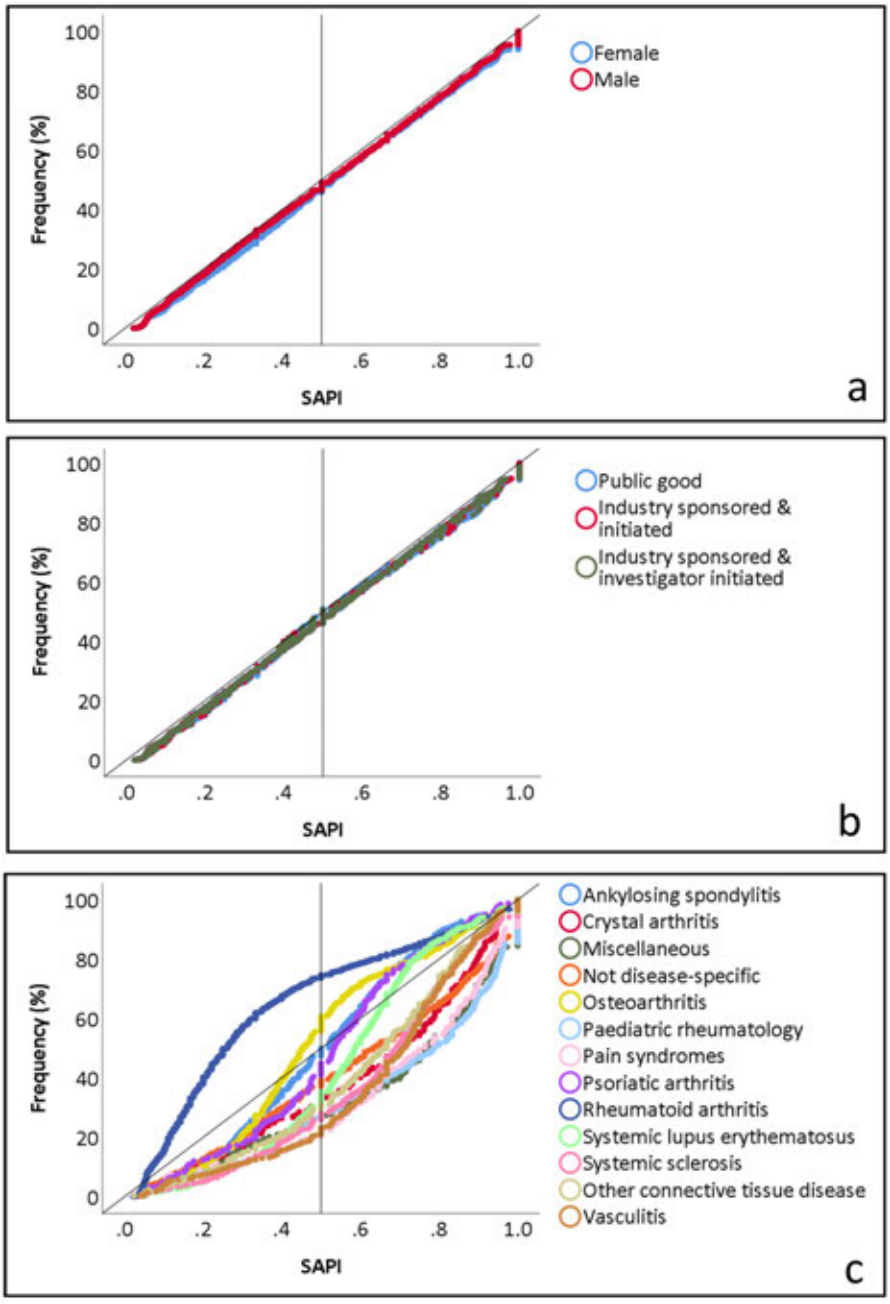

Figure. Cumulative distribution function plots of Standardised Article Placement Indices (SAPI) for (a) first author gender; (b) industry funding; and (c) disease categories. Left skewed distributions suggest publication prioritisation.

Conclusion: Contemporary rheumatology journals do not demonstrate presentation order bias for author gender, country of origin, or industry funding. However, differences in the presentation order of disease categories are evident. Editorial choices about the serial position of articles within journals can influence prioritization of certain rheumatic diseases.

Adverse Events During Colchicine Use: A Systematic Review and Meta-Analysis of Randomized Controlled Trial Events

Sarah Stewart ,[1] Kevin Yang,[2] Kate Atkins,[2] Nicola Dalbeth,[2] and Philip Robinson[3], [1]University of Auckland, Auckland, Auckland, New Zealand, [2]University of Auckland, Auckland, New Zealand, [3]The University of Queensland, Brisbane, Australia

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Metabolic & Crystal Arthropathies Poster I: Clinical
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Colchicine is a widely used drug used to treat rheumatic and inflammatory conditions. Due to its long historical use in medicine, controlled clinical trials of colchicine have been small, precluding clear understanding about safety profile. The aim of the study was to systematically examine the adverse event (AE) profile of colchicine in randomized controlled trials (RCTs) across all published indications.

Methods: A systematic search was undertaken using electronic databases and manual searching of reference lists. The analysis included double-blind RCTs that compared the effects of oral colchicine to placebo or active comparator. Trials were included if they reported the incidence of AEs per group. AE data were extracted under pre-defined categories: diarrhoea, gastrointestinal events (including diarrhoea), liver events, hematology events, muscle events, sensory events, infection events and death, and any reported AE. Meta-analyses were undertaken to determine the pooled risk ratios (RR) of AEs in the colchicine group compared to the placebo and/or active comparator groups. Subgroup analyses were used to explore the effects of disease indication, dose, and exposure duration.

Results: Thirty-two studies were included involving participants with liver diseases (n = 6), gout (n = 5), Bechet's and related conditions (n = 4), pericarditis and related conditions (n = 6), and other (n = 11). The pooled sample size was 3,774 participants. Any adverse event was reported in 26.6% of colchicine users compared to 20.9% of comparator groups, with an estimated risk ratio (RR) (95% confidence interval (CI)) of 1.72 (1.33-2.23) (**Table**). Sub-group meta-analyses showed no significant difference in RR of AEs in colchicine users between placebo and active comparator groups, or between different disease indications, duration of drug exposure, daily dose or cumulative dose. The RR (95% CI) in colchicine users compared to comparator groups for diarrhoea was 2.63 (1.67-4.16), and for any gastrointestinal AE was 1.97 (1.50-2.58), both $P < 0.001$. The RRs of liver, muscle (including myalgia, cramps, myotoxicity, and weakness), sensory, and infection AEs in colchicine users compared to comparators were not significant (**Table**). No study reported rhabdomyolysis, hematology AEs or deaths.

Table. Meta-analysis results showing pooled risk ratio of adverse events between colchicine and pooled comparator groups

	N. studies	n/N, % (95% CI) participants		Pooled risk ratio (95% CI)	I^2 (p-value)	Overall effect, Z (p-value)[a]
		Colchicine	Comparator			
Any event	26	437/1641, 26.6% (24.5, 28.8)	370/1773, 20.9% (19.0, 22.8)	1.72 (1.33, 2.23)	86% (<0.001)	4.16 (**<0.001**)
Diarrhoea	17	189/797, 23.7% (20.0, 26.8)	54/712, 7.6% (5.8, 9.7)	2.32 (1.51, 3.57)	39% (0.05)	3.83 (**<0.001**)
Gastrointestinal[b]	27	299/1744, 17.1% (15.4, 19.0)	121/1874, 6.5% (5.4, 7.6)	1.97 (1.50, 2.58)	29% (0.08)	4.88 (**<0.001**)
Liver	12	15/1129, 1.3% (0.8, 2.1)	11/1343, 0.8% (0.4, 1.4)	1.63 (0.76, 3.50)	0% (0.82)	1.24 (0.21)
Muscle[c]	8	33/851, 3.9% (2.7, 5.3)	23/850, 2.7% (1.8, 4.0)	1.41 (0.87, 2.30)	0% (0.90)	1.40 (0.16)
Sensory	2	3/201, 1.5% (0.4, 4.0)	2/190, 1.1% (0.2, 3.4)	1.35 (0.27, 6.74)	0% (0.58)	0.37 (0.71)
Infection	4	42/327, 12.8% (9.5, 16.8)	74/548, 13.5% (10.8, 16.6)	1.19 (0.65, 2.16)	47% (0.13)	0.55 (0.58)

[a]Bolded p-values indicate a significant overall effect in the risk ratio for an adverse event between colchicine and comparator groups. [b]The gastrointestinal category includes diarrhoea. [c]The muscle category includes myalgia, muscle cramps, myotoxicity, muscle weakness and elevated CPK. No study assessed or reported rhabdomyolysis.

Conclusion: Although AEs are more common with colchicine compared with placebo or active comparator, these relate mostly to well-recognized gastrointestinal AEs. Increased incidence of liver, sensory, muscle, infection, or haematology AEs or death was not observed.

Excessive Alcohol Intake Is Associated with Tophi Formation in Gout Patients

Qian-Hua Li,[1] Chao Deng,[1] Li-Juan Yang,[1] Jin-Jian Liang,[1] Jian-Zi Lin,[1] Ying-Qian Mo,[1] and **Lie Dai[1]**, [1]Department of Rheumatology, Sun Yat-Sen Memorial Hospital, Sun Yat-Sen University, Guangzhou, Guangdong, China (People's Republic)

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Metabolic & Crystal Arthropathies Poster I: Clinical
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Dietary factors have been recognized as risk factors of hyperuricemia and gout. However, their association with tophi formation remain elusive. The aim of this study was to identify the dietary factors associated with the presence of tophi in gout patients.

Methods: Consecutive gout patients who fulfilled the 2016 ACR/EULAR classification criteria were recruited from July 2017 to April 2019. A 10-items food frequency questionnaire was developed which included alcohol, red meat, animal offal, seafood, hotpot, slow-cooking soup, fructose-containing beverages (FCB), tea, coffee and milk/milk products. Patients were asked to report the average consumption frequency over the one year prior to the first gout

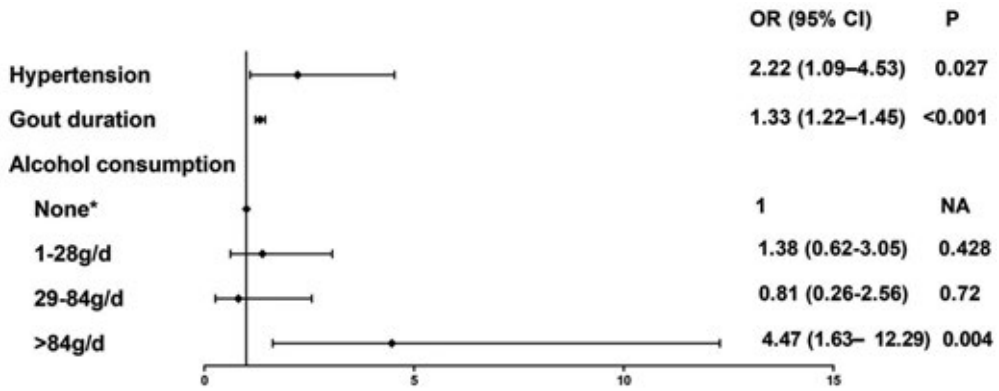

Figure 1. Risk factors of tophi formation by multivariate logistic regression analysis. Independent variables included age, gender, gout duration, sUA, eGFR, obesity, hypertension, diabetes, dyslipidemia, coronary heart disease and ten dietary factors. *: reference group.

attack. The alcohol intake was divided into four categories: none, 1-28 grams per day (g/d), 29-84 g/d, > 84 g/d. Intake of red meat was recorded as < 100 g/d, 101-200 g/d, 201-300 g/d and > 300 g/d. The consumption of other dietary factors were categorized as < 1 time/w, 1-2 times/w, 3-4 times/w, and > 4 times/w. Tophi was identified by physical examination, ultrasonography or dual energy CT.

Results: Among 430 recruited gout patients, 96.0% were male with median age of 39 (IQR 30-53) years and gout duration 3 (IQR 2-7) years. The median serum uric acid (sUA) was 9.3 (IQR 7.8-10.4) mg/dl. There were 14.0% gout patients consuming alcohol >84 g/d and 4.4% patients eating red meat >300 g/d. There were 41.4% patients drinking tea, 18.8% drinking FCB and 11.6% drinking slow-cooking soup >4 times/w, respectively. Tophi were identified in 77 patients (17.9%). Compared with non-tophi group , the tophi group presented higher age (median 47 vs. 38 years), longer gout duration (median 8 vs. 3 years), more affected joints (median 7 vs. 3), higher prevalence of hypertension (59.7% vs. 34.8%) and diabetes (18.2% vs. 8.5%), but lower estimated glomerular filtration rate (eGFR, 79.5±18.3 vs. 84.7±16.4 ml/min/1.73 m2, all P< 0.05). For dietary factors, there were more patients in tophi group consumed alcohol >84g/day (31.2% vs. 10.2%, P< 0.01). To evaluate the risk factors of tophi, multivariate logistic regression analysis was performed with independent variables including age, gender, duration of gout, sUA, eGFR, obesity, hypertension, diabetes, dyslipidemia, coronary heart disease and ten dietary factors, The result showed gout duration (OR=1.33, 95%CI: 1.22-1.45), hypertension (OR=2.22, 95%CI: 1.09-4.53) and alcohol intake >84g/day compared with those without alcohol intake (OR=4.47, 95%CI: 1.63-12.29) were associated with the presence of tophi (Figure 1).

Conclusion: Excessive alcohol intake may promote tophi formation.

Acute Gout Attacks Among Patients Admitted Due to Heart Failure: Analysis of NIS Database

Estefania Gauto-Mariotti ,[1] Soumyasri Kambhatla,[2] Setri Fugar,[3] and AUGUSTINE MANADAN[4], [1]Cook County Health, chicago, [2]John H. Stroger Hospital of Cook County, Chicago, [3]Rush University Medical Center, Chicago, IL, [4]Rush University Medical Center, chicago

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Metabolic & Crystal Arthropathies Poster I: Clinical
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Acute gout arthropathy is a well-described side effect of aggressive diuresis in patients hospitalized with heart failure. This study aims to determine the prevalence and predictors of acute gout attacks of patients admitted primarily for heart failure exacerbation as well as analyze its impact on health care resource utilization.

Methods: Data were obtained from the National Inpatient Sample (NIS) between 2009 and 2015. ICD-9-CM codes were captured to identify patients with a principal diagnosis of heart failure (ICD-9 428.x; 402.01, 402.11, 402.91; 404.01, 404.03, 404.11, 404.13, 404.91, 404.93) and a secondary diagnosis of acute gouty arthropathy (ICD-9 274.01). Outcomes measured were length of stay (LOS), inpatient total cost, and prevalence of acute kidney injury (ICD-9 584.x). Multivariable logistic regression was used to identify predictors of acute gout arthropathy.

Results: We identified a total of 1,130,374 patients (>18years) who were admitted for heart failure exacerbation over the study period with 4116 (0.4%) having an acute gout attack during that admission. Patients who developed gout were younger (67.9 vs. 61.7 years, P-value < 0.001) and had a higher prevalence of alcohol abuse, iron deficiency anemia, coagulopathy, diabetes, and obesity (all P< 0.05). With regards to the observed outcomes, acute kidney injury (AKI) rates were higher in patients who developed acute gout attacks compared to those who did not (43.8% vs. 22.0%, P< 0.001). Total hospital cost ($ 9,999 vs.$ 6,941; P< 0.001) and LOS (6 days vs. 4 days; P< 0.001) were higher in patients that had acute gout attacks.Of the patients with acute gout and heart failure, only 8.9% of them received either an intra-articular joint injection or arthrocentesis. Multivariable logistic regression revealed that some significant predictors of gout were chronic kidney disease (OR 2.43; 95% CI 2.27-2.60; P-value < 0.001), chronic alcohol use (OR 1.27; 95% CI 1.08 -1.49; P-value < 0.004), Obesity (OR: 1.84; 95% CI 1.71-1.98; P-value < 0.0001), dyslipidemia (OR 1.16; 95% CI 1.09-1.24; P-value < 0.001).

Conclusion: Inpatient gout attacks result in an increment of days of hospital stay, AKI rates, and total charges in patients hospitalized with heart failure exacerbation. CKD, chronic alcohol use, obesity, and dyslipidemia showed a statistically significant increase in the risk of development of gouty arthritis flare in heart failure patients. Intra-articular injections or arthrocentesis were not commonly done in these patients per coding records. Our analysis indicates acute gout during a hospitalization for heart failure negatively impacts health care resource utilization.

* Idiopathic gout diagnosis codes include ICD-10: M10.0* and M1A.0*

** Secondary gout diagnosis codes include ICD-10: M10.1*, M10.2*, M10.3*, M10.4*, M1A.1*, M1A.2*, M1A.3*, and M1A.4*

*** Unspecified gout diagnosis codes include M10.9* and M1A.9*

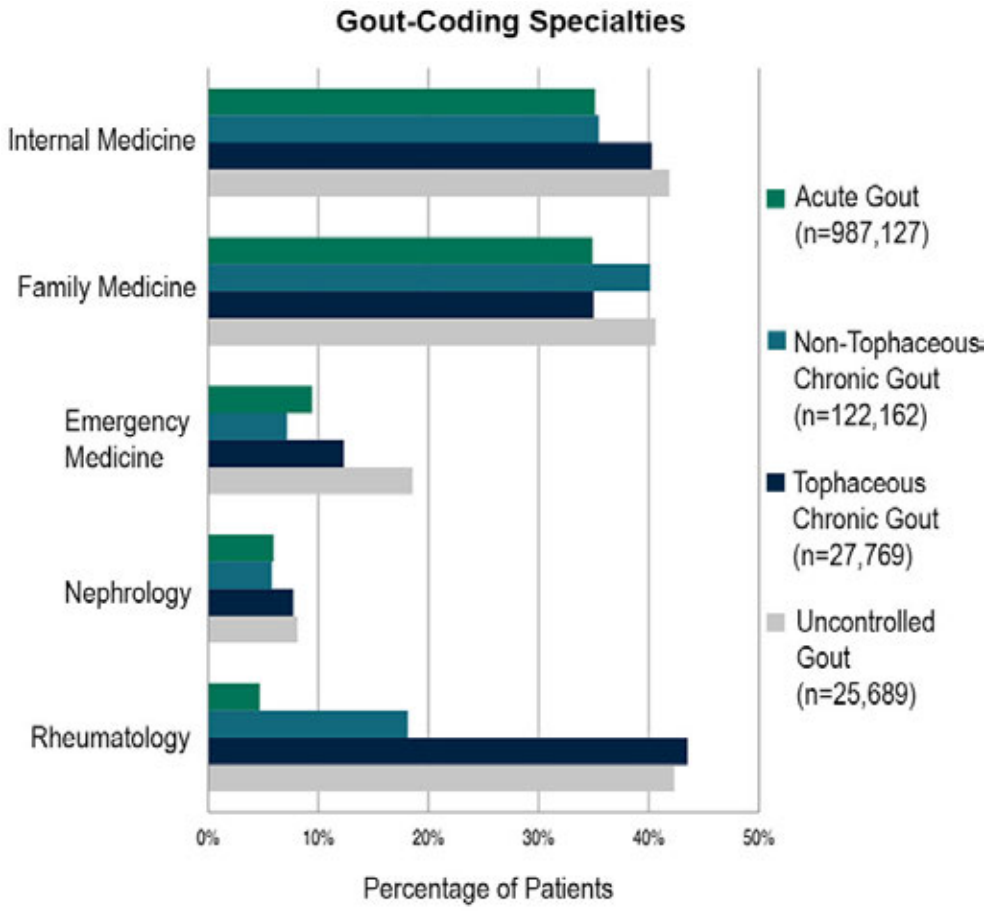

Figure 1. Frequency with which gout subsets are seen by various physicians.

Background/Purpose: Gout is one of the most common inflammatory arthropathies. Despite available urate lowering therapies (ULT), many patients progress to chronic or advanced gout, characterized by the development of tophi, chronic inflammatory arthritis, and other manifestations resulting from persistent urate deposition. Although numerous guidelines exist for the management of gout, there is little information on the frequency of their implementation in the medical community.

Population	Urate Tests / Year			ULT Prescriptions / Patient		
	With Rheumatology Visit	No Rheumatology Visit	p-value	With Rheumatology Visit	No Rheumatology Visit	p-value
Acute Gout	0.68	0.55	<0.001	5.66	4.27	<0.001
Non-Tophaceous Chronic Gout	0.93	0.59	<0.001	6.70	5.10	<0.001
Tophaceous Chronic Gout	1.35	0.75	<0.001	7.20	4.97	<0.001
Uncontrolled Gout	3.17*	3.12*	0.06	8.25	5.77	<0.001

* Definitional

ULT = urate lowering therapies

Table 2. Comparison of annual frequency of urate testing and urate lowering therapies in patients with or without a history of a rheumatology visit

The objective of this research was to evaluate the real-world practice patterns in patients diagnosed with gout using a large administrative claims database from the United States.

Methods: We carried out a retrospective analysis to identify patients with gout over an approximately 6-year period from October 2012 to August 2018. This study used data from the Symphony Integrated Dataverse, an administrative database covering over 250 million patients across the United States. Patients were identified as having gout if they were >18 years of age and had at least two medical claims for the diagnosis of gout on different days, separated by at least 3 months. Patients with acute gout were identified by ICD-10 code M10.*, chronic non-tophaceous gout (M1A.***0), tophaceous gout (M1A.***1) and uncontrolled gout (M10.*, M1A.*), the latter manifested by three gout codes (any) in the primary diagnosis position and three urate tests within the same calendar year. Percent and frequency of urate testing, rheumatology specialist visits, and prescriptions for ULT (allopurinol, febuxostat, probenecid, and lesinurad) were evaluated for each diagnostic group.

Results: We identified 1,162,747 gout patients (Table 1). The median age was 63 (range: 19-80), 74.1% were male, and the average duration of claims history in the database was 5.6 years. As shown in Figure 1, gout patients were seen most frequently by internists and family medicine practitioners. Patients with acute gout were infrequently see by rheumatologists, but the likelihood of encountering a rheumatologist progressively increased in subjects with advanced gout (chronic nontophaceous< tophaceous=uncontrolled). In all groups, the frequency of serum urate testing and receipt of a prescription for ULT significantly increased in gout patients seen by a rheumatologist (Table 2).

Conclusion: Most subjects with acute gout are not seen by a rheumatologist and less than half of those with advanced gout encounter a rheumatologist. However, measurement of serum urate and prescriptions for ULT are more frequent in those seen by a rheumatologist, but measurement of serum urate and prescriptions of ULT are not uniform. More frequent referral to rheumatologists and closer adherence to guidelines may improve outcomes for gout patients.

Abstract Number: 0332

Incident Gout After Renal Transplantation in Gout-naïve Patients: Large Database Analysis

Brian LaMoreaux ,[1] Megan Francis-Sedlak,[1] and Robert Holt[1], [1]Horizon Therapeutics plc, Lake Forest, IL

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Metabolic & Crystal Arthropathies Poster I: Clinical
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Patients undergoing kidney transplantation are at increased risk for developing hyperuricemia and gout compared to the general population (generally attributed to the frequent use of calcineurin inhibitors, cyclosporine and tacrolimus). However, the proportion of renal transplant patients that develop gout and the timing in which this occurs post-transplant is less established. This study sought to describe and quantify the incidence of gout in gout-naïve patients undergoing renal transplantation.

Methods: This retrospective analysis of Humana Research Database 2007-2017 claims data (private insurance and Medicare) was performed by identifying kidney transplant patients who were in plan for at least 6 months before and 5 years after transplant. Only patients without an ICD-9/10 gout diagnostic code within 6-months prior to transplant were included. Included patients were then examined for cumulative incidence of gout post-transplant.

Results: The database contained 16,454 patients that underwent kidney transplant. Of these, 920 patients underwent renal transplant, were in plan for at least 6 months before and 5 years after transplant, and did not have a gout diagnostic code before transplant. Of these, 212 patients (23%) had a post-transplant gout code while in plan, and 175 (19%) developed gout within 5 years post-transplant. The proportion of patients with gout progressively increased over time post-transplant and did not plateau. (**Figure 1**)

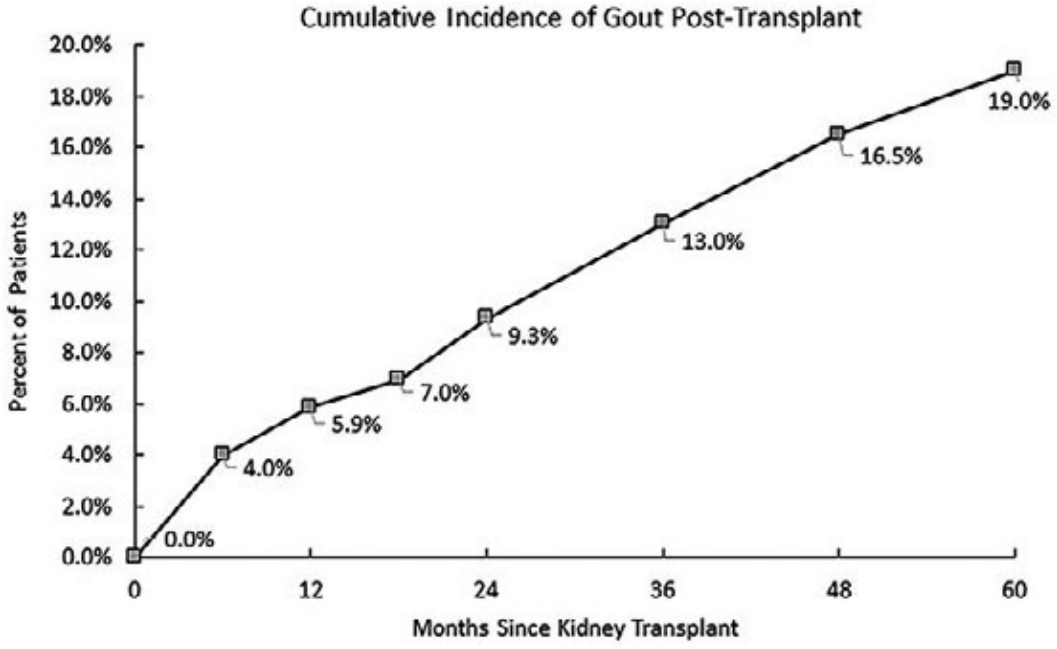

Figure 1. Proportion of gout-naïve kidney transplant patients who developed gout over 5 years post-transplant

Conclusion: Gout is a known frequent comorbidity in solid organ transplant patients, but the timing and proportion of transplant patients who develop gout is not well described. Using a large database analysis, this analysis showed that the proportion of gout-naïve patients undergoing kidney transplantation who develop gout is high and that this proportion only increases as patients are followed over a longer period of time.

Abstract Number: 0333

Assessing the Relationship Between Gout and Return to Hemodialysis Among U.S. Renal Transplant Patients

Justin Li ,[1] David Yin,[1] Zheng Wang,[1] Mark Brigham,[1] Brian LaMoreaux,[2] Jeffrey Kent,[2] Megan Francis-Sedlak,[2] Richard Johnson,[3] Nandini Hadker,[1] and Gavin Miyasato[1], [1]Trinity Partners, Waltham, MA, [2]Horizon Therapeutics plc, Lake Forest, IL, [3]University of Colorado Denver, Aurora, CO

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Metabolic & Crystal Arthropathies Poster I: Clinical
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Although gout has been shown to be associated with poor renal outcomes among chronic kidney disease populations, this relationship is not well understood among renal transplant recipients. This analysis compared rates of return to maintenance hemodialysis, a negative transplant outcome, across three primary renal transplant patient cohorts based on gout status: non-gout, pre-existing gout, and new-onset gout following transplantation.

Methods: This retrospective study of the United States Renal Data System examined Medicare beneficiaries who received a primary renal transplant between 2008-2013. Patients' Medicare claims data were used to identify pre-existing gout in the 2 years prior to transplant and new-onset gout in the 3 years post-transplant. To mitigate the effect of complications associated with acute allograft rejection/ failure, recipients who died, returned to dialysis, or received re-transplantation within 3 years after primary renal transplantation were excluded. Patients' return to hemodialysis was observed in the period between 3-5 years post-transplantation. The association between gout status (non-gout, pre-existing, and new-onset) and 5-year return to dialysis was evaluated via chi-squared tests.

Results: 39,780 patients received a primary renal transplant between 2008-2013 with Medicare as their primary payer after exclusions. Of these patients, 33,105 (83.2%) were non-gout, 4,747 (11.9%) had pre-existing gout, and 1,928 (4.8%) developed new onset gout post-transplant. 2,211 (5.6%) primary renal transplant recipients returned to hemodialysis between 3 and 5 years post-transplantation. The rate of return to hemodialysis 3 to 5 years after transplantation for non-gout, pre-existing gout, and new onset gout was 5.6, 4.6, and 7.5%, respectively (all pairwise comparisons yielded $p < 0.05$).

Conclusion: Compared to non-gout and pre-existing gout patients who received a primary renal transplant, patients who developed new-onset gout after transplantation were more likely to require maintenance hemodialysis, a negative renal transplant outcome. Further investigation is needed to determine if the presence and timing of gout relative to renal transplantation is an independent predictor for return to dialysis.

Abstract Number: 0334

The Role of a 'Treat-to-Target' Approach on Long-term Renal Outcomes in Patients with Gout

Woo-Joong Kim,[1] **Jung-Soo Song** ,[1] and Sang Tae Choi[1], [1]Chung-Ang University College of Medicine, Seoul, Republic of Korea

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Metabolic & Crystal Arthropathies Poster I: Clinical
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Although gout is accompanied by the substantial burden of kidney disease, there is limited data to assess renal function as a therapeutic target. There remains some discordance between the indication and goal of urate-lowering therapy (ULT) and unanswered questions about its effects on renal function. Thus, we evaluated the clinical importance of implementing the "treat-to-target" approach in the long-term management of gout in relation to renal function and the factors influencing this outcome.

Methods: In this 10-year retrospective study, the research subjects consisted of patients with gout who were newly treated with allopurinol (n = 42), febuxostat (n = 145), or benzbromarone (n = 57) and had continued ULT for at least 1 year. The upward titration of ULT doses was recommended according to the "treat-to-target" approach proposed by major international rheumatology groups such as the American College of Rheumatology and the European League Against Rheumatism. The efficacy of ULT in improving renal function was investigated through a sequential comparison of the estimated glomerular filtration rate (eGFR) after the duration of ULT. Multivariate logistic regression was used to assess the factors associated with the improvement in renal function.

Results: Out of 719 patients, a total of 244 subjects with a diagnosis of gout who received ULT for more than 12 months were enrolled in this study. The study population was predominantly male (96.7%). The mean age was 50.9 ± 14.2 years, and 17.6% were ≥65 years old. A serum uric acid (SUA) target concentration of < 6 mg/dL was attained for 191 patients (78.3%). Improvement in renal function was only demonstrated in the subjects in whom the SUA target was achieved (76.40 ± 18.81 mL/min/1.73 m2 vs. 80.30 ± 20.41 mL/min/1.73 m2, $p < 0.001$). A statistically significant difference in the mean change in eGFR with respect to SUA target achievement was apparently shown in individuals with chronic kidney disease (CKD) stage 3 (-0.35 ± 3.87 mL/min/1.73 m2 vs. 5.33 ± 11.64 mL/min/1.73 m2, $p = 0.019$). The patients who developed acute kidney injury during ULT had a considerable decline in the mean eGFR as opposed to the rest of the patients (-13.21 ± 16.26 mL/min/1.73 m2 vs. 4.23 ± 12.73 mL/min/1.73 m2, $p < 0.001$). There was no significant difference in the proportion of subjects with improved renal function ($p = 0.543$) and the mean change in eGFR ($p = 0.101$) among the three groups of urate-lowering agents selected for ULT. Multivariate analysis predicted that patients ≥65 years old had a decreased likelihood of improvement in renal function (OR 0.35, 95% CI 0.15-0.85, $p = 0.020$).

Conclusion: This study clarifies that long-term SUA lowering to below 6 mg/dL after initiation of ULT is associated with the significant improvement of renal function in patients with gout, which has proven to be highly beneficial for conditions associated with renal impairment. The proper utilization of the "treat-to-target" approach in clinical practice would provide implications for better management and outcomes not only in gouty arthritis but also in comorbid kidney disease.

Abstract Number: 0335

Renal Transplant Complications in Patients with and Without Gout

Megan Francis-Sedlak ,[1] Brian LaMoreaux,[1] and Robert Holt[1], [1]Horizon Therapeutics plc, Lake Forest, IL

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Metabolic & Crystal Arthropathies Poster I: Clinical
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Graft-related complications are among the most serious issues solid-organ transplant recipients and their healthcare teams face post-operatively. Gout is a known frequent co-morbidity in transplant patients. Whether renal transplant patients with gout suffer from higher rates of transplant-related complications, as compared to transplant patients without gout, has not been investigated. We analyzed a large US population database to determine the overall transplant complication rate in patients having a renal transplant with and without gout.

Methods: A retrospective review of Humana Research Database claims data (2007-2017) was undertaken to identify kidney transplant patients with ≥6 months in plan before and after transplant. Diagnostic gout codes (ICD 9/10) were used to categorize patients into gout and non-gout groups. Additionally patients were classified as having gout pre- or post-transplant based on when the first gout code occurred. Transplant complications were determined using the ICD 9 code for complications of transplanted kidney and ICD 10 codes for unspecified and other complications of kidney transplant, kidney transplant rejection, failure, and infection.

Results: The database contained 6085 patients with a kidney transplant and ≥6 months in plan both pre and post-transplant. Of these, 1504 patients had ≥1 gout codes (the first code occurred in 909 patients pre-transplant and 595 post-transplant), and 4581 patients never had a gout code. The renal transplant complication rate in the overall cohort was 36.0%. Patients with gout had a higher complication rate (40.4%) than those without gout (34.6%, OR: 1.28, 95% CI: 1.136–1.443, p< 0.001). The higher complication rate in gout patients was driven by those who developed gout post-transplant.(Table 1)

Group	Number of Patients	Number with Complications	% with Complications
Enrolled Patients:	6085	2191	36.0%
-Gout and Transplant:	1504	607	40.4%
Gout Pre-Transplant	909	304	33.4%
Gout Post-Transplant	595	303	50.9%
-No Gout	4581	1584	34.6%

Table 1. Renal transplant-related complications in patients with and without gout

Conclusion: Our analysis indicates that patients with gout, especially those with gout arising post-transplant, suffered from higher rates of overall transplant-related complications. In addition to more research on this topic, an increased focus on awareness and screening of renal transplant patients for gout is warranted.

Abstract Number: 0336

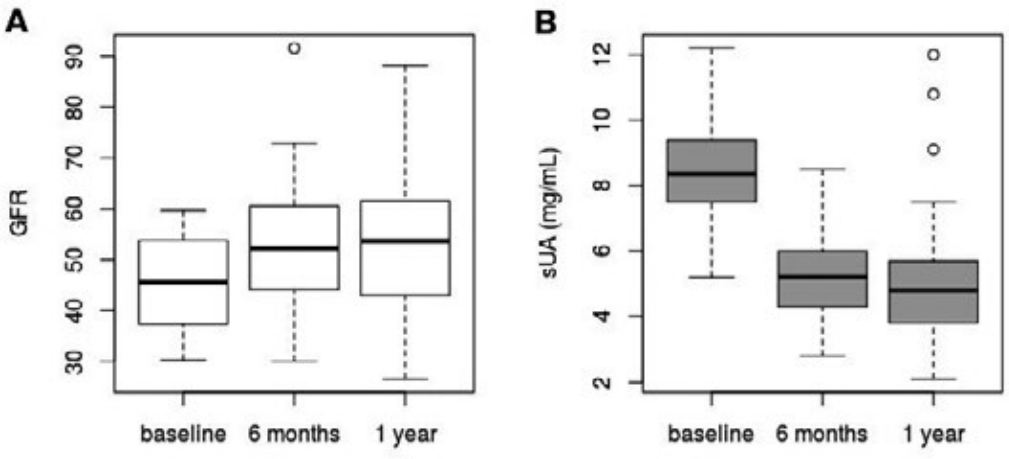
Treating Gout to Target Entails Renoprotective Effect in Patients with Moderate Chronic Kidney Disease

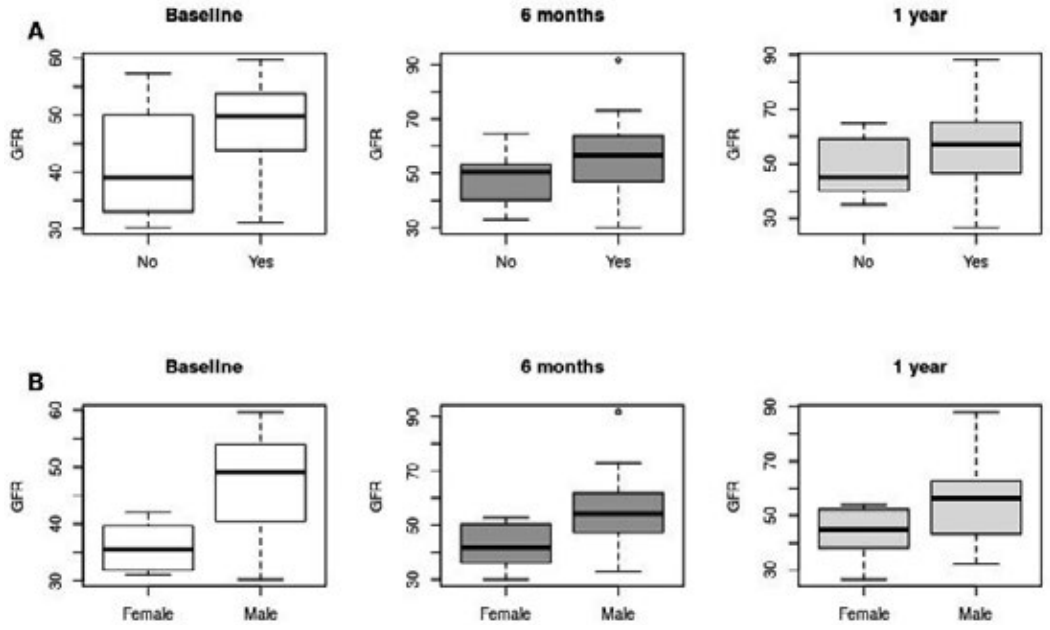
enrique Calvo-Aranda ,[1] Marta Novella-Navarro,[2] jOSE LUIS CABRERA-ALARCON,[3] Francisco Aramburu,[2] Iustina Janta,[4] Alejandro Prada-Ojeda,[5] Luis Sala-Icardo,[5] Maria del Carmen Ortega de la O,[6] Cesar Diaz-Torne,[7] and A. Urruticoechea-Arana[8], [1]Hospital Universitario Infanta Leonor, Madrid, Spain, [2]Hospital Universitario HM Sanchinarro, madrid, Spain, [3]Bioinformatica CNIC, madrid, Spain, [4]Hospital General Universitario Gregorio Marañón, madrid, Spain, [5]Hospital Universitario de Torrejon, madrid, Spain, [6]Hospital Universitario Santa Elena, madrid, Spain, [7]Hospital de la Santa Creu i Sant Pau, barcelona, Catalonia, Spain, [8]HU Can Misses, Ibiza, Spain

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Metabolic & Crystal Arthropathies Poster I: Clinical
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Approximately 25% of patients with gouty arthritis suffer from chronic kidney disease (CKD). High serum uric acid (sUA) levels have been related to glomerular filtration-rate (eGFR) imbalance. Beneficial effect of treatment with xanthine oxidase inhibitors (XOI), mostly allopurinol, has already been proved in patients with CKD and asymptomatic hyperuricemia. Although several studies have described the efficacy and renal safety of treatment with XOI in gout, few authors have analyzed the effect of treating gout to target (T2T) on eGFR in patients with gouty arthritis and moderate CKD. Our objective is to assess the effect of treating gout to target in patients with gouty arthritis and moderate CKD, in terms of eGFR changes.

Methods: In this multicenter, longitudinal, observational study, we included patients from 7 different hospitals, between January 2014 and December 2018. All diagnosed with gout (ACR/EULAR 2015 criteria) and stage-3 CKD according to Cockroft-Gault formula (eGFR 30-59 ml/min/m2) who received XOI (febuxostat or allopurinol) with a





follow-up for 6 and 12 months. Exclusion criteria were: primary kidney disease, kidney transplantation or single-kidney. Data were provided from clinical records at baseline visit, 6 and 12 months. Those patients whom data were not collected at that schedule were also excluded. Demographic and clinical features included were: age, sex, age at gout onset, pattern of joint involvement, presence of tophi, sUA levels, nephrolithiasis, comorbidities, concomitant treatments, smoking and alcohol intake. Statistical analysis: linear mixed-effects model was used. To fit this model a stepwise approach was adopted considering p-value < 0.05 statistically significant for feature coefficients. Nmlev-3.1-137 R package.

Results: Complete data were obtained from 50 patients (44 males and 6 females). Mean age 72.90±8.94 years. Mean baseline sUA was 8.55±1.57 mg/dl and mean eGFR 45.52±9.21 ml/min/m^2. Time, sUA levels, smoking and sex were variables with significant effects according to the linear mixed effects model for eGFR. A significant improvement in eGFR was observed in first 6 months (16.7±5.1 ml/min/m^2) (p=0.004), associated to an inverse relation in sUA levels (p=0.04). Non-smokers presented better eGFR than smokers (p=0.01) and males had higher eGFR in all considered points than females (p=0.008). No significant differences were obtained between allopurinol or febuxostat administration regarding eGFR variations.

Conclusion: Reduction of sUA levels in patients with gout and CKD stage-3 treated with XOI following the T2T approach entitles an improvement of eGFR. These findings suggest that the response to urate-lowering treatment takes place in the first 6 months, leading to a significant improvement in eGFR in this period, and both (sUA and eGFR) remain stable between 6 and 12 months. So that, an optimal management of gout can preserve and improve kidney function in patients with arthritis and moderate CKD.

Abstract Number: 0337

Gout in the US: Significant Association with Cardiovascular and Renal Disease Hospitalizations - A Nationwide Study

Alka Mithal,[1] Maanek Sehgal,[2] and **Gurkirpal Singh** [1], [1]ICORE, Woodside, [2]UCLA, Los Angeles

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Metabolic & Crystal Arthropathies Poster I: Clinical
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Gout is a disorder of uric acid metabolism and often presents as acute severe joint pain. Previous work from our group suggests that all-cause hospitalizations in patients with gout in the United States (US) have significantly increased in the last 22 years. The current study focused on identifying potential reasons for the excess hospitalizations.

Methods: The Nationwide Inpatient Sample (NIS) is a stratified random sample of all US community hospitals. It is the only US national hospital database with information on all patients, regardless of payer, including persons covered by Medicare, Medicaid, private insurance, and the uninsured. We examined all inpatient hospitalizations in the NIS in 2016 among patients 40 years or older with a primary or secondary diagnosis of gout and compared them to total all-cause hospitalizations in patients without a gout diagnosis in the same age group during the same period. Over 69,800 ICD 10 diagnoses codes were collapsed into a smaller number of clinically meaningful categories, consistent with the Centers for Disease Control (CDC) Clinical Classification Software. The top 15 primary causes for hospitalization were evaluated and compared between the two cohorts.

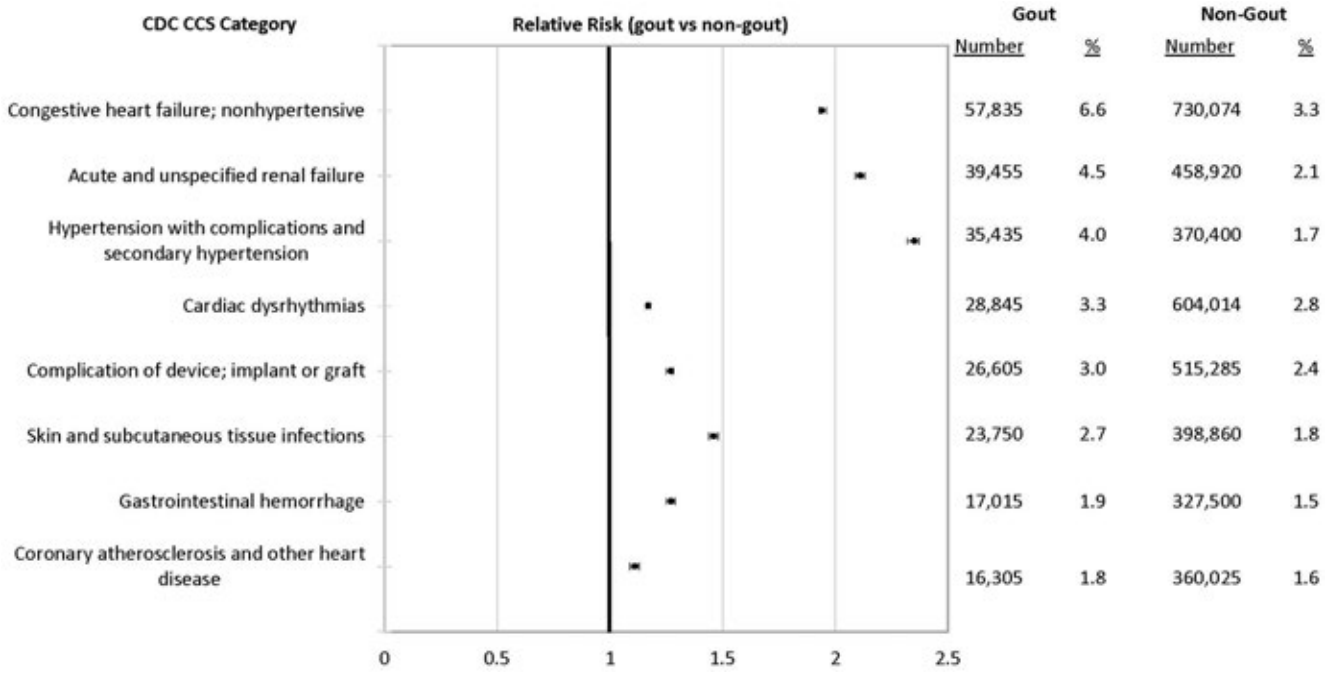

Figure Relative risk of comorbidities in Gout vs No Gout

Results: In 2016, there were 892,379 all-cause hospitalizations in the US in patients with gout with 14,135 (1.6%) of these for primary diagnosis of gout. The primary diagnoses for remaining 878,244 hospitalizations in patients with gout were compared with those in 21.9 million hospitalizations in the general US population without gout. The most common primary cause of hospitalizations in both cohorts was septicemia (7.8% in gout vs. 7.4% in general population). Significant differences were seen in several other categories. For example, acute renal failure was twice as frequent among gout patients (39,455 hospitalizations, 4.5%) compared to the general population (458,920 hospitalizations, 2.1%) (Relative Risk (RR) 2.11, 95% CI 2.08 – 2.13, p< 0.0001). Hospitalizations for "hypertensive complications and secondary hypertension" were also higher (35,435, 4.0% in gout vs 370,400, 1.7% in general population, RR 2.35, 95% CI 2.32 – 2.37, p< 0.0001). Hospitalizations from gastrointestinal bleeding were 30% more common in gout patients, perhaps associated with concomitant NSAID treatments (Figure).

Conclusion: Among patients with gout, a far greater proportion of serious hospitalizations are related to renal and cardiovascular complications as compared to age-matched general population.

This calls for an increased awareness and management of serious co-morbid conditions in patients with gout.

Effect of Serum Urate Lowering with Allopurinol on Blood Pressure in Young Adults

Angelo Gaffo ,[1] David Calhoun,[2] Elizabeth Rahn,[1] Suzanne Oparil,[2] Peng Li,[2] Tanja Dudenbostel,[2] David Redden,[2] Amy Mudano,[2] Jeffrey Foster,[1] Daniel Feig,[2] Stephanie Biggers,[2] and Kenneth Saag[1], [1]University of Alabama at Birmingham, Birmingham, AL, [2]University of Alabama at Birmingham, Birmingham

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Metabolic & Crystal Arthropathies Poster I: Clinical
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The association between serum urate and hypertension continues to be a matter of controversy. Studies in adolescents provided evidence for the efficacy of urate lowering therapy to improve early hypertension, while at least one study in adults failed to find benefit. The Serum Uric acid Reduction to Prevent HypERtension (SURPHER) study tested whether serum urate reduction with allopurinol would lead to blood pressure reductions in pre-hypertensive young adults.

Methods: Single center, double-blinded, crossover trial in which participants were randomly assigned to allopurinol (300 daily mg) or placebo for a period of one month each separated by a 2-4 week washout. Adults ages 18-40 with baseline systolic blood pressure (SBP) ≥ 120 and < 160 mm Hg or diastolic blood pressure ≥ 80 and < 100 mm Hg, and serum urate ≥ 5.0 mg/dL for men or ≥ 4.0 mg/dL for women were enrolled. Main exclusion criteria included chronic kidney disease, gout, or use of urate-lowering therapies. The primary outcome was change from study treatment period baseline (allopurinol or placebo) in SBP assessed by 24 hour ambulatory blood pressure monitoring at four time points. Missing data was handled with a multiple imputation approach. Safety assessments were conducted as part of the study.

Results: 99 participants were randomized and 73 completed study participation. The characteristics of study participants are shown in Table 1. Serum urate decreased by 1.33 ± 1.21 mg/dL during the allopurinol period (p< 0.001) and by a non-significant 0.04 ± 0.75 mg/dL while taking placebo. SBP changed by -0.71 ± 8.21 mmHg during the period assigned to allopurinol versus -0.16 ± 7.33 mmHg during the period assigned to placebo. The difference between these changes in SBP was not significant (p=0.52) (Table 2). Changes in diastolic blood pressure and mean ambulatory blood pressure also were not significantly different during allopurinol and placebo exposure periods. There was a trend to significant blood pressure decreases in the small participant subset with average serum urate of >6.5 mg/dL at the initiation of study periods (Figure). No allopurinol hypersensitivity events or other serious adverse events were observed.

Conclusion: In the intention-to-treat analysis urate-lowering therapy with allopurinol in young adults did not lead to reductions in blood pressure when compared with placebo. Blood pressure reductions were observed in participants with high baseline serum urate levels.

Table 1. Baseline characteristics of participants (n=99)

	Mean or frequency
Age (years)	28.0 ± 7.0
Gender	
Male	62 (63%)
Female	37 (37%)
Race/Ethnicity	
African American	40 (40%)
Not African American	59 (60%)
Serum urate at baseline	
Male	6.4 ± 1.0 mg/dL
Female	4.9 ± 0.7 mg/dL
Blood pressure at enrollment	
Mean Systolic (mmHg)	133.8 ± 10.0
Mean Diastolic (mmHg)	84.3 ± 8.8

Table 2. Change in blood pressure parameters during allopurinol and placebo treatment phases (n=99). Mean (SD)

Outcomes (mmHg)	Placebo	Allopurinol	p
Systolic Blood Pressure	- 0.16 (7.33)	-0.71 (8.21)	0.52
Diastolic Blood Pressure	-0.22 (5.81)	-0.28 (6.58)	0.68
Mean Arterial Pressure	-0.43 (5.63)	-0.54 (6.86)	0.54

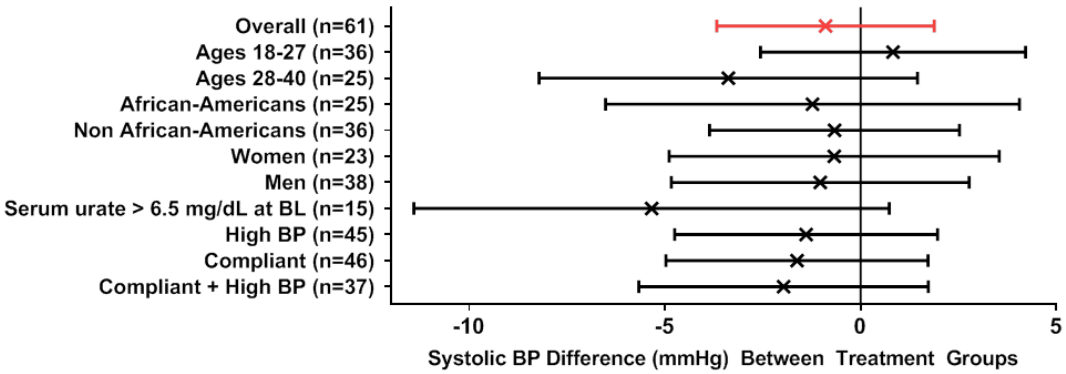

Figure. Change in systolic blood pressure between allopurinol and placebo treatment phases in selected participant subgroups. BL = average baseline at the initiation of treatment phases (allopurinol and placebo), BP= blood pressure, Compliant = any detectable oxypurinol at end of allopurinol phase

Depressive Symptoms Influence Success of Allopurinol in Reducing Serum Urate

Sylvie Mrug,[1] Catheryn Orihuela,[1] Elizabeth Rahn,[2] Amy Mudano,[1] Kenneth Saag,[2] Jeffrey Foster,[2] and **Angelo Gaffo** [2], [1]University of Alabama at Birmingham, Birmingham, [2]University of Alabama at Birmingham, Birmingham, AL

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Metabolic & Crystal Arthropathies Poster I: Clinical
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Elevated levels of serum urate (sUA) are central to the pathogenesis of gout and have been associated with cardiovascular disease. Urate-lowering therapies are effective at treating gout and are being explored as novel approaches for cardiovascular disease. However, less is known about factors that influence the effectiveness of urate-lowering therapies. Depression has shown strong relationships with treatment noncompliance, which may translate into reduced effectiveness of urate-lowering therapies. This study tested the role of depressive symptoms in the effectiveness of allopurinol for lowering sUA and treatment compliance in the context of a clinical trial.

Methods: Within a larger within-subject cross-over clinical trial of allopurinol vs. placebo, 67 patients had complete data for depressive symptoms at the beginning of each treatment period, as well as sUA before and after a 4-week treatment period with allopurinol and a 4-week placebo period (order of allocation was randomized). The 67 patients had average age 27.01 years (SD=6.5, range 18-40), 39% were African-Americans and 64% were males. Depressive symptoms were assessed with the Center for Epidemiologic Studies Depression Scale (CESD) 10 tool. Treatment compliance was assessed by oxypurinol levels being present at the end of the allopurinol allocation study period. Paired samples t-test evaluated change in sUA from pre- to post-treatment during active treatment and placebo. Then, linear regressions predicted change in sUA over each treatment period from pre-treatment depressive symptoms, adjusting for sex and race which were associated with baseline sUA levels. Logistic regression predicted treatment compliance during the medication period based on the same predictors.

Results: Over the 4-week active treatment period with allopurinol, sUA levels decreased from average 5.8 mg/dL (SD=1.2) to 4.4 mg/dL (SD=1.2), p< 0.001. However, sUA did not change during the 4-week placebo period (both 5.8 mg/dL, SD=1.1 and 1.3, p=0.707). Pre-treatment depressive symptoms ranged from “no symptoms” (0) to “severe symptoms” (16 or 20), with mean in the “no to mild” range (M=4.6, SD=4.1 before active treatment; M=6.1, SD=4.8 before placebo). After adjusting for pre-treatment sUA, sex and race, pre-treatment depressive scores predicted higher levels of sUA at the end of the active treatment period (b=.07, beta=.25, p=0.028) but not at the end of the placebo period (b=.03, beta=.11, p=0.102). After 4 weeks of allopurinol, the estimated difference in sUA between individuals with pre-treatment depressive scores of 0 vs. 16 was 1.12 mg/dL, which was similar to the average treatment effect of 1.4 mg/dL. Depressive symptoms did not predict treatment compliance (OR=0.93, p=0.39), perhaps because of reduced sample size (N=55).

Conclusion: Even in the absence of clinical diagnosis of depression, depressive symptoms are associated with reduced effectiveness of allopurinol treatment for hyperuricemia in the context of a clinical trial. We could not associate this with reduced compliance, assessed by presence of measurable oxypurinol. Our findings could have implications in gout and hyperuricemia research and clinical practice.

Increased Physical Activity in Gout Patients Correlates with Better Prognosis, Decreased Pain, and Suppressed C-Reactive Protein Levels

Naomi Schlesinger ,[1] Kyle Jablonski,[2] Peter Harb,[3] Caitlin Henry,[3] Emily Schwarz,[3] Ifeoma Okafor,[3] Wael Jarjour,[4] and Nicholas Young[5], [1]Rutgers Health- RWJ Medical School, New Brunswick, NJ, [2]The Ohio State University Wexner Medical Center, Division of Immunology and Rheumatology, Columbus, [3]Ohio State College of Medicine, Columbus, [4]Ohio State College of Medicine, Columbus, OH, [5]The Ohio State University Wexner Medical Center, Division of Immunology and Rheumatology, Columbus, OH

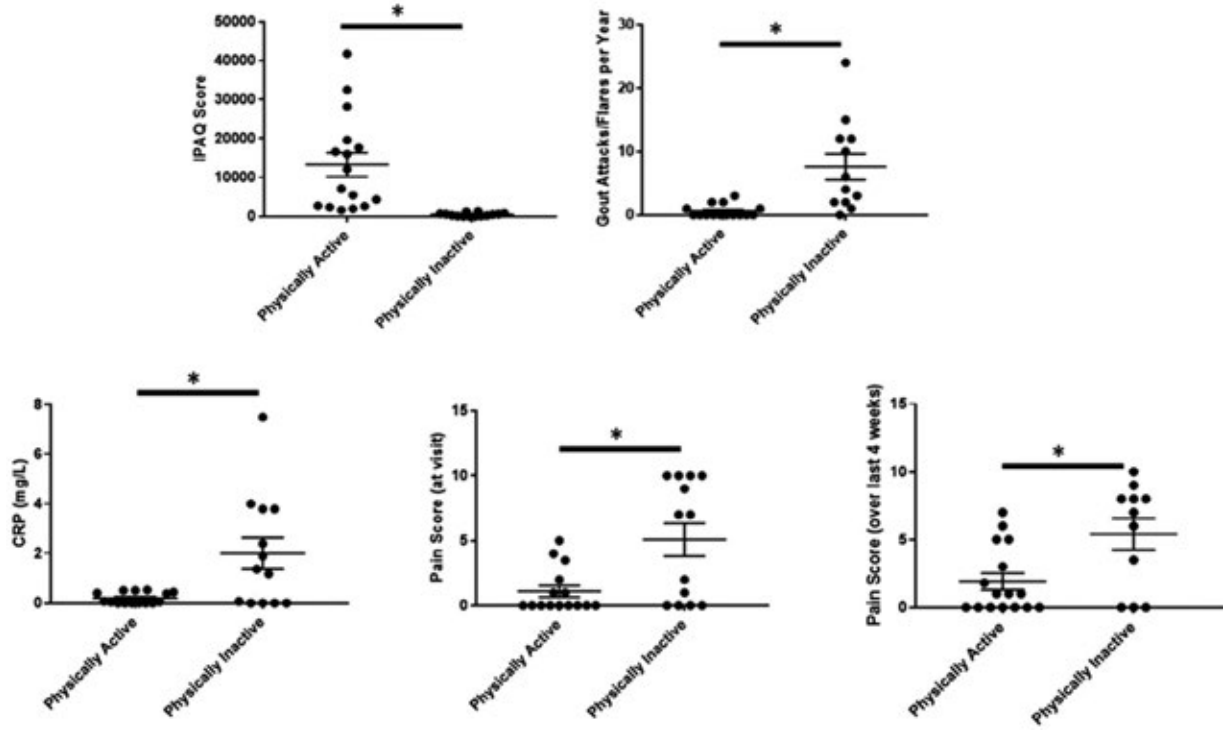
SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Metabolic & Crystal Arthropathies Poster I: Clinical

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM



Physically active gout patients have lower C-reactive protein levels, less flares per year, and decreased pain perception compared to those that are not physically active.

Background/Purpose: Regular exercise programs were previously thought to be inappropriate in patients with rheumatic diseases because of the potential to exacerbate inflammation. However, while recent paradigm-shifting studies have demonstrated that moderate physical activity can suppress inflammatory burden in chronic disease states, the impact in patients with gout has not been studied extensively hitherto. Consequently, clinical practice guidelines for gout released by the ACR (2012) and the ACP (2017) do not even address exercise as an interventional strategy. In a mouse model of gout, we have recently demonstrated that regular low/moderate intensity exercise regimens can reduce localized MSU crystal-induced inflammation. Therefore, the objective of this study was to examine the correlation of physical activity levels with clinical data in gout patients.

Methods: During scheduled appointments, gout patients not experiencing a flare at the time of visit were recruited from our clinics and consented to participate in the study (N = 30). International physical activity questionnaires (IPAQ) were completed to access current levels of daily/weekly physical activity. Clinical data was collected during the patient visit, including BMI, age, years since diagnosis, flares per year, perceived pain at the time of visit and in the past 4 weeks, and C-reactive protein (CRP) levels. Results were analyzed with individual unpaired t-tests with Welch's correction and one-way ANOVA without Gaussian distribution and multiple comparisons to analyze the mean rank of each data set with that of every other to obtain p-values. Statistical significance was determined to be $p < 0.05$.

Results: The IPAQ survey, which has been previously used in studies of rheumatologic diseases, separated the gout patients in this study into physically active (IPAQ > 1400; N = 16) and physically inactive cohorts (IPAQ < 1400; N = 14) ($p < 0.001$). Average age, BMI, or years since diagnosis did not significantly differ between cohorts. However, physically active gout patients had 7 fewer flares per year, which corresponded to a 12-fold reduction ($p < 0.01$). Furthermore, physical activity correlated with a 10-fold decrease in CRP levels by an average of 2 mg/L ($p < 0.01$). In addition, perceived pain at the time of visit and over the past 4-week period was down 4.6-fold ($p < 0.01$) and 2.8-fold ($p < 0.05$), respectively.

Conclusion: These epidemiological and clinical data suggest that increased physical activity is beneficial in patients with gout and should be explored further as a therapeutic intervention. Regular exercise may be efficacious during intervals between flares and could function as a flare prophylaxis. While rest and decreased movement will still be recommended to a patient experiencing a gout flare, further characterization of exercise therapy may lead to a standardized exercise regimen to be performed during times of clinical inactivity and serve as part of the treatment for flare prophylaxis.

Abstract Number: 0341

Development of a Multivariable Improvement Measure for Gout

Naomi Schlesinger ,[1] N. Lawrence Edwards,[2] Anthony Yeo,[3] and Peter Lipsky[4], [1]Division of Rheumatology, Department of Medicine, Rutgers, The State University of New Jersey, New Brunswick, NJ, [2]Department of Medicine, University of Florida, Gainesville, FL, [3]Horizon Therapeutics plc, Lake Forest, IL, [4]AMPEL BioSolutions, LLC, Charlottesville, VA

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Metabolic & Crystal Arthropathies Poster I: Clinical
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Gout is a multifactorial inflammatory disease in which patients experience a wide range of signs and symptoms, including flares, inflammatory arthritis, tophi and disability. Most assessments of gout and response to urate-lowering therapy (ULT) have focused primarily on the ability to lower serum urate and decrease the frequency of flares. Recognition that assessment of ULT and other treatments for gout could be facilitated by endpoints that more closely reflect the multidimensional impact of the disease has prompted an interest in developing composite measures, although there is no consensus on the most appropriate composite measure to employ.

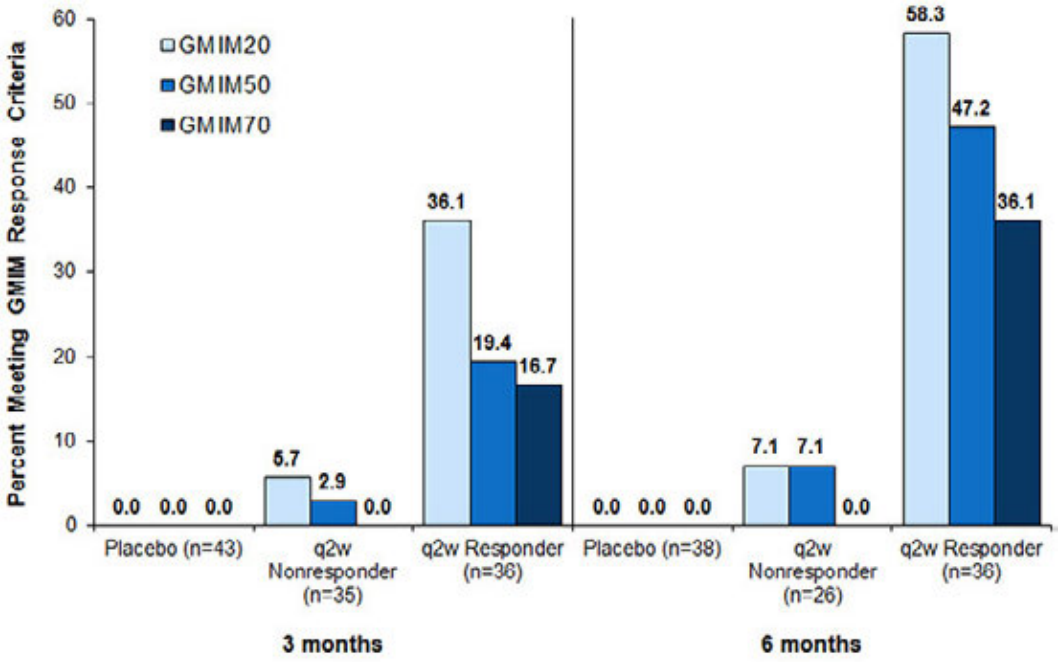

Figure 1. Percentage of subjects attaining GMIM 20/50/70 criteria

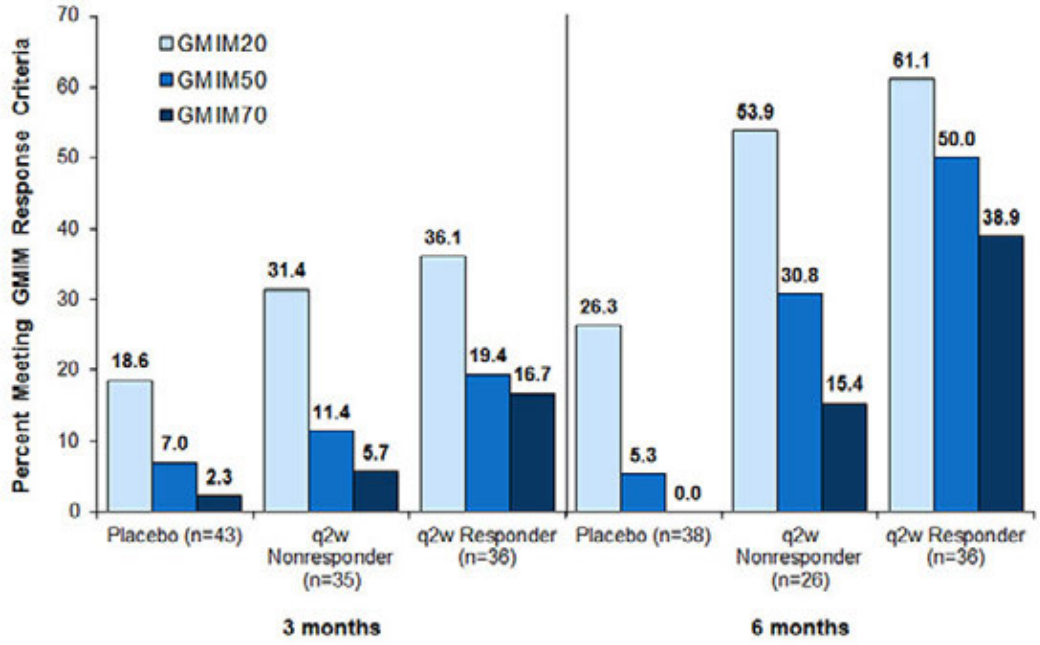

Figure 2. Percentage of subjects attaining GMIM 20/50/70 criteria omitting the requirement for urate <6mg/dL

The goal of this research was to develop an evidence-based gout multivariable improvement measure (GMIM) that captures the spectrum of gout manifestations and is sensitive to change.

Methods: Databases from patients with chronic refractory gout who participated in two randomized 6-month clinical trials (RCTs) of pegloticase were reviewed. Sub-sets who had persistent urate lowering (responders) to biweekly pegloticase (n=36) and those who had only transient urate lowering (non-responders, n=49) were identified and compared to those who received placebo (n=43). Initially individual patients were assessed for achievement of previously reported criteria for remission: serum urate < 6 mg/dL, absence of tophi and flares, patient global assessment, and pain (each < 2 on a 10-point visual analog scale). A repeated measures mixed effects model controlling for repeated observations with backward elimination using data from these patients was employed to determine the model components that best correlated with time to maximum benefit. This analysis resulted in the addition of swollen and tender joints to the outcome measure. In order to assess the degree of improvement, each subject was scored based upon a serum urate < 6 mg/dL and 20, 50 or 70% improvement in ≥4 of the 6 clinical evaluations and termed GMIM20, 50, 70.

Results: GMIM was able to capture gradation of change in the treated populations and also distinguish responses in those with persistent versus those with transient urate lowering and subjects treated with placebo (Figure 1). At 3 and 6 months, achievement of GMIM20, 50 and 70 in persistent responders occurred significantly more often vs placebo and versus non-responders without persistent urate lowering. By eliminating the requirement for urate < 6mg/dL, the improvement in clinical features could be assessed (Figure 2). Improvement greater than that noted in subjects receiving placebo could be discerned in both responders and non-responder to pegloticase. Sensitivity analysis indicated that flares and pain contributed minimally to the model.

Conclusion: GMIM effectively captures changes in disease severity in response to treatment in patients with advanced gout treated with pegloticase. GMIM20,50,70 may serve as an evidence-based tool for assessment of the quality of response to therapies in subjects with gout in medical practice or in clinical trials.

Rheumatologist Care Is Associated with Fewer Emergency Room Visits by Persons with Gout

Naomi Schlesinger ,[1] N. Lawrence Edwards,[2] Sanders Clark,[3] and Peter Lipsky[4], [1]Division of Rheumatology, Department of Medicine, Rutgers, The State University of New Jersey, New Brunswick, NJ, [2]Department of Medicine, University of Florida, Gainesville, FL, [3]HVH Precision Analytics, LLC, Wayne, PA, [4]AMPEL BioSolutions, LLC, Charlottesville, VA

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Metabolic & Crystal Arthropathies Poster I: Clinical
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Gout is one of the most common inflammatory arthropathies, although care of gout patients is not always optimal. By searching a large administrative data base (Symphony Integrated Dataverse), we found

that persons with acute gout see a rheumatologist infrequently, whereas those with advanced gout are seen by a rheumatologist more often, but still less than 50% of advanced gout patients are seen by a rheumatologist. Notably, however, gout patients seen by rheumatologists have more frequent urate measurements and are prescribed urate lowering therapy more frequently. The objectives of this study were to validate these results using an additional administrative data base and also to determine whether involvement of a rheumatologist in gout care had a positive impact on health outcomes.

Methods: We carried out a retrospective analysis to identify persons with gout over an approximately 3-year period from October 2015 to December 2018. This study used data from the Truven Marketscan® database, an administrative database covering over 190 million patients across the United States and based on fully adjudicated and paid insurance claims. Patients were identified as having gout if they were >18 years of age and had at least two medical claims for the diagnosis of gout on different days, separated by at least 3 months. Patients with acute gout were identified by ICD-10 code M10.*, chronic nontophaceous gout (M1A.***0), tophaceous gout (M1A.***1) and uncontrolled gout (M10.*, M1A.*), the latter manifested by three gout codes (any) in the primary diagnosis position and three urate measurements within the same calendar year. Particular attention was placed on Emergency Room (ER) visits by individuals in each category and by individuals who had been evaluated by a rheumatologist.

Results: We identified 284,877 gout patients. The median age was 59.2 years and 79.0% were male. Of the 230,998 persons coded as acute gout, 10.7% were seen by a rheumatologist, whereas 26.9% of the 32,942 coded as chronic nontophaceous gout, 47.2% of the 7,723 coded as tophaceous gout and 43.6% of the13,514 coded as uncontrolled gout were seen by a rheumatologist. In each gout category, the frequency of ER visits was significantly reduced in persons who had been seen by a rheumatologist. In acute gout, the frequencies of ER visits in those with and without rheumatologist care were 5.6% vs 6.6% ($p< 0.001$), respectively. In chronic nontophaceous gout it was 5.5% vs 6.7% ($p=0.001$); in tophaceous gout it was 10.3% vs 14.7% ($p< 0.001$); and in uncontrolled gout it was 12.8% vs 19.0%, respectively. If the frequencies of rheumatologist-associated gout patient ER visits were applied to all gout subjects, there would have been 3,088 less ER visits in this cohort of gout patients.

Conclusion: Most subjects with acute gout are not seen by a rheumatologist and only about half of those with advanced gout encounter a rheumatologist. However, there appears to be a positive impact of rheumatologist care, manifested by a significant decrease in the frequency of ER visits. Considering the inconvenience and cost of ER visits, rheumatologist care may have a significant impact on the well-being of gout patients and on the overall cost of their care.

Emergency Department Length of Stay in Patients with Acute Gout

Nadine Mbuyi ,[1] Steven Reinert,[2] Ross Hilliard,[3] Anthony Reginato,[3] and Deepan Dalal[3], [1]George Washington University, Washington, DC, [2]Lifespan Health System, Providence, RI, [3]Brown University, Rhode Island Hospital, Providence, RI

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Metabolic & Crystal Arthropathies Poster I: Clinical

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Emergency department (ED) visits for acute gout increased by approximately 20% between 2006 and 2014 in the United States. (1) Reducing ED length of stay (LOS) can help reduce ED crowding and cost of care for gout patients. The aim of our study was to assess ED LOS and to identify factors associated with prolonged ED LOS in patients with acute gout.

Methods: In this retrospective analysis, we included the first ED visit of adult patients (>18 years) with acute gout who presented to the 3 EDs affiliated with Lifespan Health Systems, the largest healthcare provider in Rhode Island. The study period was between 3/30/2015 and 9/30/2017. We calculated ED LOS as the time spent by patients in the ED until they were discharged. Patients presenting to the ED and subsequently admitted to the hospital were excluded given the differential effect of systems factors in these patients. We assessed the following factors' association with being in the upper quartile of ED LOS: (a) patient factors – demographics, comorbidities and clinical presentation of gout (number of joints involved, severity as gauged by an ED triage nurse on a scale of 1 to 5; 1 being the worst) and (b) systems factors – time of day, day of the week, and time of year at presentation to the ED, and teaching versus non-teaching hospital setting. We performed univariate and multivariable analyses.

Table 1. factors associated with longer ED length of stay for patients with acute gout

	< 4.3 hours in ED (n = 265)	> 4.3 hours in ED (n = 90)
Patient factors		
Age < 65	185/265 (69.8%)	51/90 (56.7%)
Male gender	213/264 (80.7%)	75/90 (83.3%)
Comorbidities		
Diabetes	68/228 (29.8%)	29/76 (38.2%)
Hyperlipidemia	132/228 (57.9%)	53/76 (69.7%)
History of gout	160/228 (70.2%)	54/76 (71.1%)
Hypertension*	162/228 (71.1%)	65/76 (85.5%)
Coronary artery disease	49/228 (21.5%)	21/76 (27.6%)
Heart failure*	32/228 (14.0%)	26/76 (34.2%)
Chronic kidney disease	44/228 (19.3%)	21/76 (27.6%)
Cerebrovascular disease	19/228 (8.3%)	4/76 (5.3%)
Other inflammatory arthritis	10/228 (4.4%)	3/76 (4.0%)
Clinical presentation of gout		
Oligo/polyarticular gout	33/265 (12.4%)	13/90 (14.4%)
Arthrocentesis*	21/265 (7.9%)	51/90 (56.7%)
ED Severity Score*		
Score 2 and 3	117/265 (44.1%)	67/90 (74.4%)
Score 4 and 5	148/265 (55.8%)	23/90 (25.6%)
Systems factors		
Type of Hospital*		
Academic center	204/265 (77%)	82/90 (91.1%)
Community center	61/265 (23%)	8/90 (8.9%)
Time of Day		
Time of day (12 AM – 8 AM)	52/265 (19.6%)	20/90 (22.2%)
Time of day (8 AM – 12 PM)	124/265 (46.8%)	51/90 (56.7%)
Time of day (12 PM – 12 AM)	89/265 (33.6%)	19/90 (21.1%)
Time of Year		
January to March	43/265 (16.2%)	21/90 (23.3%)
April to June	94/265 (35.5%)	28/90 (31.1%)
July to September	78/265 (29.4%)	19/90 (21.1%)
October to December	50/265 (18.9%)	22/90 (24.2%)
Weekend presentation	94/265 (35.5%)	24/90 (26.7%)

*Represents statistically significant results (p <0.05)

Results: A total of 355 patients (mean age 56.6 ± 16.03 years, 81.3% males) were included. The median ED LOS was 2.65 hours (1.75, 4.3 hours). In the univariate analysis, older age (> 65 years), comorbidities (hypertension, congestive heart failure) and worse ED severity score among patient factors and being treated at a teaching hospital ED among systems factors were associated with being in the upper quartile of ED LOS. Performing arthrocentesis was also associated with being in the upper quartile of ED LOS (Table 1). In a multivariable analysis, age > 65 years, performing arthrocentesis, and worse acuity score continued to be associated with longer ED LOS.

Conclusion: In our study settings, patients with acute gout spent a longer time in the ED than the national median of 120-150 minutes. (2) We noted that older age and higher acuity score in addition to procedural delays led to longer length of stay in the ED.

Session Title: Metabolic & Crystal Arthropathies Poster I: Clinical

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Rotator cuff calcific tendinopathy is a common condition causing up to 20% of the painful shoulder. Ultrasound guided percutaneous lavage (UGPL) is indicated after failure of conservative treatments. We have shown that this treatment led to clinical improvement and complete resorption of the calcification in 43 % of the patients at 3 months (1). However, it is currently unclear if the baseline characteristics of the calcification or the success of the procedure (withdrawal of calcium) are associated with the disappearance of the calcific deposit. The goal of this post-hoc analysis was to find characteristics associated with the resorption of the calcific deposit 3 months after UGPL.

Table 1.

	Disappearance (n=53)	Persistance (n=70)	p
Age, years, mean	49,5	50,6	NS
Sexe (F/M), n	39/14	43/27	NS
Symptoms duration (years), mean	2,6	2,7	NS
Nocturnal pain, n (%)	44 (83%)	56 (80%)	NS
Baseline VAS at rest, mm, mean	30,1	30	NS
Baseline VAS during activities, mm, mean	72,7	66,4	0,007
Maximum size (mm), mean	16,1	15,3	NS
Calcification > 2cm, n (%)	17 (32%)	20 (28,6%)	NS
X-Ray Calcification type (A/B)	25/27	23/47	NS
Doppler signal on ultrasound, n (%)	14(26%)	11 (15,7%)	NS
Calcium extraction, n (%)	48 (90.6%)	53 (75%)	0,033
Large amount extracted, n (%)	33 (62%)	36 (51%)	NS
Communication SAB and calcifc deposit, n (%)	37 (69%)	31 (45%)	0,008
Hard calcification, n (%)	12 (23%)	36 (51%)	0,002
Blurred aspect on X-Ray at day 7, n (%)	30 (63%)	19 (27,5%)	<0.001
Day 7 VAS at rest, mean	14,5	15,8	NS
Day 7 VAS during activities, mean	35,7	31	NS

Methods: This was a post-hoc analysis of a multicentric prospective double blinded randomized controlled study (1). Patients with shoulder pain for more than 3 months and a type A (dense) or B (split/separated with clear contours) calcification > 5 mm on X-Ray were included. Patients were treated with UGPL using a single needle technic. X-Ray was performed at 3 months and resorption of the calcific deposit defined as more than 90% of decrease of size or complete disappearance of the calcific deposit. Clinical, radiological and procedure characteristics was compared between patient with or without resorption. Multivariate logistic regression was performed to identify baseline and procedure characteristics associated with the disappearance of the calcific deposit.

Results: 134 patients were included in the study, mean age 49.8 (+/-9.7) years, 89 were females (67.4%). X-Ray at 3 months were available for 123 patients. At this time point 53 (43%) of the patients had more than 90% decrease or complete disappearance of their calcification. Baseline and procedure characteristics of the 2 groups are summarized in table 1. None of the baseline radiological characteristics were significantly different between the 2 groups (size of the calcific deposit (even calcification more than 2 cm wide) or radiologic type). Baseline pain at activity was the only clinical variable higher in patients that had resorption of their calcification. Consistence of the calcification during the procedure, the possibility of calcium extraction and the presence of a communication between the calcification and the sub-acromial bursa (SAB) at the end of the procedure were all associated with the calcific disappearance. However, no difference was found according to the amount of calcium extracted. Finally, blurred aspect of the calcification at 7 days but not pain at this time point was associated with resorption. In multivariate logistic regression, we found that only the pain during activity (p=0.046) at baseline and the communication between the subacromial bursa (p=0.046) remains significant.

Conclusion: Disappearance of the calcification after UGPL occurs more frequently in patients in which a communication can be created between the calcification and the SAB, leading to the migration of the calcium deposit and its resorption. Importantly nor the size of the calcification neither the radiological aspect seemed important showing that UGPL can be offered to any patients with symptomatic calcific tendonitis.

Associations of Serum Uric Acid with Cardiovascular Disease Risk: Data from the Korea National Health and Nutrition Examination Survey

Kyong-Hee Jung ,[1] Seung Yun Lee,[1] Won Park,[1] Young Ju Suh,[1] Mie Jin Lim,[1] Seong-Ryul Kwon,[1] Joo-Hyun Lee,[2] and Young Bin Joo[3], [1]Inha University Hospital, Incheon, Republic of Korea, [2]Inje University Ilsan Paik Hospital, Goyang, Republic of Korea, [3]St. Vincent's Hospital, Seoul, Republic of Korea

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Metabolic & Crystal Arthropathies Poster I: Clinical
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The cardiovascular risk of gout is already well known, and the debate over the cardiovascular risk of uric acid lower agents is currently hot. Although hyperuricemia has been reported to be associated with a higher cardiovascular risk, it is not yet conclusive and guidelines for the management in patients with hyperuricemia are still lacking. We investigated associations of serum uric acid level with cardiovascular disease (CVD) risk in general population.

Methods: We examined data from a survey conducted during the first and second years of the seventh Korea National Health and Nutrition Examination Survey (KNHANES,2016-2017). We included subjects who were aged from 30 to 74 years without prevalent CVD. We estimated CVD risk by 10-year CVD risk score prediction formula. Fractional polynomial model was chosen to estimate relationship of serum uric acid, physical activity, and BMI with 10-year CVD risk score.

Results: There was no significant difference of 10-year CVD risk score in men by serum uric acid level, but there was significant difference in women. In the fitted fractional polynomial model, an approximate U-shaped association between serum uric acid level and 10-year CVD risk score with an inflection point at 6.9 mg/dL of serum uric acid level in men was found. An approximate J-shaped association between serum uric acid level and 10-year CVD risk score in women was found.

Table 1. Associations of serum uric acid, physical activity and body mass index with 10-year cardiovascular disease risk by gender

Parameter	Men			Women		
	β-coefficient	SE	*p* value	β-coefficient	SE	*p* value
Serum uric acid #1	-0.241	0.033	< 0.001	0.075	0.013	< 0.001
Serum uric acid #2	0.023	0.031	< 0.001			
Aerobic physical activity	-1.071	0.214	< 0.001	-0.834	0.172	< 0.001
Muscular strength exercise	0.432	0.234	0.066	0.039	0.214	0.854
Body mass index	0.146	0.032	< 0.001	0.505	0.030	< 0.001

There was no significant difference of 10-year CVD risk score in men by serum uric acid level, but there was significant difference in women. In the fitted fractional polynomial model, an approximate U-shaped association between serum uric acid level and 10-year CVD risk score with an inflection point at 6.9 mg/dL of serum uric acid level in men was found. An approximate J-shaped association between serum uric acid level and 10-year CVD risk score in women was found.

Conclusion: Our study showed that hyperuricemia is associated with increased CVD risk, hypouricemia is also associated with increased CVD risk in men and practicing aerobic physical activity and lower BMI is associated with reduced CVD risk.

Subtypes of Gout Based on Comorbidity Patterns Among Black Patients in the US General Population - Cluster Analysis of the National Health and Nutrition Examination Survey 2007-2016

Chio Yokose ,[1] Na Lu,[2] Michael Chen-Xu,[3] Natalie McCormick,[4] Michael Pillinger,[5] Yuqing Zhang,[1] and Hyon K. Choi[1], [1]Massachusetts General Hospital, Boston, MA, [2]Massachusetts General Hosptial, Boston, MA, [3]Capital and Coast District Health Board, Wellington, New Zealand, [4]Massachusetts General Hospital and Harvard Medical School, Boston, MA, [5]New York University School of Medicine, New York

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Metabolic & Crystal Arthropathies Poster I: Clinical
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Gout is a very prevalent condition associated with many metabolic and cardiorenal comorbidities. A few studies have investigated the comorbidity subtypes of gout patients by cluster analyses; however, such analyses have not yet been performed among Blacks nor confirmed in a general population cohort. As such the generalizability of these findings remains unknown. Thus, our objective was to identify gout subtypes based on comorbidities using cluster analysis among Black adults with gout in the US general population. Furthermore, we sought to compare these findings to that of White adults with gout.

Methods: We used data from 371 Black and 656 White participants in the 2007-2016 cycle of the National Health and Nutrition Examination Survey (NHANES), a nationally representative sample of adults in the US with detailed clinical and physical examination data. Diagnosis of gout was based on survey of physician- or health professional-diagnosed gout. We employed Ward's minimum variance method of clustering to group patients with gout into clusters (i.e., subtypes) based on distinct comorbidity patterns according to 8 variables: obesity, hypertension, diabetes, dyslipidemia (i.e., hypercholesterolemia and/or hypertriglyceridemia), coronary heart disease (CHD), heart failure (HF), chronic kidney disease (CKD), and non-alcoholic fatty liver disease (NAFLD).

Results: Metabolic and cardiorenal comorbidities were prevalent among both Black and White participants with gout (**Table 1**). Cluster analysis identified 5 comorbidity subgroups among Black patients with gout (**Table 2**). All patients in Group 1 had dyslipidemia and hypertension. Group 2 had the highest proportion of patients with diabetes (95%), and nearly all patients with NAFLD belonged to this group. Group 3 consisted of patients with gout but few

other comorbidities. All patients in Group 4 had CKD. Group 5 had the highest proportion of patients with CHD and HF. Cluster analysis among Whites also identified subgroups with isolated gout (Group 2) and dyslipidemia and hypertension (Group 1) (**Table 3**). It also identified a subgroup that combined cardiac and renal disease (Group 5). Key differences among Whites was the presence of obese (Group 3) and hypertension only (Group 4) clusters, and the lack of a diabetes group. The higher prevalence of obesity in Blacks and the smaller number of Black participants likely contributed to these differences.

Conclusion: These findings from a nationally representative sample of Black US adults identified 5 subgroups of gout based on comorbidities: dyslipidemia/HTN, diabetes, isolated gout, CKD, and heart disease. Notable differences from the European population and American White cohorts included the separation of CKD and cardiac disease

and the absence of a group defined by obesity among US Blacks. Overall, these subgroups could be broadly classified as i) isolated gout, ii) dyslipidemia/hypertension, iii) obese or diabetes, and iv) cardiorenal disease (separately or together). These subgroups may shed light on pathophysiologic mechanisms that contribute to gout and have implications for personalized interventions to reduce the burden of gout and its comorbidities.

Patterns and Clinico-Radiological Correlates of Symptomatic Atlantoaxial Joint Involvement in Patients with Calcium Pyrophosphate Deposition Disease

Joana Silva-Dinis ,[1] Catarina Tenazinha,[2] Nikita Khmelinskii,[2] Vítor Teixeira,[2] Pedro Ávila-Ribeiro,[1] João Eurico Fonseca,[1] and José-Carlos Romeu[2], [1]Rheumatology and Bone Diseases Department, Hospital de Santa Maria, Centro Hospitalar Universitário Lisboa Norte; Unidade de Investigação em Reumatologia, Instituto de Medicina Molecular, Faculdade de Medicina, Universidade de Lisboa; Centro Académico de Medicina de Lisboa; Lisbon, Portugal., Lisbon, Portugal, [2]Rheumatology and Bone Diseases Department, Hospital de Santa Maria, Centro Hospitalar Universitário Lisboa Norte; Lisbon, Portugal., Lisbon, Portugal

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Metabolic & Crystal Arthropathies Poster I: Clinical

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Atlantoaxial joint involvement in calcium pyrophosphate deposition disease (CPPD) may present as crowned dens syndrome (CDS), a clinico-radiological tetrad defined as the presence of periodontoid calcifications, acute cervical pain with neck stiffness, fever, and raised inflammatory markers. Though 40-60% of CPPD patients exhibit periodontoid calcifications, only a small percentage develop CDS. Risk factors associated with CDS development in these patients remain unknown. The purpose of this study was to identify differences between symptomatic and asymptomatic CPPD patients with periodontoid calcifications.

Methods: Single-center cross-sectional analysis of CPPD patients with periodontoid calcifications identified by cervical or head CT done for various unrelated reasons. All the analyses were performed using STATA 14.2.

Results: Forty-one patients with CPPD and periodontoid calcifications were identified. Median age at diagnosis was 78 years (73-83) and 26 (63.4%) were female. Peripheral arthritis was present in 27 patients (65.9%) as monoarthritis

Patients with symptomatic atlantoaxial joint involvement	n=25
Symptoms at presentation	
CDS - acute cervical pain with neck stiffness, fever, and raised inflammatory markers, n (%)	2 (8.0%)
Incomplete CDS - acute cervical pain with raised inflammatory markers, without fever or neck stiffness, n (%)	9 (36.0%)
Fever of unknown origin, n (%)	1 (4.0%)
Polymyalgia rheumatica-like, n (%)	6 (24.0%)
Chronic neck pain, n (%)	6 (24.0%)
Retrodontoid pseudotumor with tetraparesis, n (%)	1 (4.0%)
Fever, n (%)	6 (24.0%)
Raised inflammatory markers, n (%)	14 (56.0%)
Median ESR - mm/h (IQ)	72 (48 – 110)
Median CRP - mg/dL (IQ)	6.9 (2.4 – 16.3)

Table 1. Clinico-laboratorial presentation of symptomatic atlantoaxial joint involvement

Variable	Asymptomatic (n=16)	Symptomatic (n=25)	p-value
Median age (IQ)	79 (73-82)	78 (67-83)	0.544
Male gender, n (%)	7 (43.8%)	8 (32.0%)	0.517
Presence of peripheral arthritis, n (%)	12 (75.0%)	15 (60.0%)	0.501
Monoarthritis, n (%)	7/12 (58.3%)	1/15 (6.7%)	0.008
Oligo/polyarthritis, n (%)	5/12 (41.7%)	14/15 (93.3%)	0.008
CT findings			
Transverse (cruciform) ligament calcifications, n (%)	16 (100%)	23 (92.0%)	0.512
Apical and/or alar ligament calcifications, n (%)	4 (25.0%)	16 (64.0%)	0.025
C1 erosions, n (%)	1 (6.3%)	4 (16.0%)	0.632
C1-C2 subluxation, n (%)	0	1 (4.0%)	N.A.
Transverse ligament involvement stage			
Stage 1, n (%)	2 (12.5%)	6 (24.0%)	0.468
Stage 2, n (%)	10 (62.5%)	13 (52.0%)	
Stage 3, n (%)	4 (25.0%)	4 (16.0%)	
Stage 4, n (%)	0	2 (8.0%)	

Table 2. Comparative analysis between patients with asymptomatic versus symptomatic periodontoid calcifications

(8), oligoarthritis (11), or polyarthritis (8). All patients had radiographic chondrocalcinosis at other sites. Metabolic changes were present in 20 patients (48.8%): low 25(OH)D (17), hyperparathyroidism (9), hypomagnesemia (2), and hypophosphatemia (1). Eleven patients had chronic kidney disease (26.8%). Periodontoid calcifications were documented at the transverse (cruciform) ligament in 39 patients (95.1%), alar ligaments in 19 (46.3%), and apical ligament in 6 (14.6%). CT staging of the transverse ligament changes identified curvilinear deposits (>1mm) in a single band (stage 2) in 23 patients (56.1%).

Twenty-five patients (61.0%) had symptomatic atlantoaxial joint involvement (Table 1). All symptomatic patients were treated with a combination of colchicine (16; 64.0%), NSAIDs (13; 52.0%), and/or systemic corticosteroids (13; 52.0%). Four patients (16.0%) with peripheral polyarthritis were treated with methotrexate.

Comparative analysis (Table 2) showed that, in patients with peripheral arthritis, monoarthritis was more frequent in patients with asymptomatic periodontoid calcifications and oligo/polyarthritis was more common in patients with symptomatic disease. Apical and/or alar ligament calcifications were more frequent in patient with symptomatic atlantoaxial joint involvement.

Conclusion: Atlantoaxial joint involvement in CPPD is heterogeneous, classical CDS being uncommon. The pattern of peripheral arthritis and ligament calcification is associated with the presence of symptoms in CPPD patients with periodontoid calcifications.

Patterns of Newer Gout Medication Use in a U.S. Electronic Health Record-Based Registry

Kenneth Saag ,[1] Andreas Reimold,[2] Lang Chen,[1] Huifeng Yun,[1] and Jeffrey Curtis[1], [1]University of Alabama at Birmingham, Birmingham, AL, [2]UT Southwestern Medical Center, Dallas

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Metabolic & Crystal Arthropathies Poster I: Clinical
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: A variety of newer gout therapies have been introduced in recent years, some with potential safety concerns. However, uptake of these therapies and associated dose/duration of use is not clear. We used the American College of Rheumatology's electronic health record-based registry (RISE) to examine patterns of gout drug use over time.

Methods: We used RISE data to identify gout patients by ICD9/10 diagnosis (ICD9: 274.*; ICD10: M10.*, M1A.*) with at least one physician visit in 2016, excluding patients with diagnoses for other types of inflammatory arthritis. Gout medications were identified based on written prescriptions and infusion orders and classified in the following hierarchy so as to assign uniquely: pegloticase, lesinurad, febuxostat, allopurinol, and probenecid. Baseline characteristics including demographics, comorbidities, serum uric acid, and estimated glomerular filtration rate (eGFR) were classified on the date of initiation or using the most recent preceding value. Descriptive characteristics compared initiators of various gout drugs over calendar time 2015-2018.

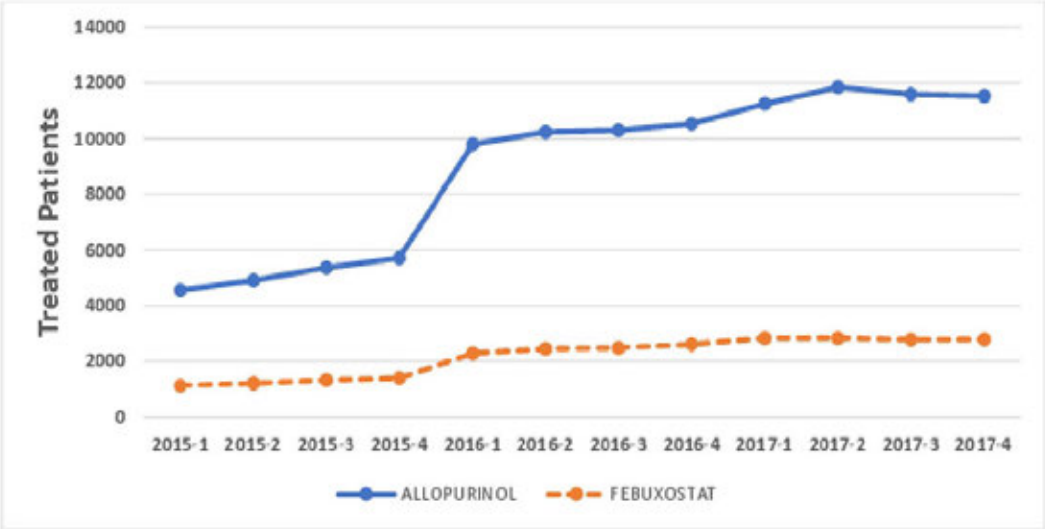

Figure 1. Use of Allopurinol and Febuxostat Over Time in RISE

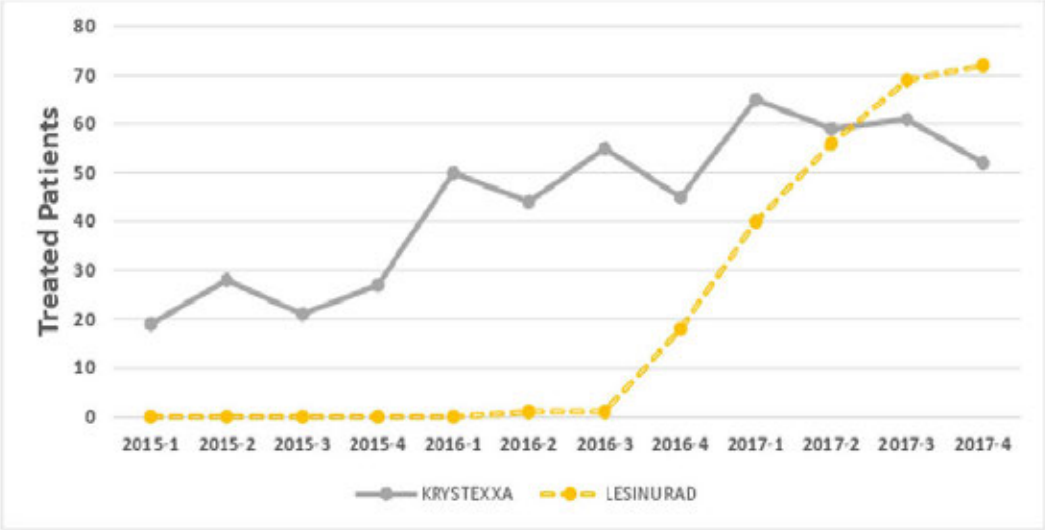

Figure 2. Use of Pegloticase and Lesinurad Over Time in RISE

Results: Patterns of gout drug use are shown in Figures 1 and 2. Allopurinol was the most common drug used, followed by febuxostat. Krystexa and lesinurad were used much less frequently, approximately 1/200 of allopurinol use. In total, 338 patients received pegloticase, prescribed by approximately 150 unique clinicians. Of these, 53% of patients receive only 1 pegloticase dose. For those who received more than 1 dose, the median (IQR) duration of treatment was 105 (24, 294) days.

Overall a total of 19,763 met eligibility criteria for the gout cohort. Mean [SD] age was highest in the febuxostat group: 64 [14] years compared to allopurinol (63 [14]) and pegloticase (61 [16]). Black race was most common in the febuxostat group (12.3%) and lowest in allopurinol (7.8%). Febuxostat-treated patients had a higher prevalence of coronary atherosclerosis (4.8%) vs. allopurinol users (2.8%), and chronic kidney disease was more common in febuxostat patients (median eGFR 57 ml/min) vs. allopurinol patients (68 ml/min). NSAIDs were used by approximately one-third of allopurinol (36%) and febuxostat (31%) users and more than half (56%) of pegloticase patients. Colchicine was used even more frequently (allopurinol: 50%; febuxostat: 59%; pegloticase: 83%). Opioids were commonly used as concomitant treatment: 24%, allopurinol; 32%, febuxostat; and 40%, pegloticase.

Conclusion: The EHR-based ACR RISE registry appears useful to examine prescribing trends for gout medication use, even for relatively uncommonly used therapies. Febuxostat users had a higher prevalence of cardiovascular-related comorbidities compared to allopurinol users, inviting caution in the selection of patients to receive this therapy given recent FDA warnings.

Carotid Atherosclerosis and Sonographic Signs of Urate Crystal Deposits in Patients with Gout: An Association Study

Irene Calabuig ,[1] Agustín Martínez-Sanchis,[2] and Mariano Andrés[3], [1]Hospital General Universitario de Alicante-ISABIAL, Alicante, Spain, [2]Hospital General Universitario de Alicante, Alicante, Spain, [3]Hospital General Universitario de Alicante-ISABIAL, Universidad Miguel Hernández, Alicante, Spain

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Metabolic & Crystal Arthropathies Poster I: Clinical
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Carotid subclinical atherosclerosis is prevalent in patients with gout, although poorly predicted by cardiovascular risk assessment tools. Gout itself is deemed to contribute to its development. However, a previous report did not show association between clinical characteristics of gout and the presence of subclinical atherosclerosis [Ann Rheum Dis. 76:1263]. The aim of this study was to explore the association between sonographic signs of urate crystal deposits and carotid atherosclerosis.

Methods: Consecutive new patients with crystal-proven gout attended in a tertiary Rheumatology unit were eligible for the study. This included musculoskeletal and carotid ultrasound assessment, performed by a trained sonographer blinded to clinical data. Patients were examined during intercritical periods; flare prophylaxis with low-dose colchicine or other agents was permitted, but patients under urate-lowering treatment were excluded. The musculoskeletal scans evaluated wrists, 2nd MCPs and 1st MTPs joints, and triceps and patellar tendons, for the presence of signs suggestive of urate crystal deposits (double contour, hyperechoic aggregates, and tophi), following OMERACT definitions. Also, local power-Doppler (PD) signal was registered and graded as 0 to 3. The sum of locations showing crystal deposits or positive PD signal (≥1) was chosen to assess the crystal and inflammatory burden, respectively. Carotid arteries were scanned for increased intima-media thickness (IMT) and presence of atheroma plaques, according to Mannheim consensus. The association analysis was done by logistic regression, considering increased IMT or atheroma plaques as the independent variable.

Table 1. Results of the association analysis by simple logistic regression.

	Increased IMT		Atheroma plaques	
	OR (95%CI)	p	OR (95%CI)	p
Sum of locations with deposits	1.03 (0.90-1.19)	0.653	1.05 (0.93-1.19)	0.436
Sum of locations with DC	0.92 (0.51-1.65)	0.778	0.87 (0.55-1.39)	0.556
Sum of locations with HA	0.95 (0.77-1.17)	0.620	0.98 (0.83-1.16)	0.785
Sum of locations with tophi	1.26 (0.95-1.67)	0.108	1.27 (1.00-1.60)	0.047
Sum of locations with positive PD	0.85 (0.48-1.52)	0.591	1.93 (1.12-3.34)	0.019

95%CI: 95% confidence interval; DC: double-contour; HA: hyperechoic aggregates; IMT: intima-media thickness; OR: odds ratio; PD: power Doppler.

Results: Seventy-four new patients with gout were enrolled, mean aged 62.2 years (SD 14.7), 89.2% males. Mean gout duration was 5.6 years (SD 9.2), clinical tophi were observed in 15.9% of patients and mean serum urate level at diagnosis was 8.2 mg/dl (SD 1.6). All participants showed at least one sonographic sign of crystal deposits at the examined locations, with a mean sum of locations of 9 (SD 3.9). Regarding individual signs, their mean (SD) sum was as follows: 4.4 (2.2) for tophi, 3.7 (2.8) for aggregates and 0.8 (1.0) for double contour. The mean sum of locations with positive PD signal was 1.1 (SD 1.0). Regarding carotid scans, increased IMT was seen in 17 patients (24.3%), and atheroma plaques in 41 (55.4%). Table 1 shows the results of the association analysis. Tophi and positive PD signal were significantly associated with the presence of atheroma plaques, while no sonographic sign showed association with an increased IMT.

Conclusion: Sonographic deposits were consistently observed in new patients with gout. Tophi and positive PD signal, indicators of crystal and inflammatory burden, were significantly associated with carotid atheroma plaques. This new finding may contribute to understand the complex relationship between gout and atherosclerosis.

Rapid Reduction in Uric Acid Is Associated with Recurrent Cardiovascular Events

Su Jin Choi ,[1] Jung Sun Lee,[1] So Hye Nam,[1] Doo-Ho Lim,[2] Ji Seon Oh,[3] Seokchan Hong,[4] Yong-Gil Kim,[1] Chang-Keun Lee,[1] and Bin Yoo[1], [1]Division of Rheumatology, Department of Internal Medicine, University of Ulsan College of Medicine, Asan Medical Center, Seoul, Republic of Korea, [2]Division of Rheumatology, Department of Internal Medicine, Ulsan University Hospital, Ulsan, Republic of Korea, [3]Department of Biomedical Informatics, Asan Medical Center, Seoul, Korea, Seoul, Republic of Korea, [4]Division of Rheumatology, Department of Internal Medicine, University of Ulsan College of Medicine, Asan Medical Center, Seoul, Korea, Seoul, Republic of Korea

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Metabolic & Crystal Arthropathies Poster I: Clinical

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: A recent study showed that febuxostat had a higher risk of cardiovascular and all-cause mortality than allopurinol. Because febuxostat is more potent than allopurinol, we hypothesized that an abrupt change in serum uric acid levels caused by urate-lowering agent might influence the risk of cardiovascular events.

Methods: We included patients with cardiovascular disease (CVD) treated with allopurinol or febuxostat. Cardiovascular events were defined as follows: nonfatal myocardial infarction, nonfatal stroke, unstable angina requiring coronary revascularization procedure, and cardiovascular death. The change in serum uric acid level was determined by the difference or reduction rate in uric acid within 6 months after exposure to allopurinol or febuxostat. The factors associated with cardiovascular events were evaluated by Cox regression analysis.

Results: In total, 207 patients with CVD exposed to allopurinol or febuxostat were included. Cardiovascular events occurred in 25 patients (12.1%). In univariate analysis, hypertension, difference in uric acid levels between baseline and post-exposure to urate-lowering agent, and reduction rate in uric acid levels were associated with cardiovascular events. In multivariate analysis, hypertension [hazard ratio (HR) 3.450, 95% confidence interval (CI), 1.167–10.202, $p = 0.025$] and reduction rate in uric acid to the lowest levels (HR 26.133, CI, 6.876–99.319, $p < 0.001$) were associated with cardiovascular events.

Conclusion: Rapid reduction in serum uric acid levels was associated with the recurrence of cardiovascular events in patients with CVD. Thus, careful attention should be paid to abruptly changed serum uric acid levels after treating urate lowering agent in high-risk CVD patients.

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Metabolic & Crystal Arthropathies Poster I: Clinical

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Allopurinol (ALLO), the leading hypouricemic drug worldwide, exposes to mild (M) and severe (S) cutaneous adverse reactions (CARs). SCARS have been associated with HLA*B-58 01. However, the reported strength of the association has varied across ethnicities and has been little studied in Vietnam. Little is known about risk factors for MCARs.

The aim of this prospective study was to investigate risk factors, including HLA*B-58 01, for MCARs and SCARs in the predominant Kinh ethnicity of Vietnam.

Methods: All patients were Kinh Vietnamese and were prospectively recruited in Ho Chi Minh City, after Ethics committee approval. SCARs were recruited in dermatology and allergy hospital departments, MCARs in the same departments and at the Vien Gut clinic (specialized in gout care), and tolerant gouty patients (no skin reaction after at least 3 months from the last increment in ALLO dose) at the Vien Gut clinic. Clinical data were prospectively collected and HLA*B-58 01 genotype was obtained using the PG5801 DNA detection kit (Pharmigene-Taiwan). Fisher exact test for categorical variables and Kruskal/Wilkonson test for quantitative variables were used for statistics.

Results: Between March 2017 and May 2019, 31 patients with a non-fatal SCAR. (29 toxic necrotic epidermolysis/ Stevens-Johnson syndrome and 2 DRESS), 74 patients who stopped ALLO because of MCAR and 395 ALLO-tolerant patients were recruited. Table 1 shows the main features of interest in the 3 groups. The Odds ratios of lack of dose escalation, HLA*B-58 01 presence and GFR< 60 ml/min to develop SCARs were calculated at 883 (, 95%CI:128; 4504), 185(95 % CI: 43; 1595) and 104 (95%CI:28;454), respectively.

Conclusion: In the studied Vietnamese Kinh population, lack of ALLO titration was the strongest risk factor for SCARs. HLA*B-58 01 and other known factors, including renal failure but not high ALLO dose, were also significantly associated with SCARs. MCARs associated with lack of ALLO titration and renal failure but not with HLA*B-58 01

Primary Hyperparathyroidism Is Associated with a Higher Level of Serum Uric Acid: A Systematic Review and Meta-analysis

Ben Ponvilawan,[1] Nipith Charoenngam,[1] and **Patompong Ungprasert** [2], [1]Mahidol University, Bangkok, Thailand, [2]Cleveland Clinic, Cleveland, OH, Bangkok, Thailand

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Metabolic & Crystal Arthropathies Poster I: Clinical
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Studies have suggested that primary hyperparathyroidism could be a risk factor for hyperuricemia although the results were inconsistent across the studies. This systematic review and meta-analysis was performed in order to identify all available studies and summarize their results together.

Methods: A systematic review was performed using EMBASE and MEDLINE from inception to August 2018 to identify all cohort studies that consisted of two cohorts, cohort of patients with primary hyperparathyroidism and cohort of individuals without hyperparathyroidism. Eligible studies must provide data on mean serum uric acid level and standard deviation of both cohorts, which would be extracted to calculate mean difference (MD). Pooled MD was then calculated by combining MDs of each study using random-effects model. Funnel plot was used for evaluation for publication bias.

Results: A total of nine cohort studies met the inclusion criteria and were included into the meta-analysis. The pooled analysis found that patients with primary hyperparathyroidism had a significantly higher level of serum uric acid than individuals without hyperparathyroidism with the pooled MD of 65.00 µmol/L (95% CI, 37.74 - 92.25). The statistical heterogeneity was high with I^2 of 90 %. The forest plot of this meta-analysis is shown as figure 1. The funnel plot was relatively symmetric and did not provide evidence for publication bias (figure 2). Reduced renal tubular secretion of urate due to the direct effect of PTH on renal tubules is one of the possible explanations for this observation.

Conclusion: Patients with primary hyperparathyroidism had a significantly higher level of serum uric acid compared to individuals without hyperparathyroidism.

Allopurinol Use and Type 2 Diabetes Incidence Among Patients with Gout: A VA Cohort Study

Anastasia Slobodnick ,[1] Michael Toprover,[2] Courtney Pike,[3] Daria Crittenden,[4] Jeffrey Greenberg,[5] and Michael Pillinger[2], [1]New York University School of Medicine, New York, NY, [2]New York University School of Medicine, New York, [3]Rheumatology Section, NY Harbor VA Healthcare System, New York, [4]Amgen Inc., Thousand Oaks, CA, [5]Corrona, LLC; NYU School of Medicine, Waltham, MA

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Metabolic & Crystal Arthropathies Poster I: Clinical

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Several studies implicate gout and/or xanthine oxidase activity as risk factors for type 2 diabetes. However, no studies have directly evaluated the effect of the xanthine oxidase inhibition on type 2 diabetes development. We therefore assessed the impact of allopurinol use on diabetes incidence in a retrospective cohort study of Veterans' Affairs patients with gout.

Methods: The New York Harbor VA Computerized Patient Record System was searched to identify patients with an ICD-9 code for gout also meeting at least 4 1977 American Rheumatology Association gout diagnostic criteria. Pharmacy records were reviewed, and subjects divided into subgroups based on >30 continuous days of allopurinol prescription, versus no allopurinol. Incident diagnoses of diabetes, defined as first hemoglobin A1c ≥ 6.5% or physician documentation, were identified during an observation period from January 1, 2000 through December 31,

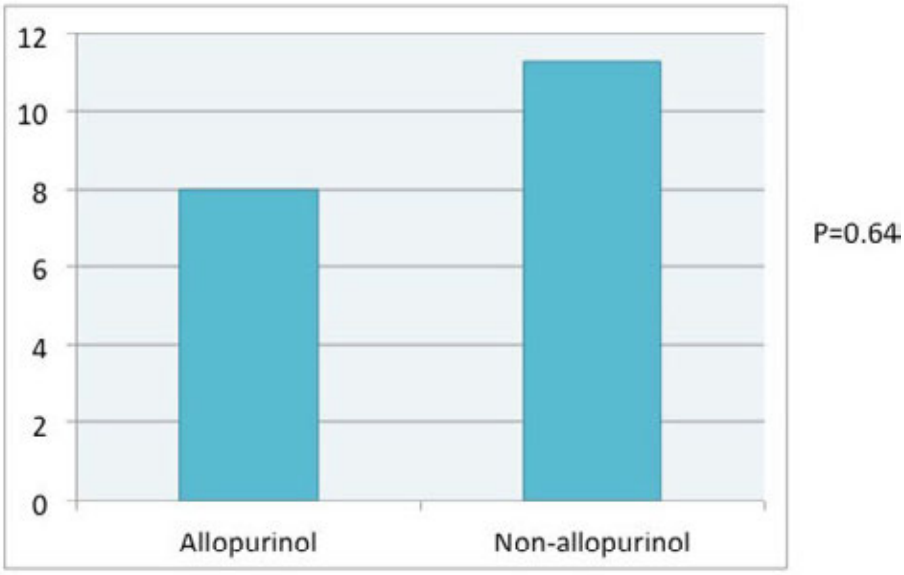

Figure 1. Diabetes incidence per 1000 person-years

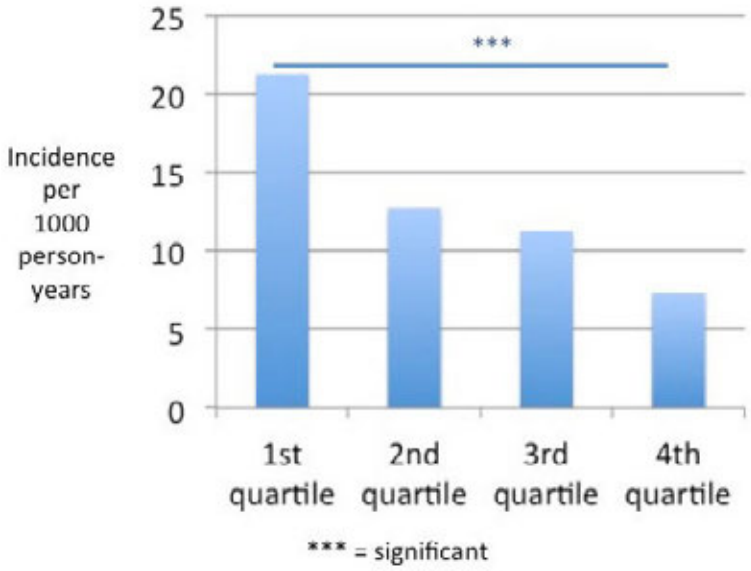

Figure 2. Diabetes incidence by duration of allopurinol use/observation

2015. Categorical variables, including the primary endpoint, were analyzed utilizing Fisher's exact test. Continuous variables were analyzed using binomial regression and the Student's T test.

Results: 1032 subjects were allopurinol users, and 485 subjects were allopurinol never-users. The average duration of allopurinol use was 48.4 months. There were significantly more Black subjects in the allopurinol group, whereas there were significantly more Asian subjects and subjects with chronic kidney disease in the non-allopurinol group. Over a mean 94.3 months of follow-up, there was no significant difference in diabetes incidence between the allopurinol and non-allopurinol groups (8.0/1000 person-years versus 11.3/1000 person-years, p=0.64). There was also no significant difference in diabetes incidence when subjects were analyzed by baseline serum urate level, colchicine use, allopurinol dose, extent of urate lowering with allopurinol or achieving target urate level. When stratified into quartiles by duration of allopurinol use, a significant difference was observed between diabetes incidence in the

longest and shortest quartiles among subjects in the allopurinol cohort (7.3 per 1000 person-years versus 21.3 per 1000 person-years, p=0.007).

Conclusion: In this study, allopurinol use was overall not associated with reduced diabetes incidence, but longer durations of allopurinol use may have been associated with decreased diabetes. Prospective studies may further elucidate the relationship between hyperuricemia, gout, xanthine oxidase activity and diabetes, and the potential impact of gout treatments on diabetes incidence.

Abstract Number: 0354

Evaluation of Opioid Analgesia in Hospitalized Patients with Acute Crystal Induced Arthritis

Sukhraj Singh ,[1] Anthony Ocon,[1] Mark Riley,[2] Jennifer Tchervenkov,[1] and Ruben Peredo-Wende[1], [1]Albany Medical Center, Albany, NY, [2]Albany Medical Center, Albany

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Metabolic & Crystal Arthropathies Poster I: Clinical
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The Opioid Epidemic has been declared a public health emergency since 2017. The use of opioids in the acute crystal induced arthritis (ACIA) population has not been well evaluated. Despite availability of effective gout treatments, opioid use remains prevalent in hospitalized patients [1]. Traditionally, treatment for acute flares includes non-steroidal anti-inflammatories, colchicine, and glucocorticoids. Anakinra is a relatively new immunomodulator that has been shown to be non-inferior to traditional treatments for acute gout flares, suggesting that anakinra is an effective alternative treatment for acute gout flares [2]. We proposed to look at the total amount of opioid use in the inpatient population suffering from acute crystal induced arthritis and also evaluate whether anakinra use may reduce opioid prescribing.

Methods: Retrospective chart review of all adult in-patients who were admitted between 2015 through 2018 with gout or pseudogout flare were evaluated. A total of 204 patients met ACR/EULAR criteria for ACIA. Of those, seventeen had received anakinra for ACIA and thirty-four patients receiving traditional treatment were matched with the anakinra group in a 1:2 ratio. The two groups were matched for age, gender and number of joints affected. Data collection included demographics, home medications, comorbidities, and Visual Analog Pain Scale (VAS-pain). Response to treatment was defined as decrease in VAS-pain by more than 2 points on a 0-10 scale at 24, 48, and 72 hours. The total opioid dose in morphine milliequivalents was reviewed for both groups. Repeated measures ANOVA was used to compare each group at each time-point of pain assessment. Tukey-Kramer multiple comparisons test was used for post-hoc comparisons. Significance was set at $p< 0.05$.

Results: All the patients in traditional treatment group had significantly more use of opioids for their joint pains compared to the anakinra group ($p< 0.05$). All patients receiving anakinra had statistically significant improvement in VAS-pain compared to the conventional group ($p< 0.001$). Within the anakinra group, pain was significantly improved at 24 hours ($p< 0.05$) and at 48 hours ($p< 0.001$) compared to baseline. The conventional group had significant improvement at 48 hours compared to baseline ($p< 0.05$) but was not significantly improved at 24 hours ($p >0.05$). Between

Mean ESR [95% CI]	67.2 [55.8 – 78.4]	54.1 [36.2 – 71.9]
Mean Renal Function		
Blood Urea Nitrogen [95% CI]	28.9 [23.8 – 34.0]	25.6 [19.7 – 31.5]
Serum Creatinine [95% CI]	1.59 [1.26 – 1.93]	1.79 [1.01 – 2.58]
Glomerular Filtration Rate [95% CI]	44.4 [38.6 – 50.1]	46.6 [38.1 – 55.1]
•Mean VAS-pain Scores [95% CI]		
Before Treatment	7.8 [7.1 – 8.4]	7.9 [6.9 - 8.9]
24 hours after Treatment	7.3 [6.6 – 8.1]	6.3 [5.3 – 7.4]
48 hours after Treatment	6.7 [5.7 – 7.8]	4.0 [2.5 – 5.5]
72 hours after Treatment	6.7 [5.7 – 7.6]	3.1 [1.3 – 4.9]
•Mean Morphine Milliequivalents [95% CI]	120.8 [64.2 – 177.3]	46.7 [0 – 95.4]
Odds Ratio for Opioid prescription at Discharge [95%CI]	3.35 [0.37-30.9]	0.30 [0.03-2.7]
Mean Number of Days in Hospital after Flare diagnosis, [95% CI]	7.2 [5.2 – 9.2]	5.2 [CI 3.9 – 6.5]
Mean doses of Anakinra [95% CI]	0	3.1 [2.3 – 3.9]

•Indicates statistically significant with $p<0.05$

groups pain was not different at baseline or at 24 hours ($p > 0.05$). On average the number of days of hospitalization since treatment initiation was nearly 2 days shorter in the anakinra group compared to conventional. In addition, prescription for opioids at discharge was more likely in the traditional treatment group [OR = 3.34, (CI 0.37-30.70)], but this did not reach statistical significance. No significant adverse events were noted in the anakinra group.

Conclusion: A significant amount of opioid analgesia is employed in treating inpatients with ACIA. Significant pain reduction with anakinra highlights the availability of safe alternative for inpatients with ACIA. Additional investigations are warranted to evaluate the appropriate role of opioids in ACIA population and how to control its utilization.

Comparative Risk of Cardiovascular Events in US Veterans with Gout Treated with Febuxostat versus Allopurinol

Hanna Zembrzuska ,[1] Yubo Gao,[1] Saket Girotra,[1] Brian Lund,[2] Kenneth Saag,[3] Jeffrey Curtis,[3] Mary Vaughan-Sarrazin,[2] and Namrata Singh[4], [1]University of Iowa Hospitals and Clinics, Iowa City, IA, [2]Iowa City VA Health Care System, Iowa City, IA, [3]University of Alabama at Birmingham, Birmingham, AL, [4]University of Iowa, Iowa City

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Metabolic & Crystal Arthropathies Poster I: Clinical
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Gout is the most common inflammatory arthritis and is particularly common among veterans. Recent studies, a randomized controlled trial (CARES, White et al. NEJM 2018) and an observational study using administrative claims data (Zhang et al. Circulation 2018) point to a higher all-cause and cardiovascular mortality with febuxostat relative to allopurinol. However, the CARES trial was limited to patients with a history of major cardiovascular disease and 45% subjects were lost to follow up. Therefore, the objective of our study was to evaluate the comparative risk of cardiovascular events in veterans with gout on allopurinol versus febuxostat.

Methods: We identified patients age >=18 with gout who initiated allopurinol during 2009-2017 using encounter and claims data from the Corporate Data Warehouse housed within the Veteran Affairs Informatics and Computing Infrastructure (VINCI). The Index date was the date of first allopurinol fill. Patients were followed in monthly increments for up to 8 years and, for patients who subsequently initiated febuxostat, the date of first febuxostat fill was noted. Exclusion criteria included patients with end stage renal disease or on dialysis; use of pegloticase or rasburicase in the 365 days before the index date. The primary outcome was development of major adverse cardiovascular events (MACE) defined as hospitalization for myocardial infarction (MI), stroke (including TIA), or heart failure (new-onset heart failure or heart failure exacerbation). The secondary outcomes were myocardial infarction, stroke, new and recurrent heart failure, and all-cause mortality. Marginal structural models (MSM) were used to determine the hazard of MACE events with febuxostat relative to allopurinol while accounting for changes in patient characteristics over time that influence the use of febuxostat (serum uric acid and glomerular filtration rate). Censoring events included death, date of last available allopurinol or febuxostat, or end of follow up (whichever comes first).

Results: We identified 151,184 new allopurinol users, of which 3,693 (2.4%) subsequently initiated febuxostat over the study period. Allopurinol-only users were predominantly male (98.4%) and white (63.7%), respectively, with similar attributes in those switching to febuxostat. 56% of allopurinol users had uric acid >8-< 12 mg/dl compared to 70.3% of febuxostat group at drug initiation. There were 186 MACE events over 8,768 patient years of febuxostat use (crude incidence rate (IR)=2.12/100 patient-yrs) compared to allopurinol 6,623 events over 554,916 patient years (crude IR=1.19/100 patient-yrs); adjusted hazard ratio (HR) being 1.11 (95% CI 0.95-1.29, p=0.19) after multivariable adjustment. We also observed no statistically significant differences between months of allopurinol use or febuxostat use for MI, stroke or composite of MACE and all-cause mortality (Table 1).

Table 1 Risk of major adverse cardiovascular events in allopurinol compared to febuxostat use

	Febuxostat (n=3693)			Allopurinol (n=147491)			
	Event (n)	Patient-Years	Crude IR	Event (n)	Patient-Years	Crude IR	Adjusted HR (95%CI)
Primary Outcome

Stroke	31	9194	0.34	1343	564948	0.24	1.09 (0.76-1.56)
Heart failure	139	8924	1.56	4483	560443	0.80	1.09 (0.91-1.31)
All-cause mortality	718	8768	8.19	32248	554916	5.81	1.02 (0.95-1.11)

CI = confidence intervals; IR = incidence rate is per 100 person-years; MI = myocardial infarction

Conclusion: By using marginal structural model to reduce bias caused by non-random censoring and treatment assignment, we found no differences in the risk of MACE events between febuxostat and allopurinol users in a large cohort of veterans with gout.

Gout Flares Become Infrequent During a Treat-to-target Strategy over One Year: Data from the NOR-Gout Study

Till Uhlig ,[1] Lars Fridtjof Karoliussen,[2] Espen A Haavardsholm,[2] Tore Kvien,[1] and Hilde Hammer[2], [1]Diakonhjemmet Hospital, Dept. of Rheumatology / University of Oslo, Faculty of Medicine, Oslo, Norway, [2]Diakonhjemmet hospital, Oslo, Norway

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Metabolic & Crystal Arthropathies Poster I: Clinical
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Urate lowering therapy (ULT) is expected to prevent new gout flares. Treat-to-target ULT is however often not performed, and more evidence on how often patient experience flares during ULT is needed.

We studied how many patients had a gout flare during months 6-12 in the first year during a treat-to-target strategy, and which factors predicted a flare during that time.

Methods: In a prospective observational study, 208 patients with crystal-proven gout with a recent gout attack and insufficiently treated serum urate (sUA) level (>360 μmol/L/ >6 mg/dl) were included. They received ULT with drug escalation during monthly follow-up until the target sUA level was met (sUA < 360 μmol/L, or < 300 μmol/L if clinical tophi). Assessments in this ongoing data collection included demographic and clinical variables, serum urate levels, previous medication with allopurinol, colchicine and NSAIDs, co-morbidities, and health related quality of life (SF-36). Flares during the last six months in the first year of follow-up with "treat-to-target" were recorded. Bivariate analyses and logistic regression analyses examined factors associated with and prediction (odds ratio with 95% confidence interval) of a flare during months 6-12.

Results: 208 patients were included, and 164 completed a 12-month follow-up: 94.3% males, 90.5% Caucasian, mean (SD) age 56.3 (13.7) years, disease duration 7.9 (7.7) years), body mass index 28.8 (4.6), sUA level 496 (81) μmol/L, and 17.9% had tophi. Allopurinol had previously been used by 27.2% (57/186), colchicine by 50.7% (106/200), NSAIDs by 75.6 % (158/203), and prednisolone by 43.5% (91/198). 67.7% of patients had no flare between 6 and 12 months. After 12 months 87.0% (141/162) had reached the treatment target sUA < 360 μmol/l, but this was not related to whether patients had a flare between months 6-12 (p=0.83). A number of variables at baseline were bivariately related to a flare: higher BMI (p< 0.002), presence of tophi (p=0.02), co-morbidities (p=0.03), previous use of colchicine (p< 0.001) or NSAIDs (p=0.04), worse physical function summary score (SF-36) (p< 0.03), and high level joint pain during strongest attack ever (p=0.001).

In multivariate logistic regression analyses, also adjusting for age and gender in the final model, a high BMI (OR 1.11 per unit (95% CI 1.02-1.21), low baseline serum urate (OR 1.006 per unit, 95% CI 1.001-1.012) and previous use of colchicine (OR 4.8, 95% CI 2.1-11.1) predicted a flare during months 6 and 12. Also, NSAID use (OR 5.1, 95% CI 1.6-16.0), when substituting colchicine, was a predictor of a flare-free period during this period.

Conclusion: One of three patients experienced a flare during the second half of one year with treat-to-target ULT strategy. A low baseline level of sUA and high BMI increased the risk of a flare, as did previous experience with colchicine or NSAID.

Longitudinal Variation in Repeat Serum Urate Levels: Relationship with Hyperuricemia Classification

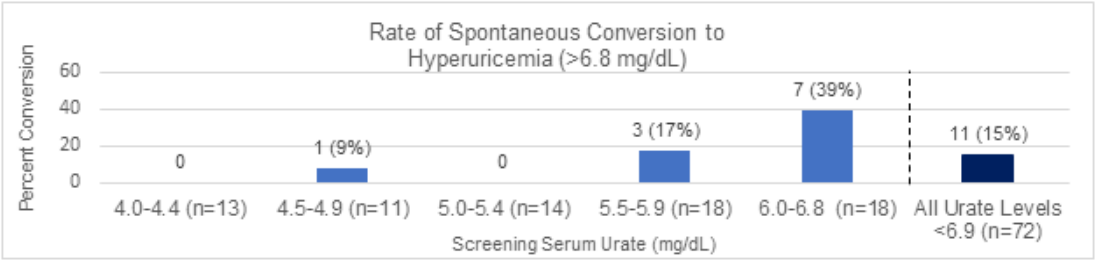
Andrew Shaffer ,[1] Elizabeth Rahn,[2] Kenneth Saag,[2] Amy Mudano,[3] and Angelo Gaffo[2], [1]University of Alabama at Birmingham, Vestavia, AL, [2]University of Alabama at Birmingham, Birmingham, AL, [3]University of Alabama at Birmingham, Birmingham

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Metabolic & Crystal Arthropathies Poster I: Clinical
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Previous studies have noted significant variation in serum urate (sUA) levels, and it is unknown how this influences the accuracy of hyperuricemia classification based on single data points. Despite this known variability, hyperuricemic patients are often used as a control group in gout studies. Our objective was to determine the accuracy of hyperuricemia classifications based on single data points versus multiple data points given the degree of variability observed with serial measurements of sUA.

Methods: Data was analyzed from 85 young adults without a gout diagnosis participating in a single center, double-blinded, crossover trial in which participants were randomly assigned to receive allopurinol (300 mg daily) or placebo for a period of 4 weeks. Serum urate levels were measured at five clinic encounters (2 -4 week intervals between measurements). For this analysis, sUA levels collected at screening, post-placebo and post-washout (i.e., no intervention) were considered (up to 4 sUA levels per participant). Mean coefficient of variation for sUA was determined. The rates of conversion from normouricemia (sUA ≤6.8 mg/dL) to hyperuricemia (sUA >6.8 mg/dL), and from hyperuricemia to normouricemia at were calculated. The rates of conversion to hyperuricemia were then compared across subgroups defined by the sUA level at initial screening (4-4.4, 4.5-4.9, 5-5.4, 5.5-5.9, 6-6.8).

Results: Mean study participant (n = 85) age was 27.8±7.0 years and mean body mass index was 31.1±7.9. 39% of participants were women. 41% of participants were African-American. Mean sUA coefficient of variation was 8.5% ± 4.9% (1% to 23%). There was no significant difference in the coefficient of variation between men and women, or between participants whose screening values were normouricemic (sUA ≤6.8 mg/dL) and those whose values were hyperuricemic (sUA >6.8 mg/dL). Among those with an initial sUA value in the range of normouricemia (n=72), 15% converted to hyperuricemic levels during at least one subsequent measurement (figure 1). The subgroup with initial sUA < 6.0 (n=54) was much less likely to have future values in the range of hyperuricemia compared to the group with screening sUA values between 6.0-6.8 (n=18) (20% vs 39%, p = 0.0037). Of the study participants with a screening



Rate of spontaneous conversion from normouricemia to hyperuricemia at any later measurement by groups stratified by initial (screening) serum urate level

sUA value in the range of hyperuricemia (n=13), 46% had values in normouricemia ranges during at least one later measurement.

Conclusion: Single sUA measurements were unreliable in hyperuricemia categorization (defined as sUA >6.8 mg/dL) due to spontaneous variation in urate levels. This is likely a result of multiple factors such as time of sample collection, diet, and change in weight. Those with an sUA measurement of < 6.0 mg/dL were less likely to demonstrate sUA values classified as hyperuricemic at future evaluations, and this could be considered a safer threshold to rule out intermittent hyperuricemia based on a single measurement point.

Abstract Number: 0358

Emergency Department Encounters in a Large US Payer Database: Tophaceous versus Non-tophaceous Gout Patients

Meron Mezgebe ,[1] Megan Francis-Sedlak,[1] Brian LaMoreaux,[1] and Robert Holt[1], [1]Horizon Therapeutics plc, Lake Forest, IL

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Metabolic & Crystal Arthropathies Poster I: Clinical
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: From 2006 to 2012, gout was the primary indication for ~0.2% of all emergency department visits for adults, as reported in the Nationwide Emergency Department Sample (NEDS).[1] The rate of emergency department visits for gout in the NEDS increased by 14% between 2006 and 2012 rising from 75.0 to 85.4 per 100,000 US adults.[1] A cross-sectional study of 296 gout patients reported that a composite gout severity score, composed of mean serum uric acid, patient-rated and physician-rated gout severity, was a significant predictor of emergency/urgent care service utilization for gout treatment.[2] The relationship between the presence or absence of tophi, visible monosodium urate crystal masses representing an uncontrolled stage of gout,[3] and emergency department utilization has not been previously reported. The objectives of this study were to analyze the utilization of emergency department services and compare the diagnostic codes present among tophaceous and non-tophaceous gout patients.

Methods: A retrospective review of Humana Research Database data from 2007 to 2017 in private pay and Medicare patients was performed to identify patients with at least 1 gout ICD-9 diagnosis code and enrolled in the plan for at least 6 months (N=370,484). Patients were divided by gout codes into patients with at least one tophi code (tophaceous group) and patients without any tophi codes (non-tophaceous group). To decrease bias non-tophaceous patients were matched to tophaceous patients based on age, gender and race. Relevant comorbidity codes were grouped and examined. Occurrence of ICD codes during emergency department encounters were analyzed in the two groups.

Results: The tophaceous and non-tophaceous group included 6,889 patients each. The patients were mean age 70.7 years, 69.4% male, and 71.7% white. Patients in the tophaceous group had a shorter time in plan since gout diagnosis (average of 3.3 years) compared to non-tophaceous patients (average 3.7 years in plan). During the time in plan analyzed, more patients with tophaceous gout had at least one emergency department encounter than patients

	Tophaceous N=6889 n (%)	Non-tophaceous N=6889 n (%)	OR	95% CI	P-value
Joint/Limb Pain	1042 (15.1)	847 (12.3)	1.27	1.153-1.402	<0.001
Renal Disease	734 (10.7)	598 (8.7)	1.25	1.120-1.405	<0.001
Chronic Kidney Disease (Stage 1-4)	131 (1.9)	81 (1.2)	1.63	1.233-2.154	<0.001
End Stage Renal Disease (Stage 5)	59 (0.9)	30 (0.4)	1.98	1.271-3.069	0.003
Acute Kidney Injury	369 (5.4)	231 (3.4)	1.63	1.379-1.930	<0.001
Calculus of kidney	102 (1.5)	118 (1.7)	0.86	0.660-1.126	0.277

Table 1. ICD- Codes during an Emergency Department Encounter

without tophi (71.2% tophaceous vs. 67.4% non-tophaceous; OR 1.19, 95%CI of 1.109 to 1.282, p< 0.001). On average, during this period, patients with tophi had 4.01 visits to the emergency department and the patients without tophi had 3.51.The percentage of patients with renal and cardiovascular comorbid emergency department codes were increased in the tophaceous group. Table 1 compares the percentage of patients with and without tophi with emergency department codes.

Conclusion: In this large matched database study more patients with visibly tophaceous gout had at least one emergency department encounter during the time in plan analyzed as compared with their non-tophaceous gout counterparts. Additionally, patients with tophi had a greater number of emergency department encounters in this time period. In these encounters renal and cardiovascular complications were increased in the tophaceous group.

Abstract Number: 0359

Impact of Hospital Admissions on Adherence to Allopurinol Therapy After Discharge

Nicholas Lebedoff ,[1] Andrea Barker,[2] Curry L. Koening,[3] Trevor Jones,[4] Richard Rose,[4] Peter Yarbrough,[4] and Michael Battistone[5], [1]University of Utah, Salt Lake City, [2]Salt Lake City Veterans Affairs Medical Center & University of Utah, North Salt Lake, UT, [3]University of Utah Hospital, Salt Lake City, UT, [4]Salt Lake City Veterans Affairs Medical Center & University of Utah, Salt Lake City, [5]Salt Lake City Veterans Affairs Medical Center & University of Utah, Salt Lake City, UT

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Metabolic & Crystal Arthropathies Poster I: Clinical
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Gout is a common disease with effective medical therapies, yet many cases are complicated by providers' hesitancy to prescribe an adequate dose of urate-lowering therapy (ULT), or patients' reluctance to take it. In addition, patients with gout often have comorbidities resulting in frequent and complex interactions with the

healthcare system. In this study, we sought to investigate the effect of inpatient admission on adherence to allopurinol therapy in patients with gout.

Methods: All hospital admissions to the Salt Lake City (SLC) Veterans Affairs (VA) Health Care System (HCS) between March 2018 and March 2019 involving patients who had an active prescription for allopurinol, and who had been requesting regular refills at the time of hospitalization, were identified. Prevalence of allopurinol prescription rates and adherence to refill requests following discharge were determined, and medical records of patients who had discontinued therapy were reviewed.

Results: From March 7, 2018 through March 25, 2019, 193 patients with an active prescription of allopurinol were admitted for inpatient care at the SLC VA HCS. These data are summarized in Figure 1. Thirty-one (16%) had not refilled their prescription in the 90 days preceding admission, and were excluded from further analysis. Of the 162 remaining patients, 91 (56%) continued to take allopurinol without change after discharge. The remaining 71 patients did not fill their allopurinol prescription for 90 days after discharge, and were assumed to have stopped taking it. Of these 71 patients, 22 were excluded from the final analysis because they were either taking allopurinol for Tumor Lysis Syndrome (TLS) prophylaxis and no longer needed it (11), were deceased within 90 days of leaving the hospital (7), or filled their prescriptions outside of the VA system (4). Medical records of the remaining 49 patients were reviewed to determine why they stopped taking allopurinol; the findings are summarized in Table 1. In 42 cases (86%), patients did not continue allopurinol despite the inpatient physician recommending they continue it after discharge. The

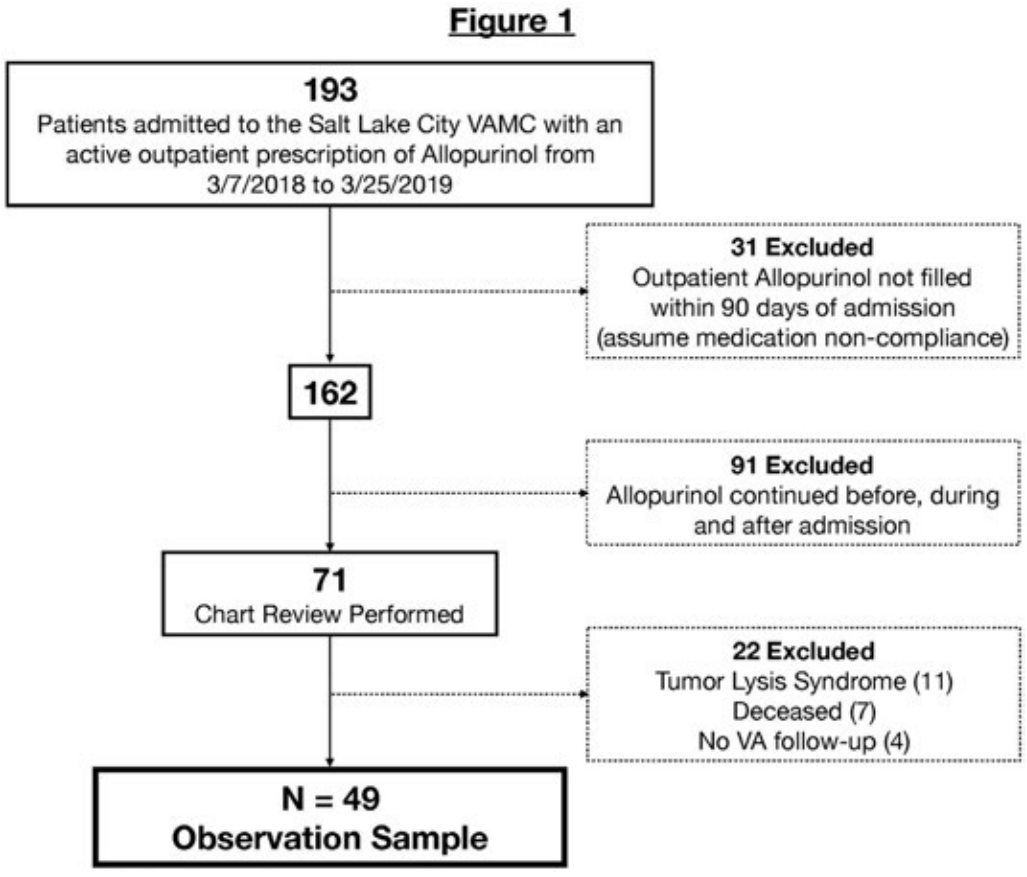

Figure 1. Patient Admissions with Active Outpatient Allopurinol Prescriptions

Table 1 – Summary of Findings for Patients with Active Outpatient Allopurinol Prescriptions Prior to Hospital Admission in Whom Allopurinol was Not Continued Following Hospital Discharge

	N	(% of 49)
Patient Compliance Issue – Did not refill the outpatient Allopurinol following discharge	42	(86%)
Patient expressed the preference to discontinue Allopurinol during admission	3	(6%)
Inpatient provider discontinued Allopurinol for undetermined reasons	2	(4%)
Unknown	2	(4%)
Total	49	

remaining 7 patients had it stopped while inpatient and did not resume it after discharge. The reasons for this were provider recommendation (2), patient preference (3), and unknown (2).

Conclusion: Admission to the hospital is strongly associated with the development of poor adherence to allopurinol therapy in gout patients, even for those who appear to be taking this medication as prescribed before hospitalization. Since patients with gout often have other health problems that require inpatient treatment, this phenomenon may contribute substantially to the major problem of nonadherence to ULT. Additional work is needed to better understand patients' motivations for stopping treatment, as well as to identify timely and effective interventions in the post-discharge period.

Abstract Number: 0360

Colchicine Prophylaxis of Gout Flares When Commencing Allopurinol Is Very Cost Effective: A Health Economic Analysis

Philip Robinson ,[1] Nicola Dalbeth,[2] and Peter Donovan[3], [1]University of Queensland, Brisbane, Queensland, Australia, [2]University of Auckland, Auckland, New Zealand, [3]University of Queensland, HERSTON, Australia

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Metabolic & Crystal Arthropathies Poster I: Clinical
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Prophylaxis of acute gout flares when commencing urate lowering therapy is recommended by international guidelines. Whether this is a cost-effective intervention is currently unknown. Colchicine was awarded orphan drug status by the US Food and Drug Administration in 2009 and the price increased from 9 cents per tablet to $5 per tablet (Kesselheim, 2015). Therefore, the economics of using colchicine for all of its indications altered substantially.

To perform a cost effectiveness analysis of co-prescribing colchicine when initiating urate lowering therapy for gout using both a United States healthcare system input model and an Australian healthcare system cost input model.

Methods: This cost-effectiveness analysis was completed from the point of view of the third-party payer (This therefore excluded costs such as the cost of the patient driving to their doctor or the hospital). We used a two decision-tree with one arm commencing allopurinol with no colchicine prophylaxis and the other with colchicine prophylaxis. Model inputs were drawn from published literature, where available. We completed univariate and probabilistic sensitivity analysis to confirm the robust nature of the modelling. The time frame for the model was 6 months.

Results: In the US model, the colchicine prophylaxis arm resulted in a cost of US$1109 and 0.49 quality adjusted life-years (QALYs). This was cost-effective compared to placebo (cost of US$536 and 0.47 QALYs, Incremental cost-effectiveness ratio of $25,666 per QALY gained). In the Australian model the colchicine arm dominated placebo (AUD228 in colchicine arm vs. AUD523 in placebo) due to lower colchicine cost. Univariate and probability sensitivity analysis demonstrated that results were robust to changes in input parameters, but were most sensitive to cost of colchicine and the rate of reduction of flares from colchicine treatment. In probabilistic sensitivity analysis, the probability of colchicine prophylaxis being the most cost-effective option was 78% in the US and 99% in Australian setting, at a willingness-to-pay threshold of $50,000 per QALY gained.

Conclusion: Colchicine prophylaxis of gout flares whilst commencing allopurinol in gout appears to be cost effective both in the US healthcare system with elevated unit cost for colchicine and in the Australian healthcare system where the unit cost of colchicine is substantially lower.

Abstract Number: 0361

Frequency of Allopurinol Dose Reduction in Hospitalized Patients with Gout Flares

Irvin Huang ,[1] Alison Bays,[2] and Jean Liew[3], [1]University of Washington - Boise Internal Medicine Residency, Boise, ID, [2]University of Washington Division of Rheumatology, Seattle, WA, [3]University of Washington, Seattle, WA

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Metabolic & Crystal Arthropathies Poster I: Clinical
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: It is a common misconception that allopurinol should either be held or reduced during gout flares and renal insufficiency. However, current guidelines recommend the continuation of allopurinol during flares as long as an effective anti-inflammatory therapy is in place [Khanna, et al 2012]. Additionally, allopurinol has been shown in recent studies to have no association with worsening renal function or increased risk of allopurinol hypersensitivity syndrome in acute renal insufficiency [Vargas-Santos, et al 2018]. In this retrospective observational study, we assessed the frequency of allopurinol dose reduction or discontinuation in patients with gout who had acute flares during inpatient admissions.

Variables	All admissions N = 73	Allopurinol decreased or discontinued N = 15	Allopurinol unchanged or increased N = 58
Median age (IQR), years	58 (16)	57 (15)	58.5 (16)
Male gender	67 (92%)	14 (93%)	53 (91%)
Caucasian ethnicity	43 (59%)	9 (60%)	34 (59%)
Acute kidney injury	30 (41%)	9 (60%)	21 (36%)
Chronic kidney disease	53 (73%)	10 (67%)	43 (74%)
Tophaceous disease	19 (26%)	3 (20%)	16 (28%)
Flare prophylaxis	39 (53%)	4 (27%)	35 (60%)
Rheumatology consult	29 (39%)	2 (13%)	26 (45%)
Flare within 3 months of discharge	21 (29%)	8 (53%)	13 (22%)*

*p=0.03 for this comparison

Table Baseline demographics, comorbidities, and post-hospitalization gout flares between exposed and comparator groups.

Methods: A clinical database was utilized to query patients with ICD-10 diagnosis of gout with prescriptions for allopurinol, who were admitted to two medical centers from 2014-2019. Patients with acute gout flares during the hospitalization were included in the study. Charts were reviewed for patient demographics, comorbidities, allopurinol dose on admission and discharge, reasons for dose changes, use of flare prophylaxis, rheumatology consultation, and gout flares within three months after discharge. Descriptive statistics were performed for patient baseline characteristics and outcomes. We used Fisher's exact test to assess for the difference between post-hospitalization gout flares between allopurinol dosage change groups.

Results: We identified 59 patients with a total of 73 admissions who met inclusion criteria (Table). Of all the admissions, 92% were males with a median age of 58 years. Allopurinol was either reduced or discontinued in 15 admissions (allopurinol reduced group), which comprised 21% of total admissions. Allopurinol was increased or unchanged in the other 58 admissions (comparator group). The proportion of chronic kidney disease was similar between the groups, while there was a greater proportion of admissions with acute kidney injury in the allopurinol reduced versus the comparator group (60% vs. 36%, respectively). The allopurinol reduced group also had a significantly higher rate of gout flares within three months of discharge at 53% compared to the comparator at 22% (P =0.03).

Conclusion: In hospitalized patients with gout who experienced acute flares, allopurinol was decreased or discontinued in nearly a quarter of admissions despite current recommendations. There were significantly more gout flares following these admissions, compared to those in which allopurinol dose was unchanged or increased. Improved clinician awareness of the current gout recommendations, as well as the risks and benefits of allopurinol in the setting of concomitant renal disease, is necessary to improve patient outcomes.

Methods to Efficiently Recruit Minority Patients with Gout for Clinic-Based Registries

Giovanni Adami ,[1] Giovanna Rosas,[2] Joshua Melnick,[3] Jeffrey Foster,[2] Elizabeth Rahn,[2] Amy Mudano,[4] Jeffrey Curtis,[2] Tony Merriman,[5] S Louis Bridges,[4] and Kenneth Saag[2], [1]University of Verona, Verona, Italy, [2]University of Alabama at Birmingham, Birmingham, AL, [3]University of Alabama at Birmingham, Birmimgham, AL, [4]University of Alabama at Birmingham, Birmingham, [5]University of Otago, Birmingham, AL

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Metabolic & Crystal Arthropathies Poster I: Clinical

Session Type: Poster Session (Sunday)

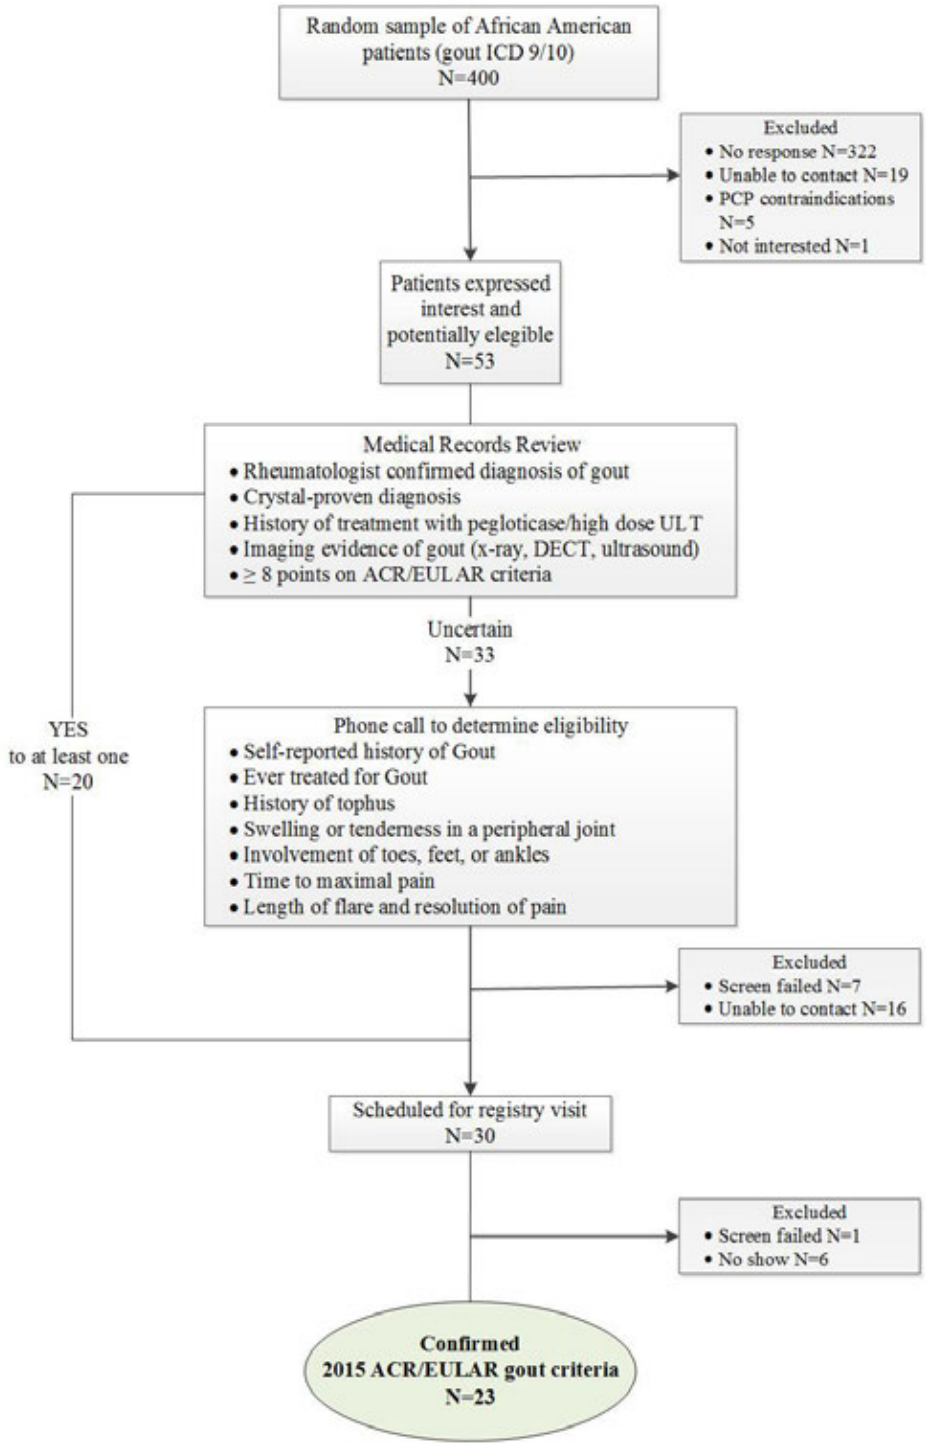
Session Time: 9:00AM–11:00AM

Background/Purpose: Gout is frequently misdiagnosed and/or miscoded, making approaches to identifying eligible patients for observational and interventional studies more challenging. Ethnic and racial minorities are underrepresented in many gout studies. Methods to better identify minorities and patients with confirmed gout will ensure studies have better validity and more generalizability. We defined efficient methods for identifying African Americans (AA) interested in participating in a gout registry who satisfied the American College of Rheumatology (ACR) and European League Against Rheumatism (EULAR) gout classification criteria.

Methods: We identified all AA patients seen at University of Alabama at Birmingham from 01/09/2017 to 31/08/2018 with an ICD 9/10 code for gout. Patients not "opted out" by their primary care provider (PCP) were invited to participate via electronic letters and/or mailed invitations. Those interested underwent detailed medical record review followed by phone contact to determine gout eligibility. Those with a high likelihood of meeting gout diagnostic criteria were invited for an in-person visit to confirm diagnosis (Figure 1). We compared descriptive characteristic of participants enrolled in the registry with the larger populations of potentially eligible subjects.

Results: From 3,032 AA patients with an ICD 9 /10 gout diagnosis we generated a random sample of 400 patients. 5 patients were excluded by their PCPs, thus 395 patients were preliminarily eligible who we attempted to contact. 1 patient (< 1%) communicated lack of interest, 19 (4.8%) were unreachable, 322 (81.5%) did not respond to our invitation, and 53 (13.4%) expressed preliminary interest and underwent medical record review. We successfully scheduled 30 subjects for a registry visit, 24 completed the visit, and 23 (6% of initial sample) satisfied 2015 ACR/EULAR gout classification criteria (see **Table 1**). We found no significant difference in age, sex, and the number of medical encounters in the last year between enrolled patients and the remaining population.

Conclusion: We present an efficient strategy for identifying and recruiting AA patients with ACR/EULAR classified gout into a population-based registry. Among a randomly selected cohort of AAs with an initial ICD 9/10 diagnosis code of presumed gout, slightly under 15% expressed interest and eventually 6% satisfied the 2015 ACR/EULAR criteria and successfully enrolled in the registry. Our experience emphasizes a potential approach as well as some challenges in creating a generalizable gout registry of under-represented minority patients.



Random sample of African American patients (gout ICD 9/10) N=400
Excluded
• No response N=322
• Unable to contact N=19
• PCP contraindications N=5
• Not interested N=1
Patients expressed interest and potentially elegible N=53
Medical Records Review
• Rheumatologist confirmed diagnosis of gout
• Crystal-proven diagnosis
• History of treatment with pegloticase/high dose ULT
• Imaging evidence of gout (x-ray, DECT, ultrasound)
• ≥ 8 points on ACR/EULAR criteria
Uncertain N=33
YES to at least one N=20
Phone call to determine eligibility
• Self-reported history of Gout
• Ever treated for Gout
• History of tophus
• Swelling or tenderness in a peripheral joint
• Involvement of toes, feet, or ankles
• Time to maximal pain
• Length of flare and resolution of pain
Excluded
• Screen failed N=7
• Unable to contact N=16
Scheduled for registry visit N=30
Excluded

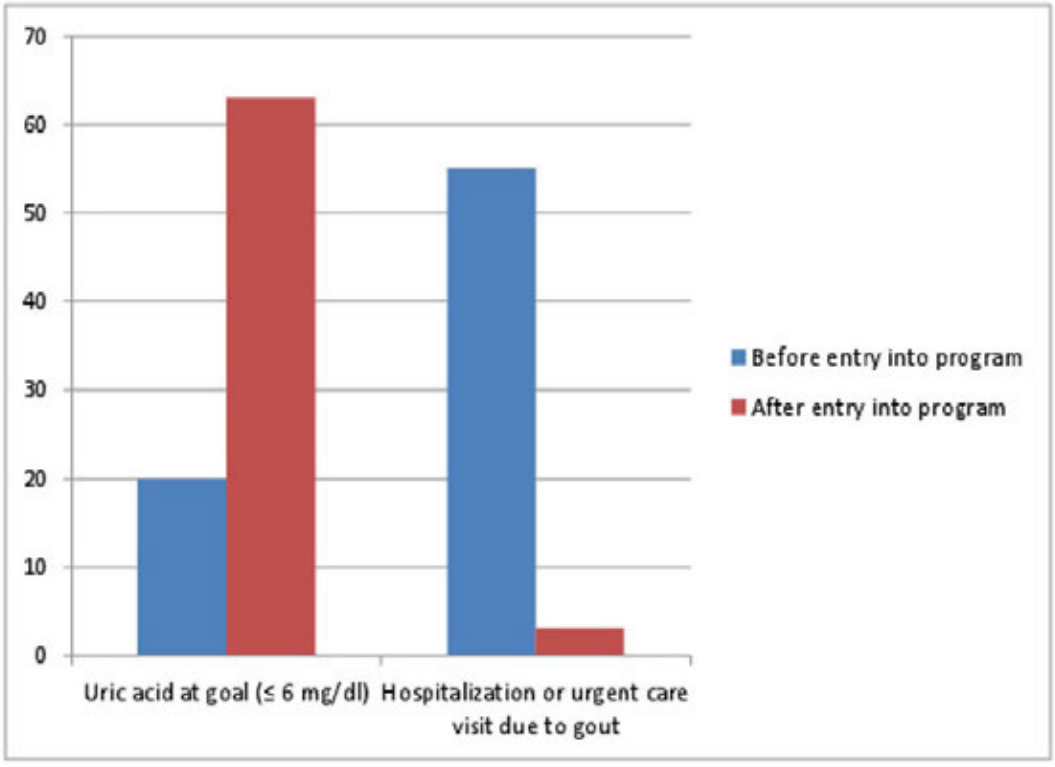
Efficacy and Outcomes of Telephone-Based Management Program in Patients with Gout

Abdalhamid Al Harash ,[1] Tarun Sharma,[1] Brenda Dunmire,[2] Mary Chester Wasko,[3] and William Ayoub[1], [1]Allegheny Health Network, Pittsburgh, PA, [2]AHN, Pittsburgh, PA, [3]Allegheny Health Network-West Penn Hospital, Pittsburgh, PA

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Metabolic & Crystal Arthropathies Poster I: Clinical
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Gout is the most common inflammatory arthritis in the US, and causes significant morbidity. Despite published guidelines and available effective treatment, management remains suboptimal, leading to unnecessary morbidity and increased cost of care. We have designed the gout disease management program (GDMP) to improve outcomes and to decrease healthcare cost in gout patients. To date, no such study was conducted to evaluate healthcare utilization, patients' satisfaction and clinical outcomes.

Methods: Gout patients were seen at their usual rheumatology clinical visit and offered participation in the GDMP. Enrollees were contacted by phone every 2-4 weeks until serum uric acid (SUA) level is at goal. Data were analyzed on patients enrolled between April 2017 and May 2019. During telephone encounters, made by a rheumatology provider, recent hospitalizations since last encounter, and emergency visits due to gout were ascertained. Self-reported gout medication usage and adherence were determined. SUA levels were measured at initial outpatient encounter, when entered into the GDMP and checked every 2-4 weeks until SUA is at goal, and the most recent SUA while in



Chart

the telephone phase. Patient satisfaction with GDMP (compared with usual care of office visits) was surveyed using a 5-point Likert scale.

Results: 125 patients have enrolled into the GDMP; 66 have ≥1 telephone encounter for follow-up and are reported here. At enrollment, 15 (23%) had a crystal proven diagnosis, 15 (23%) had tophaceous gout, and 13 (20%) had SUA levels at goal (≤6.0 mg/dl). Prior to enrollment, 7 (10%) had been hospitalized due to gout, and 23 (45%) had required emergency or urgent care service due to gout. After entry into GDMP, 65 patients were treated with a urate lowering agent coupled with appropriate prophylaxis (one patient lost to follow up). Allopurinol was prescribed in most patients (56/66, 85%) as a urate lowering therapy. Forty-one (63%) have achieved the serum uric acid level goal of ≤6.0 mg/dl. Two patients (3%) required hospitalization or visits to an emergency department or urgent care center due to gout flare (chart). Patients were extremely satisfied with the telephone encounters, 62 (95%) have rated their encounter as a 5 on a 5-point Likert scale.

Conclusion: A gout disease management program consisting of typical visit with rheumatology provider followed by a novel telephone-based follow-up management program leads to improved clinical outcomes as defined by the ACR guidelines, may prevent hospitalization and urgent care visits, and has high patient satisfaction.

Calcium Pyrophosphate Crystal Arthritis During Hospitalizations: A Prospective, Crystal-Proven Case Series

Laura Ranieri ,[1] Francisca Sivera,[2] and Mariano Andrés[3], [1]Hospital General Universitario de Alicante-ISABIAL, Alicante, Spain, [2]Hospital General Universitario de Elda, Elda, Spain, [3]Hospital General Universitario de Alicante-ISABIAL, Universidad Miguel Hernández, Alicante, Spain

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Metabolic & Crystal Arthropathies Poster I: Clinical
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Despite more than fifty years after its initial description, key questions for calcium pyrophosphate (CPP) crystal disease, such as clinical spectrum, diagnosis or management schemes, remain unsolved. Acute flares often occurred during hospitalizations, but scant reports have addressed this common setting for CPP crystal disease. Whether these patients behave similarly to ambulatory cases is unknown. Our aim was to describe a prospective, crystal-proven case series of patients developing acute CPP crystal arthritis during hospitalizations for other conditions.

Methods: Observational, cross sectional descriptive study, conducted in two Spanish centers from November 2013 to December 2018. A prospective convenience sampling was used to select patients with crystal-proven CPP acute arthritis occurred during hospital admissions. Demographic, clinical and CPP-related variables were collected. X-rays of pelvis, knees, hands, and affected joint when different - to assess chondrocalcinosis (CC) - and laboratory tests - to rule out associated metabolic conditions - were systematically requested. A descriptive analysis is presented.

Results: We included 90 episodes of acute CPP arthritis in 87 patients, with an average age of 81.8 years (SD 7.7), 50.6% of them men. 26.4% of patients referred prior flares, most of them (68.4%) as outpatients. Three patients were

on flare prophylaxis (colchicine in two, low-dose glucocorticoids in one). The reasons for admission were diverse, with a mean of 7.7 days (SD 9.1) from admission to flare. Flares were mostly monoarticular (81.0%) and involving knees (46.0%). In X-rays, 23.8% of patients showed absence of CC [61/80]; in 57.1%, CC was noted in the affected joint [44/77], while in 74.3% in knees [55/74], 51.5% in triangular carpal ligaments [34/66], 25.4% in metacarpophalangeal joints [17/67], 20% in pubic symphysis [14/70], and 17.6% in coxofemoral joints [12/68]. Secondary osteoarthritis was seen in 10 patients (12.5%). Hyperuricemia was noted in 12 patients (13.3%), hypomagnesemia at the time of the flare in five (5.7%), and one case of primary hyperparathyroidism was diagnosed. In all six patients with a polyarticular presentation, rheumatoid factor and ACPA were negative.

Conclusion: From this prospective, crystal-proven series of CPP crystal arthritis during hospitalizations, we can remark: i) the low numbers of prior flares as outpatients may suggest a different clinical entity; ii) CC was absent in around a quarter of patients despite an extensive assessment, so synovial fluid analysis remains essential for accurate diagnosis; and, iii) the rarity of associated metabolic diseases runs against systematic screening for secondary causes of CPP disease in this setting.

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Metabolic & Crystal Arthropathies Poster I: Clinical
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Identifying pseudogout in large administrative datasets has been difficult due to lack of specific billing codes for this acute subtype of calcium pyrophosphate (CPP) crystal deposition disease. While several machine learning approaches exist to phenotype patients using electronic health record (EHR) data, they are largely validated in chronic conditions with relatively accurate billing codes. Pseudogout poses unique challenges due to its lack of specific billing codes and episodic nature. We evaluated a novel machine learning approach for classifying definite/probable pseudogout using EHR data.

Methods: We created an EHR dataset of 30,089 patients with ≥1 relevant billing code (Table 1 footnote) or ≥2 natural language processing (NLP) mentions of pseudogout or chondrocalcinosis in narrative notes, 1990-2017. We randomly selected 900 patients for gold standard chart review to label as: (1) definite pseudogout, synovitis+synovial fluid CPP crystals; (2) probable pseudogout, synovitis+chondrocalcinosis; (3) not pseudogout. Presence of synovial fluid CPP crystals was determined by manual review of lab results recorded as free text in the EHR. To develop an algorithm for identifying definite/probable pseudogout vs. not, we applied a semi-supervised topic modeling approach; presence of CPP crystals was not included since it required manual review. The approach included the score from an unsuper-

Table 1. Performance of algorithms to identify definite/probable pseudogout in an electronic health record datamart

	Performance among gold-standard labels (N=900)				Cases identified in datamart (N=30,089)
Algorithm	**Sensitivity**	**Specificity**	**PPV**	**AUC**	
Billing codes [a]	0.65	0.63	0.22	0.64	12,035
Semi-supervised topic modeling [b]	0.29	0.98	0.79	0.86	1,870
Presence of CPP crystals [c]	0.29	1.00	0.92	0.64	1,630
Combined algorithm: semi-supervised topic modeling + presence of CPP crystals	0.42	0.98	0.81	0.70	2,490

[a] ≥1 ICD-9 or 10 code for chondrocalcinosis or calcium metabolism disorder (ICD-9 712.1*, 712.2*, 712.3*, 275.49; ICD-10 M11.1*, M11.2*, M11.8*, E83.59). Adapted from Bartels CM, et al. J Clin Rheumatol 2015;21(4):189-92, which only included ICD-9 codes, by also including ICD-10 codes

[b] Semi-supervised topic modeling model includes: topic modeling score for propensity of pseudogout from an unsupervised topic modeling method including all relevant features, NLP mentions of pseudogout, whether synovial fluid crystal analysis was performed regardless of result

[c] Presence of synovial fluid CPP crystals was ascertained via manual review of lab results recorded as free text in the EHR

Table 2. Comparison of cohorts identified by three algorithms for definite/probable pseudogout applied to a datamart of 30,089 patients

	Billing codes	Presence of CPP crystals	Combined algorithm: semi-supervised topic modeling + presence of CPP crystals
Number of patients (n)	12,035	1,630	2,490
Age at last medical visit, years	72.8 (15.6)	76.4 (13.0)	76.3 (12.8)
Female	55.6	50.6	50.8
Race			
White	84.7	79.5	81.0
African American	4.8	8.8	7.8
Other	10.5	11.7	11.2
≥1 pertinent billing code	100.0	72.6	74.1
≥1 NLP mention of pseudogout	34.3	86.1	90.8
Synovial fluid crystal analysis performed regardless of result	18.9	100.0	86.0
Synovial fluid CPP crystals present	9.8	100.0	65.5
Prescription medications in EHR			
Colchicine	17.3	35.1	43.4
NSAID	59.1	69.1	72.7
Oral glucocorticoids	44.4	62.9	67.4

Presented as mean (SD) or percentage unless otherwise indicated

vised topic modeling method including all relevant features; NLP mentions of pseudogout; and whether synovial fluid crystal analysis was performed regardless of result. We created a combined algorithm including information from the semi-supervised topic modeling approach and the manually reviewed CPP crystal results. We compared algorithm accuracy and cohorts identified by: (1) billing codes, (2) presence of CPP crystals, (3) the combined algorithm.

Results: Among the 900 subjects, 123 (13.7%) had pseudogout by chart review (68 definite, 55 probable). Billing codes alone had a sensitivity 65% and PPV 22% for definite/probable pseudogout (**Table 1**). Presence of CPP crystals had a sensitivity 29% and PPV 92%. Without using the CPP crystal result, the semi-supervised topic modeling algorithm had a sensitivity 29% and PPV 79%. The combined algorithm yielded a sensitivity 42% and PPV 81%. The cohort identified by the combined algorithm (n=2490) was 50% larger than that identified by presence of CPP crystals (n=1630); the latter only captured patients with definite pseudogout and did not identify patients with probable pseudogout. **Table 2** demonstrates important differences between cohorts identified via billing codes vs. the combined algorithm, and similarities between cohorts identified by the presence of CPP crystals vs. the combined algorithm.

Conclusion: For pseudogout, a condition without a specific billing code, combining NLP and machine learning methods with synovial fluid CPP crystal lab results yielded an algorithm that significantly boosted PPV compared to billing codes alone, with modest sensitivity. This balance allows classification of a large pseudogout cohort for future research.

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Metabolic & Crystal Arthropathies Poster I: Clinical
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: High serum uric acid (SUA) level is the main prerequisite for gout, and it might be associated with obesity, hypertension, glucose intolerance, insulin resistance, and dyslipidemia which are the known risk factors for coronary artery disease. Although the association of SUA level with coronary artery disease has been investigated in previous studies, the results are conflicting**.** Further, there are limited data regarding the association between SUA and subclinical coronary atherosclerosis in asymptomatic individuals. This study investigated the influence of SUA level on subclinical coronary atherosclerosis, as detected by coronary computed tomography angiography (CCTA), in an asymptomatic population.

Methods: We evaluated 6,431 asymptomatic individuals with no prior history of coronary artery disease who voluntarily underwent laboratory tests and CCTA as part of a general health examination. The participants were stratified

CI = confidence interval
*Coronary artery calcification is defined as coronary artery calcium score >10.
Covariates in the multivariable model include age, sex, obesity, diabetes mellitus, hypertension, hyperlipidemia, current smoking status, family history of coronary artery disease, and high-sensitivity C-reactive protein ≥2 mg/l.

first quartile. However, the adjusted odds ratios for any atherosclerotic plaque (1.39; 95% CI 1.15–1.67; p = 0.001) and non-calcified plaque (1.38; 95% CI 1.11–1.71; p = 0.004) were significantly higher in the fourth SUA quartile (Table 2).

Conclusion: In asymptomatic individuals, high SUA level was an independent predictor of non-calcified plaques, suggesting an increased cardiovascular risk.

Figure 3. The Treatment used for each organ manifestation (Number) with statistically significant values highlighted and p value indicated.

Background/Purpose: Sarcoidosis is an inflammatory disorder of unknown etiology characterized by tissue infiltration with non-caseating granulomas which can affect any organ. The most common organ involved is the lungs but involvement of eyes (Uveitis), skin (Cutaneous), lymph nodes, gastrointestinal (GI), upper respiratory tract (URT), musculoskeletal system (Arthritis), heart and central nervous system can be seen as well. Systemic glucocorticoid therapy has been proven to improve and stabilize pulmonary and extrapulmonary Sarcoidosis but are associated with a plethora of undesirable side effects. There is a paucity of guidelines and clinical trial data are limited for the steroid sparing agents to treat chronic Sarcoidosis, so majority of the treatment decisions are based solely on extrapolation from studies done for other autoimmune diseases and expert opinion. This study aims to review the various organ manifestations and treatment options used to successfully treat patients of Sarcoidosis at our academic center.

Methods: This is a retrospective chart review of 172 patients seen in our rheumatology clinic with the diagnosis of Sarcoidosis. Categorical analysis was performed by Chi-squared analysis unless the underlying assumptions were violated when Fisher's exact test was used instead. Continuous measures, such as age, were compared between groups by a Student's t test. P value of < 0.05 was considered significant.

Results: Sarcoidosis was seen to affect patients between the age of 17 – 83 years (Mean 49.3). Females diagnosed with Sarcoidosis were older than males (p value 0.006). There was no association found between the age, gender and race except that Pulmonary Sarcoidosis was significantly associated with African American population (p value 0.005) and GI involvement was seen in females (p value 0.024) (Fig. 1). The most common organ manifestations were Pulmonary Sarcoidosis seen in 97 patients (56.4%), Uveitis in 36 patients (20.9%) and cutaneous Sarcoidosis in 35 patients (20.3%) (Fig 2). 81 patients (46.8%) had more than one organ involvement. Amongst the treatment agent for each organ manifestations, statistically significant associations were found with Prednisone for Lymph node involvement (p value 0.015); Hydroxychloroquine for Cutaneous Sarcoidosis (p value 0.025); Methotrexate (p value 0.033), Azathioprine (p value 0.019) and Infliximab (p value 0.016) for GI involvement; Infliximab (p value 0.027) and Cyclophosphamide (p value 0.019) for Neurosarcoidosis; and Cyclophosphamide for renal involvement (p value < 0.01). The Prednisone dose was variable between 5 mg to 60 mg with a mean of 15 mg.

Conclusion: The most common manifestation was noted to be Pulmonary involvement followed by Uveitis and cutaneous Sarcoidosis and Pulmonary Sarcoidosis was more common in African Americans. The prescribing practice at our center for chronic Sarcoidosis with statistical significance included Hydroxychloroquine for Cutaneous; Methotrexate and Azathioprine for GI involvement, Infliximab for GI and Neurosarcoidosis. Long term prospective studies need to be done to outline a treatment protocol for patients with chronic Sarcoidosis to limit the use of long term steroids.

Abstract Number: 0368

Practice Patterns in Bone Health and Vitamin D Management in Sarcoidosis: A Survey of Physicians Who Manage Sarcoidosis

Huzaefah Syed ,[1] Thieroff George,[2] Thomas Iden,[1] Aamer Syed,[1] Alicia Gerke,[3] and Trang Le[1], [1]VCU Medical Center, Richmond, VA, [2]VCU Medical Center, Richmond, VA, [3]University of Iowa, Iowa City, IA

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Miscellaneous Rheumatic & Inflammatory Disease Poster I: Fibroinflammatory & Granulomatous Disorders & Therapies
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Sarcoidosis is a multisystem disease caused by granulomatous inflammation of unclear etiology. Hypercalcemia, seen in 2-30% of patients with sarcoidosis, is caused by calcitriol overproduction by macrophages within granulomas. Low Vitamin D 25OH (VitD) is common and contributes to low bone mass. VitD repletion can lead to hypercalcemia, but there are limited data regarding safe VitD repletion in these patients. We surveyed physicians from varying specialties who manage patients with sarcoidosis to assess current practice patterns.

Methods: Two clinical vignettes regarding bone health and VitD in sarcoidosis were presented. Clinical Vignette #1 presented a patient with hypercalcemia, elevated calcitriol, and VitD insufficiency. Clinical Vignette #2 presented a patient with normal calcium and calcitriol, VitD insufficiency, and low bone mass. These were followed by questions regarding evaluation and therapy. The survey was distributed to physicians (1) in the divisions of Pulmonary/Critical

Care, Rheumatology, Neurology, Endocrinology, and Cardiology at the Virginia Commonwealth University, (2) who attended the 2019 annual Americas Association of Sarcoidosis and other Granulomatous Disorders meeting, and (3) in a national listserv for sarcoidosis which includes approximately 100 physicians with an interest in sarcoidosis. Participants were asked to complete the vignettes they felt were pertinent to their practice and were informed that there were no incorrect answers.

Results: 45 physicians responded to the survey; the majority were pulmonologists (55.5%), followed by rheumatologists (26.7%) and endocrinologists (8.9%). They were predominantly from an academic hospital setting (93.4%). Over 75% of all physicians assessed patients for 6 of the 9 listed risk factors related to bone health. Only 31.1% assessed for symptoms of male hypogonadism. More than half of all respondents chose PTH, DXA scan, VitD, and calcitriol as part of their evaluation, while response rates to obtain serum ACE level varied between 0 to 33% among specialists. In patients with hypercalcemia, 46.7% opted not to give VitD supplementation for the VitD level that was presented. In patients without hypercalcemia, 33.3% chose not to supplement VitD at the presented level, while at least 28.9% would supplement with low dose VitD. In patients with osteopenia, 80% of respondents would recommend weight-bearing exercise and 35.6% would recommend a bisphosphonate. For patients with osteoporosis, 71.1% recommend a bisphosphonate and only 35.6% would opt to maintain VitD above 30ng/mL.

Conclusion: Maintaining strong bone health in a patient with sarcoidosis can be complicated given the risk of hypercalcemia. Though not all patients are hypercalcemic at baseline, it is unclear if Vitamin D supplementation can lead to

Table 1. Baseline Characteristics of Survey Responders for Bone Health/Vitamin D Vignettes

Practice Details		N = 45, n (%)
What is your area of specialty?	Pulmonary	25 (55.5%)
	Rheumatology	12 (26.7%)
	Endocrinology	4 (8.9%)
	Cardiology	3 (6.7%)
	Critical Care	1 (2.2%)
What is your degree?	MD/DO	44 (100%)
How many years since you have completed training?	<5	9 (20%)
	6-10	14 (31.1%)
	11-20	10 (22.2%)
	>20	12 (26.7%)
How would you describe your practice setting?	Academic Hospital	42 (93.4%)
	Private Practice	1 (2.2%)
	Other	2 (4.4%)
How many patients with sarcoidosis do you see per month?	<5	13 (28.9%)
	5-15	11 (24.4%)
	15-25	10 (22.3%)
	>25	11 (24.4%)

hypercalcemia. This survey highlights the differences in practices in promoting healthy bones in sarcoidosis patients, stressing the importance of developing guidelines for safe Vitamin D repletion.

Table 2. Survey Answers for Bone Health/Vitamin D Vignettes

Question	Answers	N=45, n (%)	Comments
Case 1. Hypercalcemic patient, normal GFR, chronic prednisone daily x 2.5 years			
1. Which risk factors are parts of your routine history-taking for assessing bone health in sarcoidosis?	a. high alcohol intake	30 (66.7%)	
	b. tobacco use	30 (66.7%)	
	c. sedentary lifestyle / weight-bearing exercise	38 (84.4%)	
	d. post-menopausal status	35 (77.8%)	
	e. symptoms of male hypogonadism	14 (31.1%)	
	f. glucocorticoid use history	43 (95.6%)	
	g. calcium / vitamin D intake (supplements or dietary)	39 (86.7%)	
	h. history of prior fractures	39 (86.7%)	
	i. nephrolithiasis	34 (75.6%)	
2. Which of the following would be part of your initial evaluation?	a. iPTH	33 (73.3%)	
	b. DXA scan	27 (60%)	
	c. 25-OH Vitamin D	39 (86.7%)	
	d. 1,25OH Vitamin D (calcitriol level)	37 (82.2%)	
	e. ACE level	8 (17.8%)	
	f. Spot urine calcium / creatinine ratio	9 (20%)	
	g. 24 hour urine calcium	22 (48.9%)	
	h. refer to endocrinology	10 (22.2%)	
3. PTH undetectable, calcitriol elevated, Vit D 17.0ng/mL (30.0-100.0). Which would you recommend?	a. increase glucocorticoid dosage	23 (51.1%)	"Other":
	b. add steroid sparing agents	27 (60%)	• Refer to endocrinology
	c. do not treat with any vitamin D supplementation	21 (46.7%)	• Add HCQ
	d. Start vitamin D3, 800-1000 IU daily.	3 (6.7%)	• Stop Vit D and calcium
	e. Other	12 (26.7%)	• Replete Vit D only when Ca level normalized
			• Encourage hydration
			• Replete with Vitamin D 400 IU daily
			• Decision is contingent on other studies
Case 2. Post-menopausal woman with normal Ca and GFR, on chronic prednisone 10mg daily x 2 years.

Methotrexate and Interstitial Lung Disease in Patients with Inflammatory Articular Disease: A Systematic Review

Esteban Rubio ,[1] Alejandro Muñoz,[1] and Núria Casamira[2], [1]Rheumatology Department, University Hospital Virgen del Rocío, Sevilla, Spain, [2]Medical Department, Gebro Pharma S.A., Barcelona, Spain

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Miscellaneous Rheumatic & Inflammatory Disease Poster I: Fibroinflammatory & Granulomatous Disorders & Therapies
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Methotrexate (MTX) is a commonly used drug for inflammatory joint diseases. Occasionally, its use has been associated with diffuse interstitial lung disease (DILD) development[1]. A systematic review (SR) has been carried out using the PRISMA methodology[2] in order to determine the extent of involvement of MTX in DILD development in patients with rheumatoid arthritis (RA), psoriatic arthritis (PsA), psoriasis (Pso), juvenile idiopathic arthritis (JIA) or Crohn's disease-associated arthritis (CD-A).

Methods: Regarding the study selection, eligible studies were SR of randomized controlled trials (RCTs) with/without meta-analysis, RCTs, cohort studies, case-control studies and abstracts with relevant content, published from the year 2008 onwards, with adult population (≥18 years, except in JIA studies) diagnosed with any of the aforementioned pathologies and treated with MTX. The outcome was the onset/exacerbation of DILD.

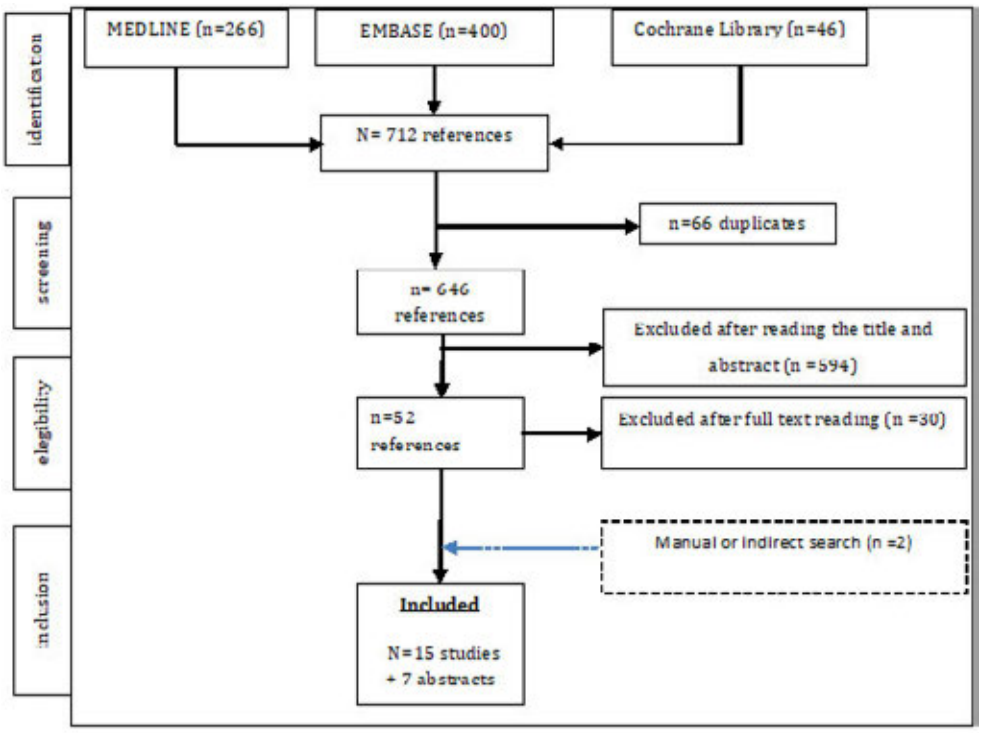

Figure 1. Flow-chart of the systematic review according to the PRISMA

5. Rojas-Serrano J, Herrera-Bringas D, Perez-Roman DI, Perez-Dorame R, Mateos-Toledo H, Mejia M. Rheumatoid arthritis-related interstitial lung disease (RA-ILD): methotrexate and the severity of lung disease are associated to prognosis. Clinical rheumatology. 2017;36:1493-500.
6. England BR, Sayles H, Michaud K, Thiele GM, Poole JA, Caplan L, et al. Chronic lung disease in U.S. Veterans with rheumatoid arthritis and the impact on survival. Clinical rheumatology. 2018;37:2907-15.
7. Kiely P, Busby AD, Nikiphorou E, Sullivan K, Walsh DA, Creamer P, et al. Is incident rheumatoid arthritis interstitial lung disease associated with methotrexate treatment? Results from a multivariate analysis in the ERAS and ERAN inception cohorts. BMJ open. 2019;9, e028466; doi 10.1136/bmjopen-2018-028466.
8. Cabello Zurita C, Grau Perez M, Hernandez Fernandez CP, Gonzalez Quesada A, Valeron Almazan P, Vilar Alejo J, et al. Effectiveness and safety of Methotrexate in psoriasis: an eight-year experience with 218 patients. The Journal of dermatological treatment. 2017;28:401-5.
9. Leiskau C, Thon A, Gappa M, Dressler F. Lung function in children and adolescents with juvenile idiopathic arthritis during long-term treatment with methotrexate: a retrospective study. Clinical and experimental rheumatology. 2012;30:302-7.
10. Alkady EA, Helmy HA, Mohamed-Hussein AA. Assessment of cardiac and pulmonary function in children with juvenile idiopathic arthritis. Rheumatology international. 2012;32:39-46.

The search and selection of studies for the SR was performed in Medline, Embase and Cochrane, as well as among conference abstracts. Quality assessment and grading of the level of evidence was performed using SIGN[3].

According to the attached flow chart (Figure 1), 712 documents were initially retrieved. After full-text selection 15 studies of interest were identified. A meta-analysis was ruled out due to the heterogeneity of the papers.

Results: RA: Conway 2015[4] evaluated the relative risk (RR) of DILD/RA in patients treated with MTX, and detected a small increase in pneumonitis cases among these patients . Rojas-Serrano 2017[5] prospectively evaluated the role of MTX in a RA/DILD cohort, and observed better survival in the MTX cohort. England 2018[6] assessed the association of MTX with mortality risk in patients with/without lung diseases in a large RA cohort, and found no statistical significance. Kiely 2019[7] performed a multivariate analysis on two early RA cohorts, and found no association between MTX and RA/DILD development; on the contrary, MTX may delay DILD development.

PsA, Pso and CD-A: Conway 2015[4] found no association between MTX and RR of respiratory adverse events, respiratory infections, or non-infectious respiratory events. Cabello-Zurita 2017[8] retrospectively evaluated the overall

safety related to MTX in a cohort of patients with Pso without finding strong associations with any type of respiratory event.

JIA: Leiskau 2012[9] performed a retrospective analysis on the influence of cumulative MTX dose and its impact on respiratory function tests or the onset of new long-term respiratory events without finding any association. Alkady 2012[10] conducted a case-control study evaluating cardiopulmonary evolution in children with asymptomatic JIA. Impairment of lung function parameters was inversely correlated to longer MTX use.

Conclusion: The analysed studies offer no data to establish an association between the use of low-dose MTX and DILD onset in patients with inflammatory diseases. The association of MTX with recurrent acute episodes of previously established lung disease has also not been confirmed.

Use of Serum Lung Injury Biomarkers for Predicting the Severity of Interstitial Lung Disease in Patients with Connective Tissue Disease Associated Interstitial Lung Disease and Interstitial Pneumonia with Autoimmune Features

Sogol Amjadi ,[1] Tracy Frech,[2] Jessica Chan,[3] Mary Beth Scholand,[4] Troy Jaskowski,[5] Sonia La'ulu,[5] Jonathan Genzen,[6] Dorota Lebiedz-Odrobina,[7] and Ann Tebo[6], [1]University of Utah, Department of Internal Medicine, Division of Rheumatology, West Jordan, UT, [2]Division of Rheumatology, University of Utah and Salt Lake VAMC, Salt Lake City, UT, [3]University of Utah, Department of Radiology, salt lake city, UT, [4]University of Utah, Department of Internal Medicine, Division of Pulmonary Medicine, salt lake city, UT, [5]ARUP Institute for Clinical and Experimental Pathology, salt lake city, UT, [6]ARUP Institute for Clinical and Experimental Pathology , University of Utah, Department of Pathology, salt lake city, UT, [7]University of Utah, Division of Rheumatology, Salt Lake City, UT

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Miscellaneous Rheumatic & Inflammatory Disease Poster I: Fibroinflammatory & Granulomatous Disorders & Therapies

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Fibrotic lung diseases encompass a wide spectrum of clinical entities including connective tissue disease related interstitial lung disease (CTD-ILD) and interstitial pneumonia with autoimmune features (IPAF). Prior research on serum Krebs von den Lungen-6 (KL-6), surfactant proteins A (SP-A) and D (SP-D) levels have shown independent correlation to disease severity in patients with CTD-ILD. To our knowledge, no studies have evaluated the utility of all three biomarkers in predicting disease severity among US patients with CTD-ILD/IPAF. The goal of this study is to assess 1) the correlation between these biomarkers and lung disease severity; 2) their combined use with forced volume capacity (FVC, % predicted) in predicting lung disease severity using high resolution computed tomography (HRCT) as reference for disease severity.

Methods: This retrospective cross-sectional study involves 20 patients who had testing performed for ILD autoantibodies and KL-6, SP-A, and SP-D biomarkers at ARUP laboratories. In addition, they were diagnosed with CTD-ILD/IPAF per ACR criteria and had HRCT and pulmonary function testing available within 3 months from the date of the laboratory assessments. Positive KL-6, SP-A and SP-D levels were defined as >500 U/mL, >200 ng/mL and >300 ng/mL respectively. Extent of pulmonary fibrosis on HRCT was estimated as 0 to 100 percent using the Athol-Wells

Table 1. *Summary statistics for serum biomarker levels (KL-6, SP-A and SP-D) are given as median and range and as mean ± standard deviation and range for age, FVC and HRCT. They are otherwise reported as total number and percentage. ** ILD autoantibodies includes: ANA, RF, CCP, Jo-1, EJ, OJ, PL-7, PL-12, SRP, SCL-70, centromere, RNAP III, U1RNP, PM/SCL-100, Ku, SSA-52, and SSA-60. Testing performed at ARUP Inc.

Table 1. Cohort demographics and clinical characteristics (n = 20)

Variable	Summary Statistics*
Gender, female (%)	13 (65)
Age, years (SD)	61.4 ± 11.6, (41-84)
Ethnicity, white (%)	15 (75)
Positive ILD autoantibodies panel** (%)	20 (100)
Positive KL-6 (%)	15 (75)
Serum KL-6 level (U/ ml)	771 (328-6175)
Positive SP-A (%)	5 (25)
Serum SP-A level (U/ ml)	137 (63-491)
Positive SP-D (%)	15 (75)
Serum SP-D level (U/ ml)	383 (91- 861)
FVC, % predicted (0 – 100)	66.8 ± 15.7, (42 – 94)
HRCT score (0 -100%)	33.5 ± 20.9, (5 – 88)

method. We evaluated correlations between each biomarker and disease severity and assessed the individual and combination weights of KL-6, SP-A and SP-D levels and FVC in predicting disease severity (dependent variable) using HRCT as reference for disease severity.

Results: 75% of patients were white and 65% were females. 75, 25 and 75% had positive KL-6, SP-A and SP-D levels respectively (Table 1). All three biomarkers had positive correlations with disease severity, but only SP-D level had significant correlation with disease severity (r = 0.51, p: 0.02) (Table 2). KL-6 levels had significant negative correlation with FVC (r = 0.50, p: 0.03), but not with HRCT. In addition, SP-A levels were elevated in patients with severe disease as compared to those without (p: 0.03) (Table 3). In univariate regression analyses of KL-6, SP-A, SP-D and FVC only SP-D level had significant correlation in predicting disease severity (r = 0.05, p: 0.02) whereas in a multiple regression model using KL6, SPA, SPD, and FVC as independent variables, SPD (r = 0.08, p: 0.006) and FVC (r =

Table 2. Associations are shown in terms of magnitude (correlation coefficients, r), direction and statistical significance defined as p-value of < 0.05 *Quantitative high resolution CT score used to determine disease severity **Forced vital capacity used to determine disease severity

Table 2. Association of KL-6, SP-A and SP-D biomarkers with disease severity using HRCT and FVC as references for disease severity

		HRCT*		FVC, % predicted**	
	N	r	p	r	p
KL-6	20	0.22	0.36	-0.50	0.03
SP-A	20	0.18	0.45	-0.09	.72
SP-D	20	0.51	0.02	-0.07	.78

Table 3 Serum biomarker (KL-6, SP-A and SP-D) levels are reported as mean ± standard deviation. Severe and mild disease were defined as HRCT total score of > 20 and < 20 % respectively. P-value < 0.05 is considered statistically significant.

Table 3. Difference in serum biomarker levels between patients with severe and mild disease using HRCT as reference

Serum Biomarkers	Severe disease* (n=14)	Mild Disease* (n=6)	p
KL-6	1611.8 ± 1564. 3	710.5 ± 499.3	0.19
SP-A	242.9 ± 150.6	99.1 ± 33.2	0.03
SP-D	487 ± 219.6	319.8 ± 156.1	0.11

- 0.74, p: 0.03) were found to have statistically significant coefficients. Thus, all other predictor variables being equal, a one unit increase in SP-D is associated on average with a 0.064 increase in disease activity (R^2: .47, F-Value: 0.03).

Conclusion: The findings in this single-center retrospective study of patients with CTD-ILD/IPAF suggest that use of lung injury specific biomarkers and FVC together may be valuable in predicting disease severity and offer a cost-effective approach in monitoring disease progress. To our knowledge, this is the first US cohort study evaluating the utility of all three biomarkers in predicting disease severity among patients with CTD-ILD/IPAF.

Session Title: Miscellaneous Rheumatic & Inflammatory Disease Poster I: Fibroinflammatory & Granulomatous Disorders & Therapies

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Cardiac sarcoidosis (CS) is a rare, life-threatening disease and the second leading cause of death in patients with sarcoidosis. Currently, the recommended treatment for CS includes corticosteroids, optimal heart failure therapy, arrhythmia management, and prevention of heart block complications. The role of steroid sparing agents in the treatment of CS is not well described. Our aim was to review the clinical characteristics and treatment modalities of CS in our center and analyze patient outcomes who received oral immunosuppressive agents or a Tumor Necrosis Factor-alpha inhibitor (TNFi) as a part of their CS management.

Methods: We performed a retrospective chart review of all patients diagnosed with sarcoidosis from 2014 to 2019 at Loma Linda Medical Center. Patients that were diagnosed with CS (as defined by the Heart Rhythm Society diagnostic criteria) were included in the analysis.

	Immunosuppresive therapy					Conventional heart therapy					Cardiac Intervention

Table 1: Immunosuppresive therapy and Conventional Heart Therapy of Patients Diagnosed with CS

Results: Out of 496 patients who have been diagnosed with sarcoidosis, 14 patients were diagnosed with CS in accordance with the Heart Rhythm Society guidelines. The average age was 58, 2:5 male to female ratio, and an average body mass index of 30.3. Seventy one percent of patients had biopsy proven sarcoidosis and the remaining 29% were diagnosed by clinical and imaging criteria. The most common presenting cardiac manifestation was new onset heart failure (64%), followed by cardiac arrhythmias (46%) of which more than half of patients presented with AV blocks (29%). All patients except one were initially diagnosed with sarcoidosis involving other organs (lungs (71%), skin (28%), lymph node (28%) joints (14%), GI tract manifestation (21%), neurological manifestations (21%). Cardiac manifestation was the initial presenting symptomatology of sarcoidosis in one patient. The average duration between initial diagnosis of sarcoidosis until diagnosis of CS was 5 years. The average duration between initial cardiac symptom onset and CS diagnosis was 4 years. Abnormal findings were noted on echocardiography (46%), cardiac magnetic resonance imaging (46%) noted as patchy myocardial scar, myocardial late gadolinium enhancement and positron emission tomography scan (40%). Patients were treated with corticosteroids (78%), azathioprine (36%), methotrexate (14%), infliximab (21%), mycophenolate (7%), hydroxychloroquine (7%), adalimumab (14%), cyclophosphamide (14%), and tacrolimus (7%) in addition to their conventional heart therapy. (Table 1). Three patients did not undergo any treatment for CS given their subclinical/asymptomatic status. Six of the analyzed patients had echocardiogram after initiation of immunosuppressive therapy. All patients except for one demonstrated either improvement, or no worsening of their left ventricular ejection fraction (LVEF) (table 1). One patient showed worsening of the LVEF due to noncompliance.

Conclusion: There are no formal guidelines for management of CS. We describe clinical manifestations and treatment outcomes of 14 patients with CS managed with an oral immunosuppressive agent or TNFi with favorable outcomes. Further larger scale prospective studies are required to identify the most appropriate immunosuppressant regimen and conclude its efficacy in management of CS.

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Miscellaneous Rheumatic & Inflammatory Disease Poster I: Fibroinflammatory & Granulomatous Disorders & Therapies

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Immunoglobulin G4-related disease (IgG4-RD) is an immune-mediated fibroinflammatory condition that may involve multiple organ systems. IgG4-RD can also lead to large vessel vasculitis and chronic periaortitis have been reported in patients with IgG4-RD. Furthermore, a Classification of IgG4-related periaortitis/periarteritis distribution was also reported.

This study is aimed to compare demographic and clinical features of IgG4RD patients with periaortitis/periarteritis with patients without periaortitis/periarteritis patients. Also distribution of patients according to classification reported is analyzed.

Methods: A total of 66 patients fulfilling the Comprehensive Diagnostic Criteria for IgG4-RD and admitted our vasculitis center between 2014 and 2018 were included in the study. Periaortitis and coronary arteritis was defined as

Table. Demographic characteristics and clinical findings of IgG4-RD patients with and without periaortitis

	Patients with periaortitis (n=29)	Patients without periaortitis (n=37)	p
Male	**19 (65.0)**	**15 (40.0)**	**0.038***
Age (years)	52 (±11)	51 (±19)	0.739
Age at disease onset (years)	49 (±13.6)	49 (±14.2)	0.832
Allergy	3/23 (13.0)	5/27 (18.5)	0.448
Ever smoked	13/23 (56.5)	8/27 (30.0)	0.051
Hypertension	**8/23 (34.8)**	**3/27 (11.0)**	**0.047***
Elevated acute phase reactants at diagnosis	22 (75.8)	18 (48.6)	0.025*
Elevated serum IgG4 level	15.0 (60.2)	14 (53.8)	0.303
Involved organ systems			
Multiple organ involvement	**23 (79.3)**	**17 (45.9)**	**0.006***
Lacrimal glands	4 (13.8)	11 (29.7)	0.107

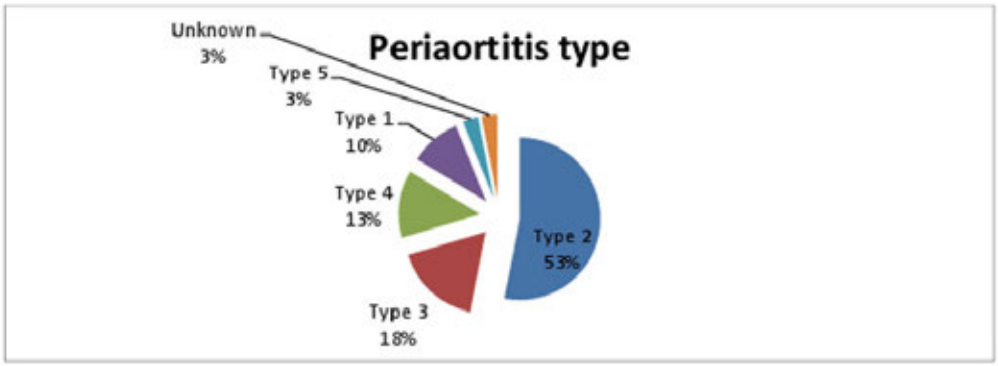
Respiratory organs	9 (31.0)	7 (18.9)	0.197
Pancreas	7 (24.1)	8 (21.6)	0.519
Biliary tract/liver	5 (17.2)	3 (8.1)	0.227
Kidney/urinary tract	9 (31.0)	3 (8.1)	0.019*
Lymph nodes	13 (44.8)	12 (32.4)	0.245
Coronary periarteritis	**6 (21.4)**	**0**	**0.005***
Periorbital involvement	4 (13.8)	11 (29.7)	0.107

* Data was shown as n(%) and mean (standart deviation) *Elevated serum IgG4 level is defined >135mg/dl and was available in 50 patients.

Figure. Classification of IgG4-related periaortitis type



vessel wall thickness, wall enhancement and perivascular soft tissue thickening on CT or MR angiography. Type 1 aortitis was localized at the infra-renal artery portion of the abdominal aorta, Type 2 added continuation to medium sized arteries, Type 3 added seperate location at the ascending aorta, Type 4 affected medium-sized arteries only and Type 5 was other involvement. Demographic, clinical, laboratory and imaging features of IgG-RD patients with and without periaortitis were compared.

Results: Among 66 (F/M=32/34) patients, 29 had periaortitis (43.9%). Mean age and disease duration was 51.4 ± 13.5 and 2.6 ± 2.7 years, respectively. Demographic and clinical characteristics of patients were summarized in Table. Male sex, hypertension, elevated acute phase reactants at diagnosis, urinary/kidney involvement and coronary arteritis was more frequent in periaortitis (+) patients whereas salivary gland involvement was more frequently observed in patients without periaortitis (Table).Median number of involved organ systems was 2 (1-5) and 1 (1-4) in patients with and without periaortitis, respectively (p=0.02).There was no difference in terms of serum IgG4 levels between groups.

In our cohort the most common periaortitis type was Type 2 that localized at the infra-renal artery portion of the abdominal aorta and was seen in 15 patients (53%). Second most common type was Type 3 (18%) followed by Type 4 (13%), Type 1 (10%) and Type 5 (3%) respectively. Classification of IgG4-related periaortitis type was given in Figure. Of the 66 IgG4-RD patients 6 (9%) had coronary arteritis. All patients with coronary involvement also had periaortitis and IgG4-RD patients without periaortitis had no coronary involvement (21.4% vs. 0%, p=0.005). In Type 3 periaortitis patients coronary artery involvement was significantly higher than other types of periaortitis (80% vs 8%, p=0.003).

Conclusion: Periaortitis is frequent in our IgG4-RD cohort and seen more in patients with male sex, hypertension, increased acute phase reactants at diagnosis and urinary/kidney involvement. The most common periaortitis type was Type 2 as reported. Since coronary arteritis is a serious involvement, screening of patients with periaortitis, especially Type 3 for coronary involvement might be rational.

Prognostic Factors and Long-term Outcomes in Cardiac Sarcoidosis

Patrice Cacoub ,[1] Catherine Chapelon Abric,[2] Matthieu Resche-Rigon,[3] David Saadoun,[2] Anne Desbois,[2] and Lucie Biard[3], [1]AP-HP, Groupe Hospitalier Pitié-Salpêtrière, Department of Internal Medicine and Clinical Immunology, F-75013, Paris, France, Paris, France, [2]GHPS, Paris, France, [3]Hôpital Saint Louis, Paris, France

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Miscellaneous Rheumatic & Inflammatory Disease Poster I: Fibroinflammatory & Granulomatous Disorders & Therapies
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: To identify prognostic factors and to assess the effects of immunosuppressive drugs on relapse risk in patients presenting with cardiac sarcoidosis (CS).

Methods: From a cohort of 157 patients with CS with a median follow-up of 7 years, we analysed all cardiac and extra-cardiac data and treatments, and assessed relapse-free and overall survival.

Results: The 10-year survival rate was 90% (95% CI, 84-96). Baseline factors associated with mortality were the presence of high degree atrioventricular block (HR, 5.56, 95% CI 1.7-18.2, p=0.005), left ventricular ejection fraction below 40% (HR, 4.88, 95% CI 1.26-18.9, p=0.022), hypertension (HR, 4.79, 95% CI 1.06-21.7, p=0.042), abnormal pulmonary function test (HR, 3.27, 95% CI 1.07-10.0, p=0.038), delayed myocardial hypersignal enhancement on cardiac magnetic resonance (HR, 2.26, 95% CI 0.25-20.4, p=0.003), and older age (HR per 10 years 1.69, 95% CI 1.13-2.52, p=0.01). The 10-year relapse-free survival rate for cardiac relapses was 53% (95% CI, 44-63). Baseline factors that were independently associated with cardiac relapse were kidney involvement (HR, 3.35, 95% CI 1.39-8.07, p=0.007), wall motion abnormalities (HR, 2.30, 95% CI 1.22-4.32, p=0.010), and left heart failure (HR 2.23, 95% CI 1.12-4.45, p=0.023). After adjustment for cardiac involvement severity, treatment with intravenous cyclophosphamide was associated with a lower risk of cardiac relapse (HR 0.16, 95% CI 0.033-0.78, p=0.024).

Conclusion: Our study identifies putative factors affecting morbidity and mortality in cardiac sarcoidosis patients. Intravenous cyclophosphamide is associated with lower relapse rates.

Session Title: Miscellaneous Rheumatic & Inflammatory Disease Poster I: Fibroinflammatory & Granulomatous Disorders & Therapies

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Some patients with autoimmune disease develop progressive fibrosing interstitial lung disease (ILD) characterized by increasing fibrosis on HRCT, decline in lung function, worsening symptoms and high mortality. Nintedanib, a tyrosine kinase inhibitor, has established efficacy and safety in patients with idiopathic pulmonary fibrosis (IPF) and is an approved treatment for IPF. Recently nintedanib was shown to reduce the rate of decline in lung function in patients with systemic sclerosis-associated ILD. The efficacy and safety of nintedanib in patients with chronic fibrosing ILDs with a progressive phenotype are being investigated in the INBUILD trial. Here we describe the subgroup of patients with autoimmune disease-related ILDs enrolled in this trial.

Table. Baseline characteristics of patients with autoimmune disease-related ILDs in the INBUILD trial

Characteristic	All autoimmune ILDs (n=171)	Rheumatoid arthritis-associated ILD (n=88)	Systemic sclerosis-associated ILD (n=40)	Mixed connective tissue disease ILD (n=20)	Other fibrosing autoimmune ILDs (n=23)
Female	91 (53.2)	34 (38.6)	31 (77.5)	16 (80.0)	10 (43.5)
Age, years	64.3±10.6	66.9±9.7	58.6±10.0	64.4±9.3	63.9±12.5
Weight, kg	72.9±16.9	76.8±16.8	64.5±14.6	73.0±18.1	72.5±15.8
Race					
White	114 (66.7)	63 (71.6)	24 (60.0)	16 (80.0)	11 (47.8)
Asian	51 (29.8)	23 (26.1)	14 (35.0)	2 (10.0)	12 (52.2)
Other/missing	6 (3.5)	2 (2.3)	2 (5.0)	2 (10.0)	0
Criteria for ILD progression met in 24 months before screening*					
Relative decline in FVC ≥10% predicted	88 (51.5)	48 (54.5)	20 (50.0)	9 (45.0)	11 (47.8)
Relative decline in FVC ≥5–<10% predicted and increased extent of fibrotic changes on HRCT	49 (28.7)	22 (25.0)	13 (32.5)	8 (40.0)	6 (26.1)
Relative decline in FVC ≥5–<10% predicted and worsened respiratory symptoms	27 (15.8)	11 (12.5)	5 (12.5)	7 (35.0)	4 (17.4)
Worsened respiratory symptoms and increased extent of fibrotic changes on HRCT	57 (33.3)	34 (38.6)	13 (32.5)	5 (25.0)	5 (21.7)
FVC % predicted	70.8±14.8	71.4±16.2	69.5±12.6	71.3±12.2	70.4±15.5
DLco, % predicted	49.1±19.0	47.5±15.6	53.2±26.4	50.7±19.8	46.7±14.1
Usual interstitial pneumonia (UIP)-like fibrotic pattern only† on HRCT	127 (74.3)	77 (87.5)	24 (60.0)	12 (60.0)	14 (60.9)

Mean±SD or n (%) of patients treated with ≥1 dose of trial drug. *≥1 category could be ticked.
†Based on criteria used to identify UIP in the INPULSIS trials (Richeldi et al. N Engl J Med 2014;370:2071–82).

Methods: Patients with a physician-diagnosed ILD other than IPF were eligible to participate in the INBUILD trial if they had features of diffuse fibrosing lung disease of >10% extent on HRCT, forced vital capacity (FVC) ≥45% predicted, diffusing capacity of the lungs for carbon monoxide (DLco) ≥30–< 80% predicted, and met ≥1 of 4 criteria for ILD progression (Table) in the 24 months before screening, despite treatment of ILDs in clinical practice as applicable.

Patients were randomized to receive nintedanib 150 mg bid or placebo double-blind. Randomization was stratified by HRCT pattern (usual interstitial pneumonia [UIP]-like fibrotic pattern only or other fibrotic patterns). The primary endpoint is the annual rate of decline in FVC (mL/year) assessed over 52 weeks.

Results: Of 663 patients in the trial, 171 (25.8%) had autoimmune disease-related ILDs, of which the most common were rheumatoid arthritis-associated ILD (RA-ILD) (n=88), systemic sclerosis-associated ILD (n=40), and mixed connective tissue disease ILD (n=20) (Table). At baseline, the mean±SD age of patients with autoimmune ILDs was 64.3±10.6 years, FVC was 70.8±14.8% predicted and DLco was 49.1±19.0% predicted; about half had a relative decline in FVC ≥10% predicted in the 24 months before screening. Almost three-quarters of patients with autoimmune ILDs (74.3%) had a UIP-like fibrotic pattern only on HRCT. This pattern was most common in patients with RA-ILD (87.5%). The trial is ongoing.

Conclusion: The INBUILD trial will provide insights into the efficacy and safety of nintedanib in patients with progressive fibrosing ILDs, including those with autoimmune diseases. The results will be presented at the conference.

Experience with Biologic Agents for the Treatment of Cardiac Sarcoidosis in a U.S. Academic Medical Center

Anjani Pillarisetty ,[1] Mithun Devraj,[2] Farooq Sheik,[3] and Florina Constantinescu[1], [1]MedStar Washington Hospital Center, Department of Rheumatology, Washington, DC, [2]MedStar Washington Hospital Center, Department of Internal Medicine, Washington, DC, [3]MedStar Washington Hospital Center, MedStar Heart and Vascular Institute, Washington, DC

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Miscellaneous Rheumatic & Inflammatory Disease Poster I: Fibroinflammatory & Granulomatous Disorders & Therapies

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Sarcoidosis is a multisystem granulomatous disease of unclear etiology characterized histologically by non-caseating granulomas. While clinically manifest cardiac involvement occurs in only about 5% of patients with sarcoidosis, a significant proportion have clinically silent disease. Symptomatic cardiac involvement portends a poorer prognosis with manifestations varying from heart failure and conduction abnormalities to ventricular arrhythmias including sudden death. Immunosuppression with corticosteroids and DMARDs has been the mainstay of treatment despite a paucity of data. There is a subset of patients that are either non-responders to these agents or in whom the side effect profile is prohibitive for their long-term use. Biologic agents, mainly TNF alpha antagonists, have been used as salvage therapies in these patients. However, the evidence regarding their efficacy and safety is limited to a few case reports. In fact, there remains much apprehension regarding the use of TNF alpha antagonists in patients with systolic heart failure due to concerns that they can exacerbate heart failure. Our objective was to study the efficacy and safety of using biologics for the treatment of cardiac sarcoidosis.

Methods: We conducted a retrospective and prospective observational study of all adult patients with cardiac sarcoidosis treated with biologics at an academic medical center in Washington D.C, USA between 2013 and 2018.

Results: We identified 9 patients (3 men and 6 women) diagnosed with cardiac sarcoidosis at our institution. The mean age at diagnosis was 49.9 ± 8.6. 1 patient was Caucasian and the rest (n=8) were African American. Lungs were the most common extra cardiac organ involved (n=7) followed by CNS (n=4), liver (n=4) and skin (n=3). 5 of the patients presented with systolic heart failure (EF< 50%), 3 with arrhythmias and 1 was found to have incidental abnormal myocardial uptake on PET imaging. 8 of the 9 patients had abnormal myocardial uptake on PET imaging. All patients were initially treated with oral steroids and 7 of the 9 patients also received oral DMARDs; MTX (n=6), AZA (n=2), HCQ (n=2) and MMF (n=1). Biologics used were adalimumab (n=5), infliximab (n=3) and rituximab (n=1). The most common indication for biologics was progression of disease despite optimal doses of standard therapy, followed by intolerance or contraindication to standard therapy. 75% of the patients were noted to have marked clinical improvement with the addition of a biologic. 5 out of 9 patients had decreased myocardial uptake on PET following treatment with a biologic. 1 patient had no change on PET and 3 have not had repeat imaging done yet. None of the patients had worsening of left ventricular systolic function with the addition of a TNF alpha antagonist. There were no reported major infections or significant adverse events that were attributable to the use of biologics.

Conclusion: Based on our small cohort, biologics (mainly TNF alpha antagonists) appear to be safe and efficacious as salvage therapy for cardiac sarcoidosis. However, there is a need for prospective studies to further validate these findings as well as to identify the subset of patients that would benefit from early initiation of these therapies.

SESSION INFORMATION
Session Date: Sunday, November 10, 2019

Session Title: Miscellaneous Rheumatic & Inflammatory Disease Poster I: Fibroinflammatory & Granulomatous Disorders & Therapies
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with idiopathic interstitial pneumonia (IIP) may have features of connective tissue diseases (CTDs). The term interstitial pneumonia with autoimmune features (IPAF) has been recently proposed for such patients. Factors reported to indicate a poor prognosis in IPAF include age, smoking history, non-specific interstitial pattern in HRCT, anti-RNP antibody positivity, decline in %DLCO and presence of a multi-compartment feature within the morphological domain [1-3]. To date, however, no study has comprehensively described outcomes over a long-term period and factors of exacerbation. The aim of study was to identify prognostic factors for exacerbation in patients with IPAF, and compare long-term outcomes among patients with IPAF, IIP, and CTD-ILD.

Methods: Six hundreds- and seventy-two patients who visited our department between April 2009 and March 2019 and were evaluated by chest HRCT scan. Then, they were clinically and radiologically diagnosed as having interstitial lung disease (ILD), IIP or connective tissue diseases associated ILD were enrolled. We applied IPAF criteria to these patients and then purified 68 patients. The prognostic factors for exacerbation were prospectively calculated and statistically analyzed using clinical, laboratory and imaging data collected from medical records.

Results: Of 68 patients with IPAF, 60% were women and mean age at diagnosis was 64.2 ± 13.8 years old. Mean observation period was 27.1 ± 29.6 months. Exacerbation rate was 25% (n=17). Overall death rate was 5.9% (n=4). Comparison of characteristics at diagnosis between the exacerbation group and non-exacerbation group showed that the exacerbation group had a significantly elevated rate of smoking, KL-6, and SP-D (P=0.034, 0.016, and 0.007). When we compared characteristics at diagnosis between the treatment group and non-treatment group in patients with IPAF, and those between the exacerbation group and non-exacerbation group in IPAF patients with treatment, the treatment group was significantly associated with signs of mechanic's hands, arthritis, anti-SS-A antibody positivity, and anti-ARS antibody positivity (P=0.009, 0.05, 0.05, and 0.007), and the exacerbation group in IPAF patients with treatment had a significantly elevated rate of smoking and KL-6 (P=0.008 and 0.019). When we compared

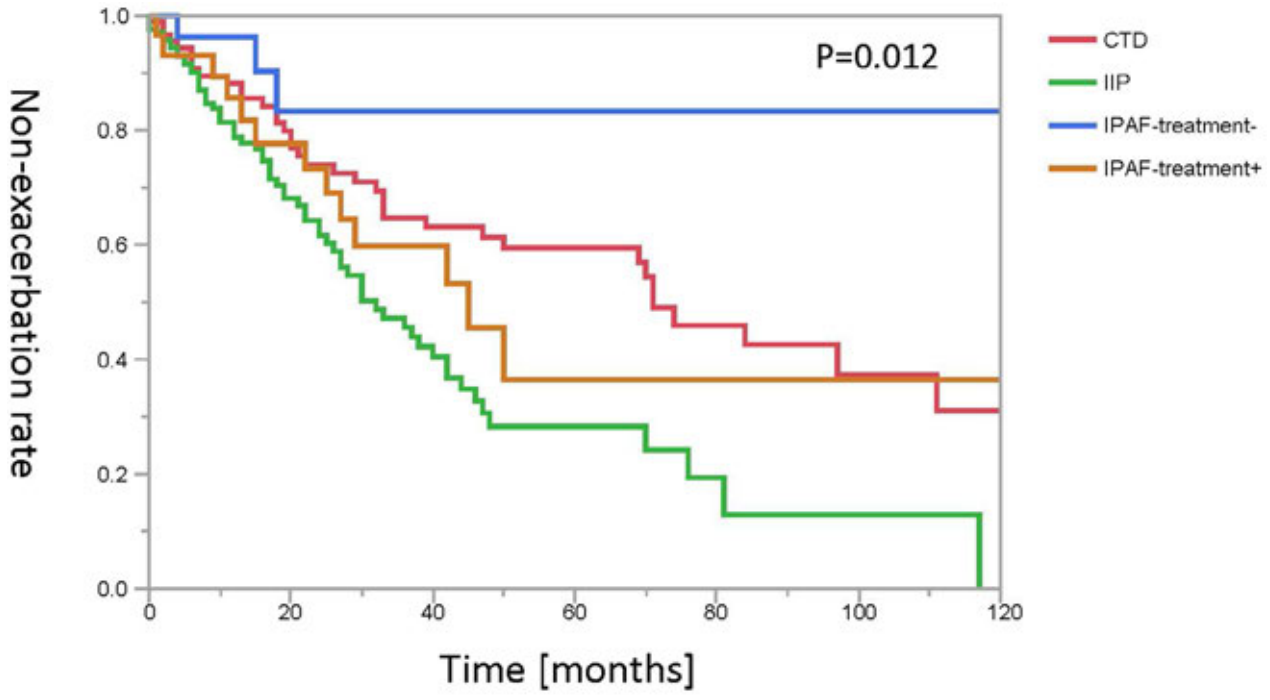

Figure 1. Kaplan-Meier survival curves of interstitial pneumonia with autoimmune features (IPAF) with or without treatment (n=38 and 30), idiopathic pulmonary fibrosis (IIP) (n=170) and connective tissue disease (CTD)-interstitial lung disease (ILD) (n=92).

long-term outcomes among patients with IPAF, IIP, and CTD-ILD, 5-year non-exacerbation rate in IPAF patients with treatment, those without treatment, CTD-ILD patients, and IIP patients was 36.5%, 83.3%, 59.5%, and 28.3%, respectively. (Figure 1)

Conclusion: Our large-scale cross-sectional cohort study identified unique prognostic factors of exacerbation and long-term outcome in patients with IPAF.

Novel Approach to the Treatment of Cardiac Sarcoidosis with TNF-alpha Inhibition

Matthew Baker ,[1] Khushboo Sheth,[1] Julia Simard,[2] Stanford Shoor,[1] and Mark Genovese[3], [1]Stanford University, Palo Alto, CA, [2]Stanford University School of Medicine, Palo Alto, CA, [3]Stanford University, Stanford, CA

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Miscellaneous Rheumatic & Inflammatory Disease Poster I: Fibroinflammatory & Granulomatous Disorders & Therapies
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Sarcoidosis is a systemic inflammatory disease characterized by the presence of noncaseating granulomas. When it affects the myocardium, it can result in electrical conduction abnormalities, heart failure, and sudden death. There are no FDA-approved treatments for cardiac sarcoidosis, but the standard of care includes glucocorticoids and disease modifying anti-rheumatic drugs (DMARDs). When these therapies fail, tumor necrosis factor alpha (TNF-a) inhibitors are considered as a possible option. No formal studies have examined TNF-a inhibitors in cardiac sarcoidosis, and there is a theoretical concern that they may worsen heart failure. The aim of this retrospective review is to characterize cardiac sarcoidosis patients treated at Stanford University and to evaluate the response to TNF-a inhibitor treatment.

Methods: This is a retrospective study conducted at Stanford University. Sarcoidosis patients were identified by searching all patients seen between 2009 and 2017, ages 18 years and older, with an ICD-9/10 code for sarcoidosis, and at least one clinical note mentioning “sarcoidosis.” Each chart was manually reviewed to verify the sarcoidosis diagnosis, to determine which patients had cardiac involvement, and to extract relevant data for analysis. Continuous variables were summarized as mean and standard deviation. Categorical variables were summarized as frequencies and percentage of the total.

Results: A total of 1,186 potential sarcoidosis patients were identified (*Figure 1*), and 250 patients were excluded for not meeting diagnostic criteria. Of the 936 sarcoidosis patients remaining, 77 were identified as having cardiac sarcoidosis (8.2%). Baseline demographics (*Table 1*) demonstrate that the mean age at diagnosis was 55 years, 39% of patients were female, and the most common clinical presentations were heart block and tachyarrhythmia. Twenty patients (26%) received a TNF-a inhibitor (*Table 2*). The mean dose of prednisone before starting a TNF-a inhibitor was 23 milligrams (mg) daily, which decreased to 4 mg daily within 6 months after treatment initiation. Likewise, the mean left ventricular ejection fraction (LVEF) within one year before TNF-a inhibitor treatment was 44%, which

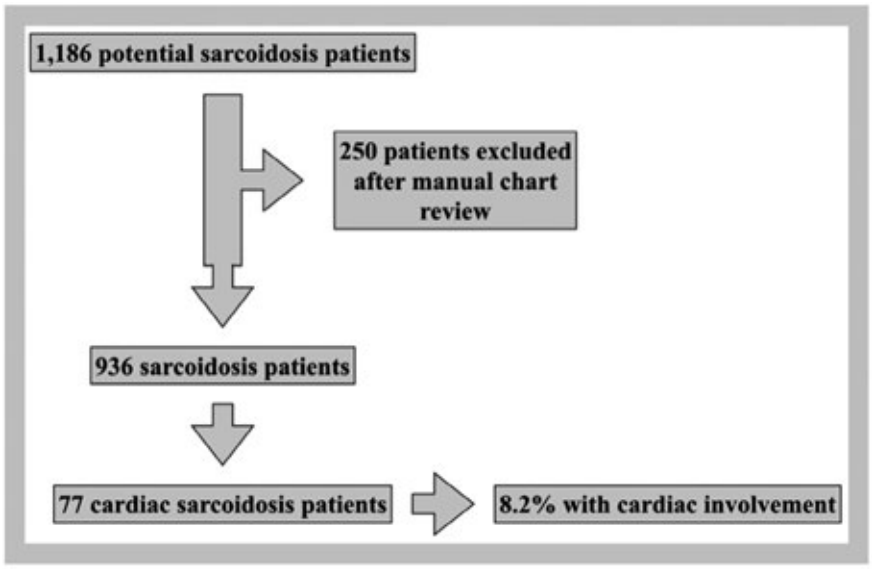

Figure 1: Sarcoidosis cohort patient selection

Table 1: Baseline characteristics of 77 cardiac sarcoidosis patients seen at Stanford University between 2009 and 2017

Clinical Characteristic	n (%)
Age at diagnosis in years, mean (SD)	55 (11.8)
Women	30 (39)
Race	
White	51 (66)

Table 2: Treatment outcomes for 20 cardiac sarcoidosis patients treated with TNF-α inhibitors

TNF-α Inhibitor Indication/Outcome	n (%)
Reason for initiating TNF-α inhibitor	
Worsening heart failure	3 (15)
Worsening arrhythmia	8 (40)
Worsening findings on imaging	17 (85)
Improvement in imaging after TNF-α inhibitor initiation	16 (94)
Time from diagnosis to TNF-α inhibitor initiation in months, mean (SD)	16 (14.0)
Prednisone dose 6 months before TNF-α inhibitor initiation in mg, mean (SD)	23 (11.9)
Prednisone dose 6 months after TNF-α inhibitor initiation in mg, mean (SD)	4 (8.6)
Time to stop prednisone after TNF-α inhibitor initiation in months, mean (SD)	9 (8.9)
LVEF within 12 months before TNF-α inhibitor initiation, mean (SD)	44 (14.1)
LVEF within 12 months after TNF-α inhibitor initiation, mean (SD)	47 (14.8)
Serious infections	
Patients on TNF-α inhibitors	0 (0)
Patients on non-TNF-α inhibitor immunosuppression	7 (9)

remained stable at 47% within one year after starting treatment. This included 5 patients with an LVEF £ 30% at the time of TNF-a inhibitor initiation.

Conclusion: Twenty cardiac sarcoidosis patients in our cohort (26%) received a TNF-a inhibitor, with the overall experience being positive. Despite concerns that TNF-a inhibitors can worsen heart failure, no patients had a notable decline in LVEF within one year after treatment initiation, and most saw an improvement. This included 5 patients who had a LVEF £ 30% at the time of starting a TNF-a inhibitor. In addition, those patients who were on glucocorticoids at the time of TNF-a inhibitor initiation were all able to reduce their dose. This study supports the notion that patients with cardiac sarcoidosis who continue to have active disease despite conventional therapies can be treated with TNF-a inhibitors, and it provides a strong rationale for larger, prospective studies to be conducted in the future.

Systemic and Ocular Sarcoidosis Study of 381 Patients from a Single Universitary Centre in the Last 20 Years

Lara Sanchez-Bilbao ,[1] Belén Atienza-Mateo,[1] Iñigo Gonzalez-Mazon,[2] Jose Luis Martín-Varillas,[1] Rosalia Demetrio,[3] Vanesa Calvo-Río,[4] Eva Peña Sainz-Pardo,[5] Raul Fernandez-Ramon,[3] Jorge Javier Gaitan-Valdizan,[3] Miguel A Gonzalez-Gay,[1] and Ricardo Blanco[1], [1]Rheumatology, Hospital Universitario Marques de Valdecilla, Santander, Spain, [2]Rheumatology, Hospital Universitario Marques de Valdecilla, Santander, Cantabria, Spain, [3]Hospital Universitario Marqués de Valdecilla, Santander, Spain, [4]Hospital Universitario Marques de Valdecilla, Santander, Spain, [5]Pediatrics, Hospital Universitario Marques de Valdecilla, Santander, Cantabria, Spain

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Miscellaneous Rheumatic & Inflammatory Disease Poster I: Fibroinflammatory & Granulomatous Disorders & Therapies

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Sarcoidosis is a multisystemic inflammatory disease characterized by non-caseating epitheliod granulomas. Ocular involvement is the presenting symptom in approximately 20-30% in form of uveitis, conjunctivitis, episcleritis/scleritis, optical nerve disease or orbital inflammation. Our objective was to define an epidemiological context in the last 2 decades, focusing on the ocular affectation and its correlation with the IWOS (International Workshop on Ocular Sarcoidosis) criteria, which classify ocular sarcoidosis as definitive, presumed, probable and possible, according to certain ophthalmological and analytical findings. They are very useful if a biopsy is not obtained or it is negative

Methods: Retrospective study of patients admitted to a single reference University Hospital between 01/01/1999 and 01/01/2019 with diagnosis of sarcoidosis trough biopsy and/or compatible symptoms and imaging tests. Demographics features, clinical findings, complementary tests and treatment were recorded.

	Patients (n=50)
Age, mean (SD) years	45.5 (16.7)

Results: We studied 381 patients (190 women/191 men), mean age at diagnosis 45.5±15.4 years, 94.8% of Spanish nationality. 33% were smokers and 6.3% had had tuberculosis. The incidence rate of sarcoidosis was 3.3 cases/ 100,000 people/year, like other national series. The most affected organ was lung (72.3%), followed by skin (31%) (TABLE 1). In addition, at diagnosis 11.5% and 0.5% of patients had a Löfgren and a Heerdfort syndrome, respectively. A simple x-ray chest was performed in all patients, with alterations in 83.7%, the majority at stages I and II. Moreover, 29.9% and 10.5% presented pathological scintigraphy and PET scan, respectively. A biopsy was performed in 81.9% of the cases, with a mediastinal approach in 43.3%. After a median follow-up of 11.0 [6.0-17.0] years, 32% had never received treatment and in the remaining 68% the most used therapy was oral glucocorticoids. Other therapies were conventional and/or biological immunosuppressants (TABLE 2).

- Mediastinum, n (%)	166 (43.3)
- Lung, n (%)	67 (17.5)
- Liver, n (%)	9 (2.4)
- Skin, n (%)	45 (11.7)
- Lymphadenopathy, n (%)	3 (0.8)
TREATMENT	
Not treated, n (%)	**122 (32.0)**
Glucocorticoid treatment	
- Topical treatment, n (%)	39 (10.2)
- Prednisone, n (%) / mean dose (mg/day), mean±SD	206 (54.1) / 43.4±19.1
- Bolus MTP, n (%)	15 (3.9)
Conventional immunosupressants	
- Methotrexate, n (%) / mean dosage (mg/week), mean±SD	53 (13.9) / 15.4±5.5
- Azathioprine, n (%) / mean dosage (mg/day), mean±SD	17 (4.5) / 91.6±32.2
- Cyclophosphamide, n (%)	2 (0.5)
- Mycophenolate mofetil, n (%)	2 (0.5)
Biological agents	
- Infliximab, n (%)	14 (3.7)
- Adalimumab, n (%)	19 (5.0)
- Etanercept, n (%)	1 (0.3)
- Golimumab, n (%)	2 (0.5)
- Tocilizumab, n (%)	3 (0.8)
- Rituximab, n (%)	3 (0.8)
- Secukinumab, n (%)	1 (0.3)

Besides, patients with ocular involvement were selected (n=50, 13%), 40 of them with uveitis. Thirty-nine patients (78%) met one of the 4 IWOS diagnostic categories: 22 definite (44%), 13 presumed (26%) and 4 possible (8%) sarcoidosis. The most common ocular signs were bilaterality (44%), snowballs or strings of pearls (38%), mutton-fat KPs (24%), multiple chorioretinal peripheral lesions (14%) and periphlebitis (10%). Regarding the treatment of this group, 44 patients (88%) received oral corticosteroids, 21 (42%) methotrexate, 11 (21%) another conventional immunosuppressor and 11 (21%) a biological treatment. TABLE 3 shows the main demographic and clinical features of this group.

Conclusion: The results obtained are reproducible to those published in national and international series, except for the non-predominance of females and the highest percentage of ocular involvement in our study. Currently, biological treatment (especially anti-TNF) is used more frequently. In our population the IWOS criteria had a sensitivity of 78%.

Even though there is no gold standard for diagnosing ocular sarcoidosis yet, IWOS signs can help clinicians suspect it.

Abstract Number: 0379

Neurosarcoidosis: An Evaluation Based on the Neurosarcoidosis Consortium Consensus Group

Thieroff George ,[1] Huzaefah Syed,[2] Thomas Iden,[2] Aamer Syed,[2] Trang Le,[2] and Alicia Zukas[3], [1]VCU Medical Center, Richmond, VA, [2]VCU Medical Center, Richmond, VA, [3]Virginia Commonwealth University, Richmond, VA

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Miscellaneous Rheumatic & Inflammatory Disease Poster I: Fibroinflammatory & Granulomatous Disorders & Therapies
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The 2018 Neurosarcoidosis Consortium Consensus Group (NCCG) attempted to increase specificity in diagnosing neurocsarcoidosis from the 2013 World Association of Sarcoidosis and Other Granulomatous Diseases (WASOG) Organ Assessment Criteria. We assessed whether treatment response varied within these new classifications.

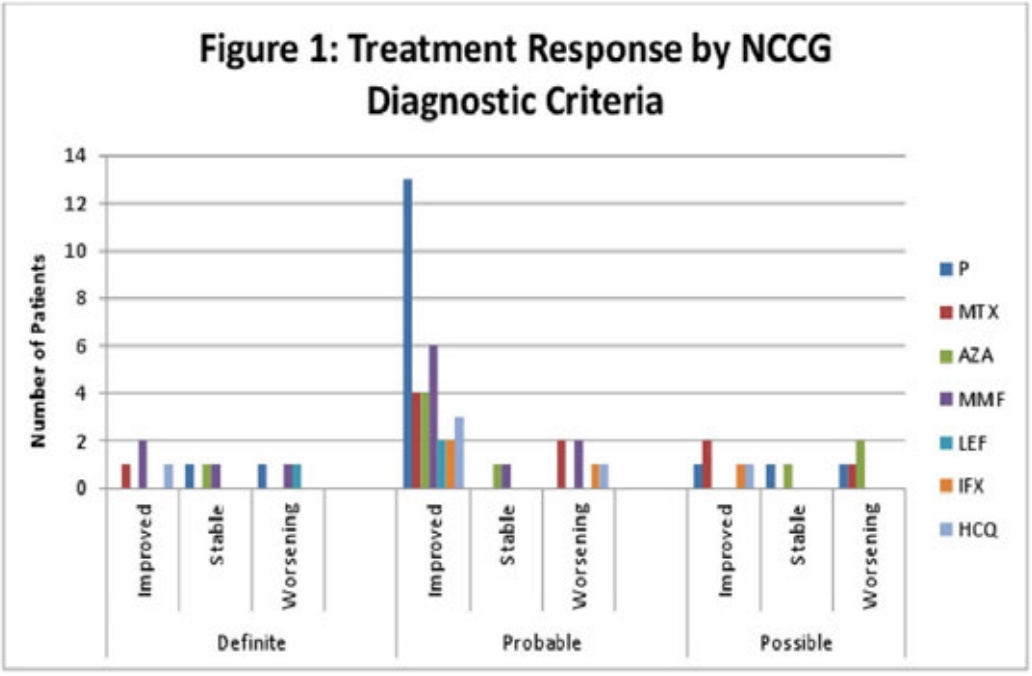

Table 1: Demographics (n=48)	
Age (years)	Median (49), IQR (42.5 – 54.5)
Race (%)	Black (83), White (15), Other (2)
Sex (%)	Male (50)
MRI n = 40, % abnormal	97.5
CSF n = 24, % abnormal	60
Brain bx n = 7, % abnormal	100

Methods: We performed a single center, retrospective study of patients with diagnosis of neurosarcoidosis from the VCU Sarcoidosis database containing data on 1298 patients from 2009 to 2019. Patients were classified by WASOG and NCCG criteria. Response to therapy was defined as improvement in symptoms on most recent therapeutic agent.

Results: 48 subjects (50% male, 83.3% black) were enrolled with a median of age 49. Of the 46 previously diagnosed as Highly Probable or Probable by WASOG criteria, 32 (66.7%) dropped from Highly Probable to Probable or from Probable to Possible by NCCG criteria. 7 (14.6%) dropped from Highly Probable to Possible due to lack of tissue biopsy from any source. 7 patients were defined as Definite by NCCG criteria due to positive brain biopsy and were previously Highly Probable by WASOG criteria. 28 (58.3%) patients improved on any therapy and 16 (33.3%) improved with exposure to glucocorticoids. There was no appreciable response to any specific therapy, both between NCCG classifications or the group as a whole (Figure 1).

Table 3: Change in Diagnosis Group

	NCCG		
WASOG	Definite	Probable	Possible
Highly Probable	7	31	8
At Least Probable	0	2	0

Conclusion: NCCG criteria likely increase specificity for neurosarcoidosis by placing a greater emphasis on tissue biopsy. There was no observable difference in response to therapy, regardless of classification, emphasizing the need for future randomized controlled trials.

Seasonal Clustering of Acute Sarcoidosis in South-West Germany and Associations with Particulate Matter Air Pollution

Philipp Rustler ,[1] Dirk Schindler,[2] Reinhard Voll,[1] and Florian Kollert[3], [1]Division of Rheumatology and Clinical Immunology, Medical Centre - University of Freiburg, Freiburg, Germany, [2]Environmental Meteorology, University of Freiburg, Freiburg, Germany, [3]Department of Rheumatology, Immunology and Allergology, Inselspital, University Hospital Bern, Bern, Switzerland

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Miscellaneous Rheumatic & Inflammatory Disease Poster I: Fibroinflammatory & Granulomatous Disorders & Therapies
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Sarcoidosis is a multisystemic granulomatous disorder of unknown origin. The central role of macrophages and granuloma formation, the predominant involvement of lung and skin, and risk populations (e.g. fire fighters) points towards causative airborne antigen(s). This study has been set to analyze seasonal clustering of acute sarcoidosis in south-west Germany and correlations to particulate matter air pollution.

Methods: Patients with acute sarcoidosis (as defined by bihilar lymphadenopathy, ankle swelling and/ or erythema nodosum) who presented between January 1994 and December 2018 were included in this retrospective study. Disease onset (seasonal clustering) and associations to air pollution (particulate matter (PM_{10})) were analyzed.

Results: We were able to include 186 patients (47.3% female, mean age 37, complete Löfgren triad in 72%) with acute sarcoidosis. Over the whole study period disease onsets peaked in the first third of the year (January 17.7 % of cases, February 11.8 %, March 12.4 %, April 12.4 %, May 9.7 %, June 9.7 %, July 7.5 %, August 3.2 %, September 2.7 %, October 1.1 %, November 2.1 %, December 9.7 %). Increase of local PM_{10} (values ranging between 15 and 40 µg/m^3) was followed by a higher number of disease cases in the study period from 2004 to 2015.

Conclusion: In south-west Germany the onset of acute sarcoidosis clusters in the first third of the year. Particulate matter air pollution might be one factor involved.

Effect of Vitamin D Supplementation on Calcium Levels in Patients with Sarcoidosis: A Retrospective Analysis

Christopher Overton ,[1] Trang Le,[1] Thomas Iden,[1] Aamer Syed,[1] Markos Kashiouris,[1] and Huzaefah Syed[1], [1]VCU Medical Center, Richmond, VA

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Miscellaneous Rheumatic & Inflammatory Disease Poster I: Fibroinflammatory & Granulomatous Disorders & Therapies

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Hypercalcemia is seen in 2-30% of patients with sarcoidosis and is caused by the overproduction of Vitamin D (VitD) 1,25OH (calcitriol) by macrophages within granulomas. Low VitD 25OH is also commonly seen, but VitD repletion can potentially cause hypercalcemia. There are currently limited data regarding safe VitD

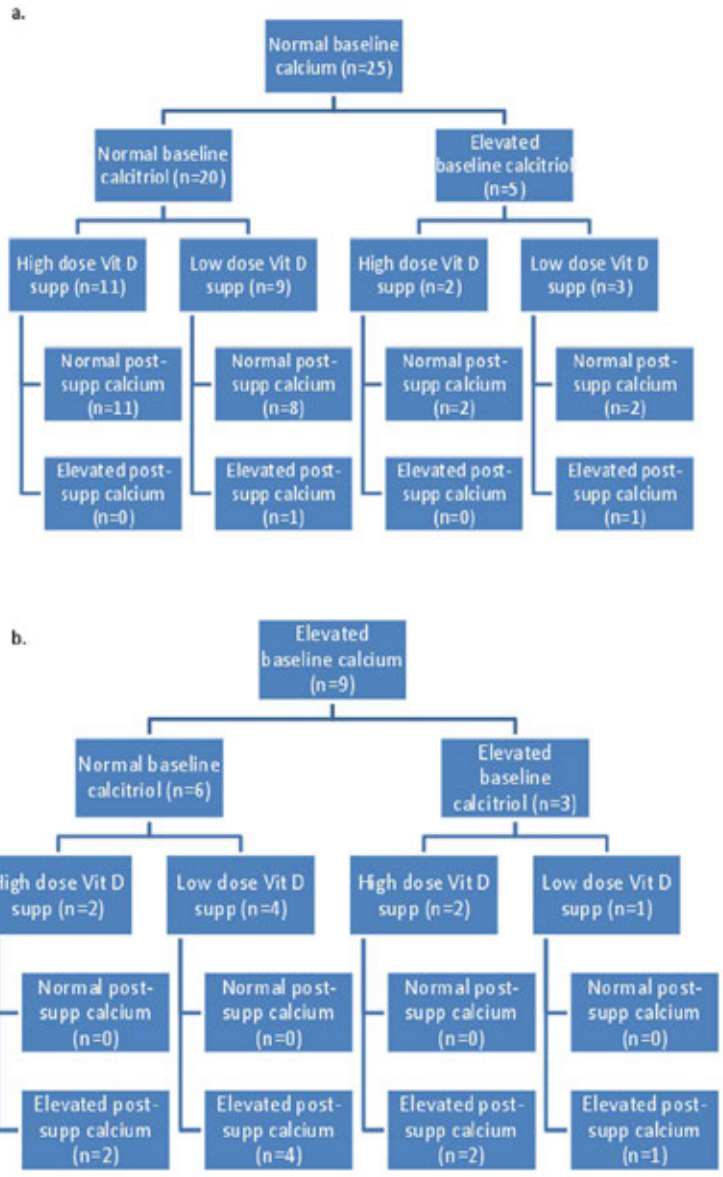

Figure 1. Levels of post-supplementation calcium in patients with normal baseline calcium (a) and elevated baseline calcium (b). Stratified by baseline calcitriol and dosage of Vitamin D supplementation. Only patients with a documented baseline calcitriol included. All patients with baseline hypercalcemia remained hypercalcemic post-supplementation, but only two with normal baseline calcium developed hypercalcemia.

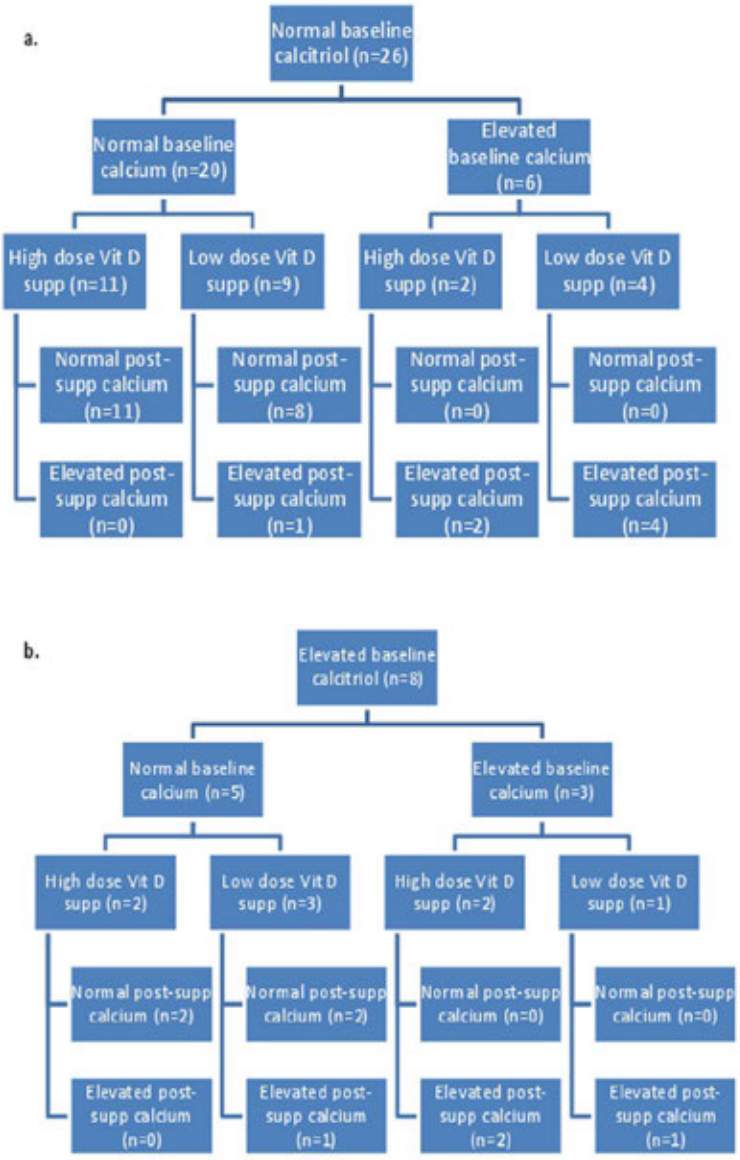

Figure 2. Levels of post-supplementation calcium in patients with normal baseline calcitriol (a) and elevated baseline calcitriol (b). Stratified by baseline calcium and dosage of Vitamin D supplementation. All patients with elevated baseline calcium remained hypercalcemic after receiving supplementation, whereas only 2 patients with normal baseline calcium developed hypercalcemia after supplementation.

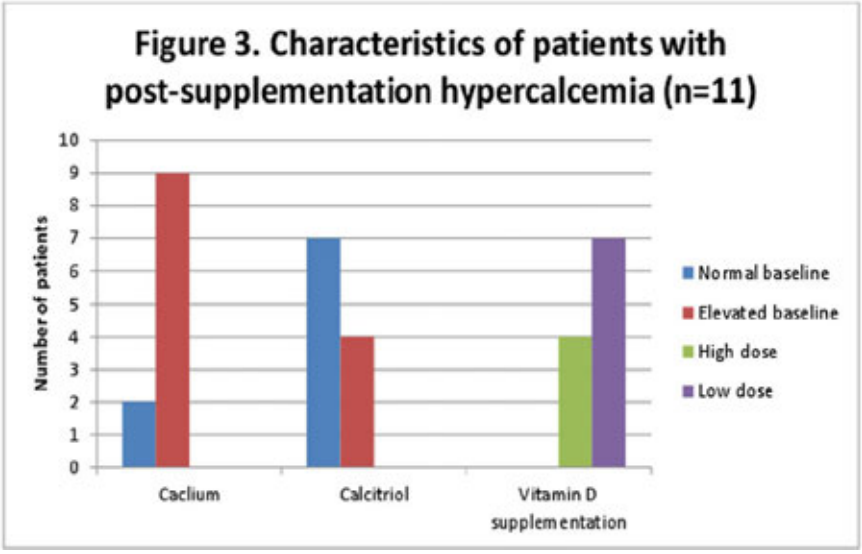
repletion in sarcoidosis patients. We sought to identify patients with sarcoidosis receiving VitD supplementation and determine the incidence of hypercalcemia among them.

Methods: Records of patients with at least one visit for sarcoidosis between January 2010 and December 2015, one recorded baseline calcium, and at least two recorded VitD 25OH levels were reviewed. Serum calcium, VitD 25OH, and calcitriol levels and VitD supplementation data were collected. Hypercalcemia was defined as > 10.7mg/mL. Elevated calcitriol level was defined as >79.3pg/mL. High dose VitD supplementation was defined as vitamin D2 or D3 ^{3}50,000 units weekly, or its equivalent.



Results: One hundred twenty patients were identified (70.8% female, 84.3% African-American, median age of 50 years). Sixteen (13%) patients demonstrated baseline hypercalcemia. Of the 36 patients with available baseline calcitriol, 8 (22%) were elevated. The mean baseline VitD 25OH level was 15.64ng/mL (SD 6.88). For patients in whom repletion duration was available (n=71), median duration for repletion was 12 weeks. Two of the 25 (8%) patients with normal baseline calcium developed post-supplementation hypercalcemia, whereas 9 of the 9 (100%) patients with elevated baseline hypercalcemia had hypercalcemia after supplementation. Seven of the 26 (26.9%) patients with normal baseline calcitriol were hypercalcemic post-supplementation, whereas 4 of the 8 (50%) patients with elevated baseline calcitriol were hypercalcemic after supplementation. Of the total cohort, 11 (9.2%) patients were noted to be hypercalcemic after supplementation. Of these, 9 (81.8%) had baseline hypercalcemia, 4 (36.4%) had elevated baseline calcitriol, and 4 (36.4%) received high dose supplementation. Only one patient who received VitD supplementation developed VitD levels above the normal limit, but did not develop hypercalcemia.

Conclusion: Our data suggests that VitD supplementation can be considered in those with normal baseline calcium, but should be given with caution in those with elevated baseline calcium. Baseline calcitriol did not appear to be a risk factor for hypercalcemia induced by VitD supplementation, but additional data are needed to inform more standardized supplementation algorithms.

Neurofilament Light Chain Levels in Cerebrospinal Fluid and Plasma in Neurosarcoidosis

Keld-Erik Byg ,[1] Tobias Sejbaek,[2] Helle Nielsen,[3] Zsolt Illes,[4] Jonna Skov Madsen,[5] Dorte Olsen,[6] and Torkell Ellingsen[1], [1]Department of Rheumatology, Odense University Hospital, Denmark, Odense, Syddanmark, Denmark, [2]Department of Neurology, Odense University Hospital; Department of Clinical Research, University of Southern Denmark, Denmark, Odense, Syddanmark, Denmark, [3]Department of Neurology, Odense University Hospital, Department of Clinical Research, University of Southern Denmark, Denmark, Odense, Syddanmark, Denmark, [4]Department of Neurology, Odense University Hospital, Department of Clinical Research, University of Southern Denmark, Denmark, Odense, Midtjylland, Denmark, [5]Department of Biochemistry and Immunology, Lillebaelt Hospital, Vejle, Department of Regional Health Research, University of Southern Denmark, Denmark, Vejle, Syddanmark, Denmark, [6]Department of Biochemistry and Immunology, Lillebaelt Hospital, Vejle, Denmark., Vejle, Syddanmark, Denmark

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Miscellaneous Rheumatic & Inflammatory Disease Poster I: Fibroinflammatory & Granulomatous Disorders & Therapies
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Neurofilament Light Chain (NFL) is an emerging biomarker that is specific for neuronal and axonal damage/degeneration but unspecific regarding the origin of destruction. NFL has been suggested as biomarker in neurological diseases. No study has so far examined relation between neurosarcoidosis (NS) and NFL.

The purpose is to compare NFL levels in plasma and cerebrospinal fluid (CSF) in sarcoidosis patients with NS compared to healthy controls (HC).

Methods: Plasma and CSF from consecutive biopsy positive sarcoidosis patients with suspected NS and/or relapsing NS (n=19). Based on WASOG-criteria, patients were characterized into two groups: highly probable NS (n=14) and a non-NS group (n=5). Results were compared to the HC (n=11). NFL concentrations were analyzed using Single Molecular Array (SIMoA) from Quanterix. NFL Levels above 807.5pg/ml in CSF and 13.0 pg/ml in plasma were considered elevated. Group medians were compared using Kruskal-Wallis and Mann-Whitney tests. Range is given in brackets.

Results: The average mean age of NS patients was 45 years (23-59) and disease duration median 5.5 (2-259) months. Of the patients with NS 79 % (n=11) initially presented with CNS symptoms. The remaining patients: one developed NS after 4 months under glucocorticoid treatment, one had chronic NS with symptom aggravation under immunosuppression and one had skin sarcoidosis with relapse of NS. Elevated serum angiotensin converting enzyme (ACE) was found in 14 % (n=2) and elevated plasma Interleukin-2 in 57 % (n=8). Abnormal MRI of brain was found in 50% (n=7) and medulla 21 % (n=3). Pleocytosis (LKC >5/ml) of the CSF was found in 79 % (n=11) and protein elevation in 79% (n=11). Oligoclonal bands were found in 21% (n=3). NFL was elevated in 64% (n=9) in plasma and 57% (n=8) in CSV. The average mean age in the non-NS group was 45 years (26-60), and disease duration median 45 (11-272) months. 20% (n=1) had elevated ACE, 40% (n=2) had elevated IL-2. Median CSF NFL was significantly higher ($p< 0.005$) in NS (1537 pg/ml; 184-43961) compared to non-NS (426 pg/ml; 249-689) and HC (336 pg/ml; 81-499). Also, median plasma NFL level was significantly higher ($p< 0.05$) in NS (16.8 pg/ml; 4.8-191.8) compared to non-NS (9.2 pg/ml; 5.1-11.4) and HC (7.1 pg/ml; 3.0-10.9). Plasma and CSF NFL in NS patients was not found to be significantly different between NS patients with or without MRI pathology. No patient in non-NS group and HC group had abnormal NFL in plasma or CSV.

Conclusion: Both plasma and CSF NFL were significantly higher in NS patients compared to non-NS patients and HC´s. Plasma and CSF NFL were elevated in 64% and 57% of NS patients, respectively, compared to none of the patients in non-NS or HC group. NFL could be related to extend of CNS affection, but our study was underpowered to demonstrate a significant different difference in NS patient with and without MRI and CSF abnormalities. This is the first study demonstrating elevation of NFL in both blood and CSF in patients with NS. Further studies are needed to evaluate the potential use of NFL as a biomarker supporting the diagnosis of NS, prognosis of the disease and if NFL could be used clinically to monitor response of immunological treatment.

Retroperitoneal Fibrosis- a Single Center Experience

Mert Oztas ,[1] Emir Cerme,[2] Izzet Altun,[3] and Serdal Ugurlu[4], [1]Istanbul University-Cerrahpasa,Department of Medicine, Division of Rheumatology, Istanbul, Turkey, [2]Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Department of Internal Medicine, Istanbul, Turkey, [3]Mayo Clinic, Scottsdale, AZ, [4]Istanbul University - Cerrahpasa, Cerrahpasa Medical Faculty, Department of Internal Medicine, Division of Rheumatology, istanbul, Turkey

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Miscellaneous Rheumatic & Inflammatory Disease Poster I: Fibroinflammatory & Granulomatous Disorders & Therapies
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Idiopathic retroperitoneal fibrosis (iRPF) is a rare, chronic, progressive disorder of unknown etiology and characterized by the presence of inflammatory and fibrous retroperitoneal tissue that often encompasses the ureters or abdominal organs. We evaluated iRPF cases of a single institution cohort to describe the features of patients (pts) with iRPF.

Methods: Twenty-eight iRPF patients who were being followed in our outpatient clinic between 2009 and 2018 were reviewed retrospectively. The demographic characteristics, clinical and radiologic findings,medical and interventional therapies were retrospectively collected and reported.

Results: We evaluated the data of 28 patients (17M/11F). The mean age at the time of diagnosis was 53±10,57, median follow up was 46 (IQR:23-67) months. Fifteen (%50) patients were presented with abdominal-pain which was the most common initial complaint. Twenty-one patients had hydronephrosis (11 bilateral hydronephrosis, 5 right) at

Table 1: Types of medical and surgical therapy

Types of medical therapy	**n, (%)**
Glucocorticoid	27(96,5)
Glucocorticoid only	3 (10,5)
Tamoxifen	8 (28)
Azathioprine	8 (28)
Cyclophosphamide	1 (3,5)
Methotrexate	10(35)
Rituximab	13(46)
Mycofenolate Mofetil	1 (3,5)
Types of interventional therapy	n, (%)
Left ureteral stents	15(53,5)
Right ureteral stents	16(57)
Right nephrostomy	4 (14)
Left nephrostomy	2 (7)
Ureterolysis	2 (7)
Temporary Hemodialysis	1 (3,5)

Table 2: Baseline clinical,laboratory and radiologic findings

Characteristic	Value
General characteristics	
Age,mean (S.D), years	53±10,57
Male, n (%)	17 (60)
Follow-up duration, median (IQR),months	46 (23-67)
Clinical symptoms, n (%)	
Abdominal pain	15 (50)
Flank pain	9 (32)
Nausea	2 (8)
Anuria	1 (5)
Nocturia	1 (5)
Laboratory	
ESR, median (IQR), mm/h	39 (17-88)
CRP, median (IQR), mg/L	11 (5,5-46,5)
Serum creatinine mean (IQR), mg/dL	1,14 (0,83-1,9)
Radiologic findings	
Hydro-ureteronephrosis, n(%)	21 (75)
Bilateral	10 (48)
Unilateral	11 (52)
^{18}F-FDG-PET scan, n(%)	19 (69)
Positivity	16 (84)

initial visit and one patient diagnosed while on temporary hemodialysis therapy. Laboratory tests showed that ESR was elevated in 15 of 23 cases with a median value of 39 mm/h (IQR:17-88); CRP was elevated in 19 of 28 patients (68%), with median value 11 (IQR:5,5-46,5). Mean serum creatinine level was 1,14 mg/dl IQR (0,83-1,9). Tissue involvement was detected with computed tomography in 25 (89%) patients. In addition, 18 F-FDG-PET was ordered for 19 patients and 16 of them (84%) was positive for tissue involvement of iRPF. Among these 16 pts, control 18 F-FDG-PET scan was obtained in 13 after at least 6 months of follow-up. Remission was observed in 7 pts in control 18 F-FDG-PET scan.Histopathological samples were available for further analysis in 8 cases and 5pts' findings were consistent with iRPF (storiform fibrosis and dense lymphoplasmacytic infiltration were observed). Medical and interventional therapies are presented in Table 2. Twenty-seven pts were initially treated with glucocorticoids and the mean initial oral prednisone dose was 45,5±13,8 mg/day. Prednisone was discontinued in 4 patients after remission and for the remaining 23 pts; 12 pts' prednisone was tapered < 5 mg/day at mean 9 (IQR:6,7-22,5) months. The remaining patient was treated with tamoxifen. One patient diagnosed AML-M2 during the follow-up and had allogenic stem cell transplantation. Final median values of ESR and CRP were 10 mm/h (IQR:4,7-17,7) and 4,4 mg/l (1,9-7,7), respectively (p= 0.001 and p=0.002). Final median serum creatinine level was 1,03 (IQR:0,78-1,28) (p=0,2). Thirteen pts (%46) were treated successfully with Rituximab who were not responded initial prednisone therapy. Twenty-one pts had ureteral stents and 11 of them are stent free at the final visit. 2 pts had ureteroysis but the procedure was failed in one patient. None of the pts was deceased on the follow-up.

Conclusion: Steroids are the mainstay treatment for iRPF and steroid resistant cases could be treated with rituximab rescue therapy. Prompt interventional approaches are valuable bridging therapies for pts who presented with hydronephrosis. Obtaining a biopsy sample could be hazardous or not possible; so imaging modalities add great value on the diagnose of İRPF.

Prevalence and Predictors of Fibrosis in Rheumatological Patients on Therapy and Risk Factors for Chronic Liver Disease

Connie Lam,[1] Stephen Bloom,[2] and **Alberta Hoi** [3], [1]School of Clinical Sciences, Monash University, Melbourne, Victoria, Australia, [2]Eastern Health Clinical School, Monash University, Melbourne, Victoria, Australia, [3]School of Clinical Sciences, Monash University, Meloburne, Victoria, Australia

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Miscellaneous Rheumatic & Inflammatory Disease Poster I: Fibroinflammatory & Granulomatous Disorders & Therapies
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The assessment of liver stiffness using liver elastography (Fibroscan) has facilitated early diagnosis of hepatic fibrosis in patients with chronic liver disease, but its use has not been evaluated extensively in rheumatological patients. The use of methotrexate in these patients is considered first-line disease modifying therapy for many inflammatory arthritides, and one of its potential adverse effects is hepatotoxicity which can present either as asymptomatic transaminitis, progressive liver fibrosis, or liver cirrhosis.

This is the first Australian study to examine the predictors for abnormal liver elastography in rheumatological patients, and its clinical utility in the management of methotrexate users.

Methods: A retrospective chart review of patients attending a Melbourne metropolitan rheumatology practice between 2011-2018, who has had liver elastography done as part of their liver assessment, was studied. Liver stiffness measure (LSM) of >8 kPa was used as a surrogate for liver fibrosis. Baseline diagnosis, comorbidities, laboratory results, and medication use were correlated to abnormal liver elastography using univariate and multivariate analysis.

Results: One hundred twenty nine patients were identified with rheumatological conditions that underwent LSM assessment during the 7-year period. Commonest indications for assessment were methotrexate use (47.3%), non-alcoholic steatohepatitis (27.9%), and chronic viral hepatitis (9.3%) and at-risk alcohol consumption (3.9%). Elevated LSM was associated significantly with the diagnosis of spondyloarthritis (OR 1.22 p=0.008) and with high BMI (OR 4.64 p=0.058). Biochemically, GGT was the only significant predictor of abnormal LSM. The presence or absence of methotrexate use, nor its duration, were associated with abnormal LSM. There was no difference in baseline demographic features between users and non-users of methotrexate. Median LSM were similar in methotrexate exposed patients compared to non-exposed patients (4.8kPa respectively p=0.707). The proportions of patients with LSM >8 were similar in methotrexate exposed and non-exposed group (6.6% vs 13.2% respectively, p=0.202). The discontinuation of methotrexate was associated with increased LSM (13.8% discontinued versus 2.1% that did not p=0.046) and those with increased LSM were less likely to be commenced on MTX following LSM assessment (0.0% vs 31.8% p=0.002).

Conclusion: Abnormal liver elastography in rheumatological patients was associated with high BMI and the diagnosis of seronegative spondyloarthritis. Methotrexate use was not associated with increased fibrosis but LSM did affect its use. Positive correlation with the diagnosis of spondyloarthritis with increased LSM is consistent with current theories suggesting an increase in insulin resistance and therefore an increased risk of fatty liver that may be observed in this group.

Distinctive Clinical Features and Biomarkers of Connective Tissue Disease Associated Interstitial Lung Disease

Sang Wan Chung ,[1] So-Yun Lee,[1] Sang-Hoon Lee,[1] Seung-Jae Hong,[1] and Yeon-Ah Lee[1], [1]School of Medicine, Kyung Hee University, seoul, Republic of Korea

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Miscellaneous Rheumatic & Inflammatory Disease Poster I: Fibroinflammatory & Granulomatous Disorders & Therapies
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The connective tissue diseases (CTD) are a group of rheumatologic diseases characterized by inflammation and immune-mediated organ damage including interstitial lung disease (ILD). The reported frequency of ILD associated with CTD (CTD-ILD) is variable, depend on definitions of disease and demographic factors. However, studies of clinical risk factor and serologic biomarkers on CTD-ILD in Korean patients are sparse.The aim of this study is to investigate clinicoserologic biomarkers associated with development, progression, and prognosis of CTD-ILD in Korean patients

Methods: We conducted a single center, a retrospective study including 70 incident patients diagnosed with CTD-ILD and 70 age-, sex-, type of CTD-matched patients without ILD at Kyung Hee University medical center. Clinical information including the time of developing ILD, pulmonary function test, and imaging findings of chest CT were reviewed using medical record. To find serologic biomarkers, serum concentrations of interferon-r-induced protein 10 (IP-10), interleukin (IL)-6, IL-8, IL-10, and matrix metalloproteinase 7 (MMP-7) in patients with CTD-ILD and CTD without ILD were measured using Luminex multiplex bead assay.

Results: Total 140 patient (70 CTD-ILD, 70 CTD without ILD) were enrolled, the mean age of the study group was 63.4 ± 11.2 years, 103 (73.6%) patients were female. To analyze clinical risk factors for developing ILD in CTD, we compared clinical features and laboratory findings between CTD-ILD group and CTD without ILD group. Raynaud`s phenomenon (OR 8.1, 95% CI 2.1-31.2) was the risk factor for developing ILD in CTD in multivariable logistic regression analysis. Rheumatoid arthritis (RA) was the most common type of CTD associated with ILD and idiopathic inflammatory myopathy (IIM)-ILD group had more deteriorated pulmonary functions. Non-specific interstitial pneumonia (NSIP) pattern was the most frequent radiographic pattern (41/70, 58.6%). For analysis of distinctive clinical features according to the onset of ILD, we stratified CTD-ILD patients into three groups: ILD-preceding (12/70, 17.1%), simultaneous (25/70, 35.7%), and CTD-preceding (33/70, 47.1%). In the ILD-preceding group, ILD preceded CTD by 27 months on average, UIP and NSIP had similar proportion. Majority of ILD-preceding group (75%) had worse baseline pulmonary function which required treatment (DLCO < 65%), while 51.5% of in CTD-preceding group did. In CTD-preceding group, NSIP was more common than UIP. Initial DLCO was the risk factor for ILD progression. Serum MMP-7 levels were associated with the developing ILD in CTD patients and had a significant correlation with CT extent score in the present study.

Conclusion: In this study, Raynaud`s phenomenon was a clinical risk factor for ILD in CTD. Patients with preceding ILD prior to CTD had more deteriorated lung function at baseline, and it was associated with poor prognosis. Serum MMP-7 levels had a correlation with ILD development and CT score. Therefore, it is necessary to pay attention to the clinicoserologic biomarkers assoiated with ILD in patients with CTD, this will be beneficial to provide more proper management

Inflammatory arthritis/arthralgias (n,%)	4 (14)
Erythema nodosum (n,%)	5 (18)

1. Data not available in the following numbers of patients, as listed by clinical feature: max-size at diagnosis- 6; positive bacterial culture or gram stain/any positive-1; positive tuberculosis-2
2. Two additional patients with gram stain showing gram positive bacilli
3. Defined as positive acid fast bacilli (AFB) culture, interferon gamma release assay (IGRA), tuberculin skin test (TST), chest x-ray (CXR) with suggestive findings. Of the 4 positive results, 1 patient with history of previously treated latent tuberculosis (TB), 1 patient with positive TST but negative CXR and IGM biopsy specimen with negative AFB staining, 1 patient had history of treated pulmonary TB 20 years prior and IGM biopsy specimen with negative AFB staining, 1 patient with positive IGRA and PPD and chest x-ray with transient hilar lymphadenopathy, however AFB staining, broad range polymerase chain reaction from biopsy was negative

Background/Purpose:: Idiopathic granulomatous mastitis (IGM) is an inflammatory breast disease occurring primarily in young to middle-aged women (1, 2). IGM typically presents with a tender, firm breast mass that may be accompanied by redness, irritation, and drainage. The diagnosis of IGM is made by breast biopsy showing non-caseating granuloma after other causes of granulomatous mastitis have been excluded (1, 4). IGM is a poorly understood disease; there is no consensus regarding underlying cause, risk factors, and optimal treatment of this condition (3). However, IGM is being increasingly recognized as an inflammatory condition and referred to rheumatologists to aid in immunomodulatory management. IGM is primarily managed by breast surgeons and most of our understanding about this disease comes from surgical literature. However, a growing body of evidence, including this case series, suggests that IGM is a systemic inflammatory disease, and that rheumatologists are important and well situated to help care for these patients.

Methods:: IGM patients were identified via the OHSU Cohort Discovery tool who carried a diagnosis of “granulomatous mastitis”. 30 patients seen between 2007-2018 where identified. Retrospective chart review was used to verify that IGM diagnosis was accurate, collect data on baseline characteristics, clinical features and treatment course/outcomes. 2 patients were excluded (1 diagnosed with alternative condition and 1 without adequate follow-up).

Results:: Of the 28 IGM patients, all were female, the mean age was 32, the majority (60.7%) were Hispanic. The mean follow-up was 27 months and 17% of patients were treated by rheumatologists. Consistent with previous reports, the majority of patients had a history of pregnancy (93%) and breastfeeding (92%). Interestingly, 4 patients had inflammatory arthritis/arthralgias and 5 had erythema nodosum. 23 patients had adequate follow-up to assess treatment response. Treatment groups were divided into surgery plus high dose steroids (n=3), high dose steroids alone (n=12), methotrexate (MTX) and high dose steroids (+/- surgery) (n=3) and other (n=5). A rheumatologist saw all patients who received MTX. 7 patients (30%) had disease relapse after initial treatment and 4 patients (17%) had

Table 3: Idiopathic Granulomatous Mastitis Treatment Outcomes in 23 patients

	All treatment groups	High dose steroids + surgery[1] N=3	High dose steroids alone[1] N=12	Methotrexate and high dose steroids (+/- surgery)[1] N=3	Other (none, surgery alone, antibiotics/surgery alone, antibiotics alone) N=5
Remission without relapse	12 (52%)	2 (66%)	5 (42%)	3 (100%)	2 (40%)
Relapse	7 (30%)	0	5 (42%)	0	2 (40%)
1 relapse	5 (22%)	0	4	0	1
> 1 relapse	2 (8.7%)	0	1	0	1
Mean length of time until 1st remission (mo)	7.9	15	7.3	8	5.3
Mean length of time until 1st relapse (mo)	11.4	n/a	9.6	n/a	16
Persistent disease	4 (17%)	1 (33%)	2 (17%)	0	1 (20%)
Disease free off of treatment	19 (83%)	2 (66%)	10 (83%)	3 (100%)	4 (80%)

1. All patients received varying courses of antibiotics, without significant clinical improvement except in 1 case (listed in "other")

Note: Total number of patients included in outcomes table is 23. Of the 5 excluded patients, 3 had insufficient follow-up to determine outcomes and 2 excluded because treatment still ongoing

persistent disease. The highest rates of relapse were in the steroids alone group (42%) and lowest rate of relapse was in the methotrexate group (0%). Overall, 83% of patients eventually achieved a disease free remission with post-remission follow-up of over 1 year in 74%.

Conclusion:: This case series of 28 IGM patients suggests that MTX in combination with high dose steroids may successfully treat IGM, although larger prospective studies are needed. We also report a higher incidence of arthritis/arthralgia and erythema nodosum than previously described—it is possible that these systemic findings are more likely to be recognized by a rheumatologist. IGM is an inflammatory disease and a rheumatologist is a valuable addition to the treatment team for IGM patients.

Early Mortality in IgG4-Related Disease

Rachel Wallwork ,[1] Tyler Harkness,[1] Xiaoqing Fu,[1] Cory Perugino,[1] Hyon K. Choi,[2] John Stone,[3] and Zachary Wallace[1], [1]Massachusetts General Hospital, Boston, [2]Massachusetts General Hospital, Boston, MA, [3]Massachusetts General Hospital Rheumatology Unit, Harvard Medical School, Boston, MA

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Miscellaneous Rheumatic & Inflammatory Disease Poster I: Fibroinflammatory & Granulomatous Disorders & Therapies

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: IgG4-related disease (IgG4-RD) is a fibroinflammatory disorder characterized by tumefactive lesions that can occur in nearly any organ or anatomic site. Manifestations can include pancreatitis, sclerosing cholangitis, tubulointerstitial nephritis, retroperitoneal fibrosis, aortitis, and pulmonary disease. Prior to treatment and as a complication of treatment (e.g., Whipple procedure, glucocorticoids), IgG4-RD patients are at risk of organ dysfunction and failure which can lead to death. However, the risk of death in IgG4-RD is poorly understood, especially in reference to the general population. We evaluated all-cause mortality and investigated cause of death in a large cohort of IgG4-RD patients.

Methods: We identified patients seen in the Center for IgG4-RD at Massachusetts General Hospital who were diagnosed with IgG4-RD between 2010 and 2018 and had complete baseline records available for review. We determined patients' vital statuses through the electronic medical record (EMR) and by contacting patients or next of kin. Patients were followed from the date of their first visit until date of death, last visit, or December 31st, 2018, whichever came first. Person-years (PY) of follow-up were measured and the all-cause mortality rate was calculated. We used CDC WONDER to extract expected deaths for the US general population and calculated age- and sex-standardized mortality ratios (SMR). Cause of death was determined by review of the EMR.

	IgG4-RD Cases
N	205
Male	129 (63%)

Cause of Death in IgG4-Related Disease

Results: We included 205 IgG4-RD patients with a mean age of 57.8 (±13.1) years; 63% were male (**Table 1**). During 647.7 PY of follow-up, ten patients died, yielding an all-cause mortality rate of 15.4 (95% CI 7.8-27.5) /1,000 PY. Death was associated with IgG4-RD in four (40%) cases. The first patient had pancreatic involvement and died of hemorrhagic shock secondary to a GI bleed in the setting of treatment-refractory disease. The second patient had aortic involvement and died from a retroperitoneal bleed. The third patient died of hemorrhagic shock bacteremia with gram negative bacilli in the setting of progressive cholangitis. The fourth patient died from complications related to progressive cholangitis (**Table 2**). Compared to the general US population, the overall SMR was 1.30 (95% CI 0.70-2.41). During follow-up, all deaths occurred in male patients. Among male patients, the all-cause mortality rate was 26.6 (95% CI: 13.5-47.4) / 1,000 PY and the corresponding SMR was 1.75 (95% CI 0.94-3.26).

Conclusion: In the early period following diagnosis, IgG4-RD mortality appears similar to that of the general population. Of the deaths related to IgG4-RD, severe pancreato-hepatobiliary disease contributed in three cases. We observed few deaths and had a relatively short follow up which may limit our power to detect significant differences in mortality. However, we observed a trend suggesting that male IgG4-RD patients may have a higher rate of death compared to the general population. Future studies with larger cohorts are necessary to further evaluate the risk of death in IgG4-RD, especially differences in late mortality. Our findings may be useful for discussing overall prognosis with IgG4-RD patients.

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Muscle Biology, Myositis & Myopathies Poster I

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Anti-HMGCR myopathy has recently been defined as a subset of immune-mediated necrotizing myopathies characterized by proximal muscle weakness, elevated CK levels and the presence of anti-HMGCR autoantibodies (aAbs). Statin-induced anti-HMGCR myopathy with elevated serum CK but normal muscle strength has scarcely been reported. Our objective was to describe the natural history of this subset.

Methods: All our patients with elevated serum CK, anti-HMGCR aAbs and statin exposure were studied retrospectively for demographics, myologic features, chronology of events leading to induction as well as maintenance therapy. Early treatment was defined as treatment when muscle strength was still normal, whereas delayed treatment was defined as treatment when proximal weakness was apparent. Remission was defined by serum CK ≤ 500 UI/L, and successful steroid sparing immunosuppressant (SSI) maintenance as remission for 1 year with ≤ 5 mg/day of prednisone. Anti-HMGCR aAbs were detected by ALBIA or ELISA.

Results: Fifty-five patients with statin-induced anti-HMGCR myopathy were identified. Twenty-two patients (40%) presented with normal muscle strength, with median CK of 1501 IU/L (range 500-5613) and median age of 64.7 years. Of these 22 patients, 9 (41%) had early treatment and 13 (59%) had delayed treatment. All patients were treated with at least one SSI, with or without steroids and/or intravenous immunoglobulins (IVIg). All patients achieved remission.

- ***Early treatment group (n=9):*** median time from presentation (defined as first CK elevation) to treatment was 13.4 months (range 2.6-78.4). Median CK at presentation and at treatment initiation were 1501 IU/L (range 617-2132) and 2684 IU/L (554-13339), respectively. Successful steroid-free induction was used in 5 patients (56%), and IVIg induction in 2 patients (22%). Successful SSI monotherapy maintenance was possible in 5 patients (56%), with only one patient still on IVIg and steroids. At last follow-up, all patients had normal strength.
- *Delayed treatment group (n=13):* median time from presentation to treatment was 21.6 months (range 7-95). Median CK at presentation and at treatment initiation were 1700 IU/L (range 500-5613) and 6400 IU/L (1556-14098), respectively. Successful steroid-free induction was used in 1 patient (8%), and IVIg induction in 8 patients (62%). Successful SSI monotherapy maintenance was possible in 4 patients (31%) while 6 patients were on maintenance IVIg and 3 (23%) on steroids. At last follow-up, normal strength was present in 9 patients (69%).
- Thus, steroid-free induction was proposed by the treating physicians and used successfully in 56% of patients in the early treatment group versus only 8% of patients in the delayed treatment group (p=0.023).

Conclusion: In this cohort of statin-induced anti-HMGCR myopathy, 22 patients (40%) presented with normal strength. While successful in all patients, steroid-free induction was proposed in 5 patients (56%) with normal strength, but only once (8%) in patients in whom proximal weakness had ensued (p=0.023). Anti-HMGCR myopathy presenting with normal strength may be an ideal subset for initiating steroid-free induction.

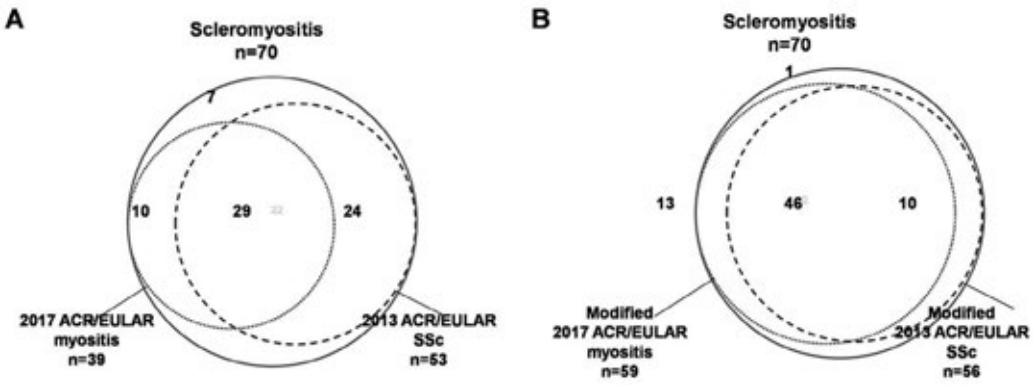
SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Muscle Biology, Myositis & Myopathies Poster I
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Autoimmune myositis consists of a group of diseases with heterogeneous muscular and systemic manifestations. Prognosis also varies widely across the spectrum. Thus, myositis subgroups are being identified to facilitate personalized care. Systemic sclerosis (SSc) is a disease characterized by vasculopathy, autoimmunity, inflammation and fibrosis affecting multiple organs including muscle. The association of myositis and SSc is referred to as "scleromyositis". Classification criteria for both myositis and SSc have been endorsed by ACR/EULAR but their performance for scleromyositis is unknown.

Methods: Patients with scleromyositis were identified in two centers. Diagnosis of scleromyositis was based on the co-existence of myositis and features of SSc according to expert opinion. Patients were systematically assessed for the presence or absence of items in the 2017 ACR/EULAR criteria for myositis and 2013 ACR/EULAR criteria for SSc at last follow-up. Additional organ involvement and auto-antibodies associated with myositis and SSc were also systematically recorded.

Results: Seventy (70) patients with scleromyositis (sex ratio F/M 3.7) were included. Age at myositis onset was 51.5 ± 15.8 years. Only 39 (56%) patients fulfilled the 2017 ACR/EULAR criteria for myositis (21 definite, 14 probable, 4 possible) and 53 patients (76%) fulfilled the 2013 ACR/EULAR criteria for SSc (Figure 1). Of these, only 29 (41%) fulfilled both sets of criteria. Seven (10%) patients fulfilled neither set of criteria (Figure 1a). The ACR/EULAR criteria that were most frequently lacking for myositis were anti-Jo1 antibodies (n=70, 100%) and dermatomyositis rash (Gottron sign, Gottron papule and/or heliotrope rash n=61, 87%). The criteria that were most frequently lacking for SSc were pulmonary arterial hypertension (n=68, 97%) and "classical" SSc auto-antibodies (anti-Scl70, -centromere, -RNA polymerase III, n= 63, 90%). The 7 patients fulfilling neither ACR/EULAR criteria for myositis nor SSc all had increased creatinine kinase and Raynaud's phenomenon, but the frequency of the other items in the criteria were all < 50%. Four of the 7 patients (56%) had well-known complications of SSc some of which are not included in the criteria: interstitial lung disease (n=3), calcinosis (n=1) and/or renal crisis (n=1). All 7 patients had auto-antibodies associated with scleromyositis that are also not included in ACR/EULAR criteria: anti-Ku (n=3), anti-SMN1 (n=2), anti-PM/Scl (n=1), anti-U1RNP (n=1) and/or anti-RuvBL1/2 (n=1), When ACR/EULAR criteria for myositis and SSc were modified to take into account these additional clinical features and auto-antibodies, the rate of patients who fulfilled myositis and SSc criteria increased from 41% to 66% (Figure 1b).

Conclusion: In our cohort, ACR/EULAR criteria for myositis and SSc alone and together had low sensitivity for scleromyositis. Additional clinical features and serologies could lead to improved sensitivity. Studies of scleromy-



ositis will require careful consideration of inclusion criteria to ensure that the full spectrum of this important subset is included.

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Muscle Biology, Myositis & Myopathies Poster I
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Juvenile dermatomyositis (JDM) is a systemic autoimmune disease with a prominent interferon (IFN) signature. Treatment often requires prolonged high-dose steroids and other immunosuppressive medications. In a compassionate use program, we assessed efficacy and safety of baricitinib (JAK 1/2 inhibitor) in active refractory JDM.

Methods: Active (based on ≥3 core set measures (CSM)) and refractory (use of high dose steroids and ≥2 other medications, including ≥1 biologic therapy) patients with JDM were enrolled after washing out biologic agents other than IVIG. Baricitinib was dosed based on weight and renal function. Primary outcome was reduction in symptom daily diary score (DDS) of weakness, fatigue, musculoskeletal pain, and rash. Other assessments included International Myositis Assesment and Clinical Studies (IMACS) disease activity CSMs and Cutaneous Dermatomyositis Disease Area and Severity Index (CDASI). Peripheral 28 gene inteferon-regulated gene (IRG) score and serum CXCL10 (IP-10) were assessed. Paired t-test was used to compare baseline to 24 weeks. Safety and tolerability were also assessed.

Results: Four JDM patients (5.8-20.7 years old) were enrolled (NCT01724580).Patients received baricitinib 4-8 mg/day PO divided BID. After 24 weeks, DDS reduced from a mean of 2.0 (range 1.1-2.3) to 1.0 (0.7-1.1; mean decrease 49%, p=0.02) (Figure or Fig 1A). Physician global activity visual analog scale (VAS) decreased from a mean of 5.1 (3.5-7.4) to 3.9 (3.0-6.1; 24% decrease, p=0.04) (Fig 1B). Extramuscular global activity VAS decreased from mean 5.1 (3.0-7.3) to 3.6 (1.0-5.0; mean 34% decrease, p=0.03). CDASI activity score reduced from mean 43 (27-53) to 26 (14-48; mean improvement 41%, p=0.04) (Fig 1C). In 2/4 with baseline weakness, manual muscle testing (MMT8) increased from 108 to 135 and 116 to 142 (mean improvement 24%) (Fig 1D). By the ACR-EULAR JDM response criteria, the Total Improvement Score (TIS) was mean 39, range 17.5-62.5. In 2 pts with baseline weakness, the TIS

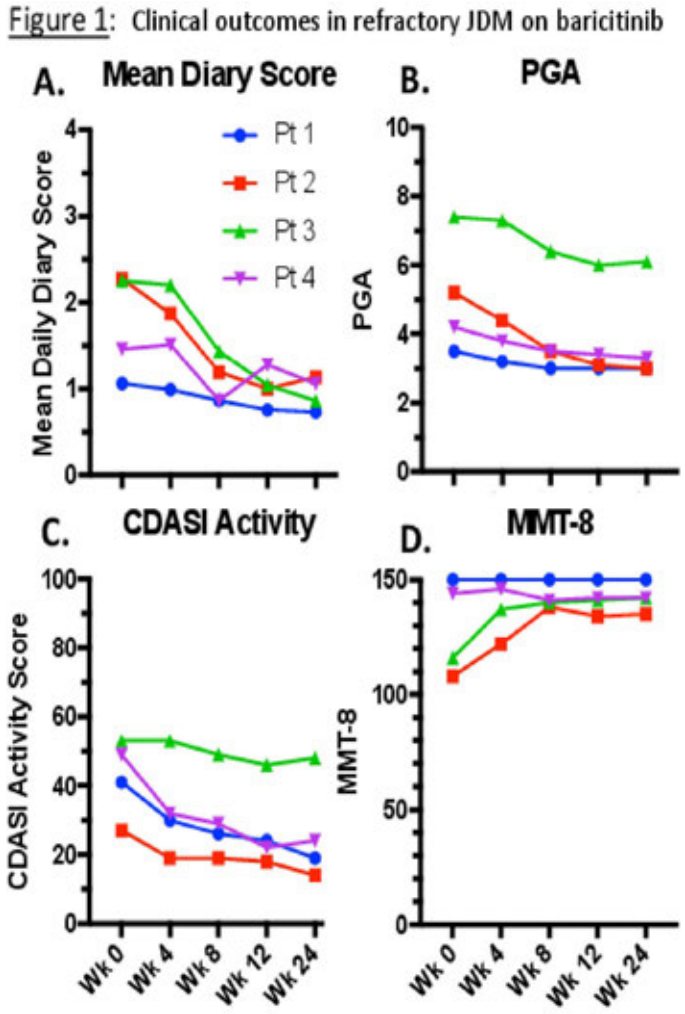

Figure 1. Clinical outcomes are shown at baseline (week or wk 0), and then at week 4, 8, 12, and 24 for (A) mean daily diary score (DDS) out of 4 (B) Physician Global Activity (PGA) out of 10, (C) Cutaneous Dermatomyositis Disease Area and Severity (CDASI) Activity Score out of 100, and (D) Manual Muscle Testing-8 out of 150

improved moderately, with a change of 55 and 62.5. Two patients reduced prednisone (21 to 15 and 10 to 7.5 mg/day); 2 patients' doses remained unchanged (5 and 10 mg/day). Baricitinib was generally well tolerated. One patient had an increase in plasma BK viral titer; the other 3 patients were negative for BK virus in blood and urine. No adverse events required holding/discontinuing baricitinib. IRG score was significantly lower at 24 weeks (p value < 0.01) and serum IP-10 at 12 weeks was trending lower ($p = 0.056$).

Conclusion: Preliminary data on the use of baricitinib (JAK 1/2 inhibitor) in 4 refractory JDM patients are encouraging, showing improvement in symptom DDS as well as in validated measures of rash (4/4) and strength (2/2 with baseline weakness), and other CSMs. Patients with baseline weakness met clinically significant moderate improvement by the ACR-EULAR response criteria. A corresponding decrease in IRG and trend down in IP-10 was observed. Baricitinib was generally well tolerated and further evaluation in JDM should be considered.

Disclosures: Baricitinib provided by Eli Lilly and Company, expanded access program sponsor. Other support: IRP of NIH, NIAMS, NIEHS, CC.Figure 1. Clinical outcomes are shown at baseline (week or wk 0), and then at week 4, 8, 12, and 24 for (A) mean daily diary score (DDS) out of 4 (B) Physician Global Activity (PGA) out of 10, (C) Cutaneous Dermatomyositis Disease Area and Severity (CDASI) Activity Score out of 100, and (D) Manual Muscle Testing-8 out of 150.>

The Beneficial Effects of Rituximab Treatment in Myositis May Be Due to the Binding of a Non B-Cell Protein, SMPDL3B, in Skeletal Muscle

Joanna Parkes ,[1] Jessica Boehler,[2] Ning Li,[1] and Kanneboyina Nagaraju[1], [1]Binghamton University, Johnson City, NY, [2]Solid Biosciences, Boston, MA

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Muscle Biology, Myositis & Myopathies Poster I
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Rituximab was developed to treat B cell lymphomas but has now been shown to have clinical efficacy in multiple disease conditions (endocrine, neurological, dermatological etc) where B cells are not the primary mediators of pathogenic processes. Likewise, beneficial effects of Rituximab appear to outweigh the relative contribution of B cells to disease pathogenesis in inflammatory myopathies. Therefore, we hypothesized that Rituximab is recognizing proteins other than CD20 that are expressed outside of the B cell lineage (e.g., skeletal muscle cells) in myositis. We have tested this hypothesis by evaluating effects of Rituximab in CD20+ B cells (Raji cells), macrophages (THP-1 cells) and human skeletal muscle cells.

Methods: CD20 expression was assessed in Raji B-cells (ATCC CCL-86), THP-1 macrophages (ATCC TIB-202) and immortalized human myoblasts by Fluorescent Activated Cell Scanning. These cells were treated with 5, 10, 20, or 40 μg/mL Rituximab to assess cell viability (CCK-8 reagent and Trypan Blue), cytokine production by ELISA and activation of down stream transcriptional targets by RTqPCR. Protein sequence homology search has identified previously known protein, Sphingomyelin Phosphodiesterase Acid Like 3B (SMPDL3B) as the alternate target for Rituximab.

Results: CD20 was only expressed in Raji cells but not human myoblasts or macrophages. As expected, Rituximab treatment at higher concentrations (>20ug/ml) induced cell death in Raji cells but not in macrophages and muscle cells. However, Rituximab treatment increased IL-13 production by Raji cells and decreased TNF-alpha production by macrophages suggesting that Rituximab recognized non-CD20 proteins expressed on macrophages. More interestingly, Rituximab showed an effect neither on cell survival nor on cytokine production in human muscle cells. However, analysis of transcripts from treated muscle cells showed dose dependent increase in Estrogen receptor 1 (ESR1), a protein known to be associated with reduction of pro-inflammatory NF-κB activation as well as increased mitochondrial function. These observations also demonstrated that Rituximab binds to non-CD20 protein target in proliferating muscle cells. We have identified SMPDL3B as the alternative target of Rituximab in skeletal muscle cells.

Conclusion: Our data suggests that binding of Rituximab to a non-CD20 target such as SMPDL3B in muscle cells activates ESR1 which is known to down regulate inflammation and enhance muscle mitochondrial function. Likewise, Rituximab by binding to macrophages also reduces TNF-alpha leading to overall reduction in pro-inflammatory signaling in muscle microenvironment of myositis patients. Our results explain reasons for the clinical efficacy of Rituximab in a variety of non-B lymphocyte mediated disease conditions.

Management of Idiopathic Inflammatory Myopathies Using Intravenous Immunoglobulin Therapy: A Retrospective Cohort Study

Raymond Chu,[1] Susan Nahirniak,[1] Jan Willem Cohen Tervaert,[1] and Elaine Yacyshyn[1], [1]University of Alberta, Edmonton, Canada

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Muscle Biology, Myositis & Myopathies Poster I
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose:: Dermatomyositis (DM) and polymyositis (PM) are idiopathic inflammatory myopathies characterized by weakness and inflammation of the muscles. First line therapy typically involves high dose systemic steroids to establish disease control along with steroid sparing agents to minimize steroid induced morbidities. Other immunosuppressive agents are typically initiated as an adjunct to systemic steroids, with scarce evidence supporting use of various agents in the clinical context. Intravenous immunoglobulin therapy (IVIG) in particular has demonstrated evidence in severe refractory disease. Our study aims to investigate the efficacy of IVIG in the treatment of various clinical manifestations of inflammatory myopathies.

Methods: A retrospective chart review was performed on patients identified through the Sunquest Laboratory Information System who had received IVIG for the treatment of DM or PM between January 1st, 2012 to January 1st, 2018 at the University of Alberta Hospital. Data extracted included patient's age at initiation of treatment, sex, duration of treatment, presenting symptoms (weakness, myalgias, skin rashes, calcinosis, dysphagia and interstitial lung disease [ILD]) and outcome of treatment.

Results: A total of 46 DM and 19 PM patients were identified. Median age of treatment onset was 54 (interquartile range [QR], 40 – 64) years, with 49 (75%) female patients. The median duration of treatment was 13 (QR, 3 – 37) months. Fifty-six of sixty-five (86%) patients had weakness, 7/65 (11%) patients had myalgias, 40/65 (62%) patients had rashes, 5/65 (8%) had calcinosis, 16/65 (25%) had dysphagia and 6/65 (9%) had ILD. Initiation of IVIG improved symptoms of weakness for 41/56 (73%) patients, myalgias for 6/7 (86%) patients, rashes for 33/40 (83%) patients, calcinosis for 0/5 (0%) patients and dysphagia for 12/16 (75%) patients. IVIG improved the ILD for 1/6 (17%) patients and the remaining 5/6 (83%) patients did not demonstrate progression of their ILD.

Conclusion: This large retrospective cohort study indicates the utility of IVIG in the management of idiopathic inflammatory myopathies. The results of our study suggest that a course of IVIG at 2 g/kg per month administered over 2-5 days is effective in treating refractory inflammatory myopathies and particularly effective in treating symptoms of weakness, myalgias, rashes and dysphagia. IVIG however appears generally ineffective in treating calcinosis as well as ILD.

Session Title: Muscle Biology, Myositis & Myopathies Poster I

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Surfactant protein D (SP-D) is considered a serum biomarker of various forms of interstitial lung disease (ILD). However, the usefulness of SP-D for prediction of mortality remained unknown in detail in patients with ILD associated with polymyositis/dermatomyositis (myositis-associated ILD). Thus, we aimed to examine the utility of SP-D as a predictive biomarker for mortality in patients with myositis-associated ILD using our large-scale multicentre cohort data.

Methods: We recently established a multicentre retrospective cohort of Japanese patients with myositis-associated ILD (JAMI), which involved 44 institutions across Japan. We enrolled 381 patients with incident myositis-associated ILD in the JAMI cohort based on the availability of serum SP-D at the baseline. Demographic and clinical characteristics as well as the presence of autoantibodies to melanoma differentiation-associated gene 5 (MDA5) and aminoacyl tRNA synthetase were measured at the time of diagnosis, and follow-up survival data were collected prospectively.

Results: Seventy-eight patients died during the median observation period of 18 months, and the majority of patients died of ILD. The mortality rate was significantly higher (P = 0.0057) in a subset of patients with SP-D < 95.4 ng/mL, the cut-off value estimated by the receiver operating characteristic curve (ROC), than a subset with SP-D ≥95.4 ng/mL. (P = 0.0065; Figure 1A). However, interestingly, the survival curves intersected at 78 months, suggesting a dimorphic role of the SP-D level in the survival of patients with PM/DM-associated ILD:, i.e., short-term mortality was associated with a lower SP-D level, while long-term mortality was associated with a higher SP-D level. Therefore, we divided the enrolled patients into two subsets, anti-MDA5-antibody-positive group and negative group. In anti-MDA5 antibody-positive patients, survival rates were similar between those with SP-D levels at diagnosis < 95.4 ng/mL and ≥95.4 ng/mg (P = 0.90; Figure 1B). In contrast, in anti-MDA5 antibody-negative patients, survival rates were significantly worse in patients with SP-D levels ≥95.4 ng/mL than in those with SP-D levels < 95.4 ng/mL (P = 0.02; Figure 1C). Surprisingly, in anti-MDA5 antibody-negative patients, none of the patients with SP-D levels < 95.4 ng/mL died . In other words, all deceased patients with SP-D level < 95.4 ng/mL were positive for the anti-MDA5 antibody. We re-estimated the optimal cut-off value of SP-D for mortality in anti-MDA5 antibody-positive and anti-MDA5 antibody-negative patients individually with ROC curve analyses, resulting in optimal cut-off levels of 59.8 ng/mL in

Figure 1.

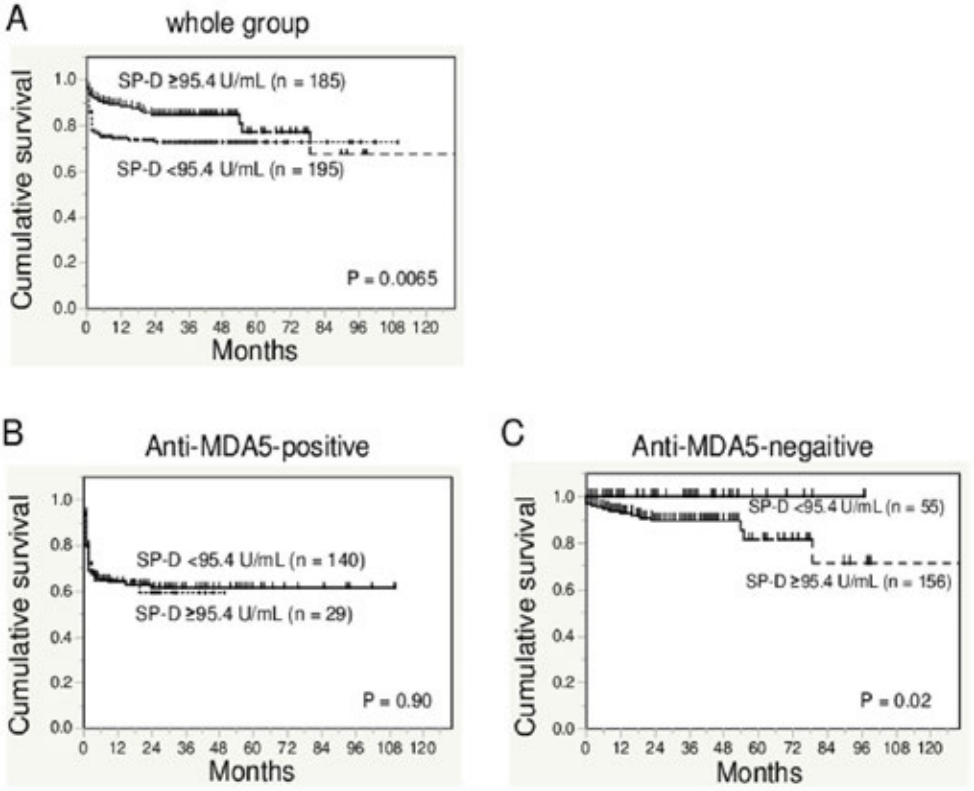

Figure 2

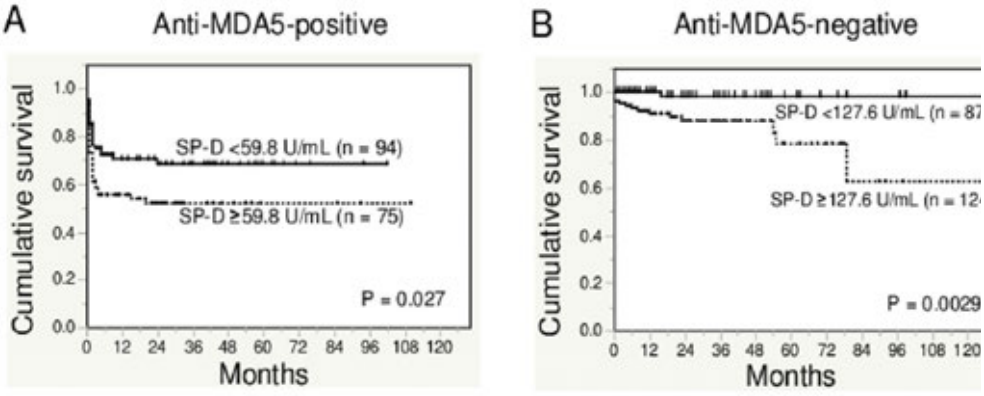

anti-MDA5 antibody-positive patients (P = 0.027;Figure2A) and 127.6 ng/mL in anti-MDA5 antibody-negative patients (P = 0.0029;Figure2B).

Conclusion: Serum SP-D is a useful predictor for the prognosis of patients with myositis-associated ILD. We successfully demonstrated the dimorphic role of the SP-D level in the prediction of outcomes on the basis of the presence or absence of anti-MDA5 antibody.

Sexual Health in 39 Female Patients with Idiopathic Inflammatory Myopathies

Barbora Hermankova,[1] Maja Spiritovic,[2] Sabina Oreska,[3] Hana Storkanova,[4] Petr Cesak,[1] Katerina Kubinova,[5] Martin Klein,[4] Karel Pavelka,[3] Ladislav Senolt,[3] Herman Mann,[3] Jiří Vencovský,[3] and **Michal Tomcik** [3], [1]Faculty of Physical Education and Sport, Department of Physiotherapy, Charles University, Prague, Czech Republic, Prague, Czech Republic, [2]Faculty of Physical Education and Sport, Department of Physiotherapy, Charles University, Prague, Czech Republic, Prague 2, Hlavni mesto Praha, Czech Republic, [3]Institute of Rheumatology, Department of Rheumatology, 1st Faculty of Medicine, Prague, Czech Republic, Prague 2, Czech Republic, [4]Institute of Rheumatology, Department of Rheumatology, 1st Faculty of Medicine, Prague, Czech Republic, Prague, Czech Republic, [5]Institute of Rheumatology, Department of Rheumatology, 1st Faculty of Medicine, Prague, Czech Republic, Prague 2

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Muscle Biology, Myositis & Myopathies Poster I
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Idiopathic inflammatory myopathies (IIM) are characterized by inflammation and weakness of skeletal muscles, pulmonary and articular involvement, which can have a negative impact on all aspects of quality of life including sexual life. The aim of this study was to assess sexual functioning in female IIM patients compared to age-/sex-matched healthy controls (HC) and to determine the association between sexual health impairment and disease activity, treatment, physical and psychological aspects of the disease.

Methods: In total, 39 women (29 currently have a partner) with IIM [mean age: 54.7, disease duration: 11.8 years, dermatomyositis (DM, 19)/ polymyositis (PM, 16)/ necrotizing myopathy (IMNM, 3)/ inclusion body myositis (IBM, 1)], who fulfilled the Bohan/Peter 1975 criteria for DM/PM, and 39 healthy controls (30 currently have a partner, mean age: 54.7 years) without rheumatic diseases filled in 11 well-established and validated questionnaires assessing sexual function (FSFI, SFQ28, BISFW, PISQ-12), quality of sexual life (SQoL-F), pelvic floor function (PFIQ-7), fatigue (FIS, MAF), physical activity (HAP), and depression (BDI-II). A standard laboratory testing was performed. Data are presented as mean ± SEM.

Results: Patients with IIM had significantly higher prevalence and greater severity of sexual dysfunction (FSFI, BISF-W, SFQ28, PISQ-12) and worse sexual quality of life (SQoL-F) compared to HC (table). Worse scores in IIM patients were associated with increased inflammation [CRP: FSFI (r=-0.378, p=0.0190), SFQ-28 Satisfaction domain (r=-0.346, p=0.0356), SQoL-F (r=-0.331, p=0,0479], greater muscle weakness of m. gluteus maximus/ m. gluteus medius/ m. iliopsoas [FSFI: (r=0.426, p=0.0368), (r=0.370, p=0.0368), (r=0.394, p=0.0252), SQoL-F (r=0.504, p=0.0044), (r=0.421, p=0.0204), (r=0.462, p=0.0100)], greater fatigue [FIS: FSFI (r=-0.358 , p=0.0154), BISF-W (r=-0.415, p=0.0084), SQoL-F (r=-0.327, p=0.0481)], more severe depression [BDI-II: FSFI Arousal domain (r=-0.357, p=0.0299)], deteriorated quality of life [HAQ: BISF-W (r=-0.464, p=0.0033)], and worse ability to perform physical activities [HAP: FSFI (r=0.405, p=0.0105), BISF-W (r=0.480, p=0.0019)]. No associations were found with disease duration, prednisone dose or serum levels of muscle enzymes.

Questionnaire: score range (meaning)	Idiopathic inflammatory myopathies (n=39)	Healthy controls (n=39)	p-value
FSFI: Female Sexual Function Index: 2(worst)-36(best)	15.7±2.1	20.7±2.0	p=0.0421
BISF-W: Brief Index of Sexual Function for Women: -16(worst)-75(best)	14.6±2.8	24.5±3.0	p=0.0134
SFQ28 Desire domain: Sexual Function Questionnaire: 5(worst)-31(best)	11.7±1.0	14.7±1.0	p=0.0457
PISQ-12: Pelvic Organ Prolapse/Urinary Incontinence Sexual Questionnaire short form: 0(best)-48(worst)	14.9±0.8	10.1±1.0	p=0.0005
SQoL-F: Sexual Quality of Life Questionnaire – Female: 0(worst)-100(best)	31.8±5.1	80.7±2.5	p<0.0001
PFIQ7: Pelvic Floor Distress Inventory Questionnaire – short form 7: 0(best)-300(worst)	24.7±6.3	10.1±2.7	*p=0.0820*
FIS: Fatigue Impact Scale: 0(best)-160(worst)	55.3±5.5	33.2±4.3	p=0.0025
MAF: Multidimensional Assessment of Fatigue Scale: 1(best)-50(worst)	22.0±2.0	15.7±1.4	p=0.0021
BDI-II: Beck's Depression Inventory II: 0(best)-63(worst)	12.8±1.5	6.6±0.9	p=0.0013
HAP: Human Activity Profile – adjusted activity score: 0(worst)-94(best)	51.0±3.5	80.2±1.6	p<0.0001
HAQ: Health Assessment Questionnaire: 0(best)-3(worst)	1.1±0.1	0.1±0.1	p<0.0001

Conclusion: Women with IIM reported significantly impaired sexual function and sexual quality of life compared to age-matched healthy controls. Worse scores in IIM were associated with disease activity, physical activity, fatigue, depression and quality of life.

Younger Age at Presentation Is a Risk Factor for Failure to Achieve Remission in Adult Dermatomyositis

Soumyasri Kambhatla ,[1] Carrie Richardson,[2] Prasanth Lingamaneni,[3] and Augustine Manadan[2], [1]John H. Stroger Hospital of Cook County, Chicago, [2]Rush University Medical Center, Chicago, IL, [3]John H. Stroger Hospital of Cook County, Chicago, IL

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Muscle Biology, Myositis & Myopathies Poster I
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: A subset of patients with dermatomyositis may fail to achieve remission despite treatment. Nevertheless, the risk factors for failure to achieve remission in dermatomyositis are largely unknown.

Methods: We conducted a retrospective chart review of patients seen between 2006 and 2011 at John H. Stroger Medical Center of Cook County (Illinois, USA) with a diagnosis of dermatomyositis. All patients met 1975 Bohan and Peter criteria for "probable" or "definite" dermatomyositis. Remission could occur at any time point during follow-up and was defined as normal strength, creatine kinase < 200 mg/dL, and the absence of active dermatomyositis rash. Clinical features were defined at baseline within 1 month of presentation. We compared demographics, dermatomyositis-related clinical and serologic parameters, and treatments between those who achieved remission

Table 1. Characteristics of patients with dermatomyositis who failed to achieve remission versus those who achieved remission			
Values listed as mean (95% CI) or % (N/Total)	No remission (N=22)	Remission (N=43)	P value
Age at first visit in years	40.6 (35.1-46.2)	49.1 (44.6-53.6)	0.025
Female sex	81.8 (18/22)	79.1 (9/43)	0.793
Race			0.810
African-American	54.6 (12/22)	53.5 (23/43)	
Hispanic	36.4 (8/22)	39.5 (17/43)	
Other	9.2 (2/22)	7.0 (3/43)	
Myositis features			
Follow-up time, months	45.9 (20.6-71.3)	60.7 (47.1-74.3)	0.253
Biopsy-proven myositis	50.0 (11/22)	48.8 (21/43)	0.929
Full strength at first visit	38.9 (7/18)	18.0 (7/39)	0.314
Initial creatine kinase, mg/dL	3955.4 (793.2-7117.7)	4031.5 (1920.7-6142.2)	0.967
Neck weakness	50.0 (4/8)	33.3 (6/18)	0.664
Dysphagia	42.9 (6/14)	46.2 (12/26)	0.842
Fever	9.5 (2/21)	2.4 (1/42)	0.256
Raynaud's	27.3 (6/22)	20.9 (9/43)	0.566
Myalgias	52.9 (9/17)	44.1 (15/34)	0.552
Arthritis	44.4 (8/18)	57.1 (20/35)	0.380
ILD	27.3 (6/22)	32.6 (14/43)	0.662
Anti-Jo1 antibodies	25.0 (3/12)	36.0 (9/25)	0.711
ANA	66.7 (14/21)	55.0 (22/40)	0.379

and those who did not. We used Chi square tests to compare categorical variables and Student's t-tests to compare continuous variables. We then conducted a multivariable logistic regression to examine the outcome of failure to achieve remission. We forced age, sex, race, and follow-up time into the model and included clinical variables based on a p-value of < 0.2 in univariate screen. Treatments were not included in the multivariable model due to inability to adjust for confounding by treatment severity in this small sample.

Results: 65 patients, of whom 92.3 % (60/65) were African-American or Hispanic, were included in this study. Mean follow-up time for patients who did not achieve remission was 45.9 months vs. 60.7 months for those who did

Table 2. Multivariable logistic regression model of factors associated with failure to achieve remission in dermatomyositis				
	Unadjusted OR (95% CI)	P-value	Adjusted OR (95% CI)	P-value
Age, per year increase	0.96 (0.92-1.00)	0.030	0.95 (0.90-0.99)	0.030
Female sex	1.19 (0.32-4.41)	0.793	1.61 (0.26-9.91)	0.610
African-American race	1.04 (0.37-2.93)	0.936	1.66 (0.43-6.44)	0.463
Months of follow-up	0.99 (0.98-1.01)	0.256	0.98 (0.97-1.00)	0.077
Full muscle strength at baseline	2.91 (0.83-10.17)	0.095	3.17 (0.73-13.8)	0.125
OR=odds ratio				

achieve remission (p-=0.253). 33.8% (22/65) of patients failed to achieve remission at any point during follow-up. Patients who failed to achieve remission were younger (mean age 40.6 years vs. 49.1 years; p=0.025) at first visit than patients who achieved remission. Patients who failed to achieve remission were more likely to have been treated with intravenous immunoglobulin (27.3% vs. 4.7%; p=0.009) at any point during follow-up. A multivariable logistic regression with age at presentation, female sex, African-American race, follow-up time, and full strength on presentation as predictors demonstrated that younger age at presentation was an independent risk factor for failure to achieve remission (OR 0.95 [95% CI 0.91-0.99] per 1-year increase in age; p=0.030).

Conclusion: In this small cohort of largely African-American and Hispanic patients with dermatomyositis seen at a US medical facility largely serving poor and uninsured patients, younger age at presentation was an independent risk factor for failure to achieve remission. Patients who failed to achieve remission were more likely to have been treated with second-line agents than those who achieved remission. Given that patients who failed to achieve remission were more likely to have normal baseline muscle strength than those who achieved remission, we hypothesize that younger age at presentation may be associated with more treatment-refractory cutaneous disease.

SESSION INFORMATION

Session Date: Sunday, November 10, 2019
Session Title: Muscle Biology, Myositis & Myopathies Poster I
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Juvenile idiopathic inflammatory myopathies (JIIM) are a heterogeneous group of autoimmune diseases affecting children, characterized by symmetric muscular weakness, cutaneous rash and systemic organ involvement. The clinical manifestations of the IIMs differ between children and adults, for example, JIIM have a higher prevalence of calcinosis, lipodystrophy and vasculopathy, as well as a minor incidence of neoplastic disease or interstitial pneumonia. Given the low incidence of the JIIM, there are few studies describing the characteristics of this disease and its different subtypes.

The objective of this study is to describe the demographic, clinical and analytical characteristics of patients with JIIM from the multicentric REMICAM registry, and to compare those measures between polymyositis (PM) and juvenile dermatomyositis (JDM) subgroups.

Methods: A multicenter retrospective study from the REMICAM registry was performed. Patients were selected if they were 18 years or younger at onset of JIIM and met definite or probable criteria for IIM as defined by the modified Bohan and Peter criteria. We included patients with JDM or PM subgroups, overlap myositis patients were excluded.

Results: A total of 86 patients were included, 12 (14%) classified as PM and 74 (86%) as JDM. 70% were women, most of the subjects were Caucasian (96%). Disease characteristics are shown in Table 1. 13% of the patients had fever and 15% weight loss. Regarding musculoskeletal manifestations, 44% and 28% had arthralgias and arthritis, respectively, and 93% presented muscular weakness. Gottron sign was present in 76% of the patients, and calcinosis was present in 31.4%. CPK and aldolase levels at diagnosis are 431 U/L and 8 U/L respectively. Antinuclear antibody (ANA) was positive in 40% of the sample, but only 2 cases were anti-Jo1 positive. The rest of the complementary analysis are shown in table 2.

Clinical features	Total (n=86)	PM (n=12)	JDM (n=74)	p-value
Fever	23 (29,1%)	6 (50,0%)	17 (25,4%)	0,084
Weight loss	12 (15,2%)	1 (8,3%)	11 (16,4%)	0,680
Arthralgia	38 (44,2%)	7 (58,3%)	31 (41,9%)	0,287
Arthritis	24 (28,4%)	6 (50%)	18 (24,7%)	0,071
Gottron'sign	66 (76,7%)	-	65 (87,8%)	
Heliotrope erythema	46 (53,5%)	-	46 (62,2%)	
Mechanic hands	10 (12,3%)	-	10 (14,5%)	
Skin ulcers	3 (3,7%)	-	3 (4,3%)	
Raynaud	12 (13,9%)	3 (25,0%)	9 (12,2%)	0,362
Calcinosis	27 (31,4%)	2 (16,7%	25 (33,8%)	0,325
Muscular weakness	80 (93,0%)	11 (91,7%)	69 (93,2%)	1,000
Myalgias	68 (83,9%)	8 (66,7%)	60 (87,0%)	0,095
Miocarditis	2 (2,3%)	-	2 (2,7%)	
Arrhytmia	3 (3,5%)	1 (8,3%)	2 (2,7%)	0,370
Heart failure	1 (1,2%)	-	1 (1,4%)	1,000
Interstitial lung disease	1 (1,2%)	1 (8,3%)	-	0,140
Dysphagia	19 (22,1%)	2 (16,7%)	17 (23,0%)	1,000
GE reflux	7 (8,1%)	1 (8,3%)	6 (8,1%)	1,000
GI hemorrhage	1 (1,2%)	-	1 (1,3%)	1,000

Table 1. Clinical features.

Laboratory features	Total (n=86)	PM (n=12)	JDM (n=74)	p-value
Anemia	13 (15,1%)	4 (33,3%)	9 (12,2%)	0,079
Leucopenia	4 (4,6%)	1 (8,3%)	3 (4,0%)	0,458
Trombopenia	3 (3,5%)	2 (16,7%)	1 (1,3%)	0,050
ANA+	34 (40,5%)	7 (58,3%)	27 (37,5%)	0,173
CPK at diagnosis	431 (97-3131)	206 (36-7428)	659 (104-3110)	0,730
Aldolasa at diagnosis	12 (9-18)	9 (5-12)	12 (9-19)	0,230
CRP	0,35 (0-1,3)	0,12 (0-2,8)	0,42 (0-1,3)	0,817
ERS	19 (11-29)	25 (13-42)	19 (11-29)	0,450
Anti-Jo1	2 (2,6%)	-	2 (3,0%)	1,000
Myopathic pattern (EMG)	72 (92,3%)	12 (100%)	60 (90,1%)	0,508

Table 2. Laboratory features and complementary diagnosis

Conclusion: JDM was the most frequent clinical form of JIIM in our study, which corresponded to more than 80% of the cases, like other cohorts. The most frequent manifestations in patients with JIIM of our registry were the muscular and dermatological ones, but an important group also presented arthralgia/arthritis and fever. There was no statistical difference between both groups, regardless, cutaneous manifestations, myalgias and dysphagia were more common in JDM group, as well as higher CPK values and aldolase. PM group patients were older at diagnosis, had more fever and arthritis, also, cytopenia and ANA positivity were more frequent in this subtype.

Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Polymyositis (PM) and dermatomyositis (DM) are autoimmune inflammatory diseases characterized by proximal myositis. Dysphagia has been reported to develop in 35 to 62% of PM/DM patients and known as poor prognosis factor. This study aimed to determine the clinical feature of PM/DM patients presenting severe deglutition disorder.

Methods: Consecutive patients with PM/DM who visited National Hospital Organization Tokyo Medical Center between April 2010 and March 2019 are included in this study. We compared the following clinical features between the patients with and without severe dysphagia: age of onset, maximum levels of serum creatine kinase (CK), sense

of dysphagia, manual muscle test (MMT) score, and complication of malignancy. Severe dysphagia was defined as having difficulty swallowing which needed gastrostomy.

Results: A total of 73 patients with PM/DM were identified. Among them, 5 patients developed severe dysphagia. Patients with severe dysphagia presented older age of onset (mean age 69.4 ± 12.0 vs 51.8 ± 15.7, p = 0.016), more frequent muscle weakness (MMT grade ≦ 4)(100% vs 56.6%, p = 0.048), more frequent complication of malignancy (80.0% vs 11.8%, p= 0.0005) and sense of dysphagia (100% vs 10.7%, p< 0.0001). On the other hand, there were no significant differences in maximum serum CK levels between the patients with and without severe dysphagia (21884.0 ± 10275 U/L vs 5544.5 ± 3043 U/L, p = 0.1788).

Conclusion: These results indicate that severe dysphagia develops frequently in PM/DM patients with older onset, muscle weakness, complication of malignancy and sense of dysphagia. When any of these clinical features are noticed, it is necessary to consider the risk of severe dysphagia.

Seasonal Variation in Idiopathic Inflammatory Myopathies Incidence and Presentation: A Retrospective Study in Beijing and Hong Kong

Ho SO,[1] **Yawen SHEN** ,[2] Victor Tak Lung WONG,[1] Roy HO,[1] and Xin LU[2], [1]Kwong Wah Hospital, Kowloon, Hong Kong, [2]China Japan Friendship Hospital, BeiJing, China (People's Republic)

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Muscle Biology, Myositis & Myopathies Poster I
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Seasonal patterns of disease onset and severity in idiopathic inflammatory myopathies (IIMs) as a whole are conflicting. In recent years, over 10 myositis-specific antibodies (MSAs) have been identified. They are able to divide patients into homogenous subgroups and inform on prognosis. We conducted a large multicentred study of a homogeneous disease group, based on serology and ethnicity, aiming to investigate the seasonal variation of IIMs.

Methods: This was a retrospective observational study. Consecutive Chinese patients with IIMs admitted to the rheumatology wards of the participating major regional hospitals in Beijing and Hong Kong from July 2013 to June 2018 were recruited. The diagnosis of IIMs was based on the Bohan and Peter's criteria with definite or probable cases being included. Patients with clinically amyopathic disease must have the typical Gottron's papules or heliotrope rash as determined by rheumatologists or dermatologists, and with no symptoms or signs of muscle involvement according to Sontheimer. Patients with juvenile myositis, inclusion body myositis, cancer-associated myositis and myositis associated with a previously diagnosed connective tissue disease were excluded. A commercial line blot immunoassay kit (EUROIMMUN) was used to detect the MSAs. The primary objective of the study was to investigate the seasonal variation of onset of IIMs characterised serologically. The secondary objective was to examine the seasonal patterns of the various clinical manifestations.

Results: All together 416 patients were studied. The mean age of the patients at disease onset was 48.1 years (S.D. 13.3). There was a female predominance (68.5%). The subgroups of IIMs were: dermatomyositis (63.9%), polymyositis (22.4%), clinically amyopathic dermatomyositis (10.1%), immune mediated necrotising myopathy (3.1%) and nonspecific myositis (0.5%). No particular seasonal pattern in disease onset was observed in IIM patients as a whole or in any classical subgroups. However, significantly more patients with any one MSA had their disease started in the first half of the year (p=0.013). The same pattern was also seen in the hospitalisation rate in patients with either anti-synthetase or anti-MDA5 antibodies (p=0.029). It was also found that rapidly progressive interstitial lung disease (RPILD) which was a well known severe complication associated with the anti-MDA5 antibody occurred more in the first half of the year (p=0.044). At the same time, most of the mortalities in our patients happened in the first quarter of the year (January to March) (p=0.013). Further analyses showed that infection was significantly associated with anti-MDA5 antibody, RPILD and mortality (p< 0.001).

Conclusion: Apparent seasonal patterns were noticed in our ethno-serologically defined IIM patients. Certain environmental factors, particularly infection, could be potential triggers. Our findings could shed light on the identification of etiologic factors and enhance our understanding of disease pathogenesis. They could also increase our awareness of the disease and its complications during the peak seasons.

Seasonal and Temporal Analyses of Disease Onset and Diagnosis in Myositis Autoantibody Phenotypes in Juvenile Dermatomyositis (JDM)

Gulnara Mamyrova ,[1] Min Shi,[2] Ira N. Targoff,[3] Rodolfo V. Curiel,[1] Frederick W. Miller,[4] and Lisa G. Rider[5], [1]George Washington University, School of Medicine and Health Sciences, Washington, DC, [2]Biostatistics&Computational Biology Branch, NIEHS, NIH, Research Triangle Park, NC, [3]Arthritis Immunology Section, Oklahoma Medical Research Foundation, Oklahoma City, OK, [4]NIEHS, NIH, Bethesda, MD, [5]Environmental Autoimmunity Group, Clinical Research Branch, NIEHS, NIH, Bethesda, MD

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Muscle Biology, Myositis & Myopathies Poster I
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Published studies suggest seasonal occurrence of disease onset and disease activity in patients with adult idiopathic inflammatory myopathies (IIM).Our objective was to evaluate seasonal variation of disease onset and diagnosis and the distribution over time of myositis autoantibodies in JDM.

Methods: This study includes disease onset and diagnosis data of 383 myositis patients enrolled in NIH studies from 1994 to 2015. We tested myositis-specific autoantibodies (MSA) by standard immunoprecipitation (IP) and IP-immunoblotting methods and identified five autoantibody subtypes: 35 patients with JDM diagnosed before age 18 years with anti-melanoma-differentiation gene 5 (MDA5) autoantibodies, 157 with anti- transcriptional intermediary factor 1 (TIF1), 116 with anti-nuclear matrix protein 2 (NXP2), 15 with anti-synthetase (ARS) autoantibodies and 60 MSA-negative JDM patients, all meeting probable or definite Bohan and Peter criteria. We studied overall seasonable patterns of disease onset and diagnosis dates (by month) and performed comparisons between autoantibody subtypes. Circular statistics were used with seasonality and differences between the groups assessed by the Rayleigh

test and Watson two sample test for homogeneity, respectively. Proportion trend test was used to assess the trend of anti-MDA5 Ab over time compared to anti-TIF1 and anti-NXP2 autoantibodies.

Results: There was no seasonal clustering of the month of disease onset in JDM patients as a whole nor in the anti-ARS, anti-MDA5, anti-TIF1, anti-NXP2 autoantibody-positive and MSA-negative JDM subgroups. Anti-ARS autoantibody positive JDM patients had a seasonal pattern of disease diagnosis, with a peak time of diagnosis from May to July, and no patients with anti-ARS autoantibodies were diagnosed from January to April (p=0.03, Figure 1a). There were no differences in the seasonal patterns of disease onset and disease diagnosis of anti-MDA5 autoantibody-positive JDM patients compared to anti-TIF1 and anti-NXP2 autoantibody-positive, and MSA-negative patients (p >0.1, Figure 1b). In examining temporal trend of anti-MDA5 autoantibodies compared to anti-TIF1 and anti-NXP2 autoantibodies over time, from 1988 to 2015, we found no significant differences in the trend of occurrence of these subgroups based on year of symptom onset or of diagnosis (p >0.2).

Conclusion: Similar to adult IIM patients, JDM patients with anti-ARS autoantibodies demonstrate a spring to early summer seasonal peak in diagnosis, suggestive of certain environmental factors contributing to illness onset in these patients. In contrast, other MSA groups, including anti-MDA5, anti-TIF1, anti-NXP2 autoantibodies and MSA-negative JDM groups, did not exhibit seasonality in onset or diagnosis. In contrast to non-US cohorts, the frequency of anti-MDA5 autoantibodies has not increased over the past three decades and did not differ compared to anti-TIF1 and anti-NXP2 autoantibody-positive groups.

Figure 1a. Seasonal distribution was significantly skewed (p=0.03) based on month of diagnosis for anti-ARS autoantibody-positive JDM.

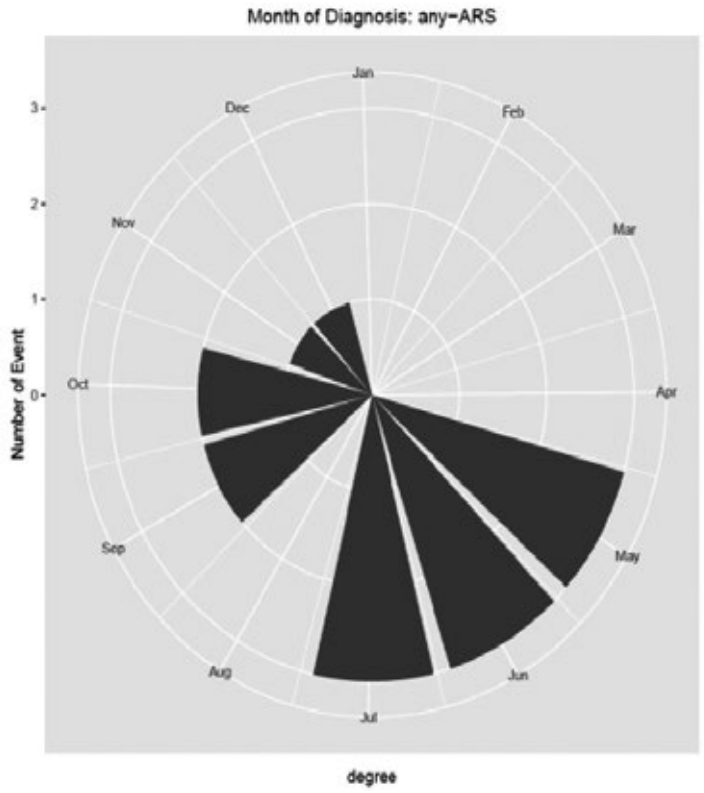

Figure 1b. Seasonal distribution was not significantly skewed based on month of diagnosis for anti-MDA5 autoantibody-positive JDM.

Session Title: Muscle Biology, Myositis & Myopathies Poster I

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Table 1. Performance of all criteria in our cohort. EULAR-ACR criteria were considered positive if patient fulfilled probable or definitive criteria

	EULAR/ACR Criteria with muscle biopsy		EULAR /ACR criteria without muscle biopsy		Boham and Peter Criteria	
	Positive	Negative	Positive	Negative	Positive	Negative
Patients with biopsy N=37	29 (78%)	8 (21%)	29 (78%)	8 (22%)	37 (100%)	0
Patients without biopsy N= 95			76 (80%)	19 (20%)	72 (76%)	23 (24%)
All patients N= 132			105 (79%)	27 (20%)	109 (83%)	23 (17%)

Table 2. Sensitivity of EULAR/ACR criteria according to the physician diagnosis as gold standard

EULAR/ACR criteria	True positive	False negative	Sensitivity % (95% CI)
Probable IIM	39	24	61.9 (4-84.6)
Definitive IIM	66	24	73 (56.7-93.3)

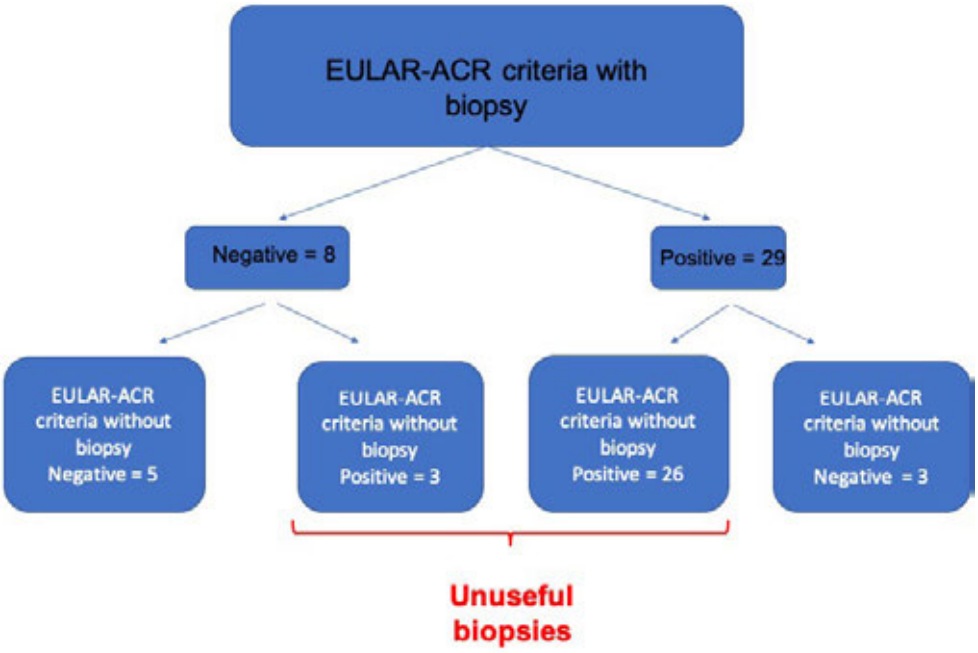

Figure 1. Performance of EULAR/ACR criteria in patients who underwent muscle biopsy

Background/Purpose: Patients with Idiopathic Inflammatory Myopathies (IIM) have been classified mainly according to Bohan and Peter (B&P) criteria, proposed in 1975. In 2017 the new EULAR/ACR criteria were proposed. They are able to classify patients with IIM and they are applicable even without results of a muscle biopsy.

The objective of this study was to evaluate the performance of the new EULAR-ACR myositis classification criteria in a large retrospective cohort of IIM patients from Argentina.

We applied the EULAR-ACR criteria in an external real-world cohort of consecutive IM cases from the Argentinean Rheumatology Society Myositis study group. Consecutive patients with IM based on physician diagnosis were included in the database. Data were collected form a preexisting database.

Methods: B&P criteria and EULAR-ACR were applied to each patient. For the purpose of this study we applied the non-biopsy EULAR/ACR criteria to non-dermatomyositis (DM) patients without biopsy (in the original paper those criteria only applied to DM patients). And we also applied the non-biopsy criteria to patients with a biopsy to be able to evaluate whether IM diagnosis might have been done without a biopsy.

We compared the performance of EULAR-ACR criteria with physician diagnosis and with B&P criteria.

Results: A cohort of 132 patients with physician diagnosis of IM were included in the study.

Seventy-seven percent were females, mean age at IM diagnosis was 45 (SD 17) years. Ninety- four (71%) without muscle biopsy and 37 (29%) with biopsy.
Table 1 shows the performance of all criteria in our cohort. EULAR-ACR criteria were considered positive if patient fulfilled probable or definitive criteria.

Figure 1 shows the performance of EULAR/ACR criteria (with and without biopsy) in patients who underwent muscle biopsy (37 patients)

Table 2 shows sensitivity of EULAR/ACR criteria according to the physician diagnosis as gold standard.

When we analyzed the sensitivity of EULAR-ACR (criteria without biopsy) according to B&P criteria as gold standard, the sensitivity was 86% (73.2-94.9). We were not able to evaluate the sensitivity of EULAR/ACR criteria with biopsy according to B&P criteria because all patients with biopsy fulfilled this criteria.

Conclusion: The sensitivity of EULAR-ACR criteria according to physician diagnosis in our cohort was lower than previous reports for both probable and definitive cut-off points. Sensitivity of EULAR-ACR criteria performed better using B&P criteria as gold standard. If criteria without biopsy are applied to patients with biopsy most of them fulfill criteria. Only in 6 patients of 37 the biopsy would change diagnosis.

Abstract Number: 0401

Performance of EULAR/ACR Classification Criteria for Idiopathic Inflammatory Myopathies in a Real-life Cohort of Adult Patients

Ana Campar ,[1] and Carlos Vasconcelos[2], [1]Centro Hospitalar do Porto, Porto, Portugal, [2]University of Porto, UMIB Abel Salazar Biomedical Sciences Institute, Porto, Portugal

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Muscle Biology, Myositis & Myopathies Poster I
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Idiopathic Inflammatory Myopathies (IIM) are rare and heterogenous diseases, remaining a clinical challenge and persisting with high morbidity and mortality. The lack of consensus in their classification has added difficulties to the development of novel and effective therapeutic strategies, precluding clinical trials with significant and reproductible results. The recently published EULAR/ACR criteria were developed to overcome the fragilities of the previous most used criteria.

The objective of this study is to evaluate the performance of the new classification criteria in a real-life cohort of adult patients with IIM.

Methods: Retrospective review of the cohort of adult patients followed in a dedicated unit of a tertiary hospital, between January 2008 and December 2018. Clinical, serological and histological data were collected. EULAR/ACR classification criteria were applied to each individual patient using the web calculator. Clinical diagnosis was obtained from 2 experts, for each case, and all the patients with a definitive IIM were included in the analysis. Sensibility, sensitivity, positive and negative predictive values were calculated for each of the classification subtypes.

Results: Ninety-two patients were included, 79 women (85.9%) and 15 men, with a medium age at diagnosis of 47 years-old and a medium follow-up period of 12 years. Muscle biopsy results were available in 43.5% of cases, but only 62.5% presented parameters compatible with the criteria specifications. EULAR/ACR classification criteria re-

Table 1. EULAR/ACR classification criteria performance

Classification criteria-assigned IIM subtype	Sensitivity (%)	Specificity (%)	Positive predictive value (%)	Negative predictive value (%)
PM	30	90	27	91
DM	100	66	51	100
IBM	100	100	100	100
ADM*	63	99	83	96

*ADM: amyopathic dermatomyositis

sulted in a definitive diagnosis of IIM in 52/92 cases (56.5%) and a probable diagnosis in 25/92 cases (27.2%), with the remaining 15 cases (16.3%) having a probability of IIM of less than 50%. Regarding IIM assigned subtypes, we found overall high negative predictive values and good specificity (table 1). Sensitivity was heterogenous among the subtypes: very high for Dermatomyositis (DM) and Inclusion-Body Myositis (IBM) and low for Polymyositis (PM). The most strinking differences between expert clinical diagnosis and classification criteria-assigned subtypes were in PM, reducing drastically the sensitivity. Overlap myositis, anti-synthetase syndrome and paraneoplastic myositis were the cases that contributed the most for the group that did not score enough for a diagnosis of IIM using the criteria, as well as for the differences between clinical diagnosis and classification results in PM and DM.

Conclusion: EULAR/ACR criteria applied to this cohort presented high specificity but only moderate sensitivity, particularly in some subtypes, as PM. A number of factors may be contributive, namely the absence of pulmonar involvement in the clinical variables and the stringicity of cutaneous involvement parameters and histological features. The most recent developments in the pathogenesis of IIM, particularly regarding myositis-specific antibodies, could be of interest to be added to the classification in order to include those patients with an atypical clinical presentation.

Chronic Disease Course and IVIg-dependance in Long-term Follow-up of Anti-HMGCR Immune-mediated Necrotizing Myopathy

Océane Landon-Cardinal ,[1] Kuberaka Mariampillai,[2] Céline Anquetil,[3] Aude Rigolet,[2] Baptiste Hervier,[4] Nicolas Champtiaux,[2] Olivier Benveniste,[3] and Yves Allenbach[3], [1]Centre Hospitalier de l'Université de Montréal, Montréal, Canada, [2]Pitié-Salpêtrière University Hospital, Paris, France, [3]Sorbonne Université, Paris, France, [4]Hopital Pitie-Salpetriere, Paris, France

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Muscle Biology, Myositis & Myopathies Poster I
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Anti-HMGCR antibodies have been associated with a severe form of immune-mediated necrotizing myopathy (IMNM) with a poor muscle strength recovery and early muscle damage. These patients tend to require aggressive immunosuppressive therapy and present relapsing disease course. Our objective was to evaluate real-life treatment strategies in anti-HMGCR IMNM patients.

Methods: This monocentric study included all patients with anti-HMGCR IMNM with at least 12 months of follow-up. Medical records were retrospectively reviewed to assess clinical features at diagnosis, HLA typing, treatment

strategies over the follow-up period (including corticosteroid (CS) use, number of immunosuppressive (IS) agent and intravenous immunoglobulin (IVIg) duration), disease course, and clinical status and therapeutic profile at last follow-up. Remission was defined as the presence of CK level ≤ 2 times the upper limit of normal associated with a stable manual muscle testing for ≥3 months. Quantitative variables are reported as median [IQR1-IQR3].

Results: Thirty-five patients were included. Age at diagnosis was 47.1 [26.1-60.2] years, 74% of patients were female, 29% were statin-exposed, all patients presented with muscle weakness (deltoid and psoas MRC-5 was 4.0 [2-4] and 4.0 [3-4], respectively) and highest CK level was 8146 [5000-12090] IU/L. Time from symptoms onset to treatment initiation was 0.8 [0.3-4.7] years. During the follow-up period, 91% of patients were treated with CS in combination with an IS agent, the majority of patients received IVIg (91%) and the number of treatment intensification was 2 [1-4]. Fourty percent of patients also received plasma exchanges as part of induction therapy.

All patients demonstrated a chronic disease course and no patients were in treatment-free remission at last follow-up after 4.9 [3.1-8.9] years. At last follow-up, 60% of patients were in remission - most of which with IVIg (71%) -, 57% of patients were still receiving CS (CS dose was 8 [5-10] mg/day) and 54% of patients had an IS agent. At last follow-up, only 40% of patients had a normal muscle strength, deltoid and psoas MRC-5 was 5 [4-5] and 4 [3-5], respectively, and CK level was 299 [200-559] IU/L. No predictors of remission or IVIg use at last follow-up were identified, including demographic features, HLA-DRB1*11:01 and HLA-DRB1*07:01 status, muscle disease severity at onset and statin use. Therapy-related side effects were reported in 26% of patients.

Conclusion: In our population, anti-HMGCR IMNM was associated with a chronic disease course associated with IVIg-dependance.

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Muscle Biology, Myositis & Myopathies Poster I

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Autoantibodies (aAbs) to proteins comprising the survival of motor neuron (SMN) macromolecular complex have not been thoroughly studied. Only two publications described clinical associations related to anti-SMN: the seminal publication reported three patients for which anti-SMN was associated with myositis and myositis/SSc overlap, while the second reported a patient with necrotizing myopathy and aAbs to SMN1 and gemin3. aAbs to the SMN complex may be suggested by indirect immunofluorescence (IIF) on HEp-2 cells showing a pattern referred to as few nuclear dots (known as AC-7 in the International Consensus on ANA patterns). The AC-7 pattern has been reported to have a low predictive value for any disease. Interestingly, deletion or mutation of SMN gene causes spinal muscular atrophy. The aim of this study was to describe the ANA pattern of patients with a SSc/myositis (scleromyositis) overlap syndrome (SMOS) with no known other SSc or myositis-specific aAbs; and to evaluate the clinical features of patients with a SMOS and anti-SMN aAbs.

Methods: Patients with a SMOS with no known SSc or myositis-specific aAbs were identified from 2 retrospective cohorts of patients with myositis and/or SSc. Both the diagnosis of myositis and SSc were made by expert opinion, since fulfilling the new classification criteria for both SSc and myositis may be insensitive in early disease. Sera from patients with the AC-7 pattern were tested for anti-SMN by an addressable laser bead immunoassay (ALBIA) and validated by immunoprecipitation (IP) of homogenates of metabolically labelled cells. ALBIA results were expressed as median fluorescence units (MFU) and the cut-off was set at 3 standard deviations above normal and unrelated disease controls.

Results: Twenty-one patients with SMOS and no known SSc or myositis-specific aAbs were identified, 6 of whom had an AC-7 IIF pattern. Anti-SMN aAbs were present on ALBIA in 5/6 (83.3%) of these patients (median 13 661 MFU; range 7433–21146). In these 5 patients positive on ALBIA, IP confirmed the reactivity to SMN and gemins 2, 3 or 4. Key myopathic features at presentation of these 5 patients were proximal weakness in all, with a mean CK elevation of 2564 IU/L (range 1738-3675). SSc features at the time of myositis diagnosis included Raynaud phenomenon (100%), limited (60%) or sine (40%) skin involvement, and bilateral trigeminal neuropathy (20%). At last follow-up, all patients met the ACR/EULAR classification criteria for SSc and notable SSc features included calcinosis (60%), pneumatosis intestinalis (20%), retro-pneumoperitoneum (20%) and interstitial lung disease (20%). Although all patients had been treated with corticosteroids, SSc renal crisis did not occur. Other overlap features included arthritis (60%), Sjögren syndrome (40%) and SLE (20%). One patient had 3 siblings with spinal muscular atrophy.

Conclusion: Single-specificity anti-SMN complex aAbs may define a novel SMOS, with absent or limited skin involvement at myositis diagnosis. The few nuclear dots (AC-7) pattern may be associated with clinically relevant information and be a sensitive screening test for anti-SMN aAbs in SMOS.

Session Title: Muscle Biology, Myositis & Myopathies Poster I

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Myopathy is an important cause of morbidity in systemic sclerosis (SSc). Nevertheless, scleromyositis remains incompletely characterized owing at least in part to its clinical heterogeneity. Sub-classifying patients with either SSc or autoimmune inflammatory myositis (AIM) by autoantibody profiles is a useful way of identifying more homogeneous subsets. We hypothesized that grouping patients with scleromyositis based on their autoantibody profile would also allow us to identify distinct clinical phenotypes.

Methods: Thirty-six subjects from a referral centre were identified as having a concomitant diagnosis of SSc and AIM by two rheumatologists. A retrospective chart review was performed and data on demographics, clinical features, laboratory tests and other relevant investigations were extracted. Autoantibodies were assessed by indirect immunofluorescence (IIF) on Hep-2 substrates and line immunoassay (LIA, myositis and systemic sclerosis profiles: Euroimmun, Lübeck, Germany). Subjects were divided into 3 groups based on their autoantibody profiles: group 1 included subjects with SSc-specific autoantibodies (anti-centromere, -topoisomerase 1, -RNA polymerase III, -Th/To, -fibrillarin), group 2 with SSc-overlap autoantibodies (anti-PM/Scl, -U1RNP, -Ku), and group 3 without any fine specificities (hereinafter referred to as 'seronegative').

Results: Of the 36 subjects with scleromyositis, 8 (22%) had SSc-specific autoantibodies, 11 (31%) had SSc-overlap autoantibodies and 17 (47%) were seronegative on LIA (Table 1). However, 14 (82%) of the seronegative subjects had positive IIF staining: 6 nuclear speckled and cytoplasmic; 5 nuclear speckled; 2 cytoplasmic; and 1 nucleolar. Most of the subjects were women (83%), had Raynaud's phenomenon (92%), and abnormal nailfold capillaroscopies (79%). One third of the scleromyositis subjects had no skin involvement and the absence of skin disease was seen more frequently in SSc-overlap and seronegative subjects. Subjects with SSc-specific autoantibodies had lower median creatine kinase (CK) levels (290 IU/L (48-1344)). Subjects with SSc-overlap autoantibodies presented a more classical pattern of weakness associated with significant CK elevation (median (range) 2860 IU/L (159-5075)). Distal weakness was a major feature of seronegative subjects (65%) and head drop was found more frequently in both SSc-associated (38%) and seronegative individuals (29%).

Table 1. Comparison of scleromyositis subjects based on autoantibody profiles

	SSc-specific ab (ACA, ATA, RNApol, Th/To, fibrillarin) (n = 8)	Overlap SSc-myositis ab (PM/Scl, Ku, U1RNP) (n = 11)	No SSc-associated ab (n = 17)

Trigeminal neuropathy	0	2 (13)	0

Abbreviations: ACA, anti-centromere antibodies; ATA, anti-topoisomerase I (Scl-70) antibodies; HRCT, high resolution computed tomography; PM/Scl, antibodies to polymyositis/scleroderma exosome antigen; RNAP, RNA polymerase III antibodies; Th/To, mitochondrial RNA processing (MRP) complex (note LIA detects only anti-hPOP1); U1-RNP, U1-ribonucleoprotein.

*Including scleroderma and scleroderma-like patterns.

**Right heart catheterization available for only 7 patients of which one had pulmonary arterial hypertension. The rest of the cohort was screened by cardiac echocardiography and showed no signs of pulmonary hypertension.

Conclusion: In this carefully phenotyped cohort, autoantibody profiles identified three subsets of scleromyositis associated with distinct patterns of muscle involvement. Just under 50% of subjects had no SSc- or myositis-specific autoantibody identified by LIA, although most of these had positive IIF. Studies are underway to correlate these results with muscle histopathology and to identify novel autoantibodies associated with scleromyositis.

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Muscle Biology, Myositis & Myopathies Poster I

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Anti-MDA5 dermatomyositis is characterized by little or no muscle involvement, distinct cutaneous features and an increased risk of severe interstitial lung disease (ILD) with high mortality. We aim to describe clinical presentation, radiological features and disease course in 6 patients and to perform a systematic review and meta-analysis of the literature on proportions of clinically-amyopathic form and ILD/rapidly progressive ILD (RPILD) in anti-MDA5 dermatomyositis according to the ethnicity of the published cohorts.

Methods: A total of six patients fulfilling diagnostic criteria of dermatomyositis with MDA5 antibodies, followed between 2014 and 2018 at the Department of Internal Medicine of Lille University Hospital and Roubaix Hospital, were retrospectively reviewed.

For the systematic review, we searched MEDLINE up to May 2019 for cohorts describing clinical and radiological features in dermatomyositis with MDA5 antibodies, using the following search terms (dermatomyositis OR interstitial lung disease) AND (MDA-5 OR (melanoma differentiation-associated protein 5) OR anti-CADM-140) AND English [language]. We calculated weighted pooled summary estimates of proportions of clinically amyopathic dermatomyositis, ILD and RPILD. For each meta-analysis, we used the DerSimonian and Laird method. A random-effects model was used to combine data. The overall effect was estimated using a weighted average of individual effects, with weights inversely proportional to variance in observed effects.

Results: In our case series, median age at diagnosis was 54.4 years (39.3-55.4). There were four women. Five patients had clinically amyopathic dermatomyositis. Three patients had a characteristic cutaneous phenotype consisting of skin ulcerations and palmar papules (Figure 1 A, B). Among five patients with ILD, one patient had a rapidly progressive course leading to respiratory failure (Figure 1 C) one week after admission, three patients had a severe

ILD and received pulsed methylprednisolone and intravenous cyclophosphamide. Among these three patients, add-on immunosuppressant therapy with rituximab was given in one case, mycophenolate mofetil in another, and plasma exchange with intravenous immunoglobulin in the last case.

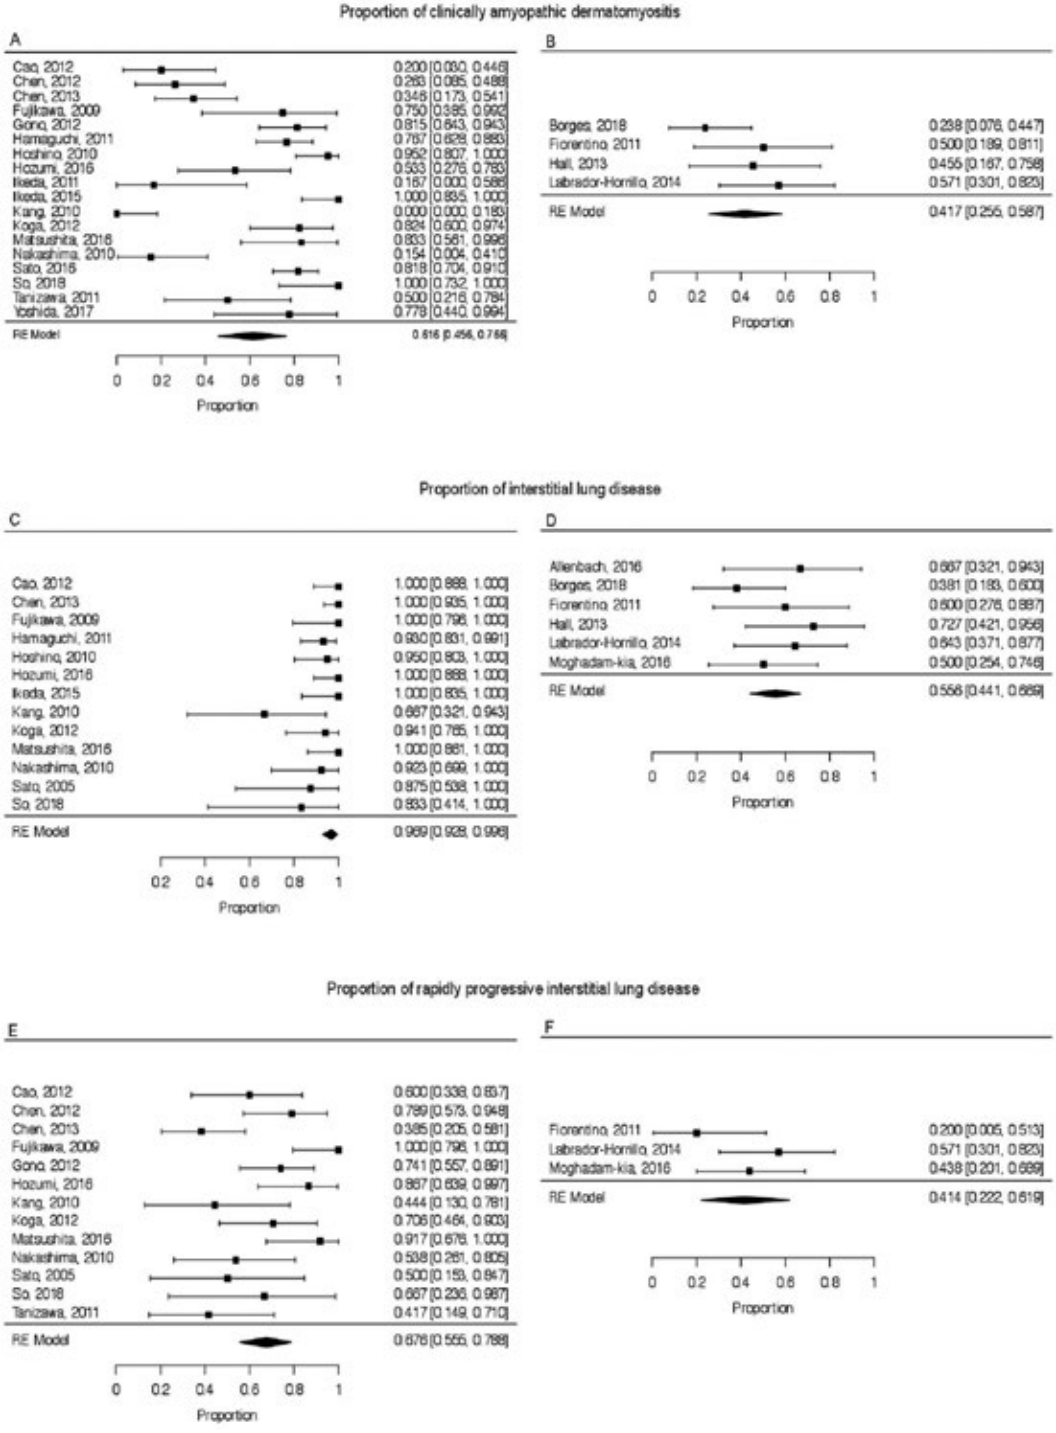

Figure 2. Forest plots of meta-analysis of proportion of clinically amyopathic dermatomyositis in A) Asian cohorts and B) American/European cohorts; proportion of interstitial lung disease in C) Asian cohorts and D) American/European cohorts; proportion of rapidly progressive interstitial lung disease in E) Asian cohorts and F) American/European cohorts.

A total of 25 studies (Table 2), consisting of 19 Asian cohorts and 6 American/European cohorts were included in the meta-analysis. Pooled proportion of clinically amyopathic dermatomyositis was 61.6% [95% CI 45.6%-76.6%] in Asian cohorts and 41.7% [25.5%-58.7%] in American/European cohorts (Figure 2). Pooled proportion of ILD was 96.9% [92.8%-99.6%] in Asian cohorts and 55.6% [44.1%-66.9%] in American/European cohorts. Pooled proportion of RPILD was 67.6% [55.5%-78.8%] in Asian cohorts and 41.4% [22.2%-61.9%] in American/European cohorts.

Conclusion: Our results show higher proportions of clinically amyopathic dermatomyositis and ILD/RPILD in Asian cohorts than in American/European cohorts.

Session Date: Sunday, November 10, 2019
Session Title: Muscle Biology, Myositis & Myopathies Poster I
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Idiopathic inflammatory myopathies (IIM) comprise a group of autoimmune diseases associated to different myositis related antibodies (MRA), that determine distinct phenotypes but share some symptoms, including myositis, skin rash and high prevalence of interstitial lung disease (ILD), the latter being particularly associated with some MRA. Some patients with MRA and ILD will fulfill IIM classification criteria, but others will not and may be classified as ILD with autoimmune features (IPAF). The aim of our study is to describe the clinical and radiological features of a group of patients with ILD and MRA, and their association with baseline and longitudinal pulmonary function (PF).

Methods: Descriptive study of a multicentric cohort of 211 patients evaluated between 2016-2018 in 3 multidisciplinary ILD clinics in Argentina, Chile and México. Every patient was confirmed to have ILD by thoracic high-resolution computed tomography (HRCT). Descriptive statistics, univariate and multivariate analysis were performed.

Results: 211 patients were included, (Chile = 119, México = 50 and Argentina = 42). Most patients were women (77,4%), mean age of 57 +-12 years. In 146 patients (70%) ILD was diagnosed first, in 43 patients (18%) ILD and connective tissue disease (CTD) were diagnosed simultaneously, and CTD was diagnosed first in 25 patients (12%). Mean interval between ILD and CTD diagnosis was 7.6 months (Table 1). Anti-Synthetase (AS) antibodies were the most frequent (Jo-1, PL12, PL-7), followed by Ro-52, PM-Scl 75-100 and Ku. Most frequent CTD diagnoses were AS syndrome and IPAF. Most prevalent HRCT patterns were non-specific interstitial pneumonia /organizing pneumonia

overlap (NSIP/OP) and NSIP (Table 1). Worse baseline PF was defined as forced vital capacity (FVC) < 70% and/or diffusion capacity of carbon monoxide (DLCO) < 60% at debut. Worse baseline PF was associated to ILD alone as initial diagnosis, NSIP/OP HRCT pattern, absence of dermatomyositis rash and absence of positive ANA and Ro (uni/ multivariate analysis, Table 2). Functional improvement was defined as an increase of FVC greater than 10% in follow up. 121 patients with > 3 months of follow-up were included. Functional improvement was associated with absence of ILD as the first manifestation of disease and absence of sclerodactily, presence of OP HRCT pattern and mechan-

Table 3: Variables associated with *functional improvement* (n = 121)			
Univariate analysis	**OR**	**p value**	**CI 95%**

ic´s hands (uni/mulitvariate analysis, Table 3). First line immunosuppressive treatments consisted in corticosteroids (CS) associated with a CS sparing agent like mycophenolate mofetil, azathioprine, cyclophosphamide, leflunomide, tacrolimus or rituximab (Table 1).

Conclusion: In our MRA-ILD cohort, AS antibodies and AS Syndrome were the most common findings, followed by IPAF. NSIP and NSIP/OP were the most prevalent HRCT patterns. Worse baseline PF could be related to the absence of extra-thoracic symptoms and “classic” antibodies of CTD (e.g ANA, Ro), causing delay in diagnosis and treatment. On the contrary, better functional improvement could be related to the presence of extra-thoracic signs that allow an opportune diagnosis and therapy, and more acute-subacute forms of ILD, as OP HRCT pattern.

Session Title: Muscle Biology, Myositis & Myopathies Poster I
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Idiopathic inflammatory myopathies (IIM) are chronic autoimmune diseases affecting multiple organ systems and associated with a diverse autoantibody profile. Anti-SSA/SSB are the most frequent myositis associated antibodies. Historically, anti-Ro/SSA reporting has been combined for autoantigens Ro 52 and Ro 60

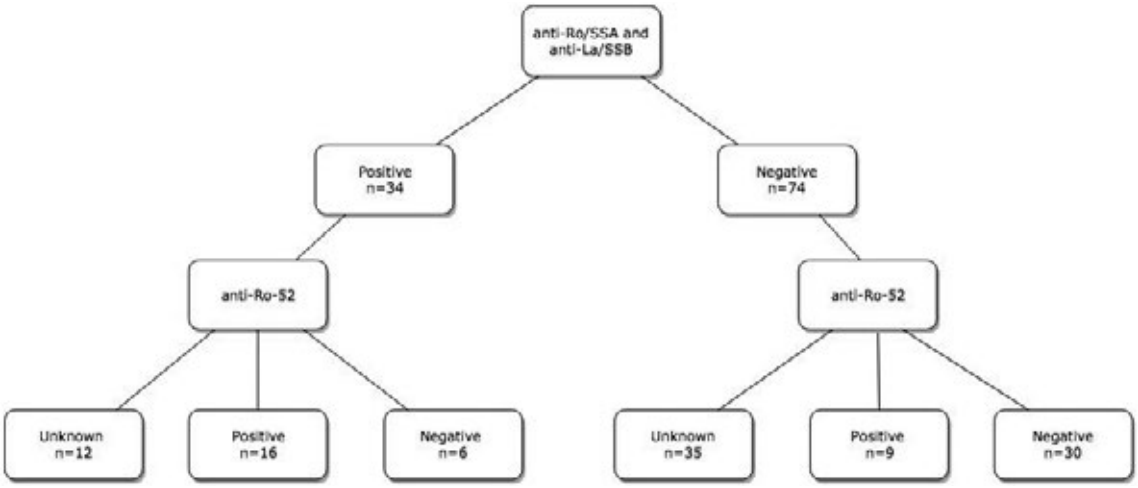

Table 1. Patient stratification based on autoantibody profile.

kDa. Recent data suggest that anti-Ro 52 and anti Ro 60 differ significantly in their clinical associations. Correlation of anti-Ro 52 with higher frequency of ILD has been demonstrated, but not been verified for commercially available anti-SSA/SSB assay.

Table 2. Comparison of demographics, clinical characteristics and autoantibody subtypes in anti-Ro 52 positive and anti-Ro 52 negative groups

Aim: To compare commercially available anti-SSA/SSB assay positivity and anti-Ro52 assay positivity as determinants of Interstitial Lung Disease (ILD) in IIM.

Methods: We queried the Northwell Myositis Center database for patients with IIM and available data for anti SSA/SSB and anti Ro52 between 1/1/2007 to 4/6/2018. All patients met 2017 EULAR/ ACR classification criteria for IIM. Anti-SSA and anti-SSB was measured by commercially available multiplexed bead-based immunoassay. Anti-SSA and anti-SSB were combined and analyzed as a single group because SSB was only found in association with positive SSA in our cohort. Anti-Ro52 was measured by commercially available immunoenzymatic assay (EIA). Patients were divided in 6 groups based on positivity/availability of each test (Table1)**.** The frequency of ILD was calculated for each group. Statistical analyses included Chi-square, Fisher's Exact test, and Wilcoxon Rank Sum test to determine statistical differences in group distributions and McNemar's test was performed to compare groups.

Results: There were 108 patients that met criteria for inclusion of which 31% (34/108) were anti-SSA/SSB positive. Anti-Ro 52 data were available for 61 patients and was positive in 41% (25/61). Some Ro 52 positive patients were nested in SSA/SSB negative group 36% (9/25) but majority of these had low titers of Ro 52. Both Ro 52 positive and negative patient groups had similar distribution for age, gender and race, as well as subtypes of IIM. Demographics, clinical characteristics and distribution of myositis associated antibodies in both groups are listed in Table 2**.**

As anticipated, the frequency of ILD was significantly higher in anti-Ro 52 positive compared with anti-Ro52 negative patients (64% vs 25%, p value= 0.0041). Similarly, anti-SSA/SSB positive status was associated with higher rate of ILD, independent of anti-Ro 52 status (56% vs 28%, p = 0.0084). Likewise, when patients with unknown anti-Ro 52 status were excluded from analysis, the difference remained statistically significant although weaker (55% vs 33%, p = 0.0038). There was no statistically significant difference in frequency of ILD between anti-Ro52 positive and anti SSA/SSB positive individuals (64% vs 56% p=0.5).

Conclusion: Both commercially available assays for anti-SSA/SSB and anti-Ro 52 positivity conferred the increased rate of ILD in our IIM cohort. Our data suggests that commercially available anti SSA/SSB assay can be used as a surrogate to the Ro52 assay to determine risk of ILD in IIM in clinical practice.

Frequency of Concomitant Non-aminoacyl-transfer-RNA Synthetase Autoantibodies in Patients with Antisynthetase Syndrome

Alexis Katz ,[1] Soumya Chatterjee,[2] and Yuxuan Jin[3], [1]Cleveland Clinic, Cleveland, OH, [2]Cleveland Clinic, Cleveland, [3]Quantitative Health Science, Cleveland Clinic, Cleveland, OH

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Muscle Biology, Myositis & Myopathies Poster I
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Antisynthetase syndrome (ASSD) is an autoimmune disease with features including interstitial lung disease (ILD), myositis, inflammatory arthritis, Raynaud phenomenon, and mechanic's hands.[1] Eight aminoacyl-transfer-RNA (tRNA) synthetase autoantibodies (Ab) have been described so far: Jo-1, PL-7, PL-12, EJ, OJ, YRS, KS, and Zo.[1] Sometimes, additional autoantibodies associated with other autoimmune rheumatologic dis-

orders can be detected in patients with ASSD including ANA, anti-U1-RNP, anti-Sm, anti-ds-DNA, rheumatoid factor (RF), and anti-CCP.[2,3,4] In ASSD, the coexistence of these autoantibodies may increase the prevalence of Raynaud phenomenon, dermatomyositis, and deforming arthropathy.[2,3,4] Also, copresence of anti-SSA/Ro antibody in ASSD has been variably correlated with more severe interstitial lung disease.[2,4,5] We completed a subset analysis evaluating the presence of other (non-tRNA synthetase) antibodies in patients with ASSD.

Table 1. Overall summary of antibody

Statistics presented as N (column %).
p-values: c=Pearson's chi-square test, d=Fisher's Exact test.

Methods: We obtained clinical data by retrospective review of electronic medical records from 2004 – 2017. The diagnosis of ASSD was confirmed by a rheumatologist, based on clinical phenotype and presence of one of the following autoantibodies: Jo-1, PL-7, PL-12, EJ, or OJ. Additional autoantibody positivity was determined by positive or negative values. Categorical variables were summarized using frequencies and percentages, and were compared using Pearson's chi-square tests or Fisher's exact tests. For all measures, a p-value of < 0.05 was considered significant.

Results: A total of 88 ASSD patients met criteria for inclusion in this study. The mean age was 57 years; 64% were female. The largest subset of patients was positive for Jo-1 Ab (N = 62). A positive ANA was noted in 63/88 patients (71.6%). ANA was more frequently positive in Jo-1 (87.1%) than those with 'non-Jo-1 ASSD antibody' (34.6%, p< .001) and PL-12 groups (23.1%, p< 0.001). RF was positive more frequently in PL-12 positive patients 5/13 (38.5%) than both in Jo-1 (11.3%, p=0.015) or 'Non-PL-12 ASSD antibody' groups (10.7%, p=0.009). Only 2/15 RF positive patients had radiographic evidence of deforming arthropathy, one of whom was also anti-CCP antibody positive and had erosions. No statistical comparisons were made for PL-7, EJ, and OJ antibodies due to small sample sizes.

Conclusion: Concomitant non-tRNA synthetase antibodies are common in patients with ASSD. Eighty five percent of our ASSD patients had at least one additional non-tRNA synthetase autoantibody, and almost 30% had at least three such additional autoantibodies, the most common ones being ANA, SSA, and RF. The impact of these autoantibodies on the phenotype and prognosis of ASSD patients remains unclear, and additional research is needed in this field.

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Muscle Biology, Myositis & Myopathies Poster I
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The antisynthetase syndromes (ASSD) are characterized by the presence of anti-aminoacyl transfer RNA synthetase (ARS) autoantibodies and a clinical classic triad of myositis, arthritis, and interstitial lung disease (ILD). Two ASSD diagnosis criteria have been proposed; those from Connors, and the stricter from proposed by Solomon.
Regarding ARS detection, previous studies have shown differences in the specificity between different myositis immunoblots. Nevertheless, an adequate clinical correlation and the ARS positivity in another monospecific-assays or HEp-2 indirect immunofluorescence assay (IIFA), can safeguard a high specificity of myositis-specific autoantibodies in the immunoblots.
Objective:
To evaluate the performance of IIFA patterns in the ASSD diagnosis in patients with ARS positivity and adequate ASSD or IIM clinical suspicion.

Methods: We analyzed data from one center (period 06/2008-06/2018). We searched all the myositis immunoblots (Euroimmun assay) requested by Rheumatologists under suspicion of ASSD or myositis and assessed: 1) the rate of cases with positive ARS; 2) the rate of cases with Connor´s or Solomon´s diagnosis criteria fulfillment; and 3) their relation with the IIFA patterns (Hep-2 cells; ≥1/80).

Results: A total of 140 myositis immunoblots were searched. Twenty-seven cases (19.3%) presented positive ARS: anti-Jo1 (n=13), anti-PL-12 (n=7), anti-PL-7 (n=1), anti-EJ (n=2), and anti-OJ (n=4). Twenty-five of these (92.6%) fulfilled Connors´ criteria, and 15 (55.5%) also met Solomon´s criteria. Additionally, all cases with positive ARS presented positive IIFA: 19 (70.4%) showed a cytoplasmic speckled pattern (10 of them with an associated nuclear pattern) and 8 cases (29.6%) presented only a nuclear pattern. Correlating, 13 of 27 cases with clinical suspicion of IIM or ASSD and positive ARS (48.1%) presented a cytoplasmic speckled IIFA pattern and also fulfilled Solomon´s criteria; representing the 68.4% of the cases with these IIFA patterns and the 86.6% of those that met Solomon´s criteria. On the other hand, 71 of the 113 cases (62.8%) with negative ARS presented positive IIF: 29 of them (40.8%) showed a cytoplasmic pattern (21 with an associated nuclear pattern) and 42 cases (59.2%) presented only a nuclear pattern.

Conclusion: Our results suggest that in patients evaluated by a Rheumatologist, with an adequate clinical suspicion of ASSD or IIM and with ARS positivity, the probability of fulfilling Solomon´s criteria is higher when the IIFA presents a cytoplasmic speckled pattern than when only a nuclear pattern is observed.

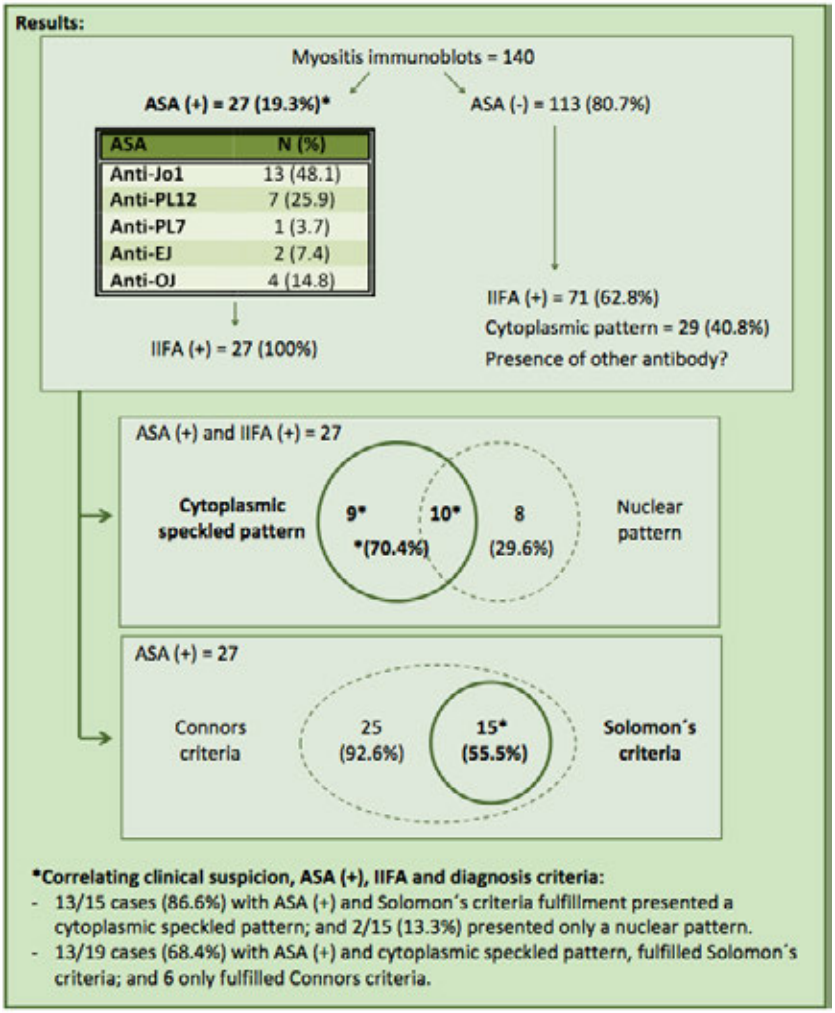

Image 1. Correlation of clinical suspicion, antisynthetase antibodies (ASA) and indirect immunofluorescence assays (IIFA).

Additionally, the high rate of positive IIFA in patients without positive ARS, suggests the presence of other positive antibodies and is in favor of good clinical judgment of the Rheumatologists when requesting the tests and of the auto-immunity expert when accepted them. This highlights the importance of the International Autoantibody Standardization (IAS) and the International Consensus on Antinuclear antibodies Patterns (ICAP) initiatives; whose implementation clinical laboratories could facilitate the harmonization of these tests and consequently the development of multicenter studies.

Prevalence of Malignancy in Myositis Patients with Anti-aminoacyl-tRNA Synthetase Antibodies: A Single Center Retrospective Study and Literature Review

Taiga Kuga ,[1] Yoshiyuki Abe,[2] Kurisu Tada,[3] Masakazu Matsushita,[1] Ken Yamaji,[1] and Naoto Tamura[1], [1]Department of Internal Medicine and Rheumatology, Juntendo University School of Medicine, Tokyo, Japan, [2]Department of Rheumatology, Juntendo University, Tokyo, Japan, Tokyo, Japan, [3]Juntendo University School of Medicine, Tokyo, Japan

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Muscle Biology, Myositis & Myopathies Poster I
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Anti-aminoacyl-tRNA synthetase antibodies (anti-ARS antibodies) are related to Idiopathic Inflammatory Myopathy (IIM) and Anti-Synthetase Syndrome (ASS). While anti-TIF1-γ antibody and anti-NXP-2 antibody are highly related to malignancy, anti-Jo-1 antibody is reported as protective factor against complicating malignancy. We recently experienced a case of anti-PL-7 antibody positive clinically amyopathic dermatomyositis (CADM) with rapidly progressive interstitial lung disease (RP-ILD) and colon cancer (stage IIIa). Regarding clinically difficult situation of this case with severe ILD activity and massive tumor indication for surgery, we thought it is important to clarify the risk factors and incidence of malignancy in myositis patients with anti-ARS antibodies.

Methods: Anti-ARS antibodies were detected by EUROLINE Myositis Profile 3. IIM diagnosis was made by the 2017 EULAR/ACR classification criteria and 'probable' cases meeting Bohan And Peter classification were included in this study between 2009 and 2018. Clinical features, laboratory and instrumental data were reviewed in this single center retrospective study. Cancer associated myositis(CAM) was defined by incidence of malignancy within 3 years from the diagnosis of IIM.

Results: We identified 38 patients positive for Anti-ARS antibodies (Anti-Jo-1 13 cases, Anti-PL-7 12 cases, Anti-PL-12 5 cases, Anti-EJ 8 cases, Anti-OJ 0 case). Malignancies were complicated in 6/38 patients (15.8%, Anti-Jo-1 1/13 case, Anti-PL-7 5/12 cases), while patients negative for anti-ARS antibodies showed lower incidence (8/83 patients, 12.0%). All 6 patients with malignancy complicated with ILD and 3/6 patients (50%) developed RP-ILD. Prevalence of malignancy in Anti-PL-7 antibody positive patients was significantly high compared to other myositis associated antibodies. We then analyzed clinical features, laboratory data of Anti-PL-7 antibody positive patients with or without malignancy. No significant differences in clinical characteristics were seen but interestingly all 3 CADM patients complicated with malignancy.

We identified 429 cases of anti-ARS antibody positive IIM and ASS in the literature. Incidence of malignancy in anti-ARS antibody positive patients was reported around 6% up to 16% and controversial. No patients positive for Anti-PL-7 antibody complicated with malignancy. Anti-Jo-1 antibody showed the highest incidence of malignancy contrary to the previous reports.

Conclusion: We should pay attention to malignancy screening in anti-ARS antibody positive patients same as other IIMs. Since all CADM patients positive for anti-PL-7 antibody complicated with malignancy, we may need to be cautious of malignancy in anti-PL-7 antibody positive CADM patients. Regarding the high frequency and severity of ILD in anti-ARS antibody positive patients even with malignancy, early detection and intervention of malignancy may lead to beneficial prognosis.

Frequency and Staining Patterns of Antinuclear Antibodies in Myositis Patients Without Known Myositis-specific Autoantibodies

Maria casal-Dominguez ,[1] Iago Pinal-Fernandez,[1] Ana Marin,[2] Maria Teresa Sanz-Martinez,[2] Andres Baucells-de la Pena,[3] Katherine Pak,[4] Yuji Hosono,[1] Lisa Christopher-Stine,[5] and Andrew L Mammen[4], [1]NIH, Bethesda, [2]Vall d'Hebron Hospital, Barcelona, Spain, [3]Hospital de la Santa Creu i Sant Pau, Barcelona, Spain, [4]National Institutes of Health, Bethesda, [5]Johns Hopkins University School of Medicine, Baltimore, MD

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Muscle Biology, Myositis & Myopathies Poster I

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: To determine the frequency and staining patterns of antinuclear antibodies (ANA) in myositis patients who do not have known myositis-specific autoantibodies.

Methods: Sera from dermatomyositis (DM), inclusion body myositis (IBM), and polymyositis (PM)patients without known myositis-specific autoantibodies, as well as serum from healthy control patients, were tested for ANA by indirect immunofluorescence (IIF) assay on HEp-2 cells. In sera from ANA-positive patients and controls, the pattern of positivity was classified according to the International Consensus on ANA Patterns (ICAP). The prevalence and pattern of ANA in different myositis subgroups was compared to those of healthy sera.

Results: Sera from189 myositis-specific autoantibody-negative myositis patients (76 DM, 50 IBM and 63 PM) and 91 healthy comparators were included in the study. Most DM sera were moderately or strongly ANA positive (53%, $p< 0.001$). Only 33%, 22%, and 15% were moderately or strongly ANA positive in the PM, IBM, and healthy control groups, respectively (all $p >0.05$). ANA positivity was mostly nuclear (as opposed to cytoplasmic or mitotic) and the most common pattern was fine speckled. The only difference in ANA pattern among myositis subgroups was a higher prevalence of a nuclear fine speckled pattern in DM patients (61%, $p=0.02$).

Conclusion: Most myositis-specific autoantibody-negative DM patients have moderate/strong ANA positivity, predominantly in a fine speckled pattern. In contrast, myositis-specific autoantibody-negative PM and IBM patients show similar rates of ANA positivity as healthy controls. These findings suggest that currently ANA-positive unidentified autoantibodies are more likely to exist in DM patients than in IBM or PM.

Elevated Serum BAFF Levels in Patients with Dermatomyositis: Association with Interstitial Lung Disease

Takashi Matsushita ,[1] Tadahiro Kobayashi,[1] Miyu Kano,[1] Yasuhito Hamaguchi,[1] and Kazuhiko Takehara[2], [1]Kanazawa University, Kanazawa, Japan, [2]Department of Dermatology, Kanazawa University, Kanazawa, Japan

SESSION INFORMATION

Session Date: Sunday, November 10, 2019
Session Title: Muscle Biology, Myositis & Myopathies Poster I
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with dermatomyositis (DM) frequently have myositis-specific autoantibodies (MSAs), which are closely associated with different clinical features. Patients with anti-aminoacyl-tRNA synthetase (ARS) antibody (Ab) and anti-melanoma differentiation-associated gene-5 (MDA5) Ab often have interstitial lung disease (ILD); however, anti-MDA5 positive ILD is rapidly progressive and a life-threatening disease. Recently, anti-MDA5 Ab levels have been shown to correlate with disease activity in DM patients.Thus, B cells that are stimulated by excess B-cell activating factor (BAFF) play an important role in the pathogenesis of DM through autoAb production. In this study, we investigatedthe role of BAFF in DM patients.

Methods: We measured the serum BAFF levels in 56 adult DM patients (14 patients with anti-ARS Ab, 18 with anti-MDA5 Ab, 7 with anti-Mi-2 Ab, and 17 with anti-TIF1-γ Ab)using ELISA. For a longitudinal study, 130 serum specimens from 10 DM patients with anti-MDA5 Ab were analyzed.

Results: Serum BAFF levels were significantly higher in DM patients [median (range); 1.51 (0.39 – 6.11) ng/mL] than in healthy controls [0.65 (0.46 – 0.99)]. DM patients with elevated serum BAFF levels more frequently had ILD. In subgroup analysis, DM patients with anti-ARS Ab [1.74 (0.47 – 4.08)] and DM patients with anti-MDA5 Ab [2.42 (0.55 – 6.11)] exhibited increased BAFF levels compared to those in healthy controls, while DM patients with other MSAs showed BAFF levels comparable to those of healthy controls (Figure 1). In the longitudinal study, serum BAFF levels in DM patients with anti-MDA5 Abwere decreased after immunosuppressive therapy along with anti-MDA5 Ab level, which is a biomarker of the disease activity (Figure 2).

Conclusion: These results suggest that BAFF plays an important role in the pathogenesis of ILD in DM patients with anti-ARS and anti-MDA5 Abs.Furthermore, serum BAFF level is associated with disease activity in DM patients with anti-MDA5 Ab.

Session Title: Patient Outcomes, Preferences, & Attitudes Poster I: Patient Reported Outcomes

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: The Patient-Reported Outcomes Measurement Information System (PROMIS) was developed to improve measurement of patient-reported outcomes. A large study from the US reported guarded support for the use of PROMIS-29 in RA, OA, FM and SLE patients[1]. Validity of PROMIS-29 for assessing quality of life in an Australian limited scleroderma cohort was demonstrated by comparison to SF36 and the HAQ-DI[2]. Our objective was to examine performance of the static 29 item PROMIS profile (PROMIS-29) compared to two legacy disease activity measures in RA, the CDAI and the RAPID3. We report a cross-sectional analysis of PROMIS-29 domain T scores according to CDAI and RAPID3 high, moderate, low and remission disease activity scores in a cohort of Australian patients with RA.

Methods: All patients attending one academic Rheumatology center complete the Multidimensional Health Assessment Questionnaire (MDHAQ) and PROMIS29 questionnaires at each visit. PROMIS29 questionnaires are scored on a 0 to 100 scale normed to the US population and reported as a T score (mean=50; 1 standard deviation (SD) =10). RAPID3 scores (range=0-30) are the sum of the patient physical function score (0-10), patient global assessment (0-10 VNS) and physician global assessment (0-10 VNS) derived from the MDHAQ. CDAI (range=0-76) is the sum of the patient global assessment (0-10 VAS), physician global assessment (0-10 VAS), tender joint count (0-28) and swollen joint count (0-28). T scores were compared across CDAI and RAPID3 disease activity (DA) categories by ANOVA. Minimum clinically important differences (MCIDs) from the population mean of 50 were estimated at 0.5 of the population SD, equivalent to 5 points[3].

CDAI	Remission (n=15)	Low (n=35)	Medium (n=33)	High (n=13)	*P value
Physical function	48.6 (6.4)	42.2 (8.7)	35.8 (6.2)	35.4 (9.9)	0.0001
Satisfaction with social role	56.5 (6.1)	48.6 (11.1)	42.2 (9.2)	40.6 (10.9)	0.0004
Fatigue	44.3 (9.3)	49.3 (10.2)	57.8 (9.5)	60.2 (14.6)	0.0008
Pain interference	48.5 (7.6)	58.5 (7.5)	62.8 (6.6)	67.6 (8.7)	0.0008
Sleep	46.9 (6.6)	51.9 (7.3)	58.0 (7.9)	58.6 (9.8)	0.02
Anxiety	46.4 (8.0)	53.3 (10.8)	54.1 (11.1)	58.6 (11.6)	0.04
Depression	44.8 (6.5)	51.4 (10.4)	55.5 (10.9)	55.5 (11.8)	0.04
RAPID3	Remission (n=22)	Low (n=8)	Medium (n=28)	High (n=55)	*P value
Physical function	51.0 (6.4)	46.6 (6.9)	41.9 (4.4)	33.6 (6.0)	<0.0001
Satisfaction with social role	57.8 (6.4)	54.0 (6.9)	47.6 (7.6)	40.0 (9.4)	<0.0001
Fatigue	44.8 (7.8)	42.8 (8.2)	51.2 (10.0)	57.5 (11.3)	<0.0001
Pain interference	47.9 (6.6)	54.9 (6.1)	58.1 (4.3)	66.0 (5.9)	<0.0001
Sleep	46.9 (5.4)	48.9 (7.2)	55.3 (7.8)	57.1 (8.2)	<0.0001
Anxiety	46.1 (7.5)	43.9 (6.8)	51.5 (10.4)	56.9 (11.1)	0.0003
Depression	44.1 (5.5)	44.5 (6.5)	51.0 (10.5)	56.2 (10.)	<0.0001

*** P values refer to the difference between high disease activity and remission**

Results: The mean (SD) CDAI was 12.4+/-10.4 with 15.6% in remission, 36.5% in low DA, 34.4% in moderate DA and 13.5% in high DA. All PROMIS domains were significantly worse in patients with high CDAI DA (>22) compared to remission (≤2.8) (Table). The mean (SD) RAPID3 score was 12.0+/-7.9 with 19.5 % in remission, 7.1% in low DA, 24.8% in moderate DA and 48.7% in high DA. All PROMIS domains were significantly worse in patients with high RAPID3 DA (>12) compared to remission (≤3.0) (Table). The majority of PROMIS scores in the high and moderate disease activity groups (23 out of 28) by CDAI and RAPID3 met MCID for worse scores than the population mean. Patients in CDAI or RAPID3 remission had PROMIS T scores equivalent to or better than the population mean.

Conclusion: All PROMIS domains in people with high RAPID3 or CDAI disease activity were significantly worse than in people in RAPID3 or CDAI remission. As expected, most PROMIS scores in those with high and moderate disease activity met MCID for being worse than the population mean. Further examination with larger patient numbers in each CDAI and RAPID3 DA category is required to confirm these findings.

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Patient Outcomes, Preferences, & Attitudes Poster I: Patient Reported Outcomes
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: With the advent of biologic therapy for RA, the American College of Rheumatology advocates a treat to target (TTT) approach in the treatment of RA with the goal of achieving remission or low disease activity. In this study we analyse the frequency of use of clinical disease activity measures such as DAS28 and the clinical disease activity index (CDAI) in elderly RA as a measure of how aggressively rheumatologists treat elderly RA patients to minimal disease activity. We hypothesized that rheumatologists are less likely to measure disease activity in elderly patients and less likely to treat them to minimal disease activity with biologic and targeted synthetic DMARDs.

Methods: In this retrospective cohort study, patient data was collected by review of electronic medical records of patients in our academic rheumatology clinic for 34 months (March 2015-December 2017). Patients over the age of 75 with a diagnosis of RA based on two ICD9 or ICD10 codes on at least 2 office visits were included in the study. A control group consisted of RA patients of ages 41-70. Patients with history of positive TB testing, HIV infection, active viral hepatitis, liver disease with AST/ALT 2x normal limits, history of organ transplantation, and/or active malignancy were excluded from the study.

Results: A total of 72 elderly RA patients were included in the study group; the control group had a total of 459 patients. 23% (n=17) of study group patients had disease activity measures as compared to 53% (n=246) in the control group. Out of the patients who had disease measurements, 64% (n=11) of the study group had low/minimal disease activity as compared to 59% (n=140) of controls.

Conclusion: Our results suggest a provider bias in treating elderly patients with RA with a less aggressive approach. Rather than using objective disease activity scores with a TTT approach to achieve minimal levels of disease activity and better patient outcomes, our clinic experience shows that providers less frequently use disease activity measures

	Elderly RA	Non-Elderly RA
Females	86% (63)	81% (405)
Clinical Disease Activity Measures (CDAI or DAS-28)	23% (17)	53% (264)
Steroids >5mg/day	25% (18)	27% (113)
Oral DMARD use	63% (45)	73% (363)
Biologic/Synthetic DMARD use	14% (10)	40% (201)
Osteoporosis Screening	60% (43)	59% (294)

Elderly and Non-Elderly RA demographics

in elderly patients, and less frequently use biologic and targeted synthetic DMARDs. As rheumatologists increasingly adopt the TTT approach in management of RA, including objective documentation of disease activity, it is important to extend this to all segments of the population, including older patients.
